 - a. Dystrophic pattern
2. Missense mutation of the dystroglycan gene

Laboratory Evaluation

1. High serum CK
2. EMG:
 - a. Dystrophic pattern

LGMD2Q*General Characteristics*

1. LGMD2Q is caused by mutations in the Plectin (PLEC1) gene located in chromosome of 8q243
2. LGMD2Q occurs from a homozygous 9-bp deletion that affects a muscle-specific transcript plectin 1. Other mutations in the gene cause epidermolysis bullosa simplex, EBS-muscular dystrophy with a myasthenic syndrome, EBS with pyloric atresia and EBS-Ogna3 type
3. Plectin is a widely expressed giant cytolinker protein

Clinical Manifestations

1. Early onset and slowly progressive phenotypic LGMD
2. Usually no cranial muscle involvement
3. An Iranian family with ptosis and ophthalmoparesis without skin lesions has been described

Neuropathology

1. Plectin's absence in skeletal muscle
 - a. Ultrastructural evaluation in patients with EBS (epidermolysis bullosa simplex)- MD(muscular dystrophy)
 - i. Widening and vacuolization adjacent to the sarcolemma
 - ii. Disorganization of Z-lines
 - iii. Disrupted filamentous bridge between Z-lines
 - b. Postulated that fiber specific plectin expression is associated with the desmin-cytoskeleton, Z-lines and myocyte membrane linkage
 - c. Plectin may function as:
 - i. Organizer of intermediate filament networks
 - ii. Scaffolding platforms for muscle signaling proteins
 - d. No skin pathology in LKGM2Q

Laboratory Evaluation

1. EMG:
 - a. Myopathic pattern
2. High serum CK levels

LGMD2R*General Characteristics*

1. LGMD2R is caused by mutations in the Desmin gene (DES) located in chromosome 2q35
2. It is a member of the intermediate filament (IF) protein gene family which is muscle-specific
3. Desmin is the major class III IF protein in striated and smooth muscle cells
4. Desmin mutations are associated with different phenotypes that include:
 - a. Limb-girdle muscular dystrophy
 - b. Scapuloperonal pattern
 - c. Generalized myopathy
5. A meta analysis of patients with 40 different heterozygous desmin mutations demonstrated:
 - a. Combined distal and proximal weakness in 67% of patients
 - b. Distal and proximal myopathies occurred in 27% of patients
 - c. Desmin mutations account for 2% of pure dilatative cardiomyopathy
 - d. Desminopathies have been described in diverse ethnic groups in both men and women

Clinical Manifestations

1. Onset in the teens or twenties
2. Progressive proximal muscle weakness and non-specific atrophy of both the upper and lower extremities
3. A-V conduction block but no cardiomyopathy

Neuropathology

1. Immunofluorescent staining and Western blot analysis show that the cytoskeletal network formation of mutant desmin is preserved. In the AD desminopathies ultrastructure evaluation reveals disruption of myofibrillar organization, formation of myofibrillar degradation products and dislocation or aggregation of membranous organelles

Laboratory Evaluation

1. CK most often is normal
2. EMG:
 - a. With desminopathy there is a myopathic pattern, but frequent positive sharp waves, fibrillation potentials and pseudomyotonic/myotonic discharges occur

LGMD2S*General Characteristics*

1. LGMD2S is caused by mutation in the transport protein particle complex 11 (TRAPPC11) gene in chromosome 4q35
2. Mutations have been identified in a consanguineous family and five Hutterite patients
3. A splice site mutation in the foie gras domain has been demonstrated of TRAPPC11 in the Hutterite patients

Clinical Manifestations

1. Infantile hyperkinetic movements
2. Ataxia
3. Cognitive impairment
4. Limb girdle proximal myopathy
5. Hip dysplasia and scoliosis
6. Muscle pain

Neuropathology

1. TRAPPC11 encodes a component of the multiprotein TRAPP complex that is involved in anterograde membrane transport from the endoplasmic reticulum to the ER-to-Golgi intermediate compartments
2. Mutations cause alteration in TRAPP complex composition, in Golgi morphology and cell trafficking. Golgi organelles are fragmented in some patients
3. Defects of the secretory pathway

Laboratory Evaluation

1. Elevated CK
2. EMG:
 - a. Myopathic pattern

LGMD2T*General Characteristics*

1. LGMD2T is caused by mutations in the GPP-mannose pyrophosphorylase B (GMPPB) gene that is located in chromosome 3p21
2. The LGMD phenotype has been reported in 3 patients
3. This mutation has been associated primarily with congenital muscular dystrophies due to decreased glycosylation of alpha-dystroglycan

Clinical Manifestation

1. LGMD phenotype of muscle weakness
2. Microcephaly
3. Cognitive impairment
4. Exercise intolerance

Neuropathology

1. Muscle biopsy:
 - a. Dystrophic pattern

Laboratory Evaluation

1. Increased serum CK
2. EMG:
 - a. Myopathic pattern

LGMD2U*General Characteristics*

1. LGMD2U is caused by a loss of function recessive mutations in the gene isoprenoid synthase (ISPD) in chromosome 7p21
2. The mutations disrupt dystroglycan mannosylation

Clinical Manifestations

1. Mutations in ISPD and the TMEM5 gene cause cobblestone lissencephaly:
 - a. A cortical dysplasia that is caused by neuroglial overmigration into the subarachnoid space
 - b. The extra cortical layer is either agyric or has multiple small gyri “cobblestone” in appearance
2. Walker-Warburg phenotype or “cobblestone lissencephaly” is caused by null alleles of ISPD
3. The allele causing LGMD is manifest by:
 - a. Progressive limb girdle weakness
 - b. The ability to walk is lost in the early teenage years similar to DMD
 - c. Muscle pseudohypertrophy that includes the tongue
 - d. There is cardiac and respiratory muscle involvement

Neuropathology

1. Reduction of functional glycosylation of α -dystroglycan
2. Muscle biopsy:
 - a. Dystrophic pattern

Laboratory Evaluation

1. EMG:
 - a. Myopathic pattern (in those with LGMD phenotype)
2. MRI:
 - a. Structural characteristics of WWS in those with this phenotype that includes:
 - i. Cobblestone lissencephaly
 - ii. Eye malformations
 - iii. Hypoplastic cerebellum and brainstem
 - iv. Hydrocephalus

LGMD2V*General Characteristics*

1. Mutations in the acid alphaglucohydrolase gene (GAA) that is located in chromosome 17q25.3
2. GAA mutations cause glycogen storage disease type 2

Clinical Manifestations

1. The infantile form of Pompe disease presents with massive accumulation of glycogen in muscle heart and liver
2. Infantile Pompe disease:
 - a. Floppy infant
 - b. Enlarged tongue
 - c. Heart failure
 - d. Respiratory involvement
3. Late onset Pompe disease:
 - a. May present from the second to the seventh decade
 - b. Progressive proximal muscle weakness, the lower limbs being more severely affected
 - c. Quantitative assessment of lingual strength reveals that it is diminished in late onset Pompe's disease

Neuropathology

1. Muscle biopsy:
 - a. Mild vacuolar myopathy of glycogen storage within skeletal and smooth muscle
 - b. Degenerating and regenerating fibers
2. Transmission electron microscopy:
 - a. Lysosomal glycogen storage within skeletal, cardiac and vascular smooth muscle cells

Laboratory Evaluation

1. Measurement of alphaglucohydrolase activity in cultured fibroblasts if the dried blood spot test demonstrates decreased enzyme activity
2. Genetic testing
3. EMG:
 - a. Increased insertional and spontaneous activity manifested by positive sharp waves, fibrillation potentials, complex repetitive discharge and occasional myotonic discharges
 - b. Myopathic MUAP
4. MRI/CT evaluation:
 - a. Early and severe involvement of the adductor magnus and semimembranosus muscles with later involvement of the long head of the biceps femoris, semitendinosis and anterior thigh muscles
5. EKG evaluation:
 - a. Left axis deviation
 - b. Short PR interval
 - c. Large QRS complexes
 - d. Inverted T-waves
 - e. ST depression
 - f. Wolff-Parkinson-White syndrome
6. ECHO cardiography:
 - a. Hypertrophic cardiomyopathy

LGMD2W*General Characteristics*

1. LGMD2W is caused by mutations in the LIM and senescent cell antigen-like-containing domain protein2 (LIMS2/PINCH2) gene located in chromosome 2q14
2. LIMS2 encodes a focal adhesion protein which interacts with ILK (integrin-linked kinase) which is essential for protein-protein interactions with the extracellular matrix

Clinical Manifestations

1. Childhood onset of LGMD
2. Macroglossy
3. Calf enlargement
4. In the third decade, patients developed decreased cardiac ejection fraction with global left ventricular dysfunction
5. Over time, patients develop severe quadriparesis with minimal facial involvement
6. A triangular tongue

Neuropathology

1. Unavailable

Laboratory Evaluation

1. Unavailable

Congenital Muscular Dystrophy**Overview**

Congenital muscular dystrophies are a clinically and genetically heterogeneous group of inherited muscle diseases whose major categories include:

1. Disorders associated with mutations in genes that encode structural proteins in the basal lamina, extracellular matrix or the sarcolemmal proteins that bind the basal lamina
2. Glycosylation defects of α -dystroglycan
3. Disorders due to selenoprotein 1 mutations

Muscle weakness occurs from birth to early infancy, the affected infants appearing “floppy” due to poor muscle tone and decreased spontaneous movements. Affected children often have delay or arrest of gross motor milestones in conjunction with joint or spinal rigidity. Generally, there is progressive weakness, joint contractures, spinal deformities, and respiratory compromise. Characteristic of the dystroglycanopathies are cognitive impairment, structural brain or eye abnormalities and seizures. The laminin alpha-2-deficient subtype has characteristic white matter abnormalities but no major cognitive defects.

In the autosomal recessive subtype, the siblings of an affected patient have a 25% chance of inheriting the disease, a 25% chance of being unaffected and not a carrier and a 50% chance of being an unaffected carrier.

In the autosomal dominant forms of the disease, 50% of the children of affected patients will inherit the disease. The

risk to siblings of a patient with an apparent de novo mutation is low, but not zero because a parent may harbor a germline mosaicism.

Congenital muscular dystrophy with genetic defects of structural proteins of the basal lamina or extracellular matrix.

Congenital Muscular Dystrophy with Laminin Merosin Deficiency*General Characteristics*

1. MDC1A is caused by mutations in the LAMA2 gene located in 6q21-6q22
2. Merosin is present in the basal lamina of myelinated nerves that is postulated to interfere with myelinogenesis and hypomyelinations in the central and peripheral nervous systems
3. Merosin binds to α -dystroglycan and A7BID integrin. Mutations may disrupt the dystrophin-glycoprotein complex
4. Mutations that alter the α -2 subchain of merosin markedly depress expression of the A7BID integrin with no or minimal effect on the dystroglycan or sarcoglycan complexes on the sarcolemma
5. Absent or decreased merosin occurs in approximately 30–40% of patients with congenital muscular dystrophy
6. There are patients with partial merosin deficiency as occurs with dystrophinopathies and sarcoglycanopathies
7. Patients may have secondary deficiency from glycosylation deficiency alterations that occur with the alpha-dystroglycanopathies

Clinical Manifestations

1. MDC1A infants have hypotonia, delayed, or arrested motor milestones and difficulty feeding
2. Neck, shoulder, and hip girdle muscles are progressively involved
3. Calf hypertrophy may be evident early in the clinical course
4. Respiratory insufficiency and orthopedic complications that include diffuse joint contractures and spinal rigidity become manifest
5. Nocturnal mechanical ventilation or continuous ventilation with tracheostomy may be required in early stages or in patients 10–15 years of age
6. Most children are unable to walk although rarely a patient can stand and walk with assistance
7. Children develop typical myopathic facies and in late disease a subset develop ophthalmoparesis
8. Some children develop a cardiomyopathy
9. Patients with partial merosin deficiency present in childhood with a DMD phenotype or in early adulthood with a BMD or LGMD phenotype
10. Intelligence is normal in most children
11. Approximately 20–30% of patients develop epilepsy
12. A small group of patients with MDC1A have epilepsy, occipital agyria and cognitive disability

Neuropathology

1. Muscle biopsy:
 - a. Variation in fiber size
 - b. Increased endomysial connective tissue
 - c. Decreased or absent merosin

Laboratory Evaluation

1. Serum CK levels are usually markedly elevated in merosin negative infants; partial merosin deficient patients have normal or minimally elevated levels
2. Brain MRI:
 - a. Diffuse white matter hyperintensities on T2-weighted sequences in children older than six years of age
 - b. Occipital polymicrogyria/agyria
 - c. Hypoplasia of the pons and/or cerebellum (rarely)
 - d. Patient with partial merosin deficiency may or may not demonstrate cerebral hypomyelination
3. Visual and somatosensory evoked potentials
 - a. Delayed latencies
4. EMG:
 - a. Slow nerve conduction velocities

Merosin-Positive Chronic MDC*General Characteristics*

1. Merosin-positive MDC are genetically heterogeneous
 - a. MDIB maps to chromosome 1Q42
2. Some partial merosin deficiency patients have mutations in glycosyltransferases that cause a secondary α -dystroglycanopathy
3. Mutations of the α -alpha 7' subunit of the integrin gene mapped to chromosome 12q13 have been described in three patients

Clinical Manifestations

1. α -alpha 7' subunit of integrin gene mutations:
 - a. Congenital onset of weakness and hypotonia
 - b. Delayed motor milestones
 - c. Cognitive deficits were demonstrated in one child
2. Secondary deficiency of alpha-laminin-2:
 - a. AR inheritance; mapped to chromosome 1q42
 - b. Deficiency of laminin alpha 2 in muscle
 - c. Clinical Manifestations from one family from the United Arab Emirates:
 - i. Generalized muscle hypertrophy
 - ii. Rigidity of the spine
 - iii. Contractures of the Achilles tendons
 - iv. Severe diaphragmatic muscle involvement that caused early respiratory failure
 - v. No cognitive deficit

Neuropathology

1. Muscle biopsy (α -alpha 7' subunit of integrin gene):
 - a. Mild variation of fiber size
2. Slight elevation of serum CK
3. MRI of the brain:
 - a. Normal

The Collagen VI-Deficient Congenital Muscular Dystrophies*General Characteristics*

1. The collagen deficient CMDs were formerly known as Ullrich and Bethlem Myopathy
2. Collagen V is an extracellular matrix protein composed of three chains. They are encoded by three genes COL6A1 and COL6A2 that map to chromosome 21q22.5 and COL6A3 that maps to chromosome 2q37
3. Recent evidence supports the classification that Ullrich CMD and Bethlem myopathy are a clinical continuum that can clinically be categorized as:
 - a. Early onset and severe:
 - i. Walking is not achieved
 - b. Moderate progressive:
 - i. The ability to walk is achieved and then lost
 - c. Mild:
 - i. The ability to walk is maintained into adulthood
4. The myopathies are caused by the genes that encode the three chains that compose collagen VI:
 - a. Homozygous premature termination codon-causing mutations in the triple helix domains cause the early severe phenotype (formerly Ullrich MCD); mutations in COL6A2 and COL6A3
 - b. Dominant de novo inframe exon skipping mutations and glycine missense mutations cause the moderate progressive phenotype (formerly Bethlem myopathy)
 - c. Mutations may be seen in COL6A1, COL6A2 and COL6A3 genes

Clinical Manifestations

1. Weakness at birth or early infancy
2. Contractions of the proximal joints
3. Hyperextensibility of the distal joints
4. Abnormal protuberant calcanei
5. Delayed motor milestones
6. No cognitive deficits

Neuropathology

1. Muscle biopsy:
 - a. Variation in muscle fiber size
 - b. Scattered degenerating and regenerating fibers
 - c. Increased endomysial connective tissue
 - d. Immunohistochemistry:
 - i. Collagen VI is present in the interstitial tissue but absent from the sarcolemma
2. Electron microscopy:
 - a. Interstitial collagen VI does not bind normally to the basal lamina surrounding muscle fibers

Laboratory Evaluation

1. Serum CK may be normal or only slightly elevated
2. EMG:
 - a. Myopathic pattern

Dystroglycanopathies

Overview

The dystroglycanopathies have a wide phenotypic spectrum that may present as LGMD or severe weakness with associated cognitive impairment, eye and brain involvement. Mutations in seven genes ISPD, POMT1, POMT2, POMGNT1, FKTN, FKRP and LARGE cause the alpha-dystroglycan-related muscular dystrophies. The proteins encoded by these genes are involved in both O-mannosylation and glycan chain synthesis and placement on alpha-dystroglycan. These proteins include:

1. Isoprenoid synthase that is involved in early O-mannosylation
2. The glycosyltransferases that are encoded by POMT1, POMT2, and POMGNT1
3. Proteins that are involved in a specific glycan epitope critical for laminin binding that are encoded by FKTN, FKRP and LARGE

Recent evidence supports the concept that mutations in any of these seven genes can cause wide phenotypic variations. Mutations in FKTN and FKRP may cause WWS to CMD, LGMD, elevated creatine kinase, and exercise intolerance with normal intelligence and no structural defects on MRI.

Glycosylation of alpha-dystroglycan is essential for normal binding to merosin as well as normal CNS neuronal migration.

Fukayama Congenital Muscular Dystrophy

General Characteristics

1. FCMD is caused by mutations in the fukutin gene which maps to chromosome 9q31
2. Fukutin is localized to the cis-golgi compartment and is involved in post-translational glycosylation of α -dystroglycan
3. Normal α -dystroglycan is essential as well for neuronal CNS migration and differentiation

Clinical Manifestations

1. FCMD is the most common congenital muscular dystrophy in Japan
2. Infants present with proximal greater than distal weakness and hypotonia
3. There are decreased fetal movements and an increased incidence of abortions of affected fetuses
4. Approximately 50% of children demonstrate pseudohypertrophy of calf muscles
5. Decreased muscle stretch reflexes are noted
6. Some children are born with arthrogryposis which continues to progress
7. 50% of children have seizures
8. Delayed motor and mental milestones
9. Severe cognitive impairment
10. The majority of patients can never stand or walk
11. Death occurs between 10–12 years of age from respiratory failure

Neuropathology

1. Muscle biopsy:
 - a. Dystrophic pattern
 - b. An occasional patient may demonstrate inflammatory features
 - c. Structural brain abnormalities include:
 - i. Microcephaly
 - ii. Lissencephaly
 - iii. Cortical dysplasia
 - iv. Pachygyria
 - v. Polymicrogyria
 - vi. Hydrocephalus

Laboratory Evaluation

1. The serum CK level is elevated 10–50 times normal
2. MRI/CT of the brain:
 - a. Structural abnormalities of migrational disorders
 - b. Hypomyelination
3. EEG:
 - a. Generalized slowing and epileptic activity

Walker-Warburg Syndrome

General Characteristics

1. Gene mutations in POMT1, POMT2 fukutin and FKRP all cause WWS
2. Mutations in POMT1 gene that maps to chromosome 9q31-11 cause 20% of patients with WWS
3. A homozygous loss of function frame shift mutation in the DA1 gene causes absence of both α -alpha and β -dystroglycan and also can cause the WWS

Clinical Manifestations

1. WWS is the most severe cerebro-ocular dysplasia and has a life expectancy of less than three years
2. Infants have generalized weakness, hypotonia and may be blind due to ocular malformations
3. The ocular manifestations of WWS syndrome include:
 - a. Unilateral or bilateral microcornea or microphthalmia
 - b. Hypoplastic or absent optic nerves
 - c. Coloboma with retinal involvement
 - d. Cataracts
 - e. Iris hypoplasia or malformation
 - f. Shallow anterior chamber angle with glaucoma
 - g. Retinal dysplasia or detachment
 - h. In patients with a less severe phenotype only high myopia or optic disc pallor may be manifest
 - i. Iridolental synechia
 - j. Seizure disorder
 - k. Mild LGMD phenotype with or without cognitive impairment

Neuropathology

1. Structural brain abnormalities include:
 - a. Cobblestone lissencephaly

- b. Polymicrogyria
 - c. Hydrocephalus
 - d. Hypomyelination of subcortical white matter
 - e. Hypoplasia of the brainstem and cerebellar vermis
 - f. Cerebellar cysts
2. White matter abnormalities may regress over time
 3. There may be partial absence of the corpus callosum and hypoplasia of the pyramidal tracts
 4. Immunostaining:
 - a. Reduced immunostaining for α -dystroglycan on the sarcolemmal membrane
 5. Muscle biopsy:
 - a. Dystrophic pattern

Laboratory Evaluation

1. Serum CK levels are elevated
2. Brain MRI:
 - a. Structural defects from migrational disorders (noted in neuropathology section)
 - b. Hydrocephalus
 - c. Negative in the LGMD phenotype
3. EEG:
 - a. Generalized slowing
 - b. Epileptic features

Muscle-Eye-Brain Disease (MEB)

General Characteristics

1. MEB is caused by mutations in the O-mannase-B1-2-N-acetylglucosaminyl transferase (POMGnT1) gene that map to chromosome 1p32-p34
2. The enzyme catalyzes the transfer of N-acetylglucosamine to O-mannos of glycoproteins
3. Mutations may also cause LGMD2M

Clinical Manifestations

1. MEB has brain and eye defects as well as muscle weakness, but the phenotype is less severe
2. Infants are weak and motor development is slow, many children can sit and stand and rarely walk
3. Severe cognitive impairment
4. The eye abnormalities include progressive myopia, glaucoma, and cataracts
5. In one series of patients 12 patients from 10 families demonstrated severe hypotonia at birth with varying stages of spasticity as the disease progressed

Neuropathology

1. Frontoparietal pachygyria
2. Polymicrogyria
3. Vermis hypoplasia
4. Cysts
5. Pontine hypoplasia
6. Abnormal midline structures

Laboratory Evaluation

1. Elevated serum CK levels

2. MRI of the brain:
 - a. Frontoparietal pachygyria
 - b. Hypoplasia of pons and cerebellum
 - c. Abnormal midline structures

MDC1C

General Characteristics

1. MD1C is caused by mutations that map to chromosome 19q13.3
2. The gene encodes the protein FKRP that localizes in the rough endoplasmic reticulum
3. The protein is involved in an early step in the synthesis of O-mannosylglycan of alpha-dystroglycan
4. Evidence supports the concept that FKRP is a Golgi resident type II transmembrane protein

Clinical Manifestations

1. FKRP-related myopathies are common in both English and Northern European populations
2. The age of onset is congenital to the fourth decade
3. Phenotypes include:
 - a. Similar to MDC1A
 - b. WWS/MEB
 - c. LGMD2I
 - d. Elevated creatine kinase
 - e. Exercise intolerance without cognitive impairment and a normal brain MRI
4. There is early involvement of cardiac and respiratory muscles
5. One of the mutations with the most phenotypic variability

Neuropathology

1. Reduction of alpha-dystroglycan glycosylation

Laboratory Evaluation

1. Serum CK levels are elevated at 10–75 times normal
2. Echocardiography:
 - a. May demonstrate a dilated cardiomyopathy
3. Pulmonary function tests:
 - a. Reduced forced vital capacity and inspiratory pressure generation
4. Brain MRI:
 - a. Microcephaly
 - b. Cerebellar atrophy and cysts
 - c. Hypoplasia of the vermis
 - d. Demyelinating white matter

MDC1D

General Characteristics

1. MDC1D is caused by mutation in the LARGE gene which maps to chromosome 22q12
2. It is a bifunctional glycosyltransferase with xylosyltransferase (Xyl-T) and glucuronyl transferase (GlcA-T) activity

3. LARGE-dependent modification of α -dystroglycan by the addition of the polysaccharide-repeating unit [3-xylase- α -1, 3-glucuronic acid –B1-Jn] is essential for α -dystroglycan to function as a receptor for proteins in the extracellular matrix
4. Patients with increased severity of disease have fewer LARGE glycan repeats

Clinical Manifestations

1. Global developmental delay
2. Generalized weakness
3. Cognitive impairment
4. Motor milestones are delayed but patients may be able to walk

Neuropathology

1. Experimental evidence demonstrates a correlation between LARGE glycan extension and its binding capacity (α -DG) to extracellular matrix ligands

Laboratory Evaluation

1. Serum CK levels are mild to moderately elevated
2. Variable MRI structural abnormalities

Congenital Muscular Dystrophy with Selenoprotein N1 Mutations (SEPN1)

Rigid Spine Syndrome

General Characteristics

1. SEPN1 has been mapped to chromosome 1p35-36 in some patients with rigid spine syndrome
2. SEPN1 mutations also cause:
 - a. Multiminicore myopathy
 - b. Congenital fiber-type disproportion myopathy
 - c. A desminopathy with Mallory body-like inclusions
3. Selenoprotein N1 is an endoplasmic reticulum glycoprotein:
 - a. The protein contains a selenocysteine (sec) residue at its active site
 - b. The selenocysteine is encoded by the UGA codon that signals translation termination. Mutations cause a stop signal rather than translation termination

Clinical Manifestations

1. The rigid spine phenotype:
 - a. Hypotonia in infancy
 - b. Proximal weakness
 - c. Delayed motor milestones
2. Progressive limitation of spine mobility
3. Thoracic spinal lordosis with S-shaped thoracic scoliosis
4. Progressive respiratory insufficiency that is exacerbated by diaphragmatic weakness
5. Early nocturnal hypoventilation prior to adulthood
6. Contractures of the knees and elbows (similar to EDMD and collagen V1-deficient MDC)
7. Medial thigh wasting in adults

Neuropathology

1. Muscle biopsy:
 - a. Variability of fiber size
 - b. Increased central nuclei
 - c. Type 1 fiber predominance
 - d. Moth eaten and lobulated fibers on NADH-TRstains
2. Multiple minicores (subset of patients)
3. Cytoplasmic Mallory bodies (subset of patients)
4. Increased desmin expression, sarcoplasmic and intranuclear tubulofilamentous inclusions (features of myofibrillar myopathy) in another subset of patients
5. Endomysial fibrosis occurs in axial musculature that includes paraspinous and rectus abdominus muscles

Laboratory Evaluation

1. Serum CK levels are normal to slightly elevated
2. EKG:
 - a. Conduction alterations
3. EMG:
 - a. Myopathic MUAPs
 - b. Rare abnormal spontaneous activity and normal insertional activity
4. MRI of muscle:
 - a. Selective involvement of the sartorius and major adductor muscles in the thigh

Differential Diagnosis of Congenital Muscular Dystrophies

MDC1A

1. Laminin-X-2 chain (Merosin deficiency in chromosome 6q22-23)
2. Neck, shoulder, hip girdle weakness
3. Contractions
4. Normal intelligence
5. Seizures
6. White matter changes on MRI

Merosin-Positive Classic MDC

1. Some partial merosin deficiencies map to chromosome 1q42
2. More benign

Ullrich Disease

1. Contractions of the proximal joints
2. Hyperextensive distal joints
3. Protruberant calcanei
4. Normal intelligence

Fukuyama Congenital Muscular Dystrophy

1. Allelic to LC and 2L; fukutin (chromosome 9q31-33)
2. Proximal > distal weakness at birth
3. Calf pseudohypertrophy (50%)
4. Arthrogryposis (some children)
5. Severe brain structural abnormalities (Microcephaly, dysplasia and lissencephaly)

Walker-Warburg Syndrome

1. DOnT1; (chromosome 9q3c)
2. Severe generalized weakness and hypotonia in infancy
3. Ocular malformation
4. Migrational and developmental abnormalities
5. Hypoplasia of the brain stem and veins
6. Seizures

Muscle-Eye-Brain Disease

1. POMGnT1 (chromosome 1p32)
2. MEB is less severe than WWS
3. Slow motor development
4. Eye abnormalities (glaucoma, cataracts)
5. Cognitive impairment
6. Hypoplasia of the vermis and pons; abnormalities of the midline structure

MDC1C

1. MDC1C is allelic to LGMD2I; mutation in the gene FKRP that maps to 19q13
2. Northern European ancestry
3. Onset is from infancy to the fourth decade
4. Weakness similar to MDC1A (rare WWS phenotype)
5. Early cardiac and respiratory muscle involvement

MDC1D

1. Mutation of the LARGE gene (chromosome 22q12-13.1)
2. Generalized weakness, cognitive impairment and developmental delay
3. Nystagmus (one patient)

Rigid Spine Syndrome

1. Selenoprotein (chromosome 1p35-36)
2. Rigid spine muscular dystrophy manifests in infancy
3. Hypotonia, proximal weakness and delayed milestones
4. Limited spine mobility with scoliosis and contracture of the knees and elbows
5. Respiratory involvement from rib cage restriction and diaphragm weakness
6. Similar phenotype is seen with:
 - a. EDMD
 - b. Ullrich CMD
 - c. Bethlem myopathy
 - d. Scapuloperoneal syndrome

LMNA-Related Congenital Muscular Dystrophy*General Characteristics*

1. LMNA-related congenital muscular dystrophy is caused by mutations in the LMNA gene that maps to chromosome 1q22
2. The gene encodes prelamin A and lamin C
3. There is a wide spectrum of disorders caused by mutations in the LAMA gene that cause:
 - a. Muscular dystrophy
 - b. Cardiomyopathy
 - c. Partial lipodystrophy
 - d. Progeria syndromes

4. The "laminopathies" primarily affect mesenchymal tissue (striated muscle, bone, and fibrous tissue) although recent work has identified functions for nuclear lamins in the CNS
5. The nuclear lamina is a meshwork of proteins underneath the nuclear envelope
6. L-CMD has been postulated to be an early onset variant of Emery-Dreifuss muscular dystrophy, but recent work has identified several de novo dominant mutations that have not been identified in the milder forms of ED muscular dystrophy

Clinical Manifestations

1. Presentation within the first six months of life with poor head control or progressive loss of head control after the ability to sit or walk has been acquired
2. Progressive weakness and hypotonia of axial-cervical muscles
3. Sequential proximal weakness of the upper limb associated with distal lower limb involvement
4. Sequentially there is head lag, thoracic and lumbar rigidity, lower limb contractures with talipes equinovarus; contractures do not occur in the upper extremities
5. Respiratory insufficiency occurs from restrictive lung disease due to muscle weakness. Severely affected patients may require mechanical ventilation prior to two years of age
6. Facial muscles are spared

Neuropathology

1. Lamins are the main proteins of the nuclear lamina and are the ancestors of intermediate filament proteins
2. They form complexes with intra-cellular proteins of the inner nuclear membrane as well as with transcriptional regulators, histones, and chromatin modifiers
3. The exact mechanism of how LMNA mutations cause muscular dystrophy has not been determined but studies in fibroblasts suggest that they cause a weakening of the structural support network in the nuclear envelope

Neuropathology

1. Muscle biopsy:
 - a. Dystrophic changes
 - b. Some children demonstrate non-specific myopathic changes

Laboratory Evaluation

1. Serum CK levels are mildly to moderately increased
2. EMG:
 - a. Myopathic pattern

Rare Congenital Muscular Dystrophies

Integrin Alpha-7 Deficiency

General Characteristics

1. Congenital muscular dystrophy with integrin-alpha-7 deficiency is caused by mutations in the ITGA7 gene that maps to chromosome 12q13.2
2. This CMD has been described in three patients with phenotypic variation
3. Integrin alpha-7/beta-1 is a receptor for the basal membrane proteins laminin-1 and laminin-2
4. It is expressed primarily in striated muscle and is thought to function in muscle maintenance through mechanical links between muscle fibers and the basal membrane. It may also have a role in muscle differentiation and migration during myogenesis

Clinical Manifestations

1. Neonatal hypotonia
2. Proximal muscle weakness and atrophy
3. Cognitive deficit
4. Scoliosis
5. Delayed motor milestones
6. Respiratory muscle weakness and dyspnea
7. One patient has been described with congenital hip dislocation and torticollis

Neuropathology

1. Muscle biopsy:
 - a. Dystrophic pattern
 - b. Absence of integrin alpha-7 staining

Laboratory Evaluation

1. EMG:
 - a. Myopathic pattern
2. CK is mild to moderately elevated

Integrin Alpha 9 Deficient Congenital Muscular Dystrophy

General Characteristics

1. Integrin alpha 9 deficient congenital muscular dystrophy is caused by mutations in the ITGA9 gene that map to chromosome 3p21.3
2. This CMD overlaps with collagen V1-deficient CMD
3. The mutation has been described in the French-Canadian population in Quebec
4. This integrin is a heterodimeric integral membrane glycoprotein composed of an alpha and beta chain
5. The encoded protein with its beta 1 chain forms an integrin that is a receptor for:
 - a. VCAM1
 - b. Cytotactin
 - c. Osteopontin
6. The integrin:
 - a. Participates with different ligands to effect cell adhesion in the extracellular matrix
 - b. Ligands include:
 - i. Extradomain A (EDA) fibronectin
 - ii. Tenascin C
 - iii. ADAMs
 - iv. Osteopontin
 - v. VEGF
 - vi. EMELINI

Clinical Manifestations

1. Presents with hypotonia
2. Distal hyperlaxity localized to metacarpal phalanges as opposed to the fingers
3. Scoliosis
4. Normal intelligence
5. Proximal weakness
6. Distinguishing features from COLA VI deficiency (that are seen in COLA VI deficiency) are:
 - a. Spine rigidity
 - b. High arched palate
 - c. Prominent calcaneus
7. Maintain the ability to walk into later decades
8. Some respiratory deficit

Neuropathology

1. Muscle biopsy:
 - a. Dystrophic changes

Laboratory Evaluation

1. CK is normal to mildly elevated
2. EMG:
 - a. Myopathic pattern

SYNE1-Related CMD

General Characteristics

1. SYNE1 (spectrum repeat-containing nuclear envelope protein 1) is causative
2. The gene encodes enaptin (nesprin-1) a nuclear envelope protein that is found in myocytes and synapses
3. The protein functions in the maintenance of nuclear organization and structural integrity by tethering the cell nucleus to the cytoskeleton. It interacts with the nuclear envelope and with F-actin in the cytoplasm
4. Mutations in the gene are associated with autosomal recessive spinocerebellar ataxia as well as CMD. Two unrelated probands with Emery-Dreifuss muscular dystrophy have been shown to have two different heterozygous mutations in the gene

Clinical Manifestations

1. Study of a Palestinian consanguineous family demonstrated:
 - a. Bilateral clubfoot

- b. Decreased fetal movements
- c. Delayed motor milestones
- d. Progressive motor decline after the first decade
- 2. Emery-Dreifuss phenotype in two unrelated probands
- 3. Two Japanese patients:
 - a. Adult onset of SCAR8
- 4. Nesprin-1 mutation:
 - a. Adducted thumbs
 - b. Severe cognitive deficits
 - c. Congenital muscular dystrophy phenotype
 - d. Cerebellar hypoplasia

Neuropathology

- 1. Muscle biopsy (Palestinian patients):
 - a. Variation in muscle fiber size
 - b. No necrosis or fibrosis
- 2. The basic pathology may be uncoupling of the nucleoskeleton and cytoskeleton by a dominant-negative effect

Laboratory Evaluation

- 1. Muscle biopsy:
 - a. Myopathic pattern
- 2. MRI:
 - a. Cerebellar hypoplasia in spinocerebellar ataxia AR phenotype and with some patients with nesprin-1 mutations

CHKB-Related Muscle Disease (Megaconial CMD)

General Characteristics

- 1. Congenital megaconial type muscular dystrophy has been mapped to chromosome 22q13.33
- 2. Choline kinase β -catalyzes the phosphorylation of choline by ATP with Mg^{2+} that produces phosphocholine and ADP. This is the initial step in the enzymatic pathway for choline in the synthesis of phosphatidylcholine
- 3. Japanese, Turkish, British, French and one African American patient have had detected mutations of the CHKB gene. All patients have a homogeneous phenotype

Clinical Manifestations

- 1. Early onset muscle wasting
- 2. Severe cognitive disability
- 3. Dilated cardiomyopathy and other cardiac defects in a subset of patients

Neuropathology

- 1. Muscle biopsy:
 - a. Reveals mitochondrial structural abnormalities:
 - i. Enlargement of the mitochondria at the muscle fiber periphery
 - ii. Depletion of mitochondria at the fiber center
 - iii. Most biopsies had no detectable choline kinase activity and decreased amounts of phosphatidylcholine

- iv. Mutations cause loss of function deficits
- v. Electron microscopy:
 - 1. Central mitochondria were subject to autophagy and had no cytochrome C oxidase

Laboratory Evaluation

- 1. EMG:
 - a. Myopathic pattern
- 2. Echocardiography:
 - a. Dilated cardiomyopathy

Congenital Muscular Dystrophy of Unknown Cause

Overview

These patients have a subtype of CMD that does not have a phenotypic resemblance to known subtype and their genes have not been identified.

- 1. CMD with cerebellar cysts, hypoplasia, or dysplasia
- 2. CMD with cognitive deficits and minimal ventriculomegaly or minor white matter abnormalities
- 3. CMD with normal intelligence and a normal MRI
- 4. CMD with cognitive deficits, microcephaly, cerebellar hypoplasia, feeding problems and severe myoclonic seizures

Differential Diagnosis of CMD by the Medical History

- 1. Central nervous system involvement manifest by delay in obtaining motor milestones and psychomotor development
- 2. Dystroglycanopathies
- 3. Laminin alpha-2 of life stages:
 - a. L-CMD
 - b. Hypotonic infants with laminin alpha-2 deficiency
- 4. A slowly progressive course with severe respiratory insufficiency in the first decade:
 - a. Non-ambulatory:
 - i. Laminin alpha-2 deficiency
 - ii. Collagen VI deficient CMD
 - iii. L-CMD
 - iv. Dystroglycanopathy
 - b. Ambulatory:
 - i. SEPN1-related CMD

Development of Skeletal Complications

- 1. Diffuse proximal and distal joint contractions, spinal stiffness, paravertebral muscle rigidity and scoliosis:
 - a. Collagen VI-deficient CMD (formerly Ullrich/Bethlem myopathy)
 - b. Laminin alpha-2 deficiency
 - c. Late-stage L-CMD
 - d. Dystroglycanopathies
- 2. Selective involvement of the spine:
 - a. SEPN1-related CMD
 - b. Early in the course of laminin alpha-2-deficiency in children that are able to walk
 - c. Collagen VI-deficient CMD

- d. L-CMD
- 3. Rapid developing course with loss of head control (dropped head syndrome):
 - a. L-CMD

Severe Cervicoaxial Hypotonia and Progressive Stiffness with Congenital Head Lag

- 1. SEPN1-CMD

Differential Diagnosis by Family History

- 1. Most congenital muscular dystrophies are autosomal recessive. In non-consanguine small nuclear families often, only one individual is affected
- 2. Collagen VI deficient CMD and all L-CMD patients have de novo autosomal dominant mutations and have only one occurrence in a family

Differential Diagnosis of CMD by the Physical Examination

- 1. Muscle pseudohypertrophy:
 - a. Dystroglycanopathies
- 2. Diffuse joint contractures:
 - a. Laminin alpha-2 deficiency
 - b. Collagen VI-deficient CMD
- 3. Distal hyperlaxity:
 - a. Collagen VI-deficient CMD
- 4. Skin manifestations that include hypertrophic scars or keloids:
 - a. Collagen VI-deficient CMD
- 5. Spinal stiffness without limb joint contractures:
 - a. SEPN1-related CMD
- 6. Axial hypotonia and weakness that precedes spinal rigidity:
 - a. Early laminin alpha-2 deficiency
 - b. L-CMD
 - c. Collagen VI-deficient CMD
- 7. Cardiac involvement:
 - a. L-CMD-arrhythmias
 - b. Cardiomyopathy with the dystroglycanopathies
 - c. Right heart failure from pulmonary hypertension in any CMD with respiratory insufficiency
- 8. Nocturnal hypoventilation or respiratory failure in a patient that can walk:
 - a. SEPN1-related CMD
 - b. Rarely collagen VI-deficient CMD
- 9. Location of the spinal deformity:
 - a. Thoracic kyphosis:
 - i. Collagen VI-deficient CMD
 - b. Thoracic lordosis:
 - i. Laminin alpha-2 deficiency
 - ii. SEPN1 related CMD
 - iii. L-CMD
 - iv. Dystroglycanopathies (late stage)
 - c. Lumbar hyperlordosis may occur in all subtypes

Differential Diagnosis of CMD by the Neurologic Examination

- 1. Occipital frontal circumference abnormalities:
 - a. Macrocephaly with laminin alpha-2 deficiency
 - b. Dystroglycanopathies may have micro- or macrocephaly
- 2. Muscle pseudohypertrophy of calves and tongue:
 - a. Dystroglycanopathies
- 3. Structural brain lesions and white matter demyelination:
 - a. Pyramidal signs and cognitive deficits:
 - i. Dystroglycanopathies
 - b. Seizure (routine treatment):
 - i. Laminin alpha-2 deficiency
 - c. Refractory seizures:
 - i. MEB (POMGNT1 subtype)
 - d. Cognitive deficits with behavioral disorder:
 - i. MEB (POMGNT1 subtype)

Differential Diagnosis of CMD by Serum CK Level

- 1. Normal merosin expression have normal or minimally elevated CK levels and include:
 - a. Collagen VI-deficient CMD
 - b. SEPN1-related CMD
 - c. L-CMD
- 2. Primary merosin deficiencies have high CK levels (>4x normal) and include:
 - a. Laminin alpha-2 deficiency
 - b. Dystroglycanopathies (secondary merosin deficiency)

Differential Diagnosis of CMD by Neuroimaging

- 1. Brain MRI:
 - a. Laminin alpha-2 deficiency:
 - i. Abnormal white matter is detected after six months of age
 - b. Dystroglycanopathies:
 - i. Brain stem hypoplasia
 - ii. Cerebellar cysts
 - iii. Hydrocephalus
 - iv. Migrational defects (lissencephaly or polymicrogyria)
- 2. Muscle imaging in spinal rigidity:
 - a. Specific patterns of muscle degeneration, normal merosin of skin or muscle and normal CK levels differentiate:
 - i. Collagen VI deficient CMD
 - ii. SEPN1-related CMD
 - iii. L-CMD

These parameters are normal in patients with spinal rigidity from:

- 1. RYR1 mutations
- 2. Acid maltase
- 3. DNM2

Differential Diagnosis of Rare Congenital Muscular Dystrophies

1. Congenital MD with Joint Hyperlaxity
2. Congenital MD with CNS atrophy and absent large myelinated peripheral nerve axons
3. Walker-Warburg syndromes
 - a. The gene disorders generally produce abnormal glycosylation of α -dystroglycan
 - b. The systems that are affected are:
 - i. Brain
 - ii. Muscle
 - iii. Eye
 - c. Mutations in:
 - i. POMT1 (chromosome 9q34)
 - ii. POMT2 (14q24)
 - iii. POMGnT1 (1p34)
 - iv. Fukutin (9q31)
 - v. FKR1 (19q13)
 - vi. LARGE (22q12)
 - vii. ISPD (7p21)
 - viii. GTDC3 (3p22)
 - ix. TMEM5 (12q14.2)
 - x. B3GALNT2 (1q42)
 - xi. SGK196 (8p11)
 - xii. B3GNT1 (11q13)
 - xiii. GMPPB (3p21)
4. Congenital muscular dystrophy with familial junctional epidermolysis bulbosa
5. Congenital muscular dystrophy with mitochondrial (mitochondrial) structural abnormalities
6. Congenital muscular dystrophy with early spine rigidity
7. Congenital muscular dystrophy with respiratory failure and muscular hypertrophy
8. Early-onset myopathy with areflexia, respiratory distress and dysphagia
9. Congenital muscular dystrophy with muscle hypertrophy
10. Scleroatonic muscular dystrophy (Ullrich)
11. Congenital muscular dystrophy with mental retardation and abnormal glycosylation
12. Congenital muscular dystrophy with adducted thumbs, ophthalmoplegia and mental retardation
13. Congenital muscular dystrophy and myasthenic syndrome

Regional Muscular Dystrophies

Facioscapulohumeral Muscular Dystrophy (FSHD)

General Characteristics

1. There are two forms of FSHD. FSHD1 and FSHD2 that have an identical phenotype but different genetic and epigenetic mechanisms
2. 95% of FSHD patients have autosomal dominant FSHD1

3. The incidence of FSHD is approximately 4 per million and its prevalence is 50 patients per million persons
4. There is a variable degree of clinical penetrance and a significant proportion of affected family members are unaware that they have the disease

Clinical Manifestations

1. The onset is usually between 3 and 44 years of age
2. The orbicularis oculi, zygomaticus, and orbicularis oris are affected early. Patients may be unable to close their eyes against resistance and may sleep with their eyes open
3. A horizontal smile, weak lip puckering, and a prominent Bell's phenomena appear early
4. Facial muscles are often asymmetrically involved
5. Extraocular muscles and those of mastication are typically unaffected
6. Other muscles affected early in the course of the illness are:
 - a. Serratus anterior
 - b. Rhomboids
 - c. Middle trapezius
 - d. Latissimus dorsi
- e. Weakness of these muscles cause:
 - i. Upward and lateral rotation of the scapular that includes scapular winging
 - ii. Weakness of the sternocostal head of the pectoralis major causes horizontal and downward displacement of the clavicles. Combined with internal rotation of the upper arms there is horizontal rather than the normal vertical position of the anterior axillary fold
 - iii. There is weakness and atrophy of the biceps brachii and relative sparing of forearm muscles. Wrist extensors are weaker than wrist flexors
 - iv. A subset of patients only manifests scapular winging or a limb-girdle muscle phenotype
 - v. There can be striking unilateral involvement of affected muscle groups
 - vi. The tibialis anterior is often the first muscle of the lower extremity to be affected and rarely a patient may present with foot drop. The gastrocnemius muscle is usually normal
 - vii. Pelvic muscle girdle involvement may occur which produces a hyperlordic posture and a waddling gait
 - viii. Approximately 20% of patients have severe difficulty walking and require a wheelchair
 - ix. Abdominal muscles are often involved which produces a positive Beever's sign (movement up or down of the umbilicus when the patient flexes the head against resistance); the direction of movement depends on relative weakness of the upper or lower rectus abdominal musculature
 - x. Sensation is intact to all modalities

- xi. Reflexes are diminished or absent, reflecting the degree of muscle wasting
- xii. A subgroup of patients suffers a late exacerbation of weakness in affected muscles that had been stable for a long time
- xiii. Severe progressive respiratory muscle weakness occurs in 1% of patients. This is exacerbated by kyphoscoliosis, severe extremity weakness, and wheelchair dependency
- xiv. Rare patients manifest cardiac signs and symptoms that include:
 - 1. Supra or ventricular arrhythmias
 - 2. Conduction defects
 - 3. May require a pacemaker

Clinical Variants

1. Infantile onset FSHD:
 - a. Severe weakness that is manifest in the first two years of life
 - b. Wheelchair dependence by 9 to 10 years of age
2. Coats' disease:
 - a. Facioscapulohumeral weakness
 - b. Sensorineural hearing loss
 - c. Retinal telangiectasia
3. Infants:
 - a. May present with severe facial diplegia similar to Moebius syndrome

Neuropathology

1. There are two forms of FSHD. FSHD1 and FSHD2 are phenotypically similar but have a different genetic and epigenetic basis. Autosomal dominant FSHD that accounts for 95% of patients is caused by chromatin relaxation induced by a macro-satellite repeat D4Z4 located on the 4q subtelomere; FSHD1 patients have 1–10 D4Z4 repeat units. The chromatin relaxation causes abnormal expression of Dux4, a retrogene that induces muscle apoptosis and inflammation, two allelic variants 4qA and 4QB have been identified that lie distal to the last D4Z4 unit. 4qA has a functional polyadenylation consensus site. Only D4Z4 contractions in this allele cause disease because this Dux4 transcript is polyadenylated and translated into a functional protein. FSHD2 is a digenic disease in which two mutations are required for the full expression of the disease phenotype. One mutation has no or only a slight deleterious effect. Chromatin relaxation of the D4Z4 locus is caused by heterozygous mutations in the SMCHD1 gene that encodes an essential protein for chromatin condensation. These patients have to have at least one 4qA allele to express functional Dux4 transcripts. There may be additive effects of FSHD1 and FSHD2 mutations as patients with D4 contraction and those with SMCHD1 mutations have a severe clinical phenotype. In summary, both forms of FSHD cause aberrant epigenetic regulation

of the chromosome 4q35 D4Z4 macrosatellite. Both variants of FSHD, type 1 caused by large deletions of heterochromatin and mutations in chromatin regulatory proteins (FSHD2) cause relaxation of epigenetic repression and thus increased expression of the pathogenic Dux4 gene that is encoded within the distal D4Z4 repeat. However, there are individuals with the genetic background that would predict FSHD who remain asymptomatic. Recent studies have demonstrated that the epigenetic status of the distal 4qA D4Z4 repeat correlates with the FSHD phenotype. Hypomethylation of DNA is seen in FSHD-affected patients, unaffected individuals have hypermethylation and non-manifesting individuals demonstrate intermediate methylation. The stability of epigenetic repression upstream of Dux4 expression is a major regulator of the disease

2. Muscle biopsy:
 - a. Variation in muscle fiber size
 - b. Atrophic and hypertrophic fibers
 - c. Scattered necrotic and regenerating fibers
 - d. Increased endomysial connective tissue
 - e. Increased internal nuclei
 - f. A subset of patients has an active mononuclear inflammatory infiltration of the endomysium that is similar to that of polymyositis
 - g. A membrane attack complex may be demonstrated on the sarcolemma of non-necrotic muscle fibers

Laboratory Evaluation

1. Serum CK levels may be normal or moderately elevated
2. EMG:
 - a. Myopathic pattern
3. Genetic testing:
 - a. 95% of patients have large deletions in the D4Z4 region (FSHD1)
 - b. FSHD2 has mutations in the SMCHD1 gene
 - c. False positives occur from non-pathologic contractions from the 4qB allele or complex 4q-10q rearrangements

Scapuloperoneal Muscular Dystrophy

General Characteristics

1. Scapuloperoneal muscular dystrophy has been linked to mutation in the desmin gene mapped to chromosome 2q35 (a form of MFM) and to chromosome 12 in another family. It is autosomally dominantly transmitted
2. Mutations in the DES gene also cause desmin related myopathy and a form of dilated cardiomyopathy

Clinical Manifestations

1. Peroneal weakness and atrophy accompanied by bilateral foot drop and talipes equinovarus is the usual initial presentation
2. Scapular weakness occurs within the first two decades of life. Weakness is frequently asymmetric

3. A subset of patients demonstrates hypertrophy of the extensor digitorum brevis
4. Ankle contractures may be severe
5. Scapular muscle weakness is similar to that of FSHD although humeral musculature is relatively spared. The peroneal muscles are more atrophic and weaker than those of FSHD
6. Facial weakness can occur but is much less severe than that of FSHD
7. The muscle weakness is slowly progressive
8. Dysphagia and gynecomastia have been reported from the kindred first reported by Kaeser. Phenotypic variability of the Kaeser large multigenerational kindred included:
 - a. Scapuloperoneal phenotype (12%)
 - b. LGMD phenotype (60%)
 - c. Distal phenotypes 18%
 - d. Cardiac and respiratory involvement occurred in 41% of affected patients

Neuropathology

1. Fiber size variation
2. Atrophic and hypertrophic fibers
3. Split fibers
4. Necrotic and regenerating fibers
5. Increased endomysial connective tissue
6. Some patients have inclusions that are similar to those seen in MFM

Laboratory Evaluation

1. Serum CK levels may be normal to moderately elevated:
 - a. EMG: Decreased CMAPs in severely affected muscles
 - b. Rare fibrillation potentials
 - c. Myopathic pattern
 - d. Normal motor and sensory nerve conduction velocities

X-Linked Emery-Dreifuss Muscular Dystrophy

General Characteristics

1. X-linked Emery-Dreifuss muscular dystrophy is caused by mutations in the (STA) gene that maps to chromosome Xq28 that encodes the protein emerin
2. Emerin is located on the inner nuclear membrane of cardiac, skeletal and smooth muscle
3. The carboxy terminal tail of emerin attaches it to the inner nuclear membrane and the remainder of the protein extends into the nucleoplasm
4. Emerin is a member of the nuclear LAP family which is composed of the intermediate filaments lamins A, B and C. They are attached to the nucleoplasmic surface of the inner nuclear membrane and bind laminin-associated proteins. These include LAP1, LAP2 and lamin B receptors that are localized to the inner nuclear membrane. The LAP2, lamin B receptors and lamins also attach to chromatin and augment its binding to the nuclear membrane
5. Mutations in emerin may disorganize the nuclear lamina and heterochromatin

Clinical Manifestations

1. Early contractures of the Achilles tendons, elbows, and posterior cervical musculature
2. Progressive muscle weakness that affects the humeroperoneal distribution early
3. Cardiomyopathy with conduction defects
4. The contractures are evident in early childhood or by teenage years
5. Patients may toe walk early due to heel cord contractures
6. Reduced spinal column mobility with difficulty flexing their neck and axial musculature
7. Contractures may precede weakness that is a differential point of EDMD and the other dystrophies with prominent contractures
8. Children are normal at birth
9. Pes cavus foot deformity
10. Patients can walk into the third decade
11. There is no calf hypertrophy
12. Muscle stretch reflexes are decreased or absent early in the course of the illness
13. Severe cardiac conduction defects are evident by the end of the second or the early third decade and include:
 - a. Syncope
 - b. First-degree A–V block
 - c. Complete heart block
 - d. Sudden death
14. Male carriers do not have weakness or contractures, but they may develop the arrhythmias

Neuropathology

1. Muscle biopsy:
 - a. Fiber size variation
 - b. Type 1 fiber atrophy
 - c. There may be type 4 or type 2-fiber predominance
 - d. Central nuclei
 - e. Muscle fiber splitting
 - f. Increased endomysial fibrosis
2. Immunostaining:
 - a. Absent emerin
 - b. Abnormal lamin A/C and lamin B2 or the nuclear membrane
3. Electron microscopy:
 - a. Focal absence of peripheral heterochromatin between the nuclear pores
 - b. Irregular and uniform thickening of the nuclear lamina and compaction of heterochromatin in areas of heterochromatin detachment

Laboratory Evaluation

1. Serum CK may be normal to moderately increased
2. EMG:
 - a. Myopathic MUAPs
 - b. Normal motor and sensory conduction velocities
3. EKG:
 - a. Sinus bradycardia

- b. Prolonged PR interval
- c. Conduction blocks
- d. Total permanent auricular paralysis

Autosomal Dominant EDMD2

General Characteristics

1. Autosomal dominant inheritance
2. EDMD2 and LGMD1B are allelic disorders
3. The disorders are caused by mutations in the lamin A/C gene that map to chromosome 1q11-23
4. Hereditary dilated cardiomyopathy is caused by mutations of the rod domain of the LMNA gene. Conduction alterations occur with or without skeletal muscle weakness
5. De-novo mutations may account for over 70% of cases
6. Alternative splicing of the laminin A/C RNA transcripts produces laminins A and C
7. LMNA genes encode the lamins that are intermediate filament proteins; these form a meshwork of filaments that underlie the inner nuclear membrane. The function of the lamin network has been postulated to include:
 - a. Interaction with signaling proteins and transcription factors
 - b. Structural integrity of the nuclear membrane
8. Additional genes that have been associated with EDMD are SYNE1 (spectrin repeat containing nuclear envelope protein1) and SYNE2
9. These genes encode nesprin-1 and -2 that are multi-isomeric, spectrin-repeat proteins that bind emerin and lamins that form a network that link the nucleoskeleton to the INM, the outer nuclear membrane, organelles in the membrane as well as the sarcomere and the actin cytoskeleton SYNE1 is mapped to chromosome 6q24 and SYNE2 is mapped to chromosome 14q22

Clinical Manifestations

1. Affected members have a later onset of the disease than patients with X-linked EDMD
2. The disease starts between ages 7 and 42
3. Similar manifestations as patients with X-linked EDMD

Neuropathology

1. Similar to X-linked EDMD

Laboratory Evaluation

1. Serum CK may be normal to moderately elevated
2. EMG:
 - a. Myopathic pattern
3. EKG:
 - a. Conduction defects

Autosomal Recessive EDMD3

General Characteristics

1. A rare disorder reported in only a few families
2. Mutations in the LMNA gene are causative

Clinical Manifestations

1. Early onset of extremity contractures and severe rigidity of the spine
2. Onset is within the first two years of life
3. No cardiac abnormalities
4. Children were unable to walk by age 8

Neuropathology

1. Muscle biopsy:
 - a. Dystrophic changes

Laboratory Evaluation

1. EMG:
 - a. Myopathic pattern
2. Moderate elevation of CK
3. EKG:
 - a. Normal

Bethlem Myopathy

General Characteristics

1. Bethlem myopathy is caused by heterogeneous autosomal dominant mutations of the genes COL6A1, COL6A2, and COL6A3
2. The alpha 1 and alpha 2 subunits of collagen VI map to chromosome 21q while the α -3 subunit is encoded from COL6A3 that is mapped to chromosome 2q37
3. Two patients have had a Bethlem myopathy phenotype who were compound heterozygotes for a truncating and missense mutation that mapped to the COL6A2 gene
4. As noted earlier Ullrich congenital muscular dystrophy can be caused by mutations in any of the genes that encode the subunits of collagen type VI. Mutations are both homozygous (recessive) and heterozygous (dominant)
5. Two additional phenotypes have recently been described:
 1. limb girdle; 2. autosomal recessive myosclerosis in one family with mutations in the COL6A2 gene
6. Glycine substitutions in the conserved Gly-s-y motif in the triple helical (TH) domain of collagen VI are the most common mutations in the collagen VI myopathies
7. In one large series intermediate phenotypes between the severe Ullrich and more benign Bethlem phenotype were the most common

Clinical Manifestations

1. Onset is at birth or during early childhood
2. Decreased fetal movements may be ascertained and infants may demonstrate generalized hypotonia
3. Delay of motor milestones
4. Weakness may only become evident in early adulthood
5. There is variability of phenotypic expression within affected families
6. Proximal greater than distal weakness, legs are more affected than the arms, and extensor musculature is more affected than flexor

7. There is mild neck and axial muscle involvement
8. No cranial muscle involvement
9. Contractures of the elbows and interphalangeal joints and plantar contractures of the ankles often occur prior to muscle weakness
10. Rarely there is proximal shoulder and hip girdle weakness without contractures
11. Muscle stretch reflexes are usually reduced
12. Recent study has demonstrated heart involvement in approximately 10% of patients
13. Respiratory insufficiency occurs with diaphragmatic muscle involvement
4. Restricted extensor neck muscle weakness may remain for years although there may be concurrent upper thoracic involvement demonstrated radiographically or by EMG
5. A positive family history has been documented in two kinships that only involved women
6. In addition to myasthenia gravis and ALS dropped head/bent spine has been described in:
 - a. Monophasic inflammatory myopathy restricted to paraspinal muscles
 - b. Dysferlinopathies
 - c. Myotonic dystrophy
 - d. Late onset nemaline myopathy

Neuropathology

1. A myopathic pattern on muscle biopsy with variation of fiber size, fiber splitting, central nuclei, and endomysial fibrosis
2. Histochemistry reveals lobulated moth-eaten type one fibers on NADH-TR staining

Laboratory Evaluation

1. Serum CK is normal or only mildly elevated
2. EKG (in approximately 10% of patients):
 - a. Atrial fibrillation
 - b. Intraventricular conduction delay
 - c. Supraventricular tachycardia
 - d. Right bundle branch block
 - e. Q waves in V1, V6 and AVL
3. Echocardiology:
 - a. Decreased ejection fraction
 - b. Ventricular dilatation
4. Respiratory function tests:
 - a. Reduced vital capacity
 - b. A subset of patients requires mechanical ventilation

Bent Spine/Dropped Head Syndrome

General Characteristics

1. There are several neuromuscular disorders primarily amyotrophic lateral sclerosis and myasthenia gravis that manifest severe neck extensor weakness
2. This syndrome pertains to patients with weakness that is restricted to the cervical, upper thoracic and paraspinal musculature

Clinical Manifestations

1. Onset begins after 60 years of age and progresses to head drop on the chest
2. This syndrome pertains to patients with weakness that is restricted to the cervical, upper thoracic and paraspinal musculature
3. There may be severe kyphoscoliosis from thoracic paraspinal muscle involvement that causes the bent spine posture when standing. The posture returns to normal on recumbency. This does not occur in patients with fixed spinal contracture

Neuropathology

1. Muscle biopsy (cervical paraspinal muscles):
 - a. Fiber size variability
 - b. Atrophic and hypertrophic fibers
 - c. Increased central nuclei
 - d. Fiber splitting
 - e. Some fibers have rimmed vacuoles
 - f. Rare endomysial inflammation
 - g. Moth eaten fibers
 - h. Increased endomysial connective tissue
 - i. Proximal muscle biopsies may be normal or demonstrate similar but less severe myopathic changes
 - j. Ragged red fibers and cytochrome C-oxidase negative fibers may be seen, but may be just age related

Laboratory Evaluation

1. Serum CK levels are normal to mildly elevated
2. Monoclonal gammopathy may occur in patients with the late-onset nemaline myopathy phenotype
3. EMG:
 - a. Short duration, small amplitude MUAPs with early recruitment are demonstrated in cervical and thoracic paraspinal muscles
 - b. Normal motor and sensory conduction velocities
 - c. Fibrillation potentials and positive sharp waves may be seen in cervical and thoracic paraspinal muscles
 - d. Extremity EMG is usually normal

Oculopharyngeal Muscular Dystrophy

General Characteristics

1. Oculopharyngeal muscular dystrophy is caused by expansion of GCG repeats within the poly (A) binding protein nuclear gene (PABPN1) that maps to chromosome 14q11.1. The gene expansion is usually 8–13 repeats
2. Homozygous expansions may present at an earlier age and have a more severe phenotype
3. Patients with a polymorphism (7GCG repeats) heterogeneous for the GCG repeat also have a more severe phenotype
4. A late onset phenotype may be seen in patients with homozygous polymorphisms (7GCG repeats)

5. The encoded protein is in dimeric and oligomeric states and is a component of the process of polyadenylation of mRNA. It is bound to the polyadenylated mRNA complex that is then transported through the nuclear pores into the cytoplasm. Once in the cytoplasm, the PABPN1 encoded protein detaches from the mRNA and is transported back to the nucleus. The mRNA undergoes translation
6. It is postulated that the GCG expansion repeats in the polyalanine domains of the PABPN1 gene encode a protein that is misfolded. The proteins are ubiquitinated, but do not undergo proteasomal degradation. The misfolded proteins accumulate as intranuclear tubulofilamentous inclusions that are seen on electron microscopy
7. There is a correlation with increased numbers of myonuclear inclusions and phenotypic severity

Clinical Manifestations

1. Onset is the fourth to sixth decade
2. Presenting feature is increasing ptosis
3. The ptosis is usually bilateral but is often asymmetric
4. Extraocular muscles are involved in approximately 50% of patients
5. There is no pupillary involvement and complaints of diplopia are rare
6. Approximately 25% of patients may have dysphagia as their initial presentation
7. Progressive weight loss and weakness supervenes
8. In a subset of patients there is facial weakness, masticatory and laryngeal involvement
9. The gag reflex may be impaired
10. The neck and proximal muscles may be slightly involved and there is a distal muscle variant
11. There is no sensory loss
12. Muscle stretch reflexes are decreased or absent

Neuropathology

1. Muscle biopsy:
 - a. Variation in fiber size
 - b. Degeneration and regenerating muscle fibers
 - c. Central nuclei
 - d. Increased endomysial connective tissue
 - e. Rimmed vacuoles are common
 - f. Electron microscopy:
 - i. In approximately 10% of patients, there are inclusions in the muscle fiber nuclei
 - ii. The inclusions are tubulofilamentous with an outer diameter of 8.5 μm , and inner diameter of 3 μm and may be 0.25 μm in length. They form tangles or palisades
 - iii. Inclusions may also occur in the cytoplasm that is also seen in inclusion body myositis, hereditary inclusion body myopathy and some distal myopathies
 - g. There are reports of abnormal mitochondrial number and structure in some patients

Oculopharyngeal Muscular Dystrophy Variants

1. Infantile or early childhood variant:
 - a. Ptosis, ophthalmoparesis, generalized muscle weakness with respiratory involvement
 - b. Distal myopathy variant:
 - i. Primarily in Japanese patients
 - ii. Earlier onset than classic OPMD
 - iii. Onset in the first decade of life

Laboratory Evaluation

1. Serum CK levels are normal or only slightly increased
2. Swallowing studies reveal impaired pharyngeal and esophageal function
3. EMG:
 - a. Myopathic pattern
4. The clinical variants are similar to classic OPMD

Distal Myopathy (Muscular Dystrophies)

Overview

Molecular genetic studies support the concept that distal myopathies are forms of muscular dystrophy. Some distal myopathies are allelic to specific types of LGMD as evidenced by tibial myopathy and LGMD2J (titin mutations) and Miyoshi myopathy and LGMD2B (dysferlin mutations). There is also an overlap of some distal myopathies with variants of hereditary inclusion body myopathy and myofibrillar myopathy. In general, they manifest distal progressive atrophy and weakness of the extremities and myopathic features on muscle biopsy. They form specific entities based on clinical features that include mode of inheritance, age of onset and muscle histology and CK levels.

In the distal myopathies: 1. there are no monogenetic classical phenotypes; 2. there are no phenotypes with different genotypes and 3. there are phenotypes with different genotypes that are usually associated with non-distal muscular clinical manifestations.

Welander Distal Myopathy

General Characteristics

1. Welander distal Myopathy is caused by heterozygous mutations in the TIA1 gene that map to chromosome 2p13
2. A subset of patients has a homozygous mutation that causes a more severe phenotype
3. The myopathy is seen predominately in Sweden and Finland
4. The myopathy is autosomal dominant

Clinical Manifestations

1. The onset is usually in the fifth decade; rare patients have been reported with onset prior to age 30
2. Weakness is initially in the wrist and finger extensors and slowly progresses to the ankle dorsiflexors to a greater degree than plantar flexors

3. In approximately 10% of patients, weakness is first noted in the distal lower extremities or simultaneously in the arms and legs
4. There is no sensory loss
5. Muscle stretch reflexes are lost in the biceps brachii and at the Achilles tendon

Neuropathology

1. Muscle biopsy:
 - a. Variability in fiber size
 - b. Increased central nuclei
 - c. Split fibers
 - d. Increased endomysial connective tissue in long standing patients
 - e. Rimmed vacuoles occur in scattered fibers
2. Electron microscopy:
 - a. 15–18 Nm cytoplasmic and nuclear filaments may be detected that are similar to those noted in IBM, ICBM and OPMD
 - b. Disruption of myofibrils
 - c. Z-disc derived material, similar to that seen in MFM, accumulates
 - d. Sural nerve biopsy:
 1. Moderate loss of small diameter myelinated fibers

Laboratory Evaluation

1. Serum CK is normal or only slightly increased
2. EMG:
 - a. Early recruitment of small amplitude, short duration MUAPs
 - b. Quantitative EMG supports a myopathy
 - c. Motor and sensory conduction velocities are normal
3. A subgroup of patients have decreased temperature and vibration threshold by QST (quantitative sensory testing)

Udd Distal Myopathy

General Characteristics

1. Tibial muscular dystrophy is caused by heterozygous mutation in the gene that encodes the muscle protein titin (TTN)
2. Homozygous mutation in the gene causes LGMD type 2J
3. The gene maps to chromosome 2q31-33
4. Dominant mutations cause a late onset distal myopathy while recessive mutations of the titin gene cause early onset LGMD2J

Clinical Manifestations

1. Usual presentation is after 35 years of age
2. Presenting sign is weakness of the anterior compartment of the leg with unilateral or bilateral foot drop
3. Weakness begins in the toe extensors and then gradually progresses to involve the anterior tibialis muscle
4. The proximal leg muscles and the intrinsic hand and wrist extensors are affected

5. Rare patterns of weakness include:
 - a. Arms are affected to a greater degree than the legs
 - b. The gastrocnemius and soleus muscles are affected and the anterior tibialis is spared
 - c. LGMD phenotype
6. Facial muscles are spared; rarely bulbar weakness occurs
7. Normal sensation
8. Decreased Achilles muscle stretch reflexes

Neuropathology

1. Muscle biopsy:
 - a. Non-specific myopathic pattern
2. The protein is attached to the Z-line in the M-line of the sarcomere
3. Functions include the structural attachment of the myosin filaments with the Z-disc; possible role in myofibrillar genesis

Laboratory Evaluation

1. The serum CK is normal or minimally increased
2. EMG:
 - a. Early recruitment of small amplitude, brief duration MUAP
 - b. Motor and sensory conduction velocities are normal
 - c. Fibrillation potentials and positive sharp waves occur

Markesbery-Griggs Distal Myopathy

General Characteristics

1. Markesbery-Griggs distal myopathy is caused by mutations in the ZASP gene that maps to chromosome 10q22.3-23.2
2. The core of skeletal muscle Z-discs is composed of actin filaments from neighboring sarcomeres that are cross-linked by α -actinin hemodimers
3. Z-disc-associated alternatively spliced, PDZ motif-containing protein ZASP/Cypher interacts through its PDZ domain with Z-disc proteins that include: 1. α -actin, 2. motilin and 3. other Z-disc proteins
4. ZASP protein directly interacts with skeletal muscle actin filament through its actin-binding domain between the modular PDZ and LIM domains
5. Alternative splicing of this region imparts each isoform with unique actin-binding domains
6. Expression of mutant ZASP causes Z-disc disruption and F-Actin accumulation that is similar to what is seen in myofibrillar myopathy

Clinical Manifestations

1. Late onset autosomal dominant distal myopathy that has initial anterior compartment lower extremity weakness and atrophy
2. A subset of patients develops proximal leg and wrist/finger extensory weakness
3. Cardiomyopathy is common

Neuropathology

1. Muscle biopsy:
 - a. Rimmed vacuoles
 - b. Disruption of skeletal muscle Z-discs and an accumulation of myofibrillar degradation products

Laboratory Evaluation

1. CK is mildly elevated
2. EMG:
 - a. An irritative myopathy

Nonaka Distal Myopathy (Autosomal Recessive Inclusion Body Myopathy)*General Characteristics*

1. Nonaka myopathy is an autosomal recessive illness caused by a mutation in the GNE gene that encodes UDP-N-acetylglucosamine-2-epimerase/N-acetylmannosamine kinase
2. The gene maps to chromosome 9p13.3
3. This myopathy is allelic to autosomal recessive inclusion body myopathy
4. The disease occurs worldwide but the largest ethnic cluster is in Jews that originated from Iran and the Middle East. A similar number patients has been reported from Japan

Clinical Manifestations

1. The initial presentation is usually weakness and atrophy of the anterior compartment of the lower extremities
2. Foot drop occurs in the second or third decade
3. The posterior leg compartments and the distal upper extremities are affected early in the disease course, but to a lesser degree
4. Proximal arm and leg muscles and the neck are gradually involved
5. The quadriceps muscle is relatively spared even to adulthood
6. There are no sensory signs or symptoms
7. Extraocular and bulbar muscles are spared
8. There is a report of a patient with asymmetric hand weakness presentation

Neuropathology

1. Muscle biopsy:
 - a. Non-specific myopathic changes
 - b. Rimmed vacuoles with acid phosphatase-positive autophagocytic activity have been described
2. Absent inflammatory cell infiltrate
3. Electron microscopy:
 - a. 15–18 nm intranuclear and cytoplasmic tubulofilaments that is similar to those seen in sporadic IBM

Laboratory Evaluation

1. The serum CK is normal or minimally elevated
2. EMG:

- a. Needle evaluation in weak muscles demonstrates positive sharp waves
- b. Early recruitment of low amplitude, brief duration MUAPs

Miyoshi Distal Myopathy*General Characteristics*

1. Miyoshi muscular dystrophy is caused by homozygous mutation in the dysferlin gene. It is an autosomal recessive illness and maps to chromosome 2p13.2
2. Mutation in the dysferlin gene also causes LGMD2B

Clinical Manifestations

1. The onset is in young adulthood
2. There is weakness of distal extremity musculature of both upper and lower extremities with sparing of the intrinsic hand muscles
3. There is predominant atrophy and weakness of the gastrocnemius and soleus muscles that later spreads to involve the thigh and gluteal muscles
4. Patients are unable to stand on their tiptoes, have difficulty climbing stairs and walking
5. Decreased ankle muscle stretch reflexes

Neuropathology

1. Muscle biopsy:
 - a. Dystrophic features
 - b. Active muscle fiber necrosis and regeneration
 - c. Disorganization of the intermyofibrillar network
 - d. Usually dysferlin reduction is less than 20% of normal

Laboratory Evaluation

1. Elevated serum CK (35–200x normal)
2. EMG:
 - a. Myopathic pattern

Laing Distal Myopathy*General Characteristics*

1. Laing distal myopathy has been linked to mutations in the slow beta cardiac MyHC1 gene or MyH7 gene that maps to chromosome 14q

Clinical Manifestations

1. The onset is in young adulthood with weakness and atrophy of the anterior compartment
2. When anterior compartment weakness occurs that includes the extensor hallucis longus muscle the “hanging toe” sign is prominent
3. The age of onset may be between 4 and 25 years
4. Over time, weakness spreads to the neck flexors and finger extensors. The shoulder and hip girdle musculature may be affected
5. Hand intrinsic muscles and finger flexors are spared
6. An infantile form has been reported

Neuropathology

1. MyHC is the most prominent myosin isoform of type 1 muscle fibers
2. Muscle biopsy:
 - a. Non-specific myopathic pattern
 - b. No rimmed vacuoles
 - c. Large deposits of myosin heavy chain (MyHC) are demonstrated in subsarcolemmal areas of type 1 muscle fibers

Laboratory Evaluation

1. The serum CK may be normal or only mildly elevated
2. EMG:
 - a. Small amplitude, brief duration polyphasic MUAPs are demonstrated in distal > proximal muscles
 - b. Occasional fibrillation potentials and positive sharp waves are seen
 - c. There are normal motor and sensory conduction velocities

Distal Myopathy with Vocal Cord Paralysis and Pharyngeal Weakness*General Characteristics*

1. Distal Myopathy with vocal cord paralysis has been mapped to chromosome 5q31

Clinical Manifestations

1. Autosomal dominant inheritance has been determined for this myopathy in one large kindred
2. The onset is in the fourth to sixth decade with weakness of the anterior tibial musculature
3. After limb muscle weakness, there is involvement of the vocal cords and pharyngeal musculature

Neuropathology

1. Non-specific myopathic pattern with rimmed vacuoles on muscle biopsy
2. Electron microscopy:
 - a. No filamentous inclusions

Laboratory Evaluation

1. EMG:
 - a. Mixed neuropathic and myopathic characteristics
 - b. In some patients, there is mild slowing of conduction velocities
2. The serum CK is normal or moderately increased

Myofibrillar Myopathy (MFM)*General Characteristics*

1. Myofibrillar Myopathy is a compilation of muscle diseases that are clinically and genetically heterogeneous but have electron microscopic evidence of myofibrillar disruption and desmin accumulation in muscle fibers

2. A major component of the pathogenesis of MFM is disruption of the Z-disc. Mutations have been described in proteins important to Z-disc function and integrity in:
 - a. Desmin
 - b. α - β crystalline
 - c. Myotilin
 - d. Filamin-C
 - e. ZASP (Z-band alternatively spliced PDX motif containing protein)
3. Most familial cases are autosomal dominant although autosomal recessive and possible X-linked heritability have been described
4. Desmin gene mutations which maps to chromosome 2q35 have been reported in autosomal dominant MFM and also in some sporadic patients
5. Other gene mutations that produce the MFM phenotype includes:
 - a. Mutations in the α - β -crystalline gene that map to chromosome 11q21-23 have been described in some autosomal dominant kinships
 - b. Myotilin gene mutations that map to chromosome 5q22-31. Some patients with late-onset MFM are allelic to LGMD1A
 - c. Missense mutations in the ZASP gene that maps to chromosome 10q22.3-10q23.1; dominant inheritance occurs in greater than 50% of these patients. The Markesbery-Griggs distal myopathy also is due to mutations in the ZASP gene
 - d. Mutations in the selenoprotein N-gene (SEPNI) that maps to chromosome 1p36 cause autosomal recessive MFM with Mallory-body-like inclusions. Mutations of SEPNI gene also cause congenital muscular dystrophy with the rigid spine phenotype and multi/minicore myopathy
 - e. Nonsense mutations in the filamin-L gene (FLNC) that maps to chromosome 7q32 cause autosomal-dominant phenotype of MFM
 - f. Antiapoptotic BCL2-associated athanogene 3 may cause the phenotype

Clinical Manifestations

1. MFM is associated with a wide spectrum of clinical phenotypes
2. Onset is usually between 25–45 years of age; patients have been described in infancy or late adulthood
3. Phenotypic variants include:
 - a. Facioscapulohumeral
 - b. Scapuloperoneal
 - c. Weakness can be predominately proximal, distal, or generalized
4. Facial and pharyngeal muscles may be affected in some patients
5. Spinal rigidity occurs in a subset of patients
6. Cardiomyopathy occurs with both arrhythmias and congestive heart failure that in severe patients requires heart transplantation or pacemaker insertion

7. There may be smooth muscle involvement with intestinal pseudo-obstruction
8. Respiratory insufficiency may develop
9. Patients with desminopathy, α - β -crystallinopathy or Bag3opathies have an infantile or juvenile disease onset
10. Cardiac involvement is common and may be the only manifestation of desminopathy

Specific Clinical Manifestations of Gene Defects That Cause Myofibrillar Myopathy

1. Alpha- β -crystallin gene
 - a. Autosomal dominant type that maps to chromosome 11q21-23
 - b. Infantile and adolescent form with rapid progression
2. Titan gene:
 - a. Mutations in the titin gene that maps to chromosome 2q31.2
 - b. Associated with hereditary early respiratory failure
3. Myotilin gene:
 - a. Missense mutation in the myotilin gene that maps to chromosome 5q22-31
 - b. The late onset patients that are allelic to LGMD1A manifest:
 - i. Late onset distal > proximal weakness
 - ii. Polyneuropathy
 - iii. Cardiopathy
4. ZASP gene:
 - a. Missense mutations in the ZASP gene that maps to chromosome 10q22.3-10q23.2 demonstrate:
 - i. Dominant inheritance
 - ii. Distal > proximal weakness
 - iii. Onset is between 44–73 years of age
 - iv. A subset has a cardiomyopathy with arrhythmias or a low ejection fraction
 - v. Some patients develop a polyneuropathy
5. Selenoprotein N gene (SEPN1):
 - a. Mapped to chromosome 1p36 were associated with autosomal recessive MFM
 - b. They manifested axial weakness, respiratory insufficiency
 - c. Rigidity of the spine
6. Filamin-C gene (FLNC):
 - a. Nonsense mutations in the FLNC gene that maps to chromosome 7q32 are associated with autosomal dominant subtype of MFM
 - b. Patients initially present with proximal muscle weakness that subsequently involve distal and respiratory muscles
7. BAG3 gene:
 - a. Myofibrillar Myopathy-6 is caused by heterozygous mutations in the BAG3 gene (BCL2-associated antho-gene 3) that map to chromosome 10q26.11
 - b. Patients manifest in the first decade:
 - i. Rapidly progressive generalized and proximal muscle weakness
 - ii. Respiratory insufficiency (restrictive)
 - iii. Cardiomyopathy
 - iv. Skeletal abnormalities due to muscle weakness cause scoliosis
 - v. Contractures of the Achilles tendon and limited spine mobility in a subgroup of patients

Neuropathology

1. Desmin is an intermediate filament protein that is prominent in skeletal, cardiac and smooth muscle
2. It functions to link the Z-band with the sarcolemma and the nucleus
3. The intermediate filament network stabilizes the muscle fiber and also is important during mitosis and muscle regeneration
4. Mutated desmin filaments form from insoluble aggregates that block the genesis of the normal filamentous network
5. Alpha- β -crystalline acts as a molecular chaperone and in concert with desmin functions in the construction of the intermediate filament network
6. Myotilin is a Z-disc protein and interacts with α -actinin, actin, and filamin-C in myofibrillar construction
7. ZASP protein is expressed in both skeletal and cardiac muscle binds to α -actinin at the Z-disc that cross-links thin filaments of adjacent sarcomeres
8. Selenoproteins play a role in the regulation of oxidative stress and calcium homeostasis. Filamin-C is involved in the formation of the Z-disc and binds actin. It also binds gamma- and L-sarcoglycan at the sarcolemmal membrane. It is postulated to play a role in signaling from the sarcolemma to the myofibril

Muscle Biopsy

1. Variability in fiber size
2. Central nuclei
3. Occasional type 1 fiber predominance
4. Hyaline structures and non-hyaline structures are the two major types of lesions seen on light and electron microscopy

Hyaline Structures on EM

1. Hyaline structures resemble cytoplasmic, spheroid or Mallory bodies
2. Non-hyaline structures:
 - a. Are dark green amorphous areas demonstrated with the Gomori Trichrome stain
 - b. On EM:
 - i. The non-hyaline lesions are foci of myofibrillar destruction. They consist of disrupted myofilaments, Z-disc-dense material, dense Z-disc structures and straining of the Z-disc. There may be an accumulation of 14–20 nm tubulofilaments that are typically seen in IBM

Immunohistochemistry

- Both hyaline and non-hyaline lesions contain desmin and other proteins
- Non-hyaline lesions contain desmin, dystrophin, gelsolin, N terminus of B-amyloid precursor protein and NCAM. They are depleted of actin, α -actinin, myosin, titin and nebulin
- Hyalin structures consist of:
 - Compacted and degraded components of thick and thin filaments
 - Histochemically hyaline structures react to: 1. actin; 2. α -actinin; 3. myosin; 4. dystrophin; 5. gelsolin; 6. filamin-C and 7. the N-terminus of amyloid-beta precursor protein
- Both granular and non-granular lesions react for alpha- β -crystalline, L-1 antichymotrypsin and ubiquitin
- Affected muscle fibers abnormally express cyclin-dependent kinase that includes CDC/CDK in the cytoplasm (CDC2, CDK2, CDK4 and CDK7)

Nerve and Intramuscular Nerve Biopsies Reveal (on a Subset of Patients)

- Enlarged axons with the accumulation of intermediate neurofilaments
- Axonal spheroids (subset of patients)

Laboratory Evaluation

- The serum CK may be normal to slightly elevated
- EMG:
 - Complex repetitive discharges, early recruitment of short-duration small amplitude polyphasic MUAPs
 - Increased insertional activity with positive sharp waves, pseudomyotonic potentials
 - Long duration, large amplitude MUAPs may be seen in chronic patients
 - Most often nerve conduction velocities are normal although in a subset of patients, low amplitude of motor and sensory potentials and decreased conduction velocities occur
- EKG:
 - Arrhythmias and conduction blocks
- Echocardiography:
 - Reveals a dilated or hypertrophic cardiomyopathy

Hereditary Inclusion Body Myopathy**General Characteristics**

- Autosomal recessive inclusion body myopathy is caused by homozygous or compound heterozygous mutations in the GNE gene that map to chromosome 9p13.3
- There are autosomal dominant forms of the disease and autosomal recessive forms; h-IBM is allelic to Nonaka distal myopathy
- Autosomal recessive h-IBM has been extensively studied in Iranian Jews but has been found in other Middle Eastern Jewish populations as well as non-Jews

GNE Involved in the Post-Translational Glycosylation of Proteins**Clinical Manifestations**

- H-IBM presents in the second or third decade with foot drop from anterior tibial muscle involvement
- There is slow, but progressive weakness of the iliopsoas, thigh adductors, and glutei
- The quadriceps is usually spared or is minimally affected in contrast to sporadic IBM
- The neck flexors and proximal arm muscles can be affected which may be asymmetric
- Severity of the weakness is variable and some patients are able to walk for decades while others are wheelchair bound early in the course of the illness
- Autosomal dominant h-IBM has predominantly limb girdle pattern of weakness although distal muscles may occasionally be affected. There is no involvement of extraocular or bulbar musculature. Deep tendon stretch reflexes are normal
- There may be a familial predisposition for s-IBM in some patients that is confused with hereditary forms
- Variant with cerebral hypomyelination:
 - Infantile onset
 - Autosomal recessive inheritance
 - Progressive proximal greater than distal weakness
 - The legs are affected to a greater degree than the arms
 - Normal intelligence
 - Leukoencephalopathy by MRI
 - EMG demonstrates mildly slow conduction velocities

Neuropathology

- Muscle biopsy:
 - Autosomal recessive and dominant h-IBM have similar biopsy findings as are noted with s-IBM except that there is no endomysial inflammation of non-necrotic muscle fibers
 - Fiber size variability
 - Central nuclei
 - Fiber splitting
 - Rimmed vacuoles:
 - The vacuoles are autophagic and are characterized by an accumulation of ubiquitinated and congophilic multiprotein aggregates that contain amyloid- β
 - Recent studies have demonstrated that there is no activation of the unfolded protein response in hereditary GNE inclusion body myopathy that occurs in the sporadic form of the disease
- Electron microscopy:
 - Abnormal accumulation of 15–18 nm tubulofilaments in the nuclei and cytoplasm of muscle fibers

Laboratory Evaluation

- Serum CK levels are normal or only minimally elevated
- EMG:

- a. Fibrillation potentials, positive sharp waves and complex repetitive discharges
- b. Small amplitude brief duration polyphasic MUAPs
- c. There may also be large amplitude, long duration polyphasic MUAP

Hereditary Inclusion Body Myopathy and Paget's Disease of Bone and Dementia (IBMPFDI)

1. IBM with Paget's disease and frontotemporal dementia (IBMPFDI) is caused by heterozygous mutations in the VCP gene that map to chromosome 9p13.3
2. It is an autosomal dominant disorder with incomplete penetrance
3. Nineteen missense mutations have been identified
4. It is allelic with:
 - a. Familial ALS
 - b. Familial spastic paraparesis
 - c. Distal myopathy and dementia
 - d. CMT2

Clinical Manifestations

1. A high degree of intrafamilial variability
2. Onset is in the 3rd and 4th decades
3. Its major features are:
 - a. Muscle weakness (90%)
 - b. Osteolytic bone lesions similar to those of Paget's disease (51%)
 - c. Frontotemporal dementia (32%)
4. Onset may be variable manifesting as back pain, weakness, or dementia
5. The mean age of onset is 43 years of age (3–66 years)
6. Adult onset of proximal and distal muscle weakness that may be variable in degree and asymmetric in pattern within families
7. Respiratory muscles are involved (vital capacity 29–70% of normal) that progress and may cause respiratory insufficiency
8. Scapular winging from supra- and infraspinatus weakness
9. Rarely face and tongue involvement
10. Posterior neck muscle weakness with dropped head (rare)
11. Camptocormia
12. Slow progression over 1 to 2 decades with severe weakness and death in the 40th–60th years
13. Bone disease:
 - a. Paget's disease occurs in 43–49% of patients
 - b. The spine is the most common location but lesions occur in the hip, skull, pelvis
14. Pain in involved bony locations
15. Onset at a mean age of 42 (29–61 years)
16. Lumbar lordosis
17. Dementia:
 - a. Occurs in 30%–37% of patients
 - b. Onset is 52–54 years (mean; range 39–62 years)

18. Cardiomyopathy:
 - a. Occurs occasionally late in the course of the disease
 - b. Congestive heart failure from dilated cardiomyopathy
19. Rarely there are associated:
 - a. Liver disease
 - b. Cataracts
 - c. Sensorimotor polyneuropathy

Neuropathology

1. Muscle biopsy:
 - a. Non-specific myopathic pattern
 - b. Increased endomysial connective tissue
 - c. Rimmed vacuoles
 - d. VCP staining inclusions in the sarcoplasm and myonuclei
 - e. Electron microscopy:
 - i. Tubulofilamentous inclusions
2. Brain pathology:
 - a. Cortical atrophy
 - b. Widespread cortical and subcortical neuronal loss
 - c. Ubiquitin and TDP-43 positive intranuclear inclusions
3. VCP belongs to the AAA-ATPase super family and its functions include:
 - a. Cell-cycle control
 - b. Membrane fusion
 - c. Ubiquitin proteasome degradation pathways
4. The mutated protein causes:
 - a. Increased levels of ubiquitinated cell proteins
 - b. Sensitization to proteasome stress
 - c. Decreases degradation of proteins by the endoplasmic reticulum associated degradation (ERAD) mechanisms
 - d. Increase the formation of aggregates
 - e. Upregulation of autophagy related proteins

Laboratory Evaluation

1. Serum CK levels are normal in 80% of patients or mildly increased
2. Serum alkaline phosphatase is elevated with Paget's disease
3. EMG:
 - a. Low amplitude, polyphasic, short duration MUAPs
 - b. Fibrillations and positive sharp waves
 - c. Chronic denervation changes are seen in long standing patients
4. Muscle MRI:
 - a. Widespread degenerative changes that include axial musculature
5. Skeletal x-ray:
 - a. Compatible with Paget's disease of bone
6. Echocardiography:
 - a. Dilated cardiomyopathy late in the course of the illness
7. Variant syndromes:
 - a. Familial ALS
 - b. Distal myopathy
 - c. Progressive spastic paraparesis
 - d. CMT2 sensory motor neuropathy

Myopathy with Paget's Disease of Bone with or Without Cognitive Deficit or Motor Neuron Disease (IBMPDID2)

General Characteristics

1. IBMPDID2 is caused by mutations in the heterogeneous nuclear ribonucleoprotein A2/B1 (HNRNPA2B1) gene that maps to chromosome 7p15.2 which is autosomal dominant
2. The disease has been described from 1 US family with 5 patients
3. The HNRNPA2 protein is the most abundant isoform
4. The mutation is missense and is located in the prion-like domain of the genes

Clinical Manifestations

1. Onset is in the 3rd to 5th decades
2. Weakness is distal in the lower extremities and affects the ankles and toes
3. Proximal muscles are affected in the upper extremity that causes scapular winging from supra and infraspinatii weakness
4. A slowly progressive process with atrophy of the affected muscles
5. 100% of patients have Paget's disease of bone that may be severe, widespread and affects long bones
6. Cognitive deficiency occurs in 40% of patients
7. Motor neuron disease occurs in approximately 40% of patients

Neuropathology

1. Muscle biopsy:
 - a. Variation in fiber size
 - b. Central nuclei
 - c. Increased endomysial connection tissue
 - d. Rimmed vacuoles
 - e. TDP-43 inclusions
 - f. The protein is localized to the nucleus to a greater degree than the cytoplasm and binds RNA
 - g. In the cytoplasm there are mRNA granules that contain untranslated mRNAs
 - h. The mutated protein assembles into self-seeding fibrils that are recruited to stress granules

Laboratory Evaluation

1. Serum CK may be normal to high
2. Serum alkaline phosphatase is high
3. EMG:
 - a. Myopathic pattern
4. Skeletal x-rays:
 - a. Paget's disease of bone

Myopathy with Paget's Disease of Bone (IBMPFD3)

General Characteristics

1. Mutation in the heterogeneous nuclear ribonucleoprotein A1 (HNRNPA1) gene that maps to chromosome 12q13.13 dominant

2. The mutation is missense and is located in the prion-like domain
3. Protein functions are:
 - a. RNA-binding
 - b. Packaging of pre-mRNA into hnRNP particles
 - c. Essential in the mechanism of assembly of ribonucleo-protein granules

Clinical Manifestations

1. Onset in childhood with clumsiness
2. Myopathy occurs in 100% of patients:
 - a. Initial weakness is in the iliopsoas muscle
 - b. Foot dorsiflexors are subsequently involved
 - c. Subsequent spread to the abdominal wall
 - d. Arms are usually spared except for slight scapular winging
 - e. The weakness is progressive and most patients are wheelchair bound in the 5th or 6th decade
3. Paget's disease (50% of patients)
4. Normal cognition

Neuropathology

1. Muscle biopsy:
 - a. Variation on fiber size
 - b. Central nuclei
 - c. Rimmed vacuoles
 - d. TDP-43 inclusions
2. Involved in the transport of poly (A) mRNA from the nucleus to the cytoplasm. The disease-mutated protein exacerbates the abnormal protein into self-seeding fibrils

Laboratory Evaluation

1. Serum CK normal to mildly elevated
2. Alkaline phosphatase is normal to 8x normal
3. EMG:
 - a. Myopathic

HNRNPA1 Variant Syndrome

1. ALS 20

Hereditary IBM Type 3

General Characteristics

1. h-IBM type 3 is caused by heterozygous, compound heterozygous or homozygous mutations in myosin heavy chain II a (MYHC2A) gene or the MYH2 gene that maps to chromosome 17p13
2. Autosomal dominant and autosomal recessive inheritance has been reported
3. The protein encodes MyHC11a that is expressed in type 2A muscle fibers

Clinical Manifestations (AD Form)

1. Congenital joint contractures that disappeared during early childhood

2. Proximal muscle weakness
3. External ophthalmoplegia
4. Adults have progressive muscle weakness that starts between 30 to 50 years of age
5. Patients may not progress during childhood
6. Autosomal recessive form:
 - a. Onset in childhood
 - b. Reported from 16 patients from 8 Arab families
 - c. Mild proximal limb girdle weakness
 - d. Neck flexor weakness
 - e. Facial weakness
 - f. Variable extraocular muscle involvement
 - g. Slowly progressive course
 - h. Patients develop myopathic facies, nasal voice
 - i. High arched palate
 - j. Some patients develop scapular winging, scoliosis, and intrinsic hand muscle weakness

Neuropathology

1. Muscle biopsy:
 - a. Rimmed vacuoles
 - b. Tubulofilamentous inclusions (15–21 nm size)
 - c. Dystrophic changes
 - d. In some patients, there were hypotrophic type 2 fibers

Laboratory Evaluation

1. Serum CK normal to mildly elevated
2. EMG:
 - a. Myopathic

Myopathy with Early Respiratory Failure

General Characteristics

1. Titin (TTN) gene that maps to chromosome 2q31.2
2. Autosomal dominant missense mutation whose deficit in the encoded protein is located in the myosin-binding component of the A-band
3. Primarily seen in English and Swedish patients

Clinical Manifestations

1. The onset is variable and most common in the 4th to 5th decade (18–71 years)
2. Weakness is variable:
 - a. Distal weakness occurs in 30% proximal in 40% of patients
 - b. Legs > arms
3. Leg weakness encompasses distal and proximal muscles that include the tibialis anterior
4. Arm weakness involves the wrist flexors and extensors as well as the deltoid; weakness may be diffuse
5. Axial muscle weakness
6. Strong ankle extensor
7. Mild facial muscle involvement in some patients
8. Weakness is symmetric in 90% of patients
9. The course is slowly progressive. The progression is proximal legs to shoulders. There may be quadriceps

sparing. Patients often require non-invasive nocturnal ventilator support

10. Respiratory failure:
 - a. Vital capacity and FEV1L 75% of predicted values at presentation with progressive deterioration
11. No contractures
12. No cardiac involvement
13. Some patients demonstrate calf hypertrophy

Neuropathology

1. Muscle biopsy:
 - a. Variability of fiber size
 - b. Central nuclei
 - c. Fiber splitting
 - d. Myofibrillar pathology
 - e. Eosinophilic inclusions; cytophilic inclusions may contain amyloid-beta desmin, SMI-31 binding proteins
 - f. Cytophilic bodies (in 95% of patients):
 - i. Stain for F-actin
 - ii. “Necklace” pattern
 - g. Vacuoles (rimmed in 50% of patients)
 - h. Type 1 fiber predominance in 50% of patients
 - i. Reduced calpain-3
 - j. Electron microscopy

Laboratory Evaluation

1. Serum CK normal to slightly elevated
2. EMG:
 - a. Myopathic with irritative features
 - b. Normal nerve conduction velocities
3. MRI of muscle:
 - a. Selective early involvement of the semitendinosus and obturator externus
 - b. The proximal part of the muscle is more severely involved
 - c. Adductor longus muscle is spared
 - d. Tibialis anterior is most severely involved with relative sparing of the gastrocnemius and soleus muscles
 - e. Moderate involvement of the supra- and infraspinus, the serratus anterior, subscapularis and trapezius muscles

Myopathy with Ringed Muscle Fibers

General Characteristics

1. Sporadic inheritance

Clinical Manifestations

1. Onset in the third decade
2. Weakness in the quadriceps and ankle dorsiflexors
3. Progression occurs in 1 to 5 years

Neuropathology

1. Muscle biopsy:
 - a. Variation in fiber size

- b. Central nuclei
- c. Increased endomysial connective tissue
- d. Rings in the outer sarcoplasm, the middle annular myofibrils with a normal central myofibril

Laboratory Evaluation

1. Serum CK is normal
2. EMG:
 - a. Myopathic with irritable features

Distal Myopathy (MPD3)

General Characteristics

1. Two possible gene loci that map to chromosome 8p22-q11 and 12q13-q22
2. Described in a single Finnish family

Clinical Manifestations

1. Onset between 32 to 45 years of age with clumsiness of the hands or legs
2. Leg involvement includes the tibialis anterior, extensor digitorum longus, gluteus medius and tibialis flexor longus
3. Arm involvement includes opponens pollicis, first dorsal interosseous, abductor digiti minimi
4. The involvement may be asymmetric and progresses to involve the proximal limb muscles, infraspinatus, triceps, and proximal leg muscles
5. Patients are able to walk throughout the illness

Neuropathology

1. Muscle biopsy:
 - a. Variation in fiber size
 - b. Severe endomysial fibrosis
 - c. Rimmed vacuoles
 - d. Cytoplasmic inclusion bodies

Laboratory Evaluation

1. Serum CK is normal or minimally elevated
2. EMG:
 - a. Myopathic pattern

Distal Myopathy with Spared Anterior Leg Muscles (Williams Distal Myopathy)

General Characteristics

1. Williams distal myopathy is caused by heterozygous mutations in the FLNC gene that map to chromosome 7q32.1
2. The mutations are missense and dominant; they occur in the actin-binding domain
3. The disease is allelic with:
 - a. Myofibrillar myopathy
 - b. Distal myopathy with upper limb predominance

Clinical Manifestations

1. Onset of the disease is at birth to 30 years of age
2. It has been described in Australian and Italian families

3. The phenotype is variable within families and some family members are asymptomatic
4. Arm involvement includes forearm pronators, finger flexors and intrinsic hand muscles
5. Leg muscle involvement includes the ankle evertors and plantar flexors (calf atrophy)
6. There is sparing of the anterior leg compartment and the posterior arm musculature
7. There is distal muscle wasting
8. Cramps and deep muscle pain with exercise
9. Deep muscle stretch reflexes demonstrate absent ankle reflexes
10. Cardiomyopathy has been reported in two patients
11. There is no respiratory involvement
12. A slowly progressive course but patients are able to walk throughout the illness

Neuropathology

1. Muscle biopsy:
 - a. Variation in fiber size
 - b. Internal muscle architecture is disrupted in some biopsies
 - c. There are neomyofibrillar aggregates, vacuoles, or inflammation
 - d. Dysferlin is normal

Laboratory Evaluation

1. Serum CK is normal or minimally increased
2. EMG:
 - a. Myopathic pattern
3. Muscle MRI:
 - a. Involvement of posterior and lateral leg muscles
 - b. Some asymmetry of involvement

Distal Myopathy with Upper Limb Predominance

General Characteristics

1. FLNC mutation with variant syndrome:
 - a. A frame shift mutation produces a stop codon
 - b. Haploinsufficiency of filamin-C
 - c. Autosomal dominant with partial penetrance

Clinical Manifestations

1. Onset between 20–54 years of age with weakness of the fingers and foot extensors
2. Distal weakness is greater than proximal
3. Arms are affected prior to legs in some patients
4. Finger extensors and interossei may be severely affected
5. There is sensory loss in 40% of patients
6. Pes cavus in 20%, hypertension in 30% and cardiomyopathy in 10% of patients
7. Atrophy of distal arms and legs

Neuropathology

1. Muscle biopsy:

- a. Fiber size variability
- b. Necrosis with pyknotic nuclear clumps
- c. Type 1 fiber predominance
- d. Few myofibrillar aggregates or none demonstrated
- e. Electron microscopy:
 - i. Myofibrillar disorganization

Distal Nebulin Myopathy

General Characteristics

1. Distal nebulin myopathy is caused by missense often homozygous mutation in the NEB gene that maps to chromosome 2q23.3. It is an autosomal recessive disease
2. Its encoded protein is postulated to have a role in the regulation of thin filament length and muscle contraction
3. Allelic with rod myopathy

Clinical Manifestations

1. The onset may be in childhood or rarely in adults
2. Weakness is distal and demonstrates the “hanging big toe” sign
3. There is extensor finger weakness. The index finger is spared
4. Neck flexor weakness
5. Patients are slender
6. The pattern of weakness resembles that of Laing myopathy

Neuropathology

1. Muscle biopsy:
 - a. Rods and cores may be demonstrated but are not prominent
 - b. A childhood onset patient demonstrated both cores and rods
2. Electron microscopy:
 - a. Z-line streaming
 - b. Minor rod changes

Laboratory Evaluation

1. Serum CK is normal
2. EMG:
 - a. Myopathic pattern
3. Muscle MRI:
 - a. Predominant distal involvement of the anterior compartment

Nephropathic Cystinosis

General Characteristics

1. Nephropathic cystinosis is caused by missense mutations in the CTNS gene that maps to chromosome 17p13.2
2. Cystinosis is classified as lysosomal storage disorder because of the intralysosomal localization of stored cysteine
3. Intracellularly cystine is compartmentalized with acid phosphatase and is membrane bound
4. There are multiple systemic effects of the illness

Clinical Manifestations

1. Age of onset is from the first year of life to adulthood
2. Infants have a failure to thrive
3. Multiple systems are involved that include:
 - a. Skeletal:
 - i. Short stature
 - ii. Frontal balding
 - iii. Hypophosphatemic rickets
 - b. Eyes:
 - i. Retinopathy
 - ii. Corneal cystine crystal deposition
 - c. Renal:
 - i. Fanconi syndrome that leads to renal failure
 - d. Endocrine:
 - i. Hypothyroidism
 - ii. Insulin dependent diabetes mellitus
 - iii. Delayed puberty
 - iv. Skin:
 - 1. Pigmentary alterations
 - 2. Hypohidrosis
 - v. CNS:
 - 1. Cognitive impairment
 - 2. Visual spatial processing defects
 - 3. Cerebral atrophy
 - vi. Muscle:
 - 1. Distal weakness and wasting
 - 2. Dysphagia

Neuropathology

1. Muscle biopsy:
 - a. Variation in fiber size
 - b. Rimmed vacuoles that are acid phosphatase positive
 - c. Cystine deposition in muscle fibers

Laboratory Evaluation

1. Increased cystine deposition in leukocytes
2. Urine proteinuria, glycosuria and microscopic hematuria
3. Blood hyponatremia, hypokalemia, and hypophosphatemia
4. Carnitine deficiency
5. Generalized aminoaciduria

Early Onset Distal Weakness

General Manifestations

1. Early onset distal weakness is caused by a missense mutation in Kelch-like homologue 9 gene that maps to chromosome 9p22 which is autosomal dominant
2. The KLHL9 protein complexes with cullin 3 and is involved in the ubiquitin dependent protein degradation pathway
3. Described in a German family

Clinical Manifestations

1. The onset is between 8 to 16 years of age

2. Weakness of the intrinsic hand muscles and distal leg muscles
3. Atrophy of the anterior tibialis muscles
4. Proximal muscles are normal
5. Late in the disease course, there is distal sensory loss in the extremities
6. A prolonged course and patients are able to walk throughout life

Laboratory Evaluation

1. CK is usually mildly elevated
2. EMG:
 - a. Motor nerve conduction velocities are normal; occasionally there is prolonged distal latency
 - b. Sensory conduction velocities are normal
 - c. Fibrillation potentials and large polyphasic motor unit potentials are seen in affected distal muscles

Neuropathology

1. Muscle biopsy:
 - a. Variation in fiber size

Distal Weakness, Hoarseness, Hearing Loss (CPNMHH)

General Characteristics

1. CPNMHH is caused by a mutation in the MyH14 gene that maps to chromosome 19q13.33
2. It is an autosomal dominant missense mutation
3. It is allelic with autosomal dominant deafness (DFNAI)
4. The mutation affects microRNA (mR-199)
5. Described in a Korean family

Clinical Manifestations

1. The onset is between 5 and 13 years of age
2. Distal muscle weakness that is followed by progressive atrophy of affected muscles
3. Lower extremities are affected to a greater extent than the upper
4. The weakness is seen first in the anterior lower leg compartment and then the posterior
5. Thigh muscles become involved at approximately 40 years of age
6. Most patients have foot deformity
7. Loss of muscle stretch reflexes
8. No sensory loss
9. 53% of patients developed hoarseness but none had dysphagia or vocal cord paralysis
10. Late onset sensorineural hearing loss was noted in 45% of patients

Neuropathology

1. Muscle biopsy:
 - a. Variation in fiber size
 - b. Fiber type grouping
 - c. Two patients demonstrated subsarcolemmal accumulation of enlarged mitochondria with rectangular or elongated rhomboidal paracrystalline inclusions by EM

Laboratory Evaluation

1. Serum CK varied from normal to 2.5 times normal
2. EMG:
 - a. Fibrillation potentials in affected muscles
 - b. Low amplitude CMAP
 - c. Normal nerve conduction velocities

Congenital Myopathies

Overview

The congenital myopathies are diverse skeletal muscle diseases that most often present at birth or early infancy. The natural history of a large pediatric cohort of 125 patients revealed that the genetic basis could be determined in approximately 80% of patients and mutations in the RYR1 gene was the most common. Approximately 70% of patients had a neonatal or infantile onset. Approximately 30% required mechanical ventilation at birth and 25% needed nasogastric alimentation. Twelve percent of patients died within the first year and had mutations in ACTA1, MTM1 or KLHL40 genes. All patients with RYR1 mutations survived. Patients with recessive mutations required gastrostomy more than those with dominant mutations. Approximately 75% of patients were able to walk although this milestone was acquired late in 60% of patients. Approximately 10% of patients lost the ability to walk. Bulbar involvement occurred in 40% of patients. Scoliosis of varying degree occurred in those who were able to walk and in 40% of patients who could not. Respiratory impairment occurred in 64% of patients and approximately 50% of these patients required nocturnal non-invasive ventilation.

The congenital myopathies usually present in infancy with generalized weakness and hypotonia. Motor milestones and development are delayed. Progressive weakness may gradually develop. The disorders are inherited in autosomal dominant, autosomal recessive or in an X-linked pattern. There is frequent intrafamilial variation in both presentation and severity. Mutations in many different genes may cause similar pathology and mutations in the same gene may result in different pathologies. Recent studies suggest that there are five major mechanisms that cause congenital myopathies which include:

1. Sarcolemmal and intracellular membrane remodeling and excitation-contraction coupling
2. Mitochondrial distribution and function
3. Myofibrillar generation of force
4. Atrophy
5. Autophagic mechanisms

In the past, congenital myopathies were classified according to their clinical features and microscopic structural differences on muscle biopsy. Next generation sequencing techniques is revealing a genetic diagnosis in these patients as a basis for diagnosis.

Central Core Myopathy (CCD)*General Characteristics*

1. Central core disease (CCD) and its variants are caused by heterozygous, homozygous or compound heterozygous mutations in the ryanodine receptor RYR1 gene that maps to chromosome 19q13.2
2. Biallelic mutation in the RYR1 gene causes minicore myopathy with external ophthalmoplegia

Clinical Manifestations

1. The onset is usually at birth or in early childhood with generalized weakness and hypotonia
2. There is considerable variability of weakness both inter- and infrafamily
3. The muscle weakness is stable or slowly progressive
4. Motor milestones are delayed
5. Proximal muscles of the leg as more affected than the arms
6. A wide-based hyperlordotic gait and Gowen's sign may be seen
7. There may be neck flexor and mild facial weakness
8. There is no extraocular muscle weakness or ptosis that are distinguishing clinical signs from centronuclear and nemaline myopathies
9. Muscle hypertrophy, atrophy, or contractures are usually not appreciated
10. Muscle stretch reflexes are normal or slightly reduced
11. Skeletal abnormalities include:
 - a. Pes plavus and cavus
 - b. Kyphoscoliosis
 - c. Congenital hip dislocation
12. Respiratory muscle involvement with nocturnal hypoxemia may occur
13. Patients are at risk for malignant hyperthermia

Neuropathology

1. Cores may be eccentric and multiple within a muscle fiber
2. In central core disease, the cores extend the entire length of the muscles
3. Cores are regions of sarcomeric disorganization without mitochondria and lack oxidative activity
4. In multicore disease, the multicores are in both type I and type II fibers and also have less mitochondria and lack of oxidative activity in the core lesion
5. Electron microscopy:
 - a. Changes in the sarcoplasmic reticulum and t-tubules
 - b. Structured cores demonstrate streaming of the Z-band but the sarcomeres are preserved
 - c. Unstructured cores have myofibrillary disruption
 - d. Cores contain desmin, dystrophin, actin, α -actinin, gelsolin, nebulin, myotilin, amyloid-beta precursor protein, NCAM and cyclin-dependent kinesin

Laboratory Evaluation

1. The serum CK level is normal or minimally elevated

2. EMG:

- a. Fibrillation potentials and positive sharp waves may occur in affected muscles
- b. Myopathic MUAPs with early recruitment
- c. Some long duration, polyphasic MUAPs

Multiminicore Myopathy (MmD)*General Characteristics*

1. MmD is inherited primarily as an AR disease with some patients mapping to the selenoprotein N1 gene on chromosome 1p36. Other patients show AD and sporadic inheritance

Clinical Manifestations

1. Onset is in infancy with hypotonia and weakness
2. Delayed motor milestones are seen but most patients are able to walk
3. Generalized proximal muscle weakness
4. A subset of patients may have predominant distal hand weakness
5. Skeletal abnormalities include: 1. muscle contractures; 2. kyphoscoliosis; 3. high arched palate and 4. clubfoot
6. Facial muscle weakness, ptosis, and occasionally ophthalmoparesis are manifest
7. Weakness may be slowly progressive
8. Neck extensor and axial musculature contraction leads to decreased spine mobility
9. Cardiomyopathy and respiratory insufficiency may develop over time. The respiratory involvement is disproportionate to the degree of scoliosis that may require mechanical ventilation

Neuropathology

1. Muscle biopsy:
 - a. Minicores are seen which are non-continuous along the length of the muscle fibers
 - b. The minicores occur in both type 1 and type 2 fibers
 - c. Variation in fiber size
 - d. Type 1 fiber predominance with atrophy
 - e. Increased endomysial connective tissue
 - f. Electron microscopy:
 - i. Myofibrillar disorganization is seen that is similar to that of central core disease
2. Patients have been described with mutations in the PYR1 gene that is seen in central core myopathy
3. The SEPN1 gene is also responsible for congenital muscular dystrophy with rigid spine deformity and some patients with myofibrillar myopathy
4. Two siblings have been reported with cofilin-2 gene mutations that map to chromosome 14q13 and demonstrated nemaline rods as well as minicores on muscle biopsy

Laboratory Evaluation

1. The serum CK level is normal or only minimally increased
2. EMG:

- a. Normal insertional and spontaneous activity
- b. Short duration, low amplitude early recruited MUAPs are seen
- c. Normal nerve conduction velocities
- 3. Pulmonary function tests:
 - a. Reduced forced vital capacity
- 4. Polysomnography:
 - a. Nocturnal desaturation with short apneic periods

Nemaline Myopathy

General Characteristics

1. The genetics of nemaline myopathy are heterogeneous with mutations in multiple genes that determine different phenotypes of the disease
2. Mutations in the nebulin gene (NEM2) is the most common and maps to chromosome 2q21.2-q22
3. Other genes that cause the syndrome are mutations in:
 - a. ACTA1 (AR/AD) that maps to 1q42
 - b. TMP3 (AR/AD) that maps to 1q21-1q23
 - c. TMP2 (AD) that maps to 9q13
 - d. TNNT1 (AR) that maps to 19q13
 - e. TMP1 (AR/AD) that maps to 15q21-23
 - f. CFL2-that maps to 14q12

Clinical Manifestations

1. There are three major clinical presentations of nemaline myopathy:
 - a. A severe infantile form
 - b. A slowly progressive form
 - c. Adult onset form

Infantile Form

1. Severe generalized weakness and hypotonia at birth
2. Absent motor and muscle stretch reflexes
3. Weak suck and cry
4. Mechanical ventilation is required for many patients
5. Arthrogryposis and neonatal respiratory insufficiency are associated with early mortality

Early Childhood

1. This is a non-progressive or very slowly progressive illness with both proximal and distal weakness and decreased muscle bulk
2. Delayed motor milestones
3. A subset of patients manifests a facioscapulohumeral pattern of weakness
4. Wide-based lordotic waddling gait
5. Slight facial and masticatory weakness
6. Dysmorphic features of high arched palate, micrognathia and narrow face
7. Skeletal abnormalities include:
 - a. Pectus excavatum
 - b. Kyphoscoliosis
 - c. Pes cavus
 - d. Clubbed feet
8. Diminished or absent deep muscle stretch reflexes

Adult Onset

1. Mild proximal and occasionally slight distal muscle weakness
2. Cardiomyopathy may predominate over muscle weakness in some patients
3. No dystrophic or skeletal abnormalities that are seen in the early onset forms

Neuropathology

1. Muscle biopsy:
 - a. Type 1 fiber predominance and hypotrophy is seen in the congenital forms
 - b. Modified Gomori trichrome stain demonstrates nemaline rods in the subsarcolemma and occasionally perinuclear areas
 - c. Electron microscopy:
 - i. Rod bodies are 3–6 μm in length and 1–3 μm in diameter
 - ii. Their density is similar to that of Z-discs
 - iii. Intranuclear rods are seen in all severe infantile patients but also can be seen in the milder adult onset patients
 - iv. Histochemistry analysis reveals that both the Z-discs and rods are immune-reactive for α -actinin
 - v. Rods are seen in:
 1. Tenotomy
 2. HIV associated myopathy
 3. Myofibrillar myopathy
 4. Myositis
 5. Hypothyroidism

Laboratory Evaluation

1. The serum CK is normal or only minimally increased
2. EMG:
 - a. Early recruitment of low amplitude short duration MUAPs
 - b. In severe infantile forms, there may be fibrillation potentials and positive sharp waves

Late Onset Nemaline Myopathy

General Characteristics

1. A sporadic disorder that in 50% of patients is associated with a monoclonal gammopathy of undetermined significance

Clinical Manifestations

1. Presents after the age of 40, but has been reported in the ninth decade
2. The weakness involves proximal or distal muscles but may be generalized
3. Isolated neck extensor weakness may cause the “dropped head” syndrome
4. In patients with associated gammopathy, respiratory insufficiency may be severe

Neuropathology

1. Rods are identified by both light and electron microscopy
2. Rods are short

Laboratory Evaluation

1. Serum CK levels are usually normal
2. EMG:
 - a. Increased insertional activity with positive sharp waves and fibrillation potentials
 - b. Early recruitment of brief duration low amplitude MUAP
 - c. Motor and sensory nerve conduction velocities are normal
3. Approximately 50% of patients have a monoclonal gammopathy of undetermined significance

Centronuclear Myopathy*General Characteristics*

1. There is genetic heterogeneity among the different type of centronuclear myopathy:
 - a. The severe neonatal type is caused by mutations in the myotubularin gene (MTM1) that maps to chromosome xp28
 - b. Late onset centronuclear myopathy is autosomal dominant and has been mapped to the DNM2 gene on chromosome 19p13.2. Several sporadic patients have also been linked to this locus and manifest the severe neonatal phenotype of this myopathy
 - c. Mutations in the DNM2 gene also cause autosomal dominant intermediate or D1-CMTB

Clinical Manifestations

1. Infantile-early childhood phenotype:
 - a. Maybe autosomally dominant or recessively inherited
 - b. Mild hypotonia and generalized weakness are detected in infancy
 - c. Motor milestones are delayed
 - d. Patients can walk but often have a wide-based hyperlordotic gait. Dysmorphic features include:
 - i. Narrow face and high arched palate
2. Ptosis and ophthalmoparesis are common and a differential point from other congenital myopathies
3. X-linked recessive myotubular myopathy:
 - a. A common form of centronuclear myopathy presents at birth with hypertonic, generalized weakness and often requires mechanical ventilation and nasogastric or gastroscopy tubes
 - b. Polyhydramnios is often present during pregnancy
 - c. Ptosis and ophthalmoparesis are noted in early childhood
 - d. Arthrogryposis may occur
4. A few manifesting females have been described with X-linked myotubularin deficiency:
 - a. They can present in adulthood
 - b. Childhood onset and some adult patients have:

- i. Axial and proximal weakness
 - ii. Bilateral ptosis
 - iii. External ophthalmoparesis
 - iv. Possible mechanism is skewed inactivation of the X-chromosome
- c. Childhood or less severe form that presents with:
 - i. Mild muscle weakness that is slowly progressive
 - ii. A variable pattern of muscle weakness occurs with some patients more affected proximally and others with more distal muscles involvement
 - iii. Facial muscles may be involved
 - iv. Ptosis and ophthalmoparesis is seen in some patients
 - v. A facioscapulohumeral phenotype has been described
 - vi. In the adult form of centronuclear myopathy, there are no facial dysmorphic features or skeletal abnormalities

Neuropathology

1. Muscle biopsy:
 - a. Central myonuclei that may form chains or occasionally there are nuclear clusters in the fiber center
 - b. Central nuclei occur in 25–95% of both type I and type II fibers
 - c. There is type 1 fiber predominance and hypotrophy; Type 2 fibers are normal
 - d. Electron Microscopy:
 - i. There are reduced myofibrils and an excess of mitochondria and glycogen granules in the center of muscle fibers that have peripheral nuclei

Laboratory Evaluation

1. The serum CK is normally or only minimally increased
2. EMG:
 - a. Increased insertional and spontaneous activity manifest by positive sharp waves, fibrillation potentials, complex repetitive discharges and myotonic discharges
 - b. Low amplitudes, short duration and increased recruitment of MUAPs
 - c. Some patients with dynamic 2 gene mutations have reduced amplitude and slow motor and sensory nerves conduction studies

Congenital Fiber-Type Disproportion (CFTD)*General Characteristics*

1. CFTD can be caused by mutations in the ACTA1, SEPN1, and TPM3 genes
2. Most patients are sporadic but others have been described with autosomal dominant or autosomal recessive inheritance

Clinical Manifestations

1. At birth, patients have generalized hypotonia and weakness associated with a weak cry and suck reflex

2. There is delay in acquiring motor milestones
3. Motor weakness is usually static. Patients have been reported with a progressive course marked by respiratory insufficiency
4. Dysmorphic fascies, high arched palate, congenital hip dislocation, kyphoscoliosis, arthrogryposis, and a rigid spine may be seen
5. Approximately 1/3 of patients may have CNS manifestations that have been postulated to be caused by impaired glycosylation of L-dystroglycan

Neuropathology

1. Muscle biopsy:
 - a. There is disproportion in the size and proportion of type 1 versus type 2 muscle
 - b. Type 1 fibers predominate in a number, but are only 15% the size of type 2 fibers that are normal or slightly hypertrophic
 - c. Type 1 fiber predominance and hypotrophy are found in:
 - i. Nemaline myopathy
 - ii. Centronuclear myopathy
 - iii. Congenital muscular dystrophies
 - iv. Spinal muscular atrophy
 - d. Electron microscopy:
 - i. Non-specific ultrastructural deficits

Laboratory Evaluation

1. The serum CK level is normal or only minimally increased
2. EMG:
 - a. There may be increased insertional and spontaneous activity
 - b. Nerve conduction velocities are normal
 - c. There may be early recruitment of MUAPs
 - d. The electrodiagnostic studies only be normal

Sarcotubular Myopathy

General Characteristics

1. Sarcotubular myopathy is allelic to LGMD2H
2. The mutation that is causative in the original Hutterite families is in TRIM32 that maps to chromosome 9q33.1
3. A subset of Hutterite patients (LGMD2I) have been described with mutations in the FKRP gene that map to chromosome 19q13
4. TRIM32 regulates skeletal muscle stem cell differentiation that is important for generation of processes of adult skeletal muscle during growth or following injury
5. TRIM32 may also play a role in the recognition of proteins that are targeted for ubiquitination

Clinical Manifestations

1. Patients may present in infancy or adulthood
2. Exertional myalgia
3. Proximal muscle weakness

4. Scapular winging and foot drop
5. Calf hypertrophy
6. Mild facial weakness
7. Depressed muscle stretch reflexes
8. South Dakota Hutterite families may have a scapuloperoneal phenotype

Neuropathology

1. Increased central nuclei
2. Fiber splitting
3. Fibers (primarily type 2) may have small vacuoles
4. Electron microscopy:
 - a. The vacuoles are adjacent to T-tubules and are membrane bound
 - b. The vacuoles may be empty or contain amorphous material
 - c. Immunostains reveal that vacuoles are positive for sarcoplasmic reticulum associated ATPase

Laboratory Evaluation

1. Serum CK levels may be normal or elevated to 20 times normal
2. EMG:
 - a. Myopathic pattern
 - b. Normal

Fingerprint Body Myopathy

General Characteristics

1. Most patients have sporadic inheritance although the disease has been reported in identical twins and in familial form

Clinical Manifestations

1. Onset is in infancy or early childhood
2. The infants have generalized hypotonia, weakness, and atrophy
3. Muscle strength is stable or progresses minimally
4. Some patients have cognitive deficits, febrile seizures, kyphoscoliosis, and pectus excavatum

Neuropathology

1. Muscle biopsy:
 - a. Type 1 fiber predominance and hypotrophy
 - b. Type 2 fiber hypertrophy
 - c. Type 1 fibers have decreased oxidative activity in the subsarcolemmal and perinuclear regions

Electron Microscopy

1. Fingerprint bodies appear as a complex lamellar body that resembles a finger print. They may be composed of cytoskeletal proteins

Laboratory Evaluation

1. Serum CK levels are normal or only minimally elevated
2. EMG:
 - a. Low amplitude short duration MUAPs
 - b. Normal insertional and spontaneous activity

Trilaminar Myopathy*General Characteristics*

1. Only one infant has been described
2. Genetics have not been determined

Clinical Manifestations

1. The infant was born with rigid axial and extremity muscles
2. Weak cry and suck reflexes
3. Joint contractures
4. Intact muscle stretch reflexes
5. Patients have delayed motor milestones and were able to walk

Neuropathology

1. Muscle biopsy:
 - a. Variability in fiber size
 - b. Approximately 25% of fibers were hypertrophic that demonstrated three concentric zones with a differential histochemical staining pattern:
 - i. The inner and outer zones stained with the Gomori trichome and NADH stains
 - ii. An inverse pattern was seen with ATPase staining
 - c. Electron microscopy:
 - i. Myofibrillar disorganization of the innermost zone that also was filled with mitochondria, glycogen granules and myofilaments
 - ii. The intermediate zone had Z-band streaming
 - iii. The outer zone demonstrated disorganized myofibrils, mitochondria, lipid droplets, and vesicles

Laboratory Evaluation

1. The serum CK was 40x normal
2. EMG:
 - a. The EMG and NCS were normal

Hyaline Body Myopathy (HBM)*General Characteristics*

1. Hyaline body myopathy is caused by missense mutations in the MYH7 gene that maps to chromosome 14q11.2. An autosomal dominant form of the disease has also shown a heterozygous mutation in the same gene
2. Mutations in MYH7 have been identified in a form of familial cardiomyopathy
3. The MYH7 gene encodes for slow beta cardiac MYH7 proteins although a cardiomyopathy does not occur in hyaline body myopathy
4. Normal MyHC is necessary for the assembly of thick filaments
5. Mutations in chromosome 3p22.2-p21.3 have been described with this phenotype

Clinical Manifestations

1. Onset may be in infancy to the fifth decade

2. Patients may have a limb girdle or scapuloperoneal phenotype
3. The disease is stable or demonstrates only a slight deterioration of muscle strength
4. Rarely there is a cardiomyopathy
5. Muscle stretch reflexes are preserved
6. Some adult patients have demonstrated calf hypertrophy
7. There is variability in clinical symptomatology within families

Neuropathology

1. Muscle biopsy:
 - a. Subsarcolemmal "hyaline bodies" are demonstrated with the Gomori trichome stains
 - b. Hyaline bodies occur in type 1 fibers that are hypotrophic and do not stain with oxidative enzyme or periodic acid Schiff stains, but are positive for myofibrillar ATPase
 - c. Some biopsies demonstrate angular fibers with type grouping
 - d. Some hyaline bodies are positive for slow myosin heavy chain MyHC activity
 - e. Electron microscopy:
 - i. Hyaline bodies are composed of granulomatous debris with fragments of sarcomeres that are surrounded by an area of sarcomere disorganization

Laboratory Evaluation

1. Serum CK levels are normal or minimally elevated
2. EMG:
 - a. Increased low amplitude, short duration polyphasic MUAPs
 - b. May be normal
 - c. Echocardiogram:
 - i. In a subset of patients, there is evidence of a dilated cardiomyopathy with a low ejection fraction

MYH2 Myopathy*General Characteristics*

1. Hereditary myosin myopathies are a group of muscle disorders with variable age at onset and variable phenotypes
2. They are caused by mutations in the skeletal muscle heavy chain MyHC genes. There are three major isoforms in adults that include:
 - a. MYHC1 is encoded by MYH7:
 - i. Expressed in slow type I muscle fibers and in heart ventricles
 - ii. MyHC II is encoded by MYH2 gene and is expressed in fast IIA muscle fibers
 - iii. MyHC that is expressed in fast IIB fibers
 - iv. The MYH2 gene has been mapped to chromosome 17p13.1
 - v. Homozygous, compound heterozygous, truncating and missense mutations have been demonstrated to cause these muscle disorders

Clinical Manifestations

1. Phenotype includes:
 - a. An autosomal recessive proximal myopathy with external ophthalmoparesis
 - b. Congenital arthrogryposis
 - c. Mild proximal weakness myalgias that begin in adulthood or early childhood (autosomal dominant)

Neuropathology

1. Many biopsies reveal rimmed vacuoles and tubulofilamentous inclusions similar to hereditary inclusion body type 3
2. Missense mutation has demonstrated small or absent type 2A muscle fibers
3. Muscle biopsy from long standing patients may demonstrate dystrophic changes. Variability of fiber size with increased perimysial and endomysial connective tissue without inflammation and necrosis has been described

Laboratory Evaluation

1. Serum CK levels may be minimally elevated
2. EMG:
 - a. Myopathic pattern
3. Muscle MRI (in recessive MYH2 missense mutation patients):
 - a. Diffuse fatty infiltration with predominant involvement of the medial gastrocnemius muscle of the lower leg
 - b. Predominant involvement of the semitendinosus gracilis and vastus lateralis in the thigh

CAP Myopathy*General Characteristics*

1. CAP myopathy is caused by mutations in the skeletal muscle isoform of the tropomyosin genes:
 - a. CAP myopathy-2 is caused by heterozygous mutation in the tropomyosin-2 gene (TPM2) that maps to chromosome 9p13
2. CAP myopathy-1 is caused by heterozygous mutation in the alpha tropomyosin 3 gene (TPM3) that maps to chromosome 1q21
3. Mutations affecting muscle isoforms of the tropomyosin genes cause a variety of disorders that include:
 - a. Nemaline myopathy
 - b. Core-rod myopathy
 - c. Congenital fiber type disproportion
 - d. Distal arthrogryposis
 - e. Escobar syndrome
4. There are at present thirty variants of TPM2 and 20 of TPM3; most are heterozygous and are associated with autosomal dominant disease

Clinical Manifestations

1. Neonatal onset with muscle weakness and hypotonia
2. Skeletal deformities
3. Decreased muscle stretch reflexes

4. The respiratory muscles are frequently affected
5. Patients with TPM2 mutations are less affected than those with TPM3 mutations
6. Five mutations in the TPM2 and one in TPM3 cause hypercontraction of muscles. The hypercontractible phenotypes have more limb joint and jaw contractions than those patients with the non-hyper contracture phenotype. Patients with the non-hyper contracture phenotype had axial contractures to a greater degree than the contractual phenotype

Neuropathology

1. Muscle biopsy:
 - a. Many muscle fibers contain a peripheral crescent that strongly stains for NADH-TR, PAS and phosphorylase
 - b. The "caps" contain fast myosin, desmin, tropomyosin, and alpha-actinin
2. Electron Microscopy:
 - a. Widened Z-bands
 - b. Disorganization of myofibrils
 - c. Lack of thick filaments

Laboratory Evaluation

1. The serum CK level is normal
2. EMG:
 - a. Myopathic MUAPs
 - b. Normal conduction in velocities

Zebra Body Myopathy*General Characteristics*

1. Zebra body myopathy is caused by mutations in the ACTA1 gene

Clinical Manifestations

1. Only a few patients have been reported
2. One patient presented with generalized muscle weakness and atrophy from birth
3. A second patient manifested severe hypotonia, dysphagia and asymmetric upper extremity weakness
4. Muscle weakness is stable or slightly progressive

Neuropathology

1. Muscle biopsy:
 - a. Central nuclei
 - b. Variability in fiber size
 - c. Occasional vacuoles
2. Electron Microscopy
 - a. The z-bodies are striae with a periodicity that appear as stripes
 - b. The density of the striae is similar to Z-discs
 - c. There may be streaming of the X-bands and Nemaline rods
3. Zebra bodies may be found in:
 - a. Myofibrillar myopathy
 - b. Cardiac muscle

Laboratory Evaluation

1. The serum CK can be 2–3 x normal
2. EMG:
 - a. Myopathic pattern
 - b. No abnormal insertional or spontaneous activity

Tubular Aggregate Myopathy*General Characteristics*

1. Autosomal dominant tubular aggregate myopathy may be caused by a heterozygous mutation in the STIM1 gene that maps to chromosome 11p15.4
2. Tubular aggregates are a non-specific finding that may be seen in disorders that include:
 - a. Alcohol and drug-induced myopathies
 - b. Hereditary periodic paralysis
 - c. Hyperthyroidism
 - d. Congenital slow channel myasthenia
 - e. Hypoxia
 - f. Some toxic myopathies
3. The STIM1 gene (stromal interaction molecule 1) encodes the main calcium sensor in the sarcoplasmic reticulum

Clinical Manifestations

1. There are various phenotypes associated with tubular aggregates:
 - a. Slowly progressive limb girdle weakness that begins in childhood or early adulthood
 - b. A form whose phenotype resembles congenital myasthenia and responds to acetylcholinesterase
 - c. Myalgias with exercise. The muscle bulk and strength are normal

Neuropathology

1. Tubular aggregates are located subsarcolemmally and are only in type 2 muscle fibers in patients with periodic paralysis and those with muscle pain with exercise. They are present in both fiber types in patients with the limb girdle phenotype
2. They appear as abnormal accumulations of densely packed single-walled or double-walled membrane tubules in muscle fibers
3. They are basophilic in A- and E-stain; they react to NADH-TR but not to SDH
4. Electron microscopy:
 - a. The aggregates are bundles of tubules of 60–80 nm in diameter

Laboratory Evaluation

1. Serum CK is normal or only minimally elevated
2. EMG:
 - a. Patients with the congenital myasthenic phenotype have a decremental response that corrects with pyridostigmine (improves)
 - b. Normal in those with muscle pain syndrome
 - c. Some patients demonstrate myopathic MUAPs and have fibrillation potentials
 - d. Motor and sensory NCS are normal

Reducing Body Myopathy*General Characteristics*

1. Sporadic or inherited missense mutations in four-and-a-half LIM to main protein 1 (FHL1) cause alteration in the expression of FHL1 protein and clinically heterogeneous myopathies
2. X-linked early onset severe myopathy has been mapped to Xq26.33
3. FHL1 mutations cause:
 - a. Reducing body myopathy (RBM)
 - b. Scapuloperoneal myopathy
 - c. X-linked myopathy with postural muscle atrophy (XM-PMA)

Clinical Manifestations

1. The infantile form may present with severe generalized weakness, hypotonia, and joint contractures. Patients may have ptosis. Deep tendon reflexes are depressed. Some patients have respiratory muscle involvement with increased mortality
2. Onset may be late childhood or as an adult:
 - a. There may be asymmetrical involvement of either proximal or distal muscles
 - b. Some patients develop contracture of the major joints, sclerosis and spinal rigidity
 - c. There is recently described adult onset involvement of the sternocleidomastoid and trapezius muscles

Neuropathology

1. Muscle biopsy:
 - a. “Reducing” bodies are characterized by their ability to reduce nitro blue tetrazolium mediated by menadione
 - b. They have no oxidative enzyme staining but some fibers demonstrate desmin at the periphery of some reducing bodies
 - c. There is type 1 fiber predominance
 - d. Reducing bodies are seen in both type 1 and type 2 fibers
 - e. Electron microscopy:
 - i. Reducing bodies are composed of electron dense granules associated with tubulofilaments
 - ii. Some biopsies reveal:
 1. Variation in fiber size
 2. Central nuclei
 3. Mild inflammation
 4. Rimmed vacuoles
 5. Reducing bodies in the majority of fibers

Laboratory Evaluation

1. Serum CK levels are usually normal or can be minimally elevated
2. EMG:
 - a. Myopathic pattern
 - b. NCS are normal

Myofibrillar Myopathies

General Characteristics

1. The myofibrillar myopathies (MFMs) are sporadic or inherited muscle disease
2. The six genes that have been identified with this disease include:
 - a. Alpha-B crystallin (CRYAB)
 - b. Myotilin gene mutations occur in both myotilinopathy and spheroid body myopathy
 - c. ZASP-related MFM is caused by mutations in the ZASP gene
 - d. FLNC-related MFM
 - e. BAG-3 related MFM
3. The causative genes encode sarcomeric Z-disc proteins:
 - a. Desmin
 - b. α - β crystallin
 - c. Myotilin
 - d. Z-band alternatively spliced PDD motif containing protein (ZASP)
 - e. Filamin C
 - f. Anti-apoptotic Bcl2-associated athanogene 3 (BAG-3). These genes account for approximately 50% of patients with MFM

Clinical Manifestations

1. Most patients have an adult onset with slow progression
2. Desminopathy, α - β crystallinopathy and BAG2opathies have an infantile or juvenile disease onset
3. Cardiomyopathy is characteristic in patients with desminopathies and may be the only sign
4. Respiratory symptoms occur in childhood patients with β -crystallinopathies
5. Early severe cardiac and respiratory insufficiency occur in Bag3-opathies

Neuropathology

1. Muscle biopsy:
 - a. Variability in fiber size
 - b. Central nuclei
 - c. Some biopsies demonstrate type 1 fiber predominance and related rimmed vacuoles
 - d. Hyaline and non-hyaline structures:
 - i. Central desmin and other proteins
 - e. Nerve and intramuscular nerve biopsy reveal:
 - i. Enlarged axons with accumulated intermediate neurofilaments and axonal spheroids

Laboratory Evaluation

1. Serum CK is normal or only minimally elevated
2. EMG:
 - a. Increased insertional and spontaneous activity with fibrillation potentials and positive sharp waves
 - b. Pseudomyotonic potentials
 - c. Complex repetitive discharges

- d. Early recruitment of short duration, low amplitude polyphasic MUAP
- e. In chronic patients, there may be long duration, large amplitude MUAPs
- f. Nerve conduction may have low amplitude and slow motor and sensory NCS
3. EKG:
 - a. Conduction defects and arrhythmias
 - b. Echocardiography:
 - c. Dilated or hypertrophic cardiomyopathy

Metabolic Myopathies

Overview

Primary metabolic myopathies may be classified according to their underlying biochemical defects of 1. carbohydrate, 2. lipid, 3. adenine nucleotide and 4. mitochondrial effects on the function of the muscle itself. Secondary metabolic defects of muscle occur in disorders of endocrine function on the thyroid, parathyroid or adrenal gland.

The immediate energy source for muscle contraction is derived from the hydrolysis of adenosine triphosphate (ATP). During rest, ATP production for muscles is derived from the metabolism of long chain fatty acids. Disorders that effect β -oxidation of fatty acids that occurs in mitochondria cause muscle weakness. In exercising muscle, ATP is generated from metabolism of carbohydrates as fatty acids and ketone bodies. The first forty-five minutes of exercise ATP is generated from glucose that is available or generated from glycogenolysis. After this period, there is a shift to fatty acid metabolism which accounts for approximately 70% of ATP production.

Glycogen is the primary sarcoplasmic source of carbohydrate while fatty acids are derived from adipose tissue and intracellular lipid stores. Carbohydrates can be metabolized both anaerobically and aerobically while fatty acids are metabolized only aerobically. During short periods of intense exercise, the carbohydrate utilized is from glycogen stores that is initiated by myophosphorylase. After glycogen stores are depleted, oxidation of fatty acids provides the source for ATP production. Increased blood concentration of β -hydroxybutyrate is a marker of fatty acid oxidation while increased concentration of blood lactate is a marker of anaerobic metabolism of glucose. The cytochrome system is essential for both aerobic and anaerobic muscle metabolism.

Disorders of Muscle Carbohydrate Metabolism

Type II Glycogenosis (Pompe Disease, Acid Maltase Deficiency, α -Glucosidase Deficiency)

General Characteristics

1. Pompe disease is caused by mutation in the α -glucosidase gene that maps to chromosome 17q25.2-q25.3

2. The incidence of infantile Pompe disease is 1 in 31,000 to 1 in 38,000 of the population
3. The incidence of the late onset form is 1 in 53,000 of the population

Clinical Manifestations

1. Infantile form:
 - a. Infants have generalized weakness and hypotonia
 - b. Cardiomegaly and mild to moderate hepatomegaly
 - c. The onset is during the first several months of life
 - d. Enlarged tongue
 - e. Feeding difficulties
 - f. The illness is usually fatal by two years of age from cardiorespiratory failure
2. Juvenile form:
 - a. Onset is in the first decade
 - b. Motor milestones may be delayed
 - c. There is progressive proximal greater than distal weakness
 - d. Hypertrophy of calf muscles, hyperlordosis and a waddling gait may be prominent
 - e. Rarely patients present with a rigid spine phenotype
 - f. Rare cardiomegaly, hepatomegaly and an enlarged tongue
 - g. Scapuloperoneal phenotype may occur
 - h. Respiratory insufficiency with apnea and nocturnal hypoxemia may occur in 10–33% of patients
3. Adult form:
 - a. Onset is in the third or fourth decade to 70 years of age
 - b. Proximal greater than distal weakness which may be asymmetric
 - c. The tongue and face may be involved
 - d. Muscle pain (particularly in the thigh) is a complaint in 50% of patients
 - e. Decreased muscle stretch reflexes
 - f. No cardiomegaly or hepatomegaly
 - g. A predilection for respiratory muscle involvement

Neuropathology

Muscle Biopsy

1. Glycogen filled vacuoles are seen within muscle fibers in the infantile form
2. In childhood and adult types, they are demonstrated in 25–75% of clinically affected muscles
3. In late onset disease there may only be non-specific muscle changes
4. The staining characteristics of vacuoles confirm that they are secondary liposomes filled with glycogen
5. Variation in fiber size, necrotic and regenerating fibers and splitting may be demonstrated
6. In late stages, there is endomysial connective tissue fibrosis and fiber atrophy
7. Some patients demonstrate neurogenic features of type grouping and group atrophy due to motor neuron degeneration from glycogen storage in anterior horn cells, bulbar nuclear and Schwann cells

8. The correlation between genotype and phenotype is close. Patients with the most severe phenotype have two pathogenic mutations, one in each GAS allele
9. Adult onset patients have higher levels of GAA activity
10. Alpha-glucosidase is a liposomal enzyme that cleaves the 1, 4 and 1, 6 linkages in glycogen, maltose and isomaltose. Enzyme deficiency causes glycogen accumulation
11. Mechanisms that cause pathology that have been suggested include:
 - a. Progressive expansion of glycogen-filled lysosomes with release of muscle destructive proteases
 - b. Increased muscle metabolism which has been demonstrated in approximately 1/3 of patients
 - c. Decreased mean protein balance

Laboratory Evaluation

1. Assay of α -glucosidase activity is possible in muscle, fibroblasts, leukocytes, lymphocytes and in the urine
2. Dried blood spot analysis
3. Serum CK is moderately increased in infantile forms but may be normal in adults
4. EMG
 - a. Increased insertional and spontaneous activity with positive sharp waves, fibrillation potentials, complex repetitive discharges and occasional myotonic discharges
 - b. Myopathic MUAPs
 - c. NCS are normal
 - d. In mild types of disease initial features may only be demonstrated in paraspinal muscles
5. MRI/CT of muscle:
 - a. Early and severe involvement of the adductor magnus and semimembranosus muscles; as the disease progresses there is fatty infiltration of the long head of the biceps femoris, semitendinosus and the anterior thigh muscles
 - b. In late stages there is selective sparing of the sartorius, rectus femoris, graciles and components of the vastus lateralis
6. EKG:
 - a. Left axis deviation, short PR interval, large QRS complexes, ST depression and persistent sinus tachycardia
 - b. Wolffe-Parkinson-White syndrome may be seen in both infantile and adult patients
7. Echocardiography:
 - a. Hypertrophic cardiomyopathy
8. Pulmonary function studies:
 - a. Restrictive deficits
 - b. Decreased forced vital capacity
 - c. Decreased maximal inspiratory and expiratory pressures
 - d. Diaphragmatic fatigue

Type III Glycogenosis (Debranching Enzyme Deficiency)*General Characteristics*

1. Mutations in the debranching enzyme gene AGL that maps to chromosome 1p21 causes both GSDIIIa and GSDIIIb
2. The differential expression of the AGL gene is caused by alternative splicing and differential RNA transcription
 - a. The enzyme has two catalytic functions, oligo-1, 4-1, 4-glucotransferase and amylo-1-6-glucosidase activities
 - b. Subsequent to phosphorylase shortening of the peripheral glycogen chain to four glucosyl units, the debrancher enzyme removes the remaining end in two stages:
 - i. The transferase activity moves a maltose unit to an acceptor chain
 - ii. The single remaining glucosyl unit then is hydrolyzed by the amylo-1-6 glucosidase which severs the branch

Clinical Manifestations

1. In GSDIIIa there is an enzyme deficiency in both the liver and muscle whereas in GSDIIIb the deficiency only occurs in the liver
2. Clinical Manifestations of GSDIIIa:
 - a. Onset of muscle weakness occurs in infancy or childhood but is not clinically manifest until the third or fourth decade
 - b. In approximately 50% of patients there is weakness and atrophy of distal extremity muscles particularly the peroneal and calf musculature
 - c. Toe walking associated with fibrotic heel cords is seen
 - d. A subgroup of patients has a superimposed sensorimotor neuropathy
 - e. Pseudohypertrophy of proximal muscle groups may occur
 - f. Respiratory muscles are involved and insufficiency can progress rapidly
 - g. A cardiomyopathy may be seen with or without extremity weakness
 - h. Rarely there may be cramps, myalgias, exercise intolerance and myoglobinuria

Neuropathology

1. Muscle biopsy:
 - a. Vacuoles filled with glycogen in subsarcolemmal and intermyofibrillar regions of muscle fibers are seen. The vacuoles stain with PAS and are digested by diastase and do not stain with acid phosphatase
 - b. Free glycogen and some Wiltens liposomes are seen
 - c. Abnormal glycogen can accumulate in the skin and peripheral nerves
 - d. Muscle tissue demonstrates loss of debrancher enzyme activity

Laboratory Evaluation

1. Serum CK is elevated two to twenty times normal
2. EMG:
 - a. An irritative myopathy with myopathic MUAPs similar to the findings seen in acid maltase deficiency
3. Exercise testing reveals a normal rise of serum ammonia but no increase in lactate levels
4. Pulmonary function studies are positive in those with respiratory muscle involvement with decreased forced vital capacity
5. EKG demonstrates conduction defects and arrhythmias
6. Echocardiography
 - a. Hypertrophic obstructive cardiomyopathy

GSDIV (Branching Enzyme Deficiency)*General Characteristics*

1. GSDIV is caused by deletions or nonsense mutations in the glycogen branching enzyme gene (GBE1) that maps to chromosome 3q12
2. Enzyme deficiency causes the deposition of amylopectin – like polysaccharide that has fewer branching points and longer outer chains than normal glycogen
3. There are two infantile forms and an adult form known as adult polyglucosan disease

Clinical Manifestations

1. Fetal akinesia is characterized by:
 - a. Arthrogryposis
 - b. Pulmonary hypoplasia
 - c. Craniofacial dysmorphism
 - d. Intrauterine retarded growth
 - e. Abnormal amniotic fluid volume
 - f. Perinatal death
2. The classic most common type:
 - a. Presents in infancy
 - b. Progressive hepatic dysfunction with hepatosplenomegaly
 - c. Failure to thrive
 - d. Muscular weakness, hypotonia, atrophy and depressed muscle stretch reflexes
 - e. Patients die of liver failure by 5 years of age
 - f. A benign hepatic form has been described
 - g. There is a primary manifestation of muscle weakness, atrophy and cardiomyopathy with either proximal or distal muscle involvement
 - h. A deficit in RBCK1, a ubiquitin ligase, has been described in cardiomyopathy polyglucosan disease
3. Adult form:
 - a. Presentation in adulthood
 - b. Progressive upper and lower motor neuron signs
 - c. Sensory neuropathy
 - d. Neurogenic bladder
 - e. Dementia occurs in approximately 50% of patients
 - f. Cerebellar ataxia
 - g. Rarely polyglucosan neuropathy occurs in children
 - h. A report of two adults with fluctuating signs

Neuropathology

1. Deposition of finely granular and filamentous polysaccharide polyglucosan bodies in the CNS, in axons and Schwann cells, the skin, liver, cardiac and skeletal muscle
2. Polyglucosan bodies are PAS-positive and diastase resistant (not glycogen) which resembles amylopectin
3. Amylopectin-like material can be seen in motor neurons of the brainstem and spinal cord as well as systemically

Laboratory Evaluation

1. Serum CK is normal or only minimally elevated
2. EMG:
 - a. Myopathic pattern
 - b. Hyperactive pattern with increased insertional activity, positive sharp waves and fibrillation potentials
 - c. Similar pattern to that seen in GSDII and III
 - d. In patients with polyglucosan neuropathy EMG reveals:
 - i. An axonal sensorimotor neuropathy with superimposed polyradiculopathy
3. EKG:
 - a. Conduction alterations that may lead to complete AV block
4. Echocardiography
 - a. Dilated cardiomyopathy
5. The enzyme deficiency can be demonstrated in muscle, fibroblasts and leukocytes:
 - a. In patients with primary neuromuscular involvement, the deficiency of GBE may only be seen in muscle and can be normal in adult polyglucosan disease

Type V Glycogenosis (McArdle's Disease)
(Myophosphorylase Deficiency)

General Characteristics

1. Myophosphorylase deficiency is an autosomal recessive disorder caused by mutations in the PYGM gene that maps to chromosome 11q13 and encodes myophosphorylase
2. Myophosphorylase catalyzes the first step of glycogen catabolism by utilizing glucose-1-phosphate from glycogen storage deposits
3. It lyses α -1,4 glucosyl residues from the outer branches of glycogen and generates glucose-1-phosphate
4. It has been recently shown that lack of the generation of ATP may not be the cause of the disease, which is caused by a series of biochemical events that include:
 - a. An increase of adenosine diphosphate
 - b. An intracellular pH that is not low enough in response to exercise
 - c. Low inorganic phosphate levels
 - d. A higher intracellular calcium level that normally occurs in ischemic exercised muscle

- e. It has been postulated that the increase in ADP may inhibit dissociation of the actin-myosin from bridges, which would increase contraction
- f. McArdle's disease patients also demonstrate:
 - i. Decreased concentration of muscle sodium-potassium pump ATP
 - ii. Higher serum potassium concentration with exercise
 - iii. Increased heart rate greater than controls with exercise
 - iv. Increased extracellular potassium partially depolarizes the muscle membrane which inactivates sodium channels and decreases membrane excitability
 - v. The mechanisms that reduce sodium-potassium pump activity in skeletal muscles are not known and may not be the mechanism of disease

Clinical Manifestations

1. Usually presents in childhood or in young adults with exercise intolerance
2. Exercise induced pain and cramps during brief high intensity activity and during prolonged low intensity exercise
3. If exercise is continued after pain is noted, electricity silent contractures may occur
4. A subset of patients present with undue fatigue after exercise without cramps or muscle pain
5. Patients may develop a "second wind" phenomenon that is characterized by less pain and the ability to continue the activity at a low level of function. This effect is due to the metabolism of blood-derived recently mobilized glucose
6. Myoglobinuria is usually not evident until the second or third decade
7. Approximately 50% of myoglobinuria attacks occur with vigorous exercise and 1/3 of them cause renal insufficiency
8. Most patients have normal strength although approximately 1/3 may develop proximal weakness after recurrent bouts of rhabdomyolysis
9. Rarely patients present with proximal muscle weakness rather than exercise intolerance. The weakness may be in the arms to a greater degree than the legs and may be asymmetric
10. Rare congenital patients have developed respiratory failure within the first years

Neuropathology

1. Muscle biopsy:
 - a. Glycogen accumulation occurs subsarcolemmally and between myofibrils
 - b. Variation in fiber size
 - c. Scattered necrotic and regenerating fibers
 - d. Reduced or absent myophosphorylase enzyme activity

Laboratory Evaluation

1. Serum CK is elevated
2. The forearm ischemic exercise test:
 - a. Normal rise in serum ammonia and no significant rise in lactic acid
3. EMG:
 - a. Normal

Type III Glycogenosis (PFK Deficiency)*General Characteristics*

1. PFK deficiency is an autosomal recessive disorder mapped to mutations in the PFK gene in chromosome 12q13
2. PFK is a tetrameric enzyme encoded by three autosomal genes; PFK encodes the muscle subunit, PFKL the liver subunit and PFKP the platelet subunit
3. Mature human muscle expresses only the M subunit and only the M4 homotetramer whereas erythrocytes express both the M and L subunits
4. PFK mutations cause a total lack of enzyme activity in muscle but only a partial deficiency in red blood cells
5. PFK catalyze the conversion of fructose 6-phosphate to fructose 1, 6 diphosphate
6. There is ADP accumulation in muscle, but the status of sodium-potassium pumps has not been defined

Clinical Manifestations

1. Clinically patients have exercise intolerance, muscle pain and contractures and relief by rest
2. There is no “second wind phenomena”
3. There is a lower incidence of myoglobinuria than that which occurs with McArdle’s disease
4. There may be jaundice from mild hemolysis
5. Gouty arthritis may occur due to “myogenic hyperuricemia”
6. Variability of the clinical phenotypes include:
 - a. Hemolytic anemia without myopathy
 - b. Later onset adulthood type with fixed proximal weakness or a scapuloperoneal phenotype; the patients may have had only mild exercise intolerance early in the course of their illness but no cramps or myoglobinuria
 - c. An infantile form with severe generalized weakness and cardiomyopathy may occur with contractures, cortical blindness, and corneal opacifications. They do not have hemolytic anemia. Death occurs from cardiorespiratory failure during infancy or childhood

Neuropathology

1. Muscle biopsy:
 - a. There is an abnormal accumulation of glycogen and polysaccharide (the latter most prominent in older patients) that stains for PAS but is diastase resistant
 - b. Non-specific myopathic changes without abnormal glycogen deposits may occur in the infantile form

Laboratory Evaluation

1. CK is usually elevated and there may be a mild anemia and increased reticulocyte count
2. Exercise forearm testing demonstrates a normal rise in ammonia but minimal increase in lactic acid
3. EMG:
 - a. Normal
4. Glucose or fructose infusion increase exercise intolerance because these patients rely on free fatty acids as their energy source. Glucose reduces blood levels of free fatty acids

Type VIII Glycogenosis (Myophosphorylase Kinase)*General Characteristics*

1. Phosphorylase B kinase is a multimeric enzyme composed of four different subunits α , B, R, J
2. PBK deficiency has been associated with several syndromes that include:
 - a. X-linked recessive hepatopathy
 - b. An autosomal liver and muscle disease
 - c. A pure myopathy predominant in men
 - d. An autosomal liver disease with cirrhosis and
 - e. A cardiomyopathy of infancy
3. The pure myopathy has been best described in men and is due to α mutations in the X-linked gene PBKA1

Clinical Manifestations

1. AR PBK deficiency is associated with various clinical manifestations. The alpha-subunit is muscle-specific
2. Presents in infancy and adulthood
3. The most common presentation is exercise intolerance with cramps and myoglobinuria
4. The infantile form can be associated with mild weakness and delay in achieving motor milestones; a fatal cardiomyopathy may occur
5. Approximately 50% of patients develop from a separate mutation (mutations in any of the PBK genes) in the PRKAG2 gene that encodes the gamma 2 subunit of the AMP activated protein kinase (AMPK)

Neuropathology

1. Muscle biopsy:
 - a. Variability in fiber size, some scattered necrotic fibers and minimal sarcolemmal glycogen
 - b. The biopsy may be normal, other than showing a deficit in myophosphorylase b kinase activity
 - c. PBK catalyzes the conversion of inactive myophosphorylase to an active form as well as converting active glycogen synthetase to an inactive form

Laboratory Evaluation

1. The serum CK is normal or minimally elevated
2. The EMG is usually normal
3. The ischemic forearm exercise test usually demonstrates a blunted lactate rise

Type IX Glycogenosis (PGK Deficiency)*General Characteristics*

1. PGK deficiency is caused by mutations in the PGK gene that map to chromosome Xq11
2. The clinical presentation depends on the isolated or combined involvement of three tissues 1. erythrocytes (hemolytic anemia), 2. skeletal muscle, 3. CNS
3. PGK catalyzes the reaction of acetyl phosphate transfer of 1,3 diphosphoglycerate to ADP that forms 3-phosphoglycerate and ATP in the later stage of glycolysis

Clinical Manifestations

1. Commonly present in male children as hemolytic anemia, mental retardation and seizures
2. The myopathy is associated with exercise intolerance, cramps and recurrent myoglobinuria
3. Some patients develop a slowly progressive proximal myopathy
4. Two patients have been reported with juvenile Parkinson's disease

Neuropathology

1. Muscle biopsy
 - a. May demonstrate mild and diffuse PAS-positive material but is usually normal
2. Electron microscopy
 - a. Reveals abnormal glycogen
3. PGK enzyme activity is decreased

Laboratory Evaluation

1. Serum CK levels are two to three times normal
2. Hemolytic anemia may occur with the myopathy
3. Ischemic forearm exercise test demonstrates normal lactate rise
4. EMG
 - a. Usually is normal

Type X Glycogenosis (PGAM Deficiency)*General Characteristics*

1. PGAM deficiency is caused by mutation in the PGAM gene that has been mapped to chromosome 7p13-p12.3. It is an autosomal recessive disease
2. The enzyme is dimeric and composed of a muscle-specific (M) subunit and a brain specific (B) subunit; normal human muscle contains the MM homo-dimer (that accounts for approximately 95% of the total enzyme activity)
3. None of the fourteen patients reported with the muscle defect have been African-American which suggest a founder effect
4. PGAM catalyzes the interconversion of 2- and 3-phosphoglycerate which is deficient in PGAM myopathy

Clinical Manifestations

1. Presents in childhood or early adulthood

2. Exercise intolerance, cramps and recurrent myoglobinuria

Neuropathology

1. Muscle biopsy:
 - a. PAS staining demonstrates increased glycogen
 - b. Association with tubular aggregates in type 2B muscle fibers
 - c. There may be a severe decrease of PGAM muscle activity with minimally elevated glycogen content

Laboratory Evaluation

1. CK in the serum is minimally increased
2. Ischemic forearm exercise test demonstrates an abnormal lactate response
3. EMG:
 - a. Normal

Type XI Glycogenosis (Lactate Dehydrogenase Deficiency)*General Characteristics*

1. The muscle isoform of lactate dehydrogenase is encoded by the LDHA gene that has been mapped to chromosome 11p15
2. The LDH isoenzyme in muscle has 4M subunits
3. LDH deficiency is autosomal recessive
4. The enzyme catalyzes the interconversion of pyruvate to lactate when oxygen is absent or in short supply. If the concentration of lactate is high, the enzyme decreases the rate of conversion of pyruvate to lactate. The enzyme also catalyzes the dehydrogenation of 2-hydroxybutyrate to a lesser degree

Clinical Manifestations

1. Exercise intolerance, muscle cramps and recurrent myoglobinuria
2. Muscle strength is normal
3. Some patients develop a scaly, erythematous rash
4. Uterine abnormalities in early pregnancy, which has not occurred with other glycogenoses
5. Renal insufficiency may be seen from the recurrent myoglobinuria

Neuropathology

1. Muscle biopsy:
 - a. The histology is normal but there is reduced LDH enzyme activity

Laboratory Evaluation

1. Serum CK is moderately elevated
2. The ischemic forearm exercise test demonstrates no rise in lactate but a normal increase in pyruvate
3. The LDH-M isoform may be less than 5% of normal in muscle
4. EMG:
 - a. Normal

Type XII Glycogenosis (Aldolase A Deficiency)*General Characteristics*

1. Homozygous point mutations in the Aldolase A gene that maps to chromosome 16q22-24 have been reported in patients with myopathy
2. Aldolase catalyzes the reaction of fructose 1,6 phosphate to dihydroxyacetone phosphate and glyceraldehyde-3-phosphate

Clinical Manifestations

1. Exercise intolerance and weakness that is temperature dependent and can occur without hemolysis
2. Myoglobinuria was always triggered by a febrile illness in 3 affected siblings
3. Red cell aldolase deficiency is associated with nonspherocytic hemolytic anemia

Neuropathology

1. Muscle biopsy:
 - a. Histologically normal by light microscopy
2. Electron microscopy:
 - a. Accumulation of lipid
3. Reduced aldolase activity in muscle

Laboratory Evaluation

1. Serum CK is elevated

Type XIII Glycogenosis (Triosephosphate Isomerase Deficiency)*General Characteristics*

1. Triosephosphate isomerase deficiency is an autosomal recessive multisystem disorder caused by homozygous or compound heterozygous mutations in the TPI gene that maps to chromosome 12p13.31
2. TPI adjusts the rapid equilibrium between dihydroxyacetone phosphate and glyceraldehyde-3-phosphate produced by aldolase during glycolysis. This reaction is interconnected to the pentose phosphate pathway by triosephosphates

Clinical Manifestations

1. The phenotype is variable
 - a. An infant onset patient who develops generalized hypotonia, cognitive disability and hemolytic anemia
 - b. Two Bulgarian siblings:
 - i. Hemolytic anemia in infancy
 - ii. Muscle weakness and fatigue at 2 years of age
 - iii. One sibling developed a scissoring gait, areflexia, extensor plantar responses, generalized hypotonia, muscle atrophy, ataxia and jerky movement of the upper extremities; the second sibling had an intention tremor and never gained the ability to walk
 - iv. Other children were born with hypotonia, weakness, hemolytic anemia, and loss of reflexes

Neuropathology

1. Increased glycogen accumulation by both light and electron microscopy

Laboratory Evaluation

1. The serum CK may be normal to moderately elevated
2. EMG:
 - a. Some patients had a myopathic pattern
 - b. Anterior horn cell involvement with neurogenic pattern

Type XIV Glycogenosis (β -Enolase Deficiency)*General Characteristics*

1. Muscle β -enolase deficiency is a rare mutation in the β -enolase gene 3 (ENO3) that maps to chromosome 17p13.2
2. The enzyme catalyzes the interconversion of 2-phosphoglycerate and phosphoenolpyruvate

Clinical Manifestations

1. Exercise intolerance
2. Myalgias
3. Recurrent rhabdomyolysis

Neuropathology

1. Muscle biopsy:
 - a. Abnormal sarcoplasmic glycogen accumulation
 - b. 10–15% of muscle β -enolase activity

Laboratory Evaluation

1. Serum CK levels can be normal to mildly elevated
2. EMG:
 - a. Myopathic pattern

Lysosomal Glycogen Storage Myopathies**Danon Disease***General Characteristics*

1. Danon disease is caused by mutations in the LAMP-2 gene that maps to chromosome Xq24
2. It is an X-linked dominant disease that predominately affects cardiac muscle with skeletal muscle and cognitive impairment as variable components

Clinical Manifestations

1. The initial description by Danon described the triad of hypertrophic or dilated cardiomyopathy, myopathy and cognitive impairment
2. Men are more severely affected than women, although female carriers can be symptomatic
3. Patients are normal at birth but develop proximal muscle weakness and cardiomyopathy by early adulthood
4. Approximately 70% of men are cognitively impaired compared to 6% of women
5. Ophthalmologic features may be concomitant with myopathy, pinhead pigmentary retinopathy, and abnormal visual fields. Cones may be affected more than rods

Neuropathology

1. Muscle biopsy:
 - a. Variation in fiber size
 - b. Autophagic vacuoles
 - c. Increased free glycogen is noted between disrupted myofibrils and within membrane sacs and vacuoles
2. Electron Microscopy:
 - a. Some vacuoles are bound by basal lamina
 - b. Absence of liposome-associated membrane protein-2 (LAMP-2)
 - c. There is no membrane deposition of attack complex in muscle fibers

Laboratory Evaluation

1. Serum CK is moderately elevated
2. EMG:
 - a. Irritative features that include increased insertional activity, positive sharp waves, fibrillation potentials, and complex repetitive discharges. Rarely myotonic discharges occur
 - b. Increased recruitment of low amplitude, short duration polyphasic MUAPs
 - c. Normal NCS
3. EKG:
 - a. Wolffe-Parkinson-White is the most frequent arrhythmia. Other arrhythmias include 1. atrioventricular block, 2. bundle branch block, 3. bradycardia, 4. arterial fibrillation
4. Echocardiography:
 - a. Hypertrophic or dilated cardiomyopathy

X-Linked Myopathy with Excessive Autophagy*General Characteristics*

1. X-linked myopathy with excessive autophagy is an autophagic myopathy frequently classified with Pompe-Danon disease due to some shared features seen in muscle biopsy that include an aberrant accumulation of autophagic vacuoles
2. It is caused by mutations of the XMEA gene that map to chromosome Xq28
3. The mutation reduces the activity of lysosomal hydrolases. XMA2 protein regulates the construction of an ATPase that is required to acidify lysosomes. The increased lysosomal pH and failure to degrade cellular debris may induce the increase in autophagic lysosomes

Clinical Manifestations

1. The onset is variable with presentation both during infancy or early adulthood
2. There is slowly progressive proximal weakness and atrophy
3. Respiratory weakness occurs but it is unusual to develop the cardiomyopathy that is characteristic of Danon disease
4. Cognitive function is intact

Neuropathology

1. Muscle biopsy:
 - a. Variation in fiber size
 - b. Many fibers have vacuoles that are not PAS-positive that distinguishes them from acid maltase deficiency and Danon disease
 - c. LAMP-2 is seen in the vacuoles and the cytoplasm
 - i. Calcium and membrane attack complex (C5 b-q) are seen on the sarcolemmas of affected muscle fibers
 - d. Electron microscopy:
 - i. Some vacuoles are bound by basal lamina adjacent to the sarcolemma where they fuse with the cell membrane. This permits discharge of their contents into the extracellular space
2. Reduction folds of basal lamina surround muscle fibers

Laboratory Evaluation

1. The CK is normal or minimally increased
2. EMG:
 - a. Irritative features include increased insertional activity with positive sharp waves, fibrillation potentials, complex repetitive discharges, and myotonic discharges
 - b. Early recruitment of low amplitude, short duration polyphasic MUAPs
3. Normal NCS (nerve conduction studies)

Disorders of Purine Nucleotide Metabolism***Myoadenylate Deaminase (MAD Deficiency)****General Characteristics*

1. Myoadenylate deaminase deficiency is caused by homozygous and heterozygous mutations in the AMPD gene that maps to chromosome 1p13.2. AMPD1 deficiency causes muscle symptomatology while AMPD3 is found in RBCs

Clinical Manifestations

1. The relationship of clinical symptomatology to myoadenylate deaminase MAD deficiency is controversial because:
 - a. In sustained isometric muscle contraction with ischemic oxygen use, resting and post excessive lactate, phosphocreatine levels are normal
 - b. It has been suggested that the mutations associated with MAD deficiency may be polymorphic
2. Patients may develop exertional muscle pain, fatigue and myoglobinuria which occurs in adolescence to middle age
3. Normal neurological examination

Neuropathology

1. Muscle biopsy:
 - a. Histologically normal
 - b. Low myoadenylate deaminase activity in muscle

2. Myoadenylate deaminase (MAD) catalyzes the reaction that removes an ammonia group from adenosine monophosphate that forms inosine monophosphate. The result of converting AMP to inosine monophosphate is an increase in ATP formation
3. The production of ammonia in the initial reaction buffers lactic acid that is formed during exercise
4. Inosine monophosphate stimulates glycolysis by its effect on the enzyme PFK that is important in the formation of fumarate, a substrate in the Krebs cycle
5. AMPD deficiency covers the level of adenosine. Activated AMP protein kinase (AMPK) is controlled by the concentration of intracellular AMP which may act as an energy sensor. AMPD may control some aspects of muscle metabolism by regulating AMPK activity through the muscle cell AMP concentration

Laboratory Evaluation

1. The serum CK level may be normal or minimally increased
2. EMG:
 - a. Normal
3. Forearm exercise test:
 - a. There is a normal rise of serum lactate but no rise of serum ammonia levels

Lipid Metabolic Disorders

Overview

Long chain fatty acids are the major source of energy for skeletal muscle at rest and during sustained exercise or fasting. Fatty acids pass through the mitochondrial membrane to undergo beta-oxidation by binding with carnitine. Carnitine is primarily synthesized in the liver and is actively transported into muscle against a concentration gradient. Fatty acids are activated upon by fatty acyl CoA synthetase that converts them to acyl coenzyme A (CoA) compounds. Acyl CoA is attached to carnitine by carnitine palmityl transferase (CPT1) on the outer mitochondrial membrane. Acyl carnitine translocase transports the complex through the inner mitochondrial membrane. The compound is converted to free fatty acids and carnitine by carnitine palmitoyl transferase 11 (CPT11) within the mitochondrial matrix. Beta-oxidation of long chain fatty acids occurs within the mitochondria.

Beta-oxidation of fatty acids is accomplished by a sequence of four sequential enzymatic reactions:

1. Flavin-dependent, length specific acyl CoA dehydrogenases (that consist of short, medium, long and very long chain compounds that are converted into enoxl-CoA's) that reduce flavin adenine nucleotides (FAD)
2. Length specific enoxl-CoA hydratase catalyzes the reaction to form 3-hydroxy acyl-CoA compounds

3. 3-hydroxy acyl-CoA dehydrogenases catalyze the reaction that forms 3-ketoacyl CoA esters that is due to a second dehydrogenation reaction
4. During the last step, 3-Keto-thiolase catalyzes the reaction that converts 3-Ketoacyl CoA to acetyl-CoA and fatty acyl-CoA that has shortened the Acyl CoA by two carbons. Electrons that were transferred to FADH₂ and NADH are transferred to the respiratory chain of the inner mitochondrial membrane. Electrons from FADH are transferred to coenzyme Q while the electrons from NADH are transferred to complex I of the respiratory chain. The electrons are transported down an energy gradient that generates a proton motive force that is essential in the production of ATP.

Carnitine Transporter Deficiency (Primary Carnitine Deficiency)

General Characteristics

1. Primary carnitine deficiency is caused by homozygous mutations in the SLC22A5 gene that map to chromosome 5q31
2. Carnitine is generated by endogenous synthesis or supplied by the diet
3. Intracellular levels are 20–50 times higher than extracellular concentrations due to an active transport system
4. Carnitine deficiency decreases the transport of long chain fatty acids into the inner mitochondrial matrix

Clinical Manifestations

1. Systemic primary carnitine deficiency is clinically heterogeneous:
 - a. Early childhood type:
 - i. Acute attacks of vomiting
 - ii. Hypoglycemia
 - iii. Altered mental status
2. Patients may worsen during pregnancy or the post-partum

Neuropathology

1. The defect in the high affinity carnitine transporter that is expressed in muscle, heart, kidney, lymphoblasts and fibroblasts results in impaired fatty acid oxidation in these tissues
2. Impaired or absent carrier dependent uptake of carnitine in fibroblast from patients has been demonstrated
3. Muscle biopsy:
 - a. Variability in fiber size
 - b. Abnormal accumulation of subsarcolemmal and intermyofibrillar lipid primarily in type 1 fibers
4. Electron microscopy:
 - a. Increased lipid
5. Muscle carnitine levels are decreased to less than 4% of normal
6. Secondary carnitine deficiency occurs from:
 - a. Respiratory chain defects
 - b. Organic acidurias

- c. Renal wasting
- d. Liver failure
- e. Toxic medications
- f. Malnutrition

Laboratory Evaluation

1. In primary carnitine deficiency there are very low levels of carnitine in muscle (<4%) while in secondary forms there is only a moderate 25–50% reduction
2. Serum CK levels are normal in 50% of patients with the myopathic form of the disease. They may be markedly elevated in primary systemic carnitine deficiency
3. Fasting in patients with carnitine deficiency may be associated with increased CK levels, hypoglycemia, acidosis (without ketone bodies), and increased liver enzymes
4. EMG:
 - a. May have irritative features of positive sharp waves, fibrillation potentials, increased insertional activity, and complex repetitive discharges
 - b. There is early recruitment of low amplitude, short duration polyphasic MUAPs
5. Echocardiography:
 - a. May demonstrate a biventricular or hypertrophic cardiomyopathy

Carnitine Palmitoyl Transferase 2 (CPT2) Deficiency

General Characteristics

1. CPT2 deficiency is autosomal recessive and is caused by mutations in the CPT2 gene that map to chromosome 1p32
2. Mutations impair the transport of acyl carnitine across the inner mitochondrial membrane that reduces ATP production from fatty acids

Clinical Manifestations

1. Onset is usually in the second or third decade with muscle pain and myoglobinuria after intense or prolonged exercise
2. Fasting and infections may precipitate signs and symptoms
3. The neurologic examination is normal between intervals of rhabdomyolysis and myoglobinuria
4. A severe cardiomyopathy occurs during infancy or early childhood

Neuropathology

1. Muscle biopsy:
 - a. Normal histology with light microscopy
 - b. Electron microscopy:
 - i. Increased lipid content

Laboratory Evaluation

1. Serum CK levels are normal at rest but may be elevated with intense exercise or during fasting
2. Normal forearm exercise tests that are a distinguishing feature from glycogen storage diseases

3. Muscle and serum carnitine levels are normal
4. EMG:
 - a. Usually normal but may show a myopathic pattern
5. EKG is normal

Very Long Chain Acyl CoA Dehydrogenase (VLCAD) Deficiency

General Characteristics

1. VLCAD deficiency is caused by mutations in the VLCAD gene that map to chromosome 17p11.2-p13.1

Clinical Manifestations

1. There are 3 clinical types of VLCAD deficiency:
 - a. A severe early-onset form with cardiomyopathy
 - b. Childhood onset intermediate form with hypoketotic hypoglycemia
 - c. Adult onset myopathic form with isolated muscle involvement:
 - i. The isolated muscle form most often demonstrates rhabdomyolysis

Neuropathology

1. There is abnormal accumulation of lipid in muscle biopsies
2. One adult patient was found to have <10% of residual enzyme activity

Laboratory Evaluation

1. Serum CK is increased during episodes of myoglobinuria but may be normal between attacks
2. Consistent with a defect in beta oxidation of long chain fatty acids in which the serum demonstrates:
 - a. An increased plasma concentration of tetradecanoic acid (C14:1) with normal levels of myristic acid (C14:0)
3. There is reduced VLCAD activity in cultured fibroblasts
4. During episodes of hypoketotic hypoglycemia there is dicarboxylic aciduria
5. EMG:
 - a. Myopathic MUAP

Long Chain Acyl Dehydrogenase (LCAD) Deficiency

General Characteristics

1. Long chain acyl dehydrogenase deficiency is due in some patients to mutations in the ACADL gene that maps to chromosome 2q34-q35

Clinical Manifestations

1. The disease most often presents in infancy with:
 - a. Failure to thrive
 - b. Hepatomegaly
 - c. Cardiomegaly
 - d. Encephalopathy similar to Reye's syndrome
2. Adult patients may develop:
 - a. Exercise intolerance
 - b. Rhabdomyolysis and proximal muscle weakness

Neuropathology

1. Muscle biopsy:
 - a. Increased lipid

Laboratory Evaluation

1. Increased serum CK during attacks of rhabdomyolysis
2. Total and free carnitine levels are decreased in the serum and muscle
3. Long-chain acyl carnitine esters are increased
4. Decreased LCAD in cultured fibroblasts

Medium Chain Acyl Dehydrogenase (MCAD) Deficiency*General Characteristics*

1. MCAD deficiency is caused by homozygous or compound heterozygous mutations in the medium-chain acyl-CoA gene (ACADM) that maps to chromosome p31
2. The enzyme acts on fatty acyl-CoA derivatives whose acyl residues contain four to fourteen carbons

Clinical Manifestations

1. Rare cardiac or skeletal muscle involvement
2. Onset is usually in infancy but symptomatology can occur in later life
3. Intolerance to prolonged fasting
4. Recurrent episode of hypoglycemia and coma
5. Sudden death in early childhood
6. Episodes of rhabdomyolysis and acute encephalopathy can occur in infancy and late in life

Neuropathology

1. Muscle biopsy:
 - a. Increased lipid
2. Enzyme activity is <10% in muscle, muscle fibroblasts and the liver
3. Secondary carnitine deficiency occurs

Laboratory Evaluation

1. Genetic evaluation of the ACADM gene
2. Medium-chain acyl-coenzyme A dehydrogenase deficiency is the most common disorder of mitochondrial fatty acid oxidation
3. Elevated serum CK during episodes of rhabdomyolysis
4. EMG:
 - a. Myopathic pattern
5. Increased urinary secretion of dicarboxylic, adipic and sebatic acids

Short Chain Acyl Dehydrogenase (SCAD) Deficiency*General Characteristics*

1. SCAD deficiency is an autosomal recessive disorder of fatty acid beta-oxidation due to mutations in the SCAD gene that maps to chromosome 12q24.31

Clinical Manifestations

1. There are two clinical phenotypes of SCAD deficiency that present:

a. Infantile type:

- i. A generalized disease in infants
- ii. Failure to thrive
- iii. Metabolic acidosis
- iv. Developmental delay
- v. Seizures
- vi. Myopathy

2. There are no episodes of non-ketotic hypoglycemia that distinguishes this disorder from MCAD deficiency and VLCAD deficiency

a. Early to mid-adulthood type:

- i. Progressive proximal weakness
- ii. Myalgias
- iii. Exercise intolerance

b. Variable signs include:

- i. Facial weakness
- ii. Ophthalmoplegia
- iii. Respiratory muscle involvement
- iv. Cardiomyopathy

Neuropathology

1. Increased lipid in muscle
2. Secondary carnitine deficiency
3. Decreased SCAD in muscle
4. Multicore myopathy has been described with SCAD deficiency

Laboratory Evaluation

1. Serum CK is normal or minimally elevated
2. Ethyl malonate and methyl succinate may be excreted in the urine

Mitochondrial Trifunctional Protein (TFP)*General Characteristics*

1. Trifunctional protein is a complex attached to the inner mitochondrial membrane that catalyzes three specific steps in the beta-oxidation of long chain fatty acids:
 - a. It is composed of four alpha- and four beta-subunits which contain three functional domains:
 - i. The four alpha-subunits contain the enoyl-CoA hydratase and 3-hydroxyacyl-CoA dehydrogenase enzymatic activity
 - ii. The four beta-subunits mediate beta-ketothiolase enzymatic activity
 - iii. The alpha-subunits are encoded by the HADHA gene
 - iv. The HADHA and HADHB genes map to chromosome 2p23.3
 - v. Mitochondrial trifunctional protein catalyzes three of the four steps in beta-oxidation of fatty acids
 - vi. Association with the electron transport chain:
 1. Fatty acid beta-oxidation and oxidative phosphorylation are two of the major metabolic pathways in mitochondria

2. The reducing equivalents from fatty acid beta-oxidation enter the mitochondrial respiratory chain through complexes I and III
3. The trifunctional protein channels substrate between the two enzymes

Long Chain HAD Deficiency (Long-Chain 3-Hydroxy Acyl CoA Dehydrogenase Deficiency)

General Characteristics

1. The muscle disorder is autosomal recessive and maps to chromosome 2p23
2. The enzyme catalyzes the third step in beta-oxidation of fatty acids that converts 3-hydroxyacyl-CoA derivatives to 3-ketoacyl-CoA derivatives

Clinical Manifestations

1. This is a clinically heterogeneous disease:
 - a. Infantile type:
 - i. Presents in infancy or early childhood:
 1. Nausea and vomiting
 2. Seizures
 3. Hypoketotic hypoglycemic
 4. Cardiomyopathy
 5. Respiratory failure
 - b. Childhood early adult form:
 - i. Progressive proximal muscle weakness
 - ii. Recurrent episodes of myoglobinuria
 - iii. Subset of patients develops a progressive sensorimotor polyneuropathy
 - iv. Pigmentary retinopathy
 - v. Mothers of affected patients may develop acute fatty liver of pregnancy or the HELLP syndrome (hemolysis, elevated liver enzymes, low platelets)

Neuropathology

1. Muscle biopsy:
 - a. Increased lipid content
2. Sural nerve biopsy (one patient):
 - a. Loss of myelinated fibers and axonal degeneration

Laboratory Evaluation

1. Elevated serum CK and lactate levels
2. Fibroblast culture identifies the reduced long-chain 3-hydroxyacyl CoA-dehydrogenase deficit
3. EMG:
 - a. Myopathic MUAPs
 - b. NCS reveal features of axonal sensory neuropathy

Glutaric Aciduria Type II

General Characteristics

1. The disorder is also known as multiple acyl-coenzyme A dehydrogenase (MADD) deficiency
2. The disease can be caused by mutations in three different genes:

- a. ETFA that maps to chromosome 15q24.2 – q24.3 (glutaric aciduria II A)
- b. ETFB that maps to chromosome 19q13.41 (glutaric aciduria II B)
- c. ETF-QO that maps to chromosome 4q32.1 – qter (glutaric aciduria II C)
- d. The genes are all involved in electron transfer to the mitochondrial respiratory chain
- e. There is no difference in the clinical phenotypes from mutations in the specific genes
- f. These enzyme defects cause the inability to oxidize the reduced forms of VLCAD, LCAD, MCAD and SCAD

Clinical Manifestations of MADD Deficiency

1. Neonatal onset:
 - a. With congenital anomalies (type I)
 - b. A neonatal form without congenital anomalies (type II)
 - c. These forms are characterized by:
 - i. Severe non-ketotic hypoglycemia
 - ii. Metabolic acidosis
 - iii. Hepatomegaly
 - iv. Both types are usually fatal:
 1. Childhood type:
 - a. May present with progressive proximal muscle weakness and atrophy that are associated with:
 - i. Episodic confusion
 - ii. Nausea and vomiting
 - iii. Ataxia and tremor
 - iv. Recurrent episodes of exercise induced Myoglobinuria
 2. Late onset type:
 - a. Symptoms and age at presentation are variable and are associated with:
 - i. Episodic lethargy
 - ii. Vomiting
 - iii. Hypoglycemia
 - iv. Metabolic acidosis
 - v. Hepatomegaly that is often preceded by metabolic stress
 - vi. Muscle involvement includes:
 1. Pain
 2. Weakness
 3. Intermittent and may only be experienced during illness or catabolic stress
 - vii. Cardiomyopathy

Neuropathology

1. Muscle biopsy:
 - a. Increased lipid

Laboratory Evaluation

1. Decreased ETF-QO concentration in cultured fibroblasts

2. Secondary carnitine deficiency occurs in the plasma, liver, and muscle
3. EMG:
 - a. Myopathic MUAPs
 - b. NCS reveal an axonal sensory neuropathy

Neutral Lipid Storage Disease with Myopathy

General Characteristics

1. Neutral lipid storage disease with myopathy (NLSMD) is an autosomal recessive disease and is caused by mutations in two genes:
 - a. Homozygous or compound heterozygous mutation in the PNPLA2 gene that maps to 11p15.3
2. Encodes adipose triglyceride lipase

Clinical Manifestations

1. Adult onset
2. Slowly progressive proximal muscle weakness affecting both upper and lower extremities
3. Distal musculature may be affected
4. Cardiomyopathy occurs in 50% of patients in the late course of the disease
5. Variable features include:
 - a. Diabetes mellitus
 - b. Hepatic steatosis
 - c. Has sensorineural hearing loss
6. Patients have muscle pain, fatigue and atrophy
7. The pattern of muscle involvement may be asymmetric and variable in severity
8. Patients do not have ichthyosis

Neuropathology

1. Increased lipid droplets in muscle are seen on muscle biopsy
2. Triglyceride containing cytoplasmic droplets are noted in leukocytes, bone marrow and muscle
3. Rimmed vacuoles may be seen

Laboratory Evaluation

1. Jordan anomaly:
 - a. The intracytoplasmic lipid storage in leukocytes
2. Biochemical investigations for abnormalities in lipid metabolism are normal

Chanarin-Dorfman Syndrome (CDS)

General Characteristics

1. Chanarin-Dorfman syndrome is caused by mutation of the abhydrolase domain containing 5 (ABHD5) gene that map to chromosome 3p21.33
2. The enzyme is an acyltransferase that is important for the synthesis of phosphatidic acid which is the major intermediate in membrane and storage lipid biosynthesis. It is also a coactivator of adipocyte triglyceride lipase

Clinical Manifestations

1. Chanarin-Dorfman syndrome is a rare form of non-bullous congenital ichthyosis form of erythroderma (NBCIE)
2. Muscle weakness may begin in adulthood and affects proximal muscles
3. Hepatosplenomegaly in infancy
4. Cognitive impairment
5. No cardiomyopathy

Neuropathology

1. Increased lipid droplets
2. MR spectroscopy (2 patients):
 - a. Lipid accumulation in cerebral white matter, cortex, and the basal ganglia

Laboratory Evaluation

1. Muscle biopsy:
 - a. Lipid droplets in muscle
2. Jordan anomaly in leukocytes of the peripheral blood
3. EMG:
 - a. Myopathic pattern

Mitochondrial Myopathies

Overview

Mitochondrial biogenesis occurs with cell division, but is also induced by: oxidative stimuli; an increased energy requirement by the cell; in specific mitochondrial diseases; exercise training; by electrical stimulation; from hormones and during development. Mitochondrial biogenesis is the process by which cells increase their mitochondrial mass. It is a dynamic process. Mitochondria are the major producer of reactive oxygen species as well as the producer of antioxidants. They have a crucial role in apoptosis, detoxification, Ca^{2+} buffering and ATP productions. In general, mutations in the mitochondrial DNA lead to a loss of function in the OXPHOS respiratory chain system with a decrease in ATP production and an increase of reactive oxygen species (ROS) that cause further mtDNA mutations. In mitochondrial diseases, there are compensatory mechanisms that induce mitochondria to increase ATP production.

These mechanisms include:

1. Overexpression of antioxidant enzymes
2. Increased mitochondrial biogenesis
3. Overexpression of respiratory complex subunits
4. A metabolic shift to glycolysis
5. The pathways that have been defined as a compensatory adaptation to energy deficits are PGC-1, sirtuins and AMPK

Mitochondria are pivotal in the conversion of carbohydrates, proteins and lipids into ATP. In the mitochondria:

1. Fatty acids are converted into acetyl-CoA
2. Amino acids are processed to pyruvate

3. Carbohydrates are metabolized to pyruvate in the cytoplasm and are then transported into the mitochondria where pyruvate is converted into Acetyl-CoA to enter the Krebs's cycle

The electrons generated are transferred to the respiratory chain complexes (I–V) that generate ATP. One classification of mitochondrial disease is based on specific metabolic defects:

1. In transport of substrate
2. Substrate utilization
3. Krebs cycle
4. Oxidation phosphorylation coupling
5. Respiratory chain dysfunction

Mitochondrial DNA and Proteins

General Characteristics

1. The mitochondrial genome is a 16.5 KB circular double-stranded DNA
2. It contains no introns
3. There is a single promoter site
4. Transcription is polycistronic which transcribes mitochondrial gene or two large RNAs which are cleaved into:
 - a. 13 messenger RNAs
 - b. 2 ribosomal RNAs
 - c. 22 transfer RNAs
5. The 13 mRNAs are translated into the subunits of the respiratory chain complexes:
 - a. A mutation in a transfer RNA may compromise the translation of the 13 mitochondrial mRNAs
6. Approximately 95% of mitochondrial proteins are encoded by the nuclear genome, translated in the cytoplasm, and transported into the mitochondrion
7. The mitochondrial contribution to the respiratory chain:
 - a. Complex I (NADH-CoQ reductase):
 - i. 7% of 41 subunits are encoded by mtDNA
 - b. Complex II (succinate dehydrogenase CoQ reductase):
 - i. All four subunits are encoded by nuclear genes
 - c. Complex III (CoQH₂-cytochrome C reductase):
 - i. 1 of 11 polypeptides is encoded by mtDNA
 - d. Complex IV (cytochrome C oxidase):
 - i. 3 of 13 subunits are encoded by mtDNA
 - e. Complex V (ATPase synthase):
 - i. 2 of its 4 subunits are encoded by mtDNA

Genetics of Mitochondrial Diseases

1. During fertilization, all mitochondria are derived maternally
2. All cells contain hundreds of mitochondria and each mitochondrion contains several copies of mtDNA
3. Mutations that involve mitochondria are more likely to manifest clinically than nuclear genes because they have no introns and a minimal DNA repair system
4. During germ cell meiosis and somatic cell mitosis, mitochondrial DNA mutations are randomly distributed

Hereditary Patterns of Mitochondrial Distribution

1. Normal homoplasmy:
 - a. Few or no mutant genome
2. Heteroplasmy:
 - a. A mixture of mutant and normal (wild-type) mitochondrial DNA
3. Mutant homoplasmy:
 - a. Predominantly contain mutant genome
4. The phenotype is determined by the relative proportion of mutant and wild-type mitochondria within each cell. The threshold for normal cell function is determined by the number of mutated mitochondria. If a specific threshold is exceeded patients manifest clinically
5. During meiosis and mitosis, there may be a shift in the proportion of mutant mitochondria in daughter cells that can alter genotype (mitotic/meiotic segregation)
6. Mutated mitochondria can utilize both normal mitochondrial encoded mRNA and tRNA from adjacent mitochondria that are known as complementation. Thus, mitochondria with DNA deletions may be able to translate some mtDNA-encoded protein
7. Energy requirements determine the susceptibility of a specific tissue to mitochondrial deficits. The CNS, heart, and exercising skeletal muscle have high requirements and thus a small decrease in ATP generation is symptomatic
8. Primary mtDNA mutations are only inherited from the mother:
 - i. Mitochondrial segregation and heteroplasmy determine the degree of phenotypic expression
 - ii. Women and men are equally affected
9. Mutations in nuclear genes that encode 95% of mitochondrial proteins are inherited in an autosomal dominant pattern (some types of progressive external ophthalmoplegia), autosomal recessive (MNGIE) and an X-linked pattern (Leigh's syndrome)
10. Inheritance may be sporadic in Kearns-Sayre syndrome
11. There may be nuclear gene control over the mitochondrial genome which results in:
 - a. A role in syndrome that have depletions or multiple mtDNA deletions
 - b. In these instances, there may be an autosomal recessive dominant inheritance pattern
12. There is significant genetic heterogeneity within clinical syndromes (point mutations, multiple DNA deletions) and specific mutations may manifest with heterogeneous phenotypes
13. Clinical phenotype variability occurs within families with identical mtDNA mutations

General Laboratory Evaluation

1. Serum CK, lactic acid, and pyruvate concentrations can be normal or elevated
2. Lactic acid levels can be elevated in the cerebrospinal fluid

3. mtDNA depletion is associated with renal tubular defects
4. Ergometry demonstrates a low workload correlated with tachycardia and increased oxygen consumption. The degree of exercise intolerance correlates with decreased oxidative phosphorylation demonstrated by the peak capacity for muscle oxygen extraction and the mitochondrial mutation load
5. The forearm exercise test demonstrates increased and prolonged lactate generation and increased venous oxygen saturation in patients with mitochondrial myopathies with exercise intolerance
6. Nerve conduction studies are normal in mitochondrial myopathy with the exception of NARP (axonal neuropathy) and MNGIE (demyelinating neuropathy)
7. EMG:
 - a. Most often it is normal
 - b. Some myopathies are irritative with increased insertional activity and spontaneous activity
 - c. Small MUAPs with early recruitment in weak muscles
8. EKG:
 - a. Conduction defects
9. MRI:
 - a. Abnormal in patients with mitochondrial encephalomyopathy
 - b. Muscle MRI may resemble that seen with dystrophic disorders
10. Magnetic Resonance Spectroscopy (MRS):
 - a. Decreased creatine phosphate with increased inorganic phosphates with exercise
 - b. Delay in replenishment of phosphocreatine concentration after exercise
11. Mutational analysis

Neuropathology

1. Muscle biopsy:
 - a. Utilizing the modified Gomori trichrome stain:
 - i. Ragged red fibers are present which react with NADH and SDH
 - ii. Lipid droplet accumulation may also occur in these fibers
 - iii. Disorders without mutations mtRNA may not demonstrate ragged red fibers and may have normal NADH and SDH staining:
 1. COX stain which reacts with a subunit encoded by mtDNA may be sensitive in these instances (reveals reduced COX staining) in both ragged red fibers and normal appearing fibers
 - iv. Variable COX staining with intense SDH staining occurs with mtDNA mutations. COX staining variability is a reflection of heteroplasmy while increased SDH staining (all subunits are encoded by nuclear DNA) reflect a compensatory increase of mitochondria
 - v. Electron microscopy:
 1. Abnormalities include:
 - i. Increased numbers of normal mitochondria
 - ii. Enlarged mitochondria with abnormal cristae
 - iii. ParacrySTALLINE inclusions (increased dimeric mitochondrial creatine kinase)

Myoclonic Epilepsy and Ragged Red Fibers (MERRF)

General Characteristics

1. Approximately 80% of MERRF patients have a point mutation in nucleotide 8344 of the mitochondrial genome:
 - a. The mutation causes an A to C transition in the transfer RNA gene (MTTK)
2. There is great genetic heterogeneity in MERRF with mutations in:
 - a. Other different mutations in the tRNA gene (8350; 8366)
 - b. Mutations in MTTL1 (most commonly seen in MELAS)
 - c. Other tRNA mutations that occur with MERRF include:
 - i. tRNA Leu (MTTH)
 - ii. tRNA Phe (MTTF)
 - iii. tRNA Ser (MTTS1)
 - iv. A MERRF phenotype occurs with POLG (multiple mitochondrial DNA deletions) and ND5 (MTND5) gene mutations

Clinical Manifestations

1. The age of onset of disease severity and the specifics of the phenotype are highly variable due to the percentage of mitochondria that segregate into various tissues
2. Onset in childhood or adulthood
3. Myoclonic and generalized tonic-clonic seizures
4. Cognitive impairment
5. Ataxia
6. Sensorineural hearing loss
7. Optic atrophy
8. Muscle weakness and atrophy:
 - a. Generalized
 - b. Predilection for proximal extremity muscles
9. Sensorimotor polyneuropathy
10. Pes cavus
11. The myoclonus may be present at rest but is stimulus sensitive
12. There is no ptosis, ophthalmoparesis, or pigmentary retinopathy, which are distinguishing points from KSS or PEO
13. Cardiomyopathy with conduction block and CHF are frequent
14. Respiratory muscle weakness
15. A subset of patients has multiple symmetric lipomatosis

Neuropathology

1. Muscle biopsy:

- a. Ragged red fibers
- b. COX-negative fibers with increased SDH staining
- 2. CNS neuropathology (brain):
 - a. Neuronal loss and gliosis occurs in:
 - i. Dentate nucleus
 - ii. Globus pallidus
 - iii. Substantia nigra
 - iv. Cerebellar cortex
 - v. Inferior olivary nuclei
 - vi. Optic nerves
- 3. Neuropathology of the spinal cord:
 - a. Demyelination and gliosis of:
 - i. Spinothalamic tract
 - ii. Posterior columns
 - iii. Corticospinal tracts
- 4. Assays of mitochondrial enzyme activity:
 - a. Decreased activity of complex I and IV
 - b. Approximately 90% of mitochondria must be involved to produce clinical symptomatology

Laboratory Evaluation

- 1. Serum CK levels are normal or minimally elevated or occur with serum lactate elevation
- 2. EEG:
 - a. Generalized background slowing with spike-and-wave complexes
- 3. MRI:
 - a. Cortical and cerebellar atrophy
- 4. EMG:
 - a. May be normal
 - b. Low amplitude, early recruitment of MUAPs in weak muscles
 - c. NCS:
 - i. Reduced sensory nerve action potentials from superimposed axonopathy in a subset of patients

Mitochondrial Myopathy with Lactic Acidosis and Strokes (MELAS)

General Characteristics

- 1. MELAS is maternally inherited in a non-Mendelian fashion
 - a. Approximately 70% of patients carry an mtDNA mutation at nucleotide 3243 that causes an A to G substitution in the (MTTL1) gene that encodes tRNA^{Leu}
 - b. Genetic heterogeneity includes:
 - i. Mutation sites at 3252, 3260, 3271, 3291 in the tRNA^{Leu} gene
 - ii. Genes mutations also occur in:
 - 1. tRNA^{val}(MTTU)
 - 2. tRNA^{lys}(MTTK)
 - 3. tRNA^{phe}(MTTF)
 - 4. tRNA^{ser}(MTTS1)
- 5. Dehydrogenase ubiquinone oxidoreductase Subunits of complex I-NDI (inTND1)

- 6. ND4 (nTND4)
- 7. ND5 (nTND5)
- 8. Cytochrome b of complex III (MTCYB)

Clinical Manifestations

- 1. Onset occurs in the first year of life in less than 10% of patients
- 2. Approximately 60–80% manifest by 15 years of age although there can be a late adult onset
- 3. Recurrent stroke-like episodes
 - a. Nausea and vomiting
 - b. Hemiparesis
 - c. Hemianopia
 - d. Cortical blindness
 - e. Patients may develop cognitive impairment
 - f. Proximal muscle weakness with myalgias and easy fatigability with exercise
 - g. Short stature as occurs with many mitochondrial diseases
 - h. Variable signs and symptoms:
 - i. Myoclonic seizures
 - ii. Ataxia
 - iii. Overlap of symptomatology with MERRF
 - iv. 100% of patients may develop ptosis, ophthalmoparesis, pigmentary retinopathy and cardiomyopathy

Neuropathology

- 1. Muscle biopsy:
 - a. Similar to the usual mitochondrial myopathy
 - i. Ragged red fibers with variable COX staining which may be more prominent than with MERRF
 - ii. COX-negative fibers stain with SDH
 - iii. Increased mitochondria are seen in the muscular walls of small blood vessels
 - iv. Mitochondrial enzyme analysis demonstrates decreased activity of complexes I, III, IV and V
 - v. Mitochondrial dysfunction activates mitochondria-to-nucleus signaling pathways:
 - 1. The mutant mt-tRNA causes oxidative stress in muscles and cybrid cells from patients
 - 2. Mutant MELAS patients lack the taurine containing modification normally present at the wobble uridine (U34) of wild type mt-tRNA^{leu} which may be a cause of MELAS
 - 3. MELAS cybrids have a decrease in several mt-tRNA modification enzymes that are not under transcriptional regulation. Oxidative stress mediates an NFkB-dependent induction of microRNA-9/qd which affects the U34 modification state of wild type tRNAs and may be important in the MELAS phenotype
 - 4. MELAS patients have demonstrated that disease severity and mutation load are inversely correlated with interictal cerebral vascular resistance (CVR) and are directly correlated with frontal CBF

Laboratory Evaluation

1. Serum CK may be normal or elevated while lactate levels are usually increased in the serum and the CSF
2. EMG:
 - a. Early recruitment of myopathic MUAPs
 - b. NCS are normal
 - c. EEG:
 - i. May have epileptic features
 - d. MRI:
 - i. Cortical atrophy
 - ii. High T2 signal and FLAIR abnormalities in the cerebral cortex, basal ganglia, and thalamus
 1. Most often the ADC of the lesions is increased but may be decreased
 2. The pattern of the lesions does not correspond to a vascular territory
 - iii. Magnetic resonance spectroscopy (MRS)
 1. During acute cortical lesions demonstrates:
 - a. Increased lactate levels
 - b. Reduced concentration of N-acetyl aspartyl compounds (neurons), and myoinositol
 - c. MRS of muscle:
 - i. Decreased phosphocreatine
 - ii. Increased inorganic phosphate and free adenosine 5-diphosphate
 - iii. Low phosphorylation potential

Kearns-Sayre Syndrome (KSS)*General Characteristics*

1. Most patients with KSS demonstrate large mtDNA deletions, approximately 43% of patients have a H19KB deletion
2. Muscle tissue is a better source for mutation analysis than peripheral leukocytes
3. Large deletions affect several tRNA genes that impair translation of multiple mtDNA encoded proteins
4. Single deletions rarely occur sporadically

Clinical Manifestations

1. Onset is most often before 20 years of age
2. Short stature
3. Proximal muscle weakness and exercise intolerance
4. Endocrinopathies:
 - a. Diabetes mellitus
 - b. Hypothyroidism
 - c. Hypoparathyroidism
5. Sensorineural hearing loss
6. Cognitive impairment
7. Ataxia
8. Depressed ventilatory drive
9. Pigmentary retinopathy
10. Sensitivity to sedatives
11. 50% of patients develop cardiac conduction defects:
 - a. Bradycardia related conduction defects
 - b. Complete atrioventricular block
12. Cataracts

Neuropathology

1. Muscle biopsy:
 - a. Ragged red fibers most of which lack COX staining
 - b. There is a correlation of the number of ragged red fibers with the number of mitochondria with large deletions
 - c. CNS evaluation reveals spongy degeneration of white matter

Laboratory Evaluation

1. Elevated serum lactate and pyruvate with normal CK levels
2. Elevated CSF protein and lactate
3. EMG:
 - a. Low amplitude small polyphasic MUAP in weak muscles
 - b. Normal insertional activity
 - c. NCS are usually normal but some patients demonstrate low amplitudes consistent with an axonal sensory or sensory motor neuropathy
4. EKG:
 - a. Bradyarrhythmias to complete atrioventricular block
5. Cardiac magnetic resonance imaging:
 - a. Monomorphic ventricular tachycardia and myocardial scarring (demonstrated in one patient)
 - b. May demonstrate presymptomatic disease

Progressive External Ophthalmoplegia*General Characteristics*

1. Most patients with PEO have single large mtDNA deletions (60–70%) that is also seen with Kearns-Sayre syndrome and Pearson syndrome. These are sporadic mutations
2. Point mutations in specific tRNA genes have been described
3. Autosomal dominant PEO is genetically heterogeneous and is associated with multiple DNA deletions
4. The three autosomal dominant genes described for PEO are:
 - a. PEOA1
 - i. Due to mutations in the polymerase gamma gene (POLG) that maps to chromosome 15q25
 - b. PEOA2
 - i. Caused by mutations in the ANT1 gene that maps to chromosome 10q24
 - ii. Encodes adenine nucleotide translocator
 - c. PEOA3
 - i. Caused by mutations in the twinkle gene (100RF2) that maps to chromosome 1q24
 - d. There may be a fourth locus that maps to chromosome 3q14.1-21.4
5. ANT1 functions to transport adenosine triphosphate across the inner mitochondrial membrane
6. Twinkle and polymerase gamma are essential for mitochondrial DNA replication

7. Autosomal recessive progressive external ophthalmoplegia (PEOB)
 - a. Maps to chromosome 15q26.1
 - b. Is caused by homozygous or compound heterozygous mutations in the nuclear encoded DNA polymerase-gamma gene
 - c. Recessive mutations in the POLG also cause SANDO (sensory ataxic neuropathy, dysarthria, and ophthalmoplegia)
 - d. Mutations in POLG also cause Alpers syndrome (psychomotor retardations, intractable epilepsy, and limb failure) in infants and young children
 - e. A case of genetic inheritance has been described

Clinical Manifestations

1. Adult onset of extraocular muscle weakness and ptosis
2. Ptosis
3. Symmetry of EOM limitation
4. Exodeviation
5. No pigmentary retinopathy, cardiac conduction defect or endocrinopathy
6. Patients with sporadic single large mtDNA deletions may demonstrate:
 - a. Proximal muscle weakness
 - b. Cataracts
 - c. Hearing loss
 - d. Ataxia
 - e. Parkinsonism
 - f. Mitral valve prolapse
 - g. GI dysmotility
7. There may be facial and neck muscle weakness

Neuropathology

1. Muscle biopsy:
 - a. Minimal variability in fiber size
 - b. Ragged red fibers without COX

Laboratory Evaluation

1. Serum CK, lactate and CSF are mildly variable, elevated or normal
2. CSF protein may be mildly elevated
3. EMG:
 - a. Myopathic MUAP in weak muscles

Autosomal Recessive Cardiomyopathy and Ophthalmoplegia (ARCO)

General Characteristics

1. Multiple mtDNA deletions often occur from mutations in enzymes that are involved in mtDNA maintenance. POLG1 and POLG2 genes encode polymerase gamma that are essential for mtDNA maintenance and map to chromosome 15q26.1

Clinical Manifestations

1. Onset in childhood

2. Progressive external ophthalmoplegia
3. Facial weakness
4. Proximal muscle weakness
5. Severe cardiomyopathy (dilated)
 - a. Distinguishes the entity from AD and maternally inherited PEO
6. Decreased or absent muscle stretch reflexes

Neuropathology

1. Muscle biopsy:
 - a. Ragged red fibers that are positive for SDH and have no COX staining
 - b. Decreased activity of respiratory chain enzymes whose subunits are encoded by mtDNA
 - c. SDH and citrate synthetase have normal activity

Laboratory Evaluation

1. Serum CK is minimally elevated
2. Serum lactate is normal at rest but is prominently increased with exercise
3. EKG:
 - a. Cardiac conduction defects
4. Echocardiography
 - a. Dilated cardiomyopathy with low ejection fraction
5. EMG:
 - a. Myopathic MUAPs
 - b. NCS are normal

Mitochondrial DNA Depletion Syndrome

General Characteristics

1. Approximately 50% of patients have sporadic mutations as the cause of the disorder. It is inherited in an autosomal recessive fashion
2. There is a correlation with the quantity of mtDNA and the severity of the syndrome. A 99% reduction causes the fatal infantile form, while the more benign myopathy has 36–88% of normal mtDNA
3. Nuclear genes regulate the mitochondrial genome and cause mitochondrial DNA depletion. Specific genes that have been identified include:
 - a. Thymidine kinase 2 (TK2) gene
 - i. Has been mapped to chromosome 16G21
 - ii. Is a mitochondrial deoxyribonucleoside kinase that phosphorylates thymidine, deoxycytidine, deoxyuridine as well as antiviral and anticancer nucleosides or analogues
 1. Deoxyguanosine kinase gene (DGK)
 - a. Maps to chromosome 2P13.1
 2. Succinate – COA ligase gene (SUCLA2)
 - a. Otherwise known as the cause of mitochondrial depletion syndrome 5 is autosomal recessive and maps to chromosome 13q14.2
 - b. The mutations are homozygous or compound heterozygous in the beta-subunit of the succinate COA ligase gene

4. TK2 and DGK:
 - a. Are essential for mitochondrial deoxynucleotide metabolism
5. MPU17 Gene
 - a. Maps to chromosome 2p24
 - b. Encodes an inner membrane protein of unknown function

Clinical Manifestations

1. The mitochondrial depletion syndrome is an autosomal recessive disorder that has a decreased mtDNA copy number in affected tissues
2. The hepatocerebral form, in which there is mitochondrial depletion in liver and brain, is associated with mutations in the POLG, PEO1 (Twinkle) DGK and MPU17 genes
3. Other genes associated with mitochondrial depletion syndromes include: 1. TYMP, 2. SUCA1, 3. OPA1, and RRM2B
4. Onset is usually in infancy or early childhood
5. There is a wide clinical spectrum of severity
6. Infant severe fatal form:
 - a. Generalized hypotonia and weakness
 - b. Infants may appear normal the first years of life
 - c. Proximal muscle involvement
 - d. Ptosis and ophthalmoplegia
 - e. A subset in infants has polyneuropathy
 - f. Absent or decreased muscle stretch reflexes
 - g. Affected infants have systemic involvement that includes:
 - i. Cardiomyopathy
 - ii. De Toni-Fanconi-Debré syndrome (renal tubular defect)
 - iii. Seizures
 - iv. Liver failure
7. Muscle weakness is severe, progressive and causes feeding difficulties, respiratory failure and death usually in the first year
8. Benign infantile form:
 - a. Initially resembles the fatal myopathy
 - b. May present shortly after birth or in childhood
 - c. Muscle strength gradually improves although there may be bulbar and respiratory problems initially
 - d. Motor milestones are delayed but are attained and children may be normal by 2–3 years of age
 - e. Some patients succumb within the first two decades of life but others have a normal life expectancy
 - f. These patients do not have the renal tubular defect

Neuropathology

1. The various mutations cause defects in proteins that are directly involved in mtDNA replication or in the availability of deoxyribonucleotide triphosphates for mtDNA synthesis
2. Muscle biopsy:
 - a. COX-negative fibers

- b. No ragged red fibers
- c. Electron microscopy
 - i. Enlarged mitochondria
 - ii. Concentric or whorled cristae
 - iii. Dense bodies
 - iv. Paracrystalline inclusions

Laboratory Evaluation

1. Both serum CK and lactate can be normal or moderately elevated
2. If the renal tubular defect is present:
 - a. Glycosuria, proteinuria, and aminoaciduria occur
3. EMG:
 - a. Increased insertional activity with positive sharp waves and fibrillation potentials
 - b. Motor units may have a myopathic or neuropathic pattern
 - c. NCS may demonstrate characteristics of an axonal or demyelinating neuropathy
4. MRI:
 - a. Cerebral atrophy
 - b. Hypomyelination of subcortical white matter

Focal Mitochondrial Depletion

General Characteristics

1. Autosomal dominant inheritance has been shown in some patients
2. Mitochondrial abnormalities have been determined
3. Similar muscle biopsy abnormalities have been described in patients with selenium deficiency

Clinical Manifestations

1. A father and two siblings that were evaluated demonstrated in the two children:
 - a. Onset of symptoms in the second decade
 - b. Muscle pain with exercise
 - c. Fatigue
 - d. Mild proximal muscle weakness
2. The father demonstrated a high CK
3. Other patients have shown:
 - a. Weakness at birth
 - b. Hypotonia
 - c. Delayed motor milestones
 - d. Cognitive deficits
4. Axial muscle weakness:
 - a. Increased mitochondrial respiratory chain defects were detected in cervical and lumbar paraspinal muscles that increased with age

Neuropathology

1. Muscle biopsy:
 - a. Approximately 1/3 of type II fibers are centrally devoid of mitochondria
 - b. Remaining mitochondria are enlarged but otherwise normal
 - c. Scattered degenerating and regenerating fibers are noted

Laboratory Evaluation

1. Serum lactate levels are normal. CK levels are elevated both at rest and increase moderately with exercise
2. EMG:
 - a. Myopathic MUAPs
 - b. Normal NCS
3. Decreased selenium level has been reported in one patient

Mitochondrial Neurogastrointestinal Encephalomyopathy (MNGIE)*General Characteristics*

1. MNGIE is caused by mutations in the TYMP gene that map to chromosome 22q13.33. It is a rare autosomal recessive disorder
2. The gene encodes thymidine phosphorylase (TP). Loss of the enzyme causes an accumulation of thymidine and deoxyuridine nucleosides that are incorporated by the mitochondrial salvage pathway. Their accumulation causes a deoxynucleotide triphosphate pool imbalance thought to cause mtDNA instability
3. A few patients with MNGIE have been associated with POLG gene and MTTK gene mutations

Clinical Manifestations

1. Onset is prior to age twenty (range is 2.5 to 32 years)
2. Distal greater than proximal weakness
3. Gastrointestinal dysmotility
4. Stocking and glove sensory loss
5. Decreased muscle stretch reflexes
6. Ptosis and extraocular muscle weakness
7. Rare patients have cognitive deficits
8. Pigmentary retinopathy
9. Sensorineural hearing loss
10. Facial weakness
11. Hoarseness and dysarthria

Neuropathology

1. Muscle biopsy:
 - a. Ragged red fibers
 - b. Ragged blue fibers (NADH and SDH histochemical stains)
 - c. COX-negative fibers
 - d. Neurogenic atrophy of distal muscles
2. Sural Nerve biopsy
 - a. Loss of myelinated fibers
 - b. Demyelination with remyelination with rare onion bulbs
 - c. Electron microscopy:
 - i. Abnormal mitochondria
 - ii. Paracrystalline inclusions in both muscle fibers and Schwann cells
 - d. Enzymatic assay of muscle fibers:
 - i. COX and other respiratory enzyme deficits
 - e. Autopsy:

- i. Endoneurial fibrosis and demyelination of peripheral nerves
- ii. White matter abnormalities in the cerebral cortex and cerebellum
- iii. Cranial nerve and spinal roots are demyelinated to a degree
- iv. Loss of neurons and fibrosis of the autonomic ganglia, celiac and myotonic plexuses

Laboratory Evaluation

1. Serum CK levels are normal or slightly elevated
2. Increased lactate, pyruvate and CSF protein is typical
3. EMG:
 - a. Increased insertional activity, positive sharp waves and fibrillation potentials
 - b. Decreased recruitment of MUAPs may be seen in distal muscles
 - c. Proximal muscles reveal small brief duration MUAPs
 - d. NCS:
 - i. Slow motor and sensory nerve induction velocities to the demyelinating range with prolonged F-wave latency
 - ii. Reduced amplitudes of sensory nerve action potentials
 - iii. Rare reduced amplitude of CMAPs
 - e. MRI:
 - i. Abnormalities of cerebral and cerebellar white matter (leukoencephalopathy)
 - f. Gastrointestinal radiology
 - i. Dilatation and dysmotility of the esophagus, stomach and small intestine
 - g. EKG:
 - i. Conduction defects in a subset of patients that are asymptomatic

Leigh Syndrome*General Characteristics*

1. The incidence is 1 in 40,000 live births, two familial mutations have increased incidences. The mitochondrial mutation in an isolated population near Quebec leads to disease occurrence in 1 in 7000 births and a nuclear encoded mutation in the Faroese populations with a homo- or heterozygous frequency of 1:2,500 births
2. Leigh syndrome is an extremely heterogeneous mitochondrial disorder. The syndrome can be caused by more than 35 different genes that are mitochondrial or nuclear. They involve all five respiratory chain complexes. As noted earlier, there are 13 mtDNA-encoded structural proteins of complex I, II, IV and V and approximately 77 structural protein subunits that are nuclear encoded. Coenzyme Q10 and cytochrome C are also nuclear encoded proteins
3. Mutations in any structural components of the respiratory chain, the Krebs cycle and coenzyme Q can also cause phenotypic Leigh syndrome
4. The mutated genome can be inherited by:

- a. Maternally inherited (mtDNA – encoded)
- b. Autosomal recessive pattern from nuclear genes that encode the mitochondrial chain complex subunits, complex assembly proteins, coenzyme Q, or/and mitochondrial tRNA synthetases
- c. X-linked genes involved in PDHA1 and complex I assembly factor NDUFA1 (nuclear encoded)
- d. Most Leigh affected patients have mutations in nuclear DNA. Approximately 25% have mutations in mtDNA
- e. Leigh syndrome nuclear mutations have been mapped to
 - i. Chromosome – 2q35 and 2q37.3
 - ii. Chromosome – 5p15.33, 5q11.2, 5q12.1 and 5q31.3 (Complex I deficiency)
 - iii. Chromosome – 8q22.1 (complex I deficiency)
 - iv. Chromosome – 9q34.2 (COX deficiency)
 - v. Chromosome – 10q24.2 (cytochrome C-oxidase deficiency)
 - vi. Chromosome – 11q13.2, 11q24.2 (complex I deficiency)
 - vii. Chromosome – 12q22, 12p13.32 (complex I deficiency)
 - viii. Chromosome – 17p12 (COX4 deficiency)
 - ix. Chromosome – 19p13.1
 - x. Mutation in complex I genes (mitochondrial)
 1. MTND2, MTND3, MND5, MTND6
 2. Nuclear encoded: NDUFS1, NDUFS3, NDUFS4, NDUFS7, NDUFS8, NDUFA2, NDUFA9, NDUFA10, NDUFA12, NDUFAF6 and C200RF7
 3. Complex assembly factor NDUFAF2
 4. Mutation in the MTFMT gene that is involved in mitochondrial translation occurs with complex I deficiency
 - xi. Mutations occur in flavoprotein subunit A complex II gene
 - xii. Mutation in the BCS12 gene of complex III involved in the assembly of complex III
 - xiii. The complex IV gene mutations include mitochondrial encoded MTCO3 and nuclear encoded COX10, COX15, SCO2, SURF1 that are involved in the assembly of complex IV. Other mutations affecting complex IV occur in TACO1 and PET100 genes
 - xiv. A mutation in the mitochondrial encoded MTATP6 complex V gene has been described
 - xv. Mitochondrial tRNA gene mutations have been found in MTTV, MTTK, and MTTN genes
 - xvi. Mutations in components of the pyruvate dehydrogenase complex cause Leigh syndrome which include:
 1. The DLD gene that encodes dihydrolipoamide dehydrogenase that is a component of the pyruvate dehydrogenase, alpha-lactoglutarate dehydrogenase complex as well as the branch-
ed – chain alpha – keto acid dehydrogenase complex
 - xvii. The Saguenay-Lac Saint Jean form of Leigh syndrome is caused by a mutation in the leucine-rich PPR motif containing protein gene (LRPPRC). It encodes a mRNA-binding protein pivotal in the processing and trafficking of mtDNA encoded transcripts that cause COX deficiency (LSFC)

Clinical Manifestations

1. Onset in infancy or early childhood but can present in adulthood
2. Recurrent vomiting
3. Cognitive deficits
4. Hypotonia
5. Generalized weakness and muscle atrophy
6. Ptosis and ophthalmoplegia
7. Nystagmus
8. Optic atrophy
9. Sensorineural hearing loss
10. Seizures
11. Spasticity
12. Involuntary movements
13. Peripheral neuropathy
14. A progressive and most often fatal disorder

Neuropathology

1. Muscle Biopsy:
 - a. COX deficient fibers
 - b. Usually there are no ragged red fibers
 - c. COX deficiency is noted in muscle spindles and the smooth muscle of intravascular blood vessels
2. CNS and spinal cord:
 - a. Symmetric optic necrosis
 - b. Spongiform degeneration
 - c. Demyelination
 - d. Areas of vascular proliferation (the mammillary bodies may be hemorrhagic and enlarged)
 - e. Areas affected include:
 - i. The brainstem (medulla)
 - ii. Cerebellum (white matter)
 - iii. Thalamus
 - iv. Basal ganglia
 - v. Dentate nucleus
 - vi. Dorsal columns
 - f. Mechanisms of lesion formation:
 - i. ATP depletion
 - ii. Hyperlacticacidemia
 - iii. Reactive oxygen species
 - iv. Excitotoxicity

Laboratory Evaluation

1. Serum lactate and pyruvate are abnormally elevated with exercise but may be normal at rest
2. Defects in respiratory complex proteins may be demonstrated in muscle tissue which are particularly prominent

in COX, complex I and the pyruvate dehydrogenase complex

3. MRI:

- a. Systemic lesions:
 - i. The brainstem
 - ii. Occasional hemorrhagic mammillary bodies
 - iii. Cerebellum
 - iv. Thalamus
 - v. Spinal cord

Mitochondrial Myopathies Associated with Exercise Intolerance and Recurrent Myoglobinuria

General Characteristics

1. This is a very heterogeneous group of disorders that include:
 - a. The multiple mtDNA deletion syndrome
 - b. Point mutations in tRNA genes
 - c. Microdeletions in genes encoding for COX III (MTCO3)
 - d. Mutations in the gene encoding tRNA subunit 4 of NADH dehydrogenase
 - e. Mutations in cytochrome b (MTCYB)
 - f. Mutations in SDH

Clinical Manifestations

1. Onset may be infancy or early adulthood
2. Short stature
3. Decreased muscle bulk but may have normal strength
4. Patients may have slight proximal weakness
5. Recurrent episodes of myoglobinuria are provoked with exercise and alcohol
6. Progressive deafness may occur

Neuropathology

1. Muscle biopsy:
 - a. Scattered ragged red fibers
 - b. COX-negative fibers
 - c. Increased SDH and NADH fibers
 - d. COX histochemistry may be normal in patients with MTCO3, ND4 and MTCYB mutations
2. Electron microscopy:
 - a. Paracrystalline inclusion in mitochondria

Laboratory Evaluation

1. Serum lactate and pyruvate are abnormally elevated with aerobic exercise
2. CK is elevated during attacks associated with myoglobinuria
3. EMG:
 - a. Needle studies and NCS are usually normal

Myotonic Dystrophies

General Characteristics

1. Myotonic dystrophy is an autosomal dominant muscle disorder caused by a heterozygous trinucleotide repeat expansion (CTG) in the 3-prime untranslated region of the dys-

trophic myotonic protein gene DMPK that maps to chromosome 19q13.32

2. This is a toxic RNA gain of function disease
3. The mutant RNAs that contain the expanded DUGG repeats aggregate in discrete inclusions and are retained in the nucleus. The sequestering of splicing factors of the MBN2 family triggers upregulation of the CUGBP family of proteins. This results in the mis-splicing of their target transcripts from various genes that include those that encode:
 - a. The chloride channel
 - b. Insulin receptor
 - c. Cardiac troponin
 - d. Ryanodine receptor
 - e. Sarcoplasmic/endoplasmic reticulum Ca²⁺ ATPase
4. There is abnormal translation of the mis-spliced RNAs into functional proteins which explains the organ specific systemic manifestations of the disease
5. DM1 has an approximate incidence of 13.5 per 100,000 live births and a prevalence of 3–5 per 100,000 of the population

Clinical Manifestations

1. Onset is variable but may be seen in infancy
2. Limb weakness is distal early in the illness but progresses to involve proximal muscles
3. The course is slowly progressive
4. The neck flexors are weak and atrophy is early
5. Severe atrophy and weakness of facial and jaw muscles leads to the dysmorphic “hatchet face” physiognomy
6. There may be involvement of pharyngeal and lingual musculature that cause dysarthria and dysphagia
7. Myotonia is evident in affected muscles which does not appear to be symptomatic in many patients
8. Myotonia decreases with repeat muscle contraction (“warm-up” sign)
9. Delayed relaxation occurs following percussion of affected muscles (percussion myotonia)
10. Decreased muscle stretch reflexes
11. Normal sensation
12. Congenital disease is associated with severe cognitive dysfunction; adults may have mild cognitive deficits
13. Congenital Myotonic Dystrophy
 - a. Much more severe phenotype than is seen with adult DM1
 - b. Affected infants are born to mothers with myotonic dystrophy
 - c. Pregnancy can be associated with polyhydramnios with decreased fetal movement
 - d. Severe weakness and hypotonia at birth
 - e. Arthrogryposis
 - f. Inducible myotonia is not present at birth but is apparent by five years of age
 - g. Ventilatory assistance is required in a subset of infants
 - h. Severe cognitive deficits affect 75% of surviving children

14. Systemic medical complications:

- a. Decreased gastrointestinal mobility which may cause chronic pseudo-obstruction
- b. Alveolar hypoventilation can occur from weakness of both the diaphragm and intercostal muscles
- c. Sleep apnea
- d. Pulmonary hypertension
- e. Cardiac abnormalities
- f. Conduction defects in the EKG are seen in 70% of patients
- g. Sudden death from arrhythmia correlates with age, male gender and duration of disease
- h. Cognitive impairment and neurobehavioral abnormalities occur in a significant portion of patients
- i. Posterior subcapsular ("stellate") cataracts
- j. Frontal balding
- k. Testicular atrophy
- l. Hyperinsulinemia and glucose intolerance

Neuropathology

1. Muscle biopsy:
 - a. Increased central nuclei
 - b. Type I fiber predominance and atrophy
 - c. Hypertrophic type II fibers
 - d. Ring fibers
 - e. Atrophic fibers with pyknotic nuclear clumps (small angulated fibers)
 - f. Sarcoplasmic masses
2. CNS:
 - a. Neurofibrillary degeneration with abnormal tau-expression

Laboratory Evaluation

1. Mildly elevated or normal CK
2. EMG:
 - a. Myotonic discharges
 - b. Positive sharp waves and fibrillation potentials
 - c. Myopathic MUAPs
3. Muscle MRI (T1-weighted sequences)
 - a. High intensity signals in:
 - i. Flexor digitorum profundus
 - ii. Flexor pollicis longus
 - iii. Abductor pollicis longus
 - iv. Extensor pollicis muscles
 - v. Long standing patients show muscle involvement of proximal muscles

Myotonic Dystrophy Type 2 (DM2)*General Characteristics*

1. DM2 is a multisystem autosomal dominant disease caused by heterozygous expansion of a CCTG repeat in intron 1 of the zinc finger protein-9 gene that maps to chromosome 3q21.3
2. Normal alleles contain up to 30 repeats; mutated alleles have from 75–11,000 repeats

3. Myotonic dystrophy-2 and proximal myotonic dystrophy (PROMM) are now classified as DM2
4. The expanded CCTG transcribed mRNA repeats aggregate as focal collections in the nucleus similar to the CTG repeat found in DM1
5. The aggregates of mutated mRNA sequester RNA-binding proteins that cause abnormal splicing of pre-mRNA from target genes, such as those that encode the chloride channel, insulin receptor, tau, and cardiac tropomyosin. The abnormal translation of these RNAs into proteins in the affected tissues cause the disorder

Clinical Manifestations

1. The onset is between 20–60 years of age but may be seen in childhood
2. Usually presentation is intermittent stiffness and pain in thigh muscles which may be asymmetric
3. Myotonia affects facial and extremity muscles but may be variable and is not always evident
4. Myotonia may be precipitated or worsen during pregnancy
5. The "warm up" phenomenon occurs with continual muscle contraction
6. They myotonia is not exacerbated by cold; some patients demonstrate increased myotonia with heat
7. Patients have episodic pain that is burning and lancinating in the thighs, shoulders, upper arms and chest
8. Most patients have slowly progressive proximal and distal muscle weakness which involves:
 - a. The neck flexors
 - b. Elbow extensors
 - c. Thumb and deep finger flexors
 - d. Hip flexors
 - e. Leg extensors
9. The weakness may fluctuate and periods of exacerbation may last from hours to weeks which improves with exercise
10. Approximately 100% of patients develop muscle atrophy of proximal muscles later in life
11. Calf hypertrophy may occur and may be asymmetric
12. Myoglobinuria has been described
13. Anticipation occurs
14. There is no congenital form of the disease
15. Medical complications:
 - a. Myoglobinuria that usually develops prior to age 50 but has been seen in late childhood
 - b. Cardiac manifestations include
 - i. Syncope
 - ii. Symptomatic tachycardia (8%)
 - iii. Conduction defects (20%)
 - iv. Cardiomyopathy (7%)
16. Sleep apnea
17. Cognitive deficits are not prominent (in contrast to DM1) although there is a subset of patients who demonstrate defects in executive function

18. Variable features:
 - a. Stroke-like episodes
 - b. Seizures
 - c. Hypersomnia
 - d. Parkinsonism
19. Frontal baldness occurs in 20–50% of patients
20. Testicular atrophy with testicular insufficiency
21. No gastrointestinal dysmotility
22. Rare late onset deafness (one kinship with atypical DM2)

Neuropathology

1. Muscle biopsy:
 - a. Mild to moderate central nuclei
 - b. Variable fiber size
 - c. Type 2 fiber atrophy with pyknotic nuclear clumps
 - d. In contrast to DM1 minimal or absent sarcoplasmic masses, type 1 fiber atrophy and ringed fibers
2. CNS:
 - a. Neurofibrillary tangles and abnormal tau expression as seen in DM1

Laboratory Evaluation

1. Serum CK may be minimally elevated
2. Low testosterone levels occur in 30% of male patients
3. Insulin resistance occurs in 75% of patients
4. Low IgG is seen in approximately 65% of patients; low IgM in 11%
5. EMG:
 - a. Myotonic discharges which may be seen more prominently in distal rather than proximal muscles
 - b. NCS are normal
6. EKG:
7. MRI (brain):
 - a. White matter abnormalities
8. Single photon emission computed tomography:
 - a. Frontal and parietal-occipital hypoperfusion

Differential Diagnosis of Myotonic Disorders

1. Myotonic dystrophy type 1
2. Myotonic dystrophy type 2
3. Myotonia congenita
4. Paramyotonia congenita
5. Hyperkalemic periodic paralysis
6. Chondrodystrophic myotonia
7. Drug-induced:
 - a. Statins and fibrates
 - b. Cyclosporine
 - c. Chloroquine

Muscle Channelopathies, Non-Dystrophic Myotonias and Periodic Paralysis

Overview

The muscle channelopathies are caused by mutations in muscle ion channels that cause an increase or decrease in mem-

brane excitability which lead to a spectrum of clinical phenotypes. The non-dystrophic myotonias cause delayed relaxation after muscle contraction that causes stiffness and pain. The periodic paralyses are characterized by various degrees of flaccid paralysis. Non-dystrophic myotonic syndromes are heterogeneous and can be separated into those in which gene mutations cause defects in chloride or sodium channel proteins of the sarcolemma membrane.

Mutations in the chloride channel cause myotonia congenita and can have autosomal dominant or recessive inheritance. The sodium channelopathies include:

1. Hyperkalemic periodic paralysis (HyperKPP; potassium sensitive)
2. Paramyotonia congenita (PMC)
3. Potassium aggravated myotonias that include:
 - a. Myotonia fluctuans
 - b. Myotonia permanens
 - c. Acetazolamide-responsive myotonia
4. Familial hypokalemic periodic paralysis type 2 (HypoKPP2)

Hypokalemic periodic paralysis type 1 (HypoKPP1) is not associated with either clinical or electrical myotonia and is caused by mutations in the dihydropyridine receptor, a calcium channel of the endoplasmic reticulum. The mechanism by which hypokalemic periodic paralysis leads to a depolarized but unexcitable sarcolemma membrane, is a novel gating pore current. Thyrotoxic hypokalemic periodic paralysis has recently been shown to be determined by mutations in a gene that encodes an inwardly rectifying potassium channel Kir2.6. Recent work has also shown that 90% of the known mutations that cause hypokalemic periodic paralysis (HypoKPP) are due to loss of positively charged enzyme residues in the S4 segments of either the SCN4A or CACN15 that carries a gating current.

The Andersen-Tawil syndrome is a hereditary periodic paralysis in which some forms are caused by mutations in a potassium channel.

The EMG in association with both the short and long exercise tests is pivotal in distinguishing the muscle channelopathies. The short exercise test requires the patient to isometrically contract a muscle for 10 seconds, which is followed by measurement of the compound muscle action potential amplitude immediately after the exercise, and then at ten second intervals for 50 seconds (five measurements). The test is first done at room temperature and then with cooling of the tested muscle. In a normal subject, the CMAP may increase 6–14% and then return to baseline levels within 10 seconds. If performed after cooling of the tested muscle, the CMAP amplitude decreases approximately 25% but its duration increases 140%. Changes in CMAP amplitude with the short exercise test distinguish the muscle channelopathies by categorizing them into one of five patterns.

Contract a muscle for five minutes (3–4 seconds of rest are allowed every 30–45 seconds). The CMAP amplitudes

are measured every minute during exercise, immediately after its completion and then every minute for five minutes. Measurements are recorded every five minutes for the next 40–45 minutes.

Normally the CMAP amplitudes only decrease after the period of exercise to a slight degree (mean of 6%) while amplitudes return to normal within 30–60 seconds and do not change over the next 45 minutes. Five patterns of change in CMAP amplitudes have been determined with the short exercise test. These are helpful in distinguishing the muscle channelopathies. Patterns I–III are altered in the non-dystrophic myotonias and patterns IV and V, in association with the long exercise test, distinguish the periodic paralyses.

Chloride Channelopathies

Myotonia Congenita

General Characteristics

1. The CLC-1 chloride channel belongs to the CLC channel/transporter family
2. Mutations in the chloride gene (CLCN-1) which maps to chromosome 7q85 is responsible for Thomsen disease (autosomal dominant) and Becker disease (autosomal recessive) form of myotonia congenita
3. The CLCN-1 gene encodes the chloride channel that is primarily expressed in skeletal muscle
4. The CLC-1 channel is a dimer of two homologous subunits, each forming a chloride ion conducting pore that allows CLC-1 to function as a “double barrel” channel
5. Channel opening in CLC-1 is regulated by two distinct gating patterns:
 - a. The slow gate opens and closes the two subunits simultaneously
 - b. The fast gate regulates the function of independent pores
6. The neurilemma of skeletal fibers at rest has a high chloride conductance. This large inhibitory chloride conductance balances the excitatory depolarizing currents. After the action potential is triggered, repolarization starts with sodium channel fast inactivation and is completed by potassium efflux affected by delayed rectifier potassium channels (the cell is more negative by loss of the K^+ ion). Potassium accumulation in the T-system is responsible for the transient after-depolarization following muscle contractions. The high resting chloride conductance prevents propagation of the depolarization along the neurilemmal membrane
7. In myotonic muscle fibers:
 - a. The chloride conductance is reduced by more than 50%
 - b. The potassium accumulation triggers autonomous muscle fiber action potentials that produce prolonged electrical activity exhibited by myotonia after discharges

Clinical Manifestations

1. In Thomsen disease (AD) the onset of disease is during the first few years of life
2. Infants may have difficulty opening their eyes after crying and stiffness of leg muscles may lead to falls
 - a. Stiffness of arm muscles occurs with age
 - b. Muscles of mastication and swallowing may be involved
 - c. Affected muscles often demonstrate the “warm up” phenomenon and have less myotonia with repeated contraction
 - d. Myotonia is exacerbated by cold and pregnancy
 - e. The severity of the myotonia fluctuates and may be variable in severity among affected family members
 - f. There are no systemic features or increased mortality
 - g. Patients with late onset disease may present with proximal weakness and muscle stiffness
 - h. There is an increased risk of malignant hyperthermia with inhalational anesthetics
 - i. Neurological examination:
 - i. Hypertrophy of muscles
 - ii. Muscle strength is usually normal but there may be slight proximal weakness in some patients
 - iii. There is delayed relaxation of contracted muscles (action myotonia)
 - iv. There is percussion myotonia

Becker Autosomal Recessive Myotonia Congenita

Clinical Manifestations

1. Onset is between 4 and 12 years of age
2. The severity of weakness is worse
3. Transient weakness of the distal arm and other musculature can occur after a severe episode of myotonia
4. There is mild proximal weakness of the extremities and neck flexor musculature
5. There are no systemic manifestations

Neuropathology

1. The CLCN1 mutations include small deletions, insertions, frameshifts, stop codons and splice sites
2. CLCN1 exon deletions or duplications from a single recessive mutation can cause recessive myotonia congenita

Laboratory Evaluation

1. Serum CK is normal or only minimally elevated
2. EMG:
 - a. Motor and sensory conduction velocities are normal
 - b. Repetitive nerve stimulation demonstrates a decremental response after a train of stimuli at 10 Hz. In this subset of patients, there may be a significant decrease of CMAP amplitude with higher rates of stimulation
3. The short exercise test:

- a. PEMP (post-exercise myotonic potentials in motor conduction studies) may or may not be present
- b. In the AR form: CMAP amplitudes are decreased after the last trial which does not occur in the AD form. The reduction in amplitudes decreases after the second and third trials
- c. In autosomal recessive MC, there is no change with cold
- d. There is a reduction in amplitudes after the first trial in autosomal recessive MC that improves after several trials
- 4. Long exercise test:
 - a. There is a slight decrease or no change in CMAP amplitudes immediately after exercise or up to 45 minutes
- 5. Needle EMG:
 - a. Myotonic discharges occur at rest and with voluntary muscle contraction
 - b. There is no exacerbation with cold
 - c. Morphology and recruitment of MUAPs is normal
 - d. Weak muscles may demonstrate short duration and small MUAPs
- b. Increased potassium intake
- c. Fasting
- d. Stress
- 8. Weakness is usually mild but can be severe after prolonged vigorous exercise
- 9. Paresthesias and dysesthesias may occur in muscles prior to weakness
- 10. Thigh and calf muscles may be initially affected prior to spread to other muscles
- 11. Weakness can be focal
- 12. Rarely generalized flaccid weakness occurs which is in contrast to hypokalemic periodic paralysis
- 13. Bulbar and respiratory musculature is rarely involved
- 14. The sphincters are not involved
- 15. The duration of weakness is most often less than 1 hour but residual weakness may persist for a few days (unusual)
- 16. The frequency of attacks is highly variable but may occur several times a day
- 17. The occurrence of paretic attacks decreases with age
- 18. Mild exercise after strenuous exercise may prevent weakness (walking after running)
- 19. Pain may occur in affected muscles after an episode of weakness
- 20. Reflexes are usually decreased or lost during attacks; sensation is normal
- 21. Eyelid myotonia may be the only physical sign between attacks although some patients develop slowly progressive mild proximal weakness

Sodium Channelopathies

Hyperkalemic Periodic Paralysis

General Characteristics

- 1. Hyperkalemic periodic paralysis or potassium sensitive periodic paralysis is inherited as an autosomal dominant disease with high penetrance that maps to chromosome 17q23.3
- 2. Allelic disorders that have overlapping phenotypic features are:
 - a. Paramyotonia congenita
 - b. The potassium aggravated myotonias
- 3. The mutations occur in the subunit of the voltage-dependent sodium channel gene (SCN4A)

Clinical Manifestations

- 1. The disease has three manifestations:
 - a. Weakness without myotonia
 - b. Myotonia (clinical) that can be demonstrated by electrodiagnostic testing
 - c. Associated with paramyotonia congenita
- 2. Attacks of weakness are similar in all forms except that paramyotonia is exacerbated by cold
- 3. Clinical myotonia is generally mild and can be elicited in the face and extremities by percussion or activity
- 4. Myotonia improves with repeat muscle contraction except with paramyotonia in which it is exacerbated along with muscle stiffness
- 5. Onset is usually during the first decade
- 6. Attacks often occur in the morning
- 7. Precipitating factors include:
 - a. Rest following exercise

Neuropathology

- 1. Muscle biopsy:
 - a. Vacuoles may be present

Laboratory Evaluation

- 1. Serum CK may be minimally increased
- 2. Between attacks serum potassium concentrations are usually normal
- 3. During attacks:
 - a. Precipitated by potassium concentration is usually 5–6 mEq/L; occasionally attacks occur with normal potassium serum levels
 - b. Sodium levels may be decreased during attacks of weakness
- 4. EKG:
 - a. Increased precordial T wave amplitude
- 5. Secondary causes of hyperkalemia usually have a serum concentration that is greater than 7 mEq/L, have no family history, and demonstrate no clinical electrical myotonia
- 6. EMG:
 - a. Motor and sensory nerve conduction studies are normal between and during attacks of weakness
 - b. CMAP amplitude may be decreased during attacks
 - c. Short exercise test:
 - i. No PEMP

- ii. There is an increase in CMAPs after the first trial with further increases after the second and third trials
- d. Long exercise test:
 - i. There is a transient increase in CMAP amplitude immediately after exercise
 - ii. Gradual decrease in amplitude over the next 40 minutes
 - iii. Ten seconds of exercise during the paretic phase may increment the CMAP amplitudes
- e. Needle EMG:
 - i. Myotonic discharges occur in 50–75% of patients although clinical myotonia may only occur in 20%
 - ii. Affected muscles in patients with myotonia demonstrate between attacks:
 - 1. Increased insertional activity with positive sharp waves and fibrillation potentials
 - 2. Spontaneous myotonic discharges that may be increased by lowering the limb temperature
 - 3. A slight increase in small amplitude, brief duration polyphasic potentials
 - 4. In plegic muscles during attacks MUAPs decrease in amplitude and duration and may disappear

Paramyotonia Congenita (PMC)

General Characteristics

1. PMC is an autosomal dominant disease with high penetrance caused by mutations of the voltage-gated sodium channel alpha-subunit gene SCN4A that maps to chromosome 17q23.3
2. It is an allelic disorder with hyperkalemic periodic paralysis and the potassium-aggravated myotonias

Clinical Manifestations

1. Onset is within the first decade of life
2. Infants may have difficulty opening their eyes after crying due to myotonia of the orbicularis oculi
3. Cold induced muscle weakness can last for hours and may not reverse even when the extremity is warmed
4. Weakness can be induced by a potassium load
5. Patients may complain of muscle pain that is not as severe as that which occurs with DM2/PROMM
6. Paramyotonia of the eyelids is prominent in most patients
7. Exercise exacerbates muscle stiffness and myotonia
8. There is minimal percussion myotonia
9. Proximal and distal weakness may develop with time

Neuropathology

1. PMC is caused by mutations in the SCN4A gene. Patients may or may not demonstrate myotonia
2. Muscle biopsy:
 - a. Mild fiber size variation with a mixture of normal, atrophic, and hypertrophic fibers

- b. In patients with associated periodic paralysis, there may be intracytoplasmic vacuoles
- c. Electron microscopy:
 - i. Myofibrillar disorganization
 - ii. Tubular aggregates

Laboratory Evaluation

1. Serum CK levels are mildly to moderately elevated
2. Serum potassium may be elevated during an attack with paralysis
3. EMG:
 - a. Normal motor and sensory conduction velocities between attacks
 - b. Repetitive stimulation at greater than 5 Hz may induce a decremental CMAP in a subset of patients
4. Short exercise test:
 - a. PEMP are noted
 - b. CMAP amplitudes may be amplified or decrease with the first trial and decrease after the second or third trial
 - c. Amplitude reduction of CMAPs is exacerbated by cold
5. Long exercise test:
 - a. Decrease in CMAP amplitudes during and following exercise that may persist for hours
6. Needle EMG:
 - a. Normal MUAPs
 - b. Patients with associated periodic paralysis, cooling may induce fibrillation potentials and decreased MUAP production
 - c. In flaccid paralyzed muscles myotonic discharges cease and there may be complete electrical silence
 - d. In pure PMC (without periodic paralysis), local cooling exacerbates myotonic discharges in the face of normal recruitment and morphology of MUAPs
7. Single fiber EMG:
 - a. Slight increase in jitter and fiber density

Potassium Aggravated Myotonias

Myotonia Fluctuans

General Characteristics

1. Myotonia fluctuans is caused by mutations in the SCN4A gene that map to chromosome 17q23.3

Clinical Manifestations

1. Onset is usually in early childhood
2. Fluctuating myotonia that is variable in severity
3. Myotonia may be increased following exercise (delayed onset of minutes)
4. Paramyotonia affects the eyelids
5. The “warm-up” phenomenon for the myotonia occurs in the extremities
6. There are no episodes of weakness following cold, an increased potassium load or exercise
7. There is increased myotonia with a potassium load but not cold

8. The fluctuating myotonia distinguishes this entity from PMC, myotonia congenita and the patients with myotonia that have hyperKPP
9. The severity of myotonia has a wide spectrum from minimal stiffness to that which affects extraocular muscles, bulbar musculature, and the extremities
10. Exercise induces myotonia that may be delayed in onset and is not exacerbated by cold

Neuropathology

1. Muscle biopsy:
 - a. Fiber size variation
 - b. Central nuclei
 - c. May be normal
 - d. Electron microscopy:
 - i. Vacuoles may be demonstrated in some fibers

Laboratory Evaluation

1. Serum CK is minimally evaluated
2. Short exercise test:
 - a. Mildly decreased amplitude of CMAP that improves with repetitive activity
 - b. No PEMP
3. Long exercise test:
 - a. No change

Myotonia Permanens

General Characteristics

1. Myotonia permanens is caused by the G1306A mutation of the SCN4A gene that maps to 17q23.3

Clinical Manifestation

1. The myotonia causes constant muscle stiffness
2. Aggravated by a potassium load
3. Is exacerbated by activity
4. Respiratory muscle involvement
5. No episodic weakness nor increase of myotonia with cold

Neuropathology

1. The mutation may cause a positive shift in voltage dependence
2. "Leaky" closed sodium channels

Laboratory Evaluation

1. Normal or slightly elevated CK levels
2. Short exercise test:
 - a. No PEMP
3. Long exercise test:
 - a. No change

Acetazolamide-Responsive Myotonia

General Characteristics

1. Acetazolamide-responsive myotonia is caused by mutations in the SCN4A gene that map to chromosome 17q13.1-13.3

Clinical Manifestations

1. Onset in childhood with painful muscle stiffness that worsens in early adulthood
2. Myotonia is most severe in the face and hands
3. The myotonia is exacerbated by a potassium load, fasting and mildly by exercise
4. Muscle pain may be benefited by high carbohydrate meals
5. Patients demonstrate action and percussion myotonia
6. There is normal strength
7. Paradoxical myotonia occurs in the eyelids

Neuropathology

1. Muscle biopsy:
 - a. Normal in many patients
 - b. Generalized muscle fiber hypertrophy

Laboratory Evaluation

1. Mildly elevated CK level
2. Short exercise test:
 - a. No PEMP
 - b. Mild decrease in CMAP amplitude that improves with repetitive muscle contraction
3. Long exercise test:
 - a. No change

Familial Hypokalemic Periodic Paralysis Type 2

General Characteristics

1. A subset of patients with familial hypokalemic periodic paralysis (hypoKPP) have mutations in the SCN4A gene that maps to chromosome 17q13.1-13.3
2. The mutations are clustered in the second repeat (D2S4). This region is the voltage sensor that decreases sarcolemmal membrane excitability by enhancing inactivation of sodium channels

Clinical Manifestations

1. The age of onset is approximately 16 years
2. The duration of attacks may be shorter, approximately 1 hour
3. HypoKPP2 patients do not develop fixed proximal muscle weakness
4. Acetazolamide may exacerbate weakness
5. Attacks otherwise are similar to those of hypokalemic PP1

Neuropathology

1. Muscle fibers may demonstrate tubular aggregates rather than non-rimmed vacuoles which are seen with Hypokalemic PP Type 1
2. Recent expression studies have demonstrated anomalous hyperpolarization-activated gating pore currents in mutant channels. This gating pore conductance causes a small inward current at the resting membrane potential that contributes to susceptibility to depolarization in the presence of low K^+ concentration during attacks of weakness

Laboratory Evaluation

1. Serum potassium decreases during attacks of paralysis
2. CK may be normal or slightly elevated
3. Short exercise test:
 - a. No PEMPs
 - b. No change
4. Long exercise test:
 - a. Slight increase of CMAP amplitude may occur during and immediately following exercise which after 10–20 minutes decreases. The decay is less than that which occurs with hyperKPP
5. EMG:
 - a. The EMG is normal between attacks
 - b. There are no myotonic discharges
6. EKG:
 - a. May not demonstrate the usual changes expected with very low serum potassium concentrations in some instances

Primary Hypokalemic Periodic Paralysis Type 1 (HypoKPP1)
General Characteristics

1. Most patients with familiar hypokalemic periodic paralysis have mutations in the α -subunit of the skeletal muscle L-type channel gene that maps to chromosome 1q31-32.5
2. The mutations occur in the arginine residues of the voltage-sensing segments of the calcium channel
3. Hypokalemic periodic paralysis may also be caused by mutations in:
 - a. KCNE3 gene
 - b. SCN4A gene
 - c. Mutations that affect the thiazide sensitive sodium chloride cotransporter (Gitelman syndrome)
4. Calcium channel (Cav1.1 structure):
 - a. The Cav1.1 has five subunits ($\alpha 1$, $\alpha 2$, β , δ and μ)
 - b. The $\alpha 1$ -subunit has four domains which contain six transmembrane segments and the dihydropyridine receptor
 - c. The dihydropyridine receptor is a calcium ion channel for the T-tubular but is also a voltage sensor for excitation-contraction coupling
 - d. The remaining subunits of the calcium channel regulate the $\alpha 1$ -subunit
 - e. The S4 segment of the $\alpha 1$ -subunit is the voltage sensor for the channel and the site of most mutations that occur in hypoKPP1
 - f. The voltage-gated Ca^{2+} channels couple membrane depolarization to Ca^{2+} -dependent intracellular physiologic signaling. The mechanism is by mediating Ca^{2+} ion influx or by direct conformational coupling to intracellular Ca^{2+} release channels
- g. Mechanisms:
 - i. Muscle fibers are depolarized and inexcitable during an attack of paralysis. Possible mechanisms include:

1. Loss of function due to defect that causes reduced ionic current density
2. Reduction in ATP-sensitive K current
3. Reduced calcium influx through the T-tubule system may impair excitation-contraction coupling
4. Myotube electrophysiologic recordings that express mutant calcium channels show a decreased calcium current density and a negative shift in the steady state inactivation current
5. The kinetics of the sodium channel are affected by CACN1A mutations
6. Sodium conduction is increased which leads to depolarization of the resting membrane potential from -80 mV to -50 mV which is a partially depolarized state. Thus there would not be sufficient repolarized sodium channels to conduct an action potential

Clinical Manifestations

1. HypoKPP1 is the most frequent periodic paralysis with a prevalence of 1/100,000 of the population
2. Male to female ratio of 3–4:1
3. It is autosomal dominant but with reduced penetrance in women
4. The onset of episodic weakness with paralysis occurs within the first two decades of life
5. Precipitating causes include:
 - a. Intense physical exercise followed by rest, sleep or a high carbohydrate or sodium meal (pizza and ice cream)
 - b. Emotional stress
 - c. Menstruation
 - d. Viral illness
 - e. Beta-agonists, steroids and insulin
6. Most attacks occur in the morning often upon awakening. They may occur at any time during the day
7. The severity of attacks are variable and range from minimal weakness to complete flaccid paralysis
8. There is no myotonia or paramyotonia as opposed to PMC and hyperKPP
9. Most often facial and respiratory muscles and sphincters are spared. Some patients feel as if their bladder is full and that their muscles are swollen
10. Rare instances of respiratory muscle involvement and cardiac arrhythmias have been reported
11. Absent muscle stretch reflexes
12. Severe muscle weakness can last for hours to days. The muscles that are first affected are the last to recover
13. Attacks can occur several times a week to less than once per year. Attacks may start to diminish when the patient reaches 30 and some patients have had a remission in their forties and fifties
14. Fixed proximal muscle weakness occurs more severely in the legs than the arms

15. A prodrome for an oncoming attack is a sensation of heaviness in or pain in the back and swelling in the thighs and calves that spreads to proximal arm muscles. Low grade exercise during the prodrome may ward off or lessen the degree of weakness

Neuropathology

1. Muscle biopsy:
 - a. Intracellular vacuoles (often in the center of muscle fibers), dilatation of the sarcoplasmic reticulum, and tubular aggregates
 - b. Vacuoles are more common in the hyperkalemic periodic paralysis 1, while tubular aggregates are seen with hypokalemic periodic paralysis 2
 - c. Fiber size variability, split fibers, both hypertrophic and atrophic fibers are seen. Rarely necrotic and degenerating fibers occur

Laboratory Evaluation

1. The serum potassium levels are below 3.0 mEq/L and rarely fall below 2 mEq/L
2. The EKG usually demonstrates:
 - a. Bradycardia
 - b. Flattened T-waves
 - c. Prolonged PR and QT intervals
 - d. The EKG may not reflect the degree of hypokalemia
3. CK is mildly to moderately elevated between paralytic attacks and rises during attacks
4. EMG:
 - a. Motor and sensory nerve conduction velocities are normal between attacks of weakness
 - b. During a paralytic attack:
 - i. CMAP amplitudes are decreased
 - ii. Repetitive stimulation may prevent the decrease of CMAP to a degree (simulating the prevention of attacks by exercise in the prodromal period)
 - c. Short exercise test:
 - i. No PEMP
 - ii. No change
 - d. Long exercise test:
 - i. A slight increase in CMAP amplitude occurs during and immediately after exercise that is followed by a delayed decrease in CMAP after 10–20 minutes

Secondary Hypokalemic Periodic Paralysis

General Characteristics

1. Secondary hypoKPP may occur with severe potassium loss from either kidney or gastrointestinal disease, an acid base disturbance that causes a shift of K^+ into cells or may be stimulated by drugs or endogenous hormones

Clinical Manifestations

1. Attacks of generalized weakness without extraocular, respiratory or bulbar involvement

2. Residual weakness may last for days (usually proximal musculature)
3. May be associated with cardiac arrhythmias
4. Renal tubular acidosis may be associated with seizures due to calcium loss
5. Emesis gravidarum with prolonged vomiting (may also be associated with Wernicke disease)
6. Bartter's and Gitelman disease may be associated

Neuropathology

1. Necrotizing myopathy

Laboratory Evaluation

1. Dependent on the underlying condition

Thyrotoxic Periodic Paralysis

General Characteristics

1. Recent evidence demonstrates that the loss of function mutations of skeletal muscle-specific inward rectifying K^+ (Kir) channels (Kir2.6) cause thyrotoxic periodic paralysis
2. The reduced outward K^+ efflux from skeletal muscle due to potassium channel mutations or inhibition of the channels by adrenalin or insulin leads to paradoxical depolarization. This inactivates Na^+ channels, which in turn causes unexcitability of the muscle and paralysis

Clinical Manifestations

1. The disease is most seen in Asian patients, primarily in males
2. The paralysis only occurs with associated hyperthyroidism
3. Attacks can occur at any time but are most frequently seen in the morning (attacks occur at night)
4. Flaccid, areflexic paralysis that may be generalized or can affect the legs primarily
5. During attacks the serum K^+ is depleted. A full recovery usually occurs with replenishment of potassium. The disease responds to treatment of the hyperthyroidism
6. Patients have the clinical signs of variable degrees of hyperthyroidism
7. Attacks may be prolonged without treatment (1–2 days)
8. Attacks may be precipitated after carbohydrate meals and post-exercise rest as well as with alcohol

Neuropathology

1. Skeletal muscle is the largest single pool of total body K^+ and plays a major role in K^+ homeostasis
2. Na^+-K^+ ATPase and inward rectifying K (Kir) and delayed rectifying K^+ channels are the major mechanism for the influx and efflux of K^+ across the muscle membrane
3. Thyroid hormone also stimulates the Na^+-K^+ ATPase pump by acting on the thyroid hormone responsive elements that upregulate the transcription of the gene coding Na^+-K^+ ATPase and enhance its membrane insertion through non-genomic mechanisms

4. Thyroid hormone also enhances the stimulation of the pump by β_2 -adrenergic agonists by amplifying intracellular cAMP activity
5. Hyperinsulinism also occurs in acute attacks of thyrotoxic periodic paralysis. It may induce intracellular K^+ shifts by stimulating Na^+-K^+ pump activity or enhancing the pump's membrane insertion
6. Present evidence supports the mutations in the gene encoding Kv2.6 as the major cause of thyrotoxic periodic paralysis. In familial hypoKPP mutations in the voltage sensor of Nav1.4 and Cav1.1 channels cause an aberrant gating pore current and an imbalance between an inward leak current and an outward current. In thyrotoxic periodic paralysis, the loss of function for the Kv2.6 (decreased K^+ efflux) causes an imbalance between inward leak current and outward K^+ current that causes paradoxical depolarization
 - d. Palpitations
 - e. Syncope
 - f. Cardiac arrest
9. Developmental anomalies include:
 - a. Clinodactyly
 - b. Hypertelorism
 - c. Mandibular hypoplasia
 - d. Syndactyly
 - e. Scoliosis
10. Dysmorphisms
 - a. Low set ears
 - b. Short stature
 - c. Broad nose and forehead
 - d. Cleft and high arched palate
 - e. Vaginal atresia
 - f. Bradydactyly
 - g. Cardiac valve lesions
 - h. Hypoplastic kidneys
 - i. Cognitive deficits

Laboratory Evaluation

1. Most patients have a significant decrease in serum K^+ concentration but there are examples of thyroid periodic paralysis (TPP) with normal and even increased potassium levels
2. EMG:
 - a. Similar to familial hypoKPP

Andersen-Tawil Syndrome (ATS)

General Characteristics

1. Two-thirds of patients with the ATS syndrome have heterozygous mutations in the KCNJ2 gene that maps to chromosome 17q24. There is marked intrafamilial variability and incomplete penetrance of this autosomal dominant disease
2. The gene encodes an inwardly rectifying potassium channel (Kv2.1) that is expressed in heart, skeletal muscle and the brain
3. The disease is characterized by periodic paralysis, cardiac arrhythmias, and skeletal dysmorphisms

Clinical Manifestations

1. Approximately 60% of patients manifest the entire triad
2. De novo inheritance occurs although this is primarily an autosomal dominantly inherited disease
3. Onset is during the first or second decade of life
4. The attacks consist of episodic weakness that can be spontaneous or are triggered by rest after exercise
5. The attacks vary from hours to days in duration. They may occur only once in a lifetime to daily
6. Proximal weakness of extremities may occur over time
7. There is no myotonia or paramyotonia
8. Cardiac manifestations include:
 - a. Bidirectional ventricular tachycardia
 - b. Polymorphic ventricular tachycardia
 - c. Torsades de Pointes

Neuropathology

1. Muscle biopsy:
 - a. Tubular aggregates
2. The Kv2.1 mutation causes alterations of muscle membrane depolarization and repolarization by failing to stabilize resting membrane potential
3. Sustained depolarization is accompanied by Na^+ channel activation with loss of action potential induction
4. In the heart muscle, it causes delayed after-depolarization in the terminal phase of repolarization

Laboratory Evaluation

1. Serum CK is usually normal but may be minimally elevated
2. Potassium levels are often decreased during attacks but may be normal or even elevated
3. EKG:
 - a. Prolonged QT interval occurs in 80% of patients
 - b. Ventricular tachyarrhythmias
4. EMG:
 - a. Motor and sensory nerve conduction velocities are normal

KCNE3 Channelopathy

General Characteristics

1. Mutations in the KCNE3 gene that maps to chromosome 11q13.4-q14 may cause attacks of episodic weakness
2. A missense mutation in the KCNE3 potassium channel gene is associated with susceptibility to thyrotoxic hypokalemic periodic paralysis
3. The subthreshold voltage-gated potassium channel of skeletal muscle contains MinK-related peptide 2 (MiRP2) and the pore-forming subunit Kv3

Clinical Manifestations

1. Age at onset: early childhood
2. Attacks occur during sleep and last for approximately 12 hours
3. One patient suffered weakness of the lower extremities that lasted for hours to days; precipitated by strenuous exercise that was followed by rest or prolonged sitting
4. Attacks in 1 patient occurred during wakefulness
5. G-to-A transition in the KCNE3 gene has been identified in a Danish family with the Brugada syndrome
6. Possible association with the long QT syndrome

Neuropathology

1. KCNE3 protein forms a complex with the pore-forming unit Kv3.4. The resulting potassium channel has increased conductance, faster inactivation recovery, and slower cumulative inactivation. The channels are active at -40 mV and are important in maintaining the muscle membrane potential

Laboratory Evaluation

1. Patients have low potassium levels during attacks
2. EKG:
 - a. Possible association with the long QT syndrome

Additional Calcium Channelopathies***Malignant Hyperthermia****General Characteristics*

1. Malignant hyperthermia is usually triggered by exposure to volatile anesthetics or succinylcholine
2. Susceptibility is usually inherited in an autosomal dominant pattern
3. The most frequent gene involved encodes the ryanodine receptor (RYR1) that maps to chromosome 19q13.1. Mutations in this gene also cause central core disease
4. Only a small number of patients with malignant hyperthermia (MH) carry this gene mutation
5. Malignant hyperthermia syndrome 2 [MHS2] maps to chromosome 17q11.2-24 and is allelic to 1. hyperKPP, 2. PMC, and 3. PAM
6. MHS3 has been mapped to chromosome 7q24-7q22
7. MHS4 maps to chromosome 3q13.1
8. MHS5 is caused by mutations in the dihydropteridine receptor gene that maps to chromosome 1q31 which is allelic to HyKPP
9. MHS6 maps to chromosome 5P
10. Patients with dystrophinopathies are susceptible to MH

Clinical Manifestations

1. The incidence of MH in patients that have been exposed to inhalation anesthetics varies from .5–.0005%
2. Approximately 50% of patients had previous anesthesia without incident

3. Attacks usually begin during surgery but they have been documented post-operatively
4. During an attack:
 - a. The earliest sign often includes masseter muscle contracture after the administration of succinylcholine
 - b. Increased minute ventilation
 - c. Unexplained tachycardia
 - d. Severe muscle rigidity
 - e. Elevation of body temperature is most often a late sign but may be seen early in severely affected patients

Neuropathology

1. Muscle biopsy:
 - a. Variation in fiber size
 - b. Increased central nuclei
 - c. Moth eaten fibers
 - d. Necrotic fibers following an attack
2. Release of excess calcium into the cytoplasm

Laboratory Evaluation

1. Respiratory acidosis (end-tidal CO_2 above 55 mm Hg and arterial pCO_2 above 60 mm Hg)
2. Metabolic acidosis (base excess lower than -8 ; $\text{pH} < 7.25$)
3. CK $> 20,000$ units
4. Myoglobin in the urine or serum
5. Potassium above $8 \mu\text{eq/L}$
6. Temperature increase ($T > 39.9^\circ\text{C}$)
7. EMG:
 - a. Normal between attacks
 - b. NCS are normal between attacks
8. Susceptibility test:
 - a. "Caffeine halothane contracture test" that requires a muscle biopsy

Brody Disease*General Characteristics*

1. Brody disease is caused by mutations in the ATP2A1 gene that maps to chromosome 16p12.2-12. It is inherited in an autosomal recessive pattern
2. Brody syndrome has the same phenotype but no mutations in the ATP2A1 gene
3. The ATP2A1 gene encodes the fast-twitch skeletal muscle sarcoplasmic reticulum Ca^{2+} ATPase (SERCA1) in type 2 muscle
4. The mutations result in a decreased rate of ATP-dependent calcium transport across the channel
5. During a normal muscle contraction/relaxation cycle, Ca^{2+} is released from the lateral cisterns of the sarcoplasmic reticulum. It then binds to troponin (in the cytoplasm) of the thin filament that initiates actin and myosin interaction which causes muscle contraction. Calcium is pumped back into the sarcoplasmic reticulum which initiates relaxation. In Brody disease the calcium-ATPase that is located in the sarcoplasmic reticulum is deficient which results in decreased rate of removal of Ca^{2+} from the sarcoplasm

Clinical Manifestations

1. Onset is most often in childhood
2. Patients demonstrate impaired muscle relaxation after muscle contraction which is manifest by cramps and stiffness
3. The muscle contractions may be painful
4. A subset of patients have the problem in the orbicularis oculi which causes difficulty in reopening the eye after forced closure
5. The stiffness worsens with activity
6. There is no percussion myotonia
7. A subset of patients may have mild proximal weakness
8. Patients with Brody syndrome:
 - a. Have more severe myalgias in exercised muscle

Neuropathology

1. Muscle biopsy:
 - a. Type 2 fiber atrophy
 - b. Increased central nuclei in muscle fibers
 - c. Decreased calcium ATPase in type 2 muscle fibers
2. Electron microscopy:
 - a. Rare swollen mitochondria with crystalline inclusions
3. Skeletal muscle fibers are extremely sensitive to caffeine

Laboratory Evaluation

1. Serum CK is normal or only minimally elevated
2. Potassium concentration is normal
3. Exercise forearm test:
 - a. A normal rise in lactate and ammonia
4. EMG:
 - a. Needle EMG demonstrates electrical silence in muscles that demonstrate impaired relaxation
 - b. NCS and EMG are otherwise normal

Schwartz-Jampel Syndrome (Chondrodystrophic Myotonia)*General Characteristics*

1. Schwartz-Jampel syndrome (SJS) is an autosomal recessive disease due to mutations in the HSPG2 gene that maps to chromosome 1p34-36.1
2. It encodes perlecan which is the major heparan sulfate proteoglycan of basement membrane
3. Truncating mutations cause instability of HSPG2 mRNA from nonsense mRNA-mediated decay
4. Missense mutations involve the cysteine residues, which causes intracellular retention of perlecan

Clinical Manifestations

1. Onset is at birth
2. Affected children have dysmorphic features that include:
 - a. Micrognathia
 - b. Narrowed palpebral fissures
 - c. Low set ears
3. As the disease progresses there is:

- a. Kyphoscoliosis
 - b. Short stature
 - c. Bowing of the diaphysis in long bone
 - d. Irregular epiphyses
 - e. Pectus carinatum
4. Infants may demonstrate bulbar weakness as manifested by a decreased suck reflex and weak high-pitched cry
 5. Myotonia of the face may be prominent as it is in myotonia congenita
 6. Developmental milestones are delayed
 7. Movement is slow due to stiffness from the myotonia and muscles may be mildly hypertrophic

Neuropathology

1. Muscle biopsy:
 - a. Variation in fiber size
 - b. Mixture of hypertrophic and atrophic fibers
 - c. Scattered degenerating and regenerating fibers
 - d. Replacement of muscle fibers with fat and connective tissue occurs with time

Laboratory Evaluation

1. Serum CK levels are normal or minimally increased
2. EMG:
 - a. Complex repetitive discharges, myokymic discharges, myotonic and pseudomyotonic discharges can be seen
 - b. Motor and sensory conduction velocities are normal

Inflammatory Myopathies*Overview*

The major categories of idiopathic inflammatory myopathies include:

1. Dermatomyositis (DM)
2. Overlap myositis (OM)
3. Polymyositis
4. Necrotizing myositis (immune-mediated)
5. Inclusion body myositis
6. A large array of autoantibodies that are associated with well-defined clinicopathological disorders includes:
 - a. Antisynthetase
 - b. AntiSRP
 - c. 200/100(HMGCR)
 - d. CADM-140(MDA5)
 - e. SAE-p155
 - f. MJ(NXP-2)
 - g. PMS1

Specific entities may cause inflammatory changes in muscle and include human immunodeficiency virus and human T-cell lymphotropic virus. Drugs that include statins, tumor necrosis factor inhibitors, and proton pump inhibitors can also mimic idiopathic inflammatory myopathies. Muscle mimics include muscular dystrophies and some metabolic myopathies.

The idiopathic inflammatory myopathies are rare and have an annual incidence of 1 in 100,000 of the population. They are primarily diseases of adults with the exception of juvenile dermatomyositis. They are more frequent in women than men, as are many autoimmune processes.

Dermatomyositis

General Characteristics

1. Adult onset with the exception of the juvenile form
2. Women are affected more than men
3. Often diagnosed before the other inflammatory myopathies because of the characteristic rash
4. May have systemic manifestations

Clinical Manifestations

1. The onset can be at any age including infancy but is most often in childhood
2. The course may be insidious over months to subacute over weeks
3. The pattern of weakness is usually symmetric with proximal muscles of the legs > than proximal muscles of the arms; neck flexors are weaker than neck extensors
4. Bulbar and oropharyngeal involvement occurs in 20–30% of patients that causes difficulty chewing and swallowing and rarely dysphasia
5. Children most often have an insidious onset of muscle weakness and pain often preceded by fatigue, a low grade fever and a rash
6. Reflexes are often maintained in accordance with the degree of weakness of the affected muscle. Rarely they can be increased during periods of exacerbation (particularly the patellar reflexes)
7. The rash:
 - a. Often precedes or accompanies muscle weakness. It can develop years after the onset of the weakness
 - b. In dermatopathic DM, patients develop the rash without muscle weakness with isolated myositis
 - c. A heliotrope rash is a purplish discoloration of the eyelids and adjacent subcutaneous tissue that is often associated with periorbital edema (most common in the juvenile form)
 - d. Generalized or limb edema is rare
 - e. Gottron's papules are erythematous lichenoid papular scaly eruptions on the extensor surface of the hands and fingers. The papules may occur on the volar aspect of the extremities ("inverse Gottron's papules")
 - f. The macular erythematous rash may be most prominent in the face, neck and anterior chest ("V-sign") or the upper back ("the shawl sign"). Gotton's sign refers to its distribution over the extensor surfaces of the elbows, knuckles, knees or toes. It is often most evident over the knuckles. In SLE involvement in the hands is between the interphalangeal joints. The rash may be prominent over the hip ("holster sign")

- g. Nail beds may demonstrate dilated capillary loops with periungual hyperemia. In SLE, there may be a distal nail bed capillary flush
- h. Nail fold capillary density is decreased in juvenile dermatomyositis (JDM)
- i. Subcutaneous calcinosis may occur in up to 30% of JDM patients but is uncommon in adults
- j. Thickened and cracked skin occurs in the dorsal and ventral surfaces of the hand in patients with anti-synthetase syndrome (arthritis, Raynaud's phenomenon, interstitial lung disease)
- k. Patients may have severe pruritus

Associated Medical Complications

1. Cardiac:
 - a. Less than 10% of patients develop cardiac symptomatology which includes:
 - i. Arrhythmias
 - ii. Wall motion abnormalities
 - iii. Low ejection fraction
 - iv. Pericarditis and myocarditis
 - v. Congestive heart failure
2. Pulmonary:
 - a. Interstitial lung disease occurs in 10–20% of patients
 - b. Bronchiolitis with pneumonia (rare)
 - c. The manifestation of interstitial lung diseases are primarily a dry non-productive cough and dyspnea:
 - i. Insidious onset
 - ii. May precede the rash or muscle weakness
 - iii. X-ray demonstrates a reticulonodular pattern that is most prominent at the lung base or a ground glass pattern with severe disease
 - iv. Pulmonary function test demonstrate a restrictive pattern with decreased forced vital capacity and diffusion pattern
 - v. Anti-Jo-1 antibodies (against t-histidyl transfer RNA synthetase) occur in approximately 50% of ILD patients with inflammatory myopathies
3. Gastrointestinal system:
 - a. Vasculopathy of the gastrointestinal tract is much more common in JDM than in adults and causes mucosal ulceration, perforation and severe hemorrhage
 - b. Involvement of both striated muscles (oropharynx) and smooth muscles cause esophageal, aspiration and delayed gastric emptying
4. Joints:
 - a. Involves both large and small joints with pain and arthritis
 - b. Contractions can occur across major joints (flexion)
 - c. Toe walking form flexion contracture across the ankles occur in children
5. Vasculopathy:
 - a. Vasculopathy may involve the skin, muscles and gastrointestinal tract
 - b. Massive GI hemorrhage may occur in JDM

- c. Muscle infarction causes myoglobinuria and if severe renal tubular necrosis
- 6. Association with malignancy:
 - a. The association with malignancy is approximately 10% (range 6 to 45%)
 - b. There is no malignancy association with JDM; the association in adults is in patients > 40 years of age
 - c. The risk of malignancy is equal between men and women
 - d. Malignancies are usually diagnosed within 2 years of the onset of the myositis
 - e. There is no correlation of malignancy with clinical symptomatology

Neuropathology

- 1. Muscle biopsy:
 - a. The pathognomonic finding is perifascicular atrophy; this may be a late finding and is seen in <50% of biopsies
 - b. Perifascicles contain degenerating and regenerating necrotic fibers
 - c. Scattered necrotic fibers
 - d. Wedge shaped microinfarcts
 - e. Inflammatory cell infiltrates which is composed of macrophages, B-cells, and CD4⁺ lymphocytes which is seen in both perimysial and perivascular areas. The CD4⁺ cells are primarily phasmocytoid, dendritic cells (PDC) and T-helper cells
 - f. Little invasion of non-necrotic muscle fibers which is in contrast to PM and IBM
 - g. Muscle fibers express MHC-1 antigen, STAT 1 and interferon -alpha/beta-inducible protein myxovirus resistance (MxA) in the sarcolemmal membrane early in the pathologic process
 - h. The microangiopathy of DM is seen by the decreased number of capillaries per area of muscle with compensatory dilation of unaffected vessels
 - i. An early initial histochemical feature is the deposition of the complement membrane attack complex perivascularly which may occur prior to perifascicular atrophy
 - j. Deposition of C3 and C9 complement components, IgM and less frequently IgG are also deposited around the walls of intramuscular blood vessels
 - k. MxA is also expressed on capillaries
- 2. Electron microscopy:
 - a. Endothelial hyperplasia of microvacuoles and tubule reticular cytoplasmic inclusions
- 3. Pathogenesis:
 - a. There are competing hypotheses:
 - i. Humorally/complement mediated microangiopathy demonstrated by the presence of MAC complexes
 - b. Increased expression of genes induced by Type I interferons which supports the initiation of the disease from a viral infection that triggers an autoimmune response
 - c. Dysregulated interferon X/B production that is damaging to small blood vessels

Laboratory Evaluation

- 1. Necrosis of muscle fibers causes increased serum levels of:
 - a. CK which is the most sensitive and specific marker of muscle damage and is seen in 90% of patients
 - b. Aldolase, lactate dehydrogenase, aspartate aminotransferase (AST) and alanine aminotransferase (ALT)
 - c. Serum CK may not correlate with the severity of weakness particularly in children and patients with an insidious cause
 - d. LDH, ALT and AST may correlate with the weakness
 - e. Erythrocyte sedimentation is usually slightly elevated and is not a reliable marker of disease activity
 - f. Anti-nuclear antibodies are seen in 30–60% of patients but are more common in overlap syndromes
 - g. Myositis specific antibodies are seen in some patients and include:
 - i. Antibodies against tRNA synthetases (8 described) and the antisignal recognition particles
 - ii. Antibodies against Mi-2 and Mas antigens
 - iii. The most common anti-synthetase antibody is the Jo-1 which is associated with myopathy and interstitial lung diseases
 - iv. The other anti-synthetase antibodies are seen in approximately 25% of patients
 - v. Mi-2 antibody:
 - 1. Associated with dsA nuclear protein and is seen in 15–20% of DM patients
 - 2. Associated with:
 - a. Acute onset
 - b. Severe rash
 - c. Good response to therapy and good prognosis
- 2. EMG:
 - a. Increased insertional activity that manifests as spontaneous firing, positive sharp waves, fibrillation potentials, pseudomyotonic or complex repetitive discharges
 - b. MUAPs are of brief duration, small amplitude and show polyphasic
 - c. Early recruitment of MUAP at normal frequencies. Recruitment may be decreased if there is marked loss of muscle tissue
 - d. Decreased insertional activity occurs in chronic disease from fibrosis
 - e. In long standing disease fiber splitting and regeneration cause long deviation high amplitude polyphasic MUAPs

Polymyositis (PM)

General Characteristics

- 1. PM is caused by an HLA-restricted cell-mediated cytotoxic immune response against muscle fibers
- 2. MHC-1 antigens are expressed in the surface of non-invaded intact myocytes. A rare plasmic reticular pattern of internal MHC-1 reactivity is seen. The autoantigens expressed by MHC-1 may be endogenous muscle peptides

3. The endomysial CD8+ cytotoxic cells are antigen specific and lyse myocytes through the perforin pathway
4. Myeloid dendritic cells surround non-necrotic fibers and act as antigens presenting cells
5. Microarray studies demonstrate increased immunoglobulin gene expression. The immunoglobulin is secreted by endomysial plasma cells
6. The type 1 interferon signature is overexpressed and is correlated with disease severity
7. There is no correlation between other cytokine levels that include IL-1Q, IL-13, IL-1B or TNF-alpha and disease severity
8. A viral infection could trigger an autoimmune response by molecular mimicry or by loss of self-tolerance
9. Cytotoxic T-cell muscle destruction occurs through the perforin pathway. Granzymes (serine proteases) are released by cytoplasmic granules within cytotoxic T-cells that are packaged with perforin. The cytotoxic granules are released by exocytosis, the granules are released into an immune synapse with the target cell (muscle fiber) and finally the sarcoplasm. Pore formation occurs in the sarcolemma that also contributes to muscle fiber destruction by osmolysis

Clinical Manifestations

1. Onset is usually over the age of 20 years. Extremely rare to occur in childhood
2. More prevalent in women
3. Symmetrical proximal arm and leg weakness that is slowly progressive over weeks or months
4. Some distal muscle involvement but not to the degree that occurs in proximal muscles
5. A significant number of patients have muscle pain
6. Neck flexor muscle weakness
7. Dysphagia occurs in approximately 1/3 of patients; there may be mild facial weakness in a small subset of patients
8. In patients with an acute quadriparetic presentation weakness of jaw opening occurs which is rare in Guillain-Barré syndrome
9. Extraocular muscles are not affected
10. Muscle stretch reflexes are usually preserved but depressed in accordance with the degree of weakness

Medical Complications

1. Myositis with congestive heart failure has been reported in approximately 1/3 of patients. It is probably more common when investigated with modern technology
2. Anti-signal recognition particles (SRP) are associated with cardiac myositis; this finding is controversial as histopathology appears more compatible with necrotizing myopathy. Other studies have demonstrated a microvasculopathy on muscle biopsy more supportive of a diagnosis of DM
3. Interstitial lung disease occurs in approximately 10% of patients at least 50% of whom have anti-Jo-1 antibodies

ies; however, muscle biopsy may be more compatible with DM

4. At the time of diagnosis, approximately 45% of patients have oligo arthritis
5. The risk of malignancy is unclear but appears to be lower than with DM but higher than expected in the general population

Neuropathology

1. Muscle biopsy:
 - a. Variation in fiber size
 - b. Scattered necrotic and regenerating fibers
 - c. An inflammatory cell infiltrate
 - d. Invasion of non-necrotic muscle fibers by T-cells
 - e. Perivascular, perimysial and endomysial inflammatory cells are seen in PM but may also occur in IBM, DM and some dystrophies
 - f. In PM, the endomysial inflammatory cells are activated CD8+ cells that are cytotoxic, alpha and beta T-cells
 - g. Rarely reported are patients that demonstrate CD4+, gamma and delta T-cell infiltration
 - h. Myeloid dendritic cells in the endomysium that surround non-necrotic fibers and present antigen to cytotoxic T-cells
 - i. Plasma cells are seen in the endomysium and expression of immunoglobulin genes are noted with gene assay
 - j. There is an oligoclonal pattern of gene arrangement in plasma cells
 - k. There is no deposition of complement, MAC or immunoglobulins on the microvasculature

Laboratory Evaluation

1. The CK is greatly elevated (>5x normal) in most cases. It is never normal in acute cases which is different from DM and IBM
2. The CK does not correlate with the degree of weakness
3. Erythrocyte sedimentation rate (ESR) is most often normal
4. Positive ANA occurs in 16–40% of patients
5. The relationship of muscle-specific antibodies to PM is not settled
6. EMG:
 - a. Increased insertional activity is demonstrated by positive sharp waves, fibrillation potentials and complex repetitive discharges
 - b. Short-duration, small amplitude and polyphasic MUAPs

Differential Diagnosis of Polymyositis

1. Inclusion body myositis
2. Dermatomyositis (without dermatitis)
3. Necrotizing myopathy
4. Inflammatory myopathy associated with infections:
 - a. HIV
 - b. HTLV-1

- c. Hepatitis B & C
- 5. Muscular dystrophies:
 - a. FSH
 - b. Congenital myopathy
 - c. Dysferlinopathies
 - d. Limb-girdle dystrophies
 - e. Myotonic dystrophy type 2
 - f. Amyloid myopathy (light chain or familial)
 - g. Metabolic myopathy with rhabdomyolysis
 - h. Endocrine myopathy:
 - i. Hypothyroidism
 - ii. Hyperparathyroidism
 - iii. Diabetic muscle infarction
 - iv. Acromegaly
 - i. Drug-induced myopathies:
 - i. Cholesterol lowering drugs
 - ii. Cyclosporine
 - iii. Amiodarone
 - iv. Colchicine
 - v. D-penicillamine
 - j. Juvenile or adult onset spinal muscular atrophy (including) Kennedy's disease
 - k. Polymyalgia rheumatism

Serum CK Elevation in PM

While it is normal in fibromyalgia and polymyalgia rheumatism and can be normal in IBM. MRI abnormalities are seen in muscular dystrophies, rhabdomyolysis, toxic reactions to medications (statins) and diabetic vasculopathy. The pattern of muscle involvement (anterior less than posterior by compartment), extent and replacement of muscle by fat and connective tissue in the absence of edema on MRI differentiate PM from a dystrophic process. Diffuse myotonic discharges are seen in myotonic dystrophy (DM type 2). Muscle biopsy reveals specific diagnostic features that suggest IBM, other myopathies, and include rimmed vacuoles, eosinophilic inclusions, ragged red fibers, cytochrome oxidase negative fibers, and cycloid deposits. Muscle biopsy is important to rule out dystrophy, metabolic myopathy, (acid maltase deficiency, lipid droplets) or necrotizing myopathy.

Overlap Syndrome

DM and PM are often associated with other connective tissue disorders that include:

1. Scleroderma
2. Mixed connective tissue disease (MCTD)
3. Sjögren's syndrome
4. Systemic lupus erythematosus (SLE)
5. Rheumatoid arthritis

In general, muscle biopsy in patients with overlap syndromes are similar to DM or non-perimyopathic disorders where CD8⁺ cells invade non-necrotic muscle fibers. These diseases may be more responsive to immunotherapy than DM or PM.

Scleroderma

General Characteristics

1. 5–17% of scleroderma patients have muscle involvement which occurs in:
 - a. Progressive systemic sclerosis
 - b. CREST (calcinosis, Raynaud's phenomena, esophageal dysmotility, sclerodactyly, and telangiectasia)

Clinical Manifestations

1. Proximal muscle weakness

Neuropathology

1. Muscle biopsy
 - a. Mild variability in fiber sizes
 - b. Type 2 fiber atrophy
 - c. Perimysial fibrosis
2. It is a complex systemic autoimmune disease that targets the vasculature, connective tissue-producing cells (fibroblasts/myofibroblasts) and components of the innate and adaptive immune system. The clinical and pathologic manifestations are caused by:
 - a. Production of autoantibodies and cell-mediated immunity
 - b. Microvascular endothelial cell/small vessel fibroproliferative vasculopathy
 - c. Dysfunction of fibroblast production of collagen and matrix components of the skin and internal organs

Laboratory Evaluation

1. Normal serum CK unless there is myositis in which case it may be moderately elevated
2. EMG:
 - a. Is usually normal although it may demonstrate imitative feature during myositis
3. CREST is associated with anti-centromere antibodies while progressive systemic sclerosis has anti-Scl-70 antibodies
4. Patients with scleroderma myositis may also have anti-PM-Scl antibodies

Sjögren's Syndrome

General Characteristics

1. Characterized by the sicca complex that includes:
 - a. Xerophthalmia (dry eyes)
 - b. Dry mouth and dryness of other mucous membranes
 - c. Complicated by both peripheral and CNS involvement
 - d. More common in women than men

Clinical Manifestations

1. Sicca complex
2. PNS features:
 - a. Length dependent axonal sensorimotor neuropathy; patients may have the neuropathy without signs of the sicca complex

- b. Distal predominant weakness
- c. Pure small fiber neuropathy
- d. Autonomic neuropathy that involves the cardiovascular system
- e. Cranial neuropathy often involving the fifth cranial nerve
- 3. CNS complications:
 - a. Transverse myelitis
 - b. Posterior columns may be predominantly involved
 - c. Most often presents in middle age
 - d. Loss of muscle stretch reflexes

Neuropathology

- 1. Pathogenesis of the peripheral neuropathy and sensory neuronopathy/ganglionopathy is most likely autoimmune
- 2. Necrotizing vasculitis may be a cause of the neuropathy particularly in patients with asymmetric, multiple mononeuropathy patterns of involvement
- 3. Nerve biopsy:
 - a. Axonal degeneration and some degree of secondary segmental demyelination
 - b. Rarely perivascular inflammation of perineurial or endoneurial blood vessels is seen
 - c. Loss of large myelinated fibers and perivascular lymphocytes; CD8+ cells are seen in the endomysial and perineurial vessels

Laboratory Evaluation

- 1. Approximately 90% of patients have positive ANA, SS-A/Ro and SS-B/La antibodies
- 2. The CSF is usually normal
- 3. Schirmer's test is positive in those patients with keratoconjunctivitis
- 4. Autoimmune destruction of salivary glands (biopsy)
- 5. EMG:
 - a. Absent or reduced SNAPs particularly in patients with sensory neuropathy/ganglionopathy
 - b. Normal or minimally slowed motor and sensory NCVs

Systemic Lupus Erythematosus

General Characteristics

- 1. Central nervous system manifestations that include seizures, psychosis and stroke are the most common neurological complications of systemic SLE

Clinical Manifestations

- 1. Myositis occurs in SLE but weakness is often exacerbated by disuse atrophy and pain as well as immunosuppressive medication (steroids)

Neuropathology

- 1. SLE is a prototype type II hypersensitivity reaction in which local deposition of anti-nuclear antibodies in complex with released chromatin activate the complement system that induces severe inflammation

Laboratory Evaluation

- 1. The great majority of patients demonstrate ANA titers against DNA and ribonuclear proteins (RNPs)
- 2. Anti-RNP antibodies are demonstrated in approximately 50% of patients (SS-A and SS-B); anti-SM antibodies are specific for SLE while RNP antibodies occur with Sjögren's disease and anti-V1 RNP is seen with mixed connective tissue disease
- 3. There is upregulation of type I interferon inducible genes that is also seen in the muscle biopsies of DM patients
- 4. MxA is highly expressed in the blood of SLE patients as in the muscle of dermatomyositis patients
- 5. Electron microscopy:
 - a. Tubular reticular inclusion bodies are seen in endothelial cells in SLE and DM

Rheumatoid Arthritis (RA)

General Characteristics

- 1. Most often weakness in RA occurs from type II atrophy, disuse and medications
- 2. A myositis may be seen

Clinical Manifestations

- 1. The clinical picture is dominated by severe joint pain and destruction
- 2. Steroids as well as disuse cause type 2 fiber atrophy that is associated with proximal muscle weakness
- 3. Disruption of the transverse collateral ligament may be associated with odontoid compression of the medulla and quadriplegia. It is usually manifest with paresthesias and dysesthesias of the of the upper extremities prior to spinal cord compression and weakness
- 4. Severe joint involvement in the hand (ulnar deviation and joint destruction) is associated with intrinsic hand muscle atrophy

Neuropathology

- 1. Muscle biopsy:
 - a. Type 2 fiber atrophy
- 2. Post-translational modifications of proteins is a major mechanism of pathology in RA B-cell responses to citrullinated antigens that include vimentin, fibrinogen and α -enolase

Mixed Connective Tissue Disease

General Characteristics

- 1. Mixed connective tissue disease is defined by patients who have components of scleroderma, rheumatoid arthritis, SLE and muscle inflammation
- 2. Two or more systemic autoimmune diseases need to be present

Clinical Manifestations

- 1. Most common signs and symptoms reported from different cohorts:

- a. Polyarthritis
- b. Raynaud's phenomena
- c. Puffy fingers
- d. Lung involvement
- e. Esophageal involvement

Pulmonary arterial hypertension and interstitial lung disease accrue over the long course of the disease. Myositis occurs in a subset of patients.

Neuropathology

1. Muscle biopsy:
 - a. DM is more common than PM
2. The antigen recognized by the distinct autoantibody originally termed ribonuclear sensitive extractable nuclear antigen (RNAase sensitive ENA) is a V1 ribonucleic protein (RNP complex)
3. Antibody may be detected prior to the onset of the disease
4. The specificity of these antibodies is most closely related to a 70 KD epitope on V1RNP molecules. The epitope is characterized as containing the RNA-binding domain on the peptide component of the V1RNP cell dependent B-cell maturation complex
5. The 70KD anti-V1RNP antibody response is associated with CD4/Th1 T-cells that express HLA-DR4 or Dr2-phenotype which share a common set of amino acids in the beta chain. These amino acids form a pocket for antigen binding

Laboratory Evaluation

1. EMG:
 - a. Axonal sensorimotor polyneuropathy
 - b. RNP complex antibodies in the serum

Inclusion Body Myositis

General Characteristics

1. The pathogenesis of IBM is not entirely clear. There is evidence that it is a primary inflammatory myopathy due to its clinically restricted inflammatory cell infiltrate of cytotoxic T-cells
2. It is the most common inflammatory myopathy of older patients

Clinical Manifestations

1. Onset is most often after the age of 50 years
2. It presents with insidious slowly progressive proximal and distal weakness
3. Males are more commonly affected than females
4. The pattern of weakness:
 - a. Early weakness of the quadriceps, wrists and finger flexors and the ankle dorsiflexors
 - b. This pattern of weakness is seen in approximately 2/3 of patients
 - c. The deep finger flexors such as the flexor pollicis longus are most often severely affected

- d. Muscle weakness in IBM is often asymmetric
- e. Atrophy of the forearm flexor compartment with sparing of intrinsic hand muscles
- f. Esophageal and pharyngeal muscle weakness causes dysphagia in approximately 40% of patients
- g. Mild facial weakness occurs in approximately 1/3 of patients
- h. There is neck flexor weakness
- i. A subset of patients has a generalized sensory neuropathy
- j. Reflexes are maintained in parallel with muscle strength. The patellar reflexes may be lost early

Associated Medical Complications

1. IBM patients do not have associated lung disease, myocarditis or increased risk of malignancy
2. IBM patients (15%) may have another autoimmune disease that includes SLE, Sjögren's syndrome, scleroderma, sarcoidosis, thrombocytopenia or immunoglobulin deficiency

Neuropathology

1. Muscle biopsy:
 - a. Rimmed vacuoles with granular material
 - b. Endomysial inflammation
 - c. Grouped atrophy
 - d. Eosinophilic cytoplasmic inclusions
 - e. Amyloid deposition in vacuolated muscle fibers and within muscle nuclei
 - f. Ragged red fibers and COX-negative fibers
 - g. Abnormal myonuclei
 - h. Electron microscopy:
 - i. 15–21 nm cytoplasmic and intranuclear tubulofilaments are seen in vacuolated muscle fibers
 - ii. Vacuolated fibers may also contain 6–10 nm amyloid-like fibrils
 - iii. The endomysial infiltrate contains macrophages and CD8⁺ cytotoxic suppressor T-lymphocytes
 - iv. Myeloid dendritic cells surround non-necrotic muscle fibers. MHC class I antigens are expressed in both necrotic and non-necrotic muscle fibers
 - v. T-cell receptors demonstrate an oligoclonal pattern of gene rearrangement. Some patients have been demonstrated to show a persistent clonal restriction of T-cell receptors that support the mechanism of pathology as an antigen driven immune response against muscle
 - vi. The cytotoxic T-cells in IBM release perforin granules that cause pores in the muscle membrane that result in osmolysis

Laboratory Evaluation

1. CK levels are normal or only minimally increased
2. Muscle-specific antigens are not found but approximately 20% of patients have positive ANAs

3. HLADR3 phenotype is increased in IBM
4. EMG:
 - a. Increased spontaneous and insertional activity
 - b. Early recruitment of low amplitude polyphasic MUAPs
 - c. In approximately 1/3 of patients there may be large polyphasic MUAPs (which have been described in PM, DM and muscular dystrophy) and are thought to represent chronicity of disease rather than reinnervation in a neurogenic process
 - d. NCS are slow, axonal sensory neuropathy

Differential Diagnosis of Inclusion Body Myositis

The most common misdiagnosis is PM. The diagnosis of IBM clinically is supported by slowly progressive asymmetric weakness of the quadriceps and wrist, finger flexor with atrophy in patients older than 50 years of age.

In early stages the disease has been misdiagnosed as ALS. A major distinction is intrinsic hard muscle weakness (particularly the first dorsal interosseous in ALS) whereas in IBM the atrophy and weakness is in the forearm flexor musculature.

In hereditary IBM:

1. Onset is in early adult life
2. There is preferential involvement of the tibial anterior muscle in those patients with the autosomal recessive form of the disease
3. Shoulder and hip girdle musculature is affected
4. Valosin gene mutation (AD), causes IBM with Paget's disease and frontal temporal dementia

Pathologic Differential Diagnosis

1. Rimmed vacuoles, amyloid deposition, and tubular or filamentous inclusions are seen in hereditary forms of IBM but can also be encountered in:
 - a. Limb-girdle muscular dystrophy type IA (myotilin)
 - b. LGMD2J (titinopathy)
 - c. Oculopharyngeal dystrophy
 - d. Welander distal myopathy
 - e. Myofibrillar myopathy

Necrotizing Myopathy

General Characteristics

1. Probably 20% of inflammatory myopathy is due to necrotizing myopathy
2. Several forms have been distinguished neuropathologically that includes:
 - a. "Pipestem" capillaries
 - b. Malignancy associated form with connective tissue staining for alkaline phosphatase
 - c. SRP associated

Clinical Manifestations

1. Onset of proximal weakness which may be acute or insidious

2. Underlying diseases include:
 - a. Scleroderma
 - b. Mixed connective tissue disease
 - c. Paraneoplastic necrotizing myopathy from cancers of the gastrointestinal tract or adenocarcinoma both small and large cell types of the lung
 - d. May occur with statin use
3. Patients may improve with immunotherapy
4. Proximal muscle weakness
5. May be accompanied by myalgias
6. If associated with statins, weakness may continue after the statins have been withdrawn

Neuropathology

1. Muscle biopsy:
 - a. The hallmark of autoimmune necrotizing myopathy is:
 - i. Scattered necrotic myofibers with myophagocytosis
 - ii. Absence or paucity of T-lymphocyte inflammation
 - iii. Microvascular deposition of complement MAC (support for a hemorally mediated microangiopathy)
 - iv. Minimal perivascular inflammation
 - v. No endothelial tubuloreticular inclusions by electron microscopy
 - b. Specific subtypes of necrotizing myopathy:
 - i. "Pipestem" capillaries
 1. Thick-walled and enlarged capillaries of normal number
 - ii. Malignancy associated with necrotizing myopathy (NM)
 1. Alkaline phosphatase muscle connective tissue proclivity
 - iii. SRP-associated NM
 1. Bimodal distribution of fiber sizes, increased endomysial and decreased endomysial capillaries, the remaining being enlarged and thickened
 2. Marked fibrosis ensues with MAC deposited in endomysial capillaries
 3. There is no perifascicular atrophy
 - c. Statin-induced autoimmunity
 - i. Statins block 3-hydroxy 3-methylglutaryl coenzyme A reductase protein that is thought to be the antigen in statin induced autoimmune myopathy. The process may be driven by the levels of HMGCR expression in regenerating muscle fibers

Laboratory Evaluation

1. Serum CK level is markedly increased
2. ANA antibodies may be detected
3. Anti-HMGCR are highly sensitive for autoimmune NM
4. EMG:
 - a. Increased insertional and spontaneous activity
 - b. Myopathic MUAPs that show early recruitment

- c. Newer antibodies associated with necrotizing myopathy and severe DM include:
 - i. Encompass enzymatic proteins that are involved in gene transcription or post-translational modification and include:
 - 1. TIF-V
 - 2. NXP-2
 - 3. MDA5
 - 4. SAE
 - 5. MNGCR

Rarer Inflammatory Myopathies

Eosinophilic Myopathies

General Characteristics

1. Eosinophilic myopathy may occur as a part of the hyper-eosinophilic syndrome whose diagnostic criteria are:
 - a. Eosinophilic of at least 1500 eosinophilic/mm³ for 6 months
 - b. No other cause of eosinophilia
 - c. Organ system involvement from eosinophilic infiltration
 - d. The subclassification of eosinophilic myopathy includes:
 - i. Focaleosinophilic myositis
 - ii. Eosinophilic polymyositis
 - iii. Eosinophilic perimyositis

Clinical Manifestations

1. Focal eosinophilic myositis and polymyositis:
 - a. Focal or generalized muscle weakness
 - b. Often with myalgias
 - c. Skin abnormalities
2. Perimyositis with eosinophilia
 - a. Myalgias without significant weakness
3. Hypereosinophilic syndrome:
 - a. Muscle weakness
 - b. Encephalopathy
 - c. Cranial nerve involvement
 - d. Mitochondrial involvement that includes:
 - i. Pericarditis
 - ii. CHF
 - iii. Arrhythmia
 - iv. Conduction block
 - e. Pulmonary involvement
 - i. Pleuritis
 - ii. Asthma
 - f. Renal involvement
 - g. Gastrointestinal involvement
 - h. Skin changes:
 - i. Petechiae rash
 - ii. Nail bed splinter hemorrhages
 - iii. Raynaud's phenomena
 - iv. Livedo reticularis

Neuropathology

1. Muscle biopsy:
 - a. Focal eosinophilic myositis and eosinophilic myositis:
 - i. Endomysial inflammatory cell infiltrate most often containing eosinophils
 - ii. Inflammatory cells surround muscle fibers
 - iii. Nodular granules
 - b. Eosinophilic perimyositis
 - i. An inflammatory cell infiltrate (may not be invariant) is restricted to the fascia and superficial perimysium
 - c. Oligoclonal expansion of T-cells within muscle in eosinophilic polymyositis
 - d. Interleukin-5 and 3 are secreted by T-lymphocytes that grow and differentiate eosinophils. Eosinophils release a toxic major basic protein that targets cell membranes

Laboratory Evaluation

1. CK levels are usually increased in eosinophilic polymyositis and focal disease; may be normal in eosinophilic perimyositis
2. Hypereosinophilia usually greater than 1500 cells/mm³
3. Hypergammaglobulinemia
4. Anemia
5. Increased rheumatoid factor
6. ESR is elevated in approximately 50% of patients
7. Negative ANA
8. EKG:
 - a. Cardiac arrhythmia
9. Chest X-ray
 - a. Pulmonary infiltrates
10. EMG:
 - a. Increased insertional activity as manifested by positive sharp waves, fibrillation potentials
 - b. Early recruitment of low amplitude polyphasic MUAP
 - c. Nerve conduction velocities may be decreased due to superimposed neuropathy

Differential Diagnosis of Eosinophilic Myopathy

1. Parasitic infection
2. Churg-Strauss syndrome
3. T-cell lymphoma
4. Aplastic anemia
5. Toxic oil syndrome
6. L-tryptophan
7. Idiopathic
8. HES and variants
9. LGMD2A

Diffuse Fasciitis with Eosinophilia

General Characteristics

1. A rare scleroderma-like disease most likely due to an autoimmune process, clinically and histologically it is similar to L-tryptophan induced muscle disease and rapeseed oil intoxications. A few patients describe its onset after intense physical exercise

Clinical Manifestations

1. Men are affected 2:1 > than women
2. Most commonly it affects patients between 30–60 years of age; children can be affected
3. The onset is with myalgias, low-grade fever, muscle weakness (possibly due to pain), and arthralgias
4. Contracture of the hands, elbows, and knees and rarely in the hips and shoulders
5. Involvement of the extremities and trunk with a morphea-like skin lesion (painful peau d'orange-like lesions)
6. Visceral organs are usually not involved which distinguishes it from HES and eosinophilic PM
7. Possible association with hematologic diseases that include:
 - a. Aplastic anemia
 - b. Idiopathic thrombocytopenia
 - c. Leukemia
 - d. Lymphoma

Neuropathology

1. Fascial and skin biopsy:
 - a. The fascia is thickened and is infiltrated with lymphocytes, macrophages plasma cells and eosinophils
 - b. Some patients demonstrate the deposition of immunoglobulin and C3 in the fascia
 - c. The inflammatory infiltrate may infiltrate adjacent subcutaneous tissue, the perimysium and endomysium in association with scattered necrotic atrophy
 - d. Interstitial myositis has been reported in over 50% of patients but most often does not cause clinically significant weakness

Laboratory Evaluation

1. Approximately two thirds of patients have peripheral eosinophilia over 7%
2. Elevated ESR and hypergamma globulinemia occur in approximately one third of patients
3. Positive ANA occurs in one quarter of patients
4. CK is normal
5. EMG:
 - a. Superficial muscle may demonstrate membrane instability and myopathic MUAPs
6. MRI of muscle:
 - a. In 80% of patients in the acute phase there is increased T2 signal within the fascia and gadolinium enhancement
 - b. The fascia is thickened

Granulomatous Myositis*General Characteristics*

1. Granulomatous or giant cell myositis is most often seen with myasthenia gravis or thymoma (benign or malignant)

Clinical Manifestations

1. Proximal muscle weakness

2. If associated with myasthenia gravis there are bulbar features and extraocular muscle involvement
3. Associated with granulomatous myocarditis

Neuropathology

1. Granulomatous inflammation with multinucleated giant cells
2. Cell mediated immunities supported by histologic inflammation and giant cell formation. The association with MG is evidence for a component of humorally mediated immunity in the pathologic process

Laboratory Evaluation

1. Elevated serum CK
2. Patients with associated MG demonstrate acetylcholine receptor antibodies
3. EMG:
 - a. Myopathic MUAPs
 - b. Increased insertional activity
 - c. If MG is causal there may be a decremental response
 - d. Chest CT to R/O thymoma
 - e. EKG: 1. Conduction block and arrhythmias in patients with myocardial involvement
 - f. Echocardiography: 1. Low ejection fraction and 2. Ventricular wall motion abnormalities in those with Myocarditis

Sarcoid Myopathy*General Characteristics*

1. Granulomas are frequently encountered in muscle biopsies of patients with sarcoid that are asymptomatic
2. More prevalent in black than Caucasian patients; rarely affects children
3. Most patients with sarcoid are diagnosed from pulmonary manifestations. Erythema nodosum and ankle lesions may be early signs

Clinical Manifestations

1. Proximal weakness is predominant but distal weakness occurs
2. Focal myalgias and atrophy occur in a subset of patients as well as a generalized chronic myopathy that may involve the trunk
 - a. May present similarly to DM and IBM
 - b. May have an associated peripheral neuropathy
 - c. Systemic complications:
 - i. Myocardial involvement with cardiomyopathy and conduction defects
 - ii. Pulmonary involvement with diffuse nodular or interstitial forms
 - iii. Skin and joint involvement
 - iv. Visceral infiltration

Neuropathology

1. Muscle biopsy:

- a. Non-caseating granulomas that contain epithelial cells, lymphocytes and giant cells around blood vessels in the perimysium and endomysium
- b. Epithelioid granulomas have CD4 positive lymphocyte infiltration, the sarcolemma membrane stains with HLA-ABC, HLA-DR and intercellular adhesion molecules-1 antibodies which supports active antigen presentation

Laboratory Evaluation

1. Serum CK is normal or only minimally elevated
2. Elevated serum angiotensin-converting enzyme levels are frequently seen
3. Skin antigen energy
4. Chest x-ray:
 - a. Hilar lymphadenopathy
 - b. Interstitial pattern
5. EMG:
 - a. Normal (some patients)
 - b. Usually a myopathic pattern or mixed myopathic pattern may be seen in chronic patients and in those with a superimposed neuropathy
6. MRI (one patient with acute sarcoidmyositis):
 - a. Multiple bilateral, nodular and spindle-shaped lesions in the gastrocnemius and soleus muscles

Behçet's Disease

General Characteristics

1. Behçet's disease is a systemic vasculitis with the clinical triad of oral and genital ulcers and ocular lesions

Clinical Manifestations

1. Onset may occur in childhood or adult life
2. Patients may develop generalized myalgias with or without weakness
3. Medical associations:
 - a. Ocular lesions:
 - i. Iritis
 - ii. Uveitis
 - b. Colitis
 - c. Thrombophlebitis
 - d. Erythema nodosum
 - e. Meningoencephalitis
 - f. Oral and genital ulcers
 - g. Myocarditis
 - h. The calves are predominant with lower extremity muscle involvement

Neuropathology

1. Muscle biopsy:
 - a. CD4+ and CD8+ lymphocytes and neutrophils that invade non-neurotic muscle fibers
 - b. Expression of MHC-1 antigen on muscle fibers similar to what is seen in PM
 - c. Complement factor C3 and immunoglobulins on blood vessel walls similar to DM support its role as a systemic vasculitis

Laboratory Evaluation

1. Serum CK is normal or minimally elevated
2. Elevated ESR and C-reactive protein
3. HLA-beta5 positivity is documented in approximately 50%

Focal Myositis

General Characteristics

1. Is a rare benign inflammatory pseudotumor of muscle

Clinical Manifestations

1. Onset in adults but occasionally affects children
2. It usually presents as a localized painful swelling within the soft tissue of an extremity, that is painless and insidiously enlarges over weeks
3. The leg is the most common site of involvement but it has been described in the upper extremities, sternocleidomastoid muscle, head and abdomen
4. Rarely, it may progress to polymyositis
5. Lesions may resolve spontaneously and respond to steroids
6. It may be recurrent (rare)
7. The mass is moveable and unattached to the overlying skin
8. Unusual sites of involvement include the tongue, eyelid and esophagus
9. Focal myositis has been reported with chronic S1 radiculopathy

Neuropathology

1. Muscle biopsy:
 - a. Immunohistochemical studies reveal increased macrophage and CD4+ and CD8+ T-lymphocytes that invade the endomysium
 - b. Neurosis and phagocytosis of muscle fibers
 - c. Variability of fiber size, central nuclei, split fibers with endomysial fibrosis
 - d. The macrophage and T-cell lesions may be replaced by B-cell and dendritic plasmacytosis if there is marked inflammation

Laboratory Evaluation

1. Serum CK and ESR are often normal or minimally elevated
2. MRI and CT of muscle:
 - a. Diffuse swelling of the involved muscle with edema

Differential Diagnosis

1. Thrombophlebitis
2. Myositis ossificans
3. Proliferative myositis
4. Infections
5. Eosinophilic fasciitis
6. Localized nodular myositis
7. Amyloidosis
8. Neurogenic hypertrophy

9. Pseudohypertrophy
10. Dystrophies
11. Rhabdomyoma
12. Intramuscular lipoma
13. Fibromatosis
14. Malignancies
 - a. Rhabdomyosarcoma
 - b. Leiomyosarcoma
 - c. Liposarcoma
 - d. Lymphoma

Viral Infections

Human Immunodeficiency Virus

General Characteristics

1. Patients with HIV may develop an inflammatory myopathy that is more common in adults than children
2. It can develop in the early stages of HIV and in those with prolonged seroconversion but is most common in patients with AIDS

Clinical Manifestations

1. A subacute or chronic progressive symmetrical proximal muscle weakness associated with myalgia
2. There often is associated HIV-related neuropathy with sensory loss of both large and small fiber modalities
3. Rhabdomyolysis may occur with HIV infection alone or with antiretroviral therapy and/or statin use
4. Patient may have a clinical picture that resembles DM
5. Concomitant medical associations include:
 - a. Rash
 - b. Arthritis
 - c. Myocarditis
 - d. Secondary infections

Neuropathology

1. Muscle biopsy:
 - a. Perimysial and endomysial inflammation that is composed of macrophages and CD8+ cytotoxic T-cells which invade non-necrotic muscle fibers
 - b. Perivascular inflammation occurs without necrotizing vasculitis
 - c. Rarely ragged red fibers, nemaline rods and cytoplasmic bodies and rimmed vacuoles are seen
2. Electron microscopy:
 - a. The virus is only seen in inflammatory cells
3. The present hypotheses is that the HIV virus triggers a T-cell mediated and MHC-1 restricted immune response to muscle antigens

Laboratory Evaluation

1. CK elevation
2. EMG:

- a. Increased muscle membrane irritability with positive sharp waves fibrillation potentials and complex repetitive discharges
- b. Low amplitude MUAPs

Human T-Cell Leukemia Virus Type I

General Characteristics

1. Most often HTLV-1 causes spastic paraparesis and adult T-cell leukemia
2. A myositis can occur in patients without leukemia or spastic paraparesis

Clinical Manifestations

1. Subacute onset of proximal myopathy with myalgias
2. In patients with tropical spastic paraparesis HTLV-1 myositis causes proximal upper extremity and neck flexor weakness

Neuropathology

1. Muscle biopsy:
 - a. Similar to HIV myositis and PM
 - b. Rimmed vacuoles similar to IBM occur
2. Electron microscopy:
 - a. HTLV-1 can be demonstrated in inflammatory cells but not in muscle fibers
 - b. Evidence supports a T-cell mediated and MHC-1 restricted process similar to that of HIV
 - c. HIV/HTLV-1-coinfected patients have greater production of Th-1 cytokines

Laboratory Evaluation

1. The serum CK is increased
2. EMG:
 - a. Myopathic features
 - b. In patients with TSP there may be an altered pattern of recruitment that is seen with upper motor neuron disease

Influenza Virus

General Characteristics

1. Influenza A, B and C cause upper respiratory infections and concomitant myalgias with fever and the sickness response; posited to be caused by release of proinflammatory cytokines
2. Children and adults may develop a myositis that has a different clinical course

Clinical Manifestations

1. Children:
 - a. Severe pain, swelling and tenderness of the calves as the infection resolves
 - b. Children may toe walk or crawl rather than walk due to the severe pain
 - c. Signs and symptoms usually last <1 week
 - d. Myoglobinuria may occur

2. Adults:
 - a. The myositis is usually more severe in adults
 - b. Proximal muscle weakness occurs in approximately 50% of patients
 - c. Myoglobinuria with renal involvement is more common in adults than in children
 - d. There is generalized muscle pain

Neuropathology

1. Muscle biopsy (children):
 - a. Interstitial mononuclear and polynuclear inflammatory cells
 - b. Scattered necrotic and regenerating fibers
2. Electron microscopy:
 - a. No viral particles in muscle tissue
3. Muscle biopsy in adults:
 - a. Scattered necrotic and regenerating fibers with minimal infiltration of mononuclear cells
 - b. Electron microscopy:
 - i. Viral particles within membrane-bound vacuoles adjacent to the sarcolemma have rarely been seen
 - ii. Intranuclear inclusions have been demonstrated in fibers that had no viral particles. The inclusions consisted of 7–9 nm parallel filaments

Laboratory Evaluation

1. Serum CK is elevated in patients with myositis
2. EMG:
 - a. Characteristics of an active necrotizing myopathy

Rarer Viral Myositides

1. Coxsackie virus
2. Mumps
3. Measles
4. Adenovirus
5. Herpes simplex
6. Cytomegalovirus
7. Hepatitis B and C
8. Epstein-Barr
9. Respiratory syncytial
10. Echovirus
11. Arbovirus

Bacterial Infection of Muscle

Pyomyositis

General Characteristics

1. Pyomyositis is a pyogenic infection of skeletal muscle most often seen in tropical countries
2. The incidence is increasing in developed countries from HIV infection and intravenous drug abuse

Clinical Manifestations

1. Onset is with muscle pain, tenderness and fever

2. The most common sites of infection are the quadriceps, glutei and deltoid musculature
3. Rarely the paraspinal muscles are infected which causes severe back pain
4. Spread into the epidural space has been reported with spinal cord involvement

Neuropathology

1. Muscle biopsy:
 - a. Abscess with necrotic tissue that contains polymorphonuclear cells, lymphocytes and rarely eosinophils
2. The most common organisms are:
 - a. Staphylococcus aureus
 - b. Streptococcus
 - c. Escherichia coli
 - d. Yersinia enterocolitica
 - e. Legionella
3. The pyomyositis may arise as an extension from an adjacent infection or by hematogenous spread

Laboratory Evaluation

1. Serum CK may be normal or markedly increased
2. An elevated ESR and C-reactive protein as well as leukocytosis is usually seen
3. MRI:
 - a. Helpful in localizing the extent of the infection

Lyme's Disease

General Characteristics

1. Lyme's disease is most often associated with peripheral and CNS manifestation although myalgia is common

Clinical Manifestations

1. Patients with myositis present with focal or generalized weakness with myalgias
2. Associated medial complications include:
 - a. The migratory rash
 - b. Arthritis (knee is the most common joint)
 - c. Myocarditis
3. Rhabdomyolysis may occur with severe myositis

Neuropathology

1. Muscle biopsy:
 - a. Focal nodular infiltrates
 - b. Perimysial inflammation
 - c. Scattered necrotic muscle fibers
 - d. Lymphocytic and plasma cell infiltrates have been described adjacent to small endomysial blood vessels
 - e. Infiltrates are composed of CD4+ T-lymphocytes and macrophages with a minor contribution from CD8+ T-lymphocytes and B-cells

Laboratory Evaluation

1. CK levels are normal or minimally elevated

2. Intrathecal IgG antibodies to *Borrelia burgdorferi*
3. PCR of CSF is not very sensitive
4. In patients with early disease the serum may be negative while the CSF has a positive antibody response
5. EMG:
 - a. Myopathic pattern
 - b. May have concomitant polyradiculoneuropathy

Fungal Myositis

General Characteristics

1. Fungal muscle infections are almost always encountered in a setting of severe immunosuppression or hematologic malignancy
2. *Candida* is the most common organism and most infections are seen with its systemic spread
3. Invasive *Candida* infections are seen with:
 - a. Immunocompromised states
 - b. Hematopoietic stem cell transplantation
 - c. Solid organ transplantation
 - d. Chemotherapy within the past three months
 - e. Severe neutropenia
 - f. Surgery within the past 30 days
 - g. Acute renal failure
 - h. Liver failure
 - i. Increased baseline creatine

Clinical Manifestations

1. Diffuse myalgias, tenderness and weakness of involved muscles

Neuropathology

1. Muscle biopsy:
 - a. Infiltration of the muscle by hyphae and yeast forms
 - b. Inflammation and hemorrhagic necrosis
2. The cytokine IL-10 gene rs1800896GG genotype polymorphism may be important as this genotype was associated with a higher risk of invasive *Candida* infections

Laboratory Evaluation

1. Setting of neutropenia and severe immunosuppression, liver and renal failure
2. (1 to 3)-B-D-glucan (BDG) and *Candida albicans* germ tube antibody (CAGTA) tests are being evaluated

Parasitic Infections

Trichinosis

General Characteristics

1. Trichinosis is caused by *Trichinella spiralis* and is the most common parasitic disease of muscle worldwide
2. Its incidence has declined in the USA as awareness of the illness has increased and pigs are less likely to be fed raw garbage
3. Most infections arise from the ingestion of inadequately cooked pork

Clinical Manifestations

1. Approximately two to twelve days after ingestion there is
 - a. Hematogenous spread of larvae to muscle
2. The muscles infected include: 1. the diaphragm, 2. extraocular muscles, 3. tongue, 4. masseter, 5. laryngeal, 6. intercostal, 7. trunk and 8. extremities
3. There is generalized muscle pain and weakness
4. Fever, abdominal pain and gastrointestinal symptoms
5. Periorbital edema and ptosis are prominent
6. Subconjunctival hemorrhage
7. Erythematous or petechial rash may be seen
8. Weakness and myalgias are most severe in the third week of the infection but can be prolonged
9. Rarely there is myocarditis and meningoencephalitis

Neuropathology

1. Muscle biopsy:
 - a. In the early stages of infection there is muscle infiltration by eosinophils and polymorphonuclear leukocytes
 - b. In the chronic stages the inflammatory profile shifts to mononuclear cells
2. The parasite induces long-lasting molecular cross talk with the host by means of muscle larvae excretory secretory products (ESL1). These molecules modulate parasite-specific immune responses. This immunomodulatory network encompasses Th2 and Treg-type responses
3. In chronic stages there is focal calcification of cysts, fibrosis and granuloma formation

Laboratory Evaluation

1. Eosinophilic leukocytosis
2. Increased serum CK
3. Serum antibodies against *Trichinella spiralis* can be detected 3–4 weeks after the infestation

Cysticercosis

General Characteristics

1. Cysticercosis is usually caused by the ingestion of undercooked meat, primarily pork that contains the larva form of *Taenia solium*
2. The tongue and calves are frequently involved
3. Muscle involvement is frequently overshadowed by seizures, encephalopathy, and focal neurologic deficits

Neuropathology

1. Muscle biopsy:
 - a. Larvae may be surrounded by eosinophils, plasma cells, macrophages, lymphocytes and occasional giant cells within a fibrotic capsule
 - b. Chronic lesions calcify

Laboratory Evaluation

1. Serum CK is elevated
2. Increased serum eosinophil counts

Toxoplasmosis

General Characteristics

1. Toxoplasmosis is caused by the protozoa *Toxoplasma gondii* and is a life-threatening infection in immunocompromised patients
2. Cerebral toxoplasmosis is extremely common in HIV immune-compromised patients as well as patients undergoing solid organ transplantation and hematopoietic stem cell transplantation. It can occur in immunocompetent patients

Clinical Manifestations

1. Myositis can occur in isolation or may be associated with systemic disease
2. Onset is with fever, myalgias and weakness

Neuropathology

1. Muscle biopsy:
 - a. Lymphocytes, macrophages and some giant cells invade the endomysium and perimysium
 - b. Cysts that contain the bradyzoite stage are more common in muscle than the free tachyzoite form
2. The mode of infection is by ingestion of oocysts from contaminated food or cysts that contain bradyzoites from undercooked food. The organisms mature to tachyzoites which spread through the bloodstream and lymphatics

Laboratory Evaluation

1. Serum CK levels are increased
2. EMG:
 - a. An inflammatory myopathic pattern
3. Definitive diagnosis relies on parasite DNA detection by PCR:
 - a. Serologic tests include:
 - i. Sabin-Feldman dye
 - ii. Complement fixation
 - iii. Indirect hemagglutination
 - iv. Indirect fluorescent antibody test

Differential Diagnosis of Myositis Autoantibodies

Overview

1. The well tested clinically relevant autoantibodies are separated into two groups based on their diagnostic accuracy in determining a specific myositis phenotype:
 - a. The myositis-specific antibodies (MSA) include:
 - i. Their diagnostic specificity for autoimmune myositis is greater than 90%
 - ii. They target cytoplasmic or nuclear ribonucleoproteins that are involved in gene transcription, protein synthesis, translocation and innate antiviral immune responses

- iii. They are associated with distinct disease phenotypes
- b. Myositis-associated antibodies (MAA):
 - i. May be present in 50% of myositis patients
 - ii. Are not disease-specific
 - iii. Primarily found in myositis overlap symptoms

Myositis-Specific Antibodies (MSA)

Anti-ARS Antibodies

1. ARS are cytoplasmic enzymes that catalyze the reaction that synthesizes the antibodies. Eight t-RNA synthetases have been identified as immunologic targets and include:
 - a. Histidyl (Jo-1)
 - b. Threonyl (PL-7)
 - c. Alanine (PL-12)
 - d. Glycyl (EJ)
 - e. Isoleucyl (PL-12)
 - f. Asparaginyl (KS)
 - g. Tyrosyl (Ha)
 - h. Phenylalanyl (Zo)
2. Anti-Jo-1:
 - a. Is found in 20–30% of patients with PM and 60–70% of myositis patients with interstitial lung disease
 - b. Anti PL-7, PL-12 occur in <5% of PM and DM patients
 - c. Anti-KS, OJ, EJ, Zo and Ha in less than 2% of PM or DM
 - d. Anti-ARS antibodies are associated with myositis and:
 - i. Interstitial lung disease (ILD)
 - ii. Raynaud's phenomenon
 - iii. Thick and cracked hand skin

Anti-SRP Antibody

1. SRP is a cytoplasmic multimeric ribonucleoprotein that is a complex of six polypeptides with one 7SL RNA
2. It is involved in secretory protein recognition and translocation across the rough endoplasmic reticulum
3. Anti-SRP antibodies are specific for idiopathic inflammatory myopathies
4. They are found in 4–8% of PM patients
5. They are associated with the anti-SRP syndrome:
 - a. Necrotizing myopathy
 - b. Myofiber necrosis and regeneration with little inflammation
 - c. Rapidly progressive weakness with poor response to treatment

Anti-TiF1-V Antibody

1. The antibody is found in 20–30% of adult and juvenile DM patients
2. It is directed against nuclear transcription factors that belong to the Transcriptional intermediary factor (TiF-1) family

3. The antibody is associated with severe skin lesions in both adult and juvenile DM
4. It is also associated with paraneoplastic DM in adult patients (>50 years of age)

Anti-NXP-2 Antibody

1. The autoantibody is detected against a nuclear protein (nuclear protein 2; NXP2)
2. These antibodies have been detected in approximately 25% of juvenile or adult DM patients but rarely in PM
3. In adolescent onset DM:
 - a. Severe cutaneous lesions that include calcinosis
 - b. Muscle contractures
 - c. An association with cancer has been documented in male adults
 - d. If both anti-TiF-1-V and anti-NXP-2 antibody testing is done for cancer-associated DM, the yield is approximately 50%

Anti-MDA5 Antibody

1. IFN-induced melanoma differentiated-associated proteins 5 (MDA5):
 - a. Is seen in 20–30% of Asian patients with DM
 - b. Clinical Manifestations include:
 - i. Amyopathic DM
 - ii. Rapidly progressive interstitial lung disease
 - c. MDA5 regulates the innate antiviral immune response against cytoplasmic viral RNA
 - d. Anti-MDA5 may also be seen in Caucasian patients with idiopathic inflammatory myopathy with ILD

Anti-SAE Antibody

1. Anti-small ubiquitin-like modifier activating enzyme (SAE) antibodies are found in 8% of adult DM patients
2. Clinical manifestation include:
 - a. Severe skin disease
 - b. Dysphagia
 - c. Systemic features
3. Related to a specific HLA haplotype
4. Antibodies are directed against SUMO-1 activating enzyme heterodimer which is a small nuclear protein that resembles ubiquitin
5. The enzyme effects sumoylation which is a post-translation enzymatic aggregation of protein

Anti-HMGCR Antibody

1. The autoantibody has been detected in 3–8% of adult idiopathic inflammatory myopathies (IIM)
2. The antibody is directed against 3-hydroxy-5-methylglutaryl-Coenzyme A reductase (HMGCR); an important component of cholesterol synthesis inhibited by statins
3. A putative marker of a necrotizing myopathy most often but not invariably induced by statins exposure
4. Associated Clinical Manifestations include:
 - a. Similar to other IIM

- b. Proximal muscle weakness
- c. Elevated CK levels
- d. Myopathic EMG pattern
- e. Response to immunosuppressive therapy
- f. Myofiber necrosis and degeneration with inflammatory cells

The Major Myositis Associated Antibodies

1. Include anti-Ro/SSA, anti-PM/Scl, anti-Ku and anti-U1RNP antibodies
2. They are found when PM/DM phenotype is seen with another connective tissue disease as a component of an overlap syndrome
3. These antibodies may also be detected in the absence of another Connective tissue disease (CTD)
4. The overlap of PM/DM and systemic sclerosis (PDM/SSc) accounts for 44% of scleroderma overlap syndrome

Anti-Ro/SSA

1. The antibody is directed against the Ro52 subunit and is the most common MAA in myositis
2. Anti-Ro/SSA and anti-LA/SSA are most often detected in PDM/Sjögren's syndrome patients
3. Anti-Ro/SSA is detected in approximately 30% of myositis patients in conjunction with ARS and other MAA antibodies
4. In anti-Jo-1 positive patients, the anti-Ro52 antibody association has been detected in patients with:
 - a. Severe ILD (interstitial lung disease)
 - b. Myositis
 - c. Joint involvement
 - d. Cancer risk

Anti-PM/Scl and Anti-Ku Antibodies

1. Are primarily markers of PDM/SSc, although they are found in PM, DM and systemic sclerosis without overlap
2. In patients with overlap PDM/SSc these antibodies are encountered in approximately 60% of patients
3. In addition to myositis in PM/Scl-positive PDM/SSc patients other clinical features include:
 - a. Raynaud's phenomenon
 - b. ILD
 - c. Arthritis
 - d. Thickened hand skin
4. Anti-PM/Scl and anti-Ku positive PDM/SSc are most often detected in the limited form of cutaneous scleroderma. These patients demonstrated less digital ulcer, more myositis, ILD and arthritis compared to anti-centromere antibody positive limited SSc
5. The HLA haplotype DGA1*0501, DQB1*02 and DRB1*0301 occur with anti-PM/Scl antibody that is associated with PDM/SSc

Anti-U1RNP

1. Anti-U1RNP are more common in patients with systemic lupus

2. Associated Clinical Manifestations in the overlap syndrome include:
 - a. Erosive arthritis
 - b. Alopecia
 - c. ILD
 - d. Oral ulcers
 - e. Renal disease is rare
 - f. DM is more common than PM

Summary of Myositis-Specific Antibodies (MSA)

Evidence Supports the Hypothesis

1. Myositis autoantigens are able to induce and maintain a B-cell antigen specific immune response in muscle
2. There is aberrant expression of Jo-1, Mi-2, HMGCR in the regenerating fibers of PM and DM
3. Classic and novel myositis antigens are over expressed in other organs:
 - a. Jo-1-lungs
 - b. M1-2-epidermal basal lamina
 - c. TiF-1-V (gamma) and NXP-2 in adenocarcinoma
4. Myositis antigens in target tissues act as proinflammatory and immunostimulants
5. Most myositis autoantigens are associated with nucleic acids which suggest that they stimulate IFN type 1 secretion pathways that increase antigen concentration and the extent of the immune response

Myopathies of Systemic Disease

Thyrototoxic Myopathy

General Characteristics

1. Thyroid hormone is a major determinant of the composition of muscle fibers
2. MicroRNA 133a1 targets the gene associated with thyroid hormone in muscle. It regulates slow-to-fast twitch muscle fiber type conversion by targeting TEA antigen domain family member
3. 1 (TEAD1) which is a major regulator of slow muscle gene expression
4. TH negatively regulates the transcription of myosin heavy chain 1 indirectly via miR-133a/TEAD
5. It is proposed that TH inhibits the slow muscle phenotype through an epigenetic mechanism involving microRNA-133a1
6. The exact molecular mechanism of thyroid hormone on muscle in deficit or excess is not known

Clinical Manifestations

1. Most hyperthyroidism has its onset in the 5th decade
2. The myopathy severity may not correlate with the degree of thyrotoxicosis
3. The onset of myopathy is often after the other manifestations of hyperthyroidism are manifest

4. Thyrotoxicosis is more common in females while the myopathy is more frequently seen in males
5. Approximately 60–80% of patients with hyperthyroidism have proximal myopathy by exam. It is a rare chief complaint
6. Proximal muscle weakness and atrophy. It may preferentially affect the shoulder girdle and rhomboid muscles
 - a. Distal weakness may predominate in 20% of patients
 - b. Bulbar and intercostal muscles may be affected:
 - i. Thyroid ophthalmopathy and proptosis (Collier's sign) occurs with Grave's disease
7. Rhabdomyolysis can occur with severe thyrotoxicosis
8. Muscle stretch reflexes are increased; rarely fasciculation and myokymia are seen:
 - a. The tongue is very active and may demonstrate apparent fibrillation
9. There may be associated MG (myasthenia gravis). Thyrotoxicosis myopathy does not fluctuate, has more atrophy than what is seen in MG, and does not respond to anticholinesterase therapy
10. Association with hypokalemic periodic paralysis:
 - a. Sporadic occurrence, but appears to be most common in Asian patients
 - b. More common in males
 - c. Attacks are similar to those of familial hypokalemic periodic paralysis but occur later in life
 - d. Most often, the serum potassium concentration is low during attacks but may be normal
 - e. Treatment of the thyrotoxicosis stops the attacks

Neuropathology

1. Muscle biopsy:
 - a. May be normal
 - b. Rare patients demonstrate:
 - i. Variability of fiber size
 - ii. Central nuclei
 - iii. Type 1 and 2 fiber atrophy
 - iv. Rare necrotic fibers
2. Electron microscopy (in some patients demonstrate):
 - a. Z-band streaming
 - b. Swelling of T-tubules
 - c. Elongated mitochondria
 - d. Decreased mitochondria
 - e. Subsarcolemmal glycogen
3. EM in patients with periodic paralysis:
 - a. Vacuoles (centrally placed in myofibers)
 - b. Sarcolemmal blebs filled with glycogen
 - c. Dilated terminal cisternae of the sarcoplasmic reticulum
4. Thyroid hormone causes increased potassium reflux from muscle; there may be an increased number of Na/K ATPase pumps in the muscle membrane that causes this reflux

Laboratory Evaluation

1. CK concentration is usually normal

2. TSH level is decreased in the face of increased thyroxine (T₄) and T₃ elevation
3. EMG:
 - a. It is usually normal
 - b. Rarely repetitive and complex discharge may be seen
 - c. NCS are normal

Hypothyroid Myopathy

General Characteristics

1. Approximately one-third of patients with hypothyroidism develop muscle symptomatology
2. Hypothyroidism is associated with reduced oxidative metabolic capacity and is associated with fiber type switching from fast- to slow-twitch as well as insulin resistance

Clinical Manifestations

1. The Kocher-Debre-Semelaig syndrome may be seen in congenital hypothyroidism which is characterized by:
 - a. Generalized muscular hypertrophy
 - b. Predominant calf hypertrophy
2. Adult hypothyroid patients:
 - a. Proximal extremity muscle weakness
 - b. Myalgias, cramps and fatigue
 - c. A subset of patients may develop generalized muscle hypertrophy (Hoffman syndrome)
 - d. Rarely the respiratory muscle may be involved
 - e. Rhabdomyolysis can occur in severe patients
 - f. Delayed deep tendon reflex relation
 - g. Myoedema (painless and electrically silent mounding of muscle) can be elicited with percussion
 - h. There may be associated myasthenia gravis

Neuropathology

1. Muscle biopsy:
 - a. Variability of fiber size
 - b. Atrophy of type 2 fibers; rarely type 1 fibers are affected
 - c. Hypertrophic muscle fibers
 - d. Rare necrotic fibers
 - e. Central nuclei
 - f. Ring fibers
 - g. Increased glycogen
2. Electron Microscopy:
 - a. Mitochondrial swelling and inclusions
 - b. Myofibrillar disorganization; central core-like material
 - c. Autophagic vacuoles
 - d. Increased lipid and glycogen accumulation
 - e. Dilated sarcoplasmic reticulum
 - f. T-tubule proliferation

Muscle Biopsy in Hashimoto Disease

1. Moderate to severe muscle fiber atrophy
2. Autophagosomes

3. Capillary alterations
4. Fiber type 2 predominance
5. Infiltration of muscle cells by mast cells and macrophages
6. Immunoglobulin deposition occurs in 80% of patients

Laboratory Evaluation

1. The serum CK is markedly elevated (10–100x normal)
2. Low serum concentrations of T₃ and T₄ with elevated TSH levels
3. EMG:
 - a. Short duration, low amplitude polyphasic MUAPs in affected muscle
 - b. Normal motor and sensory conduction velocities unless there is a concomitant neuropathy

Hyperparathyroidism and Osteomalacia

General Characteristics

1. Muscle weakness occurs in > 70% of patients with osteomalacia and approximately 2%–10% in those with hyperparathyroidism
2. Primary hyperparathyroidism is most often caused by parathyroid edema or hyperplasia or pituitary edema
3. Secondary hyperparathyroidism is most often encountered in the setting of chronic renal failure which causes the reduction of 1, 25-dihydroxy-vitamin D conversion. In turn, there is decreased intestinal absorption of calcium and decreased renal phosphate clearance, which induces secondary hyperparathyroidism and osteomalacia
4. There are hereditary forms of both primary hyperparathyroidism and vitamin D deficiency leading to osteomalacia
5. Parathyroid hormone:
 - a. Increases muscle proteolysis
 - b. Decreases muscle energy production, transfer and utilization
 - c. Decreases the sensitivity of contractile myofibrillar proteins to calcium
6. Vitamin D:
 - a. Increases muscle adenosine triphosphatase concentration, which accelerates amino acid protein incorporation into muscle
 - b. Enhances calcium uptakes by the sarcoplasmic reticulum and mitochondria

Clinical Manifestations of PTH and Osteomalacia

1. Symmetric proximal muscle weakness that is more severe in the lower extremities
2. Concomitant microfractures of bone with pain
3. Neck extensor weakness may cause the “dropped head” syndrome
4. Unusual signs and symptoms (controversial):
 - a. Hoarseness
 - b. Dysphagia
 - c. Spasticity
 - d. Respiratory muscle involvement

5. Increased muscle stretch reflexes with no Babinski sign
6. Approximately 50% of patients have severe cramps and paresthesia
7. A significant number of patients have a stocking-and-glove pattern of large or small fiber sensation and decreased muscle stretch reflexes that support the diagnosis of peripheral neuropathy
8. Psychiatric and behavioral manifestations from the hypercalcemia
 - a. In secondary hyperparathyroidism:
 - i. Proximal muscle weakness occurs in a setting of renal failure
 - ii. Muscle neurosis and myoglobinuria occur and may be due to arterial calcification in some patients

Neuropathology

1. Muscle biopsy:
 - a. No specific myopathy
 - b. Type 2 fiber atrophy; rarely Type 1 atrophy
2. The calcium-sensory receptor (CaR) modulates renal calcium reabsorption and parathyroid hormone PTH secretion; it is involved in the secondary hyperparathyroidism of chronic kidney disease. Pathophysiologic PH (acidification) that occurs in chronic kidney disease (CKD) inhibits CaR activity

Laboratory Evaluation

1. Serum CK concentration is most often normal in primary and secondary hyperparathyroidism as well as osteomalacia
2. In primary hyperparathyroidism:
 - a. Calcium serum concentrations are elevated and phosphate concentrations are low
 - b. Urinary calcium excretion is low and excretion of phosphate is high
 - c. Elevated excretions of cyclic adenosine monophosphate with hypercalcemia
 - d. Serum PTH levels and 1,25-dihydroxy-vitamin D levels are elevated in PTH
 - e. There are low levels of 1,25-dihydroxy-vitamin D levels (and therefore decreased calcium intestinal absorption) in secondary hyperparathyroidism due to renal failure
3. In osteomalacia:
 - a. Low serum calcium concentration
 - b. Serum phosphate concentration is low
 - c. Low serum 25 OH vitamin levels are low
 - d. Urinary excretion of calcium is low except with renal tubular acidosis and when phosphate excretion is elevated
 - e. Serum alkaline phosphatase is elevated in osteomalacia
4. Bone X-ray with primary hyperparathyroidism:
 - a. Salt-and-pepper lesions in the skull
 - b. Bone erosion and resorption of the phalanges (radial side of the index finger) and acromial portion of the clavicle

- c. Brown tumors and cysts
- d. Diffuse demineralization
- e. Pathological fractures of the long bones
5. DEXA X-ray absorptiometry (DEXA) scan and the trabecular bone (gray-level) textural analyses of DEXA images demonstrates an indirect index of trabecular microarchitecture
6. Loss of trabeculae, thinned bone cortices and abnormal trabecular microstructures are demonstrated

Hypoparathyroidism

General Characteristics

1. Hypoparathyroidism occurs in a wide spectrum of diseases that include:
 - a. Surgical complications
 - b. Osteomalacia
 - c. Hypo- or hypomagnesemia
 - d. X-RT
 - e. Drugs
 - f. Sepsis
 - g. Infiltrative diseases
 - h. Hereditary and developmental diseases

Clinical Manifestations

1. A few patients have been described with proximal muscle weakness
2. Painless myoglobinuria without weakness may occur (rare)

Neuropathology

1. Muscle biopsy:
 - a. Variability of fiber size
 - b. Central nuclei
 - c. Decreased glycogen phosphorylase activity

Laboratory Evaluation

1. The serum CK is normal or minimally elevated
2. Low serum PTH with high serum phosphate levels
3. EMG:
 - a. Needle EMG reveals normal insertional activity but doublets or triplets or multiple MUAPs
 - b. MUAP morphology and recruitment are normal
 - c. Normal motor and sensory nerve conduction studies

Hyperadrenalism

General Characteristics

1. Approximately 60% of patients with Cushing's disease have muscle weakness
2. The zona fasciculata of the adrenal gland produces and secretes glucocorticoids. Adrenal tumor or hyperplasia of the adrenal gland often cause excess secretion of glucocorticoids and proximal myopathy
3. Rarely the zona glomerulosa, which is the source of mineralocorticoids such as aldosterone cause a proximal myopathy by means of a hypokalemic mechanism
4. Anabolic steroids from the zona reticularis increase muscle mass and strength

Steroid Myopathy

General Characteristics

1. Steroid myopathy, most often from exogenous use for immunosuppression, and rarely from adrenal or pituitary tumors, are the most common endocrine-induced myopathy
2. The fluorinated glucocorticoids such as dexamethasone, triamcinolone and beta-methasone are more destructive to muscle than other glucocorticoid preparations

Clinical Manifestations

1. Approximately 50–80% of endogenous or iatrogenic induced Cushing's disease develop proximal myopathy
2. Distal extremity, ocular, bulbar and facial muscles are not affected
3. Women have a higher risk of developing steroid myopathy than men
4. Alternate day dosing may decrease the risk of developing a myopathy
5. Proximal weakness occurs after several weeks of high dose therapy (>30 mg of prednisone) but is usually noted with chronic usage
6. Acute quadriplegia may occur with high dose intravenous usage with or without neuromuscular blocking agents in critically ill patients or those treated for asthma

Neuropathology

1. Muscle biopsy:
 - a. Atrophy of Type 2B fibers
 - b. Less atrophy and increased lipid deposition in Type I fibers
2. The catabolic effects of glucocorticoids on muscle proteolysis may be due to activation of the major cellular proteolytic systems:
 - a. Ubiquitin proteasome
 - b. The lysosomal system (cathepsin)
 - c. Calcium dependent system (calpain)
3. The microfibrillar proteins are primarily affected. Actin and myosin are dissociated by calpain and then are acted upon by the ubiquitin proteasomal system
4. The mechanisms of glucocorticoid inhibition of protein synthesis include:
 - a. Inhibition of amino acid transport into muscle
 - b. Inhibition of insulin, insulin-like growth factor and leucine in the phosphorylation of 4E-BP1 and S6K1. These transcriptional factors control the initiation of mRNA translation
 - c. Possible role of glucocorticoids in inhibiting myogenesis by down-regulation of myogenin, a transcription factor that is essential for satellite cell differentiation into muscle cells
 - d. Glucocorticoid muscle atrophy may be caused by:
 - i. Decreasing the production of IgF-1, which increases protein synthesis and myogenesis

- ii. Stimulating the production of myostatin which down-regulates the proliferation and differentiation of satellite and protein synthesis
- e. Glucocorticoids may have a deleterious effect on mitochondria as well as producing hypokalemia
 - f. Endogenous Cushing's syndrome
 - i. Elevated levels of ACTH decrease the quantal content of the endplate potential, which impairs neuromuscular transmission

Laboratory Evaluation

1. Serum CK is not affected
2. Serum potassium and phosphate may be low and sodium slightly elevated
3. EMG:
 - a. EMG and NCS are normal

Adrenal Insufficiency

General Characteristics

1. Adrenal insufficiency is the deficient production or action of glucocorticoids, mineralocorticoids and adrenal androgens
2. It is classified as: 1. primary (the adrenal cortex is affected), 2. secondary from anterior pituitary gland dysfunction and 3. tertiary from disorders of the hypothalamus

Clinical Manifestations

1. The primary features include:
 - a. Anorexia
 - b. Abdominal pain
 - c. Weight loss
 - d. Orthostatic hypotension
 - e. Hyperpigmentation of the skin with primary adrenocortical failure
2. In secondary or tertiary adrenal insufficiency, clinical features result from glucocorticoid deficiency
3. Subjective muscle weakness
4. Overwhelming fatigue
5. Objective weakness (proximal muscles) may be the result of hyperkalemia or other associated endocrinopathies

Neuropathology

1. Muscle biopsy
 - a. Normal

Laboratory Evaluation

1. Serum CK concentration is normal
2. EMG is normal

Acromegaly

General Characteristics

1. Growth hormone producing adenomas in 10–15% of all pituitary adenomas. The two most common types are densely and sparsely granulated
2. The muscle weakness is correlated with the length of the illness rather than the level of growth hormone

Clinical Manifestations

1. Patients develop slowly progressive proximal arm and leg weakness with slight muscle hypertrophy
2. Associated neurologic complications that cause weakness include:
 - a. Entrapment neuropathies (particularly carpal tunnel syndrome)
 - b. Bony overgrowth of face and joints and spinal exit foramina with concomitant nerve root and spinal cord compression
 - c. Severe arthropathy with pain that causes disuse atrophy

Neuropathology

1. Muscle biopsy:
 - a. Variation of muscle fiber size
 - b. Hypertrophy and atrophy of all fiber types
 - c. Scattered necrotic fibers
 - d. Hypertrophy of satellite cells
 - e. Electron microscopy:
 - i. Myofibrillar loss
 - ii. Abnormal glycogen accumulation
 - f. Effects of increased growth hormone:
 - i. Increased protein synthesis of muscle fibers that causes hypertrophy
 - ii. Decreased respiratory quotient of muscles
 - iii. Switch from carbohydrate to lipid metabolism
 - iv. Decreased myofibrillar ATPase activity

Laboratory Evaluation

1. Serum CK is normal or minimally increased
2. EMG:
 - a. Myopathic pattern with short duration and low amplitude MUAPs of affected proximal muscles
 - b. NCS are normal or demonstrate compression entrapment neuropathies, the most common of which are at the carpal cubital tunnels

Panhypopituitarism*General Characteristics*

1. Mutations in genes encoding both signaling molecules and transcription factors have been described in hypopituitarism that occur with and without specific syndromic features which include:
 - a. Dominant and recessive mutation in HESX1 are associated with septo-optic dysplasia
 - b. Duplications and polyalanine expansions within the SOX3 transcription factor are associated with infundibular hypoplasia, hypopituitarism and cognitive deficiency
 - c. Mutations in the transcription factor SOX2 cause hypopituitarism, cognitive deficits, and, esophageal atresia
 - d. Mutations within the LIM domain of the LHX3 gene are recessive and cause GH, TSH, LH and FSH deficiencies but spare the corticotrophs. These patients manifest a short, stiff neck with restricted lateral rotation

- e. Mutations of the LHX4 gene are dominantly inherited and cause GH, TSH, and ACTH deficiencies. They are associated with a hypoplastic anterior pituitary, deficits in the posterior pituitary and alterations of the cerebellar tonsils
- f. PROP1 and POV1F are recessive mutations within pituitary-specific transcription factors. Mutations of Pit1 or POP1 cause deficiencies of GH, prolactin and TSH; variable LH and FSH deficiencies. This mutation may be associated with an enlarged sella turcica that simulates an intrasellar tumor. The mutation may also be associated with ACTH deficiency
- g. POOF1 mutations may cause a hypoplastic anterior pituitary that is associated with GH, and prolactin deficiencies
- h. Acquired pan-hypopituitarism more frequently occurs from intrasellar compression and destruction from enlarged chromophobe adenomas, X-RT therapy for gliomas post-surgery and rarely hemorrhage (apoplexy, lymphocytic hypophysitis and Sheehan syndrome)

Clinical Manifestations

1. Generalized muscle weakness and severe fatigue
2. Patients may have the muscle manifestations of secondary hypothyroidism and glucocorticoid deficiency
3. Prepubertal pan-hypopituitarism is associated with dwarfism and deficient sexual and muscle development. These patients may have an alabaster white complexion due to lack of MSH

Neuropathology

1. Thyroid and cortical steroid deficiencies as well as decreased GH, thyroid and sexual hormones all determine aspects of muscle pathology

Laboratory Evaluation

1. Dependent on the spectrum of hormonal deficiencies incurred

Diabetic Muscle Infarction (Diabetes Myoneurosis)*General Characteristics*

1. Diabetic myoneurosis is an unusual and underdiagnosed complication of poorly controlled diabetes
2. The setting is in patients with retinopathy, nephropathy and neuropathy

Clinical Manifestations

1. The usual presentation is acute pain and swelling in the thigh. The calf may be affected rarely
2. The mean age of patients is 44.5 years (range 20 to 67 years); the length of time patients had diabetes was 19 years (range 5 to 33 years)

3. A tender mass may be palpated in the vastus lateralis, biceps femoris, thigh adductors and the gastrocnemius muscle
4. Nephropathy is the most common diabetic complication and is seen in approximately 75% of patients

Neuropathology

1. Muscle biopsy:
 - a. Muscle infarction with areas of necrosis, edema, hemorrhages and inflammatory infiltrate. Chronically, the infarcted areas are replaced by connective and adipose tissue
 - b. There is thickening of the basement membrane, hyperplasia of the media, fibrin occlusion of the lumen and calcification of small and medium-sized muscle blood vessels
 - c. Suggested mechanisms for diabetic myonecrosis include:
 - i. Reperfusion of ischemic tissue associated with endothelial dysfunction
 - ii. Hypercoagulability
 - iii. Inflammatory vasculopathy

Laboratory Evaluation

1. The serum CK concentration is usually normal
2. EMG:
 - a. Muscle membrane instability with positive sharp waves and fibrillation potentials
 - b. Small polyphasic MUAPs with early recruitment
3. MRI:
 - a. T2-weighted signal abnormalities in the infarcted tissue

Myopathies Associated with Electrolyte Abnormalities (Hypokalemia)

General Characteristics

1. Hypokalemia with muscle weakness is similar to familial hypokalemic periodic paralysis both clinically and electrodiagnostically

Clinical Manifestations

1. Most often patients present with symmetric proximal weakness, although there may be asymmetry and distal involvement
2. Weakness is often associated with cramps, myalgia and a feeling of swelling in the affected muscles
3. Reflexes are absent (deep tendon) and there are no myotatic reflexes (muscle contractions from percussion)
4. Rarely there is rhabdomyolysis with myoglobinuria and renal involvement
5. Cardiac arrhythmia

Neuropathology

1. Muscle biopsy:
 - a. Vacuoles in myofibers
 - b. Scattered necrotic fibers
2. The muscle membrane may not be excitable in the face of decreased extracellular K^+ concentration

Laboratory Evaluation

1. The serum potassium level is less than 2.5 mEq/L before the muscle is affected
2. Serum CK concentrations are elevated
3. EMG:
 - a. Positive sharp waves and fibrillation potentials
 - b. Small amplitude and brief durations of MUAPs with early recruitment
 - c. NCS are normal
4. EKG:
 - a. Brachycardia
 - b. Prolonged PR and QT intervals
 - c. Flattened T-waves
 - d. U waves

Differential Diagnosis of Secondary Hypokalemia

1. Thyrotoxic periodic paralysis
2. Renal tubular acidosis
3. Villous adenoma of the intestine
4. Bartter syndrome
5. Gitelman syndrome
6. Sjögren's syndrome
7. Hyperaldosteronism
8. Diuretics, glucocorticoids, licorice
9. Amphotericin B toxicity
10. Alcoholism
11. Toluene toxicity
12. Barium poisoning

Hyperkalemia

General Characteristics

1. Hyperkalemia causes prolonged depolarization of the sarcolemmal membrane that inactivates sodium channels, which blocks the initiation of an action potential
2. Increased muscle membrane excitability

Clinical Manifestations

1. Generalized muscle weakness
2. Chvostek sign
3. Myotonic lid lag

Neuropathology

1. Muscle biopsy:
 - a. Normal

Laboratory Evaluation

1. In patients with severe weakness the potassium level is usually greater than 7 mg/L (most often in renal failures)
2. Serum CK levels are usually normal
3. EMG:
 - a. Small amplitude MUAPs, with early recruitment
 - b. No myotonic discharges occur with acquired hyperkalemia
 - c. Nerve conduction studies are normal

Differential Diagnosis of Secondary Hyperkalemic Paralysis

1. Addison's disease

2. Hyperaldosteronisms
3. Isolated aldosterone deficiency
4. Increased potassium intake
5. Potassium sparing diuretics (spironolactone and triamterene)
6. Chronic renal failure
7. Rhabdomyolysis

Hypophosphatemia

General Characteristics

1. A wide spectrum of diseases are associated with hypophosphatemic myopathy, the most common of which are hyperalimentation, phosphate-binding antacids, diabetic ketoacidosis and severe diarrhea
2. Usually serum phosphate levels less than .4 M/L are required to produce muscle disease

Clinical Manifestations

1. Generalized muscle weakness
2. Associated:
 - a. Guillain-Barré-like syndrome
 - b. Paresthesias and dysesthesias
 - c. Hypophosphatemia osteomalacia
 - d. Bone and joint pain

Neuropathology

1. Muscle biopsy:
 - a. Not described
2. Abnormalities in muscle density and decreased peak force probably occur if it is associated with hypophosphatemia rickets

Laboratory Evaluations

1. Dependent on the associated disease
2. In hypophosphatemic rickets there may be associated hyperglycemia and increased hydroxyprolinuria
3. In adult hypophosphatemic osteomalacia with myopathy there may be associated low levels of 25 – OHY-Vitamin D3

Differential Diagnosis of Hypophosphatemia

1. Diabetic ketoacidosis
2. Hyperalimentation
3. Primary Sjögren's syndrome
4. Hypophosphatemic rickets
5. Fanconi syndrome (adefovir)
6. Burn patients
7. Severe diarrhea

Rare Myopathies Associated with Systemic Disease

Amyloid Myopathy

General Characteristics

1. Primary systemic myositis usually presents with nephrotic syndromes, cardiomyopathy, hepatomegaly and peripheral

neuropathy. Amyloid myopathy is rare. It does not occur in secondary amyloidosis. It does occur in familial forms

Clinical Manifestations

1. Presents with the serum indices, subacute onset of primarily proximal myopathy. A subset of patients may have distal involvement. (may be related to a concomitant peripheral neuropathy)
2. Hypertrophy of involved muscles
3. Tongue involvement (macroglossia)
4. Muscles of respiration may be involved from myopathy of the diaphragm or phrenic nerve neuropathy
5. Pain, stiffness and indurations of involved muscle occurs

Neuropathology

1. Muscle biopsy:
 - a. Variability of fiber size
 - b. Hypertrophied and atrophied fibers
 - c. Increased central nuclei
 - d. Scattered degenerating and regenerating fibers
 - e. Grouped atrophy (associated denervation)
2. Amyloid deposits surround small arterioles and venules but may also encase muscle fibers
3. In primary amyloidosis the deposits are composed of K light chains, which may be associated with membrane attack complexes
4. APOE may be concomitantly deposited
5. Electron microscopy:
 - a. Deposition of non-branching 10 nm amyloid filaments that surround small blood vessels and muscle fibers

Laboratory Evaluation

1. Elevation of serum CK 2–5 times normal but has been described as markedly elevated with gelsolin familial amyloidosis
2. Primary amyloid (light chain amyloidosis): there is increased monoclonal immunoglobulin in the serum or urine
3. EMG:
 - a. Irritable muscle membrane with positive sharp waves and fibrillation potentials (prominent in paraspinal and proximal arms and legs). There may be complex and repetitive myotonic discharges
 - b. Weak proximal muscles demonstrate low amplitude polyphasic MUAPs, which are recruited early
 - c. Nerve conduction studies are abnormal in those patients with concomitant peripheral neuropathy
4. MRI of muscle:
 - a. Hypointense reticular appearance of subcutaneous fat with minimal muscle signal intensity supports the diagnosis of primary amyloidosis

Polymyalgia Rheumatica (PMR)

General Characteristics

1. PMR is the second most common inflammatory autoimmune rheumatic disease in the United States

2. Annual incidence is 58.7 per 100,000 people over the age of 50
 - a. The mean age at diagnosis is 73 years. Its incidence increases with age; it is more common in Caucasian people of northern latitudes

Clinical Manifestations

1. An insidious onset is usual, but cases of acute onset occur in patients between 70–79 years of age
2. A diffuse muscular non-articular pain occurs in the neck, shoulder or pelvic girdle
3. A low grade fever and fatigue often accompany the muscle pain
4. Strength is normal although most patients complain of weakness
5. Approximately 16% of patients develop concomitant temporal arteritis
6. Stiffness that lasts for a half hour or longer occurs in the morning or after periods of activity which may improve with activity which contrasts with osteoarthritis
7. Constitutional symptoms, in addition to low grade fever, include fatigue, malaise, anorexia, weight loss, are common
8. A subset of PMR patients has swelling of distal joints in the hands and feet due to tenosynovitis that results in seronegative symmetrical synovitis with pitting edema syndrome

Neuropathology

1. Muscle biopsy:
 - a. Usually normal
 - b. Variation in fiber size
 - c. Type 2 fiber atrophy
 - d. Moth eaten fibers
 - e. No inflammatory changes

Laboratory Evaluation

1. Increased ESR, usually over 40 mm/hr; normal in 6–20% of patients
2. Normal serum CK
3. Normal EMG and NCS
4. Ultrasonography and MRI imaging:
 - a. Affects primarily the periarticular structures:
 - i. Subacromial bursitis
 - ii. Subdeltoid bursitis
 - iii. Trochanteric bursitis
 - iv. Glenohumeral and hip joint effusions and synovitis
 - b. Variabilities in temporal arteries can occur in (<8%) in asymptomatic patients (giant cell arteritis)

Toxic Myopathies

Overview

Cholesterol lowering medications that include 3-hydroxy-3-methyl-glutaryl-coenzyme A (3-HMG-CoA) reductase inhibitors, fibric acid derivatives, niacin, and ezetimibe all can

cause a toxic myopathy and are in wide use. There is a wide spectrum of clinical phenomena from asymptomatic increase in serum creatine kinase concentration to a severe necrotizing myopathy with myoglobinuria and renal failure. In general the degree of increased CK in the serum corresponds with the extent of muscle damage and discontinuance of the medication resolves the myopathy. However, in a subset of patients, these drugs can trigger a severe immune-mediated inflammatory or necrotizing myopathy. A mechanistic approach to toxic myopathies includes those caused by 1. necrotizing myopathy, 2. amphiphilic toxicity, 3. antimicrotubular myopathy, 4. mitochondrial dysfunction, 5. inflammation, 6. hypokalemia and 7. critical illness.

HMG-CoA Reductase Inhibitors

General Characteristics

1. Statins inhibit 3-HMG-CoA reductase the rate limiting enzyme for cholesterol synthesis
2. The downstream pathways from this enzyme blockade that are important for muscle metabolism and may be a component of 3-HMG-CoA reductase toxicity include:
 - a. Geranylgeranyl which is pivotal in the biosynthesis of coenzyme Q
 - b. Dolichol, which is a component of glycoprotein synthesis
3. Isopentylamine, which is component of tRNA and regulatory proteins
4. Squalene is the first metabolite in the synthesis of cholesterol and is derived from mevalonate, the first product of HMG-CoA reductase

Clinical Manifestations

1. The major statins include:
 - a. Lovast
 - b. Simvastatin
 - c. Pravastatin
 - d. Atorvastatin
 - e. Fluvastatin
 - f. Cerivastatin
2. All may cause:
 - a. Asymptomatic elevation of CK
 - b. Proximal muscle weakness
 - c. Myalgia
 - d. Myoglobinuria
3. There is a 2–7% incidence of myalgia and a .1–1% incidence of weakness or elevated CK; myoglobinuria occurs in <.5% of patients
4. A recent study of 35% of biopsied patients, 233 of whom fulfilled criteria for inflammatory/immune-mediated myopathy show that this complication of statin is increasing (anti-HMGCR autoantibodies)
5. The risk of toxic myopathy increases with the addition of fibric acid drugs, niacin, erythromycin, cyclosporine and ezetimibe. These combinations also raise the risk of kidney and liver complications. The combination of lovastatin

and cyclosporine causes a severe myopathy in as many as 30% of patients

6. Statin use can cause dermatomyositis
7. Recently it has been demonstrated that progressive proximal weakness, elevated serum CK levels, a necrotizing myopathy or muscle biopsy and autoantibodies to HMGCR is a major cause of immune-mediated myopathy that occurs with statin use

Neuropathology

1. Muscle biopsy:
 - a. Muscle fiber necrosis with phagocytosis
 - b. Lipid-filled vacuoles within myofibers
 - c. Cytochrome oxidase-negative fibers
 - d. No endomysial inflammatory infiltrate involving non-necrotic muscle fibers

Laboratory Evaluation

1. Elevated CK serum concentration that is proportional to the degree of muscle destruction
2. EMG:
 - a. Increased insertional activity with positive sharp waves, fibrillation potentials (statins and cyclosporine)
 - b. Myopathic MUAPs
3. Antibodies to CR HMGCR in patients with statin induced autoimmune myopathy

Differential Diagnosis of Drugs Causing Necrotizing Myopathy

1. Cholesterol lowering agents
2. Cyclosporine
3. Labetalol
4. Propofol
5. Alcohol

Fibric Acid Derivatives

General Characteristics

1. Clofibrate and gemfibrozil are branched-chain fatty acid esters that can cause a myopathy usually within 2 to 3 months of use. The myopathy has been described to start after two years of use

Clinical Manifestations

1. Generalized weakness
2. Myalgias and cramps
3. Myoglobulinuria and rhabdomyalgia are rare complications
4. Patients using both clofibrate gemfibrozil or with concomitant HMG-CoA reductase inhibitors are at increased risk of developing a severe myopathy
5. Chronic kidney disease increases myopathy risk

Neuropathology

1. Muscle biopsy:

- a. Scattered necrotic fibers
- b. Experimental models demonstrate:
 - i. Non-inflammatory necrosis of muscle fibers
 - ii. Small atrophic fibers
2. Putative destabilization of the lipophilic muscle membrane

Niacin

General Characteristics

1. At pharmacologic doses niacin lowers total cholesterol, LDL-C, non-HDL-C, triglycerides, apolipoprotein B and lipoprotein(a). It increases levels of HDL-C and apolipoprotein A

Clinical Manifestations

1. May cause myalgia and cramps
2. Symptoms improve with discontinuance of the drug
3. Rhabdomyolysis has been reported in patients taking concomitant statins

Neuropathology

1. Muscle biopsy:
 - a. Not defined
2. Putative similar mechanism of action as statins (inhibit HMG-CoA reductase)

Laboratory Evaluation

1. Serum CK concentration may be markedly elevated
2. Electrodiagnostic studies have not been reported in detail

Ezetimibe

General Characteristics

1. Ezetimibe is a synthetic 2-azetidininone that inhibits the absorption of sterols (including cholesterol) in the intestine
2. It is primarily used as monotherapy or in combination with statins to reduce low-density lipoprotein cholesterol

Clinical Manifestations

1. Weakness
2. Myalgias
3. Increased serum CK concentration
4. Most complications occur in combination with statin therapy
5. Myopathy usually resolves within a short time after drug withdrawal

Neuropathology

1. A few patients have developed a probable necrotizing myopathy on an autoimmune basis

Laboratory Evaluation

1. Elevated serum CK concentrations in symptomatic patients

Cyclosporine and Tacrolimus*General Characteristics*

1. The immunophilins are the targets of cyclosporine and tacrolimus
2. Immunophilins are endogenous cytosolic peptidyl-prolyl isomerases that interconvert between the cis and the trans/positions. Cyclophilin catalyzes the esterous isomerizations of peptic bonds

Clinical Manifestations

1. Cyclosporine and tacrolimus are utilized primarily as immuno suppressants in transplant patients
2. They may cause the insidious onset of proximal myopathy after months of use
3. Myoglobinuria may be induced particularly with the concomitant use of anticholesterol agents and colchicines
4. Myalgias, weakness and cardiomyopathy (from tacrolimus) improve with withdrawal from the drugs
5. Associated tremor, myoclonus, mental status changes, seizures and movement disorders and posterior reversible encephalopathy may overshadow the myopathy with cyclosporine use

Neuropathology

1. Muscle biopsy:
 - a. Necrosis, vacuoles and type 2 muscle fiber atrophy
 - b. No endomysial inflammatory cell infiltrate of non-necrotic fibers

Laboratory Evaluation

1. Elevated CK serum concentration
2. EMG:
 - a. Increased insertional activity with positive sharp waves, fibrillation potentials and myotonic discharges
 - b. Early recruitment of small amplitude, brief duration MUAPs
 - c. NCS are normal
3. Putative mechanism is destabilization of lipophilic muscle membrane

Labetalol*General Characteristics*

1. Only a few patients have been reported with labetalol induced necrotizing myopathy

Clinical Manifestations

1. Patients may develop an acute or insidious onset of proximal myopathy or myalgia that resolves with medication withdrawal

Neuropathology

1. Muscle biopsy:
 - a. Normal
 - b. Necrotic and regenerating fibers
2. Electron microscopy (one patient):
 - a. Subsarcolemmal vacuoles

Laboratory Evaluation

1. Elevated CK levels in the serum
2. EMG:
 - a. Increased insertional activity
 - b. Myopathic pattern of short duration, small amplitude, polyphasic and early recruiting MUAPs

Propofol*General Characteristics*

1. Propofol is a widely used anesthetic and sedative often used in mechanically ventilated patients and for the treatment of status epilepticus
2. Its use in intensive care settings is due to:
 - a. Rapid onset of action with short half-life
 - b. Decreased cerebral oxygen consumption
 - c. Reduction of intracranial pressure
 - d. It is not associated with malignant hyperthermia

Clinical Manifestations

1. Propofol-related infusion syndrome:
 - a. Cardiac failure and arrhythmias (bradyarrhythmias, ventricular fibrillation)
 - b. Metabolic acidosis
 - c. Rhabdomyolysis
 - d. Acute kidney injury
 - e. Hyperlipidemia
 - f. Hepatomegaly
2. In one large study the reported incidence of propofol-related infusion syndrome was 1.1% (<1000 patients in the trial). There is reported 80% mortality with this complication
3. Acute quadriplegic myopathy has been reported with propofol use and high-dose intravenous corticosteroids

Neuropathology

1. Muscle biopsy:
 - a. Necrosis of skeletal and cardiac muscle
 - b. In patients with acute quadriplegic myopathy there may be necrosis and loss of thick filaments
2. Propofol alters the function of the mitochondrial respiratory chain that decreases adenosine triphosphate. Soya bean is added to propofol to increase its solubility that increases its triglyceride load. There is impaired fatty acid oxidation with an accumulation of toxic fatty acid intermediates in addition to cellular hypoxia and inability of the liver to metabolize lactate exacerbates acidosis. The impairment of lipid metabolites in both cardiac and skeletal muscle in addition to decreased ATP synthesis is the putative mechanism for myocytolysis. Other triggering mechanisms include excess exogenous and endogenous catecholamines and steroids administered to critically ill patients

Laboratory Evaluation

1. Markedly elevated serum CK levels

2. Hyperlipidemia
3. Usually severe metabolic acidosis
4. Rhabdomyolysis with myoglobinuria
5. EKG:
 - a. Brachyarrhythmias and ventricular fibrillation
 - b. ST-segment elevation in right precordial leads

Amphiphilic Drug Myopathies (Drug-Induced Autophagic Lysosomal Myopathy)

General Characteristics

1. Chloroquine is a quinolone derivative that is used in the treatment of malaria and autoimmune diseases that include: 1. SLE, 2. sarcoid, 3. connective tissue diseases
2. It is amphiphilic, with separate hydrophobic and hydrophilic domains that enable it to interact with the anionic phospholipids of cell membranes

Clinical Manifestations

1. A subset of patients develops a slowly progressive, painless, proximal myopathy with atrophy
2. The lower extremities are more severely affected than the arms
3. The usual dose that is required for the myopathy is 500 mg/day for one year
4. There is often an associated neuropathy with sensory loss and decreased muscle stretch reflexes
5. A cardiomyopathy and retinopathy may also be associated

Neuropathology

1. Cardiac and skeletal muscle fibers demonstrate autophagic vesicles that preferentially affect type I fibers
2. The vacuoles are of lysosomal origin
3. Electron microscopy:
 - a. Vacuoles are filled with concentric lamellar myeloid material and curvilinear bodies
 - b. Autophagic vacuoles are also noted in peripheral nerves and Schwann cells
4. Chloroquine interacts with lipid membranes to form drug-lipid complexes that are not digested by liposomal enzymes, which causes the formation of autophagic vacuoles

Laboratory Evaluation

1. Serum CK levels are elevated
2. EMG:
 - a. Increased insertional activity with positive sharp waves, fibrillation potentials and myotonic discharges
 - b. Small amplitude, short duration polyphasic MUAPs in weak proximal muscles
 - c. If there is a concomitant neuropathy:
 - i. Motor or sensory nerve conduction velocities are minimally reduced
 - ii. Slight reduction of amplitudes on NCS

- iii. Neurogenic MUAPs with decreased recruitment is seen on distal muscles
3. Hydroxychloroquine
 - a. The myopathy is not as severe as with chloroquine, with fewer vacuoles on routine biopsy
 - b. Electron microscopy:
 - i. Demonstrates myeloid and curvilinear bodies in vacuoles

Amiodarone

General Characteristics

1. Amiodarone is a widely used antiarrhythmic agent for the treatment of both ventricular and supraventricular tachyarrhythmias
2. Its most widely recognized complications affect the eyes, lungs, liver, heart, skin and thyroid
3. The prevalence of amiodarone-induced neurotoxicity has been cited as 27.5–74% with prolonged use: These include:
 - a. Tremor
 - b. Ataxia
 - c. Peripheral neuropathy
 - d. Encephalopathy
 - e. Parkinsonism

Clinical Manifestations

1. Severe proximal and distal weakness with distal sensory loss and reduced or absent muscle stretch reflexes
2. The legs are more severely affected than the arms
3. Renal failure predisposes to toxicity
4. Concomitant use of simvastatin and amiodarone may cause rhabdomyolysis
5. Muscle strength may improve with drug withdrawal

Neuropathology

1. Muscle biopsy:
 - a. Scattered muscle fibers that contain autophagic vacuoles
 - b. Distal muscles demonstrate neurogenic atrophy
2. Electron microscopy:
 - a. Myofibrillar disorganization and autophagic vacuoles that contain myeloid debris which is also seen on nerve biopsies. They are lipid membrane inclusions that may persist for 2 years following drug withdrawal
3. Putative pathogenesis is similar to that of chloroquine

Laboratory Evaluation

1. Serum CK levels are moderately increased
2. EMG:
 - i. Increased insertional activity in both proximal and distal muscles with positive sharp waves and fibrillation potentials
 - ii. Proximal muscles demonstrate polyphasic, short duration small amplitude, early recruiting of MUAPs

- iii. Distal muscles often demonstrate a neuropathic pattern with large-amplitude, long-duration polyphasic MUAPs, with decreased recruitment

Antimicrotubular Myopathies

Colchicine

General Characteristics

1. Colchicine is weakly amphiphilic, but its effects are primarily mediated by its binding with tubulin and disruption of its polymerization that form microtubules

Clinical Manifestations

1. The neuromyopathy usually develops with prolonged use, but occasionally after I.V. administered acutely
2. Risk factors are age greater than 50 years and duration of use
3. Onset is most often with proximal muscle weakness over several months
4. Clinical myotonia has been described in a subset of patients
5. Distal sensory loss with decreased or loss of muscle stretch reflexes from a concomitant peripheral neuropathy
6. Signs and symptoms resolve in 4–6 months after the drug is discontinued
7. Toxicity increases with the use of statins

Neuropathology

1. Muscle biopsy:
 - a. Acid phosphatase-positive autophagic vacuoles that contain membranous debris
2. Immunohistochemistry:
 - a. Microtubule-associated protein light chain 3 (LC3) that binds p62/SQSTM1 which is an adapter protein selectively degraded by autophagy is positive (positive in all autophagic vacuolar myopathies)
 - b. Colchicine destabilizes the microtubule system by impairing autophagosome-lysosome fusion

Laboratory Evaluation

1. Markedly elevated CK serum levels; elevated alanine amino-transferase (ALT) and aspartate aminotransferase (AST)
2. EMG:
 - a. Increased insertional activity associated with positive sharp waves, fibrillation potentials and complex repetitive discharges
 - b. Myopathic MUAP in proximal muscles that can be marked in distal muscles from the concomitant peripheral neuropathy
 - c. Myotonic discharges
 - d. Nerve conduction studies:
 - i. Reduced amplitude
 - ii. Slightly prolonged latencies
 - iii. Slow conduction velocities of motor and sensory nerves in both upper and lower extremities

Vincristine

General Characteristics

1. Vincristine is utilized in various chemotherapeutic protocols for non-Hodgkin's and Hodgkin's lymphoma, acute lymphoblastic leukemia, and neuroblastoma
2. Major adverse off-target effects are severe peripheral neuropathy, hyponatremia, hair loss, and constipation
3. It inhibits mitosis by binding to tubulin which inhibits the separation of chromosomes during metaphase which induces apoptosis
4. The rate-limiting side effect is severe axonal polyneuropathy

Clinical Manifestations

1. Distal extremity muscle weakness
2. Initial small fiber modality sensory loss, that in severely affected patients damages all fiber sizes
3. Constipation more frequently than urinary sphincter involvement
4. Loss of muscle stretch reflexes
5. Proximal muscle weakness and myalgia may occur

Neuropathology

1. Muscle biopsy:
 - a. Neurogenic atrophy of distal muscles
 - b. Rarely, increased lipofusion or granule accumulation
 - c. Scattered necrotic fibers in proximal muscles
2. Electron microscopy:
 - a. Myofibrillar disorganization
 - b. Subsarcolemmal osmophilic material
 - c. Myonuclei may contain membrane-bound inclusions

Laboratory Evaluation

1. Serum CK specifically in myopathic patients has not been reported
2. Muscle biopsy:
 - a. Increased insertional activity with positive sharp waves and fibrillation potentials
 - b. In distal muscles there are neurogenic pattern MUAPs
3. Nerve conduction studies:
 - a. Reduced SNAP and CMAP amplitudes
 - b. Slightly prolonged distal latencies
 - c. Mildly slow conduction velocities

Drug-Induced Mitochondrial Myopathy

Zidovudine (Azidothymidine, AZT)

General Characteristics

1. At present AZT is used in conjunction with other anti-HIV drugs in highly active antiviral therapy
2. AZT is included in combivir and trizivir
3. AZT is a thymidine analogue that selectively inhibits HIV reverse transcriptase, blocking double-stranded DNA production

4. AZT inhibits mitochondrial DNA polymerase that reduces mitochondrial DNA and causes decreased respiratory chain function
5. Other postulated mechanisms for AZT function include:
 - a. Oxidative stress
 - b. Direct inhibition of mitochondrial bioenergetics
 - c. Mitochondrial depletion of L-carnitine
 - d. mtDNA depletion due to inhibition of DNA polymerase gamma

Clinical Manifestations

1. AZT myopathy patients most often present with the insidious onset of myalgias and proximal muscle weakness
2. Other HIV-related myopathies include:
 - a. Inflammatory myopathy
 - b. Microvasculitis
 - c. Necrotizing myopathy
 - d. Type 2 muscle fiber atrophy
 - e. Toxic AZT myopathy
3. Patients with HIV myopathy may have concomitant:
 - a. Inflammatory demyelinating polyneuropathy
 - b. Symmetrical lower extremity small fiber neuropathy
 - c. Myasthenia gravis
 - d. Nemaline rod myopathy

Neuropathology

1. Muscle biopsy:
 - a. Ragged red fibers (which correlates with the cumulative dose of AZT, and supports mitochondrial dysfunction)
 - b. Necrotic fibers
 - c. Cytoplasmic bodies
 - d. Nemaline rods
 - e. Microvacuolation
 - f. In pure AZT myopathy there is absence of endomysial inflammation (should not be present in non-necrotic fibers)
2. Electron microscopy:
 - a. Mitochondrial and myofilament abnormalities

Laboratory Evaluation

1. Normal or minimally elevated serum CK levels; higher CK levels suggest HIV-associated myositis
2. Needle EMG:
 - a. Increased insertional activity with positive sharp waves and fibrillation potentials
 - b. Early recruitment of short-duration, low amplitude polyphasic MUAPs
3. Mitochondrial myopathy occurs with:
 - a. Lamivudine
 - b. Zalcitabine
 - c. Didanosine
 - i. There may be associated increased serum lactate and hepatic steatosis

Drug-Induced Inflammatory Myopathies

L-Tryptophan/Eosinophilia Myalgia Syndrome

General Characteristics

1. An outbreak of acute onset of incapacitating myalgia, some muscle weakness and marked eosinophilia ($>10^9/L$) was first described in 1989 and was traced to a single manufacturer of L-tryptophan
2. Only a fraction of persons who ingested L-tryptophan contracted the disease
3. Dosage and increased age were found to be risk factors
4. The drug was found to be a contaminant in the manufacture of the compound

Clinical Manifestations

1. Subacute onset of generalized muscle pain, tenderness and weakness
2. The onset could be delayed (weeks to possibly years after L-tryptophan ingestion)
3. Associated signs and symptoms include:
 - a. Abdominal pain
 - b. Mucocutaneous ulcers
 - c. Lymphadenopathy
 - d. Dyspnea
 - e. Myalgias
 - f. Skin rash
4. Severe polyneuropathy suggestive of Guillain-Barré syndrome or vasculitis

Neuropathology

1. Muscle biopsy:
 - a. Diffuse or perivascular inflammatory infiltrate of the perimysium, fascia and endomysium with CD8+ T-cells and macrophages
 - b. Less than 3% of the invading cells are eosinophils or B-cells
 - c. No membrane attack complex deposition or small blood vessels
2. Nerve biopsy:
 - a. Perivascular mononuclear inflammatory infiltrate
 - b. Occasional eosinophils are noted in the epineurium, endoneurium, and perineurium
 - c. Axonal degeneration
3. Eosinophil-derived proteins, MBP and EDN immunostain in the fascia, perimysium and endomysium as well as around intramuscular blood vessels and nerves
4. The pathogenesis of eosinophilic syndrome in some instances is the exposure to certain preparations of L-tryptophan in a genetically susceptible host, which triggers eosinophilic activation and degranulation that causes chronic tissue fibrosis
5. Two trace adulterants in the manufacture of L-tryptophan that are possible inducers of the syndrome:
 - a. 3-phenylamino alanine (PAA)
 - b. 1,1-ethylidenebis tryptophan (EBT)

Laboratory Evaluation

1. The serum CK level can be normal or moderately elevated
2. Absolute eosinophil count is $>10^9$ cells/L
3. EMG:
 - a. Increased insertional activity with positive sharp waves and fibrillation potentials with complex repetitive discharges
 - b. Chronic myopathic pattern was demonstrated with small and large polyphasic MUAPs and early recruitment (those with primarily isolated myopathy)
 - c. Large polyphasic MUAPs with decreased recruitment in patients with severe neuropathy
 - d. Nerve conduction studies:
 - i. Decreased amplitude of compound muscle and sensory nerve action potentials
 - ii. Normal or slightly slow motor and sensory conduction velocities in patients with polyneuropathy
 - iii. In patients with severe polyneuropathy (GBS presentation):
 1. Multifocal motor neuropathy with conduction block
 2. Slow motor and sensory conduction velocities

Rare Drug-Induced Inflammatory Myopathies**Toxic Oil Syndrome***General Characteristics*

1. A single epidemic in Spain in 1981 due to the ingestion of denatured rapeseed oil as a substitute for olive oil

Clinical Manifestations

1. Acute myalgia and proximal muscle weakness

Neuropathology

1. Muscle biopsy:
 - a. Perivascular, perimysial or endomysial inflammatory cell infiltrate
 - i. The likely toxic contaminant: 3-phenylamino-1,2-propanediol

Laboratory Evaluation

1. Elevated serum CK levels
2. EMG:
 - a. Increased insertional activity with positive sharp waves and fibrillation potentials
 - b. Myopathic pattern of MUAPs

Penicillamine*General Characteristics*

1. Primarily used to treat Wilson's disease and rarely rheumatoid arthritis
2. 0.2–1% of treated patients may develop a polymyositis clinical disorder
3. May induce myasthenia gravis

Clinical Manifestations

1. Proximal muscle weakness and myalgia
2. DM/PM-like disorder
3. Associated MG

Neuropathology

1. Perivascular, perimysial or endomysial inflammatory cell infiltrate

Laboratory Evaluation

1. Elevated serum CK
2. EMG:
 - a. Increased insertional activity with fibrillation potentials and positive sharp waves

Cimetidine*General Characteristics*

1. Cimetidine is an H₂ histamine receptor antagonist

Clinical Manifestations

1. Generalized weakness and myalgia occur rarely

Neuropathology (One Patient)

1. Muscle biopsy:
 - a. Perivascular inflammation of CD8+ lymphocytes
 - b. No immunoglobulin or complement deposition on small blood vessels
 - c. Patients with cutaneous vasculitis have been reported

Laboratory Evaluation

1. Elevated serum CK levels
2. EMG:
 - a. Increased insertional activity
 - b. Myopathic MUAPs

Procainamide*General Characteristics*

1. Rarely used now as an antiarrhythmic agent
2. May cause SLE-like (lupus-like) clinical disorder

Clinical Manifestations

1. A rare cause of proximal weakness and myalgias

Neuropathology

1. Muscle biopsy:
 - a. Perivascular inflammation and rare necrotic muscle fibers
 - b. Putative lupus-like vasculitis

Laboratory Evaluation

1. Elevated serum CK levels
2. EMG:
 - a. Myopathic pattern in a patchy distribution

Phenytoin*General Characteristics*

1. Long-term use is more often associated with a minimal lower extremity sensorimotor neuropathy, or just absent ankle muscle stretch reflexes

Clinical Manifestations

1. Proximal muscle weakness and rare myalgias

Neuropathology

1. Muscle biopsy:
 - a. Scattered necrotic and regenerating muscle fibers
 - b. Putative hypersensitivity reaction

Laboratory Evaluation

1. Elevated CK levels
2. EMG:
 - a. Insertional activity is increased
 - b. Small amplitude, short duration, polyphasic MUAPs

Alpha-Interferon*General Characteristics*

1. Alpha-interferon is used to treat chronic myelogenous leukemia and melanoma

Clinical Manifestations

1. Myositis with proximal muscle weakness and myalgia
2. Autoimmune induced myasthenia gravis

Neuropathology

1. Muscle biopsy:
 - a. Perivascular, perimysial or endomysial inflammatory cell infiltrate
 - b. Alpha-interferons have possible involvement in induction of dermatomyositis

Imatinib Mesylate (Gleevec)*General Characteristics*

1. Imatinib mesylate is the standard initial treatment for adult and pediatric patients with chronic myelogenous leukemia
2. It is the paradigm for small-molecule anticancer agents that have high selectivity against a specific molecular target
3. Imatinib is a signal transduction inhibitor that targets several protein tyrosine kinases. In the case of chronic myeloid leukemia it inhibits BCR-Abl, an oncoprotein

Clinical Manifestations

1. Approximately 20–50% of patients develop myalgias
2. Proximal muscle weakness has been reported

Neuropathology

1. CML 28 antibodies were found in one patient who developed polymyositis while taking imatinib. These antibodies

are similar to LR p46p, a component of human exosomes. Antibodies to exosome components PM-Scd100 and PM-Sc175 are also found in polymyositis which suggests an autoimmune basis for the muscle involvement with this agent

Laboratory Evaluation

1. Elevated serum CK
2. EMG:
 - a. Myopathic pattern

Myopathies Due to Impaired Protein Synthesis or Increased Catabolism**Steroid Myopathy***General Characteristics*

1. Glucocorticoid-induced myopathy is the most common type of drug-induced myopathy

Clinical Manifestations

1. Insidious onset of proximal muscle weakness and atrophy, more severe in the legs than in the arms
2. Distal extremities, extraocular muscles, and bulbar muscles are not affected
3. Myopathy usually occurs with a dosage of prednisone 30 mg/d or equivalent doses of other glucocorticoids
4. Fluorinated synthetic glucocorticoids such as triamcinolone, betamethasone, or dexamethasone may be more toxic to muscle
5. Women have a greater risk of developing the myopathy than men
6. Extra high doses (given intravenously) with neuromuscular blocking agent can cause acute quadriplegia

Neuropathology

1. Muscle biopsy:
 - a. Atrophy affects primarily fast-twitch glycolytic muscle fibers (type 2b)
 - b. Less atrophy of type 1 fibers
 - c. Lipid droplets may occur in type 1 fibers
 - d. Electron microscopy: Rare mitochondrial abnormalities
 - e. Putative mechanisms include activations of major cellular proteolytic systems that include:
 - i. The ubiquitin-proteasome system (UPS)
 - ii. The lysosomal system (cathepsins)
 - iii. Calcium-dependent calpains

Laboratory Evaluation

1. Serum CK level is normal
2. Some patients have a low serum potassium concentration
3. EMG:
 - a. Normal
 - b. NCS are normal

Finasteride*General Characteristics*

1. Finasteride is a 4-azasteroid that inhibits 5-alpha-reductase, blocking dihydrotestosterone synthesis and its resulting androgen activity
2. The agent is used to treat prostatic hypertrophy

Clinical Manifestations (One Patient)

1. Proximal greater than distal weakness
2. Sensation was normal
3. Intact muscle stretch reflexes

Neuropathology

1. Muscle biopsy:
 - a. Variation in fiber size
 - b. Increased central nuclei
 - c. Type 2 muscle fiber atrophy

Laboratory Evaluation

1. Serum CK was not elevated
2. EMG:
 - a. Small myopathic polyphasic MUAPs
 - b. NCS were normal

Emetine (Ipecac)*General Characteristics*

1. Ipecac, containing emetine and cephaeline, is an emetic that has been abused by patients with anorexia nervosa and bulimia
2. 500–600 mg/day for > than 10 days is toxic to muscles

Clinical Manifestations

1. Severe proximal myopathy and cardiomyopathy after 1–2 weeks of use
2. Myalgia, tenderness, and stiffness are seen in affected muscles
3. Normal sensation
4. Decreased muscle stretch reflexes

Neuropathology

1. Muscle biopsy:
 - a. Scattered necrotic fibers
 - b. Small atrophic and regenerating fibers
 - c. Fibers that contain cytoplasmic bodies
 - d. Oxidative stains demonstrate target and moth-eaten fibers
 - e. Electron microscopy:
 - i. Myofibrillar degeneration
 - ii. Cytoplasmic bodies that consist of compacted myofibrillar debris

Laboratory Evaluation

1. Moderate elevation of serum CK level
2. EMG:

- a. Usually increased insertional activity with positive sharp waves and fibrillation potentials
- b. Small amplitude, short duration early recruitment of MUAP
- c. Normal sensory and motor nerve conduction studies

Multifactorial Toxic Myopathies**Acute Quadriplegic Myopathy/Critical Illness Myopathy***General Characteristics*

1. Generalized weakness in intensive care patients may be due to polyneuropathy, prolonged neuromuscular blockade or myopathy that is associated with thick filament myosin loss
2. Patients frequently have a combination of all three processes
3. Acute quadriplegic myopathy may be more common than critical illness neuropathy
4. Prolonged mechanical ventilation, increased hospitalization time and persistent disability are the major complications

Clinical Manifestations

1. AQM (acute quadriplegic myopathy) often follows the use of high-dose intravenous glucocorticoids in conjunction with non-polarizing neuromuscular blocking agents
2. Patients with acute asthma attacks and organ transplant patients may be at risk
3. Approximately 10–12 days of mechanical ventilation is often utilized in patients that acquire AQM
4. There is generalized weakness of the trunk, extremities, and respiratory muscles, which is often first recognized due to difficulty in weaning patients from mechanical ventilation
5. Rarely the extraocular muscles are involved
6. Sensation is normal
7. Muscle stretch reflexes are depressed or absent

Neuropathology

1. Muscle biopsy:
 - a. Prominent type 2 muscle atrophy with or without type 1 fiber involvement
 - b. Scattered necrotic muscle fibers
 - c. Local or diffuse loss of myosin ATPase staining in type 1 > type 2 fibers that corresponds to the loss of thick filaments
 - d. Actin, titin and meloulin are relatively spared
2. Putative mechanisms
 - a. Calpain activation (calcium activated protease) may cause proteolysis of myosin
 - b. Proinflammatory cytokine effects induced by sepsis that may lead to a catabolic state of muscle

Laboratory Evaluation

1. In approximately 50% of patients there is moderate elevation of serum CK levels
2. EMG:
 - a. Nerve conduction studies:
 - i. Reduced amplitudes of CMAPs with normal distal latencies and conduction velocities
 - ii. SNAPs are normal or mildly decreased
 - iii. In AQM the muscle membrane excitability is reduced. The direct muscle stimulation and conducted CMAP are low. In critical illness, neuropathy or prolonged neuromuscular blockade, direct stimulation of the muscle membrane demonstrates normal excitability
3. EMG:
 - a. Fibrillation potentials and positive sharp waves; some patients do not have abnormal spontaneous activity
 - b. Short-duration, small amplitude polyphasic MUAPs with early recruitment

Omeprazole*General Characteristics*

1. Omeprazole is widely used to treat gastric and duodenal ulcers as well as acid reflux
2. The drug inhibits the H^+/K^+ ATPase enzyme pump at the secretory surface of the gastric parietal cell

Clinical Manifestations

1. Proximal muscle weakness with myalgia
2. Concomitant neuropathy is associated with paresthesias and stocking sensory loss more in the legs than in the arms
3. Diminished or absent biceps tendon reflexes
4. Rare rhabdomyolysis

Neuropathology

1. Muscle biopsy (2 patients):
 - a. Type 2 fiber atrophy
2. Superficial peroneal nerve biopsy:
 - a. Axonal degeneration

Laboratory Evaluation

1. Serum CK concentration may be slightly increased
2. EMG:
 - a. Small polyphasic MUAPs
 - b. NCS are normal or demonstrate an axonal sensorimotor neuropathy

Isotretinoin*General Characteristics*

1. Isotretinoin is used for the treatment of severe acne

Clinical Manifestations

1. The usually myopathic symptoms are myalgias with exercise
2. Proximal myopathy and rhabdomyolysis occur

Neuropathology

1. Muscle biopsy (one patient):
 - a. Atrophy of muscle fibers

Laboratory Evaluation

1. Serum CK levels can be markedly elevated although are usually only minimally increased
2. Low serum carnitine levels have been reported
3. EMG:
 - a. Myopathic small polyphasic MUAPs

Drug-Induced Hypokalemic Myopathy*General Characteristics*

1. Hypokalemia can be produced by a wide spectrum of medications that include diuretics, laxatives, mineral and glucocorticoids, amphotericin and lithium. Licorice has aldosterone action that is associated with hypokalemia. Hypokalemia can be caused by excessive alcohol and toluene inhalation
2. Clinical, electrodiagnostic and laboratory manifestations of hypokalemia are similar regardless of etiology

Clinical Manifestations

1. The onset may be acute or subacute generalized weakness that when severe can resemble Guillain-Barré syndrome
2. The usual potassium levels associated with muscle weakness are below 2 mg/L
3. Extraocular, bulbar and respiratory muscles are spared
4. Muscle stretch and myotactic reflexes are usually absent

Neuropathology

1. Muscle biopsy:
 - a. Scattered necrotic and regenerating fibers
 - b. Vacuoles whose origin is from T-tubules

Laboratory Evaluation

1. Serum CK concentration may be increased
2. EMG:
 - a. May be normal
 - b. Fibrillation potentials and positive sharp waves

Myopathies Associated with Anesthetics and Centrally Acting Drugs*General Characteristics*

1. Malignant hyperthermia is a genetically heterogeneous group of disorders
2. A basic mechanism in some patients is excessive calcium release from the sarcoplasmic reticulum that causes excessive muscle contraction with increased oxygen and ATPase utilization with consequent production of heat
3. Mutations have been documented in the ryanodine receptor located on chromosome 19q13.1 (MHS1) which is between the sarcoplasmic reticulum and the T tubule. These mutations may alter the calcium channel such that when

activated there is excess Ca^{2+} release into the cytoplasm. Ryanodine receptor mutations also cause central core disease

4. MHSQ has been mapped to chromosome 17q11.2-24 possibly allelic to potassium-sensitive periodic paralysis and paramyotonia congenita
5. MHS3 maps to chromosome 7q21-7q22 and may encode a subunit of a calcium channel
6. MHS4 maps to chromosome 3q13.1
7. Dihydropyridine receptor mutations which maps to chromosome 1q31 and are allelic to hypokalemic periodic paralysis cause MHS5
8. Malignant hyperthermia can occur in patients with:
 - a. Muscular dystrophies
 - b. Myotonic dystrophy
 - c. Mitochondrial myopathies
 - d. Some congenital myopathies particularly central core disease

Clinical Manifestations

1. Malignant hyperthermias most often precipitated by:
 - a. Succinyl choline, a depolarizing muscle relaxant
 - b. Inhalation anesthetics such as halothane and enflurane
2. Approximately 50% of patients have had anesthesia without complication
3. The master muscle may be the first to become rigid which is quickly followed by generalized rigidity
4. Tachycardia, cardiac arrhythmias, metabolic acidosis with tachypnea, fever and myoglobinuria rapidly occur

Neuropathology

1. Muscle biopsy:
 - a. Variation in fiber size
 - b. Central nuclei
 - c. Moth-eaten fibers
 - d. Necrotic fibers

Laboratory Evaluation

1. Serum CK is often normal or mildly elevated between attacks; during attacks the serum CK is markedly elevated
2. Severe metabolic and respiratory acidosis during attacks
3. Myoglobinuria
4. Lactic acidosis, hypoxia and hypercarbia
5. EMG:
 - a. Normal between attacks
 - b. Shortly after an attack may demonstrate increased spontaneous activity and a myopathic pattern with early recruitment of small amplitude MUAPs

Myopathies of Drug Abuse

Alcohol Myopathy

General Characteristics

1. Alcoholic myopathy occurs independently of peripheral neuropathy, malnutrition and overt lung disease

2. Myopathy is estimated to occur in approximately 50% of patients that abuse alcohol
3. Skeletal muscle is 40% of body mass and is a major component of whole-body protein turnover
4. The toxic myopathy from alcohol abuse include:
 - a. Acute necrotizing myopathy
 - b. Acute hypokalemic myopathy
 - c. Chronic alcoholic myopathy
 - d. Asymptomatic myopathy
 - e. Cardiac myopathy

Clinical Manifestations

1. Acute necrotizing myopathy
 - a. May occur following a binge and presents as:
 - i. Acute muscle pain and tenderness
 - ii. Mechanical hyperalgesia of affected muscles
 - iii. Edema
 - iv. Cramps
 - v. Primarily proximal muscle weakness
 - vi. Myoglobinuria in severe episodes with renal failure
2. Acute hypokalemic myopathy
 - a. Generalized weakness that evolves over 1–2 days
 - b. Serum potassium is usually <2 mg/L
3. Limb girdle weakness
 - a. Evolves insidiously
 - b. More severe weakness of the legs than arms
4. Asymptomatic myopathy
 - a. Elevated CK

Neuropathology

1. In patients with necrotizing myopathy
 - a. Muscle biopsy:
 - i. Muscle fiber necrosis
 - ii. Occasional tubular aggregate
 - iii. Electron microscopy:
 1. Degeneration of mitochondria
 2. Disorganized sarcomeres
2. Hypokalemic myopathy
 - a. Vacuoles within muscle fibers
3. Limb girdle weakness
 - a. Muscle biopsy:
 - i. Type 2 fiber atrophy
4. Alcohol and acetaldehyde inhibit muscle protein synthesis and both contractile and non-contractile proteins are affected
5. Muscle RNA is reduced by increased RNAase
6. Muscle protease activity is either reduced or unaltered
7. Markers of muscle membrane damage are increased possibly by reactive oxygen species
8. Low levels of alpha-tocopherol may predispose muscle to metabolic damage
9. Alcohol-induced autophagy contribute to loss in skeletal muscle mass

Laboratory Evaluation

1. Minimally elevated serum CK levels are seen in asymptomatic patients while markedly elevated levels occur in those with necrotizing myopathy
2. The potassium level is usually less than 2 mg/L in those patients with hypokalemic myopathy
3. EMG:
 - a. Positive sharp waves, fibrillation potentials
 - b. Short-duration, low amplitude MUAPs that demonstrate early recruitment (in patients with necrotizing myopathy)
 - c. Decreased amplitude of sensory > motor nerve conduction studies (in patients with concomitant neuropathy)

Myopathies from Illicit Drugs*General Characteristics*

1. The most common illicit drugs that are associated with myopathy include:
 - a. Heroin
 - b. Meperidine
 - c. Pentazocine
 - d. Phenyntion
 - e. Amphetamines
 - f. Cocaine
 - g. Toluene (severe hypokalemia)
2. Mechanisms of muscle injury include:
 - a. Direct toxic effect (Pentazocine)
 - b. Prolonged coma (pressure necrosis)
 - c. Ischemia (vasoconstriction)
 - d. Needle injury
 - e. Status epilepticus (rhabdomyolysis)

Clinical Manifestations

1. Weakness from specific muscle involvement
2. Concurrent pressure induced neuropathy from coma
3. Rhabdomyolysis with myoglobinuria (status epilepticus)
4. Hypokalemia (toluene)

Neuropathology

1. Muscle biopsy:
 - a. Necrosis of sarcomeres

Laboratory Evaluation

1. Extremely high CK
2. Myoglobulinuria
3. Associated medical complications:
 - a. Pulmonary edema (IV narcotics)
 - b. Severe malnutrition, wasting and poor dentition (amphetamine)
 - c. Fibrous destruction of muscle (pentazocine)
4. EMG:
 - a. Myopathic pattern with features of associated peripheral neuropathy

Differential Defects of Specific Muscles***Congenital Fibrosis of Extraocular Muscles****General Characteristics*

1. Kinesin family member 21A (KIF21A) gene mutation that maps to chromosome 12.12; AD and sporadic inheritance

Clinical Manifestations

1. Bilateral congenital ptosis
2. EOM defects that involve vertical extraocular muscles
3. The eyes may be fixed 20–30° below the horizontal
4. Posterior head tilt

Neuropathology

1. Decreased number of neurons in the third nerve nucleus
2. Developmental absence of the superior division of the oculomotor nerve

Laboratory Evaluation

1. Demonstrated oculomotor deficits of the superior rectus and the levator palpebrae muscles

Congenital Fibrosis of Extraocular Muscles 2*General Characteristics*

1. Aristalless homeobox, drosophila, homology of (ARIX; PHOX2A) genes, AR; that map to chromosome 11q13.4
2. Splice site and missense mutations
3. Patients described are from Saudi Arabia and Turkey

Clinical Manifestations

1. The eyes are fixed in abduction
2. Vertical movement is deficient but eyes can be raised above the horizontal; involvement may be unilateral
3. Ptosis
4. Amblyopia in the eye with a covered lid
5. Meiotic pupils with a sluggish reaction to light; pupils may be fixed

Neuropathology

1. Loss of oculomotor and fourth neurons

Laboratory Evaluation

1. Pupils may not respond to mydriatics
2. Loss of IIIrd and IVth nerve function

Congenital Fibrosis of Extraocular Muscles 3*General Characteristics*

1. Tubular Beta-3 (TUBB3) gene mutation that maps to chromosome 16q24.3; AD

Clinical Manifestations

1. Variable phenotype
2. Asymmetric

3. Deficient function of the IIIrd and IVth nerves with limited vertical movement
4. Severe involvement:
 - a. In primary gaze the eye may be eso- or exotropic with marked restriction of movement to all fields of gaze
5. Marcus-Gunn phenomenon is present
6. Deficits associated with specific mutations include:
 - a. Aberrant innervation by the trigeminal nerve
 - b. Cognitive and behavioral deficits
 - c. Paralysis of the VIIth nerve
 - d. Axonal sensorimotor neuropathy
 - e. Wrist and finger contractions

Neuropathology

1. Hypoplasia of the IIIrd nerve
2. Hypoplasia of the IIIrd nerve innervated muscles
3. Aberrant innervation of the IIIrd nerve by the VIth nerve
4. Dysgenesis of the corpus callosum, anterior commissure and internal capsule

Laboratory Evaluation

1. TUBB3 protein deficit
2. Complete to partial loss of oculomotor function in both eyes
3. MRI:
 - a. Hypoplasia of the IIIrd nerve and the muscles it innervates
 - b. Generalized loss of white matter
 - c. Boral ganglia involvement with specific mutations
 - d. Normal cortex
4. Variant syndromes include (congenital fibrosis of EOM):
 - a. CFEOM3 plus hypogonadism
 - b. TUBB3 variants with polyneuropathy
 - c. CFEOM with polymicrogyria
 - d. CFEOM with ulnar hand anomalies (Tukel syndrome)
 - e. CFEOM with congenital cranial dysinnervation disorder

Duane Syndrome

General Clinical Manifestations

1. Restriction of adduction, abduction or both
2. If adduction is restricted:
 - a. Globe retraction
 - b. Narrow palpebral fissure
3. Strabismus:
 - a. Esotropia is most common
4. Most commonly the syndrome is unilateral and sporadic
5. The bilateral syndrome manifests:
 - a. Amblyopia and strabismus most often seen in familial patients
6. Associated congenital anomalies include:
 - a. Skeletal
 - b. Ear
 - c. Ocular

- d. Neural
7. The usual pathology is in absent abduction nucleus and nerve:
 - a. The lateral rectus muscle is denervated and is aberrantly innervated by the inferior division of the oculomotor nerve which also innervates the ipsilateral medial rectus muscle

Duane Syndrome Type 1

General Characteristics

1. Sporadic inheritance; maps to chromosome 8q13

Clinical Manifestations

1. Weakness of abduction
2. Retraction of the eye and palpebral narrowing with adduction
3. Associated C2–C3 vertebral fusion (Klippel-Feil syndrome)
4. Thenar hypoplasia
5. Deafness

Neuropathology

1. Absence of the VIth nerve nucleus in the pons; absent VIth nerve; fibrosis of the lateral rectus muscle

Laboratory Evaluation

1. Ocular mobility studies demonstrate contraction of the medial and lateral rectus muscle; the globe may slip up or down under the tight lateral rectus muscle

Duane Syndrome Type 2

General Characteristics

1. $\alpha 2$ -chimaerin gene mutation (CHN1) that maps to chromosome 2q31; heterozygous missense mutations
2. Some mutations enhance $\alpha 2$ -chimaerin translocation to the cell membrane and its ability to self-aggregate

Clinical Manifestations

1. Congenital ophthalmoplegia:
 - a. Absent or reduced abduction
 - b. Adduction is decreased in some patients
 - c. Adduction produces globe retraction and ptosis (some patients)
 - d. There is a high incidence of bilateral involvement and vertical extraocular muscle weakness

Neuropathology

1. Absent abducens nucleus and nerve in the pons
2. Hypoplastic oculomotor innervated muscles; hypoplastic oculomotor nerves

Laboratory Evaluation

1. Motility function is consistent with absent or reduced abduction
2. Reduced adduction in some patients

Duane Anomaly with Radial Ray Abnormalities and Deafness

General Characteristics

1. Sal-like 4 (SALL4) gene mutations that map to chromosome 20q13.2

Clinical Manifestations

1. Hypoplasia of the thenar muscles; absence of the thumb and first metacarpal bone
2. Duane syndrome
3. Coloboma
4. Narrow external and auditory meatus; sensorineural deafness
5. Malrotation or absence of the kidney
6. Imperforate anus
7. Foot anomalies

Neuropathology

1. The SALL4 gene has been hypothesized to play a critical role in abducens motoneuron development
2. SALL4 is an oncofetal protein (zinc finger transcription factor) that has also been implicated in hepatic cancer with poor prognosis

Laboratory Evaluation

1. Ocular motility evaluation consistent with abducens deficit and absent oculomotor innervation
2. Some variants demonstrate midline brain anomalies on MRI
3. Kidney malrotations, foot anomalies as well as upper limb involvement

Bosley-Salih-Alorainy Syndrome

General Characteristics

1. Homeobox A1 (HOXA1) gene that maps to chromosome 7p15.2; AR

Clinical Manifestations

1. Bilateral Duane syndrome:
 - a. Limited horizontal gaze in both abduction and adduction
 - b. Vertical gaze preserved
 - c. Normal convergence
 - d. Globe retraction
 - e. Deafness and mutism (89% of patients)
 - f. Delayed motor development (66% of patients)
 - g. Walking after 3 years
 - h. Cognitive impairment
 - i. Autism spectrum disorder

Neuropathology

1. Absent VIth nerve
2. Carotid artery:

- a. Hypoplasia or absence of the base of the skull canal and arteries
 - b. Enlargement of the posterior communicating and basilar arteries
3. Absent cochlea, semicircular canals and vestibule
 4. Normal brainstem, cerebellum and cortex

Laboratory Evaluation

1. MRI:
 - a. Absent arterial canals at the skull base
 - b. Absent internal carotid artery with compensatory hypertrophy of the posterior communicating and basilar arteries
 - c. Absent cochlea, semicircular canals and vestibule with deficient BAER (brainstem auditory evoked response)
 - d. Ocular motility evaluation of the VIth nerve:
 - i. Duane syndrome (absent VIth nerve)

Allelic Disorder: Athabaskan (Navaho) Brainstem Dysgenesis Syndrome (ABDS)

General Characteristics

1. R26X mutation of the HOXA1 gene that maps to chromosome 7p15.2; AR

Clinical Manifestations

1. Congenital onset
2. Facial musculature weakness
3. Cerebral hypoventilation
4. Twenty percent of patients have vocal cord paralysis
5. Hypoventilations
6. Developmental delay
7. 50% of patients have seizures
8. Horizontal gaze palsy; convergence is normal

Neuropathology

1. Congenital heart defects in approximately 50% of patients that have tetralogy of Fallot and double aortic arch

Laboratory Evaluation

1. Ocular motility evaluation reveals horizontal gaze palsy
2. Abnormal brainstem auditory evoked potentials
3. MRI:
 - a. Similar to other HOXA1 defects with ICA malformation spectrum that included unilateral hypoplasia to bilateral agenesis

PEO (Horizontal Gaze Palsy) and Scoliosis

General Characteristics

1. AR: mutations in the ROBO gene that maps to chromosome 11q.24.2

Clinical Manifestations

1. Onset is congenital or within the first decade of life
2. No conjugate smooth pursuit, saccades or vestibulo-ocular reflexes

3. Vertical extraocular movements are unaffected; convergence is intact
4. Esotropia in 30% of patients
5. Pendular nystagmus
6. Cognitive impairment in 30% of patients
7. Progressive scoliosis (thoracolumbar)
8. Ipsilateral hemiparesis (uncrossed CST corticospinal fibers in some patients)

Neuropathology

1. The ROBO3 gene is important in the regulation of hind-brain axonal midline crossing, directs cell migration and is important in the lateral position of longitudinal pathways

Laboratory Evaluation

1. MRI:
 - a. DT1 demonstrates the absence of major crossing pathways in the pons and midbrain

Axenfeld-Rieger Syndrome

General Characteristics

1. AD; three chromosomal loci have been mapped with a demonstrated link to Axenfeld-Rieger syndrome and related phenotypes
2. The gene at chromosome 4q25 PITX and the FKHL7 at 6p25
3. The incidence of ARS is 1 in 200,000 of the population

Clinical Manifestations

1. Ocular anterior segment dysgenesis includes:
 - a. Heterochromia
 - b. Aniridia
 - c. Coloboma of the iris
 - d. Persistent papillary membrane
 - e. Corneal opacities
2. Proptosis
3. Hypertelorism
4. Partial absence of extraocular muscles
5. Malformation of the ears:
 - a. Mild sensorineural deafness
6. Communicating hydrocephalus
7. Cognitive impairment
8. Other malformations:
 - a. Facial
 - b. Dental
 - c. Abdominal
 - d. Cardiac defects (dextrocardia)

Neuropathology

1. ARS is an ocular anterior segment dysgenesis syndrome
2. Caused by impaired neural crest cell and ectodermal migration and differentiation during embryonic development

Laboratory Evaluation

1. Slit lamp (tears in Descemet's membrane)

2. Ocular motility studies
3. Ophthalmic ultrasonography (no posterior segment abnormality)

Congenital Ptosis Type 1

General Characteristics

1. AD; chromosome 1p32-p34/1
2. The disorder is distinct from blepharophimosis syndrome that maps to chromosome 3q and non-congenital fibrosis of extraocular muscles that map to chromosome L2

Clinical Manifestations

1. Ptosis that may be symmetric or asymmetric
2. Normal ocular movements
3. Incomplete penetrance

Neuropathology

1. Putative failure of differentiation of the levator palpebrae muscles

Laboratory Evaluation

1. Ocular motility studies are normal
2. Rarely the superior rectus may be involved

Congenital Ptosis Type 2

General Characteristics

1. Dominant; chromosome Xq24-q27.1

Clinical Manifestations

1. Congenital onset
2. Bilateral symmetric ptosis
3. Normal extraocular movements

Neuropathology

1. Failure of differentiation of the levator palpebrae
2. Levator palpebrae superioris fiber size is equal between control patients and patients with congenital ptosis
3. No change in the distribution or range of muscle fiber diameter in patients with congenital ptosis

Laboratory Evaluation

1. Ocular motility evaluation is normal

Blepharophimosis

General Characteristics

1. Definition:
 - a. Blepharophimosis is bilateral ptosis with shortened vertical horizontal palpebral fissures
2. Blepharophimosis, epicanthus inversus and ptosis, either with premature ovarian failure (BPES type I) or without (BPES type II) are caused by mutations in the FOXL2 gene which maps to chromosome 3q22.3
3. Polyalanine repeat expansion are seen in 30% of patients

Clinical Manifestations

1. Ptosis

2. Telecanthus
3. Lid phimosis
4. Epicanthus inversus which is a small skin fold arising from the lower lid and extending inwards and upwards toward the nose
5. Plus or minus ovarian failure
6. Low nasal bridge
7. Common CNS abnormalities suggest a contiguous gene syndrome
8. Some patients are cognitively impaired

Neuropathology

1. 3q23 deletion is accompanied by microcephaly, ear and nose dysmorphism, cognitive impairment and comptodactyly
2. Truncated FOXL2 encoded proteins are deficient in both type I and type II BPEX patients

Laboratory Evaluation

1. If primary amenorrhea is evident there are increased gonadotropins, and low estrogen and progesterone levels
2. MRI:
 - a. Microcephaly
 - b. Nasal bone dysmorphism
3. Rare Syndromes with congenital ptosis:
 - a. ROCA syndrome
 - b. Saethre-Chotzen syndrome
 - c. Ohdo syndrome
 - d. Dubowitz syndrome
 - e. Schwartz-Jampel syndrome
 - f. Marden-Walker syndrome

Congenital Brown's Syndrome

General Characteristics

1. Brown's syndrome is a congenital disorder of limited volitional and passive elevation of the affected eye in adduction
2. Originally proposed as mechanical restriction of the trochlear muscle or tendon sheath

Clinical Manifestations

1. Congenital superior oblique palsy

Neuropathology

1. Absence of trochlear nerve
2. Abnormal development of the trochlear nerve that results in abnormalities in the superior oblique muscle-tendon-trochlear complex
3. The tendon is either long and lax, absent or abnormally inserted that causes superior oblique paresis

Laboratory Evaluation

1. Ocular motility studies
2. MRI:
 - a. To evaluate the skull base, orbit and brain (midbrain parenchyma)

ECEL1 Related Strabismus

General Characteristics

1. ECEL1 gene (ECEL-1 endothelin-converting enzyme 1) gene maps to chromosome 2q36-37.1 and has been associated with autosomal recessive distal arthrogryposis
2. The mutations are homozygous or compound heterozygous

Clinical Manifestations

1. Distal arthrogryposis
2. Ptosis
3. Complex strabismus
4. Abnormal synkinesis

Neuropathology

1. Expression of ECEL 1 during embryogenesis in both the human spinal cord and skeletal muscle
2. Distal arthrogryposis
3. Club foot
4. Hip dysplasia

Laboratory Evaluation

1. Skeletal X-ray survey
2. MRI:
 - a. Brain and orbit
3. Ocular motility evaluation

Differential Diagnosis of the Genes Involved in Congenital Cranial Dysinnervation Disorders (CCDD)

The congenital cranial dysinnervation disorders (CCDD) are phenotypes of congenital inconstant strabismus or ptosis that are related to orbital dysinnervation.

Seven different gene mutations that are dominant or recessive cause the major described phenotypes and include:

1. Duane retraction syndrome
2. Congenital fibrosis of the extraocular muscles
3. Horizontal gaze palsy with progressive scoliosis
4. ECEL-1 related strabismus

The identified genes include:

1. CHN1
2. SALL4
3. HOXA1
4. KIF21A
5. TUBB3
6. ROBO3
7. ECEL1

Congenital Facial Paresis

Hereditary Congenital Facial Paresis (HCFP1)

General Characteristics

1. Several loci for HCFP1 have been identified and mapped to chromosome 3q, 10q and the HOXB1 gene on chromosome 17q21
2. Although there is clinical overlap HCFP is considered to be different than Moebius syndrome

Clinical Manifestations

1. There may be unilateral or less frequently bilateral facial weakness
2. No extraocular muscle involvement

Neuropathology

1. HCFP may be a primary disorder of the fourth rhombomere from which facial motoneurons originate
2. Decreased neurons in the facial nerve nuclei (vicinity) that can be uni- or bilateral
3. Facial nerve roots and nerves are poorly developed (few fibers)

Laboratory Evaluation

1. Absent stapedial reflex (some patients)
2. EMG:
 - a. Enlarged polyphasic MUAP and prolonged distal latencies
3. MRI:
 - a. Normal brainstem without hypoplasia or malformation

Moebius Syndrome*General Characteristics*

1. The definition and diagnostic criteria for Moebius syndrome are controversial. As defined by a conference at the Moebius Syndrome Foundation in 2007:
 - a. A congenital non-progressive facial weakness with limited abduction of one or both eyes
 - b. Additional cranial nerve and neurodevelopmental features
2. Some patient families have a gene defect mapped to chromosome 13q12.2-q13

Clinical Manifestations

1. Patients may have unilateral or bilateral involvement; bilateral > unilateral
2. There is often asymmetric facial involvement; in some series there may be relative sparing of muscles in the lower half of the face
3. A significant number of patients have feeding problems at birth due to palatal and pharyngeal involvement
4. Impairment of ocular abduction; some patients have been described with oculomotor and trochlear nerve involvement
5. Additional manifestations include:
 - a. Tongue hypoplasia
 - b. Nasal dysarthria
 - c. Delayed language development
 - d. Mastication muscle involvement
 - e. Partial defect of sensory components of the trigeminal nerve
 - f. Craniofacial dysmorphisms:
 - i. Epicanthal folds
 - ii. Flattened nasal bridge

- iii. Microgathia
 - iv. High arched palate
 - v. External ear defects
 - vi. Teeth defects
 - vii. Hypertelorism
- g. Extremity malformations:
 - i. Brachydactyly
 - ii. Clinodactyly
 - iii. Syndactyly
 - iv. Metacarpal abnormalities
 - v. Pes planus
 - vi. Hypoplasia of the lower legs
 - vii. Talipes equinovarus
 - viii. Arthrogryposis multiplex
 - ix. Approximately 10% with Poland syndrome
6. Poor coordination

Neuropathology

1. Towfighi classification:
 - a. Hypoplasia of cranial nerve nuclei due to congenital rhombencephalon development
 - b. Neuronal loss and degeneration secondary to defects in the facial peripheral nerve
 - c. Decreased neurons, degeneration of the facial nerve with gliosis and calcifications in the brainstem nuclei from vascular insufficiency or infection
 - d. Primary myopathic changes without lesions in the cranial nerve nuclei or nerves
2. A complex regional developmental disorder

Laboratory Evaluation

1. EMG:
 - a. A spectrum of electrophysiological abnormalities at supranuclear, nuclear or peripheral levels
2. MRI:
 - a. Brainstem hypoplasia and cranial nerve atresia
 - b. Absence or hypoplasia of cranial nerve VI and VII may be the most common defect in sporadic Moebius syndrome
 - c. Evaluation of a novel familial Moebius-like syndrome revealed:
 - i. Hypoplasia of extraocular muscles that were abnormally inserted.

Cayler Cardiofacial Syndrome*General Characteristics*

1. The Cayler cardiofacial syndrome in some instances is due to 22q11 deletion and is paternally derived

Clinical Manifestations

1. Facial weakness of variable severity:
 - a. Mild cases have unilateral lower lip weakness
 - b. Severe involvement causes complete facial paresis
2. Cardiac anomalies:
 - a. Arterial septal defect

- b. Ventricular septal defect
- c. Situs inversus totalis
- 3. Skeletal defects:
 - a. Adducted thumbs
 - b. Cervical vertebral body fusion
 - c. Facial dysmorphism
- 4. Approximately 10% of patients have:
 - a. Microcephaly
 - b. Cognitive impairment
- 5. Ear microtia
- 6. Asymmetric crying facies
- 7. Bifid uvula

Neuropathology

1. 22q11 deletion syndrome

Laboratory Evaluation

1. EKG and echocardiography:
 - a. ASD and VSD
 - b. Greater than 40% of patients have heart abnormalities
 - c. Tetralogy of fallot
 - d. Patent ductus arteriosus
2. Immune system:
 - a. T-cell abnormalities
 - b. Thymic hypoplasia
3. Skeletal survey:
 - a. Cervical vertebral fusion
 - b. Adducted thumbs
4. MRI:
 - a. Microcephaly
5. Myopathy
 - a. Normal strength
 - b. May have high CK

Congenital Diaphragmatic Hernia (CDH)

General Characteristics

1. Congenital diaphragmatic hernia (CDH) is characterized by the herniation of abdominal viscera into the chest cavity due to incomplete formation of the diaphragm
2. CDH affects 1 in 3000 births
3. Chromosomal anomalies that include whole chromosome and segmental aneuploidies are the most common genetic cause of CDH
4. The CDH may occur as an isolated defect but is associated with anomalies 40% of the time
5. Mutations in GATA binding protein 6 that maps to chromosome 18q11.2:
 - a. GATA factors are transcriptional regulatory proteins that have distinct developmental and tissue specific profiles

Clinical Manifestations of GATA 6 Mutations

1. Usually associated with congenital heart disease
2. Pancreatic agenesis

3. Congenital absence of the pericardium
4. Manifestations of diaphragmatic weakness:
 - a. Infants are more clinically affected than adults
 - b. Unilateral involvement:
 - i. 50% of patients are asymptomatic
 - ii. 25% have mild exertional dyspnea
 - iii. Vital capacity is 75% of predicted value
 - c. Bilateral involvement:
 - i. Severe exertional dyspnea
 - ii. Orthopnea
 - iii. Nocturnal hypoxemia
 - iv. Hypercapnea
 - v. Vital capacity less than 45% of predicted value

Neuropathology

1. GAT6 is involved in the development of the diaphragm and the pericardium

Laboratory Evaluation

1. EKG and echocardiography to evaluate for congenital heart disease (VSD, patent ductus arteriosus and absence of the pericardium)
2. Abdominal CT:
 - a. Agenesis of the pancreas
3. Chest CT:
 - a. Pulmonary hypoplasia and pulmonary hypertension

Types of Congenital Diaphragmatic Hernia

1. Bochdalek:
 - a. 70–90% of CDH patients
 - b. Most often left-sided
 - c. Posterolateral herniation
2. Morgagni:
 - a. Anterior retrosternal
3. Central:
 - a. 1–2% of CDH
 - b. Midline of the septum transversum

Differential Diagnosis of Specific Syndromes with Diaphragmatic Hernia

1. Fryns (coarse facies, cloudy cornea, absence of lung lobulation and distal limb deformities)
2. Simpson-Golabi-Behmel:
 - a. Xq26.2 with mutation in the glypican 3 (GPC3 gene)
 - b. Coarse facies, congenital heart disease, enlarged tongue and short hands and fingers
3. Tetrasomy 12p
4. Brachmann-deLange syndrome:
 - a. AD or duplication of the long arm of chromosome 3
 - b. Growth retardation; short stature
 - c. Severe cognitive deficits
 - d. Depressed nasal bridge
 - e. Bushy eyebrows that meet in the midline
 - f. Hirsutism
 - g. Malformation of the hands

5. Lethal multiple pterygium:
 - a. The syndrome is caused by mutations in the gamma or fetal subunit of the nicotinic acetylcholine receptor that maps to chromosome 2q37.1
 - b. It is a multiple congenital anomaly syndrome that includes:
 - i. CHD
 - ii. Pterygia (webbing) of the neck, elbows and knees
 - iii. Joint contractures (arthrogryposis)
6. SMARD1
7. EMARDO (early myopathy, arreflexia, respiratory distress and dysphagia)
8. MDC1B
9. Myotubularin female carriers (elevated hemidiaphragm)
 2. Radius is absent or hypoplastic in 64% of patients
 3. Contracture of the elbow and wrist
 4. Severe patients may have total absence of the arm (phocomelia)
 - ii. Cardiac defects:
 1. ASD, VSD
 2. AV block
 3. Atrial fibrillation
 4. Sinus node dysfunction
 - iii. Thenar abnormalities:
 1. Distal displacement of the thenar eminence with or without a triphalangeal digit
 2. Patients may have an aplastic thumb on one side with a triphalangeal thumb contralaterally

Differential Diagnosis of Genetic Cause of Congenital Diaphragmatic Hernia

1. DIH1 (chromosome 15q26.1)
2. DIH2 (chromosome 8p23.1):
 - a. Most often unilateral
 - b. Associated with hypoplasia of the left lung
 - c. Atrial septal defect
3. DIH3:
 - a. The mutations occur in the zinc finger protein multiple 2 gene (ZFPm2) that maps to chromosome 8q23.1
4. Diaphragmatic defects with skull ossification and limb anomalies (or) AR
5. Congenital anterior diaphragmatic hernia:
 - a. X-linked
 - b. High mortality

Congenital Hand Muscle Abnormalities

Holt-Oram Syndrome

General Characteristics

1. This developmental hand disorder is caused by mutations in the TBX5 gene that maps to chromosome 12q24.21. The dominant phenotype is the result of haploinsufficiency of TBX5. The gene encodes the T-box transcription factor

Clinical Manifestations

1. Absent or hypoplastic muscles include:
 - a. Thenar muscles (100% of patients)
 - b. Non-opposing thumbs
 - c. Trapezius muscle
 - d. Rarely:
 - i. Deltoid, biceps, triceps
 - ii. Wrist extensors, ulnar abductors, and the supinators
 - iii. Normal
 - e. Normal lower limbs
 - i. Skeletal dysgenesis:
 1. Defects may be bilateral; the left side is more often affected than the right in 70% of patients

Neuropathology

1. TBX5 mutation that results in haploinsufficiency, encodes a protein that lacks T-box residues and causes limb and heart abnormalities
2. T-box gene family encodes transcription factors. The T-box domain is the DNA-binding domain

Laboratory Evaluation

1. EKG:
 - a. Atrial fibrillation
 - b. Brachycardia (sinus dysfunction)
 - i. Echocardiography:
 1. Primarily ASD and VSD
 2. Secundum defects
 - ii. X-ray of hands and upper extremities:
 1. Congenital anomalies of the thumb and upper extremity

Axial Musculature

Poland Syndrome

General Characteristics

1. Usually sporadic inheritance; familial patients have been reported
2. Male: female 2.4:1
3. Right to left 1.7:1
4. Prevalence is 1 in 30,000 patients
5. Onset may be in the sixth week of gestation

Clinical Manifestations

1. Unilateral absence or hypoplasia of the pectoralis muscles that most frequently involves the sternocostal portion
2. Anomalies of the breasts and nipples
3. Ipsilateral hand and digit abnormalities that include symbrachydactyly; short fingers
4. Occasional absence of the trapezius, supraspinatus and serratus anterior muscles

5. The anomalies may occur bilaterally
6. The lower limb equivalent has been described with unilateral gluteal hypoplasia and brachysyndactyly
7. Craniofacial anomalies:
 - a. Moebius syndrome
 - b. Ptosis
 - c. Mandibular prognathism
 - d. Craniofrontal nasal dysplasia
 - e. Parry-Romberg syndrome (progressive facial hemiatrophy)
 - f. External ear anomalies
8. Skeletal defects:
 - a. Scoliosis
 - b. Hemivertebrae
 - c. Agenesis of ribs
 - d. Klippel-Feil syndrome
 - e. Sprengel's deformity
 - f. Pectus excavatum and carinatum
9. Lower limbs:
 - a. Popliteal webs
 - b. Club foot
 - c. Toe syndactyly
10. Gastrointestinal complications:
 - a. Ulcerative colitis
 - b. Pyloric stenosis
 - c. Liver herniation
11. Genitourinary anomalies:
 - a. Renal agenesis
 - b. Ureteral reflex
 - c. Undescended testes
12. Cardiovascular anomalies:
 - a. Dextrocardia
 - b. ASD
 - c. Vascular malformations
13. Possible neoplastic associations:
 - a. Thoracic teratoma
 - b. Pleural fibroma
 - c. Leukemia and lymphoma

Neuropathology

1. Putative interruption of the early embryonic blood supply in the subclavian arteries, the vertebral arteries and/or their branches
2. It has been suggested that Poland syndrome, Klippel-Feil anomaly, Moebius syndrome, isolated absence of the pectoralis major muscle with breast hypoplasia, isolated transverse limb defects and Sprengel's anomaly are the spectrum for this early embryonic loss of subclavian and vertebral artery blood supply

Laboratory Evaluation

1. 3-D CT imaging of the chest to evaluate anomalies
2. MRI:
 - a. MRI evaluation of the brain if Moebius syndrome is evident
3. Echocardiography:
 - a. ASD or other cardiac anomalies

Abdominal Musculature

Prune Belly Syndrome

General Characteristics

1. A homozygous frameshift mutation has been identified in the CHRM3 gene that maps to chromosome 1q43 (1 Turkish family)
2. Most patients have autosomal recessive inheritance
3. CHRM3 protein is the major receptor that mediates urinary bladder contraction with micturition

Clinical Manifestations

1. The full syndrome is more common in males
2. Congenital onset
3. Severe abdominal distension due to absent abdominal musculature
4. Autonomic deficits:
 - a. Deficient pupillary light reflex
 - b. Dry mouth
5. Genitourinary deficits:
 - a. Bladder outflow obstruction
 - b. Cryptorchidism
6. Imperforate anus
7. Pectus excavation, club foot and hip dislocation
8. Patent ductus arteriosus

Neuropathology

1. Putative hypothesis that the entity is due to marked distention of the abdomen in the fetal period due to obstruction of the urinary tract from posterior urethral valves

Laboratory Evaluation

1. Abdominal ultrasound:
 - a. Absence of abdominal muscles
2. CT of the abdomen:
 - a. Determination of associated malformations and visceral position
3. Urinary tract evaluation
4. Chest X-ray:
 - a. Multiple segmentation defects:
 - i. Bilateral cervical ribs
 - ii. T8 to T12 and S3 hemivertebrae

Lower Extremity CHILD Syndrome

General Characteristics

1. The CHILD syndrome is caused by an X-linked dominant mutation in the NSDHL gene that maps to chromosome Xq28 and in the EBP gene
2. The CK syndrome is allelic and has a less severe phenotype
3. NADCPJ steroid dehydrogenase-like (NSDHL) gene:
 - a. Encodes a 3B-hydroxy steroid dehydrogenase in the cholesterol biosynthetic pathway

Clinical Manifestations

1. The CHILD occurs overwhelmingly in females because the disorder is X-linked dominant
2. Most often the right side of the body is poorly developed. This deficient development involves the ribs, neck, vertebrae and limbs. Internal organs may be affected
3. At birth or shortly thereafter, erythroderma (red, inflamed patches) and flaky scales (ichthyosis) are noted in the hemidystrophic side of the body. Hair loss may be noted
4. Limb anomalies:
 - a. Fingers on the hand or toes of the foot are missing on the affected side
 - b. Rarely an arm or leg may be shortened or missing
5. Hypoplasia occurs in:
 - a. The psoas muscle
 - b. Cranial nerves V, VII, XI, and X
 - c. Anomalies in the pons medulla, cerebellum and spinal cord
6. Hypoplasia of the lung and thyroid gland

Clinical Manifestations of the CK Syndrome

1. Affected males:
 - a. Weak fetal movements
 - b. Severe cognitive deficits
 - c. Seizures
 - d. Spasticity
 - e. Atrophy of the optic nerve
 - f. Strabismus
 - g. Micrognathia
 - h. High nasal bridge

Neuropathology

1. Putatively, some patients with CHILD syndrome may have less activity of 2 peroxisomal enzymes, catalase and dihydroxyacetone
2. A decrease of the 3-beta-hydroxysterol dehydrogenase may allow toxic metabolites of cholesterol synthesis to accumulate that disrupts growth and development of body parts

Laboratory Evaluation

1. Skin biopsy of the characteristic ichthyotic skin lesion
2. MRI:
 - a. Hypoplasia:
 - i. Cranial nerves V, VII, VIII, IX and X
 - ii. Pons, cerebellum and cortex

Differential Diagnosis of Congenital Absence or Hypoplasia of Muscles

1. Extraocular muscles:
 - a. Congenital cranial dysinnervation
 - b. Axenfeld-Rieger syndrome
 - c. Blepharophimosis
 - d. Congenital fibrosis of EOM:

- i. CFEOM1 (K1F21A; 12q12)
 - ii. CFEOM2 (PHOX2A; 11q13)
 - iii. CFEOM3 (TUBB3; 16q24)
 - iv. CFEOM4 (Tukel21qter)
 - v. CFEOM5 (COL25A1; 4q25)
 - vi. CFEOM (TUBB2B; 6p25)
- e. Duane syndromes:
 - i. DURS1 (8q13)
 - ii. DURS2 (CHN1, 2q31)
 - iii. DURS (SALL4, 20q13)
 - iv. Navajo (HOXA1; 7p15)
 - v. DA5E (PIEZ02; 18p4)
 - vi. CCDD (COLA25A1; 4q25)
 2. Moebius syndrome
 3. PEO (horizontal gaze palsy with scoliosis); ROBO3
 4. Absence of the superior rectus muscle
 5. Axenfeld-Rieger anomaly
 6. Hereditary congenital ptosis:
 - a. Type 1 (1p32-34)
 - b. Type 2 (Xq24-q27)
 7. Blepharophimosis syndromes:
 - a. Blepharophimosis-ptosis-epicanthus inversus syndrome (BPES type I) (FOXL2; 3q22.3)
 - b. BPES type II (Saethre-Chotzen syndrome [TWIST; chromosome 7p21.1])
 - c. Blepharophimosis with short stature; autosomal recessive
 - d. Ohdo syndrome (deletion of the short arm of chromosome 3)
 8. Face:
 - a. Hereditary congenital facial paralysis (3q; HOXB1 17q21)
 - b. Cardiofacial syndrome (22q11.2)
 - c. Moebius syndrome
 9. Diaphragm:
 - a. Congenital (X-linked)
 - b. Associated with specific syndromes:
 - i. Fryns
 - ii. Tetrasomy 12p
 - iii. Simpson-Golabi-Behmel
 - iv. SMARD1
 - v. EMARDD
 - vi. MDC1B
 - vii. Female carriers of myotubularin
 - c. Diaphragmatic hernias:
 - i. D1H1 (15q.26.1)
 - ii. D1H2 (8p23.1)
 - iii. D1H3 (ZFPM2; 8q23.1)
 - iv. Diaphragmatic defects with skull ossification and limb anomalies (AR)
 - v. Congenital anterior diaphragmatic hernia (X-linked)

Hand Muscle Hypoplasia or Absence

1. Holt-Oram syndrome (TBX5; 12q24.1)
2. Absence of the Palmaris longus muscle (AD)

Axial Musculature

1. Pectoral muscles (Poland syndrome)
2. Trapezius (8q12.2–q21.2)
3. Superior transverse scapular ligament calcification (AD)
4. Prune belly syndrome (CHRM3; 1q43; recessive and sporadic)

Lower Extremity

1. CHILD syndrome (Xq28) with absent psoas muscle

Putative Gluteal Muscle Atrophy as the Lower Extremity Component of Moebius Syndrome

1. Absence of the peroneus tertius muscle (AR)

Rhabdomyolysis and Myoglobinuria**Overview**

Rhabdomyolysis is the lysis of skeletal muscle whose major features are myalgia of the affected muscle, pigmenturia and elevated serum creatine kinase. Acute renal failure, cardiac arrest and nerve damage from compartment syndromes are the major systemic complications. In general, muscle enzymes are elevated to five times normal and serum and urinary myoglobin are present.

The balance of extracellular and intracellular calcium across the muscle membranes is maintained by:

1. Sodium-potassium pumps regulated by sodium/potassium activated adenine-triphosphatase
2. Calcium channels
3. Specific calcium-ATPase
4. Sodium-calcium exchanges

Disruption of the muscle and sarcoplasmic reticular membrane occurs (possible osmotic mechanism due to failure of the Na pump mechanism) and calcium homeostasis is lost which causes a dramatic rise in intracellular calcium. This calcium overload activates phospholipase-A2 and neutral proteases which further destroy muscle membranes. The elevated cytoplasmic calcium induces myofibrillar hypercontractures by enhanced action of myosin filament interaction.

Rhabdomyolysis causes myoglobinemia and myoglobinuria. The latter at levels above 300 mg/liter causes renal failure (at levels of 1000 mg/liter in greater than 82% of patients). The clearance of myoglobin through the kidneys is rapid as well as its conversion to bilirubin. Serum values may return to normal after an attack of rhabdomyolysis between 1–4 hours. Myoglobin levels in the serum precede an increase in CK. Myoglobin levels may be detected by radioimmunoassay, pigmented casts in the urine, absence of red cells and a normal haptoglobin.

The most sensitive test for rhabdomyolysis is the serum CK which is often 5 times normal. Approximately 200 grams of muscle needs to be involved to affect a rise in serum

CK. The CK isoenzyme CKMM (cardiac greater than skeletal muscle) is also elevated. CK-BB is found in brain tissue. Serum CK rises 2–12 hours after the onset of rhabdomyolysis, peaks in 1–3 days and decreases 3–5 days after the muscle damage. Immunologic measurement of carbonic anhydrase III is a very specific marker of skeletal muscle injury and is not present in cardiac tissue.

Rhabdomyolysis is associated with hyperkalemia, hypocalcemia and hyperphosphatemia. Approximately 150 grams of muscle destruction releases 15 millimoles of potassium which may elevate plasma levels and can contribute to or cause cardiac arrhythmias. Hypocalcemia seen in early rhabdomyolysis has been attributed to the deposition of calcium in affected muscle. Hypocalcemia may also be secondary to a decrease of 1, 25-dihydroxycholecalciferol due to hyperphosphatemia. In later stages of rhabdomyolysis, hypercalcemia may be seen as calcium is mobilized from necrotic tissue.

Rhabdomyolysis is also associated with elevated aldolase, lactic dehydrogenase, aminotransferase, creatine and uric acid. Troponin I and troponin T may be elevated.

Muscle signs and symptoms are generally similar for all causes of rhabdomyolysis. Patients suffer muscle pain and edema, have thin, shiny skin, weakness, stiffness and eventually experience contractures. The most commonly affected muscles are the quadratus lumborum (paraspinal muscles), the quadriceps and major muscles of the upper extremities. Rarely, muscles of the chest, abdomen, throat and masseter muscles are affected. All striated muscles may be affected focally or diffusely depending on specific etiology.

Rhabdomyolysis ranges from an asymptomatic illness with elevation of CK to severe elevation of serum CK, electrolytic disturbance, acute renal failure and disseminated intravascular coagulation. In general, a CK level of >5000 units/L portends serious muscle injury.

Approximately 10–50% of patients with rhabdomyolysis develop acute renal failure (ARF) and rhabdomyolysis occurs in up to 85% of patients with traumatic injuries.

Burst muscle activity such as sprinting utilizes anaerobic metabolism and Type 2 muscle fibers. Prolonged less than maximal intensity exercise (measured by oxygen utilization) requires glucose derived from glycogen stores as the primary energy source. Prolonged exercise such as distance running, utilizes free fatty acids (FFA) for ATP production. Many mitochondrial myopathies suffer weakness and exercise intolerance with minimal activity. Exhaustion of glycogen is correlated with fatigue and myoglobinuria which is seen with energy failure and muscle breakdown from any cause of inadequate ATP production with or without exercise.

Episodic weakness of muscle occurs with:

1. Phosphorylase deficiency
2. Phosphofructokinase deficiency
3. Carnitine palmitoyl transferase deficiency (CPT₂)
4. Acid maltase deficiency

5. Debrancher deficiency
6. Brancher deficiency

Disorders of Glycogen Metabolism

1. Type II – Acid maltase deficiency
2. Type III – Amylase 1, glycositase deficiency (brancher)
3. Type IV – Amylase, 4-6 1, 6 transglycosylase deficiency (brancher)
4. Type V – Myophosphorylase deficiency (McArdle disease)
5. Type VII – Phosphofructose kinase deficiency (PFK)
6. Type VIII – Myophosphorylase kinase
7. Type IX – phosphoglycerate kinase deficiency (PGK)
8. Type X – Phosphoglycerate mutase deficiency (PGM)
9. Type XI – Lactate dehydrogenase deficiency (LDH)
10. Type XII – Aldolase A deficiency
11. Type XIII – β -enolase deficiency

Lysosomal Glycogen Storage Myopathies

1. Danon disease (X-linked vacuolar cardiomyopathy and myopathy)
2. X-linked myopathy with excessive autophagy

Disorders of Purine Nucleotide Metabolism

1. Myoadenylate deaminase (MAD) deficiency

Disorders of Lipid Metabolism

1. Carnitine transporter deficiency (Primary carnitine deficiency)
2. CP2 deficiency
3. VLCAD deficiency
4. LCAD deficiency
5. MCAD deficiency
6. SCAD deficiency
7. Long-chain HAD deficiency
8. ETF-ETF-QO deficiency

Mitochondrial Dysfunction

1. Exercise intolerance
 - a. All mitochondrial disorders
2. Mitochondrial disorders with progressive weakness
 - a. Kearns-Sayre syndrome
 - b. ATPase deficiency
 - c. Cytochrome-c-oxidase deficiency
 - d. MERRF
 - e. MELAS
 - f. AD-PEO

Myoglobinuria

General Characteristics

1. Myoglobinuria may develop with:
 - a. Severe and excessive stress upon the fuel reserves of working muscle
2. During moderate exercise muscles utilize:

- a. High energy phosphate to generate ATP
- b. Muscle glycogen for the first 5–10 minutes
3. 15–20 minutes of exercise:
 - a. Blood glucose is derived from liver glycogen
 - b. Requires insulin for uptake
4. Greater than 90 minutes of exercise:
 - a. Glucose
 - b. Free fatty acids
5. Myoglobin:
 - a. Facilitates rapid diffusion of O_2 from capillaries to mitochondria in exercising muscles

Clinical Manifestations Associated with Rhabdomyolysis

1. Swelling of affected muscles
2. Pigmenturia with myalgia
3. Weakness of the involved muscle groups
4. Pain free episodes may still be associated with pigmenturia and leakage of muscle enzymes

Neuropathology

1. Myoglobinemia and myoglobinuria may occur with strenuous exercise performed under conditions of high temperature and humidity
2. Hypokalemia increases the risk of rhabdomyolysis with myoglobinuria
3. Myoglobinuria with serum levels greater than 300 mg/liter may cause renal failure
4. Two crucial factors in the development of myoglobinuric ARF are:
 - a. Hypovolemia/dehydration
 - b. Aciduria
5. Mechanisms of heme protein toxicity include:
 - a. Renal vasoconstriction that causes decreased renal circulation
 - b. Intraluminal cast formation
 - c. Direct heme protein toxicity:
 - i. Scavenging of nitric oxide which is a vasodilator
6. Activation of endothelin receptors due to free radical formation that is induced by heme protein (causes vasoconstriction)

Laboratory Evaluation

1. Myoglobin is cleared rapidly through the kidneys:
 - a. May return to normal 1–6 hours after muscle injury
 - b. Concomitantly metabolized to bilirubin
2. Myoglobin:
 - a. The urine dipstick reacts with hemoglobin and myoglobin; possibly detects myoglobin at the same concentration as hemoglobin (3 mg/liter)
 - b. Myoglobin gives urine its red-brown color at concentrations above 300 mg/L
 - c. Positive toluidine blue test
 - d. Colorless serum
 - e. Normal haptoglobin
 - f. RIA
 - g. ELISA assays

Differential Diagnosis of Genetic Causes of Rhabdomyolysis and Myoglobinuria

Rhabdomyolysis Associated Mutations in LP1N1

General Characteristics

1. Mutations in the LP1N1 gene that maps to chromosome 2p25.1
2. May be a common cause of recurrent rhabdomyolysis in children

Clinical Manifestations

1. Onset is in early childhood >5 years
2. Recurrent attacks of rhabdomyolysis associated with muscle pain and weakness that are followed by excretion of myoglobin in the urine
3. There is no relation to exercise
4. Attacks are triggered by intercurrent illness, most often upper respiratory tract infections
5. Episodes may last 7–10 days

Neuropathology

1. Lipin 1 dephosphorylates, phosphatidic acid to form diacylglycerol (phosphatidic acid and phosphohydrolase; PAP)
2. PAP is a transcriptional regulatory protein that controls metabolic gene expression
3. Muscle biopsy:
 - a. Rhabdomyolysis
 - b. Deficient PAP activity

Laboratory Evaluation

1. Myoglobinuria
2. Glycolytic Defects
 - a. Myophosphorylase deficiency
 - b. Phosphofructokinase
 - c. Phosphoglycerate mutase
 - d. Phosphoglycerate kinase
 - e. Lactic dehydrogenase
 - f. Phosphorylase kinase
 - g. Lipid metabolic defects with myoglobinuria and rhabdomyolysis
 - h. Primary carnitine deficiency
 - i. CPT2 deficiency
 - j. VLCAD deficiency
 - k. LCAD deficiency
 - l. MCAD deficiency
 - m. SCAD deficiency
 - n. Long-chain HAD deficiency
 - o. ETF and ETF-QO deficiencies (glutaconic aciduria type 2)

Differential Diagnosis of Rhabdomyolysis and Myoglobinuria from Drug Use

1. Opioids:
 - a. Clinical signs and symptoms may be delayed
 - b. Lower limbs affected to a greater degree than upper limbs
 - c. Transverse myelitis is associated
 - d. Pulmonary edema after IV use
2. Barbiturates:
 - a. Myonecrosis may occur with one large oral dose
 - b. Barbiturate coma may be associated with bullous skin lesions
3. Amphetamines:
 - a. Thin patients
 - b. Agitated; attention and problems with concentration
4. Meprobamate:
 - a. Dilated unresponsive pupils
 - b. Depression
5. Diazepam
6. Phencyclidine (PCP):
 - a. Severe nystagmus
 - b. Self-mutilation
 - c. Acute dystonic reaction
7. Beta blockers:
 - a. Slow heart rate
8. Clofibrate:
 - a. Generalized cramps, weakness and muscle tenderness
9. 3-hydroxy-3methyl glutaryl coenzyme A reductase inhibitors (3HMG-CoA reductase)
 - a. Rhabdomyolysis may be acute or delayed
 - b. Triggers are intercurrent illness, strenuous exercise and drug interaction
10. Phenformin/fenfluramine:
 - a. Right heart valve lesions
 - b. Pulmonary hypertension
11. Hypokalemic-induced myonecrosis:
 - a. Patients utilizing purgatives and diuretics
 - b. Acute potassium loss from:
 - i. Amphotericin
 - ii. Licorice and carbenoxolone
 - iii. Azathioprine
12. Chloroquine:
 - a. Doses of 250–500 mg daily for months (usually in the treatment of autoimmune disorders)
 - b. Face may be affected
 - c. Heart involvement
 - d. Macular retinopathy
 - e. Slow progressive muscle weakness
13. Emetine hydrochloride:
 - a. Generalized muscle weakness, pain and tenderness
14. Vincristine:
 - a. Minimal muscle weakness
 - b. Small fiber neuropathy
15. Colchicine:
 - a. Weakness and atrophy of all muscle groups of the lower extremities
16. Succinylcholine:
 - a. Associated malignant hyperthermia

17. Strychnine:
 - a. An adulterant with IV heroin
 - b. Extreme continuous extensor positions while maintaining consciousness
18. Cocaine:
 - a. Common cause of both traumatic and non-traumatic rhabdomyolysis
 - i. Prolonged vasoconstriction
 - ii. Direct toxic effect that causes myofibrillar degeneration
 - iii. Coma with muscle compression
 - iv. Prolonged generalized clonic-tonic seizures
19. Immunosuppressive drugs:
 - a. Primarily cyclosporin
 - b. Setting of solid organ transplantation
20. Rapeseed oil ingestion (toxic oil syndrome):
 - a. Initial symptoms of a respiratory illness
 - b. Myalgias and numbness of the extremities
 - c. Muscle weakness and atrophy (3rd–4th week)
 - d. Severely affected patients:
 - i. Sclerodermal features
 - ii. Hypertension
 - iii. Respiratory failure
 - iv. CTS (carpal tunnel syndrome)
21. Penicillamine:
 - a. Autoimmune induced myositis
22. Acute alcoholic myopathy (myonecrosis or rhabdomyolysis)
 - a. 5–10% of severely intoxicated alcoholics
 - b. Alcoholics of long duration
 - c. Previous attacks of long duration with pain and swelling of affected muscle
 - d. Acute attacks occur during:
 - i. Bouts of heavy drinking
 - ii. Withdrawal
 - iii. Sustained heavy drinking
 - e. Abrupt onset
 - f. Pain and tenderness may occur without cramps:
 - i. Usually cramps last 20–30 seconds but may last for hours
 - g. Process may affect single muscle groups; rarely the rectus abdominus muscle
 - h. Occasionally one or most of one extremity is involved
 - i. Pain, tenderness and swelling lasts 1–2 weeks; weakness lasts 10–14 days
 - j. One attack increases susceptibility to future attacks

Differential Diagnosis of Severe Hypokalemia

1. Severe Hypokalemia with Myoglobinuria at a level of 0.6–23 mEq/L
 - a. Renal tubular acidosis
 - b. Amphotericin B therapy
 - c. Primary aldosteronism
 - d. Regional enteritis

- e. Nasogastric suction and hyperalimentation
- f. Laxative abuse
- g. Hyponatremia
- h. Water intoxication

Differential Diagnosis of Direct Toxic Effects on Muscle Membrane with Myoglobinuria and Rhabdomyolysis with Envenomation

1. Sea snake (*Enhydra schistosa*) envenomation (SE Asia)
2. The Australian tiger snake (*Pseudechis*)
3. North and South American rattlesnake (*Crotalus viridis*):
 - a. Myotoxin
 - b. Phospholipases A
4. Hornet sting:
 - a. Alteration of the sarcoplasmic reticulum
5. Spiders:
 - a. Damage to the endoplasmic reticulum
6. Scorpions
 - a. Damage to the endoplasmic reticulum

Differential Diagnosis of Rhabdomyolysis with Myoglobinuria with Heat and Exercise

1. Exertional myoglobinuria:
 - a. Specific repetitive exercise (squat jump)
 - b. Military recruits
 - c. Long distance runners
 - d. Determining factors:
 - i. State of fitness of the individual
 - ii. Ability to terminate the exercise if severe cramps or pain develop
 - iii. Core temperature during the exercise
 - iv. Ambient temperature
 - v. Ischemia of specific muscles in particular positions
 - vi. Myoglobinuria during violent muscle contractions:
 1. Status epilepticus
 2. Electroshock therapy
 3. Delirium tremens
 4. Prolonged myoclonus
 5. Tetanus
 6. Prolonged dystonic postures
 7. Status asthmatics
 8. Cross country soldiers
 9. Anterior tibial syndrome
 10. Wrestling
2. High body temperature and excessive muscle work:
 - a. Exercise in hot, humid climate
 - b. Malignant hyperthermia
 - c. Neuroleptic malignant syndrome
 - d. Strychnine poisoning
 - e. Amphetamine intoxication
 - f. Heat stroke with myoglobinuria
 - g. Toxic shock syndrome with myoglobinuria (staphylococcus toxin)

Differential Diagnosis of Rare Toxins Causing Myoglobinuria and Rhabdomyolysis

1. Licorice ingestion:
 - a. Licorice abuse
 - b. Muscle pain
 - c. Neck weakness
 - d. Quadriplegia
 - e. Depressed but maintained reflexes
2. Cicuta (water hemlock):
 - a. Seizures
 - b. Myoglobinuria renal failure
3. Toluene:
 - a. Leukoencephalopathy
 - b. Dorsal column involvement
4. Clozapine:
 - a. Basal ganglia involvement
5. Gasoline vapor (Huffer's disease):
 - a. Leukoencephalopathy
6. Carbon monoxide:
 - a. Involvement of the globus pallidus, cerebellum and cortex
7. Haff disease:
 - a. East Prussia, Sweden and Russia
 - b. Ingestion of fish
8. Hellebore (veratrum alkaloid):
 - a. Ingestion of quail

Differential Diagnosis of Crush Injury and Ischemia with Rhabdomyolysis and Myoglobinuria

1. Intoxicated patients that have suffered prolonged muscle compression
2. Elderly patients that have suffered a fall
3. Trauma and crash injuries
4. Motor vehicle accidents
5. Collapse of buildings
6. Patients that struggle against restraints

Differential Diagnosis of Infections with Rhabdomyolysis and Myoglobinuria

1. Bacterial infections:
 - a. Shigella
 - b. Salmonella
 - c. E. coli
 - d. Legionnaire's disease
 - e. Leptospirosis
 - f. Clostridium perfringens
2. Viral infections:
 - a. Influenza
 - b. Herpes simplex
 - c. Herpes zoster
 - d. Epstein-Barr
 - e. Coxsackie
 - f. Adenovirus
 - g. Enteroviruses (ECHO 9,21,24)
3. Cysticercosis

Differential Diagnosis of Agents That Cause Focal Rhabdomyolysis

1. Tetracycline
2. Paraldehyde
3. Colistimethate
4. Ceftriaxone
5. Talwin (pentazocine)
6. Meperidine
7. Penicillin

Differential Diagnosis of Acid Maltase Deficiency

The infantile form of the disease presents with severe weakness and hypotonia. The differential diagnosis includes Werdnig-Hoffman disease (SMA1) and other congenital metabolic and myopathic disorders. The major differential feature is severe congestive heart failure and macroglossia. Mitochondrial disorders such as COX deficiency may involve proximal muscles and the heart but not to the same degree. Macroglossia is not a feature of mitochondrial disease.

Debrancher deficiency presents with massive hepatomegaly and hypoglycemia. There is no rise of blood glucose to epinephrine. Phosphorylase kinase deficiency may present with severe cardiomegaly in infancy, but lacks muscle weakness. Duchenne dystrophy has clear X-linked genetics, more prominent calf hypertrophy and the EMG does not demonstrate initiative features. Carnitine deficiency does not have the same degree of cardiac dysfunction or macroglossia.

Congenital myopathies occasionally present with a similar body habitus and include myotubular myopathy, central core disease and nemaline myopathy. Thinness, high arched palate, and long facies are characteristics of nemaline myopathy while bilateral symmetrical ptosis is present. Muscle biopsy clearly differentiates these congenital myopathies.

Adult acid maltase deficiency is frequently misdiagnosed as limb-girdle muscular dystrophy or polymyositis. The early respiratory muscle involvement as well as paraspinal myotonic discharges and complex repetitive action potentials differentiate the entities.

The adult variants of autophagic vacuolar myopathy have a similar phenotype. One variant with cardiomyopathy and cognitive deficiency due to a mutation of the gene for lysosome associated membrane protein-2 (LAMP-2 gene) and the other with myopathy and multisystem involvement. Muscle biopsy differentiates the vacuoles from PFK. Glycogen positive acid phosphatase containing vacuoles in acid maltase disease distinguishes this entity from chloroquine vacuolar myopathy which may also have concomitant macular retinopathy.

Differential Diagnosis of Myophosphorylase Deficiency

The major myopathies that comprise the differential diagnosis are other metabolic myopathies and the terminal glycolysis which include:

1. PFK (phosphofructokinase)
2. PGK (phosphoglycerokinase)
3. PGAM (phosphoglyceromutase)
4. LDH (lactate dehydrogenase)

Patients with PFK differ from those with McArdle's disease in that they manifest:

1. Less of a second wind phenomenon; intravenous glucose may be deleterious for them during testing
2. Severe nausea and vomiting occurs during exercise induced cramps
3. Less myoglobinuria
4. Increased bilirubin in the serum
5. An increased reticulocyte count

Patients with terminal glycogenosis, PGAM, PGK, and LDH have an abnormally low lactate rise during the ischemic forearm exercise test, but is not absent.

Carnitine palmitoyl transferase deficiency Type II is the most common cause of recurrent adult myoglobinuria. It occurs not only with exercise, but also during fasting without exertion. The forearm ischemic exercise test is negative in CPT2 deficiency. In myophosphorylase deficiency the myoglobinuria occurs with and following intense exercise. Exercise induced myoglobinuria may also occur with DMD, BMD and malignant hyperthermia. The autosomal recessive genetic pattern, interval rather than consistent elevated CK and clinical presentation rule out the dystrophinopathies. Malignant hyperthermia is AD and there is often a family history of death during anesthesia or unexpected anesthetic complications.

Undue fatigue with exercise and without myoglobinuria occurs with terminal glycogenosis as well as with adenosine monophosphate deaminase (AMPD) deficiency. In this myopathy, the forearm ischemic exercise test demonstrates a normal rise in lactate but no increase in ammonia.

Differential Diagnosis of Carnitine Deficiency

1. Chanarin-Dorfman
2. Lipid storage myopathy
3. Polymyositis
4. Debrancher enzyme deficiency
5. Infantile acid maltase deficiency
6. Fructose-1, 6-diphosphate deficiency (intermittent encephalopathy)
7. Phosphoenolpyruvate carboxy kinase deficiency

Seminal Points in the Differential Diagnosis

1. Carnitine deficiency:
 - a. Recurrent encephalopathy resembling Reye's syndrome
 - b. Recurrent hypoglycemia with or without keto acidosis precipitated by:
 - i. Caloric deprivation
 - ii. Exercise
 - iii. Infection
 - iv. Pregnancy

- c. Myalgias and exacerbated fatigue with exercise
- d. Lactic acidemia with exercise
- e. Cardiomyopathy:
 - i. High precordial T-waves
 - ii. Left axis deviation
- f. Unexplained hepatomegaly
- g. Hypertrophic cardiomyopathy with or without family history of sudden death
- h. Established organic aciduria
2. Chanarin-Dorfman disease:
 - a. AR
 - b. Inability of cells to degrade endogenously synthesized triglycerides
 - c. Clinical Manifestations:
 - i. Congenital ichthyosis
 - ii. Age of onset is the second decade
 - iii. Ichthyosis:
 1. Lamellar ichthyosis
 2. Accentuated over the skin creases
 3. Mild erythema in affected areas
 4. Ectropion (eyelids)
 - iv. Steatorrhea
 - v. Muscle weakness:
 1. Proximal greater than distal
 2. Cranial muscles are spared
 3. Moderate severity
 - vi. Associated ataxia, nystagmus, and neurosensory hearing loss
 - vii. Laboratory Evaluation:
 1. Increased liver enzyme
 2. Increased serum CK
 3. No ketone body formation during a fast
 4. Sudanophilic droplets in granulocytes
 - viii. Neuropathology:
 1. Triglyceride storage in all tissues
3. Sporadic myopathic carnitine deficiency versus polymyositis:
 - a. Both disorders have proximal myopathy and increased serum CK
 - b. Dysphagia in some PM patients
 - c. Absence of fibrillation potentials on EMG and muscle biopsy excludes an inflammatory myopathy
4. Carnitine deficiency versus debrancher enzyme deficiency:
 - a. Common to both entities:
 - i. Intermittent episodes of hypoglycemia
 - ii. Abnormal liver function tests
 - iii. Lactic acidemia
 - iv. Hyperuricemia
 - b. Debrancher enzyme deficiency:
 - i. Glycogen is stored in tissue rather than lipid
 - ii. Distal weakness occurs in debrancher enzyme deficiency
 - iii. EMG demonstrates more irritative features than in carnitine deficiency

5. Infantile maltase deficiency versus secondary carnitine deficiency that occurs in maltase deficiency
 - a. Enlarged tongue with fibrillation potentials occur in infantile maltase deficiency
 - b. Progressive weakness is not associated with episodic metabolic crises (maltase deficiency)
 - c. Cardiac myopathy (more severe with maltase deficiency)
 - d. Irritative EMG with pseudomyotonic discharges (maltase deficiency)
 - e. Glycogen rather than lipid accumulates in skeletal muscle
6. Systemic carnitine deficiency with intermittent encephalopathy versus urea cycle deficits:
 - a. Metabolic acidosis does not occur in urea cycle defects
 - b. Branched chain aminoacidurias may also suffer protein intolerance
 - c. Secondary carnitine deficiencies:
 - i. Plasma levels of arginine and citrulline are normal (elevated in urea cycle defects) in carnitine deficiency
7. Fructose 1, 6 diphosphatase deficiency and phosphoenolpyruvated carboxykinase deficiency:
 - a. Impaired gluconeogenesis
 - b. Have episodes of hypoglycemia
 - c. Fatty liver
 - d. Ketoacidosis
 - e. Hypotonia
- a. DNA polymerase gamma (POLG, POLG2)
- b. Twinkle
5. The gene products function directly at the mtDNA replication fork. Adenine nucleotide translocator 1, thymidine phosphorylase thymidine kinase 2, deoxyglucosamine kinase, ADP-forming succinyl-CoA synthetase, ligase, MPV17 (supply the mitochondria with deoxyribonucleotide triphosphate pools for mtDNA replication)
6. The most common mutated genes that phenotypically present with adult onset mitochondrial depletion syndromes (MDS) include:
 - a. POLG1
 - b. TK2
 - c. TYMP
 - d. RRM2B
 - e. PEO/twinkle
7. Adult MDS has the same phenotype spectrum as early onset MDS. Adult mitochondrial depletion syndrome may present with mild manifestations
8. Human mitochondrial DNA encodes 13 of the 82 structural proteins of the electron transport chain. There is a constant need for mitochondrial nucleotide synthesis due to the requirements of mitochondrial maintenance
9. De novo enzymes are not present in mitochondria and therefore synthesis proceeds through the salvage pathway
10. Defective mtDNA synthesis and maintenance is manifest by multiple deletions or by depletion of the mitochondrial genome
11. mtDNA depletion is usually a disease of infants whose phenotype is severe muscle weakness, hepatic failure or renal tubular failure
12. In families with multiple mtDNA deletions there are defects in proteins that are involved in mtDNA replication from mutations in the mitochondrial DNA polymerase gene, the twink gene (helicase), the adenine nucleotide translocator and the thymidine phosphorylase gene. Mutations involved in the nucleotide salvage pathways are the deoxyguanosine kinase gene and thymidine kinase gene that are also involved in mtDNA replication

Differential Diagnosis of Lipid Storage Myopathies

1. Type I glycogenesis (Von Gierke disease)
2. Pyruvate decarboxylase deficiency
3. Familial beta-hypolipoproteinemia
4. Arthrogryposis multiplex congenita (rare)
5. Scapuloperoneal dystrophy pattern (rare)
6. Autoimmune dysfunction (rare)

Mitochondrial Depletion Syndrome (MDS)

General Characteristics

1. Mitochondrial DNA depletion is caused by mutations in the nuclear genes that maintain mtDNA or deoxyribonucleotide pools and mtDNA biogenesis
2. mtDNA depletion syndrome (MDS) categories include:
 - a. Progressive External Ophthalmoplegia (PEO)
 - b. Predominant myopathy
 - c. Mitochondrial NeuroGastro-intestinal Encephalomyopathy (MNGIE)
 - d. Sensory Ataxic Neuropathy, Dysarthria and Ophthalmoplegia (SANDO)
 - e. Hepatoencephalopathy
3. The most common organs involved in MDS are the brain, liver and muscles
4. The most common involved genes are divided into two groups:

Specific Mitochondrial Depletion Syndromes of Adults

PEO1

General Characteristics

1. The mitochondrial helicase Twinkle gene is an essential component of mitochondrial replication. Heterozygous mutations in its coding gene (PEO1) are a cause of progressive external ophthalmoplegia. It is inherited as an autosomal dominant disorder

Clinical Manifestations

1. The onset is usually prior to the fifth decade, but may be in childhood

2. Slowly progressive symmetrical ptosis
3. Ophthalmoplegia
4. Rare diplopia
5. Proximal myopathy
6. Cataracts
7. Tremor
8. Ataxia
9. Peripheral neuropathy
10. Rare respiratory involvement

Neuropathology

1. Ragged red muscle fibers
2. COX deficient muscle fibers
3. Multiple mtDNA deletions are detected in muscle

Laboratory Evaluation

1. Creatine kinase and lactate are normal
2. EMG:
 - a. Normal
3. Optical coherence tomography:
 - a. Normal optic nerve and retina

Differential Diagnosis of CPEO

1. Oculopharyngeal muscular dystrophy
2. Kearns-Sayre syndrome (KSS)
3. MNGIE
4. Myasthenia gravis
5. Progressive supranuclear palsy
6. Spinocerebellar ataxia Type III

Mitochondrial Neurogastrointestinal Encephalomyopathy

General Characteristics

1. MNGIE is caused by mutations in the TYMP gene that maps to chromosome 22q13.33. It is a rare autosomal recessive disorder
2. The gene encodes Thymidine Phosphorylase (TP). Loss of the enzyme causes an accumulation of thymidine and deoxyuridine nucleotides that are incorporated by the mitochondrial salvage pathway. Their accumulation causes deoxynucleotide triphosphate pool imbalance thought to cause mtDNA instability
3. A few patients with MNGIE have been associated with POLG gene and MTTK gene mutations

Clinical Manifestations

1. Onset is prior to age twenty (range is 2.5–22 years)
2. Distal greater than proximal weakness
3. Gastrointestinal dysmotility (pseudo-obstruction)
4. Stocking and glove sensory loss
5. Decreased muscle stretch reflexes
6. Ptosis and extraocular muscle weakness
7. Rare patient has cognitive deficits
8. Pigmentary retinopathy
9. Sensorineural hearing loss
10. Facial weakness
11. Hoarseness and dysphasia

Neuropathology

1. Muscle biopsy:
 - a. Ragged red fibers
 - b. Ragged blue fibers
 - c. COX-negative fibers
 - d. Neurogenic atrophy of distal muscles
2. Sural nerve biopsy:
 - a. Loss of myelinated fibers
 - b. Demyelination with remyelination with rare onion bulbs
 - c. Electron microscopy:
 - i. Abnormal mitochondria
 - ii. Paracrystalline inclusions in both muscle fibers and Schwann cells
 - iii. Enzymatic assay of muscle fibers:
 1. COX and other respiratory enzyme deficits
 - iv. Autopsy:
 1. Endoneurial fibrosis and demyelination in peripheral nerves
 2. White matter abnormalities in the cerebral cortex and cerebellum
 3. Cranial nerve and spinal roots are demyelinated to a degree
 4. Loss of neurons and fibrosis of the autonomic ganglia, celiac and myenteric plexuses

Laboratory Evaluation

1. Serum CK levels are normal or slightly elevated
2. Increased lactate, pyruvate and CSF protein is typical
3. EKG:
 - a. Conduction defects in some asymptomatic patients
4. EMG:
 - a. Increased insertional activity, positive sharp waves and fibrillation potentials
 - b. Decreased recruitment of MUAPs may be seen in distal muscles
 - c. Proximal muscles reveal small brief duration MUAPs
5. NCS:
 - a. Slow motor and sensory nerve conduction velocities to the demyelinating range with prolonged F-wave latency
 - b. Reduced amplitudes of sensory nerve action potentials
 - c. Rare reduced amplitude of CMAPs
6. MRI:
 - a. Abnormalities of cerebral and cerebellar white matter (leukoencephalopathy)
7. Gastrointestinal radiology:
 - a. Dilation and dysmotility of the esophagus, stomach and small intestine

Polymerase Gamma 1 (POLG1)

General Characteristics

1. POLG1 is a nuclear gene that maps to chromosome 15q.26.1 which causes disease by affecting mtDNA
2. It encodes the catalytic subunit of the mtDNA polymerase gamma that is required for mtDNA replication

Clinical Manifestations

1. Alpers syndrome
2. PEO with or without myopathy
3. Ataxia-neuropathy syndrome
4. Epilepsy
5. Childhood progressive encephalopathy
6. Parkinsonism
7. Stroke-like episodes
8. Isolated exercise intolerance
9. Propofol-related infusion syndrome

Neuropathology

1. Muscle biopsy:
 - a. COX deficient ragged red fibers
2. Analysis of mtDNA of clinically affected tissue reveals deletion, multiple deletions, or point mutations

Laboratory Evaluation

1. Resting pyruvate and lactate levels may be elevated
2. EMG:
 - a. Usually normal

RRM2B*General Characteristics*

1. RRM2B (ribonucleotide reductase small subunit 2-like) maps to chromosome 8q22.3
2. The RRM2B gene encodes the small subunit of p53-inducible ribonucleotide reductase
3. The heterotetrameric enzyme converts ribonucleotide diphosphates into deoxynucleoside diphosphates that are critical for DNA synthesis
4. Mutations in RRM2B are the third most common cause of multiple mitochondrial deletions in adults
5. Transcription of RRM2B is regulated by the tumor suppression protein p53
6. Mutations in the RRM2B gene have been documented with dominant and recessive inheritance
7. Recessively inherited RRM2B mutations have a more severe phenotype

Clinical Manifestations

1. Ophthalmoparesis is severe and most often associated with ptosis (90%)
2. Proximal muscle weakness
3. Bulbar dysfunction (42%):
 - a. Dysarthria and dysphagia
 - b. Dysphonia
 - c. Facial weakness
 - d. Neck flexor muscle weakness
 - e. Sensorineural hearing loss (36%)
 - f. Gastrointestinal dysfunction (19%)
 - g. Cerebellar ataxia (39%)
 - h. Stroke-like episodes (10%)
 - i. Cardiac complications

Neuropathology

1. Muscle biopsy:
 - a. COX deficient ragged red fibers
 - b. EMG:
 - i. Normal
 - c. Multiple mtDNA deletions in affected tissue

Laboratory Evaluation

1. Normal or elevated resting lactate and pyruvate levels
2. Muscle biopsy:
 - a. Ragged red fibers
 - b. COX deficient fibers
3. EKG:
 - a. Cardiac conduction defects

Thymidine Kinase Deficiency (Myopathic Type)**TK2***General Characteristics*

1. Thymidine Kinase (TK2) is a mitochondrial deoxyribonucleotide that is encoded by the TK2 gene that maps to chromosome 16p21
2. It phosphorylates thymidine, deoxycytidine, and deoxyuridine
3. TK2 along with DGUOK are important in mitochondrial salvage pathway enzymes that are critical for the maintenance of balanced mitochondrial dNTP concentrations

Clinical Manifestations

1. TK2 related mitochondrial DNA depletion syndrome has a wide phenotypic spectrum
2. In infants and children:
 - a. There is generalized hypotonia and proximal muscle weakness
 - b. Loss of previously acquired motor skills
 - c. Poor feeding and respiratory failure after a few years
 - d. A form in infants is characterized by rapidly progressive proximal muscle weakness, encephalopathy, epilepsy and an early demise that resembles spinal muscular atrophy
 - e. A variant early presentation is progressive myopathy with sensorineural hearing loss and hepatomegaly
 - f. Late or adult onset forms include:
 - i. Progressive proximal muscle weakness
 - ii. Chronic progressive ophthalmoplegia (with multiple mtDNA deletions and no DNA depletion)

Neuropathology

1. Muscle Biopsy:
 - a. Increased SDH activity (succinic dehydrogenase) with low to absent COX (cytochrome oxidase activity)
 - b. Severely decreased mitochondrial DNA copy number (5% to 30%) of control values
 - c. Ragged red fibers

Laboratory Examination

1. Elevated CK concentration that is usually 5–10 times normal
2. Pulmonary function abnormalities in the infantile and early childhood forms (may also be present in adults)
3. Normal serum lactate may occur concomitantly with high CK Levels

Adult Mitochondrial DNA Depletion Symptoms with Mild Manifestations*General Characteristics*

1. Report of an adult patient with mitochondrial depletion syndrome with mild clinical symptomatology

Clinical Manifestations

1. Onset at 47 years of age
2. Positive family history for mitochondrial disease
3. Daytime sleepiness
4. Exercise intolerance
5. Myalgia in the lower extremities
6. Painful neck muscles
7. Bilateral ptosis
8. Decreased Achilles tendon reflexes

Neuropathology

1. Muscle Biopsy:
 - a. Detached lobulated fibers with subsarcolemmal NADH and SDH staining
 - b. Depletion of mtDNA to 9% of normal

Laboratory Evaluation

1. Hyperlipidemia; pyruvate and lactic acid were normal
2. EMG:
 - a. Normal

The Differential Diagnosis of the Genes Involved in DNA Replication and Maintenance

1. The mechanism that underlies mitochondrial maintenance disorders is offset by either replication machinery of the biosynthesis pathways of deoxyribonucleotide 5' triphosphates that is critical for mtDNA synthesis
2. Mitochondrial DNA is replicated by:
 - a. POLG
 - b. POLG2
 - c. DIOD or F2, and
 - d. MGME1 (mitochondrial genome maintenance exonuclease 1). The products of these genes function directly at the mtDNA replication fork
3. Genes involved in the supply of the mitochondria with deoxyribonucleotide triphosphate pools that are needed for mtDNA replication include:
 - a. Adenine nucleotide translocator 1 (ANT 1)
 - b. Thymidine phosphorylase
 - c. Thymidine Kinase 2

- d. Deoxyguanosine kinase
- e. ADP forming succinyl CoA synthetase ligase
- f. MPV17
- g. RRM2B

POLG

1. DNA polymerase gamma in conjunction with its accessory proteins that include:
 - a. Mitochondrial DNA helicase
 - b. Single-stranded DNA-binding protein
 - c. Topoisomerase
 - d. Initiating factors
2. Genes directly involved in replication:
 - a. POLG
 - b. POLG2
 - c. Twinkle gene
 - d. MGME1
 - e. C10 or F2
3. Genes whose products supply the mitochondria with deoxyribonucleotide triphosphate pools for mtDNA replication:
 - a. Adenine nucleotide translocator 1 (ANT 1)
 - b. Thymidine phosphorylase
 - c. Thymidine kinase 2
 - d. Deoxyguanosine kinase
 - e. ADP-forming succinyl CoA synthetase ligase
 - f. MPV17

Differential Diagnosis of Mitochondrial Myopathy

Any adult patient that presents with exercise intolerance, easy fatiguable, bilateral symmetrical ptosis, ophthalmoplegia, diabetes, short stature, and sensorineural hearing loss and migraine should alert the clinician to the possibility that he is dealing with a mitochondrial myopathy. There is a wide spectrum of clinical manifestations from the same mutation and great variability of the severity of the disorder among family members and between families. Rarely, mitochondrial myopathies that are usually restricted to infants and childhood are seen in adults. Some have adult onset. A specific genetic defect may cause different phenotypes. Primary carnitine deficiency primarily presents in infancy with hypoketotic hypoglycemia and hepatomegaly although secondary forms are seen with many diseases and may present with severe weakness. Carnitine palmitoyl transferase deficiency (CPT2) may present with proximal myopathy and cardiomyopathy. Coenzyme Q deficiency has several presentations that include: 1. encephalopathy, seizures and ataxia (infants and childhood), 2. multisystem involvement, 3. cardiomyopathy, encephalopathy and renal failure, 4. Leigh phenotype and 5. isolated primarily proximal myopathy. All defects in the respiratory chain cause failure of generation of ATP. Complex II has an elevated serum CK, spasticity, and leukoencephalopathy. Complex II manifests as exercise intolerance. Complex IV has a wide clinical spectrum from an isolated

myopathy to multisystem disease. Its onset is from infancy to adulthood. Most severe forms manifest lactic acidemia, a Leigh's disease presentation with white matter abnormalities, basal ganglia lesions and cerebellar atrophy. Complex V may present with psychomotor retardation, growth retardation, leukoencephalopathy, lactic acidemia and 3-methyl glutaconic aciduria. The benign form of pyruvate carboxylase deficiency may have normal strength but episodes of metabolic acidosis with increased serum levels of lactate, pyruvate, lysine, proline and beta-hydroxybutyrate. Pyruvate decarboxylase deficiency is primarily seen in infants and manifests with hypotonia with subsequent psychomotor retardation, seizures, facial dysmorphisms, metabolic and lactic acidosis. Defects of oxidative phosphorylation coupling occur with Luft disease which manifests a hypermetabolic state characterized by profuse sweating, exercise intolerance, fever, generalized weakness and heat intolerance. Mitochondrial depletion syndromes are characterized by myopathy, encephalopathy and hepatocerebral symptomatology.

There are few neurologic disorders that demonstrate bilateral ptosis and ophthalmoplegia in concert with heart block. Syncope may be the presenting feature of Kearns-Sayre syndrome (KSS). Congenital myasthenic syndromes have no cardiac symptomatology although interstitial myocarditis may occur in adult patients with myasthenia and thymoma. The ptosis an ophthalmoparesis in myasthenia is asymmetric. Niemann-Pick Type C has failure of upgaze and a supranuclear palsy, but ptosis and heart conduction defects do not occur.

Oculopharyngeal muscular dystrophy may demonstrate the same pattern of weakness as KSS but begins in the fourth to sixth decade, where KSS starts prior to age 20. There are no cardiac defects with oculopharyngeal dystrophy. AD-PEO with multiple mtDNA depletion has prominent ptosis associated with face, neck flexor and proximal weakness, but no other manifestations of KSS. AR-PEO has ocular manifestations, no myopathy but an often severe hypertrophic cardiomyopathy, cataracts and early death. MNGIE's most dominant feature is gastrointestinal dysmotility and peripheral neuropathy, whereas ARCO is dominated by a severe cardiomyopathy rather than conduction defect.

Leigh's syndrome is usually a pediatric disease but occasionally presents in adulthood. There is a wide clinical spectrum that includes hypotonia, recurrent vomiting and psychomotor deficits in childhood with generalized weakness, ophthalmoplegia, ptosis, hearing loss and optic atrophy in later life.

The sentinel features of MERRF are the myoclonic seizures, dementia and lipomatosis (some patients).

MELAS is characterized by stroke-like episodes that are out of a vascular distribution and may evolve rather than present abruptly. Most patients are symptomatic in adolescence but rarely may it present very late in adulthood. In addition to the stroke-like episodes there is generalized muscle weakness and high serum and CSF lactate levels. Some mitochondrial myopathy patients only have exercise induced

muscle pain, reduced muscle bulk and occasional recurrent myoglobinuria. In general, they are of short stature and may have sensorineural hearing loss. Dementia is prominent in MELAS, MERRF and KSS. Ptosis and ophthalmoplegia in AD-PEO, Leigh's syndrome, KSS, MNGIE and ARCO. Rarely, it occurs in MELAS that is differentiated from other mitochondrial disorders by associated posterior leukoencephalopathy and migraine. The stroke-like episodes are differentiated from ischemic events by: 1. not being restricted to a vascular territory (often parietal and posterior territories); 2. evolving over hours to days rather than presenting with an apoplectic onset and 3. with recurrence and recovery. Pigmentary retinopathy is seen in KSS, MELAS and MERRF. Optic atrophy occurs with LHON, MERRF and Leigh's disease. Peripheral neuropathy is seen in NARP and MNGIE but the gastrointestinal dysmotility dominates the later disorder. An unusual condition is hypoparathyroidism that may be seen with KSS.

Differential Diagnosis of Chronic Progressive Ophthalmoplegia

1. Oculopharyngeal muscular dystrophy:
 - a. Bulbar symptomatology is more severe than in AD-PEO
2. KSS (Kearns-Sayre syndrome):
 - a. Heart block with syncope may dominate the clinical picture
 - b. Younger age than PEO
 - c. Pigmentary retinopathy
3. Myasthenia gravis:
 - a. Fluctuation of cranial nerve signs; may be induced at the bedside
 - b. Asymmetrical ophthalmoplegia and ptosis
 - c. Diplopia; most PEO patients have minimal diplopia or none
4. Progressive supranuclear palsy (PSP):
 - a. Dramatic vertical gaze deficits
 - b. Falls
 - c. Parkinsonian features (not responsive to L-Dopa)
 - d. Cognitive decline
 - e. Head held in extension (idiopathic Parkinson's disease the head is invariably flexed)
5. MNGIE:
 - a. Severe GI dysmotility
6. Spinocerebellar ataxia (Type III):
 - a. Cerebellar degeneration and ataxia are the most prominent features

Defects of Oxidative Phosphorylation Coupling

Luft Disease

General Characteristics

1. Hypermetabolism and abnormal muscle respiration
2. The hypermetabolism is caused by extensive uncoupling of mitochondrial respiration in skeletal muscle

Clinical Manifestations

1. Onset in adolescence
2. Fever
3. Heat intolerance
4. Profuse sweating
5. Exercise intolerance
6. Hypermetabolic state
7. Polyphasia and polydipsia
8. Tachycardia
9. Death in middle age
10. Generalized weakness

Neuropathology

1. Muscle biopsy:
 - a. Peripheral aggregates of abnormal mitochondria:
 - i. Overabundant tightly packed disorganized cristae of the mitochondria
 - ii. The mitochondrial cristae form a zigzag pattern
2. Electron microscopy:
 - a. Small electron dense osmophilic bodies are identified in the mitochondria
 - b. Occasional paracrystalline inclusions
3. The mitochondrial enzymes function normally
4. The zigzag mitochondrial structural conformational change is caused by an absence of some tricarboxylic acid cycle enzyme from the cristae which exposes the interior of the cristae to the matrix flux
5. Leakage of protons from the cristae impairs coupling of respirational and ATP synthesis

Laboratory Evaluation

1. The basal metabolic rate is dramatically elevated

Defects of the Mitochondrial Respiratory Chain***Mitochondrial Complex I****General Characteristics*

1. Complex I deficiency involves mutation in NADH-CoQ reductase
2. Two electrons are removed from NADH and transferred to a lipid-soluble carrier, ubiquinon (Q); the reduced product is ubiquinol
3. Ubiquinol (QH₂) diffuses within the membrane and translocates four protons (H⁺) across the membrane which produces the mitochondrial proton gradient
4. Mitochondrial gene mutations encode defective subunit 4 of complex I

Clinical Manifestations

1. Fatal infantile multisystem disorder
2. Congenital lactic acidosis
3. Cognitive deficits
4. Hypotonia

5. Most often death in infancy from cardiorespiratory failure
6. Myopathy with associated carnitine deficiency:
 - a. Onset in childhood or adult life
 - b. Exercise intolerance
 - c. Muscle pain
 - d. Progressive primarily proximal muscle weakness
 - e. Female affected relatives

Neuropathology

1. Muscle biopsy:
 - a. Accumulation of lipid
 - b. Ragged red fibers

Laboratory Evaluation

1. Low plasma and muscle carnitine
2. EMG:
 - a. Normal

Complex Deficiency with Normal Carnitine Levels*General Characteristics*

1. NADH is oxidized to NAD⁺ by reducing flavin mononucleotide to FMN in electron steps from the FMN to Fe-S clusters and then to ubiquinone
2. Complex I is a major site for the production of reactive oxygen species (superoxide)

Clinical Manifestations

1. Age at onset is between 16–46 years of age
2. Fatigue
3. Muscle pain
4. Weakness
5. Remittent paralysis (rare) associated with lactic acidosis
6. Heart failure (rare)
7. Dementia, dystonia, blindness (one patient)

Neuropathology

1. Muscle biopsy:
 - a. Ragged red fibers

Laboratory Evaluation

1. Metabolic acidosis
2. Hypoglycemia
3. Lactic acidemia
4. Increased serum CK
5. EMG:
 - a. Normal

Mitochondrial Complex II (Succinate Dehydrogenase or Succinate – CoQ Reductase)*General Characteristics*

1. Complex II delivers additional electrons into the quinone pool that originate from succinate and are transferred via FAD to Q
2. Complex II is composed of four protein subunits

3. Although complex II is a parallel electron transport pathway (to complex I) it does not transport protons to the inner mitochondrial space
4. SDH is a nuclear encoded enzyme
5. AR inheritance; involvement of the Fe-S unit of the complex

Clinical Manifestations

1. May present in adulthood
2. Optic atrophy
3. Proximal myopathy
4. Growth retardation
5. Spasticity
6. Pulmonary edema
7. Kearns-Sayre-like presentation

Neuropathology

1. Ragged red fibers and small arteries stain less intensely with SDH stains
2. Accumulation of lipid droplets in abnormal fibers

Laboratory Evaluation

1. Excessive and prolonged lactate production and increased venous oxygen saturation with the forearm exercise test
2. EMG:
 - a. Usually normal

Coenzyme Q10 (CoQ) Deficiencies

General Characteristics

1. Primary coenzyme Q10 deficiency-1 (CoQ10D1) is caused by homozygous or compound heterozygous mutation in the CoQ2 gene that maps to chromosome 4q21; AR
2. Coenzyme Q10 is ubiquinone which is a mobile lipophilic electron carrier of the inner mitochondrial membrane respiratory chain
3. Multiple genes may be mutated that encode proteins directly involved in the synthesis of coenzyme Q
4. Secondary CoQ10 deficiency is associated with glutaric aciduria type IIC (ETFDH gene on chromosome 4q) and mutation in the APTX gene in chromosome 9p13 that causes ataxia syndrome (AOA-1)
5. CoQ10 transfers electrons from complex I and II to complex III

Clinical Manifestations

1. There are 5 major phenotypes:
 - a. Encephalomyopathic:
 - i. Seizures
 - ii. Ataxia
 - b. Multisystem infantile form:
 - i. Encephalopathy, cardiomyopathy and renal failure
 - c. Cerebellar form with ataxia and cerebellar atrophy
 - d. Leigh's syndrome with growth retardation
 - e. Isolated myopathic form:
 - i. Proximal weakness
 - ii. Exertional recurrent myoglobinuria
 - iii. Exercise intolerance
 - iv. Some patients have bilateral ptosis in childhood

Neuropathology

1. Muscle biopsy:
 - a. Ragged red fibers
 - b. Cytochrome C, oxidase deficient fibers
 - c. Excess lipid droplets
 - d. Muscle tissue demonstrates low levels of CoQ10

Laboratory Evaluation

1. Serum CK, lactic acid and pyruvate levels can be normal to moderately elevated
2. Excessive and prolonged lactate production with increased venous oxygen saturation during and following exercise

Mitochondrial Complex III (Mutation in the Cytochrome b Gene)

General Characteristics

1. Cytochrome b is a protein that is encoded by the MT-CYB gene
2. It is a subunit of the respiratory chain protein ubiquinol cytochrome c reductase. The complex is composed of the products of one mitochondrially encoded gene MT-CYB and ten nuclear genes
3. The complex is involved in the electron transport complex and the pumping of protons to form the proton gradient
4. The complex leaks electrons to molecular oxygen to form the reactive oxygen species superoxide

Clinical Manifestations

1. Encephalopathy:
 - a. Infant presentation (fatal)
2. Childhood or adult presentation:
 - a. Myopathy:
 - i. Exercise intolerance
 - ii. Fixed proximal weakness
 - iii. Cardiomyopathy (histiocytoid cardiomyopathy in infancy)
3. Pigmented retinopathy
4. Sensory neuropathy
5. May respond to vitamin K3 (menadione)

Neuropathology

1. Muscle biopsy:
 - a. Ragged red fibers
 - b. Lipid accumulation

Laboratory Evaluation

1. Serum lactate and pyruvate may be elevated at rest and are exacerbated by the forearm exercise test

Cytochrome C Oxidase Deficiency (Complex IV)*General Characteristics*

1. Cytochrome c oxidase deficiency can be caused by mutation in several nuclear encoded and mitochondrially encoded genes
2. The mitochondrial gene mutations include:
 - a. COX
 - b. MTCO1
 - c. MTCO2
 - d. MTCO3
 - e. MTTS1 (mitochondrial tRNA)
 - f. MT-TL1 (transfers leucine)
3. Mutations in nuclear genes include:
 - a. COX20 (1q44)
 - b. COAS (2q11.2)
 - c. FASTKE2 (2q33.3)
 - d. COX14 (12q13.12)
 - e. APOPT1 (14q32.33)
 - f. COX10 (17p12)
 - g. TACO1 (17q23.3)
 - h. PET100 (19p13.2)
 - i. COX6B (19q13.2)
4. The mitochondrially encoded proteins in the cytochrome oxidase complex are the catalytic subunits and also function in electron transport
5. Isolated COX deficiencies have autosomal recessive inheritance and are caused by mutations in nuclear-encoded genes

Clinical Manifestations

1. The deficiency of cytochrome c oxidase is clinically very heterogeneous
2. Onset may be from infancy to adulthood
3. Myopathic phenotypes:
 - a. Fatal infantile form:
 1. Lactic acidosis
 2. Respiratory distress
 3. Renal failure
 4. Death in the first year
 - b. Benign form:
 1. Patients improve and are normal by age three
 2. Return of COX in muscle
 3. Subunit VII, Z, b and II are involved
 - c. Adolescent form:
 1. Exercise induced myoglobinuria
 2. Normal neurological examination between attacks
 3. Mild proximal muscle weakness
 4. No multisystem involvement
 5. Fatigue and myalgia with exercise

Neuropathology

1. Muscle biopsy:
 - a. Ragged red fibers
 - b. Increased lipid accumulation

2. Magnetic resonance spectroscopy:
 - a. Rapid decrease of creatine phosphate and an abnormal increase of inorganic phosphate with exercise
 - b. Delay of phosphocreatine to baseline concentrations regeneration after exercise

ATP Synthase Deficiency (Complex V)*General Characteristics*

1. ATP synthase deficiency nuclear type 2 may be caused by homozygous mutations in the TMEM70 gene that maps to chromosome 8q21.11; subunit 6 (mtDNA 8993)
2. A large percentage of patients have been described from Roma families

Clinical Manifestations (MC5DN2)

1. Intrauterine growth retardation
2. Severe hypotonia at birth
3. Some children developed pulmonary arterial hypertension in the neonatal period
4. Hypertrophic cardiomyopathy
5. Microcephaly
6. Dysmorphism
7. Hypospadias
8. Growth retardation
9. Cryptorchidism

Clinical Manifestations in Patients with Subunit 6 (mtDNA 8993)

1. Mild progressive muscle weakness
2. Fatigue on exertion
3. Growth retardation
4. Sensorineural hearing loss
5. Recurrent vomiting
6. Pigmentary retinopathy
7. Cognitive impairment
8. Peripheral sensory neuropathy
9. Cerebellar ataxia
10. Multisystem involvement

Neuropathology (mtDNA 8993)

1. Muscle biopsy:
 - a. Ragged red fibers
 - b. Lipid accumulation (often exacerbated by secondary carnitine deficiency)
 - c. Electron microscopy:
 - i. Paracrystalline deposits in the inner mitochondrial membrane

Laboratory Evaluation

1. Lactic acidosis
2. 3-methylglutaconic aciduria
3. MRI:
 - a. Cerebellar atrophy; leukoencephalopathy
 - b. Basal ganglia calcification (mtDNA 8993 mutation)

Defects of Mitochondrial Substrate Utilization and Gluconeogenesis

Pyruvate Carboxylase Deficiency

General Characteristics

1. Categorized into 3 phenotypic subgroups:
 - a. North American patients (group A)
 - b. Patients from France and the UK (group B)
 - c. Group C is relatively benign
2. Mutations in the pyruvate carboxylase gene have been mapped to chromosome 11q13.2

Clinical Manifestations in Group A (North American Patients)

1. Cognitive impairment
2. Proximal renal tubule acidosis
3. Leigh-type necrotizing encephalopathy
4. Episodes of lactic acidosis
5. Developmental delay
6. Muscle hypotonia
7. Some patients with clonus or athetosis

French Form

1. Neonatal and congenital lactic acidosis
2. Cognitive impairment
3. Macrocephaly
4. More severe phenotypes than the North American form
5. Hepatomegaly

Benign Form

1. Normal motor and cognitive abilities
2. Episodes of metabolic acidosis
3. Mild cognitive impairment (in 1 patient)

Neuropathology

1. Necropsy (North American and French forms):
 - a. Severe ischemic brain lesions (2 patients) associated with periventricular leukomalacia
 - b. Periventricular cysts and diffuse hypomyelination

Laboratory Evaluation

1. Severe forms Type A and B:
 - a. Increased plasma lactate pyruvate, glutamic acid, proline and alanine
 - b. Low pyruvate carboxylase activity in skin fibroblasts
2. French form:
 - a. Hyperammonemia
 - b. Lysinemia
 - c. Citrullinemia
3. Benign form:
 - a. Metabolic acidosis with elevated lactate, pyruvate, alanine, beta-hydroxybutyrate, acetoacetate
4. MRI (Type A and B):
 - a. Periventricular leukomalacia and cysts
 - b. Stroke-like lesions (2 patients)

Pyruvate Dehydrogenase (E-1 Alpha Deficiency (PDHAD))

General Characteristics

1. PDHAD is caused by mutations in the PDHAD gene that is localized to chromosome Xq 22.12
2. Mutations in the E-1 alpha-subunit gene are the most common but PDH deficiency is also caused by mutations in genes coding for other subunits of the PDH complex and include:
 - a. PDHX gene (11p)
 - b. PDHB gene (3p)
 - c. DLAT gene (11q)
 - d. PDP1 gene (11q)
 - e. LIAS gene (4p14)
3. Components of the PDH complex are:
 - a. Pyruvate decarboxylase (E-1)
 - b. Dihydrolipoyl transacetylase (E2)
 - c. Dihydrolipoyl dehydrogenase (E3)
4. There are two regulatory enzymes of the complex:
 - a. Pyruvate dehydrogenase kinase
 - b. Pyruvate dehydrogenase phosphatase

Clinical Manifestations

1. There are two major clinical presentations of PDH deficiency:
 - a. Metabolic:
 - i. Severe lactic acidosis of the newborn with mortality
2. Neurologic manifestations:
 - a. Intermittent ataxias
 - b. Intermittent movement disorders
 - c. Clinical neurologic manifestations depend on the severity of the deficit and not on the subunit or enzyme that is deficient
3. Presentation at birth with:
 - a. Psychomotor retardation
 - b. Progressive encephalopathy
 - c. Seizures
 - d. Generalized hypotonia
 - e. Metabolic and lactic acidosis
 - f. Rapid respiration
 - g. Facial dysmorphisms
 - h. Ataxia

Neuropathology

1. Necropsy of a 50 year old patient:
 - a. Cerebellar degeneration
 - b. Necrosis around the IIIrd ventricle and aqueduct similar to that seen in Leigh's or Wernicke's encephalopathy
2. Structural changes in children:
 - a. Cerebral atrophy
 - b. Cystic lesions of the cortex, basal ganglia and brain stem; lesions similar to Leigh's disease

Laboratory Evaluation

1. Metabolic acidosis (newborns)

2. Elevated blood and CSF lactate and pyruvate levels
3. Identification of specific subunit mutations in mitochondrial fractions
4. Increased lactate, pyruvate and alanine can be determined in the urine
5. If there is decreased dihydrolipoyl dehydrogenase activity (CE3):
 - a. Increased blood levels of branch chain amino acids and α -ketoglutarate

Mitochondrial Importation Defects

General Characteristics

1. Transport of nuclearly encoded proteins from the cytoplasm into mitochondria:
 - a. Targeted to different intramitochondrial compartments
2. Defects of translocation steps:
 - a. Address signals:
 - i. Amino terminal leader peptides
 - ii. Cytoplasmic heat shock proteins
 - iii. Peptide transport proteins
 - iv. Leader-peptide receptor interaction at the mitochondrial membrane
 - v. Energy dependent translocation through the mitochondrial membrane
 - vi. Intramitochondrial cleavage of leader peptides by peptidases

Clinical Manifestations

1. Infantile encephalopathy, lactic acidosis, defective heat shock proteins
2. Methylmalonic aciduria:
 - a. Mutation that causes defective methylmalonic CoA-mutase:
 - i. Defective leader peptide
 - ii. Inability to enter the mitochondrion
3. Friedreich's ataxia:
 - a. Trinucleotide expansion of intron 9 on chromosome 9q21.11
 - b. Defective encoded protein is frataxin
4. Loss of regulation of iron transport into the mitochondrion
5. Dysfunction of enzymes that contain iron sulfur subunits:
 - a. Aconitase
 - b. Complex I, II, III
6. Paraplegia (spastic):
 - a. Chromosome 16q
 - b. AR
 - c. Regulation of metalloproteinase
7. Reye's syndrome:
 - a. Putative defect of translocation associated with multiple mitochondrial enzyme dysfunction

Neuropathology

1. Dependent on the specific disorder

Laboratory Evaluation

1. Dependent on the specific disorder

Inflammatory Myopathies

Diagnostic Criteria for Dermatomyositis

1. Clinical inclusion criteria:
 - a. Onset in childhood or adulthood
 - b. Subacute or insidious onset
 - c. Symmetric proximal weakness:
 - i. Legs > arms
 - ii. Neck flexors > neck extensors
 - d. Rash:
 - i. Heliotrope
 - ii. Gottron's papules
 - iii. V-sign
 - iv. Shawl sign
 - v. Holster sign
2. Exclusion criteria:
 - a. Oculomotor involvement
 - b. Isolated dysarthria
 - c. Neck extensor > neck flexor weakness
3. Muscle biopsy:
 - a. Perifascicular atrophy (definite DM)
 - b. Probable DM:
 - i. Myxovirus resistance 1 protein (or other type 1 interferon regulated proteins) that are deposited in small blood vessels or muscle fibers
 - ii. MAC deposition on small blood vessels
 - iii. Tubuloreticular inclusions in endothelial walls by electron microscopy
 - iv. MHC-1 expression of perifascicular fibers
 - v. Perifascicular, perineurial inflammatory cell infiltrate
4. Amyopathic DM criteria:
 - a. No subjective or objective muscle weakness
 - b. Normal serum CK
 - c. Normal EMG
 - d. Typical DM rash
 - e. Skin biopsy:
 - i. Reduced capillary density, deposition of MAC on small blood vessels at the dermal-epidermal junction
5. Dermatomyositis without rash
 - a. Clinical criteria for DM but without a rash
 - b. Muscle biopsy:
 - i. Perifascicular atrophy
 - ii. MAC deposition on small blood vessels or muscle fibers
 - iii. Reduced capillary density
 - iv. Electron microscopy:
 1. Tubuloreticular inclusions in endothelial cell walls
 - v. MHC-1 expression of perifascicular fibers
 - c. Elevated CK plus one other laboratory criterion for DM that includes myositis antibodies
6. Non-specific myositis:

a. Clinical Manifestations

i. Inclusion criteria:

1. Onset in childhood or adulthood
2. Subacute or insidious onset
3. Symmetrical proximal > distal weakness

ii. Exclusion criteria:

1. Rash typical of DM
2. Clinical features of IBM
3. Extraocular muscle involvement
4. Isolated dysarthria
5. Neck extensor weakness > than flexor
6. Allergies to myotoxic drugs
7. Endocrinopathy
8. Amyloidosis
9. SMA
10. Dystrophies

iii. Muscle biopsy:

1. Perivascular, perimysial inflammatory cell infiltrate but without perifascicular atrophy, perifascicular MHC-1 expression, MAC deposition on small blood vessels, reduced capillary density and no tubuloreticular inclusions
2. There may be scattered endomysial CD8+ T-cells infiltration which does not surround or invade muscle fibers
3. Exclusion of:
 - a. Necrotizing myopathies
 - b. Dystrophies
 - c. IBM

iv. Elevated CK

v. One of three other laboratory criteria:

1. Myositis – specific antibodies
2. Skeletal muscle MRI
3. Positive EMG criteria for myositis

Immune-Mediated Necrotizing Myopathy

1. Inclusion criteria:

- a. Onset usually after 18 years of age
- b. Subacute or insidious onset
- c. Symmetrical proximal > distal weakness

2. Exclusion criteria:

- a. Typical DM rash
- b. Clinical exclusion criteria of PM

3. Muscle biopsy:

- a. Predominance of necrotic muscle fibers
- b. Minimal inflammatory cell response with slight perivascular perimysial infiltrate
- c. MAC deposition on small blood vessels
- d. Rare tubuloreticular inclusions in endothelial cells
- e. Electron microscopy:
 - i. Pipestem capillaries
- f. No mononuclear inflammatory cell invasion of non-necrotic fibers
- g. No perifascicular atrophy

4. Serum CK is elevated

5. One laboratory criteria (EMG, skeletal MRI or myositis-specific antibodies)

Differential Diagnosis of Dermatomyositis

1. Polymyositis
2. Amyopathic DM
3. DM size dermatitis (solitary)
4. Non-specific myositis
5. Immune-mediated myopathy
6. Necrotizing myopathy
7. Muscular dystrophies
8. IBM
9. Active endocrinopathies:
 - a. Hyper- or hypothyroidism
 - b. Hyperparathyroidism
10. Myotoxic drugs
11. Amyloidosis
12. Spinomuscular atrophy (SMA)

Diagnostic Criteria for Polymyositis

1. Clinical Manifestations

a. Inclusion criteria:

- i. Onset most often after 18 years of age
- ii. Subacute or insidious
- iii. Symmetric proximal > distal weakness

b. Exclusion criteria:

- i. Clinical features of IBM that include
 1. Asymmetric weakness
 2. Wrist and finger flexor weakness equal to or worse than that demonstrated in the deltoids, knee extensors and/or ankle dorsi flexors; same or greater weakness in hip flexors
 3. Extraocular muscle weakness, isolated dysarthria, neck extensor > than neck flexor weakness
 4. Exposure to myotoxic drugs, active endocrinopathy that affects muscle, amyloidosis, and a family history of muscular dystrophy or proximal motor neuropathies (SMA)

2. Elevated creatine kinase in the serum

3. One of three positive laboratory studies:

a. EMG:

i. Inclusion criteria:

1. Increased insertional and spontaneous activity
2. Short duration, small amplitude, polyphasic MUAPs

ii. Exclusion criteria:

1. Prominent myotonic discharge consistent with proximal myotonic dystrophy or other channelopathy
2. Long duration, large amplitude MUAPs
3. Decreased recruitment MUAP pattern

b. Skeletal muscle MRI:

- i. Diffuse or patchy increased signal (edema) within muscle tissue or STIR images

c. Myositis specific antibodies in the serum

4. Muscle biopsy:

- a. Endomysial inflammatory cell infiltrate (T-cells) that surround and invade non-necrotic muscle fibers

- b. Exclusion criteria:
 - i. Rimmed vacuoles, ragged red fibers, cytochrome oxidase-negative fibers (supportive of IBM)
 - ii. Perifascicular atrophy, deposition of MAC on small blood vessels, reduced capillary density tuboreticular inclusions in endothelial cells; pipestem capillaries (support DM or another form of humorally mediated microangiopathy)
 - iii. Dystrophic features or MAC deposition

Differential Diagnosis of Polymyositis

1. IBM
2. Dermatomyositis
3. An immune-mediated necrotizing myopathy
4. Infectious inflammatory myopathy
 - a. HIV
 - b. HTLV-1
 - c. Hepatitis B and C
5. Metabolic myopathies with rhabdomyolysis
6. Muscular dystrophies:
 - a. Facioscapulohumeral
 - b. Congenital
 - c. Dysferlinopathies
 - d. Limb girdle dystrophies
7. Myotonic dystrophy type 2
8. Amyloid myopathy:
 - a. Light chain
 - b. Familial
9. Endocrine myopathies:
 - a. Hypo- and hyperthyroidism
 - b. Hyperparathyroidism
 - c. Diabetic muscle infarction
10. Drug-induced myopathies
 - a. Statins and other cholesterol lowering agents
 - b. Cyclosporine
 - c. Chloroquine
 - d. Amiodarone
 - e. Colchicine
 - f. D-penicillamine
 - g. Cocaine
11. Juvenile or adult-onset spinal muscular atrophy
12. Kennedy's disease
13. Polymyalgia rheumatica
14. Mixed connective tissue disease (MCT)

Diagnostic Criteria for Inclusion Body Myositis

1. Clinical inclusion criteria:
 - a. Duration of illness > 6 months
 - b. Age of onset > 30 years
 - c. Muscle weakness is predominant in the proximal and distal muscles of the arms and legs; patients must have at least one of the following manifestations:
 - i. Finger flexor weakness
 - ii. Wrist flexor > wrist extensor weakness
 - iii. Quadriceps muscle weakness

Laboratory Evaluation

1. Serum creatine kinase < 12 times normal
 - a. Inflammatory myopathy in which there is mononuclear cell invasion of non-necrotic muscle fibers
- b. Vacuolated muscle fibers:
 - i. Intracellular amyloid deposits
 - ii. 15-18-nm tubulofilaments are identified with electron microscopy
- c. EMG:
 - i. Consistent with features of an inflammatory myopathy (long-duration potentials are allowed)
- d. Family history:
 - i. Rarely IBM is observed in families
 - ii. Familial IBM requires:
 - a. Documentation of mononuclear inflammatory cells that invade non-necrotic muscle fibers
 - b. Vacuolated muscle fibers and intracellular amyloid deposits on 15-18-nm tubulofilaments
- e. Associated disorders; usually immune-mediated
- f. Definite IBM:
 - i. A definitive diagnosis of IBM can be made if patient's muscle biopsy has all of the features of IBM that include:
 - a. Invasion of non-necrotic muscle fibers by mononuclear cells
 - b. Vacuolated muscle fibers
 - c. Intracellular amyloid deposits or 15-18 tubulofilaments

Differential Diagnosis of Inclusion Body Myositis

1. PM
2. ALS
3. Hereditary inclusion body myopathy
4. LGMD-1A (myotilinopathy)
5. LGMD-2
6. Welander distal myopathy

Diagnostic Criteria for Non-Specific Myositis

1. Clinical Manifestations
 - a. Inclusion criteria:
 - i. Onset in childhood and adulthood
 - ii. Subacute or insidious onset
 - iii. Proximal > distal weakness
 - b. Exclusion criteria:
 - i. DM rash
 - ii. Similar to those for DM
2. Muscle biopsy:
 - a. Perivascular and perimysial inflammatory cell infiltrate without
 - i. Perifascicular atrophy
 - ii. Perifascicular MHC-1 expression
 - iii. MAC deposition in small blood vessels
 - iv. Reduced capillary density
 - v. Tubuloreticular inclusions in EM

- b. A scattered endomysial CD8+ T-cell infiltrate may be present but does not:
 - i. Surround or invade non-necrotic muscle fibers
- c. Requires exclusion of:
 - i. Necrotizing myopathy
 - ii. IBM
 - iii. Dystrophies
- 3. Elevated serum CK
- 4. One corroborating laboratory test:
 - a. EMG
 - b. Skeletal muscle MRI
 - c. Myositis specific antibodies

Differential Diagnosis of Non-Specific Myositis

- 1. PM
- 2. DM (dermatomyositis)
- 3. IBM
- 4. Muscular dystrophy
- 5. Necrotizing myopathy

Diagnostic Criteria for Immune-Mediated Necrotizing Myopathy

Clinical Manifestations

- 1. Inclusion criteria
 - a. Onset over 18 years of age
 - b. Subacute or insidious onset
 - c. Symmetric proximal > distal weakness
- 2. Exclusion criteria
 - a. Rash
 - b. Similar to those for PM

Laboratory Evaluation

- 1. Muscle biopsy:
 - a. Multiple necrotic muscle fibers
 - b. A perimysial infiltrate
 - c. Few perivascular inflammatory cells
 - d. MAC deposition on small blood vessels
 - e. No mononuclear cell invasion of non-necrotic muscle fibers
 - f. No perifascicular atrophy
 - g. Electron microscopy:
 - i. Rare or absent tubuloreticular endothelial cell inclusions
 - ii. Pipestem capillaries
- 2. Elevated serum CK
- 3. One of three corroborating laboratory criteria (EMG, muscle MRI and myositis-specific antibodies)

Differential Diagnosis of Non-Specific Myositis

- 1. DM
- 2. PM
- 3. IBM
- 4. Toxic myopathies

- 5. Endocrine myopathies
- 6. Infectious myopathies
- 7. Amyloidotic myopathy
- 8. Congenital myopathies
- 9. Mitochondrial myopathies
- 10. Dystrophies
- 11. Proximal neuropathies
- 12. Proximal myotonic dystrophy

Neural Disorders of Skeletal Muscle Overactivity

Overview of Cramps and Fasciculations

A muscle cramp is a sudden involuntary and painful contraction of the whole or part of a muscle. It terminates within seconds to minutes and is frequently associated with a palpable lump in the muscle. The exact etiology of cramps has not been defined, but it is clear that they occur from either peripheral or central mechanisms. Cramps may be elicited from hyperexcitability of motor neurons that are elicited by afferent input. Support for this mechanism includes:

- 1. The triceps surae H-reflex is enhanced after a cramp of the homologous muscle
- 2. Voluntary contraction of antagonistic muscles contralateral to the cramping muscle induces reciprocal inhibition or cross-reflex effects which modify the EMG findings associated with cramps. Spinal involvement in cramp generation is further supported by the finding that cramp generated EMG and voluntary EMG are both inhibited by stimulation of tendon afferents

Support for the peripheral generation of cramps is that it has been demonstrated that they can be elicited by electrical stimulation distal to a peripheral nerve block which may be the result of spontaneous motor nerve discharges or abnormal excitability of the terminal branches of motor axons. Cramps may be preceded and followed by fasciculations which are thought to originate primarily from the terminal portions of motor axons. Cramps can be elicited with or without proximal nerve block.

Those elicited during nerve block in healthy subjects:

- 1. Require greater stimulus frequency
 - 2. Last for a shorter interval
 - 3. Demonstrate different motor unit characteristics
- This evidence demonstrates spinal involvement in both the origin and maintenance of cramps.

Another recent pathophysiological mechanism suggested to explain cramps is that increased afferent muscle spindle activity occurs with decreased inhibition from the golgi tendon organ which causes an increase in alpha motor neuron discharge. The firing frequencies are comparable to those seen during normal voluntary contractions. Muscle cramps most often occur at short muscle lengths and are relieved by muscle stretch. In shortened muscle, the inhibition of the golgi tendon organ is depressed at the same time there is a lowered excitation threshold at motor end plates.

Fasciculations are random spontaneous discharges of all muscle fibers of a given motor unit. They are most often benign when confined to a simple muscle and when they occur in isolation. Fasciculation potentials are the electrodiagnostic correlate of fasciculations. They are ominous if widespread and associated with atrophy and weakness. Most fasciculations originate distally in the motor nerve in both normal subjects and patients with motor neuron disease.

Cramps

General Characteristics

1. A muscle cramp is a sudden involuntary and painful contraction of a muscle (or part of one) with visible and palpable muscle hardening. There may be associated abnormal position of joints. They may be acutely relieved by massage or stretching. They usually spontaneously extinguish within seconds or minutes
2. Their estimated prevalence on a weekly basis is 35% of a normal population

Clinical Manifestations

1. Cramps occur with greater frequency in the elderly, during pregnancy and those who do not exercise
2. Gastrocnemius soleus complex muscle is the most commonly involved, particularly at night in the elderly
3. Cramps are most often associated with benign processes. They portend a serious neuromuscular disorder if accompanied by weakness, atrophy or are elicited with muscle activity
4. They may occur with disease at any level of the motor unit

Neuropathology

1. ALS and other motor neuron diseases including Kennedy's disease and SMAD
2. Toxic myopathies
3. Metabolic disorders that include:
 - a. Carbohydrate
 - b. Lipid
 - c. Mitochondrial
 - d. Purine
 - e. X-linked Becker's muscular dystrophy

Laboratory Evaluation

1. Specific to the underlying pathology
2. Persistent cramps may cause an elevation of CK in the serum that lasts for 3–8 days
3. EMG:
 - a. A physiologic contraction is associated with muscle shortening and electrical silence
 - b. A cramp discharge:
 - i. Involuntary discharge of multiple normal different action potentials
 - ii. Fasciculations:
 - a. Simple, random and spontaneous discharges of normal appearing but different motor unit action potentials

Cramp-Fasciculation Syndrome

General Characteristics

1. Clinical features occur most often in healthy subjects but can be disabling

Clinical Manifestations

1. Myalgias
2. Stiffness
3. Cramps
4. Myokymia
5. Fasciculations
6. Exercise intolerance

Neuropathology

1. Antibodies to potassium channels have been reported in some patients
2. Possible limited form of neuromyotonia
3. Some patients have neurogenic features in muscle biopsy

Laboratory Evaluations

1. Persistent cramps can cause an elevation of serum CK
2. EMG:
 - a. Cramp discharges
 - b. Fasciculation potentials
 - c. Repetitive stimulation of peripheral nerves:
 - i. After discharges in some patients similar to Isaacs' syndrome

Isaacs' Syndrome

General Characteristics

1. The syndrome is frequently referred to as that of continuous muscle fiber activity or generalized myokymia
2. Most often it is sporadic; some families with AD inheritances

Clinical Manifestations

1. Diffuse muscle stiffness
2. Widespread and continuous myokymia and cramps
3. Abnormal postures include:
 - a. Carpopedal spasm (rare)
 - b. Plantar flexion of the foot
 - c. Exaggerated lordosis
 - d. Facial grimacing
 - e. Flexion of the elbows, wrists, hips and knees
4. Distal > axial and proximal muscles are affected
5. Abnormal movements may persist during sleep
6. Increased muscular activity may be focal
7. Muscle stiffness increases with activity
8. Pseudomyotonia may be prominent (difficulty relaxing muscles after maximal contraction)
9. Physical Examination
 - a. Slight trunk flexion, shoulder abduction and elevation with elbow flexion

- b. Prominent myokymia is apparent in the face, pectoral and calf muscles after muscle contraction
- c. Sensation is normal
- d. Muscle stretch reflexes are normal or depressed
- e. Chvostek's and Trousseau's signs are present

Neuropathology

1. Primarily an autoimmune but occasionally a paraneoplastic disorder
2. Voltage gated potassium channel antibodies are primarily directed against associated proteins that complex with the VGKC rather than the channels themselves
3. Isaacs' syndrome has been reported with:
 - a. Small cell carcinoma of the lung
 - b. Thymoma
 - c. Plasmacytoma
 - d. Hodgkin's disease
4. Sural nerve biopsy:
 - a. Normal or a reduction of myelinated fibers

Laboratory Evaluation

1. Radioimmunoassay may detect antibodies directed against VGKC complexes in both the serum and CSF
2. Associated autoimmune markers include:
 - a. Immunoglobulins
 - b. Oligoclonal bands in the CSF
3. EMG:
 - a. Usually the motor and sensory NCS are normal in both the idiopathic and familial forms of the disease although there may be a polyneuropathy in some patients
 - b. Repetitive after-discharges are noticed both with standard EMG recordings and by microneurographic studies in both motor and sensory nerves
 - c. Neuromyotonic discharges are prominent in skeletal, facial and extraocular muscles. They are high frequency (200–300 Hz) and not self-sustaining
 - d. Frequent myokymic discharges are noted:
 - i. Grouped discharges of a single motor unit that occur spontaneously in bursts
 - ii. There are intervening periods of electrical silence
 - e. Neuromyotonic discharges are characterized by:
 - i. Interpotential intervals of 2–5 milliseconds
 - ii. Interburst frequencies of > 150 Hz to 500 Hz which may be triggered by exercise, muscle movement, limb ischemia or mechanical nerve stimulation. They have abrupt onset and offset
 - f. Isaacs' syndrome may demonstrate combinations of individual or grouped discharges that include
 - i. Fasciculation potentials
 - ii. Doublet and triplet discharges
 - iii. Multiplex and complex repetitive discharges
 - iv. Myokymic and nerve myotonic discharges
 - g. Experimental studies support neuromyotonic discharges as originating in the terminal nerve arborization

- h. In some patients there has been a reduction of abnormal muscular activity that suggests:
 - i. The existence of impulse generators in both the peripheral and central nervous systems
- i. Differential diagnosis of neuromyotonic discharges
 - i. Myasthenia gravis
 - ii. Amyloidosis
 - iii. CIDP
 - iv. Graft-versus-host disease
 - v. Radiation therapy
 - vi. Hereditary neuropathies
 - vii. Pontine demyelination (most often glioma; associated myokymia around the orbit)
 - viii. Rattle snake envenomation (may be very long lasting)
 - ix. ALS
 - x. Penicillamine treatment
- j. Both myokymia and neuromyotonic discharges have been reported in patients with antibodies to VGKC complexes

Morvan's Syndrome

General Characteristics

1. Morvan's syndrome is primarily neuromyotonia with an associated encephalopathy

Clinical Manifestations

1. Hallucinations, confusion and insomnia
2. Respiratory muscle involvement with dyspnea
3. Hoarseness and dysphagia
4. Hyperhidrosis
5. Loss of weight
6. Ocular neuromyotonia that causes diplopia
7. Numbness and paresthesia
 - a. Overactive sensory nerves
 - b. Associated sensory neuropathy

Neuropathology

1. CASPR2 (Contactin-associated protein-2) complex
 - a. Primarily involved in the hippocampus and paranodally at the node of Ranvier in peripheral nerves

Laboratory Evaluation

1. CASPR2 antibody complex levels in the serum
2. EMG:
 - a. Neuromyotonic discharges
 - b. Continuous muscle fiber activity
 - c. Myokymia

Satoyoshi Syndrome

General Characteristics

1. Most patients are Japanese but the systemic disorder has a worldwide distribution

Clinical Manifestations

1. Onset in adolescence

2. Female predominance
3. Painful muscle spasms of the extremities, usually the legs, that progressively involves the trunk, neck and muscles of mastication
4. The spasms last for a few minutes then recur often
5. Distortion of posture
6. Alopecia
7. Diarrhea
8. Growth retardation
9. Endocrine dysfunction
10. Amenorrhea:
 - a. Hypogonadotropic hypogonadism from primary ovarian failure (in some patients)
11. Skeletal defects (secondary to spasms)
12. May occur in adults

Neuropathology

1. Presumed to be immunologically mediated
2. Skin biopsy (one patient) in an area of hyperpigmentation demonstrated lymphocytic infiltration

Laboratory Evaluation

1. Anti-acetylcholine, anti-GAD as well as anti-nuclear antibodies have been reported in isolated patients
2. Female sex hormones are low and gonadotrophins are elevated in post-pubescent young women
3. Mildly elevated serum CK levels
4. EMG (surface recordings during involuntary contractions)
 - a. High amplitude, synchronous motor unit discharges that are widespread throughout the muscle
5. Hyperexcitability of the H-reflex (one patient) that suggests the spinal cord as the origin of spasms

Stiff Person Syndrome

General Characteristics

1. A heterogeneous syndrome that is thought to be due to dysfunction of inhibitory synaptic transmission of motor neurons in the brainstem and spinal cord

Clinical Manifestations

1. The onset is most often in middle age with lower axial muscle involvement
2. Patients note the insidious onset of muscle stiffness associated with painful spasms that are triggered by movement, touch, emotional and auditory stimuli
3. The rigidity and spasms concomitantly affect both agonist and antagonist muscles
4. Spasms are relieved by general anesthesia, neuromuscular blockade and sleep
5. Dysautonomic features are seen during episodes of severe spasms and include:
 - a. Diaphoresis
 - b. Hypertension

- c. Tachycardia
- d. Tachypnea and pupillary dilation
6. Paraspinal and abdominal muscle contraction cause hyperlordosis
7. Spasms may be severe enough to break bones, dislocate joints and produce opisthotonus
8. Facial and oculomotor involvement may occur
9. Stiff person syndrome (SPS) – plus (stiff person subtypes) includes:
 - a. Stiff-limb form in which the disorder is limited to the lower extremities
 - b. Jerking stiff-person syndrome that is manifested by chronically progressive stiffness and myoclonus
 - c. Acute onset and progressive encephalomyelitis with rigidity and myoclonus (PERM). It's associated manifestations include:
 - i. Myoclonus
 - ii. Nystagmus
 - iii. Opsoclonus
 - iv. Dysarthria
 - v. Dysphagia
 - vi. Corticospinal tract signs
 - vii. Seizures
10. Associations of SPS:
 - a. Approximately 5% of patients have an underlying malignancy that include Hodgkin's disease, thymoma, breast, colon and small cell cancer of the lung
 - b. There is an increased incidence of other immune-mediated disorders which is particularly high in patients with GAD antibodies
 - c. The comorbidities may occur in 80% of patients and include:
 - i. Encephalomyelitis with seizures, cerebellar syndrome and myasthenia gravis
 - ii. Hypo- and hyperthyroidism
 - iii. Pernicious anemia
 - iv. Celiac disease
 - v. Systemic lupus erythematosus
 - vi. Adrenal insufficiency
 - vii. Ovarian failure
 - viii. Vitiligo
 - ix. Diabetes mellitus (may occur in up to 70% of patients)

Neuropathology

1. Most patients with SPS have antibodies directed against glutamic acid decarboxylase, the rate-limiting enzyme in the production of γ -amino butyric acid (GABA)
2. Antibodies against glycine γ 1 receptor and GABA receptor-associated protein have also been detected
3. Anti-GAD65 antibodies are frequently detected in type 1 diabetes that is associated with SPS in 30–40% of patients
4. Anti-amphiphysin antibodies are seen in breast cancer, thymoma, small cell cancer of the lung and ovarian cancer

- a. Amphiphysin is a membrane protein that functions in synaptic vesicle endocytosis
- b. Amphiphysin and GAD are located in the cytosolic surface of synaptic vesicles in nerve terminals that are identified targets in CNS autoimmunity
- c. Experimental antibody transfer models support the association of amphiphysin and SPS
- d. Autopsy evaluation:
 - i. Loss of anterior horn cells and interneurons
 - ii. Loss of both small alpha and gamma motor neurons in the spinal cord
 - iii. In the encephalomyelitic subtype:
 1. Perivascular inflammation in the spinal cord, brainstem and brain

Laboratory Evaluation

1. Serum and CSF antibodies that include:
 - a. GAD-65 (possibly 90% of patients with classic SPS)
 - i. These antibodies have also been detected in:
 1. Cerebellar syndromes
 2. Palatal myoclonus
 3. Epilepsy
 4. Ceroid lipofuscinosis
2. Patients with breast cancer:
 - a. Antibodies to 128KD protein amphiphysin consolized to synapses
3. Patients with SPS (encephalomyelitic type) with Opso-clonus:
 - a. Anti-Ri antibodies
4. Antibodies against gephyrin:
 - a. Gephyrin is a protein associated with receptors for glycine and GABA
5. Oligoclonal bands occur in the CSF
6. EMG:
 - a. Routine nerve conduction in studies are normal
 - b. In symptomatic muscles:
 - i. Spontaneous discharge of normal MUAPs which also occur in the antagonist muscle; both discharge spontaneously and concomitantly
 - ii. There should be no myotonic, myokymic or neuromyotonic discharges
 - iii. Vibration induced inhibition of the H-reflexes (GABA-ergic) may be abnormal
 - iv. Enhanced blink reflex
 - v. Increased and widespread response to the startle reflex

Tetanus

General Characteristics

1. Tetanus is decreasing both in industrial nations and in the developing world
2. The World Health Organization estimated that there has been a 93% decrease in newborn fatality from the late 1980's to 2010

3. Tetanus is caused by the obligatory anaerobic Gram-positive bacillus clostridium tetani
4. The threat is still extant among farm workers and intravenous drug addicted patients

Clinical Manifestations

1. The disease is most often associated with a penetrating wound that inoculates the anaerobic organism
2. The usual incubation period is eight days but may be as long as two months; the majority of patients become symptomatic within 30 days of exposure
3. Disease progression is usually 10–14 days; a shorter duration portends severe disease; recovery begins within one month
4. Clinical symptomatology depends upon:
 - a. The site of the wound
 - b. The patient's immunization status
 - c. The extent of toxin spread
5. In generalized tetanus, the initial symptoms include
 - a. Irritability
 - b. Akathisia
 - c. Diaphoresis
 - d. Tachycardia
6. The predominant sign and symptom of tetanus is painful muscle stiffness:
 - a. Onset is often in the paraspinal and masseter muscles ("trismus")
 - b. Facial muscle involvement causes "risus sardonicus"
 - c. Masseter spasm may be triggered from mechanical stimulus of the posterior pharyngeal wall
 - d. The order of muscle involvement is usually cranial, trunk and lastly, extremities
 - e. Tetanus may remain local, affecting muscles proximal to the site of injury ("cephalic tetanus")
 - f. Generalized tetanus involves both the abdominal and paraspinal muscles which may cause respiratory insufficiency
 - g. Opisthotonus may occur in severe patients which is extremely mechanical, emotional and sensory sensitive
 - h. Spasm of bulbar musculature causes dysarthria, dysphagia and laryngospasm
 - i. Dysautonomia is manifest by hypertensive episodes, cardiac arrhythmia, sialorrhea and hyperhidrosis
 - j. Fever
 - k. Alteration of consciousness may occur from hypoxia
 1. Local tetanus may occur from anaerobic infections in the middle ear, paranasal sinuses that cause trismus and cranial nerve dysfunction
 - m. Uterine tetanus may occur from non-hygienic abortion

Neonatal Tetanus

1. Primarily seen in developing countries from umbilical stump infection, whose mother was not immunized
2. Symptoms occur within the first two weeks of life that manifest as poor suck and muscle twitching
3. Cranial nerve involvement may be prominent

Neuropathology

1. Portals of entry in patients that have acquired tetanus from *C. tetani* most often are:
 - a. Contaminated puncture wounds
 - b. Parental drug abuse
 - c. Septic abortion
 - d. Compound fractures
2. Clinical manifestations are due to the release of tetanus toxin
 - a. It may be diffused locally where it binds to peripheral nerve terminals and is retrogradely transported in motor nerves to the CNS. It may also spread hematogenously
 - b. Trans-synaptic migration occurs from the perikaryon of the motor nerves to presynaptic terminals where the toxin binds irreversibly to the presynaptic inhibitory interneurons in the brainstem and spinal cord
 - c. The toxin inhibits GABA in the brainstem and glycine in the spinal cord which disinhibits anterior horn cells both from sensory stimuli and descending motor tracts
 - d. The intermediolateral column of the sympathetic nervous system is similarly disinhibited

Laboratory Evaluation

1. *Clostridium tetani* can be cultured from wounds in approximately 1/3 of patients
2. There may be elevated CSF protein and immunoglobulin
3. EMG:
 - a. Continuous discharge of motor units with normal morphology in agonist and antagonist muscles
4. Secondary complications include:
 - a. Inappropriate secretion of ADH
 - b. Renal failure
 - c. Rhabdomyolysis with myoglobinuria

Differential Diagnosis of Skeletal Muscle Overactivity

1. Tetany
 - a. Decreased serum ionized calcium with or without a decreased serum 24 hydroxyvitamin D levels
 - b. Tetany induced by hyperventilation:
 - i. Decreased PCO₂ and elevated pH (respiratory alkalosis)
 - c. Chvostek's and Trousseau's signs are prominent
 - d. EMG demonstrates spontaneous grouped discharges of normal MUAPs that constitute doublets, triplets and multiplets
2. Trismus
 - a. Dental trauma or infection
 - b. Paraneoplastic or inflammatory causes of brain stem encephalitis
3. Drug-induced dystopia
 - a. Oculogyric crises
 - b. Writhing rather than tonic movements
4. Hyperekplexia

a. General Characteristics

- i. Hyperekplexia may be caused by heterozygous, homozygous, or compound heterozygous mutations in the GLRA1 gene that localizes to chromosome 5q32
- ii. Hyperekplexia may be caused by heterozygous, homozygous or compound heterozygous mutations in the GLRA1 gene that localizes to chromosome 5q32
- iii. It has also been described in association with autoimmune encephalomyelitis

b. Clinical Manifestations

- i. Genetic forms often have a neonatal onset
- ii. Exaggerated startle response to sudden unanticipated auditory or tactile stimuli
- iii. Patients have brief episodes of intense generalized hypertonia in response to stimulation
- iv. Adults may experience drop attacks
- v. Neonates may suffer impaired swallowing and breathing

c. Neuropathology

- i. In AD patients there is defective alpha-1 subunit of the glycine receptor
- ii. AR disorders have defective beta subunits of the glycine receptor
- iii. Non-familial patients demonstrate the pathology of the underlying illness which is usually an autoimmune-mediated encephalomyelitis such as PERM

d. Laboratory Evaluation

- i. Glycine receptor antibodies in PERM and related syndromes
- ii. Genetic testing in familial patients for mutations in the GLRA1 and GLBR genes

5. Meningoencephalitis:

- a. Muscle and paraspinal rigidity
- b. Seizures
- c. Altered mental status
- d. Diagnostic CSF studies

6. Metabolic muscle disease:

- a. No involvement of cranial nerve or paraspinal muscles
- b. Electrically silent EMG of a rigid muscle

7. Multiple sclerosis

- a. Most often confused with stiff person syndrome
- b. SPS upper and lower motor nerve findings
- c. Diagnostic MRI for MS; SPS has little pathology on brain and spinal cord imaging

8. Neuroleptic malignant syndrome:

- a. Severe metabolic acidosis
- b. History of exposure to phenothiazine or butyrophenones
- c. Dysautonomic features
- d. High CK
- e. Fever and altered mental status

9. Rabies

- a. Possibly confused with cephalic tetanus
 - b. Severe bulbar involvement
 - c. Altered mental status
 - d. Lymphocytic pleocytosis of the CSF
 - e. Dysautonomic involvement (cholinergic)
10. Abdominal tetanus:
- a. Setting of possible peritonitis
 - b. More often umbilical stump infection of neonates
11. Strychnine:
- a. Rat poison and adulterant in i.v. heroin abuse
 - b. CNS glycine antagonist
 - c. Similar to tetanus although there is no trismus
 - d. Reflex spasms are superimposed on tonic rigidity
 - e. Most often there is a clear mental status

Differential Diagnosis of Rare Disorders of Muscle Overactivity

1. Neuroleptic malignant syndrome
2. Malignant hyperthermia
3. Glycogen storage disease
4. Lipid storage disease
5. Myotonic disorders
6. Rippling muscle disease
7. Brody disease

Differential Diagnosis of Congenital Muscular Dystrophies

MDC1A

1. Laminin-X-2 chain (Merosin deficiency in chromosome 6q22-23)
2. Neck, shoulder, hip girdle weakness
3. Contractions
4. Normal intelligence
5. Seizures
6. White matter changes on MRI

Merosin-Positive Classic MDC

1. Some partial merosin deficiencies map to chromosome 1q42
2. More benign

Ullrich Disease

1. Contractions of the proximal joints
2. Hyperextensive distal joints
3. Protruberant calcanei
4. Normal intelligence

Fukuyama Congenital Muscular Dystrophy

1. Allelic to LC and 2L; fukutin (chromosome 9q31-33)
2. Proximal > distal weakness at birth
3. Calf pseudohypertrophy (50%)
4. Arthrogryposis (some children)
5. Severe brain structural abnormalities (Microcephaly, dysplasia and lissencephaly)

Walker-Warburg Syndrome

1. DONT1; (chromosome 9q3c)
2. Severe generalized weakness and hypotonia in infancy
3. Ocular malformation
4. Migrational and developmental abnormalities
5. Hypoplasia of the brain stem and veins
6. Seizures

Muscle-Eye-Brain Disease

1. POMGnT1 (chromosome 1p32)
2. MEB is less severe than WWS
3. Slow motor development
4. Eye abnormalities (glaucoma, cataracts)
5. Cognitive impairment
6. Hypoplasia of the vermis and pons; abnormalities of the midline structure

MDC1C

1. MDC1C is allelic to LGMD2I; mutation in the gene FKRP that maps to 19q13
2. Northern European ancestry
3. Onset is from infancy to the fourth decade
4. Weakness similar to MDC1A (rare WWS phenotype)
5. Early cardiac and respiratory muscle involvement

MDC1D

1. Mutation of the LARGE gene (chromosome 22q12-13.1)
2. Generalized weakness, cognitive impairment and developmental delay
3. Nystagmus (one patient)

Rigid Spine Syndrome

1. Selenoprotein (chromosome 1p35-36)
2. Rigid spine muscular dystrophy manifests in infancy
3. Hypotonia, proximal weakness and delayed milestones
4. Limited spine mobility with scoliosis and contracture of the knees and elbows
5. Respiratory involvement from rib cage restriction and diaphragm weakness
6. Similar phenotype is seen with:
 - a. EDMD
 - b. Ullrich CMD
 - c. Bethlem myopathy
 - d. Scapuloperoneal syndrome

Mutations in Genes That Produce Abnormal Glycosylation of X-Dystroglycan

1. POMT1 (9q34)
2. POMT2 (14q24)
3. POMGnT1 (1p34)

C5

1. Fukutin (9q31)
2. FKRP (19q13)
3. LARGE (22q12)

4. ISPD (7p21)
5. GTDC2 (3p22)
6. TMES (12q14.2)
7. BSGALNT2 (1q42)
8. SGK 196 (8p11)
9. B3GNT 1 (11q13)
10. GMPPB (3p21)

Congenital Muscular Dystrophy with Integrin X-7 Mutations

General Characteristics

1. Integrin X-7 (ITGA7) gene mutations that map to chromosomes 2q13.2; recessive
2. Codes for the X-7B1 integrin protein
3. X-7B1 integrin is the primary integrin in muscles

Clinical Manifestations

1. Hypotonia
2. Delayed milestones
3. Some patients walk by age 3
4. Proximal muscle weakness
5. Respiratory involvement during disease progression

Neuropathology

1. Muscle biopsy
 - a. Variation in fiber size
 - b. Decreased staining for integrin X-7
2. Laminin receptor; links the cytoskeleton to the extracellular matrix
3. Important in the formation of myotendinous function, the postsynaptic membrane and myoblast migration

Laboratory Evaluation

1. CK is mildly elevated
2. Normal brain MRI

Differential Diagnosis of Rare Congenital Muscular Dystrophies

1. Congenital MD with joint hyperlaxity
2. Congenital MD with CNS atrophy and absent large myelinated peripheral nerve axons
3. Walker-Warburg syndromes
 - a. The gene disorders generally produce abnormal glycosylation of x-dystroglycan
 - b. The systems that are affected are:
 - i. Brain
 - ii. Muscle
 - iii. Eye
 - c. Mutations in:
 - i. POMT1 (chromosome 9q34)
 - ii. POMT2 (14q24)
 - iii. POMGnT1 (1p34)
 - iv. Fukutin (9q31)
 - v. FKRP (19q13)

- vi. LARGE (22q12)
- vii. ISPD (7p21)
- viii. GTDC3 (3p22)
- ix. TMEM5 (12q14.2)
- x. B3GALNT2 (1q42)
- xi. SGK196 (8p11)
- xii. B3GNT1 (11q13)
- xiii. GMPPB (3p21)

4. Congenital muscular dystrophy with familial junctional epidermolysis bulbosa
5. Congenital muscular dystrophy with mitochondrial (megaconical) structural abnormalities
6. Congenital muscular dystrophy with early spine rigidity
7. Congenital muscular dystrophy with respiratory failure and muscular hypertrophy
8. Early-onset myopathy with areflexia, respiratory distress and dysphagia
9. Congenital muscular dystrophy with muscle hypertrophy
10. Scleroatonic muscular dystrophy (Ullrich)
11. Congenital muscular dystrophy with mental retardation and abnormal glycosylation
12. Congenital muscular dystrophy with adducted thumbs, ophthalmoplegia and mental retardation
13. Congenital muscular dystrophy and myasthenic syndrome

Differential Diagnosis of Duchenne and Becker Muscular Dystrophy

Duchenne Dystrophy

1. Weakness apparent at 2–3 years
2. Calf enlargement
3. Gowers' sign
4. Neck flexor weakness > than with Becker
5. Loss of walking by age 12
6. Severe systemic involvement

Becker Dystrophy

1. Age at onset 5–15 years
2. Milder involvement than DMD but same pattern
3. Patients survive to 30–60 years
4. Neck flexors are affected later in the course
5. May walk throughout the course
6. A few patients manifest with only myalgia, myoglobinuria and cardiomyopathy

Outliers of DMD and BMD

1. Phenotype between DMD and BMD
2. Walk after the age of 12
3. Maintain antigravity neck muscle strength

Female Carriers of DMD and BMD

1. The daughters of men with BMD and the mothers of affected children with a family history of DMD or BMD are obligate carriers
2. Usually asymptomatic
3. Manifesting carriers have a limb girdle pattern of weakness

Limb Girdle Muscular Dystrophies

1. The absence of cognitive deficit
2. Less frequent cardiomyopathy
3. Less marked calf hypertrophy
4. Autosomal dominant inheritance rules out dystrophinopathy

Limb Girdle Presentation in a Girl

1. Rule out DMD or BMD with 45XO
2. Non-random X chromosome inactivation

Acid Maltase Deficiency

1. Calf hypertrophy
2. Fibrillation tongue
3. Early cardiomyopathy

Spinal Muscular Atrophy

1. May have prominent proximal weakness in childhood
2. CK is minimally elevated
3. Neuropathic EMG

Emery-Dreifuss Muscular Dystrophy

1. AD not X-linked inheritance
2. No pseudohypertrophy
3. Early elbow and heel contractures
4. Mild CK elevation
5. Prominent early cardiac abnormalities

Unexplained Persistent Elevation of Liver Enzymes Alanine Aminotransferase (ALT) and Aspartate Aminotransferase (AST)

1. May represent dystrophinopathy in:
 - a. Women who become symptomatic (DMD/BMD)
 - b. Asymptomatic carriers
2. Other dystrophies
3. CK is elevated highest of the other enzyme elevations are from muscle

Isolated Dilated Cardiomyopathy

1. Need to rule out dystrophinopathy

DMD, Glycerol Kinase Deficiency and Adrenal Hypoplasia Congenital

1. Severe psychomotor delay
2. Episodic stupor (GKL)
3. Proximal weakness from the DMD component

Muscle Cramp with Myoglobinuria*General Characteristics*

1. Female relatives of boys with DMB/BMD
 - a. Heterozygous carriers with mutated dystrophies gene
 - i. Random "X" inactivation
2. Inversions

Clinical Manifestations

1. Clinically evident weakness is seen in 2.5–10% of carriers (proximal muscles)
2. May have calf hypertrophy
3. A family with cardiomyopathy and muscle cramps without clinical weakness has been reported

Neuropathology

1. Muscle biopsy:
 - a. A mosaic of fibers with either normal or absent dystrophin
 - b. Exons 40–44 and 45–47 of the dystrophin gene may be mutated

Laboratory Evaluation

1. Approximately 70% of female carriers have elevated CK

Differential Diagnosis of Autosomal Dominant LGMD

1. LGMD1A
 - a. Myotilin (5q22.3-31.3)
 - b. Proximal weakness early or late adult life
 - c. Scapula humeral pelvic muscles
 - d. Early contracture of elbow and heel cord
 - e. Cardio myopathy
 - f. Calf hypertrophy is rare
2. LGMD1B
 - a. Lamin AC (1q11-21)
 - b. Girdle weakness of humeral peroneal muscle cramp
 - c. Cardiac conduction defects (severe)
3. LGMD1C
 - a. Caveolin-3 (3p25)
 - b. Childhood or adult onset
 - c. Proximal weakness or exertional myalgia
 - d. Calf hypertrophy
 - e. Rippling muscle disease (anterior tibial or gastrocnemius weakness)
 - f. Asymptomatic CK-emia
4. LGMD1D
 - a. Chromosome 6q23
 - b. Slowly progressive weakness
 - c. Associated cardiomyopathy
5. LGMD1E
 - a. Chromosome 7q
 - b. Onset late adult life
 - c. Dysphagia and extremity weakness
6. LGMD1F
 - a. Chromosome 7q32.1-32.2
 - b. Onset infancy to adulthood
 - c. Slowly progressive proximal muscle weakness

Differential Diagnosis of Autosomal Recessive LGMD

1. LGMD1A
 - a. Calpain-3 (chromosome 15q15.1-21.1)

- b. Onset early childhood to mid-adulthood
- c. Pelvic muscles and posterior thigh muscle early involvement; later periscapular and humeral
- d. Deltoid/brachioradialis and distal leg and supraspinati relational response
- e. Mild weakness of neck muscles
- f. Early contracture of elbow and calves
- g. Rare calf hypertrophy
- 2. LGMD2B
 - a. Dysferlin (chromosome 2p13)
 - b. Onset early teens or early 20s
 - c. Limb girdle or early involvement of the posterior calf muscles, or early anterior tibial muscles
 - d. Miyoshi phenotype with gastrocnemius/soleus weakness and atrophy
 - e. Rare rigid spine
 - f. Early loss of Achilles tendon reflex
- 3. Sarcoglycanopathies
 - a. VF-LGMD2C-V-sarcoglycan (chromosome 13q12)
 - b. LGMD2D-X-sarcoglycan (chromosome 17q12-21.3)
 - c. LGMD2E-B-sarcoglycan (chromosome 4q12)
 - d. LGMD2F-F-sarcoglycan (chromosome 5q33-34)
 - i. Similar to dystrophinopathies
 - ii. Some with early onset similar to DMD and others with later onset and slower progression similar to BMD
 - iii. Early proximal muscle weakness
 - iv. Cardiomyopathy
- 4. Congenital fibrosis of the extraocular muscles
 - a. Chromosome 12p11.2
 - b. Congenital fibrosis of the extraocular muscles
- 5. LGMD2G
 - a. Telethonin (chromosome 17q11-q12)
 - b. Early quadriceps and anterior tibial muscle weakness
 - c. Onset mean is 12.5 years
 - d. Miyoshi pattern occurs (calf weakness occurs)
- 6. LGMD2H
 - a. E3-ubiquitin ligase (TRIM 32) (chromosome 9q31-q33)
 - b. Onset 8–27 years of age
 - c. Manitoba Hutterites
 - d. Can walk with assistance to 40 years of age
- 7. LGMD2I
 - a. Fukutin-related protein (FKRP) (chromosome 19q13)
 - b. Onset in infancy (MDC1C) to the fourth grade
 - c. Variable limb girdle pattern (arm vs. legs)
 - d. Hypertrophy calves
 - e. Dilated cardiomyopathy
 - f. Respiratory muscle involvement
- 8. LGMD2J
 - a. Titin gene mutation (chromosome 2q31)
 - b. Late adult onset
 - c. Childhood presentation may be limb girdle; involvement of the upper limbs, others posterior calves
- 9. LGMD2K

- a. POMT protein (chromosome 9q3)
- b. Most often Walker-Warburg phenotype
- 10. LGMD2L
 - a. Fukutin (chromosome 9q31-33)
 - b. Fukuyama muscular dystrophy
- 11. LGMD2M
 - a. POMGnT1 protein (chromosome 1p32)
 - b. Muscle-eye-brain disease

Differential Diagnostic Points of Dystrophies

- 1. DMD/BMD
 - a. Calf hypertrophy
 - b. High CK
 - c. Systemic complications
- 2. DMD/glycerol kinase/adrenal hypoplasia congenital
 - a. Severe cognitive deficit
 - b. Intermittent catatonic stupor
 - c. Muscle weakness
- 3. LGMD1A
 - a. May be adult onset
 - b. Scapula-humeral-pelvic pattern
 - c. Early contracture elbow/heel
- 4. LGMD1B
 - a. Humeral-peroneal pattern
 - b. Cardiac conduction defects
- 5. LGMD1C
 - a. May have adult onset
 - b. Calf hypertrophy
 - c. Rippling muscle
- 6. LGMD1D
 - a. Adult onset
 - b. Cardiomyopathy
- 7. LGMD1E
 - a. Late adult onset
 - b. Dysphagia
- 8. LGMD1F
 - a. Onset infancy to adulthood
- 9. LGMD2A
 - a. No calf hypertrophy
- 10. LGMD2B
 - a. Early thigh or posterior calf involvement (Miyoshi phenotype)
- 11. Sarcoglycanopathies (LGMD2C, LGMD2D, LGMD2E, LGMD2F)
 - a. Similar to dystrophinopathies
 - b. No cardiac involvement
- 12. LGMD2G
 - a. Quadriceps and anterior tibial involvement
- 13. LGMD2H
 - a. Manitoba Hutterites
- 14. LGMD2I
 - a. MDC1C to fourth decade
- 15. LGMD2J
 - a. Titin (chromosome 2q31)

- b. Late adulthood
- c. Anterior tibial weakness
- 16. LGMD2K
 - a. POMT (chromosome 1p32)
 - b. Walker-Warburg syndrome
- 17. LGMD2L
 - a. Fukutin (chromosome 9q31-33)
- 18. LGMD2M
 - a. POMGnT1 (chromosome 1p32)
 - b. Muscle-eye-brain disease

Differential Diagnosis of Distal Myopathy/Muscular Dystrophy

Welander Myopathy

1. AD; mutation in the T1A1 gene that maps to chromosome 2p13
2. Late onset 5th decade
3. Site of onset
 - a. Finger and wrist tensors that progresses to toe and ankle dorsiflexors
 - b. Proximal involvement in some families
 - c. No neck flexor weakness
 - d. Loss of brachioradialis and Achilles
4. Normal to slightly elevated CK; Myopathic EMG
5. Rimmed vacuoles

Markesbery-Griggs Distal Myopathy

1. AD; 2 ASP; chromosome 10q22, 3-23.2;
2. Late onset
3. Initially involves the anterior compartment of the legs; some patients develop wrist and finger extensor weakness
4. Cardiomyopathy
5. Rimmed vacuoles and features of myofibrillar myopathy

Udd Distal Myopathy

1. AD; titin gene mutation that maps to chromosome 2q31
2. Onset after age 35
3. Weakness of the anterior compartment of the legs; begins in the toe extensors
4. May progress to intrinsic hand muscles
5. Facial muscles are spared; rare involvement of bulbar musculature
6. Decreased Achilles reflex
7. Rimmed vacuoles may be seen in muscle biopsy

Nonaka Distal Myopathy

1. AD; mutations in GNE that maps to chromosome 9p1-q1; allelic to AD IBM
2. Weakness of the anterior compartment of the distal lower extremity; foot drop in the second or third decade of life
3. With time neck flexor and proximal muscle weakness
4. Quadriceps relatively spared
5. Rimmed vacuoles on muscle biopsy; absent inflammatory infiltrate

Miyoshi Distal Myopathy

1. AR; dysferlin gene that maps to 2p13
2. Early adult onset of calf atrophy and weakness
3. Distal upper and lower extremities are affected; intrinsic hand muscles are spared
4. Gastrocnemius and soleus are severely affected
5. Markedly increased CK; muscle biopsy demonstrates myopathic and dystrophic changes

Laing Distal Myopathy

1. AD; mutated gene is MYH7 that maps to chromosome 4q1,2
2. Initial weakness in the anterior compartment of the distal lower extremities and neck flexor
3. Onset is between 4 and 25 years
4. Finger extensors may be affected; finger flexors and hand extrinsic muscles are spared
5. Muscle biopsy reveals deposits of myosin long chain (MyHC) in subsarcolemmal areas of type 1 fibers

Distal Myopathy with Pharyngeal and Vocal Cord Paralysis

1. AD
2. Onset fourth to sixth decade
3. Anterior tibial and vocal cord paralysis

Differential Diagnosis of Distal Myopathy

Myotonic Dystrophy

1. Severe ptosis
2. Mental and behavioral abnormalities
3. Stellate cataracts; (posterior)
4. Severe facial muscular atrophy
5. Systemic manifestations

Emery-Dreifuss Muscular Dystrophy

1. Contracture
2. Cardiac abnormalities

Oculopharyngeal Dystrophy

1. French connection
2. Severe ptosis and dysphagia

Scapuloperoneal Dystrophy

1. Early and more symmetrical involvement of the shoulder girdle and anterior compartment of the legs

Distal Myopathy with Vocal Cord Paralysis

1. Late onset
2. Vocal cord and pharyngeal weakness

Differential Diagnosis of Regional Muscular Dystrophies

Facioscapulohumeral Dystrophy (FSHD)

1. AD; contraction of the D4Z4 macrosatellite repeat in the subtelomeric region of chromosome 4q35
2. Variable age onset

3. Facial muscles are affected early (orbicularis ocula, zygomaticus and orbicularis oris)
4. Weakness of scapular stabilizers with scapular winging and trapezium hump
5. Stenocostal head of the pectoralis major is weak and atrophic that results in lateral displacement of clavicle (more horizontal)
6. Tibialis anterior is affected earliest in the lower extremity
7. Inflammatory infiltrate of the endomysium confused with polymyositis

Scapuloperoneal Muscular Dystrophy

1. AD; mutation in the desmin gene that maps to 2q35
2. Foot drop followed by scapular weakness
3. Compensatory hypertrophy of the extensor digitorum brevis (subset of patients)
4. Ankle contractions
5. Relative sparing of humeral muscles
6. Greater involvement of peroneal muscles than FSHD
7. Variants
 - a. Davidenkov
 - i. Scapuloperoneal weakness
 - ii. Distal sensory loss on the extremities
 - iii. Pes cavus
 - iv. Depressed reflexes
 - v. Decreased motor and sensory nerve conduction velocities
 - b. Kaeser variant
 - i. 12 members over 5 generations
 - ii. Anterior horn cell loss is the primary pathology

Emery-Dreifuss Muscular Dystrophy

1. X-linked EMG
2. EDMD caused by mutations in STA that map to Xq28
3. Contractions of Achilles tendons, elbows and posterior cervical muscles
4. Humeral peroneal distribution of weakness
5. Cardiac arrhythmia

Autosomal Dominant

1. EDMD2/LGMD1B
 - a. AD; mutations in lamin A/C gene that maps to chromosome 1q11-23
 - b. Similar phenotype to X-linked EDMD1
 - c. Mutations in the rod domain of LMNA cause a dilated cardiomyopathy (there may not be skeletal muscle involvement)

Autosomal Recessive EDMD3

1. Contracture and severe spinal rigidity
2. Onset in the first 2 years of life
3. Mutation in the LMNA

EDMD Phenotype form Mutations in

1. SYNE 1 (chromosome 6q34)
2. SYNE 2 (chromosome 14q23)

Differential Diagnosis of Weakness in the Facioscapular Distribution

1. Scapuloperoneal syndrome
 - a. Neurogenic and myogenic forms
 - b. May have mild facial weakness
 - c. Some FSHD patients may have mild facial weakness
2. Hereditary proximal spinal muscular dystrophy
 - a. No facial involvement
 - b. The entire shoulder girdle including the deltoid muscle is involved
3. Restricted polymyositis
 - a. The cause may be similar to that of FSHD
 - b. AD inheritance has been described in two patients
 - c. Facial, scapular and anterior tibialis muscles may be involved
 - d. Muscle biopsy and EMG are compatible with polymyositis
 - e. Facial weakness and atrophy is much more prominent in FSHD
 - f. Polymyositis has minimal facial weakness
4. Coats' disease (VIIIth nerve defects retinal disease)
 - a. Begins in infancy
 - b. Uni- or bilateral sensorineural hearing loss
 - c. Retinal telangiectasia and detachment
5. Limb girdle dystrophies
 - a. Less prominent facial weakness
 - b. Proximal upper and lower extremity weakness
6. Emery-Dreifuss muscular dystrophy
 - a. Prominent contractures
 - b. Early long finger flexion contractures
 - c. Quadriceps involvement
7. Mitochondrial myopathy
 - a. Ophthalmoplegia
 - b. Fatigue with exercise
 - c. Short stature
 - d. Symptomatic VIIIth nerve deficits
 - e. Severe dilated cardiomyopathy
8. Acid maltase deficiency
 - a. Enlarged fibrillation tongue
 - b. Congestive heart failure
 - c. Membrane instability on EMG
9. Desmin myopathy
 - a. Weakness and atrophy of the distal muscles of the lower limbs
 - b. Progression to the hands, then to the trunk, neck and face
10. Congenital centronuclear myopathy
 - a. Prominent ptosis
 - b. Limb girdle weakness
 - c. Less prominent cardiac defects
11. Bethlem Myopathy
 - a. Allelic and mild variant of Ullrich congenital muscular dystrophy
 - b. AD; 21q22 and 2q37 that encode collagen 6A1 and 6A3

- c. Onset birth or early childhood
 - d. Delayed but attained motor milestones
 - e. Proximal > distal muscle weakness; extensors > flexors
 - f. Early contracture of elbows and ankles; late wrist and finger contractures
 - g. Heart is involved in 10% of patients
 - h. Ventilatory muscle involvement
12. Bent spine/Dropped head syndrome
- a. Involvement is prominent in the cervical musculature; rarely the thoracic and paraspinal musculature is involved
 - b. Neck extensor weakness onset is after 60 years of age
 - c. Involvement of thoracic paraspinal musculature causes severe kyphoscoliosis most prominent with standing
 - d. When supine the posture is normal
 - e. Myasthenia gravis and ALS both may have a dropped head
13. Oculopharyngeal Dystrophy (OPMD)
- a. AD; GCG expansion repeat within PABN (gene that maps to chromosome 14q11.1)
 - b. Presents in the fourth to sixth decade
 - c. Bilateral often asymmetric ptosis; extraocular muscle involvement in 50% of patients (rare diplopia)
 - d. Dysphagia that when severe leads to weight loss and aspiration
 - e. Rare facial and masticatory weakness as well as proximal > distal muscle involvement
 - f. No heart, cognitive and VIIIth nerve involvement that occurs with mitochondrial myopathies
14. OPMD Variants
- a. Infantile or early childhood variant
 - i. Ptosis and ophthalmoparesis
 - ii. Severe generalized weakness
 - iii. Respiratory failure
 - b. Oculopharyngeal distal variant
 - i. Earlier weakness
 - ii. Distal OPMD with pseudo-obstruction (one patient)

Differential Diagnosis of Oculopharyngeal Dystrophy (OPMD)

- 1. Myotonic muscular dystrophy
 - a. Systemic manifestation
 - b. Myotonia
 - c. Cardiac involvement
- 2. AD distal myopathy
 - a. Welander
 - b. Markesbery/Griggs/Udd
 - c. Nonaka
 - d. Specific leg compartment atrophy
 - e. Less swallowing difficulty than OPMD
 - f. No ophthalmoplegia
- 3. Myasthenia gravis

- a. Fluctuating signs and symptoms
 - b. Pattern of weakness (MG > proximal than distal)
 - c. Severe extraocular muscle involvement that fluctuates
4. Mitochondrial myopathy with or without external ophthalmoplegia
- a. Severe cardiac involvement
 - b. Fatigue with exercise
 - c. VIIIth nerve deficit
 - d. Short stature
5. Polymyositis and progressive bulbar palsy
- a. No ptosis and extraocular muscle involvement
6. Recessive OPMD
- a. Late onset ptosis and dysphagia

Differential Diagnosis of Rare Muscular Dystrophies

- 1. Myofibrillar myopathy
 - a. Heterogeneous with a wide phenotype spectrum
 - b. Onset 25–45 years of age
 - c. Proximal distal or generalized weakness; scapuloperoneal pattern
 - d. Cardiac involvement
 - e. Some patients develop severe respiratory insufficiency
 - f. Muscle biopsy demonstrates hyaline and non-hyaline structures
- 2. Hereditary inclusion body myopathies
 - a. AD and AR forms
 - b. AR form is allelic to Nonaka distal myopathy; mutations in the GNE gene that maps to chromosome 9p1-q1
 - c. AR form is in Iranian and Afghani-Jewish patients; North American families

Differential Diagnosis of Myopathy by Genetics and Pattern of Weakness

- 1. Male with proximal weakness
 - a. X-linked or sporadic
 - i. DMD/BMD
 - b. No mutation; non-rimmed vacuoles
 - i. Danon disease
 - ii. XMEA
- 2. Sporadic or AR female or male with proximal weakness
 - a. Early cardiac/respiratory involvement
 - b. English or Northern European ancestry
 - c. LGMD2I or MDC1C with FKRP mutation
 - d. No FKRP mutation
 - i. EDMD and LGMD1B if there are early contractures
 - ii. MFM
 - iii. Pompe disease
 - e. Scapular muscle wing; thigh adductor weakness; thin calves
 - f. Eastern and southern European ancestry
 - g. Calpain 3 mutation with LGMD2A
 - h. No mutation identified

- i. FSHD (limb girdle phenotype)
- i. Onset in late teens to age 30
- j. Early calf atrophy
- k. Absent dysferlin
 - i. LGMD2B
 - ii. Miyoshi myopathy
- l. Early cardiomyopathy and contractures
- m. Emerin lamin A/C mutations
 - i. EDMD
- 3. Sporadic or AR female or AR male with distal muscle weakness
 - a. Early calf atrophy and weakness
 - i. Dysferlin is absent
 - 1. LGMD2B
 - 2. Miyoshi myopathy
 - b. Early anterior atrophy
 - i. Rimmed vacuoles on muscle biopsy
 - 1. h IBM
 - c. Hyaline/non-hyaline inclusions:
 - i. Myofibrillar myopathy
- 4. Autosomal Dominant with proximal weakness
 - a. Scapular winging with facial weakness
 - i. FSHD
 - b. Early contractures with no cardiomyopathy
 - i. Bethlem myopathy
 - ii. LMNA/C
 - 1. LGMD1B/EDM2
 - c. Rippling muscles, distal leg weakness with proximal weakness; no cardiac or respiratory weakness
 - i. LGMD1C
- 5. Childhood to late adult onset with or without cardiac or respiratory involvement
 - a. Myofibrillar myopathy
 - b. LGMD1A (myotilinopathy)
 - c. ZASP-related myofibrillar myopathy
 - d. Desminopathy
- 6. Autosomal Dominant with early anterior tibial weakness
 - a. Late adult onset
 - i. Tibial myopathy
 - ii. LGMD2J

Differential Diagnosis by Muscle Biopsy

- 1. Immunohistochemistry
 - a. Emerin – EDMD
 - b. Desm/Myotilin/ZASP
 - i. MFM
 - c. Myosin heavy chain
 - i. Myosin storage myopathy
 - d. Alpha-actinin/nebulin
 - i. Nemaline myopathy
 - e. LAMP-2 and membrane attack complex
 - i. Danon disease
 - ii. XMEA
 - iii. Associated with non-rimmed vacuoles in a male

- 2. Immuno blot
 - a. Dystrophin
 - b. Dysferlin
 - c. Calpain
- 3. Electron microscopy
 - a. Myofibrillar myopathy
 - b. Danon disease
 - c. XMEA
 - d. Storage diseases
 - e. Mitochondrial myopathies
- 4. Immunohistochemistry
 - a. Dystrophin (dystrophinopathies)
 - b. Sarcoglycan
 - c. Beta-dystroglycan
 - d. Merosin
 - e. Dysferlin
 - f. Caveolin 3

Differential Diagnosis of Congenital Myopathies

Central Core Myopathy

- 1. AD; Ryanodine receptor gene (RYR1) that maps to chromosome 19q13.1
- 2. Infant or childhood onset; rare adult onset
- 3. Proximal muscle weakness
- 4. Skeletal abnormalities:
 - a. Congenital hip dysplasias
 - b. Scoliosis
 - c. Foot deformities
- 5. Malignant hyperthermia

Multi/Minicore Myopathy

- 1. AD, AR and sporadic
- 2. AR; Selenoprotein; N1/1p36 (some patients)
- 3. Infancy or childhood onset
- 4. Weakness proximal > distal; moderate weakness and wasting of the hands; respiratory muscles
- 5. Hyperlaxity of joints of the hands; patellar, hip and knee dislocations
- 6. Heel contractures; rare arthrogryposis
- 7. Risk for malignant hyperthermia

Nemaline Myopathy

- 1. AR – mutations in nebulin gene NEM2 that maps to chromosome 2q21.20q22
 - a. Infantile form (severe)
- 2. AR/AD – mutations in the X-Actin (ACTA 1) gene that maps to chromosome 1q42
- 3. AR/AD – X-Tropomyosin (TMP3) gene that maps to chromosome 1q21–q23
- 4. AD – B-Tropomyosin (TPM2) gene that maps to chromosome 9q13
- 5. AR-slow troponin (TNNT1) gene that maps to chromosome 11q13
- 6. AR/AD – X-tropomyosin (TMP1) gene that maps to chromosome 15q21-23

7. AD – cofilin-2 gene (CFL2) that maps to chromosome 14q12

Infantile Forms (Nebulin, X-Actin, X-Tropomyosin, B-Tropomyosin)

1. Infantile onset with severe generalized hypotonia and weakness
2. Respiratory weakness
3. Skeletal defects
4. Fatal first year of life

X-Tropomyosin (TMP1 Gene) That Maps to 15q21-q23

1. Encodes Relch-repeat and BTB (PO2) domain containing 13 (KBT BD13) AD
 - a. Childhood onset
 - b. Proximal weakness that includes neck flexor
 - c. Unable to run; poor postural connection; slow movements

Cofilin-2 Gene; AR; Maps to Chromosome 14q12

1. Onset in infancy or childhood
2. Mild generalized hypotonia and weakness; facial muscles are involved as are EOM in some patients
3. High arched palate
4. Thorax deformities

Nemaline Myopathy – Adult Onset

1. Some sporadic; often no family history
2. Onset is 3rd to 9th decade
3. Proximal > distal weakness
4. 50% of patients have posterior cervical involvement
5. Respiratory failure 30%; may be presenting feature
6. Myalgia
7. Cardiomyopathy

Centronuclear Myopathy

1. X-linked
 - a. Myotubularin (MTM1) gene that maps to Xq28; recessive
 - i. Severe neonatal hypotonia and weakness
 - ii. Respiratory insufficiency
 - iii. Ptosis and extraocular muscle involvement
 - iv. Large ear (70%); narrow face (80%); long digits (60%)
 - v. Death at <6 months

Centronuclear Myopathy (Neonatal or Late Infantile)

1. Sporadic, AR or AD
2. Dynamin-2
 - a. Allelic to dominant Charcot-Marie-Tooth type B
 - b. D1-CmTB (on chromosome 19p13.2)
 - c. Onset late infancy or early childhood
 - d. Generalized weakness and hypotonia
 - e. Facial weakness, ptosis, extraocular muscle weakness
 - f. Facial dysmorphisms
 - g. Later onset may not have ophthalmoparesis

Autosomal Dominant Centronuclear Myopathy Late Childhood or Adult Type

1. Dynamin-2 gene; maps to chromosome 19p13.2; allelic to D1-CmTB
2. Onset in late childhood or adulthood
3. Mild proximal or distal weakness
4. Ptosis
5. Variable weakness of facial and extraocular muscles
6. No skeletal abnormalities or facial dysmorphisms

Centronuclear Myopathy (BINI)

1. Mutations in bridging integrator 1 (BINI: Amphiphysin 2) gene that maps to chromosome 2q14.3
2. BINI protein functions
 - a. Membrane remodeling
 - b. Regulated by phosphoinositide
 - c. Organization of T-tubules
3. Onset from birth to childhood
4. Mild proximal weakness
5. Some patients have ptosis and ophthalmoparesis
6. Bulbar, facial involvement; dysarthria
7. No respiratory failure
8. Diffuse muscle atrophy
9. Mild facial dysmorphism

Congenital Fiber Type Disproportion 1

1. Sporadic AD or AR; 43% have a family history
2. CFTD 1
 - a. X-actin (ACTA 1) gene that maps to chromosome 1q42.13; dominant
 - b. Clinical Manifestations of the severe phenotype
 - i. Onset with congenital weakness that is severe and affects respiratory muscles
 - ii. No ophthalmoparesis
 - iii. Respiratory failure < 4 years
3. Differential of other X-actin diseases
 - a. Nemaline rod myopathy
 - b. Intramuscular rod myopathy
 - c. Rod myopathy with cores
 - d. Actin myopathy (congenital myopathy with an excess of thin filaments)

Congenital Fiber Type Disproportion 2

1. Chromosome xq13.1–q22.1; recessive
2. Onset is congenital
3. Bilateral ptosis
4. Facial weakness
5. Weak suck and cry
6. Generalized hypotonia
7. Respiratory insufficiency
8. Dilated cardiomyopathy
9. Death by respiratory failure in 6–14 weeks

Congenital Fiber Type Disproportion 3

1. Selenoprotein N1 (SEPN 1) gene that maps to chromosome 1p36; recessive

2. SEPN 1-like syndrome
 - a. Early trunkal hypotonia
 - b. Early neck flexor weakness
 - c. Respiratory impairment starts from adolescence to early adulthood
 - d. Minimal limb strength
 - e. Scoliosis (adolescence); lordosis of upper spine

Congenital Fiber Type Disproportion 4

1. Myosin light chain 2 that maps to chromosome 12q24; recessive
 - a. Allelic disorders
 - i. Hypertrophic cardiac myopathy 10 (CMH10)
 - ii. Dilated familial cardiomyopathy with type 1 muscle fiber hypotrophy
 - iii. Onset during infancy
 - iv. Generalized hypotonia and weakness
 - v. Facial dysmorphisms:
 1. Tented mouth
 2. Ptosis (some patients)
 - vi. Generalized tremors and clonus
 - vii. Dilated cardiomyopathy

Reducing Body Myopathy

1. FHL1 gene (Four-and-a-half-LIM) that maps to chromosome Xq26.3; sporadic
2. Early onset has a severe clinical course (sporadic inheritance)
3. Late onset (childhood to adult)
4. Onset in the 4th decade
5. Early development is normal
6. Pattern of weakness
 - a. Proximal > distal; asymmetric
 - b. Scapuloperoneal
 - c. PCHA spinal muscle involvement
7. Skeletal abnormalities
 - a. Rigid spine

Hyaline Body Myopathy

1. AD or AR; AD gene (MYH7 that maps to chromosome 14q11.2); encodes cardiac B heavy chain
2. The myopathy is also known as myosin with lysis of type 1 myofibrils and myosin storage myopathy
3. AR; gene has not been defined; maps to chromosome 3p22.2-p21-32
4. Onset in infancy
5. Limb girdle or scapular peroneal pattern; may have distal muscular weakness

H-IBM3/Myosin Storage Myopathy

1. AD; gene is myosin heavy chain type 11 or (MYH2) that maps to chromosome 17p13.1
2. Arthrogryposis
3. Ophthalmoparesis
4. Adult onset of proximal muscle weakness and myalgia

Cap Myopathy

1. AD; B-Tropomyosin 2 gene (TPM2) that maps to chromosome 9p13.3
 - a. Congenital or childhood onset
 - b. Weakness of proximal and distal muscles
 - c. The face and respiratory muscles are involved
 - d. Facial dysmorphism
 - i. Long and narrow
 - ii. High arched palate

Zebra Body Myopathy

1. X-Actin gene (ACTA1) that maps to chromosome 1q42.13
2. Onset at birth
3. Weakness that is proximal, distal and axial that can be asymmetric
4. Some patients have greater arm than leg weakness
5. Normal tendon reflexes
6. Static course; some patients have improved

Tubular Aggregate Myopathy

1. Type 1
 - a. AD; mutation in the STIM 1 gene that maps to chromosome 11p15
 - b. Mutations in the STIM 1 gene also causes Stormorken syndrome
 - i. Tubular aggregate myopathy
 - ii. Platelet dysfunction
 - iii. Thrombocytopenia
 - iv. Asplenia
 - v. Congenital meiosis
 - vi. Ichthyosis
 - vii. Stroke-like episodes
2. Type 1 clinical features
 - a. Childhood or early adult onset
 - b. Limb girdle weakness
3. Type 2 Tubular Aggregate Myopathy
 - a. AD; caused by mutation in the ORAI 1 gene that maps to chromosome 12q24
 - b. Onset in infancy
 - c. Congenital myasthenia
 - d. Fatigable weakness
4. Type 3 Tubular Aggregate Myopathy
 - a. Sporadic; gene not defined
 - b. Excessive induced cramps, pain and stiffness

Metabolic Muscle Disease

Differential Diagnosis of Carbohydrate Muscle Metabolism

General Characteristics

1. Type I (glucose 6 phosphatase deficiency) and type VI (liver phosphorylase deficiency) only involve the liver

2. Type II (lysosomal X-glucosidase), type V (phosphatase deficiency), type VII (phosphofructokinase deficiency), type X (phosphoglycerate mutase) and type XI (lactate dehydrogenase) primarily cause muscle disease
 3. Types III, IV, XI, XII, XIII and IV may involve both the liver and muscle
 4. Type II (acid X1, 4 glucosidase)
 - a. Infant
 - i. Hypertonia and generalized weakness
 - ii. Fibrillating tongue
 - iii. Congestive heart failure
 - b. Adult
 - i. Proximal > distal muscle weakness
 - ii. Ventilatory muscle involvement with respiratory failure
 5. Type III (Cori-Forbes disease)
 - a. Debrancher (amylo-1,6-glucosidase deficiency)
 - b. Infancy
 - i. Hypotonia and generalized weakness
 - c. Childhood/adult onset
 - i. Adult onset 3rd to 4th decade
 - ii. 50% weakness of distal extremity muscles (peroneal and calf)
 - iii. Pseudohypertrophy of proximal muscles
 - iv. Ventilatory involvement
 - v. Cardiomyopathy
 - vi. Spasticity, dementia, incontinence (late)
 6. Type IV (Andersen disease)
 - a. Branching enzyme deficiency (amylo-(1,4 to 1,6) transglycosylase)
 - b. Infantile onset
 - i. Hepatomegaly, liver disease
 - ii. Muscle weakness, hypotonia, atrophy and contractures
 - c. Childhood/adult onset
 - i. Proximal or distal weakness
 - ii. An adult form presents as polyglucosan disease with upper and lower motor neuron signs and symptoms
 - d. A subgroup with muscle weakness, atrophy and cardiomyopathy
 7. Type V (McArdle's disease)
 - a. Myophosphorylase deficiency
 - b. Infantile onset
 - i. Rare weakness
 - c. Childhood/adult onset
 - i. Exertional muscle pain and cramps (intense exercise)
 - ii. Second wind phenomenon
 - iii. Myoglobinuria in the second or third decade
 - iv. Rare proximal muscle weakness and atrophy
 8. Type VII (Tarui disease) PFK
 - a. Phosphofructokinase deficiency
 - b. Exercise intolerance, muscle pain, contractures and relief with rest
 - c. No warm-up phenomenon
 - d. Low incidence of myoglobinuria
 - e. Rarely hemolytic anemia without myopathy
 - f. Subgroup in adulthood presents with proximal or a scapulo-peroneal pattern of weakness
 - g. Infant presentation can occur with generalized weakness and cardiomyopathy
 9. Type VIII (PBK)
 - a. Phosphorylase b kinase deficiency
 - b. Infancy and childhood
 - i. May present with mild weakness and delay in milestones
 - c. Adult presentation
 - i. Exercise intolerance with cramps and myoglobinuria
 - ii. 50% of patients develop proximal or distal weakness
 10. Type IX (PGK)
 - a. Phosphoglycerate kinase deficiency
 - b. Childhood
 - i. Male children may present with hemolytic anemia, cognitive deficits and seizure
 - c. Adulthood
 - i. Exercise intolerance, cramps and recurrent myoglobinuria
 - ii. Slowly progressive proximal myopathy
 11. Type X (PGAM)
 - a. Phosphoglycerate mutase deficiency
 - b. May present in childhood or early adulthood
 - i. Exercise intolerance, cramps and recurrent myoglobinuria
 12. Type XI
 - a. Lactate dehydrogenase deficiency
 - b. Childhood – adult onset
 - i. Exercise intolerance, cramps and recurrent myoglobinuria
 - ii. Normal muscle strength
 - iii. Erythematous scaly skin lesions
 - iv. Uterine stiffness that may require Cesarean section
 13. Type XII
 - a. Aldolase A deficiency
 - b. Infancy-childhood (one patient)
 - c. Exercise and weakness after febrile illness
 14. TYPE XIII
 - a. Trioisomerase deficiency
 - b. Infantile onset of generalized hypotonia, cognitive deficits, weakness and hemolytic anemia
 15. Type XIV
 - a. β -enolase deficiency (one patients)
 - b. Childhood-adult onset
 - i. Exercise intolerance and myalgia
- Rare Lysosomal Glycogen Storage Myopathies**
- Vascular Cardiomyopathy and Myopathy (Danon Disease)*
1. Patients are normal at birth

2. Childhood development of proximal muscle weakness and cardiomyopathy
3. Men are more severely affected than women but women carriers may manifest signs
4. Men are dramatically more often cognitively impaired than women (60% vs. 6%)
5. Death from CHF or arrhythmia by the 3rd decade

X-Linked Myopathy with Excessive Autophagy (XMEA)

1. May present in infancy or early adulthood
2. Slowly progressive proximal weakness and atrophy
3. No cardiomyopathy or cognitive deficits
4. Respiratory involvement may occur

Differential Diagnosis of Myoadenylate Deaminase Deficiency (MAD)

1. Exertional pain, fatigue and rarely myoglobinuria
2. Onset in late adolescence to middle age
3. Normal neurologic exam
4. Patients may be asymptomatic
5. MAD deficiency may be seen incidentally in:
 - a. ALS
 - b. Spinal muscular atrophy
 - c. Inflammatory myopathy
 - d. Some dystrophies

Differential Diagnosis of Lipid Metabolic Disorders

1. Primary Carnitine Deficiency
 - a. Mutation of the OCTN2 gene on chromosome 5q33.1
 - b. Childhood
 - i. Reye's-like syndrome (vomiting, mental status changes, hypoglycemia, hepatomegaly)
 - ii. Proximal muscle weakness and dilated cardiomyopathy
 - iii. Rhabdomyolysis
 - iv. Respiratory weakness
 - c. Adult
 - i. May worsen with pregnancy or in the post-partum
2. Secondary carnitine deficiency occurs with:
 - a. Respiratory chain defects
 - b. Organic acidurias
 - c. Endocrinopathies
 - d. Renal and hepatic failure
 - e. Toxic effect of medications
 - f. Malnutrition
 - g. Total parenteral nutrition in infants
 - h. Chronic renal dialysis
3. CPT2 deficiency
 - a. AR; CPT2 gene maps to chromosome 1p32
 - b. Onset in the second or third decade
 - c. Muscle pain and myoglobinuria after intense exercise
 - d. Rare cardiomyopathy in infancy or early childhood
4. VLCAD deficiency

- a. Myopathy is caused by mutations in VLCAD gene that maps to chromosome 17p11.2
- b. Childhood:
 - i. Hypertrophy cardiomyopathy
 - ii. Hypoketotic hypoglycemia
 - iii. Dicarboxylic aciduria
- c. Adulthood:
 - i. Similar to CPT with exercise induced myoglobinuria

5. LCAD deficiency
 - a. Mutations in the ACADL gene that maps to chromosome 2q34-q35
 - b. Infancy:
 - i. Failure to thrive
 - ii. Non-ketotic hypoglycemia
 - iii. Cardiomyopathy
 - iv. Hepatomegaly
 - v. Encephalopathy
 - c. Adolescent/adult
 - i. Exercise intolerance, rhabdomyolysis and proximal weakness
6. MCAD deficiency
 - a. Mutation of the MCAD gene that maps to chromosome 1p31
 - b. Rare cardiac or skeletal muscle involvement
 - c. Rhabdomyolysis and encephalopathy have been reported in infancy and adulthood
7. SCAD deficiency
 - a. Mutations in the SCAD gene that maps to chromosome 12q22-qter
 - b. Onset in infancy or early adulthood
 - c. Infants
 - i. May have failure to thrive with episodes of non-ketotic hypoglycemia
 - d. Adults
 - i. Myalgia and exercise intolerance
 - ii. Progressive proximal muscle weakness
 - iii. Facial weakness, ptosis, progressive external ophthalmoplegia
 - iv. Respiratory insufficiency
 - v. Cardiomyopathy
8. Mitochondrial Trifunctional Protein Deficiency
 - a. Mutations in long chain HAD, ETF, ETF-QO
 - b. Chronic progressive proximal muscle weakness
 - c. Cardiomyopathy
 - d. Recurrent rhabdomyolysis
9. Long chain 3-hydroxyacyl-CoA dehydrogenase deficiency (HAD)
 - a. AR; the gene maps to chromosome 2p23
 - b. Presentation in infancy and early childhood is similar to that of Reye's syndrome with high mortality
 - c. Adulthood
 - i. Progressive proximal muscle weakness
 - ii. Recurrent episodes of myoglobinuria

- iii. A subset of patients develop a progressive sensorimotor neuropathy and pigmentary retinopathy
- iv. Mothers of affected fetus may develop the HELLP complication during pregnancy (hemolysis, elevated liver enzymes, low platelets and acute fatty liver)

Differential Diagnosis of Mitochondrial Myopathies

1. Myoclonic Epilepsy and Ragged Red Fibers (MERRF)
 - a. AR; multiple mtDNA deletions; point mutations at nucleotide position 8344 in the tRNA gene MTTK; other tRNA mutations and deletions; POLG and MTND5 mutations can present with a similar phenotype
 - b. Myoclonus
 - c. Generalized seizures (GTC and myoclonic)
 - d. Atoxic
 - e. Cognitive impairment
 - f. Sensorineural hearing loss
 - g. Optic atrophy
 - h. Progressive proximal myopathy
2. Mitochondrial Myopathy Lactic Acidosis and Stroke (MELAS)
 - a. 705 of patients have mtDNA mutation at nucleotide 3243 in the MTTL1 gene that encodes to RNA. Mutations have been described at multiple other nucleotide sites and in genes that encode other tRNAs and other subunits of the respiratory chain
 - b. Proximal muscle weakness
 - c. Stroke-like episodes (that do not respect a vascular distribution)
 - d. Increased lactate levels in the serum and CSF
3. Kearns-Sayre syndrome
 - a. Single large mtDNA deletions (1.3 to 8.8 KB) that involve several tRNA genes
 - b. Onset prior to age 20
 - c. PEO, pigmentary retinopathy and cardiomyopathy are the core clinical features
 - d. Associated features include:
 - i. Short stature
 - ii. Proximal muscle weakness
 - iii. Cognitive impairment
 - iv. Sensorineural hearing loss
 - v. Depressed ventilatory drive
 - vi. Endocrinopathies
 - vii. Sensitive to sedatives and anesthesia
4. Progressive external ophthalmoplegia (PEO)
 - a. PEO sporadic
 - i. Approximately 40–70% with PEO have a single large mtDNA deletion
 - b. PEO Autosomal dominant
 - i. Multiple mtDNA deletions
 - ii. Three genes have been defined
 1. PEO A1
 - a. Due to mutations in POLG (polymerase gamma) that maps to chromosome 15q25
 2. PEO A2
 - a. Mutations in the ANT 1 gene (adenosine nucleotide translocator) that maps to chromosome 4q34-q35
 3. PEO A3
 - a. Mutations in the twinkle gene (C100RF2) that maps to chromosome 10q24
 4. A fourth locus has been identified that maps to chromosome 3q14.1-21.4
 5. Autosomal recessive PEO
 - a. Due to mutations in the POLG gene at chromosome 15q25
 6. Clinical Manifestations
 - a. Ptosis and ophthalmoparesis
 - b. Some patients have proximal muscle weakness
 - c. No systemic manifestations, cardiac conduction defects or pigmentary retinopathy
5. Autosomal recessive cardiomyopathy and ophthalmoplegia
 - a. Multiple mitochondrial DNA deletions
 - b. Childhood onset
 - i. Facial and proximal muscle weakness
 - ii. Severe cardiomyopathy (dilated)
 - iii. Reduced muscle tendon stretching reflexes
6. Mitochondrial DNA depletion syndromes
 - a. Approximately 50% of patients are sporadic
 - b. The more mtDNA depleted the more severe the clinical symptoms
 - c. The syndrome is associated with mutations in thymidine kerase² (TK2) and deoxyguanosine kinase (DGK) gene mutations (these nuclear genes are pivotal in regulation the mitochondrial genome)
 - d. Onset is usually in infancy or early childhood
 - e. Wide clinical spectrum
 - i. Severe fatal infantile form with generalized hypotonia and weakness; associated proximal weakness, ptosis and ophthalmoplegia; subset with neuropathy
 - ii. A more benign form with delayed motor milestones but without renal tubular defect
7. Focal mitochondrial depletion
 - a. No molecular defects of mtDNA have been delineated
 - b. May present in the second decade of life with myalgia, fatigue and myoglobinuria
 - c. Congenital weakness, hypotonia, delayed motor milestones and cognitive deficits may occur
8. Mitochondrial neurogastrointestinal encephalomyopathy (MNGIE)
 - a. AR with multiple mtDNA deletions; mutations occur in the thymide phosphorylase gene (ECG1) that maps to chromosome 22q13.2-1ter; rare patients have mutations in the polymerase gamma (POLG) and the tRNA gene (MTTK)

- b. Distal proximal weakness and atrophy
 - c. Stocking and glove sensory loss
 - d. Ptosis and EOM paresis
 - e. Minimal CNS involvement although there is a clear leukoencephalopathy on MRI (rare cognitive impairment occurs)
 - f. Associated clinical features include:
 - i. Pigmentary retinopathy
 - ii. Sensorineural hearing loss
 - iii. Facial weakness
 - iv. Hoarseness and dysarthria
 - v. Gastrointestinal dysmotility
 - g. Onset prior to age 20
9. Leigh syndrome
- a. Great genetic heterogeneity
 - i. Maternal with point mutations of mtDNA in transfer RNA genes:
 1. MTND3
 2. MTND5
 3. MTND6
 4. MTCO3
 5. MTATP6
 - ii. Autosomal recessive Leigh syndrome
 1. No mitochondrial DNA mutations
 2. Gene mutations include:
 - a. NDUFV1
 - b. NDUF51
 - c. NDUF53
 - d. NDUF54
 - e. NDUF57
 - f. NDUF58
 - g. SDHA
 - h. BCS1L
 - i. COX10
 - j. SCO2
 - k. SURF1
 - l. LRPPRC
 - iii. X-linked Leigh syndrome
 1. No mitochondrial DNA mutations
 2. Mutations in the PDHA1 gene (pyruvate dehydrogenase lipoamide) alpha 1; xp22.1
 - iv. Sporadic Leigh
 1. Single large mtDNA deletion
 2. Microdeletions of mtDNA; mTCO3
 - b. Clinical Manifestations of Leigh syndrome
 - i. Onset in infancy or early childhood; rare presentation in adults
 1. Recurrent vomiting
 2. Cognitive deficits
 3. Generalized weakness and hypotonia
 4. Ptosis and ophthalmoparesis
 5. Bulbar symptomatology in infants (poor suck and cry, respiratory failure)
 6. Nystagmus, optic atrophy, ataxia spasticity and peripheral neuropathy
10. Mitochondrial myopathies
- a. Sporadic
 - b. Microdeletions of mtDNA; MTCO 3 gene
 - c. Point mutations of mtDNA; MTCYB, ND4 genes
 - d. Maternal inheritance
 - i. Point mutations of mtDNA; tRNA^{PHE}
 - e. Short stature
 - f. Normal strength but decreased muscle bulk
 - g. May have mild proximal muscle weakness
 - h. Recurrent myoglobinuria may be triggered by alcohol or exercise
 - i. A subset of patients with sensorineural hearing loss
11. Mitochondrial myopathy and sideroblastic anemia
- a. MLAS1 is caused by a homozygous mutation in the PVS1 gene that maps to chromosome 12.q24
 - b. MLAS1 is caused by mutations in the YARS 2 gene that maps to chromosome 12p11
 - c. MLASA3 is caused by a heteroplasmic mutation in the mitochondrially encoded MTATP gene
 - d. Myopathy
 - e. Lactic acidosis
 - f. Sideroblastic anemia
12. Fatal infantile myopathy
- a. AR; mt depletion
 - b. TK2 (thymidinekinase mutation) that maps to chromosome 16q21

Differential Diagnosis of the Myotonic Dystrophies

DM1 is caused by an expansion of unstable cytosine-thymine-guanine (CTG) repeats in the 3' untranslated portion of the myotonin protein kinase (DMPK) gene that maps to chromosome 19q.13.2; AD

1. Onset at any age
2. Distal weakness initially that progresses to proximal muscles
3. Neck flexors are affected early
4. Facial and masticatory weakness and atrophy cause the facial dysmorphism ("hatchet face")
5. Involvement of pharyngeal and lingual muscles
6. Myotonia in both action induced and evoked by percussion of muscle groups (thenar eminence)
7. Cognitive impairment in approximately 50% of adults; neurobehavioral deficits
8. Systemic involvement
 - a. Gastrointestinal (dysmotility and pseudo-obstruction)
 - b. Respiratory muscle involvement (alveolar hypoventilation)
 - c. Probable decreased central respiratory drive
 - d. Posterior Stellate cataracts
 - e. 90% of patients with conduction defects by EKG; increased cardiac sudden death
 - f. Testicular atrophy
 - g. Frontal balding
 - h. Hyperinsulism with glucose tolerance testing

Myotonic Dystrophy Type 2 (DM2) or Proximal Myotonic Myopathy (PROMM)

1. DM2 and PROMM are allelic disorders caused by:
 - a. CCTG repeat expansion in the zinc finger protein of gene (ZNF9) that maps to chromosome 3
 - b. Onset between 20–60 years of age
 - c. Initial symptoms are intermittent stiffness and unilateral or bilateral thigh pain
 - d. Myotonia is evident in proximal, distal and facial muscles; may be exacerbated during pregnancy
 - e. “warm-up” phenomenon; no exacerbation with cold; small group exacerbate with heat
 - f. Episodic pain (neuropathic)
 - g. Slowly progressive proximal and distal weakness (fluctuates)
 - h. Atrophy of proximal muscle (10%) in later life
 - i. Rare calf hypertrophy
 - j. Myoglobinuria
 - k. Anticipation is less in DM2 than DM1; no congenital form
 - l. Cataracts, testicular atrophy, cardiac conduction defects, hypogammaglobulinemia, and glucose intolerance

Differential Diagnosis of Nondystrophic Myotonia and Periodic Paralysis

Chloride Channelopathies

Myotonia Congenita

1. Thomsen disease
 - a. AD; CLCN-1 gene that maps to chromosome 7q35
 - b. Onset in the first decade of life
 - c. Infants have difficulty opening eyes after crying
 - d. Adults:
 - i. Stiffness in the legs initially which progresses to the arms
 - ii. Myotonia in muscles of mastication
 - iii. “Warm-up” phenomenon is present (lessened myotonia with continued muscle contraction)
 - iv. Myotonia increases with cold
 - v. In later life phenotype may be similar to PROMM
 - vi. Percussion myotonia is present
2. Becker’s disease
 - a. AR
 - b. Onset between 4–12 years of age (later than Thomsen’s disease)
 - c. Severity of weakness worse
 - d. Distal weakness may occur following severe episode of myotonia
 - e. Mild fixed proximal weakness of the neck flexor musculature and in the extremities

Sodium Channelopathies

1. Hyperkalemic Periodic Paralysis

- a. AD; mutation in the SENA4A that maps to chromosome 17q13.1–13.3
- b. Three clinical forms:
 - i. Without myotonia
 - ii. With clinical or electrical myotonia
 - iii. In conjunction with paramyotonia congenita (PMC)
 - iv. Cooling triggers weakness in the PMC variant
 - v. Myotonia can be elicited in the eyelids, tongue; percussion. Myotonia can be seen particularly well in the forearm finger extensors
 - vi. Myotonia decreases with continued muscle contraction except with the PMC variant where it is increased with exercise and cold
 - vii. Parasthesias in the muscle occur often before weakness (feeling of swelling)
 - viii. Weakness is really mild and lasts for 20 minutes to 2 hours; rare flaccid paralysis
 - ix. Rare involvement of bulbar musculature
 - x. A brief period of exercise after sustained physical exertion may prevent or postpone weakness
 - xi. Affected muscles can be painful after attacks
 - xii. Eyelid myotonia may be the only sign between attacks
 - xiii. Mild fixed proximal weakness can evolve over time

2. Paramyotonia congenita

- a. Caused by mutations in the SCN4A gene that maps to chromosome 17q13.1–13.3; AD and allelic to potassium-sensitive periodic paralysis
- b. Repeated muscle contracture increases the myotonia as does cold
- c. A subset of patients may develop focal or generalized weakness
- d. Onset within the first decade
- e. Cold induced weakness can last for hours
- f. Rarely weakness can be induced by a potassium load
- g. Myalgias may occur but are not as severe as those that occur with DM2/PROMM

3. Potassium exacerbated myotonia

- a. Caused by mutation in SCN4A
 - i. The myotonia:
 1. Fluctuates
 2. Onset is delayed after exercise
 3. Eyelid paramyotonia
 4. The warm-up myotonia phenomenon occurs in the extremities
 5. Potassium, exercise and cold does not trigger weakness
 6. When the myotonia is severe it can affect EOM and bulbar musculature

4. Myotonia Permanens

- a. Caused by the G1306A mutation of the SCN4A gene that maps to chromosome 17q
- b. Constant muscle stiffness

- c. May affect respiratory muscles severely enough to cause hypoxia
- d. There is no episodic weakness or cold exacerbation
- 5. Acetazolamide responsive myotonia
 - a. Caused by mutations in the SCN4A gene that maps to chromosome 17
 - b. Onset in childhood that worsens by early adulthood
 - c. The myotonia is most severe in the hands and face
 - d. Myotonia is exacerbated by potassium, fasting and exercise
 - e. Stiffness and pain may be relieved by carbohydrates
 - f. There is both action and percussion myotonia
 - g. Strength is normal
 - h. There may be paradoxical myotonia of the eyelids
- 6. Facial hypokalemic periodic paralysis type 2
 - a. A subset of hypoKPP is caused by mutations in the SCN4A gene; most hypoKPP is caused by mutation in the voltage-gated calcium channel X-1 subunit gene (CACL1A3)
 - b. In the SCN4A hypoKPP:
 - i. Age of onset is earlier
 - ii. Attacks are similar to those that occur in hypoKPP1 but no fixed muscle weakness develops as it does with hypoKPP1
 - iii. Acetazolamide may exacerbate weakness
- i. The last affected muscles are the first to recover
- j. Frequency of attacks is very variable
- k. After age 30, the frequency of attacks diminish
 - l. Proximal muscles may gradually develop fixed weakness that is seen more in the legs than arms
- m. Attacks may be heralded by heavy sensation in the lower back; thighs and calves
- n. Exercise may block an impending attack in some instances
- 2. Secondary hypokalemic paralysis
 - a. Urinary and gastrointestinal potassium loss may cause proximal muscle weakness
 - b. Onset is usually after the age of 30
 - c. No family history of periodic weakness
 - d. If severe, the hypokalemia may cause a necrotizing myopathy
 - e. Weakness improves with correction of the hypokalemia
- 3. Thyrotoxic periodic paralysis
 - a. Most often occurs in Asian patients
 - b. Similar to hypokalemic periodic paralysis
 - c. More common in men than women
 - d. Beta-blockers may be helpful whereas acetazolamide is not
 - e. Correction of the hyperthyroidism stops the attacks

Calcium Channelopathies

- 1. Hypokalemic periodic paralysis type 1 (HypoKPP1)
 - a. HypoKPP1 is caused by mutations in the CACN1A3 gene that maps to chromosome 1q31-32 (in 70% of patients)
 - b. Onset is within the first two decades of life
 - c. They have no clinical or electrophysiological myotonia or paramyotonia
 - d. Episodic weakness is triggered by:
 - i. Exercise followed by rest or sleep
 - ii. High carbohydrate meals
 - iii. High sodium intake
 - iv. Emotional stress
 - v. Alcohol
 - vi. Viral illness
 - vii. Menstruation
 - viii. Sleep deprivation
 - ix. Beta agonists
 - x. Insulin
 - e. Attacks may be mild with focal weakness that can occur at any time of day but most often are seen in the morning
 - f. Severe attacks cause generalized flaccid weakness that usually spare facial, respiratory musculature and the sphincters
 - g. Muscle is unexcitable during attacks of profound weakness
 - h. Weakness usually lost > for hours to a day but residual weakness may persist for several days

Differential Diagnosis of Rarer Causes of Periodic Paralysis

- 1. Andersen-Tawil syndrome (ATS)
 - a. Approximately 2/3 of patients have mutations or small deletions in the KCNJ2 gene (AST1) that maps to chromosome 17q24; AD
 - b. Periodic paralysis
 - c. Ventricular arrhythmia with long QT interval
 - d. Developmental deficits
 - e. Episodic weakness that occurs spontaneously or after exercise and then rest
 - f. Onset is during the first or second decade
 - g. Attacks may last from hours to days with wide frequency variations
 - h. Patients may develop fixed proximal weakness
 - i. No myotonia or paramyotonia
 - j. Severe ventricular arrhythmias
 - k. Developmental anomalies include:
 - i. Scoliosis
 - ii. Short stature
 - iii. Hypertelorism
 - iv. Cleft palate
 - v. Mandibular hypoplasia
- 2. KCNE3 mutations that map to chromosome 11q13.4
 - a. Attacks of weakness associated with low serum potassium in some patients

Differential Diagnosis of Rare Channelopathies

- 1. Central core disease with malignant hyperthermia

- a. Mutations in the ryanodine receptor gene (RYR) that maps to chromosome 19q13.1
2. Malignant hyperthermia
 - a. MHS1
3. Mutation in the RYR gene that maps to chromosome 19q13.1
 - a. MHS2
 - i. Mutations in the RYR gene that maps to chromosome 17q11.2–q24
 1. May be allelic to hyperKPP, PMC and PAM
 - b. MHS3
 - i. Mutations in gene that maps to chromosome 7q21–22
 - c. MHS4
 - i. Gene not identified; maps to chromosome 3q13.1
 - d. MHS5
 - i. Caused by mutation in the dihydropyridine receptor gene that maps to chromosome 1q31 (allelic to hypoKPP1)
 - e. MHS6
 - i. Mutations that map to chromosome 5p
4. Clinical features are severe muscular rigidity (masseter muscles may be first)

Differential Diagnosis of Malignant Hyperthermia

The diagnosis of malignant hyperthermia is relatively straightforward. A volatile anesthetic agent or succinylcholine is used during induction of anesthesia which causes an elevation rather than a slight depression of temperature. Masseter rigidity, tachycardia, acidosis, an increase in end tidal CO₂ and severe acidosis supervenes. Generalized muscle rigidity follows.

Suspicion of malignant hyperthermia should be raised if a family member of the patient has died or had a major complication during uncomplicated anesthesia. An increased resting CK in a patient with an affected family member is also a clue that the patient is at risk. Baseline CK may be normal in patients at risk. The congenital myopathies, muscular dystrophies, phosphorylase deficiency, carnitine palmityl transferase deficiency and periodic paralysis have all been implicated in MH or a MH-like syndrome.

Fever, metabolic acidosis, tachycardia and cardiac arrhythmias

1. Triggers for MHS include:
 - a. Depolarizing muscle relaxants (succinylcholine)
 - b. Inhalational anesthetics (halothane)

Differential Diagnosis of Uncontrolled Metabolic State of Abrupt Onset

1. Rhabdomyolysis
 - a. Anesthetic agents
 - b. Drug-induced
2. Intense physical exercise
3. Acute intermittent porphyria

4. Ketamine induced catatonia
5. Thyroid storm
 - a. Precipitated by surgery
 - b. Anesthesia
6. Agents and illnesses that have produced MH response in humans:
 - a. Ketamine
 - b. Phencyclidine
 - c. Viral infections
 - d. Lymphoma
 - e. MAO inhibitors
 - f. Tricyclic antidepressants

Chapter 10

Brainstem and Cranial Nerves

The Regulation of Breathing

The pattern and depth of breathing is determined by acid/base balance. The central chemoreceptors (CCRs) stimulate breathing and are regulated by the PaCO_2 . Peripheral receptors respond to pH and PaCO_2 that is a feedback servo-control-sensory system that regulates breathing.

The Medullary Respiratory Center

Rhythmic cyclical breathing originates in the medulla. Multiple higher nuclear centers (for voluntary control) as well as systemic pulmonary and aortic receptors and reflexes modify medullary respiratory drive.

The Dorsal Respiratory Group (DRG)

The DRG is located in the dorsomedial medulla and is composed of cells in the solitary tract nucleus. The DRG generates the respiratory rhythm and the initiation of respiration. Its afferent input is from the apneustic center of the lower pons and part of the solitary tract neurons that are recipients of chemoreceptive and mechanical receptors from the carotid sinus, carotid body, aorta, and the lungs. The DRG is inhibited by the pneumotaxic center of the upper pons.

Inspiration is initiated from the firing of DRG cells of the solitary tract nucleus in concert with cells of the ventral respiratory group. The output from the medulla to the diaphragm and somatic muscles of respiration is caused by the phrenic and intercostal nerves. The thoracic cavity expands and a negative pressure is achieved that expands the lungs with air. The inspiratory cells are inhibited by mechanical and chemoreceptive reflexes, the inspiratory muscles relax, and inspiration ceases. In normal conditions, the DRG produces a respiratory rate of 12 to 16 breaths/minute. Inspiration lasts approximately 2 seconds and expiration approximately 3 seconds.

The ventral respiratory group (VRG) is a column of neurons that are located in the ventrolateral medulla and extend from the caudal facial nucleus to the obex (about 400 μm).

The VRG is composed of four cell groups:

1. Rostral nucleus retrofacialis
2. Caudal nucleus retroambiguus
3. Nucleus para-ambiguus
4. The pre-Bötzinger complex

The VRG contains both inspiratory and expiratory neurons.

Function of the VRG includes:

1. A component of the initiation of inspiration
2. Para-ambiguus fires during inspiration

3. Nucleus retrofacialis is active during expiration
4. The VRG controls inspiration and expiration during exercise
5. The pre-Bötzinger complex is posited to be the central respiratory rhythm pattern generator from pacemakers' cells that initiate spontaneous breathing

These brainstem respiratory neurons are interconnected and function in concert with respiratory related sensory afferent receptors from the carotid body and sinus, the lungs and aortic arch to effect autonomic and adaptive changes in breathing from environmental stimuli

1. The brainstem respiratory circuits are compartmentalized within the medulla and pons. Neural groups in the brainstem and forebrain innervate brainstem respiratory compartments and include afferences from:
 - a. Serotonergic and catecholaminergic neurons
 - b. Neurons in the periaqueductal gray (PAG)
 - c. The hypothalamus, amygdala, and cerebral cortex
2. The dorsal respiratory group of neuron (DRG) fire bursts of action potentials is independent of afferent input in a fixed phase relationship with breathing:
 - a. In experimental preparation approximately 60% of DRG neurons project monosynaptic excitatory afferents to the phrenic nerve nucleus. There are less extensive projections to C1–C2 motor neurons of the spinal cord (inspiratory neurons) that are the origin of propriospinal projections to interneurons of the phrenic and thoracic motor neurons that innervate intercostal musculature. Vagally myelinated afferent fibers from the lungs and airways activate slowly adapting receptors (SARs) that initiate Hering-Breuer reflexes in which lung inflation terminates an ongoing inspiration. SARs release glutamate in second order nucleus tractus solitarius (NTS) relay neurons (pump cells) that in turn project to central rhythm and pattern neurons in the ventral respiratory chain and pons. Pump cells are primarily GABA-ergic
3. The ventral respiratory column:
 - a. The ventral respiratory column (VRC) is located in the ventral lateral medulla along its entire length
 - b. The generation of the respiratory rhythm is the result of circuit interactions in its rostral half. Bulbosplinal neurons in the caudal half of VRC transmit the generated rhythm but modify the amplitude of respiratory motor output
4. Rostral and caudal divisions of the ventral respiratory group have different functions:
 - a. In the caudal half of the medulla:
 - i. Neurons have been identified as excitatory. These neurons are glutamatergic and project to the cervical motor neurons that comprise the phrenic nerve that innervates the diaphragm as well as to the inspiratory motor neurons of the thoracic cord. The caudal VRC neurons also innervate expiratory neurons of the abdomen and thoracic spinal cord

The Rostral VRG (Ventral Respiratory Group)

1. The Bötzing Complex (BötC):
 - a. Comprises an aggregate of neurons that are located immediately caudal to the facial nucleus and project to the NTS. Neurons of the complex provide widespread inhibitory projections within the VRG that include both inspiratory and expiratory neurons
 - b. Expiratory neurons in the BötC receive SAR afferents (receptors from the lung and airway)
 - c. The BötC mediates the expiratory lengthening of the Hering-Breuer reflex
2. The pre-Bötzing Complex (pre-BötC):
 - a. The pre-Bötzing complex is located between the BötC and rVRG neurons
 - b. Its neurons discharge with greatest frequency between the expiratory and inspiratory phases of the respiratory cycle
 - c. It is essential for respiratory rhythm generation
3. The Retrotrapezoid Nucleus (RTN):
 - a. The Retrotrapezoid nucleus is located along the ventral surface of the pons slightly below the facial nucleus and extending caudally beneath the BötC
 - b. RTN neurons are central chemoreceptors that increase their firing rate in response to a decreased pH. They provide an extensive excitatory projection (glutamatergic) to neurons of the VRG
 - c. RTN neurons also integrate central and peripheral chemoreceptor afferents. Second order neurons that receive peripheral chemosensory afferents that are located in the caudal commissural NTS also project to the RTN
4. The Parafacial Respiratory Group (pFRG):
 - a. The pFRG are located beneath the caudal end of the facial nucleus that extends caudally beneath the BötC
 - b. The function of this aggregate of neurons is controversial. It has been suggested that circuits of the pFRG form the expiratory rhythm generator that is coupled by reciprocal inhibition to the inspiratory generator of the pre-BötC
5. Pontine Respiratory Areas:
 - a. The VRG extends rostrally into the lateral pons:
 - i. Respiratory neurons are intermingled between the motor nucleus V and principal sensory V that comprises the paratrigeminal area
 - ii. Dorsally from the paratrigeminal area, respiratory neurons extend into the Kölliker-Fuse nucleus that merges with parabrachial areas medially
 - iii. Tracing studies reveal that the greatest number of positive respiratory neurons is in the Kölliker-Fuse nucleus and the ventrolateral parabrachial complex
 - iv. The functional role of the respiratory neurons of the ventrolateral pons has not been completely defined. It has been suggested that they are important in the shaping of the hypoxic ventilatory response
6. The Pontine Respiratory Group (PBr):
 - a. Neurons of the PBr complex (respiratory neurons) and those of the Kölliker-Fuse nucleus are the primary constituents of the pontine respiratory group
 - b. This group of neurons contains:
 - i. Phasic inspiratory and expiratory neurons
 - ii. Tonically active neurons that are modulated by the respiratory cycle which in neurons increase their firing with arousal and pain
 - iii. The Kölliker-Fuse (KF) nucleus projects to:
 1. Ventral Respiratory Complex (VRC)
 2. Respiratory areas of the NTS (most heavily to the ventrolateral areas)
 3. Spinal projections to the motor neurons that comprise the phrenic nerve and bulbospinal neurons of the rostral ventral respiratory group (rVRG)
 4. Respiratory neurons of the ventrolateral medulla and spinal cord
7. The neuroanatomical and chemical anatomy of respiration is extremely complex. There are interacting circuits at almost all levels. In outline form:
 - a. The pre-BötC complex initiates inspiration that is facilitated and maintained by neurons in the dorsal medulla and the rostral component of the ventral respiratory complex (VRC) of the pons
 - b. Hering-Breuer reflexes are elicited by myelinated fibers of the IXth and Xth nerves that project to the nucleus tractus solitarius to decrease inspiration in the face of the inflated lungs utilizing slow adapting receptors (SARs)
 - c. The retromedial trapezoid/parabrachial complex is the initiator for expiration (RTN/pFRG)
 - d. The retrotrapezoid body nucleus (RTN) is the central chemosensory nucleus that adjusts the rate and shape of respiration in conjunction with pH and other chemical stimuli
 - e. The A5 cell group in the ventrolateral pons contains glutamatergic and noradrenergic neurons that modulate cardiovascular and respiratory functions. It projects to the medullary and cardiorespiratory centers as well as the sympathetic premotor neurons of the intermediolateral column of the spinal cord
 - f. The Kölliker-Fuse nucleus:
 - i. Is part of the off-switch for inspiration
 - ii. Important as a determinant of breathing rate
 - iii. Controls airway potency during the respiratory cycle
 - iv. Important for the phase transition between inspiration and expiration
 - g. The pons receives extensive projections from the mid-brain, limbic system and forebrain. It is a supramedullary control center for breathing
8. Almost all pathologies that affect the brainstem interfere with some aspect of respiratory control:

- a. Mutations in the PHOS-2 gene causes congenital hypoventilation syndrome
- b. Some evidence that SIDS (Sudden Infant Death Syndrome) is due to deficient medullary pontine serotonergic interaction
- c. The Kölliker-Fuse area may be involved in neurodegenerative diseases. Tauopathy shifts the post-laryngeal constrictive activity towards inspiration that cause glottal constriction during inspiration during sleep that may be a component of obstructive sleep apnea
- d. Demented patients have severe tauopathy in the Kölliker-Fuse area
- e. There are strong projections from the carotid body afferents to the KF complex. It has been suggested that this is a component of the adaptation of central or peripheral arterial chemoreception and that is critical for homeostasis. The KF area demonstrates increased activity during hypoxia, hypercapnia, or carotid sinus stimulation
- f. The lateral PB complex receives strong nociceptive projections that mediate cardiorespiratory functions that include apnea/tachypnea, tachycardia/bradycardia, and blood pressure during painful stimuli
- g. Achondroplasia and other cervical spinal cord anomalies may be associated with Ondine's curse, the failure of automatic breathing during sleep

The Neurogenic Regulation of Short Term Blood Pressure

The short-term control of blood pressure is mediated by vasoceptors, the most sensitive of which are in the carotid sinuses and aortic arch. Carotid sinus baroreceptor axons are within the glossopharyngeal nerve while those from the aortic arch travel with the vagus nerve to synapse within the nucleus tractus solitarius (NTS). NTS neurons project glutamatergic excitatory fibers to the caudal ventrolateral medulla (CVLM). Inhibitory CVLM projections which are GABAergic inhibit the rostral ventrolateral medulla (RVLM). This nucleus (RVLM) is a major brainstem regulator of the sympathetic nervous system by its projections (glutamatergic) to sympathetic intermediolateral column neurons of the spinal cord. Baroreceptors are mechanical stretch receptors and when activated by increased blood pressure, project to the NTS which in turn activates the CVLM that inhibits the rostral ventrolateral medulla (RVLM). This circuit decreases sympathetic activity which decreases blood pressure. There is less activation of pain receptors with a drop in blood pressure and thus less inhibition of RVLM and greater sympathetic tone.

The parasympathetic outflow to the heart is maintained from baroreceptor activation and their projections to the sinoatrial and atrioventricular nodes from the nucleus tractus solitarius and the dorsal vagal nucleus.

Baroreceptors are stretch-sensitive mechanoreceptors that are active to some degree at normal resting blood pressure

although a subgroup activates only after a pressure stretch threshold is exceeded. Cardiovascular reflexes are mediated by high pressure and that can be observed in beat-to-beat changes of heart rate. The nucleus tractus solitarius coordinates these cardiovagal, cardiosympathetic and vasosympathetic reflexes. The arterial baroreceptors discharge when the blood volume affected by the ventricle distends the ventricular wall that modifies heart rate and vascular smooth muscle tone. These rapid modifications cause beat-to-beat blood vessel variability.

The role of the sympathetic nervous system is the maintenance of blood pressure and the regulation of blood flow for seconds to minutes via the arterial baroreflex. Cardiac sympathetic innervation of the SA node increases the slope of diastolic depolarization during the SA node action potential which increases heart rate. Sympathetic innervation of the myocardium increases myocardial contractility and thus stroke volume. Peripheral arterial sympathetic stimulation causes vasoconstriction through norepinephrine and neuropeptide activation of α -adrenergic receptors.

Increases in afferent input from vasoconstriction through norepinephrine and neuropeptide activation causes a decrease in sympathetic outflow which in conjunction with parasympathetic innervation of the SA node decreases heart rate. A drop in blood pressure causes vasoconstriction, an increase in stroke volume and increased heart rate.

As with breathing, brainstem pathologies interfere with short-term cardiovascular control of blood pressure.

The Brainstem and Arousal

Consciousness is dependent upon the action of the ascending reticular activating system (ARAS). It is composed of several neuronal circuits that originate primarily in the reticular formation of the brainstem which relay in the intralaminar nuclei of the thalamus which in turn projects to the cerebral cortex.

Brainstem nuclei of the system include:

1. The locus cereleus
2. Dorsal and median raphe nuclei
3. Pendunculopontine nucleus
4. The parabrachial nucleus

Other components of the system are non-specific thalamic nuclei, the hypothalamus (orexin neurons in the lateral hypothalamus), and the basal forebrain.

In general, the specific connections of the ARAS nuclei are important for arousal while those of the thalamic nuclei modulate arousal.

Hypothalamic orexin is excitatory to the entire ARAS including the midline and intralaminar thalamic nuclei. Orexin causes a slow depolarization mediated by a cation current in cholinergic lateral dorsal tegmental/pendunculopontine nuclei as well as the serotonergic dorsal raphe neurons. The orexin current of significant high frequency input generates Ca^{2+} dependent oscillations that peak in the theta to alpha frequency range (4–14 Hz) that extended to 100 Hz

(gamma activity is 30–60 Hz). The waking state shifts ECG power to higher frequencies that include synchronized periods (epochs) of intracortical gamma activity. The ARAS and the lateral dorsal tegumental (LDT), pedunculopontine (PPT) and serotonergic dorsal raphe neurons are pivotal in the shift of EEG activity to high frequencies associated with wakefulness and cognitive function. Some neurons in the system may be gamma wave generators because they produce high threshold Ca^{2+} dependent oscillators at gamma frequencies.

Lesions of these diffuse brainstem circuits form a broad spectrum of pathologies that affect decreased arousal, wakefulness, and cognitive function.

Cranial Nerves

General Characteristics

1. The olfactory nerve penetrates the cribriform plate of the ethmoid bone to synapse in the olfactory bulbs
2. Axons of mitral and tufted cells form the olfactory tract
3. The olfactory tract divides into a medial and lateral olfactory stria
4. The lateral stria project to the piriform lobe of the temporal cortex (the primary olfactory cortex)
5. There are projections to the amygdala, septal nuclei and the hypothalamus

Clinical Manifestations

1. Anosmia
2. Parosmia:
 - a. Perversion of smell
3. Disturbance of complex olfactory function:
 - a. Detection is preserved to a greater degree than discrimination
 - b. Olfactory hallucinations

Neuropathology

1. Trauma:
 - a. Fracture of the cribriform plate of the ethmoid bone
 - b. Closed head injury without fracture (tear of the olfactory nerve filaments)
2. Tumors
3. Syndromic anosmia
4. Systemic disease
5. Degenerative diseases
6. Abscess of the frontal lobe
7. Mucocele of the frontal sinus
8. Post-viral infection
9. Siderosis (Fe^{++} deposition on the nerve from recurrent cerebral bleeding from AVMs, aneurysms and cavernous hemangiomas)
10. Nasal inflammatory disease:
 - a. Allergic rhinitis
 - b. Chronic rhinosinusitis

Clinical Manifestations

1. Olfactory testing that includes:

- a. Odor threshold
 - b. Odor discrimination
 - c. Odor identification
2. Cranial MRI
 3. Blood tests for B12 deficiency
 4. Gonadotrophins and sex hormones in amenorrheic young women
 5. EEG if olfactory hallucinations are prominent

Differential Diagnosis of Anosmia

1. Trauma:
 - a. Fracture of the cribriform plate and basilar skull fracture
 - b. Closed head injury without fracture
2. Tumor:
 - a. Olfactory groove meningioma (Foster-Kennedy syndrome):
 - i. Ipsilateral anosmia
 - ii. Ipsilateral optic atrophy
 - iii. Contralateral papilledema
 - b. Differential diagnosis of Foster-Kennedy syndrome:
 - i. Mucocele
 - ii. Subdural hematoma (subfrontal)
 - iii. Esthesioblastoma:
 1. Tumor of the olfactory epithelium
 2. Frontal lobe behavioral changes
 3. CSF leak through the nostril
 4. May present with a seizure
 - c. Glioma of the frontal lobe
 - d. Pituitary adenoma with frontal suprasellar extension
 - e. Carcinomatosis of the meninges
 - f. Osteoma of the sphenoid or frontal bone
3. Syndromic anosmia:
 - a. Walker-Warburg syndrome
 - b. Kallmann syndrome (ovarian dysgenesis)
 - c. Hencken's syndrome (post-viral)
 - d. Foster-Kennedy syndrome
 - e. Pseudo Foster-Kennedy:
 - i. Papilledema of the spared eye in a patient with prior optic atrophy in the contralateral eye
 - ii. Gyrus rectus pressure
 - f. Machado-Joseph disease (SCA3)
 - g. Turner syndrome
 - h. Down syndrome
4. Parosmia and cacosmia:
 - a. Head trauma
 - b. Psychiatric disease
5. Olfactory hallucinations:
 - a. Primary olfactory cortical injury (piriform cortex of the temporal lobe)
 - b. Direct disruption of the olfactory pathway
 - c. Unilateral paroxysmal olfactory hallucination (paroxysmal dysosmia); irritation of the olfactory bulb or nerve
 - d. Complex partial seizure of the temporal lobe

- e. Hyperosmia occurs with migraine headache and hyperemesis gravidarum
- f. Hyposmia and parosmia:
 - i. Associated with hypogeusia (diminished and perverted taste)
- 6. Neurodegenerative Diseases:
 - a. Alzheimer's disease
 - b. Parkinson's disease
 - c. Spinocerebellar degeneration (Machado-Joseph disease)
 - d. Huntington's disease
- 7. Allergic Rhinitis
- 8. Infections:
 - a. Herpes simplex (meningoencephalitis)
 - b. HIV
 - c. Hansen disease
- 9. Liver disease:
 - a. Acute viral hepatitis
 - b. Cirrhosis
- 10. Nasal obstruction:
 - a. Adenoid hypertrophy
 - b. Large inferior turbinates
 - c. Polyposis
 - d. Sjögren's syndrome
- 11. Uremia (dialyses)
- 12. Iatrogenic:
 - a. Ethmoidectomy
 - b. Orbitofrontal surgeries
 - c. Rhinoplasty
 - d. Submucous resection of the nasal septum
 - e. X-RT therapy
 - f. Laryngectomy
- 13. Endocrine disorders:
 - a. Adrenal insufficiency
 - b. Diabetes mellitus
 - c. Hypothyroidism
 - d. Pseudohypoparathyroidism
- 14. Detection of odor > discriminative ability:
 - a. Korsakoff's syndrome
 - b. Thalamic lesions
 - c. Prefrontal lesions
 - d. Alzheimer's disease
 - e. Parkinson's disease
 - f. Huntington's disease
- iv. Medial chiasm lesion – decreased visual acuity bilaterally
- v. Lateral chiasmatic lesions decrease acuity in the ipsilateral eye
- vi. Visual acuity remains intact if the macular fovea fibers are intact
- 2. Retrochiasmatic bilateral lesions decrease visual acuity equally in both eyes:
 - a. Impaired contrast sensitivity, more subtle defects than loss of visual acuity that occurs with macular and optic nerve dysfunction
- 3. Color Perception:
 - a. Decreased in areas of the visual field (VF) deficit
 - b. Desaturation of red in lesions of the visual pathways
 - c. Retinal photoreceptor damage affects the perception of blue
 - d. Color loss occurs with macular dysfunction (macular projections may also be affected by optic nerve and chiasmatic lesions)
 - e. Color vision loss usually parallels VA loss:
 - i. Optic neuritis color loss > VA (visual acuity) defects; in optic neuritis there is chromatic sensitivity loss and decreased luminance sensitivity
 - f. Impairment of color perception may occur from posterior VF deficits
 - g. Bilateral lesions of the anteromedial occipital lobe cause color blindness
- 4. Visual Field Defects (Retinal):
 - a. General Characteristics:
 - i. Macular lesions cause central defects
 - ii. Retinal lesions cause inverted deficits:
 - 1. Superior lesion produces an inferior deficit
 - 2. Lateral retinal lesion causes a medial visual field deficit
 - 3. Centrocecal scotoma:
 - a. Extends from central vision to the blind spot
 - b. Macula and components of the papillomacular bundle
 - 4. Nasal field peripheral nerve fiber deficit:
 - a. Arcuate shape
 - 5. Small deep retinal lesions:
 - a. Discrete defects localized to the point of lesion:
 - i. The fiber layer is spared
 - 6. Large deep retinal lesions:
 - a. Superficial fiber layer is affected
 - b. Fan shaped arcuate defect, the tip of the fan is toward the lesion with the base fanning peripherally toward the nasal horizontal meridian
 - 7. Nerve fiber bundle defects (retinal):
 - a. Most common with lesions of the optic nerve head
 - b. Tip of the defect reaches the blind spot

Cranial Nerve II

General Characteristics

- 1. Visual Acuity:
 - a. Visual discrimination of fine details of high contrast
 - b. Macular functions or its projections
 - c. Impaired by:
 - i. Changes in the shape of the globe
 - ii. Refractory characteristics of the vitreous
 - iii. Compressive and non-compressive lesions of the optic nerve

8. Defects from lesions of nasal retinal fibers (subserve the temporal field lateral to the blind spot) are sectoric. The nasal retinal fibers are straight rather than arcuate
9. Ring VF defects (retinal):
 - a. There is preserved vision centrally with preserved vision central and peripheral to the scotoma. Most often, the center coincides with the fovea
 - b. A unilateral pericentral scotoma is macular
 - c. Fusion of superior and inferior arcuate defects causes the ring scotoma
 - d. The horizontal step of the ring is a mismatch of the superior or inferior arcuate defect
 - e. Nerve fiber bundle defects:
 - i. A visual field deficit in which part of the burden (scotoma) corresponds with the course of the retinal nerve fiber layer
5. Central Visual Field Defects:
 - a. Hemianopia:
 - i. A visual field defect that involves one-half of the visual field (both eyes are involved)
 - ii. There is a sharp cut off in the vertical and horizontal meridians
 - b. Unilateral visual inattention:
 - i. Most often occurs with parieto-occipital lesions
 - ii. There is no deficit with unilateral visual field testing; if stimuli are placed in both right and left hemifields simultaneously, the patient fails to see the object in the field opposite the lesion
 - c. Vertical hemianopia can be nasal or temporal
 - d. Altitudinal defects are superior or inferior
 - e. Bilateral homonymous defects are similarly located in both visual fields. They are congruent if their shape is superimposable, if not they are incongruous
 - f. Riddoch phenomenon:
 - i. The patient can appreciate a moving object within a dense VF deficit but can't see the object if it is stationary
 - ii. Dissociation between a kinetic and static stimulus:
 1. Possible non-striated vision via the superior colliculus – pulvinar prestriate cortex
 2. Occipital lobe > optic tract > chiasm
6. Pupillary Light Reflex:
 - a. Some optic nerve fibers leave the visual sensory pathway prior to the lateral geniculate body to synapse in the pretectal region of the dorsal midbrain
 - b. Direct stimulation should elicit a brisk symmetrical constriction if it does not there is often a retinal or optic nerve lesion
 - c. Shining the light in the unaffected eye constricts both pupils; if swinging the light to the affected eye that then elicits dilation to direct light has been attributed to a defect in the ipsilesional retina or the optic nerve

- d. The affected pupillary response is most likely a defect in midbrain neurons that control the reflex ("slippage of the light reflex")
- e. Rarely, this phenomenon may be demonstrated with an optic tract lesion which is known as a Behr's pupil. The light has to be focused (slit lamp) on the affected retinal photo receptors (in the territory of the field loss from the optic tract lesion)
- f. The lateral geniculate body (LGB), optic radiation and cortical lesions do not affect the pupillary light reflex

Ophthalmoscopic Observations

1. Optic atrophy:
 - a. Sharp disc margins
 - b. Loss of the lamina cribrosa (of the optic cup)
 - c. Decreased ratio of the cup of the optic nerve head to the disc margin
 - d. Sharpness of the margin, particularly on its temporal side
 - e. Decreased visual acuity
 - f. Loss of disc capillaries (Less than 14)
 - g. Thinness of the retinal arteries
2. Glaucoma:
 - a. Deepening of the optic cup
 - b. Nasalization of the optic cup:
 - i. Present by the time of decreased visual acuity or arcuate Bjerrum (step) scotoma appear
3. Papilledema order of occurrence of signs:
 - a. Fat veins
 - b. Loss of venous pulsations
 - c. Hyperemic disc (dilation of the capillaries of the disc surface)
 - d. Protrusion of the lamina cribrosa
 - e. Loss of the disc margin: superior prior to inferior; the last is the temporal margin; the nasal margin is always slightly blurred
 - f. Slit hemorrhages off the disc margin
 - g. Retinal and choroidal folds
4. Optociliary shunts and veins:
 - a. Appear at the disc margin or on the disc
 - b. Increased pressure in the optic canal or intracranially
 - c. Anastomosis between the central retinal vein and the peripapillary choroidal venous system
 - d. Differential diagnosis:
 - i. Optic nerve sheath meningioma of Schwalbe
 - ii. Optic nerve glioma
 - iii. Neonatal hydrocephalus
 - iv. Pseudotumor cerebri
 - v. Drusen of the optic disc (pseudopapilledema)
 - vi. Glaucomatous atrophy
 - vii. Chronic atrophic papillitis
 - viii. Central retinal vein occlusion
 - ix. Arachnoid cyst
 - x. Neurofibromatosis
 - xi. Optic nerve coloboma
 - xii. Arteriosclerosis
 - xiii. Hematoma of the disc

Color Perception

General Characteristics

1. Color perception may be decreased in an area of a visual field deficit when vision for a white target is preserved
2. Desaturation for red is often caused by lesions of the visual pathways
3. Color vision loss usually parallels visual acuity loss with ischemic lesions; an exception is in optic neuritis where color vision may be much more affected; in optic neuritis chromatic sensitivity is much worse than luminance sensitivity
4. Patients with nystagmus usually have normal color vision:
 - a. Color vision does not depend on foveation or a well-focused retinal image
5. Visual acuity is usually normal with acquired achromatopsia due to cortical lesions
6. Congenital color vision defects:
 - a. More common in men than in women
 - b. Defects are primarily of red and green
7. Acquired color vision defects:
 - a. Blue-purple or blue-green hues
8. Patients with primary optic nerve disease:
 - a. Difficulties with red and green hues
9. Primary retinochoroidal diseases:
 - a. Blue discrimination defects between blue and yellow
10. Bright light color phenomenon:
 - a. Reveals color processing defects
 - b. Shining a bright light into the patient's eye usually induces a succession of colors; usually decreased with acquired dyschromatopsia
11. Lesions of the posterior visual pathways:
 - a. Decreased color perception
 - b. Bilateral anteromedial occipital lobe lesions may have color blindness with normal visual acuity

Anatomy of the Visual System

General Characteristics

1. The rods and cones are located deep in the retina in the retinal pigment epithelium
2. They project via bipolar and horizontal connecting amacrine cells to the more superficially placed ganglion cells which in turn relay primarily in the lateral geniculate body with a concomitant projection to the superior colliculus
3. The rod pigment is a glycoprotein, rhodopsin, that is stimulated by light within the visible wavelength of 400–800 nm. The rods are most dense in the fundus of the globe and are absent in the macula and optic disc
4. There are three types of cones that are activated primarily by red, green or blue light
5. There are seven million cones. Approximately 100,000 are concentrated in the macular region at the center of which is the fovea which measures 35 mm yet has no vessels or

neural elements other than tightly packed cones. It is the area that has the greatest visual discrimination. This is an area that has direct access to light

6. There are 1.2 million ganglion cells whose receptive fields become smaller in the posterior area of the globe. Cones in this area synapse one to one with ganglion cells. In the periphery of the globe there is extensive overlap between receptive fields of cones and ganglion cells. Thus peripheral vision may be spared with some ganglion disorders
7. There are two major classes of ganglion cells, M- and P-cells. They project to different layers of the lateral geniculate body which in turn projects to the visual cortex
8. M-cells are approximately 10% of ganglion cells and subserve spatial location of the target. They convey depth perception (stereopsis), do not detect color and have high contrast sensitivity:
 - a. They project to the magnocellular neurons of layer one and two of the LGD that in turn projects to 4C alpha neurons of visual area 17 of the occipital cortex. There are further projections to 4 beta area 17 neurons and then to the MT middle temporal gyrus of the temporal lobe
 - b. The macula is 90% P-cells which determine target identification and are characterized by:
 - i. High spatial resolution
 - ii. Color vision
 - iii. Low contrast sensitivity
 - iv. Also are in the peripheral retina
 - v. Project to parvocellular neurons in layers 3, 4, 5 and 6 of the LGD; they project to 4C beta neurons in layers 2 and 3 of cortical area 17. These neurons in turn project to cortical area 18 which projects and synapses with visual area V3 and V4
 - vi. M- and P-cells may be differentially affected
 - vii. Ganglion cell axons constitute the innermost retinal layer that is separated from the vitreous by a thin basement membrane
 - viii. Ganglion cells closest to the disc project their axons through the entire nerve fiber layers; the more peripherally located ganglion cell axons are deeper in the nerve fiber layer. Nasal fibers (located nasally to the optic disc) and those from the nasal side of the macula (the papillomacular bundle) run directly to the disc; the remaining fibers have a superior and inferior accurate projection to the disc
 - ix. Axons from the temporal side ganglion cells (vertical line through the fovea) project to the ipsilateral LGD whereas those from the nasal side run in the optic chiasm (contralaterally)
 - x. Macular neurons are a vertical strip of 1 degree of the fovea and project bilaterally to the LGD

Visual Field Defects*General Characteristics*

1. The central 20–30 degrees of vision are very important as few disorders affect the peripheral fields alone. The exceptions to this rule are:
 - a. Tapetoretinal degenerations
 - b. Retinal detachments
 - c. Anterior visual cortex lesions
2. Ametropia:
 - a. A condition in which an optic defect involves an error of refraction that is most often seen with astigmatism, hyperopia or myopia as well as presbyopia and must be accounted for when testing visual fields:
 - i. Uncorrected astigmatism may cause depression of the upper temporal quadrant (does not respect the vertical meridian) thus differentiating it from chiasmatic lesion; it also spans central fixation
 - ii. Spherical ametropia:
 1. Generalized field depression
 2. Rarely causes an upper temporal depression that may be found under the blind spot (blurring of the blind spot) due to local ametropia from abnormal retinal curvature
 - iii. Angioscotomata:
 1. Due to superficial retinal vessels and the blind spot are physiological scotoma
 - iv. Absolute defects involving the outer limits of the visual fields are known as contractures while depressions are smoothly tapering but not absolute visual field deficits

Specific Visual Field Deficits

1. A central defect of vision is most often from lesions of the macula and its ganglion cells and their axonal projections
2. A centrocecal defect:
 - a. Affects the macular area and the papillomacular bundle
 - b. A scotoma between the point of fixation and the blind spot
3. Nerve fiber bundle defect:
 - a. At least part of the border of the VF defect is coincident with the course of the retinal nerve fiber layer
4. Peripheral nerve fiber bundle in the nasal field:
 - a. If there is an arcuate shape of the lesion it is in the retina or optic nerve
5. Differential diagnosis of arcuate visual field deficits include:
 - a. Glaucoma
 - b. Anterior ischemic optic neuropathy
 - c. Drusen of the disc
 - d. Congenital optic pits
6. Small deep retinal lesions:
 - a. Discrete defect (dependent on the projection zone of the affected ganglion cells)

7. Retinal lesions that affect the superficial fiber layer cause a fan shaped arcuate lesion with its tip pointing to the lesion with the fan facing peripherally and toward the nasal horizontal median (arcuate shaped)
8. Nerve fiber bundle defects:
 - a. Most commonly occur with lesions of the optic nerve head
 - b. Tip of the defect reaches the blind spot
 - c. Differential diagnosis:
 - i. Branch retinal artery or vein occlusion
 - ii. Juxtapapillary inflammation
9. Defects in the temporal field (from nasal fibers that see the temporal field but project directly to the disc) cause sector defects
10. Defects of the temporal field:
 - a. Do not respect the horizontal meridian because neither the blood supply nor nasal retinal fibers are arranged along a horizontal raphe
11. Enlargement of the blind spot:
 - a. Any process that enlarges the disc head by swelling or deposition of material (drusen or hematomas)

Monocular Altitudinal VF Defects

1. Monocular altitudinal defects often have macular sparing
 - a. Central retinal artery territory occlusions cause the defect
 - i. Macular sparing may occur from blood supply derived from the cilioretinal artery
 - b. Anterior ischemic optic neuropathy
 - i. Involves the anterior component of the optic nerve
2. Secondary to ischemia of the posterior ciliary arteries
3. The defect is usually inferior
4. Differential diagnosis of altitudinal VF deficits include:
 - a. Choroiditis
 - b. Choroidal coloboma
 - c. Retinal detachment
 - d. Glaucoma
 - e. Optic nerve hypoplasia
 - f. Chronic atrophic papilledema
 - g. Drusen
 - h. Optic nerve trauma
 - i. Masses that affect the optic nerve and chiasm
5. Differential diagnosis of bilateral altitudinal VF deficits:
 - a. Bilateral ischemic lesions of the retina or optic nerves
 - b. Bilateral occipital lobe lesions
 - c. Prechiasmatic lesion:
 - i. Compresses the optic nerve inferiorly
 - ii. Superior altitudinal defects
 - d. Inferior compression of the optic nerves:
 - i. The nerves are compressed at the intracranial end of the optic canals:
 1. Produces bilateral inferior altitudinal defects
 - e. Bilateral lesions of the medial aspects of the lateral geniculate bodies (LGD)
 - i. Cause bilateral inferior altitudinal deficits

- f. Incomplete altitudinal VF deficits:
 - i. More common with retinal lesions:
 - 1. The nerve fiber layer only respects the horizontal meridian in the nasal VF
- g. Occipital pole lesions:
 - i. Altitudinal VF defects spare macular vision:
 - 1. Due to dual blood supply to the occipital pole (branch from the MCA or well as PCA supply)

Bilateral Ring VF Deficits

- 1. Most often are caused by retinal disorders but can occur from bilateral occipital lobe disorders
 - a. Occipital lesions are associated with a vertical step between the two halves of the ring

Chiasmatic Visual Field Deficits

- 1. General characteristics:
 - a. The ratio of crossed to uncrossed fibers in the chiasm is 53:47
 - b. Dorsal and ventral uncrossed fibers are lateral in the chiasm and project into the ipsilateral optic tract
 - c. Dorsal extramacular crossing fibers:
 - i. Decussate posteriorly in the chiasm
 - ii. Project in the dorsomedial contralateral optic tract
 - d. Crossing macular fibers:
 - i. Central and posterior chiasm
 - e. Inferonasal retinal fibers
 - i. Comprise peripheral fibers and make Von Willebrand's loop
- 2. Chiasmatic syndromes:
 - a. Anterior chiasm:
 - i. Central defect in one field with a superior defect in the contralateral VF
 - ii. The lesion is at the anterior angle of the chiasm that involves the ipsilateral optic nerve and the inferonasal retinal crossing fibers of Von Willebrand's knee (a junctional scotoma)
 - iii. Differential diagnosis of junctional scotomas
 - 1. Pituitary tumors
 - 2. Suprasellar meningioma
 - 3. Supracallosal aneurysm
 - 4. Craniopharyngioma
 - 5. Glioma
 - 6. Demyelinating disease (loss of neuro optica)
 - 7. Pachymeningitis
 - 8. Trauma
 - b. Body of the chiasm:
 - i. Bitemporal heteronymous VF defects:
 - 1. The defects may be peripheral, central or a combination of the two
 - 2. They may or may not split the macula
 - 3. They may be quadrantic or hemianopic
 - 4. Visual acuity is usually normal
 - 5. The optic discs may be normal or pale
 - c. The posterior chiasm syndrome:

- i. Bitemporal heteronymous scotoma
- ii. The peripheral VFs are intact; the defect is central
- iii. Normal visual acuity and optic discs

Binasal Hemianopsias

General Characteristics

- 1. Asymmetric
- 2. Do not respect the vertical meridian
- 3. Differential diagnosis
 - a. Usually due to bilateral intraocular disease of the retina or optic nerve
 - i. Chronic papilledema
 - ii. Schemic optic neuropathy
 - iii. Optic nerve drusen
 - iv. Sector retinitis pigmentosa
 - v. Compression of the lateral chiasm
 - vi. Hydrocephalus with IIIrd ventricular enlargement
 - vii. Empty sella syndrome
 - viii. Dural CSF leak

Homonymous Hemianopsia

General Characteristics

- 1. Causative lesions are in: 1. the optic tract, 2. LGD, 3. occipital lobe
- 2. Homonymous defects affecting the optic tract and LGD are incongruous
- 3. The more posterior the lesion, the greater the degree of congruity in the two VF (the fibers from the LGD are more closely packed and all are more likely to be lesioned)
- 4. Tumors produce sloping defects while vascular lesions produce sharp delineated VF deficits
- 5. Optic tract lesions:
 - a. Macular fibers are dorsolateral; peripheral fibers from the upper retina are dorsomedial and peripheral fibers from the lower retina are ventrolateral
 - b. Complete lesions of the optic tract cause:
 - i. Complete macular splitting, homonymous hemianopia with retained visual acuity
- 6. Most optic tract lesions are incomplete and cause an incongruous VF deficit
- 7. May be associated with a relative afferent pupillary defect in the eye with the temporal field deficit (contralateral to the lesion)
- 8. May be associated with a concomitant IIIrd nerve injury
- 9. Chronic optic tract lesions may cause bilateral optic atrophy with a wedge or band pallor in the contralateral eye and generalized pallor in the ipsilateral eye
- 10. Differential diagnosis of optic tract lesions:
 - a. Glioma
 - b. Meningioma
 - c. Craniopharyngioma
 - d. Pituitary adenoma
 - e. Ectopic pinealoma

- f. Abscess
 - g. Aneurysms
 - h. Metastases
 - i. AVM
 - j. Demyelinating disease
 - k. Iatrogenic surgical procedures
11. Lateral geniculate body
- a. Anatomy:
 - i. Axons that originate from ganglion cells above the fovea synapse medially while those from ganglion cell below the fovea synapse laterally
 - ii. Macular fibers synapse centrally
 - b. Post-geniculate fibers
 - i. With the optic radiations the superior retinal fibers are located in the superior component of the radiation and synapse above the calcarine fissure
 - ii. Upper VF fibers originate from the medial LGD and course through the parietal lobe
 - iii. Lower fibers that have originated in the lateral LGD comprise Von Willebrand's loop in the temporal lobe
 - iv. Clinical manifestation of LGD lesions:
 - 1. Complete macular splitting homonymous hemianopia
 - 2. Hemianopic optic atrophy (transsynaptic degeneration) may occur
 - 3. Occlusion of the anterior choroidal artery causes:
 - a. Homonymous defect in the upper and lower quadrants with sparing of a horizontal sector (quadruple sectoranopia) due to the anatomical organization of the LGD. Vertical columns within the LGD represent horizontal parallel portions of the retina
 - 4. Occlusion of the posterior lateral choroidal artery
 - a. Perfuse the central component of LGD
 - b. Cause a horizontal homonymous sector defect which may also be seen with optic radiation or rarely from occipital cortex lesions in the area of the calcarine fissure, temporo-occipital function or parieto-pero-occipital areas
 - 5. Differential diagnosis of LGD lesions:
 - a. Infarction (most common)
 - b. Arteriovenous malformations
 - c. Trauma
 - d. Mass lesions (tumors)
 - e. Demyelinating disease
 - f. Methanol poisoning

Superior Homonymous Quadrantic VF Defects

- 1. Large lesions of the inferior bank of the calcarine fissure; small lesions cause scotoma
- 2. Temporal loop of the optic radiations (Von Willebrand's knee)
- 3. Deep parietal lesions affect the dorsal component of the optic radiations, which produce inferior quadrantic defects
- 4. Quadrantic defects are most often due to optic radiation lesions

Lesions of the Striate Cortex

- 1. Anterior lesions:
 - a. Lesions are usually adjacent to the parieto-occipital fissure
 - b. Involve the monocular temporal crescent of the contralateral visual field
- 2. Posterior lesions:
 - a. Located in the posterior 50–60 percent of the striate cortex that includes the occipital pole which affects macular vision
- 3. Intermediate lesions
 - a. Are located between the anterior and posterior areas and affect 10 to 60 degrees of vision in the contralateral hemifield
- 4. Differential diagnosis of unilateral occipital lobe disorders include:
 - a. Infarction from disease of the posterior cerebral artery
 - b. Venous infarction
 - c. Intracranial hemorrhage
 - d. AVM and fistulas
 - e. Tumor
 - f. Abscess
 - g. Trauma

Bilateral Occipital Lobe Infarction

- 1. May cause unilateral homonymous scotoma
- 2. Usually have some macular sparing (ring scotoma) that respect the vertical meridian
- 3. Bilateral altitudinal defects
- 4. Bilateral homonymous hemianopia may cause cortical blindness or Anton's syndrome from:
 - a. Embolus to the top of the basilar artery that affects both PCAs
 - b. Serial PCA stroke
 - c. Anoxic insults
 - d. Complications of cerebral angiography
 - e. Migraine
 - f. Tentorial herniation (PCA is occluded under the tentorium)
 - g. Anton's syndrome occurs if there is cortical blindness and includes:
 - i. Denial of blindness
 - ii. Normal pupillary light reflex
 - iii. May have a small portion of the peripheral VF spared and thus patients can navigate around large objects
 - iv. Emotional aberrations (usually early euphoria)

Differential Points from Changes in Visual Perception

1. Lesions of the anterior optic pathways
 - a. Patients complain of:
 - i. Difficulty reading
 - ii. Dimness of vision
 - iii. Altitudinal deficiency:
 1. A downward shade over the eye
 2. Looking over the horizon
2. Vertical hemianopic defects:
 - a. Bumping into objects on the blind side
 - b. Unable to see half of a page
3. Metamorphopsia:
 - a. Objects appear misshapen
 - b. Micropsia (objects appear too small)
 - i. The photoreceptor cells are separated by edema (macular edema)
 - ii. Micropsia may also be seen with chiasm lesions
 - iii. Retinal photoreceptors are too tightly packed
 - iv. Metamorphopsia may occur from complex partial seizures that emanate from posterior temporal or occipital lobe
4. Irregular metamorphopsia:
 - a. Retinal photoreceptors are not evenly spaced
5. Distorted visual perception may occur with migraine or focal seizures
6. Hemimicropsia:
 - a. Decreased size of objects when placed in one hemi-field
 - i. Lesions have been documented in area 18, 19 and the underlying white matter
7. Optic neuritis:
 - a. Movement phosphenes (flashes of light when moving the eyes in the dark)
 - b. Putatively arises from the optic nerve (spontaneous discharge of optic nerve fibers or when they are stimulated by movement)
8. Dazzle:
 - a. Painless intolerance of the eyes to bright light
 - b. Peripheral causes of dazzle include:
 - i. Albinism
 - ii. Cone degeneration
 - iii. Achromatopsia
 - iv. Corneal, lenticular and vitreous opacities
 - c. Central causes of dazzle include:
 - i. Lesions of the optic nerve, chiasm thalamus, occipitotemporal junction and rarely the brainstem
9. Chiasmatic lesions:
 - a. Respect the midline vertical meridian
 - b. Patients may lose central vision with convergence as the bitemporal VF deficits merge
 - c. Image displacement:
 - i. Occurs in the face of normal extraocular muscle function
 1. Small ocular muscle imbalance is compensated by binocular fixation when the VF are full; with

a VF deficit they became manifest (with bitemporal VF defects)

2. Horizontal or vertical deviation of the images from either eye (hemifield slide phenomenon)
10. Moving visual deficit:
 - a. Caused by bilateral temporo-occipital lesions
 - b. The lesions affect the upper components of the occipital gyri and adjacent middle temporal gyrus:
 - i. Patients have difficulty in perceiving motion stimuli
 - ii. Moving stimuli induce an unpleasant feeling

Vascular Supply of the Visual Pathways

1. The retina is supplied by the central retinal artery (CRA) that branches from the ophthalmic artery 5–15 mm in the optic canal:
 - a. The CRA pierces the nerve and divides into superior and inferior branches at the optic disc
 - b. The macula may be supplied by the cilioretinal artery that branches into superior or inferior divisions
 - c. The ophthalmic artery gives off several posterior ciliary arteries that supply the optic disc, outer layers of the retina and the choroid
 - d. In a small percentage of patients the macula and the papillomacular bundle is supplied by the cilioretinal artery that derives from the posterior ciliary arteries; this supply may spare central vision after CRA occlusion
 - e. Posterior ciliary arteries are involved by vasculitis; CRA ischemia is usually from microthrombi, emboli, migraine and hypercoagulable states
 - f. CRA and posterior ciliary artery occlusion cause altitudinal VF deficits
2. The chiasm:
 - a. The proximal optic chiasm is supplied by the ophthalmic carotid and anterior cerebral arteries
 - b. The anterior communicating artery (ACoA) supplies the dorsum
 - c. The inferior chiasm is supplied by:
 - i. Carotid
 - ii. PCOM
 - iii. PCA
 - d. Optic tract is supplied by:
 - i. PCOM
 - ii. PCA
 - iii. Anterior choroidal artery
 - e. Lateral geniculate body (LGD) is supplied by:
 - i. Anterior choroidal artery (laterally)
 - ii. Lateral posterior choroidal artery (medially)
 - f. The optic radiations are supplied by:
 - i. Upper portion (MCA)
 - ii. Lower portion (PCA)
3. Occipital pole anastomosis occurs between the:
 - a. Angular or posterior temporal arteries (MCA branches)
 - b. Calcarine branch PCA

Cranial Nerve II

General Characteristics

1. Intraocular portion of the nerve
 - a. The optic nerve head is 1 mm long; the areas where ganglion cell axons become myelinated
2. Intraorbital portion:
 - a. Is S-shaped and 25 mm in length; the shape allows mobility of the nerve
 - b. The nerve is surrounded by fat in the cone which is formed by the ocular muscles. The ophthalmic artery, the ciliary ganglion and the extraocular muscle nerves are closely approximated to the optic nerve in this area
3. The intracisternal portion of CN II
 - a. This component of the nerve is approximately 9 mm long. The optic canal is oriented postero-superomedially at 45 degrees to the sagittal and horizontal planes
 - b. Sympathetic nerve fibers and the ophthalmic artery also occupy the canal
4. The intracranial portion of CN II
 - a. This component of the nerve varies from 4–16 mm in length depending on whether the optic chiasm is pre- or post-fixed (relationship to the sella turcica). This portion of the nerve bridges the area between the proximal opening of the optic canal and the optic chiasm. The nerve lies above the carotid artery as the vessel exits the cavernous sinus and gives off the ophthalmic artery
 - b. The nerve overlies the sphenoid sinus and the sella turcica when it is post-fixed (posteriorly placed in regard to the sella)
 - c. The horizontal portion of the anterior cerebral artery overlies the nerve superiorly
 - d. The chiasm is below the suprachiasmatic recess
 - e. The lamina terminalis and the anterior communicating artery are above the chiasm

Clinical Manifestations

1. The clinical features of optic neuropathy include:
 - a. Decreased visual acuity
 - b. Decreased color vision
 - c. Central visual field deficit
 - d. Ipsilateral relative afferent pupillary defect in unilateral bilateral asymmetric patient
 - e. Light-near dissociation of the pupils in bilateral and symmetrically affected patients (better constriction with convergence than to direct light)
 - f. Optic disc edema or atrophy; the disc is often normal with retrobulbar disorders (central scotoma is present; the patient sees “nothing” and so does the physician)

Neuropathology

1. Anterior ischemic optic neuropathy (AION)
2. Optic neuritis (ON)
3. The above are the most often cause but there is a very wide clinical group of disorders that affect the nerve (discussed under differential diagnosis)

Laboratory Evaluation

1. Ophthalmoscopic evaluation is excellent for retinal disease and multiple systemic and intracranial disorders
2. OCT (ocular computed tomography) for evaluation of the nerve head
3. Electroretinography (retinal diseases)
4. MRI:
 - a. Specifically of the optic nerves and central nervous system (excellent for all pathologies but demyelinating diseases in particular)
5. Evaluation of visual acuity, contrast sensitivity, color perception and visual fields
6. Laboratory Evaluation:
 - a. Aquaporin 4 antibody titer (Devic’s disease)
 - b. Autoimmune antibodies

Differential Diagnosis of CN II Disorders

Vascular Disorders

1. Anterior ischemic optic neuropathy:
 - a. General characteristics:
 - i. The most frequent cause of a swollen disc in a patient older than 50 years of age
 - ii. Usually is seen in the sixth to eighth decade
 - b. Clinical manifestations (non-arteritic):
 - i. Acute or subacute loss of vision
 - ii. Painless
 - iii. Altitudinal defect (inferior > superior)
 - iv. Small cup to disc ratio in the contralateral eye
 - v. Swollen optic disc:
 1. Pale
 2. Peripapillary flame shaped hemorrhages
 3. Visual loss is often permanent with subsequent optic atrophy
 - c. Clinical manifestations of arteritic AION:
 - i. Affects older patients
 - ii. Associated with amaurosis fugax in 10% of patients
 - iii. Greater visual loss
 - iv. Association with headache, jaw claudication and polymyalgia rheumatic
 - v. Elevated sedimentation rate and C-reactive protein
 - vi. Response to steroids
2. Central retinal artery emboli:
 - a. General characteristics:
 - i. Source:
 1. Burst carotid plaques
 2. Arch of the aorta
 3. Heart valves
 4. Rarely air, nitrogen or tumor emboli
 - b. Clinical manifestations:
 - i. Altitudinal visual field defect (a “shade” coming down over my eye)
 - ii. Painless
 - iii. Birefringent yellow cholesterol plaques; appear larger than the occluded vessel (Hollenhorst plaque)

- iv. The episode generally lasts 1–2 minutes; the embolus leaves the branch point of the arteries and moves peripherally
- c. Neuropathology:
 - i. Rarer sources of emboli (other than cholesterol from a burst plaque):
 1. White emboli:
 - a. Platelet fibrin
 - b. Heart valve is the usual origin
 2. Fat emboli:
 - a. Lung bone fracture
 3. Air emboli:
 - a. ENT and neurosurgical procedures in which the patient is sitting
 - b. Open heart procedures
 - ii. Ischemia of the chiasm and cranial nerve II from surgery:
 1. A-COM aneurysm clipping:
 - a. Disruption of dorsal chiasmatic blood flow
 - b. Ophthalmic artery surgery for aneurysm repair:
 - i. Disruption of the blood supply to the optic nerve
 - c. P-COM artery aneurysm surgery:
 - i. Disruption of the ventral chiasmatic blood supply
 - iii. Watershed ischemia of the optic nerve head:
 1. Decreased perfusion between the central retinal artery from the ophthalmic artery and the posterior ciliary arteries from the ophthalmic artery branches
 2. Vasculitic processes
 3. Distal field ischemia
 4. Central scotoma
 - iv. Delayed effects of X-RT:
 1. X-RT affects the vascular endothelium
 2. Delayed ischemia from proliferative endarteritis
 3. 1–5 years post-X-RT; ischemia due to decreased blood supply from the vasovasorum of the optic nerve and chiasm or from involvement of the carotid, ophthalmic or posterior ciliary vessels
 - ii. Sequential infarction (rare)
3. Ischemic disc swelling:
 - a. Marked or recurrent systemic blood loss (G.I. tract)
 - b. May be delayed for days to weeks
 - c. May occur with bypass surgery (coronary)
4. Uremic optic neuropathy:
 - a. Possibly ischemic
 - b. Disc swelling may occur but most often the disc is pale
 - c. Occurs with severe renal disease (uremic state)
 - d. Bilateral visual loss
 - e. Complicating features of this process include:
 - i. Increased CSF pressure
 - ii. Consecutive episodes of ischemic optic neuropathy
 - iii. Possibly a complication of hemodialysis
5. Carotid artery disease
6. Atrial fibrillation (emboli to the posterior ciliary arteries)
7. Coronary bypass surgery (hypotension)
8. Cardiac catheterization (emboli)
8. Eclampsia (vasoconstriction)
10. Platelet induced hypercoagulability

Tumors of the Orbit

General Characteristics

1. Tumors of the orbit cause visual loss that is associated with:
 - a. Optic disc swelling with consequent atrophy
 - b. Optociliary shunt vessels, a pale white disc and visual loss comprise the Hoyt-Spencer sign that is characteristic of compressive optic nerve lesions such as optic nerve dural meningiomas (meningioma of Schwalbe)
 - c. Diplopia and restriction of extraocular muscle movement
 - d. Proptosis which is protrusion of the optic globe. This may also occur with:
 - i. Thyroid ophthalmopathy
 - ii. Pseudotumor of the orbit
 - iii. Tumor of the middle cranial fossa:
 1. Due to pressure on the veins of the cavernous sinus that leads to intraorbital venous congestion
- iv. Intermittent proptosis occurs with an orbital venous angioma and is induced with any form of valsalva maneuver (strains, bends, coughs) or if the jugular vein is compressed:
 1. During an episode:
 - a. The eye may become tense and painful
 - b. The pupil may dilate
 - c. Bradycardia and syncope may develop (oculocardiac syndrome)
- e. Pulsation of the globe:
 - i. Occurs with congenital absence of the sphenoid bone associated with NFI (chromosome 17)

Differential Diagnosis of Rare Causes of Ischemic Optic Neuropathy

1. Cataract surgery:
 - a. Occurs 4–15 months post-operatively
 - b. Sudden visual loss
 - c. Disc infarction may occur with both retrobulbar or general anesthesia
 - d. The second eye may be involved if previously operated
2. Ischemic optic neuropathy in young patients:
 - a. Cluster headache and migraine:
 - i. Unilateral or bilateral disc infarction (rare)

- ii. Orbitocranial encephalocoele with neurofibromatosis
- iii. Orbital AV malformations
- iv. Venous varices
- v. Transmission of CSF pulsations by defects in the orbital wall
- f. Exophthalmos:
 - i. The most common cause is Grave's disease; most often it is unilateral
- g. Pseudoexophthalmos is caused by:
 - i. An enlarged globe from:
 - 1. Myopia
 - 2. Buphthalmos
 - 3. Congenital cystic eye
 - ii. Shallow or asymmetric bony orbits
 - iii. Contralateral enophthalmos makes the normal appear exophthalmic:
 - 1. Scirrhou breast metastasis
 - 2. Orbital floor fracture
 - 3. Congenital orbital bony defects
- h. Enophthalmos:
 - i. May be caused by:
 - 1. Scirrhou breast carcinoma
 - 2. Carcinoma of the GI tract, lungs or prostate
 - 3. The enophthalmos is due to fibrosis induced by the tumor with posterior traction and tethering of the globe or destruction of the orbital wall
 - ii. Other causes of enophthalmos include:
 - 1. Senile orbital fat atrophy
 - 2. Parry-Romberg disease:
 - a. Facial hemiatrophy
 - 3. Facial osteomyelitis
 - 4. Spontaneous enophthalmos and ptosis:
 - a. Putatively associated with unilateral chronic maxillary sinusitis or hypoplasia in association with orbital floor resorption
 - i. Chemosis and eyelid edema
 - j. Gaze-evoked amaurosis:
 - i. Loss of vision when the globe is placed in an eccentric position
 - ii. Most commonly observed with cavernous hemangiomas and optic nerve sheath meningiomas
 - iii. The differential diagnosis of gaze-evoked amaurosis also includes:
 - 1. Orbital osteoma
 - 2. Glioma of the optic nerve
 - 3. Medial rectus granular cell myoblastoma
 - 4. Venous varix
 - 5. Pseudotumor cerebri
 - 6. Orbital trauma
 - 7. Orbital metastases
 - iv. The putative mechanism for gaze-evoked amaurosis is decreased blood flow to the retina or optic nerve from compression of the central retinal artery. Alternatively, positional change may directly compress the optic nerve

- k. Facial pain:
 - i. Branches of the trigeminal nerve traverse the orbit. The ophthalmic division branches are most often affected
 - ii. The lacrimal, supraorbital and supratrochlear nerves are affected by diseases of the orbital roof; the zygomatic and infraorbital nerves are affected by disorders of the orbital floor
 - iii. Disease of the orbital apex and superior orbital fissure may affect several periorbital dermatomes
 - iv. Corneal hypesthesia may occur with any disease of the orbit that compresses VI
 - v. If the orbital floor is eroded the maxillary division of cranial nerve V may be affected

Patterns of Involvement with Orbital Metastatic Tumors

- 1. Infiltrative:
 - a. Restriction of motility
 - b. Ptosis
 - c. Enophthalmos
 - d. Firm orbit
- 2. Mass effect:
 - a. Proptosis
 - b. Displacement of the globe
 - c. Palpable orbital mass
- 3. Inflammatory:
 - a. Pain
 - b. Chemosis, erythema
 - c. Periorbital swelling
- 4. Functional:
 - a. Ocular motility deficit; out of proportion to orbital involvement
- 5. Asymptomatic
- 6. Direct metastasis to orbital muscle occurs with carcinoma of the breast and malignant melanoma

Tumors of Cranial Nerve II

General Characteristics

- 1. Optic disc swelling with orbital lesions
- 2. Direct metastasis to the orbit with compression of the optic nerve
- 3. Compression by dural attachment or subdural (optic dura) infiltration
- 4. Meningeal involvement of the optic nerve dura

Clinical Manifestations

- 1. Optic disc swelling
- 2. Proptosis may be minimal or absent
- 3. Fundoscopic changes induced by retrobulbar mass lesions:
 - a. Compression of the posterior wall of the globe:
 - i. Choroidal retinal striae

- b. Compression of the equator of the globe:
 - i. Diffuse retinal flattening
- c. Dilatation and tortuosity of the veins as a consequence of high orbital pressure
- d. Papilledema early with later optic atrophy
- e. Decreased visual acuity
- f. Decreased contrast light sensitivity
- g. Color perception poor (desaturation; red often appears brownish)
- h. VF (visual field) deficits:
 - i. Central scotoma
 - ii. Arcuate defects
- i. Relative pupillary afferent defect (Marcus Gunn phenomenon)

Neuropathology

1. Lymphoma:
 - a. Most often in the inferior and anterior orbit
 - b. Superior rectus muscle may be preferentially involved
 - c. Displacement of the globe > exophthalmos
 - d. The optic nerve is affected by compression
2. Chloroma:
 - a. Associated with both myelogenous and lymphatic leukemia
 - b. Greenish mass
 - c. Affects the base of the skull but has a predilection for the orbit
 - d. May be bilateral
 - e. Hemorrhage into the lids and orbit is common
3. Malignant melanoma:
 - a. Primary malignant melanoma is rare (origin is in the choroid pigment epithelium)
 - b. Recurrence after enucleation does occur
 - c. Brownish mass
 - d. Extrusion of an implant or poor retention of a prosthesis from a recurrence is common
4. Rhabdomyosarcoma:
 - a. Exophthalmos may be a presenting sign
 - b. Associated with tuberous sclerosis
 - c. Eye displacement is out and down > forward; mass occupies the upper nasal orbit
 - d. Progresses rapidly without pain
 - e. Ptosis occurs in 2/3rds of patients
 - f. 10% of patients have a nosebleed and orbital pain
 - g. Frequent conjunctival chemosis and congestion
 - h. Retinal venous congestion and striae; rare disc edema
5. Retinoblastoma:
 - a. Almost always a childhood illness
 - b. 25% are bilateral
 - c. Origin is intraocular; grows along the optic nerve
 - d. May grow through the sclera to form an orbital mass
 - e. Endophytum (endophytic) vs. exophytum (exophytic) type:
 - i. Endophytum type:
 1. Inner retinal layers
 - ii. Exophytum type:
 1. Outer retinal layers
 2. May grow through central optic pathways
 3. Necrosis and calcification in the orbit
 4. May present with leukocoria (white pupil)
- f. Sarcoma of the orbit:
 - i. Specific types:
 1. Rhabdomyosarcoma
 2. Osteosarcoma
 3. Chondrosarcoma
 4. Myxosarcoma
 5. Fibrosarcoma
 - ii. The tumors may be primary, metastatic or involve the orbit by extension
 - iii. Approximately 2% present with proptosis
 - iv. Leiomyosarcoma:
 1. Usually arise in the uterus, GI tract or the genitourinary system
 2. Originates from the smooth muscle of blood vessels
 3. Grows rapidly and metastasizes
 - v. Fibrosarcoma:
 1. Rare in the orbit
 2. Extends locally rather than metastasizes
 - vi. Chondrosarcoma:
 1. Arise from bone primarily
 2. Orbital tumors arise from bone
 3. Usually affect the orbit by extension (from the greater wing of the sphenoid)
 - vii. Osteosarcoma:
 1. Associated with fibrous dysplasia
 - viii. Liposarcoma:
 1. 20% of malignant tumors of soft tissue
 2. Extremely rare in the orbit
 - ix. Malignant granular cell myoblastoma:
 1. Average age of onset is between 20–30 years of age
 2. Metastases or recurrence may be delayed
 3. Bone formation may occur within the tumor
 - x. Primary orbital melanoma:
 1. The majority of orbital melanotic tumors are extensions of choroidal melanoma
 2. Possible association with the nevus of Ota
 - xi. Post-irradiation orbital tumor:
 1. Sarcoma may occur following XRT of a retinoblastoma
 2. Delayed development (4–25 years following therapy)
 3. Other induced tumors include: 1. fibrosarcoma and 2. mesenchymal tumors
 4. The tumors occur in the areas that were irradiated
 5. The mass is frequently at the orbital margin

g. Lacrimal Gland Tumors:

i. Mixed tumor:

1. Benign or malignant
2. 50% are epithelial tumors of the lacrimal gland
3. Myxomatous stroma and epithelial elements
4. Benign mixed tumors:
 - a. Most common type of epithelial tumor of the lacrimal gland
 - b. Encapsulated
 - c. May recur and invade bone

ii. Adenoid cystic carcinoma:

1. The lacrimal gland > frequency than the salivary gland
2. 50% of the epithelial tumors of the lacrimal gland are carcinomas (adenocystic is the most common)
3. Occurs in adulthood
4. Presents as a lump in the upper outer orbit
5. Exophthalmos is slight or late
6. May have early disc edema
7. Decreased vision due to pressure on the optic nerve
8. May invade bone and cause pain

Intraocular Metastatic Tumors*General Characteristics*

1. Primarily affect the posterior choroid
2. Left side is involved > right; more direct course of the carotid artery
3. There are twenty short posterior ciliary arteries; seven anterior ciliary arteries and two long posterior ciliary arteries. Metastases are more likely to go to the short posterior ciliary arteries
4. Occurs in less than 1% of primary malignant intraocular tumors
5. Tumor emboli metastasize to the uveal tract while infectious emboli go to the retina (smaller than metastatic tissue; the infectious material traverses the central retinal artery)
6. Uveal metastases females > males
7. In 25% of patients, metastases are bilateral
8. Breast carcinoma > 50% of uveal metastasis
9. Lung metastases have a higher incidence of iris and ciliary body metastasis
10. Prostate metastasizes to the orbit > uveal tract
11. Neuroblastoma occurs after the age of 20 in 13% of patients
12. GI tract tumors account for approximately 7% of intraocular metastases
13. Rare primary tumors that metastasize to the orbit are:
 1. thyroid, 2. liver, 3. ovary, 4. pancreas, 5. kidney, 6. uterus, 7. bladder, 8. parotid or 9. testicle

Clinical Manifestations

1. Choroidal:

- a. Usually are located temporal to the disc and near the macula
 - b. Visual impairment with a rapidly progressive course (involvement of the macula), retinal detachment that causes a central scotoma
 - c. Rarely painful
 - d. Extraocular muscle extension is rare; involvement of the retina is rare except by detachment
2. Anterior uveal metastasis:
 - a. There may be no visual loss
 - b. Single or multiple metastases
 - c. Discrete nodules are in the iris and ciliary bodies
 3. Metastasis to the retina:
 - a. Rarely occurs
 - b. Does occur in a setting of widespread metastases
 - c. Painless loss of vision
 4. Adnexal metastasis:
 - a. Rare
 5. Metastasis to the optic nerve:
 - a. Extremely rare
 - b. May involve the nerve or the nerve sheath
 - c. Progressive loss of vision

Neuropathology

1. Orbital metastases are less common than tumors that extend from the paranasal sinuses
2. Tumor emboli metastasize to the uveal tract
3. Specific neuropathology dependent on the type of tumor

Laboratory Evaluation

1. Complete ophthalmologic evaluation
2. CT and MRI of the orbit
3. Visual evoked potentials
4. Metastatic and primary tumor diagnostic workup

Orbital Cysts*General Characteristics*

1. Most often are congenital and include:
 - a. Dermoid
 - b. Teratoid
 - c. Meningocele
 - d. Encephalocele

Clinical Manifestations

1. Increased intraorbital pressure with compression of the optic nerve
2. Central scotoma; rarely arcuate deficits in the VF (visual field)

Neuropathology

1. Parasitic:
 - a. Hydatid
 - b. Cysticercosis
2. Epidermoid:

- a. Present at puberty
- b. Located most frequently at the upper and outer quadrant of the orbit; rarely seen near the lacrimal gland or deep in the orbit
3. Dermoid:
 - a. The cysts may have multiple diverticulae
 - b. Involve the choroid
 - c. Most commonly located at the limbus of the globe or the upper outer quadrant of the orbit
 - d. Associated with coloboma of the lid and aniridia
 - e. Inflammatory reactions occur around cysts that have perforated
 - f. Deep dermoids compress the optic nerve
 - g. Primary cholesteatoma of the orbit can only be differentiated from a dermoid histologically
 - h. Dermoids may span the orbit
4. Orbital bone cysts:
 - a. The cysts contain channels with thin or thick septa
 - b. Usually located in the orbital roof
 - c. Blood may be present in the cyst
5. Cystic orbital teratoma
6. Congenital cystic eyeball
7. Orbital encephalocele
8. Meningocele

Laboratory Evaluation

1. Complete ophthalmoscopic evaluation
2. CT and MRI of the orbit
3. VEP (visual evoked potentials)

Differential Diagnosis of Tumors Affecting the IInd Cranial Nerve and/or the Orbit

1. Meningioma of Schwalbe (optic nerve sheath; perioptic meningioma)
2. Sphenoid wing meningioma
3. Lymphoma
4. Rhabdomyosarcoma
5. Leukemia (particularly CLL)
6. Chloroma (plasma cell tumor)
7. Optic nerve glioma (neurofibromatosis type I; chromosome 17)
8. Ganglioneuroma
9. Hemangioma of the orbit
10. Hypereosinophilia (involves CN II directly) toxic proteins are released that damage the nerve
11. Carcinomatosis of the meninges (lung > breast > GI tract > melanoma)
12. Dermoid
13. Epidermoid

Masses of the Optic Disc

General Characteristics

1. Papilledema must be distinguished from pseudopapilledema

Clinical Manifestations

1. Pseudopapilledema:
 - a. An absent central cup with a small disc diameter
 - b. Vessels originate from the central apex of the disc
 - c. Anomalous vessel branching
 - d. Increased number of disc vessels
 - e. Venous pulsations are present
 - f. Irregular disc margins with abnormalities of the peripapillary retinal pigment epithelium
 - g. Absence of superficial capillary telangiectasia
 - h. No hemorrhage
 - i. No cotton wool spots

Neuropathology

1. Drusen are usually clearly seen but may be small and buried in the disc head
2. Anomalies that may simulate papilledema:
 - a. Hyperopic discs
 - b. Tilted discs
3. Gliotic dysplasia
4. Fibrillary astrocytoma (NFI)
5. Glial remnants of the hyaloid vasculature (their membranes or gray nodules attached to the disc)
6. Capillary and cavernous hemangioma
7. Racemose malformation (Wyburn-Mason disease)
8. Melanocytoma
9. Sarcoid granuloma
10. Leukemic infiltrate
11. Metastatic carcinoma

Vascular Masses of the Orbit

General Characteristics

1. Usually present in children
2. Plateau of growth by adulthood

Clinical Manifestations

1. Compression of the optic nerve
2. Central and arcuate scotoma
3. Venous congestion of the retina
4. Several involve the lids, conjunctiva, and facial structures

Neuropathology

1. Orbital lymphangioma:
 - a. Benign slowly progressive tumor
 - b. Most often in children
 - c. Approximately 50% of patients have involvement of the lids, conjunctiva, face and palate
 - d. Involves both the lymph and vascular systems
 - e. Resembles a cavernous hemangioma (the spaces within the tumor contain lymph rather than blood)
 - f. Hemorrhage into the tumor occurs frequently
2. Hemangioma:
 - a. Approximately 23% of orbital tumors
 - b. Cavernous hemangiomas:

- i. Epithelium lined spaces
- ii. The tumors are long and encapsulated
- c. Racemose form:
 - i. Completely formed blood vessels; veins predominate
 - ii. Isolated masses of blood vessels that may pulsate
 - iii. They may have A-V aneurysms in the retina
 - iv. The tumors occur within the muscle core
 - v. Proptosis is straightforward without deviation of the globe
 - vi. Engorgement of retinal vessels, disc edema, loss of vision
 - vii. Occasional ocular bruit may be heard with ocular pulsation
 - viii. Intermittent exophthalmos
- 3. Hemangioliomyoma:
 - a. Composed of thick walled vessels
 - b. Contain smooth muscle
 - c. An encapsulated tumor
- 4. Hemangioendothelioma:
 - a. Originates from endothelial cells
 - b. Contains anastomosing vascular channels
 - c. May be malignant and can metastasize
 - d. May occur in soft tissue
- 5. Hemangiopericytoma:
 - a. Proliferating cell is the pericyte
 - b. Potentially malignant
 - c. May invade the bone and erode into the cranial cavity

Optic Neuritis

General Characteristics

1. An inflammatory or autoimmune disease that affects the optic nerve
2. More common in females than males and usually affects patients between 20 to 50 years of age

Clinical Manifestations

1. Loss of vision that progresses over hours to days
2. Visual loss is often most severe by the end of the first week
3. The disc is normal in approximately 2/3rds of patients and swollen in approximately 1/3
4. If the process is retrobulbar, there is pain induced or exacerbated by eye movement. It is usually periorbital or may be projected to the forehead
5. There is decreased visual acuity most frequently in the central 20° of vision with associated:
 - a. Decreased brightness
 - b. Hue desaturation; color vision may be more affected than visual acuity
 - c. An afferent pupillary response (Marcus Gunn pupil)
 - d. Arcuate and altitudinal defects may be seen
6. Vision usually starts to improve by the second to third week and if the demyelinated segment is short may return to normal by six weeks. There is a correlation of length of

the optic nerve lesion in demyelinating disease and visual deficit. The lesion may be more severe and initially bilateral with Devic's disease (aquaporin 4 antibodies). Multiple sclerosis presents overwhelmingly with unilateral disease (Devic's may be simultaneously bilateral)

7. Uhthoff's phenomenon may be seen:
 - a. Decreased vision with increased temperature (failure of conduction of partially demyelinated fibers with increased temperature)
 - b. Failure of vision with bright light suggests decreased photoreceptor replenishment that may occur with severe carotid stenosis

Neuropathology

1. Demyelination of the optic nerve is the primary pathology of CN II in multiple sclerosis
2. Aquaporin antibody disease affects the astrocytic foot processes of blood vessels throughout the optic nerve and for long segments of the spinal cord (at least 3 vertebral segments) as well as some periventricular areas
3. Autoimmune processes that may affect the optic nerve include:
 - a. Demyelinating disease (MS) [multiple sclerosis]
 - b. Acute disseminated encephalomyelitis (ADEM)
 - c. AIDP/CIDP (rare)
 - d. Post-viral infections
 - e. Devic's disease (NMD)
 - f. Paraneoplastic disorders
4. Specific viral infections:
 - a. Measles
 - b. Mumps
 - c. Herpes zoster
 - d. HIV
 - e. Any viral encephalitis
5. Contiguous inflammation:
 - a. Orbital disease
 - b. Sinusitis
 - c. Meningeal disorders
6. Deep fungal infection:
 - a. Cryptococcosis:
 - i. The fungus surrounds the nerve under the dural sheath
 - b. Aspergillus
 - c. Mucormycosis (destroys the contents of the orbit most often in severely immunosuppressed patients)
7. Syphilis
8. Sarcoid:
 - a. Compression of the nerve from infiltration of the meninges
9. IgG pachymeningitis (dural hypertrophy with nerve compression)
10. Intraocular inflammation:
 - a. Serous retinopathy
 - b. Neuroretinitis
11. Carcinomatosis of the meninges

Laboratory Evaluation

1. Complete ophthalmoscopic examination
2. CT (if there is sinus disease or bony orbital involvement)
3. MRI of the head and orbit
4. Appropriate serum and CSF evaluation for autoimmune disorders, infectious agents, paraneoplastic antibodies, aquaporin-4 antibodies
5. OCT particularly in demyelinating disease

Toxic and Nutritional Optic Neuropathies*General Characteristics*

1. Toxic and nutritional neuropathies are most often seen in malnourished and addicted patients in the Western world
2. In general, famine, introduction of new drugs, nutritional deficiencies, and toxic exposures cause large-scale outbreaks of cranial nerve II involvement

Clinical Manifestations

1. Present with a slowly progressive loss of central vision
2. No pain or photopsias
3. Associated paresthesias, ataxia and sensorineural hearing loss occur with general nutritional deficiencies; if found in equatorial countries they have been termed "tropical amblyopias"
4. Bilateral decrease of visual acuity (VA 20/200) or minimal 20/25. VA loss is usually symmetrical
5. Loss of color vision may be worse than visual acuity; early patients may present with isolated color vision deficiency
6. Centrocecal scotoma:
 - a. Initially nasal to the blind spot and extends to the point of fixation on both sides of the vertical meridian. There is a bridge between the scotoma of the blind spot and at the point of fixation
7. Loss of red color perception
8. Relative afferent pupillary defect brightness is normal
9. May demonstrate nerve fiber layer loss in the papillomacular bundle; there may be swelling in the arcuate bundles; mildly pale temporal disc late in the disease course

Neuropathology

1. Ethambutol:
 - a. Primarily used for pulmonary tuberculosis
 - b. Toxic neuropathy (CN II) occurs in approximately 5% of patients
 - c. Severe dyschromatopsia, central or cecocentral scotoma
 - d. Mitochondrial dysfunction:
 - i. Ethambutol chelates copper which is required for cytochrome C oxidase activity
2. Disulfiram:
 - a. A chelating agent
 - b. Similar clinical manifestations as ethambutol
3. Linezolid:
 - a. An oxazolidinone antimicrobial drug utilized against gram-positive infections

- b. Causes a reversible optic neuropathy
- c. Putatively inhibits mitochondrial protein synthesis
- d. Usually the optic neuropathy is apparent after 3 months of continued use
4. Isoniazid:
 - a. Utilized for tbc (tuberculosis) treatment
 - b. Severe bilateral optic disc swelling
 - c. Bitemporal hemianopic scotomas
5. Tacrolimus:
 - a. A cytotoxic T-cell suppressor primarily used in transplant medicine
 - b. Only a few reported patients; one with a rapid onset similar to ischemic optic neuropathy
6. Amiodarone:
 - a. Primarily utilized to treat ventricular arrhythmias
 - b. Similar presentation as isoniazid and a more rapid course than ethambutol
 - c. Disc swelling; severe visual field deficits similar to anterior ischemic optic neuropathy
7. Phosphodiesterase-5 inhibitors (sildenafil, tadalafil and vardenafil):
 - a. Treatment of erectile dysfunction
 - b. Clinically similar to non-arteritic anterior ischemic optic neuropathy
8. Methanol:
 - a. Methanol most often accompanies illegally brewed alcohol taken orally after being filtered:
 - i. Causes a severe metabolic acidosis from its toxic metabolite formalin which is metabolized to formaldehyde
 - ii. Vision loss occurs within hours
 - iii. A characteristic hyperemic and swollen disc
 - iv. Decreased pupillary light reflex portends a poor prognosis
9. Ethylene glycol:
 - a. Antifreeze; usually ingested in a suicide attempt
 - b. May cause blindness with a similar course to methanol
10. Cuban optic neuropathy:
 - a. Epidemic optic neuropathy occurred between 1992–1993
 - b. The neuropathy of CN II was associated with weight loss and deficiency of vitamins and protein (vitamin B12 and folate)
 - c. Swelling of the nerve fiber layer in the arcuate bundles; thinning of the nerve fiber layer approximate to the papillomacular bundle
11. Cassava root neuropathy:
 - a. Seen in epidemic proportions during the Nigerian civil war
 - b. Cassava root and leaf diet in starving patients
 - c. Associated with sensorineural hearing loss and sensory ataxia
 - d. Putative cyanide toxicity that is found primarily in the cassava root
12. Jamaican optic neuropathy:

- a. Affects young adults
- b. May be seen in all of the Caribbean islands
- c. Rapidly progressive visual loss
- d. Bilateral optic atrophy
- e. Visual acuity may be reduced to 20/200 with dense central scotoma
- f. A putative mitochondrial disorder
- 13. Tobacco-alcohol amblyopia:
 - a. Probable dietary deficiency of B-complex vitamins
 - b. Elderly patients
 - c. Some patients have been found to have concomitant B12 deficiency
 - d. Bilateral symmetric centrocecal scotoma (between the blind spot and the point of fixation)
 - e. No nerve fiber deficit
 - f. VA 20/200 is typical
 - g. The defect may extend across the vertical meridian
 - h. Rare hemorrhages are seen on or off the disc (splinter variety); rare disc swelling
 - i. Cyanide in tobacco and free radicals may impair mitochondrial metabolism
- 14. Tamoxifen:
 - a. Reported to cause bilateral optic neuropathy
- 15. Tumor necrosis factor α inhibitors (golimumab):
 - a. TNF α inhibitors are now increasingly being utilized for Crohn's disease, psoriatic arthritis, rheumatoid arthritis, ankylosing spondylitis and uveitis:
 - i. Anterior optic neuropathy may occur with influx; mab
 - ii. Retrobulbar neuritis
 - iii. Sudden onset of visual loss during treatment
- 16. Nutritional optic neuropathy:
 - a. Insufficient dietary intake primarily of vitamin B12 or folic acid in a setting of:
 - i. Unbalanced diet
 - ii. Malnutrition
 - iii. Chronic alcoholism and drug abuse
 - iv. Severe anemia
 - v. Bariatric surgery
- 17. Decreased retinal ganglion layer thickness and volume is demonstrated by optical coherence tomography

Hereditary Optic Neuropathies

- 1. Hereditary Optic Nerve disease:
 - a. Leber hereditary optic neuropathy (ADOA) and autosomal-dominant optic atrophy are the two most common inherited optic neuropathies
 - b. Both have selective loss of retinal ganglion cells (RGCs) and early involvement of the papillomacular bundle
 - c. Inherited optic neuropathies are seen in 1 in 10,000 individuals

Leber's Hereditary Optic Neuropathy (LHON)

General Characteristics

- 1. LHON is caused by multiple genes encoded by the mitochondrial genome
- 2. Drugs/Toxins
 - a. Ethambutol (green cones are affected)
 - b. Chloromycetin
 - c. Streptomycin
 - d. Isoniazid
 - e. Chlorpropamide
 - f. Digitalis
 - g. Chloroquine (macular lesion)
 - h. Placidyl
 - i. Antabuse
 - j. Heavy metals
 - k. Methanol (optic nerve destruction; hemorrhagic papilledema)
 - l. Halogenated hydroxyquinolones: subacute myeloptic neuropathy (SMON)
 - m. Toluene (glue sniffing)
 - n. D-penicillamine
 - o. Intracarotid BCNU (glioma treatment)
 - p. Amiodarone
 - q. Hexachlorophene
 - r. 5-fluorouracil

Clinical Manifestations

- 1. Disease onset is usually an acute loss of central vision which is bilateral in 25% of patients; if unilateral the contralateral eye is affected within eight weeks (invariably within 1 year)
- 2. Patients become symptomatic in the second and third decade of life
- 3. Central or centrocecal scotoma
- 4. Decreased color vision
- 5. Pupillary light reflex is not affected as severely as the extent of visual loss
- 6. Funduscopic evaluation:
 - a. Tortuosity of the central retinal vessels
 - b. Swelling of the nerve fiber layer
 - c. Circumpapillary telangiectatic microangiopathy
 - d. 90% of patients have normal discs
 - e. At approximately six weeks optic nerve pallor is more marked temporally
 - f. Pathologic cupping of the disc occurs with extensive axonal loss within the papillomacular bundle in long standing patients
 - g. Extraocular manifestations include:
 - i. Psychiatric disorders
 - ii. Spastic dystonia
 - iii. Encephalopathy

Neuropathology

- 1. The majority of patients with LHON (90–95%) have one of three primary mtDNA point mutations

- Visual loss occurs if the mutational load exceeds 60% which is required to cause a bioenergetic defect

Laboratory Evaluation

- Complete ophthalmological evaluation
- OCT (ocular coherence tomography):
 - RGC loss and early involvement of the maculopapillary bundle
- All three primary LHON mutations have been shown to involve complex 1 subunits which decrease oxidative phosphorylation and ATP synthesis

Autosomal Dominant Optic Atrophy

General Characteristics

- Affects approximately 1 in 35,000 individuals (North of England)

Clinical Manifestations

- Insidious visual loss that starts within the first two decades of life
- A milder phenotype than LHON with approximately 25% of patients visually asymptomatic
- There is marked inter- and intrafamilial variability in the rate of disease progression
- Most patients have generalized dyschromatopsia; approximately 10% have pure tritanopia (blue-yellow color blindness)
- Involvement of the papillomacular bundle causes central, centrocecal and paracentral scotomata
- The pupillary light reflex is relatively preserved
- Funduscopy evaluation:
 - Optic disc pallor may be diffuse and involve the entire neuroretinal rim or demonstrate a temporal wedge
 - Approximately 1/3 of patients have normal discs
 - Peripapillary atrophy
 - Enlarged cup-to-disc ratio (greater than .5)
- Associated neurologic manifestations include:
 - Bilateral sensorineural deafness that begins in late childhood and early adulthood (occurs in approximately 2/3rds of patients)
 - Ataxia
 - Myopathy
 - Peripheral neuropathy
 - Chronic progressive extraocular ophthalmoplegia
 - OPA1 mutations have been identified in patients with spastic paraplegia and in individuals with a multiple sclerosis-like disorder

Neuropathology

- Approximately 50–60% of patients with AD optic atrophy have mutations in the OPA1 gene located at chromosome 3q29:
 - The majority of OPA1 mutations cause premature termination codons; approximately 30% of patients have missense mutations

- OPA1 is a transmembrane protein that is located within the mitochondrial inner membrane
- Pathologic hallmark of OPA1 mutations is mitochondrial network fragmentation with isolated dysmorphic aberrant balloon-like enlargements, disorganized cristae and paracrystalline inclusion bodies
- Cytochrome c molecules lose their sequestration within tight cristae junctions, leach into the cytosol and activate apoptotic cascades
- OPA1 is a component of oxidative phosphorylation regulation through its interaction with respiratory chain complexes

Laboratory Evaluation

- Complete ophthalmologic evaluation
- Genetic testing
- Ocular coherence tomography
- Visual evoked potentials
- MRI:
 - Particularly useful in patients with extraocular manifestations

Hereditary Motor and Sensory Neuropathy type VI

General Characteristic

- HMSN-VI is a subtype of Charcot-Marie-Tooth (CMT) disease

Clinical Manifestations

- Childhood onset
- Severe peripheral neuropathy
- Severe visual loss that starts in late childhood
- A subgroup of patients has had return of vision later in life

Neuropathology

- Mutations in the MFN1 and MFN2 genes:
 - Encode outer mitochondrial membrane proteins with GTPase domains
 - The MFN1,2 and OPA1 proteins function synergistically in mitochondrial fusion
 - MFN2 is involved in regulating the expression of nuclear-encoded respiratory chain subunits

Laboratory Evaluation

- EMG:
 - Severe peripheral neuropathy
- Ophthalmoscopic evaluation
- Direct genetic testing

Spastic Paraparesis (EPGF7)

General Characteristics

- Prevalence in 3–10/100,000 patients in the general population
- The uncomplicated form causes slowly progressive spastic paraparesis
- Complicated forms have additional neurologic deficits
- SPGF7 that maps to chromosome 16q24,3 is an AR HSP that has prominent optic atrophy in some patients

Clinical Manifestations

1. Variability in the spectrum of clinical features that include:
 - a. Bilateral optic atrophy
 - b. Spastic paraparesis
 - c. Peripheral neuropathy
 - d. Cognitive dysfunction

Neuropathology

1. Muscle biopsy (2 patients):
 - a. Ragged red fibers and COX-negative fibers
 - b. Electron microscopy:
 - i. Abnormal mitochondria that contain paracrystalline inclusions
2. Defect in complex I activity and impaired oxidative phosphorylation
3. There is interaction between the defective paraplegin protein and OPA1 proteins that are associated with mitochondrial network fusion

Laboratory Evaluation

1. Genetic testing
2. Ophthalmic evaluation
3. MRI of the spinal cord
4. Muscle biopsy

Friedreich's Ataxia*General Characteristics*

1. Autosomal recessive
2. The mutation is in the FXN gene that maps to chromosome 9q13-q21.1:
 - a. There is a pathologic expansion of the ⁹GAA trinucleotide repeat in FXN that encodes the protein frataxin

Clinical Manifestations

1. Onset is usually the second decade
2. Progressive gait ataxia
3. Scoliosis and pes cavus
4. Distal limb weakness
5. Dorsal column deficits
6. Dysarthria
7. Hypertrophic cardiomyopathy
8. Optic nerve dysfunction

Neuropathology

1. Diffuse and progressive atrophy of the retinal nerve fiber layer loss without papillomacular bundle involvement (in distinction to LHON and OPA1)
2. Frataxin is located in the inner mitochondrial membrane and functions in the assembly of iron-sulfur clusters that are essential for the respiratory chain
3. In addition to defects in oxidative phosphorylation, there is intramitochondrial accumulation of iron. Frataxin has antioxidant properties and its deficiency has been suggested as a cause of reactive oxygen species damage in the disorder

Laboratory Evaluation

1. Genetic testing
2. Ophthalmologic evaluation
3. Echocardiogram and EKG
4. MRI of the brain

Autosomal Recessive Non-Syndromic Optic Atrophy*General Characteristics*

1. Mutations of the TMEM 26 A gene that maps to chromosome 11q14.1-q21:
 - a. Encodes a transmembrane mitochondrial protein which is located in the retinal ganglion cell layer and the optic nerve head
 - b. Gene function is unknown but no mitochondrial network fragmentation or mtDNA depletion has been found

Clinical Manifestations (Simple Recessive)

1. Optic Atrophy:
 - a. Severe visual impairment with optic atrophy
 - b. Associated with nerve deficit in a subgroup
2. Complicated (recessive) disorders:
 - a. Behr's syndrome:
 - i. Optic atrophy
 - ii. Mild cognitive impairment
 - iii. Spasticity
 - iv. Ataxia
 - b. Onset by nine years of age
 - c. Temporal disc pallor
 - d. Strabismus occurs in 2/3rds of patients

Neuropathology

1. Atrophy in the optic nerves, LGB (lateral geniculate body) visual radiation and the striate cortex

Laboratory Evaluation

1. Ophthalmological evaluation
2. Visual evoked response
3. OCT
4. MRI of the brain

Recessive Optic Atrophy and Juvenile Diabetes (Wolfram Syndrome)*General Characteristics*

1. The Wolfram syndrome is caused by mutations in the WFSI gene that maps to 4p16.1

Clinical Manifestations

1. Optic atrophy with severe visual loss (20/200)
2. Insulin-dependent diabetes mellitus
3. Diabetes insipidus
4. Deafness
5. Cognitive and psychiatric disorders
6. Some patients have had ataxia, nystagmus, ptosis, seizures and short stature

Neuropathology

1. Smaller than control intracranial volume that primarily affects gray and white matter in the brainstem, cerebellum and optic radiations
2. Pattern of deficits suggests that the disorder affects brain development as well as later neurodegeneration

Laboratory Evaluation

1. Genetic testing for the WFSI gene
2. MRI of the brain
3. Ophthalmologic evaluation
4. Serum abnormalities for both diabetes mellitus and lipids
5. Increased CSF protein

Mitochondrial Protein-Import Disorders***Mohr-Tranebjaerg Syndrome****General Characteristics*

1. The Mohr-Tranebjaerg or deafness-dystonia-optic neuropathy (DDON) syndrome is caused by mutations in the TIMM8A gene that maps to Xq22

Clinical Manifestations

1. Sensorineural deafness
2. Dystonia and ataxia in late childhood
3. Visual loss with optic atrophy with onset at approximately 20 years of age
4. Cognitive deficits and psychiatric disorders by age 50

Neuropathology

1. Visual loss is secondary to retinal ganglion cell loss
2. The TIMM13 protein is a 70 KDa hetero-oligomeric complex that is located in the mitochondrial intermembrane space:
 - a. In conjunction with TIMM8A (another mitochondrial membrane translocase), facilitates the import and insertion of inner mitochondrial proteins
3. Decreased complex I–IV mitochondrial chain activity

Laboratory Evaluation

1. Genetic testing
2. MRI of the brain
3. Hearing evaluation

Dilated Cardiomyopathy with Ataxia (DCMA)*General Characteristics*

1. DCMA also known as 3-methyl glutaric aciduria type Vis caused by mutations in the DNA JC19 gene that maps to chromosome 3q26.33
2. The encoded protein is within mitochondria
3. It is an autosomal recessive disorder of Hutterite patients of the Northern United States and Canada

Clinical Manifestations

1. Growth failure
2. Early onset cardiomyopathy
3. Optic atrophy in a subset of patients
4. Cerebellar ataxia
5. Muscle weakness
6. Genital abnormalities in males

Neuropathology

1. The encoded protein localizes to the mitochondrial inner membrane and is putative translocase that functions to import proteins into the mitochondrial matrix

Laboratory Evaluation

1. Ophthalmologic evaluation
2. Microcytic anemia
3. Excretion of 3-methylglutaconic acid

Optic Atrophy in Mitochondrial Encephalomyopathies

The optic neuropathy in the clonic mitochondrial syndromes listed is a secondary feature that is overshadowed by the more significant associated deficits:

1. MELAS
2. MERRF
3. Kearns-Sayre syndrome
4. Maternally inherited Leigh syndrome
5. MNGIE

Glaucoma from OPTN Mutations*General Characteristics*

1. Primary open angle glaucoma may be caused by mutations in 4 genes:
 - a. Optineurin (OPTN)
 - b. Myocilin (MYOC)
 - c. CYP1B1
 - d. WDR 36
2. OPTN mutations are detected in approximately 17% of families with normal tension glaucoma and are causative of 2% of sporadic patients
3. It has been suggested that the OPTN variant (PM98K) may be a risk factor for glaucoma
4. The optineurin gene maps to chromosome 10p13
5. The protein optineurin interacts with Huntington (HTT) transcription factor IIIA and RAB8
6. Phosphorylation of it may be associated with its action as an autophagy receptor

Clinical Manifestations

1. Associated with primary open angle glaucoma
2. One gene mutation has been associated with normal tension glaucoma
3. Associated with autosomal recessive amyotrophic lateral sclerosis

Neuropathology

1. OPTN is a pleiotropic protein and one of its functions is to protect against oxidative stress which is accomplished by regulating NF- κ B:
 - a. Upregulation of NF- κ B inhibits cytochrome-c oxidase and cytochrome b mRNA which decreases ATP production
 - b. OPTN also colocalizes in the Golgi apparatus that suggests a role in protein membrane trafficking and vesicular transport
 - c. Mitochondrial dysfunction of RGCs

Laboratory Evaluation

1. Complete ophthalmologic evaluation
2. OCT
3. Detailed visual field testing

Idiopathic Intracranial Hypertension*General Characteristics*

1. Definition:
 - a. Raised intracranial pressure
 - b. Papilledema
 - c. No clinical or radiological structural lesions noted
 - d. Normal CSF (the exception is increased pressure)
2. Associated neurological signs and symptoms:
 - a. Increased size of the blind spot
 - b. VIth nerve palsy (due to generalized increased intracranial pressure; the nerve is trapped in Dorello's canal under the petroclinoid ligament)
 - c. Tinnitus (may be pulsatile)
 - d. Visual obscuration (variable pressure on the chiasm from the suprachiasmatic recess)
 - e. Severe headaches

Clinical Manifestations

1. Female preponderance (teen years through the fifth decade); most often patients have an increased BMI
2. Twenty percent of the disorder occurs in men
3. Visual field defects:
 - a. The most common feature is an enlarged blind spot
 - b. Arcuate nerve bundle defects (within the central 80% of vision)
 - c. The defects are usually along the horizontal meridian

Neuropathology

1. Visual acuity loss occurs from both outer retinal changes (often reversible) or optic neuropathy

Laboratory Evaluation

1. MRI:
 - a. Empty sella syndrome
 - b. Transverse sinus stenosis (some patients)

- c. Flattening of the posterior globe
- d. Optic disc protrusion
- e. Increased perioptic nerve CSF space

Differential Diagnosis of Idiopathic Intracranial Hypertension (Pseudotumor Cerebri)

1. Congenital defects:
 - a. Aqueductal stenosis:
 - i. Forked aqueduct
 - ii. Small multichannel aqueduct
 - iii. Congenitally small aqueduct (less than 3 mm)
 - b. Syringomyelia
 - c. Chronic sepsis (obliteration of the Pacchionian granulations)
- d. Drugs:
 - i. Amiodarone
 - ii. Tetracycline
 - iii. Nalidixic acid
 - iv. Steroid withdrawal
 - v. Birth control pills
 - vi. Lithium
 - vii. Hypervitaminosis A and D
- e. Venous thrombosis:
 - i. Venous anomalies of sinuses:
 1. Lateral sinuses (otitic hydrocephalus)
 2. Transverse sinuses
 3. Sagittal sinus (usually the superior > inferior)
 4. Hypercoagulable state
- f. Hypothyroidism
- g. Pernicious anemia
- h. Iron deficiency anemia
- i. Addison's disease
- j. SLE
- k. Polythemia vera
- l. Hypothalamic pituitary dysfunction:
 - i. Stein-Leventhal syndrome

Differential Diagnosis of Unusual Cause of Optic Nerve Disease

1. Orbital complications of sinus disease:
 - a. Frontal sinusitis:
 - i. Microcode:
 1. Orbital mass
 2. Exophthalmos
 3. Naso-orbital hyperostosis
 - ii. Encrypted empyema:
 1. Upper inner angle of the orbit
 2. Swelling and ptosis of the lids
 3. Orbital osteoperiostitis
 4. Diffuse orbital suppuration and abscess
2. Maxillary sinusitis:
 - a. Osteoperiostitis
 - b. Early optic nerve involvement
 - c. Lacrimal apparatus destruction

- d. Iritis, iridocyclitis, neuroretinitis
3. Ethmoidal sinusitis:
 - a. Associated mucocele in young patients
 - b. Suppuration
 - c. Osteoperiostitis
4. Sphenoidal sinusitis:
 - a. Associated with cavernous sinus thrombosis
 - b. Orbital abscess
 - c. Optic neuritis (inflammatory)
 - d. Associated ocular nerve palsies; the VIth nerve is most frequently involved
5. Thyroid ophthalmopathy:
 - a. The most common cause of unilateral exophthalmos
 - b. Often preceded by exophthalmos without ocular globe deviation
 - c. Orbital edema
 - d. Inflammation and fibrosis of extraocular muscles
 - e. Insertions of the muscles are not involved
 - f. Inferior rectus more severely affected (controversial) > medial recti > superior recti > oblique muscles
 - g. Vertical diplopia may occur from asymmetric involvement of the inferior or superior recti is a common early presentation
 - h. Abduction may cause extortion of the globe (due to involvement of the inferior oblique muscle)
 - i. Orbital congestion
 - j. Upper lid retraction (Dalrymple's sign)
 - k. Lid lag on down gaze (Von Graefe's sign)
 - l. Infrequent blinking (Stellwag's sign)
 - m. Convergent weakness (Moebius' sign)
 - n. Optic nerve compression with central scotoma (due to severe orbital compression by swollen muscles at the orbital apex)
6. Paget's disease:
 - a. Overgrowth of bone that compresses the orbital canal
7. Fibrous dysplasia of bone:
 - a. Compression of optic canal
8. Osteopetrosis:
 - a. Compression of the optic canal
9. Increased intracranial pressure:
 - a. Suprachiasmatic recess pressure compresses the chiasma (transient visual obscurations)
 - b. Venous congestion of the cavernous sinus with secondary orbital venous congestion
10. Idiopathic pachymeningitis
11. Paraneoplastic involvement
12. Traumatic optic nerve injury:
 - a. Orbital and facial fractures:
 - i. Penetrating orbital lesions
 - ii. Blunt trauma to the eye:
 1. Putative contusion of retrobulbar axons
 2. Hemorrhage of the nerve or the nerve sheath
 - iii. Loss of vision during orbital surgery:
 1. Post-operative orbital hemorrhage
2. Direct optic nerve injury
3. Repair of orbital floor fracture
4. After rhinoplasty
5. Blepharoplasty (orbital hemorrhage)
6. Neurosurgical procedures (face down):
 - a. Malposition of the headrest tamponades the globe
 - b. Retinal choroidal infarction
- iv. Optic nerve tethered to the bone:
 1. Areas of injury:
 - a. Orbital opening of the canal
 - b. Canal (12 mm)
 - c. Intracranial entrance of the canal is compressed with head trauma
 2. Anterior frontal impact (rapid acceleration):
 - a. Falls, windshield trauma, frontal head trauma
 - b. Instantaneous severe visual loss
13. Radiation injury of the optic nerve:
 - a. Usually secondary to X-RT of a pituitary tumor, paranasal malignancy or temporal lobe glioma
 - b. Radiation necrosis:
 - i. Proliferative endarteritis of the vasa vasorum (endothelial cells)
 - ii. Fibrinoid arterial necrosis
 - iii. Necrosis of retrolaminar nerve
 - iv. Delayed visual loss with optic atrophy
14. Thermal burns:
 - a. Delayed optic neuropathy
 - b. Bilateral involvement
 - c. Early visual loss due to diffuse cerebral edema or hypoxia
15. Infection of the optic nerve:
 - a. Syphilis:
 - i. Neuroretinitis
 - ii. Papillitis
 - iii. Perineuritis
 - b. A manifestation of second stage disease
 - c. Reoccurrence (particularly in AIDS patients)
 - d. Slowly progressive atrophy (Stage III)
 - e. Retrobulbar neuritis
 - f. Neuroretinitis in secondary syphilis:
 - i. Clouding of the central retina
 - ii. Hemorrhages
 - iii. Migration of the pigment epithelium (retinitis pigmentosa; the pigment localizes around blood vessels)
 - iv. Vitreous cellular debris
 - v. Disc swelling
 - vi. Vasculitis
16. Optic neuritis in association with HIV:
 - a. CMV neuroretinitis and papillitis
 - b. Syphilitic optic perineuritis
 - c. Hepatitis B
 - d. HIV:

- i. Bilateral optic neuritis
- e. Lyme's disease
- f. Toxoplasmosis (inflammatory papillitis)
- g. Taxocara canes (inflammatory papillitis)

Differential Diagnosis of the Swollen Disc

1. Congenital causes:
 - a. Anomalous disc:
 - i. Tilted and elevated
 - b. Hyalin bodies
 - c. Gliotic dysplasia:
 - i. Embryonic vascular remnants
2. Intraocular disease:
 - a. Uveitis
 - b. Hypotony
 - c. Vein occlusion
3. Inflammatory:
 - a. Papillitis
 - b. Neuroretinitis
 - c. Papillophlebitis
4. Infiltrative:
 - a. Lymphoma
 - b. Leukemia
5. Reticuloendothelial disease
6. Systemic disease (Fe deficiency, B12):
 - a. Anemia
 - b. Hypoxemia
 - c. Severe hypertension (encephalopathy)
 - d. Acute blood loss
 - e. Uremia
7. Disc Tumors:
 - a. Hemangioma
 - b. Glioma
 - c. Metastatic
 - d. Hamartoma
8. Vascular disease:
 - a. Ischemic optic neuropathy
 - b. Arteritis (giant cell)
 - c. Arteritis associated with collagen vascular disease
9. Juvenile diabetes
10. Proliferative retinopathies
11. Orbital tumors:
 - a. Perioptic meningioma (Schwalbe)
 - b. Glioma
 - c. Sheath tumor (cylindromas)
 - d. Retrobulbar masses
12. Graves's disease
13. Elevated intracranial pressure:
 - a. Mass lesion
 - b. Idiopathic Intracranial Hypertension (IIH)
14. Hypertension encephalopathy

Papilledema Secondary to Increased Intracranial Pressure

1. Increased nerve sheath pressure

2. Optic nerve fibers:
 - a. Compressed by increased CSF pressure in the sub-arachnoid space
 - b. The intraorbital part of the nerve is affected
 - c. Water and protein diffuse into the prelaminar region of the disc
3. Later evaluation of the process:
 - a. Venous obstruction
 - b. Nerve fiber layer hypoxia
 - c. Vascular telangiectasia

Rare Causes of Papilledema

1. Cyanotic congenital heart disease
2. Decreased arterial saturation
3. Polycythemia vera
4. Sleep apnea (CO₂ retention)
5. Syringomyelia without hydrocephalus
6. Spinal cord tumors (increased CSF protein) blocks absorption through the Paccianian granulations
7. AIDP/CIDP (increased CSF protein; cytotoxic antibodies to the nerve)

Different Mechanisms That Cause Papilledema

1. Increased intracranial pressure from mass lesions (direct pressure on the nerves and venous outflow obstruction)
2. Increased CSF production (choroid plexus papilloma)
3. Decreased CSF absorption (obstruction of Paccianian granulations)
4. Obstructive hydrocephalus
5. Increased cerebral blood volume (AVM)
6. Venous outflow obstruction:
 - a. Arteria of venous sinuses
 - b. Obstruction of venous sinuses (inflammatory, hyper-coagulable state with thrombosis)
7. Neck surgery (compression of venous outflow)
8. Jugular vein compression
9. Increased thoracic pressure
10. Chronic unilateral papilledema:
 - a. Nerve sheath tumor
 - b. Intraorbital mass
 - c. Rarely with generalized increased intracranial pressure
 - d. Previous optic atrophy in the contralateral eye (pseudo Foster-Kennedy syndrome; an atrophic disc cannot be swollen)

Clinical Manifestations of Papilledema

1. Infants with open sutures and elderly patients with cortical atrophy do not get papilledema
2. It usually takes days to weeks to develop
3. Papilledema may develop within hours with:
 - a. Severe head trauma (loss of autoregulation)
 - b. SAH (acute obstruction of CSF absorption by blood and protein)
 - c. Intracranial hemorrhage with > than 60–80 ml of blood
4. There is no visual acuity loss

5. There is enlargement of the blind spot
6. There is a normal pupillary light reflex
7. Visual fields are intact
8. Late or long standing papilledema:
 - a. Irregular peripheral VF constriction
 - b. There are nerve fiber bundle defects
 - c. Transient visual obscurations occur and are characterized by:
 - i. Momentary dimming of vision
 - ii. One eye at a time
 - iii. Lasts a few seconds (< than 10–15 seconds)
 - iv. Occurs with postural change or spontaneously
 - v. Clears completely
 - vi. Pressure on the globe may reproduce the obscuration
 - vii. A proposed mechanism is fluctuation of optic disc perfusion
 - viii. Late VF loss has tendency to involve the nasal quadrants; a late sign is:
 1. General visual field constriction
 - ix. Ophthalmoscopic evaluation:
 1. Blurring of the nerve fiber layer: nasal quadrant earlier than:
 - a. Superior > inferior > temporal
 - b. Veins are engorged, dusky and tortuous
 2. Spontaneous pulsations cease:
 - a. They are seen in 80% of normal patients
 - b. Cease at 200 ± 25 mm H₂O
 - c. The optic cup is pushed forward and the lamina cribrosa is indistinct
 - d. Splinter hemorrhages are seen off the disc; they may also be seen with drusen, glaucoma and rarely in the elderly
 - e. In patients with chronic increased pressure intracranially or in the optic canal, optociliary vessels may be prominent. They are anastomotic channels between the central retinal veins and the peripapillary choroidal venous system that bypass the compressed optic nerve venous system
 3. Optociliary shunt vessels may also be seen with:
 - a. Central retinal vein occlusion
 - b. Optic nerve glioma
 - c. Neonatal hydrocephalus
 - d. Idiopathic intracranial hypertension
 - e. Drusen of the optic disc
 - f. Glaucoma
 - g. High myopia
 - h. Chronic atrophic papillitis
 - i. Arachnoid cyst of the optic nerve
 - j. Optic nerve coloboma
 - k. Osteosclerosis
 - x. Nerve fiber layer infarcts:
 1. Cotton wool spots
 - xi. Disc hyperemia (dilation of the superficial capillary bed on the disc)
 - xii. Retinal folds (Patent lines); circumferential retinal microfolds that may extend to the macula
 - xiii. Rare concomitants of severe papilledema:
 1. Choroidal folds
 2. Ischemic infarction of the disc
 3. Infarction of the central retinal artery

The Optic Chiasm

General Characteristics

Anatomy

1. The chiasm is in the suprasellar cistern
2. It forms the floor of the suprachiasmatic recess
3. It lies 8–13 mm above the plane of the clinoid processes
4. The intracranial optic nerve:
 - a. Lies 45 degrees above the horizontal
 - b. $17 (\pm 2.5)$ mm in length
5. The lateral portion of the chiasm is adjacent to the supraclinoid carotid artery
6. The anterior cerebral arteries are dorsal to the optic nerves

Clinical Manifestations

1. Visual acuity may be decreased bilaterally if lesions involve macular fibers medially or posteriorly
2. Decreased acuity in the ipsilateral eye from lateral lesions (uncrossed fibers)
3. Color perception desaturation is common
4. Visual field deficits:
 - a. Junctional scotoma
 - b. Ipsilateral temporal or paracentral defect (anterior chiasm)
 - c. Bitemporal superior heteronymous quadrantanopsia (lesion of the paracentral chiasm; upper crossing fibers are inferior)
 - d. Impaired central vision on convergence
 - e. Hemislide of the visual field with pseudodiplopia (VF defect that has unmasked minor ocular motor imbalance that had been controlled by fixation)
 - f. Marcus Gunn phenomenon with an ipsilateral lesion
 - g. Nerve fiber layer atrophy of straight nasal retinal fibers “bow tie” configuration (crossing fibers)
 - h. Insidious progressive visual loss
 - i. Usually asymmetrical
 - j. Tumors or aneurysms may cause alterations of vision
 - k. Non-paretic diplopia
 - l. Clumsiness with motor functions
 - m. Diminished fusional capacity (non-fixed nasal fields):
 - i. Vertical and horizontal slippage:
 1. Doubling of images
 2. Gaps in a visual image
 3. Steps in the perception of horizontal lines

- n. Extinction of objects beyond the fixation point
- o. Optic nerve atrophy
- p. The vertical meridian is respected in chiasmatic defects
- q. Rare chiasmatic VF deficits:
 - i. Bilateral optic atrophy with central scotomas
 - ii. Posterior chiasm angle defect:
 - 1. Homonymous hemianopsia
 - 2. Depression of the inferior temporal VF near fixation
- r. A pseudochiasmatic VF defect:
 - i. The vertical meridian (isopter defect “8–12”) is involved in true chiasmatic defects
 - ii. Bilateral intrinsic eccentric central or centrocecal scotoma:
 - 1. Intrinsic optic nerve or retinal disease is causative
 - iii. Nasal sector retinal disease (bilateral retinitis pigmentation)
 - iv. Congenitally tilted discs (inferior crescents; nasal fundus ectopia)

Neuropathology

1. Congenital chiasmatic defects:
 - a. Maldevelopment of the optic vesicles:
 - i. Unilateral or bilateral anophthalmos
 - ii. Micro-ophthalmic cysts
 - b. Nerve hypoplasia:
 - i. May occur in isolation
 - ii. Occurs with ocular and forebrain malformations
 - iii. Partial aplasia; micropapilla
 - c. Bilateral optic nerve hypoplasia:
 - i. Associated with forebrain or developmental anomalies
 - d. Septo-optic dysplasia (De Morsier syndrome):
 - i. Short stature
 - ii. Nystagmus
 - iii. Disc hypoplasia
 - iv. Holoprosencephaly
 - v. GH and ADH deficiency
 - vi. Small pituitary
 - vii. Cognitive dysfunction
 - e. Dysplastic disc development:
 - i. Congenital tumor:
 1. Associated with a hypoplastic, truncated, irregularly shaped oval disc
 - f. Coloboma:
 - i. A congenital malformation that enlarges or distorts the nerve head circumference
 - ii. Faulty closure of the embryonic ventral fissure of the optic stalk and cup
 - iii. An enlarged disc that is excavated
 - iv. Retained glial and vascular remnants
 - v. Posterior displaced disc within excavated peripapillary coloboma

- vi. Excavated disc adjacent to retinochoroidal coloboma
- vii. Pits within the optic nerve head
- viii. Rare AD inheritance of colobomas; most are sporadic

Association of Disc Malformations and Forebrain Anomalies

1. Basal encephalocele:
 - a. Pulsating exophthalmos (spheno-orbital encephalocele)
 - b. Hypertelorism with pulsatile nasopharyngeal mass
 - c. Frontonasal mass (frontoethmoidal encephalocele)
2. Coloboma of the disc with hypertelorism or midface abnormality:
 - a. Associated with basal encephalocele
3. Bilateral disc coloboma:
 - a. Bilateral retrobulbar arachnoid cyst
 - b. Dandy-Walker malformation
4. Unilateral coloboma:
 - a. Carotid occlusion
 - b. Moyamoya syndrome with dolichoectasia
 - c. Absent carotid artery
5. Pits of the disc:
 - a. Intrapapillary pearly gray dimples or slits
 - b. Contain glial elements
 - c. Located within the scleral rim of the disc margin
 - d. Single: temporal location > central > inferior > superior or nasal quadrant
 - e. Temporal pits are associated with serous detachment of the macula
6. Diversion (tilted disc) and associated crescents of the optic discs:
 - a. Inferior crescent most frequent (inferior conus; Fuchs coloboma)
 - b. Adjacent retinal sector disorganization of the choroid and pigment epithelium
 - c. Inferior crescents are associated with:
 - i. Myopia
 - ii. Astigmatism
 - iii. Decreased visual acuity
 - iv. Decreased foveal reflex
7. Disc abnormalities are associated with:
 - a. Hypertelorism
 - b. Crouzon syndrome
 - c. Apert syndrome

Neoplasms Affecting the Optic Chiasm

1. Adenoma of the pituitary:
 - a. The most common presentation is in the 4–7th decade; they are uncommon in patients younger than 20 years old
 - b. Non-secretory adenoma:
 - i. Larger than secretory tumors

- ii. Present at 50–60 years of age
 - iii. More frequent in males than females
- c. Visual field deficits:
 - i. Superior bitemporal hemianopia
 - ii. Hemianopic scotoma near the fixation point adjacent to the vertical meridian
 - iii. Asymmetric deficits
 - iv. The eye with the greater deficit may demonstrate loss of visual acuity (papillomacular bundle fibers are affected)
 - v. Posteriorly located adenomas that may extend into the optic tract cause:
 - 1. An incongruous hemianopia
 - 2. Decreased central visions (of the ipsilateral eye)
 - 3. Optic atrophy
 - 4. Rarely: a β -ferrum arcuate scotoma is demonstrated
- 2. Prolactinoma:
 - a. The most common pituitary tumor
 - b. Females > males
 - c. Microadenomas (<10 mm in size)
 - d. Amenorrhea and galactorrhea
 - e. Males:
 - i. Decreased libido
 - ii. Impotence
 - iii. Gynecomastia
- 3. Suprasellar optic tumors:
 - a. Irritate the pituitary stalk (stalk effects increases the prolactin level)
 - b. Disrupt fiber tracts in the hypothalamus
 - c. Cause hyperprolactinemia
- 4. Pituitary apoplexy:
 - a. Acute change in the volume of a pituitary adenoma causes necrosis, edema or infarction of the pituitary:
 - i. Sheehan's syndrome:
 - 1. Acute hemorrhage during pregnancy (extremely rare in developed countries)
 - ii. The mean age of apoplexy is 50 years
 - iii. MRI has demonstrated that in a large percentage of glands that have hemorrhaged are asymptomatic
 - b. Differential diagnosis of pituitary apoplexy:
 - i. Large adenomas
 - ii. Pregnancy
 - iii. Coagulation defects
 - iv. X-RT
 - v. Trauma
 - vi. Adrenalectomy
 - c. Clinical manifestations:
 - i. Acute severe retro-orbital or infrabrow pain
 - ii. Rapid expansion into the cavernous sinus with unilateral or bilateral partial ophthalmoplegia
 - iii. Asymptomatic ophthalmoplegia
 - iv. Epistaxis or CSF rhinorrhea (from erosion into the sphenoid sinus)
 - v. Pseudomeningitis
 - vi. Decreased mental status or stupor is rare
 - vii. Late effects are panhypopituitarism
 - viii. If there is upward expansion:
 - 1. There is visual loss without ophthalmoplegia
 - 2. Downward expansion:
 - a. Ophthalmoplegia without visual loss
- 5. Perichiasmal or optic nerve compression by meningioma:
 - a. Characteristic locations:
 - i. Posterior perioptic foramina
 - ii. Medial sphenoid ridge
 - iii. Tuberculum sellae
 - iv. Olfactory groove (posterior extension)
 - v. Planum sphenoidale (posterior extension)
 - b. Clinical manifestations:
 - i. Slowly progressive monocular visual loss
 - ii. VF deficits:
 - 1. Markedly asymmetric; an extensive defect develops ipsilaterally prior to contralateral deficits
 - iii. More frequent in middle-aged women
 - iv. Enlargement of the meningioma during pregnancy
 - v. Infrabrow or frontal headache occurs with suprasellar meningiomas
 - vi. Onset of visual loss (unilateral) to bilateral visual deficits is (1–8 years)
 - vii. Periorbital eye pain that is exacerbated by movement is more common with optic neuritis
- 6. Craniopharyngioma:
 - a. The origin of the tumor is from vestigial epidermoid remnants of Rathke's pouch; scattered cell rests in the infundibulohypophyseal area
 - b. Calcification occurs in the tumor in 80% of children
 - c. There is a bimodal incidence:
 - i. The first two decades and again between 50–70 years of age
 - d. Accounts for 2 to 4% of intracranial tumors
 - e. In adults, 20% of the tumors are suprasellar; 15% are intrasellar
 - f. Clinical manifestations:
 - i. Visual deterioration
 - ii. Endocrine deficits:
 - 1. D1 (diabetes insipidus)
 - 2. Amenorrhea/galactorrhea
 - 3. Hypopituitarism
 - iii. VF deficit:
 - 1. Asymmetric bitemporal hemianopia (inferior quadrants)
 - 2. If there is optic tract extension:
 - a. Incongruous homonymous defect with decreased visual acuity
 - iv. The chiasm and optic nerve may be infiltrated and thickened
 - v. The optic canal may be enlarged
- 7. Optic and hypothalamic glioma:
 - a. Onset is usually during middle age

- b. Rapid severe unilateral visual loss; may be bilateral with chiasmatic extension
- c. Invasive malignant astrocytoma that may metastasize
- d. Death within months to two years
- 8. Chiasmatic glioma:
 - a. More common than is the orbital type
 - b. Unilateral or bilateral visual loss
 - c. More aggressive growth of chiasmatic gliomas in adults
 - d. Primary malignant glioblastoma of visual pathways is rare in adults:
 - i. Age of onset is 40–50 years of age
 - ii. Monocular loss of vision early if it has an optic nerve origin
 - iii. Retro-orbital pain
 - iv. Disc edema
 - v. There may be 5 to 6 weeks of progressive visual loss that causes bilateral blindness
 - vi. Death is usually within 2 years
- 9. Dysgerminoma:
 - a. Origin is from cell rests of the anterior floor of the IIIrd ventricle
 - b. Suprasellar location
 - c. Histological resemblance to a typical pineal teratoma
 - d. Clinical manifestations:
 - 1. Chiasmatic VF deficit
 - 2. May have concomitant anterior optic pathway involvement
 - 3. Diabetes insipidus in 80% of patients
 - 4. Partial hypopituitarism
 - 5. The age of onset is the first or second decade
 - 6. Growth retardation
 - 7. Most often an insidious visual loss

Arachnoidal and Epithelial Cysts

- 1. Serous cavity lined by neuroepithelium
- 2. Suprasellar cysts may arise in the floor of the IIIrd ventricle
- 3. Cysts of the sella turcica:
 - a. Cysts of the Rathke's pouch
 - b. Epithelial cysts
 - c. Colloid cysts
 - d. Clinical manifestations
 - i. May extend into the chiasmatic cistern
 - ii. Chiasmatic VF deficits
 - iii. Pituitary dysfunction
- e. Arachnoid cysts
 - i. 70% occur at the base of the skull
 - ii. Temporal fossa (29%) > posterior fossa (21%) > parasellar region (18%)
 - iii. Clinical manifestations
 - 1. A large percentage is asymptomatic
 - 2. Headache (50%)
 - 3. Blurred vision (40%)
 - 4. Seizures (40%; temporal lobe cysts)

- 5. Diplopia (15%)
- 6. Rarely, optic nerve sheath cysts are associated (disc swelling)

Suprasellar Aneurysm

- 1. Supra-arachnoid carotid aneurysm
 - a. Greater than 25 mm (giant aneurysm)
 - b. Women in the 5th to 6th decade
 - c. Compresses both the optic nerve and the chiasm
 - d. Clinical manifestations
 - i. Severe visual loss of the ipsilateral eye
 - ii. The aneurysm arises below the ipsilateral optic nerve and compresses it; it expands anteriorly and superiorly
 - iii. Most often there is an insidious progression of visual loss
 - iv. If the chiasm is prefixed there may be VF tract deficit

Multiple Sclerosis

- 1. Chiasmatic defects are much rarer than those of the optic nerve
- 2. VF deficits
 - a. Junctional scotoma (decreased acuity of the ipsilateral eye; temporal crescent contralaterally)
 - b. Bitemporal defects

Metastatic Disease of the Optic Nerves and the Chiasm

- 1. Rapid unilateral or bilateral visual loss
- 2. Usually there is no disc swelling
- 3. Hematogenous spread through CSF spaces
- 4. Most often associated with rapid sequential multiple cranial nerve palsies
- 5. Malignant lymphoma grows through the perivascular spaces and may also cause segmental demyelination
- 6. Chronic lymphocytic leukemia involves the chiasm
- 7. Metastases to the pituitary gland (breast cancer) may secondarily grow into the chiasm and may be associated with diabetes insipidus
 - a. Seeding of the posterior > anterior lobe
 - b. Associated diplopia

Sphenoidal Mucocele

- 1. Mucocele of the posterior ethmoid and sphenoid paranasal sinus:
 - a. Chronic headache (may project to the top of the head)
 - b. Varying ophthalmoplegia from involvement of the orbital apex
 - c. Visual loss (central) with various peripheral chiasmatic defects

Trauma

- 1. Visual loss after closed head trauma:

- a. Neuropraxia, contusion or laceration of the optic nerve to fixed points of the entry into and exit from the optic canal
- b. Immediate visual loss
2. Chiasmatic traumatic syndrome
 - a. Much less common than optic nerve lesions
 - b. Visual field deficits
 - i. Complete monocular blindness with contralateral temporal deficits (functional type)
 - ii. Bitemporal arcuate scotomas
3. Associated neurologic deficits:
 - a. Transient diabetes insipidus
 - b. Anosmia and associated defects of CN III, IV, VII and VIII
 - c. CSF rhinorrhea and otorrhea
 - d. Carotid – cavernous fistula
 - e. Carotid pseudoaneurysm
 - f. Delayed onset of meningitis
 - g. Mechanics of chiasmatic injury:
 - i. Sagittal tearing of the chiasm from sphenoidal fractures
 - ii. Thrombosis or shearing of the carotid artery blood supply to the chiasm
 - iii. Contusion or hemorrhage of the chiasm itself

Complications of X-RT

1. Radiation necrosis occurs approximately 8–12 months after treatment
2. The radionecrosis is greater in the anterior visual system than the chiasm
3. Rapidly progressive visual loss in one eye; decreased vision in the second eye follows after a short interval
4. There is a relentless progression to a severe deficit
5. Visual field deficits
 - a. Central scotoma or nerve fiber bundle defects
 - b. Chiasmatic defects
 - c. Optic tract defects
6. Chiasmatic defects are associated with pituitary X-RT
7. Optic atrophy occurs two to three months after visual loss
8. Doses clearly associated with radionecrosis (5000 cGY): complications may occur with daily fractional doses of 200 to 220 cGY treatments
 - a. The pathology is a proliferative endarteritis of small blood vessels with anoxia

Hydrocephalus

1. Pressure of the anterior aspect of the IIIrd ventricle (suprachiasmatic recess) on the chiasm that produces a neuropractic injury
2. Bitemporal VF deficit
3. Progressive optic atrophy from pressure of the nerve against the bones of the sella turcica or the carotid body

Chiasmatic Pathology with Pregnancy

1. Increase of suprasellar meningioma growth during the 2nd and 3rd trimester

2. Optic neuritis is more common after delivery (usually 6–8 weeks)
3. Lymphocytic adenohypophysitis:
 - a. Occurs often concomitantly with pregnancy
 - b. Diffuse lymphocytic infiltration of the pituitary gland
 - c. Immune-mediated
 - d. Apparently exclusive to women

The Empty Sella Syndrome

1. There is an extension of the subarachnoid space through the diaphragm sella
2. Defects in the diaphragm sella that are greater than 5 mm occur in 40% of the general population
3. There is a normal volume of the sella; glandular pituitary tissue is compressed against its posterior wall
4. The empty sella is associated with:
 - a. Arachnoid cysts
 - b. Infarction of the pituitary gland
 - c. Idiopathic intracranial hypertension
 - d. Pituitary surgery
 - e. X-RT
 - f. Pituitary apoplexy
 - g. Clinical manifestations
 - i. Chiasmal herniation into the sella
 - ii. Visual defects due to adhesions of the optic nerves and the chiasm that lead to diplopia and micropsia
 - iii. The syndrome is more common in obese women between 20–70 years of age (mean is 50 years of age)
 - iv. Headache is usually frontal or bitemporal
 - v. Rarely there is pituitary dysfunction (growth hormone, thyroid decreased secretion; increased prolactin)
 - vi. Occasional CSF rhinorrhea
 - vii. Blurred vision, diplopia and micropsia are rare visual complaints

Devic's Disease

1. Bilateral optic neuritis that may extend into the chiasm
2. At least 3 vertebral body segment spinal cord immune-mediated inflammation
3. The demonstration of aquaporin antibodies in the serum

Infectious Meningitis

1. Chiasmatic arachnoid inflammation (possibly infectious)
2. CMV of the optic nerve and chiasm as well as the retina (necrotizing)
3. Cryptococcus (extension from the optic nerve subdural infection)
4. Pseudomonas aeruginosa
5. EBV (direct infection)
6. Staphylococcus (hematogenous)
7. Streptococcal pneumonia (hematogenous)
8. HIV (direct infection)

Optochiasmatic Arachnoiditis

1. Associated with meningovascular syphilis
2. Polyarteritis
3. Cystic adhesive fibrous arachnoidal thickening with lymphocytes

Sarcoidosis

1. Involves the posterior hypothalamus
2. Pituitary
3. Optic nerve sheath
4. Chiasm
 - a. May cause chiasmic VF defects

Laboratory Evaluation

1. Specific serum markers that identify autoimmune, infectious or specific entities (aquaporin antibodies)
2. Ophthalmologic evaluation
3. MRI for intracranial processes
4. CT scan for sinus pathology
5. OCT for genetic abnormalities

Cranial Nerve III**General Characteristics***Anatomical Features*

1. The third nerve nuclear complex is located in the midbrain at the level of the superior colliculus; it extends rostrocaudally for approximately 5 mm
2. The complex is anatomically organized such that:
 - a. Dorsal neurons of the lateral nucleus innervate the inferior rectus; intermediate neurons of the lateral nucleus innervate the inferior oblique and its ventral neurons the medial rectus muscle
 - b. The central caudal nucleus innervates the levator muscles of both eyes
 - c. There is both ipsilateral and contralateral innervation of the superior rectus muscle
3. The Edinger-Westphal nucleus overlies the dorsal rostral portion of the oculomotor complex
 - a. The anteromedian nucleus and EW nucleus supply pre-ganglionic parasympathetic axons to the ciliary ganglion
 - b. Post-ganglionic sympathetic fibers reach the eye by way of short ciliary nerves
 - c. Approximately 3–3.5% of ocular parasympathetic axons supply the iris sphincter while greater than 90% supply the ciliary muscle and mediate pupillary constriction with ocular convergence (accommodation)
 - d. Pressure sensitive axons for pupillary constriction occupy the dorsomedial margin of the IIIrd nerve by some counts while it is postulated by others that they are spread equally throughout the nerve

4. Within the IIIrd nerve fibers to each muscle are organized with:
 - a. The pupillomotor fibers most medially
 - b. From medial to lateral – the IR, MR, SR and inferior oblique (most lateral)
 - c. The levator fibers are dorsal to the IR and MR
 - d. Fibers for accommodation course with pupillomotor fibers in the nerve
 - e. Clinically several syndromes can be identified from the various lesions that affect the nerve from its origin in the midbrain to the orbit. They include:
 - i. A nuclear IIIrd nerve
 - ii. Fascicular IIIrd nerve
 - iii. Cavernous IIIrd nerve syndrome
 - iv. Involvement of the IIIrd nerve in the superior orbital fissure
 - v. In the orbit
5. The IIIrd nerve separates into two divisions within the anterior cavernous sinus or the orbit:
 - a. The superior division innervates the superior rectus and the levator of the lids
 - b. The inferior division innervates the medial rectus, the inferior rectus, the inferior oblique; parasympathetic fibers to the pupil course with the branch to the inferior oblique muscle
6. The blood supply to the IIIrd nerve:
 - a. Small arteries from the posterior cerebral and basilar arteries supply the IIIrd nerve complex
 - b. A branch of the meningohypophyseal trunk (origin is in the inferior cavernous sinus)
 - c. Recurrent branches from the ophthalmic artery to the orbital branches of the nerve

Clinical Manifestations

1. Diplopia in the field of gaze of the affected component muscle of the IIIrd nerve complex
2. Associated neurological deficits at the level of IIIrd nerve involvement
3. Complete IIIrd nerve palsy (peripheral) of the eye is abducted and down with a dilated unresponsive pupil
4. Pupillary involvement of the IIIrd nerve:
 - a. Internal carotid artery disease
 - i. Fibromuscular dysplasia, dissection, carotodynia, ischemia of the carotid (atherosclerosis or arteritis) all may cause sympathetic paresis. The internal carotid artery branches of the vasovorum supply the internal branch of the sympathetic innervation of the eye
 - ii. Complete Horner's syndrome
 1. Myosis
 2. Ptosis (sympathetic innervation of the tarsal muscles of the upper and lower lid; the upper lid droops to cover the upper iris while the lower lid rises)

3. Decreased sweating of the face (if the common carotid bifurcation and/or the external carotid branch is affected)
4. Apparent enophthalmos; decreased sympathetic innervation of Mueller's muscle behind the globe
5. Iris ischemia that causes a large pupil in severe carotid disease (<10%) of patients
6. Argyll Robertson pupil
 - a. Secondary to syphilis; a pretectal lesion
 - b. Six components:
 1. Small (approximately 1 mm)
 2. Irregular
 3. Does not respond to light
 4. Responds to accommodation
 5. No response to ciliospinal reflex
 6. No response to mydriatics
5. Behr's pupil:
 - a. Slightly dilated
 - b. Ipsilateral to an optic tract lesion
6. Holmes-Adie pupil:
 - a. Responds sluggishly to light and accommodation
 - b. May be unilateral
 - c. More common in young women
 - d. Associated with absent ankle jerks: occasionally loss of knee deep tendon reflexes
 - e. A component of a generalized small fiber neuropathy
7. Wernicke's pupil
 - a. Slit lamp is directed at the area of the retina that subserves the VF deficit from a stroke
 - b. Slower contraction of the contralateral pupil
8. Elliptical pupil (cat's eye pupil)
 - a. Pretectal lesion
 - b. Usually seen after severe head trauma
9. Oval pupil (tadpole pupil)
 - a. Diabetes mellitus
 - b. Syphilis
 - c. Herniation or other compressions of the third nerve
10. Light-near dissociation:
 - a. Diabetes mellitus
 - b. Amyloid
 - c. Syphilis
 - d. Rarely from pressure in the IIIrd nerve nuclear complex or the pretectal area
 - e. Anisocoria
 - i. 25% of the population
 - ii. Equally reactive to light and convergence
11. Leukocoria (white pupil)
 - a. Glioma
 - b. Retrocentral fibroplasia
 - c. Nematode enophthalmos
 - d. Massive retinal fibrosis
 - e. Retinoblastoma
 - f. Metastatic retinitis
 - g. Retinal dysplasia

- h. Coats' disease
 - i. Disease of young men
 - ii. Onset in the second to third decade
 - iii. Unilateral
 - iv. Massive macular exudative retinitis

Neuropathology

1. Vascular IIIrd nerve syndromes:
 - a. Nuclear IIIrd nerve syndrome:
 - i. The interpeduncular branch of the P1 division of the PCA is most often involved from an embolus or atherosclerosis
 - ii. Clinical manifestations include:
 1. Bilateral ptosis
 2. Bilateral pupillary dilatation
 3. Bilateral superior rectus palsy
2. Fascicular IIIrd nerve syndrome:
 - a. Weber's syndrome:
 - i. Ipsilateral IIIrd nerve lesion may or may not be pupil sparing that is accompanied by a contralateral hemiparesis
 - ii. The patient usually has no alteration in mental status
3. Benedict's syndrome:
 - a. Ipsilateral IIIrd nerve palsy with a contralateral movement disorder of the extremities
 - b. No mental status alterations
4. Claude's syndrome:
 - a. Ipsilateral IIIrd nerve palsy with a contralateral cerebellar outflow tremor
5. Subdural hematoma:
 - a. Ipsilateral IIIrd nerve palsy
 - b. The pupil is dilated, poorly responsive to light and may be oval in shape
 - c. Severe headache associated with lethargy (develops over hours to days)
 - d. Contralateral spastic hemiparesis
6. Cavernous sinus IIIrd nerve lesion:
 - a. Involved concomitantly with the IVth CN, VIth CN, and the first division of V1
7. Orbital IIIrd nerve lesion:
 - a. Concomitantly involved with cranial nerve IVth, VIth and the first division of Vth (at the superior orbital fissure)
 - b. Superior division involvement impairs the SR and the levator palpebrae
 - c. Inferior branch involvement impairs pupillomotor fibers and the innervation of the IR, MR, and inferior oblique muscles
8. Nuclear IIIrd and IVth nerve (Masugi's syndrome):
 - a. Infarction of the posterior lateral choroidal artery from the terminal PCA (P4)
 - b. Simultaneous nuclear IIIrd and IVth nerve paralysis
 - c. Crossed hemisensory deficit

- d. Rare contralateral mild internal capsule deficit
9. Hematoma of the midbrain:
 - a. Lethargy to obtundation (involvement of the periaqueductal gray)
 - b. Impairment of vertical gaze
 - c. Large 3–5 mm pupils that react sluggishly to light
 - d. Quadriplegia (if there is pressure on the cerebral peduncles)
 - e. Nystagmus refractories
 - f. Rarely there is convergent nystagmus
 - g. Hydrocephalus
10. Vascular malformations of the midbrain:
 - a. Cavernous hemangioma
 - b. Capillary telangiectasia (rare; these are usually in the pons or the cerebral cortex)
 - c. Arteriovenous malformation:
 - i. Different clinical manifestations that may involve the IIIrd nerve from size, recurrent bleeding and location
 - ii. Arterial venous malformations occur in association with Wyburn-Mason and Von Hippel-Lindau malformations
 - iii. Cavernous hemangiomas rebleed repeatedly
 - iv. Capillary telangiectasia (often are asymptomatic)
11. IIIrd nerve involvement may also occur from emboli or infarction secondary to “top of the basilar syndrome”
12. Aneurysmal Involvement of the IIIrd Nerve:
 - a. P-COM aneurysms often affect the IIIrd nerve in isolation
 - b. The pupil is often involved early from aneurysmal compression due to pupillomotor motor fiber vulnerability; they are located at the periphery of the dorso-medial part of the nerve or are of pressure sensitive axons that are spread throughout the nerve. The pupil may be spared with aneurysmal disease in a percentage of patients
 - c. Carotid artery aneurysm:
 - i. May involve the ipsilateral IIIrd nerve and cause contralateral face, arm and leg weakness
 - d. Between the posterior cerebral and superior cerebellar artery the IIIrd nerve may be compressed in isolation
 - e. Giant aneurysms at the top of the basilar artery (the IIIrd nerve is involved in the interpeduncular fossa) and is associated with hydrocephalus and contralateral spastic hemiparesis
 - f. IIIrd nerve may be compressed by a ceroid posterior cerebral artery (elongated and tortuous)
 - g. Retro-orbital pain is more severe and prolonged than occurs with a diabetic IIIrd nerve neuropathy
 - h. An intracavernous aneurysm may erode into the sphenoid sinus and present with nose bleed; usually there is VIth CN weakness and first division trigeminal nerve pain
13. Ischemia of the intracavernous internal carotid artery:
 - a. Inferolateral trunk of the ECA (external carotid artery):
 - i. The superior or terminal branch
 - ii. Anteromedial branch of the ILT (inferolateral trunk of the ECA) anastomoses with the distal portion of the internal maxillary artery and the posterior branch anastomoses with the accessory and middle meningeal arteries
 - iii. The IIIrd and IVth nerve are supplied by the superior or tentorial branch of the ILT
 - iv. Cranial nerves IIIrd, IVth, VIth are supplied by the anteromedial branch
 - v. The vascularization of the IIIrd nerve depends on the specific territory supplied by the ILT; the nerve is most often supplied by the superior or tentorial components of the anteromedial branch
 - b. Clinical manifestations of ischemia of the IIIrd nerve from external carotid artery disease:
 - i. Isolated IIIrd nerve palsy
 - ii. IIIrd nerve associated with Vth nerve (sensory component)
 - iii. IIIrd nerve associated with Vth, IVth, and VIth nerve
 - iv. IIIrd and IVth nerve may be involved concomitantly
 - c. In general, ischemia affects the central portion of the nerve

Congenital IIIrd Nerve Disorders

1. Congenital absence of the IIIrd nerve nuclei in association with absence of other cranial nerves
2. Congenital abnormalities of innervation; fascicles of the IIIrd nerve may innervate the VIth nerve
3. In association with Moebius syndrome (facial diplegia and ptosis)

Trauma of the IIIrd Nerve

1. Head trauma (with cerebral edema):
 - a. The IIIrd nerve may be trapped between the posterior cerebral artery and the superior cerebellar artery
 - b. At the tentorial edge
 - c. Damaged in the cavernous sinus
 - d. Disrupted by fractures of the orbital wall
 - e. Compressed by the uncus of the hippocampal gyrus
2. Aberrant regeneration:
 - a. Classic misdirection syndrome:
 - i. Engagement of the IIIrd nerve causes pathological lid retraction
 - ii. There is no up or down movement of the globe (simultaneous innervation of the superior and inferior rectus muscles)
 - iii. Adduction of the eye and pupillary constriction are intact
 - iv. Fully developed misdirection syndrome causes:

1. Minimal retraction of the globe
2. Slight enophthalmos
3. Droop of the upper lid on abduction

Neoplasms of the IIIrd Nerve

1. Account for approximately 20% of IIIrd nerve paralysis
2. Midbrain tumors that involve the intraparenchymal portion of the IIIrd nerve include:
 - a. Glioma
 - b. Medulloblastoma
 - c. Hemangioma
 - d. Metastatic lesions
3. Parinaud's syndrome:
 - a. Compression of the tectal plate (pinealoma)
 - b. Paralysis of upward or downward gaze
 - c. Dissociation vertical and horizontal gaze with optokinetic nystagmus
 - d. Pupillary abnormalities:
 - i. Large poorly reactive 3–4 mm pupils
 - ii. Dissociated light and accommodation pupillary response
 - e. Associated bilateral sensorineural hearing loss
 - f. Failure to converge
 - g. Nystagmus retractorics
 - h. Tumors of the quadrigeminal plate (primarily gliomas) do not produce motility disorders until they extend beyond the tectal plate:
 - i. Mild head trauma may precipitate IIIrd nerve palsy from a parasellar or clival tumor (needs to be ruled out if there is no fracture or the palsy lasts longer than 1–2 months)
 - ii. Pituitary adenoma:
 1. May spread into the cavernous sinus with compression of the IIIrd nerve against the dura at the entrance of the cavernous sinus
 - iii. Pituitary apoplexy (associated with headache, sudden loss of vision, cranial nerve palsy) may have an associated unilateral or bilateral IIIrd nerve palsy; CT and MRI have demonstrated a more benign clinical picture of pituitary apoplexy than was formerly taught (many hemorrhages are asymptomatic)
 - iv. There may be intermittent signs and symptoms with pituitary tumors
4. Nasopharyngeal tumors:
 - a. May affect the IIIrd nerve in the cavernous sinus
 - b. The tumor originates in the fossa of Rosenmüller and extends into the middle cranial fossa through the foramen lacerum or ovale
 - c. Squamous cell carcinoma, lymphoepithelioma and lymphoma may present similarly
5. Sphenoid sinus tumor:
 - a. May produce a cavernous sinus syndrome
6. Intrinsic IIIrd nerve tumors:

- a. Schwannoma
- b. Neurofibroma
- c. Fibroblastic tumors
7. Metastatic Tumors:
 - a. Intracranial metastases constitute approximately 30% of neoplasms that affect the IIIrd nerve
 - b. Nasopharyngeal tumors are the most frequent metastatic tumors (by extension)
 - c. Metastases occur with breast, thyroid, lung, and lymphoid tumors
 - d. The metastases most frequently affect the nerve by direct invasion
 - e. 10–25% of late stage lymphomas invade the CNS; affect the nerve by involvement of the meninges and by direct extension
8. Orbital Tumors:
 - a. Metastatic:
 - i. Breast, lung, melanoma of the choroid, lacrimal gland, lymphosarcoma, lymphoma, leukemia and hypereosinophilic syndrome
 - b. Intraorbital masses:
 - i. Hemangioblastoma of the conus
 - ii. Dermoid
 - iii. Pseudotumor of the orbit
 - iv. Meningioma

Muscle Disease Affecting the IIIrd Nerve

1. Oculopharyngeal dystrophy:
 - a. Middle aged to older patients
 - b. Bilateral ptosis that may be severe
 - c. French Canadian ancestry
2. Myotonic dystrophy:
 - a. Severe ptosis
 - b. AD; chromosome 17
 - c. Multisystem disorder:
 - i. Cardiac arrhythmias
 - ii. Cognitive impairment
 - iii. Glucose intolerance
 - iv. Frontal balding
 - v. Stellate cataracts
 - iv. Small testicles with elevated FSH/LH
3. Mitochondrial Diseases:
 - a. Kearns-Sayre:
 - i. Complete ophthalmoplegia
 - ii. Heart block
 - iii. Syncope
 - b. PEO:
 - i. Associated myopathy
 - ii. Neuropathy
 - c. Late onset mitochondrial myopathy:
 - i. Ptosis
 - ii. Short stature
 - iii. VIIIth nerve involvement
4. Myotubular myopathy:

- a. Primarily bilateral ptosis with minimal proximal weakness
- 5. Thyroid muscle disease (Hoffman's syndrome):
 - a. Inferior rectus muscle may enlarge first
 - b. All muscles become thickened and enlarged
 - c. Elevated long acting thyroid stimulating hormone
 - d. The sclera and tendinous insertions of muscle are not involved (they are in pseudotumor of the orbit)

Neuromuscular Junction Disorders and the IIIrd Nerve

1. Acquired myasthenia gravis:
 - a. Asymmetric ptosis and IIIrd nerve involvement
 - b. The pupil is not clinically involved
 - c. May be associated with pseudointranuclear ophthalmoplegia
 - d. Rapid nystagmus
2. Congenital myasthenia gravis:
 - a. Poor bulbar muscle functions at birth
 - b. Ptosis and cranial nerve involvement
 - c. Floppy infant syndrome
 - d. Most often little or no response to acetylcholinesterases
3. Tetanus:
 - a. IIIrd nerve is involved with pupillary dysfunction
 - b. Systemic muscle involvement
 - c. Opisthotonus in late stages
 - d. Extreme sensitivity to auditory and mechanical stimuli (induces muscle spasms)
4. Botulinum toxin:
 - a. Nausea and vomiting
 - b. Bilateral ptosis
 - c. Bilateral dilated pupils
5. Snake bite (primarily Elapidae species):
 - a. Nausea, vomiting and vertigo rapidly occur after envenomation
 - b. Ptosis
 - c. Diplopia, IIIrd nerve and other cranial nerve involvement
 - d. Estimated 2–3 million deaths world-wide
6. Lambert-Eaton syndrome:
 - a. Most often asymmetrical ptosis
 - b. IIIrd nerve as well as other cranial nerve involvement
 - c. Autonomic involvement (dry mouth)
 - d. "Load in the pants gait"
 - e. Improved strength with exercise
 - f. Loss of reflexes

Collagen Vascular Diseases

In general the arteritic process associated with these disorders affects the vascular supply to the nerve that irrigates the central rather than the peripheral component of the nerve. Most experts state that the pupillomotor fibers are in the peripheral dorsomedial area of the nerve.

1. SLE: affects the IIIrd and VIth nerve most frequently
2. Wegener's granulomatosis:

- a. Affects the Vth nerve most frequently (adjacent to the involved sinus)
- b. The IIIrd and VIth nerves may also be affected
- 3. Tolosa-Hunt:
 - a. Severely painful ophthalmoplegia:
 - i. All eye muscles may be involved in the affected eye (IIIth, IVth and Vth)
 - ii. Vth nerve, IInd and periarterial sympathetic fibers may be involved
 - iii. Painful episodes persist for days to weeks; remission and exacerbations are common
 - iv. Non-specific granulomatous involvement in the cavernous sinus
 - v. Steroid responsive
- 4. Periarthritis nodosa:
 - a. IIIrd nerve involvement is rare
 - b. Usually the peripheral manifestation is that of a mononeuritis multiplex
- 5. Hypereosinophilic syndromes:
 - a. $>20,000$ eosinophils/mm³ for longer than 6 weeks
- 6. Granulomatous angitis

Infections That Involve the IIIrd Nerve

1. Viral infection:
 - a. IIIrd nerve involvement may rarely be seen with:
 - i. St. Louis encephalitis
 - ii. Eastern and Western Equine encephalitis
 - b. In polio and Von Economo encephalitis IIIrd nerve palsy was occasionally reported
 - c. In most viral illnesses the IIIrd nerve palsy occurs 2–3 weeks after the febrile illness
 - d. IIIrd nerve palsy may occur with:
 - i. Hz
 - ii. EBV
 - iii. Pertussis
 - iv. Measles
 - v. Influenza
 - vi. HIV

Bacterial Infection

1. In acute bacterial meningitis the IIIrd and VIth nerve are frequently involved; the deficits may clear with recovery after treatment
2. Perineural inflammation may extend into the nerve substance (most commonly seen with meningococcal, pneumococcus and *Haemophilus influenzae* meningitis)
3. Syphilitic IIIrd nerve involvement occurs with basilar meningitis:
 - a. Pupillomotor and medial rectus fibers are most vulnerable
4. Lyme's disease:
 - a. IIIrd nerve involvement may be the initial manifestation of the disease
5. Tuberculosis:
 - a. Tuberculosis affects the IIIrd nerve:
 - i. The pupillomotor fibers are vulnerable

Fungal Infections

1. Mucor mycosis (genus *Rhizopus*):
 - a. Occurs in severely immunocompromised patients (cancer, anemias, diabetic ketoacidosis, and HIV)
 - b. Origin is from the cranial sinuses
 - c. May concomitantly involve the venous sinuses with consequent thrombosis
 - d. Black palate syndrome (lateral and jugular sinus thrombosis)
 - e. Often with complete unilateral ophthalmoplegia
2. Cryptococcosis:
 - a. Associated with HIV infection
 - b. Cranial nerve II > involvement than III
 - c. Indolent meningitis with headache and dementia

Systemic Diseases

1. Diabetes mellitus:
 - a. Painful or painless ophthalmoplegia:
 - i. May project pain to retro-orbital areas
 - b. Pupil sparing
 - c. Usually the recovery occurs without “misdirected re-innervation”; much more common after traumatic IIIrd nerve injury (aneurysm clipping)
2. Cranial nerve amyloid:
 - a. Primary uveal veil (occurs in the vitreous)
 - b. Associated with meningeal involvement
 - c. Light-near dissociation
3. Hypertrophic pachymeningitis:
 - a. An exuberant overgrowth of the meninges that traps cranial nerves
 - b. Differential diagnosis includes: 1. sarcoid, 2. lymphoma, 3. syphilis, 4. tuberculosis and 5. as a component of the IgG4 syndrome
 - c. Patients are afebrile, do not appear ill and the IIIrd nerve is usually involved
 - d. Pupil sparing
4. Carcinomatosis of the meninges:
 - a. MRI reveals that carcinomatosis of the meninges may be associated with few signs and symptoms; a percentage of patients are asymptomatic
 - b. The IIIrd nerve is commonly involved but not as frequently as Ist, VIth, VIIth and VIIIth
5. Wernicke-Korsakoff syndrome:
 - a. Cranial nerve II and VI are frequently involved bilaterally
 - b. IIIrd may be involved
 - c. Associated with thiamine deficiency
 - d. Encephalopathy, ataxia and neuropathy are associated
 - e. Ophthalmoparesis is less common in black patients
6. Sarcoid:
 - a. Primarily affects the VIIth nerve
 - b. There is meningeal involvement of the IIIrd nerve as well as an arteritic infarction
7. Immune-mediated IIIrd nerve palsy:

- a. Multiple sclerosis:
 - i. The IIIrd nerve is relatively uncommonly involved directly; commonly involved as a component of intranuclear ophthalmoplegia
- b. Miller-Fisher variant of GBS:
 - i. GD1b or GQ1b epitopes
 - ii. Ophthalmoparesis, areflexia, ataxia are concomitant neurological findings
- c. Descending GBS:
 - i. IIIrd, VIth and VIIIth are involved concomitantly
 - ii. Pharyngeal innervated cranial nerves are involved (cervical-brachial pattern)
- d. CIDP:
 - i. There is rarely an associated IIIrd nerve palsy
8. Trauma:
 - a. Orbital fractures injure either the superior or inferior division of the nerve
 - b. The nerve may be injured during uncus herniation or anterior temporal lobectomy during complex partial seizures

Cranial Nerve IV**General Characteristics****Anatomy**

1. The trochlear nerve nucleus lies caudal to the IIIrd nerve complex and dorsal to the medial longitudinal fasciculus and is at the level of the inferior colliculus, ventrolateral to the cerebral aqueduct. It courses posteroinferiorly around the aqueduct to decussate in the anterior medullary velum of the dorsal midbrain. It emerges in the dorsal midline below the inferior colliculus
2. Its cisternal segment traverses the quadrigeminal, ambient, crural and pontomesencephalic cisterns
3. It is closely associated with the under surface of the tentorium (where it is frequently injured by neurosurgical procedures and various traumas)
4. It enters the cavernous sinus below the IIIrd nerve along the lateral side of the clivus below the petroclinoid ligament
5. It lies below the IIIrd nerve in the wall of the cavernous sinus dorsal to the first division of the Vth nerve in a common connective tissue sheath
6. It enters the superior orbital fissure to innervate the contralateral superior oblique muscle

Blood Supply

1. Anastomosis of ascending and descending branches of nutrient subial arteries
2. Superior cerebellar artery branches supply the IVth nerve nuclei
3. The superior division of the intermediolateral trunk of the external carotid artery supplies the nerve in the superior orbital fissure
4. It also is supplied by a branch of the posterior lateral choroidal artery from the PCA

Neuropathology*Vascular Lesions*

1. Nuclear IVth nerve is involved as part of a superior cerebellar artery stroke
2. Masugi's syndrome in which the IIIrd and IVth nerve are infarcted simultaneously with associated ipsilateral ataxia and loss of pain and temperature sensitivity below the clavicle contralaterally (superior cerebellar artery infarction)
3. The IVth nerve nuclei may be involved in isolation from a posterolateral choroidal artery infarction from infarction of the PCA 4 branch; there is concomitant pulvinar involvement

Congenital Defects of the IVth Nerve

1. Unilateral or bilateral absence of the IVth nerve may be seen in association with absence of the IIIrd, VIth and other brainstem nuclei

Trauma

1. Approximately 5% of cranial nerve palsies that follow severe head trauma affect the IVth nerve
2. Approximately 30% of IVth nerve palsies are traumatic; the brainstem is compressed against the lateral edge of the tentorium during herniation
3. The nerve may be damaged in an orbital fracture
4. Surgical procedures that involve the tentorium, injure the nerve and include anterior temporal lobectomy and top of the basilar artery procedures
5. The nerve may be injured by traumatic intracavernous aneurysms

External Carotid Artery Ischemia

1. The lesions involve the ILL of the external carotid artery or its superior branch (usually during the course of embolization treatment of vascular lesions or tumors)
2. Diabetic infarction
3. Arteritic syndromes

Systemic Diseases That Affect the IVth Nerve

1. Cavernous sinus infection and tumor (simultaneous involvement of IIIrd, VIth and the first division of Vth)
2. Superior orbital fissure syndrome
3. Collagen vascular disease with infarction of the blood supply to the nerve from arteritis
4. Diabetes mellitus (small vessel infarction)
5. Wegener's and other necrotizing arthritides
6. Scleroderma

Neuromuscular Junction Diseases

1. Congenital and acquired MG
2. Tetanous
3. Botulinum poisoning
4. Neurotoxic snake envenomation
5. Lambert-Eaton syndrome

Ocular Muscle Diseases

1. PEO
2. Kearns-Sayre syndrome
3. Other mitochondrial diseases
4. Thyroid ophthalmopathy
5. Orbital pseudotumor

Superior Oblique Muscle Myokymia

1. Rapid spontaneous firing of the superior oblique muscle
2. Congenital superior oblique palsy

Neoplasms of the IVth Nerve

1. Tumors that invade the cavernous sinus which include, pituitary adenomas, meningioma and lymphoma
2. Nasopharyngeal cancer
3. Isolated neurinoma or Schwannoma
4. Carcinoma of the sphenoid sinus

Infections of the IVth Nerve

1. Herpes zoster (rare); much more commonly involves Vth and IIIrd nerve
2. EBV, St Louis, Eastern and Western equine viral infections
3. Syphilis
4. Lyme's disease
5. HIV
6. Purulent bacterial infections (meningeal involvement)
7. Rarely involved with polio
8. Mucormycosis

Immune-Mediated Diseases of the IVth Nerve

1. Miller-Fisher syndrome
2. CIDP
3. Descending GBS
4. MS (extremely rare)
5. Brown's superior oblique tendon sheath syndrome

The Vth Cranial Nerve**General Characteristics***Anatomy*

1. The motor nucleus of the Vth nerve is in the mid-pons and lies medial to the main sensory nucleus near the floor of the IVth ventricle
2. After exiting the pons it traverses the posterior fossa to enter a cavity in the dura mater (Meckel's cave) beneath the attachment of the tentorium to the tip of the petrous bone. It leaves the skull through the foramen ovale and joins the mandibular branch of the trigeminal nerve that then becomes the mandibular nerve
3. The mandibular nerve innervates the muscles of mastication which include the masseter, temporalis and the medial and lateral pterygoid muscles. It also innervates the tensor tympani, tensor veli palatini, mylohyoid and the anterior belly of the digastric muscle

4. The sensory portion of the nerve originates in the gasserian ganglion that lies near the apex of the petrous bone in the middle cranial fossa. The sensory fibers from the gasserian ganglion traverse the dorsomedial pons to synapse in the nuclear complex of the sensory trigeminal nerve. A group of sensory fibers that enter the mid-pons descends as the spinal tract of the Vth nerve (the spinal tract of the trigeminal nucleus). The tract descends through the medulla to terminate in the third and fourth segments of the cervical spinal cord. Its continuation is Lissauer's tract. The descending spinal tract synapses with the three components of the nucleus of the trigeminal nerve:
 - a. The pars oralis (located from the mid-pons to the inferior olive)
 - b. The pars interpolaris (extends from the rostral third of the inferior olive to the obex of the IVth ventricle)
 - c. The pars caudalis (extends into the 4th segment of the spinal cord) that is continuous with the dorsal horn of the spinal cord. The pars caudalis is also the termination of cervical root innervations from the pre- and post-auricular nerves
 - d. The ophthalmic divisions of the Vth nerve traverse the most ventral part of the spinal tract to synapse at C2
 - e. Mandibular division fibers are located dorsally in the spinal tract and synapses in the most rostral level of spinal nucleus
 - f. Midline facial representation of the nose and mouth are represented rostrally in the spinal nucleus while lateral aspects of the face terminate more caudally. Intramedullary lesions may cause an "onion skin" sensory loss and perioral numbness from rostral spinal nuclear and tract lesions:
 - i. Ascending fibers of the spinal nucleus carry the modalities of pain, temperature, and light touch from the face and mucous membranes ipsilaterally in the trigeminothalamic tract that synapses in thalamic VPM and the intralaminar nuclei
 - ii. The main sensory nucleus of V, which receives fibers from the Gasserian ganglion, carries tactile and proprioceptive modalities of sensation. The nucleus lies posterolateral to the motor nucleus of V in the lateral pons. Axons travel in the ventral crossed trigeminothalamic tract and the ipsilateral dorsal trigeminothalamic tract to synapse in the thalamic VPM nucleus
 - iii. The mesencephalic trigeminal nucleus is rostral to the main sensory nucleus and extends to the superior colliculus. It carries proprioception from the muscles of mastication
5. The Vth nerve innervates the head, mouth, nasal cavity, and the motor and proprioceptive muscles of mastication
6. Sensation extends to the angle of the jaw, which is innervated by C2, which also innervates the scalp to the bregma and tragus of the ear; the Vth nerve innervates the anterior wall of the external auditory meatus; the anterior portion of the tympanic membrane; the dura of the anterior and middle cranial fossa; the somatic sensation of the tongue and palate
7. The mental nerve, buccal nerve, dural innervations of the anterior and middle cranial fossa are mediated by the VI division (ophthalmic) nerve, which traverses the lateral wall of the cavernous sinus and enters the orbit through the superior orbital fissure
 - a. In the cavernous sinus the ophthalmic division divides into:
 - i. Tentorial, lacrimal, frontal and nasociliary branches
 - ii. The tentorial branch supplies:
 1. The dura of the cavernous sinus
 2. The anterior fossa and sphenoid wing
 3. The petrous ridge and its apex as well as the dura of Meckel's cave
 4. The tentorium of the cerebellum
 5. Posterior falx
 6. Dural venous sinuses
 - iii. The frontal branch divides into a supraorbital component that innervates the medial upper lid and conjunctiva, the frontal sinuses, forehead and scalp (approximately one inch into the hair line); its other component forms the supratrochlear sensory nerve that innervates the medial upper conjunctiva and ventral areas of the forehead and lateral areas of the nose
 - iv. The lacrimal nerve via its palpebral branch innervates the conjunctiva and the area of the lacrimal gland. It also carries postganglionic parasympathetic fibers that effect reflex lacrimation
 - v. The nasociliary nerve divides into nasal nerves and an infraorbital branch:
 1. Nasal nerves innervate the mucosa of the nasal septum, the lateral nasal wall, the inferior and middle turbinates
 2. An external nasal nerve branch innervates the tip of the nose (vesicles may be seen here first with HZ infection)
 3. The infraorbital branch of the nerve subserves the lacrimal sac, the caruncle, conjunctiva and the skin of the medial canthus
 4. Two long ciliary nerves transmit sensory modalities from the cornea, ciliary body and iris and also innervate (sympathetic) the dilator of the pupil
 5. Short ciliary nerves carry sensory fibers from the globe via the ciliary ganglion as well as parasympathetic post-ganglionic fibers, which innervate the constrictor of the pupil and the ciliary muscle. These sensory and pupillary fibers join the nasociliary nerve. These important parasympathetic fibers travel with the inferior division of the IIIrd nerve that innervate the inferior oblique muscle

The Maxillary Division of V (V₂)

The maxillary division exits the inferolateral area of the cavernous sinus to leave the skull via the foramen rotundum and enters the sphenopalatine fossa. It next traverses the infraorbital fissure to enter the orbit. It courses through the infraorbital canal to innervate the face via the infraorbital foramen.

1. This division gives rise to the palatine nerves, middle, posterior and superior alveolar nerves from its sphenopalatine and infraorbital canal portions
 - a. These nerves innervate the upper teeth, maxillary sinus, nasopharynx, soft palate, roof of the mouth and tonsils
 - b. After leaving the infraorbital foramen the division gives off:
 - i. An inferior palpebral branch that innervates the lower lid
 - ii. A nasal branch that innervates the side of the nose
 - iii. A superior labial branch that innervates the upper lip
 - iv. A zygomaticofacial branch that innervates the cheek
 - v. The maxillary division also supplies the dura of the middle cranial fossa from the middle meningeal nerve

Mandibular Division of V

1. The motor root of the trigeminal nerve and the mandibular division join to form the mandibular nerve
2. The mandibular nerve exits the skull through the foramen ovale and traverses the infratemporal fossa
 - a. Motor branches supply the muscles of mastication (eight)
 - b. The lingual nerve innervates the lower gums and papillae of the tongue; the mucous membranes of the anterior 2/3rds of the tongue
 - c. The inferior dental branches innervate the lower gums and teeth
 - d. Mental branches innervate the mucous membrane of the lower lip; the mental nerve may be involved in isolation with scleroderma, sickle cell disease and breast cancer ("the numb chin syndrome")

Neuropathology

Vascular Lesions of Vth nerve

1. Wallenberg's syndrome (infarction of the medial branch of PICA or more commonly the vertebral artery)
2. Pontine ischemia (occlusion of short circumferential arteries)
3. Aberrant branch of AICA that abuts the Vth nerve (a major cause of tic douloureux)
4. AVM of the Gasserian ganglion

5. Ischemia of the inferolateral trunk of the external carotid artery; often involved in association with Vth nerve ischemia or with nerves of the superior orbital fissure
6. Internal carotid artery aneurysm (compression of the trigeminal ganglion and concomitantly the IIIrd nerve)
7. Cavernous sinus aneurysm:
 - a. Primarily affects middle age women
 - b. The VIth nerve is often involved first as it is closest to the carotid artery; its involvement is usually followed by severe pain in V1 and V2
 - c. Often bilateral involvement
 - d. Pain is often the predominant symptom

Idiopathic Trigeminal Neuropathy

1. The diagnosis is tendered after the exclusion of all known entities that affect the Vth nerve
2. Motor function of the nerve is rarely affected
3. Possibly 10% of trigeminal lesions
4. Numbness is most often experienced in V2 and V3. It gradually spreads to adjacent divisions in days to weeks; recovery usually occurs over weeks to months
5. Patients experience a sensation of numbness, swelling, coldness and tingling
6. Pathologic inflammatory process of the Vth nerve ganglion
7. Has been reported with arteritides, rheumatoid arthritis, Sjögren's syndrome, mixed collagen vascular diseases and most commonly with scleroderma

Associated with Systemic Disease

1. Hypothyroidism:
 - a. Mucopolysaccharide deposition in the Gasserian ganglion with the mucopolipidoses
 - b. Rarely presents with severe facial pain
2. Sarcoid:
 - a. Rare Vth nerve involvement
 - b. Involves the dura
3. Wegener's granulomatosis:
 - a. Contiguous involvement of V(2) from inflammation of the maxillary sinus
4. SLE:
 - a. Arteritic involvement of the blood supply to the nerve
5. Sjögren's disease:
 - a. A common cause of Vth nerve involvement from arteritis
6. Periarthritis nodosa
7. Scleroderma:
 - a. Vth nerve involvement may be the presenting symptom
 - b. "Numb chin syndrome" from compression of the Vth nerve in its exit foramen
8. Mixed collagen vascular disease

Tumors of the Vth Nerve

1. Trigeminal neurinoma

- a. 0.2% of intracranial tumors
- b. Occur between 14–67 years of age. They most often occur in middle age; the incidence is equal in both sexes
- c. They arise in the distal portion of the nerve and are probably of Schwann cell origin; they may involve ganglion and rarely may extend through the foramen rotundum or ovale
- d. In general they are 2.5 cm by the time of diagnosis and may undergo malignant transformation
- e. The usual symptoms are numbness or paresthesia in the distribution of the divisions of the nerve; trigeminal neuralgia or painful paresthesia are less common
- f. The tumor may erode the medial part of the floor of the middle fossa or erode the apex of the petrous bone
2. Meningioma:
 - a. Those that affect the Vth nerve arise from the dura of Meckel's cave
 - b. They may spread in plaque along the floor of the middle fossa or along the trigeminal nerve roots into the middle fossa
 - c. Meningiomas may affect V3 more often than trigeminal neuromas
3. Gangliocytoma:
 - a. A rare primary malignant tumor of the ganglion
4. Epidermoids (primary or secondary)
5. Chondroma
6. Chondromyxoma
7. Sarcoma
8. Lymphoma
9. Fibrous xanthoma (fibrous histiocytoma)
10. Hemangioblastoma
11. Malignant Schwannoma (from the trigeminal ganglion or its divisions)
 - a. Numbness or paresthesias in the distribution of the nerve or its branches in 2/3rds of affected patients
 - b. Painful burning and paresthesia in 1/3 of patients
 - c. May erode into the cavernous sinus with involvement of IIIrd, IVth, VIth and V1 involvement with proptosis and visual loss
12. Nasopharyngeal cancer that originates from the fossa of Rosenmüller
13. Maxillary sinus cancer
14. Neural spread of squamous cell cancer of the face
15. Prostate cancer metastasis to Meckel's cave or the petrous apex
 - a. The spread is through the valveless Batson's plexus of paravertebral veins
16. Cholesterol granulomatosis that is benign and is located at the petrous apex
 - a. Striking positive T2-weighted MRI sequences
17. Spread of a salivary gland adenoma
18. Submaxillary gland cylindroma

Congenital Trigeminal Anesthesia

1. May be isolated and is usually bilateral

2. Associated with ectodermal or mesenchymal structural defects
 - a. Goldenhar syndrome
 - b. Abnormalities of the first and second branchial arches, vertebrae and eyes, which include pre-auricular tags, malformed pinnae and epibulbar dermoids
 - c. Associated with Moebius syndrome:
 - i. Congenital facial diplegia and horizontal gaze dysfunction

Trauma

1. Dental treatment
2. Pressure on the mental nerve from dentures (bone resorption)
3. Surgical trauma
4. Head and facial trauma
5. Skull base fracture:
 - a. Trigeminal abducens nerve synkinesis may occur with lesions at the petrous apex
6. Migraine variants:
 - a. Facial paresthesias and numbness are common with both common and classic migraine
 - b. Lower face migraine affects V2 and V3
 - c. Paroxysmal hemifacial pain:
 - i. Multiple attacks of severe pain primarily in the V2 division daily
 - ii. Responsive to indomethacin
 - d. Classic cluster migraine with severe orbital and retro-orbital V1 pain
 - e. Raeder's paratrigeminal neuralgia pain in the V1 distribution with associated photophobia, phonophobia and nausea:
 - i. Type 1 with ptosis and miosis
 - ii. Type 2 with no cranial nerve abnormality
 - f. SUNCT (sudden unilateral neuropathic pain in V1 with conjunctival injection and tearing)
7. Trigeminal Neuralgia:
 - a. In older patients:
 - i. Idiopathic
 - ii. Vascular loop compression of the nerve root entry zone that originates from:
 1. Superior cerebellar artery > AICA > basilar artery
 - b. In younger patients:
 - i. Multiple sclerosis
 - ii. A vascular loop compressing the nerve root entry zone
 - iii. Rare in some spinocerebellar degenerations (Behr's syndrome)
 - c. Clinical presentation of tic douloureux:
 - i. Lancing severe pain
 - ii. Less than 15 seconds in duration
 - iii. More often unilateral; V3 > V2 < 10% in V1
 - iv. No associated motor or sensory signs

- v. There is an absolute refractory VI period following attacks of varying lengths
- d. Triggering events include:
 - i. Light touch in the affected division
 - ii. Chewing, swallowing, and speaking
 - iii. Positional change (if there is arterial compression)
 - iv. Cold
- e. "Tic convulsive":
 - i. Associated with hemifacial spasm; need to r/o (rule out) extracranial lesions of the VIIth nerve
 - ii. Either pain or the paroxysmal movement may occur independently
 - iii. The usual cause is an arterial loop from the superior cerebellar, vertebral or basilar artery that touches the nerve in the cerebellopontine angle
 - iv. Differential diagnosis of pathologies in this location includes:
 - 1. Meningioma
 - 2. Neurofibroma
 - 3. Arteriovenous malformation
 - 4. Cirsoid aneurysm of the vertebral artery
- f. Immune-mediated trigeminal neuralgia:
 - i. Multiple sclerosis:
 - 1. 2% of trigeminal neuralgia patients have MS
 - 2. It may occur bilaterally
 - 3. Triggers that induce attacks are less common in MS
 - 4. The demyelinating plaque is most often in the root entry zone
 - ii. CIDP
 - iii. Idiopathic trigeminal sensory neuropathy
- 8. Infection:
 - a. Syphilitic:
 - i. Lesion may occur from meningeal involvement or a proliferating endarteritis
 - ii. Causes mid-face numbness; rarely a gumma of the mid-pons is causative
 - b. Herpes simplex:
 - i. V₂, V₃ pain following oral outbreaks
 - c. Herpes zoster:
 - i. V₁ infection is often associated with encephalitis (may be asymptomatic but there is a lymphocytic pleocytosis, increased protein in the CSF)
 - ii. Rarely there is clinically evident encephalitis
 - iii. A delayed MCA stroke may occur on the ipsilateral side (7–14 days after the infection). Viral particles have been identified in the vessel wall that have triggered a severe inflammatory response in the affected carotid or MCA
 - d. Gradenigo's syndrome:
 - i. In the past, the major pathology was recurrent purulent middle ear infection
 - ii. There needs to be a pneumatized petrous bone for the infection to spread from the middle ear through the petrous bone
 - iii. The infection causes a petrous apicitis with:
 - 1. Vth and VIth nerve involvement
 - 2. The VIth nerve is involved in Dorello's canal under the petroclinoid ligament
 - 3. This infection occasionally is associated with lateral sinus thrombosis that causes "otitic hydrocephalus"
 - e. Actinomycosis:
 - i. Lung infection with spread through the blood or venous sinuses
 - f. Leprosy
- 9. Toxins and Physical Agents that Affect the Vth Nerve:
 - a. Trichloroethylene (detergent)
 - b. Stilbamidine (used in the treatment of North American blastomycosis)
 - c. Post-radiation therapy
- 10. Structural lesions of the Vth Nerve:
 - a. Meckel's cave arachnoid cyst
 - b. Brainstem syringobulbia
 - c. Brainstem glioma
 - d. Fibrous dysplasia of bone:
 - i. Foraminal stenosis with nerve entrapment
- 11. Unusual Entities that Affect the Vth Nerve:
 - a. Kennedy's disease (motor V)
 - b. ALS (in association with bulbar involvement; patients are unable to close their mouth properly from involvement of the muscles of mastication)
 - c. Spinocerebellar atrophy type 4
 - d. A component (division V₁) of the superior orbital syndrome
 - e. The "numb chin and cheek" syndrome:
 - i. Lesions of the mental nerve from the mandibular (division V₃) most often from scleroderma, breast cancer and sickle cell disease
 - ii. Elderly patients:
 - 1. Impingement of the mental nerve at the mental foramen
 - iii. Inferior alveolar nerve involvement (branch of V₃):
 - 1. Metastasis (lung, breast and nasopharyngeal cancer)
 - 2. Lower lip anesthesia
 - 3. Numb cheek:
 - a. Malar anesthesia

The VIth Cranial Nerve

General Characteristics

- 1. Intraparenchymal anatomy:
 - a. The VIth nerve nucleus is located in the dorsal lower pons; dorsally it is covered by the genu of the VIIth nerve that lies under the floor of the IVth ventricle
 - b. Its motor neurons that effect abduction are intermixed with internuclear neurons that project from the mid-

- line to join the opposite medial longitudinal fasciculus which synapses in the IIIrd nerve
- 2. As the nerve courses along the ventral pons it is crossed by AICA and the interauditory arteries
- 3. It enters the cavernous sinus beneath the petroclinoid ligament (Gruber's ligament) to lie adjacent to the carotid artery

Clinical Manifestations

1. Failure of abduction of the ipsilateral eye in the horizontal plane
2. Abducting nystagmus contralateral to a MLF lesion that causes an internal intranuclear ophthalmoplegia
3. Esotropia of the globe in primary gaze
4. Congenital defects of innervation:
 - a. Unilateral or bilateral, congenital absence of the VIth nerve may be seen in association with abnormalities of CN III; these defects may occur in association with other cranial nerve abnormalities and hypoplasia or aplasia of components of the brainstem
 - b. There may be innervation of the lateral rectus muscle by the IIIrd nerve in the absence of the IVth nerve nucleus
 - c. Congenital absence of the VIth nerve nucleus may also be associated with an ipsilateral horizontal gaze paralysis as there are no interneuronal neurons to activate the contralateral IIIrd nerve adductor neurons by means of the medial longitudinal fasciculus
5. Duane's retraction syndrome:
 - a. Narrowing of the palpebral fissure with adduction and retraction of the globe (rare); the globe rarely moves up with adduction:
 - i. Type I: abduction is limited but adduction is normal
 - ii. Type II: normal abduction but impaired adduction
 - iii. Type III: impairment of both abduction and adduction
 - b. The syndrome is caused by the anomalous innervation of the rectus muscle by the inferior division of the IIIrd nerve
 - c. The syndrome is more common in females than males; it may be unilateral or bilateral
 - d. The left eye is affected more often than the right
 - e. Acquired Duane's syndrome occurs with:
 - i. Pontine glioma
 - ii. Rheumatoid arthritis
 - iii. Trigeminal rhizotomy
 - iv. Post-removal of an orbital cavernous hemangioma
 - f. Moebius syndrome:
 - i. Facial diplegia usually in association with bilateral abducens palsy
 - ii. Convergence strabismus occurs in approximately 50% of patients
 - iii. There is rare ptosis and paralysis of the IIIrd nerve
 - iv. There is no internal ophthalmoplegia
 - v. Rarely there are other associated congenital deformities that include: 1. paralysis and atrophy of the tongue, 2. hearing loss, 3. clubfoot and 4. other skeletal deformities
- g. Congenital horizontal gaze palsy:
 - i. No convergent strabismus
 - ii. No facial diplegia
 - iii. Substituted convergence and cross fixation is used to accomplish lateral gaze
 - iv. Vertical eye movements are spared
- h. Chiari malformation
- i. Basilar impression
- j. Vascular Lesions Affecting the VIth Nerve:
 - i. Penetrating pontine branch artery that causes Ramon syndrome:
 1. Ipsilateral VIth nerve palsy with a contralateral hemiparesis
 - ii. Millard-Gubler syndrome:
 1. Ipsilateral VIth and VIIth nerve palsy
 2. Contralateral hemiparesis
 3. Ipsilateral Vth and Horner's syndrome (rare)
 4. Contralateral spinothalamic (pain and temperature) loss of sensation
 5. Most often caused by a hemorrhage rather than an ischemic lesion
 - iii. Infarction of the inferolateral trunk of the external carotid artery:
 1. Superior division (associated infarction of IIIrd, IVth and VIth in the superior orbital fissure)
 2. Emboli (during ablation of AVM or hemorrhagic tumors that involve the external carotid artery); diabetic small vessel disease
 - iv. Gradenigo's syndrome:
 1. Short circumferential artery occlusion that originates from the basilar artery
 - a. Facial numbness
 - b. Weakness of the masseter, pterygoid, temporalis, anterior digastric mylohyoid and tensor tympani muscles
 - c. Contralateral loss of pain and temperature below the clavicle
 - d. Contralateral hemiparesis
- k. Neoplasms of the VIth nerve:
 - i. Primary tumors:
 1. Pontine glioma
 2. Meningioma
 3. Pinealoma
 4. Hemangioma
 5. Craniopharyngioma
 6. Acoustic neurinoma (late)
 7. Chordoma
 8. Pituitary adenoma (extension into the cavernous sinus)

9. Neuroma
10. Malignant pituitary tumor
11. Cerebellopontine angle tumor
- ii. Secondary tumors:
 1. Carcinomatosis of the meninges
 2. Lymphoma/leukemia
 3. Nasopharyngeal cancer:
 - a. Squamous cell carcinoma
 - b. Lymphoepithelioma
 - c. Lymphosarcoma
 4. Pilocytic adenoma
 5. Breast, thyroid and lung metastasis
- l. Trauma of the VIth nerve:
 - i. Head trauma:
 1. A few patients suffer combined IVth and VIth injury; more commonly the VIth and IIIrd nerves are injured concomitantly
 2. VIth nerve injuries are commonly due to:
 - a. A long course along the basiocciput
 - b. Dural attachment over the clivus
 - c. A 90° bend under the petroclinoid ligament
 - d. A fracture through the temporal bone or the posterior clinoid injures the nerve directly
 - e. Fractures of the orbital wall
 - f. Transient injury of the VIth nerve after maxillary sinus surgery
 - m. Infections that affect the VIth Nerve:
 - i. It rarely occurs in Eastern and Western equine encephalitis, St. Louis encephalitis, bulbar poliomyelitis, HZ, measles, influenza, pertussis and EBV, HIV-CMV
 - ii. Bacterial meningitis:
 1. IIIrd and VIth are affected equally
 2. There is usually partial recovery with treatment
 - iii. Syphilitic meningitis (Stage II):
 1. The nerve is affected at the entry zone
 - iv. Tuberculous meningitis (associated stroke)
 - v. Lyme's disease (common and may be bilateral)
 - vi. Cryptococcosis (IInd nerve often involved concomitantly)
 - vii. Mucormycosis:
 1. Associated immunosuppression and ophthalmoparesis
 - viii. Coccidioidomycosis:
 1. Often associated with lumbosacral vertebral involvement
 2. Erythema nodosum
 - ix. Aspergillosis:
 1. Aggressively invades veins
 2. Immunosuppressed patients
 3. CNS involvement with lung abscesses
 - x. Gradenigo's syndrome (purulent mastoiditis with spread through a pneumatized petrous bone to the petrous apex)
 - xi. Cysticercosis (rare parenchymal lesions)
 - xii. Retropharyngeal infection
 - n. VIth Nerve Palsy Following Procedures:
 - i. Lumbar puncture (neurapractic traction injury)
 - ii. Various lumbar or ventricular shunts (neurapractic injury)
 - iii. Post-myelography
 - iv. Spinal and epidural anesthesia
 - v. Cervical traction
 - vi. Intrathecal glucocorticoid injections
 - vii. Post-radiofrequency rhizotomy for trigeminal neuralgia
 - o. Increased intracranial pressure:
 - i. Idiopathic intracranial hypertension
 - ii. Meningitis
 - iii. Mass lesion
 - iv. Sagittal sinus thrombosis
 - v. Trauma (loss of autoregulation)
 - vi. Subdural and epidural hematoma
 - p. Immune-mediated:
 - i. AIDP
 - ii. CIDP
 - iii. Miller-Fisher variant of GBS (GD1b or GQ1b epitopes)
 - iv. Multiple sclerosis (VIth nerve is more frequent than IIIrd)
 - v. ADEM (acute disseminated encephalomyelitis)
 - vi. Post-vaccinations
 - vii. Tolosa-Hunt (possibly autoimmune)
 - viii. Necrotizing vasculitis
 - ix. Bone marrow transplantation with cyclosporin, tacrolimus, and steroids
 - q. Collagen vascular diseases:
 - i. SLE (IIIrd and VIth nerves are most commonly affected)
 - ii. Periarteritis nodosa
 - iii. Mixed collagen vascular disease (MCVD)
 - iv. Hypereosinophilic syndrome (interleukin driven)
 - v. Wegener's granulomatosis (granulomatosis with polyangiitis)
 - r. Systemic diseases that affect the VIth nerve:
 - i. Wernicke-Korsakoff syndrome (chronic alcoholism, dialysis, emesis gravidarum, severe malnutrition)
 - ii. Diabetes mellitus (IIIrd nerve involvement much more frequent than VIth)
 - iii. Chronic hypertension:
 1. Small lacunar infarct of the nerve in the parenchyma
 2. Isolated VIth nerve palsy in an elderly hypertensive patient
 - iv. Idiopathic intracranial hypertension (thyroid and adrenal insufficiency, acute intermittent porphyria, vitamin A and D excess, and iron deficiency anemia)

- v. Sarcoidosis:
 - 1. Meningeal involvement
 - 2. Arteritic infarction of the nerve
- vi. Thyroid ophthalmopathy
- vii. Cranial arteritis (giant cell); usually the muscle is more involved than the nerve
- viii. Histiocytosis X

Rare Causes of VIth Nerve Palsy

- 1. Persistent primitive trigeminal artery
- 2. PICA and vertebral artery aneurysm
- 3. Capillary hemangioma of Meckel's cave
- 4. Spontaneous CSF leak (ruptured perineural cyst) with intracranial hypotension
- 5. Thrombosis of the inferior petrosal, transverse or sigmoid sinus
- 6. Sphenoid sinus mucocele
- 7. Squamous cell cancer of the pterygopalatine fossa
- 8. Internal carotid artery disorders:
 - a. Dolichoectasia
 - b. Balloon test occlusion (prior to surgery)

Cranial Nerve VII

General Characteristics

- 1. Anatomy:
 - a. The motor division is located in the reticular formation of the caudal pontine tegmentum
 - b. The facial nucleus is composed of four longitudinal subnuclei that supply specific muscle groups:
 - i. The dorsal medial group innervates the auricular and occipital musculature
 - ii. The intermediate group innervates the frontalis and corrugator muscles
 - iii. The ventromedial group innervates the platysma muscle
 - iv. The lateral subnucleus supplies the buccinator and buccolabial muscles
 - v. The orbicularis oculi motor neurons are clustered in the dorsolateral margin of the nucleus
 - vi. Another proposal for facial nuclear group organization proposes that:
 - 1. Lower facial muscles innervating motor neurons are in the lateral component of the nucleus
 - 2. Neurons that innervate the upper facial muscles are in the dorsal part of the nucleus
 - 3. Medial motor neurons innervate the platysma and posterior auricular muscles
 - vii. The intrapontine axons ascend rostrally and dorsally over the VIth nerve nucleus (genu of the facial nerve) and then course ventrolaterally in the pons to exit laterally
 - viii. Corticobulbar fibers provide supranuclear control of facial movement. Their origin is the lower 1/3

of the precentral gyrus and they descend through the corona radiata, the genu of the internal capsule, and the medial cerebral peduncle to the pons. The majority of pontine fibers decussate and synapse in the motor nucleus contralaterally. The ventral nucleus of the VIIth nerve nuclear complex, which innervates the lower 2/3rds of the face, is predominantly innervated by crossed supranuclear fibers. The dorsal nucleus of the motor VIIth nerve complex, which supplies the upper 1/3 of the face, has bilateral supranuclear innervation. The mimetic fibers to the VIIth nerve complex are thought to originate in the basal ganglia and temporal lobe. Their exact path to synapse with the motor nuclear complex has not been established. Thus voluntary and emotional activation of the motor nucleus can be disassociated by specific lesions

- 2. The Nervus Intermedius of Wrisberg:
 - a. The parasympathetic and sensory division of the facial nerve is the nervus intermedius of Wrisberg
 - i. Parasympathetic fibers carried in the nerve have their origin in the superior salivatory nucleus that is located in the pontine tegmentum
 - ii. Fibers that control lacrimation originate in the lacrimal nucleus
 - iii. The parasympathetic fibers reach but do not synapse in the geniculate ganglion. Some preganglionic parasympathetic axons course with the greater petrosal nerve as it projects from the geniculate ganglion to synapse in the pterygopalatine ganglion that innervates the lacrimal gland. Preganglionic parasympathetic fibers join the mixed facial nerve as it courses through the facial canal. After the facial nerve has given off a branch to the stapedius muscle, it gives off the chorda tympani nerve, which exits in the skull through the petrotympanic fissure. It then merges with the lingual nerve and parasympathetic fibers synapse in the submandibular ganglion. Post-ganglionic parasympathetic fibers innervate the submandibular and sublingual glands. The sensory component of the VIIth nerve innervates the external auditory meatus, the mucous membranes of the nasopharynx and nose as well as taste from the anterior 2/3 of the tongue, floor of the mouth and part of the soft palate. The greater petrosal nerve conveys sensation from the mucous membranes of the nasopharynx and palate. The chorda tympani and lingual nerve convey sensory afferent fibers from the anterior 2/3 of the tongue, floor of the mouth and palate. The cell bodies of the sensory afferent input of the VIIth nerve are in the geniculate ganglion
- 3. The Peripheral Course of the VIIth Nerve

- a. The meatal canal segment of the VIIth nerve (7–8 mm)
 - i. The motor division is on the super anterior surface of the VIIth nerve
 - ii. The nervus intermedius is in between the VIIth and VIIIth nerve
 - iii. The VIIth nerve is closely approximated with the vestibular and cochlear division of the VIIIth nerve in this segment
- b. The Labyrinthine Segment of the VIIth Nerve (3–4 mm)
 - i. The nervus intermedius and motor division of the nerve enter the facial canal, course above the labyrinth and synapse in the geniculate ganglion. As noted above the greater superficial petrosal nerve takes origin from the apex of the geniculate ganglion
- c. The Tympanic Segment of the VIIth Nerve (12–13 mm)
 - i. After synapsing in the geniculate ganglion the VIIth nerve courses backward which is medial and below the horizontal semicircular canal
- d. The Mastoid Segment of the VIIth Nerve
 - i. At the level of the posterior middle ear (sinus tympani) the VIIth nerve courses inferiorly and gives off the nerve to the stapedius muscle from its proximal portion. The other major branch of this segment is the chorda tympani. The nerve exits the facial canal through the stylomastoid foramen. This segment gives rise to the posterior auricular nerve that innervates the occipitalis, posterior auricular, transversal, and oblique auricular muscles. Its digastric branch innervates the posterior belly of the digastric muscle, and its stylohyoid branch innervates the stylohyoid muscle. In the parotid gland the VIIth nerve divides into the temporofacial and cervicofacial branches, which supply all facial mimetic muscles or as well as the platysma
- e. The Vascular Supply of the VIIth Nerve
 - i. The intracranial components of the nerve are supplied by the anterior inferior cerebellar artery
 - ii. The intrapetrosal component of the nerve is supplied by both the superficial branch of the middle meningeal and the stylomastoid branch of the posterior auricular artery
 - iii. The extracranial portions of the nerve is supplied by the stylomastoid, posterior auricular, superficial temporal and the transverse facial arteries
- b. Associated VIth nerve ipsilateral weakness
- c. Contralateral hemiparesis
- d. Ipsilateral facial sensory loss (midline or peripheral depending on associated Vth nerve involvement); contralateral sensory loss
3. Cerebellopontine angle:
 - a. Associated VIIIth nerve and often Vth nerve signs and symptoms
4. Meatal level:
 - a. Unilateral (ipsilateral) peripheral VIIth nerve weakness
 - b. Decreased taste of the anterior 2/3 of the tongue (ipsilateral)
 - c. Impaired lacrimation
 - d. Deafness (associated VIIIth nerve involvement)
5. The facial canal distal to the meatal segment but proximal to the stapedial branch:
 - a. The motor nerve and the nerve of Wrisberg are involved
 - b. No deafness
 - c. Ipsilateral VIIth nerve muscle weakness
 - d. If the lesion is proximal to the greater superficial petrosal nerve lacrimation is impaired
 - e. Geniculate ganglion involvement causes eardrum pain
 - f. There is decreased taste in the anterior 2/3 of the tongue
 - g. Hyperacusis
6. Facial canal between the stapedius and chorda tympani
 - a. Peripheral facial paralysis
 - b. Loss of taste on the anterior 2/3 of the tongue
 - c. No hyperacusis
7. Distal facial canal lesions (at the stylomastoid foramen level)
 - a. Peripheral VIIth muscle weakness
 - b. No loss of taste
 - c. No hyperacusis
8. Lesions distal to the stylomastoid foramen:
 - a. Individual facial nerve branches to specific facial muscles
 - b. Differential diagnosis if pathology is at this level includes:
 - i. Inflammation of retromandibular lymph nodes
 - ii. Cylindroma and adenocarcinoma
 - iii. Obstetric forceps
 - iv. Bell's palsy
 - v. Lyme's disease
 - vi. Mycoplasma
 - vii. Post-infections (autoimmune)

Clinical Manifestations

1. Supranuclear lesions
 - a. Weakness of the lower 2/3 of facial musculature contralateral to the lesion
2. Nuclear and fascicular lesions:
 - a. Ipsilateral complete facial musculature weakness
1. Supranuclear lesions
2. Brainstem (nuclear lesion)
3. Peripheral VIIth nerve lesion
4. Neuromuscular defects
5. Precentral gyrus cortical or subcortical lesions; volitional eye closure is paretic; mimetic (emotionally induced is normal)

6. Acquired inability to blink (Reviloid's sign); is an early sign of corticobulbar disease
7. Compulsive eye opening:
 - a. A bilateral frontal or non-dominant frontal lobe lesion:
 - i. Reflex eye closure is retained
 - ii. The patient is able to comprehend the task
 - iii. Described with Creutzfeldt-Jakob disease
8. Apraxia of eyelid opening:
 - a. Patients often complain of blindness
 - b. Usually from bilateral prefrontal lesions
9. Motor impersistence of eye closure:
 - a. The patient is unable to complete the command to close the eyes
 - b. The eyes close, develop a fine tremor and then open
 - c. This sign is seen with disorders of the basal ganglia, bilateral hemisphere or non-dominant hemispherical disease
10. Decreased blinking:
 - a. Parkinson's disease, subcortical glial sclerosis, progressive supranuclear palsy, multiple system atrophy (basal ganglia predominant), corticobasal ganglia degeneration
 - b. Bálint's syndrome
 - i. Usually vascular disease
 - ii. Head trauma
 1. Anoxic episodes (cardiac arrest)
11. Increased blinking:
 - a. Any induced dyskinesia (dopamine agonists)
 - b. Schizophrenia
 - c. Gilles de la Tourette's syndrome
12. Excessive eyelid closure and blepharospasm:
 - a. Contralateral frontal eye field seizure (often most evident in the orbitalis oculi as rhythmic muscle twitches)
 - b. Blepharospasm:
 - i. Focal dystonia
 - ii. Meige's syndrome:
 1. There may be concomitant spasmodic dystonia or axial dystonia
 - iii. Multiple sclerosis
 - iv. Bilateral infarction of the rostral brainstem, diencephalon and striatum
 - v. Irritative painful eye diseases
 - vi. Tardive dyskinesia
 - vii. Parkinson's disease
 - viii. Wilson's disease
 - ix. Pantothenate kinase deficiency (formerly Hallervorden-Spatz disease)
 - x. Familial apoceruloplasmin deficiency with retinal degeneration
 - xi. Reflex blepharospasm after a stroke if the non-dominant temporoparietal area is involved
 - xii. Bilateral blepharospasm following bilateral parietal lobe degeneration
 - c. Abnormal Facial Movements
 - i. Dyskinesia:
 1. They may be spontaneous in the elderly
 2. A side effect of neuroleptic drugs
 3. Edentulous dyskinesia
 4. Extrapyrmidal disease
 - ii. Dystonia:
 1. Extrapyrmidal disorder
 2. Meige's syndrome:
 - a. Associated blepharospasm
 - b. Sustained abnormal mouthing movements
 - c. Platysma contraction
 - d. Sustained neck flexion
 - e. One or both arms and the trunk may be involved
 3. Hemifacial spasm:
 - a. Intermittent spasm of the orbicularis oculi and the orbicularis oris muscles; the process may spread to all facial muscles; stapedius muscle involvement causes the patient to hear clicking on the involved side
 - b. Aggravated by stress and fatigue
 - c. Rarely the disorder is bilateral
 - d. The syndrome is caused by lesions in the cerebellopontine angle and includes:
 - i. Tumor
 - ii. An aberrant artery (most often AICA that intermittently compresses the nerve)
 - iii. Dolichoectasia of the vertebral artery
 - iv. Lacunar infarction (rare)
 - v. Brainstem displacement
 - vi. MS
 - vii. Lesions of the root entry zone
 - viii. May be associated with multiple cranial neuropathies
 - ix. Follows Bell's palsy
 - x. Trauma
 4. Post-paralysis spasm and synkinetic movements:
 - a. In addition to post-paralytic hemifacial palsy (following a Bell's Palsy), there is usually some residual muscle function
 - i. Crocodile tears (lacrimation with ingesting food)
 - ii. Jaw-winking (opening the mouth causes blinking (Marin-Amat phenomenon))
5. Facial myokymia:
 - a. Multiple sclerosis (rare)
 - b. Pontine glioma (common; often most easily seen in the orbicularis oculi muscle); seen in pontine gliomas of childhood
 - c. GBS
 - d. Myokymia with spastic parietic facial contracture
 - e. A dorsal pontine lesion at the facial nucleus

6. Focal cortical seizures
 - a. Originate from the lower precentral gyrus (the facial component of the cortical homunculus)
 - b. Post-ictal paralysis:
 - i. Sparing the forehead
7. Tics and habit spasms:
 - a. Gilles de la Tourette syndrome
 - b. Psychological causes
8. Myoclonus:
 - a. Associated with palatal myoclonus
 - b. Occurs with lesions within Mollaret's triangle (dentate, inferior olive and the red nucleus or their connections)
- a. Trauma at the time of birth
- b. Congenitally narrow facial canal
- c. Alexander's disease (AD/AR)
- d. Hemifacial spasm:
 - i. Narrow posterior fossa
- e. Newborn neuropathic facial paralysis:
 - i. Intrapartum compression
 - ii. Abnormal intrauterine posture
 - iii. Forceps trauma
 - iv. Nuclear atresia
- f. Moebius syndrome:
 - i. Facial diplegia with Vth nerve palsy
 - ii. Lower lip weakness with VIth nerve palsy
 - iii. The facial paralysis is incomplete in 2/3 of patients with Moebius syndrome:
 1. The frontalis and orbicularis oculi > perioral muscles
 - iv. Associated abnormalities include:
 1. Ptosis
 2. Anterior lingual atrophy
 3. Pectoral muscle defects
 4. Poland's anomaly
 5. Club foot
 6. Cognitive disability arm malformations

Neuropathology

1. Vascular lesions affecting the VIIth nerve:
 - a. Middle cerebral artery:
 - i. Thrombosis or embolic occlusion of the central sulcus artery (a pial branch of the superior division of the MCA)
 - ii. Internal capsule ischemia:
 1. Anterior choroidal artery ("top of the carotid")
 2. Lenticulostriate branches of the MCA
 3. Thalamoperforate branches of the MCA
 4. Recurrent artery of Heubner (A1 of the ACA)
 - b. Lacunar infarction in:
 - i. Corona radiata
 - ii. Pons
 - iii. Centrum semiovale
 - iv. Medulla
 - v. Cerebral peduncle
 1. AVM (pons or anywhere in the intraparenchymal course of the nerve)
 2. Venous telangiectasia of the pons (usually asymptomatic)
 3. Cavernous hemangioma (pons > thalamus/IC > corona radiata)
 4. AICA Infarction:
 - a. Affects the peripheral branches of the nerve outside of the brainstem:
 - i. Internal auditory artery
 - ii. Subarcuate artery
 5. Basilar artery aneurysm:
 - a. Most often fusiform that blocks perforations and short circumferential arteries
 6. AICA aneurysm (vasospasm after rupture)
 - a. Dolichoectasia of the vertebral and basilar artery
 - b. Millard-Gubler syndrome (obstruction of the short circumferential arteries)
 - c. Foville syndrome (obstruction of short circumferential arteries)
2. Congenital Diseases Affecting the VIIth Nerve
 3. Melkersson-Rosenthal syndrome:
 - a. Recurrent facial palsy with facial edema
 - b. Lingua Plicata (scrotal tongue)
 - c. Facial weakness begins prior to age 16
 - d. Edema affects the upper lip most frequently; over time there is permanent lip and facial enlargement
 - e. Cheilitis granulomatosa:
 - i. Small granulomas occur in the diffusely edematous interstitial tissue
 4. Collagen Vascular Diseases/Arteritis that affects the VIIth nerve:
 - a. SLE
 - b. Periarteritis nodosa
 - c. Sarcoid (vasculitic form)
 - d. Giant cell arteries
 - e. Wegener's granulomatosis
 - f. Mixed collagen vascular disease
 5. Immune-Mediated Disorders of the VIIth Nerve:
 - a. MS
 - b. ADEM
 - c. AIDP
 - d. CIDP
 - e. Graft-versus-host disease
 - f. CMF variant of GBS
 - g. Post-immunizations
 - h. Bell's Palsy
 - i. Necrotizing leukoencephalopathy (associated with increased serum IGM)
 - j. PML (leukoencephalopathy in pons)
 6. Systemic disease:
 - a. Diabetes mellitus

- b. Hypertension
- c. Amyloidosis
- d. Whipple's disease
- e. Sarcoid:
 - i. Heerfordt's syndrome:
 - 1. VIIth nerve associated with uveitis
- f. Idiopathic hypertrophic pachymeningitis
- g. Infections Involving the VIIth Nerve
 - i. Herpes Zoster (Ramsay Hunt syndrome)
 - 1. Acute facial paralysis
 - 2. Grouped vesicles in the external auditory canal and over the mastoid bone and behind the ear
 - 3. Less than 1% of patients with Bell's palsy
 - ii. Herpes simplex (HS)
 - iii. VIIth nerve involvement occurs in a few patients with a new infection or reactivation of CMV, adenovirus, EBV, more common in HIV infected patients
 - iv. Otitis media:
 - 1. 0.5 to 1% of chronically infected patients are complicated by facial paralysis
 - 2. Leprosy
 - 3. Syphilis
 - 4. Osteomyelitis of the petrous bone
 - 5. Bacterial meningitis
 - 6. Tuberculous meningitis
 - 7. Fungal meningitis
 - 8. Lyme's disease (Bannwarth's syndrome)
 - 9. Malaria
 - 10. Infectious mononucleosis, mumps, rubella
 - 11. Polio
 - 12. Parvovirus B19
 - 13. Cat-scratch disease (*Bartonella henselae*)
 - 14. *Mycoplasma pneumoniae*
 - 15. HIV
 - 16. Trichinosis
 - 17. Cysticercosis
 - 18. Behçet's disease
 - 19. Rhombencephalitis
- 7. Neoplasms Affecting the VIIth Nerve:
 - a. Pontine glioma
 - b. Pilocystic astrocytoma (Von Recklinghausen's disease)
 - c. (Neurofibromatosis type I)
 - d. Metastases
 - e. Carcinomatosis of the meninges
 - f. Intracranial metastasis from a pinealoma
 - g. Melanoma metastasizes to the nerve
 - h. Leukemia/lymphoma
 - i. Adenocarcinoma of the salivary gland
 - j. Cholesteatoma
 - k. Carcinoma of the ear
 - 1. Glomus jugulare
 - m. Meningioma
 - n. Yolk sac tumor:
 - i. Endodermal sinus tumor
 - o. Rhabdomyosarcoma of the middle ear
 - p. Neurofibroma (Von Recklinghausen's disease, chromosome 17)
 - q. Mixed parotid gland tumor
 - r. Adenocarcinoma of the salivary gland
- 9. Traumatic Facial Nerve Injuries:
 - a. Closed head injury:
 - i. Acute facial nerve paralysis:
 - 1. Longitudinal fracture (parallel to the long axis of the petrous pyramid)
 - 2. Transverse fracture of the petrous pyramid
 - 3. A temporal bone fracture is demonstrated in almost all cases of traumatic fracture
 - b. Delayed onset of facial nerve paralysis:
 - i. Bleeding from the ear and evidence of temporal bone fracture is prognostic for a delayed VIIth nerve paralysis
 - c. Surgical trauma (primarily ear surgery):
 - i. VIIth nerve paralysis may be immediate or delayed
 - ii. Birth trauma
 - iii. Extratemporal lacerations
- 10. Drugs that Affect the VIIth Nerve:
 - a. Lidocaine
 - b. Diatrizoate
 - c. Isoniazid
 - d. Stevens-Johnson syndrome (numerous drugs)
 - e. Thalidomide
- 11. Rarer Causes of VIIth Nerve Palsy:
 - a. Tick bite paralysis
 - b. Diphtheria
 - c. Paget's disease (bone overgrowth)
 - d. Osteopetrosis (constriction of the nerve in its various canals)
 - e. Hyperostosis cranialis interna
 - f. Temporal dysplasias
 - g. Hemorrhage into the facial canal
 - h. Temporal bone arachnoid cyst
 - i. Kawasaki's syndrome
 - j. Dental block
 - k. Hemophilia and other coagulopathies
 - l. Hereditary facial paralysis:
 - i. Juvenile onset in some families
 - ii. Recurrent facial palsy
 - iii. May occur in association with other cranial nerve palsies

Differential Diagnosis of Bilateral VIIth Nerve Palsy

- 1. Syndrome:
 - a. Wernicke-Korsakoff (concomitant IIIrd and VIth nerve involvement)
 - b. Melkersson-Rosenthal (scrotal tongue)
 - c. Moebius syndrome (concomitant VIth nerve)

- d. Poland's anomaly
- e. Stevens-Johnson syndrome (severe mucous membrane involvement)
- f. Familial Finnish amyloidosis (abnormal sagging facies)
- g. Kennedy's disease (fasciculations in the facial musculature)

Cranial Nerve VIII

General Characteristics

1. General Anatomy:
 - a. Auditory nerve:
 - i. Afferents of the cochlea
 - b. Vestibular nerve
 - c. Afferents from the saccular and utricular macula:
 - i. Sense linear acceleration
 - d. Cristae of the semicircular canals:
 - i. Sense angular acceleration
2. An outline of the anatomy and physiology of the auditory pathways:
 - a. The neuroepithelial hair cells of the organ of Corti are the auditory receptors:
 - i. The cochlear apex senses low tones while hair cells at the base are stimulated by high frequency tones
 - b. The first order neurons of the auditory system are located in the spiral ganglion of the cochlear nerve in Rosenthal's canal at the base of the bony spiral lamina. The afferents of these neurons are in contact with the inner hair cells primarily, although a lesser number diverge to contact outer hair cells
 - c. Activation of hair cells depolarize spiral ganglia neurons whose axons make up the cochlear nerve
 - d. The cochlear nerve enters the brainstem at the junction of the medulla and pons where it divides to synapses in:
 - i. The dorsal cochlear nucleus
 - ii. The anteroventral and posteroventral nuclei of the cochlear complex
 - iii. Dorsal components of the complex process afferents from "high frequency" basal hair cells while ventral neurons process afferent information from the "low frequency" apical hair cells
 - iv. The second order neurons of the dorsal and ventral cochlear complex give origin to projections of the contralateral brainstem that form the lateral lemniscus, which in turn synapses in the central nucleus of the inferior colliculus. The three major crossing projections are:
 1. Dorsal acoustic striae (whose origin is the dorsal cochlear nucleus)
 2. The intermediate acoustic stria (derived from the dorsal component of the ventral cochlear nucleus)
 3. The ventral acoustic striae, derived from the ventral cochlear nucleus, a component of the trapezoid body. Decussating fibers from the trapezoid body in conjunction with projections from the superior olivary complex synapse in the contralateral lateral lemniscal nucleus and the inferior colliculus
4. The ventral acoustic striae also project bilaterally to the reticular formation, the superior olivary nuclei, and the trapezoid body
- v. The inferior colliculus:
 1. Is the central relay nucleus of the auditory system and receives both ascending and descending afferent input:
 - a. Lateral lemniscus projections synapse in the central nucleus
 2. Afferent fibers from the inferior colliculus synapse in the medial geniculate body tonotopically; low frequency fibers in an apical lateral location and high frequency fibers in medial nuclei
- vi. Medial geniculate body afferent fibers give rise to the geniculotemporal auditory radiations that synapse in lamina IV of area 41, the primary auditory cortex, and area 42, the associate auditory cortex. High tone afferents terminate medially and low tone afferents synapse laterally
- vii. Core pathway for audition:
 1. Central nucleus of the inferior colliculus
 2. Components of the medial geniculate body
 3. The primary auditory cortex
 4. Tonotopically organized throughout
- viii. The bilaterality of audition is accomplished through commissural connections that include:
 1. Nucleus of the superior olivary complex that receives afferents from both ears
 2. Connections between the cochlear nuclei
 3. Bilateral connections between the dorsal nuclei of the lateral lemniscus through the commissure of Probst
 4. The inferior colliculi are connected through the commissure of the inferior colliculus
 5. Connections between the central nucleus of the inferior colliculus and the contralateral medial geniculate body via the brachium of the inferior colliculus
 6. There are two projection systems from the inferior colliculus:
 - a. The core system:
 - i. The central nucleus of the inferior colliculus
 - ii. A component from the medial geniculate body
 - iii. The primary auditory cortex
 - iv. A direct tonotopically organized direct auditory pathway
 - b. The belt projection:

- i. Pericentral neurons of the inferior colliculus
- ii. Non-laminated medial geniculate body (MGB) neurons
- iii. Area 42 (the secondary auditory cortex)
- iv. This system is less tonotopically organized
- v. Is a polymodal system whose afferents are both auditory and from other sensory domains

The Blood Supply to the Cochlea and Auditory System

1. Primarily the internal auditory artery from the anterior inferior cerebellar artery supplies the cochlea and the auditory brainstem nuclei
2. The internal auditory artery within the internal auditory canal supplies cochlear:
 - a. Ganglion cells
 - b. Nerves
 - c. Dura
 - d. Arachnoid membranes
3. The internal auditory artery divides into the common cochlear artery and the anterior vestibular artery
4. The superior olivary complex and the lateral lemniscus are supplied by circumferential branches of the basilar artery
5. The inferior colliculus is supplied by:
 - a. Branches from the superior cerebellar artery
 - b. Quadrigeminal arteries
6. The medial geniculate body is supplied by thalamogeniculate arteries derived from the P1 division of the PCA (posterior cerebral artery)
7. Branches of the middle cerebral artery supply the primary and associate auditory cortex

An Outline of the Anatomy and Physiology of the Vestibular System

General Characteristics

1. Anatomy:
 - a. The vestibular system monitors angular and linear accelerations of the head and body
 - b. Accelerations are transduced into action potentials in the components of the membranous labyrinth that comprises: 1. utricle; 2. saccule and 3. semicircular canals:
 - i. Linear acceleration is registered by macules, specialized receptors that are located in the utricle and saccule
 - ii. Angular acceleration is registered by the cristae of the semicircular canals. They are composed of hair cells that act as transducers by converting mechanical deformation of sensory hairs to receptor potentials in the hair cells and their afferent neurons

- c. There are three semicircular canals oriented at right angles to each other which detect angular accelerating head movements:
 - i. The horizontal canal has an outward convexity
 - ii. The anterior or superior canal is oriented upward
 - iii. The posterior semicircular canal has a backward convexity
- d. The head in the erect position orients the semicircular canals such that:
 - i. The horizontal canal forms a 30° angle with the horizontal plane
 - ii. The superior and posterior canals are in the vertical plane that form a 45° angle with the frontal and sagittal planes
- e. The utricle and saccule are at right angles; the utricle is parallel to the base of the skull while the saccule is parallel to the sagittal plane:
 - i. Horizontal head movement activates the utricle linearly
 - ii. Tilting the head stimulates the saccule
- f. The cell bodies of cristae and macules are located in the vestibular ganglia of Scarpa in the internal acoustic meatus, which is the origin of the vestibular nerve:
 - i. The anterior, horizontal semicircular canal and the utricular afferents comprise the superior portion of the vestibular nerve
 - ii. The posterior semicircular canal afferents and those from the sacculus are the inferior portion of the nerve
 - iii. The vestibular nerve synapses in the vestibular complex that comprises:
 1. The superior nucleus of Bechterew
 2. The lateral nucleus of Deiters' (afferents from the macules of the utricle, and sacculus) which make up the neurons whose axons make up the spinal vestibular tract
 3. The medial vestibular nucleus of Schwalbe
 4. Inferior nucleus of Roller (afferents from axons of the utricle and sacculus)
- iv. Vestibular nerve efferents:
 1. The medial longitudinal fasciculus (MLF). The superior nucleus is ipsilateral; the other nuclear efferents are contralateral
 2. The medial vestibulospinal tract provides excitation or inhibition to the cervical and upper thoracic spinal segment of the contralateral spinal cord
 3. The lateral vestibulospinal tract:
 - a. This pathway takes origin from the lateral and inferior vestibular nuclei
 - b. Traverses the ipsilateral spinal cord; cervical cord efferents arise from the rostral part of the nucleus, while efferents to the lumbosacral. Segments take origin from its dorsal caudal neurons

- c. This tract enhances extensor trunk and anti-gravity axial muscle tone in keeping with its afferent input from the utricle (the “anti-gravity monitor”)
- d. The cerebellum receives efferents from:
 - i. Inferior and medial nuclei
 - ii. Lateral vestibular nuclei that innervate the ipsilateral floccular nodular lobe as well as the uvula and fastigial nucleus
- e. The reticular formation receives efferents from the vestibular nuclei (primarily its lateral nucleus and the nucleus reticularis pontis caudalis) as does the ventroposterolateral and posterior nuclear group of the thalamus
- f. There are wide areas of the cortex that receive vestibular projections that include:
 - i. The intraparietal sulcus
 - ii. Brodmann’s area 2, 5, and 6
 - iii. Superior temporal gyrus
- 4. The blood supply to the membranous labyrinth:
 - a. The major supply is from the labyrinthine artery whose origin is the internal auditory artery that branches from AICA or less frequently the basilar artery
 - b. The internal auditory artery gives off:
 - i. The anterior vestibular artery that supplies the anterior and lateral semicircular canals and the utricular macula
 - ii. The posterior vestibular artery that supplies the posterior semicircular canal, the saccular macula and a portion of the cochlea
 - iii. The cochlear artery
- b. More frequent with peripheral nerve and external middle ear disease than with central pathologies
- 4. Low roaring tinnitus:
 - a. Cochlear hydrops (Ménière’s disease)
- 5. High-pitched tinnitus:
 - a. Presbycusis
 - b. VIIIth nerve tumor
- 6. Pulsatile tinnitus:
 - a. Glomus jugulare tumor
 - b. Intracranial or cervical aneurysm
 - c. Increased intracranial pressure often associated with idiopathic intracranial hypertension (may be unilateral)
 - d. Middle ear congenital defects
 - e. Arteriovenous malformations
- 7. Rare causes of tinnitus:
 - a. Gaze-evoked tinnitus following removal of tumors of the CPA angle; may occur with saccadic, smooth pursuit or vestibular induced movements
 - b. TMJ disease
 - c. Labyrinthitis
 - d. Brainstem lesions
 - e. High cardiac output
 - f. Palatal myoclonus – patients hear clicking in association with the myoclonus

Localization of Lesions Causing Sensorineural Deafness by Clinical Manifestation

Clinical Manifestations

- 1. Decreased perception of tones or speech:
 - a. The lesion is central to the oval window
- 2. Cochlear deficit (sensory):
 - a. Decreased perception of sound
- 3. Abnormalities of the cochlear nerve, nuclei or central pathways:
 - a. Decreased perception of sound
- 4. Sensorineural hearing loss:
 - a. Definition:
 - i. A deficit in perceiving either tones or speech that is due to a lesion proximal to the oval window
 - ii. Manifestations of sensorineural hearing loss:
 - 1. Greater difficulty appreciating high-pitched sounds
 - 2. Loss of speech discrimination > pure tone deafness
 - 3. Tinnitus (varies in pitch and intensity):
 - a. May be paroxysmal or continuous
- b. Peripheral nerve and cochlea:
 - a. Cochlear lesion:
 - i. Deafness
 - ii. Tinnitus
 - iii. High-frequency hearing loss
 - b. Peripheral nerve lesions:
 - i. Sensorineural hearing loss (unilateral)
 - ii. Causes:
 - 1. Basal skull fracture
 - 2. Syphilis/bacterial infection
 - 3. Deep fungal or any cause of suppurative meningitis
 - 4. Siderosis
 - 5. Toxins (gentamicin)
 - 6. AICA aneurysm
 - 7. CPA tumors
 - c. Brainstem lesions:
 - i. Lesions above the cochlear nucleus do not cause clinical hearing loss
 - ii. Bilateral hearing loss:
 - 1. Trapezoid body (stroke or hemorrhage)
 - 2. Pons (stroke or hemorrhage)
 - 3. Midbrain tegmentum:
 - a. Hemorrhage

- b. Pineal and other tumors (central deafness from pressure on the isthmus acousticus)
- 4. Lower midbrain or rostral pons:
 - a. Auditory hallucinations:
 - i. Release type
 - ii. Clear sensorium
 - iii. Hearing loss
 - iv. Auditory hallucinosis has been reported with lower pontine tegmental hemorrhages
- iii. Irritative lesions of the temporal cortex
 - 1. Simple auditory hallucinations (tinnitus) > complex hallucinations (voice or music)
 - 2. Involvement of Brodmann's areas BA42 and BA22 cause more hallucinations than Brodmann's area 41
 - 3. Temporal lobe seizures have both acoustic and vertiginous auras
- iv. Cerebral lesions of Brodmann's areas BA41, BA42 and BA22
 - 1. There is no complete deafness even with bilateral lesions of the cortex
 - 2. Unilateral cortical lesions:
 - a. The hearing loss is subtle
 - b. Patients have difficulty locating sounds
 - c. If the lesions are primarily posterior temporal or bilateral temporal lesions (head injury or blast injuries):
 - i. Patients may suffer pure word deafness:
 - 1. Inability to comprehend spoken language, with normal auditory acuity retained
 - 2. Reading, writing, naming and comprehension of non-language sounds is intact
 - 3. Bilateral lesions of the auditory cortex cause:
 - a. Cortical deafness
 - b. Generalized auditory agnosia
 - c. Selective auditory agnosia
 - d. Pure word deafness
 - e. Amusia
 - f. Depressed temporal analysis of sound
- ii. Optic atrophy
- iii. Deafness
- iv. Urinary tract anomalies
- v. Abnormalities of endocrine glands
- vi. Norrie disease (atrophia oculi congenita)
- vii. X-linked recessive inheritance
- viii. Bilateral deafness at birth
- ix. Phthisis bulbi
- x. Dementia or psychosis in 25% of patients
- xi. Pseudotumor of the retina
- xii. Lens and corneal opacities
- d. Differential diagnosis of Norrie disease
 - i. Retinoblastoma
 - ii. Retrolental fibrous dysplasia
 - iii. Toxoplasmosis
 - iv. Falciform detachment of the retina
 - v. Juvenile retinoschisis
 - vi. Sex-linked micro-ophthalmia
 - vii. Sex-linked cataract and congenital retinal detachment
- e. Romano-Ward syndrome
 - i. AD [autosomal dominant] (mutations in the HERG gene)
 - ii. Long QT interval
 - iii. Sudden death from tachyarrhythmia
- f. LEOPARD syndrome
 - i. Lentigines of the skin
 - ii. Ocular hypertelorism
 - iii. Cognitive dysfunction
 - iv. Growth retardation
 - v. Deaf mutism
- g. Albinism with Deafness
- h. Vogt-Koyanagi-Harada
 - i. White forelock
 - ii. Dementia
 - iii. Cerebellar degeneration
 - iv. Uveitis
 - v. Recurrent meningitis
 - vi. Sensorineural deafness
- i. Pendred syndrome:
 - i. AR [autosomal recessive]
 - ii. Congenital bilateral sensorineural hearing loss
 - iii. Progressive visual loss from retinitis pigmentosa
 - iv. Type 1 that maps to chromosomes 14q, 11q, 10q, 21q
 - 1. Congenital deafness
 - 2. Absent vestibular function
 - v. Type II Usher syndrome (USH2) that maps to chromosome 1q
 - 1. Moderate to severe congenital hearing loss
 - 2. Normal vestibular function
 - vi. Type III Usher syndrome (USH3) that maps to chromosome 3q
 - 1. Progressive hearing loss

Neuropathology

- 1. Syndromic deafness (selected)
 - a. Ménière's disease
 - b. Susac's syndrome
 - i. Retinal vascular loops
 - ii. Stroke
 - iii. Sensorineural hearing loss
 - iv. Vertigo
 - c. Wolfram syndrome (DIDMOAD): familial or sporadic
 - i. Diabetes insipidus

2. Normal vestibular function
- vii. Myo7A gene (encodes myosin VIIA) in Usher syndrome type 1B
- viii. USH2A (Laminin is encoded)
- j. Alström syndrome:
 - i. AR [autosomal recessive]; French Canadians; North Africans
 - ii. Retinal pigment degeneration
 - iii. Neurogenic deafness
 - iv. Infantile obesity
 - v. Hyperlipidemia
 - vi. Non-insulin-dependent diabetes mellitus
 - vii. Chromosome 2p12-13 mutation
- k. Rogers syndrome
 - i. Thiamine-responsive megaloblastic anemia
 - ii. AR [autosomal recessive] that maps to chromosome 1q23.2-1q23.3
 - iii. Diabetes mellitus
 - iv. Sensorineural deafness
 - v. SLC19A2 gene encodes the thiamine transporter 1 (THTR-1)
- l. Otodental syndrome
 - i. AD [autosomal dominant]
 - ii. Bulbous canine teeth; globe-shaped posterior teeth; agenesis of the maxillary premolars
 - iii. High frequency sensorineural hearing loss
 - iv. Abnormalities of deciduous and permanent dentition
- m. Branchio-oto-renal syndrome (BOR)
 - i. AD [autosomal dominant]; BOR maps to chromosome 8q13
 - ii. Pre-auricular pits
 - iii. Branchial fistulas
 - iv. Renal anomalies
 - v. Sensorineural hearing loss
 - vi. In some families, there are branchial anomalies, pre-auricular pits and hearing loss with no renal anomalies; other families have branchial and renal anomalies with no hearing impairment
- n. CHARGE syndrome
 - i. Coloboma (70%)
 - ii. Heart malformations (85%)
 - iii. Choanal atresia (57%)
 - iv. Genital anomalies (34%)
 - v. Deafness (62%)
 - vi. Ear anomalies (91%)
 - vii. Semicircular canal hypoplasia
 - viii. Cranial nerve palsies
 - ix. Facial dysmorphism
 - x. Neonatal brainstem deficits
 - xi. Developmental deficits that involve the neural tube and neural crest cells
- o. Large Vestibular Aqueduct syndrome – progressive sensorineural hearing loss
- p. Cogan's syndrome
 - i. Ocular inflammation
 - ii. Vestibular-auditory dysfunction
 - iii. Vasculitis of cerebral, abdominal, and mesenteric arteries
- q. Vohwinkel syndrome
 - i. Mutilating keratoderma
 - ii. Papular and honeycomb keratoderma
 - iii. Constriction of the digits with autoamputation
 - iv. Starfish acral keratosis
 - v. Sensorineural deafness
 - vi. Mutation in the connexin 26 gene (CX26 gene)
 1. Encodes portions of intercellular gap junctions
 2. Non-conservative mutation of D66H in CX26
- r. SAPHO syndrome
 - i. Synovitis
 - ii. Acne
 - iii. Palmoplantar pustulosis
 - iv. Hyperostosis
 - v. Osteitis
 - vi. Diffuse sclerosing osteomyelitis of the mandible; inflammatory spread from the TMJ to the cochlea that causes sudden deafness
- s. Perrault syndrome
 - i. Ovarian dysgenesis
 - ii. Deafness
- t. Treacher Collins (Mandibular Dysostosis) syndrome
 - i. Clinical manifestations:
 1. Antimongoloid slant of the eye
 2. Coloboma of the lid
 3. Micrognathia
 4. Microtia and other ear deformities
 5. Hypoplastic zygomatic arches and macrostomia
 6. Cleft palate
 7. Conductive hearing loss
 - ii. Genetic heterogeneity of the syndrome exists:
 1. Treacher Collins syndrome 1; AD (autosomal dominant); mutation in the TCOF1 gene that maps to chromosome 5q32
 2. Treacher Collins syndrome 2; heterozygous mutation in the POLR1D gene that maps to chromosome q12.2
 3. Treacher Collins syndrome 3; caused by compound heterozygous mutations in the POLR1C gene that maps to chromosome 6
 - iii. The disorder is putatively thought to involve a defect in a nucleolar trafficking protein that is required for craniofacial development; in TCOF1 gene mutations there are truncated proteins mis-localized within the cell
- u. Wildervanck syndrome:
 - i. A variant of the Klippel-Feil syndrome
 - ii. Retraction of the globe of the eye
 - iii. Deaf mutism

- v. Waardenburg syndrome:
 - i. AD [autosomal dominant]; mutations of the PAX3 gene that maps to chromosome 2q36.1 in type 1
 - ii. Lateral displacement of the medial canthus
 - iii. Approximation of the eyebrows
 - iv. White forelock
 - v. Heterochromia iridis
 - vi. Absence of the organ of Corti
 - vii. Atrophy of the spinal ganglion
 - viii. Congenital sensorineural hearing loss
- w. Alport syndrome:
 - i. Alport syndrome is genetically heterogeneous:
 - 1. All mutations cause defects in type IV collagen, which is a major structural component of the basement membrane
 - 2. Approximately 85% of patients are X-linked and 15% are autosomal recessive
 - ii. Progressive renal failure (glomerulopathy)
 - iii. Variable sensorineural hearing loss
 - iv. Variable ocular anomalies
- x. Cockayne syndrome (type A):
 - i. The syndrome is caused by homozygous or compound heterozygous mutation in the AR [(autosomal recessive)] ERCC8 gene that maps to chromosome 5q12.1:
 - 1. The encoded protein is the group 8 excision repair cross-complementing protein
 - 2. There is defective DNA repair in the disorder
 - ii. Abnormal slow growth and development that is seen within early childhood ("cachectic dwarfism")
 - iii. Cutaneous photosensitivity
 - iv. Thin, dry hair
 - v. Progeroid dysmorphism
 - vi. Progressive pigmentary retinopathy
 - vii. Sensorineural hearing loss
 - viii. Disproportionate long limbs and large hands
 - ix. Flexion joint contractures
 - x. Delayed development and cognitive impairment
 - xi. Cerebellar ataxia
 - xii. Peripheral neuropathy
 - xiii. Loss of subcutaneous fat
- y. Laurence-Moon-Biedl syndrome:
 - i. AR [autosomal recessive]; genetic heterogeneity occurs in the syndrome
 - ii. Genes responsible for the syndrome have been mapped to chromosome 11q13 (type 1), 16q21 (type 2), 3p12 (type 3) and 15q22 (type 4). The most common type is type 1 and the rarest is type 3
 - iii. Retinitis pigmentosa
 - iv. Sensorineural hearing loss
 - v. Cognitive dysfunction
 - vi. Obesity
- vii. Polydactyly
- viii. Hypogonadism
- ix. Optic atrophy
- x. Cataracts and glaucoma
- z. Refsum's disease
 - i. AR [autosomal recessive]; caused by mutation in the gene that encodes phytanoyl-CoA hydroxylase (PHYH or PAHX) that maps to chromosome 10p13
 - ii. Classic tetrad of abnormalities include:
 - 1. Retinitis pigmentosa
 - 2. Intermittent peripheral neuropathy
 - 3. Cerebellar ataxia
 - 4. Elevated CSF protein
 - iii. All patients have phytanic acid (an unusual branched chain fatty acid) in the blood and tissues
 - iv. Variable features include:
 - 1. Cardiac disease
 - 2. Sensorineural hearing loss
 - 3. Ichthyosis
 - 4. Multiple epiphyseal dysplasia
- aa. Retinitis and hearing loss
 - i. OPCA [Olivopontocerebellar atrophy]
 - ii. Juvenile and adult onset lipidoses
- ab. Optic Atrophy, Hearing Loss and Peripheral Neuropathy
 - i. Some patients with Friedreich's ataxia
- ac. Hearing Loss and Optic Atrophy
 - i. Sylvester syndrome:
 - 1. AD [autosomal dominant]
 - 2. Optic atrophy
 - 3. Ataxia
 - 4. Progressive hearing loss
 - ii. Nyssen-van Bogaert syndrome
 - 1. Opticocochleodentate degeneration
 - iii. Rosenberg-Chutorian syndrome
 - 1. Optic atrophy
 - 2. Polyneuropathy
 - 3. Sensorineural hearing loss
- ad. Brown-Vialetto-Van Laere syndrome
 - i. Caused by homozygous or compound heterozygous mutation in the SLC52A3 gene that maps to chromosome 20p13
 - ii. Sensorineural hearing loss
 - iii. Involvement of the motor components of the seventh and ninth to twelfth cranial nerves. Rarely, the third, fifth and sixth cranial nerves are involved
 - iv. Spinal motor nerves and upper motor neurons may be affected
 - v. The onset is most often in the second decade
 - vi. There is severe loss of axons of the auditory and vestibular nerves
- ae. Rare Associations of Hearing Loss

- i. Spinal muscular atrophy
- ii. Fascioscapular humeral dystrophy
- iii. Roussy-Lévy syndrome
- iv. Myotonic dystrophy
- 2. Non-Syndromic Hereditary Hearing Loss
 - a. Mitochondrial genetic disease:
 - i. MELAS
 - ii. MERRF
 - iii. PEO
 - iv. Kearns-Sayre syndrome
 - b. Identified Genes/Chromosomal Loci/Genetic Associations
 - i. CX25 (mutated in 50% of all recessive deafness)
 - ii. Myosin7A mutation – Usher type 1B – identified with syndromic and non-syndromic hearing loss
 - iii. X-linked deafness type 3 – POU3FH gene mutations
 - iv. DFNA6 that maps to chromosome 4p16.3 – progressive low frequency hearing loss
 - v. Mitochondrial mutation 12 s RNA deficit
 - vi. Enlarged vestibular aqueduct – the same 7q31 locus as Pendred syndrome
 - vii. X-linked cochlear degeneration
 - viii. Autosomal dominant cerebellar atrophy type I
 - ix. Complicated familial spastic paraparesis
 - x. Autosomal dominant recurrent VIIIth nerve deafness
 - xi. Familial amyloidosis type IV
 - xii. Late-onset peroxisomal deficiency
 - xiii. X-linked deafness
 - xiv. CADASIL
 - xv. Osteogenesis imperfecta
 - xvi. Hereditary sensory autonomic neuropathy
 - xvii. X-linked motor-sensory neuropathy type II
- b. Unilateral high-pitched tinnitus
- c. Progressive sensorineural hearing loss
- d. Early loss of speech discrimination
- e. Less than 10% have sudden deafness
- f. Vertigo, dizziness, ipsilateral unsteadiness (vestibular nerve involvement)
- g. V, VI, VIIIth nerve involvement (facial movement weakness, loss of taste anterior 2/3 of the tongue): Hitzelberger's sign (numbness of the external auditory canal)
- h. Decreased corneal reflex
- i. Hydrocephalus
- 15. Anterior extension of the tumor:
 - a. Vth (facial pain; decreased corneal reflex)
 - b. Vth nerve weakness of the tumor
- 16. Posterior inferior extension:
 - a. IXth nerve involvement with dysphagia
 - b. Absent pharyngeal reflex
 - c. Xth nerve involvement with hoarseness
 - d. XIth nerve involvement with trapezius and sternocleidomastoid muscle weakness
- 17. Infections Involving the VIIIth nerve
 - a. Blood borne infection:
 - i. Reaches the inner ear by invasion of the endolymphatic system
 - ii. Meningoencephalitis:
 - 1. Invasion along the nerves and vessels of the internal auditory meatus
 - iii. Streptococcus, pneumococcus, meningococcus, and haemophilus influenza:
 - 1. Direct invasion of the labyrinth with subtotal destruction of sensory and neural elements
 - 2. Total vestibular destruction may cause oscillopsia if any vestibular function remains; central compensation can occur with no vestibular symptoms but with profound hearing loss
 - iv. Syphilitic labyrinthitis:
 - 1. The most common cause of hearing loss in a syphilitic patient
 - v. Borrelia burgdorferi (Lyme's disease):
 - 1. There is both cochlear and vestibular involvement
 - vi. Petrositis (chronic middle ear infection)
 - 1. Gradenigo's syndrome:
 - a. Requires pneumatized petrous bone through which infection can spread to the petrous apex
 - b. Usually chronic bacterial otitis media; may be tuberculous
 - c. The VIth nerve is involved as it crosses under the petroclinoid ligament; pain behind the ipsilateral eye is from involvement of the Vth nerve ganglion in Meckel's cave

Tumors Affecting the VIIIth Nerve

- 1. Carcinomatosis of the meninges
- 2. Leukemia
- 3. Lymphoma
- 4. Acoustic Schwannoma (NF1 chromosome17)
- 5. Meningioma
- 6. Epidermoid (primary and secondary)
- 7. Metastasis
- 8. Pinealoma (CSF spread); dysgerminoma and pineocytoma
- 9. Ependymoma
- 10. Malignant melanoma (metastatic)
- 11. Exophytic glioma
- 12. Neurofibromatosis type II
 - a. Bilateral acoustic neuroma
- 13. Intravascular malignant lymphoma
- 14. Acoustic Neurinoma
 - a. The origin is on the vestibular portion of the VIIIth nerve in the IAC (internal auditory canal)

- d. Vertigo and hearing loss are due to erosion of the bony labyrinth or involvement of the VIIIth nerve in its bony canal
- vii. *Pseudomonas aeruginosa*:
 1. Malignant external otitis
 2. Debilitated patients (immunosuppressed)
 3. Severe diabetes
 4. Renal failure
 5. The organisms invade the junction of the cartilaginous and osseous portion of the external auditory canal to invade adjacent bones
- b. Viral infections that affect the VIIIth nerve:
 - i. Viruses may damage the cochlea to a greater degree than the VIIIth nerve itself
 - ii. Meningoencephalitis (viral) directly invades along the nerves and blood vessels (HZ and mumps)
 - iii. Infection of Scarpa's ganglion has been demonstrated with Herpes simplex, rubella and reovirus infection
 - iv. Vestibular neuronitis from a viral etiology:
 1. Affects patients who are:
 - a. 30–60 years of age
 - b. Have a sudden onset of vertigo that involves one ear and usually lasts for 1–3 weeks
 - c. The nystagmus is opposite to the involved ear (fast component)
 - d. There is no hearing loss or other neurologic signs
 - e. Recovery usually occurs over months
 - f. The superior and ampullary branches of the vestibular nerve are involved
 - g. The cochlea is normal
 - v. Tuberculosis (meningitis)
 - vi. Cryptococcosis (meningitis)
 - vii. Blastomycosis (meningitis)
 - viii. Histoplasmosis (meningitis)
 - ix. HIV
 - x. CMV
 - xi. Purulent bacterial meningitis
 - xii. EBV
 - xiii. Cysticercosis (racemose cyst of the CPA angle)
 - xiv. Coccidiomycosis (meningitis)
18. Drugs/toxins/physical agents:
 - a. Cisplatinum
 - b. Aminoglycosides (gentamicin the most common; especially with renal insufficiency)
 - c. Superficial siderosis (recurrent bleeding from cavernous hemangioma, other vascular malformations and subarachnoid hemorrhage)
 - d. Furosemide diuretics (loop-diuretics)
 - e. Zidovudine
 - f. Dideoxyadenosine
 - g. Interferon gamma 1
 - h. Depakote
 - i. X-RT
 - j. Increased ICP
 - k. Midbrain trauma
 - l. Basilar skull fracture
 - m. Blast injuries
 - n. Alcohol
 - o. Lead
 - p. Mercury
19. Disorders of the temporal bone
 - a. Otosclerosis:
 - i. A disease of the bony labyrinth
 - ii. Immobilization of the stapes
 - iii. Compression by otosclerotic foci of cochlear neural elements
 - b. Paget's disease:
 - i. Hearing loss is usually bilateral
 - ii. Sensorineural deficit may also have a synergistic conductive deficit
 - iii. Vestibular symptoms are usually progressive but may be episodic
 - c. Fibrous dysplasia of bone:
 - i. Compression of the VIIIth nerve in its bony canals
 - d. Osteopetrosis:
 - i. VIIIth and VIIIth nerve compression with deficits may be early symptoms
 - ii. Conductive defect:
 1. Narrowing of the internal auditory meatus
 2. Encroachment of the bones of the middle ear on the ossicles
 - iii. Sensorineural hearing loss is from compression of the cochlear nerve in the IAC
 - e. Recessive osteosclerosis (Van Buchem syndrome or hyperostosis corticalis generalisata):
 - i. Hyperostosis of the skull, ribs, clavicles, long bones and pelvis
 - ii. VIIIth and VIIIth nerve palsy occurs in approximately 50% of patients
 - iii. Encroachment of bone into the neural foramina
 - f. Hyperostosis cranialis interna:
 - i. Hyperostosis and osteosclerosis of the calvarium and base of the skull can occur in isolation
 - ii. AD inheritance
 - iii. Recurrent VIIth nerve palsy, decreased vision as well as decreased hearing and vestibular function
 - iv. Cranial nerve foraminal encroachment
 - g. Synchrondrosis of the skull
 - h. Congenitally small IAC (internal and auditory canal)
20. Trauma of the VIIIth Nerve:
 - a. Blunt trauma:
 - i. Transverse or longitudinal fracture (in relation to the long axis of the petrous bone)
 - ii. Longitudinal fractures:
 1. More common than transverse
 2. Usually no VIIIth nerve damage

- iii. Transverse fractures
 - 1. Anteroposterior trauma
 - 2. The roof of the internal auditory meatus is fractured
 - 3. There is usually complete deafness with vertigo; 40–50% of patients have a concomitant VIIIth nerve paralysis
 - iv. Blunt head trauma with a temporal bone fracture:
 - 1. Concussion of the inner ear
 - 2. Concomitant secondary neural degeneration
 - v. There may be VIIIth nerve injury from commercial and sports diving
21. Developmental Defects in the VIIIth nerve:
- a. Atresia
 - i. Complete absence of the otic capsule and VIIIth nerve from thalidomide exposure
 - b. Incomplete development of the bony and membranous labyrinth that includes dysgenesis of the spiral ganglion
 - c. Membranous cochleosaccular dysplasia of the VIIIth nerve in the porous acousticus
- The Vestibular Component of the VIIIth Nerve**
- 1. General Characteristics:
 - a. Vertigo is manifested by a combination of perceptual, ocular, motor and postural signs and symptoms
 - 2. Clinical Manifestations:
 - a. Peripheral (vestibular labyrinthine) disorders
 - i. Semicircular canal disorders cause rotational sensation; disorders of utricle and saccule (the otolith) are affected; there is a sensation of tilt or levitation
 - ii. Acute vertigo from the labyrinth:
 - 1. The diseased site may be irritated and more active for hours to days that (with the eyes closed) causes a rotational sensation to the side opposite the affected labyrinth
 - 2. In the paretic phase (the labyrinth is hypoactive)
 - a. Patients fall and past-point to the affected side (while standing with their eyes closed)
 - b. The slow component of nystagmus is to the affected side (eyes slowly deviated to the affected side with the post-cortical corrective jerk nystagmus to the opposite side)
 - iii. Patients lie on their side with the affected side upmost
 - iv. Acoustic stimuli may induce:
 - 1. Paroxysms of vertigo
 - 2. Oscillopsia (abnormal movement of objects in the environment)
 - 3. Postural unsteadiness
 - 4. The ocular tilt reaction
 - 5. Nystagmus
 - 6. The above constellation is Tullio's phenomenon
 - v. The major manifestations of peripheral vestibular disorders are:
 - 1. Short duration
 - 2. Severe paroxysmal vertigo
 - 3. May be accompanied by tinnitus and hearing loss
 - 4. The fast phase of nystagmus is to the side opposite to the lesion, is horizontal, rotary and is dampened by ocular fixation
 - 5. Subjective environmental sensations, falls, past-pointing are to the side of the lesion
 - 6. Reflex fixation saccades to the opposite side are induced when the head is rotated to the side of the lesion
 - 7. Bilateral vestibular paresis:
 - a. Head movement dependent oscillopsia (movement of the visual environment only with head movement)
 - 3. Neuropathology:
 - a. Benign positional vertigo:
 - i. Degeneration of the macula of the otolith
 - ii. Obstruction of endolymph flow
 - iii. Lesions of the posterior semicircular canal (PSCC)
 - iv. Otoconia from degenerating reticular macula attach to the cupula of the PSCC
 - v. Differential diagnosis of cupulolithiasis:
 - 1. Trauma
 - 2. Infection (herpes simplex)
 - 3. Labyrinthine fistula
 - 4. Ischemia
 - 5. Demyelinating disease
 - 6. Posterior fossa tumor
 - 7. Arnold-Chiari malformation
 - b. The nystagmus of benign positional vertigo (BPPV) and peripherally induced nystagmus:
 - i. Latency of 2–15 seconds
 - ii. Fatigue (lasts less than 10 seconds)
 - iii. Has a torsional component
 - iv. No associated cochlear or central signs or symptoms
 - v. Vertigo (less than 60 seconds)
 - vi. In the upright position (after sitting the patient up from the supine position that induced the nystagmus) there is rebound nystagmus to the opposite side
 - vii. Lying in a lateral position may cause protracted nystagmus
 - viii. May have a protracted course (years)
 - ix. The nystagmus habituates (lessens with repositioning)
 - c. The manifestations of central nystagmus and vertigo:
 - i. Short latency
 - ii. Does not fatigue
 - iii. There is no habituation

- iv. Vertigo may be absent or mild and may last ~60 seconds
- v. The nystagmus is direction-changing rather than fixed
- vi. Induced by several head positions
- vii. There are associated CNS signs

Matutinal Vertigo

1. Refers to vertigo precipitated by rising on awakening or turning over in bed prior to arising:
 - a. May be central or peripheral
 - b. Seen in disorders that cause positional vertigo
2. Vestibular neuronitis:
 - a. Acute severe vertigo associated with prominent nausea and vomiting
 - b. Absent calorics on the affected side
 - c. Self-limited; usually lasts for 7–10 days
 - d. No cochlear symptoms or other neurologic signs
 - e. Unrelated to head position
 - f. May reoccur
3. Acute labyrinthitis:
 - a. Severe vertigo, nausea and vomiting
 - b. Associated tinnitus
 - c. Hearing loss
 - d. May follow bacterial or viral labyrinthitis; aminoglycoside antibiotics, or loop diuretics
4. Aberrant branch of AICA that compresses the VIIIth nerve
 - a. Constant positional vertigo
 - b. Severe nausea
 - c. Tinnitus

Ménière's Disease

1. Episodic severe vertigo
2. Fluctuating sensorineural hearing loss
3. Fullness or pressure sensation in the ear
4. It is bilateral in 30–40% of patients
5. Endolymphatic hydrops:
 - a. An increased volume of endolymph
6. Roaring tinnitus
7. Attacks last minutes to hours
8. Between attacks some patients have dysequilibrium
9. Hearing loss occurs in low tones (<3 kHz)

Variants of Ménière's Disease

1. Cochlear Ménière's:
 - a. Vertigo is absent
2. Vestibular Ménière's disease
 - a. Severe vertigo
 - b. Hearing loss and tinnitus are later features
3. Tumarkin's otolithic catastrophe:
 - a. Severe episodic vertigo
 - b. Loss of muscle tone; the patient falls to the ground
 - c. There is no loss of consciousness

Medical Disorders That Cause Vertigo

1. Anemias:
 - a. Polycythemia vera
 - b. Waldenström's macroglobulinemia (hyperviscosity)
 - c. IgM monoclonal gammopathies
2. Hypoglycemia:
 - a. Dizziness and presyncope
 - b. Cold perspiration
 - c. Convulsion (usually the sugar peripherally is less than 30–40 mg/dl)
3. Hypothyroidism:
 - a. Sensorineural hearing loss
 - b. Cerebellar ataxia
 - c. Vertigo
4. Hyperventilation:
 - a. Perioral paresthesia
 - b. Tingling fingers (paresthesia)
 - c. Fasciculations
5. Cardiac Insufficiency:
 - a. Cardiac arrhythmia:
 - i. Tachyarrhythmia with decreased stroke volume
 1. Presyncopal sensation
 2. Visual loss (closing in from the side)
 3. Fading out of hearing
 4. "Light headed" or dizzy
 - b. Congestive heart failure
 - c. Aortic stenosis
 - d. Carotid sinus hypersensitivity
6. Infections
 - a. Congenital syphilis (bilateral disease) associated with interstitial keratitis and strawberry molars (Cogan's syndrome)
 - b. Viral and bacterial labyrinthitis
 - c. Ramsay Hunt syndrome:
 - i. HZ of the geniculate ganglion
 - ii. Vesicular eruption of external auditory canal
 - iii. Peripheral facial paralysis
 - iv. Vertigo and hearing loss
 - d. Chronic ear infections
 - e. Multiple sensory deficit syndrome:
 - i. Elderly patients
 - ii. Visual impairments (cataracts and macular degeneration)
 - iii. Proprioceptive sensory loss (neuropathy)
 - iv. Cervical spondylosis
 - v. Depression

Vascular Causes of Vertigo

1. Vertebrobasilar insufficiency
 - a. Vertigo and dizziness are moderately severe
 - b. Deafness or hearing loss is rare
 - c. Associated frequently with brainstem, cerebellar, cranial nerve or long tract signs

- d. Ischemia of the central auditory pathways or the labyrinth (internal auditory or subordinate arteries)
2. Lateral medullary syndrome (Wallenberg; PICA; most often from vertebral artery atherosclerosis)
 - a. Vertigo, dizziness, nausea and vomiting
 - b. IXth and Xth nerve involvement
 - c. Rotary nystagmus to the side of the lesion (vestibular nuclei)
 - d. Ipsilateral ataxia (involvement of the restiform body)
 - e. Ipsilateral Vth nerve involvement with decreased sensation of the face; loss of sensation below the clavicle contralaterally (temperature and pain); involvement of the ascending spinothalamic tract that decussates at its level of origin; the leg is involved to a greater degree than the arm
 - f. If the lateral branch of PICA is involved in isolation:
 - i. Patients may only have vertigo and dizziness (a rare example of a central lesion without other associated neurological signs)
3. Labyrinthine stroke:
 - a. Occlusion of the internal auditory artery (its origin is AICA); rarely occlusion is directly from the basilar artery)
 - i. Involvement of the superior vestibular branch from the internal auditory artery (IAA) causes vertigo, nausea and vomiting
 - ii. Infarction of the cochlear branch of the IAA causes sudden deafness (usually a sign of AICA infarction)
4. Bickerstaff migraine:
 - a. Vertebrobasilar migraine
 - b. Tingling and paresthesias
 - c. Dizziness, dysarthria and ataxia
 - d. Patients may have a short loss of consciousness
5. Subclavian steal syndrome:
 - a. There is severe stenosis of the subclavian artery prior to the origin of the vertebral artery
 - b. Dizziness, dysarthria and diplopia:
 - i. Occurs during continued uses, often overhead, of the right arm
 - ii. Most often this is a radiographic (angiographic) finding that is asymptomatic
6. Cerebellar infarction or hemorrhage
7. Benign positional vertigo may occur secondary to labyrinthine ischemia
8. Dolichoectasia of the vertebral, basilar and AICA arteries that compress the VIIIth nerve
9. AICA or PICA aneurysm with distal emboli or vasospasm

Vertigo from Head or Cervical Trauma

1. Inner ear concussion
2. Fracture of the temporal bone with labyrinthine and/or VIIIth nerve damage; MRI has demonstrated blood in the labyrinth and cochlea
3. Uncovertebral joint arthritis of the cervical spine as well as cervical plexus injuries:
 - a. There is unequal afferent input to the vestibular nuclei

Cranial Nerve IX

General Characteristics

1. The glossopharyngeal nerve is comprised of motor, sensory and parasympathetic fibers
2. It emerges from the brainstem in close approximation to the Xth and XIth nerves to exit the skull through the jugular foramen
3. In the upper neck the IXth nerves between the ICA and the jugular vein
4. It innervates the stylopharyngeus muscle (which elevates the pharynx) and along with the vagus nerve the constrictor muscles of the pharynx
5. It also innervates the cricopharyngeus muscle which is the external pharyngeal sphincter
6. Parasympathetic fibers take origin from the inferior salivatory nucleus and branch from the main nerve at the petrous ganglion to travel with the tympanic and superficial petrosal nerve to the otic ganglion. Post-ganglionic fibers travel with the auriculotemporal branch of the Vth nerve to innervate the parotid gland
7. Afferent sensory fibers innervate the posterior 1/3 of the tongue, the tonsils, nasopharynx, inferior surface of the soft palate, uvula, eustachian tube, tympanic cavity, a small area anterior to the tragus and a small portion of the anterior wall of the external auditory meatus
8. Taste from the posterior 1/3 of the tongue is subserved from neurons in the petrous ganglion which synapse in the nucleus of the tractus solitarius
9. It gives off the carotid sinus nerve:
 - a. That contains afferents from the chemoreceptors of the carotid bodies
 - b. Baroreceptors of the carotid sinus wall
 - c. Projects to the nucleus tractus solitarius

Clinical Manifestations

1. It is involved with the vagus in mediating:
 - a. Taste from the posterior 1/3 of the tongue
 - b. Mediates the gag reflex
 - c. Salivary secretion from the parotid gland
 - d. Bilateral surgical or traumatic section causes transient hypertension
 - e. Intramedullary involvement (Bonner syndrome)
 - i. VIIIth, IXth and Xth nerve involvement
 1. Vertigo, dysphagia and dysarthria
 2. Contralateral hemiplegia
 3. IXth nerve involvement
 4. Bonner syndrome may also be caused by tumors, syringobulbia and autoimmune disorders
 - f. Paroxysmal lacrimation (Bogorad syndrome)
 - i. Abnormal lacrimation with normal production of saliva
 - ii. Following middle ear surgery the lesser superficial petrosal nerve to the parotid gland is damaged

- iii. There is aberrant innervation from the parasympathetic fibers from the otic ganglion. Aberrant innervation of the lacrimal gland; may also be seen in Bell's palsy with lesions that are proximal to the geniculate ganglion (that supplies preganglionic fibers to the lacrimal gland, submandibular and sublingual glands)
- iv. Sphenopalatine ganglion post-ganglionic parasympathetic fibers supply the lacrimal gland

Neuropathology

1. Vascular disorders
 - a. Wallenberg's syndrome
 - b. Bonner's syndrome
 - c. Cavernous hemangioma, AVM, telangiectasia and hypertensive hemorrhage
 - d. An absent vertebral artery or DICA itself may compress the nerve
2. Tumors of the IXth nerve
 - a. Glomus jugulare
 - b. Schwannoma
 - c. Meningioma
 - d. Chordoma
 - e. Metastatic disease
 - f. Jugular foramen syndrome of Vernet:
 - i. IXth, Xth, XIth nerves are affected
3. Glossopharyngeal neuralgia:
 - a. Idiopathic or secondary to a structural lesion
 - b. Onset is between 40–60 years of age; there is an equal male and female incidence
 - c. Stabbing, severe unilateral neuropathic pain
 - d. The pain radiates to the base of the tongue, faucial areas (tonsils) in or behind the external auditory meatus and beneath the angle of the jaw
 - e. Trigeminal and glossopharyngeal neuralgia may occur concomitantly
 - f. A hacking cough may accompany the paroxysms of pain
 - g. The triggers are: swallowing, talking, pressure on the tragus or auricle, sneezing or moving the head
 - h. Associated with episodes are: salivation, flushing, sweating, tinnitus, lacrimation, tachycardia, hypertension and rarely seizures or cardiac asystole from activation of the cardiac depressor nerve
 - i. Bradycardia and syncope:
 - i. Afferents to the brainstem vasomotor centers that excite cranial nerve X
 - j. Paroxysms occur usually 2–3×/year; usually last a few minutes but may occur intermittently over several days
 - k. Differential diagnosis of glossopharyngeal neuralgia (structural lesions)
 - i. Occlusion of the ICA
 - ii. Elongation of the stylomastoid process

- iii. Tumors of the posterior foramen
 - iv. Local infection
 - v. Tortuosity of PICA
 - vi. Neck trauma
4. Carotid sinus hypersensitivity
 - a. Syncope with head and neck movement
 - b. Rarely from pressure on the neck (tight collar)
 - c. Stretching the neck
 - d. Response to carotid artery massage:
 - i. Decrease of heart rate of 50%
 - ii. Asystole if greater than 3 seconds
 - iii. A fall of blood pressure of 50 mm Hg
 - e. Cardioinhibitory effects of carotid sinus hypersensitivity:
 - i. Isolated decrease of heart rate
 - f. Mixed form:
 - i. The heart rate is maintained in the face of a falling blood pressure
 - g. Vasodepressor form:
 - i. There is isolated hypotension

Differential Diagnosis of IXth Nerve Syncope

1. Digoxin
2. Beta-adrenergic blocking drugs
3. Biliary disease:
 - a. A high bilirubin depresses the SA and AV node of the cardiac conduction system
4. Elderly patients with atherosclerotic disease of the cardiac conduction system
5. Takayasu disease
6. Chromaffin tumors of the carotid body
7. Post-carotid endarterectomy
8. Elicitation of the cardiodepressor reflex by pressure
 - a. May cause ventricular fibrillation
 - b. The right side is more dangerous to compress than the left
9. Peripheral IXth nerve involvement:
 - a. Diphtheria
 - b. AIDP
 - c. CIDP
 - d. Meningeal involvement:
 - i. Infection
 - ii. Tumor
 - iii. Pachymeningitis
 - e. Tabes dorsalis
 - i. Carotid and baroreceptor dysfunction
 - f. Hencken's syndrome
 - i. Loss of taste of the posterior 1/3 of the tongue and pharynx
 - g. Lesions within the retropharyngeal or retroparotid space
 - h. Nasopharyngeal cancer
 - i. Abscess
 - j. Adenopathy

- k. Aneurysms
 - l. Trauma
- m. Surgical procedures
 - i. Head and neck cancer surgery
- n. Carotid endarterectomy
- o. Pure glossopharyngeal syndrome:
 - i. Minimal dysphagia
 - ii. Depressed gag reflex
 - iii. Ipsilateral palatal weakness
 - iv. Loss of taste of the posterior 1/3 of the tongue
 - v. IXth sensory nerve loss
- p. Associated syndromes
 - i. Collet-Sicard syndrome:
 - 1. IXth, Xth, XIth and XIIth nerves are involved
 - ii. Villaret syndrome:
 - 1. IXth, Xth, XIth and XIIth
 - 2. Sympathetic chain
 - 3. Occasionally the VIth nerve is involved
- q. Basilar skull fracture
- r. Bogorad syndrome
 - i. Crocodile tears from aberrant regeneration of the lesser superficial petrosal nerve
- e. In the neck:
 - i. It travels with the internal carotid artery and jugular vein in the carotid sheath. It gives off:
 - 1. Cardiac rami to the cardiac plexus
 - 2. Recurrent laryngeal nerve:
 - a. On the right side the nerve ascends in the tracheoesophageal sulcus
 - b. On the left side, it travels beneath the aortic arch to the tracheoesophageal sulcus
 - c. The recurrent laryngeal nerve divides into anterior and posterior rami which supply all of the muscles of the larynx except the cricothyroid
 - d. The dorsal motor nucleus of the vagus and the nucleus ambiguus supply the motor fibers carried in the nerve:
 - i. The dorsal motor nucleus is located in the floor of the IVth ventricle lateral to the hypoglossal nucleus. It provides preganglionic parasympathetic fibers to:
 - 1. The pharynx
 - 2. Esophagus
 - 3. Trachea
 - 4. Stomach
 - 5. Heart
 - 6. Small intestine
 - 7. Ascending and transverse colon
 - 8. Liver
 - 9. Pancreas

Cranial Nerve X

General Characteristics

Anatomy

1. The vagus nerve contains motor, sensory and parasympathetic nerve fibers
2. The vagus nerve shares a dural sheath with cranial nerve XI in the jugular foramen (pars venosum)
3. Inferior to the jugular foramen or within it are its two ganglia
 - a. Jugular ganglia (general somatic afferent)
 - b. Nodose ganglia (special and general visceral afferent fibers)
- c. Between the two ganglia the nerve gives off:
 - i. The auricular ramus (the nerve of Arnold) that innervates that concha of the external ear
 - ii. The meningeal ramus that innervates the dura of the posterior foramen
 - iii. The pharyngeal ramus
 - 1. Forms the pharyngeal plexus with cranial nerve IX to innervate the muscle of the pharynx and most of the palate (except for the stylopharyngeus that is innervated by IX and the tensor veli palatini innervated by V)
- d. The superior laryngeal nerve arises from the vagus near the nodose ganglion:
 - i. Its external motor branch innervates the cricothyroid muscle
 - ii. Its internal ramus provides sensory fibers to the larynx
4. The nucleus ambiguus innervates:
 - a. All striated musculature of the soft palate, pharynx and larynx except the stylopharyngeus muscle which is innervated by cranial nerve IX and the tensor veli palatini innervated by cranial nerve V
 - b. The nodose ganglia mediates taste from the epiglottis, hard and soft palate, pharynx and projects to the nucleus tractus solitarius
 - c. Cells of origin in the nodose ganglion also mediate general visceral sensation from the oropharynx, larynx, lining of the abdominal viscera and projects to the nucleus tractus solitarius
 - d. Exteroceptive sensation from the concha is mediated by fibers that project to the jugular ganglion and then to the descending tract of V
 - e. Xth nerve lesions cause the vocal cords to assume the cadaveric position that is in between abduction and adduction

Clinical Manifestations

1. Supranuclear lesions:
 - a. The cortical representation is at the foot of the precentral gyrus
 - b. Lesions of homunculus, corona radiata and centrum semiovale cause solitary unilateral palatal weakness with no associated limb weakness

- c. Bilateral upper motor lesions may result in pseudobulbar palsy that is characterized by:
 - i. Emotional dyscontrol
 - ii. Increased gag reflex (rarely it is decreased)
 - iii. Dysphagia
 - iv. Pathologic laughing and crying
 - v. A spastic tongue
 - vi. Explosive spastic dysarthria
 - vii. The gag reflex when elicited may be associated with retching and vomiting
 - viii. Extremity spasticity
- 2. Medullary lesions of X:
 - a. Wallenberg's syndrome
 - b. Syringobulbia
 - c. Motor neuron disease
 - d. Inflammatory disease (demyelinating)
 - e. Paraneoplastic disorders
 - f. Primary and metastatic tumors
- 3. Injury to the rostral component of the nucleus ambiguus:
 - a. Palatal pharyngeal paralysis of Avellis
 - b. The larynx is spared
- 4. Vagal autonomic functional deficits:
 - a. Esophageal, gastric and intestinal motility:
 - i. Esophageal motility:
 - 1. There is denervation hypersensitivity to cholinomimetic drugs (after vagotomy) in the lower 1/3 of the esophagus
 - 2. Achalasia:
 - a. Cholinergic medicines cause uncoordinated and painful contraction of the esophagus
 - ii. Gastric motility:
 - 1. Gastroparesis when the nerve is involved primarily with diabetes and amyloidosis
 - 2. Hyperactivity:
 - a. Following gastrojejunostomy and pyloroplasty:
 - i. Increased gastric emptying may cause early dumping syndrome that manifests with:
 - 1. Post-prandial weakness
 - 2. Lightheadedness
 - 3. Flushing
 - 4. Sweating
 - 5. Palpitation
 - 6. Tachycardia
 - ii. Later dumping syndrome:
 - 1. Insulin release following sugar ingestion
 - 2. Reactive hypoglycemia
 - 3. Associated diarrhea
 - iii. Intestinal motility
 - 1. Measured by evaluation of myenteric complexes (MMCs) intestinal motility physiology
 - 2. Absent MMC is caused by a neuropathy (Xth nerve) or Intestinal muscle impairment

- iv. Pancreatic polypeptide release:
 - 1. Is vagal nerve dependent
 - 2. There are increased levels with hypoglycemia
 - 3. Polypeptide level is a measure of abdominal vagal activity
 - 4. Autonomic failure with vagal denervation is associated with:
 - a. Decreased levels of pancreatic peptide levels with hypoglycemia
 - 5. Vagovagal syncope increases pancreatic peptide level

The Clinical Manifestations of Efferent Vagal Nerve Dysfunction

- 1. Cardiac:
 - a. The neural control of heart rate is primarily under vagal control
 - b. If the vagal nerve is blocked, the heart rate is 100–110 beats per minute
 - c. Diminished cardiac vagal tone occurs with:
 - i. Multiple system atrophy:
 - 1. Degeneration of the vagal nerve nuclei
 - 2. Primary autonomic failure:
 - a. Peripheral vagal nerve degeneration
 - 3. In diabetic autonomic failure:
 - a. The heart rate is initially high and then falls with progression of the illness
 - ii. Chronic autonomic failure:
 - 1. There is a decreased heart rate response to hyperventilation
 - 2. There is a similar response with polyneuropathies and autonomic failure secondary to alcohol
 - iii. There is vagal dysfunction earlier than sympathetic loss with:
 - 1. Alcoholism
 - 2. Non-alcoholic liver disease
 - 3. Cardiac transplantation
- 2. Impaired vagal innervation of the GI tract:
 - a. Primary autonomic failure:
 - i. Decreased gastric emptying
 - ii. Impaired pancreatic polypeptide response to hypoglycemia
 - b. Diabetic neuropathy:
 - i. Peripheral vagal degeneration
 - ii. Gastric dilation with reduced peristalsis and delayed emptying
 - iii. Nocturnal watery diarrhea
 - c. There is gastrointestinal atrophy with botulism
 - d. Pure cholinergic dysautonomia:
 - i. Putative immune-mediated
 - e. Destruction of vagally innervated intrinsic gut plexuses:
 - i. Achalasia
- 3. The esophageal sphincter degenerates and fails to relax

- a. Chagas disease:
 - i. Causes a cellular immune response
 - ii. Antiparasymphathetic neuronal IgG antibodies are detected
4. Vagal nerve hyperactivity:
 - a. Vagovagal syncope:
 - i. The sight or thought of a specific stimulus triggers the episode
 - ii. Bradycardia
 - iii. Loss of consciousness (usually for seconds)
 - b. Oculocardiac reflex:
 - i. Pressure or stimulation of the globe cause loss of consciousness
 - c. Vagal reflexes are often augmented by drugs and anesthetics
 - d. Glossopharyngeal neuralgia
 - i. Some sensory radiations are into the sensory innervation territory of cranial nerve X
 - e. Syncope triggered by swallowing (Charcot's syncope)
 - f. Carotid sinus hypersensitivity
 - g. Syncope during pleural aspiration
 - h. Increased vagal nerve activity with high cervical spinal cord lesions may be caused by associated:
 - i. Hypoxia
 - ii. Pulmonary emboli
 - iii. Acidemia
 - iv. Decreased cardiac sympathetic tone
 - v. Paralysis or depression of respiration:
 1. Decreased activation of the pulmonary stretch reflex which inhibits the vagus
 - vi. Tracheal intubation in quadriplegics enhances vagal activity
 - vii. Hyperactive diving reflex; cold water in the face causes bradycardia
5. Vagal afferent dysfunction:
 - a. Cough reflex:
 - i. Supplies sensation to the mucous membranes of the larynx and the tracheobronchial tree
 - ii. The afferent limb of the cough reflex
 - iii. Bilateral lesions cause aspiration
 - iv. Stimulation of the trachea and larynx in tetanus
 - v. Cause severe hypertension:
 1. Sympathetic overactivity
 2. Hypotension and bradycardia in tetraplegia
 - b. Superior laryngeal neuralgia:
 - i. Paroxysmal lancinating pain in the larynx
 - ii. Radiation of the pain is from the side of the thyroid
 - iii. Cartilage to the angle of the jaw; occasionally to the ear
 - iv. Trigger:
 1. Pressure over the skin that overlies the thyrohyoid membrane
 - c. Pulmonary vagal afferents:
 - i. Pulmonary stretch receptors increase their activity with inspiration
 - ii. Receptors in the chest wall for stretch are more active than pulmonary afferents
 - iii. Vagal lung irritant receptors:
 1. Respond to irritants, causes over- or underexpansion of the lung, emboli or congestion (reflexes may be neuropeptide mediated)
 - d. Cardiac receptors:
 - i. Activation of cardiac vagal receptors in the ventricle are:
 1. Mechanoreceptors (substance P (SP) is the putative cotransmitter)
 2. Induces bradycardia, hypotension and syncope
 - ii. Stimulated by forceful contraction:
 1. Aortic stenosis
 2. Tilt table stress
 3. Coronary arteriography

Syndromes Involving the Xth Nerve

1. Jugular foramen (Vernet):
 - a. IX, X, XI are involved
2. Schmidt:
 - a. X, XI (the venous component); the pars venosum in the jugular foramen
3. Hughlings-Jackson:
 - a. X, XI, XII are involved
4. Collet-Sicard:
 - a. IX, X, XI, XII are involved in the neck
5. Trunk vagal nerve lesions:
 - a. Occur from neck or thorax involvement of the nerve
 - b. Ipsilateral vocal cord paralysis and unilateral laryngeal anesthesia
 - c. Differential Diagnosis:
 - i. Tumor of the lung
 - ii. Internal carotid artery aneurysm
 - iii. Trauma (MVA, sports, falls)
 - iv. Enlarged lymph nodes
6. Superior laryngeal nerve:
 - a. The nerve is primarily a sensory branch:
 - i. Cricothyroid muscle weakness
 - ii. Minimal hoarseness and hypophonia
 - b. The usual causes are surgery, trauma or tumor
7. Recurrent laryngeal nerve:
 - a. Left is damaged > than the right
 - b. A longer course of the nerve
 - c. Unilateral paralysis is associated with:
 - i. Transient hoarseness
 - ii. Flaccid dysphoria:
 1. Harshness and breathiness of speech
 2. Decreased voice volume
 3. Inhalational stridor
 - iii. Plate pharyngeal function is normal
 - iv. Diplophonia
 1. Two pitch levels are produced by unequal frequency of vibration between the two vocal cords

- v. Semon's law:
 - 1. Abductor muscles of the larynx are affected first with a peripheral nerve injury
- vi. Differential diagnosis of recurrent laryngeal disorders:
 - 1. In approximately 25% the cause cannot be identified
 - 2. Aneurysms of the aortic arch or the subclavian artery
 - 3. Enlarged tracheobronchial lymph nodes
 - 4. Mediastinal tumor
 - 5. Thyroidectomy
 - 6. Cancer that extends behind the carotid sheath at C6:
 - a. There is usually a combination of deficits that include:
 - i. Recurrent laryngeal, vagal, phrenic nerves
 - ii. Preganglionic sympathetic fibers
 - iii. Constitutes the Rowland-Payne syndrome
- 8. Bilateral recurrent laryngeal nerve disorders are caused by:
 - a. Thyroidectomy
 - b. Carcinoma of the thyroid
 - c. Carcinoma of the esophagus
 - d. AIDP (the descending form)
 - e. Bilateral abductor muscle paralysis causes:
 - i. The vocal cords to be at or near the midline
 - ii. Approximation of the vocal cords
 - iii. A weak voice that is clear
 - iv. Inspiratory stridor
 - v. Dyspnea on exertion
- 9. Bilateral lesions that affect the superior laryngeal nerve:
 - a. Lesions above the nodose ganglion
 - b. Associated palatal and pharyngeal paralysis
 - c. The vocal cords are in the cadaveric position
 - d. Phonation is severely compromised
 - e. Vocal pitch cannot be changed
- 10. Rarer disorders and syndromes that affect the Xth nerve:
 - a. Wolfram syndrome:
 - i. Adductor spasm
 - ii. Sjögren's syndrome
 - iii. Tapia's syndrome
 - 1. Ipsilateral tongue and vocal cord weakness
 - iv. Shy-Drager disease:
 - 1. Cricoarytenoid muscle weakness (recurrent laryngeal nerve)
 - 2. Upper airway dysfunction
 - 3. Central respiratory dysfunction
 - 4. Sudden death during sleep
 - b. Isra's syndrome of the larynx
 - c. Idiopathic adductor weakness or spasm (spastic dysphonia)

- d. Arnold-Chiari (type 1) syndrome
- e. Laryngeal nerve neuralgia
- f. Swallow syncope (Charcot's syncope)

Neuropathology

- 1. Vascular disease:
 - a. Wallenberg's syndrome (nucleus ambiguus)
 - b. Hypertensive hemorrhage (rare < 1% of hypertensive)
 - c. Hemorrhages in the medulla
 - d. Cavernous hemangioma, AVM, and telangiectasia of the medulla
 - e. Aortic arch aneurysm
 - f. Recurrent laryngeal nerve paralysis
 - g. Dissection of the internal carotid artery
 - h. Left atrial distension (mitral stenosis) or congestive heart failure
- 2. Autoimmune failure disorders:
 - a. AIDP
 - b. Idiopathic
 - c. Neuralgia amyotrophica (may be viral)
 - d. Sarcoidosis
 - e. Myasthenia gravis
 - f. Cholinergic dysautonomia
- 3. Neuropathy:
 - a. Neuritic Beriberi
 - b. Sjögren's syndrome
 - c. AIDP
 - d. Drug-induced
 - e. SLE
 - f. HMSN type II (vocal cord involvement)
 - g. CMTHC
 - h. Vincristine
 - i. Alcohol
 - j. Idiopathic pachymeningitis (Ig4 by compression)
- 4. Trauma:
 - a. Insertion of nasogastric or endotracheal tubes
 - i. Injury to the posterior branch of the recurrent laryngeal nerve
 - ii. The posterior cricoarytenoid and interarytenoid muscles are affected
 - iii. The nerve is damaged behind the thyroid cartilage
 - b. Bilateral laryngeal nerve injury by thyroidectomy
 - c. Injury to the recurrent laryngeal nerve:
 - i. Distension of the esophagus that causes achalasia, may be bilateral and reversible
 - ii. Delayed post-operative palsy (neuropractic injury)
 - d. Severe neck trauma
 - e. Pharyngeal plexus injury:
 - i. The terminal branches of IX and X are involved
 - ii. Flexion extension neck injury
 - iii. Surgery (tonsillectomy)
- 5. Tumors of the Xth nerve:
 - a. Schwannoma
 - b. Chemodectoma
 - c. Chordoma

- d. Meningioma (jugular foramen)
- e. Carcinomatosis of the meninges
- f. Metastatic cancer primarily from the lung, breast and thyroid
- g. Recurrent laryngeal nerve:
 - i. Malignant mediastinal tumors
 - ii. Esophageal cancer
 - iii. Lymphoma
 - iv. Thyroid cancers
- 6. Idiopathic Xth nerve palsy:
 - a. Males are affected $2\times$ > females
 - b. Usually occurs in the 3rd decade
 - c. Comprise approximately 20% of Xth nerve lesions
 - d. The left side is more frequently affected than the right
- 7. Aberrant regeneration of cranial nerve IX and X:
 - a. Gustatory sweating:
 - i. Hyperhidrosis during eating
- 8. Damage to the lesser superficial petrosal nerve:
 - a. Aberrant post-ganglionic sympathetic nerve fibers are found in the auriculotemporal distribution (Frey's syndrome):
 - i. May be caused by neck operations, thoracotomy or T2 sympathectomy
 - ii. Gustatory piloerection may be associated with the hyperhidrosis from aberrant innervation of the sympathetic ganglia
- h. Corticobulbar fibers to the trapezius muscle are primarily crossed; there is an ipsilateral termination to the SCM (sternocleidomastoid muscle); it has been postulated that there is a decussation to the opposite pons and then a decussation back to terminate on the side of origin (the ipsilateral hemisphere). The second decussation is postulated to occur in the pons
- i. The sternal head of the SCM muscle may receive bilateral cortical innervation (IPSI > contralateral) and double decussates first in the pons and then back in the cervical cord; the clavicular head of the SCM muscle tilts the head ipsilaterally
- j. Corticobulbar innervation to the SCM is located dorsally in the brainstem tegmentum while fibers to the trapezius muscle are located in the ventral brainstem
- k. The trapezius muscle:
 - i. Retracts the head
 - ii. Raises the abducted arm above the horizontal
- l. Bilateral SCM weakness causes weakness of neck flexion and the head falls backwards
- m. Unilateral trapezius weakness from lesions of the spinal accessory nerve:
 - i. Affects upper trapezius fibers; lower fibers are supplied by the anterior roots of the cervical plexus:
 - 1. A droopy shoulder on the affected site
 - ii. The scapular is displaced down and laterally
 - iii. Paresis of shoulder elevation and retraction; the patient is unable to raise the arm above the horizontal, after it has been abducted (accomplished by the deltoid and the supraspinatus)
 - iv. Bilateral trapezius weakness causes decreased neck extension

The XIth Cranial Nerve

General Characteristics

1. Anatomy:
 - a. The XIth cranial nerve arises from the medulla, the internal ramus and from the cervical spinal cord, the external ramus
 - b. The cranial component arises from the caudal part of the nucleus ambiguus and exits the medulla laterally below the vagal roots
 - c. The external ramus or spinal component of the nerve arises from the first to sixth cervical segments of the dorsal lateral ventral horn. Cord segments C1 and C2 innervate the ipsilateral sternocleidomastoid muscle while the C3–C6 segments innervate the ipsilateral trapezius muscle
 - d. The cranial part of the nerve (origin is in the N ambiguous) supplies the pharynx and larynx
 - e. The cranial and spinal components of the nerve unite and exit the skull through the jugular foramen
 - f. The internal ramus (cranial portion) branches off to join the vagus and innervate the pharynx and larynx
 - g. The external ramus (spinal component) lies between the internal carotid artery and the jugular vein and in-

Clinical Manifestations

1. Weakness of the SCM or trapezius:
 - a. The usual lesions are of the spinal accessory nerve distal to its bifurcation
 - b. SCM and trapezius weakness of the same site:
 - i. A contralateral brainstem lesion
 - ii. An ipsilateral high cervical cord lesion that interrupts the second decussation from the pons
 - iii. A proximal accessory nerve lesion
 - c. SCM weakness with spared trapezius muscle function:
 - i. A lesion of the dorsal brainstem tegmentum (SCM is represented dorsally in the tegmentum)
 - ii. Lesions of the upper anterior cervical roots affect the SCM while C3 and C4 innervate the trapezius muscle
 - d. Nuclear lesions of XIth:

- i. Atrophy, weakness and fasciculation of the affected SCM and trapezius muscles

Neuropathology

1. Nuclear lesions are caused by:
 - a. Astrocytoma
 - b. Metastatic lesions
 - c. AVM or cavernous hemangioma
 - d. Syringobulbia
2. Lesions within the skull and the foramen magnum:
 - a. Syndromic associations:
 - i. Vernet's syndrome at the jugular foramen:
 1. Tumor
 2. Fracture
 3. Infection
 - b. Schmidt's syndrome (Xth and XIth)
 - c. Collet-Sicard (IXth, Xth, XIth, XIIth):
 - i. Retroparotid or retropharyngeal space:
 1. Infection
 2. Tumor
 - d. Garcin's syndrome:
 - i. All cranial nerves may be affected on one side:
 1. Tumor (lymphoma, leukemia)
 2. Following chemotherapy
 3. Diabetes mellitus
3. Lesions that affect the XIth nerve within the neck and shoulders:
 - a. Posterior triangle surgery (usually lymph node biopsy)
 - b. Internal jugular vein catheterization
 - c. Blunt trauma to the neck or shoulder
 - d. Radiation therapy (myokymia; hypertrophy)
 - e. Dislocation of the shoulder
 - f. Brachial plexus traction injury with an associated brachial plexus injury
 - g. Partial hanging:
 - i. Suicide attempt
 - h. Aberrant vessel:
 - i. Causes cervical dystonia from pressure on the nerve
 - i. Cervical cord tumor
4. Tumors:
 - a. Meningioma
 - b. Schwannoma
 - c. Chordoma (at the jugular foramen)
 - d. Glomus jugulare
 - e. Base of the skull metastases
 - f. Cervical syrinx with astrocytoma
 - g. Hemangioblastoma with a cervical syrinx
 - h. Nasopharyngeal cancer
5. Differential diagnosis of neck extensor weakness:
 - a. MG
 - b. Motor neuron disease:
 - i. Dropped head syndrome
 - ii. Polymyositis/dermatomyositis (usually the flexors are much weaker than the extensors)

Cranial Nerve XII

General Characteristics

1. Anatomy:
 - a. The hypoglossal nerve is the motor nerve of the tongue
 - b. Its origin is from a longitudinal column of neurons that extend in the paramedial medulla, beneath the hypoglossal trigone of the floor of the IVth ventricle, from the caudal medulla to the medullary pontine formation
 - c. There are two discrete axon bundles intracranially that join after the nerve exits the skull through the hypoglossal canal
 - d. The nerve passes over the internal and external carotid artery and lies beneath the digastric, stylohyoid and mylohyoid muscles
 - e. Muscular or lingual branches supply the intrinsic tongue muscles and the extrinsic hypoglossus, styloglossus, genioglossus and geniohyoid muscles
 - f. A descending hypoglossal ramus forms the ansa hypoglossi in the neck:
 - i. Fibers from C1–C3 cervical roots are associated
 - ii. The ansa hypoglossi innervates the infrahyoid, sternohyoid, omohyoid, sternothyroid, thyrohyoid and geniohyoid muscles
 - g. Corticobulbar fibers that innervate the genioglossus are crossed: the other tongue muscles have bilateral supranuclear innervation
 - h. The lateral movements of the non-protruded tongue are executed by intrinsic muscles. The patient cannot turn the tip of the tongue to the affected side

Clinical Manifestations

1. Abnormal tongue movements:
 - a. Oral buccal lingual dyskinesia
 - b. Athetosis
 - c. Palatal myoclonus (with associated tongue movement)
 - d. Trombone tongue (moves rhythmically in and out; usually from syphilis)
 - e. Galloping tongue:
 - i. Putative pontine lesion
 - ii. Episodic
 - iii. Rhythmic
 - iv. Involuntary
 - v. May spread to the head and neck
 - vi. Starts posteriorly in the midline
 - vii. Three per second waves
 - viii. Focal tongue contractions
 - ix. Continuous lingual myoclonus after head injury
 - f. Glossodynia:
 - i. Burning pain of the tongue and oral mucosa
 - ii. Occurs in middle aged and elderly patients

- g. Macroglossia:
 - i. Cerebral gigantism
 - ii. Syndromic
 - iii. Primary amyloidosis
 - iv. Acromegaly
 - v. Hypothyroidism
 - vi. Mucopolysaccharidosis

Neuropathology

1. Vascular disease:
 - a. Medial medullary syndrome (Dejerine's):
 - i. Infarction of the vertebral or anterior spinal artery
 - ii. Ipsilateral XIIth paresis (atrophy and fasciculations)
 - iii. Contralateral hemiplegia
 - iv. Contralateral loss of lemniscal sensation (proprioception and vibration sensibility)
 - v. May occur bilaterally (quadriplegia with facial sparing):
 1. Bilateral lower motor neuron tongue paralysis
 2. Loss of lemniscal sensation of all extremities
 3. The tongue may occasionally be spared in the anterior spinal artery syndrome
 - b. Rare XIIth nerve involvement from vertebral artery ectasia due to prolonged severe hypertension
 - c. AVM, cavernous hemangioma or telangiectasia
 - d. Carotid artery dissection with pseudoaneurysm that compresses the nerve in the neck
 - e. Dolichoectasia of the vertebral artery in the medulla
2. Trauma:
 - a. Blunt head traumas with fractures through the hypoglossal canal in the foramen magnum
 - b. Penetrating neck wounds:
 - i. Pseudoaneurysms of the cervical carotid artery
 - ii. Fistula of the carotid artery
 - c. Dental operative procedures
 - d. Subluxation of the odontoid process:
 - i. Rheumatoid arthritis
 - ii. Severe flexion injury of the neck
 - iii. Tearing of the alar and cruciate ligaments
 - e. Surgical neck trauma
3. Tumors Involving the XIIth Nerve:
 - a. Retroparotid tumors
 - b. Retropharyngeal tumors
 - c. Adenocarcinoma of the salivary gland
 - d. Squamous cell carcinoma of the tongue
 - e. Metastatic tumors (bronchial, thyroid and esophageal)
 - f. Hodgkin's and non-Hodgkin's lymphoma
 - g. Leukemia
 - h. Meningioma of the foramen magnum
 - i. Tumor of the occipital condyle:
 - i. Metastases to the posterior occipital condyle
 - ii. Ipsilateral XIIth nerve involvement

- iii. Mediastinal tumors
 - j. Metastasis to the ansa hypoglossi and cervical plexus:
 - i. Numb tongue-neck syndrome:
 1. Cervical plexus (C2–C4) involvement
 2. Vth neck mandibular branch involvement
4. Anterior horn cell peripheral nerve involvement:
 - a. Kennedy's disease
 - b. Bulbar ALS
 - c. Motor neuron disease
 - d. Myasthenia gravis
 - e. Lambert-Eaton syndrome
 - f. Diphtheritic neuropathy
 - g. AIDP
 - h. CIPD
 - i. EBV (infectious mononucleosis)
 - j. Polio
 - k. X-RT
 1. Machado-Joseph disease (Facial and lingual fasciculations)
 - m. Tongue fibrillations:
 - i. Motor neuron disease
 - ii. Hyperthyroidism
 - iii. Hyperparathyroidism
5. Intraparenchymal Lesions affecting the XIIth Nerve:
 - a. Syring (syringobulbia)
 - b. Tumor
 - c. Demyelinating disease
 - d. Autoimmune diseases
 - e. Paraneoplastic syndromes
 - f. Infections (rhombencephalitis)

Differential Diagnosis of Multiple Cranial Neuropathies

1. Neuromuscular Junction disease:
 - a. MG/Lambert-Eaton syndrome
 - b. Tetanus
 - c. Botulism
 - d. Snake envenomation
2. Autoimmune cranial neuropathies:
 - a. AIDP
 - b. CIDP
 - c. CM Fisher Variant of GBS (GD1b; GQ1b epitopes)
 - d. Descending AIDP (cervical-pharyngeal variant)
3. Tumor:
 - a. Carcinomatosis of the meninges
 - b. Leukemia
 - c. Lymphoma (Hodgkin's and non-Hodgkin's)
 - d. Garcin's syndrome:
 - i. All cranial nerves are involved on one side
 - ii. Nasopharyngeal cancer
 - e. Nasopharyngeal cancer (spread along the clivus)
 - f. Adenoid cystic carcinoma of the salivary gland ("sugar coats the nerves")
 - g. Cylindroma of the parotid gland

- h. Chromophobe adenoma:
 - i. Bilateral CN palsy with visual field loss
- i. Glomus jugulare or tympanicum tumors
- j. Melanoma (metastatic to the cranial nerves)
- k. Pinealoma (CSF pathways with metastases to the nerves)
- l. Cerebellopontine angle mass or tumor (compression of adjacent nerves)
- m. Retroparotid or retropharyngeal tumors (IXth, Xth, XIth, and XIIth are affected)
- n. Mucoepidermoid cancer
- 4. Vascular disease:
 - a. Intraparenchymal syndromes
 - b. Occlusion of the peripheral blood supply:
 - i. Inferolateral branch of the external carotid artery (IIIrd, IVth, VIth)
 - ii. Ascending pharyngeal artery (IXth, Xth, XIth), arises from the arch of the aorta
 - iii. Internal maxillary artery (Vth and VIIth)
 - iv. Carotid dissection in the neck (IXth, Xth, XIIth)
 - v. Chemotherapy:
 - 1. Internal carotid artery infusion with cisplatinum (IIIrd–VIth)
 - 2. External carotid artery infusion with cisplatinum (Vth–VIIth)
 - 3. Garcin's syndrome:
 - a. Nasopharyngeal cancer in conjunction with chemotherapy (all cranial nerves are affected on one side)
 - 4. Vincristine/Vinblastine (sympathetic and parasympathetic supply of the cranial nerves are affected)
 - vi. Infectious disease:
 - 1. Mycobacterium pneumonia
 - 2. Bartonella henselae (cat-scratch fever)
 - 3. Tuberculosis meningitis
 - 4. Cysticercosis
 - 5. Deep fungal meningitides:
 - a. Histoplasmosis
 - b. Cryptococcosis
 - c. Coccidiomycosis
 - 6. Chagas disease (trypanosoma cruzi)
 - 7. Syphilis
 - 8. Lyme's disease (Borrelia burgdorferi)
 - 9. Pseudomonas aeruginosa (malignant external otitis)
 - vii. Bone disease:
 - 1. Paget's disease
 - 2. Osteogenesis imperfecta
 - 3. Hyperostosis and osteosclerosis
 - 4. South African sclerostenosis
 - 5. Congenitally small posterior fossa and internal auditory canal
 - 6. Fibrous dysplasia
 - viii. Systemic disease:

- 1. Familial primary amyloidosis
- 2. Tolosa-Hunt syndrome (cavernous sinus involvement of IIIrd, IVth, VIth and first division of Vth)
- 3. Diabetes mellitus

Congenital Abnormalities of the Brainstem

- 1. Craniocervical junction abnormalities:
 - a. General characteristics:
 - i. The craniocervical congenital abnormalities include those of the occipital bone, the foramen magnum and the first two cervical vertebrae
 - ii. Clinical manifestations are:
 - 1. Neck Pain
 - 2. Syringomyelia
 - 3. Cerebellar deficits
 - 4. Lower cranial nerve palsy
 - 5. Spinal cord deficits
 - 6. Vertebrobasilar ischemia
 - iii. Neuropathology:
 - 1. Fusion of the atlas (C1) and the occipital bone:
 - a. The occipital cervical synostosis can be complete or incomplete; the complete synostosis is more frequent
 - 2. Multiple variations of partial assimilation involve any aspect of the atlanto-occipital articulation
 - 3. The anomaly is due to defective segmentation and separation of the most caudal sclerotome during the fourth week of gestation
 - 4. Most often the fusion occurs between the anterior atlas and the anterior margin of the foramen magnum
 - 5. Associated conditions include:
 - a. Spina bifida of the atlas
 - b. Occipital vertebra
 - c. Basilar invagination
 - d. Klippel-Feil syndrome
 - e. Arnold-Chiari syndrome

Clinical Manifestations

- 1. Spinal cord compression may occur if the center to posterior diameter of the foramen magnum behind the odontoid process is <19 mm, the normal is 28–38 (sagittal) and 25–40 mm in the transverse plane
- 2. Symptoms usually develop in the second decade of life
- 3. Spinal cord compression:
 - a. Neck pain and an abnormal head posture
 - b. Lower cranial nerve palsies with dysphagia and dysarthria
 - c. Long tract motor and sensory signs
 - d. Effects of vertebral artery compression

Basilar Invagination*General Characteristics*

1. Recent craniometric studies suggest that Chiari malformation and basilar invagination belong to a spectrum of malformations
2. The common characteristics of these malformations are:
 - a. Underdevelopment of the occipital bone
 - b. Cerebrospinal fluid and neural compression at the craniocervical junction
 - c. Basilar invagination type:
 - i. The tip of the odontoid process is within the foramen magnum
 - ii. Associated with craniovertebral instability
 - iii. In basilar invagination type II the dens is oriented towards the base of the skull and not toward the foramen magnum
 - iv. Basilar invagination may be primary from a congenital or developmental anomaly or secondary from bony softening and remodeling
 - d. Chamberlain's line:
 - i. Drawn from the back of the hard palate to the posterior lip of the foramen magnum
 - ii. The Chamberlain line violation (the most common method to identify BI, type I) varies between 1 and 6.6 mm
 - e. Basilar invagination has also been defined as upward bulging of the occipital condyles

Clinical Manifestations

1. A short neck
2. Compression of the ventral brainstem, lower cranial nerves and upper spinal cord with appropriate symptomatology
3. Axial cranial dislocation or instability may be the primary cause of all types of basilar invagination. Its clinical manifestations include:
 - a. Short neck with a low hairline
 - b. Web-shaped neck muscles
 - c. Torticollis
 - d. Decreased range of motion of the neck
 - e. Associated with bone fusion abnormalities
 - f. Instability of the atlantoaxial function is suggested by neck pain, spasm and restriction of neck movement. The instability is manifested by alteration of the alignment of the facets

Acute Basilar Invagination

1. Type A where the odontoid migrates superiorly and posteriorly that compresses the brain stem
 - a. Occurs in younger patients
 - b. Clinical symptoms are acute and severe
 - c. Other neural malformations are not prominent
 - d. There is progressive slippage of the facet of the atlas over the axis (similar to spondylosis thesis of the lumbosacral cord)

- e. Chronic atlantoaxial subluxation
 - i. Chronic spinal cord compression

Klippel-Feil Malformation*General Characteristics*

1. There is fusion of the upper cervical vertebrae of the atlas to the occipital bone
2. It is putatively caused by faulty segmentation of cervical vertebrae
3. It is often associated with Platybasia
4. General associations:
 - a. Sprengel's deformity
 - b. Renal agenesis
 - c. Aortic and cardiac anomalies
 - d. Sensorineural hearing loss
 - e. Cervical cord dysraphism
 - f. Diastematomyelia
 - g. Chiari malformations

Clinical Manifestations

1. The associated neurologic malformations may be responsible for the neurologic feature of the disorder
2. There is hypermobility of the adjacent unfused segments of the cervical spinal cord with degenerative changes
3. Patients may have a smaller cross-sectional spinal cord area
4. C2–C3 are the most common congenital fusion levels followed by C3–C4
5. A significant proportion of patients are asymptomatic

Platybasia*General Considerations*

1. Is a flattening of the skull base in which the angle formed by the intersection of the clivus and the plane of the anterior fossa is greater than 135°

Clinical Manifestations

1. May be asymptomatic
2. Platybasia increases the depth of the velopharynx
3. Associated with the 22q11.2 deletion syndrome
4. May cause enlargement of the nasopharyngeal space with decreased velopharyngeal closure

Abnormalities of the Odontoid Process*General Characteristics*

1. Congenital atlantoaxial dislocation (the atlas has slipped forward in relation to the axis)
2. In Morquio syndrome:
 - a. There is absence or severe hypoplasia of the odontoid process
 - b. In conjunction with laxity or redundancy of the cruciate, alar and apex ligament cause atlantoaxial subluxation
 - c. Spinal cord compression ensues with spastic quadriplegia

Chiari Malformations

General Characteristics

1. There are four types of Chiari malformation:
 - a. Type I:
 - i. Is the most common form of the malformation
 - ii. An extension of the cerebellar tonsils into the foramen magnum
 - b. Type II:
 - i. There is extension of both the cerebellar tonsils and a component of the brainstem into the foramen magnum
 - ii. The cerebellar veins may be partially absent
 - iii. Type II is often accompanied by a myelomeningocele and syrinx
 - iv. The medulla and pons are elongated and there may be a narrow aqueduct
 - c. Type III:
 - i. The cerebellum and brainstem protrude through the foramen magnum into the spinal cord
 - ii. An occipital encephalocele may be associated
 - d. Type IV:
 - i. Cerebellar hypoplasia in association with the other deficits
2. Associated neurologic features:
 - a. Meningomyelocele of the cervical cord
 - b. Syringomyelia of the cervical cord
 - c. Polymicrogyria
 - d. A tethered cord

Clinical Manifestations

1. Type I (without meningocele):
 - a. Symptoms may not develop until adolescence or adulthood
 - b. Headache that is exacerbated by any valsalva maneuver; C2 pain
 - c. Cerebellar ataxia
 - d. Spastic quadripareisis
 - e. Downbeating nystagmus
 - f. Signs and symptoms of an associated syringomyelia:
 - i. Segmental wasting
 - ii. Loss of pain and temperature sensibility of the hands
 - iii. Charcot joint of the shoulder
 - iv. Short neck
2. Type II (childhood):
 - a. Hydrocephalus
 - b. Lower cervical nerve involvement
 - c. Fasciculations of the tongue
 - d. Weakness of the sternocleidomastoid muscle with a consequent head lag and weakness of head
 - e. Bilateral VIth nerve palsy
 - f. Deafness

These patients may also have both basilar invagination and atlantoaxial instability and often develop scoliosis

Syringobulbia

1. Associated with Chiari I malformations as well as:
 - a. Thoracic scoliosis
 - b. Klippel-Feil anomaly
 - c. Platybasia
 - d. Basilar invagination
2. Clinical manifestations:
 - a. Depends on associated anomalies
 - b. Chiari associated developmental syrinx is associated with:
 - i. Symptoms often begin in early adult life
 - ii. The onset is often insidious and the cause may be irregularly progressive
 - iii. There can be an acute onset triggered by valsalva maneuvers
 - iv. Segmented weakness and atrophy of the hands and arms
 - v. Asymmetric loss of reflexes in the upper extremities
 - vi. Loss of pain and temperature sensibility in a "shawl" distribution of the neck, shoulders and arms. The sense of touch is preserved; with progression there is weakness and ataxia of the legs
 - vii. Associated kyphoscoliosis
 - viii. Rarely the dissociated sensory loss may be the only manifestation
 - ix. Rarely in patients with the Chiari I type malformation, the reflexes are retained and may be exaggerated in the upper and lower extremities
 - x. A Horner's syndrome may occur if the syrinx extends to involve the intermediolateral column at C8-T1
 - xi. Severe central pain develops in approximately 50% of patients

Brainstem Tumors in Adults

Diffuse Intrinsic Brainstem Glioma in Adults

1. General characteristics:
 - a. Account for 12% of adult gliomas
 - b. Molecular analysis (gain or loss of function):
 - i. Increased chromosome 1q gain, 9q gain and 11q loss compared to supratentorial high grade gliomas
 - ii. Histone gene mutations are frequent
2. Clinical manifestations:
 - a. Median survival is approximately 32 months
 - b. Several patterns of signs and symptoms:
 - i. Diffuse intrinsic low grade tumors
 1. Young adults
 2. Long clinical history
 3. Diffusely enlarged brainstem on MRI without contrast enhancement
 - c. Anaplastic transformation (appearance of contrast enhancement) and progressive growth

Malignant Glioma

1. Occur in elderly patients
2. Short clinical history
3. Contrast enhancement and necrosis is common on MRI
4. Median survival of 11.2 months

Focal Tectal Gliomas

1. Occur in less than 10% of brainstem gliomas in adults
2. Occur in young patients
3. Isolated hydrocephalus
4. Indolent course
5. Median survival of 10 years

Oligodendroglioma

1. General characteristics:
 - a. An extremely rare brainstem location in an adult patient
 - b. Deletion of chromosome 1p and/or 19q; tumors with these genetic markers have a more classic morphology
 - c. A significant percentage of low grade tumors progress to higher grade tumors
2. Clinical manifestations:
 - a. Only a few oligodendrogliomas have been described in the brainstem in adult patients
 - b. Possibly more aggressive than their supratentorial counterpart and present at an earlier age

Ependymoma

1. General characteristics:
 - a. This neoplasm is of neuroectodermal origin and arises from the neuroepithelial lining of the ventricles, central canal of the spinal cord, choroid plexus, white matter adjacent to a ventricular surface and the filum terminale
 - b. A frequent site of origin is the floor of the IVth ventricle
 - c. Posterior fossa ependymomas:
 - i. Exhibit a CpG island methylated phenotype
2. Clinical manifestations:
 - a. Symptoms of increased intracranial pressure
 - b. If there is cerebellar tonsillar herniation, a head tilt may be appreciated
 - c. The tumor may extend into the cerebellar pontine angle via the foramen of Luschka to produce facial weakness, hearing loss and dysphagia
 - d. If the tumor origin is in the area postrema or obex there may be severe nausea without other signs of increased intracranial pressure

Tumors of the Choroid Plexus**General Characteristics**

1. Comprise .4-.8% of all primary neoplasms of the brain
2. Approximately 70% of these tumors occur in childhood (children are less than 2 years of age)

3. 40% occur in the fourth ventricle; both IVth ventricle and CPA locations increase with age
4. Derive from ventricular ependymal cells
5. Genetic syndromes that predispose to the formation of choroid plexus papillomas include:
 - a. Li-Fraumeni (alterations of p 53)
 - b. Neurofibromatosis type II
 - c. Aicardi syndrome
 - d. Down syndrome
 - e. Von Hippel-Lindau disease
 - f. Germline mutations in p53 and hSNF5/IN1 (familial patients)

Clinical Manifestations

1. Hydrocephalus:
 - a. Obstruction of CSF flow or its overproduction from the papilloma
 - b. Increased intracranial pressure symptomatology:
 - c. Nausea and vomiting with IVth ventricular tumors
 - d. A new marker is 5-lipoxygenase
 - e. Papilloma may be differentiated from carcinoma by utilizing arterial spin labeling (the papilloma has much greater blood flow)

Medulloblastoma in Adults**General Characteristics**

1. These are very rare tumors in adults
2. The genetic profile in adults and children < 3 years of age includes:
 - a. Activation of the sonic hedgehog pathway
 - b. Mutations of the PTCH and SUFU genes
 - c. Loss of 9q and positivity for GLI1 and SFRP1
 - d. Commonly associated with desmoplastic histology

Clinical Manifestations

1. Present with a lateral cerebellar syndrome
2. Late relapses
3. Posterior fossa symptomatology

Neuronal and Glioneuronal Neoplasms**General Characteristics**

1. A diverse group of growths that include hamartoma-like tumors as well as cellular and locally aggressive neoplasms
2. It has been suggested that glioneuronal hamartomas and neoplasms have common precursors that diverge and differentiate separately
3. Glioneuronal tumors have these basic features:
 - a. They occur in children and young adults
 - b. They are less aggressive than the usual infiltrating astrocytoma
 - c. They have two phenotypically distinct cell populations

Gangliocytoma and Ganglioglioma

General Characteristics

1. The tumors are indolent and well circumscribed
2. They occur equally in both sexes
3. They are most common in the temporal lobe but occur throughout the neuraxis that includes:
 - a. Cerebellum
 - b. Optic chiasm
 - c. Hypothalamus
 - d. Brainstem
 - e. Spinal cord
 - f. Within the sella turcica

Clinical Manifestations

1. The most common presenting symptom is seizures
2. Focal neurologic signs and symptoms depending on location

Pineal Parenchymal Tumors

General Characteristics

1. Pineal parenchymal tumors are less common than those of germ cell origin and account for less than 1% of primitive CNS tumors
2. The WHO (World Health Organization) classifies the tumors into:
 - a. Pineocytoma (PC):
 - i. Well differentiated
 - b. Pineoblastoma:
 - i. Poorly differentiated
 - c. Mixed pineocytoma and pineoblastoma with intermediate differentiation
3. Pineocytoma:
 - a. Are slow growing pineal parenchymal neoplasms that are well differentiated

Clinical Manifestations

1. Headache, nausea and vomiting due to obstruction of the aqueduct and hydrocephalus
2. Vertical gaze paresis associated with pupillary defects and other cranial nerve paresis and hearing loss
3. Convergence spasm
4. Nystagmus retractorius
5. Late cerebellar ataxia from compression of the superior cerebellar peduncle

Meningioma

General Characteristics

1. The tumor arises from the arachnoid cap cell
2. The incidence is between 2–15 per 100,000 people and accounts for approximately 20–26% of primary intracranial neoplasms
3. Approximately 2% of benign meningiomas transform into malignant forms

4. Progression from benign to atypical forms is associated with mutations that cause losses in chromosomes 1p, 6q, 14q and 10q and gain from mutations on 1q, 9q, 12q, 5q, 17q, and 10q
5. The loss of the NF2 in chromosome 22 occurs in 40–70% of all meningiomas
6. Possibly the complete loss of merlin is the major mechanism for tumorigenesis

Clinical Manifestation

1. Depends on the location of the tumor and the compression of surrounding structures. Typical symptoms include:
 - a. Olfactory groove (Foster-Kennedy)
 - b. Optic nerve sheath (Schwalbe)
 - c. At the foramen magnum (most often severe spasticity)
 - d. The cerebellopontine angle
 - e. Sub- and dorsal frontal lobe (behavioral change)
 - f. Parasagittal (seizures, precipitate micturition)
 - g. Compression of cranial nerves
 - h. Parasellar
 - i. Planum sphenoidale
 - j. Intraventricular
 - k. En plaque (on the cortex)

Craniopharyngioma

General Characteristics

1. Benign epithelial neoplasms in the sellar area
2. Arise from the embryonic squamous cells of the hypophyseal duct
3. They have a bimodal age distribution; age 5–10 years and a second peak between 50 and 60 years
4. The adamantinomatous subtype affects children and the papillary form is seen in adults
5. Both types arise from Rathke's cleft
6. A subset of tumors has increased expression of insulin-like growth factor while approximately 30% express estrogen and progesterone receptors. Elevated beta human chorionic gonadotrophins levels are seen in the CFS

Clinical Manifestations

1. Symptoms of increased intracranial pressure
2. Hydrocephalus
3. Compression of the optic chiasm
4. Headache
5. Visual symptoms occur in 80% of adult patients
6. See-saw nystagmus occurs in 5–20% of patients
7. Endocrine Dysfunction:
 - a. Children present with short stature and delayed linear growth
 - b. Adolescents may have delayed or arrested puberty
 - c. Men have a loss of libido and women have secondary amenorrhea
 - d. Endocrine deficits include: 1. GH loss (75%); 2. luteinizing hormone or follicle stimulating hormone (40%); ACTH decrease (24%) and TSH (25%)

- e. Hyperprolactinemia occurs in 20% due to:
 - 1. Hypothalamic involvement
 - 2. Pituitary stalk compression
- f. Diabetes insipidus occurs in between 9% to 12% of patients:
 - i. Behavioral abnormalities:
 - 1. Mental status changes occur in approximately 25% of adults most often from tumor growth into the frontal lobes
 - 2. Tumor extension into the temporal lobe causes complex partial seizures or if it extends into the hippocampus memory deficits

Pituitary Adenoma

General Characteristics

- 1. Benign adenomas of the pituitary gland account for approximately 10% of operated intracranial tumors
- 2. Microadenomas are less than 10 mm in diameter

Clinical Manifestations

- 1. Visual field deficits, the most common of which is heteronymous superior quadrantic hemianopsia
- 2. The most common subtypes of adenomas are prolactinomas and non-functional tumors:
 - a. Prolactinomas may present with hypogonadism and galactorrhea
- 3. Chromophobe adenomas compress hormone-secreting cells and failure appears first in LH then thyroid and last adrenocortical levels
- 4. Pituitary apoplexy causes:
 - a. Sudden infrabrow headache
 - b. Visual field deficit
 - c. Cranial nerve III or VI dysfunction
 - d. MRI has demonstrated that the clinical sequelae are not as devastating as once thought

Vascular Disease

See: Headache of Idiopathic Intracranial Hypertension (IIH)

Demyelinating Disease

Multiple Sclerosis

General Characteristics

- 1. The current view is that multiple sclerosis is an inflammatory demyelinating disease of the central nervous system. The areas of the CNS particularly prone to demyelination are the optic nerve, spinal cord, periventricular white matter and subpial gray matter
- 2. There are three major clinical patterns of MS:
 - a. Relapsing remitting
 - b. Secondary progressive

c. Primary progressive

- 3. Approximately 85% of patients are initially relapsing remitting with episodes of neurologic deficit that alternates with periods of recovery. In 20–25 years of this pattern 60–70% of RRMS patients progress to a secondary progressive pattern that is manifest by progressive neurologic dysfunction. Approximately 10% of patients are primary progressive and demonstrate a relentless decline in neurologic function

Clinical Manifestations

- 1. Deficits are separate in space and time
- 2. The brainstem deficit of great significance is a unilateral or bilateral internuclear ophthalmoplegia
- 3. Almost all patients develop over time:
 - a. Some cognitive deficit
 - b. Corticospinal movement deficits
 - c. Optic atrophy
 - d. Cerebellar ataxia
 - e. Hyperactive reflexes
 - f. Sensory loss
 - g. Loss of abdominal reflexes

Neuropathology

- 1. Acute MS:
 - a. Break down of the blood-brain barrier
 - b. Multifocal inflammation
 - c. Demyelination
 - d. Reactive gliosis
 - e. Loss of oligodendrocytes
 - f. Axonal degeneration
- 2. Axonal loss in relapsing MS:
 - a. A dramatic increase of non-phosphorylated neurofilament epitopes
 - b. Transected axons occur with axonal ovoids that occur early in the disease course when inflammatory demyelination is active and continuous
 - c. Demyelinated axons are vulnerable to proteolytic enzymes, matrix metalloproteinases, cytokines, and free radicals that are released from glial and activated immune cells that also release glutamate
 - d. The transformation of RRMS to SPMS may be due to the inability of the brain to compensate for axonal loss
 - e. The pathology of chronic progressive lesions:
 - i. These lesions contain a hypocellular gliotic core and show no acute inflammation
- 3. Cortical demyelination in MS:
 - a. Cortical and deep gray matter demyelination are significant in MS
 - b. The two major types of cortical lesions in MS are leukocortical and subpial:
 - i. Axonal and dendritic transection are prominent in the cortical portion of active leukocortical lesions
 - ii. Subpial cortical lesions are the major component of cortical lesion load; they demonstrate myelin loss in layers 1–4 and may span several gyri

- iii. B-cell follicles in deep sulci may be essential in inducing subpial demyelination
- iv. Subpial lesions are abundant in both primary progressive and SPMS and rare in acute MS or RRMS
- v. B-cell follicles may lead to an increase in meningeal infiltrates that activate microglia which may accelerate disease progression

Laboratory Evaluation

1. Prominence of CSF IgG and Oligoclonal bands

Neuroimaging

1. The utilization of 7 Tesla MRI has demonstrated that demyelination in plaques surround veins
2. White matter demyelinating lesions may be seen throughout the CNS but are particularly prominent in the:
 - a. Optic nerve
 - b. Corpus callosum (Dawson's fingers)
 - c. Periventricularly
 - d. Spinal cord

Acute Disseminated Encephalomyelitis

General Characteristics

1. In general, ADEM is an immune-mediated inflammatory disorder of the CNS of children. It can be seen in adolescence and early adulthood:
 - a. The illness most often follows infection and rarely occurs after vaccination
 - b. It is most often transitory and self-limiting

Clinical Manifestations

1. Encephalopathy and focal neurological deficits 1–3 weeks after a viral illness
2. Neurologic deficits progress rapidly
3. Possibly 25% of patients develop MS within 5 years after the initial presentation
4. Confusion and headache are often prominent

Neuropathology

1. Immune-mediated inflammatory demyelinating disease of the brain and spinal cord

Laboratory Evaluation

1. MRI Evaluation:
 - a. T2/FLAIR sequence demonstrates diffuse, ill-defined, systemic irregular and patchy areas of homogeneous signal hypersensitivity
 - b. Involves both gray and white matter
 - c. All lesions appear to be of the same age
 - d. Approximately 50% involve infratentorial structures and 30% the spinal cord
2. The CSF may demonstrate increased IgG and Oligoclonal bands

Devic's Disease (Neuromyelitis Optica)

General Characteristics

1. Neuromyelitis optica is an immune-mediated chronic inflammatory disease of the CNS
2. Its prevalence is 1–4.4/100,000 people in the western world
3. Diagnostic criteria include:
 - a. One episode of optic neuritis and one episode of myelitis with two of the three supporting features:
 - i. Contiguous spinal cord MRI lesion that extends at least 3 or more vertebral segments
 - ii. Brain MRI that meets the diagnostic criteria for MS at onset
 - iii. NMO-IgG seropositive antibodies

Clinical Manifestations

1. The optic neuritis is more severe than in MS, the lesions are longer and recovery of vision is poor
2. AQP4-Ab may be seen in isolated LETM, recurrent or isolated optic neuritis and in brainstem encephalitis (in the diencephalon or the medulla)
3. Brainstem manifestation includes:
 - a. Intractable hiccups or vomiting
 - b. Narcolepsy
 - c. Neuroendocrine dysfunction
 - d. Posterior reversible encephalopathy (PRES)
4. In a significant number of patients simultaneous bilateral myelitis and bilateral optic neuritis manifests seriatim
5. Brainstem symptoms, neuropathic pain and painful tonic spasms are more frequent than in MS

Neuropathology

1. Inflammatory demyelination
2. AQP4-Ab directed against glial endfeet

Laboratory Evaluation

1. Serum AQP4 antibodies
 - a. Brainstem encephalitis presentations are less frequently positive as are patients who present with isolated NMO
2. A subset of patients may be AQP4-AB negative
3. Oligoclonal bands are positive in approximately 30% of patients
4. Concentration of IL-6 or its receptor may be elevated
5. Visual evoked potentials may be positive; prolonged P100 latencies occur in approximately 40% of patients and reduced amplitudes or absent potentials occur in 25%
6. MRI:
 - a. Predominantly, central spinal cord lesions extend over three or more vertebral segments. Most often, enhancing may last for months after the onset of symptoms
 - b. Enhancement may be patchy and inhomogeneous
 - c. T2/FLAIR hyperintensities are seen in 60% of patients in the cortex; often they are not oval shaped as is more typical of MS, they are often clinically silent

- d. Ultra high field MRI (7 Tesla):
 - i. NMO lesions in the brain are not characterized by central veins
 - ii. There are no cortical lesions
- e. Optical Coherence Tomography (OCT):
 - i. A single acute attack may demonstrate damage to the retinal nerve fiber layer (RNFL)

Clinically Isolated Syndrome

General Characteristics

1. Approximately 85% of patients with MS present with a single demyelinating event, a clinically isolated syndrome (CIS)

Clinical Manifestation

1. Lesions involve:
 - a. The optic nerves
 - b. Brain stem
 - c. Spinal cord

Neuropathology

1. Inflammatory demyelination
2. Axonal damage occurs in CIS

Laboratory Evaluation

1. Oligoclonal bands:
 - a. A medium impact prognostic factor for conversion to MS
- b. Chitinase 3-like 1 (in the CSF):
 - i. Has been validated on a biomarker for conversion to MS
- c. Elevated CD4/CD14 ratio:
 - i. Possibly rapid transition from CIS to multiple sclerosis
- d. MRI:
 - i. Clinically silent brain lesions are detected on MRI in 50 to 89% of patients with CIS at first clinical presentation
 - ii. 10 or more brain lesions increase the risk of conversion to MS

Acute Hemorrhagic Leukoencephalitis

General Characteristics

1. Acute hemorrhagic leukoencephalitis (Hurst's disease) is a fulminant demyelinating disease
2. Possibly a hyperacute variant of ADEM

Clinical Manifestations

1. Most patients die within one week from onset of symptoms
2. Seizures
3. Severe headache
4. Focal neurological deficits (in some patients predominantly left-sided)
5. Rapid progression to coma

Neuropathology

1. Hemorrhagic perivascular demyelination has been considered the histopathologic hallmark of acute hemorrhagic leukoencephalitis (AHL); pathology varies with the acuteness of the disease
2. Later AHL:
 - a. Perivascular demyelination; perivascular microglial foci and macrophages with myelin breakdown products
 - b. Hypertrophic reactive astrocytes may be seen in patients with a longer duration of illness; a case report demonstrates astrocytic involvement (swelling of end-feet and degeneration of processes)

Laboratory Evaluation

1. MRI:
 - a. Decreased apparent diffusion coefficient (ADC) consistent with cytotoxic edema may be present prior to blood-brain barrier disruption
 - b. Meningeal inflammation
 - c. Hemorrhages have been reported in frontal, temporal and parietal lobes (some mimicking herpes simplex infection)

Stiff Person Syndrome

General Characteristics

1. A condition of persistent and intense spasms of axial, proximal lower extremity and lumbar paraspinal muscles
2. A central origin of the process is supported by its disappearance during sleep, general anesthesia and proximal nerve block

Clinical Manifestations

1. Insidious onset usually in middle age
2. The spasms are at first intermittent and then become continuous
3. They are most acute axially and in the proximal leg muscles
4. Spasms are painful; increased by external stimuli
5. In severe disease the muscles of the face, respiration and swallowing are involved; there is no trismus which is a differential point against tetanus; eye muscles are rarely affected
6. The involved muscles may hypertrophy
7. Associated hyperlordosis
8. "Stiff limb" syndrome:
 - a. Only one limb is affected (leg)
 - b. The majority of patients have antibodies to glutamic acid decarboxylase (GAD)
 - c. In general, the disorder involves one leg and may spread to the opposite leg. The spasms and rigidity remain in the lower extremities
 - d. Jerking stiff person syndrome

Neuropathology

1. Primary autoimmune immunology

2. B-cell mediated clonal production of antibodies against presynaptic inhibitory epitopes in the enzyme glutamic acid decarboxylase

Laboratory Evaluation

1. EMG:
 - a. Continuous motor unit activity in the affected limbs
 - b. Elevated levels of anti-GAD antibodies, primarily the GAD-65 isoform are present in both the serum and CSF of 60–80% of SPS patients

Paraneoplastic Variant

General Characteristics

1. The paraneoplastic variant has a different clinical and antibody profile from other variants and the classic form of SPS

Clinical Manifestations

1. Predominantly or exclusively female patients
2. Mean age of 60 years
3. Account for approximately 5% of SPS patients
4. Patients are older than classic SPS patients
5. There is no associated diabetes
6. Cervical muscle involvement
7. May improve with cancer therapy
8. Sudden death from unexplained metabolic acidosis or autonomic mechanisms

Neuropathology

1. Underlying breast cancer
2. Interruption of inhibitory spinal circuits

Laboratory Evaluation

1. Antibodies to amphiphysin in the serum and CSF
2. EMG:
 - a. Continuous muscle unit activity

Progressive Encephalomyelitis with Rigidity and Myoclonus (PERM)

General Characteristics

1. A series of patients with PERM have been identified with glycine receptor (GlyR antibodies in the absence of GAD antibodies)
2. GlyR antibodies have also been identified in saccadic oscillations that include ocular flutter or opsoclonus and opsoclonus myoclonus hyperekplexia

Clinical Manifestations

1. Generalized increased stiffness
2. Brainstem signs
3. Trismus
4. Myoclonus
5. Spasms
6. Hyperekplexia

Neuropathology

1. Antibody (primarily to the glycine receptors) in brainstem nuclei and spinal cord inhibitory interneurons

Laboratory Evaluation

1. Antiglycine receptor (anti-GlyR) antibodies are detected primarily in PERM
2. A significant percentage have GA1 (anti-asialo-GM1) antibodies as well
3. Associated diseases include:
 - a. Thyroiditis
 - b. Diabetes mellitus
 - c. Thymoma and Addison's disease
 - d. Continuous muscle fiber activity

Differential Diagnosis of Stiff Person Syndrome

1. Tetanus
2. Isaacs' syndrome
3. Subacute Myoclonic spinal neuronitis

Central Pontine Myelinolysis (CPM)

General Characteristics

1. Osmotic myelinolysis is an acute demyelinating process most often confined to the central pons after too rapid correction of hyponatremia; extrapontine myelinolysis occurs

Clinical Manifestations

1. The disorder affects males and females equally, may be seen at any age
2. Approximately 50% of patients have been reported in the late stages of chronic alcoholism often associated with Wernicke's syndrome
3. In children it has frequently been reported in burn patients
4. Small lesions may be asymptomatic (2–3 mm)
5. Other patients may be in coma from metabolic or other causes
6. The classic patient with a large ventral pontine lesion demonstrates:
 - a. A flaccid paralysis of all extremities
 - b. Bulbar involvement with inability to chew, swallow or speak
 - c. Pupillary reflexes, extraocular movement, and facial sensation may be spared
 - d. Some patients may demonstrate nystagmus and failure of conjugate horizontal gaze
 - e. If patients survive, there is spasticity of the extremities and hyperactive reflexes
 - f. Some patients may recover but are left mute and paralyzed but with intact sensation and comprehension
 - g. Rarely patients may have confusion and stupor without signs of corticobulbar or pseudobulbar palsy

Neuropathology

1. There is a rim of intact myelin between the lesion and the surface of the pons

2. The lesion may extend posteriorly to the medial lemniscus and tegmental structures; rarely it may involve the midbrain but does not extend to the medulla
3. Extrapontine myelinolysis may involve the:
 - a. Internal capsule
 - b. Deep cerebral white matter
 - c. Corpus callosum
4. Destruction of myelin sheaths is the fundamental lesion
5. Rarely there are symmetric lesions in the thalamus, subthalamic nucleus, striatum, amygdala, lateral geniculate body and white matter of the cerebellar folia
6. Destruction of myelinated sheaths is initiated in the central pons
7. There is reactive gliosis but no sign of inflammation
8. Associated conditions include:
 - a. Marchiafava-Bignami disease
 - b. Chronic alcoholism
 - c. Severe immunosuppressed state
9. Prior to correction, the usual initial serum sodium is between 110–130 meq/L; in general, slowly corrected hyponatremia <12 meq/dl and severe hyponatremia does not cause the syndrome
10. In severely burned patients, hyponatremia was not prominent and it has been suggested that the disorder is one of rapidly rising osmolarity
 1. Upright posture and controls muscles of the trunk
 2. Important for sitting, standing and walking
2. The globosus and emboliformis nuclei:
 - a. Involved with segmental reflexes that control stability
 - b. Important for initiation of movement derived from somatosensory input (proprioception)
 - c. Stabilizes proximal joints that facilitate pyramidal movement (fractionated fine movements of the fingers)
 - d. Lesions cause:
 - i. Delayed check
 - ii. Truncal titubation
 - iii. Oscillation of the extremities (when held outstretched)
 - e. Facilitate the control of oscillations during the last 1/3 of movement
3. The dentate nucleus:
 - a. Important for the facility of fine movement by promoting their initiation, coordinating extensor and flexor musculature at multiple joints, and controlling the spatial coordination of hand and finger movements
 - b. Lesions of the nucleus and its connections cause postural kinetic tremor (rubral tremor). This tremor is distinguished by its increase of amplitude of oscillation that occurs at right angles to the line of movement

Cerebellum Diseases

Overview

1. The cerebellum is parcellated both anatomically and functionally into specific zones:
 - a. The archicerebellum consists of the flocculonodular lobe; it has major connections with the vestibular system and is important for control of eye movements
 - b. The paleocerebellum is composed of the vermis of the anterior lobe (lobules I–V) as well as the pyramid, uvula and paraflocculus. Most of its afferents are from the spinal cord. Its major functional role involves muscle tone and control of axial and limb movements
 - c. The neocerebellum comprises the middle vermis and the cerebellar hemispheres
 - d. The cerebellar cortex is divided into longitudinal zones that project to specific deep nuclei
 - i. The vermal zone projects to the fastigial nucleus
 - ii. The intermediate zone projects to the nucleus globosus and emboliformis
 - iii. The lateral zone projects to the dentate nucleus
 - e. The somatotopic representation within each nucleus is:
 - i. Caudal body parts are anterior; rostral parts posterior; the trunk is lateral and the limbs are medial
 - f. Functional anatomy of the nuclei:
 - i. Fastigial nucleus:
 1. Inferior cerebellar peduncle: this cerebellar peduncle is known as the restiform body and is most often clinically involved by vertebral artery and PICA strokes, as well as compression by tumors and inflammatory demyelination in autoimmune processes
 - a. It is comprised of:
 - i. The dorsal spinal cerebellar tract which carries proprioceptive and exteroceptive information from the lower extremity and trunk. Cervical spondylosis and spinal cord compressive disease, as well as the reviewed acquired and congenital diseases of the cervical cord affect this pathway. No patient with significant cervical stenosis from any cause can tandem walk well. It takes origin from Clarke's column of the spinal cord
 - ii. The cuneocerebellar tract that arises from the external arcuate nucleus and relays proprioceptive information from the arm and neck
 - iii. The vestibular cerebellar tract projects bilaterally to the flocculonodular lobe. A cause of cervically induced nystagmus
 - iv. The reticulocerebellar tracts from the lateral and paramedian nuclei of the brainstem are important for tone and cerebellar influences on segmental reflexes
 - v. The arcuate cerebellar tract that arises from the medullary arcuate nuclei

The Afferent and Efferent Cerebellar Pathways of Clinical Relevance

1. Inferior cerebellar peduncle: this cerebellar peduncle is known as the restiform body and is most often clinically involved by vertebral artery and PICA strokes, as well as compression by tumors and inflammatory demyelination in autoimmune processes
 - a. It is comprised of:
 - i. The dorsal spinal cerebellar tract which carries proprioceptive and exteroceptive information from the lower extremity and trunk. Cervical spondylosis and spinal cord compressive disease, as well as the reviewed acquired and congenital diseases of the cervical cord affect this pathway. No patient with significant cervical stenosis from any cause can tandem walk well. It takes origin from Clarke's column of the spinal cord
 - ii. The cuneocerebellar tract that arises from the external arcuate nucleus and relays proprioceptive information from the arm and neck
 - iii. The vestibular cerebellar tract projects bilaterally to the flocculonodular lobe. A cause of cervically induced nystagmus
 - iv. The reticulocerebellar tracts from the lateral and paramedian nuclei of the brainstem are important for tone and cerebellar influences on segmental reflexes
 - v. The arcuate cerebellar tract that arises from the medullary arcuate nuclei

- vi. The trigeminocerebellar tract which originates in the spinal and main sensory nuclei of cranial nerve V. This nucleus is important for migraine, head pain and facial reflexes (trigeminal reflexes i.e. light causing cough)
- vii. Olivocerebellar tract which carries afferents for somatic modalities from the contralateral inferior olivary nucleus
- viii. Efferent tracts in the inferior cerebellar peduncle
 - 1. Fastigobulbar tract and cerebellar reticular efferents

The Middle Cerebellar Peduncle (The Brachium Pontis)

Connects the cerebellum to the pons. Corticospinal fibers synapse in the pontine gray nuclei, project to the intermediate zone of the cerebellum and then to the cerebellar area of the ventrolateral nucleus of the thalamus. These afferents project to area 3b (of S1) of the somatosensory cortex and then to area 4 of the primary motor cortex.

Lesions of this distributed pathway cause Bruns' ataxia, that demonstrates specific signs at each level of involvement.

Pontine gray lesions cause hemiparesis and ataxia of the contralateral side. Descending corticospinal fibers are responsible for the weakness and are the origin of the middle cerebellar peduncle (MCP) which projects to the intermediate zone of the cerebellum and then to the VL of the thalamus and motor cortex. Lesions are a cause of ataxia of gait.

The lateral zone cerebellar lesions cause greater ataxia of the arm than the leg as does involvement of the MCP itself. Thalamic VL lesions that involve the cerebellar radiations are notable for "ataxia of stance". Disruption of cerebellar connections from 3b of S1 to area 4 cause Bruns' frontal lobe ataxia.

The Superior Cerebellar Peduncle (SCP)

The superior cerebellar peduncle is the primary connection of the cerebellum to the midbrain. The clinically most important efferent pathways are the dentatorubral and the dentatothalamic tracts which are the anatomic basis of the postural kinetic and cerebellar outflow tremors seen with both midbrain and thalamic lesions.

Specific Anatomically Based Cerebellar Syndromes

Rostral Vermis Syndrome

1. General characteristics:
 - a. Most often seen in alcoholic patients
 - b. The anterior and superior vermis are involved (the lingula, centrales and culmen)
2. Clinical manifestations:
 - a. "Martinet" gait; broad-based with predominance of truncal extensor tone
 - b. Minimal arm ataxia
 - c. Minimal or no dysarthria and extraocular muscle impairment
 - d. No heel to shin ataxia in recumbency

Caudal Vermis Syndrome

1. General characteristics:
 - a. The primary damage is to the floccular nodular lobe
 - b. Medulloblastoma is causative in children
 - c. Posterior fossa cysts and hemorrhages, Chiari malformations are the most common etiologies in adults
2. Clinical manifestations:
 - a. Titubation
 - b. Inability to sit with a straight back
 - c. Minimal limb ataxia
 - d. Extraocular movements:
 - i. Downbeating nystagmus accentuated in lateral gaze
 - ii. Rotary nystagmus
 - iii. Hypermetric saccades (overshoot of the fixation point)

Posterior Vermal Split Syndrome

1. General characteristics:
 - a. Caused by surgical disruption of parallel fibers that cross the midline cerebellar cortex
2. Clinical manifestations:
 - a. Severe difficulty in performing tandem gait
 - b. Normal regular gait, standing and unilateral hopping

Cerebellar Hemispheric Syndrome

1. General characteristics:
 - a. Usually caused by metastases, abscesses and infarction
 - b. The muscles controlled by the precentral cortex are primarily affected
2. Clinical manifestations:
 - a. Poor fine finger movement and incoordination of the ipsilateral extremity
 - b. Dysarthria

Pancerebellar Syndrome

1. General characteristics:
 - a. Signs and symptoms of all cerebellar syndromes
 - b. Caused by autoimmune and infectious processes, hypoglycemia, paraneoplastic syndromes (anti-Yo and anti-Hu), hyperthermia, solvents, toxins, hypothyroidism and inherited disorders
2. Clinical manifestations:
 - a. Bilateral signs of cerebellar dysfunction that are both appendicular and truncal
 - b. Extraocular movements are affected

Vascular Diseases of the Cerebellum

Differential Diagnosis of Major Cerebellar Arterial Disease

1. PICA:

- a. The distinguishing features of a PICA infarction are nausea, vomiting, hoarseness, rotary nystagmus to the side of the lesion and inability to walk out of proportion to other aspects of the stroke
- b. A pure medial branch occlusion may primarily involve the nucleus ambiguus
- c. A pure lateral branch occlusion may cause isolated vertigo and dysmetria without dysarthria or vestibular signs
- d. The sensory loss is to pain and temperature of the ipsilateral face and the contralateral body below the clavicle
2. AICA Infarction:
 - a. The hallmark of an AICA occlusion is sudden hearing loss, a peripheral ipsilateral paresis (VIIIth nerve), a branch of the artery supplies the nerve peripherally and ataxia of the ipsilateral arm greater than the leg
3. The Superior Cerebellar Artery
 - a. The superior cerebellar artery is frequently infarcted by an embolus to the top of the basilar artery
 - b. The occlusion is manifest by ataxia of the ipsilateral extremities, an ipsilateral IIIrd, IVth nuclear lesion and contralateral sensory loss. In top of the basilar occlusion, there is often various degrees of midbrain, thalamic, parietal and occasionally occipital symptomology from embolic infarction of the posterior cerebral artery
 - c. If the interpeduncular artery that arises from the top of the basilar artery is involved, there is involvement of the decussation of the superior cerebellar peduncle at the level of the inferior colliculus (Wernickinck's commissure) which causes ataxia of all extremities
 - d. Rarely, patients have a contralateral IVth nerve and hearing loss (crossed fibers of the lateral lemniscus)

Oculomotor Deficits of Superior Cerebellar Artery Occlusion

1. Contrapulsion of saccadic eye movements. These complex eye movements have three major components:
 - a. Horizontal saccades away from the lesion (to the contralateral side) on upgaze, which causes an oblique rotary nystagmus
 - b. Hypermetria of contralateral saccadic movement
 - c. Hypometria of ipsilateral saccades
2. These eye movements are opposite to those seen with PICA infarction
 - a. Lateral pulsion to the side of the lesion (torsional nystagmus on attempted upgaze)
 - b. Hypometric saccades to the contralateral side
3. Lateral branch occlusion of the superior cerebellar artery signs and symptoms:
 - a. Ipsilateral extremity dysmetria
 - b. Axial lateral pulsion (ipsilaterally)
 - c. Contrapulsion of saccades
 - d. Dysarthria
 - e. Clumsy hard dysarthria syndrome
4. Medial branch superior cerebellar artery syndrome:
 - a. Dysarthria and gait abnormalities are the most prominent feature
 - b. Rarely, ipsilateral appendicular dysmetria, extensor posturing of the trunk and all extremities

Autosomal Recessive Ataxias

Overview

The autosomal recessive cerebellar ataxias are a group of inherited neurodegenerative diseases characterized by cerebellar ataxia in association with spasticity, peripheral neuropathy, seizures, optic atrophy and other neurologic deficits. More than 20 causative genes have been defined. Most have a childhood onset although there are adult onset patients. Consanguinity is higher than in the general population but is not required. The parents are asymptomatic. In small families only one child may be affected. Approximately one thousand mutations that map to 60 different loci have been identified in cerebellar ataxias. Almost 50% of patients are genetically not defined and there are differences in prevalence and the phenotypic spectrum of ataxias among geographical areas.

Friedreich's Ataxia (Classic Phenotype)

1. General characteristics:
 - a. Friedreich's ataxia is the most common recessively inherited ataxia
 - b. Most patients have a GAA repeat expansion of the first intron of the frataxin gene:
 - i. Frataxin is a nuclear encoded mitochondrial protein
 - c. The FRDA gene maps to chromosome 9q13
 - d. Long normal alleles have 25–40 repeats in Caucasian patients
 - e. 95% of patients have homozygous GAA expansions in both alleles
2. Clinical manifestations:
 - a. The onset is less than 25 years of age (mean 11–12 years)
 - b. The presentation is usually gait ataxia
 - c. Rare presentations:
 - i. Cardiac dysfunction
 - ii. Scoliosis
 - d. Loss of position and vibration sensibility of the lower extremities occurs early
 - e. Dysarthria
 - f. Pes cavus
 - g. Bilateral Babinski sign
 - h. Square wave jerks are noted with eye movement recordings
 - i. Inability to walk supervenes between 10–15 years of illness
 - j. Loss of muscle strength is late
 - k. Flexor spasms
 - l. Dysphasia
 - m. Optic atrophy

- n. VIIIth nerve involvement (late)
- 3. Neuropathology:
 - a. Reduced levels of frataxin due to the GAA-triplet repeat in the first intron of the FXN gene:
 - i. Leads to decreased frataxin levels (mitochondrial protein) that controls:
 - 1. Fe^{2+} entry into the cell and/or sulfide production
 - 2. Is essential for the assembly and production of the Fe-S cluster during the initial stage of biogenesis
 - b. Degeneration of the dorsal root ganglia and spinal roots
 - c. Dorsal column degeneration
 - d. Spinocerebellar and corticospinal tract degeneration
 - e. Degeneration of the dentate nucleus
 - f. Associated medical conditions:
 - i. Cardiomyopathy
 - ii. Diabetes
 - iii. Pes cavus and scoliosis
 - g. Lack of frataxin causes iron accumulation and impaired electron transport in the respiratory chain of mitochondria that leads to free radical formation and oxidative stress
 - h. Disease causing alleles of the FXN gene have between 70–1500 GAA repeats; 50% of the variation in phenotype is due to GAA expansion size

Atypical Phenotype of Friedreich's Ataxia

- 1. General characteristics:
 - a. Onset is later than age 25; very late onset is after 40 years of age
 - b. Another variant is a classic onset with preservation of ankle jerks
 - i. Occurs in 5–13% of patients
 - ii. A small number of patients have a late onset with preserved ankle reflexes
 - c. Larger repeat size:
 - i. May be correlated with hypertrophic cardiomyopathy and diabetes mellitus
 - ii. Somatic mosaicism may account for variability of presentation

Early Onset Friedreich's Ataxia

- 1. General characteristics
 - a. Associated with two missense mutations that are located in the amino terminal half of the frataxin gene
 - b. Loss of function mutations (D12 G130V)
- 2. Clinical manifestations:
 - a. Atypical and milder clinical presentation
 - b. Early onset of a spastic gait
 - c. Slow disease progression
 - d. No dysarthria
 - e. Retained or brisk reflexes
 - f. Minimal cerebellar ataxia
 - g. Optic disk pallor:
 - i. More severe in compound heterozygotes than in expansion homozygotes

Interfamilial Phenotypic Variability in Friedreich's Ataxia Associated with the G130V Mutation in the FXN Gene

General Characteristics

- 1. GAA expansion on one allele and a point mutation on the other allele

Clinical Manifestations

- 1. Slow disease progression
 - a. Minimal or no ataxia
 - b. Increased deep tendon reflexes
 - c. Mild gait spasticity

Neuropathology

- 1. Loss of myelinated fibers in the peripheral nerves
- 2. Decrease of large dorsal root ganglia cells
- 3. Demyelination of the dorsal columns
- 4. Distal degeneration of the corticospinal pathways
- 5. Loss of neurons occurs in Purkinje cells, cranial nerve neurons and the dentate nucleus
- 6. The cerebellum and brainstem are less affected

Laboratory Evaluation

- 1. Genetic screening
 - a. MRI of the head and spinal cord
 - i. Atrophy of the upper cervical cord is greater than cerebellar atrophy
 - b. Electrodiagnosis:
 - i. Early decrease of SNAPs
 - ii. Central conduction defects occur later in the illness

Ataxia Telangiectasia

General Characteristics

- 1. Caused by mutations in the ATM gene that maps to chromosome 11q22-23; the mutations are gene splicing and missense
- 2. It is the second most common recessive ataxia; it has an incidence of 1 in 400,000 live births in the US. It is most frequent in ethnic groups with high consanguinity

Clinical Manifestations

- 1. Early onset with a progressive course
- 2. Ataxia may be appreciated by age 2
- 3. Usually patients are wheelchair bound by 12 years of age
- 4. The oculocutaneous telangiectasia occurs several years after disease onset
- 5. Oculomotor apraxia
- 6. Dysarthria
- 7. The patients are immunodeficient and suffer frequent sinopulmonary infections
- 8. Lymphoid cancer occurs in 1/3 of patients
- 9. Short stature and cognitive deficits are common
- 10. Choreaethetosis may be prominent
- 11. The telangiectasia usually develops by age 3–5, but a few patients may not develop them

12. Choreoathetosis and/or dystonia develop in 90% of patients
13. Patients develop a large fiber neuropathy by age 8 and lose deep tendon reflexes
14. Telangiectasia of the sclera may be seen at 1 year; it develops over upper extremity flexor creases
15. Patients in their late 20s and 30s develop progressive spinal muscular atrophy

Neuropathology

1. Mutations of the ATM gene is the cause of the disorder
2. The ATM protein functions as a DNA damage responsive kinase and coordinates DNA damage response pathways
3. Involved in DNA double strand break repair (DSBR)
4. AT cells are abnormally sensitive to ionizing radiation
5. The ATM protein is also associated with cell cycle checkpoint regulation
6. Lymphomas in AT patients in general are B-cell in type; the B-cell chronic lymphocytic leukemias are B-CLL
7. Defects in the immune system with thymic hypoplasia are seen in greater than 60% of patients
8. There is cerebellar atrophy, retinal and brain telangiectasia

Laboratory Evaluation

1. Serum IgG₂ and IgA levels are decreased; IgM can be decreased or normal; IgE levels may be decreased
2. Some patients have low T-cell levels with a poor response to nitrogen
3. In vitro ionizing radiation sensitivity of AT cells
4. MRI:
 - a. Decreased volume of the cerebellum by age 10; there is progressive cerebral atrophy
 - b. In adults with AT:
 - i. 60% of patients had intracerebral telangiectasia with multiple punctuate hemosiderin deposits. They appear to be similar to radiation induced telangiectasia
 - ii. White matter hyperintensities may be seen

Ataxia Telangiectasia Variants

General Characteristics

1. A heterogeneous group of patients that is characterized by later onset of clinical symptoms, slower progression of the disease and longer life span

Clinical Manifestations

1. Telangiectasia and immunological deficiencies may be absent while neurologic signs are present
2. Some patients have no cognitive dysfunction

Neuropathology

1. The genotype of the AT variants most often is compound heterozygous
 - a. A severe mutation coupled with a mild mutation
 - b. Some ATM protein is expressed with kinase activity

Laboratory Evaluation

1. MRI:
 - a. Some cerebellar atrophy
 - b. EMG evidence of peripheral neuropathy in some patients
 - c. 15% of patients have some ATM protein

Nijmegen Breakage Syndrome Variant of AT

General Characteristics

1. Similar cellular phenotype to AT

Clinical Manifestations

1. Microcephaly
2. Cognitive impairment
3. No ataxia or telangiectasia

Neuropathology

1. NBN gene that maps to chromosome 8q21 is mutated
2. Cells are radiosensitive and there are translocations of chromosome 7 and 14
3. Immunodeficiency
4. Predisposition to cancer

Laboratory Evaluation

1. Decreased immunoglobulins
2. Radiosensitive cells

Oculomotor Apraxia Type 1

General Characteristics

1. Ataxia with oculomotor apraxia type 1 is autosomal recessive and is caused by bi-allelic mutations in the APTX gene that maps to chromosome 9p21.1

Clinical Manifestations

1. Onset of ataxia is between 2–6 years of age
2. Oculomotor apraxia
 - a. Increased horizontal saccade latencies
 - b. Hypometria
3. Sensorimotor neuropathy
4. Choreic or dystonic movements
5. Distal atrophy (some patients)

Neuropathology

1. Immunoglobulins, alpha-fetoprotein, T- and B-lymphocyte markers and chromosome 7 and 14 are normal
2. APTX interacts with poly (ADP ribose) polymerase (PARP1) that is important in the detection of DNA single strand breaks
3. Increased DNA damage (experimental models)
4. Deficiency in base excision repair

Laboratory Evaluation

1. Some patients have low serum albumin with high serum cholesterol

2. A few patients have demonstrated alpha-fetoprotein (AFP)
3. EMG:
 - a. Sensory neuropathy in some patients; primary motor peripheral motor neuropathy in others; axonal neuropathy in 100% of patients

Oculomotor Apraxia Type 2

General Characteristics

1. The oculomotor apraxia type 2 is autosomal recessive; involves the SETX gene and maps to chromosome 9q34.13

Clinical Manifestations

1. Onset is between 11–22 years of age
2. Oculomotor apraxia is not universal in these patients
3. Different signs in various families include:
 - a. Progressive ataxia; gait difficulties
 - b. Dentatorubral tremor
 - c. Distal amyotrophy (consistent with a neural form of CMT)
 - d. Strabismus
 - e. Choreic movements
 - f. Head and postural tremor
 - g. Dysarthria and dysphagia
 - h. Cognitive impairment
 - i. Nystagmus and slow saccades
 - j. Absent deep tendon reflexes (legs)
 - k. Sensorimotor neuropathy

Neuropathology

1. The SETX gene that encodes a large DNA/RNA helicase protein
 - a. Defense against DNA damage
 - b. Processing RNAs
 - c. SETX gene mutations have been described in autosomal dominant juvenile amyotrophic lateral sclerosis and dominant tremor ataxia syndromes
2. Cerebellar atrophy

Laboratory Evaluation

1. Increased serum alpha-fetoprotein
2. EMG:
 - a. Axonal sensorimotor neuropathy
 - b. MRI:
 - i. Cerebellar atrophy
 - ii. Decreased brain volume

Ataxia-Telangiectasia-Like Disorder 1 (ATLD1)

General Characteristics

1. ATLD1 is caused by homozygous or compound heterozygous mutations in the MRE11A gene that maps to chromosome 11q21

Clinical Manifestations

1. Progressive cerebellar ataxia and oculomotor apraxia

2. Telangiectasia and immune deficits do not occur

Neuropathology

1. Mutations in MRE11A from two families demonstrated:
 - a. Chromosomal instability
 - b. Sensitivity to ionizing radiation
 - c. Defective induction of stress activated signal transduction pathways
 - d. Radio resistant DNA synthesis
 - e. MRE11-RAD50-NBS1 regulates the response to DNA double strand breaks
2. It has been suggested that 6% of AT patients have MRE11-A mutations

Laboratory Evaluation

1. Ionizing radiation sensitivity
2. Some patients demonstrate spontaneous chromosome aberrations in peripheral blood lymphocytes
3. MRI:
 - a. Most but not all patients demonstrate cerebellar atrophy
 - b. No increase of alpha-fetoprotein, and normal immunoglobulin concentrations in the serum

Ataxia-Oculomotor Apraxia Type 3 (AOA3)

General Characteristics

1. AOA3 is caused by a homozygous mutation in the P1K3R5 gene that maps to chromosome 17 p13.1

Clinical Manifestations (Described in One Family)

1. Onset of a progressive unsteady gait by age 14
2. Subsequent arm dysmetria and dysarthria; wheelchair bound by age 23
3. Extraocular movements:
 - a. Slowed saccadic eye movements
 - b. Eye lag with head thrust
 - c. Normal smooth pursuit
4. Distal atrophy and weakness affecting the lower extremities to a greater degree than the upper

Neuropathology

1. The receptor-regulated class 1-phosphoinositide 3-kinases
 - a. Phosphorylate the membrane lipid phosphatidylinositol 4,5-bisphosphate (PtdIns [4,5] P2 to PtdIns [3,4,5] P3)
 - b. This reaction recruits and activates cytosolic effectors that are pleiotropic for proliferation, survival or chemotaxis
 - c. P1K3R5 is a regulatory subunit of D13 kinase

Laboratory Evaluation

1. EMG:
 - a. Absent SNAPs in the lower extremities
 - b. Increased serum alpha-fetoprotein
 - c. MRI:
 - i. Atrophy of cerebellar folia and the vermis

Autosomal Recessive Ataxia with Oculomotor Apraxia from Mutations in PNKP (AOA4)

General Characteristics

1. Ataxia-oculomotor apraxia 4 is an autosomal recessive disorder due to homozygous mutations in the PNKP gene that maps to chromosome 19q13.33

Clinical Manifestations

1. Age at onset ranges from 1–9 years (4.3 ± 2.3 years). Dys-tonia may be the presenting sign but fluctuates during the course of the disease
2. Cerebellar ataxia
3. Oculomotor apraxia
4. Distal muscle wasting weakness that in some patients is associated with tetraplegia and short atrophic hands and feet
5. Loss of the ability to walk occurs between 7–21 years after the onset of the disease
6. Cognitive impairment occurs in a proportion of patients
7. Large fiber peripheral neuropathy

Neuropathology

1. PNKP is a modular protein
 - a. The FHA domain mediates interaction with scaffold proteins (XRCC1 and XRCC4)
 - b. A DNA phosphatase domain
 - c. A DNA kinase domain
 - i. The homozygous variant (pTh or 42 GLy) located in the kinase domain causes progressive cerebellar atrophy with microcephaly, early onset and intractable seizures with developmental delay (MCS7)
 - ii. Missense substitutions in the FHA and phosphatase domains are only associated with developmental syndromes
 - d. The different mutations cause:
 - i. Defects in phosphatase or kinase activity
 - ii. Conformational protein alterations that disrupt protein-protein interactions or substrate recognition
 - e. PNKP is a component of multiple pathways involved in DNA-damage repair of both single- and double-strand breaks
2. DNA strand breaks that cause non-ligable DNA ends are from:
 - a. Ionizing radiation
 - b. Oxidative stress
 - c. Some chemotherapeutic agents
 - d. A base excision repair (BER) intermediates
 - e. Two common dirty ends, 3^1-P and 5^1-OH are processed by PNKP

Laboratory Evaluation

1. Albumin may be low or normal and cholesterol levels are normal or elevated

2. Alpha-fetoprotein is elevated in some patients
3. MRI:
 - a. Cerebellar atrophy
4. EMG:
 - a. Sensorimotor peripheral neuropathy

Autosomal Recessive Spinocerebellar Ataxia with Axonal Neuropathy (SCAN1)

General Characteristics

1. SCAN1 is caused by a homozygous mutation in the tyrosyl DNA phosphodiesterase-1 gene (TDP1) that maps to chromosome 14q 32.11
2. CAN topoisomerase, glycosylases, methyltransferases and recombinases function by forming a transient covalent intermediate with DNA; if these DNA-processing enzymes become covalently trapped on the DNA they cause DNA damage
3. SCAN1 results from a failure to repair DNA-protein covalent complexes

Clinical Manifestations

1. Ataxia
2. Normal cognitive function
3. Severe axonal sensorimotor and motor neuropathy
4. Distal muscular atrophy
5. Pes cavus
6. Steppage gait

Neuropathology

1. TDP1 is sequestered into multiprotein single-strand break repair (SSBR) complexes by interaction with DNA ligase III-alpha which is deficient in this disorder:
 - a. It cleaves the phosphodiesterase bond between a covalently stalled topoisomerase and the 3^1 strand of DNA which has occurred from DNA damage

Laboratory Evaluation

1. Mild hypercholesterolemia and borderline hypoalbuminemia
2. EMG:
 - a. Axonal sensorimotor peripheral neuropathy
3. MRI:
 - a. Mild generalized brain atrophy

Hypogonadotropic Hypogonadism with Ataxia (Gordon Holmes Syndrome)

General Characteristics

1. Mutations in the RNF216 gene that maps to chromosome 7p22.1 alone or in combination with mutations in OTVD4 that maps to chromosome 4q31.21 cause this disorder
2. Both genes encode enzymes in the ubiquitin pathway

Clinical Manifestations

1. Abnormal sexual development

2. Neurologic symptoms develop in the 3rd decade
3. Dysarthria
4. Nystagmus is most often absent
5. Progressive gait and limb ataxia
6. Cognitive dysfunction to dementia
7. Distal muscle weakness
8. Choreoathetosis:
 - a. Dorsal column defects
 - b. Retinopathy
 - c. Increased reflexes

Neuropathology

1. Normosmic hypogonadotropic hypogonadism (nHH)
2. PNPLA 6:
 - a. Encodes neuropathy target esterase (NTE) which is a lysophospholipase:
 - i. Maintains intracellular phospholipid homeostasis that converts lysophosphatidylcholine to glycerophosphocholine
3. Experimental studies support that NTE-dependent alteration of phospholipid homeostasis in GHS causes neurodegeneration and impaired LH release from pituitary gonadotropes that cause nHH
4. Autopsy (1 patient)
 - a. Cerebellar and inferior olive atrophy
 - b. Ubiquitin immune reactive nuclear inclusions were present in 1–5% of the pyramidal neurons

Laboratory Evaluation

1. Low levels of LH
2. Diminished response to GnRH
3. MRI:
 - a. Cerebellar and cortical atrophy
 - b. Patchy areas of subcortical white matter hyperintensities on T₂-weighted sequences
4. RNF26aE4 ubiquitin ligase and OTUD4, a deubiquitinase may synergize to cause the disorder

STUB1 Mutation as a Cause of Gordon Holmes Syndrome

General Characteristics

1. Exome sequencing has demonstrated that mutations in the STUB1 gene may cause the Gordon Holmes syndrome
2. STUB1 (ST1P1 homologous and U-box containing protein1) maps to chromosome 16p13.3; its alternative name is CHiP (C terminus of HSC70-interacting protein)
3. CHiP functions as:
 - a. Co-chaperone and an E3 ubiquitin ligase
 - b. Couples protein folding and proteasome mediated degradation through its interaction with heat shock proteins (HSP 70)
 - c. It ubiquitinates the misfolded heat shock protein client proteins which targets them for proteasomal degradation

Clinical Manifestations

1. Dimorphic features:
 - a. Aged appearance
 - b. Long slender fingers, increased space between the 4th and 5th digits
 - c. Adducted thumbs
 - d. Slight facial dysmorphisms
2. Neurologic features:
 - a. Delayed development
 - b. Gait ataxia
 - c. Head tremor and postural tremor
 - d. Rarely, myokymia
 - e. Cerebellar ataxia
 - f. High frequency hearing loss

Neuropathology

1. The STUB1 gene encodes CHiP which is an E3 ubiquitin protein ligase
2. Putatively, the failure of CHiP to promote N-methyl-D-aspartate subunit degradation is the underlying mechanism of the disorder

Laboratory Evaluation

1. MRI:
 - a. Cerebellar hypoplasia
 - b. Thin posterior corpus callosum
 - c. Mild pontine atrophy
2. Diabetes (some patients)
3. Secondary infertility
4. Delayed menarche

AR Cerebellar Ataxias with Defects in Ubiquitin Genes

1. STUB1
2. PNPLA6
3. OTUD4

Boucher-Neuhäuser Syndrome

General Characteristics

1. Boucher-Neuhäuser and Gordon Holmes syndromes are allelic diseases caused by recessive PNPLA6 mutations

Clinical Manifestations

1. PNPLA6-associated spectrum of neurodegenerative disorders include major features:
 - a. Ataxia
 - b. Motor neuron disease:
 - i. Both upper motor neuron with or without lower motor involvement
2. Hypogonadism
3. Chorioretinal dystrophy
4. Spinocerebellar ataxia
5. Hypogonadotropic hypogonadism
6. Onset is usually during the first decade of life
7. Mild cognitive impairment in some patients

Neuropathology

1. Atrophic pons and cerebellum (some patients)
2. Diffuse atrophy of the cerebellar hemispheres
3. Atrophic changes of the retinal pigment epithelium and chorio capillaries
4. PNPLA6 proteins:
 - a. Patatin-like phospholipase domain containing proteins
 - b. Mutations affect the phospholipid domain (EST) and effects the de-esterification of phosphatidylcholine into fatty acids and glycerophosphocholine which is a precursor for the biosynthesis of acetylcholine (decreases its availability)
 - c. PNPLA6 also has lipophospholipase activity, and when mutated alters neuronal lipid metabolism

Laboratory Evaluation

1. Loss of LH with hypogonadotrophic hypogonadism
2. Ophthalmologic evaluation for chorioretinal dystrophy (majority of patients)
3. MRI:
 - a. Primarily cerebellar hemisphere atrophy
 - b. Pontocerebellar atrophy (some patients)

PMM2-CDG (Jaeken Syndrome)*General Characteristics*

1. Congenital disorders of glycosylation (CDGs) are:
 - a. Autosomal recessive and heterogeneous
 - b. Cause defective synthesis and processing of asparagine (N)-linked glycans (oligosaccharides) on glycoproteins which are important for metabolism, cell recognition, adhesion, migration and host defense
 - c. Jaeken syndrome is caused by:
 - i. Homozygous or compound heterozygous mutations in PMM2 that maps to chromosome 16p13
 - ii. Encodes phosphomannomutase 2

Clinical Manifestations

1. Usually presents in neonatal life with:
 - a. Encephalopathy
 - b. Axial hypotonia
 - c. Abnormal eye movements
 - d. Severe psychomotor retardation
 - e. Retinitis pigmentosa
 - f. Peripheral neuropathy
 - g. Esotropia
2. Abnormal distribution of subcutaneous fat
3. Nipple retraction
4. Hypogonadism
5. Adult PMM2 – CDG:
 - a. Adults may be mildly affected with:
 - i. Mild ataxic phenotypes
 - ii. Hand tremor
 - iii. Cognitive impairment
 - iv. Dysarthria and dysphonia

Neuropathology

1. Defect in processing of N-linked oligosaccharides or their defective synthesis
2. Cerebellar trophy

Laboratory Evaluation

1. MRI:
 - a. Cerebellar hemisphere and vermal atrophy

Autosomal Recessive Cerebellar Ataxia from Mutation of ADCK3*General Characteristics*

1. ADCK3 gene maps to chromosome 1q42.13
2. Encodes the homologue of Coq8
3. CoQ10:
 - a. Lipid soluble
 - b. Located in the inner mitochondrial membrane
 - c. Shuttles electrons derived from NADH ubiquinone oxidoreductase and succinic ubiquinone oxidoreductase to complex III (ubiquinol cytochrome C oxidoreductase)
 - d. Is an antioxidant by its action on pyrimidine metabolism
4. The ADCK3 gene:
 - a. Contains the AarF domain which is in the biosynthetic pathway for CoQ10
 - b. Encodes a mitochondrial protein which is a component of the electron transferring membrane protein complex

Clinical Manifestations

1. Disease onset is usually in infancy or early childhood
2. May present with pure cerebellar ataxia
3. Complex phenotype that includes:
 - a. Cerebellar ataxia
 - b. Cognitive dysfunction
 - c. Depression
 - d. Peripheral neuropathy
 - e. Strabismus
 - f. Exercise intolerance
 - g. Myoclonus (2 patients)

Neuropathology

1. CoQ10 deficiency causes defect in bioenergetics
2. Deficit of CoQ10 is best detected in fibroblasts although most often is demonstrated in muscle

Laboratory Evaluation

1. Increased serum lactate
2. Molecular genetic analysis
3. MRI:
 - a. Mild cerebellar atrophy

Adult-Onset Autosomal Recessive Ataxia from Mutations in the Lipofuscinosis Type 5 Gene*General Characteristics*

1. The CLN5 gene maps to chromosome 13q22.3
2. Most patients are of Finnish origin

Clinical Manifestation

1. 2 adult patients:
 - a. Presentation in the mid-fifties
 - b. Gait ataxia
 - c. Dysarthria
 - d. Cognitive decline (progressive)

Neuropathology

1. Bioinformatics and in vitro studies suggest that the mutation would affect ER-lysosome protein trafficking

Laboratory Evaluation

1. MRI:
 - a. Severe cerebellar atrophy most prevalent in the vermis
 - b. Marked cortical atrophy

ANO10 Gene Mutations and AR Cerebellar Ataxia*General Characteristics*

1. ANO10 gene mutations which map to chromosome 3P22.1 cause ARSCA10
2. Some patients have low levels of coenzyme Q10 and have some improvement with supplementation

Clinical Manifestations

1. Onset is teenage years or as a young adult
2. Gait instability
3. Dysarthria
4. Limb ataxia
5. Nystagmus:
 - a. Gaze-evoked downbeat
6. Hypermetric saccades
7. Hyperactive deep tendon reflexes

Neuropathology

1. Muscle biopsy:
 - a. Isolated complex III deficiency
 - b. Low CoQ10 levels

Laboratory Evaluation

1. MRI:
 - a. Marked cerebellar atrophy

SYT14 Mutation in Adult-Onset Autosomal Recessive Spinocerebellar Atrophy*General Characteristics*

1. SYT14 gene mutations cause an autosomal recessive cerebellar ataxia that maps to chromosome 1q32.2:
 - a. The gene encodes synaptotagmin 14 which is a membrane-trafficking protein

Clinical Manifestations

1. Japanese patients that demonstrated:
 - a. Childhood onset of cognitive difficulties
 - b. Gait instability
 - c. Dysphagia
 - d. Poor smooth pursuit eye movements
 - e. Limb and truncal ataxia

Neuropathology

1. Synaptotagmins are transmembrane proteins associated with exocytosis of secretory vesicles. It is located in Purkinje cells. Disruption of exocytosis mechanisms have been suggested as a pathogenic mechanism in this degeneration
2. In functional expression studies in COS1 cells, the mutant protein formed a reticular pattern in the cytoplasm rather than the normal perinuclear and submembranous intracellular localization. The abnormal protein was retained in the endoplasmic reticulum which is consistent with improper folding

Laboratory Evaluation

1. Mild atrophy of the cerebellar vermis and hemispheres; no apparent atrophy of the brainstem or the cerebral cortex

Rundataxin Recessive Cerebellar Ataxia*General Characteristics*

1. Rundataxin AR cerebellar ataxia is caused by mutations in the K1AA0226 gene that maps to chromosome 3q28-qter:
 - a. The gene encodes the protein rundataxin that may be associated with vesicular trafficking and signaling through its RUN domain and diacylglycerol binding-like domain

Clinical Manifestations

1. Three siblings from a consanguineous Saudi Arabian family have been studied
2. Childhood onset of gait abnormalities
3. Seizures
4. Cognitive dysfunction

Neuropathology

1. The K1AA0226 gene encodes the protein rubicon which is involved in vesicular trafficking and late endosome maturation. The neuropathology may be caused by defects of Rubicon which is a negative regulator of autophagy and endocytic trafficking

Laboratory Evaluation

1. MRI:
 - a. Cerebellar atrophy

SYNE1 Mutations in Autosomal Recessive Cerebellar Ataxia*General Characteristics*

1. The SYNE1 gene (Synaptic Nuclear Envelope Protein gene that maps to chromosome 6q25.1-q25.2)
 - a. Encodes a spectrin structural protein which links the plasma membrane to the actin cytoskeleton
 - b. The mutated protein is in the synaptic nuclear envelope protein 1

Clinical Manifestations

1. Gait ataxia
2. Dysarthria
3. Limb ataxia
4. Mild oculomotor deficits
5. Variable brainstem involvement

Neuropathology

1. The protein encoded is Nesprin-1:
 - a. Forms a linking network between organelles and the actin cytoskeleton which maintains subcellular spatial organization
 - b. The protein functions as a scaffold and linker both at the nuclear envelope and subcellular domains

Laboratory Evaluation

1. MRI:
 - a. Diffuse cerebellar atrophy

Autosomal Recessive Ataxia of Charlevoix-Saguenay*General Characteristics*

1. Charlevoix-Saguenay spastic ataxia is caused by homozygous or compound heterozygous mutations in the SACS gene that maps to chromosome 13q11. ARSACS is not limited to Quebec. There are over 100 mutations that have been defined worldwide

Clinical Manifestations

1. Early childhood onset of cerebellar ataxia
2. Pyramidal tract signs
3. Peripheral neuropathy
4. Increased visibility of retinal nerve fibers (myelinated)
5. Phenotypic spectrum:
 - a. No spasticity, extensor plantar sign or cerebellar ataxia but demonstrates a severe sensorimotor axonal demyelinating neuropathy
 - b. Patients may have cerebellar ataxia without neuropathy or pyramidal signs
 - c. Patients may not have retinal nerve fiber abnormalities
 - d. Patients may demonstrate pes cavus, hammer toes and scoliosis
 - e. Rarely, the disorder may be of late onset

Neuropathology

1. Arachnoid cyst and herniation of cerebellar tonsils in some patients suggest a developmental component to the disorder
2. The function of the SAC protein has not been defined
3. Alteration of the mitochondrial network has been noted in some patients

Laboratory Evaluation

1. MRI:
 - a. Atrophy of the superior cerebellar vermis

- b. An enlarged pons with T2 sequence hypointense stripes (corticospinal tract fibers)
- c. Thinning of the corpus callosum
- d. A rim of T2-hyperintensity surrounding the thalamus
- e. Diffusion tensor imaging:
 - i. Overrepresented transverse pontine fibers
 - ii. Microstructural alterations of the supratentorial white matter of the forceps, cingulum and the superior longitudinal fasciculus
- f. Bilateral cerebral parietal atrophy (subgroup of patients)
2. EMG:
 - a. Axonal demyelinating sensorimotor neuropathy

Autosomal Recessive Ataxia from Mutations in POLG*General Characteristics*

1. Mutations in the POLG gene cause mitochondrial recessive ataxia syndrome
2. The POLG gene maps to chromosome 15q26.1
3. Homozygous or compound heterozygous mutation in the nuclear-encoded DNA polymerase-gamma gene cause SANDO (sensory ataxic neuropathy, dysarthria and ophthalmoparesis)
4. Recessive mutations in POLG may also cause a progressive external ophthalmoplegia
5. The phenotype of SANDO varies widely among families and within affected families
6. POLG mutations cause a broad spectrum of mitochondrial disorders

Clinical Manifestations

1. SANDO:
 - a. Adult onset of sensory ataxic neuropathy
 - b. Dysarthria
 - c. Ophthalmoparesis
2. The phenotype may include:
 - a. Myopathy
 - b. Seizures
 - c. Sensorineural hearing loss

Neuropathology

1. Muscle biopsy:
 - a. Myopathic changes with ragged red fibers
 - b. Molecular analysis of muscle and nerve detects multiple mitochondrial DNA deletions
2. Sural nerve biopsy:
 - a. Loss of myelinated fibers and axonal degeneration

Laboratory Evaluation

1. MRI:
 - a. Bilateral thalamic lesions
 - b. High-intensity signals in the cerebellar white matter
2. EMG:
 - a. Sensory axonal neuropathy

Spinocerebellar Ataxia with Epilepsy*General Characteristics*

1. Four unrelated families with spinocerebellar ataxia and seizures have demonstrated POLG mutations

Clinical Manifestations

1. Childhood onset (5–17 years of age)
2. By twenty years of age patients have developed:
 - a. Cerebellar and sensory ataxia
 - b. Dysarthria
 - c. Progressive external ophthalmoplegia
 - i. Myoclonus
 - ii. Migraine
 - d. Status epilepticus developed in 3 patients; others suffered recurrent seizures

Neuropathology

1. Muscle biopsy:
 - a. COX-negative fibers
 - b. mtDNA deletions

Laboratory Evaluation

1. MRI:
 - a. Deep cerebellar white matter lesions
 - b. Thalamic lesions

Ataxia with Vitamin E Deficiency (AVED)*General Characteristics*

1. Ataxia with vitamin E deficiency is an autosomal recessive disorder from mutations in the alpha-tocopherol protein gene (TTPA gene) that maps to chromosome 8q13
2. Vitamin E deficiency is usually caused by defective uptake rather than reduced intake
3. Patients with vitamin E deficiency due to malabsorption most often present with neuropathy
4. Mutations in the TTPA gene cause a defect in the integration of vitamin E in VLDL and the transfer of vitamin E from the liver to the CNS

Clinical Manifestations

1. Onset is late childhood and adolescence but varies in different ethnic groups
2. Mutations that cause a truncated protein are associated with severe neurologic deficits while missense mutations are correlated with a milder phenotype
3. Slowly progressive cerebellar ataxia
4. Diminution of vibratory and proprioceptive sensibility
5. Retinitis pigmentosa
6. Dysarthria
7. Loss of deep tendon reflexes
8. Differential points versus Friedreich's ataxia:
 - a. In AVED:
 - i. Head titubation
 - ii. Retinopathy
 - iii. Dystonia

- b. In Friedreich's ataxia:
 - i. Cardiomyopathy
 - ii. Glucose intolerance
 - iii. Scoliosis
 - iv. Pes cavus

Neuropathology

1. Vitamin E is an essential dietary antioxidant
2. In experimental models, it has been demonstrated that vitamin E deficiency causes an increase in cerebellar oxidative stress (Increased protein nitrosylation); cellular atrophy and decreased branching of Purkinje cells

Laboratory Evaluation

1. Low serum levels of vitamin E

Rare AR Cerebellar Ataxias**Behr's Syndrome***General Characteristics*

1. The disorder has been reported with OPA1, OPA3 or C12ORF65 gene mutations

Clinical Manifestations

1. Onset in infancy
2. Progressive optic atrophy
3. Cerebellar ataxia
4. Pyramidal signs
5. Athetosis in some patients

Neuropathology

1. Occurs in patients with the C19ORF12 gene mutation (previously reported with a subtype of NBIA (neurological brain iron accumulation))
2. MRI evidence of basal ganglia iron deposition

Laboratory Evaluation

1. MRI:
 - a. Bilateral hypointense basal ganglia signals compatible with brain iron accumulation
2. In patients with OPA3 there may be excretion of 3-methylglutaconic acid in the urine

Marinesco-Sjögren Syndrome*General Characteristics*

1. Marinesco-Sjögren syndrome is caused by homozygous or compound heterozygous mutations in the SIL1 gene that maps to chromosome 5q31.2
2. There are overlapping features with CCFDN (congenital cataracts, facial dysmorphism and neuropathy) that is caused by mutation in the CTDP1 gene that maps to chromosome 18q23
3. The SIL1 gene:
 - a. Encodes an endoplasmic reticular cochaperone
 - b. SIL1 mutations are associated with the combination of cerebellar ataxia and chronic myopathy

Clinical Manifestations

1. Early onset ataxia
2. Cataracts
3. Short stature
4. Myopathy
5. Delayed sexual development
6. Cognitive impairment (Some patients are normal)
7. Some patients have skeletal abnormalities
8. Chronic nail infections
9. Strabismus
10. Skeletal deformities

Neuropathology

1. Muscle biopsy:
 - a. Neurogenic atrophy
2. Electron microscopy:
 - a. Increased lysosomes in fibroblasts
 - b. Autophagic vacuoles with myeloid bodies
3. An inbred family demonstrated:
 - a. Myopathic changes on muscle biopsy
4. Electron microscopy in other patients:
 - a. Enlarged lysosomes that contained whorled lamellar bodies
5. Cerebellar atrophy with both Purkinje and granular cell loss

Laboratory Evaluation

1. Hypogammaglobulinemia (some patients)
2. EMG:
 - a. Most often myopathic
3. Mildly elevated CK (some patients)

Wolfram Syndrome (DIDMOAD)*General Considerations*

1. Wolfram syndrome-1 is caused by mutations in the WFS1 gene that map to chromosome 4p16.1

Clinical Manifestations

1. Diabetes mellitus
2. Optic atrophy
3. Diabetes insipidus
4. Deafness (higher frequencies)
5. Additional manifestations include:
 - a. Ataxia
 - b. Renal dysfunction
 - c. Cognitive disability
 - d. Psychiatric illness
6. Autosomal dominant mutations in WFS1 have:
 - a. Low frequency non-syndromic deafness
 - b. Wolfram syndrome-like phenotype
 - c. Hearing loss with diabetes mellitus or optic atrophy

Neuropathology

1. The WFS1 protein is an endoplasmic reticulum (ER) protein that functions in ER calcium homeostasis and unfolded protein responses

2. The dysfunction of the protein may cause ER stress that leads to apoptosis
3. WFS1 protein functions in insulin secretory granule acidification
4. Mitochondrial deletions in some patients

Laboratory Evaluation

1. Insulin dependent diabetes mellitus
2. Hemoglobin concentration and water loss (osmolality changes) consistent with diabetes insipidus
3. Ophthalmologic evaluation for optic atrophy and audiometric evaluation for sensorineural hearing loss

Cerebrotendinous Xanthomatosis (CTX)*General Characteristics*

1. CTX is an autosomal recessive lipid storage disease
2. Caused by mutations in the CYP27A1 gene that maps to chromosome 2q33-qter
3. The prevalence is 25/100,000 of the general population

Clinical Manifestations (Neurologic)

1. The average age of onset is 35 years of age
2. Ataxia
3. Dystonia
4. Dementia
5. Seizures
6. Psychiatric disorder
7. Peripheral neuropathy
8. Myopathy

Non-Neurologic Manifestations

1. Tendon xanthomas
2. Childhood onset cataracts
3. Infantile onset diarrhea
4. Premature atherosclerosis
5. Osteoporosis
6. Respiratory insufficiency

Neuropathology

1. Patients with CTX have decreased bile acid synthesis due to impaired oxidation of the cholesterol side-chain:
 - a. Lack mitochondrial sterol 27-hydroxylase which is located on the inner mitochondrial membranes which is important in both classic and alternative bile acid synthetic pathways
2. Brain atrophy with generalized yellowish deposits in the choroid plexus and white matter
3. Multiple dispersed lipid crystal clefts and granulomatous lesions in the cerebellar hemispheres
4. Demyelination and perivascular accumulation of foamy macrophages in the globus pallidus
5. Demyelination, gliosis of the corticospinal tracts of the spinal cord
6. Nerve biopsy:
 - a. Primary axonal degeneration
 - b. Demyelination and remyelination

Laboratory Evaluation

1. Plasma cholestanol concentration five to 10 times normal (330 ± 30 ug/dl)
2. High urine bile alcohol concentration
3. Plasma bile alcohol concentration 500 to 1000 greater than normal
4. The differential laboratory features that distinguish CTX from other disorders with xanthomas include:
 - a. High plasma cholestanol concentration
 - b. Normal to low plasma cholesterol concentration
 - c. Decreased CDCA level
 - d. Increased levels of cholestanol and apolipoprotein B in the CSF
5. A biomarker for CTX is elevated 5-alpha-cholestanol concentration determined by gas chromatography-mass spectrometry (GC-MS)
6. Neuroimaging:
 - a. Brain MRI:
 - i. Cerebellar atrophy
 - ii. White matter hyperintensities
 - iii. Symmetric hyperintensities in the dentate nuclei
 - iv. Diffusely decreased gray and white matter volumes
 - b. Magnetic resonance spectroscopy:
 - i. Increased lactate and lipid peaks in FLAIR-hypointense lesions and diffuse decreases in N-acetyl aspartate (NAA) peaks
 - c. SPECT:
 - i. Regional cerebral blood flow changes
 - d. Positive VEP, SSEP, BAEP and NCV

Differential Diagnosis

1. Sitosterolemia:
 - a. A rare inherited sterol storage disease due to mutations in the adenosine triphosphate binding cassette (ABC) transporter genes ABCG5 and ABCG8 that map to chromosome 2p21
 - b. Increased absorption and decreased excretion of plant sterols are characteristic
 - c. Clinical manifestations:
 - i. Tuberous and tendinous xanthomas
 - ii. Premature atherosclerosis
 - iii. Hemolytic anemia
 - iv. Arthritis
 - v. Thrombocytopenic purpura
 - d. Laboratory evaluation:
 - i. High plasma phytosterol concentration
 - ii. Mildly elevated cholesterol concentrations
2. Dyslipidemia:
 - a. Familial hypercholesterolemia:
 - i. Is an AD disorder caused by a deficiency of low-density lipoprotein (LDL) receptor or in LDL related genes (ApoB and PCSK9):
 1. Elevated LDL cholesterol and triglyceride concentrations
 - b. Neuropathology:

- i. Decreased clearance of apolipoprotein B-containing lipoproteins which accumulate in different tissues
- c. Clinical manifestations:
 - i. Tendinous xanthomas on the backs of the hands, elbows, knees or xanthoma tuberosum
 - ii. Premature coronary artery disease
 - iii. Familial dysbetalipoproteinemia:
 1. Palmar crease xanthomas
 - iv. Familial hypercholesterolemia:
 1. Intertriginous xanthomas in children
 - v. Sitosterolemia and CTX:
 1. Tendinous xanthomas in adults
- d. Rare inborn errors of bile acid metabolism:
 - i. 7 alpha-hydroxylase deficiency
 - ii. 3 beta-hydroxy-C27-steroid oxidoreductase deficiency
 - iii. 2-methylacyl-CoA racemase deficiency

Differential Diagnosis of Recessive Syndromes with Prominent Ataxia

1. Cerebrotendinous xanthomatosis
2. Partial hypoxanthine guanine phosphoribosyl deficiency
3. Wilson's disease
4. Late-onset hexosaminidase deficiency
5. Refsum's disease
6. Adrenomyeloneuropathy
7. Mitochondrial DNA mutations

Autosomal Dominant Cerebellar Ataxia type 1*General Characteristics*

1. Type 1 autosomal dominant cerebellar ataxias are characterized by ataxia with additional neurologic signs that include:
 - a. Oculomotor dysfunction
 - b. Cognitive impairment
 - c. Pyramidal tract and extrapyramidal signs
 - d. Bulbar dysfunction
 - e. Spinal peripheral nerve abnormalities
2. The most prevalent type 1 ADCA is SCA3, followed by SCA2, SCA1 and SCA8. There is variable prevalence in different populations and ethnicities due to founder effects
3. The onset is in adulthood but presentation in childhood occurs. Gait, trunkal and limb ataxia are the most common cerebellar deficits and are often associated with nystagmus, saccadic abnormalities, and dysarthria
4. Clinical features are specific for each SCA type and the phenotype ranges from a pure cerebellar syndrome to spinal cord and peripheral nerve dysfunction, cognitive impairment, supranuclear ophthalmologic signs, and seizures
5. ADCAs can be divided into four subtypes according to their genetic pathomechanisms
 - a. Polyglutamine disorders due to expansion of CAG triplet repeats
 - b. Intronic disorders

- c. SCAs with the usual types of mutations
- d. SCAs with large duplications or deletions:
 - i. Polyglutamine disorders are more prevalent than the other types
 - ii. Polyglutamine disorders characteristic genetic features are:
 - 1. The translated protein of the expanded triplet gene has abnormally elongated glutamine repeats
 - 2. There is an inverse correlation between the size of the expansion and the onset, rate of progression, and clinical severity which is called anticipation. This feature is most striking in SCA7 and DRPLA (dentatorubral-pallidoluysian atrophy)
 - 3. In the CAG repeat disease, imprinting is frequent such that paternal transmission is more often associated with repeat expansions than maternal transmission of the expanded allele. The triplet repeat SCAs are 1, 2, 3, 6, 7, 17 and dentatorubral-pallidoluysian atrophy (DRPLA)
- 6. The most frequent intronic disease is exemplified by SCA8
 - a. It is caused by a bidirectional expansion of CTC/CAG which causes ribonucleic acid (RNA) mediated toxicity and polyglutamine tract formation
 - b. Imprinting of maternal transmission of the CTG repeat occurs in this disorder
 - c. Intronic disease occurs in SCA8, SCA12, SCA31 and SCA36
- 7. Conventional mutations in SCAs occur in SCA5, SCA11, SCA13, SCA14, SCA19/SCA23, SCA25, SCA26, SCA27, SCA28, SCA29 and SCA35
- 8. SCAs with large duplications or deletions occur in SCA15 and SCA20
- 9. The prevalence of ADCAs is approximately 1–5 people per 100,000 population worldwide

SCA1 ADCA1

General Characteristics

1. Is caused by mutations in the ATXN1 gene that maps to chromosome 6p22.3

Clinical Manifestations

1. Onset is usually in the 4th decade (4–74 years of age)
2. Dysarthria
3. Limb ataxia
4. Nystagmus and saccadic eye movement abnormalities
5. Upper motor neuron signs and Babinski sign are present
6. Involuntary choreiform movements
7. Spastic paraplegia is seen in some families

Neuropathology

1. Spinal cord demonstrates
 - a. Loss of anterior horn cells
 - b. Demyelination of spinocerebellar tracts; the dorsal columns

- c. Involvement of CN IX, X and XII
- d. Atrophy of the cerebellum, pons and olives
- e. Loss of Purkinje cells
- f. Atrophy of Clarke's column and the spinocerebellar pathways

Laboratory Evaluation

1. Genetic evaluation to demonstrate CAG repeat in ATXN1
2. MRI:
 - a. Cerebellar and brainstem atrophy
3. EMG:
 - a. Peripheral neuropathy

SCA2

General Characteristics

1. SCA2 is caused by mutations in the ATXN2 gene that maps to chromosome 12q24.2 that also demonstrates susceptibility for ALS

Clinical Manifestations

1. High inter- and intrafamily variability
2. Anticipation occurs
3. Onset is in the third or fourth decade
4. Slow saccades
5. Ophthalmoparesis
6. Chorea
7. Parkinsonism (some patients)
8. Myoclonus
9. Areflexia

Neuropathology

1. Affected patients have 32–79 repeats (normal is 13 to 31 CAG)
2. Cerebellar and olivary degeneration
3. Dying back axonopathy in some patients; dorsal root ganglion involvement in others
4. Sensorimotor cortex and frontal lobe atrophy

Laboratory Evaluation

1. MRI:
 - a. Cerebellar, pontine and olivary atrophy
 - b. fMRI:
 - i. Functional decrease in the cerebellar network and an increase in the default mode and frontoparietal networks
2. EMG:
 - a. Peripheral neuropathy
3. PET:
 - a. Decreased dopamine in the caudate and putamen of patients with Parkinsonism phenotype

SCA3

General Characteristics

1. Machado-Joseph disease is caused by CAG expansion of the ATXN3 gene that maps to chromosome 14q32.1

Clinical Manifestations

1. The most common SCA in some populations
2. Major phenotypes:
 - a. Type I
 - i. Ataxia, ophthalmoparesis
 - ii. Pyramidal signs
 - iii. Dystonia and other movement disorders that present in adolescence
 - b. Type II
 - i. Onset in middle adulthood
 - ii. Ataxia, spasticity and dystonia
 - c. Type III
 - i. Onset after 40 years of age
 - ii. Ophthalmoparesis
 - iii. Anterior horn cell disease with fasciculation, atrophy, and weakness
 - iv. Rare
 1. Parkinsonism and faciolingual myokymia
3. Some patients have impairment of temperature sensation that is generalized over the body
4. Bulging eyes; persistent stare

Neuropathology

1. The normal repeat length is 13–41; repeat lengths associated with disease are greater than 56
2. The SCA3 gene product is ataxin 3 which is a deubiquitinating enzyme; possible deficits of proteasomal degradation of ubiquitinated substrates
3. Ataxin-3 protein functions:
 - a. In the chaperone system
 - b. Ubiquitin-proteasome system
 - c. Aggregation-autophagy
 - i. These functions support its role in clearance of misfolded protein
 - ii. The pathogenic SCA3 (ataxin-3) impairs misfolded protein clearance that is dependent or independent of its deubiquitance activity which results in accumulation of misfolded proteins with progressive loss of neurons
4. Brain atrophy and neuronal loss occurs in:
 - a. Globus pallidus
 - b. Thalamic nuclei
 - c. Pontine nuclei
 - d. CN nuclei
 - e. Superior and middle cerebellar peduncles
 - f. Dentate nucleus
 - g. Clarke's column and spinocerebellar pathways
 - h. Anterior horn cells
 - i. Posterior column and DRGs
5. Relatively spared are:
 - a. The cerebral cortex
 - b. Corticospinal tracts
 - c. Cerebellar cortex
6. Diseased protein accumulates within inclusions inside the cell nuclei; they are ubiquitin positive spheres

Laboratory Evaluation

1. MRI:
 - a. Cerebellar and pontine atrophy
2. EMG:
 - a. Peripheral axonal neuropathy
3. Sleep studies:
 - a. REM sleep behavior disorder

SCA4*General Characteristics*

1. Most often referred to as hereditary ataxia with sensory neuronopathy
2. Kindreds are described in the USA of Scandinavian ethnicity
3. The mutation is unknown but is linked to chromosome 16q22.1. Anticipation has been seen in two kindreds

Clinical Manifestations

1. Onset is in middle-aged adults
2. Cerebellar ataxia at presentation
3. Pyramidal signs
4. Peripheral sensory loss (large fiber modalities)
5. Loss of deep tendon reflexes

Neuropathology

1. Not determined

Laboratory Evaluation

1. EMG
 - a. Absent sural sensory nerve action potentials

Spinocerebellar Ataxia 5 (SCA5)*General Characteristics*

1. Gene locus is xq25-q27.1

Clinical Manifestations

1. Norwegian ancestry
2. Cerebellar hypoplasia

SCA6*General Characteristics*

1. SCA6 is due to mutations in the CACNA1A gene that maps to chromosome 19p13.13
 - a. The gene encodes the pore forming $\alpha 1A$ subunit of P/Q type calcium channels (CaV2.1) that initiate synaptic transmission at fast synapses
 - b. It is due to a small repeat expansion in exon 47 in some of the isoforms of the CACNA1A gene as a polyglutamine sequence

Clinical Manifestations

1. Late onset
2. Primarily a pure cerebellar ataxia
3. The ataxia may be preceded by an episodic phase with dysarthria, nystagmus, and vertigo
4. Migraine is often associated
5. Usually a benign course

Neuropathology

1. The CACNA1A gene product is a membrane protein rather than a nuclear or cytoplasmic protein which is the norm for most polyglutamine disorders
2. Insoluble aggregates are rare and are located in the cytoplasm and rarely to the nucleus of Purkinje cells
3. The expanded alleles are usually 20 to 33 repeats (normal 4 to 8 repeats). The small repeats are more stable than in other polyglutamine disorders
4. A hypothesis for the pathogenesis of SCA6 disease is that a fragment of the CaV2.1 channel which is detected in cytosolic and nuclear areas may initiate the process

Laboratory Evaluation

1. MRI:
 - a. Minimal cerebellar atrophy
2. EMG:
 - a. Mixed axonal and demyelinating characteristics of a peripheral neuropathy in 22% of patients
 - b. SCA6 had less axonal damage than patients with SCA1 and 2

Spinocerebellar Ataxia 7 (SCA7)*General Characteristics*

1. SCA7 is caused by an expanded trinucleotide repeat in the ATXN7 gene that maps to chromosome 3p14.1. Anticipation occurs in some families
2. In the Harding classification this would be ADCA type II
3. In some families, there is more frequent paternal transmission
4. 34–36 CAG repeats are variably associated with disease manifestations (alleles with reduced penetrance). Approximately 75% of normal alleles have 10 CAG repeats

Clinical Manifestations

1. Progressive cerebellar ataxia
2. Dysarthria and dysphagia
3. Cone-rod and retinal dystrophy with central visual loss that may lead to blindness
4. Variable signs include:
 - a. Ophthalmoplegia
 - b. Pyramidal and extrapyramidal signs (brisk reflexes and spasticity)
 - c. Dementia
 - d. Large fiber modality sensory loss
5. The age at onset, degree of severity, and rate of progression vary among and between families
6. Infant and early childhood onset:
 - a. Muscle wasting, weakness and hypotonia
 - b. Rapid cerebellar and brainstem degeneration
 - c. Onset at or before adolescence causes retinal degeneration and blindness within a few years

Neuropathology

1. Neuronal loss, loss of myelinated fibers and gliosis in the cerebellum

2. Prominent Purkinje cell loss; neuronal loss in the inferior olive, dentate and pontine nuclei. Minimal neuronal loss in the cerebral cortex, basal ganglia and midbrain
3. Posterior column and spinocerebellar tract demyelination
4. Degeneration of photoreceptors, bipolar and granular retinal cells, especially in the foveal and parafoveal areas

Laboratory Evaluation

1. Molecular genetic testing; anticipation may be dramatic
2. Cone-rod retinal dystrophy that includes:
 - a. Abnormalities of rod and cone function by electroretinogram
 - b. Blue-yellow defect on color vision testing
 - c. Macular changes in late disease (fundoscopic evaluation)
3. MRI:
 - a. Cerebellar and pontine atrophy
4. EMG:
 - a. Sensorimotor peripheral neuropathy

Differential Diagnosis

1. Retinal degeneration is the distinguishing feature of SCA7
2. SCA1
 - a. A few patients have had visual loss
3. LHON can present with ataxia and visual loss
4. Infantile and childhood onset SCA7 may have features suggestive of lipid storage diseases and neuronal ceroid lipofuscinosis

SCA8*General Characteristics*

1. SCA8 is associated with mutations of the genes ATXN8 and ATXN80S that maps to chromosome 13q21
 - a. There is bidirectional transcription at the SCA8 locus that involves an expanded CTG trinucleotide/repeat in the ATXN80S gene and a complementary CAG repeat in the ATXN8 gene

Clinical Manifestations

1. Onset is in adulthood with cerebellar ataxia
2. Cognitive dysfunction occurs in approximately 70% of patients
3. Pyramidal and sensory signs occur in approximately 30% of patients
4. Dysexecutive and psychiatric deficits
5. Spastic and ataxic dysarthria
6. Diminished vibration sensibility
7. Nystagmus
8. Parkinsonism (rarely)

Neuropathology

1. Normal alleles contain 15–50 repeats; pathogenic alleles contain 71–1,300 repeats
2. Post-mortem evaluation (one patient)
 - a. Cerebellar atrophy with loss of Purkinje cells

- b. Loss of cells in the inferior olives
- c. Depigmentation of the substantia nigra
- 3. The expanded CTG repeat in the ATXN80S gene:
 - a. Is transcribed into an mRNA with an expanded CAG repeat that confers a toxic gain of function
- 4. The ATXN80S protein accumulates as ribonuclear inclusions (RNA foci) that colocalize with the RNA-binding protein MBNL1 in cerebellar cortical neurons
- 5. Loss of MBNL1 protein is suggested as contributing to SCA8 pathogenesis. Sequestration of MBNL1 in the abnormal RNA foci disrupts downstream splicing patterns

Laboratory Evaluation

- 1. MRI:
 - a. Atrophy of the vermis and cerebellar hemispheres
 - b. Cerebellar and pontine atrophy (some patients)

Rare Clinical Manifestation

- 1. Two patients have been described with a non-ataxic phenotype
 - a. Parkinsonism with dopaminergic responsiveness
 - b. ALS with cerebellar atrophy on brain MRI
- 2. Coexistence of ataxin 8 gene repeat expansion has been reported in MSA, HD, AD and SCA1, SCA2, SCA6, 16q-linked autosomal dominant cerebellar ataxia and Friedreich's ataxia
- 3. The SCA8 transcript protein has been reported to down-regulate Kelch-like protein by an antisense mechanism. KLHL is widely expressed in the brain but primarily in the Purkinje cell layer but also in the basal ganglia, spinal cord, hippocampus, and lateral entorhinal cortex
- 4. Kelch-like protein is postulated to be essential in these other CNS regions and its down regulation may underlie the non-ataxic phenotypes of SCA8

Spinocerebellar Ataxia 10 (SCA10)

General Characteristics

- 1. SCA10 is caused by a pentanucleotide repeat expansion (ATTCT) in the ATXN10 gene that maps to chromosome 22q13.31

Clinical Manifestations

- 1. Slow progressive cerebellar syndrome
- 2. Epilepsy (complex partial)
- 3. Mild pyramidal signs
- 4. The age of onset is between 18–45 years (mean 32.2 years)
- 5. Kindreds are primarily Mexican and Brazilian
- 6. Peripheral neuropathy
- 7. Psychological disorder

Neuropathology

- 1. The expanded ATTCT pentanucleotide repeat is in intron 9 of ATXN10 gene and ranges from 800 to 4500 repeats (normal is 10–29)

- 2. The translated RNA has been postulated to cause a gain of function mechanism that results in inactivation of proteins that are involved in RNA biogenesis
- 3. The spliced intron 9 RNA that contains the expanded AUUC repeat aggregates in CNS cells and sequesters RNP K. Sequestration of this protein triggers the translocation of protein kinase C delta (PKC δ) to mitochondria that leads to activation of caspase-3 and apoptosis

Laboratory Evaluation

- 1. EEG:
 - a. Complex partial seizure or generalized tonic/clonic seizure activity (approximately 80% of patients)
- 2. EMG:
 - a. Peripheral neuropathy (sensory in some patients)
- 3. MRI:
 - a. Mild cerebellar atrophy

Spinocerebellar Ataxia 12 (SCA12)

General Characteristics

- 1. SCA12 is caused by a CAG expansion at the 5' end of the gene encoding PP2R2B that maps to chromosome 5q31-5q32
- 2. PP2R2B encodes a brain-specific regulatory subunit of the protein phosphatase 2

Clinical Manifestations

- 1. Mild cerebellar tremor
- 2. Action tremor (hallmark)
- 3. Pyramidal and extrapyramidal signs
- 4. Dementia
- 5. The age at onset ranges from 8–55 years of age with most patients presenting in the fourth decade
- 6. Parkinsonian features (late)
- 7. Hyperreflexia (late)

Neuropathology

- 1. The CAG expansion is located within or slightly upstream from exon 7 at the 5' end of the gene
- 2. The number of repeats that cause the syndrome is between 55–78
- 3. The pathogenesis has been suggested to arise from a toxic effect of the RNA level
- 4. Autopsy (1 patient):
 - a. Atrophy of the cerebral cortex
 - b. Loss of Purkinje cells

Laboratory Evaluation

- 1. Targeted mutation analysis
- 2. MRI:
 - a. Cerebral and cerebellar atrophy
 - b. Cerebral cortex may be more involved than the cerebellar cortex (some patients)
 - c. Vermian atrophy is more prominent than that of the cerebellar cortex

Differential Diagnosis

1. SCA2, SCA3, SCA6 and DRPLA may have action tremors
2. Familial essential tremor
3. Ataxia with FGF 14 mutation has an action tremor but more severe cerebellar signs
4. Multiple system atrophy
5. Familial forms of Creutzfeldt-Jakob disease
6. SCA14 (has axial myoclonus)

Spinocerebellar Ataxia 13 (SCA13)*General Characteristics*

1. SCA13 is caused by two missense mutations in the KCN3 gene that maps to chromosome 19q13.3-q13.4
2. The gene encodes the K_v3.3 potassium channel

Clinical Manifestations

1. The phenotype is associated with an early onset ataxia that progresses slowly and may be associated with cognitive dysfunction and rare seizures
2. Adult onset progressive ataxia
3. Dysphagia, urinary urgency, and bradykinesia have been reported in patients older than 50 years of age

Neuropathology

1. Non-functional K_v3.3 channel
2. The mutant protein has reduced complex glycan adducts and is not trafficked correctly to the plasma membrane; it is retained in the Golgi apparatus

Laboratory Evaluation

1. Molecular genetic testing
2. MRI:
 - a. Mild to moderately severe cerebellar atrophy; most severe in the midline
 - b. The cerebral cortex and the brainstem are normal

Spinocerebellar Ataxia 14 (SCA14)*General Characteristics*

1. SCA14 is caused by missense mutations in the PRKCG gene that maps to chromosome 19q13.42
2. The gene encodes:
 - a. Protein kinase PKC γ (gamma) is a member of the PKC family of serine and threonine kinases. PKC γ (gamma) is expressed densely in Purkinje cells

Clinical Manifestations

1. Age of onset 10–70; mean 34 years
2. Slowly progressive cerebellar ataxia
3. Dysarthria
4. Nystagmus
5. Decrease of vibration sensibility
6. Cognitive impairment (some families)
7. Hyperreflexia

8. Parkinsonism characterized by rigidity and focal dystonia
9. Axial myoclonus
10. Facial myokymia
11. Choreic hand movements
12. Seizures
13. Sensory loss
14. Sensorineural hearing loss (2 patients)
15. Lifespan is normal

Neuropathology

1. PKC γ (gamma) is essential in signal transduction, cell differentiation, and synaptic transmission

Laboratory Evaluation

1. Molecular genetic testing
2. MRI:
 - a. Mild to moderately severe cerebellar atrophy that is primarily midline
 - b. There is no atrophy of the brainstem or cerebral cortex

Differential Diagnosis

1. Specific differential signs in this cerebellar ataxia are axial myoclonus and cognitive impairment
2. Progressive myoclonic epilepsy with ataxia from mutations in the PRICKLE1 gene
3. Myoclonus-dystonia from mutations in SGCE gene

Spinocerebellar Ataxia Type 15/16 (SCA15/16)*General Characteristics*

1. SCA15 is caused by heterozygous mutations and deletions in the inositol 4,5-triphosphate receptor (ITR1) gene that maps to chromosome 3p26.1

Clinical Manifestations

1. Slowly progressive ataxia
2. Postural and kinetic tremor
3. Mild hyperreflexia (without spasticity but rarely a Babinski sign). Additional features may include:
 - a. Gaze-evoked nystagmus in approximately 80% of patients
 - b. Approximately 50% of patients demonstrate an impaired vestibulo-ocular reflex that may produce movement induced oscillopsia
 - c. In less than 30% of patients, a postural head and/or truncal tremor
 - d. Upper limb postural tremor early in the course of the disorder
 - e. Orolingual dyskinesia, perioral myokymia and chorea may occur
 - f. Cognitive impairment

Neuropathology

1. Pure cerebellar atrophy: the brainstem is normal

Laboratory Evaluation

1. Atrophy of the rostral and dorsal vermis of the cerebellum; cerebellar hemispheres are normal or minimally atrophic
2. EMG:
 - a. Nerve conduction studies are most often normal; minor slowing of sural sensory and median motor conduction velocities have been detected in one Japanese kindred

Differential Diagnosis

1. The differential diagnosis is primarily that of a pure slowly progressive ataxia with an early tremor
2. The SCAs that are primarily cerebellar include SCA5, SCA6, SCA8, SCA11, SCA12, SCA14, SCA19/SCA22, SCA21, SCA23, SCA26, SCA27, SCA28 and SCA30
3. SCA8 and SCA30 are very similar to SCA15
4. Head tremor is suggestive of SCA15
5. SCA1, SCA2, SCA3 have a more rapidly progressive course
6. SCA2 has slow saccades that do not occur in SCA15, which has gaze-evoked nystagmus that is not seen in SCA2

Spinocerebellar Ataxia 17 (SCA17)*General Characteristics*

1. SCA17 is caused by a CAG/CAA repeat expansion in the TATA-box binding protein gene (TBP) that maps to chromosome 6q27
2. TBP encodes a general transcription initiation factor

Clinical Manifestations

1. Onset is from age 3 to 75 years (mean 34.6 years)
2. Ataxia is seen in 95% of patients
3. Dementia (approximately 90%)
4. Involuntary movements (approximately 70% of patients) that include:
 - a. Dystonia (blepharospasm, torticollis, writer's cramp, foot dystonia)
 - b. Chorea
 - c. Pyramidal signs
 - d. Rigidity
 - e. Patients with full penetrance develop neurologic and/or psychiatric signs and symptoms by age 50
 - f. Ataxia as well as psychiatric symptoms and disorders are early findings with the subsequent development of involuntary movements, Parkinsonism, dementia and pyramidal signs

Neuropathology

1. Atrophy of the stratum (most severe in the caudate nucleus) and the cerebellum
2. Neuronal loss in the Purkinje cell layer, striatum, and the cerebral cortex (some patients)
3. Diffuse labeling of polyglutamine (polyQ) tracts in the neuronal nucleoplasm

Laboratory Evaluation

1. MRI:
 - a. Variable atrophy of the cerebrum, brainstem, and cerebellum
2. Molecular genetic testing:
 - a. Penetrance of alleles of 41–44 repeats occurs in approximately 50% of patients; 45–48 repeats occur in greater than 80% of patients

Differential Diagnosis

1. DRPLA causes ataxia, choreoathetosis and dementia in adults
2. Huntington's disease
3. TBP alleles > than 45 CAG/CAA repeats occur in a HD-like phenotype (HDL-4)
4. One patient resembled MSA with ataxia, autonomic dysfunction, Parkinsonism, supranuclear palsy and cognitive impairment

Spinocerebellar Ataxia 18 (SCA18)*General Characteristics*

1. SCA18 is caused by mutations in the interferon related developmental regulator 1 gene (IFRD1) that maps to chromosome 7q22-q32

Clinical Manifestations

1. The disorder does not clearly fall into either the SCA or hereditary sensory neuropathy categories; it has also been designated sensory/motor neuropathy with ataxia (SMNA)
2. In the large five-generation American family studied, there was variable expressivity and severity of signs and symptoms
3. Peripheral sensory loss may be the initial symptom
4. Onset is usually in the second and third decades of life (13–27 years of age)
5. Gait difficulty
6. Dysmetria
7. Hyporeflexia
8. Muscle weakness and atrophy
9. Decreased large fiber sensory modality loss (proprioception and vibration sensibility)
10. Pes cavus

Neuropathology

1. Muscle biopsy:
 - a. Neurogenic atrophy
2. Axonal sensory neuropathy
3. High levels of IFRD1 are expressed in the brain, spinal cord, and dorsal root ganglia
4. In the nucleus the protein acts as a transcriptional corepressor and interacts with proteins of the SIN3 histone deacetylase complex
5. Genes in the NGF-IFRD1 pathway have roles in the neuropathy

Laboratory Evaluation

1. MRI
 - a. Mild cerebellar atrophy
2. EMG:
 - a. Axonal motor/sensory neuropathy

Spinocerebellar Ataxia 19/22*General Characteristics*

1. SCA19/22 is caused by loss of function in the KCND3 (potassium voltage-gated channel, shal-related subfamily, member 3) that maps to chromosome 1p13.2
2. KCND3 encodes the voltage-gated potassium channel Kv4.3, a membrane protein
3. The Kv4.3 is rapidly activated, and inactivates in response to membrane depolarization that generates the A-type potassium currents
4. The Kv4.3 channel controls action potential repolarization and frequency of firing

Clinical Manifestations

1. Onset is variable but most patients develop disease between 10–55 years of age
2. Mild cerebellar atrophy
3. Cognitive impairment
4. Myoclonus
5. Postural tremor
6. Seizures (one patient)
7. Peripheral neuropathy
8. Hyperreflexia
9. Cogwheel rigidity (1 family)

Neuropathology

1. Atrophy of the anterior vermis is greater than that of the cerebellar hemisphere
2. Loss of Purkinje cells
3. Degeneration and atrophy of both the molecular and internal granular layers
4. Purkinje cells stain for KCND

Laboratory Evaluation

1. MRI: Mild cerebellar atrophy

Spinocerebellar Ataxia 22*General Characteristics*

1. Studies of a four generation Han Chinese family with ataxia
2. Mutation is in chromosome 1p21-q23; thought to be the same locus as noted for SCA19

Clinical Manifestations

1. Mild cerebellar ataxia
2. Onset is between 35–40 years
3. Nystagmus
4. Decreased smooth pursuit extraocular movements
5. Decreased reflexes

Neuropathology

1. KNCA1 (encodes Kv1.1), KCNC3 (encodes Kv3.3) and KCND3 (encodes Kv4.3) (all are voltage-gated potassium channel genes) cause cerebellar degeneration and ataxia
2. Neuronal excitability appears to be important in the survival of cerebellar neurons

Laboratory Evaluation

1. MRI: Mild cerebellar atrophy

Spinocerebellar Ataxia 20 (SCA20)*General Characteristics*

1. The gene locus for SCA20 is within the pericentromeric region of chromosome 11q12
2. A 260-Kb duplication of 11q12.2-11q12.3 has been defined in the Australian index family

Clinical Manifestations

1. Onset between 19–64 years of age
2. Presents with dysarthria without ataxia, which may start abruptly or subacutely
3. It may be combined with adductor dysphonia
4. Palatal tremor (~66% of patients)
5. Hypermetric horizontal saccades (without nystagmus or vestibulo-ocular dysfunction)
6. Mild hyperreflexia
7. Postural arm tremor with or without head tremor
8. Portuguese families reported with spasmodic coughing episodes

Neuropathology

1. No autopsy material reported

Laboratory Evaluation

1. CT evaluation
 - a. Dentate calcification without pallidal calcification (<3 years from onset)
2. MRI:
 - a. Mild to moderate pancerebellar atrophy
 - b. Low dentate signal on T₁- and T₂-weighted sequences
 - c. Normal cortex and brainstem except for patients with palatal tremor who may demonstrate increased inferior olivary T₂ sequence signal
 - d. Axial proton density images demonstrate inferior olivary hypertrophy and low dentate nucleus signal
3. EMG: normal nerve conduction studies

Differential Diagnosis of Spinocerebellar Ataxia 20 (SCA20)

1. Distinctive features are early dentate calcification and palatal tremor
2. Dentate calcification affects .7% of the population >65 years if age; it is rarely seen in the absence of basal ganglia calcification. In SCA20 dentate calcification may appear in isolation

3. Hyperparathyroidism and pseudohypoparathyroidism have dentate and basal ganglia calcification. Hyperparathyroidism presents with proximal muscle aches, fatigue, tongue fibrillations and decreased reflexes (rarely increased)
4. Dentatorubral-pallidoluysian atrophy may have pallidal microcalcifications in the Haw river patient phenotype
5. Familial idiopathic basal ganglia calcification presents with cognitive function deficits and Parkinsonism rather than ataxia. Basal ganglia calcification, rather than that of the dentate nucleus, is predominant

Differential Diagnosis of Palatal Myoclonus

1. Vascular disease affecting Mollaret's triangle (acquired, not genetic)
2. In association with progressive ataxia in sporadic patients, possibly a unique syndrome
3. Multiple system atrophy of the cerebellar type (rare)
4. Early adult-onset Alexander disease, bulbar and spastic tetraparesis are associated
5. A dominant branchial myoclonus with ataxia (possibly a phenotypic variant of adult-onset Alexander disease)
6. There is overlap with spinocerebellar ataxia 5 (SCA5) and it is possible that they may be the same disease

Spinocerebellar Ataxia 21

General Characteristics

1. SCA21 is caused by a heterozygous mutation in the TMEM240 gene that maps to chromosome 1p36

Clinical Manifestations

1. The family studies are of a four generational French kindred (11 members)
2. Slowly progressive cerebellar ataxia
3. Mild cognitive impairment
4. Postural and/or resting tremor
5. Bradykinesia and rigidity
6. Parkinsonism was found to be not L-Dopa responsive
7. Age of onset is 17.4 years, earlier than for most ADCA Type I SCAs
8. Follow-up in the original French patients described and an addition of seven additional French families with SCA revealed:
 - a. Delayed psychomotor development from early childhood; frontal behavior symptom with later development
 - b. Mild to severe cognitive dysfunction
 - c. Gait ataxia and incoordination between 1–20 years of age
 - d. Additional signs include:
 - i. Dysarthria
 - ii. Dysgraphia
 - iii. Nystagmus
 - iv. Slow ocular saccades
 - v. Tremor
 - vi. Increased or decreased deep tendon reflexes and Babinski sign

Neuropathology (One Patient)

1. Mild loss of Purkinje cells in the cerebellar vermis
2. No intracellular inclusions

Laboratory Evaluation

1. MRI: Cerebellar atrophy (mild); some brainstem atrophy

Spinocerebellar Ataxia 23

General Characteristics

1. SCA23 is caused by missense mutations in the PDYN gene that maps to chromosome 20p13
2. The encoded protein is the precursor of dynorphin opioid peptides
3. PDYN mutations account for approximately .1% of European SCA patients

Clinical Manifestations

1. Late onset (43–56 years of age)
2. Gait ataxia
3. Limb ataxia
4. Dysarthria
5. Slow saccades
6. Ocular dysmetria
7. Decreased lower extremity vibration sensibility
8. Distal sensory neuropathy

Neuropathology (1 Patient)

1. Frontotemporal atrophy
2. Atrophy of the cerebellar vermis
3. Atrophy of the pons and spinal cord
4. Neuronal loss in the cerebellar vermis, dentate nuclei and inferior olives but not in the pons
5. Thinning of the cerebellopontine tracts
6. Demyelination of the posterior and lateral spinal cord columns

Laboratory Evaluation

1. MRI:
 - a. Generalized cerebral cortical and subcortical atrophy
 - b. Agenesis of the corpus callosum
 - c. Severe atrophy of the cerebellar vermis, pons and the inferior olivary nucleus

Spinocerebellar Ataxia 25

General Characteristics

1. SCA25 maps to chromosome 2p21-p13

Clinical Manifestations

1. Age at onset ranges from 17 months to 39 years (most are affected in childhood)
2. Cerebellar ataxia
3. Peripheral sensory neuropathy
4. Some patients suffered more cerebellar ataxia and less sensory neuropathy while the reverse occurred in other patients

5. Areflexia of the lower limbs
6. Variable manifestations include:
 - a. Gastrointestinal dysfunction with vomiting and abdominal pain; the digestive complaints are persistent in some patients
 - b. Scoliosis
 - c. Nocturia and urinary urgency

Neuropathology

1. Sural nerve biopsy: loss of myelinated fibers

Laboratory Evaluation

1. MRI: severe global cerebellar atrophy
2. EMG: sensory neuropathy

Spinocerebellar Ataxia 26

General Characteristics

1. SCA26 is caused by heterozygous mutations in the EEF2 gene that maps to chromosome 19p13.3
2. SCA26 is rare, with only one American family of Norwegian descent having been studied (23 affected members and 14 at-risk patients)

Clinical Manifestations

1. Age at onset is usually between 26–60 years (mean of 42 years) with no anticipation
2. Late-onset, slowly progressive cerebellar signs and symptoms
3. Impaired ocular pursuit and nystagmus

Neuropathology (Two Patients)

1. Significant loss of Purkinje cells with minimal or absent neuronal loss in other brain areas
2. Entire folia were seen with no Purkinje cells
3. It has been hypothesized that the mutation causes impaired translocation that causes an increased rate of –1 programmed ribosomal frameshift read-through during translation

Laboratory Evaluation

1. MRI
 - a. Moderately severe cerebellar atrophy with a normal pons and medulla

Spinocerebellar Ataxia 27

General Characteristics

1. SCA27 is caused by mutation of the fibroblast growth factor 14 (FGF14) gene that maps to chromosome 13q33.1
2. A reverse and frameshift mutation have been described

Clinical Manifestations

1. Onset in childhood
2. Tremor and incoordination of the hands begins at 15–20 years of age

3. Saccadic dysmetria
4. Psychiatric symptoms (depression and frontal lobe dyscontrol)
5. Severe limb and gait ataxia
6. Head tremor
7. Rare variants include:
 - a. Paroxysmal non-kinesigenic dyskinesia
 - b. Fever sensitivity
 - c. Pes cavus and mild axonal sensory neuropathy

Neuropathology

1. FGF14 regulates brain sodium channels including those in the cerebellum. Sodium channels may be functionally temperature-sensitive
2. Intracellular FGF14 “knock-down” (experimentally in mice) attenuates spontaneous and evoked action potentials of adult Purkinje cells and was associated with poor coordination and balance
3. Loss of IFGF causes a hyperpolarizing shift in the voltage dependence of steady-state inactivation of sodium current in adult Purkinje neurons which are essential for cerebellar function

Laboratory Evaluation

1. MRI:
 - a. Moderate cerebellar atrophy
2. EMG (one variant):
 - a. Mild axonal sensory neuropathy

Spinocerebellar Ataxia 28

General Characteristics

1. SCA28 is caused by heterozygous mutation in the AFG3L2 gene that maps to chromosome 18p11.21
2. Mutation in the AFG3L2 gene also causes autosomal recessive (AR) spastic ataxia 5
3. Missense mutations in the AFG3L2 proteolytic domain are approximately 1.5% of the European autosomal dominant cerebellar ataxias

Clinical Manifestations

1. Onset in early adulthood (24.4 ± 14.9 years); the range is 3 to 60 years of age
2. The course is slowly progressive over decades, with minimal functional impairment
3. Cerebellar ataxia is associated with dysarthria
4. Oculomotor signs (80% of patients) include:
 - a. Limited to spontaneous gaze (~50%)
 - b. Gaze-evoked nystagmus
5. Ptosis (~50% of patients)
6. Extrapyramidal signs (24% of patients) include:
 - a. Parkinsonism: primarily rigidity and bradykinesia
 - b. Dystonia
7. Cognitive and behavioral problems in ~20% of patients
8. Decreased vibration sensibility in the lower extremities occurs in approximately 20% of patients; superficial sensation is intact

- Reflexes are increased in the lower extremities in approximately 75% of patients, with associated Babinski signs in 25%

Neuropathology

- AFG3L2 is a component of the conserved matrix ATPase
- It is associated with pleiotropic cellular activity that is involved in the maintenance of the mitochondrial proteome that is expressed in Purkinje cells
- The mutation decreases cytochrome C activity and thus cellular generation of ATP

Laboratory Evaluation

- MRI:
 - Cerebellar atrophy most prominent in the superior vermis
 - Brainstem is normal
- EMG:
 - Conduction velocities were normal in seven patients; neurogenic abnormalities were observed in two

Differential Diagnosis of SCA28

- The SCA caused by polyglutamine-expressions: SCA1, SCA2, SCA3, SCA7, SCA17 and DRPLA usually have onset prior to age 30, are more rapidly progressive, and have brainstem involvement demonstrated by MRI
- SCA6 is an adult-onset, slowly progressive ataxia with gaze-evoked nystagmus that is phenotypically similar to SCA28
- The AR ataxias that include FA and Oculomotor apraxia type I and type II (AOA1 and AOA2) are:
 - More rapidly progressive
 - Most often have a childhood onset
- Mitochondrial disorders with ophthalmoparesis and ptosis should also be considered in the differential diagnosis

Spinocerebellar Ataxia 29

General Characteristics

- SCA29 is caused by a heterozygous mutation in the ITPR1 gene that maps to chromosome 3p26-p25
- ITPR1 encodes inositol 1,4,5-trisphosphate receptor type 1
 - It is a ligand-gated ion channel that mediates calcium release from the endoplasmic reticulum
- Deletions of ITPR1 cause SCA15 (adult onset)

Clinical Manifestations

- Onset in infancy
- Delayed motor development
- Cognitive dysfunction (some)
- A slowly progressive gait and limb ataxia
- Variable neurologic deficits include
 - Nystagmus (vertical in some kinbreds)
 - Dysarthria
 - Tremor

Neuropathology

- The missense mutations in ITPR1 are localized to its coupling domain. The coupling/regulatory domain contains protein phosphorylation and proteolytic cleavage sites, ATP binding sites, and binding sites for other proteins
- It is hypothesized that the neuropathologic deficits in SCA29 are due to abnormal ITPR1-mediated Ca^{2+} signaling pathways involved in multiple cellular processes. It has also been suggested that ITPR1 is important in embryonic development

Laboratory Evaluation

- MRI:
 - Mild cerebellar atrophy; in some patients it is more prominent in the vermis
 - It has been shown to be progressive in longitudinal studies in one patient

Differential Points Between SCA29, ITPR1, and SCA15

- ITPR1 and SCA29 are congenital non-progressive SCAs that remain static, while SCA15 progresses
- SCA15 is adult-onset, and has extracerebellar features that include cognitive impairment (variable), ophthalmoplegia, and pyramidal and extrapyramidal signs

Spinocerebellar Ataxia 30

General Characteristics

- SCA30 has been mapped to a 5-mb locus on chromosome 4q34.3-q35.1. The gene has not been defined

Clinical Manifestations

- Onset mean is 52 years (range 45–76 years)
- The onset is insidious
- A relatively pure, slowly progressive gait and appendicular ataxia with dysarthria
- Hypermetric saccadic eye movements with normal vestibulo-ocular reflex gain
- Gaze-evoked nystagmus (1 patient)
- Hyperreflexia in the lower extremities (some patients)
- Dystonia (one patient)

Neuropathology

- Not defined

Laboratory Evaluation

- MRI:
 - Isolated cerebellar atrophy, predominately in the superior and dorsal vermis

Spinocerebellar Ataxia 31

General Characteristics

- SCA31 is caused by a 2.5–3.8-Kb insertion that contains pentanucleotide repeats (TGGA) within the BEAN1 gene that maps to chromosome 16q21-q22

2. SCA31 is the fourth most common autosomal dominant cerebellar ataxia (ADCA) in Japan. Otherwise it is a rare ADCA

Clinical Manifestations

1. Symptomatic disease onset is between 8 and 83 years (mean of 58 years of age)
2. The usual disease duration is greater than 10 years, it has complete penetrance and has minimal or absent anticipation
3. Gait ataxia
4. Cerebellar type dysarthria
5. Limb ataxia
6. Decreased muscle tone
7. Oculomotor abnormalities
8. Horizontal gaze-evoked nystagmus and impaired pursuit eye movement
9. Variable neurologic signs:
 - a. Pyramidal signs
 - b. Sensorineural hearing loss
 - c. Downbeat nystagmus
 - d. Head tremor
 - e. Decreased vibration sensibility
 - f. Brisk deep tendon reflexes

Neuropathology (2 Autopsy Studies)

1. The pentanucleotide repeat contains (TGGA)n, (TAGAA)n, (TAAAA)n and (TAGAATAAAA) inserted into an intron shared by two different genes (BEAN1 and TK2) located in the long arm of chromosome 16, and shown to be the critical component of SCA31
2. Abnormal RNA structures ("RNA foci") are identified in Purkinje cell nuclei, indicating that BEAN1-gene-directed mutant transcripts are pathogenic. The RNA foci containing (UGGAA)n were found in the Purkinje cells of the two autopsied patients and are considered to be pathogenic. The mechanism of pathogenesis in Purkinje cell loss has not been defined
3. A hypothesis has been suggested for the mechanism of SCA30 sequestration of proteins that bind to these foci (RNA-mediated gain of function). In other non-coding repeat expansion disorders exemplified by DM1, DM2, FX-TAS, HDL2 and SCA8 the transcript repeats form aggregates in the nuclei of affected cells. The sequestration of proteins that bind to the foci dysregulate alternative splicing
4. Accentuated Purkinje cell loss was seen in the anterior vermis

Laboratory Evaluation

1. MRI:
 - a. Cerebellar atrophy starts from the upper vermis

DRPLA

General Characteristics

1. Dentatorubral-pallidoluysian atrophy is caused by an ex-

panded trinucleotide repeat in the ATN1 gene that maps to chromosome 12p13/31

2. Normal alleles contain 6–35 CAG repeats; full penetrance alleles have >48 CAG repeats
3. The prevalence of DRPLA in the Japanese population is approximately .48 per 100,000 of the population
4. European and North American patients also have DRPLA
5. The Haw River kindred of North Carolina is a large kindred that has been extensively studied and has clinical differences from the clinic DRPLA disorder but is generally thought to be a variant

Clinical Manifestations

1. The onset of DRPLA is from childhood to late adulthood (1–62 years; mean of 30 years of age)
2. The clinical presentation varies depending on the age of onset
3. Neurological manifestations in adults include:
 - a. Ataxia
 - b. Choreoathetosis
 - c. Dementia
4. Neurological manifestations in childhood include:
 - a. Ataxia
 - b. Cognitive difficulties
 - c. Behavioral disorders
 - d. Myoclonus
 - e. Epilepsy
5. Ataxia and dementia are cardinal characteristics irrespective of the age of onset
6. Seizures occur in all patients that have onset prior to 20 years of age
7. Seizures (types):
 - a. Generalized tonic-clonic, tonic, and clonic
 - b. Progressive myoclonic epilepsy that is associated with:
 - i. Myoclonus
 - ii. Seizures
 - iii. Ataxia
 - iv. Progressive intellectual impairment
8. Myoclonic epilepsy and absence or atonic seizures is rarely observed in patients prior to twenty years of age
9. Seizures are less common in patients between 20–40 years of age and are rare in patients >40 years of age
10. Patients with onset of DRPLA > 20 years of age have cerebellar ataxia, choreoathetosis, dementia and psychiatric disorders. Psychosis is a rare presenting manifestation
11. There is prominent anticipation

Neuropathology

1. Combined degeneration of the dentatorubral and pallidoluysian systems
2. There is accumulation of the mutant DRPLA protein (atrophin-1) in neuronal nuclei
3. There is a diffuse nuclear staining that detects expanded polyglutamine stretches

4. White matter involvement demonstrates:
 - a. Diffuse myelin pallor
 - b. Preservation of axons
 - c. Reactive astrogliosis
5. The transgenic mouse model demonstrates:
 - a. Reduction in the number and size of dendritic spines
 - b. Decreased neuronal perikarya and diameter of dendrites
6. Diffuse nuclear staining of mutant protein in neuronal nuclei is not limited to the dentatorubral-pallidoluysian systems

Laboratory Evaluation

1. MRI:
 - a. Atrophy of the cerebellum and brainstem
 - b. Pontine tegmental atrophy is severe
 - c. The age at MRI and the size of the expanded repeat correlate with the degree of atrophy
 - d. Diffuse white matter hyperintensities are noted on T₂-weighted MRI sequences in adult-onset patients

The Haw River Syndrome

General Characteristics

1. The Haw River kindred is a 5 generation kindred that lives in the region of the Haw River of North Carolina and has DRPLA; a second kindred has also been studied

Clinical Manifestations

1. Onset is between 15 and 30 years of age
2. Ataxia
3. Seizures
4. Choreiform movements
5. Progressive dementia
6. Death often after 15–25 years of illness

Neuropathology (2 Patients Autopsied)

1. Severe neuronal loss in the dentate nucleus, microcalcification of the globus pallidus, neuroaxonal dystrophy of the nucleus gracilis, and demyelination of the centrum semiovale

Laboratory Evaluation

1. MRI:
 - a. Mild cerebellar atrophy

Differential Diagnosis of DRPLA in Adult-Onset Disease (non-Progressive Myoclonic Epilepsy Phenotype; PME)

1. The adult onset form of DRPLA has the cardinal features of:
 - a. Ataxia
 - b. Dementia
 - c. Choreoathetosis
2. Huntington's disease, Huntington's disease-like 1 and Huntington's disease-like 2

- a. Ataxia is an important differential point in differentiating DRPLA from Huntington's disease. Some affected DRPLA patients in which the non-PME phenotype may present with severe involuntary movements and dementia that masks ataxia
- b. Atrophy of the cerebellum and tegmentum of the pons is prominent in DRPLA while caudate atrophy is cardinal for Huntington's disease
3. Pure cerebellar ataxia type III
 - a. Some patients with DRPLA have middle expanded CAG repeats, may have pure cerebellar signs and symptoms in their clinical course. These patients have to be distinguished from SCA2, Machado-Joseph disease, SCA6 and SCA17
 - b. If the major features are progressive myoclonic movement impairment and epilepsy i.e. early-onset DRPLA (<20 years of age) then the differential diagnosis includes:
 - i. Lafora type progressive myoclonic epilepsy
 - ii. Unverricht-Lundborg disease
 - iii. Neuronal Ceroid-lipofuscinosis
 - iv. Neuroferritinopathy
 - v. MERRF
 - vi. Sialidosis
 - vii. Galactosialidosis
 - viii. Gaucher's disease
 - ix. Pantothenate kinase deficiency
 - x. Benign adult familial myoclonus epilepsy (BAFME)

Spinocerebellar Ataxia 32

General Characteristics

1. SCA32 is an autosomal dominant disease that maps to chromosome 7q32-q33; the gene has not been defined

Clinical Manifestations

1. Age at onset varies widely particularly in female patients
2. If onset <40 years of age patients have intellectual disability
3. All affected males are infertile

Neuropathology

1. Biopsy of the testicle (one patient)
 - a. Azoospermia and testicular atrophy
 - b. Complete absence of germ cells and progenitor cells

Laboratory Evaluations

1. MRI:
 - a. Cerebellar atrophy

Spinocerebellar Ataxia 34

General Characteristics

1. SCA34 is caused by heterozygous mutation in the ELOV24 gene that maps to chromosome 6q14
2. The protein elongates very long chain fatty acids (at least 26 carbons)

Clinical Manifestations

1. Studied primarily in 625 patients in 5 generations of a French Canadian kindred as well as 2 Japanese families
2. Soon after birth there is a papulosquamous erythematous ichthyosiform plaque eruption. The skin lesions resemble those seen with erythrokeratoderma variabilis (EKVP) and are primarily located on the extremities
3. Skin lesions often disappear by age 25 but may reappear after 40 years of age
4. Pure form of cerebellar ataxia
5. In later stages of the illness:
 - a. Slowly progressive syndrome
 - b. Severe gait ataxia
 - c. Dysarthria
 - d. Nystagmus
 - e. Increased reflexes
 - f. No macular degeneration
 - g. Extraocular movement disorder
6. Patients with homozygous mutations have:
 - a. Ichthyosis
 - b. Spastic paraplegia
 - c. Severe neural developmental defects
7. A milder phenotype with SCA and EKV demonstrates:
 - a. Early-onset patches of erythema and hyperkeratosis
 - b. SCA that manifests in the fourth or fifth decade

Neuropathology

1. ELOVL4 protein localizes to the endoplasmic reticulum
2. It catalyzes the formation of very-long-chain (VLC) (C28–C40) fatty acids, that are saturated and polyunsaturated (PUFA)
3. The defective gene protein is truncated at the C terminus which causes mislocalization and aggregation in other organelles
4. It has been postulated that its toxic keto intermediates of fatty acid elongation are a mechanism of disease pathogenesis due to reduced VLC-PUFA synthesis. Fatty acids are essential for multiple physiologic functions that include skin barrier formation and peroxisome β -oxidation. How they cause cerebellar degeneration has not been defined

Laboratory Evaluation

1. MRI
 - a. Pontine midline linear hyperintensity (“hot cross bun” sign)
 - b. Cerebellar and pontine atrophy
 - c. High intensity signals in the middle cerebellar peduncle

Spinocerebellar Ataxia 35*General Characteristics*

1. Spinocerebellar ataxia 35 is caused by heterozygous mutation in the TGM6 gene (transglutaminase 6 gene) that maps to chromosome 20p13; missense mutation in the gene may also cause the disorder

Clinical Manifestations

1. The major study is that of a 4 generation Chinese kindred
2. The mean age at onset was 43.9 years (range of 40–48 years)
3. Initial features include: ataxia of gait, cerebellar dysarthria; upper limb incoordination occurs later in the course of the disorder; may become wheelchair-dependent 10 years after the start of the illness. Some patients had abnormal eye movements

Neuropathology

1. Transglutaminase 6 (TG6) catalyzes the formation of a covalent bond between a free amino group and the gamma-carboxamide group of proteins
2. The mutation decreases transglutaminase activity and stability:
 - a. Experimental overexpression of TG6 sensitizes cells to staurosporine induced apoptosis by increasing caspase activity

Laboratory Evaluation

1. MRI:
 - a. Diffuse cerebellar atrophy; no cerebral hemisphere or brainstem atrophy

Spinocerebellar Ataxia 36*General Characteristics*

1. SCA36 is caused by heterozygous expansion of an intronic GGCTG hexanucleotide repeat in the NOP56 gene that maps to chromosome 20p13
2. Normal alleles have 3 to 14 repeats whereas patients carry 650 to 2,500 repeats

Clinical Manifestations

1. Onset is between 40–60 years of age
2. Initial presentation is often a gait disorder
3. Dysarthria and appendicular ataxia follow the gait instability
4. Slowly progressive sensorineural hearing loss that manifests a few years after the cerebellar signs
5. Tongue atrophy with fasciculations
6. Swallowing is preserved
7. In advanced disease, patients may develop skeletal muscle atrophy and extremity fasciculation
8. Hyperreflexia
9. Variable clinical manifestations include:
 - a. Gaze-evoked nystagmus
 - b. Ptosis
 - c. Decreased vibration sensibility
 - d. Cognitive impairment

Neuropathology

1. Loss of Purkinje cells and dentate neurons
2. Anterior horn cell loss

- Immunohistochemical analysis (1) NOP56 is localized to neurons
- GGCCVG_n binds the RNA-binding protein SRSF2
- Transcription of MIR1292, an adjacent miRNA is decreased in lymphoblastoid cells from patients
- The major mechanism for cell death has been suggested to be RNA gain of function induced by the hexanucleotide expansion

Laboratory Evaluation

- MRI:
 - Early stages:
 - Atrophy of the superior vermis
 - Intermediate stage:
 - Involvement of the pons and medulla
 - Subcortical atrophy
 - Dilatation of the IVth ventricle similar to that seen in olivopontocerebellar atrophy; no "hot cross bun" sign
 - Cortical brain atrophy, primarily frontal lobe is seen late in the course of the disease
- Brainstem auditory evoked potentials:
 - Absence or reduced amplitude of waves I and II
- Pure tonal audiometry:
 - A drop of >40 dB in frequencies beyond 2500 Hz
- Normal motor and sensory nerve conduction velocities
- Somatosensory evoked potentials of the lower extremities are mildly abnormal
- Penetrance of NOP56 GGCCCTG hexanucleotide pathogenic allele is complete but depends on age

Spinocerebellar Ataxia 37

General Characteristics

- Studies have been done on only one large Spanish kindred
- SCA37 is an autosomal dominant disorder that maps to chromosome 1p32

Clinical Manifestations

- Onset is at a mean age of 44 (range 38 to 64)
- Initial presentation is gait instability with frequent falls
- Dysarthria
- Limb incoordination
- Clinical progression is slow
- Abnormal extraocular movements:
 - Deficits in vertical saccades and irregular vertical smooth pursuit
 - Later development of horizontal smooth pursuit deficits
 - Variable nystagmus

Neuropathology

- Not defined

Laboratory Evaluation

- MRI:
 - Cerebellar atrophy without brainstem involvement

Spinocerebellar Ataxia 38

General Characteristics

- Spinocerebellar ataxia 38 is caused by heterozygous mutation in the ELOVL5 gene that maps to chromosome 6p12.1

Clinical Manifestations

- Presentation is between 34 and 51 years of age
- Gait ataxia
- Nystagmus
- Slow saccades
- Dysarthria
- Distal sensory loss
- Normal cognition

Neuropathology

- Transfection of mutations into cell lines demonstrate:
 - Mutant proteins that have a less diffuse (ER endoplasmic reticulum) signal than wild-type
 - Mutant proteins accumulate in the golgi apparatus
 - Possible activation of the unfolded protein response that leads to apoptosis in affected neurons
 - ELOVL5 is a component of the synthesis of PUFA that contain more than 20 carbons; it is prominently expressed in adult brain. It is located in the soma and proximal portion of the dendritic tree in Purkinje cells

Laboratory Evaluation

- Arachidonic and docosahexaenoic acid are decreased in the serum
- MRI:
 - Cerebellar atrophy

Spinocerebellar Ataxia 40

General Characteristics

- SCA40 is caused by heterozygous mutation in the Ccdc88C gene that maps to chromosome 14q32

Clinical Manifestations

- Onset in the fourth decade
- Presentation is with unsteady gait
- Dysarthria
- Ocular dysmetria
- Intention tremor
- Hyperreflexia
- Impaired vertical gaze (one patient)
- Spastic paraparesis (one patient)

Neuropathology

- Functional studies demonstrate that mutant Ccdc88C protein activates JNK which triggers apoptosis
- A gain of function mutation

Laboratory Evaluation

- MRI (two patients)
 - Pontocerebellar atrophy

Autosomal Dominant Cerebellar Ataxia Type I (Summary)*Definition*

1. A type of Spinocerebellar ataxia that manifests ataxia that is associated with other neurologic signs and symptoms that include:
 - a. Extraocular motor deficits
 - b. Cognitive impairment
 - c. Pyramidal and extrapyramidal dysfunction
 - d. Bulbar abnormalities
 - e. Spinal cord involvement
 - f. Peripheral neuropathy
2. The most common ADCA type I is SCA3 followed by SCA27 > SCA1
3. The cerebellar deficits:
 - a. Involve any part of the body with prominent gait, trunk and limb ataxia; there is frequent associated supranuclear gaze deficits with saccadic dysmetria and hypometric and smooth pursuit deficits; nystagmus is common
 - b. Dysarthria and scanning speech are frequently seen
 - c. The ADCAI subtypes include:
 - i. SCA1, SCA2, SCA3, SCA4, SCA8, SCA10, SCA12, SCA13, SCA14, SCA15/SCA16, SCA17, SCA18, SCA19, SCA20, SCA21, SCA22, SCA23, SCA27, SCA28 and DRPLA
4. ADCA Type I by pathogenic mechanism
 - a. Subclass I:
 - i. CAG expression:
 1. SCA1, SCA2, SCA3
 2. SCA17
 3. DRPLA
 - b. Subclass II:
 - i. Trinucleotide repeat expressions that are outside of the protein coding regions of the causative gene
 1. SCA8
 2. SCA10
 3. SCA12
 - c. Subclass III:
 - i. Disorders caused by deletions, missense mutations and nonsense mutations in specific genes:
 1. SCA13, SCA14, SCA15/SCA16, SCA27 and SCA28

Pathogenic Mechanisms

1. Trinucleotide CAG repeat expansions
 - a. Encode large uninterrupted polyglutamine tracts which are toxic to cells at an RNA level
 - b. Toxicity may be mediated by:
 - i. Interference of protein aggregation and clearance
 - ii. Deficits in calcium homeostasis that causes apoptosis
 - iii. Transcriptional dysregulation
 - iv. Abnormalities in the ubiquitin-proteasome system
2. Trinucleotide repeat expansions outside of the protein coding region
 - a. SCA8, SCA10, SCA12

- b. Toxic reaction at the RNA level; the RNA repeat sequences interfere with gene expression in affected neurons
3. Specific gene deletions, missense mutations and nonsense mutations
 - a. SCA13, SCA14, SCA15/SCA16, SCA27 and SCA28
 - b. Mechanisms of cell death include:
 - i. Transcription dysregulation
 - ii. Mitochondrial dysfunction
 - iii. RNA toxicity
 - iv. Protein aggregation
 - v. Dysregulation of protein folding
 - vi. Bioenergetic failure
 - vii. Calcium homeostasis dysregulation
 - c. All mechanisms may lead to neuronal death by apoptosis during SCA disease progression

Autosomal Dominant Cerebellar Ataxia Type II*Definition*

1. ADCA Type II is composed of cerebellar syndromes associated with maculopathy. It is characterized by SCA7 that maps to chromosome 3p12-21.1 and the gene ATXN7. Approximately 75% of normal alleles have ten CAG repeats. Fully penetrant alleles in this disorder have greater than 36 CAG repeats and expansions as high as 460 CAG repeats. Paternal transmission increases anticipation

Clinical Manifestations

1. In adults progressive cerebellar signs and symptoms usually follow the onset of visual deterioration
2. The progression of the disorder causes severe dysarthria, dysphagia and inability to walk
3. Pigmentary maculopathy is the distinguishing feature:
 - a. Retinopathy includes the macula and leads to blindness
 - b. It extends to the peripheral fundus
 - c. There are early blue-yellow color discrimination deficits
4. Supranuclear ophthalmoplegia
5. Extrapyramidal features
6. The onset is between 2–65 years of age and a subset of patients is wheelchair bound by age 15
7. Adult onset patients usually have paternal transmission; there is reduced penetrance as obligate gene carriers do not manifest disease although they may live beyond 65 years of age
8. Myoclonus
9. Chorea
10. Personality change
11. In adult-onset patients, visual deficits from retinal degeneration may precede or follow cerebellar signs

Neuropathology

1. Loss of myelinated fibers and gliosis in the Purkinje cell layer are prominent

2. There is neuronal loss in the inferior olivary, dentate and pontine nuclei, cerebral cortex, basal ganglia, thalamus and midbrain
3. Biopsies of skeletal muscle and the liver have demonstrated abnormal mitochondria
4. Degeneration of the spinocerebellar tracts and dorsal column are evident in the spinal cord
5. There is degeneration of photoreceptors, bipolar and granular cells in the retina that is most evident in the fovea and parafoveal areas

Laboratory Evaluation

1. Electroretinogram:
 - a. Abnormal early in the disease course demonstrating a disorder of the photopic response initially. Over time there is a decrease in the scotopic (rod) response
2. Farnsworth dichotomous color vision testing reveals:
 - a. Difficulty with triton (blue-yellow) axis of color discrimination
3. MRI:
 - a. Cerebellar and pontine atrophy

Autosomal Dominant Cerebellar Ataxia Type III

General Characteristics

1. ADCA III manifests with cerebellar signs and symptoms but may also have pyramidal signs, ophthalmoplegia, and tremor
 - a. Most often disease onset is in adulthood although some patients are symptomatic in adolescence
2. The most common subtype is SCA6 with SCA5, SCA11, SCA26, SCA30 and SCA31 comprising the remainder of the group
 - a. There is variability of phenotype in between subtypes and within individual affected families
 - b. SCA5 and SCA11 are caused by missense, in-frame deletions and frameshift insertions or deletions
 - c. SCA6 is a trinucleotide CAG expression disorder, while SCA31 is caused by intronic repeat expansions
 - d. The specific genes for SCA26 and SCA30 have not been defined but the chromosome locus has been determined
3. ADCA Type III is compatible with a normal life span although dysphagia and falls cause considerable morbidity

Clinical Manifestations

1. In general, this is a benign and slowly progressive group of disorders
2. Primarily cerebellar signs and symptoms that include gait and limb ataxia with dysarthria
3. Oculomotor dysfunction includes nystagmus and impaired smooth pursuit
4. Rarely observed manifestations:
 - a. Pyramidal tract signs
 - b. Peripheral neuropathy
 - c. Involuntary movements

Neuropathology

1. The defined genes for ADCA III are:
 - a. Spectrin beta, non-erythrocyte 2 (SPTBN2) gene in SCA5
 - b. Calcium channel, voltage dependent P/Q type, alpha 1A subunit (CACNA1A) gene seen in SCA6
 - c. Tau-tubulin kinase – (TTBK2) for SCA11 (conventional mutations)
 - d. BEAN1 (brain expressed associated with NEDD4 1) gene seen in SCA31
 - e. Two gene loci have also been defined for SCA26 and SCA30
2. Present consensus of pathologic mechanisms underlying neurodegeneration in the spinocerebellar ataxias
 - a. Neurodegeneration in SCAs is multifactorial and progressive
 - b. Specific mechanisms include:
 - i. Dysregulation of protein folding
 - ii. Abnormal transcription
 - iii. Failure of bioenergetics
 - iv. Failure of calcium homeostasis
 - v. Cell death due to apoptosis
3. SCAs with clear degenerative patterns:
 - a. Retinal degeneration in SCA7
 - b. Tau aggregation in SCA11
 - c. Dentate calcification in SCA20
 - d. Protein deposition in the Purkinje cells of SCA31
 - e. Azoospermia in SCA32
 - f. Neurocutaneous pathology in SCA34

Laboratory Evaluation

1. Molecular genetic testing
2. Patterns of cerebellar and pontine atrophy delineated by MRI

Summary of Autosomal Recessive Cerebellar Ataxias

1. Hereditary ataxias with autosomal inheritance have been estimated at 3/100,000 of the population worldwide. There are now 75 disorders with this pattern of inheritance
2. The most common of the recessive ataxias are:
 - a. Autosomal recessive spastic ataxia of Charlevoix-Saguenay (ARSACS)
 - b. POLG and related disorders
 - c. Ataxia telangiectasia
 - d. Cerebrotendinous xanthomatosis (CTX)
 - e. Refsum syndrome
 - f. AVED
3. Ataxia and/or cerebellar hypoplasia caused by biallelic pathogenic variants of related genes include:
 - a. Joubert syndrome
 - b. Congenital disorders of glycosylation
 - c. Pontocerebellar hypoplasia
 - d. Peroxisomal biogenesis disorders (Zellweger spectrum disorders)
 - e. Perrault syndrome

Summary of the Molecular Genetics and Clinical Features of X-Linked Cerebellar Ataxias

1. X-linked sideroblastic anemia and ataxia (XLSA/A);
 - a. ABCB7 Gene (Xq27.3)
 - b. Clinical manifestations
 - i. Childhood onset
 - ii. Anemia is asymptomatic
 - iii. Cognitive deficiency
 - iv. Microencephaly
2. CASK gene (XP11.4)
 - a. Clinical manifestations:
 - i. Hypotonia
 - b. Optic nerve hypoplasia
 - c. Growth retardation
3. FXTAS
4. FMRI gene (xq27.3)
 - a. Clinical manifestations
 - i. The most common of the x-linked ataxias
 - ii. Occurs in male and female permutation carriers
 - iii. Adult onset
 - iv. Expanded CGG sequences between 55 to 200 triplets are called permutations
 1. The alleles produce increased levels of messenger RNA
 2. These patients are cognitively normal
 3. They manifest progressive ataxia and tremor that is designated FXTAS
 4. Clinic Fragile X disease is the most common cause of genetically induced cognitive impairment
5. X-Linked mental retardation with cerebellar hypoplasia and facial dysmorphisms
 - a. General characteristics
 - i. The gene is OPHNIC
 - b. Clinical manifestations
 - i. Infantile onset
 - ii. Hypotonia
 - iii. Developmental delay
 - iv. Seizures
6. Syndromic X-linked mental retardation (Christianson type)
 - a. General characteristics
 - i. The gene is SLC9A6 (Xq26.3)
 - b. Clinical manifestations
 - i. Infantile onset
 - ii. Cognitive impairment
 - iii. Seizures
 - iv. Cognitive impairment in carrier females
 - v. May resemble Angelman syndrome

Episodic Ataxias

Overview

The episodic ataxias manifest unsteady gait often associated with nystagmus or dysarthria for minutes to hours. Associated signs and symptoms in specific types that include:

- a. Myokymia
- b. Vertigo
- c. Hearing loss

Episodic Ataxia Type 1 (EA1)

General Characteristics

1. Episodic ataxia type 1 is caused by a heterozygous mutation of the potassium channel gene KCNA1 that maps to chromosome 12p13.32

Clinical Manifestations

1. Constant myokymia
2. Episode of spastic contractions of skeletal muscles of the head and extremities that cause:
 - a. Loss of balance
 - b. Incoordination
3. Variable symptoms during attacks include:
 - a. Vertigo
 - b. Blurred vision
 - c. Nausea
 - d. Diplopia
 - e. Headache
 - f. Diaphoresis
 - g. Incoordination
 - h. Stiffening of the body
 - i. Dysarthria
 - j. Difficulty breathing
4. EA1 may be associated with epilepsy, delayed motor development, cognitive impairment, choreoathetosis and carpal spasm
5. Onset is in childhood or adolescence (average age is 8 years)
6. Duration of attacks is seconds to minutes
7. Occurrence is variable from up to 15 attacks/day to less than 1/month
8. Triggering events for attacks include:
 - a. Stress
 - b. Anxiety
 - c. Fatigue
 - d. Menstruation
 - e. Pregnancy
 - f. Temperature
 - g. Fever
 - h. Startle responses
 - i. Abrupt movement
 - j. Postural changes
 - k. Vestibular stimulation
 - l. Alcohol or caffeine
 - m. Exercise
9. Myokymia manifests both during and between attacks
10. Moderate muscle hypertrophy
11. Increased muscle tone may cause:
 - a. Hypercontracted posture
 - b. Contraction of the abdominal wall

- c. Elbow, hip and knee contractures
- d. Shortened Achilles tendon with toe walking
- 12. Difficulty in breathing during attacks
- 13. Skeletal abnormalities include:
 - a. Scoliosis and kyphoscoliosis
 - b. High arched palate
 - c. Mild craniofacial dysmorphism
- 14. Tonic-clonic and partial seizures

Neuropathology

The EA1 mutations affect fast inactivation of K^+ channels by a reduction in subunit surface expression or affinity for the inactivation domain.

Laboratory Evaluation

1. EEG:
 - a. Intermittent and generalized slow activity with intermittent spikes
2. MRI:
 - a. Usually normal; 1 patient has been reported with cerebellar atrophy
3. EMG:
 - a. Rhythmic or arrhythmic occurrence of singlets, duplets or multiplets
4. Molecular gene testing

Episodic Ataxia 2 (EA2)

General Characteristics

1. EA2 is caused by mutation in the calcium ion channel gene CACNA1A that maps to chromosome 19p13.2

Clinical Manifestations

1. Paroxysmal attacks of:
 - a. Ataxia
 - b. Vertigo and nausea
 - c. Attacks last for minutes to days
2. Neurologic signs and symptoms:
 - a. Dysarthria
 - b. Diplopia
 - c. Tinnitus
 - d. Dystonia
 - e. Hemiplegia
 - f. Migraine type headache
3. Onset is in childhood or early adolescence (range 2–32 years)
4. Frequency of occurrence varies widely from once or twice a year to three to four times/week
5. Triggering events include:
 - a. Stress
 - b. Exertion
 - c. Alcohol and caffeine
 - d. Heat and fever
 - e. Postural change
6. Patients are usually asymptomatic between attacks but gradually with time develop interictal nystagmus and ataxia

Neuropathology

1. Loss of function mutation of the CACNA1A that encodes a voltage dependent Ca^{2+} channel alpha-subunit (P/Q type; CaV 2.1)

Laboratory Evaluation

1. Molecular genetic testing
2. MRI:
 - a. Atrophy of the cerebellar vermis

Episodic Ataxia 3 (EA3)

General Characteristics

1. Described in a large Canadian kindred of Mennonite heritage (26 members are affected)
2. The locus is on chromosome 1q42

Clinical Manifestations

1. Adult onset
2. Vestibular ataxia
3. Tinnitus
4. Interictal myokymia
5. Acetazolamide responsive
6. Seizures (rare)

Neuropathology

1. Not defined

Laboratory Evaluation

1. MRI:
 - a. Not defined
2. Molecular genetic testing

Episodic Ataxia 4 (EA4)

General Characteristics

1. Also referred to as periodic vestibulocerebellar ataxia (PATX)
2. No chromosomal locus has been defined

Clinical Manifestations

1. Families described are from North Carolina of Northern European ancestry
2. Onset is early adulthood (3rd to 6th decade)
3. Recurrent attacks of vertigo, diplopia and ataxia
4. In a subgroup of patients, there is slowly progressive cerebellar ataxia
5. Abnormal eye movements that include:
 - a. Decreased smooth pursuit
 - b. Nystagmus (gaze-evoked)
 - c. Abnormal vestibular ocular reflexes
 - d. No response to acetazolamide

Neuropathology

1. Not defined

Laboratory Evaluation

1. Gene loss has not been defined

Episodic Ataxia 5 (EA5)*General Characteristics*

1. Heterozygous pathogenic variants in the CACNB4 gene that maps to chromosome 2q23 cause EA5
2. The gene encodes the beta-4 isoform of the regulatory beta-subunit of voltage-activated Ca²⁺ channels
3. EA5 is allelic with susceptibility to juvenile myoclonic epilepsy 6

Clinical Manifestations

1. Reported in a French Canadian family
2. Childhood to adolescent onset
3. Recurrent episodes of vertigo and ataxia that last for hours
4. Dysarthria
5. Imbalance
6. Acetazolamide responsive
7. Semiology of seizures is similar to EJM6
8. Downbeat and gaze-evoked nystagmus
9. Truncal ataxia

Neuropathology

1. Emerging evidence suggests a loss of intrinsic properties of Purkinje cells and synaptic dysfunction in calcium channel mutations

Laboratory Evaluation

1. Molecular genetics:
 - a. Missense mutation in the CACNB4 gene

Episodic Ataxia 6 (EA6)*General Characteristics*

1. EA6 is caused by mutation in the SL1A3 gene that maps to chromosome 5p13.2

Clinical Manifestations

1. Childhood onset
2. Slurred speech followed by headache (migraine)
3. Arm jerking with concomitant confusion
4. Episodes of ataxia precipitated by fever
5. Alternating hemiplegia
6. Interictal gaze-evoked nystagmus
7. Triggering events for ataxic attacks:
 - a. Stress
 - b. Fatigue
 - c. Caffeine
 - d. Alcohol

Neuropathology

1. Reduced glutamate uptake by mutant excitatory amino acid transporter-1 has been postulated as the major pathophysiological process of the disorder
2. The disease is associated with point mutation (P290R):
 - a. Reduces the number of excitatory amino acid transporter-1 proteins in the surface membrane

- b. Impairs excitatory amino acid transporter-1-mediated glutamate uptake
- c. Cells expressing the mutant P290R exhibit larger anion currents in the presence of external glutamate in the face of a lower number of mutant transporters in the surface membrane. These findings support a gain-of-function of excitatory amino acid transporter anion conduction as another mechanism that can cause episodic ataxia 6

Laboratory Evaluation

1. MRI:
 - a. Cerebellar atrophy
2. Molecular genetic testing

Episodic Ataxia 7 (EA7)*General Characteristics*

1. Episodic ataxia 7 is caused by an autosomal dominant mutation at locus rs1366444 and rs952108 that maps to chromosome 19q13
2. Described in a four generation family

Clinical Manifestations

1. Onset prior to age 20
2. Episodic attacks are associated with:
 - a. Weakness
 - b. Vertigo
 - c. Dysarthria
3. Attacks may last hours to days and are triggered by exercise and excitement
4. The frequency of attacks ranged from monthly to one per year; decreased with age

Neuropathology

1. Not defined

Laboratory Evaluation

1. Not defined

Episodic Ataxia 8 (EA8)*General Characteristics*

1. Autosomal dominant inheritance in a large 3-generation Irish family in which the locus was mapped
2. An 18.5 Mb locus that maps to chromosome 1p36.13-p34.3
 - a. A candidate gene is UBR4 which is a ubiquitin ligase protein that interacts with calmodulin

Clinical Manifestations

1. Onset in childhood as children learn to walk (~2 years of age)
2. Attacks are manifested by:
 - a. Unsteady gait
 - b. Generalized weakness

- c. Slurred speech
- d. Triggered by fatigue and stress
- e. Wide variation in the frequency of attacks; (2 attacks/day to months without an attack)
- f. Attack frequency may decrease with age
- g. There is no tinnitus or seizures
- h. Acetazolamide unresponsive
- i. Interictal impaired tandem gait and intention tremor
- j. Minimal gaze-evoked nystagmus (some family members)
- k. Response to clonazepam rather than acetazolamide
- l. Myokymia
- m. Mild dysarthria
- n. Twitching around the eyes

Neuropathology

1. The ubiquitin protein ligase encoded by UBR4 interacts in the nucleus with the retinoblastoma-associated protein and in the cytoplasm with the smooth endoplasmic reticulum
2. The protein interacts with calcium-bound calmodulin in the cytoplasm that suggests a role in calcium signaling
3. It has been postulated that UBR4 is a Ca^{2+} sensor, and that atypical binding of UBR4 with calmodulin and/or ITPR1 (inositol 1,4,5-triphosphate receptor) may alter the neuron's calcium sensor systems (disrupt calcium homeostasis) which is a regulator of the $\text{CaV}2.1$ channel

Laboratory Evaluation

1. MRI: (one patient)
 - a. Normal cerebellum; MRIs were taken at age 19 and 29
2. Molecular genetic testing

Differential Diagnosis of Episodic Ataxias

Sporadic Disorders

1. Multiple sclerosis
 - a. Optic nerve, spinal cord, and cognitive impairment
2. Arnold-Chiari malformations
 - a. Short neck and shallow posterior fossa
 - b. Severe C2 headache with valsalva maneuvers
 - c. Lower cranial nerve involvement
3. Vertebral basilar insufficiency:
 - a. Dizziness and diplopia
 - b. Focal motor weakness
 - c. Perioral numbness
4. Basilar migraine:
 - a. Upper extremity paresthesias
 - b. Severe vertigo
 - c. Occipital headache
 - d. Loss of consciousness
5. Labyrinthine disorders:
 - a. Severe dizziness and vertigo
 - b. Lateralizing nystagmus
 - c. Lateral pulsion
 - d. Nausea and vomiting

Hereditary Disorders

1. Disorders of mitochondrial oxidative metabolism
 - a. Pyruvate carboxylase deficiency

General Characteristics

1. Pyruvate carboxylase deficiency is caused by mutation in the pyruvate carboxylase gene that maps to chromosome 11q.32

Clinical Manifestations

1. There are 3 phenotypic subgroups:
 - a. Group A:
 - i. Patients from North America
 - ii. Psychomotor retardation
 - iii. Canadian Indian population:
 1. Seizures
 2. Respiratory distress
 3. Hypotonia
 4. Developmental delays
 5. One patient with Leigh's necrotizing encephalopathy
 - b. French form (Group B):
 - i. 2 familial cases of neonatal congenital lactic acidosis that was rapidly fatal
 - ii. Cognitive impairment
 - c. Benign type (Group C)
 - i. One patient with normal motor and cognitive ability
 - ii. A second patient with onset at 3 days of life:
 1. Psychomotor delay
 2. At age 9, cognitive impairment, dysarthria and dysgraphia

Neuropathology

1. Hypothesized that energy deprivation (bioenergetic failure) from pyruvate carboxylase (PC) deficiency decreases astrocytic buffering capacity against excitotoxicity
2. Cystic degeneration of periventricular white matter

Laboratory Evaluation

1. Primary lactic acidemia
2. In some patients there is hyperammonemia, citrullinemia, lysinemia and altered redox states
3. MRI:
 - a. General cerebral atrophy
 - b. Cystic periventricular leukomalacia

Pyruvate Dehydrogenase E1-Alpha Deficiency (PDHAD)

General Characteristics

1. PDHAD is caused by mutation in the PDHA1 gene of the pyruvate dehydrogenase complex that maps to chromosome xp221.12
2. Pyruvate dehydrogenase complex mutations are a common cause of lactic acidosis in children
3. Heterozygous females may be severely symptomatic

4. There is genetic heterogeneity of pyruvate dehydrogenase complex deficiency

Clinical Manifestations

1. The metabolic and neurologic manifestations of the disorder present with equal frequency
2. The metabolic form presents as severe lactic acidosis in newborns that is usually fatal
3. The neurologic form is characterized by:
 - a. Hypotonia
 - b. Lethargy
 - c. Cognitive impairment
 - d. Seizures
 - e. Spasticity
4. An intermediate form is characterized by:
 - a. Intermittent episodes of lactic acidosis with cerebellar ataxia
 - b. Many patients are phenotypically similar to Leigh's syndrome
5. Intermittent ataxia may be combined with choreoathetosis

Neuropathology

1. Regions surrounding the third ventricle and aqueduct demonstrate similar pathology to Wernicke's encephalopathy or Leigh's disease (some patients)
2. Cerebellar degeneration similar to olivopontocerebellar atrophy in some patients

Laboratory Evaluation

1. Elevated fasting levels of lactate and pyruvate
2. MRI:
 - a. Cerebral atrophy
 - b. Absence of the corpus callosum (some patients)
 - c. Lesions of the basal ganglia and brainstem similar to Leigh's syndrome

X-Linked Disorders That Cause Episodic Ataxia

Ornithine Transcarbamylase OTC Deficiency

General Characteristics

1. Ornithine transcarbamylase deficiency is caused by mutation in the OTC gene that maps to chromosome Xp11.4
2. In male hemizygotes clinical manifestations and age at onset depend on the mutation. In female heterozygotes, phenotypic expression depends on the extent of expression of the mutated gene

Clinical Manifestations

1. Milder mutations may be asymptomatic until the patient is exposed to high nitrogen loads
2. Age at onset varies widely (3 days to 49 years)
3. Episodic extreme irritability (100%)
4. Episodic vomiting and lethargy (100%)

5. Protein avoidance (92%)
6. Ataxia (77%)
7. Coma (46%)
8. Delayed growth (38%)
9. Developmental delay (38%)
10. Seizures (23%)

Neuropathology

1. Mutation in the gene that encodes the enzymes leads to:
 - a. Partial deficiency in heterozygous females and to complete deficiency in hemizygous males
2. Astrocytic transformation of astrocytes to Alzheimer type II glia due to the hyperammonemia
3. Cortical atrophy, widespread gliosis and atrophy in the internal granular layer of the cerebellum

Laboratory Evaluation

1. Intermittent episodes of hyperammonemia often precipitated by infection
2. Orotic acid excretion after protein loading (in the urine)
3. Citrullinemia in some patients
4. Increased plasma glutamine
5. MRI:
 - a. Cortical atrophy
 - b. Subcortical demyelination

Autosomal Recessive Ataxias Due to Urea Cycle Enzyme Deficiency

General Characteristics

1. The urea cycle enzyme deficiencies include:
 - a. Carbamoyl phosphate synthetase
 - b. Argininosuccinate synthetase (citrullinuria type 1)
 - c. Argininosuccinase
 - d. Arginase deficiency

Clinical Manifestations

1. Severe forms of hyperammonemia present in the first four days of life and manifest:
 - a. Lethargy
 - b. Focal and generalized seizures
 - c. Coma
2. Early childhood (less severe phenotype)
 - a. Intermittent ataxia
 - b. Confusion
 - c. Dysarthria
 - d. Vomiting
 - e. Headache
 - f. Ptosis
 - g. Involuntary movements
 - h. Seizures
3. Episodes are precipitated by increased protein ingestion and intercurrent infection

Neuropathology

1. Cortical atrophy

2. Alzheimer type II glia
3. Brainstem and subcortical gliosis and white matter changes

Laboratory Evaluation

1. Intermittent hyperammonemia
2. Increased citrullinemia

Intermittent Ataxia from Amino Acidurias

Hartnup Disease

General Characteristics

1. Hartnup disease is caused by homozygous or compound heterozygous mutation in the SLC6A19 gene that maps to chromosome 5p15.33
2. Incidence is approximately 1 in 15,000 of the population

Clinical Manifestations

1. Intermittent ataxia
2. Tremor
3. Chorea
4. Psychiatric disorders
5. Cognitive impairment
6. Pellagra-like skin rash
7. Triggers of attacks include:
 - a. Sunlight
 - b. Emotional stress
 - c. Sulfonamide drugs
8. Attacks may decrease with age
9. Attacks last approximately two weeks

Neuropathology

1. Defective renal and intestinal transport of monoamino monocarboxylic acids

Laboratory Evaluation

1. Multiple neutral amino acids are excreted in the urine
2. Monoamino monocarboxylic aciduria
3. Stool indoles and urinary indican may be increased after oral tryptophan loading

Intermittent Branched-Chain Ketoaciduria

General Characteristics

1. Maple syrup urine disease can be caused by homozygous or compound heterozygous mutations in 3 genes:
 - a. BCKDHA that maps to chromosome 19q13.2
 - b. BCKDHB that maps to chromosome 6q14.1
 - c. DBT that maps to chromosome 1p21.2

Clinical Manifestations

1. Intermittent ataxia
2. Cognitive impairment
3. Feeding difficulty
4. Thiamine responsive
5. Maple syrup odor of the urine

Neuropathology

1. Failure to catabolize the branched chain amino acids leucine, isoleucine and valine

Laboratory Evaluation

1. Elevation of branched-chain amino acids and ketoacids in the urine (leucine, isoleucine and valine)
2. MRI:
 - a. Demyelination of the cerebellum and middle cerebellar peduncle

Isovaleric Acidemia

General Characteristics

1. Isovaleric acidemia is caused by mutation of the isovaleryl CoA dehydrogenase gene that maps to chromosome 15q15.1

Clinical Manifestations

1. Acute neonatal type:
 - a. Massive metabolic acidosis from birth and rapid death
2. Chronic form:
 - a. Periodic attacks of severe ketoacidosis
 - b. Retarded cognitive function
 - c. Sweaty feet odor of the urine
 - d. An aversion to protein
 - e. Pernicious vomiting
 - f. Coma in severe attacks

Neuropathology

1. Branched-chain organic aciduria and isovaleric aciduria, propionic aciduria and methylmalonic aciduria may all cause ischemic stroke
2. Cerebellar hemorrhage may occur with isovaleric aciduria without acute metabolic episodes

Laboratory Evaluation

1. Isovaleric aciduria produces:
 - a. Increased hyperglycinemia
 - b. Leukopenia
 - c. Episodic ketoacidosis

Familial Paroxysmal Kinesigenic Dyskinesia (PKD)

General Characteristics

1. PKD is inherited as an autosomal dominant disorder from heterozygous mutations in the PRRT2 gene that maps to chromosome 16p11.2

Clinical Manifestations

1. The phenotype of PKD includes:
 - a. Benign familial infantile epilepsy (BFIE)
 - b. Infantile convulsions and choreoathetosis (ICCA)
 - c. Hemiplegic migraine
 - d. Migraine with and without aura
 - e. Episodic ataxia

2. The major clinical features of PKD are:
 - a. Unilateral or bilateral involuntary movements
 - b. Triggering events that include:
 - i. Standing from a sitting position
 - ii. Startle
 - iii. Stress
 - c. Manifestation of attacks include:
 - i. A combination of dystonia, ballism and choreoathetosis
 - ii. Attacks may be preceded by an aura
 - iii. There is no loss of consciousness
 - d. The frequency of attacks varies widely from up to 100/day to as few as one/month
 - e. Attacks usually last a few seconds to 5 minutes but occasionally for several hours
 - f. The age of onset is usually in childhood and adolescence
 - g. Familial PKD is usually seen in male patients

Familial Paroxysmal non-Kinesigenic Dyskinesia (PNKD1)

General Characteristics

1. PNKD1 is caused by mutation in the myofibrillogenesis regulator-1 (MRI) gene

Clinical Manifestations

1. Onset is in childhood or early adolescence
2. The attacks are characterized by unilateral or bilateral involuntary movements
3. Attacks may be spontaneous or triggered by alcohol, caffeine, excitement, stress, fatigue or chocolate
4. Clinical manifestations of an attack include:
 - a. An aura (some patients)
 - b. Dystonic posturing with choreic and ballistic movements
 - c. Not associated with seizures
 - d. The attack may last minutes to hours and may occur several times per day
 - e. The onset of the disorder may be as late as 50 years of age

Seizure Disorder

General Characteristics

1. Partial complex seizure disorders may retain consciousness to a degree during the manifestation of intermittent complex movements. These are most often generated from the frontal lobe
2. Complex automatisms from the temporal lobe are common and are characterized by altered consciousness. They may manifest as a continuation of the movement the patient was performing at its onset or the generation of a repetitive new movement
3. Epileptic seizures occur with both EA1 and EA2. Distinguishing features of these ataxias are:
 - a. Interictal myokymia occurs with EA1
 - b. Nystagmus and baseline nystagmus occurs with EA2

4. SCA10 has generalized and partial complex seizures

Migraine

General Characteristics

1. EA2 and FHM1 (familial hemiplegic migraine) are allelic disorders
2. Mutations in CACNA1A genes may be associated with other forms of migraine
3. Episodic vertigo is common with migraine and EA2

Differential Diagnosis of Autosomal Dominant Episodic Ataxia

EA1

1. Mutated gene is KCNA1
2. Maps to chromosome 12q13
3. Encoded protein Kv1.1
4. Age at onset 2–15 years of age
5. Attack duration is seconds to minutes
6. Myokymia is usual
7. No nystagmus
8. Seizures (occasional)
9. Tinnitus (rare)
10. Acetazolamide responsive (occasional)

EA2

1. Mutated gene – CACNA1A
2. Maps to chromosome – 19p13
3. Encoded protein – CaV 2.1
4. Age at onset – 2–20 years
5. Attack duration – hours
6. Myokymia – none
7. Nystagmus (usual)
8. Seizures – occasional
9. Tinnitus – usual
10. Acetazolamide responsive – usual

EA4/PATX (Periodic Vestibule Cerebellar Ataxia)

1. Mutated gene – not defined
2. Encoded protein – not defined
3. Age at onset – 23–60 years of age
4. Myokymia – none
5. Nystagmus – usual; gaze-evoked
6. Seizures – occasional
7. Not responsive to acetazolamide
8. Vertigo, diplopia combined with ataxia during attacks
9. Abnormal smooth pursuit
10. Abnormal vestibule-ocular reflexes
11. Attack duration – brief

EA5

1. Mutated gene – CACNB4
2. Maps to chromosome – 1q22-2q23

3. Encoded protein – CaV 2.1
4. Age of onset – 3 years to teens
5. Attack duration – hours
6. Dyokymia – none
7. Nystagmus – usual; downbeat
8. Seizures – usual; semiology similar to EJM6
9. Tinnitus – none
10. Acetazolamide – transient response
11. Dysarthria

EA6

1. Mutated gene is SLC1A3
2. Maps to chromosome 5p
3. Sporadic inheritance
4. Encoded protein – EAAT1
5. Age at onset – 5
6. Duration of attacks – hours to days
7. Myokymia – none
8. Nystagmus – interictal gaze-evoked nystagmus
9. Seizures – subclinical
10. Tinnitus – none
11. Not acetazolamide responsive
12. Slurred speech followed by headache
13. Alternating hemiplegia
14. Attacks are triggered by stress, fatigue, fever, caffeine and alcohol

EA7

1. Mutated gene – not defined
2. Loci maps to chromosome 19q13
3. Encoded protein – not defined
4. Age at onset – <20 years of age
5. Attacks are characterized by:
 - a. Weakness
 - b. Vertigo
 - c. Dysarthria
6. Duration of attacks – hours to days
7. Attacks are precipitated by exercise and excitement
8. The frequency of attacks varies widely from monthly to yearly
9. Attack frequency decreases over time

EA8

1. Mutated gene – not defined
2. Chromosome location is 1p36.13-p34.3
3. Encoded protein not defined
4. Age at onset – second year of life
5. Attacks manifest with unsteady gait, generalized weakness and slurred speech
6. Duration of attacks (minutes to hours)
7. Frequency of attacks varies from two attacks/day to two attacks per month
8. Variable clinical manifestations include:
 - a. Twitching around the eyes
 - b. Myokymia

- c. Dysarthria
- d. Intention tremor
- e. Migraine headache (two patients)
9. Clonazepam responsive

Spastic Ataxias**SPAX1***General Characteristics*

1. SPAX1 is caused by heterozygous mutation in the VAMP1 gene that maps to chromosome 12p13.31
2. The disorder is autosomal dominant

Clinical Manifestations

1. Age of onset is between 10–20 years of age
2. Initial presentation is with leg spasticity
3. Subsequently there is progressive
 - a. Head jerks
 - b. Dysarthria
 - c. Ocular movement abnormalities that include supranuclear gaze abnormalities
 - d. Pes cavus
 - e. Mild ptosis (some patients)
 - f. Decreased vibration sensibility in the lower extremities
 - g. Cognition is normal
 - h. Normal life span

Neuropathology

1. Degeneration of the corticospinal tracts and dorsal columns (Newfoundland families)
2. The mutation results in alternative splicing that produces an inactive isoform in neurons that causes decreased neurotransmitter exocytosis
3. VAMP1 is a member of a protein family that is involved in membrane-trafficking and axonal transport

Laboratory Evaluation

1. MRI:
 - a. Normal in a rural cohort studied from Newfoundland

SPAX2*General Characteristics*

1. SPAX2 is caused by homozygous mutation in the KIF1C gene that maps to chromosome 17q32; AR inheritance
2. Mutations in KIF1F5A and KIF1A encode motor proteins of the kinesin superfamily that cause spastic paraparesis and cerebellar abnormalities

Clinical Manifestations

1. Childhood onset
2. Dysarthria
3. Gait ataxia
4. Spasticity lower limb > than upper

5. Distal amyotrophy of the extremities
6. Babinski response (variable)
7. Palestinian kindred:
 - a. Tremor dysarthria, stance instability developing between age 6–10
 - b. Subsequent spasticity in the lower extremities
 - c. Head titubation, ataxia, dysmetria
 - d. Cerebellar ataxia was progressive while spasticity was static
 - e. Normal cognitive function
 - f. Fasciculations and nystagmus noted in Moroccan kindred (some patients)

Neuropathology

1. In the Palestinian kindred, cultured fibroblasts demonstrated absence of K1FC protein

Laboratory Evaluation

1. MRI:
 - a. Lesions varied widely among kindreds from no cerebellar atrophy to mild cerebral and cerebellar atrophy and white matter hyperintensities

SPAX3

General Characteristics

1. Autosomal recessive spastic ataxia type 3 is caused by homozygous or compound heterozygous complex genomic rearrangements that involve the MARS2 gene that maps to chromosome 2q33

Clinical Manifestations

1. 23 French Canadian patients from 17 families are reported
2. All patients of the cohort manifested:
 - a. Age of onset from 2–59 years (mean of 15 years of age)
 - b. Instability of gait
 - c. Spasticity
 - d. Hyperreflexia
3. Variable features include:
 - a. Urinary urgency (57%)
 - b. Dysarthria (74%)
 - c. Dystonic posturing (57%)
 - d. Horizontal nystagmus (44%)
 - e. Scoliosis (35%)
 - f. Sensorineural hearing loss (33%)
 - g. Cognitive impairment (44%)
 - h. 52% were wheelchair bound in their mid-thirties

Neuropathology – (Cultured Patient Cells Demonstrated)

1. Decreased complex I activity
2. Increased levels of reactive oxygen species
3. Decreased cell proliferation
4. Increased levels of MARS2 mRNA but a paradoxical decrease in protein levels hypothesized to occur from an RNAi-mediated decay mechanism
5. Cell expression techniques suggest a decrease in mitochondrial translation
6. Upregulated unfolded protein response

Laboratory Evaluation

1. MRI
 - a. Cerebellar atrophy in all patients
 - b. Cerebral atrophy in 43%
 - c. Periventricular white matter changes in approximately 50% of patients

SPAX4

General Characteristics

1. SPAX 4 is autosomal recessive and is caused by homozygous mutation in the MTPAP gene that maps to chromosome 10p11.23
2. The disorder has been described from a large consanguineous family of Old Order Amish ancestry

Clinical Manifestations

1. Early childhood onset
2. Slowly progressive
3. Ataxia
4. Spastic paraparesis
5. Dysarthria
6. Optic atrophy
7. Nystagmus (2 patients)
8. Developmental delay
9. Learning disabilities and emotional lability
10. No cognitive impairment

Neuropathology

1. Cultured fibroblast cell lines from patients with the p.N478D mutation (homozygous) revealed:
 - a. Loss of polyadenylation of all mitochondrial transcripts
 - b. Loss of oxidative phosphorylation complexes I and IV and decreased mitochondrial protein synthesis

Laboratory Evaluation

1. MRI:
 - a. Not defined

SPAX5

General Characteristics

SPAX5 is autosomal recessive and is caused by homozygous mutation in the AFG3L2 gene that maps to chromosome 18p11.21.

Clinical Manifestations

1. Childhood onset
2. Spastic gait
3. Progressive myoclonic epilepsy associated with generalized tonic-clonic seizures
4. Dysarthria and dysphagia
5. Lower extremity weakness with distal muscle atrophy
6. Oculomotor apraxia; ptosis
7. Dystonic movements
8. No cognitive impairment

Neuropathology

1. Muscle biopsy (electron microscopy)
 - a. Misplaced mitochondria associate with large lipid droplets
 - b. Decreased mtDNA copy number

Laboratory Evaluation

1. MRI:
 - a. Moderate cerebellar atrophy
2. EMG:
 - a. Axonal sensorimotor neuropathy

SPG7*General Characteristics*

1. SPG7 gene mutation that maps to chromosome 16q24.3
2. The gene encodes the protein paraplegin which is a component of the m-AAA protease
3. The m-AAA protease, a component of an ATP-dependent proteolytic complex, is located in the mitochondrial inner membrane
4. Degrades misfolded proteins and regulates ribosome assembly

Clinical Manifestations

1. Onset early adult life
2. Progressive weakness and spasticity of the lower legs
3. Decreased small and large fiber sensory modalities in the lower extremities
4. Urinary incontinence
5. Optic atrophy (variable)
6. Cerebellar dysarthria (variable) and ataxia
7. Supranuclear palsy (Turkish kindred)
8. Gait instability
9. Nystagmus

Neuropathology

1. Muscle biopsy:
 - a. Signs of OXPHOS deficiency
 - b. Ragged red fibers
 - c. Intense succinic dehydrogenase staining (SDH)
 - d. Cytochrome oxidase negative fibers
2. Experimental studies in mice lacking paraplegin
 - a. Axons contained abnormal mitochondria
 - b. Swollen axons with accumulated organelles and neurofilaments
 - c. Possible pathology due to defect of axonal transport

Laboratory Evaluation

1. MRI:
 - a. Some patients have normal spinal cord MRIs
 - b. White matter hyperintensities have been reported in the spinal cord, frontal lobe and midbrain

Differential Diagnosis of Ataxia with Mitochondrial Disorders

1. MERRF (myoclonic epilepsy with ragged red fibers)

2. NARP (neuropathy, ataxia, and retinitis pigmentosa)
3. Kearns-Sayre syndrome
4. MT-ATP6 (causes childhood and adult onset ataxia)
5. Leigh's syndrome

Cerebellar Subtype of Multiple System Atrophy*Overview*

Multiple system atrophy is a sporadic, progressive neurodegenerative disease that has basal ganglionic, autonomic, pyramidal and at times cortical dysfunction. It is subclassified into parkinsonian type MSA (MSA-P) and cerebellar-type MSA (MSA-C) that is dependent on predominant motor symptoms. Its prevalence is 1.9–4.9 patients per 100,000 people. Its incidence is 6/100,000 people. Approximately 65% of patients have the MSA-P form in Europe and the USA.

Clinical Manifestations

The mean age of onset of motor or autonomic symptoms is 56 years of age. MSA-C has never been reported in a patient younger than 30 years of age. It is extremely rare in patients older than 75 years of age. Autonomic signs and symptoms are manifested by erectile dysfunction, urinary incontinence and retention and other non-motor features that often precede motor symptoms. Reduced sweating and constipation are common while postural hypotension is a late complication.

The most common cerebellar signs at motor presentation are an ataxic unstable gait, dysarthria, limb ataxia and gaze-evoked nystagmus. In the early phase of the disorder there are defects in smooth pursuit (saccadic substitution), square wave jerks and dysmetric saccades. Hyperreflexia with Babinski signs are frequent concomitant with cerebellar signs.

Parkinsonism usually occurs approximately 5 years after cerebellar features and is of the akinetic-rigid form. In approximately 50% of patients it is L-DOPA responsive. Other motor signs include craniocervical dystonia that may induce camptocormia and Pisa syndrome.

Rarely there is dystonia of the face, hands and feet. Stridor, from laryngeal abductor palsy, usually occurs late in the disease course and has been suspected in sudden death. Poor autonomic control of extremity circulation causes the "cold hand sign". Approximately 30% of patients develop pain from musculoskeletal and dystonic posture generators.

A majority of patients develop REM sleep behavior disorder. Approximately 25% of patients experience excessive daytime sleepiness.

Cognitive impairment, primarily involving executive function and verbal learning as well as depression, anxiety and pathologic laughing and crying, affect a proportion of patients.

Neuropathology

1. Argrophilic filamentous aggregates in the cytoplasm of oligodendrocytes are seen in all MSA variants (glial cytoplasmic bodies)

2. Glial cytoplasmic bodies are associated with gliosis and neuronal loss in the:
 - a. Basal ganglia
 - b. Cerebellum
 - c. Pons
 - d. Inferior olivary nucleus
 - e. Spinal cord
3. Patients may demonstrate:
 - a. A striatonigral pattern
 - b. An olivopontocerebellar pattern (OPCA)
 - c. A balanced pattern of pathology in both systems
4. Degeneration of autonomic nuclei in the brainstem and spinal cord. Post-ganglionic denervation is also a major component of the autonomic failure. This is demonstrated by reduced sudomotor nerve density in sweat glands which may be seen prior to degeneration of ANS nuclei:
 - a. Alphasynuclein is the major component of glial cytoplasmic inclusions (GCIs). Other components of GCIs include:
 - i. Ubiquitin
 - ii. Tau
 - iii. p25-alpha
 - iv. Heat shock proteins
 - v. Dopamine
 - vi. DARPP-32
 - vii. Other proteins
5. Neuronal cytoplasmic inclusions (NCIs) and neuronal nuclear occlusions (NNIs) are also observed in MSA but GCIs are the most reliable criteria for the definitive diagnosis of MSA
6. GCIs:
 - a. May be facilitated by p25-alpha, a normal component of myelin
 - b. Cause oligodendrocyte death
 - c. There is evidence to support oligodendroglial dysfunction that leads to abnormal synthesis and release of trophic factors and other signaling molecules that triggers apoptosis as a major pathogenic mechanism in the disorder
 - d. Mitochondrial respiratory chain dysfunction may also be a factor in this degeneration due to:
 - i. COQ2 gene mutations that impair parahydroxybenzoate polyprenyltransferase (necessary for coenzyme Q10 synthesis) that have been associated with an increased risk of MSA
 - ii. Excessive generation of reactive oxygen species from mitochondrial dysfunction in activated microglia that also release:
 1. Nitrogen species
 2. Inflammatory cytokines
 - iii. An Increased risk of developing MSA has been demonstrated in:
 1. SNPs of genes that encode alpha-synuclein (the SNCA gene)
 2. SNPs in genes encoding prion protein

3. Loss of function mutations of the phenyl benzoate-polyprenyl transferase gene
- iv. There is evidence that proteosomal and autophagic degradation of alpha-synuclein is impaired in affected oligodendrocytes
- v. There may be increased uptake of alpha-synuclein from the cerebrospinal fluid that may be a component of mechanisms in the formation of GCIs

Laboratory Evaluation

1. MRI:
 - a. "Hot cross bun" sign in the ventral pons (possibly in 80% of patients); also seen in other pathologies but particularly in SCA2
 - b. Striated dopaminergic denervation or glucose hypometabolism demonstrated by SPECT or PET in patients with cerebellar symptomatology

Differential Diagnosis of MSA-C

1. Secondary cerebellar disorders are caused by:
 - a. Toxins
 - b. Infections
 - c. Vitamin deficiency
 - d. Tumors
 - e. Autoimmune demyelination
 - f. Paraneoplastic syndromes
 - g. Drugs
 - h. Superficial siderosis
 - i. Endocrine disorders
 - j. Vascular disease
 - k. Congenital defects that decompensate in middle age
2. Late onset autosomal dominant SCAs that resemble MSA-C:
 - a. SCA6 is the most common
 - b. SCA2 and SCA3
 - i. In Asian and African patients
 - ii. There is associated L-Dopa responsive Parkinsonism
3. Permutation of the FMR1 Gene
 - a. Causes FXTAS which manifests:
 - i. Cerebellar ataxia
 - ii. Postural and intention tremor
 - iii. Psychiatric disorders
 - iv. Neuropathy
 - v. Cognitive impairment
4. Sporadic adult onset ataxia:
 - a. Age at onset is approximately 50 years of age (similar to MSA-C)
 - b. Much longer survival in sporadic late onset ataxia
 - c. Approximately 50% of patients can walk after 12 years of disease whereas MSA-C are wheelchair bound after approximately 5 years
 - d. Autonomic dysfunction is severe in MSA-C
 - e. Nystagmus, gaze paralysis, decreased or absent ankle deep tendon reflexes are more commonly seen with sporadic late onset ataxia

- f. MRI demonstrates the “hot cross bun” sign in the ventral pons in MSA-C
- g. Proton MR spectroscopy
 - i. Lower levels of lactate in the pons in MSA-C
- h. Cerebral blood flow is lower in the pons in MSA-C than sporadic late onset cerebellar ataxia
- i. MSA-C
 - i. Denervation of the external anal sphincter and urethral sphincter which can be demonstrated by EMG
 - ii. Degeneration of Onuf’s nucleus in MSA-C may not occur early in MSA-C
- j. CSF biomarkers are being evaluated:
 - i. Combined neurofilament light chains, 3-methoxy-4-hydroxyphenyl ethylene glycol (MHPG) and dopamine metabolites homovanillic acid and dihydroxyphenylacetic acids are being evaluated for differentiation of MSA-C from late onset cerebellar ataxias

Congenital Defects of the Cerebellum

General Characteristics

1. There is an extended period of ontogenesis which may make the cerebellum more vulnerable to environmental factors
2. Neuroblast migration from the external granular layer lasts for one year
3. Cerebellar development occurs from 32 days of gestation to one year
4. The cerebellar cortex is susceptible to the toxic effects of drugs, chemicals, viral infections, ischemia and hypoxia

Hypoplasia or Aplasia of the Vermis

General Characteristics

1. Possible X-linked dominant inheritance

Clinical Manifestations

1. Hypotonia at birth
2. Delayed milestones
3. Mild cerebellar ataxia
4. Non-progressive course
5. Slight cognitive impairment
6. Nystagmus occasional

Neuropathology

1. Associated cerebellar hemispheric hypoplasia (many patients)
2. Enlarged posterior fossa with elevation of the torcula
3. Cerebellar hemispheres have an abnormal folial pattern with wide separation of the hemispheres and shallow sulci, thinned white matter
4. MRI:
 - a. Large posterior fossa with elevated torcula
 - b. Vermian hypoplasia
 - c. Widely separated cerebellar hemisphere, shallow sulci, thinned white matter

- d. Retrocerebellar CSF collection (some patients)
- e. Some patients demonstrate isolated vermian atrophy
- f. Associated supratentorial anomalies:
 - i. Agenesis of the corpus callosum
 - ii. Hydrocephalus
 - iii. Patients with callosum agenesis may also have the Dandy-Walker malformation
- g. Small pons (some patients)

Joubert Syndrome

General Characteristics

1. Joubert syndrome is caused by homozygous mutation in the INPP5E gene that maps to chromosome 9q34
2. There is great genetic heterogeneity in the disorder (at present mutations in 19 genes)

Clinical Manifestations

1. Developmental delay
2. Dysregulation of breathing pattern
3. Hypotonia
4. Tremor
5. Cognitive impairment
6. Facial dysmorphisms:
 - a. Large head
 - b. Prominent forehead
 - c. High rounded eyebrows
 - d. Triangular mouth
 - e. Tongue protrusion (with tremor)
 - f. Prognathism
7. Hyperpnea intermixed with central apnea
8. Behavioral problems/autism (some)
9. Oculomotor apraxia (Italian kindred)
10. Variable signs:
 - a. Retinal dystrophy
 - b. Renal abnormalities (often cysts)
 - c. Speech apraxia
11. Joubert syndrome and clinical subtypes of related disorders:
 - a. Retinal disease:
 - i. Pigmentary retinopathy similar to retinitis pigmentosa
 - ii. Coloboma
 - 1. Chorioretinal dysplasia
 - 2. Associated with hepatic fibrosis
 - b. Ocular abnormalities:
 - i. Ptosis, strabismus and/or amblyopia
 - ii. Third nerve palsy (rare)
 - c. Renal disease:
 - i. Nephronophthisis (tubulointerstitial nephropathy)
 - ii. Cystic dysplasia (corticomedullary function)
 - iii. Prevalence of renal disease is 23–30% of patients
 - d. Oculorenal disease:
 - i. Retinal and renal disease in the same patient
 - e. Hepatic disease

- i. Congenital hepatic fibrosis (ductal plate malformation)
- ii. May be associated with chorioretinal coloboma
- iii. The COACH syndrome includes:
 - 1. Coloboma
 - 2. Cognitive impairment
 - 3. Oligophrenia
 - 4. Ataxia
 - 5. Cerebellar vermis hypoplasia
 - 6. Hepatic fibrosis
- f. Orofacial digital dysmorphism:
 - i. Polydactyly occurs in approximately 8% of patients. It can be unilateral or bilateral and is postaxial; mesoaxial polydactyly (rare)
 - ii. Preaxial polydactyly of the toes
 - iii. Facial dysmorphisms:
 - 1. Broad forehead
 - 2. Arched eye brows
 - 3. Strabismus
 - 4. Ptosis
- g. Classic facial dysmorphisms:
 - i. Long face with bitemporal narrowing
 - ii. High arched eyebrows
 - iii. Ptosis
 - iv. Prominent nasal bridge
 - v. Triangular mouth
 - vi. Prognathism
 - vii. Tongue hypertrophy (due to chronic tongue movements)
- h. Musculoskeletal abnormalities:
 - i. Cone-shaped epiphyses
 - ii. Scoliosis
- i. Endocrine abnormalities:
 - i. Pituitary hormone deficiency of isolated growth hormone, or hypothyroidism to panhypopituitarism
- j. Obesity
- k. Laterality defects:
 - i. Situs inversus
- l. Rare Hirschprung's disease
- m. Rare congenital heart disease

Neuropathology

- 1. Vermal agenesis
- 2. Malformation of multiple brainstem structures
- 3. Lack of superior cerebellar commissural fibers
- 4. All of the genes associated with the disorder encode proteins that are associated with the assembly and biology of cilia
- 5. The WNT and SHH pathways as well as the WNT-planar cell polarity pathway (PCP) are putative in the pathogenesis of the disorder
- 6. Kallmann syndrome has been described with partial cerebellar vermis hypoplasia possibly related to fibroblast growth factor deficiency which is essential for cerebellar development

Laboratory Evaluation

- 1. MRI:
 - a. The "molar tooth" sign:
 - i. Deep interpeduncular fossa
 - ii. Thick and elongated superior cerebellar peduncles
 - iii. Hypoplastic or aplastic superior cerebellar vermis
 - b. Cerebellar heterotopias and cerebellar folial disorganization
 - c. Cerebrospinal fluid in the fourth ventricle or the posterior fossa that is similar to the Dandy-Walker malformation
 - d. Occipital encephalocele or meningocele (some patients)
 - e. Brainstem and hypothalamic hamartomas (most prominent in patients with oral-facial digital syndrome type VI)
 - f. Ventriculomegaly or hydrocephalus
 - g. Agenesis of the corpus callosum
 - h. Hippocampal malformations
 - i. Cortical anomalies that include:
 - i. Heterotopias
 - ii. Dysplasia
 - iii. Polymicrogyria
 - iv. Neuroepithelial cysts
- 2. Diffusion tensor imaging:
 - a. Absence of delineation of the corticospinal and superior cerebellar tracts
- 3. Functional MRI:
 - a. Abnormal activation patterns during motor tasks

Dandy-Walker Syndrome (DWM)

General Characteristics

- 1. Dandy-Walker malformation is caused by deletions of Z1C1
- 2. Zinc finger protein of the cerebellum and Z1C4
- 3. Zinc finger of the cerebellum 4 that maps to chromosome 3q24
- 4. The recurrent risk of 1–2% for non-syndromic form of the Dandy-Walker malformation is against Mendelian inheritance

Clinical Manifestations

- 1. Onset at birth with bulging occiput
- 2. Early hypocephalus
- 3. Cranial nerve palsies
- 4. Nystagmus
- 5. Truncal ataxia
- 6. Cognitive impairment (in approximately 50% of patients)
- 7. Hypotonia
- 8. Large posterior occiput in adults

Neuropathology

- 1. Decreased postnatal granule cell progenitor proliferation
- 2. Z1C1 and Z1C4 have been shown to have SHH-dependent and independent functions during cerebellar development (in genetically manipulated models)

Laboratory Evaluation

1. MRI:
 - a. Partial or complete absence of the cerebellar vermis
 - b. Posterior fossa cyst contiguous with the fourth ventricle
 - c. Elevated transverse sinuses
 - d. Thinning and bulging of the bones of the posterior fossa
 - e. Atresia of the foramina of Magendie and Luschka (some)
 - f. Associated conditions include:
 - i. Congenital heart disease
 - ii. Cleft lip and/or palate
 - iii. Neural tube defects
 - iv. Warburg syndrome
 - v. Meckel syndrome
 - vi. New association:
 1. Diabetes insipidus, central hypothyroidism, renal tubular acidosis

Pontocerebellar Hypoplasia (PcH)*General Characteristics*

1. PcH is a heterogeneous group of disorders associated with chromosomal defects, metabolic disorders and congenital muscular dystrophies
 - a. Subunits of the tRNA splicing endonuclease complex, TSEN54, TSEN34 and TSEN2 are involved in PcH2, PcH4, PcH5 and 1 patient with PcH1
 - b. Some patients with PcH1 as well as PcH6 have mutations in the mitochondrial arginyl tRNA synthetase RARS2 gene
 - c. Large deletions and mutations of the ULDLR gene as in Reelin associated lissencephaly have been reported with PcH
 - d. CASK mutations have recently been described as a new phenotype

Clinical Manifestations

1. There are seven described types
2. Severe developmental delay
3. Poor feeding, lethargy, hypotonia and apneic spells
4. Seizures (variable)
 - a. Respiratory difficulty

Neuropathology

1. Abnormally small cerebellum and brainstem
2. Type 6 demonstrates homozygous or compound heterozygous mutation in the RARS2 gene that maps to chromosome 6q15
3. The gene encodes the mitochondrial protein arginyl tRNA synthetase
4. One kindred demonstrates deficient mitochondrial activity of complexes I, II and IV
5. Patient derived lymphoblastoid cell lines demonstrate:
 - a. Reduced proliferation and increased expression of the cell cycle inhibitor INK4A (cyclin-dependent kinase inhibitor 2A p161 INK4A)

Laboratory Evaluation

1. MRI:
 - a. Progressive atrophy of the cerebellum, pons and cerebral cortex
 - b. Particular thinning of the pons and atrophy of the cerebellar hemisphere
 - c. Cerebellar vermis hypoplasia

Chiari Malformation*General Characteristics*

1. Chiari I
 - a. The vermis of the cerebellum protrudes through the foramen magnum > 5 mm
2. Chiari II
 - a. Vermis herniation
 - b. Downward displacement of the medulla with nuclear dysplasia
 - c. Occurs with a meningocele
 - d. Associated syringomyelia
3. Chiari III
 - a. Cervical spina bifida
 - b. Cerebellar encephalocele
 - c. And elongated medulla
4. Chiari IV
 - a. The attributes of malformations I–III with additional absence of the cerebellum

Clinical Manifestations

1. Short neck, low hairline and some restriction of movement to all planes
2. Shallow posterior fossa
3. Associated expected signs and symptoms of a cervical syrinx with Chiari II
4. Severe C2 headache associated with coughing or any form of valsalva maneuver
5. Sudden gait ataxia after age 30
6. Hoarseness and deficits of lower cranial nerves which may be insidious or has an acute onset
7. Increased reflexes; pyramidal signs
8. Downbeat nystagmus if there is compression of the cerebellar floccular nodular lobe
 - a. Late onset hydrocephalus

Neuropathology

1. Herniated cerebellar tissue shows:
 - a. Purkinje and granule cell loss
 - b. Shrinkage and gliosis of folia and myelin depletion
 - c. Distortion of the brainstem tracts and nuclei
 - d. Heterotopias in the cerebellar hemispheric white matter
 - e. Pontomedullary junction may be ill defined
 - f. The upper four to six cervical roots are angled upward towards their intervertebral canals
 - g. Variably there may be hypoplasia or agenesis of cranial nerve, olivary and pontine nuclei

- h. Associated anomalies include:
 - i. Subependymal nodular heterotopias in the walls of the lateral ventricles
 - ii. Thickening of the massa intermedia
 - iii. Spina bifida
 - iv. Myelomeningocele > meningocele and is located in lumbosacral segments
 - v. Hydromyelia (C8)
 - vi. Diastematomyelia
 - vii. Diplomyelia
 - viii. Aqueductal forking, forking and gliosis
 - ix. Cerebral hemisphere may demonstrate polygria

Laboratory Evaluation

1. MRI:
 - a. Chiari type I
 - i. The cerebellar tonsils are at least 5 mm below the foramen magnum
 - ii. They are usually pointed and fibrotic
 - b. Chiari type II
 - i. The vermis is herniated through the foramen magnum
 - ii. Downward displacement of the medulla
 - iii. Associated syringomyelia which is usually at the cervical medullary function
 - iv. Associated meningocele
 - c. Chiari type III
 - i. Cervical spina bifida
 - ii. Cerebellar encephalocele
 - iii. Elongated medulla
 - iv. "Beaked" collicular plate of the midbrain
 - v. Widening of the angles of the petrous pyramid
 - d. Chiari IV
 - i. Above features of the other types with absence or hypoplasia of the cerebellum

Rhombencephalosynapsis

General Characteristics

1. A developmental midline defect primarily affecting the vermis
2. Many associated anomalies

Clinical Manifestations

1. Cognition may be normal
2. Hydrocephalus may be present and is most often due to aqueductal stenosis
3. Medical associations include:
 - a. Vertebral anomalies
 - b. Anal atresia
 - c. Cardiovascular anomalies
 - d. Trachea-esophageal fistulas
 - e. Renal anomalies
 - f. Ataxia is the most common neurologic finding in non-syndromic patients

Neuropathology

1. Absence of the vermis; remnants of the nodulus may remain
2. Other midline associated anomalies include:
 - a. Atresia of the septum pellucidum
 - b. Fusion of the fornices
 - c. Holoprosencephaly
 - d. Fusion of the colliculi
 - e. Forking or atresia of the aqueduct
 - f. Fusion of the thalami
 - g. Agenesis of the corpus callosum
 - h. Neural tube defects
3. Associated syndromes:
 - a. Gómez-López-Hernández syndrome:
 - i. Cerebellotrigeminal dermal dysplasia
 - ii. Parietal skin alopecia
 - iii. Trigeminal anesthesia
 - iv. Keratitis
 - v. Corneal opacity
 - vi. Low-set ears
 - vii. Brachy-turricephaly (due to craniosynostosis); abnormal vertical height of the skull

Laboratory Evaluation

1. MRI:
 - a. A spectrum of severity, the gradient ranged between total absence of the vermis and retained parts of the anterior and posterior vermis including the nodulus
 - b. Hydrocephalus due to aqueductal stenosis
 - c. Rare findings include:
 - i. Fusion of the dentate nuclei
 - ii. Fusion of the cerebral peduncles
 - iii. Septo-optic dysplasia

Cerebellar Dysplasias

Lissencephaly with Cerebellar Dysplasia

General Characteristics

1. An autosomal recessive form of lissencephaly is associated with cerebellar, hippocampal and brainstem malformation
2. Two mutations in the reelin gene (RELN) that maps to chromosome 7q22 are causative

Clinical Manifestations

1. Varied phenotype
 - a. Microcephaly
 - b. Cognitive impairment
 - c. Spasticity
 - d. Congenital lymphedema (some)
 - e. Myopia and nystagmus (some)
 - f. Seizure (some)
 - g. Craniofacial dysmorphism

Neuropathology

1. Mutations disrupt RELN cDNA that cause low or absent reelin protein
2. The secreted protein binds to the very low density lipoprotein receptors (VLDLR) the apolipoprotein-E-receptor-2 (ApoER2), $\alpha 3\beta$ -integrin and protocadherin
3. Reelin mutations cause abnormalities of the cerebellum, hippocampus and brainstem
4. Associated cortical lissencephaly (parietal lobe) with thickened cortex and 4 rather than 6 layers

Laboratory Evaluation

1. MRI:
 - a. Small size of the vermis and cerebellar hemisphere
 - b. Smooth appearing cerebellar cortex
 - c. No folds, no fissures and no cerebellar lobulation
 - d. Small pons
 - e. Prominent agyria of the cerebral cortex (in some patients)

Differential Diagnosis of Diffuse Cerebellar Dysplasia

1. Lissencephaly with cerebellar dysplasia
2. Congenital muscle dystrophy
 - a. Fukuyama and muscle-eye-brain disease have:
 - i. Cortical or subcortical cerebellar cysts
 - ii. Multiple small cortical folia (cerebellar polymicrogyria)
 - iii. The dysplasia is most severe in the superior cerebellum
 - iv. Fukuyama has cobblestone cortex
3. Merosin deficient muscular dystrophy
 - a. Diffuse and delayed myelination of deep cerebral and cerebellar white matter
 - b. Inferior vermian hypoplasia
 - c. Normal cerebellar cortex
4. Walker-Warburg and muscle-eye-brain disease
 - a. Pontine hypoplasia with a midline longitudinal cleft
5. Congenital cytomegalovirus infection
 - a. Cerebellar hemispheres pathology parallels that of the cerebral hemispheres
 - b. Small cerebellar hemispheres with decreased foliation, shallow sulci
 - c. Rare cerebellar cortical calcification
 - d. Pontine shrinkage is dependent on the extent of cerebral cortex and cerebellar involvement
6. Diffuse cerebellar dysplasia
 - a. Bizarre, thick folia with abnormal orientation
 - b. Slight reduction of cerebellar white matter

Differential Diagnosis of Focal Cerebellar Dysplasia

1. Rhombencephalosynapsis:
 - a. Absence of the cerebellar vermis
 - b. Midline fusion of the two cerebellar hemispheres
2. Joubert syndrome
 - a. "Molar tooth" malformation

3. Lhermitte-Duclos disease

- a. Sharply defined non-enhancing cerebellar hemispheric mass
- b. An outer layer of radial and superficial parallel myelinated fibers with an inner layer of dysplastic neurons

Cerebellar Ataxic Syndromes***Ramsay Hunt Syndrome I****General Characteristics*

1. A very heterogeneous syndrome
2. A recent description of a mutation in the GOSR2 gene that maps to chromosome 17q21

Clinical Characteristics

1. Early onset ataxia
2. Action myoclonus by age 6
3. Scoliosis
4. Seizures (tonic-clonic)
 - a. Syndactyly

Neuropathology (1 Autopsied Patient)

1. Mild cerebral atrophy
2. Minor Purkinje cell loss and gliosis in the vermis
3. GOSR2 protein is a member of the SNARE family of vesicle docking proteins
4. The protein has a role in protein transport from the endoplasmic reticulum into the Golgi apparatus

Laboratory Evaluation

1. EEG:
 - a. Generalized spike-and-wave often posterior predominant
 - b. Polyspike
2. Borderline or mildly elevated CK
3. MRI:
 - a. Normal in 5/6 patients. One patient had mild cerebellar atrophy
4. Muscle biopsy and EMG may be normal

Chediak-Higashi Disease (CHS)*General Characteristics*

1. CHS is caused by homozygous or compound heterozygous mutation of the lysosomal trafficking regulator gene (LYST) that maps to chromosome 1q42; autosomal recessive deletion

Clinical Manifestations

1. Decreased hair and eye pigmentation (partial albinism)
2. Photophobia
3. Nystagmus
4. Spinocerebellar phenotype
5. Bleeding diathesis
6. Frequent infections

7. An accelerated phase:
 - a. Pancytopenia
 - b. High fever
8. Ataxia
9. Peripheral neuropathy
10. Cognitive impairment (some patients)

Neuropathology

1. Giant azurophilic granules in the peripheral blood (white cells)
2. Huge lysosomes and cytoplasmic inclusions within tissue
3. Lymphoproliferative stage:
 - a. Generalized lymphohistiocytic infiltrates, hepatosplenomegaly, lymphadenopathy, pancytopenia and often bleeding

Laboratory Evaluation

1. MRI:
 - a. Cerebellar atrophy
 - b. Hemorrhage from coagulopathy
2. Deficiency of cathepsin G and elastase
3. In cells from patients with CHS:
 - a. Peptide loading onto major histocompatibility complex class II molecules and antigen presentation are defective
4. EMG (some kindreds):
 - a. Sensorimotor axonal neuropathy

Clinical Variants of Olivopontocerebellar Atrophy (Older Classification)

1. Type I – Menzel variant
 - a. Cerebellar ataxia
 - b. Dorsal column involvement
2. Fick-Hamacher – Type II
 - a. Prominent cranial nerve involvement
 - b. Cerebellar ataxia
3. Type III
 - a. AD
 - b. Pure Cerebellar ataxia
4. Type IV
 - a. Retinitis pigmentosa
 - b. Cerebellar ataxia
5. Marie-Foix-Alajouanine syndrome
 - a. General characteristics
 - i. Primarily a slowly progressive late onset cortical cerebellar atrophy
 - b. Clinical manifestations:
 - i. Onset in the fifth and sixth decades
 - ii. Gait ataxia > appendicular in some patients
 - iii. Minimal or absent dysarthria
 - iv. Cognitive impairment may occur
 - c. Neuropathology
 - i. Loss of Purkinje cells throughout the cerebellum
 - ii. Rarefaction of the granular cell layer in areas where Purkinje cell loss is severe

- iii. Vermian involvement can be predominant
- iv. Neuronal loss in the inferior olivary nucleus occurs concomitantly with granular cell and molecular layer degeneration
- d. Laboratory evaluation
 - i. MRI:
 1. Cortical and olivary nuclear atrophy in the cerebellum and brainstem

Pelizaeus-Merzbacher Disease (PMD)

General Characteristics

1. PMD is a rare leukodystrophy caused by mutation in the PLP1 gene that maps to the Xq22.2 chromosome
2. There are a great number of PLP1 gene mutations that include duplications, point mutations and deletions that may be responsible for the wide clinical spectrum of the disorder

Clinical Manifestations

1. There are 3 types of PMD
 - a. Classic type:
 - i. Onset in infancy and death in late adolescence or young adulthood
 - ii. Initial rotary and nystagmoid eye movements
 - iii. Jerking and rolling head movements
 - iv. Nystagmus lessens as the patient matures
 - v. Ataxia, spasticity and involuntary movements sequentially appear
 - vi. Optic atrophy
 - b. Connatal type:
 - i. Rapid progression
 - ii. Fatal in infancy and childhood
 - c. The transitional form:
 - i. Onset in childhood
 - ii. Stridor occurs in some patients
 - iii. Rotary nystagmus
 - iv. Abnormal head movements
 - v. Sequential development of spasticity of the legs and arms
 - vi. Cerebellar ataxia
 - vii. Cognitive impairment
 - viii. Parkinsonian features

Neuropathology

1. Proton magnetic resonance spectroscopy
 - a. Affected white matter demonstrates increased N-acetyl aspartate, glutamine, myo-inositol, creatine and phosphocreatine
 - b. Decreased concentration of choline-containing compounds
 - c. Pattern supports enhanced neuroaxonal density, astrogliosis that supports dys- and hypomyelination
2. Absence of proteolipid apoprotein (lipophilin) in the brain

3. Possible involvement of the unfolded protein response, a stress induced signaling cascade that regulates the secretory pathway through the endoplasmic reticulum as a major pathogenic mechanism of the disorder
4. PLP1-duplications may be causative in the classic and transitional forms; lead to defective CNS myelination
5. Missense mutations may give rise to more severe forms of the disease while deletions and null mutations to mild PMD. The most common mutations are duplications that cause the classical intermediate form of the disease

Laboratory Evaluation

1. MRI:
 - a. Bilateral and multiple regions of signal hyperintensity in the periventricular and subcortical white matter
 - b. Abnormal brainstem auditory evoked potentials; waves III, IV and V (generated in the pons and midbrain) are primarily affected
 - c. Visual and somatosensory evoked potentials may demonstrate conduction delay

Seminal Features of Some Named Cerebellar Syndromes

1. Marie Sanger Brown
 - a. Cranial nerve involvement
2. Marinesco-Sjögren
 - a. Cataracts
3. Friedreich's ataxia
 - a. Dilated cardiomyopathy
 - b. Scoliosis
4. Marie-Foix-Alajouanine
 - a. Pure cerebellar cortical deficit
 - b. Late onset
5. Gordon Holmes
 - a. Cortical cerebellar atrophy
 - b. Hypogonadism
6. Ramsay Hunt type I
 - a. Progressive myoclonus
7. Madame Louis-Bar
 - a. Ataxia telangiectasia (ATM)
 - b. Involuntary movements
 - c. Lymphoma
8. Fahr's disease
 - a. Calcification of the dentate nucleus and basal ganglia
9. Menzel variant of OPCA
 - a. Posterior column involvement
10. Fick-Hamacher variant of OPCA (cranial nerve involvement)
11. Leigh's disease (m.8993T)
 - a. Optic atrophy
12. Gerstmann-Sträussler-Scheinker variant of CJ disease
 - a. Dementia (rapidly progressive)
13. Pelizaeus-Merzbacher disease
 - a. Nystagmus
14. Russell syndrome (DRPLA); SCA7

- a. Myoclonus
- b. Basal ganglia involvement
15. Adult Krabbe's disease
 - a. Increased protein in the CSF
 - b. Peripheral neuropathy
16. Behr disease
 - a. Optic atrophy
17. SCA3/Machado-Joseph disease
 - a. Bulging eyes
 - b. Distal amyotrophy
18. Spastic ataxia
 - a. HSP4
 - b. Spasticity
19. Gillespie syndrome
 - a. Aniridia
 - b. Congenital ataxia
 - c. Cognitive impairment
20. Granule cell hypoplasia
 - a. Congenital ataxia
 - b. Cognitive impairment
21. Tay-Sachs disease
 - a. Cherry red spot
 - b. Intention tremor
 - c. Neurogenic features
22. Fabry's disease
 - a. Stroke
 - b. Angiokeratomas
23. Refsum's disease
 - a. Intermittent neuropathy
 - b. Ichthyosis
 - c. Cataracts and hearing loss
24. Bassen-Kornzweig disease
 - a. Abetalipoproteinemia
 - b. Peripheral neuropathy
25. Hartnup disease
 - a. Rash on exterior surfaces
26. Joubert disease
 - a. Vermian atrophy
 - b. Episodic hyperpnea

Distinguishing Clinical Manifestations of Abnormal Dominant Cerebellar Ataxias

1. SCA1
 - a. Pyramidal signs
 - b. Peripheral neuropathy
2. SCA2
 - a. Slow saccades
 - b. Myoclonus
 - c. Areflexia
3. SCA3
 - a. Slow saccades
 - b. Extraparamidal signs
 - c. Bulging eyes
 - d. Peripheral neuropathy

- e. Amyotrophy
4. SCA4
 - a. Sensory neuropathy
5. SCA5
 - a. Early onset with slow progression
6. SCA6
 - a. Late onset
 - b. May have no family history
 - c. Nystagmus
 - d. Minimal ataxia
7. SCA7
 - a. Macular degeneration
8. SCA8
 - a. Minimal ataxia
9. SCA9
 - a. Adult onset of ataxia
 - b. Ophthalmoplegia (some patients)
 - c. Pyramidal tract signs
 - d. Dysarthria
10. SCA10
 - a. Generalized or complex partial seizures
11. SCA11
 - a. Mild
 - b. Pyramidal signs
 - c. Abnormal extraocular movements (some)
12. SCA12
 - a. Tremor
 - b. Dementia
13. SCA13
 - a. Cognitive impairment
14. SCA14
 - a. Early onset disease has intermittent myoclonus
15. SCA15/SCA16
 - a. Slowly progressive
 - b. Action and postural tremor
 - c. Pyramidal tract (some patients)
16. SCA17
 - a. Gait ataxia
 - b. Dementia
17. SCA18
 - a. Pyramidal tract signs
 - b. Extremity weakness
 - c. Sensory axonal neuropathy
18. SCA19/SCA22
 - a. Cerebellar syndrome
 - b. Myoclonus (rare)
 - c. Cognitive impairment (occasional)
19. SCA20
 - a. Palatal tremor
 - b. Dysphonia
20. SCA21
 - a. Extrapyramidal signs
21. SCA23
 - a. Distal extremity sensory loss
22. SCA24
 - a. Redesignated as autosomal recessive SCAR4
 - b. Late onset (3rd decade)
 - c. Gait, trunk, limb ataxia
 - d. Horizontal macrosaccadic oscillations of high velocity
 - e. Myoclonic jerks and fasciculations
 - f. Pes cavus
23. SCA25
 - a. Sensory neuropathy
 - b. Facial tics
 - c. Gastrointestinal symptoms
24. SCA26
 - a. Pancerebellar syndrome
25. SCA27
 - a. Cognitive impairment
 - b. Poor ocular pursuit
 - c. Gaze-evoked nystagmus
26. SCA28
 - a. Ophthalmoparesis
 - b. Ptosis
27. SCA29
 - a. Early onset and new progressive ataxia
 - b. Allelic variant of SCA15
28. SCA30
 - a. Slowly progressive
 - b. Pure ataxia
29. SCA31
 - a. Late onset
 - b. Decreased muscle tone
30. SCA32
 - a. Cognitive deficits
 - b. Azoospermia and testicular atrophy
31. SCA33
 - a. Not unique
32. SCA34
 - a. Papulosquamous erythematous ichthyosiform plaques
33. SCA35
 - a. Late onset
 - b. Slowly progressive gait and limb ataxia
34. SCA36
 - a. Late onset
 - b. Truncal ataxia
 - c. Dysarthria
 - d. Variable motor neuron disease
 - e. Sensorineural hearing loss
35. SCA37
 - a. Late onset
 - b. Dysarthria
 - c. Abnormal vertical eye movements
36. SCA38
 - a. Adult onset
 - b. Axonal neuropathy
37. SCA40
 - a. Adult onset
 - b. Brisk reflexes
 - c. Spasticity

Differential Diagnosis of Autosomal Recessive Hereditary Ataxias

1. Friedreich's ataxia
2. AOA1
3. AOA2
4. Ataxia telangiectasia (ATM)
5. Cerebrotendinous xanthomatosis (CTX)
6. Refsum syndrome
7. Vitamin E deficiency
8. ARSACS

Differential Diagnosis of Autosomal Recessive Disorders Associated with Ataxia and/or Cerebellar Hypoplasia That Are Caused by Biallelic Pathogenic Variants in Related Genes

1. Joubert syndrome
2. Congenital disorder of glycosylation
3. Pontocerebellar hypoplasia
4. Peroxisomal biogenesis disorders (Zellweger spectrum diseases)
5. Perrault syndrome

Differential Diagnosis of X-Linked Hereditary Ataxias

1. X-linked sideroblastic anemia and ataxia
2. CASK-related disorders
3. FXTAS
4. X-linked mental retardation with cerebellar hypoplasia and distinctive facial appearance
5. Systemic X-linked mental retardation (Christianson type)
6. X-linked spinocerebellar ataxia 5

Genetic Differential Diagnosis

1. More than one family member is affected
 - a. Autosomal dominant
 - i. The family history supports male and female probands in multiple generations
 - ii. The most common autosomal dominant ataxias are; SCA1, SCA2, SCA3, SCA6 and SCA7
 1. All are trinucleotide repeat expansions
 - b. Autosomal recessive
 - i. The family history shows that only siblings are affected in one generation of the family
 - ii. The parents are consanguineous
 - iii. Friedreich's ataxia, ataxia-telangiectasia, AOA1, AOA2, vitamin E deficiency, Refsum's disease and cerebrotendinous xanthomatosis are the most common
 - c. X-linked inheritance;
 - i. The family history shows that the affected members are male and are related to each other by females
 - d. Simplex patient
 - i. Only one family member is affected
 1. An acquired rather than genetic etiology for the disorder

2. A de novo mutation associated with an autosomal dominant ataxia
3. Decreased penetrance of a pathogenic variant associated with autosomal dominant ataxia
4. A single occurrence of an autosomal recessive X-linked disease in the family
5. An incorrect history with alternate paternity
- ii. If the cause is not a secondary cerebellar disorder
 1. There is an approximately 13% probability that the patient has:
 - a. SCA1, SCA2, SCA3, SCA6, SCA8 or SCA17
 - b. Friedreich's ataxia, AOA1 or AOA2

Differential Diagnosis of Intermittent Metabolic Ataxia

1. Defects of urea cycle enzymes:
 - a. Ornithine transcarboxylase (X-linked)
 - b. Argininosuccinate synthetase
 - c. Arginase deficiency
 - d. Hyperornithinemia (not a urea acid cycle enzyme)
 - e. All with hyperammonemia
2. Amino acidurias:
 - a. Branch chain ketoaciduria
 - b. Isovaleric acidemia
 - c. Hartnup disease
 - d. Without hyperammonemia
3. Pyruvate dehydrogenase deficiency (PDH)
4. Multiple biotin-dependent carboxylase deficiency

Differential Diagnosis of Progressive Ataxia Due to Enzyme Deficiencies

1. Metachromatic leukodystrophy (arylsulfatase)
2. Niemann-Pick disease (sphingomyelinase)
3. Krabbe's disease (galactosylceramide)
4. Tay-Sachs disease (hexose aminodase)
5. Deficiency of mitochondrial sterol 27 hydroxylase
6. Phenylketonuria (phenylalanine dehydrogenase)
7. Hyperornithinemia (transcarboxylase)
8. Fabry's disease (galactosylcerebrosidase)
9. Mannosidosis (alpha-D-mannosidase)
10. Fucosidosis (alpha-fucosidase)
11. 3-methyl-glutaconic aciduria (3-methyl-glutaconyl CoA hydrolase)
12. Gamma-glutamyl-cysteine synthetase deficiency
13. Triosephosphate isomerase deficiency

Differential Diagnosis of Congenital Anomalies and Structural Defects with Significant Cerebellar Symptomatology

1. Platybasia
2. Basilar impression
3. Chiari malformation
4. Craniocervical defects
 - a. Atlanto-occipital fusion

- b. Odontoid process anomalies
- 5. Dandy-Walker syndrome
- 6. Joubert syndrome
- 7. Pontocerebellar hypoplasia
- 8. Lhermitte-Duclos (gliocytoma)
- 9. Diffuse dysplasia
- 10. Focal cerebellar dysplasia
- 11. Congenital muscular dystrophy
 - a. Fukuyama type
 - b. Absent merosin
- 12. Walker-Warburg disease
- 13. Muscle-Eye-Brain disease (MEB)

Differential Diagnosis of Ataxic Disorders with Known Metabolic Causes

1. Metabolic disorder:
 - a. With hyperammonemia:
 - i. Ornithine transcarboxylase deficiency
 - ii. Argininosuccinate synthetase deficiency
 - iii. Argininosuccinase deficiency
 - iv. Arginase deficiency
 - v. Hyperornithinemia
 - b. Amino acidurias without hyperammonemia
 - i. Intermittent branch chain ketoaciduria
 - ii. Isovaleric acidemia
 - iii. Hartnup disease
 - c. Disorders of pyruvate and lactate metabolism
 - i. Pyruvate dehydrogenase deficiency (complex IV)
 - ii. Pyruvate decarboxylase deficiency (complex IV)
 - iii. Multiple carboxylase deficiencies

Differential Diagnosis of Unrelenting Ataxia Syndromes

1. Abetalipoproteinemia
2. Hexosaminidase-A deficiency
3. Cerebrotendinous xanthomatosis (CTX)
4. Mitochondrial diseases
5. Glutamate dehydrogenase deficiency
6. Partial hypoxanthine guanine phosphoribosyl transferase deficiency (Lesch-Nyhan disease)

Differential Diagnosis of Episodic Ataxia

1. Autosomal episodic ataxia Type 1-8
 - a. EA1 (KCNA1)
 - i. Attacks last seconds to minutes
 - ii. Startle or exercise induced
 - iii. Myokymia
 - b. EA2 (CACNA1A)
 - i. Attacks last minutes to hours
 - ii. Posture change induced
 - iii. Vertigo
 - c. EA3 (1q42)
 - i. Adult onset
 - ii. Vertigo and tinnitus

- d. EA4 (not defined)
 - i. Adult onset
- e. EA5 (CACNB4)
 - i. Childhood to adolescent onset
- f. EA6 (SLC1A13)
 - i. Childhood onset
 - ii. Migraine
 - iii. Associated seizures
- g. EA7 (19q13)
 - i. Childhood to adolescent onset
 - ii. Seizures
 - iii. Vertigo
2. Paroxysmal kinesigenic choreoathetosis
 - a. Induced by initiation of movement
 - b. Associated dystonia
 - c. Attacks are short-lived (minutes)
3. Spinocerebellar ataxia 6
 - a. Associated nystagmus
4. Familial hemiplegic migraine:
 - a. Associated CACN genes on chromosome 19
 - b. Most often hemiplegia rather than migraine headaches
 - c. Hemiplegia is on the same side in all affected family members
5. Basilar artery migraine (Bickerstaff)
 - a. A disease of young women
 - b. Associated paresthesia of the hands may be an initial symptom
 - c. Dysarthria and dysphagia
 - d. Brief loss of consciousness in some patients
6. Post-ictal ataxia
 - a. Associated psychiatric phenomena
7. Hartnup disease
 - a. Most often seen in alcoholic patients
 - b. Associated erythematous rash on extensor surfaces
8. Hypoglycemia
9. Hyperammonemia
10. Organic acidurias
11. Refsum's disease:
 - a. Cataracts
 - b. Deafness
 - c. Intermittent neuropathy
 - d. Ichthyosis
12. Acute intermittent porphyria
 - a. Dominated by abdominal pain
 - b. Psychosis
 - c. Peripheral neuropathy (motor)

The Differential Diagnosis of Secondary Cerebellar Disease

Overview

The major drug groups that affect the cerebellum are the anti-convulsants. Characteristic of all taken in excess are lethargy,

nystagmus (usually gaze-evoked but may be spontaneous) due to interference with “hold neurons” of the visual system that foveate the target. Dilantin has been noted to cause ophthalmoplegia as well as a slowly progressive peripheral neuropathy often limited to depressed ankle jerks. Phenobarbital, in addition to nystagmus, may cause severe dysarthria and reversible decortication and decerebration. Patients lying in coma from phenobarbital overdose may develop skin blisters.

5-fluorouracil is the usual anti-neoplastic agent that causes a mild cerebellar cortical deficit. Notably is absence of a peripheral neuropathy which is characteristic of most of the other CNS toxic and anti-neoplastic agents. Cytarabine (Ara-C) has primarily cerebellar toxicity when administered in high doses. It may also have cerebral manifestations that include headache, somnolence, seizures and altered personality. Symptoms usually start within three to eight days after beginning treatment. Cerebral toxicity rarely occurs without cerebellar involvement. Ifosfamide causes neurotoxicity in approximately 30% of patients. It is associated with depressed consciousness, ataxia, myoclonus, seizures and coma. Risk factors may include low albumin, elevated creatinine and kidney disease as well as high serum chloroacetaldehyde.

Cisplatin toxicity may be confused with cerebellar ataxia. Cisplatin affects the dorsal root ganglia with loss of large proprioceptive neurons and consequent posterior column deficits. The intention tremor is throughout all thirds of movement (cerebellar intention tremor is the last 1/3 of a movement) and patients are dramatically affected unless they have visual compensation. The neuropathy is usually severe.

Cyclosporine and lithium cause cerebellar features and render patients ataxic but their seminal features are myoclonus, impaired cognition and hyperreflexia. Hypnotic sedatives cause ataxia both of gait and limb, but dysarthria, lethargy, depressed reflexes and psychiatric problems predominate.

The primary deficiency states with cerebellar dysfunction as a core symptom are B12 and vitamin E deficiency. The former is dominated by spasticity, an active peripheral neuropathy (parasthesias), an ebullient mental status, optic atrophy and cranial nerve I dysfunction. Vitamin E deficiency from either alpha-tocopherol transporter or alimentary deficiency has very prominent dorsal column signs and symptoms. Acute B12 deficiency may be induced by nitrous oxide anesthesia. Pantothenic acid deficiency is commonly associated with chronic alcoholism and may be partly responsible for its associated ataxia.

Alcohol is by far the most serious cerebellar toxin worldwide. Its pattern of expression is appendicular in the lower extremities with imbalance and anterior vermis deterioration. The patients have a stiff legged gait (“Martinet” gait) without the usual cerebellar modulation of both the stance and swing phase. There is minimal dysarthria, nystagmus or upper extremity dysmetria.

The usual pattern of toxic agents that affect CNS and the cerebellum are:

1. Optic neuritis (always occurs with methyl alcohol poisoning by ingestion); centrocecal scotoma
2. Dorsal column dysfunction with acute vibratory and position sense impairment (the longest myelinated fibers are involved first)
3. Spasticity as a late consequence
4. Frontal lobe cognitive impairment

This pattern is seen with toluene (n-ethyl toluene) and paint solvents. Glue sniffing affects the frontal lobes and causes euphoria and then lethargy. Huffer’s syndrome (gasoline sniffing) induces prominent frontal lobe depression. Paint sniffing (usually silver paint in the Southwest USA) causes cerebellar deficits that are overshadowed by pronounced mental status alterations. Thallium is recognized by euphoria, ataxia and hair loss, while mercury poisoning is distinguished by mental status changes, dystonia and choreoathetosis in addition to ataxia. Rarely, lead, manganese and benzene derivatives have prominent ataxia. Heroin and cocaine abuse may cause severe ataxia with MRI evidence of cerebellar and middle cerebellar peduncle demyelination.

Endocrine induced ataxia is usually secondary to hypothyroidism. This is minimal and is most often accompanied by VIIIth nerve deficits, proximal myopathy (pseudohypertrophy or Hoffman’s syndrome) bilateral carpal or tarsal tunnel syndrome and failure to make ear wax or sweat normally.

Severe liver disease is associated with ataxia which is often due to degeneration of the anterior vermis (lingual, culmen and centralis) from alcohol abuse. The caudate and putamen may be hyperintense on T2-weighted sequences. Patients may demonstrate acquired hepatolenticular degeneration (usually following several episodes of delirium tremens). This syndrome manifests as subcortical dementia, severe dysarthria, extrapyramidal signs and falling backwards.

In general, tumors of the cerebellum are age specific. Children and young adults may have an ependymoma of the fourth ventricle. This tumor is suggested by vertigo with change of head position, nystagmus and papilledema. Projectile vomiting (pressure on the vomit center on the floor of the IVth ventricle) is common upon awakening. There is no preceding nausea. Ataxia, headache and hydrocephalus are prominent. The origin of medulloblastomas is the superior medullary velum of the IVth ventricle. The symptoms and signs are similar to those of an ependymoma but the spinal cord is seeded with the tumor. Cystic and solid astrocytomas may be hemispheric or vermian. In the latter, axial symptoms are more prominent than appendicular. These tumors frequently distort the IVth ventricle and put pressure on the pons and medulla. Headache, vomiting and unilateral or bilateral VIth nerve palsy may occur if there is increased intracranial pressure from hydrocephalus (the VIth nerve is trapped under the petroclinoid ligament in Dorello’s canal). Any mass in the IVth ventricle or posterior fossa may cause downbeat nystagmus accentuated by lateral gaze. Tumors involving the floccular nodular lobe cause hypermetric saccades and rotary nystagmus with a contralateral torsional component. Rarely,

oligodendrogliomas are found in the cerebellum. Most of the tumor is benign, but there is usually one section that is malignant. Hemangioblastomas are most common in the cerebellar hemispheres in adults and are midline in younger patients. They bleed intermittently. This is evident by new blood (4–8 days after the original bleed) noted by increased signal on T2-weighted MRI sequences in the center of the lesion with a surrounding hemosiderin ring (old bleed). They cause symptoms by destruction of tissue in specific locations and by pressure on contiguous structures. There are three major tumors of the cerebellopontine angle that often involve the cerebellum by pressure. A Schwannoma presents with tinnitus, ipsilateral sensorineural hearing loss and ipsilateral ataxia. Meningiomas may compress the Vth nerve and present with facial pain. Epidermoids have high signal on T2-weighted sequences (keratin) and may present with pain radiating to the inner ear (as do tumors that distort the tentorium), ipsilateral ataxia or cranial nerve involvement. A ganglioneuroma is benign and may present with vermian or hemispheric symptoms and signs. It does not enhance strongly with gadolinium.

The cerebellum is a major destination for metastatic lesions in adults (high relative cerebellar blood flow). The hemispheres are more frequently involved than the vermis. Squamous cell carcinoma of the lung is the most frequent, followed by breast and the GI tract. Prostate metastases reach the posterior fossa by means of the valveless paravertebral veins (Batson's plexus). This tumor may specifically metastasize to the petrous apex (may involve cranial nerves V and VI). Lymphomas in HIV patients are often neurotic and occasionally involve the cerebellum (they are much more frequently encountered in the corpus callosum). A cholesterol granuloma (very bright on T2-weighted sequences) at the petrous apex occasionally compresses the cerebellum. Meningiomas of the tentorium (angiographically demonstrate an enlarged feeding vessel from the meningohypophyseal trunk – the artery of Bernasconi-Cassinari) may produce headache, referred pain to the inner ear, (IX nerve) and ipsilateral ataxia. Rarely a cerebrotendinous xanthoma or amyloidoma may compress the cerebellar from the tentorium.

There are twelve paraneoplastic autoantibodies associated with autoimmune mediated cerebellar ataxia. They include:

1. Anti-Yo
2. Z1C
3. CARP VIII
4. Tr
5. R1
6. Hu
7. Ma
8. CRMP-5
9. ANNA-3
10. PCA-2
11. VGCC
12. mGlu antibodies

Anti-GAD, thyroid and gliadin antibodies are found in non-paraneoplastic cerebellar ataxia. Some of these anti-neural

autoantibodies target nuclear antigens that are widely expressed in CNS neurons (anti-Hu and anti-Ri) others target antigens present in the cytoplasm or plasma membrane of Purkinje cells. These 12 most common Purkinje cell (PC) autoantibodies are often referred to as “Medusa” head antibodies due to their characteristic somatodendritic immunohistochemical binding pattern. Most of these antibodies target antigens involved in the mGluR1/calcium pathway that is essential for Purkinje cell (PC) function and maintenance. At the present time there are approximately 30 different autoantibodies targeting brain antigens in patients with autoimmune cerebellar ataxia. Most of the “Medusa” head antibodies are involved in regulating calcium homeostasis in PCs.

Anti-Yo antibodies are one of the most common paraneoplastic antibodies. Most patients present with a subacute and severe pancerebellar syndrome that manifests truncal and appendicular ataxia, dysarthria and often downbeat nystagmus. Other associated signs include long tract involvement, peripheral neuropathy, diplopia, vertigo, dysphagia and cognitive impairment. Almost all reported patients are female with a median age at onset of 61 years. MRI reveals cerebellar atrophy. The CSF may demonstrate a lymphocytic pleocytosis and elevated protein. Anti-Yo antibodies are usually associated with malignant gynecological tumors (ovary, breast, mesovarium, fallopian tube, uterus and very rarely cervical).

In the majority of patients the paraneoplastic cerebellar degeneration precedes the tumor diagnosis. Anti-Yo positive sera recognizes CDR2 (cerebellar degeneration-related 2) antigen. The antibody stains the PC cytoplasm and some of the dendritic arbor. Anti-Yo positive paraneoplastic cerebellar degeneration demonstrates massive Purkinje cell loss. Immune cell infiltrates are positive in some patients.

Anti-Nb/AP3B2 (beta-NAP) is a PC antibody that has been described in one 35 year old female patient. She presented with a subacute pancerebellar syndrome similar to that seen with anti-Yo-positive patients. She had associated diffuse hyperreflexia with Babinski signs. Brain and spinal cord MRI studies were normal as was the CSF. The target antigen is a neuron-specific vesicle coat protein (neuronal adaptin-like protein) beta-NAP which is now termed AP3B2. Experimental work suggests that the protein is involved in the formation of neurosecretory vesicles.

PCA-2 has been reported in 9 patients whose age ranged from 43–73 years. Three of the nine patients had predominant cerebellar ataxia. Patients demonstrated a wide-based gait, limb ataxia, dysarthria and loss of fine motor control. The other 6 patients had limbic or brainstem encephalitis, autonomic neuropathy, and inappropriate ADH (one patient). MRI was normal at presentation of two patients. Most patients had a mild lymphocytic pleocytosis in the CSF. This syndrome has been primarily reported in patients with small cell lung cancer. The antigen is unknown.

Anti-Tr/DNER paraneoplastic autoantibody disorder causes a subacute pancerebellar syndrome with truncal and limb ataxia and downbeat nystagmus. Extracerebellar symp-

toms have been reported in two patients, one with a Babinski sign and the other with optic atrophy. Brain MRI demonstrates cerebellar atrophy and the CSF shows a moderate lymphocytic pleocytosis. Hodgkin's disease is the underlying tumor. The Tr antigen is the delta/notch epidermal growth factor related receptor. The cerebellar degeneration precedes the diagnosis of Hodgkin's disease in most patients.

Anti-Ri antibodies are found in association with breast, gynecological and small cell lung cancer. Their distinguishing feature is opsoclonus, Anti-Ma antibodies are seen with testicular germ cell tumors and cause limbic and brainstem encephalitis in addition to cerebellar degeneration. Anti-CV2/CRMP5 also causes encephalomyelitis with cerebellar degeneration. The antibody attack may be predominantly directed against glial cells. The most common antibodies directed against ion channels are those targeting P/Q or N-type voltage-gated calcium channels. Anti-mGluR1 antibodies have been demonstrated in patients with paraneoplastic cerebellar degeneration. They are produced intrathecally and their concentration is much higher in the CSF than the serum. Anti-mGluR5 antibodies have been detected in the CSF and serum of a few patients with Hodgkin's lymphoma and produce limbic encephalopathy (Ophelia syndrome) rather than ataxia.

Hyperosmolar syndromes from sodium excess (dehydration) or diabetes (glucose > 3000 mg/dl) may cause severe ataxia. Most often segmental myoclonus predominates. The rapid correction of low serum sodium (usually between 100–120 mg/dl) at greater than 12 mm/hr may cause pontine and extrapontine myelinolysis. The ataxia occurs from destruction of the pontine fibers that constitute the majority of the axons in the middle cerebellar peduncle.

Autoimmune induced cerebellar dysfunction is most prominent with demyelinating disease such as MS. In general, it is accompanied by frontal lobe mental changes, intranuclear ophthalmoplegia, spasticity and optic nerve inflammation. In Devic's disease there is a clear association with antibodies to aquaporin-4 antigen. The antibody attack is primarily target to the optic nerves and a long length of the spinal cord (3 vertebral segments). Acute disseminated encephalomyelitis may be associated with severe ataxia and frequently evolves into MS. A distinguishing feature is that cell lesions are of the same age on MRI. In acute hemorrhagic leukoencephalitis which may involve the cerebellum, lesions tend to selectively involve the left side of the CNS. Post-viral and -vaccination syndromes have an autoimmune component that can cause a cerebellar hemispheric or vermillion syndrome. They occur 10–14 days following the infection or vaccination. There may be periventricular MRI lesions in post-viral patients and large lesions of the centrum semiovale after vaccination. The latter may be accompanied by transverse myelitis. The white matter lesions most suggestive of MS are in the corpus callosum (Dawson's finger), optic nerve and periventricular areas.

There is an overlap between central and peripheral myelin (as regards antigen epitopes). Thus patients with GBS or

CIDP may have central inflammatory white matter lesions that involve cerebellar tracts.

Anoxic lesions of the cerebellum affect both gray and white matter. This pathology is suggested by metronomic eye movements. These are oscillations in which the eyes remain at the end of their complete excursion prior to oscillating to the opposite extreme.

Viral infections most often present with the sudden onset of headaches and stiff neck with preserved consciousness. Herpes simplex, Coxsackie and Herpes Zoster are the most severe. HS predominately affects the temporal and frontal lobes and causes seizures with loss of consciousness. Herpes Zoster encephalitis is often associated with V1 infection. There is large vessel MCA or carotid stroke 12–14 days after onset. The cerebellum may be involved but ataxia is rarely the predominant symptom. In children post-viral acute panencephalitis most often occurs 14 days after an upper respiratory or gastrointestinal infection. Bacterial cerebellar abscesses were common following chronic middle ear infection in the pre-antibiotic era. They are often accompanied by lateral sinus thrombosis, altered consciousness, a head tilt to the side of the lesion and ipsilateral ataxia.

Brainstem encephalitis (rhombencephalitis) may also affect the cerebellum. HZ, listeria monocytogenes (dorsal pons) herpes simplex (medial temporal lobe) and paraneoplastic involvement (anti-Hu) in association with limbic encephalitis are the most common etiologies. Delirium and nystagmus are prominent.

Differential Diagnosis of Acute Ataxia from Cerebellar Lesions

1. Vascular:
 - a. PICA infarction
 - i. Inability to walk
 - ii. Nausea and vomiting
 - iii. Cranial nerve IX and X involvement
 - b. AICA infarction
 - i. VIIIth nerve deficit
 - ii. Ataxia of the arm > leg
 - iii. Peripheral VIIth nerve palsy (the peripheral blood supply of the nerve is from AICA)
 - c. Superior cerebellar artery infarction:
 - i. Arm and leg have ipsilateral ataxia
 - ii. Prominent dysarthria
2. Cerebellar hemorrhage:
 - a. Severe posterior occipital headache
 - b. Closure of the ipsilateral eye
 - c. Head tilt to the side of the lesion
 - d. Nystagmus
 - e. Ipsilateral ataxia (hemispheric); severe gait instability (vermian)
 - f. Quadriparesis not quadriplegia (pontine pressure)
 - g. Small reactive pupils (pontine pressure)
 - h. Central neurogenic hyperventilation

3. Large cerebellar infarcts:
 - a. Pseudotumoral presentation on the third to fourth day from swelling
4. Cerebellar tumor:
 - a. Focal neurologic signs depending on location
 - b. Sudden exacerbation of signs from hemorrhage
 - c. Posterior occipital headache; pressure on the tentorium is associated with headache radiation to the inner ear; C2 irritation (meningeal involvement of the posterior fossa) there may be brow radiation
5. Demyelinating disease
 - a. There are associated intranuclear ophthalmoplegia, afferent pupillary defects, spasticity and cognitive impairment
6. GBS and other dis-immune processes that affect large proprioceptive dorsal root ganglia neurons (DRG) that cause ataxia from dorsal column demyelination (Richter's variant of GBS)
 - a. In sensory ataxia the intention tremor is throughout all components of a movement
 - b. In cerebellar tremor the ataxic movement is in the terminal 1/3 of a movement
 - c. In a cerebellar outflow tremor, there is an increase of tremor amplitude as the target is approached
 - i. A tremor of the proximal muscles occurs with fixation
 - ii. Abnormal finger movements ('piano playing') are seen in the outstretched upper extremities with the eyes closed. If the ataxia is cerebellar, the outstretched upper extremity rises (eyes closed) and the hand has a 'spoon' posture due to imbalance of the extensor and flexor intrinsic hand muscles
 - d. Acute proprioceptive loss from damage to the dorsal column nuclei cause ballistic rather than ataxic movements
7. Tick paralysis causes ataxia out of proportion to weakness. The attacks are similar to those seen with labyrinthine disorders. Ticks are found on the cold parts of the body
 - d. Seizures if there is an acute drop of the serum sodium (usually between 120–130 mg%)
3. Hyperammoninemia:
 - a. Related to protein intake
 - b. Altered consciousness
 - c. Increased reflexes
4. Wernicke's encephalopathy:
 - a. Primarily appendicular ataxia
 - b. Altered consciousness
 - c. Ophthalmoplegia (caucasian > black patients)
 - d. Areflexia
 - e. Mammillary body hemorrhages
5. Multiple carboxylase deficiency
6. Branch-chained amino acidurias

Differential Diagnosis of Metabolic Disorders in which Ataxia Occurs as a Minor Feature

1. Sphingomyelinase deficiency
2. Metachromatic leukodystrophy
3. Multiple sulphate deficiency
4. Adrenoleukodystrophy
5. Late onset globoid cell leukodystrophy (Krabbe's disease)
6. Ceroid lipofuscinosis
7. Sialidosis type 1

Differential Diagnosis of Acute Metabolic Ataxia

1. Hypoglycemia
 - a. The CSF sugar usually is less than 30–40 mg% (CSF sugar is 2/3 of serum sugar)
 - b. As the sugar decreases there is sympathetic overactivity with jitteriness, goose bumps, agitation and hunger
 - c. At a serum level of 30–40 mg% the symptoms are primarily parasympathomimetic with a one degree drop in temperature, hypersalivation and encephalopathy with or without seizure activity. Ataxia may occur throughout the process
2. Hyponatremia (Na level 110 mg/dl):
 - a. Lethargy
 - b. Absent reflexes
 - c. Mild ataxia and weakness

Chapter 11

Basal Ganglia and Movement Disorders

Overview

The basal ganglia are components of cortical-subcortical circuits that originate in specific cortical regions. Most movement disorders result from abnormalities of the basal ganglia thalamocortical circuit which originates from the pre- and post-central sensorimotor regions which include M1 (area 4), the supplementary motor cortex (SMA), the premotor cortex (PMC), the cingulate motor area (CMA), and primarily S1 of the sensory cortex. These areas project to the motor components of the striatum, the post-commissural putamen, the dorsal lateral subthalamic nucleus (STN) and the ventral posterolateral portion of the globus pallidus (GPi). The GPi in turn projects to the ventrolateral nucleus of the thalamus (VL) that in turn projects back to M1 and premotor areas. The striatum and STN are the initial primary projection zones for cortical and thalamic afferents to the basal ganglia. The GPi, the substantia nigra and pars reticulata are the primary basal ganglia efferents to the thalamus and brainstem.

Two primarily anatomically distinct pathways, the “direct” and “indirect” link the striatum and GPi/SNr which can rapidly modulate the GABA-ergic output of the basal ganglia to the VL thalamic motor nuclei. The “direct” pathway, from striatal medium spiny neurons, projects to GPi and SNr. The “indirect” pathway originates from striatal neurons that project to the external segment of GPe that projects to GPi and SNr directly or after synapsing in STN. The STN is glutamatergic and also receives afferent projections from cortical motor and non-motor areas as well as the centromedian (CM) and parafascicular thalamic nuclei (Pfc). Cortical projections to the STN and its subsequent modulation of GPi and SNr constitute the “hyperdirect” pathway. Collateral projections from the globus pallidus and substantia nigra (SNr) synapse in the CM and parafascicular nuclei are posited to be components of a thalamostriatal feedback circuit. The centromedian afference from the basal ganglion and its projections to the putamen and STN are motor. Input and output from the parafascicular nucleus is related to associative and limbic modulation of basal gangliar nuclei.

The basal ganglia also project by collaterals to the superior colliculus and the pedunculopontine nucleus (PPN) which is important for the regulation and initiation of gait and balance. There are projections from the PPN to the basal ganglia, thalamus and basal forebrain. The basal ganglia projection to the superior colliculus arises from the SNr and is involved in the control of saccadic eye, head and neck movements. Recent experimental work has demonstrated that the motor thalamocortical loops and the cerebellum are interconnected. The cerebellum modulates the basal ganglia through a bisynaptic pathway that involves the thalamus and synapses in the striatum.

In turn, the basal ganglia may influence the cerebellum from projections to the STN that projects to pontine nuclei whose afferents synapse in the cerebellar cortex. Abnormalities of specific movement disorders are caused by neuronal dysfunction within basal ganglia-thalamocortical circuits.

A basic approach to understanding and diagnosing movement disorders is to fit them into specific clinically useful major symptom complexes. A proposed classification is one in which a patient is moving too much, too little and at times hardly at all.

1. Conditions that are characterized by an excess of movement:
 - a. Hyperkinesia
 - b. Dyskinesia
 - c. Combinations of the two
2. Decrease of movement:
 - a. Akinesia
 - b. Bradykinesia
 - c. Decreased autonomic movement
 - d. Not associated with weakness or spasticity
3. The planning of a movement is called an engram. Planning for simple movements (one-step) has been associated with the premotor cortex and the supplementary motor area (SMA). The engram of tasks that require sequential movements are associated with the posterior parietal lobe
4. Inability to sustain a sequence of movements is “motor” impersistence that is often seen with right parietal lobe pathologies. Inability to progress from one movement to the next to perform a specific task is perseveration and is most often seen with left frontal lesions
5. Areas that are associated with movements induced by emotional triggers (fear, curiosity, joy) employ a distributed “limbic” cortical loop in which the caudate nucleus and anterior cingulate gyrus are pivotal
6. Horizontal and vertical eye movements have complicated connections that originate from multiple cortical visual areas (supranuclear ocular system) with projections to:
 - a. Midbrain ocular motor areas
 - b. Brainstem nuclei
 - c. The medial longitudinal fasciculus, multiple areas of the reticular formation, the parapontine reticular formation (PPRF, the brainstem center for horizontal gaze), the superior colliculus and the vestibular nuclei
7. Self-paced internal movements (tapping a finger to a pre-set pattern) are associated with the supplementary motor area (SMA)
8. Overlearned movements such as walking, turning over in bed, and reflex defensive movements (nocifensor movements) are initiated and coordinated in the basal ganglia

Specific Correlation of Lesions and Movement Disorders

1. Cortex:
 - a. Area 4 (M1) primary motor cortex:

- i. Pyramidal dysfunction; primarily the loss of distal extremity fine motor control and fractional digital movement
 - b. Area 6 (PMC):
 - i. Ideomotor apraxia:
 1. An apraxia is the inability to perform an individual or sequential task with normal motor, sensory and coordinative function
 2. An ideomotor apraxia (the engram for the movement is encoded in area 6) is the inability to perform a single command such as a salute or the use of a comb
 3. A limb-kinetic apraxia may also be seen in area 6 lesions. This type of apraxia is a lack of facility in performing the motor components of the task
 - ii. The inhibitory strip of Marion Hines. If this component of area 6 is stimulated (usually by a seizure), there is inhibition of area 4
 - c. Engrams, persistence, impersistence, apraxias, as well as grasp and avoidance responses occur with specific cortical lesions
 - d. Parietal lesions may cause a "loathness to move" (superior parietal lobe projection via the superior longitudinal fasciculus) are involved; these innervate areas 4 and 6
 - e. Hand-eye coordination may be affected with lesions of the superior parietal cortex (area 5) that disconnect the superior longitudinal fasciculus from the hand area of area 4. These connections are most important for the use of stereoscopic vision for fine finger movement
 - f. Corticoreticular myoclonus may be seen with diffuse lesions of the cortex
2. Putamen:
 - a. Parkinson's disease; disruption of the cortically initiated striatal-thalamocortical circuit
 - b. Dystonia
 3. Caudate nucleus:
 - a. Chorea
 - b. Emotional aspects of movement
 4. Globus pallidus:
 - a. A unilateral lesion may cause contralateral dystonia, hemiparkinsonism or tremor
 - b. Bilateral lesions may cause a flexed posture, rigidity, dystonia
 5. Red nucleus:
 - a. Fibers of passage from the dentate nucleus are involved in this area and may cause a "rubral tremor":
 - i. The oscillation of the extremities increases (at right angle) on the trajectory to the target
 - ii. An associated postural kinetic tremor
 6. Substantia nigra:
 - a. Bradykinesia; akinesia
 - b. Parkinson's disease
 7. Subthalamic nucleus (STN):
 - a. If 85% of the nucleus is affected, there is contralateral hemiballismus
 - b. The proximal musculature is more affected than distal musculature
 8. Reticular formation:
 - a. Myoclonus (nucleus gigantocellularis)
 9. Palatal myoclonus:
 - a. Lesions that affect Mollaret's triangle, that is composed of:
 - i. Fibers from the parvocellular red nucleus that project to the ipsilateral inferior olivary nucleus via the central tegmental tract
 - ii. Inferior olivary projections to Purkinje cells of the contralateral cerebellar cortex via the inferior cerebellar peduncle
 - iii. Dentate nuclear projections via the superior cerebellar peduncle to the contralateral red nucleus
 10. Pallidal putaminal lesions:
 - a. Sudden falling contralaterally while sitting, standing or walking:
 - i. Slower than falls from lack of tone, that occurs with medial reticular formation lesions
 - ii. Deficit of postural corrective reflexes
 11. Lesions of the putamen and internal capsule:
 - a. Contralateral hemiplegic-Parkinsonism
 12. Locomotor centers (gait):
 - a. The nucleus cuneiformis of the midbrain is activated by the pedunculopontine nucleus and the globus pallidus to initiate gait
 - b. The parietal lobe, cerebellum, and brainstem areas modulate spinal step generators that form the basic oscillatory circuits between flexor and extensor spinal cord motor neurons

Summary

The Direct and Indirect Systems

Recurrent collaterals from basal ganglia projections make distinct separation of the direct and indirect loops impossible. Despite earlier histological studies that demonstrated a distinct patch and matrix organization of the basal ganglia, they have been found to have a more complex physiology that cannot be easily compartmentalized. Results of surgical procedures and deep brain stimulation do not support this distinct-systems hypothesis in every instance.

The Direct System

The putamen and caudate nuclei receive excitatory input from the pars compacta of the substantia nigra (D2 receptors). Their medium spiny neurons project to and inhibit the medial globus pallidus and pars reticularis of the substantia nigra. Both the striatal neurons and the GPi and SNr release

GABA. Thus the GABA-ergic projection to the GPi and SNpr inhibits their firing and consequent release of GABA onto the motor neurons of VA and VL of the thalamus. The thalamic motor neurons are glutamatergic and excitatory to the motor cortex. The more intense the GABA-ergic outflow to the motor thalamus, the greater its inhibition and the less glutamatergic input to the motor cortex. This results in bradykinesia and the inability to sustain movement.

The Indirect System

The putamen and caudate neurons receive dopaminergic (D1 receptors) from the SNpc. They project GABA-ergic afferents to the external segment of the GPe. In turn, GPe projects inhibitory GABA-ergic afferents to the STN. The STN utilizes glutamate and projects to and stimulates GPi and SNpr the GABA-ergic outflow of the basal ganglia to the motor thalamus (VA/VL). Stimulation of GPi and SNpr lessens the firing of excitatory VA and VL neuronal projections that decreases cortical motor neuron discharge. Activation of the indirect pathway striatal neurons inhibit GPe neurons which disinhibits the STN (less GABA-ergic afference) that leads to increased GPi and SNpr GABA-ergic output to the motor thalamus. In essence, in akinetic rigid syndromes there is less inhibition of GABA-ergic output from GPi and SNpr with consequent less excitation of the motor cortex from glutamatergic VA/VL thalamic motor neurons.

Bradykinetic Disorders

Parkinson's Disease (PD)

General Characteristics

1. In PD both animal and human studies have demonstrated dysfunction in both the direct and indirect pathways that support:
 - a. Decreased neuronal discharge in GPe
 - b. Increased neuronal firing in STN, GPi and SNr from lack of dopaminergic projections from SNpc to the striatum. This leads to activation of striatal neurons of the indirect pathway which leads to inhibition of GPe with consequent disinhibition of GPi, SNpr and STN as well as decreased activation of the direct pathway
2. Recent studies have demonstrated abnormalities of neuronal firing patterns that include:
 - a. Increased basal ganglia neurons that discharge in bursts
 - b. Oscillatory firing patterns
 - c. Increased synchrony
 - d. Particularly important for the disease are synchronized neuronal oscillations in the beta frequency range, and the failure to generate gamma-band oscillations before and during movement
3. Incidence of 4/1000 of the population over the age of 40
4. Affects both sexes approximately equally
5. Prevalence rates vary worldwide, possibly due to exposure to different environmental toxins

6. Prevalence rate increases exponentially with age; at 65 possibly 1% of the population in the USA may be affected
7. Risk factors:
 - a. Age is the most important
 - b. Rural living
 - c. Herbicides
 - d. Well water (weak correlation)
 - e. Industrial or chemical exposure:
 - i. MPTP (overheated demerol) drug addicts
 - ii. Carbon disulfide (dry cleaning)
 - iii. Carbon monoxide (mechanics)
 - iv. Manganese (welders)
 - f. Smoking may reduce the risk
 - g. Family history of essential tremor (increased risk 2.1–2.4×)
 - h. Minor head trauma (3.1–4.2× increased risk)
 - i. Relative risk of PD in relatives of the proband:
 - i. Siblings – 6.7× (increased risk)
 - ii. Offspring – 3.2× (increased risk)
 - iii. Nieces and nephews – 2.2× (increased risk)

Clinical Manifestations (Idiopathic PD)

1. In general there is a 60–70% loss of dopaminergic neurons of the SNpc to effect clinical signs
2. The earliest ventral tier dopaminergic neurons of the SNpc that are lost project to the lateral putamen
3. Lewy body formation is seen in affected dopaminergic neurons
4. Cardinal features:
 - a. Bradykinesia–akinesia
 - b. Tremor at rest (4–6 Hz)
 - c. Rigidity (cogwheel in type; Negri sign)
 - d. Autonomic dysfunction
 - e. Loss of postural control
 - f. Cognitive decline in a significant proportion of patients

Bradykinesia

1. This is the most distressing symptom for patients with PD. The patient has difficulty initiating and sustaining movements. Movement is slow and performed without facility. When this aspect of PD is severe the patient is frozen – akinesia
2. Brady- and akinetic patients (usually after at least 5 years of disease) suffer “freezing” episodes; they are unable to change motor programs rapidly and freeze when turning or going through a doorway
3. Patients at the end of effective therapy with L-dopa and other D2 agonists experience “off” periods during which bradykinesia, akinesia and fatigue make any form of movement difficult
4. An akinetic patient may initiate movement rapidly if startled or frightened

Tremor

1. Occurs at rest (4–6 Hz); almost pathognomonic for idiopathic Parkinson's disease

2. The tremor occurs in the hand at rest that demonstrates metacarpophalangeal flexion; it then progresses to involve the entire arm and becomes bilateral. The hand frequently moves up and down concurrently with the “pill-rolling” nature of the finger tremors. The leg frequently becomes involved, as does the head with disease progression. The tremor in the head is “up and down”. That of essential tremor of the head is side-to-side. If severe, the tremor may persist during movement as well as at rest
3. The tremor responds well in early stages to L-dopa and trihexyphenidyl treatment

Rigidity

1. Is more in the extremities than in the axial musculature
2. “Catching” or cogwheel character (Negri sign)
3. Patients may have stiffness throughout the range of motion of the affected extremity
4. The rigidity contributes to the patient’s flexed stooped posture

Loss of Postural Reflexes

1. Frequent falls with characteristic hip and humeral fractures due to inability to extend the arms
2. Falling backwards is common. Patients are unable to control the last portion of a posturally induced movement

Autonomic Dysfunction

1. Autonomic dysfunction starts to become evident with moderately advanced disease
2. Difficulty initiating micturition
3. Severe constipation may be seen early in the disease course
4. Sexual dysfunction
5. Seborrheic dermatitis
6. Postural hypotension increases as the disease progresses

Associated Motor Deficits in Parkinson’s Disease

1. Decreased spontaneous blink and all subconscious movement (decreased turning in sleep)
2. Gait ignition failure
3. Shuffling gait with decreased swing phase and decreased associated arm swing
4. Once the patient is in motion he cannot position his body over its center of gravity so that he festinates and is unable to control the speed and stability of his gait
5. Failure of upgaze and poor smooth pursuit eye movements; the patient utilizes saccadic substitution to compensate
6. Hypomimia and hypoxemia
7. Swallowing dysfunction due to failure of the posterior pharyngeal striated muscles to deliver the bolus to the esophagus. There may be concomitant slow opening of the extremal esophageal sphincter that is the function of the cricopharyngeus muscle (cranial nerve IX)
8. Micrographia during writing (failure to maintain movements once they are initiated)
9. Sialorrhea (less spontaneous swallowing)
10. Anosmia

Non-Motor Signs and Symptoms of Parkinson’s Disease

Autonomic Dysfunction

1. Gastric hypomotility with constipation is often the most troubling feature:
 - a. Loss of weight as the disease progresses which has a central disturbance as well as peripheral components
2. Micturition difficulty
3. Sexual dysfunction
4. Orthostatic hypotension
5. Hyperhidrosis

Psychiatric Disorders

1. Depression
2. Anxiety
3. Hallucinations
4. Impulse control disorders (pounding)
5. Apathy

Cognitive Impairment

1. Mild cognitive impairment occurs in approximately 15% of PD patients at presentation
2. Executive dysfunction is the core symptom of the cognitive deficits in PD and includes:
 - a. Rigidity of thought
 - b. Inability to change mental focus
 - c. Slow cognitive processing
 - d. Inability to plan, organize and execute intellectually driven tasks
3. Memory deficits
4. Visuospatial deficits
5. Social cognitive deficits

Sleep Disorder

1. The frequency of REM sleep behavior disorder (RBD) ranges between 20–75% of PD patients
2. RBD may precede, follow or be concomitant with PD
3. RBD may be associated with hallucinations and dementia
4. Factors associated with RBD in Parkinson’s disease include:
 - a. Male gender
 - b. A non-tremor motor phenotype
 - c. Longer disease duration
 - d. Autonomic dysfunction
5. RBD is most commonly seen in PD, dementia with Lewy bodies and multiple system atrophy (the synucleinopathies)

Neuropathology

1. Parkinson’s disease is overwhelmingly a non-Mendelian disorder that occurs as a simplex condition (a single affected individual in a family)
2. The cardinal pathologic feature of non-Mendelian Parkinson’s disease is the loss of dopaminergic neurons in the substantia nigra pars compacta (the ventral tier neurons may be affected initially)
3. Intracytoplasmic inclusions (Lewy bodies) are seen in the surviving intact nigral dopaminergic neurons

4. Lewy bodies consist of the protein alpha-synuclein associated with ubiquitin, neurofilament protein, and alpha B crystallin. Rarely tau proteins are associated and Lewy bodies that rarely are surrounded by neurofibrillary tangles. Lewy neurites are also seen in PD disease and are the abnormal neurites of affected neurons. They contain granular material and α -synuclein filaments. They are also found in dementia with Lewy bodies, multiple system atrophy and in the CA2–3 areas of the hippocampus in Alzheimer's disease. Histologic evaluation of a classic Lewy body demonstrates an eosinophilic cytoplasmic inclusion that consists of a dense core surrounded by a halo of 10-nm wide radiating fibrils. The primary structural component is alpha-synuclein. A cortical Lewy body lacks a halo and is less well-defined. In addition to the substantia nigra, Lewy bodies occur in the locus coeruleus, nucleus basalis of Meynert, cranial nerve motor nuclei, central and peripheral divisions of the autonomic nervous system, hypothalamus, and the cerebral cortex. In the genetic forms of Parkinson's disease, nigral pathology may occur in the absence of Lewy bodies, as exemplified by mutation of PARK 2

Heritable Causes of Parkinson's Disease

1. Mendelian forms of PD in which mutation of a single gene is causative of the disorder may be inherited in an autosomal dominant, recessive and in an X-linked manner

PARK 1

General Characteristics

1. PARK 1 is caused by mutations of the alpha-synuclein gene (SNCA) that maps to chromosome 4q21 and is autosomal dominant
2. Pathogenic variants include single nucleotide variants as well as gene duplications and triplications

Clinical Manifestations (Contursi Kindred)

1. Patients carry the A53T mutation:
 - a. Mean age of onset is 45.6 years
 - b. Rare tremor at rest
 - c. Cortical type of dementia occurs in 20% of patients
 - d. Patients with triplication mutations (100% overexpression of alpha-synuclein) – age of onset is 34 years
 - e. Patients with the duplication mutation (50% overexpression of alpha-synuclein) – age of onset ranges between 39–65 years of age
 - f. The clinical features and response to L-dopa were typical for PD (Contursi kindred)
 - g. In the kindred reported from Greece, additional features included central hypoventilation, postural hypotension, urinary incontinence and myoclonus

Neuropathology (Seidel Kindred)

1. Neuronal dopaminergic loss in the substantia nigra

2. Neuronal loss in the locus coeruleus and dorsal motor vagal nucleus
3. Widespread SNCA-positive Lewy bodies, Lewy neuritis and glial aggregates in the cerebral cortex, brainstem, hypothalamus and cerebellum in an X-linked pattern
4. There are inherited factors that predispose to PD in families without a Mendelian pattern of inheritance
5. Approximately 10–20% of PD patients report a positive family history with 5–10% demonstrating a monogenic form of the disease

Laboratory Evaluation

1. MRI of the brain: Both MRI and CT are usually normal
2. Identification of disease-causing mutations

PARK 2

General Characteristics

1. PARK 2 is caused by mutation in the Parkin gene (PARK2) that maps to chromosome 6q25.2-q27
2. It is an autosomal recessive form of familial juvenile Parkinsonism
3. The gene product is an E3 ubiquitin ligase
4. It is the most common form of familial PD and has a worldwide distribution

Clinical Manifestations

1. The onset in general is in patients less than 21 years of age; some patients have had onset after age 40
2. Retropulsion
3. Dystonia of the feet
4. Hyperreflexia
5. Some patients have a symmetrical presentation
6. In patients with an earlier onset:
 - a. Psychiatric features
 - b. Early dyskinesia
 - c. Increased reflexes
7. Excellent response to L-dopa
8. Diurnal fluctuation
9. Sleep benefit
10. Early susceptibility to levodopa induced dyskinesia

Neuropathology

1. Moderate loss of neurons in the SNpc; the greatest loss is in the ventrolateral and medial regions
2. No Lewy bodies (in general)
3. Some loss of neurons in the locus coeruleus
4. Parkin binds and ubiquitinates target depolarized mitochondria for autophagy

Laboratory Evaluation

1. PET scan:
 - a. Decreased fluorodopa uptake in the caudate, putamen, ventral and dorsal midbrain
2. Fibroblasts from PD patients with biallelic mutations in PARK2

- a. Decreased mitochondrial complex I activity
- b. Mitochondrial morphological changes that include increased mitochondrial branching

PARK 3*General Characteristics*

1. The gene locus maps to a locus on chromosome 2p13
2. Inheritance is autosomal dominant

Clinical Manifestations

1. Similar to sporadic PD
2. Mean age of onset is 59 years of age
3. Cognitive impairment (some)
4. Excellent response to levodopa

Neuropathology

1. SNpc degeneration
2. Positive for Lewy bodies

Laboratory Evaluations

1. Genetic analysis

PARK 4*General Characteristics*

1. PARK 4 is caused by triplication of the alpha-synuclein gene (SNCA) that maps to chromosome 4q22.1
2. Lewy body dementia is also caused by mutation on the SNCA gene and has some overlapping clinical features with PARK 4

Clinical Manifestations

1. Iowa kindred (4 generations):
 - a. Onset in the thirties
 - b. Rapid progression to death in 10–12 years after onset
 - c. Early weight loss
 - d. Dopa-responsive Parkinsonism
 - e. Cognitive impairment to dementia; early memory loss and visual spatial impairment
 - f. Dysautonomia a prominent feature

Neuropathology

1. Neuronal loss in the substantia nigra and locus coeruleus
2. Widespread Lewy bodies that are especially prominent in the cerebral cortex
3. Vacuolation of the temporal cortex neuronal loss and gliosis in the CA 2/3 of the hippocampus
4. Neuronal loss in the nucleus basalis of Meynert
5. Spongiosis and gliosis of the cortex (proband of the Iowa kindred)

Laboratory Evaluation

1. Alterations in gene dosage due to duplications and triplications from rearrangements are more common than point mutations
2. PET (3 patients from Iowa kindred)
 - a. Decreased striatal uptake of fluorodopa

PARK 5*General Characteristics*

1. Autosomal dominant Parkinson's disease 5 is caused by heterozygous mutation in the VCHL1 gene that maps to chromosome 4p13
2. The gene codes for ubiquitin carboxy-terminal hydrolase L1 (deubiquitin enzyme) that is involved in the ubiquitin-proteasome degradation pathway
3. Inheritance is AD with incomplete penetrance

Clinical Manifestations

1. Reported in 2 family members (brother and sister; paternal uncle affected; father not affected)
 - a. Onset 49–51 years of age
 - b. Rigidity bradykinesia and postural instability supervene with disease progression
 - c. L-dopamine responsive

Neuropathology

1. Not defined

Laboratory Evaluation

1. Molecular genetic evaluation

PARK 6*General Characteristics*

1. PARK 6 is caused by homozygous mutations in the PINK 1 gene. Heterozygous mutation of the gene as well as mutation in the DJ1 gene combined with mutations in the PINK 1 gene have also been described
2. PINK 1 gene maps to chromosome 1p36.12; PTEN-induced kinase 1
3. Inheritance is autosomal recessive

Clinical Manifestations

1. Age at onset is between 18–56 years; most have onset in the third or fourth decade
2. The onset is asymmetric
3. Postural instability, rigidity, bradykinesia
4. Variable signs include:
 - a. Resting tremor
 - b. Sleep benefit
 - c. Dystonia at onset (some patients)
 - d. Hyperreflexia
 - e. Excellent response to levodopa but with early onset of dyskinesia
 - f. Slow disease progression
 - g. Most patients with PARK 6 have a clinical phenotype that resembles idiopathic PD, a minority has clinical features similar to PARK 2

Neuropathology

1. Reported from one autopsy:
 - a. Neuronal loss in the substantia nigra with astrocytic gliosis

- b. Lewy bodies occur in surviving neurons; the amygdala and locus coeruleus showed neither cell loss or Lewy bodies
- c. Cell culture studies suggest:
 - i. PINK 1 is located in mitochondria and may be important in the mitochondrial stress response

Laboratory Evaluation

1. Molecular genetics (evaluation)
 - a. Homozygous mutations in the PINK 1 gene
 - b. Heterozygous mutations
 - c. Digenic form of the disorder from a mutation in the DJ1 gene and mutations in the PINK 1 gene

PARK 7 (DJ1)

General Characteristics

1. PARK 7 is caused by homozygous or compound heterozygous mutations in the DJ1 gene that maps to chromosome 1p36
2. Inheritance is AR
3. As noted earlier, a digenic form of the disorder occurs from mutation in the DJ1 and PINK 1 genes

Clinical Manifestations

1. Onset of symptoms prior to age 40
2. Resting and postural tremor
3. Bradykinesia
4. Loss of postural reflexes
5. Psychiatric episodes
6. Disease progression is slow
7. One patient has been reported with classical manifestations of ALS
8. In three patients with double homozygosity for 2 mutations in the DJ1 gene there was:
 - a. Early onset parkinsonism
 - b. Amyotrophic lateral sclerosis
 - c. Cognitive impairment

Neuropathology

1. DJ1 protein is phenotropic and plays a protective role against oxidative stress-induced cell death
2. DJ1 is a stress sensor and is upregulated during oxidative stress
3. The oxidative status of C106 of DJ1 determines its functional capacity
4. Excess oxidation of C106 inactivates DJ1 protein. Highly oxidized DJ1 occurs in PARK 7
5. DJ1 has been studied in regard to its role in its mitochondria-specific autophagy (mitophagy). If mitochondrial membrane potential is decreased, DJ1 is translocated into the mitochondria that induces mitophagy which clears the damaged mitochondria

Laboratory Evaluation

1. Molecular genetic determination of mutations in the DJ1 gene

2. EMG evaluation of patients with evidence of an ALS phenotype

PARK 8

General Characteristics

1. PARK 8 is caused by heterozygous mutation of the LRRK2 gene (leucine rich repeat kinase 2) that maps to chromosome 12q12
2. Inheritance is autosomal dominant
3. The LRRK2 gene encodes a complicated protein with several domains that include:
 - a. Armadillo repeat CARM region
 - b. An ankyrin repeat (ANK)
 - c. A leucine-rich repeat (LRR) domain
 - d. A kinase domain
 - e. A RAS domain
 - f. GTPase domain
 - g. WD40 domain
4. LRRK2 is primarily in the cytoplasm but may also locate to the outer mitochondrial membrane
5. The gly2019 S mutation is a common cause of familial Parkinson's disease and also predisposes to the sporadic form of the disorder

Clinical Manifestations

1. Onset is the fourth to fifth decade
2. Bradykinesia, rigidity, postural instability
3. Resting tremor
4. Levodopa responsive
5. Patients with the G 2019S mutation manifest:
 - a. Hyposomnia
 - b. Tremor postural instability
 - c. Gait disorder
 - d. Impaired color discrimination
 - e. Frontal temporal dementia (2 patients)

Neuropathology

1. There is a wide spectrum of neuropathological findings
2. The most common neuropathology includes:
 - a. Alpha-synuclein positive Lewy bodies and Lewy neuritis
 - b. Tau (MAPT) and ubiquitin (UBB) immunoreactive inclusions are less common
 - c. LRRK2 (G2019S mutation):
 - i. Extensive loss of dopaminergic neurons in the SNpc and cell loss in the locus coeruleus
 - ii. Lewy bodies were demonstrated (2 patients)
 - iii. Autopsy of 8 patients with LRRK2 (G2019S) mutation:
 1. Lewy bodies in the brain stem to the cortex

Laboratory Evaluation

1. CSF may show decreased levels of amyloid-beta 42, total tau (MAPT) and phosphorylated tau (G2019S)
2. PET scanning:
 - a. Decreased striated dopamine

PARK 9*General Characteristics*

1. Parkinson's disease 9 is caused by homozygous or compound heterozygous mutation in the ATP13A2 gene that maps to chromosome 1p36.13
2. The gene encodes a lysosomal type 5 ATPase
3. One family with homozygous mutation in the ATP13A gene has been reported to have neuronal ceroid lipofuscinosis-12

Clinical Manifestations

1. Juvenile onset
2. Rapid progression of signs and symptoms
3. Rigidity and bradykinesia
4. Supranuclear vertical gaze palsy
5. Spasticity
6. Cognitive impairment
7. Variable features:
 - a. Facial and finger mini myoclonus
 - b. Visual hallucinations
 - c. Oculogyric dystonic spasms
 - d. Aggressive behavior
 - e. Cognition may remain relatively intact

Neuropathology

1. The P-type ATPase pump PARK9/ATP13A2 decreases L-synuclein toxicity in primary neurons
2. ATP13A2 encodes a zinc pump which confers zinc resistance in neurons
3. ATP13A2 facilitates transport of zinc into membrane bound vesicles
4. Dysfunction in endogenous ATP13A2 in multivesicular granules (MVBs) causes:
 - a. Lysosomal dysfunction
 - b. Impaired delivery of endocytosed proteins/autophagy cargo to the liposome
5. MVBs (multivesicular bodies) are also the source of intraluminal nanovesicles:
 - a. That are released extracellularly as exosomes
 - b. Contain alpha-synuclein and cause its externalization in exosomes
6. It has been proposed that ATP13A2 modulates zinc levels in MVBs that regulate the biogenesis of exosomes that contain alpha-synuclein
7. After expression of the gene due to mutation may cause:
 - a. Lysosomal impairment
 - b. Alpha-synuclein accumulation
 - c. Lysosomal and mitochondrial dysfunction

Laboratory Evaluation

1. MRI:
 - a. Loss of gray matter in the motor cortex, caudate, thalamus, PFC, and cerebellum
 - b. Diffuse brain atrophy
 - c. Iron deposition in the basal ganglia

PARK 10*General Characteristics*

1. The PARK 10 locus contains four genes: TCEANC2, TMEM58, MiR-4781 and LDLRAD1
2. The locus maps to chromosome 1p32

Clinical Manifestations

1. Mean age at onset of 65.8 years of classic Parkinson's disease
2. Controversial evidence for the risk and age of onset of Parkinson's disease with this chromosomal locus

Neuropathology

1. Not defined

Laboratory Evaluation

1. Molecular genetic analysis

PARK 11*General Characteristics*

1. Susceptibility to Parkinson's disease may be conferred with heterozygous mutation in the GIGYF2 gene that maps to chromosome 2q37.1
2. Recent studies have not replicated the association with PD in disparate populations
3. Alternate splicing causes multiple transcript variants

Clinical Manifestations

1. Classic Parkinson's disease

Neuropathology

1. Not defined

Laboratory Evaluation

1. Genetic determination of the mutation

Autosomal Dominant Parkinson's Disease

1. PARK 1 and PARK 2:
 - a. Mutation in or triplication of the SCNA gene that maps to chromosome 4q22
2. PARK 5:
 - a. Mutation of the VCHL1 gene on chromosome 4p14
3. PARK 8
 - a. Mutation of the LRRK2 gene on 12q12
4. PARK 11
 - a. Mutation in the GIGYF2 gene on chromosome 2q37
5. PARK 13
 - a. Mutation in the HTRA2 gene on chromosome 2p12
6. PARK 17
 - a. Mutation in the VPS35 gene in chromosome 16q12
7. PARK 18
 - a. Mutation in the EIF4G1 gene on chromosome 3q27
8. PARK 21
 - a. Mutation in the DNAJC13 gene on chromosome 3q22
9. PARK 3 – mapped to chromosome 2p13

Autosomal Recessive Early Onset Parkinson's Disease

1. PARK 2
 - a. Mutation in the Parkinson gene that maps to 6q25.2-q27
2. PARK 6
 - a. Mutation in the PINK 1 gene that maps to chromosome 1p36
3. PARK 7
 - a. Mutation in the DJ1 gene that maps to chromosome 1p36
4. PARK 14
 - a. Mutation in the PLA2G6 gene that maps to chromosome 22q13
5. PARK 15
 - a. Mutation in the FBX07 gene that maps to chromosome 22q12-q13
6. PARK 19
 - a. Mutation in the DNAJC6 gene that maps to 1p32
7. PARK 20
 - a. Mutation in the SYNJ1 gene that maps to chromosome 21q22

Other Parkinson's Disease Loci

1. PARK 3
 - a. Mapped to chromosome 2p13
2. PARK 10
 - a. Mapped to chromosome 1p34-32
3. PARK 12
 - a. Mapped to a locus on the X chromosome
4. Mitochondrial mutations may cause or be associated with Parkinson's disease

Susceptibility Genes for the Development of Parkinson's Disease

1. Susceptibility genes for the development of late-onset PD have been associated with mutations or polymorphisms in:
 - a. GBA – 1q22
 - b. ADH1C – 4q23
 - c. TBP – 6q27
 - d. ATXN2 – 12q24.12
 - e. MAPT – 17q21.31
 - f. HLA locus genes
2. It is postulated that each gene confers an independent risk of disease development that is small but in aggregate may have a substantial effect
3. Expanded Trinucleotide repeat gene disorder may increase susceptibility to develop PD. These genes are usually associated with spinocerebellar diseases and include:
 - a. ATXN2
 - b. ATXN3
 - c. TBP
 - d. ATXN80S

Familial Parkinson's Disease

1. An Icelandic study of patients diagnosed with PD over 50 years (772 patients). Detailed genealogic database for the study comprised 610,920 people over 11 centuries
 - a. The study revealed a genetic component to PD that included 560 patients with late onset disease (>50 years of age)
 - b. The study demonstrated:
 - i. No highly penetrant Mendelian pattern
 - ii. Both early and late-onset disease skipped generations
 - iii. The risk ratios for the development of PD in this large generation-spanning study was:
 1. 6.7 increased risk for siblings
 2. 3.2 increased risk for offspring
 3. 2.7 increased risk for nephews and nieces of patients with late-onset

The Differential Diagnosis of Parkinson's Disease**Tau-Associated Parkinsonism***General Characteristics*

1. Neurofibrillary tangles consist of insoluble fibular aggregates of hyperphosphorylated tau

Clinical Manifestations

1. Tau H1 haplotype of the tau gene is associated with progressive supranuclear palsy and corticodorsal degeneration
2. A probably risk factor for Parkinson's disease

Frontal Temporal Dementia Parkinsonism Mapped to Chromosome 17*General Characteristics*

1. Mutations in the gene encoding microtubule associated protein tau (MAPT) cause familial FTD with Parkinsonism linked to chromosome 17q21 (FTDP-17)
2. Inheritance is autosomal dominant
3. Parkinsonism is associated with exon 10 missense mutations that affect exon10 splicing

Clinical Manifestations

1. Parkinsonism with frontotemporal dementia

Neuropathology

1. Coding mutations cause decreased binding of the tau proteins to microtubules
2. Splice site mutations destabilize a stem-loop structure that regulates alternate splicing of exon 10 that increases the four repeat isoform
3. PSP and corticobasal ganglia degeneration also have the excess four repeat tau isoform

4. Patients with defined MAPT mutations have cytoplasmic neurofibrillary inclusions composed of hyperphosphorylated tau
5. Multiple FTD families:
 - a. Lack MAPT mutations
 - b. Demonstrate progranulin PGRN mutations that map to chromosome 17q21.31 and encode a growth factor involved in pleiotropic processes including development and inflammation as well as microglial activation

Clinical Variants of FTD-17 PD

Disinhibition-Dementia-Parkinsonism-Amyotrophy-Complex (DDPAC)

General Characteristics

1. Maps to 17q21-22

Clinical Manifestations

1. Presents with personality and behavioral changes
2. Rigidity, bradykinesia, loss of postural reflexes
3. Amyotrophy of the extremities
4. Rapidly progressive (mean survival of 13 years)

Neuropathology

1. Atrophy and spongiform degeneration in the frontotemporal cortex
2. Neuronal loss and gliosis in the amygdala (SNpc) and anterior horn cells of the spinal cord
3. No Lewy bodies

Pallido-Ponto-Nigral Degeneration (PPND)

General Characteristics

1. PPND is caused by an N279K mutation of the MAPT gene linked to chromosome 17
2. The disorder is autosomal dominant

Clinical Manifestations

1. Dystonia
2. Dementia
3. Ocular motility deficits
4. Pyramidal tract dysfunction
5. Frontal lobe release signs
6. Urinary incontinence
7. Severe sleep disturbance

Neuropathology

1. Degeneration of the globus pallidus and substantia nigra
2. Ballooned neurons in neocortical and subcortical areas
3. Tau inclusions in the cytoplasm of neurons and oligodendroglia similar to those found in CBD and PSP
4. Morphologic and biochemical deficits overlap with sporadic CBD and PSP
5. Tau inclusions are formed from aggregated filaments and hyperphosphorylated tau proteins

Laboratory Evaluation

1. PET:
 - a. Decreased fluorodopa uptake in the caudate and putamen
 - b. Cerebral glucose metabolism is globally reduced (maximally in the frontal cortex)

Familial Progressive Subcortical Gliosis

General Characteristics

1. Autosomal dominant inheritance
2. Tau mutation linked to chromosome 17q21-22

Clinical Manifestations

1. Onset is in the fourth to fifth decades
2. Initial personality change, depression and psychotic episodes
3. Later in the course, speech impairment and components of the Klüver-Bucy syndrome (some patients)
4. Dementia
5. Parkinsonism

Neuropathology

1. Generalized cerebral atrophy
2. Predominant involvement of the white matter of the frontal and temporal lobe
3. Microscopic evaluation:
 - a. Fibrillary astrocytosis of the subcortical white matter and at the subpial and deep layers of the overlying cerebral cortex. Severe gliosis was noted in the cingulate gyrus and insular cortex
4. Severe astrocytosis and degenerative changes occur in the substantia nigra
5. The PSG-1 mutation has a tau mutation at position +16 of the intron after exon 10 that:
 - a. Destabilizes a stem loop structure that causes overexpression of the soluble four-repeat tau isoform that results in neuronal and glial tau pathology

Laboratory Evaluation

1. MRI: (one patient)
 - a. Involvement of the frontal and temporal lobes with atrophy
 - b. Increased signal of subcortical white matter on T2-weighted sequences

Atypical Parkinsonism of the Kii Peninsula of Japan (Muro Disease)

General Characteristics

1. Atypical Parkinsonism of the Kii Peninsula of Japan is also known as Muro disease
2. There are four subtypes:
 - a. Sporadic ALS
 - b. Kii ALS/PDC with tauopathy
 - c. ALS with C9 or 672 gene mutation
 - d. ALS with the optineurin gene mutation
3. Recent epidemiological studies have shown that ALS has declined over the past 50 years while that of PDC (*Parkinsonism-dementia complex*) has risen

Clinical Manifestations

1. All patients have cognitive dysfunction that includes:
 - a. Abulia, apathy
 - b. Bradyphrenia
 - c. Hallucination
 - d. Disorientation
 - e. Delayed reaction
2. Progressive Parkinsonism
3. Late severe dementia
4. ALS
5. Levodopa unresponsive Parkinsonism

Neuropathology

1. Abundant neurofibrillary tangles in the temporal lobe, frontal lobe and brain stem
2. Motor neuron loss in the spinal cord
3. No senile plaques

Laboratory Evaluation

1. MRI:
 - a. Most have frontotemporal lobe atrophy (some patients are negative)
 - b. Hypometabolism of the frontal lobes
 - c. SPECT evaluation demonstrates decreased blood flow to the anterior cingulate gyrus

Amyotrophic Lateral Sclerosis – Parkinsonism-Dementia Complex 1 of Guam

General Characteristics

1. Mutation of the TRPM7 gene that maps to chromosome 15q21.2 confers susceptibility to the disorder (some patients)
2. A similar phenotype is seen from a double homogeneous mutation in the DJ1 gene associated with PARK7
3. There is a high incidence of the disorder among the Chamorro people of Guam
4. There is evidence by segregation analysis that the disorder is autosomal dominant with complete penetrance in males and approximately 50% penetrance in females
5. Polymorphisms in MAPT may increase risk but no mutation in MAPT or other genes have been found to be causative of the disorder
6. Some linkage analytic studies support a locus on chromosome 12

Clinical Manifestations

1. Gradual onset and progression of primary Parkinsonism and dementia
2. Signs and symptoms may follow Parkinsonian features or appear concomitantly
3. The onset is usually in the fifth to seventh decade

Neuropathology

1. Severe cortical atrophy with neuronal loss
2. Widespread neurofibrillary tangles, severe in the isocortex and hippocampal formation

3. NFTs are preferentially distributed within layers II–III in the isocortex of ALS/PDC; in Alzheimer's disease they are sparser in layers II–III but denser in layers V–VI
4. A tau triplet repeat is found in ALS/PDC in both cortical and subcortical areas

Laboratory Evaluation

1. MRI:
 - a. Atrophy of frontal and temporal lobes
2. SPECT:
 - i. Decreased blood flow to the frontal and temporal lobes

Fragile X-Mental Retardation Tremor Ataxia Disorder

General Characteristics

1. FXTAS is caused by an expanded trinucleotide repeat that maps to Xq27.3
2. Patients with the fragile X permutation express 55–200 CGG expanded repeats and elevated FMR1 messenger RNA levels
3. Full expansion of repeats, >200, cause fragile X mental retardation syndrome

Clinical Manifestations

1. Affects older male patients primarily in the sixth decade
2. Intention tremor
3. Parkinsonism
4. Cognitive dysfunction
5. Autonomic dysfunction
6. Penetrance in male carriers >50 years of age is 33%; in female carriers it is 5–10%

Neuropathology

1. Cerebral and cerebellar white matter disease
2. Enlarged astrocytes with inclusions; intranuclear inclusions in the brain and spinal cord
3. Spongiosis of the middle cerebellar peduncle
4. The intranuclear inclusions contain FMR1 mRNA, lamin A/C, neurofilaments and ubiquitin
5. Postulated that FXTAS is caused by a toxic gain of function of FMR1 RNA

Laboratory Evaluation

1. MRI:
 - a. Cerebral and cerebellar volume loss
 - b. Increased signal intensity on T2-weighted sequences in the middle cerebellar peduncles

Parkinsonism in Autosomal Dominant Spinocerebellar Ataxia

1. SCA2 Parkinsonian signs and symptoms are more common in Chinese than Caucasian patients
2. SCA3 Parkinsonism may be severe
3. 18F-dopa PET scans demonstrate basal ganglia decrease of dopamine
4. Patients may be minimally responsive to L-dopa

*Parkinsonism in Huntington's Disease***General Characteristics**

1. The gene is IT15 (expanded CAG repeats) that maps to chromosome 4p16.3

Clinical Manifestations

1. The age of onset is related to the number of repeats; juvenile onset patients have > than 50 CAG repeats
2. Patients present with neurological or psychiatric features rarely with both simultaneously
3. Extremity chorea
4. Impersistence of sustained movements (inability to hold the tongue out; milkmaids hand)
5. Lurching gait
6. Slow and hypometric saccades (vertical > horizontal); convergence paresis; inability to initiate saccades; late in the disorder choreatic eye movements
7. Parkinsonism (bradykinesia predominant)
8. Orolingual apraxia
9. Increased reflexes and clonus
10. Juvenile Variant (Westphal)
 - a. Presents in the teens
 - b. Akinetic rigid syndrome
 - c. 90% of patients are of paternal lineage
 - d. Seizures

*X-Linked Dystonia Parkinsonism***General Characteristics**

1. Primarily found in Filipino patients from the Panay Islands; known as Lubag
2. X-linked missense mutation; mutation in the TAF1 gene (Xq13.1)

Clinical Manifestations

1. Onset in adulthood (mean 39 years of age)
2. Most often the presentation is Parkinsonism
3. Focal dystonia primarily affects the jaw, neck, eyes and trunk; within 2–5 years after onset, 50% of patients develop generalized dystonia
4. Parkinsonism manifests as bradykinesia, rigidity and postural instability
5. Blepharospasm
6. Poorly responsive to L-dopa

*Rapid-Onset Dystonia Parkinsonism***General Characteristics**

1. Mutation of the ATP1A3 gene that maps to chromosome 19q13.2

Clinical Manifestations

1. Rapid onset of symptoms; progress over hours
2. Signs are initiated by physical and emotional stress
3. Presents with cranial and limb dystonia
4. Dysarthria and dysphagia
5. Parkinsonism that is not L-dopa responsive

*Parkinsonism in Dentato-Rubro-Pallido-Luysian Atrophy (DRPLA)***General Characteristics**

1. AD; a trinucleotide repeat in the ATN1 gene that maps to chromosome 12p13.31

Clinical Manifestations

1. Cerebellar ataxia
2. Parkinsonism
3. Myoclonus
4. Dystonia
5. Seizures

*Parkinsonism in Wilson's Disease***General Characteristics**

1. Wilson's disease is AR and is caused by mutation of the ATP7B gene that maps to chromosome 13q14.3

Clinical Manifestations

1. Onset is between 6–40 years of age
2. Neurologic symptomatology manifests in the patients' early twenties
3. The presentation may be psychiatric, neurologic or as liver disease
4. Usually severe dysarthria
5. Wing beating tremor (postural kinetic)
6. Postural instability
7. Dystonia
8. Parkinsonism
9. Kayser-Fleischer ring in the cornea (the copper accumulation is in Descemet's membrane)
 - a. Present in all patients with neurologic disease
10. Rare chorea
11. No sensory symptoms
12. Depression, personality change, emotional lability
13. Cognitive decline with disease progression

Differential Diagnosis of Parkinson's Disease***Lewy Body Dementia*****General Characteristics**

1. Associated with mutation of the G1GYF2 gene that maps to chromosome 2q37.1

Clinical Manifestations

1. The onset is the sixth to seventh decade; average age is 68
2. Visuospatial, attentional deficits in problem solving abilities are seen early
3. Fluctuations in cognitive abilities from day to day are striking
4. Visual hallucinations are a seminal feature
5. Variable clinical manifestations include:
 - a. Repeated falls

- b. Syncope
- c. Sensitivity to neuroleptic medications
- d. Auditory and tactile delusions
- e. Transient ischemic-like episodes
- f. Rest tremors, Parkinsonian rigidity and bradykinesia occur but not to the same degree that is seen with idiopathic Parkinson's disease

Multiple System Atrophy (MSA)

General Characteristics

1. In the past MSA has been thought to be a sporadic disorder but recently:
 - a. Small familial aggregates have been reported
 - b. Familial aggregates of alpha-synucleinopathy with PD and MSA occur in the same kindreds
2. The diagnostic criteria require:
 - a. Definite MSA has CNS alpha-synuclein positive glial cytoplasmic inclusions with neurodegenerative changes in striatonigral or olivopontocerebellar structures
 - b. Probable MSA:
 - i. Is a sporadic, progressive adult-onset disorder with autonomic failure, Parkinsonism that is not responsive to levodopa or cerebellar ataxia
 - c. Possible MSA:
 - i. A sporadic progressive adult-onset disorder with Parkinsonism or cerebellar ataxia with one feature of autonomic dysfunction plus one other clinical or neuroimaging abnormality
3. MSA core features are dysautonomia with combinations of Parkinsonism (poorly or not responsive to L-dopa), cerebellar ataxia, and pyramidal signs
4. The new criteria retain the major diagnostic categories of MSA with Parkinsonism (MSA-P) or predominant cerebellar ataxia (MSA-C)

Clinical Manifestations

1. Distribution of signs:
 - a. Approximately 28% have all four major manifestations (autonomic dysfunction, Parkinsonism, cerebellar ataxia and cognitive impairment)
 - b. 18% have Parkinsonism, corticospinal and autonomic dysfunction
 - c. 11% have Parkinsonism and autonomic dysfunction
 - d. 10% have MSA-P
 - e. Autonomic dysregulation develops to a significant degree in >90% of patients and is manifested by:
 - i. Impotence
 - ii. Urinary incontinence in females
 - iii. Orthostatic hypotension may be the most disabling manifestation:
 1. Upright hypotension
 2. Supine hypertension
 3. Syncope precipitated by heat, exercise and large meals

4. "Coat hanger headache" just prior to syncope
5. (posterior occipital and trapezius ridge discomfort)
6. Clinical manifestations of MSA-P:
 - a. Severe akinetic-rigid syndrome
 - b. Levodopa unresponsive
 - c. Dystonia (particularly of the upper extremity)
 - d. The arm levitates and the posture is maintained
 - e. The patients have greater cognitive impairment than is generally seen in idiopathic Parkinson's disease

Shy-Drager Syndrome

General Characteristics

1. Autonomic dysfunction is the seminal feature

Clinical Manifestations

1. The onset is between 40–69 years of age
2. The most prominent symptom is postural hypotension which may precede Parkinsonism
3. Forward-flexed rigid stance
4. Patients lose consciousness and fall due to severe hypotension
5. Iris atrophy (holes in the iris; deep anterior chamber of the eye)
6. Dementia
7. Ataxia
8. Bowel, bladder and sexual dysfunction early in the course of the illness
9. Cold mottled hands (livedo reticularis) at clinical presentation
10. Progression is more rapid than idiopathic Parkinson's disease

Neuropathology

1. Severe loss of cells in the intermediolateral column of the spinal cord
2. Loss of dopaminergic neurons of the SNpc

Laboratory Evaluation

1. Dopaminergic dysfunction in the basal ganglia by PET (fluorodopa) and SPECT

Progressive Supranuclear Palsy (PSP)

General Characteristics

1. Mutations in the MAPT gene that maps to chromosome 17q21.31 that also causes a form of frontotemporal dementia, have been described in both sporadic and familial PSP
2. The H1 haplotype of MAPT is a risk haplotype for PSP
3. Within the H1 haplotype, a subhaplotype (H1c) is associated with PSP

Differential Points of PSP vs PD: Clinical Manifestations

1. Median age of onset is 64 years of age (range is 50–77 years) in PSP
2. Parkinsonian patients who respond poorly to levodopa; 1–8% may have PSP pathologically
3. Supranuclear ophthalmoplegia is seminal in PSP:
 - a. Poor vertical saccades are an early feature
 - b. Downward saccades are affected first
 - c. Hypometria of saccades vertical > horizontal
 - d. Blepharospasm
 - e. Apraxia of eyelid opening
 - f. Ptosis; marked lid retraction
 - g. Decreased blinking
 - h. Pseudointernuclear ophthalmoplegia
 - i. Nystagmus
 - j. “Square wave jerks” (ocular recording)
 - k. Pathologic lid retraction
 - l. Poor convergence
 - m. Vertical saccades are accomplished by moving the eyes in a lateral arc
 - n. Complete ophthalmoplegia may occur late in the disease course
4. Personality change with frontal lobe dyscontrol
5. Falling, imbalance, gait disorder, occurs much earlier than with idiopathic Parkinson’s disease
6. Axial rigidity > appendicular
7. Dysphagia and dysarthria
8. Falling backwards
9. Rigid hyperextension of the neck (Doll’s eye maneuver to move the eyes downward); PD has a flexed neck
10. Gait abnormalities:
 - a. Stiff and broad based
 - b. Knees and trunk are extended (PD stooped with knees flexed); PSP the gait is narrow based
 - c. The arms are slightly adducted; in PD there is an increased flexion carrying angle of the arms
 - d. Patients pivot rather than turning “en bloc” as is the case with PD
11. There is no tremor in PSP
12. Characteristic faces:
 - a. Deep nasolabial folds (PSP)
 - b. Staring wide eyed expression (PSP)
13. Early in the course of illness there is prominent akinetic gait ignition failure and freezing
14. Rare manifestations of PSP:
 - a. Limb rigidity > axial
 - b. Mild tremor at rest
 - c. Upper limb apraxia, myoclonus and chorea
 - d. Respiratory dysfunction
15. Arm levitation (more commonly seen than the posterior “alien” hand that is seen with corticobasal ganglia degeneration)
16. Patients have a higher blood pressure than is seen with other neurodegenerative disorders
17. Clinical research criteria for PSP:

- a. Possible PSP:
 - i. Gradually progressive disorder
 - ii. Onset at age 40 or later
 - iii. Vertical supranuclear gaze palsy or slowing of vertical saccades
 - iv. Postural instability with falls within the first year of onset
- b. Probable PSP:
 - i. Vertical supranuclear gaze palsy
 - ii. Postural instability
 - iii. Falls within the first year of onset
 - iv. Other features of possible PSP
- c. Definite PSP:
 - i. A history of possible or probable PSP
 - ii. Histological verification of PSP

Neuropathology

1. Bilateral loss of neurons and gliosis in the periaqueductal gray, superior colliculus, subthalamic nucleus, red nucleus, the pallidum, dentate nucleus, pretectal and vestibular nuclei
2. Neurofibrillary degeneration of remaining neurons; tau deposition

Laboratory Evaluation

1. MRI:
 - a. Atrophy of the dorsal mesencephalon (superior colliculus and red nucleus)
2. PET:
 - a. Decreased CBF most marked in the frontal lobes

Differential Diagnosis of PSP

1. Progranulin (PRG) frontotemporal dementia, C9ORF72, CHMP2B and FUS
2. Kufor-Rakeb disease
 - a. Mutation in ATP13A2
3. Niemann-Pick type C (NPC1)
4. Perry syndrome (mutation in DCTN1)
5. Gaucher’s disease (mutation in GBA)
6. Mitochondrial disorders
7. Familial Creutzfeldt-Jakob disease (mutations in PRNP)

Corticobasal Degeneration (CBD)*General Characteristics*

1. The Armstrong criteria proposed 2013 include 4 CBD phenotypes:
 - a. Corticobasal syndrome (CBS)
 - b. Frontal behavioral/spatial syndrome (FBS)
 - c. Non-fluent/agrammatic variant of primary progressive aphasia (naPPA)
 - d. PSP
2. These phenotypic variants are comprised of sets of criteria:
 - a. Clinical research criteria for probable CBD (cr-CBD)

- b. Possible CBD (pCBD) that are more inclusive
- c. Two studies have failed to validate the criteria and it has been suggested that criteria need to be biomarker driven

Clinical Manifestations

1. CBD is clinopathologically heterogeneous thus its manifestations may best be considered syndromic (CBS)
2. Corticobasal ganglion degeneration (CBD) is now used for patients with histopathologic verification
3. Equal sex incidence
4. Average age of onset is 60 years of age
5. Usually a six to ten year duration of disease
6. There is symmetric presentation of extremity:
 - a. Rigidity
 - b. Clumsiness
 - c. Stiffness
 - d. Jerking of an arm or leg
 - e. Limb ideomotor apraxia
 - f. Postural instability
7. After 2–3 years:
 - a. Dystonic rigidity and akinesia of the limb
 - b. Hemimyoclonus
8. Posterior parietal alien hand or limb:
 - a. The limb moves without voluntary control
 - b. The patient may feel that the limb does not belong to him
 - c. The affected limb may assume an abnormal posture or levitate
9. Parietal S1 type sensory loss
10. Progression of the illness to:
 - a. Dysarthria
 - b. Dysphagia
 - c. Supranuclear gaze palsy
 - d. Rare cerebellar signs
11. Frontotemporal neurobehavioral disorder may develop
12. Non-fluent/agrammatic variant of primary progressive aphasia (naPPA)

Neuropathology

1. Abnormal accumulation of microtubule-associated tau protein in both neurons and glia, and filamentous threads
2. SNpc and STN are prominently involved
3. Affected cortical areas of involvement include:
 - a. Rolandic areas
 - b. The posterior frontal and parietal cortex
 - c. Late disease:
 - i. Insular cortex
 - ii. Tip of the temporal lobe

Laboratory Evaluation

1. MRI:
 - a. Asymmetrical cortical atrophy
 - i. Frontal and parietal lobes
 - b. Focal symmetric frontotemporal atrophy (some patients)

- c. Generalized atrophy
- d. Diffusion tensor imaging:
 - i. Cortical reduction of fractional anisotropy (FA) and coexistent increase in mean diffusivity (MD)

Post-Encephalitic Parkinsonism (1915–1927)

General Characteristics

1. Primarily categorized as a sequel of von Economo's or epidemic encephalitis; also known as encephalitis lethargica
2. At present very rare as most patients have died

Clinical Manifestations

1. Parkinsonism occurred weeks to years after the termination of the encephalitis
2. Tremor was as prominent as that seen in idiopathic PD
3. Oculogyric crises was prominent (usually spasm of the superior rectus and inferior oblique muscles; any ocular muscles were affected)
4. Personality and behavioral changes
5. Autonomic crisis:
 - a. Severe hypertension
 - b. Hyperhidrosis
6. Bulbar palsies
7. Ophthalmoplegia
8. Sleep wake cycle disturbance

Neuropathology

1. NFT (neurofibrillary tangles) and neuronal loss in SNpc
2. TDP-43 pathology is distributed widely

Drug-Induced Parkinsonism

MPTP (1-Methyl-4-2,3,6 Tetrahydropyridine)

General Characteristics

1. Designer drug produced from overheated demerol

Clinical Manifestations

1. An irreversible and progressive disease
2. Dramatically rapid onset of parkinsonism
3. The tremor is faster than the 4–6 Hz of PD
4. The disorder responds to L-dopa early in its course; side effects develop quickly and are dependent on the severity of dopaminergic denervation rather than the length of treatment
5. Reflexes are generally increased
6. Many other features are similar to PD

Neuropathology

1. MPTP is a lipophilic drug compound that easily crosses the blood-brain barrier
2. It is metabolized into the toxic (1-methyl-4-phenylpyridinium) MPP⁺ by the enzyme MAO-B that is located in glia
3. MPP⁺ interferes with complex I of the respiratory chain primarily in dopaminergic neurons of the SNpc

4. MPP+ has high affinity for the dopamine transporter of dopaminergic nerve terminals
5. There is severe loss of dopaminergic neurons and gliosis of the SNpc

Reversible Drug-Induced Parkinsonism

General Characteristics

1. Drug-induced parkinsonism is the second most common cause of parkinsonism after Parkinson's disease
2. Clinical differentiation may be difficult between drug-induced parkinsonism and the early stages of the primary disease

Clinical Manifestations

1. In drug-induced parkinsonism:
 - a. There is no hyposmia
 - b. No urinary urgency
 - c. Symmetry of symptoms and signs
 - d. Relative absence of resting tremor
 - e. Coexistence of oromandibular dyskinesia
 - f. The offending drug may unmask true Parkinson's disease
 - g. Signs and symptoms should clear within six months of drug withdrawal
 - h. Minimal if any response to levodopa
 - i. No REM behavior sleep disorder

Neuropathology

1. Primarily there is blockage of D2 receptors rather than destruction or degeneration of the SNpc dopaminergic system
2. Classes of drugs that cause drug-induced Parkinson's disease include:
 - a. Antipsychotic medication
 - b. Antiemetics
 - c. Cholinomimetics
 - d. Antidepressants
 - e. Anti-vertigo medications
 - f. Calcium channel blocking agents
 - g. Antiarrhythmics
 - h. Antiepileptics

Laboratory Evaluation

1. Dopamine transporter imaging (DaT-scan)
2. Cardiac MIBG uptake may be significantly reduced in patients with PD; in drug-induced parkinsonism it is normal >90% of patients

Differential Diagnosis of Toxic Causes of Parkinsonism

1. Manganese:
 - a. Manganese miners
 - b. Welders
 - c. Clinical manifestations:
 - i. Severe depression as an early symptom

- ii. Bradykinesia and akinesia are dominant signs at presentation
- iii. Severe loss of postural reflexes
- iv. Frequent falls
- v. Rare tremor

2. Post-hypoxic Parkinsonism:
 - a. Parkinsonism has a delayed onset from the sentinel event
 - b. Associated with myoclonus, choreoathetosis and cortical deficits
 - c. Bilateral GP destruction with carbon monoxide
3. Carbon Tetrachloride:
 - a. Utilized in the dry cleaning process
 - b. Akinetic rigid presentation
4. Methanol:
 - a. Suicide attempts; anti-freezes and may be an adulterant in "moonshine"
 - b. Akinetic-rigid presentation
 - c. Severe optic neuropathy with hemorrhagic optic neuritis
 - d. Increased signal in the striatum in T2-weighted MRI sequences
5. Carbon Monoxide:
 - a. Car mechanics, suicide attempts, poor inside heaters
 - b. Cherry red lips and extremities
 - c. Cortical basal ganglia and cerebellar signs and symptoms
 - d. Particular globus pallidus involvement
6. Mercury:
 - a. Industrial exposure
 - b. Akinetic-rigid presentation but some patients demonstrate severe choreoathetosis
 - c. Peripheral neuropathy
 - d. The Minamata Bay Japanese toxic exposure demonstrated the above features in various combinations

The Differential Diagnosis of Multiple System Atrophy from Parkinson's Disease

1. MSA is predominantly a preganglionic disorder; in PD the pathology is primarily post-ganglionic
2. Autonomic dysfunction in general is more severe in MSA than PD
3. Autonomic abnormalities have a more rapid progression in MSA than PD
4. Diffuse anhidrosis is more widespread in MSA than PD
 - a. Involvement of hypothalamic thermoregulatory centers in MSA

Differential Diagnosis by MRI of Familial Parkinsonism

1. The MRI may be normal
2. Pantothenate kinase 2 (PANK 2 gene)
 - a. Low signal in the internal segment of the globus pallidus
 - b. Axonal vacuolization (spheroids)

3. Fahr's disease:
 - a. Bilateral calcification of the basal ganglia
 - b. Calcification of subcortical white matter and the dentate nucleus
4. Niemann-Pick type C:
 - a. Diffuse cerebellar atrophy
 - b. Mild cerebral atrophy
5. Huntington's disease:
 - a. Severe atrophy of the caudate nucleus ("box car" atrophy)
 - b. Frontal lobe atrophy
6. Wilson's disease:
 - a. Putamen > caudate lesions on T2-weighted sequences
 - b. Midbrain and occasional thalamic lesions
7. Neuroferritinopathies
 - a. T2-weighted lesions (low intensity) of the basal ganglia
8. FTD (frontotemporal dementia) chromosome 17
 - a. Mesial temporal lobe atrophy
 - b. More severe white matter abnormalities occur with LBD
5. MSA-P and PSP:
 - a. Low FA in the primary motor cortex in MSA-P
6. In PSP:
 - a. A high ADC (high apparent diffusion coefficient) and low FA in the supplementary motor cortex
7. Anatomical connectivity studies demonstrate:
 - a. Lower number of corticospinal tract fibers in MSA and PSP relative to PD
 - b. In patients with PSP and MSA (late stage) versus PD
 - i. Fewer cortical projection fibers in PSP and MSA

Differential Diagnosis of Diffusion Tensor Imaging in Parkinsonian Syndromes

1. Parkinson's disease:
 - a. Reduction of fractional anisotropy (FA) in the substantia nigra
 - b. Reduced FA in PD patients that demonstrated anosmia in anterior olfactory structures
 - c. Reductions in FA in the motor areas of the cerebral cortex
2. Multiple System Atrophy:
 - a. Reduced FA in the pons and the cerebellum in MSA-P
 - b. Comparing MSA versus PD
 - i. FA reductions in the cerebellum (MSA-P)
 - ii. Increases in mean diffusivity (MD) in the pons and cerebellum (MSA-P)
 - iii. Utilization of FA and ADC measurement in the pons:
 1. There was a 70% similar sensitivity
 2. 100% specificity in differentiating MSA-P from Parkinson's disease
 - iv. FA and radial diffusivity are different (less in the former and greater in the latter) for MS-P than PD
 - v. Summary:
 1. Decreased FA and elevation in MD in the cerebellum, pons, and cerebellar peduncles may distinguish MSA from PD
 2. Putamen demonstrates FA decreases and increased mean diffusivity in MS-P versus PD
 3. Parkinson's disease dementia versus Parkinson's disease
 - a. Bilateral posterior cingulate FA reduction in PDD
 4. PDD and Lewy body dementia (LBD):
 - a. Similar regions of reduced FA in both disorders

Movement Disorders Associated with Long-Term Levodopa Treatment of Parkinson's Disease

1. End of dose failure:
 - a. Return to baseline of bradykinesia or akinesia
 - b. Tremor returns
2. Peak dose dyskinesia:
 - a. Choreoathetosis at period of maximum absorbed concentration of levodopa
3. Early morning dystonia:
 - a. Awakening with dystonia of the lower extremity (most often plantar flexion with inversion of the foot) with PD
4. "Off periods"
 - a. Severe bradykinesia – akinesia
 - b. May have sudden onset
 - c. May last 30 minutes to hours
 - d. Associated with "freezing" (inability to change motor programs); go through doorways; change directions
 - e. "On periods":
 - i. Duration of maximum benefit from medications
 - f. "On-off" phenomena:
 - i. Periods of benefit from medication associated with sudden episodes of bradykinesia
 - g. "On-off" dystonia
 - h. Dyskinesia-improvement-dyskinesia

Differential Diagnostic Features of Parkinsonism

The immediate clue that one is dealing with a system degeneration rather than idiopathic Parkinson's disease is the lack of response to levodopa, the symmetry of signs and symptoms, a low blood pressure and cold hands.

Shy-Drager syndrome is dominated by autonomic failure. Small cues are iris atrophy (deep anterior chamber of the eye and an atrophic iris) as well as cognitive impairment. MS-P is predominantly an akinetic-rigid parkinsonian patient that has no tremor at rest, more rigidity than an IPD patient and does not respond to levodopa. Occasionally these patients have lev-

itation of an arm. A difficult diagnostic problem may occur with early progressive supranuclear palsy (PSP) and IPD. In PSP, the supranuclear gaze palsy often is associated with eyelid apraxia, falls, and deep nasolabial folds. The head is held in extension. The hallmark of diffuse Lewy body disease is dementia, visual hallucinations and clear fluctuation of cognitive and parkinsonian features. These patients may demonstrate levitation of an extremity. Corticobasal ganglionic degeneration is suspected when a patient presents with an asymmetric akinetic rigid state, a posterior alien hand, and primary sensory (SI) modality loss. Pick's disease is dominated by a slowly progressive expressive aphasia.

Olivopontocerebellar degeneration is now MSA-C and may demonstrate dorsal column dysfunction, retinal disease and cranial nerve abnormalities in addition to clear cerebellar ataxia.

Differential Diagnosis of Secondary Parkinsonism

Hemiatrophy Hemiparkinsonism

General Characteristics

1. The incidence and prevalence of the disorder are unknown; there does not seem to be a genetic cause

Clinical Manifestations

1. Most often a childhood onset; late onset has been reported
2. Asymmetric parkinsonism
3. Slowly progressive
4. Hemiatrophy on the parkinsonian side
5. In one series, 50% of patients had dystonia at onset; dystonia was documented in 70% of patients
6. A significant proportion of patients have scoliosis
7. Some patients have a good response to levodopa
8. Difficulty walking in childhood

Neuropathology

1. In approximately 1/3 of patients there is a documented history of birth difficulties or a severe febrile illness in the first few months of life

Laboratory Evaluation

1. MRI:
 - a. Asymmetric (smaller brain volume) on the side opposite the hemiatrophy
2. The D2 receptor binding capacity is symmetrical whereas in CBD it is not

Idiopathic Normal Pressure Hydrocephalus

General Characteristics

1. A communicating hydrocephalus of the elderly

Clinical Manifestations

1. The classic clinical triad of:
 - a. Dementia
 - b. Urinary incontinence (precipitate urination)

- c. Ataxia (primarily of gait)
2. Variable features:
 - a. Falling backwards
 - b. Foot grasp (feet sticking to the floor in gait ignition)
 - c. Hyperactive patellar reflexes
 - d. Limitation of upgaze with Collier's sign (pathologic lid retraction)

Neuropathology

1. NPH may follow stroke, subarachnoid hemorrhage, head trauma or other conditions that may interfere with CSF absorption
2. It may remain as an idiopathic communicating hydrocephalus after a complete evaluation

Laboratory Evaluation

1. MRI:
 - a. Frontal convexity narrowing
 - b. Parietal convexity narrowing
 - c. Upward bowing of the corpus callosum
 - d. Empty sella
 - e. Narrowing of the CSF space at the high convexity
 - f. Marked dilatation of the Sylvian fissure
 - g. Disproportion between narrowing of the CSF space at the high convexity and dilatation of the Sylvian fissure
2. Reduced default mode network (DMN) connectivity
3. Tap test: removal of 35cc of CSF with subsequent gait analysis; response to CSF drainage

Vascular Parkinsonism

General Characteristics

1. Lacunar infarction of the basal ganglia
2. The gait and balance are most affected
3. Lower half parkinsonism
 - a. Vascular disease of the periventricular descending corticospinal tracts that project to leg anterior horn cells

Other Differentials for Secondary Parkinson's

1. Severe depression (pseudoparkinsonism)
2. Wilson's disease
3. Huntington's disease:
 - a. Juvenile akinetic-rigid phenotype
 - b. Seizures
 - c. An end-stage phenomenon in the choreic form
4. Pantothenate Kinase 2
5. Binswanger's disease
 - a. Atherosclerotic ischemic demyelination
6. Alzheimer's disease
7. Striatal Neoplasms
8. Creutzfeldt-Jakob disease
9. Repeated Head trauma
 - a. Pugilistic parkinsonism
10. Hypoparathyroidism
11. Fahr's disease

Hyperkinetic Disorders

Overview

Primary General Categories of Hyperkinetic Disorders

1. Tremor
2. Myoclonus
3. Tardive dyskinesia
4. Ballism
5. Chorea
6. Athetosis
7. Dystonia
8. Paroxysmal dyskinesia
9. Akathisia movements
10. Tics

Tremor

General Characteristics

1. Definition:
 - a. A tremor is a rhythmic oscillation of a body part
 - b. The mechanisms of the oscillations include:
 - i. Mechanical oscillations
 - ii. Reflex oscillations
 - iii. Oscillations due to central neuronal pacemakers
 - iv. Oscillations due to abnormal feedforward or feedback loops

Clinical Manifestations

Tremors are involuntary movements that are rhythmic and oscillatory about a fixed point. They are due to alternating or synchronous contractions of agonist and antagonist muscles and may occur at rest, or with movement or on holding a static posture.

Physiologic Tremor

General Characteristics

1. Physiologic tremor (PT) is generated and mediated by peripheral and central mechanisms
 - a. Central mechanism:
 - i. The central component, “the central oscillator” causes a weak 8–12 Hz low amplitude movement
 - ii. The central oscillator is minimally affected by inertial loading
 - iii. Motor units are not entrained (they don’t discharge in groups) under usual circumstances
 - iv. Under conditions of stress due to drugs, cold or emotion they become entrained
 - b. The peripheral component of physiologic tremor includes:
 - i. Mechanical factors of the body part
 - ii. Short and long loop reflexes influence the peripheral component
 - iii. The peripheral component of the physiologic tremor is termed the “mechanical reflex”

- iv. Inertial loading decreases the mechanical reflex frequency but is complicated by spindle stretch responses, muscle properties, thixotropy (time dependent viscosity) and neural membrane firing characteristics
- v. When motor units fire in groups i.e. entrained physiologic tremor develops into exaggerated physiologic tremor (EPT) that induces greater participation of the stretch reflex and the central oscillator
- vi. EPT may become clinically symptomatic with posture or movement and phenomenologically is similar to essential tremor
- vii. Physiologic tremor is enhanced by:
 1. Fatigue
 2. Anxiety
 3. Thyrotoxicosis
 4. Narcotic withdrawal
 5. Hypoglycemia
 6. Pheochromocytoma
 7. Alcohol withdrawal
 8. Catecholamine excess
 9. Steroids
 10. Caffeine
 11. Theophylline
- viii. Absent at rest
- ix. Present with maintained posture
- x. Activated by severe muscle fatigue

Pathologic Tremors

Rest Tremor

General Characteristics

1. Most often seen in PD or with parkinsonism

Clinical Manifestations

1. The tremor starts unilaterally and distally
2. It is a 3–6 Hz “pill-rolling” sinusoidal oscillation
3. It becomes more proximal as it generalizes bilaterally
4. The tremor may start anywhere in the body; the jaw is a rare example
5. Early in the course of the disease the tremor fluctuates with physical exercise or mental effort
6. There are oscillations in wrist extension and flexion, pronation and supination or finger flexion against the thumb
7. PD tremor increases with stress and disappears with sleep
8. The frequencies are similar in each extremity in patients with bilateral tremor
9. Head tremor is rare:
 - a. Up and down when present
 - b. Lip and jaw tremor are more prominent in PD than in other movement disorders
10. Thumb and finger movements of a metacarpophalangeal flexed hand give it the “pill-rolling” character
11. The chin and tongue may be affected

12. Advanced patients may demonstrate postural kinetic and intention tremor; the postural kinetic component has a latent period when the hands and arms are outstretched; essential tremor does not
13. Walking may increase the amplitude of the hand tremor

Neuropathology

1. Tremor severity does not correlate with striatal dopamine levels
 - a. Some patients have increased tremor with levodopa
 - b. It is proposed that rest tremors are modulated centrally but there may be multiple generators within both corticobasal ganglia and corticocerebellar circuits
 - i. One central generator that has been proposed is the VIM nucleus of the motor thalamus where burst neurons have been recorded that fire at the same frequency as the tremor
 - ii. Proprioceptive feedback from displaced joints modulates the tremor

Other Tremors that may Occur at Rest

Essential Tremor (ET)

1. Severe ET may occur at rest but must be differentiated from coexistent PD or incomplete postural relaxation
2. ET is asymmetric and there may be different frequencies between sides

Rubral Tremor

1. Is most often caused by midbrain lesions that involve the cerebellar outflow pathways from the dentate nucleus to the ventrolateral thalamic nucleus (VL) or the nigrostriatal pathways
2. The tremor may be seen at rest, with postural maintenance or with movement
3. The rest component:
 - a. Has a large amplitude
 - b. Is irregular
 - c. Involves both proximal and distal musculature
 - d. Its frequency is 2–5 Hz
 - e. The primary cause is midbrain infarction although it is occasionally seen in demyelinating disease or with infection and trauma

Thalamic Tremor

1. Most often causes an action tremor but a rest tremor has been reported
2. The lesion causing the tremor affects the ventrolateral posterior nucleus of the thalamus

Drug-Induced and Dystonic Tremor

1. Most often are action tremors but can occur at rest

Action Tremor

Alzheimer Disease

1. Most often encountered later in the course of the illness although it may have a variable onset

2. There is delayed onset of the tremor when the arm is held outstretched
3. The frequency is 3–6 Hz
4. Higher frequency 5–8 Hz tremor with a lower amplitude action tremor have been reported with PD

Essential Tremor (ET)

General Characteristics

1. ET is the most prevalent adult tremor disorder
2. Greater than 50% of patients have a positive family history
3. The most frequent genes linked to the disorder are LING01, FUS and TENM4 and it is thought to be autosomal dominant

Clinical Manifestations

1. The most common risk factor is age, although it has been diagnosed in children
2. It is slowly progressive
3. Initially it is of low amplitude and has a frequency of 4–12 Hz that decreases with age
4. It affects the hands and arms most severely but other body parts can be affected
5. The amplitude of the kinetic component is greater than that seen with postural tremor
6. The tremor increases as the hand approaches the target
7. Head tremor is in the horizontal plane and can rarely occur in isolation
8. The tremor can affect the jaw in distinction to PD which may affect the lower lip
9. It is more irregular and bilaterally symmetric than PD
10. Cogwheel tone may occur secondary to the tremor
11. The tremor is decreased with alcohol
12. The tremor is usually abduction, adduction or flexion-extension of the hand; rarely pronation-supination
13. Most often monosymptomatic
14. May be associated with:
 - i. Poor fine hand movement
 - ii. Balance and gait disturbance
15. Handwriting:
 - i. Large letters
 - ii. Rounded letters
16. Rare associations:
 - i. Malignant hyperthermia
 - ii. Dystonia
 - iii. Migraine (possible)
17. Commonly associations:
 - i. PD
 - ii. Fragile X-premutation

Neuropathology

1. Evidence supports that the tremor is generated in olivary cerebellar circuits
2. Recent experimental studies utilizing functional magnetic resonance imaging has demonstrated:

- a. Tremor variation during a motor task has an excitatory effect on extrinsic connections from cerebellar lobule V to the thalamus and as well as intrinsic activity of cerebellar lobule V and the motor thalamus
- b. A disease of functional connectivity between cortical and cerebellar motor regions during a motor task which correlates with an increase in tremor severity
- c. Functional MRI studies support abnormalities in the cerebello-dentate-thalamic system and cerebellar cortical connectivity as a cause of ET

Orthostatic Tremor (OT)

General Characteristics

1. Orthostatic tremor is defined as a high frequency tremor (13–18 Hz) in the legs when standing
2. In approximately one-third of patients, the tremor is related to Parkinson's disease, cerebellar or brainstem pathology and restless leg syndrome
3. Orthostatic tremor of <13 Hz is termed slow OT. There is controversy as to whether this is a component of the spectrum of OT or is a different entity as there are some clinical differences between the two patient populations

Clinical Manifestations (>13 Hz Classic OT)

1. A rapid irregular and asynchronous tremor of the legs and trunk induced by standing
2. The tremor is 13–18 Hz in frequency and is associated with burst firing in antigravity muscles
3. The onset is usually in middle age or elderly patients
4. Unsteadiness in the legs with fear of falling
5. Loss of extensor tone in the legs
6. Difficulty in initiating gait
7. Pain in the legs when standing (some patients)
8. Patients have a wide-based stance but walk normally
9. Signs and symptoms are abolished with sitting
10. The tremor may occur in the trunk and cranial musculature
11. Isometric contracture of muscles may induce tremor (16 Hz) during the supine posture
12. Asymptomatic hypertrophy of the thigh and calf musculature may occur rarely
13. Slow orthostatic tremor (<13 Hz):
 - a. Possibly greater gait disturbance
 - b. The frequencies reported are between 4 Hz to 10–11 Hz
 - c. Most patients with “slow OT” have been reported in conjunction with:
 - i. Grave's disease
 - ii. Multiple sclerosis
 - iii. Cerebellar ataxia
 - iv. Paraneoplastic syndromes
 - v. PD
 - d. There is less postural arm tremor in slow orthostatic tremor

Neuropathology

1. A central nervous system location in brainstem-cerebellar

circuits is generally thought to be the generator of the tremor

2. EMG frequency supplemented by intermuscular coherence at present appears to be the best study to confirm “classic” orthostatic tremor
3. Transcranial magnetic stimulation can reset the tremor phase which supports the existence of a supraspinal central generator
4. Frequency spectra analysis demonstrates a high degree of coherence between limbs

Dystonic Tremor

General Characteristics

1. Dystonic tremor most commonly occurs in a body part affected by dystonia; rarely in a patient without dystonia; tremor may occur in a clinically non-dystonic body part

Clinical Manifestations

1. The tremor is typically postural or task related
2. The frequency ranges from 1–6 Hz during dystonic contractions
3. It is irregular or jerky but is rhythmic and can increase in frequency with voluntary movement
4. The tremor has a null point, which is a position that dramatically dampens it
5. It may initially start with a specific movement but progressively generalizes to any task
6. Patients frequently have a “geste antagoniste”, a proprioceptive or tactile maneuver that decreases the abnormal posture
7. The tremor quality is jerky
8. Dystonic head tremor may occur in isolation which is very rare with ET in which head tremor occurs with co-existent hand tremor
9. Approximately 20% of dystonia patients have tremor
10. In some series, patients who suffered tremor had focal cervical dystonia more often than blepharospasm
11. Dystonia may be more likely to spread in patients with tremor
12. Tremor prevalence may be higher in patients with adult onset dystonia and cervical dystonia; it is highest in patients in which the dystonia has spread

Neuropathology

1. Neurophysiologic evaluation reveals decreased reciprocal inhibition between agonist and antagonist muscles
2. The generator for the tremor is suggested to be in the basal ganglia motor loop
3. Deep brain stimulation (DBS) has been successful with targets in Vim, GPi and the zona incerta

Neuropathic Tremor

General Characteristics

1. May occur with all forms of neuropathic pain but is particularly common in chronic regional pain syndrome (CRPS)

Clinical Manifestations

1. Frequency is usually 3–6 Hz in the upper limbs
2. It is usually irregular and most severe in the distal musculature
3. It is asymmetric and can occur at rest, with maintenance of posture or during movement
4. It is associated with mechanical and thermal hyperalgesia and allodynia or with sensory loss

Neuropathology

1. Abnormal sensory processing that is maladaptive
2. The basic processes occur both peripherally with sensitization of peripheral nociceptive afferent fibers and centrally by the process of central sensitization of motor and nociceptive neurons in the pain network
3. The generator is thought to be central

Task-Specific tremor*General Characteristics*

1. The tremor occurs predominantly during the movements required to accomplish a specific task. It is not associated with an abnormal posture or muscle spasm
2. The movement in which the tremor is noted occur in musicians, athletes, dentists, surgeons that perform repetitive or entrained tasks
3. Primary writing tremor (PWT):
 - a. General characteristics:
 - i. The most common form of task specific tremor
 - ii. There is controversy as to whether this tremor is a variant of ET, dystonia or a specific entity
 - iii. There is AD inheritance in some instances
 - b. Clinical manifestations:
 - i. The PWT is divided into:
 1. Type A (task induced tremor)
 2. Type B (positionally sensitive tremor)
 - ii. The frequency is 5–7 Hz
 - iii. The type B form occurs both with writing and also when the hand assumes the writing position
 - iv. Most commonly there is alternating contraction of agonist and antagonist muscles although other contraction patterns occur
 - c. Neuropathology:
 - i. PET analysis demonstrates hyperactivity of the cerebellar hemispheres
 - ii. Reciprocal inhibition of the H-reflex and intracortical excitability are normal

Drug-Induced Tremor*General Characteristics*

1. Drug-induced tremor occurs with antidepressants, sympathomimetics, antiarrhythmics and antiepileptic agents
2. A multitude of mechanisms is causative

Clinical Manifestations

1. Non-progressive

2. Usually temporally related to the onset of medication use and increase with dose escalation
3. Drug-induced rest tremor can occur in isolation or as a component of Parkinsonism with the use of antipsychotics
4. All medications that can cause secondary Parkinsonism the most common of which are lithium carbonate, valproate, or serotonin specific reuptake inhibitors, can cause a rest tremor
5. Many drugs also cause an action tremor (lithium carbonate) as well as a rest tremor
6. Specific tremorogenic drugs:
 - a. Lithium:
 - i. Tremor may occur at non-toxic levels
 - ii. It may develop acutely or after months of treatment
 - b. Valproate:
 - i. May cause a 6–9 Hz tremor
 - ii. Rhythmic postural tremor that may mimic ET and is similar to tremors from tricyclic antidepressants
 - c. Alcohol, cocaine and amphetamines all induce tremor from intoxication, chronic use or withdrawal
 - d. Caffeine and β -adrenergic agonists
 - e. Drug-induced parkinsonism:
 - i. Metoclopramide
 - ii. Neuroleptics
 - iii. Phenothiazines

Neuropathology

1. Multiple mechanisms for drug-induced tremor depend on the specific pharmacology and physiology of each specific drug. The neuroleptics block D2 dopaminergic receptors in the striatum as well as affecting other aspects of basal ganglionic circuitry. The reticular formation and cerebellothalamic cortical circuitry is often prominently involved with drug-induced tremors

Psychogenic Tremor*General Characteristics*

1. Psychogenic tremors occur as a component of somatoform or factitious disorders as well as with malingering
2. Clinical manifestations:
 - a. Unusual phenomenology
 - b. Abrupt onset
 - c. Inconsistencies in tremor pattern
 - d. Spontaneous remissions
 - e. Distractibility
 - f. Response to placebo
 - g. Increase in tremor amplitude with inertial loading
 - h. Large fluctuations in frequency and amplitude
 - i. Coactivation of antagonist muscles at tremor onset
 - j. Absence of finger tremors
3. Neuropathology:
 - a. Psychogenic tremors depend on reflex mechanisms

- b. Electrophysiologic features of psychogenic tremors include:
 - i. Variability
 - ii. Constrainability
 - iii. Coactivation
 - iv. Distractibility
 - v. Increase in amplitude and frequency with inertial coaching
- c. Differential electrophysiological features:
 - i. Psychogenic myoclonus:
 - 1. Movement-related cortical potentials (Bereitschaftspotentials) are noted
 - ii. Triphasic contraction of muscles and absence of co-contraction
 - iii. Longer latency of C-reflex as compared to organic myoclonus

Palatal Tremor

General Characteristics

1. Palatal tremor (formerly palatal myoclonus) is associated with cerebellar dysfunction

Clinical Manifestations

1. Acquired onset of palatal tremor 1–2 Hz
2. Dysarthria
3. Ataxia
4. Slowly progressive cerebellar dysfunction

Neuropathology

1. MRI is normal at the presymptomatic phase but as the disorder progresses there is concomitant olivary hypertrophy
2. Brain [18 F]-fluorodeoxyglucose (FDG) positron emission tomography (PET) demonstrates hypermetabolism in the olivary nuclei

Variant Oculopalatal Tremor

General Characteristics

1. A delayed complication of a brainstem lesion

Clinical Characteristics

1. Average age of patients is 54 years
2. Male predominance
3. Vertical pendular nystagmus occurs in 90% with the palatal tremor
4. There may be dissociated unilateral nystagmus opposite the MRI identified olivary hypertrophy

Neuropathology

1. The usual lesion is vascular that disrupts the dentato-rubro-olivary circuit
2. A dual-mechanism model proposes that the oscillatory component is the inferior olive and the modulator is the cerebellum:
 - a. Electronic coupling and specific calcium channels drive the inferior olivary neurons

Cerebellar Kinetic or Action Tremor

General Characteristics

1. Oscillation increases perpendicularity to the line of movement as the target is approached

Clinical Manifestations

1. Specific cerebellar lesions cause specific patterns of the tremor:
 - a. Lateral cerebellar hemispheric lesions that affect the dentate nucleus and superior cerebellar peduncle cause extremity tremor
2. Tremor of the head and trunk are caused by vermal or fastigial nucleus lesions
3. Postural kinetic tremors:
 - a. Usually oscillate at 6–10 Hz frequency
 - b. Often involve the superior cerebellar peduncle near the red nucleus (has been termed a rubral tremor):
 - i. In some patients the tremor is more severe with lesions that are near the red nucleus
 - ii. The usual frequency is 2–3 Hz

Neuropathology (Rubral Tremor)

1. Sequelae of severe head trauma
2. Vascular lesions:
 - a. Occlusion of the interpeduncular artery (top of the basilar artery)
3. Thalamoperforate artery (PI) branch of the posterior cerebral artery
4. Medial posterior choroidal artery (branch of the PCA)
5. Involvement of the cerebellothalamic cortical networks are critical in cerebellar induced action tremors:
 - a. The combination of electromyography and functional magnetic imaging have demonstrated:
 - i. In essential tremor, there is decreased functional connectivity between cortical and cerebellar motor regions

Wilson's Disease

General Characteristics

1. Wilson's disease is caused by homozygous or compound heterozygous mutation of the ATP7B gene that maps to chromosome 13q14.3
2. Approximately 75% of patients present with liver signs and symptoms
3. Hepatitis and cirrhosis may present prior to CNS manifestations
4. Nephropathy occurs and is associated with aminoaciduria, phosphaturia, uricosuria and increased copper excretion

Clinical Manifestations

1. Kayser-Fleischer ring (copper deposition on Descemet's membrane; seen in the upper limbus of light-eyed patients with CNS manifestations)
2. Neurologic manifestations:

- a. "Wing beating" postural kinetic tremor
- b. Cerebellar intention tremor
- c. Dystonia
- d. Chorea
- e. Myoclonus
- f. Gait disturbance
- g. Dysarthria
- h. Seizures
- i. Parkinsonism
- j. Cerebellar signs

Neuropathology

- 1. The greatest degree of atrophy is in the putamen; there is moderate atrophy of the globus pallidus
- 2. Diffuse atrophy of the cerebral cortex and cerebellar cortex
- 3. Opalski cells are detected
- 4. Excessive copper accumulation results from the inability of the liver to excrete copper in the bile from dysfunction of the copper transporting P-type ATPase
- 5. Successful DBS for tremor has targeted:
 - a. Globus pallidus pars interna
 - b. Ventral intermedialis nucleus of the thalamus

Chorea

Overview

Choreic movements are sudden irregular unpredictable brief involuntary movements (not preceded by a Bereitschaftspotential) of the extremities, face or truncal musculature that may include cocontraction of agonist and antagonist muscles. Early cortical median nerve somatosensory evoked potentials have reduced amplitudes which correlate with reduced glucose utilization in the caudate nucleus. Long latency stretch reflexes evoked from intrinsic hand muscles are depressed that suggest dysfunction of thalamocortical relay of afferent sensory input. The specific muscles that are involved depend on the illness. In Huntington's disease there is more truncal muscular involvement than appendicular, while in Sydenham's disease there is more appendicular than truncal involvement. The movements may occur at rest or with intention (in this instance they may be masked as semi-purposeful parakinesia). The movements may be unilateral or bilateral, cease in sleep and are exacerbated by stress. There may be increased or decreased muscle tone.

Hereditary Causes of Chorea

Huntington's Disease

General Characteristics

- 1. HD is caused by an expanded trinucleotide repeat (CAG) that encodes glutamine in the Huntington gene HTT that maps to chromosome 4p16. It is autosomal dominant (AD)

- 2. Its prevalence is between 4–7/100,000 of the population in the USA
- 3. The CAG repeat range for disease is 37–86 repeats
- 4. There is an inverse correlation of CAG repeat length with:
 - a. Age of onset
 - b. Age at death
 - c. Rate of progression
 - d. Other clinical features
- 5. The correlation is stronger with early-onset disease than with late-onset disease
- 6. Sporadic HD:
 - a. There may be expansion from a large repeat in an unaffected male patient
 - b. Intermediate allele number of repeats
 - c. An unstable expansion
- 7. There is no variance of repeat length in different tissues:
 - a. The repeat size is altered in gametogenesis:
 - i. Highest in spermatogenesis
 - ii. In patients with juvenile onset with paternal transmission

Clinical Manifestations

- 1. Variable onset:
 - a. Juvenile onset (4–19 years of age)
 - b. Early onset (20–45 years of age)
 - c. Late onset (greater than 50 years of age)
 - d. 10% present as juvenile onset
 - e. 25% present as late onset
- 2. Anticipation:
 - a. A progressive increase in the length of the tandem repeat
 - b. The longest tandem repeats are associated with the earliest onset
 - c. Late onset disease has maternal transmission
- 3. Clinical patterns:
 - a. Hyperkinetic:
 - i. The most common form
 - ii. Chorea is the first clinical manifestation
 - iii. The usual form: middle or late onset disease
 - iv. Hyperreflexic
 - v. Hypotonic
 - vi. Lurching gait
 - vii. Choreatic eye movements
 - viii. Dementia:
 - 1. Frontal lobe features
 - 2. Choreatic movements may precede or follow the cognitive impairment
 - b. Juvenile or early-onset disease (Westphal variant):
 - i. Inheritance of the gene from an affected father
 - ii. Rapid clinical progression
 - iii. In some patients, the neuropsychological disturbance is greater than the movement disorder
 - iv. Bradykinesia and rigidity
 - v. Seizures

- vi. Movements persist during sleep
- vii. Differential diagnosis of akinetic-rigid HD
 - 1. Wilson's disease
 - 2. Juvenile Parkinsonism
 - 3. Neuroaxonal dystrophy
 - 4. Metabolic storage disorders
- c. Late-onset disease:
 - i. Patients are uncommunicative
 - ii. Orolingual chorea
 - iii. Cognitive impairment
 - iv. Rigidity
 - v. Dystonia
 - vi. Dysphagia (frequent aspiration pneumonia)
 - vii. Duration of the disease: shorter in patients with juvenile or early-onset disease

Neuropathology

1. Loss of large pyramidal cells in the neocortex, allocortex and hippocampus in the absence of astrocytosis; some neuronal loss in the hypothalamus and substantia nigra
2. Loss of Purkinje cells particularly in early-onset patients
3. Loss of neurons in the rostral interstitial nucleus of the medial longitudinal fasciculus
4. Severe atrophy of the caudate nucleus with moderate atrophy of the putamen and globus pallidus; atrophy of the caudate nucleus is associated with astrocytosis
5. The known genetic cause of the disease has led to new therapeutic approaches that are limited to the causative mutation and include:
 - a. RNA interference or antisense oligonucleotides to reduce expression of the mutant huntingtin protein
 - b. Zinc-finger transcriptional repression to decrease mHTT expression
 - c. Modulation of mHTT phosphorylation
 - d. Chaperone upregulation
 - e. Enhancement of autophagy
6. Critical striated circuits are primarily involved, but recent work has demonstrated that mutated HTT is widely expressed outside of the CNS, which may be manifested as weight loss and proinflammatory signalling

Laboratory Evaluation

1. MRI:
 - a. Severe caudate nucleus atrophy that leads to enlarged lateral ventricles ("boxcar ventricles")
 - b. Flattening or absence of the caudate nucleus
2. PET evaluation: hypometabolism of the caudate and putamen
3. PDE10A is decreased in the striatum and pallidum and increased in motor thalamic nuclei in early Huntington's disease
4. Increased activation of central microglia as demonstrated with [¹¹C] PK11195 PET that correlate with plasma IL-1 β levels in premanifest HD gene carriers

Neuroacanthocytosis Syndrome

Overview

Neuroacanthocytosis refers to disorders with neurological signs and symptoms that are associated with acanthocytes. The term encompasses diseases of the basal ganglia and those with inherited abnormalities of serum lipoproteins that cause vitamin E malabsorption with consequent spinal cord and peripheral nerve deficits.

There are four core neuroacanthocytosis syndromes that include:

1. Chorea-acanthocytosis (ChAc)
2. McLeod syndrome
3. Pantothenate kinase associated neurodegeneration (PKAN) with brain iron accumulation (NBIA)
4. Huntington's disease-like 2 (HDL2)

Acanthocytes are seen in approximately 10% of patients with PKAN and HDL2, and rarely in mitochondrial disorders, anorexia nervosa and hypothyroidism.

Chorea-Acanthocytosis (ChAc)

General Characteristics

1. ChAc is caused by mutation in the VPS13A gene that maps to chromosome 9q21. Inheritance is autosomal recessive
2. The gene encodes the protein "chorein"
3. The affected protein functions in the polymerization of actin that is dysfunctional and causes membrane disruption and the abnormal red blood cell shape. Abnormalities of protein phosphorylation have also been described
4. Two splice variants are found; the longer variant is associated with chorea
5. The encoded VPS13B protein may also be involved in intracellular trafficking and vesicle physiology

Clinical Manifestations

1. The disorder presents in early adulthood with chorea and orolingual dystonia
2. Tongue protrusion dystonia with eating is a prominent feature; this may also be seen with tardive dyskinesia, McLeod syndrome, and PKAN
3. Self-mutilation from tongue and lip biting
4. Patients may use an object in the mouth to decrease tongue biting and tooth grinding
5. Sialorrhea
6. Patients may extend their head to push food into the back of their mouth and throat to avoid the tongue protrusion
7. "Head drops" (neck flexion) and truncal flexion
8. An abnormal gait with anterior flexion of the trunk at the hips and leg dystonia
9. Parkinsonism may be a presenting sign, but is most often seen in the later course of the illness

10. Psychiatric symptoms include depression and obsessive-compulsive behavior
11. Tics
12. Seizures:
 - a. Patients may present with seizures which most commonly are partial complex
 - b. Occur in approximately 40% of patients
13. Peripheral neuropathy (sensorimotor)
14. Autonomic nervous system involvement; cardiac abnormalities have been reported but cardiomyopathy is not typical (more common with McLeod syndrome)
15. Extraocular movements:
 - a. Squarewave jerks (similar to HD)
 - b. Impaired saccades
 - c. Limited upgaze
16. Severe swallowing and speech impairment; in the later stages of the illness, patients may become mute
17. Muscle atrophy
18. Hepatomegaly

Neuropathology

1. The primary area of involvement is the basal ganglia
 - a. The caudate nucleus demonstrates the greatest neuronal loss and gliosis. There is lesser involvement of the putamen, globus pallidus and substantia nigra. Some patients with parkinsonism have demonstrated a normal substantia nigra
 - b. Two patients with parkinsonism demonstrated selective loss of striatal substance P-containing neurons and of parvalbumin-containing interneurons (rapidly firing inhibitory interneurons) in both the striatum and cerebral cortex
 - c. Atrophy of the pyramidal tract has been described
 - d. Muscle biopsy: neurogenic atrophy

Laboratory Evaluation

1. Elevated serum creatine kinase
2. Acanthocytosis in the peripheral bloodstream is inconsistent
3. Elevated liver enzymes (in patients with hepatomegaly)

Neuroimaging

1. MRI:
 - a. Atrophy of the head of the caudate nucleus, similar to what is seen in HD
 - b. Variable features:
 - i. Iron deposition in the striatum and globus pallidus
 - ii. Cerebellar atrophy
2. PET and metabolic evaluation:
 - a. Decreased metabolism in the caudate and putamen
 - b. Dopamine and serotonin transporter binding is normal
3. MRS:
 - a. Neuronal loss and glial activation
4. EMG:
 - a. Sensorimotor neuropathy

McLeod Syndrome

General Characteristics

1. McLeod syndrome is caused by mutation of the XK gene that maps to the X chromosome
 - a. The encoded protein is XK which is localized in the surface of the erythrocytic membrane
 - b. The XK protein is linked to the Kell protein by a disulfide bond
 - c. Abnormal XK causes reduced expression of antigens that are expressed by Kell
 - d. XK is a membrane transport protein that affects the movement of divalent cations
 - e. Missense mutations may only affect the position of the protein in the erythrocyte membrane, with minimal clinical effects

Clinical Manifestations

1. There may be symptomatic female carriers (X-chromosome inactivation)
2. Clinical features overlap with those of chorea-acanthocytosis
3. There is greater phenotypic variability and severity in McLeod syndrome than ChAc (chorea-acanthocytosis)
4. Neurologic and psychiatric symptoms and signs develop in men during midlife
5. Initial presentation may be with cognitive impairment or psychiatric difficulties
6. Movement disorders include chorea, dystonia and parkinsonism
7. Variable features:
 - a. "Head drops"
 - b. Orolingual dystonia
8. Patients with chorea may progress to parkinsonism
9. No self-mutilating lip biting
10. Peripheral sensorimotor neuropathy may be an early manifestation
11. Approximately 50% of patients develop seizures that are medication-responsive
12. Hepatomegaly and splenomegaly may occur
13. A distinctive feature is cardiomyopathy, which occurs in approximately 2/3 of patients
14. Myopathy and rhabdomyolysis have been reported

Neuropathology

1. Neuronal loss and gliosis in the caudate, putamen, and globus pallidus

Laboratory Evaluation

1. McLeod phenotype on blood typing from a panel of anti-KX and anti-Kell antibodies
2. Elevated liver enzymes (in those patients with hepatic dysfunction)
3. Echocardiography is positive in those with cardiomyopathy

4. Elevated CK
5. Neuroimaging:
 - a. MRI:
 - i. Atrophy of the caudate nucleus and putamen
 - ii. Scattered white matter changes
 - b. PET evaluation:
 - i. Decreased striatal glucose metabolism
 - c. MRS: mixed results
6. EMG:
 - a. Sensorimotor neuropathy

Huntington's Disease-Like 2 (HDL-2)

General Characteristics

1. HDL2 is caused by a CTG/CAG repeat expansion within the junctophilin-3 gene (JPH3) that maps to chromosome 16q24.3
 - a. Expansion greater than 41 repeats causes disease (normal repeat size is 16–27)
 - b. Possibly a rare African ancestral mutation
 - c. The encoded junctophilin-3 protein:
 - i. Is involved in calcium regulation
 - ii. Junctional membrane structures

Clinical Manifestations

1. Onset is the 3rd to 4th decade
2. Cognitive impairment
3. Chorea, dystonia, myoclonus, or parkinsonism
4. Parkinsonism and dystonia are more severe than in HD
5. The early manifestations may be psychiatric or behavioral
6. Acanthocytosis is seen in 10% of patients
7. Eye movements are normal or demonstrate hypometric saccades; choreatic eye movements are prominent in HD

Neuropathology

1. Neuropathology is similar to HD
2. There is a gradient of neuronal loss from ventral to dorsal in the caudate nucleus and the putamen
3. Ubiquitin and expanded polyglutamine repeats are found throughout the cortex
4. HDL2 pathogenesis may be related to:
 - a. Formation of toxic mRNA inclusions in the cytoplasm
 - b. Loss of the mutant protein

Laboratory Evaluation

1. Acanthocytosis occurs in approximately 10% of patients
2. Neuroimaging:
 - a. MRI: Similar to that seen with HD
 - b. Cortical atrophy
 - c. 3 patients have demonstrated hyperintensity of the rim of the putamen

Pantothenate Kinase-Associated Neurodegeneration (PKAN)

General Characteristics

1. PKAN is the most common NBIA

2. PKAN is caused by mutation in the PKAN2 gene that maps to chromosome 20p13; AR disorder
3. The encoded protein is pantothenate kinase 2, which is critical for the synthesis of coenzyme A. The enzyme is prominent in the infantile basal ganglia and the retina
4. The enzyme deficit may cause mitochondrial dysfunction
5. It is not known if iron deposition is pathogenic or an epiphenomenon

Clinical Manifestations

1. Onset is in childhood
2. Progressive dystonia and parkinsonism
3. Retinitis pigmentosa (but late-onset patients (atypical) tend not to have retinitis pigmentosa)
4. Cognitive impairment
5. Dystonia affects the lower face with grimacing and tongue protrusion
6. Rare chorea
7. Acanthocytosis is seen in a small percentage of patients

Neuropathology

1. It is the major neurodegeneration with brain iron accumulation
2. The PKAN2 gene encodes a mitochondrial enzyme involved in the first regulatory step of coenzyme A (CoA), which is synthesized from pantothenate (vitamin B5). CoA is essential for fatty acid metabolism and amino acid synthesis. Pantothenate is phosphorylated by pantothenate kinase. There are four isoforms of pantothenate kinase. PKAN2 is located in the mitochondrial intermembrane space
3. Alteration in cholesterol and lipid metabolism has been demonstrated in some PKAN2 patients
4. Neuronal loss and gliosis of the globus pallidus, and to a lesser extent the putamen, with concomitant iron accumulation

Laboratory Evaluation

1. MRI:
 - a. "Eye-of-the-tiger" sign in the globus pallidus, consisting of central edema surrounded by iron deposition. It may not be demonstrated in all patients. In late-onset patients, the sign may appear after the onset of neurologic disability

The HARP Syndrome

General Characteristics

1. Caused by the identical mutation which causes PKAN

Clinical Manifestations

1. Hypoprebetalipoproteinemia
2. Acanthocytosis
3. Retinitis pigmentosa
4. Pallidal degeneration

Laboratory Evaluation

1. High resolution lipoprotein electrophoresis:
 - a. Absence of the pre-beta fraction and normal cholesterol, triglycerides, high- and low-density lipoprotein cholesterol and apolipoproteins A, B, and E

Differential Diagnostic Features of the Neuroacanthocytoses

1. ChAc (chorea-acanthocytosis)
 - a. Self-mutilating lip and tongue biting
 - b. Seizures
 - c. Peripheral neuropathy
 - d. Liver enzymes and CK are elevated
2. McLeod syndrome
 - a. A wider range of phenotypic variability and severity than with ChAc
 - b. Cardiomyopathy
 - c. Age of onset and gender
 - d. Elevated liver and creatine kinase enzyme levels
3. Huntington's disease-like 2 (HDL2)
 - a. Parkinsonism and dystonia more severe than in HD
 - b. Ethnic background and inheritance pattern
4. PKAN (Pantothenate Kinase Associated Neurodegeneration)
 - a. The "eye of the tiger" on MRI in the globus pallidus
 - b. Onset in childhood
 - c. Retinitis pigmentosa
 - d. Cognitive impairment
 - e. Dystonia affects the lower face with grimacing and tongue protrusion

Familial Hypobetalipoproteinemia (FHBL)*General Characteristics*

1. Genetically heterogeneous, with linkage to truncating-specifying mutations of the APOB gene that maps to chromosome 2, in a minority of patients, or to chromosome 3p21 in other families
2. Inheritance is AD
3. A percentage of familial hypobetalipoproteinemia patients have no known gene defect

Clinical Manifestations

1. Neurologic disease is secondary to vitamin E deficiency
2. Retinitis pigmentosa
3. Primarily dorsal column modality sensory loss
4. Proximal myopathy

Neuropathology

1. Impaired packaging and secretion of apolipoprotein (apo) B-containing lipoprotein particles due to mutations in both alleles of the MTP gene that encodes microsomal triglyceride transfer protein (MTP) or both alleles of the APOB gene
2. Dorsal column degeneration

Laboratory Evaluation

1. Acanthocytosis in peripheral blood smear
2. Severely decreased apo B-containing lipoproteins that include:
 - a. Chylomicrons
 - b. Very low density lipoprotein (VLDL)
 - c. Low density lipoprotein (LDL)
3. Hypocholesterolemia
4. Malabsorption of lipid-soluble vitamins
5. Heterozygous parents of homozygous hypobetalipoproteinemia (HHBL) patients have half-normal levels of apo B-containing lipoproteins, which supports autosomal co-dominant inheritance

Abetalipoproteinemia (Bassen-Kornzweig Syndrome; ABL)*General Characteristics*

1. Abetalipoproteinemia is caused by homozygous or compound heterozygous mutation in the MTP gene that maps to chromosome 4q23
2. Obligate heterozygous parents of abetalipoproteinemia patients usually have normal lipids consistent with an autosomal recessive inheritance pattern

Clinical Manifestations

1. Celiac syndrome
2. Progressive large fiber neuropathy
3. Proximal myopathy
4. Pigmentary degeneration of the retina
5. Ataxia
6. Dorsal column dysfunction; loss of proprioception, vibration sensibility and deep tendon reflexes
7. Decreased cognition in approximately 1/3 of patients

Neuropathology

1. Extensive peripheral nerve and central demyelination
2. Pathology of vitamin E deficiency
3. Impaired packaging and secretion of apolipoprotein apo B-containing lipoprotein
 - a. Lipoprotein particles
4. Steatosis occurs in some patients

Laboratory Evaluation

1. Acanthocytosis on peripheral blood smear
 - a. Decreased fluidity of the red blood cell membrane
2. Deficiency of fat soluble vitamins A and E
3. Hypocholesterolemia
4. Absence of low density lipoproteins
5. Chylomicron fragments in the plasma

Neuroferritinopathy (NBIA2)*General Characteristics*

1. Alternate name is neurodegeneration with brain iron accumulation type 2 (NBIA2)
2. AD; NBIA2 is caused by mutation in the FTL gene that maps to chromosome 19q13.33

3. It is the only AD disorder of the neurodegenerations with brain iron accumulation
4. Severe pathogenic mutations in the FTL1 gene have been described to date, six of which are frame-shift that alter the reading frame
5. Pantothenate kinase associated neurodegeneration and PLA2G6-associated neurodegeneration are present in infancy and childhood and are often classified as inborn errors of metabolism

Clinical Manifestations

1. Presentation is in mid-adult life but longitudinal studies have demonstrated that iron deposition begins in early childhood
2. The most frequent presentation is chorea (50%) of patients
3. Dystonia occurs in 42.5% of patients
4. Parkinsonism is seen in 7.5% of patients (akinetic-rigid syndrome)
5. Variable features include:
 - a. There are seven different mutations that cause clinical features
 - b. Minimal cognitive impairment (some patients)
 - c. Minimal cerebellar involvement (some patients)
 - d. Some patients with known genetic mutations and clinical features of NBIA have been reported with no iron deposition by neuroimaging

Neuropathology

1. Iron deposition in the basal ganglia with cavitation
2. Neuronal loss in the cerebral cortex, cerebellum and basal ganglia
3. Ferritin inclusion bodies have been demonstrated within neurons and glia
4. Patient derived fibroblasts and HeLa cells that express mutations in ferritin accumulate iron and demonstrate oxidative stress. The link between iron dysregulation and oxidation stress with concomitant neuronal damage is supported by the pathogenesis of Friedreich's ataxia, where the loss of frataxin impairs iron handling in mitochondria with subsequent oxidative damage

Laboratory Evaluation

1. MRI
 - a. 3D-T1 and quantitative T2 MRI demonstrate;
 - i. Iron deposition in the head of the caudate
2. Cavitation in the lateral globus pallidus
3. Voxel-based morphometry:
 - a. Neuronal loss in the substantia nigra, midbrain and dentate nucleus
 - b. Cerebellar atrophy

NBIA2B

General Characteristics

1. NBIA2B is caused by mutation in the PLA2G6 gene that maps to chromosome 22q13
2. Is allelic to infantile neuroaxonal dystrophy

Clinical Manifestations

1. Widely varying phenotypes
2. Childhood onset
3. Ataxia and gait instability
4. Optic atrophy (some patients)
5. Variable features:
 - a. Truncal hypotonia
 - b. Behavioral disturbance
6. No chorea described

Neuropathology

1. Study from 1 patient:
 - a. Generalized brain atrophy with neuronal loss and gliosis
 - b. Axonal swellings in the cortex, striatum, cerebellum brainstem and spinal cord
 - c. Lewy bodies and neurofibrillary tangles were demonstrated

Laboratory Evaluation

1. MRI:
 - a. Iron accumulation in the globus pallidus; distinct from the "eye of the tiger" sign that is seen in NBIA1 and Karak syndrome

Karak Syndrome

General Characteristics

1. Probable autosomal recessive inheritance. The disorder was described in 2 sons of consanguine patients
2. The disorder is caused by homozygous missense mutation in the PLA2G6 gene that maps to chromosome 22q13.1

Clinical Manifestations

1. Childhood onset
2. Slowly progressive ataxic gait
3. Cognitive impairment
4. Adults:
 - a. Dystonia, rigidity, spasticity
 - b. Choreiform movements

Neuropathology

1. Autopsy results have not been reported
2. By MRI the globus pallidus and the substantia nigra show excess iron accumulation

Laboratory Evaluation

1. MRI:
 - a. The "eye of the tiger" sign is demonstrated in the globus pallidus

Aceruloplasminemia

General Characteristics

1. Aceruloplasminemia is autosomal recessive and is caused by mutation in the gene that encodes ceruloplasmin that maps to chromosome 3q24-q25

2. Ceruloplasmin:
 - a. Is a multi-copper oxidase with ferroxidase activity that functions to oxidize ferrous iron after its transfer to extracellular transferrin
3. In the CNS, the major isoform is a glycosylphosphatidylinositol-linked ceruloplasmin that is bound to the cell membrane
4. Ceruloplasmin contains 95% of the copper in serum and is essential for iron efflux from brain cells due to its ferroxidase activity
5. The ferroxidase oxidizes ferrous iron subsequent to its transfer to the cell surface via ferroportin, the iron transporter
6. The transporter delivers ferric iron to cellular transferrin

Clinical Manifestations

1. Onset is middle age
2. Cognitive impairment
3. Cerebellar ataxia
4. Chorea
5. Retinal degeneration
6. Extrapyrmidal signs
7. Diabetes mellitus

Neuropathology

1. Autopsy of one patient:
 - a. Iron deposition in the basal ganglia and dentate nucleus
 - b. Iron deposition in both neurons and glial cells
 - c. Cerebral cortex showed some iron deposition in glial cells but none in neurons
 - d. Redox-active iron accumulation is more prominent in astrocytes than in neurons, characteristic findings are deformed astrocytes
 - e. Iron-mediated oxidative damage to neurons in later disease stages

Laboratory Evaluation

1. Mild anemia (microcytic), low serum iron and elevated serum ferritin
2. Absent serum ceruloplasmin
3. MRI:
 - a. T1- and T2-weighted sequences revealed low signal in the dentate nucleus, thalamus, putamen and caudate nucleus
4. Electron microscopy:
 - a. Iron deposition in hepatocytes, neuronal and glial cells

Mitochondrial Membrane Protein-Associated Neurodegeneration (MPAN)

General Characteristics

1. In patients from Western Europe a founder mutation in the gene C19orf12 that maps to chromosome 19q12 is common
2. It is estimated to account for 5% of NBIA patients worldwide

Clinical Manifestations

1. There are both early childhood and adult onset patients
2. Gait impairment
3. Spasticity of both upper and lower extremities
4. Dystonia may begin in the feet and then spread to the hands or is generalized
5. Parkinsonism occurs predominantly in late onset patients. It includes bradykinesia, resting tremor and postural instability
6. Optic atrophy (similar to PLA2G6)
7. Neuropsychiatric features
8. Dementia
9. A subset of patients have a motor axonal neuropathy; loss of proprioception has also been described
10. Incontinence
11. Dysarthria and dysphagia
12. A milder course than PKAN
13. Rarely there is rapid deterioration
14. An upper and lower motor neuron phenotype similar to juvenile ALS has been described
15. A mutation in C19orf12 has been described in spastic paraplegia 43

Neuropathology

1. Swollen and dystrophic axons and degenerating neurons ("neuroaxonal spheroids") are a hallmark. Only PLA2G6 has a similar pathology in peripheral tissue
2. Prominent alpha-synuclein positive Lewy bodies and Lewy neurites are seen
3. Tau containing inclusions have been described
4. Iron deposits occur in the globus pallidus and substantia nigra
5. Demyelination in the optic nerves and pyramidal tracts
6. Neuroaxonal spheroids are seen in the brain
7. C19orf12:
 - a. A transmembrane protein that localizes to the mitochondria
8. Putative role is in lipid metabolism

Beta Propeller Protein-Associated Neurodegeneration (BPAN)

General Characteristics

1. Mutation in WDR45 (a Beta propeller domain-containing protein) is caused by de novo heterozygous or hemizygous mutation in the WDR45 gene that maps to chromosome Xp11.23
2. BPAN is estimated to be 1–2% of NBIA patients. It is the only NBIA that has an X-linked dominant inheritance pattern
3. Most mutations are de novo

Clinical Manifestations

1. A static encephalopathy in childhood with cognitive impairment and spastic paraplegia or quadriplegia
2. Some patients have seizures

3. After childhood the disorder may not progress for decades
4. During early adulthood patients develop extrapyramidal signs and symptoms. The onset of this new symptomatology may be abrupt
5. In adulthood:
 - a. Falls
 - b. Dystonia
6. Parkinsonism
7. Intellectual impairment
8. Akinetic mutism

Neuropathology

1. Autopsy (3 suspected patients):
 - a. Cortical atrophy
 - b. Iron deposition in the globus pallidus and substantia nigra; both nuclei demonstrated axonal spheroids but were widespread
2. Neurofibrillary tangles were seen throughout the cortex, deep gray nuclei, hippocampus and brainstem
 - a. The function of WDR45 is within cellular autophagic processes. The protein family (WD-40) is characterized by a seven bladed Beta-propeller structure that provides a scaffold for protein-protein interactions which regulate the formation of multimeric protein complexes
 - b. Experimental studies suggest that abnormal autophagosomes accumulate with deficient WDR45

Laboratory Evaluation

1. MRI:
 - a. T1 hyperintensity of the cerebral peduncles and substantia nigra that may extend into the globus pallidus (pathognomonic of this form of NBIA)
 - b. T2-weighted sequences demonstrate hypointensity of the globus pallidus and substantia nigra
 - c. T1-weighted sequences show a region of hyperintensity in the substantia nigra
 - d. In BPAN, T2-weighted sequences has greater hypointensity of the substantia nigra than the globus pallidus

Lesch-Nyhan Syndrome (LNS)

General Characteristics

1. LNS is caused by mutation in the HPRT gene that maps to chromosome Xq26.2-q26.3
2. The encoded protein is the enzyme hypoxanthine guanine phosphoribosyl transferase
3. A deficiency of HGPRT in males causes a spectrum of disease that is dependent upon the extent of the deficiency
4. A complete deficiency is associated with the Lesch-Nyhan syndrome whose incidence is 1 in 100,000 of the population; less than 1.5% of enzyme activity is seen in classic patients
5. Partial deficiency is associated with gout (approximately 1 in 200 male patients with gout); approximately 8% of enzyme activity
6. The mutations (400 described) are of substitution, frame shift, micro- and macrodeletion and splicing errors

Clinical Manifestations

1. Neurologic manifestations occur in patients with 1.5–8% of HPRT activity
2. There is wide phenotypic variation
3. Severe enzyme deficiency:
 - a. Self-mutilation from biting of the fingers and lips
 - b. Cognitive impairment
 - c. Delayed development
 - d. Dystonia
 - e. Spasticity
 - f. Choreaathetosis
4. Kelly-Seegmiller syndrome:
 - a. Associated only with the consequences of increased purine production:
 - i. Renal stones
 - ii. Uric acid nephropathy
5. After puberty the hyperuricemia causes gout
6. One described family had short stature, cognitive impairment, spasticity, proximally placed thumbs and fifth finger clinodactyly

Neuropathology

1. Autopsy of 3 LNS patients
 - a. A marked reduction in the dopamine content and in the activity of DNA-synthesizing enzymes in the caudate and putamen
 - b. There is a 50–63% reduction of binding to dopamine transporters in the caudate and up to 75% in the putamen

Laboratory Evaluation

1. MRI:
 - a. Volumetric determined loss of volume in the caudate of 30%
2. It is proposed and supported by fluorodopa-F18 tracers with PET that there is an abnormality in all dopaminergic pathways that is developmental in origin
3. Patients with classic Lesch-Nyhan disease have the lowest HPRT enzyme activity (less than 1.5% normal) in intact cultured fibroblasts
4. Serum hyperuricemia
5. Megaloblastic anemia (some patients)

Dentatorubral-Pallidoluysian Atrophy (DRPLA)

General Characteristics

1. DRPLA is caused by an expanded trinucleotide repeat in the ATN1 gene that maps to chromosome 12p13.31
2. CAG repeat length in affected individuals ranges from 48 to 93 repeats
3. Inheritance is AD

Clinical Manifestations

1. Patients under age 20 have:
 - a. Ataxia
 - b. Myoclonus

- c. Seizures
- d. Progressive cognitive impairment
- 2. Patients over age 20 have:
 - a. Ataxia
 - b. Choreoathetosis
 - c. Dementia
 - d. Psychiatric disorders
- 3. The onset of DRPLA ranges from childhood to late adulthood (1–62 years; mean age of 30)
- 4. Ataxia and dementia are cardinal features irrespective of age of onset
- 5. Myoclonic epilepsy and absence or atonic seizures may occur in patients with onset prior to age 20; seizures are rare in patients with onset after age 40
- 6. Anticipation occurs

Neuropathology

- 1. Degeneration of the dentatorubral and pallidoluysian systems of the CNS
- 2. Accumulation of the protein atrophin-1 occurs in neuronal nuclei that is demonstrated as diffuse nuclear staining by antibody that detects expanded polyglutamine stretches
- 3. White matter lesions that demonstrate diffuse myelin pallor, axonal preservation, and reactive gliosis are seen in the cerebral cortex

Laboratory Evaluation

- 1. MRI:
 - a. FLAIR sequences:
 - i. Cerebral cortical atrophy
 - ii. Cerebellar and pontomesencephalic tegmental atrophy
 - iii. Cerebral white matter and a component of white matter pathways within the brainstem demonstrate high signal intensities on FLAIR sequences
 - iv. High intensity signals in the globus pallidus on proton and T2-weighted sequences

Haw River Syndrome

General Characteristics

- 1. Described from the Haw River area of North Carolina in a 5 generation kindred
- 2. Autosomal dominant inheritance; the same CTG-B37 repeat as DRPLA

Clinical Manifestations

- 1. Onset is between 15–30 years of age
- 2. Ataxia
- 3. Seizures
- 4. Choreiform movements
- 5. Progressive
- 6. Death after 15–25 years of illness

Neuropathology

- 1. Neuronal loss in the dentate nucleus

- 2. Microcalcification of the globus pallidus
- 3. Neuroaxonal dystrophy of the nucleus gracilis
- 4. Demyelination of the centrum semiovale

Laboratory Evaluation

- 1. MRI:
 - a. Not defined

Differential Diagnosis of DRPLA

- 1. Huntington's disease
 - a. Ataxia in DRPLA is a differentiating point
 - b. Atrophy of the cerebellum and the brainstem (pontine tegmentum) rather than the caudate head in DRPLA
- 2. Patients with DRPLA with minimally expanded repeats in early stages may manifest only cerebellar symptoms and signs without cognitive impairment, and choreoathetosis that resembles autosomal dominant spinocerebellar ataxias
- 3. The differential diagnosis of DRPLA patients with onset prior to age 20 that manifest cognitive impairment, myoclonus and seizures includes:
 - a. Lafora-type progressive myoclonic epilepsy
 - b. Unverricht-Lundborg disease
 - c. Neuronal ceroid lipofuscinosis
 - d. Neuroferritinopathy (globus pallidus)
 - e. MERRF (hearing loss, short stature)
 - f. Sialidosis (cherry red spots in the retina)
 - g. Galactosialidosis
 - h. Gaucher's disease
 - i. Infantile neuroaxonal dystrophy
 - j. Pantothenate kinase 2 ("eye of the tiger")
 - k. Benign adult familial myoclonus epilepsy (BAFME)

Benign Hereditary Chorea (BHC)

General Characteristics

- 1. BHC may be caused by mutation of the NKX2-1 gene that maps to chromosome 14q13.3 and mutation of ADCY5 that maps to chromosome 3q21.1
- 2. NKX2-1 gene
 - a. Encodes thyroid transcription factor T1TF1
- 3. Prevalence of 2/10,000,000 of the population
- 4. Penetrance is 100% in men and 75% in women

Clinical Manifestations

- 1. Age at onset is usually before 5 but varies from infancy to late childhood and adolescence
- 2. Late walking, incoordination and frequent falls
- 3. Speech and cognitive function are usually unaffected, a differential point from Huntington's disease
- 4. Rare progression during adulthood (some patients have improved)
- 5. Atypical manifestations include:
 - a. Dysarthria
 - b. Gait abnormalities

- c. Axial dystonia
- d. Cognitive impairment
- e. Progression in adulthood
- 6. Pulmonary disease and/or congenital hypothyroidism may be seen

Neuropathology

1. Seventy-seven mutations in the T1TF1 gene have been identified in BHC patients (large and small deletions, missense and nonsense mutations)
2. The encoded protein thyroid-specific transcription factor-1 (TTF-1) is a thyroid-specific enhancer-binding protein that regulates the expression of thyroid-specific genes that are involved in transcription of:
 - a. Thyroglobulin
 - b. Thyroid peroxidase
 - c. Thyrotropin receptor
 - d. Surfactant protein
 - e. Secretory protein in the lungs
 - f. Organogenesis of:
 - i. Thyroid
 - ii. Lung
 - iii. Brain (ventral fore brain, posterior pituitary and the hypothalamus)
3. Autopsy (1 patient)
 - a. Mild frontal-parietal-temporal atrophy
 - b. Normal striatum and pigmented striatum
 - c. Non-specific astrocytosis without neuronal loss of the globus pallidus, thalamus, hippocampus and periaqueductal gray
 - d. Reduced density of striatal met-enkephalin and substance P immunoreactive nerve fibers
4. Cystic pituitary and sella turcica abnormalities have been seen in a few patients (6.4%). They have been associated with missense, nonsense and large deletions

Laboratory Evaluation

1. MRI:
 - a. Some patients have cystic posterior pituitary mass lesions and abnormalities of the sella turcica
2. Congenital hypothyroidism
3. Pulmonary disease

ADCY5 Mutation and Benign Hereditary Chorea

General Characteristics

1. Adenylate cyclase 5 mutations that map to chromosome 3q21 is another cause of BHC
2. Other mutations also cause autosomal dominant familial dyskinesia and facial myokymia

Clinical Manifestations

1. Early childhood onset
2. Brief choreic movements at rest that affect the face and all extremities

3. The disorder is progressive
4. Painful spasms upon awakening
5. Dysarthric speech
6. Generalized chorea with facial grimacing and dystonia
7. Chorea and dystonia are present at rest; increased by stress and emotion
8. Gaze impersistence; head thrust utilized to initiate saccades
9. Normal cerebellar function
10. Choreic and dystonic elements in gait abnormality
11. No facial myokymia
12. No other major neurology abnormalities are detected
13. Normal cognitive function
14. Late in the course, 3 patients have been described with ballistic movements and severe spasms

Neuropathology

1. Expression profiling of ADCY5 and mRNA by microarray analysis:
 - a. Higher expression ADCY5 and NKX2-1 in the putamen than in other brain regions
 - b. ADCY5 has higher expression in the adult striatum than NKX2-1
 - c. Longitudinal studies of brain tissue during development demonstrate an increase of ADCY5 and decrease of NKX2-1 from 50–500 days after conception

Laboratory Evaluation

1. Molecular genetic testing (WES) to define the mutation
2. EMG:
 - a. No facial myokymia

Differential Diagnosis

1. ADCY5 mutation carriers from those patients with NKX2-1 mutations:
 - a. NKX2-1 may have pulmonary or endocrine defects
 - b. Some patients with familial dyskinesia and facial myokymia (mutations of the same gene as ADCY5) have congestive heart failure
 - c. Progression of the disorder:
 - i. NKX2-1 patients remain mildly affected and may improve after childhood while ADCY5 progresses
 - d. Dystonic posturing is more severe in the ADCY5 patients than those with NKX2-1 mutations
 - e. ADCY5 related dyskinesia are worsened by action, excitement or stress
 - f. Need to rule out the disorders with mutations in the genes most commonly associated with chorea that include:
 - i. Huntington's disease
 - ii. SCA17
 - iii. DRPLA

Acquired Causes of Chorea Vascular Hemichorea

General Characteristics

1. Vascular lesions primarily interrupt striatal cortical motor

- loops and are found in the contralateral subthalamic nucleus, thalamus or caudate nucleus in hemichorea
- 2. Middle cerebral artery and PCA occlusion have been described as causative

Clinical Manifestations

1. Hemichorea may occur in acute stroke (often the thalamoperforate artery whose origin is P1) or from hypoperfusion of the middle cerebral artery territory
2. It occasionally is delayed or progressive
3. Cerebrovascular disease is the most common cause of sporadic chorea

Neuropathology

1. Lesions are most often found in the thalamus (thalamoperforate and thalamogeniculate arteries) and less frequently in the subthalamic nucleus (most often the interpeduncular artery from P1)

Laboratory Evaluation

1. MRI:
 - a. Diffusion weighted (for acute stroke) or T1 and T2-weighted sequences demonstrate lesions in the affected territories
 - b. Extremely rarely, a vascular malformation with hemorrhage may be demonstrated
 - c. In diabetic patients the thalamoperforate artery may be involved by stenosis of P1 or thrombotic or embolic occlusion

Diabetic Hemichorea

General Characteristics

1. Often seen in the setting of hyperglycemia and non-ketotic diabetic acidosis

Clinical Manifestations

1. Acute or subacute onset of hemichorea that most often spares the face
2. After normoglycemia has been restored the movement disorder may persist for 24–48 hours
3. Most often associated with hyperglycemia and non-ketotic diabetic acidosis

Neuropathology

1. Open biopsy (1 patient):
 - a. Gemistocytic astrocytes with zinc-laden metallothionein protein
 - b. No petechial hemorrhages

Laboratory Evaluation

1. MRI:
 - a. Contralateral T1 MRI sequence hyperintensities of the putamen are almost always detected
 - b. The caudate and globus pallidus may occasionally be involved

- c. The lesion is well circumscribed and is not in a vascular distribution
- d. DWI and ADC demonstrate restricted diffusion in the affected putamen. Increased susceptibility is also seen in a similar distribution with susceptibility-weighted imaging (SWI)
- e. PET:
 - i. Relative hypometabolism in the involved areas has been demonstrated
- f. Rarely similar changes on MRI imaging sequences have been seen ipsilaterally
- g. Non-ketotic diabetic acidosis

Differential Diagnosis of Hemichorea-Hemiballism Syndrome

1. Ischemia
2. Hyperglycemia with non-ketotic diabetic acidosis
3. Neoplasm
4. Systemic lupus erythematosus
5. Wilson's disease
6. Thyrotoxicosis
7. Hyperglycemic hyperosmolar non-ketotic coma

Sydenham's Chorea (SC)

General Characteristics

1. Sydenham's chorea is the neurological component of rheumatic fever
2. It is associated with antibodies against group A beta-hemolytic streptococci that cross-react with either:
 - a. Extracellular cell surface epitopes
 - b. Intracellular cytoplasmic or cytoskeletal antigens
3. PANDAS (pediatric autoimmune neuropsychiatric disorder associated with streptococcal infection) occurs in children that develop:
 - a. Fulminant onset
 - b. Movement and behavioral disorder that include tics and OCD

Clinical Manifestations

1. Following infection by group A beta-hemolytic streptococcal infection with rheumatic fever and heart valve involvement; mitral > aortic
2. Familial tendency
3. The neurologic manifestations rarely occur without heart involvement
4. Adult recrudescence:
 - a. Associated with increased anti-streptolysin titer (ASO titer)
 - b. Jaccoud's arthritis (adults)
 - c. Generalized chorea
5. Behavioral abnormalities (hyperactivity in children and adolescents)
6. "Milk maids" hands; inability to sustain a movement
7. Incoordination and hypotonia

8. Usually the chorea has an abrupt onset that worsens over the ensuing 2–4 weeks
9. Quick semi-purposeful movements:
 - a. Jerking movements of the arms and legs
 - b. Decreased ability to walk
 - c. Involuntary movements of facial musculature with dysarthria
10. Hand posture:
 - a. Flexed wrist with extended fingers
11. Chorea may recur:
 - a. First recurrence may be during pregnancy (chorea gravidarum)
 - b. While taking oral contraceptives
12. The distal extremities are primarily involved
13. Choreiform tongue movements are common

Neuropathology

1. Elevated dopamine-2 receptor immunoglobulin G has been detected in approximately 1/3 of patients with Sydenham's chorea
2. It has been proposed that dopamine D1 and D2 receptors are the primary antibody target in SC although antibodies that bind to CNS lysoganglioside-GM and the cytoskeleton protein tubulin have also been demonstrated
3. The putative cause of the neurological symptomatology is an alteration of neuronal cell signaling transduction by calcium calmodulin-dependent protein kinase II (Camk11)
4. In acute rheumatic fever antibodies are raised against N-acetyl-beta-D-glucosamine (NABG) or GLcNAc
5. Different subsets of NABG antibodies are correlated with specific clinical manifestations of acute rheumatic fever (ARF)
6. Tubulin antibodies are not found in patients with ARF without SC

Laboratory Evaluation

1. MRI:
 - a. Non-specific signal intensities occur in the white matter, brainstem and caudate nucleus in approximately 50% of patients
 - b. PET evaluation (1 patient):
 - i. Increased glucose metabolism in the contralateral caudate and putamen that was noted to be reversible in three months
2. Increased ASO titer occurs with recrudescence of rheumatic fever and chorea

Antiphospholipid Antibodies

General Characteristics

1. Low titers of antiphospholipid (aPL) may be seen in 2–9% of the normal population
2. Titers may increase with mycoplasma, chlamydia, HIV, Lyme's disease and Hepatitis C
3. Chorea may occur in patients with high titers of aPL antibodies in the absence of concurrent autoimmune disease or clinical antiphospholipid syndrome

Clinical Manifestations (Chorea Associated with a High Titer of aPL Without APS Syndrome)

1. Age from 5–21 years
2. Increased titer of anticardiolipin aPL and absent lupus anticoagulant (LAC) in all reported patients
3. Chorea
4. Variable manifestations include:
 - a. Seizures
 - b. Cognitive impairment
 - c. Dystonia

Neuropathology

1. Putative mechanisms:
 - a. aPL antibody damage to nigrostriatal pathways due to high binding affinity of the antibodies for phospholipids of neurons in dopaminergic pathways that causes depolarization of striatal neurons
 - b. aPL-induced damage of vascular endothelium of the striatum
2. "Pre"-APS syndrome:
 - a. The detection of aPL antibodies but the condition does not meet criteria for APS but may manifest:
 - i. Livedo reticularis
 - ii. Chorea
 - iii. Thrombocytopenia
 - iv. Valvular heart disease
 - v. Nephropathy (not included in the criteria for APS)

Laboratory Evaluation

1. Pre-APS patients:
 - a. An increase of aCL antibodies (anticardiolipin) with normal lupus anticoagulant (LAC); in APS secondary to SLE there is thrombosis associated with elevated LAC antibody titers
2. High titers of IgM aCL develop in pre-APS patients that are thought to damage the striatum with consequent chorea whereas in APS there is vessel occlusion. In pre-APS the MRI is normal and in APS it may demonstrate abnormalities
3. PET (deoxyglucose) in pre-APS:
 - a. Demonstrates an increased metabolic rate for glucose utilization in the basal ganglia

Chorea in Systemic Lupus Erythematosus

General Characteristics

1. The incidence of chorea in SLE varies from 1–8% in various reports
2. It is strongly associated with aPL antibodies; most prominent are anticardiolipin and lupus anticoagulant (LAC) antibodies

Clinical Manifestations

1. Chorea usually occurs during the course of the illness but rarely may be the initial manifestation and may precede other signs and symptoms for years

2. The chorea may last days to years
3. May occur in children
4. May be episodic

Neuropathology

1. Immune-mediated mechanism is secondary to aPL antibodies primarily anticardiolipin IgG attack on the striatum
2. Ischemia of the basal ganglia, thalamus and cerebral cortex

Laboratory Evaluation

1. Positive titers of aPL antibodies, lupus anticoagulant (LAC), anticardiolipin (aCL) IgG, single or double stranded anti-DNA antibodies and positive sed rate
2. MRI:
 - a. In neuropsychiatric SLE there is periventricular white matter hyperintensities on T2 and FLAIR sequences
 - b. Scattered evidence of small vessel infarction
3. SPECT:
 - a. Scattered areas of hypoperfusion

Chorea Gravidarum

General Characteristics

1. The most common movement disorders of pregnancy are restless leg syndrome and chorea gravidarum
2. The incidence has dramatically decreased in Western countries putatively due to the decrease of rheumatic fever

Clinical Manifestations

1. It is a disorder of young patients the average age being 22
2. 80% of attacks occur during the first pregnancy; approximately 50% start during the second trimester
3. Recurrences may occur during subsequent pregnancies especially if antiphospholipid syndrome is causative
4. Some patients have a family history of transient chorea
5. Emotional stress aggravates the chorea; the movements are absent during sleep
6. The patients may be restless and fidgety and unaware of the movements
7. The extremities are primarily affected
8. The chorea may be unilateral hemichorea
9. The affected limb is hypotonic, the joints are lax and the wrist and fingers shape the hand into a spoon configuration (an imbalance of flexor and extensor musculature)
10. There may be uncontrollable tongue movements (darting in and out of the mouth)
11. The choreic movements are rapid, purposeless, and irregular. They randomly flow from one part of the body to another
12. Rheumatic encephalopathy:
 - a. May occur in patients with clinical manifestations of chorea
 - b. EEG demonstrates slow waves of 3–6 Hz which occur continually or in intermittent rhythmic paroxysms

- c. The EEG changes may be generalized or are seen predominantly over the frontal and central regions
- d. Changes are usually unilateral in hemichorea
- e. EEG improvement parallels recovery from rheumatic carditis and chorea usually within 6 months

Neuropathology

1. Putative autoimmune-mediated mechanism affecting the basal ganglia

Laboratory Evaluation

1. Dependent upon the underlying etiology
2. Approximately 50% of patients have no determined cause; most common etiologies include: 1. SLE; 2. Huntington's disease; 3. rheumatic fever; 4. APS; 5. syphilis (rare)

Post-Pump Chorea

General Characteristics

1. Definition:
 - a. Post-pump chorea is choreoathetoid movements that develop within two weeks of cardiopulmonary bypass surgery. There is often an initial asymptomatic period
2. The syndrome occurs in 1–3% of patients from infants to mid-childhood

Clinical Manifestations

1. Generalized chorea
2. Orofacial dyskinesia
3. Hypotonia
4. Ballismus
5. Supranuclear gaze palsy
6. Change in affect
7. Pseudobulbar signs
8. 10 years follow up of chorea in 8 children from a cohort of 668 who had open cardiac surgery
 - a. Clinical manifestations:
 - i. None of the children were developmentally normal 22 to 130 months after surgery
 - b. Mild learning disability
 - c. Progressive hypotonia
 - d. 3/8th patients had transient chorea while in 5 patients it was persistent
 - e. 1/8th children expired

Neuropathology

1. Strong association with deep hypothermia and circulatory arrest
2. Lack of macroscopic changes
3. Putative biochemical or microembolic etiology in some patients

Laboratory Evaluation

1. MRI:
 - a. Generalized brain atrophy but no focal changes
2. PET evaluation [¹⁸F] fluorodeoxy-glucose
 - a. Patchy areas of decreased glucose utilization

Chorea from Contraceptives*General Characteristics*

1. Use of oral contraceptives is a well-documented but rare cause of acquired chorea
2. Many patients with chorea induced by OCPs had prior or coexisting antiphospholipid syndrome, SLE or prior rheumatic fever

Clinical Manifestations

1. Insidious onset of hemichorea
2. Insidious onset of bilateral chorea

Neuropathology

1. It has been suggested that oral contraceptives cause a recrudescence of Sydenham's chorea
2. Estrogen increases the sensitivity of dopaminergic neurons
3. Anti-basal ganglia antibodies have been detected by Western immune-blot; the antigens were of 40–45 kDa in size (one patient)

Laboratory Evaluation

1. MRI:
 - a. Most often normal in all sequences
2. PET with FDG (one patient):
 - a. Increased glucose utilization in the contralateral caudate nucleus in a patient with hemichorea

Acute Carbon Monoxide Poisoning*General Characteristics*

1. Acute brain injury in CO-exposed patients are primarily caused by hypoxia
2. The affinity of CO for heme protein is 250 times that of oxygen
3. The formation of carboxyhemoglobin reduces the oxygen carrying capacity of blood that leads to varying areas of cerebral tissue hypoxia

Clinical Manifestations

1. Acute poisoning:
 - a. Diffuse hypoxic-ischemic encephalopathy that predominately involves the gray matter
2. Delayed encephalopathy after carbon monoxide poisoning is uncommon:
 - a. It may occur 14–45 days after recovery from acute poisoning and is characterized by:
 - i. Cognitive impairment
 - ii. Dementia or psychosis
 - iii. Parkinsonism
 - iv. Urinary incontinence
 - v. Generalized or mono limb chorea
 - vi. Dystonia

Neuropathology

1. Putative mechanisms include:

- a. Hypoactivity in the indirect pathway of the basal ganglia-thalamocortical motor circuit
 - b. White matter lesions that destroy subcortical inhibitory motor circuitry
2. Necrosis and apoptotic neuronal death
 3. CO inhibits the mitochondrial electron transport chain and activates polymorphonuclear leukocytes which diapede into the brain and cause brain lipid peroxidation

Laboratory Evaluation

1. MRI:
 - a. Diffuse hypoxic-ischemic and focal cortical lesions with predilection for the temporal lobe and the hippocampus
 - b. Necrosis of the globus pallidus:
 - i. The most common CNS structure involved in CO poisoning
 - ii. The medial globus pallidus demonstrates low signal intensity on T1-weighted sequences and high signal intensity on T2-weighted and FLAIR images
 - iii. DWI MRI and apparent diffusion coefficient maps demonstrate restriction of water diffusivity
 - c. The caudate, putamen and thalamus are occasionally involved
 - d. There are rare brainstem and cerebellar lesions
 - e. Diffuse brain atrophy
 - f. Cerebral white matter demyelination:
 - i. Not seen in the acute stage of CO poisoning
 - ii. The periventricular white matter and the centrum semiovale are primarily involved
 - iii. In severe poisoning, there is demyelination in the subcortical white matter, corpus callosum, external and internal capsules

Differential Diagnosis of Acquired Chorea*Stroke*

1. The most common movement disorder to occur following stroke
2. Stroke-induced chorea occurs in older stroke patients
3. It is usually hemichorea and occurs contralateral to the lesion
4. Thalamic lesions are the most common localization
5. The majority of patients show some improvement by 1 year

Post-Pump Chorea

1. Occurs in children
2. Risk factors are prolonged pump time, older aged children, preoperative cyanosis and deep anesthesia

Polycythemia Vera

1. Chorea may be acute or subacute
2. May precede the hematologic changes
3. Occurs in 1–5% of patients and is most common in elderly females
4. It improves with phlebotomy

Autoimmune Causes of Chorea*Sydenham's Chorea*

1. Occurs in approximately 25% of acute rheumatic fever patients
2. It develops weeks to months after infection with group A-B-hemolytic streptococcus
3. The average age of onset is 9 years
4. Anti-basal ganglia antibodies have been identified. The putative mechanism is "molecular mimicry"

Systemic Lupus Erythematosus

1. Chorea occurs in approximately 1% of patients with SLE
2. Often associated with the antiphospholipid antibody

Sjögren's Disease

1. Oral contraceptives:
2. Estrogen enhances central dopaminergic sensitivity

Chorea Gravidarum

1. Usually begins in the first trimester and improves in later pregnancy and after delivery

Paraneoplastic Causes of Chorea

1. Paraneoplastic chorea most often occurs with anti-CRMP-5 antibodies that are associated with small cell lung cancer
2. Paraneoplastic chorea occurs with other malignancies

Metabolic Causes of Chorea

1. Glucose metabolism:
 - a. Non-ketotic hyperglycemia induced chorea:
 - i. Most common in women and occurs with very high glucose levels (~500 mg is average)
 - ii. MRI high signal intensities occur in the putamen (T1-weighted sequences)
 - iii. Most often a reversible hemichorea
2. Thyroid disease:
 - a. Chorea rarely occurs with hyperthyroidism
 - b. Can occur with thyroid replacement therapy
 - c. May be associated with Hashimoto's encephalopathy
 - d. Putative mechanism is enhancement of catecholamine effects on striatal neurons
 - e. It may persist after patients are euthyroid
 - f. Hypothyroidism may cause chorea
3. Renal failure:
 - a. Uremia has been associated with the sudden onset of chorea
 - b. Diabetic end-stage renal disease patients may develop MRI changes in the basal ganglia consistent with vasogenic edema
4. Calcium metabolism:
 - a. Hypoparathyroidism with hypocalcemia is associated with chorea that improves when the calcium is normalized
5. Chorea may occur with other movement disorders in association with several inborn errors of metabolism

Drugs That Cause Chorea

1. Dopamine receptor antagonists:
 - a. These drugs most often cause tardive dyskinesia but may be associated with limb chorea
- b. Other drugs that may cause chorea:
 - i. Levodopa
 - ii. Phenothiazine
 - iii. Lithium
 - iv. Cimetidine
 - v. Isoniazid
 - vi. Verapamil
 - vii. Theophylline
 - viii. Baclofen
 - ix. Tricyclic antidepressants
 - x. Steroids
 - xi. Antiepileptics (Phenytoin)
- c. Drugs of abuse that cause chorea:
 - i. Cocaine ("crack dancing")
 - ii. Amphetamines

Infectious Causes of Chorea

1. Neurosyphilis
2. Lyme's disease
3. Subacute sclerosing panencephalitis (measles)

Toxins That Cause Chorea

1. Carbon monoxide
2. Mercury

Senile Chorea*General Characteristics*

1. Many known etiologies of chorea present in late adulthood, examples of which are PKAN, Huntington's disease, antiphospholipid antibody syndrome
2. Rare causes of late sporadic senile chorea are in association with tardive dyskinesia, hypocalcemia and basal ganglia calcification
3. There remains a group of late onset sporadic chorea that to date has no known cause

Clinical Manifestations

1. Insidious onset
2. Mild involvement of the limbs
3. Rare lingual facial movements
4. Slow progression

Neuropathology

1. Not defined if there is no underlying cause

Laboratory Evaluation

1. Dependent upon the underlying cause

Differential Diagnosis of Hereditary Causes of Chorea

1. Huntington's disease

2. Neuroacanthocytosis
3. McLeod disease
4. HDL-2
5. PKAN
6. Abetalipoproteinemia
7. Hypobetalipoproteinemia
8. Wilson's disease
9. Spinocerebellar ataxia 17
10. Glucose transporter (GLUT-1)
11. Fahr's disease
12. Lesch-Nyhan syndrome
13. DRPLA
14. Karak syndrome
15. ADCY5 mutations
16. NKX-2 mutations
17. Benign hereditary chorea
18. Neuroferritinopathy
19. Aceruloplasminemia

Dyskinesia

Overview

Plasticity is the ability of the nervous system to change the effectiveness of synaptic transmission in neural circuits. It occurs at neuronal, synaptic, protein or genomic structures which modulate the structure and function of neural networks. Maladaptive plasticity is the development of dyskinesia associated with dysfunctional neural plasticity from increased transmitter release, receptor regulation and synaptic changes of long term potentiation (LTP) or long term depression (LTD). It may also occur from anatomical remodeling, axonal regeneration, synaptogenesis and neurogenesis. It has been proposed that these alter cortical-thalamic and striatal circuits (the indirect pathway) that disinhibits GABA-ergic regulation of the ventrolateral thalamic (VL) neurons that project to the motor and supplementary motor cortices.

Paroxysmal Kinesigenic Dyskinesia (Paroxysmal Kinesigenic Choreoathetosis)

General Characteristics

1. Paroxysmal kinesigenic dyskinesia (PKD) may be caused by heterozygous mutation in the PRRT2 gene that maps to chromosome 16p11
2. Allelic disorders are:
 - a. Familial infantile convulsions (BF1C2)
 - b. Infantile convulsions and paroxysmal choreoathetosis (ICCA)
 - c. Inheritance for PKC is AD

Clinical Manifestations

1. Attacks are initiated by sudden movement or startle
2. Last seconds to minutes
3. Hyperventilation may induce attacks

4. Movements may be preceded by paresthesias, crawling sensations or anxiety
5. Movements consist of dystonic posture, ballism, chorea, athetosis, or various combinations of the above
6. Movements may affect speech and cause falls
7. The movements habituate
8. Incomplete atonic attacks may be more frequent in Japanese patients
9. Consciousness is maintained
10. Generalized and partial seizures have been documented in some kindreds
11. A large percentage of patients are responsive to antiepileptics
12. PRRT2 mutations are associated with an earlier age at onset, longer duration of attacks and combined phenotypes of dystonia and chorea

Neuropathology

1. Epileptic mechanisms, channelopathy and abnormalities in basal ganglionic circuitry have been suggested as etiologic

Laboratory Evaluation

1. Ictal and interictal single photon emission computed tomography (SPECT)
 - a. Perfusion changes in the left frontal/temporal cortices
2. Increased ictal perfusion of the thalamus:
 - a. One 6 year old patient demonstrated increased CBF by SPECT in the posterolateral thalamus on the contralateral side to the unilateral PKC

Acquired Etiologies

1. Head trauma
2. Demyelinating disease
3. Putaminal and thalamic infarction
4. Hypoparathyroidism with basal ganglia calcification
5. Hyperglycemia
6. Vascular malformations

Paroxysmal Non-Kinesigenic Dyskinesia (PNKD)

General Characteristics

1. PNKD is caused by heterozygous mutation in the myofibrillogenesis regulator-1 gene (MRI) that maps to chromosome 2q35
2. Inheritance is AD

Clinical Manifestations

1. Patients with MRI mutations have a more homogenous phenotype than those without the mutation; they also have an earlier age at onset of 3 months to 12 years
2. Attacks last minutes to hours
3. They may occur spontaneously at rest
4. Dystonia, chorea, athetosis and ballism occur in various combinations

5. Speech and swallowing may be involved
6. Attacks may be preceded by feelings of stiffness and occasionally by formications in the affected extremities
7. Attacks are triggered by stress, fatigue, caffeine and alcohol
8. Fewer attacks during pregnancy
9. Usually at least one attack per week
10. Good response to benzodiazepines
11. Migraine headaches occur in approximately 50% of patients
12. Patients with PNKD without the MRI mutation:
 - a. Exercise is a precipitating factor (68%)
 - b. Alcohol is not a precipitating factor
 - c. More variable age at onset
 - d. Ballism in 10% of patients
 - e. Seizure in 23% of patients

Neuropathology

1. The pathophysiology of PNKD has not been elucidated
2. 60% of patients have mutations in the PNKD gene (formerly MRI) that maps to 2q35; another locus on 2q31 (PNKD2) has been found in a Canadian kindred

Laboratory Evaluation

1. The diagnosis is purely clinical

Differential Diagnosis of PNKD

1. Wilson's disease
2. Paroxysmal kinesigenic dyskinesia
3. Infantile convulsions and choreoathetosis (ICCA syndrome)
4. Paroxysmal exertion-induced dyskinesia (PED)
5. Autosomal dominant nocturnal frontal lobe epilepsy
6. Paroxysmal dystonic choreoathetosis with episodic ataxia and spasticity
7. Huntington's disease
8. Acquired

Differential Diagnosis of Acquired PNKD

1. Demyelinating disease
2. Vascular thalamic lesions
3. Hypoparathyroidism
4. Thyrotoxicosis
5. Basal ganglia calcification
6. Brain tumor
7. Head trauma

Paroxysmal Exercise-Induced Dyskinesia (PED)

General Characteristics

1. PED is caused by heterozygous mutation in the SLC2A1 gene that maps to chromosome 1p34.2
2. It encodes the GLUT1 transporter and is autosomal dominant
3. Allelic disorders with overlapping features include:
 - a. GLUT1 deficiency syndrome-1
 - b. Dystonia-9
 - c. Idiopathic generalized epilepsy-12

Clinical Manifestations

1. Age of onset is usually in childhood but may range from 1–30 years
2. Dyskinesias are induced by exercise of 15–60 minutes duration
3. Attacks last between 5 minutes to 2 hours and are most often in the exercised extremities
4. Dystonic movements are bilateral and are exacerbated by cold, stress, fatigue and sleep deprivation
5. The frequency of attacks vary from one per day to one per month
6. Variable features include:
 - a. Increased deep tendon reflexes
 - b. Developmental delay
 - c. Cognitive impairment
 - d. Seizures and migraine can occur concomitantly in some familial forms
7. PED may be associated with:
 - a. Paroxysmal dystonic choreoathetosis with episodic ataxia and spasticity
 - b. Benign familial infantile seizures (BFIE)
 - c. Infantile convulsions and choreoathetosis (ICCA syndrome)
 - d. Rolandic epilepsy, paroxysmal exercise-induced dystonia and writer's cramp

Neuropathology

1. PED is associated with mutations in the SLC2A1 gene that encodes the glucose transporter GLUT1
2. All mutations affect the ability of GLUT1 to transport glucose into the CNS which causes bioenergetic failure with exertion

Laboratory Evaluation

1. There is hypoglycorrhachia in the CNS (CSF) and serum hypoglycemia
2. EEG and neuroimaging are normal
3. The diagnosis is confirmed with molecular genetic screening of the SLC2A1 gene

Differential Diagnosis of PED

1. PKD
2. Young adult onset Parkinsonism
3. GLUT1 deficiency
4. Pyruvate dehydrogenase deficiency:
 - a. MRI demonstrates bilateral globus pallidus involvement
 - b. Dystonia responds to thiamine

Paroxysmal Hypnogenic Dyskinesia (PHD)

General Characteristics

1. PHD in the overwhelming majority of patients is a form of mesial frontal lobe epilepsy. In familial patients it is referred to as autosomal dominant nocturnal frontal lobe epilepsy

2. Autosomal dominant nocturnal frontal lobe epilepsy is caused by heterozygous mutation in the CHRNA4 gene that maps to chromosome 20q13.33
3. It is a genetically heterogeneous condition with mutations in genes located on chromosomes 15q24, 1q21, 8p21 and 7q34

Clinical Manifestations

1. Intermittent dystonia and choreoathetoid movements that are exclusively seen during sleep
2. They often occur every night
3. Consciousness is preserved during an attack when the patient is wakened
4. Most often misdiagnosed as parasomnia

Neuropathology

1. Support for a subcortical focus includes:
 - a. The absence of EEG abnormalities
 - b. Absence of a generalized or local convulsion
 - c. No loss of consciousness or amnesia from the event
 - d. The clinical characteristics of the involuntary movements are most suggestive of a basal ganglia origin
 - e. PET scan evaluation in 12 patients with ADNFLE with the CHRNA4 gene mutation revealed:
 - i. Decreased striatal D1 receptor binding predominantly in the right putamen
 - ii. It was postulated that a gain of function in mutation of the CHRNA1 gene caused increased levels of extracellular dopamine due to the mutant CHRNA4 subunit 4 protein's failure to regulate dopamine release normally

Laboratory Evaluation

1. Normal EEG during an episode
2. Molecular genetic screening of the gene

Mixed Paroxysmal Dyskinesia

General Characteristics

1. The patients do not fall into the classic categories of paroxysmal dyskinesia

Clinical Manifestations

1. Patients have features of both paroxysmal kinesigenic and non-kinesigenic dyskinesia
2. Patients may respond to carbamazepine and clonazepam

Neuropathology

1. Not defined

Tardive Dyskinesia

General Characteristics

1. The usual cause is dopamine receptor antagonist or neuroleptic medication use
2. The most common drugs that are causative:

- a. Neuroleptics
- b. D2 dopamine receptor antagonists
- c. Metoclopramide
- d. Perphenazine
- e. Stelazine
- f. Promethazine
- g. Amitriptyline
- h. Butyrophenones

Clinical Manifestations

1. Abnormal movements occur:
 - a. During drug treatment
 - b. After drug withdrawal
 - c. May be permanent
2. Usually three months of exposure is required
3. Exacerbations of movements may occur with drug withdrawal; increasing the dose of the offending agent may dampen movements
4. Orofacial dyskinesia (the buccolingual masticatory syndrome)
 - a. Rhythmical involuntary movement of the tongue, face or mouth
 - b. Choreiform movements of the extremities
 - c. Abnormalities of gait, trunk and posture
5. Axial dystonias:
 - a. Patients > 50 years of age
 - b. May coexist with buccal lingual masticatory (BLM) syndrome and choreoathetosis
 - c. Neck flexion and lordosis
 - d. Pelvic rocking and thrusting
6. Respiratory dyskinesia with involuntary chest and diaphragmatic movements
7. Often accompanied by tardive akathisia:
 - a. Inner compulsion to move
 - b. Restlessness
 - c. Uncomfortable sensations of the body as a whole or specific body parts
8. Tardive dystonia:
 - a. Accompanied by tardive akathisia or tardive dyskinesia
 - b. Sustained and torsional movements
 - c. Facial dystonia with or without facial grimacing
 - d. Jaw deviation with sustained mouth opening (striking in DYT3 or Lubag)
 - e. Dystonic neck posturing (retrocollis)
9. Tardive dyskinesia variants:
 - a. Tardive akathisia
 - b. Tardive tics
 - c. Tardive dystonia
 - d. Tardive myoclonus
 - e. Generalized chorea
10. Associated tardive dyskinetic signs:
 - a. Respiratory dyskinesias
 - b. Body rocking
 - c. Pelvic thrusting

Neuropathology

1. The major putative hypothesis for the development of tardive dyskinesia is central blockade of dopamine receptors by dopamine antagonists that causes:
 - a. Striatal dopamine receptor supersensitivity
 - b. Reduction of D2 receptor blockade results in increased depolarization and firing of formerly blocked receptors even with less concentrations of striatal dopamine
 - c. Striatal disinhibition of the thalamocortical pathway (increased excitability of glutamatergic VL neuronal projections to the cortex) from imbalance of D1 and D2 receptors
 - d. Neurodegeneration of striatal neurons from excitotoxic or lipid peroxidative mechanisms
 - e. Abnormalities of D3, D4, and D5 receptors
 - f. There is a possible genetic vulnerability to tardive dyskinesia as demonstrated by the polymorphisms of the D3 receptor gene. The glycine allele of DRD3 is associated with neuroleptic-induced TD compared to both heterozygous and serine homozygous patients
 - g. A possible relationship between TD and nicotine agonists has been suggested
 - h. Lower levels of brain derived neurotrophic factor (BDNF) have been found in schizophrenic patients with tardive dyskinesia

Laboratory Evaluation

1. MRI:
 - a. Neuroleptic-naïve patients with schizophrenia:
 - i. Enlargement of the ventricles
 - ii. Decreased thalamic volume and decreased cortical gray matter that vary
2. In patients with tardive dyskinesia:
 - a. The volume of the caudate nuclei is smaller
 - b. Other studies demonstrate:
 - i. Usual antipsychotic medication may cause an increase of volume of the caudate nucleus while atypical antipsychotics do not change caudate volume

Differential Diagnosis of Tardive Dyskinesia

1. Tardive dyskinesia (TD) usually follows the long term use of any neuroleptic medication:
 - a. Two years of continuous use
 - b. Some patients have developed the syndrome within 3 to 6 months of use
 - c. The most common causative medications are phenothiazine, butyrophenones and antiemetic drugs
2. Schizophrenic patients (drug naïve):
 - a. Stereotyped and repetitive movements
 - b. Complex involuntary hyperkinetic dyskinesia
 - c. Isolated tics
3. Orofacial dyskinesia in normal patients:
 - a. The elderly
 - b. Early dementia
4. Huntington's disease:

- a. Protrusion of the tongue abnormally
5. Wilson's disease
6. Withdrawal emergent dyskinesia:
 - a. Usually seen in children
 - b. Dyskinesia that occurs transiently after withdrawal of neuroleptics
7. Unilateral striatal lesions may cause bilateral oral buccal dyskinesia

Differential Diagnosis of Orofacial Dyskinesia

1. Drug-induced:
 - a. Levodopa (associated chorea)
 - b. Triphenyl hexedine (dry mouth)
 - c. Antihistamines (neck muscle dystonia)
 - d. Stelazine (most potent of all drugs causing dyskinesias by milligram)
 - e. Tricyclic antidepressants (those with a basic phenothiazine structure)
2. Huntington's disease:
 - a. Associated dementia and choreatic eye movements
3. Hepatocellular degeneration:
 - a. In a setting of chronic liver failure
 - b. Dysarthria
 - c. Falling backwards
4. Cerebellar infarction:
 - a. PICA infarction
 - b. "Salt and pepper" facial pain
5. Edentulous patients:
 - a. Multiple "rodent-like" mouthing movements
6. Dystonia:
 - a. Meige's syndrome:
 - i. Dramatic associated blepharospasm
 - ii. Tardive dystonia:
 1. Associated choreiform movements
7. Tics:
 - a. Associated complex stereotyped extremity movements
8. Tremor:
 - a. Up-down head tremor; prominent chin tremor (basal ganglia)
9. Essential tremor (ET):
 - a. Side to side head tremor
10. Cerebellar tremor of the neck and head:
 - a. Associated postural kinetic tremor of the body > extremity intention tremor
11. Myoclonus:
 - a. Facial musculature (restricted)
12. Hemifacial spasm:
 - a. Large facial fasciculations
 - b. "Risus sardonicus" branch of the VIIth nerve may be the first affected muscle
13. Myokymia:
 - a. Seen around the soft tissue of the eye (may not be noticed by the patient)
14. Facial nerve synkinesia:

- a. Jaw winking
 - b. The mentalis muscle is often the most severely affected
 - c. Patients acquire a deep nasolabial fold (contractive) with nerve regeneration
15. Bruxism:
- a. Associated TMJ joint disease with atrophic masseter muscles
16. Epilepsia partialis continua:
- a. Thumb involvement (twitching) at the same rhythm as eye blinking
 - b. Cortically induced nystagmus on the contralateral side

Levodopa-Induced Dyskinesia

General Characteristics

1. After 4 to 6 years of continuous levodopa use, the therapeutic window narrows and patients suffer motor fluctuations and levodopa-induced dyskinesias

Clinical Manifestations

1. Dyskinesia most commonly occurs at the time of peak levodopa plasma concentrations (peak dose dyskinesia)
2. Diphasic dyskinesia occurs in advanced patients when the drug concentrations rises or falls

Neuropathology

1. An imbalance between the “direct” and “indirect” pathways that regulate the cortico-striatal-thalamic motor loops has been postulated
2. Underactivity of the indirect pathway and overactivity of the direct pathway
3. LIDs have more recently been associated with:
 - a. Presynaptic increased levels of dopamine
 - b. Postsynaptic gene and protein modifications
 - c. Abnormal function of other non-dopamine transmitter systems
 - d. Altered firing patterns and coherence between the basal ganglia and the cortex that leads to disinhibition of the thalamocortical neurons (projecting from VL to the premotor, motor and prefrontal cortices)

Laboratory Evaluation

1. Transcranial magnetic stimulation (TMS)
2. Demonstrates the presence of altered cortical excitability
 - a. Repetitive TMS over the supplementary motor area (SMA), the primary motor cortex (MI) induces a transient reduction in LIDs
3. Peak dose dyskinesia has been modified with theta burst stimulation delivered bilaterally to the lateral cerebellum
 - a. May modify the maladaptive sensorimotor plasticity of the motor cortex

Akathisia

General Characteristics

1. Definition:

- a. A subjective and objective motor restlessness
- b. It is most often a side effect of drugs, most often antipsychotic serotonin reuptake inhibitors and buspirone; it has also been seen with antiemetics, preoperative sedatives, calcium channel blockers and drugs for vertigo

Clinical Manifestations

1. Complex stereotyped movements of the extremities and trunk
2. Shifting weight, crossing and uncrossing the legs, rocking back and forth
3. Vocalizations: moaning, humming or groaning
4. Acute akathisia occurs with initiation of the triggering medication
5. Chronic treatment (tardive akathisia is increased by drug withdrawal)
6. Movements are present throughout the day
7. A compulsion to move
8. Occurs during any physical dependence drug withdrawal
9. May be associated with both Parkinson's disease and related syndromes
10. A sense of disquiet or anxiety
11. Many patients suffer neuropathic pain symptomatology
12. Patients may pace for hours
13. Insomnia
14. Some suggest that restless leg syndrome may be a form of focal akathisia

Classification of Akathisia

1. Acute akathisia
 - a. Duration of symptomatology for less than six months
 - b. Development:
 - i. It is induced with administration of antipsychotic medication or with increase of its dosage
 - ii. The use of high potency antipsychotic medication
 - iii. Anticholinergic withdrawal
 - c. Severe dysphoria
 - d. Awareness of restlessness and the compulsion to move
 - e. Complex, stereotyped and semi-purposeful movements
2. Chronic akathisia:
 - a. Continues for longer than six months after last dosage modification
 - b. Less sense of restlessness
 - c. Less dysphoria
 - d. Awareness of the sense of restlessness and compulsion to move
 - e. Stereotyped movement
 - f. May be associated with limb and orofacial dyskinesia
3. Tardive akathisia:
 - a. Delayed onset of approximately three months
 - b. Not related to either drug switching or dose modification
 - c. Associated with tardive dyskinesia
4. Withdrawal akathisia:

- a. Associated with change of antipsychotic medication
- b. The onset is usually within six weeks of discontinuation or decreased dosage of the drug
- c. May occur from anticholinergic discontinuation
- 5. Pseudoakathisia:
 - a. Motor manifestations without a sense of restlessness
 - b. Male predominance
 - c. No dysphoria
 - d. An overlap with limb and orofacial dyskinesia

Neuropathology

- 1. A putative imbalance between the dopaminergic/cholinergic or the dopaminergic/serotonergic transmitter systems
- 2. Some evidence to support dysfunction of D2/D3 occupancy in the ventral striatum (nucleus accumbens and olfactory tubercle)
- 3. A mismatch between the core and shell of the nucleus accumbens due to overstimulation of the locus coeruleus

Laboratory Evaluation

- 1. MRI (3 patients)
 - a. Both restless leg syndrome and akathisia were described after pontine infarction

Differential Diagnosis of Akathisia

- 1. Dopamine antagonists
- 2. Neuroleptic treatment
- 3. Parkinsonism/Parkinson's disease
- 4. Post-encephalitic parkinsonism
- 5. Tourette syndrome
- 6. Huntington's disease
- 7. Obsessive compulsive disorders
- 8. Miryachit (jumping Frenchman of Quebec)
- 9. Tic disorders
- 10. Oromandibular dystonia

Ballismus

General Characteristics

- 1. Definition:
 - a. Repetitive and varying large amplitude involuntary movements of the proximal portion of the extremities; hemiballismus is the flailing movements on one side of the body

Clinical Manifestations

- 1. Rapid large amplitude flinging movements of an extremity
- 2. Proximal girdle muscles are primarily involved
- 3. The face is usually spared
- 4. Sudden onset
- 5. Patients may restrain their affected extremity (their arm is placed under the belt or tied down)
- 6. It is often associated with hemichorea particularly if there is a metabolic cause (hyperosmolar state)

- 7. It is exhausting for patients but ceases during sleep
- 8. May occur bilaterally
- 9. Arms and legs often move together
- 10. Movement increases the disorder and relaxation dampens the involuntary movements

Neuropathology

- 1. Most often there is destruction of $\frac{2}{3}$ of the corpus Luysi (subthalamic nucleus)
- 2. Hemiballismus from lesions in the subthalamic nucleus is more severe than lesions in other brain regions
- 3. Other brain areas that are associated with ballismus include:
 - a. The globus pallidus:
 - i. Decreased output from the globus pallidus (normally produces GABA-ergic inhibition of the VL of the thalamus)
 - ii. Decreased firing rates from 70/s to 40/s of the internal segment of GPi have been demonstrated
 - b. The putamen:
 - i. Projects to the premotor cortex through the globus pallidus
 - c. Caudate nucleus:
 - i. Specific lesions have caused hemiballismus
 - d. Cortical motor areas:
 - i. Lesions of the cortex have caused hemiballismus
 - e. The usual artery that is infarcted in hemiballismus is the thalamoperforate artery whose origin is the P1 segment of the posterior cerebral artery (PCA). Infarction of the anterior choroidal artery (carotid) and the interpeduncular artery from the top of the basilar may also be causative:
 - i. Hemiballismus from stroke is seen in approximately 45 patients per one hundred thousand stroke patients
 - ii. Stroke is the most common cause of hemiballismus

Laboratory Evaluation

- 1. MRI:
 - a. P1 lesions of the PCA that primarily compromise the territories of the thalamoperforate and interpeduncular arteries (top of the basilar)
 - b. Lesions from any cause that compromise the striato-thalamocortical motor loop

Differential Diagnosis of Hemiballismus

- 1. Vascular lesions of the thalamoperforate, interpeduncular or anterior choroidal arteries
- 2. Traumatic brain injury
- 3. Non-ketotic hyperglycemia:
 - a. The second most common cause of hemiballismus
 - b. Putative subthalamic (STN) involvement or its efferents
 - c. MRI lesions are most conspicuous in the putamen with lesser involvement of the globus pallidus and caudate nucleus

- d. The ballistic movements are seen with high blood glucose levels and subside with attainment of normoglycemia. This occurs over hours
- 4. Neoplasm
- 5. Vascular malformations
- 6. Tuberculoma
- 7. Demyelinating disease
- 8. HIV infection complications
 - a. Hypoglycemia from pentamidine treatment of AIDS
 - b. Cerebral toxoplasmosis
- 9. Parkinson's disease surgery
- 10. Levodopa

Athetosis

General Characteristics

- 1. Definition:
 - a. A slow writhing involuntary large amplitude movement that primarily involves the distal extremity muscles. Facial and axial muscles may be involved
 - b. The term athetoid syndrome has now been changed to "dyskinetic cerebral palsy" and comprises a non-progressive but evolving disorder with:
 - i. Damage to the basal ganglia of the full term brain
 - ii. Impairment of postural reflexes
 - iii. Arrhythmical involuntary movements and dysarthria
 - iv. Spared sensation ocular movements and intelligence

Clinical Manifestations of Athetosis

- 1. Associated episodic hypertonic muscle contraction of affected muscle groups
- 2. Abnormal distal writhing movements may be unilateral or bilateral
- 3. Often associated with facial grimacing and dysarthria
- 4. Mixed with chorea and dystonia
- 5. The writhing movements involve the hands, toes and feet in addition to the arms, legs, neck and tongue
- 6. Kernicterus is now used to describe the clinical features of chronic bilirubin encephalopathy and includes:
 - a. Striatal movement disorder
 - b. Sensorineural hearing loss
 - c. Impaired upward gaze
 - d. Dental enamel dysplasia
- 7. Pseudoathetosis:
 - a. "Finger playing" sinuous movements of the outstretched upper extremity fingers
 - b. Updrift of the outstretched upper extremities
 - c. Severe proprioceptive deficits

Neuropathology

- 1. Neonatal asphyxia:
 - a. The loss of neurons and astrogliosis primarily affects the caudate nucleus and the putamen

- b. Bilirubin-induced neurologic dysfunction (BIND):
 - i. The risk for developing neurological deficits increases with elevated serum/plasma concentration of unconjugated bilirubin
 - ii. The risk is compounded by disorders of bilirubin-binding to albumin caused by:
 - 1. Reduction in serum albumin concentration
 - 2. Bilirubin-binding capacity and albumin affinity
 - 3. Infection
 - 4. Displacing agents
 - iii. Kernicterus occurs when unconjugated bilirubin crosses the blood-brain barrier (immature in infants)
 - 1. Bilirubin prevents the phosphorylation of many proteins; decreased phosphorylation of synapsin 1 interferes with vesicle transport at the presynaptic terminal by inhibiting exocytosis
 - 2. Neuronal loss, gliosis and demyelination of the corpus striatum is particularly severe in the globus pallidus
 - 3. Thalamic stroke:
 - a. Primarily in the distribution of the thalamogeniculate artery and portions of the thalamic perforate artery territory. There is often associated sensory loss and ataxia

Laboratory Evaluation

- 1. MRI: (infants with kernicterus)
- 2. Globus pallidus demonstrates increased signal in T1 sequences and T2 hyperintensity evolves over time
- 3. The subthalamic nucleus may be involved (FLAIR sequences)
 - a. White matter abnormalities have been described

Differential Diagnosis of Athetosis

- 1. Congenital anoxia with bilateral damage of the globus pallidus, red nucleus, midbrain tegmentum and descending periventricular corticospinal pathways
- 2. Kernicterus
- 3. Wilson's disease
- 4. Stroke or tremor that involves the striatum and thalamus which spans the cortex
- 5. Severe recovered traumatic brain injury
- 6. Post-anoxia

Differential Diagnosis of Pseudoathetosis

- 1. Large fiber 20–22 μ m finger (proprioceptive and vibratory modality) loss
- 2. Large dorsal root ganglion cell loss:
 - a. Sjögren's syndrome
 - b. Cisplatin chemotherapy
 - c. Neurosyphilis (dorsal root entry zone lesion)
 - d. Paraneoplastic antibodies that affect the DPG
 - e. Autoimmune (Richter's variant of GBS)

- f. Dorsal column and nuclear lesions
 - i. If from posterior medullary artery infarction there may be large flinging movements of the arms
 - ii. Loss of vibratory and proprioceptive sense which may also occur from lesions in the thalamic VPL nucleus

Hemifacial Spasm

General Characteristics

1. Definition:
 - a. Brief irregular, clonic twitches that may build up to a sustained contraction of facial muscles that usually lasts for seconds, but may continue for minutes

Clinical Manifestations

1. Movements may begin around the eye and later spread to the lower facial muscles
2. Persists in sleep
3. Contractures are desynchronous
4. Approximately 15% of patients have bilateral involvement
5. The orbicularis oculi is most often affected first and then there is spread to the corrugator, frontalis, orbicularis oris, platysma and zygomaticus

Neuropathology

1. In the majority of patients primary hemifacial spasm (HFS) is caused by compression of the facial nerve at its root exit zone (REZ) by a branch of AICA or the 8cA

Laboratory Evaluation

1. MRI:
 - a. Demonstrates vascular loops (most often from AICA and rarely from the superior cerebellar artery)
 - b. Intraoperative stimulation of the nerve to demonstrate abnormal muscle responses (lateral spread) often simulating a facial nerve branch and its absence after successful microvessel decompression
 - c. Neurophysiologic techniques to monitor changes in nerve excitability intraoperatively include:
 - i. Facial F-wave
 - ii. Blink reflex
 - iii. Facial corticobulbar motor evoked potentials

Differential Diagnosis of Hemifacial spasm

1. Aberrant branch of AICA (or the artery itself) that intermittently compresses the VIIth nerve
2. This diagnosis is especially likely if the patient is aware of a postural trigger or if there is a position that decreases the spasm
3. Bell's palsy
4. Neoplasm of the cerebellopontine angle
5. Cranial dystonia
6. Tic

Restless Leg Syndrome (RLS)

General Characteristics

1. Possibly 5–10% of the USA population suffers restless leg syndrome; moderate to severe RLS may affect up to 2–3% of adults; childhood restless leg syndrome occurs
2. The incidence is approximately 2× higher in women

Clinical Manifestations

1. Onset is usually middle age or older
2. Symptoms become more frequent and last longer with age
3. Patients feel uncomfortable sensations in their legs particularly when sitting or lying down
4. The abnormal sensations are accompanied by an irresistible drive to move the affected extremity. Rarely, the abnormal sensations can affect the arms, trunk and head
5. Patients may constantly move the affected extremity to prevent the sensations
6. Symptoms are worse at night; there may be a symptom free period in the early morning
7. Triggering events include:
 - a. Long car trips
 - b. Sitting for prolonged periods
 - c. Long distance flights
 - d. Immobilization in a cast
 - e. Sleep deprivation
8. The frequency of attacks varies widely among individuals but in severe patients occurs more than twice a week

Neuropathology

1. The most consistent neurophysiological finding is reduction in short interval intracortical inhibition
2. Resting motor threshold, active motor threshold, amplitude of motor-evoked potentials are typically normal
3. Conflicting results have been reported for short-interval intracortical facilitation and the contralateral silent period
4. RLS after stroke that involves the pyramidal tract and basal ganglia brainstem connections have been reported
5. Associated conditions:
 - a. Dysfunction of corticostriatal thalamic motor circuits that are dependent on dopamine
 - b. Iron deficiency
 - c. Parkinson's disease
 - d. 80% of patients have periodic limb movements of sleep that is characterized by:
 - i. Involuntary twitching or jerking movements during sleep
 - ii. May occur every 15 to 40 seconds (rarely throughout the night)
 - iii. Cause awakenings and severe disruption of sleep
 - iv. Most patients with PLMS do not have RLS
 - e. Kidney failure, diabetes and peripheral neuropathy
- f. Medications:
 - i. Prochlorperazine and metoclopramide (antipsychotics)

- ii. Haloperidol and phenothiazine derivatives (antipsychosis drugs)
- iii. Antidepressants that increase serotonin
- iv. Antihistamines
- g. Pregnancy
 - i. Primarily in the last trimester; usually ceases within 4 weeks of delivery

Laboratory Evaluation

1. Blood tests to detect iron deficiency, diabetes and vitamin deficiency and other causes of peripheral neuropathy
2. Polysomnography to evaluate for sleep apnea and PLMS
3. Transcranial magnetic stimulation for evaluation of motor cortical excitability (experimental and not validated)

Dystonia

General Characteristics

1. Definition
 - a. Slow, sustained involuntary movements and postures that involve both axial and proximal muscles

Clinical Manifestations

1. Slow and axial movements (athetosis/dystonia)
2. Superimposed involuntary jerks (myoclonic dystonia)
3. Dystonic postures:
 - a. Torticollis and tortipelvis
 - b. Scoliosis and lordosis
 - c. Dropped, inverted and plantar flexed foot
 - d. Dystonic tremor:
 - i. Fast distal tremulous movements
4. Excessive contraction of antagonist muscles during a voluntary movement
5. Spreading of contractions of muscles that are not needed for a specific movement
6. Spontaneous contraction of agonist and antagonist muscles
7. Distribution:
 - a. Generalized
 - b. Segmental (two contiguous areas)
 - c. Focal (one extremity or motor group)
 - d. Multifocal (two or more body parts)
8. Generalized dystonia is most often seen in young patients
9. Focal and segmental dystonia occurs in middle age to older patients
10. The muscle groups most frequently affected are:
 - a. Orbicularis oculi
 - b. Forearm flexors
 - c. Wrist flexors
 - d. Inverters of the foot
 - e. Sternocleidomastoid
11. Specific movements are repetitive
12. Sensory tricks to inhibit or dampen the involuntary movements
 - a. Finger to the eye to block blepharospasm

- b. Finger to the forehead to block torticollis
13. Action dystonia:
 - a. Early in the course of the disorder only the muscles that are used for a movement are affected
 - b. Over time dystonia spreads to other non-used groups of muscles
 - c. The abnormal movements are exacerbated by specific activities

Neuropathology

1. Autopsies of patients with DYT1 (GAG deletions) and those without GAG deletions demonstrated:
 - a. Larger and more compacted pigmented neurons in the substantia nigra of both forms
 - b. Smaller substantia nigra neurons have been described in Lesch-Nyhan syndrome patients with dystonia
 - c. A detailed morphometric study of 13 patients' substantia nigra who suffered various dystonia subtypes revealed:
 - i. Decreased pigmented SNpc neurons versus controls
 - ii. No volumetric changes in the cell body and nuclear or nucleolar structures
 - iii. In the majority of patients tau lesions were sparse
 - iv. It has been postulated that the reduced number of pigmented neurons represents a neurodevelopmental defect. It has been pointed out that other non-dopaminergic circuits and transmitter systems such as those utilizing acetylcholine or GABA may be involved
 - v. The somatopic neuronal organization and transmitter complexity may affect specific subregions of the SNpc that may be reflected clinically (segmental involvement)
 - vi. Rare patients have demonstrated neuronal loss in the dorsal caudate nucleus and putamen; two of the patients suffered Lubag or linked recessive dystonia-parkinsonism
 - vii. Brains from patients with spasmodic torticollis and Meige's syndrome (cranial dystonia) were normal; 2 brains from patients with Meige's have demonstrated SNpc degeneration (1 patient) and one patient had brainstem angioma
 - viii. Hemidystonia patients demonstrate:
 1. Lesions in the contralateral hemisphere that affect:
 - a. The caudate nucleus
 - b. The putamen and in some patients both the putamen and the globus pallidus or thalamus
 - ix. A possible bioamine dysfunction in dystonia has been suggested
 - x. Neurophysiological dysfunction within the corticostriato-pallido-thalamic and cerebello-thalamo-cortical loops are primarily involved in dystonia

Laboratory Evaluation

1. MRI:
 - a. Lesions of the contralateral cortex, striatum and thalamus have been identified in both focal and hemidystonia
 - b. Magnetic resonance diffusion imaging in genetic forms has demonstrated:
 - i. Reduced fractional anisotropy (FA) in white matter areas adjacent to the sensorimotor cortex and in the dorsal pons
 - ii. Reduced connectivity in cerebellar projections to the ventral thalamus in both affected and carrier dystonic patients
2. PET analysis reveals:
 - a. Abnormal disease related metabolic patterns in both clinically manifesting and non-manifesting carriers
3. Neurophysiological Evaluation:
 - a. EMG studies
 - i. Phasic bursts that predominate in antagonist muscles during movement
 - ii. Voluntary effort does not modulate involuntary activity of affected muscles; it precipitates contraction of neighboring segmental musculature ("overflow phenomenon") seen in action dystonia
 - iii. Activation of passively shortened muscles (a possible exaggeration of the shortening reflex)
 - iv. An abnormality of Ia inhibitory interneurons in the spinal cord that causes simultaneous contraction of antagonistic muscles
 - v. Hyperactivity of brainstem interneurons in patients with blepharospasm is demonstrated by:
 1. Increased amplitude and duration of the R2 component of the blink reflex
 2. Increased blink reflex recovery time in patients with blepharospasm
 3. Altered vagal reflexes in patients with spasmodic dysphonia
 4. Failure of exteroceptive suppression of cervical motor neurons in patients with spasmodic torticollis
 5. A generalized failure of reciprocal and inhibitory modulation of motor activity
 6. Serum and blood analysis for secondary causes of dystonia due to diseases with known or presumed metabolic defects

Differential Diagnosis of Primary Dystonias

1. At present there are 20 distinct primary dystonias 1–4, 5a, b, 6–8, 10–13 and 15–18
2. Loci are DYT1–4, 5a, b, 6–8, 15–18
3. DYT9, DYT19 and DYT20 map to regions in close proximity to known loci of DYT8, DYT10 and DYT18
4. There are 12 autosomal dominant, four autosomal recessive and 1 linked with recessive inheritance forms of dystonia

5. This group of movement disorders comprises pure dystonias and dystonia plus syndromes as well as paroxysmal dystonias
6. Pure dystonias may have tremor
7. Dystonia plus syndromes:
 - a. Dystonia is the primary sign
 - b. May have concurrent myoclonus and parkinsonism
8. In some dyskinesias, dystonia may occur as a paroxysmal sign and may be associated with other movement abnormalities and rarely seizures
9. The disease genes of autosomal dominant dystonias include:
 - a. DYT1-gene (TOR1A)
 - b. DYT5a (GCH1)
 - c. DYT6 (THAP1)
 - d. DYT8 (PNKD1/MRI)
 - e. DYT11 (SGCE)
 - f. DYT12 (ATPIA 3)
 - g. DYT18 (SLC 2)
10. The disease genes of autosomal recessive dystonias are:
 - a. DYT5 (TH)
 - b. DYT16 (PRKRA)
11. One chromosomal recessive form:
 - a. DYT3 (TAF1)

DYT1*General Characteristics*

1. Torsion dystonia 1 is caused by heterozygous mutation in the TOR1A gene that maps to chromosome 9q34.11; AD inheritance
 - a. Encodes the ATP-binding protein torsin-A

Clinical Manifestations

1. DYT1 is an early onset primary dystonia with onset in childhood or adolescence; very rarely in adulthood
2. Older age of onset may occur among relatives of affected individuals; late onset family members may have arm dystonia manifested as writer's cramp
3. Dystonia usually has its onset in a leg (average is 9 years); if it starts in the arm the average age is 15 years
4. Foot inversion or eversion, abnormal flexion of the knee or hip
5. Difficulty with writing
6. Rarely the onset is in the neck or a cranial muscle
7. If onset is in the leg, the dystonia progresses over years, becomes less action-specific and can occur at rest
8. The dystonia spreads to the other body regions including the trunk
9. In patients whose dystonia started in an arm, progression is more variable and generalizes in approximately 50% of patients
10. Patients with onset in the neck or a cranial muscle may have variable progression
11. Variable features:

- a. 20% of DYT1 patients have dystonia of only 1 body region (usually writer's cramp)
- b. Cranial muscles are involved in 11–18% of patients
- c. Early onset brachial dystonia
- d. Isolated blepharospasm
- e. Fluctuating unilateral myoclonic dystonia
- f. Asian patients have segmental dystonia with more frequent onset of axial dystonia as compared to Caucasians
- g. Pain is uncommon in DYT1 except with torticollis
- h. Increased rate of major depression
- i. The vast majority of patients have onset prior to 26 years of age

Neuropathology (Few Autopsies)

1. Larger dopaminergic neurons
2. 4 brains have demonstrated perinuclear inclusion bodies in the midbrain reticular formation and periaqueductal gray

Laboratory Evaluation

1. MRI:
 - a. Diffusion tensor imaging (DTI):
 - i. Microstructural abnormalities of the subcortical white matter of the sensorimotor cortex and the dorsal pons (region of the superior cerebellar peduncle) suggestive of dysfunction of the cerebello-thalamocortical motor circuitry
 - b. PET evaluation: Decreased striatal D2 receptor binding
2. Differential Diagnosis of DYT1
 - a. Dopa-responsive dystonia (GCH1)
 - b. DYT6 (THAP1)
 - c. DYT25 (GNAL)
 - d. Dramatic improvement with levodopa administration is most suggestive of dopa-responsive dystonia from heterozygous mutation of the GCH1 gene which codes cyclohydrolase 1; early onset dystonia that is also responsive to levodopa is juvenile-onset Parkinson's disease from mutation of PARK2 which encodes parkin
 - e. Genetic disorders in which dystonia is prominent include:
 - i. Wilson's disease
 - ii. Huntington's disease
 - iii. Some spinocerebellar ataxias
 - iv. Rapid-onset dystonia parkinsonism
 - v. Pantothenate kinase deficiency
 - f. Acquired dystonia that includes:
 - i. Neuroleptic exposure
 - ii. Dopamine blocking agents (tardive dystonia)
 - iii. Perinatal stroke
 - iv. Traumatic brain injury
 - v. Encephalitis
 - vi. Clinical features against a diagnosis of DYT:
 1. Onset in adulthood (>40 years of age)
 2. Isolated focal or segmental cervical-cranial dystonia that includes:

- a. Spasmodic torticollis
- b. Spasmodic dysphonia
- c. Blepharospasm
- d. Oromandibular dystonia

DYT5a

General Characteristics

1. DYT5a also known as Segawa syndrome or hereditary progressive dystonia with marked diurnal fluctuation
2. Caused by mutations in the GCH1 gene that maps to chromosome 14q22¹-q22.2 that encodes the enzyme GTP cyclohydrolase 1 (GTPCH1)

Clinical Manifestations

1. Onset occurs in childhood (the average age is 6)
2. Females are 2–4 times more frequently affected than males
3. Most often onset is with equinovarus posture of the foot that disturbs gait
4. Diurnal fluctuations; symptoms are worse in the evening and improve with sleep
5. Exercise aggravates symptoms
6. Variable features:
 - a. Arm dystonia
 - b. Postural tremor of the hands
 - c. Bradykinesia
 - d. Cervical dystonia
 - e. Brisk reflexes
 - f. Striatal toe
 - g. The disorder progresses to generalized dystonia
 - h. Patients with onset in adolescence or adulthood may develop parkinsonism (bradykinesia, rigidity and postural tremor)
7. Patients with late onset may have a milder phenotype
8. Rarely patients develop depression, anxiety, sleep disruption and obsessive-compulsive disorder
9. Dramatic response to levodopa therapy

Neuropathology

1. GTP cyclohydrolase 1 (GTPCH1) is essential in the biosynthesis of tetrahydrobiopterin which is the essential cofactor for tyrosine hydroxylase, the rate-limiting enzyme in the biosynthesis of dopamine

Laboratory Evaluation

1. Decreased levels of biopterin and neopterin are found in the CSF

GTPCH1

1. Reduced GTPCH1 activity in blood cells can be demonstrated

Differential Diagnosis

1. Autosomal recessive DRD
2. Early onset torsion dystonia
3. Myoclonic dystonia

4. Hyperphenylalaninemia
5. Spastic paraplegia
6. Young adult-onset Parkinsonism

DYT6*General Characteristics*

1. DYT6 is autosomal dominant and is caused by heterozygous mutation in the THAP1 gene that maps to chromosome 8p11

Clinical Manifestations

1. Described in Mennonite families
2. Approximately 50% of patients present with cranial or cervical involvement
3. The mean age at onset in one kindred was 16 years of age
4. Dystonia may start in an arm
5. Many patients may have first symptoms in the larynx, tongue, facial muscles, or the neck
6. Most patients have some degree of progression to other body regions

Neuropathology

1. Missense, nonsense and frameshift mutations have been reported in all three exons of the gene
2. THAP1 binds to the core promoter of Torsin A and represses its expression
3. The function of the protein is unknown

Laboratory Evaluation

1. PET:
 - a. Bilateral hypermetabolism in the presupplementary motor cortex and parietal association cortices
 - b. Hypometabolism in the putamen and hypermetabolism in the temporal cortex
 - c. Decreased availability of DRD2 in the caudate and putamen. There was no difference between manifesting and non-manifesting mutation carriers
 - d. Voxel-based analysis demonstrated that the lateral putamen and right ventrolateral thalamus are primarily affected

DYT8 (Paroxysmal Non-Kinesigenic Dyskinesia 1)*General Characteristics*

1. DYT1 (Mount-Reback disease) is caused by heterozygous mutation in the myofibrillogenesis regulator-1 gene that maps to chromosome 2q35

Clinical Manifestations

1. Mount-Reback disease has autosomal dominant inheritance
2. Symptom onset is in early childhood in many kindreds
3. Attacks of paroxysmal choreoathetosis that last a few minutes, occur several times per day and are not associated with altered mental status
4. Alcohol, coffee, hunger, fatigue and tobacco are triggering factors for attacks

5. Patients with MR1 mutations have a homogeneous phenotype with earlier onset than those that do not carry the mutation
6. Premonitory sensations (focally in the limbs) are reported in approximately 40% of mutation carriers
7. Lessened during pregnancy
8. Patients without MR1 mutations differed from mutation carriers by:
 - a. Exercise as a precipitating factor
 - b. Alcohol is not precipitant
 - c. Ballismus (18%)
 - d. Seizures (23%)

Neuropathology

1. Putative function in a pathway to detoxify methylglyoxal which is present in coffee and alcoholic drinks and is also a byproduct of oxidative stress

Laboratory Evaluation

1. MRI:
 - a. Normal

DYT11 (Myoclonic Dystonia Syndrome)*General Characteristics*

1. DYT11 is caused by heterozygous mutation in the epsilon-sarcoglycan gene (SGCE) that maps to chromosome 7q21; it is autosomal dominant in inheritance

Clinical Manifestations

1. The onset is variable but may start in early childhood
2. Myoclonic jerks of proximal muscles
3. Dystonia is manifest by torticollis or writer's cramp in most kindreds; it may be the only manifestation of the disorder
4. Psychiatric disorders occur in some kindreds as does cognitive impairment
5. Symptoms are alcohol responsive
6. Tremor and jerky movements may occur in association with head, neck and arm myoclonus
7. Variable features:
 - a. Usually the myoclonus is triggered by complex motor tasks, it is rarely seen at rest
 - b. Rarely the legs and larynx can be affected
 - c. Isolated torticollis

Neuropathology

1. The only causative gene is the epsilon-sarcoglycan (SGCE) that encodes a transmembrane protein which is part of the dystrophin-associated glycoprotein complex of skeletal and cardiac muscles
2. The epsilon-sarcoglycan protein is also expressed in monoaminergic neurons, Purkinje cells, hippocampus and cortex. Its function in these areas is unknown

Laboratory Evaluation

1. MRI:

- a. Negative
- b. Genetic molecular testing confirms the diagnosis

DYT12*General Characteristics*

1. Rapid-onset dystonia-parkinsonism is caused by heterozygous mutation in the ATP1A3 gene that maps to chromosome 19q13.2
2. It encodes the alpha-3 subunit of the NaK-ATPase
3. Heterozygous mutations of the gene also cause:
 - a. Alternating hemiplegia of childhood
 - b. CAPOS syndrome
4. Inheritance is autosomal dominant

Clinical Manifestations

1. The onset is in childhood or early adulthood (range from 4–58 years)
2. Abrupt onset of dystonia and Parkinsonism (bradykinesia and postural instability)
3. A rostrocaudal gradient:
 - a. Dysarthria and dysphagia
4. Symptoms may progress over several minutes to up to 30 days and then stabilize
5. Onset may be triggered by exertion, fever, extreme heat, childbirth, excessive alcohol or stress
6. Some patients note upper limb dystonia (primarily in the hands) and cramping prior to disease onset
7. Most patients stabilize but a few suffer a second episode of clinical deterioration 1–9 years following the initial onset
8. Variable features:
 - a. Seizures
 - b. Anxiety and depression
9. Variant phenotype in infants with:
 - a. <4 years of age
 - b. Episodic hypotonia
 - c. Gait ataxia
 - d. Motor delay
 - e. Speech and swallowing dysfunction

Neuropathology

1. Several missense mutations in the sodium/potassium-transporting ATPase subunit alpha-3 protein are causative
2. The protein is essential for maintaining the electrochemical gradients of potassium and sodium across the plasma membrane

Laboratory Evaluation

1. Low homovanillic acid concentration in the CSF
2. Normal brain imaging
3. PET and SPECT demonstrate normal dopamine reuptake in dopamine transporters

DYT18*General Characteristics*

1. GLUT1 deficiency syndrome-2 (GLUT1DS2) or dystonia-

18 is caused by heterozygous mutation of the SLC2A1 gene that maps to chromosome 1p34

2. Allelic disorders include:
 - a. GLUT1 deficiency syndrome-1
 - b. Dystonia 9
 - c. Idiopathic generalized epilepsy 12
3. Inheritance is autosomal dominant

Clinical Manifestations

1. Childhood onset
2. Transient paroxysmal exercise-induced dyskinesia that includes:
 - a. Dystonia
 - b. Choreoathetosis
 - c. Affects the exercised limbs
3. Some patients have seizures, the most common of which is childhood absence epilepsy
4. Variable features:
 - a. Cognitive impairment
 - b. Hemolytic anemia (one family)
 - c. Fasting, stress, vibration may also precipitate attacks
 - d. Involuntary flexing and extending movements that alternate with athetotic twisting movements
 - e. Migraine
 - f. Abnormal head and eye movements
 - g. In one kindred seizure types include:
 - i. Absence (64%)
 - ii. GTCS without focal onset (50%)
 - iii. Complex and simple partial seizures (14%)
 - h. PED and epilepsy may improve with age in some patients
 - i. Hand tremor was documented in one family (action tremor)
 - j. A 3 generation family with exertion-induced dystonia, choreoathetosis and ballistic movements with a monocytic hemolytic anemia
 - k. Some patients improve with the ketogenic diet

Neuropathology

1. Decreased CSF glucose metabolism in corticostriate pathways from a defect in the GLUT1 glucose transporter

Laboratory Evaluation

1. Decreased CSF glucose concentration
2. Decreased glucose uptake into erythrocytes
3. EEG:
 - a. Findings are variable but include synchronous and hypersynchronous spike-wave complexes, sharp waves and rhythmic theta- and delta-activity

Other Autosomal Dominant Dystonias*DYT7 (Adult Onset Focal Primary)*

1. AD that maps to chromosome 18pter-p11.32
2. Clinical manifestations:
 - a. Adult onset of focal dystonias that include cervical dystonia, writer's cramp, dysphonia, or blepharospasm

DYT8 (Paroxysmal Non-Kinesigenic Dyskinesia)

1. Autosomal dominant that maps to chromosome 2q34
2. Clinical manifestations:
 - a. Attacks of dystonia that are precipitated by stress, fatigue, alcohol and chocolate

DYT9 (Paroxysmal Choreoathetosis with Spasticity)

1. Autosomal dominant with a locus that maps to 1p34-p22
2. Clinical manifestations:
 - a. Attacks of dystonia, episodic ataxia and paresthesias
 - b. Double vision
 - c. Attacks are precipitated by exercise, stress and chocolate
 - d. Patients demonstrate spastic paraplegia between attacks

DYT10 (Paroxysmal Kinesigenic Dyskinesia)

1. Autosomal dominant locus that maps to chromosome 16p11.2-q12.1
2. Clinical manifestations:
 - a. Dystonic attacks precipitated by sudden movement
 - b. Paroxysmal kinesigenic choreoathetosis

DYT13

1. Autosomal dominant; locus that maps to chromosome 1p36.32-p36.12.13
2. Clinical manifestations:
 - a. Early and late onset
 - b. Focal or onset in cranial cervical distribution
 - c. A focal or segmental dystonia most often in the upper limbs
 - d. Mild course

DYT14

1. Autosomal dominant locus that maps to chromosome 14q13
2. Clinical manifestations:
 - a. Early onset with gait and postural signs
 - b. Generalized dystonia
 - c. Later in disease course parkinsonism

DYT15

1. Autosomal dominant with the locus mapping to chromosome 18p11
2. Clinical manifestations:
 - a. Onset in the first or second decade with jerky movements (myoclonus) of the upper limbs, hands and axial muscles
 - b. Alcohol responsive
 - c. Dystonia of the upper limbs primarily
 - d. Incomplete penetrance

DYT20

1. Autosomal dominant that maps to chromosome 2q31
2. Clinical manifestations:

- a. Paroxysmal non-kinesigenic dyskinesia 2
- b. Attacks of involuntary movement and dystonia that occur spontaneously at rest
- c. Attacks may be precipitated by caffeine, alcohol and stress
- d. Attacks last from minutes to hours and can occur several times/day

DYT21

1. Autosomal dominant
2. Maps to chromosome 2q14.3-q21.3
3. Clinical manifestations:
 - a. Adult onset generalized or multifocal dystonia
 - b. May start as blepharospasm

DYT23

1. DYT23 is caused by heterozygous mutation in the CACNA1B gene that maps to chromosome 9q34; inheritance is autosomal dominant
2. Clinical manifestations:
 - a. Adult onset dystonia usually during the fourth and fifth decades
 - b. Torticollis and hypertrophy of the sternocleidomastoid muscles
 - c. Head and limb tremor
 - d. Cervical dystonia
 - e. Dutch kindred (3-generation):
 - i. Writer's cramp, dysphonia, torticollis
 - ii. Generalized myoclonus (2 patients)
 - iii. Other patients with myoclonus of the voice, face, trunk or limbs
 - iv. Variable features included panic attacks and hyperventilation syndrome

DYT24

1. DYT24 is caused by heterozygous mutation in the ANO3 gene that maps to chromosome 11p14
2. Clinical manifestations:
 - a. Adult onset of dystonia
 - b. Focal dystonia that affects the neck, laryngeal muscles as well as muscles of the upper extremities
 - c. Mean age of onset is 29 (range of 19 to 40 years)
 - d. Variable features:
 - i. Blepharospasm
 - ii. Voice tremor
 - iii. Head and arm tremor
 - iv. Writing tremor
 - v. Dystonic arm posturing

DYT25

1. DYT25 is caused by heterozygous mutation in the GNAL gene that maps to chromosome 18p11
2. Clinical manifestations:
 - a. Adult onset
 - b. Focal dystonia is initially in the neck

- c. The dystonia progresses to involve the face and laryngeal muscles and less often axial and extremity musculature

Autosomal Recessive Dystonia

DYT5b

General Characteristics

1. DYT5b is caused by mutations in the tyrosine hydroxylase (TH) gene that maps to chromosome 11p15.5
2. Inheritance is autosomal recessive

Clinical Manifestations

1. The clinical phenotypes comprise:
 - a. TH-deficient dopa-responsive dystonia (DRD)
 - b. TH-deficient infantile Parkinsonism with motor delay
 - c. TH-deficient progressive infantile encephalopathy (the very severe form)
2. TH-deficient DRD:
 - a. Onset is between 12 months and six years
 - b. Initial symptoms are lower-limb dystonia with an abnormal gait and difficulty walking
 - c. Diurnal fluctuation with worsening symptoms in the evening and sleep benefit
 - d. Psychomotor development is normal
 - e. Gradual progression to generalized dystonia
 - f. Some patients demonstrate bradykinesia and primarily postural tremor
 - g. Rigidity in affected extremities
 - h. Postural instability
 - i. Some patients demonstrate pyramidal signs with:
 - i. Hyperreflexia
 - ii. Extensor plantar response
 - iii. Spasticity
 - j. Rare oculogyric crisis
 - k. Excellent response to levodopa therapy

Neuropathology

1. No autopsies have been reported
2. Tyrosine hydroxylase is the rate-limiting enzyme for catalyzing the conversion of L-tyrosine to L-dopa, the precursor of dopamine
3. There is a suggestion that mutations in the promoter region may be associated with a milder phenotype

Laboratory Evaluation

1. Brain MRI is normal in DRD
2. In patients with progressive infantile encephalopathy there may be mild to moderate cerebral and/or cerebellar atrophy
3. CSF pattern:
 - a. Reduced homovanillic acid (HVA)
 - b. Normal 5-hydroxyindoleacetic acid (5-HIAA)

- c. Reduced HVA/5-HIAA ratio
- d. Reduced 3-methoxy-4 hydroxy-phenylethyleneglycol (MHPG)
- e. Normal total biopterin (BP) primarily tetrahydrobiopterin (BH4)
- f. Normal total neopterin (NP)
4. Molecular genetic testing of the coding region and the cAMP response element region

Differential Diagnosis of Tyrosine Hydroxylase (TH) Deficiency

1. GTP cyclohydrolase 1-deficient dopa-responsive dystonia (GTPCH1-deficient DRD)
2. Autosomal recessive sepiapterin reductase (SR-deficient DRD)
3. Early-onset primary dystonia
4. Early-onset Parkinsonism
5. Cerebral palsy
6. Spastic paraplegia
7. Primary and secondary deficiencies of CSF neurotransmitter metabolites

DYT16

General Characteristics

1. DYT16 is caused by homozygous mutation in the PRKRA gene that maps to chromosome 2q31.2
2. It encodes the protein kinase interferon-inducible double-stranded RNA-dependent activator

Clinical Manifestations

1. Childhood onset
2. Early signs are gait abnormalities and leg pain
3. Dysphagia and laryngeal dystonia
4. Spasmodic dysphonia
5. Torticollis
6. Upper limb dystonia
7. Orofacial dystonia
8. Speech and language impairment
9. Some patients have mild Parkinsonism

Neuropathology

1. PACT is a stress-modulated activator of interferon-induced double-stranded RNA-activated protein kinase (PKR)
2. PKR activation induces the phosphorylation of translation initiation factor eIF2alpha inhibition of protein synthesis and apoptosis
3. It is hypothesized that altered activation of PKR enhances apoptosis in dystonia cells that cause a mutation in the PKR activator protein PACT
4. Homozygous missense mutation P222L in PACT (the activator of PKR) that leads to dysfunction of the endoplasmic reticulum stress response

Laboratory Evaluation

1. Molecular genetic testing

X-Chromosome Recessive Dystonia**DYT3***General Characteristics*

1. DYT3 ("Lubag") is caused by a retrotransposon insertion in an intron of the TATA-binding protein-associated factor-1 gene TAF1 that maps to chromosome Xq13.1
2. Primarily found in the Philippine Island of Panay

Clinical Manifestations

1. The mean age of onset is early adulthood (average age of onset is the late 30s); range 12–56 years
2. Generalized dystonia occurs approximately 7 years after onset
3. Parkinsonism may occur concomitantly or precede dystonia
4. Manifestations may begin in the head and neck
5. In a large kindred Parkinsonism was reported early in approximately 1/3 of patients
6. Approximately 50% of female carriers are symptomatic; the average age of affected women is 52 years. It has been suggested that extreme X-inactivation is the cause of the disorder in women carriers

Neuropathology

1. Post-mortem evaluation in 7 male patients revealed:
 - a. Patients with dystonia demonstrated patchy areas of preserved neurons in the striosome and relative sparing of the matrix
 - b. Parkinsonian patients had:
 - i. Severe depletion of the striosomal and matrix-based pathways
 - c. Goto hypothesized that early stage disease is dominated by loss of striosomal GABA-ergic projection neurons and disinhibition of nigral dopaminergic neurons causing the hyperkinetic symptomatology. In later stages, Parkinsonism predominates; there may be greater involvement of the matrix-based projection system
 - d. Some transcripts of DYT3 may regulate the INXG and C154 genes on the opposite strand of DYT3. Mutation in DYT3 may interfere with this regulation
 - e. Atrophy of the caudate nucleus and the putamen with mild to severe neuronal loss and gliosis
 - f. Genetic sequencing of the critical region of Xq13.1 reveals:
 - i. SVA (short interspersed nuclear element, variable number of tandem repeats and Alu composite) retrotransposon insertion in an intron of the TAF1 gene
 - ii. This mutation may reduce neuron expression of the TAAF1 isoform in the caudate nucleus and interfere with transcription of many genes including those that code for the dopamine 2 receptor
 - iii. An abnormal pattern of DNA methylation in the retrotransposon of the genome from a patient's caudate that has been hypothesized to cause decreased expression of TAF1

Laboratory Evaluation

1. Molecular genetic sequencing

Differential Diagnosis of Primary Dystonia

1. Isolated dystonia (with dystonic tremor):
 - a. DYT1 (TOR1A)
 - b. DYT4 (TUBB4)
 - c. DYT6 (THAP1)
 - d. DYT16 (PRKRA)
 - e. DYT23 (C1Z1)
 - f. DYT24 (AN03)
 - g. DYT25 (GNAL)
2. Combined dystonias with parkinsonism or myoclonus:
 - a. Persistent:
 - i. DYT5 (GCH1)
 - ii. DYT11 (SGCE)
 - iii. DYT12 (ATP1A3)
 - iv. DYT3 (TAF1)
3. Paroxysmal:
 - a. DYT8 (PNKD)
 - b. DYT10 (PRRT2)
 - c. DYT18 (SLC2A1)

Secondary Dystonia*The Requirements of the Diagnosis of Primary Dystonia*

1. Isolated dystonic movements and postures without other neurologic abnormalities (may have dystonic tremor)
2. Normal perinatal and early developmental history
3. No exposure to drugs that cause dystonia
4. The medical and neurological examination and laboratory evaluation should not be linked to any etiology of dystonias
5. Abnormally rapid progression, sudden onset, hemidystonia or generalization in an adult favors a secondary cause
6. The diagnosis of secondary dystonia is made if there is deviation from the requirements of primary dystonia

Differential Diagnosis of Dystonia with a Known Metabolic Defect

1. Wilson's disease:
 - a. Kayser-Fleischer ring
 - b. Tremor, dysarthria, clumsiness of the hands and psychiatric disorder
 - c. Dystonia is a late manifestation
2. Variant of GM1 gangliosidosis:
 - a. AR GLB1 gene that maps to chromosome 3p22.3
 - b. Dystonia, upper motor neuron signs and symptoms, rigidity and ataxia
 - c. Corneal clouding
 - d. Dystonia may begin in adulthood and be restricted to a focal or segmental region
3. GM2 gangliosidosis

4. Lesch-Nyhan syndrome
5. Homocystinuria
6. Glutamic acidemia type I
7. Metachromatic leukodystrophy
8. Methylmalonic acidemia
9. Triosephosphate isomerase deficiency

Differential Diagnosis of Dystonia with Known Disorders

1. Pantothenate kinase deficiency
2. Calcification of the basal ganglia
3. Bilateral necrosis of the basal ganglia (mitochondrial cytopathy)
4. Ataxia telangiectasia
5. Neuronal ceroid lipofuscinosis
6. Neuroacanthocytosis
7. Ferritinopathy
8. Aceruloplasminemia
9. Hartnup's disease
10. Dystonic lipidosis (Niemann-Pick disease)
11. Neuronal intranuclear inclusion disease

Differential Manifestations of Disorders with Dystonia

1. Pantothenate kinase deficiency:
 - a. In approximately 25% of patients, it is the presenting feature
2. Calcification of the basal ganglia:
 - a. Disordered calcium metabolism (hypoparathyroidism and pseudohypoparathyroidism)
 - b. HIV in children
 - c. May be autosomal dominant or recessive
 - d. Dystonia is seen in combination with cognitive impairment and psychiatric disorders, seizures, spasticity, ataxia, Parkinsonism and chorea
3. Bilateral causes of striatum and/or globus pallidus necrosis:
 - a. Wilson's disease
 - b. Leigh's disease
 - c. Mitochondrial cytopathy (cytochrome oxidase deficiency)
 - d. Dystonia with striatal lucency and optic neuropathy
 - e. Hanging with survival (most often globus pallidus necrosis)
 - f. Carbon monoxide (severe globus pallidus involvement)
 - g. Cyanide poisoning, prolonged hypotension and anoxia:
 - i. Associated cortical (layer III–V) necrosis
 - ii. Purkinje cell damage
 - iii. Vth nerve nuclear involvement
 - iv. Renshaw spinal cord cell damage
 - h. Hemolytic uremia syndrome
 - i. Sickle cell disease (associated large and small vessel strokes)
 - j. Infantile striatal necrosis (following a febrile illness)

- k. Methylmalonic acidemia
 - l. Wasp sting encephalopathy
- m. Methanol (concurrent severe hemorrhagic optic neuropathy)
- n. Carbon disulphide
- o. Disulfiram intoxication

Differential Diagnosis of Dystonia in Neurodegenerative Diseases

1. Parkinson's disease
 - a. As a complication of levodopa therapy (usually > than 5 years)
 - b. Early morning plantar flexion and inversion of the foot
 - c. Rarely seen in untreated patients but does occur in the upper extremity or foot
 - d. Dystonia is very prominent in DYT6 (Segawa disease) and DYT3 ("Lubag")
2. Progressive supranuclear palsy
3. Huntington's disease
4. Ferritinopathy
5. Aceruloplasminemia
6. Pallidal degenerations
7. Machado-Joseph disease
8. Olivopontocerebellar atrophies

Differential Diagnosis of Dystonia from Structural Lesions, Toxins and Drugs

1. Perinatal anoxia:
 - a. Abnormal motor development
 - b. Onset within the first decade
 - c. May be greatly delayed > 2 decades
2. Focal lesions:
 - a. Putamen and thalamus; rarely the caudate nucleus
 - b. Cause hemidystonia contralateral to the lesion (may or may not involve the face)
 - c. Causes of hemidystonia include:
 - i. Cerebral infarction (often with resolution of the hemiparesis)
 - ii. Arteriovenous malformations
 - iii. Brain tumors
 - iv. Multiple sclerosis (paroxysmal form)
 - v. Traumatic brain injury
 - vi. Post-thalamotomy
 - vii. Chronic regional pain syndrome (CRPS); may start focally and then generalizes; always in a setting of severe pain, edema and difficulty initiating movement
 - viii. Drugs
 1. Manganese intoxication of miners and welders
 2. Often preceded by severe depression
 3. Acute dystonic reactions:
 - a. At initiation of therapy
 - b. Involves cranial and axial musculature
 - c. Oculogyric crises

- d. Resolves rapidly with intravenous anticholinergic or antihistamine IV treatment; spontaneous resolution occurs in two days
- 4. Tardive dystonia:
 - a. Chronic disorder
 - b. Follows prolonged neuroleptic use or may occur after up to three months from drug withdrawal
 - c. Focal, segmental or generalized dystonia may occur but most often the cranial and cervical muscles are involved
 - d. May respond to a degree with anticholinergic administration
 - e. Psychogenic dystonia:
 - i. More common to have true dystonia diagnosed as psychogenic
 - ii. Characteristically there is paroxysmal variation in the clinical manifestation and its severity
- 2. Focal, segmental and multifocal:
 - a. Cranial dystonia (oculo-omandibular)
 - b. Spasmodic torticollis
 - c. Writer's cramp
 - d. Spasmodic dysphonia
 - e. Musicians dystonia
 - f. Overuse syndromes
- 3. Secondary dystonias:
 - a. Metabolic defects
 - b. Neuronal degenerations
 - c. Associated with known movement disorders
 - d. Psychogenic dystonia

Focal, Segmental, or Multifocal Dystonia

- 1. Spasmodic torticollis:
 - a. General characteristics
 - i. Usually the sternocleidomastoid and trapezius muscles are most affected; the scalene muscles are often affected early
 - ii. More frequent in women than men
 - iii. Tonic or clonic contraction of neck musculature:
 - 1. Fixed and spastic deviation of the head to an awkward position (retro, latero or anterior)
 - 2. Named by the contracting sternocleidomastoid muscle
 - 3. Movements are jerky early in the course of the disease
 - 4. Sensory tricks:
 - a. Touching the forehead
 - b. Resting the back of the head on an object
 - c. Early in the course of the disorder they lessen the specific dystonia but their effect is lost with time
 - d. Pain and tension are noted in the absence of head turning (associated cervical spondylosis and disc disease)
 - e. Possibly higher incidence of postural and essential tremor
 - f. Usually progresses for approximately 5 years and then stabilizes; a small minority of patients improve
 - g. If remissions occur they are < 5 years from onset
 - h. Sustained remissions are approximately 10%
 - i. May start in the 4–5th decade; familial loss has been reported with onset
 - j. Rarely it is caused by compression of the XIth nerve by an artery (or trauma) in the posterior triangle of the neck

Differential Diagnosis of Paroxysmal Dystonia

- 1. Genetic causes:
 - a. Paroxysmal kinesigenic dystonia
 - i. PRRT2 gene; chromosome 16p11; AD
 - ii. Paroxysmal non-kinesigenic dystonia
 - 1. MRI gene; chromosome 2q35; AD
 - iii. Paroxysmal hypnogenic dystonia
 - 1. Now classified as a frontal lobe seizure disorder
 - 2. CHRNA4 gene; chromosome 20q13.33; AD
 - b. Structural lesions and drugs
 - i. Seizures
 - ii. Cerebral palsy (anoxia, intrauterine stroke)
 - iii. Multiple sclerosis
 - iv. Transient ischemia:
 - 1. Interpeduncular artery (top of the basilar)
 - 2. Thalamoperforate artery (P1 of the PCA)
 - 3. MCA branches to M1; ACA to SMA
 - v. Traumatic brain injury:
 - 1. Interruption or damage to the cortico-pallido-thalamic and cerebellothalamic motor circuitry
 - 2. 2/3 injury of the STN (hemiballismus)
 - vi. Drugs
 - 1. Tardive dyskinesias
 - 2. Acute dystonic reactions
 - vii. Metabolic causes:
 - 1. Hypoparathyroidism
 - 2. Hyperthyroidism
 - 3. Hartnup's disease
 - 4. Pyruvate decarboxylase deficiency
 - 5. Glutaric acidemia
 - viii. Rarely Parkinson's disease and supranuclear palsy

Differential Diagnosis of Dystonia by Etiology

- 1. Primary genetic dystonias

Differential Diagnosis of Torticollis

- 1. Mechanical cervical spine defects:
 - a. Rotational atlantoaxial subluxation
 - b. Spondylosis

- c. Rotary facet subluxation
- d. Spondylolisthesis
- e. Disc herniation
- 2. Klippel-Feil syndrome:
 - a. Congenital fusion of cervical vertebra (often at C4–C5)
 - b. Metameric Sprengel's deformity may be associated with elevated shoulder and scapula
- 3. Syringomyelia
- 4. Chronic regional pain syndrome:
 - a. Often initiated by cervical posterior root traction injury (C2–C4)
- 5. Posterior fossa tumor:
 - a. Dural initiation or direct trauma to C2–C4 roots
- 6. Lesions of the lenticular or caudate nucleus
- 7. Arnold-Chiari malformation:
 - a. Downward displacement of the cerebellar tonsil with traction on cervical nerve roots
- 8. Posterior pharyngeal infection:
 - a. Tonsils and adenoid involvement (Vincent's angina)
- 9. Oromandibular dystonia:
 - a. Forced dystonic mouth opening
 - b. Tongue protrusion
 - c. Mutilation of lips and tongue
 - d. Impaired swallowing due to dystonia of the pharyngeal muscles
 - e. Very prominent in DYT3 ("Lubag"-Panay Islands in the Philippines)
- 10. Writer's cramp
 - a. Dystonia of the hand and arm develops only on attempting to write
 - b. It is a pure action dystonia
 - c. Deterioration in handwriting, increased finger pressure on the writing instrument and abnormal hand postures have been described
 - d. Some patients complain of aching in the hand and fingers but actual pain is unusual
 - e. The onset is in the second to fourth decade
 - f. Symptoms start as soon as the writing instrument is grasped
 - g. Increased pressure, abnormal extension of the fingers or hyperpronation of the forearm
 - h. Over time there may be spread to other skilled motor functions
 - i. Specific action dystonias occur with:
 - i. Musicians
 - ii. Typists
 - iii. Athletes
 - iv. Any activity that requires skilled motor activity
- 11. Laryngeal dystonia (Spasmodic dysphonia)
 - a. Adductor spasm of the vocal cords
 - i. The voice is harsh and strained with a superimposed tremulous component
 - b. A minority of patients have abductor spasm of the vocal cords that causes:
 - i. Intermittent aphonia
 - ii. Breathlessness
 - iii. Sudden drops in pitch
- c. Mixed spasmodic dystonia
- d. Manifestations of all spasmodic dysphonias:
 - i. Hoarseness
 - ii. Pitch breaks
 - iii. Poor intensity range and control
- 12. Blepharospasm
 - a. Usually is initiated as an increased frequency of blinking that gradually progresses to clonic and then tonic forced eyelid closure
 - b. It is bilateral
 - c. Severity interferes with vision:
 - i. Some patients believe they are blind
 - d. Sensory tricks are common:
 - i. Dark glasses may be helpful
 - ii. Singing, talking, neck extension, reading, chewing may either increase or decrease its occurrence
 - iii. Prying one eye open breaks bilateral blepharospasm
 - e. Blepharospasm and oromandibular dystonia (Meige's syndrome)
 - i. Often associated with spasmodic torticollis
 - f. Patients with blepharospasm demonstrate other cranio-cervical involvement that includes lower facial, masticatory, lingual, pharyngeal and cervical dystonia

Myoclonus

Overview

Myoclonus is a movement disorder that manifests with sudden, brief shock-like jerks due to a brief burst of muscular activity (positive myoclonus) or from a brief cessation of ongoing muscular activity (negative myoclonus). It may originate from several levels of the neuraxis which includes the cortex, basal ganglia, brainstem (nucleus gigantocellularis) and spinal cord. Movements may involve small muscles or the entire body and may be discrete and non-random. They are produced by a brief muscle contraction and in some instances are precipitated by sensory stimulation. Rhythmic myoclonus is most often caused by brainstem or spinal cord disease. Positive myoclonus is generally more common than negative myoclonus and is most often caused by toxic-metabolic disorders. Both may occur concomitantly in the same illness.

Myoclonus is classified in several ways. It may be focal, multifocal or generalized. If classified by provoking factors it is spontaneous or reflex. Anatomically its source is cortical, subcortical, spinal or peripheral. Its classification has been proposed by activity in which it occurs: 1. postural 2. during action or 3. at rest. More than one form of myoclonus may occur in a given patient.

Physiological Classification of Myoclonus*Cortical Myoclonus***General Characteristics**

1. Cortical myoclonus is commonly encountered in both out-patient and hospital settings

Clinical Manifestations

1. Primarily affects the distal upper limbs and face (large cortical representation of these body regions)
2. It may be focal, multifocal, or generalized due to intracortical and transcallosal spread
3. It most often occurs with action and affects speech and gait
4. It is stimulus sensitive, most frequently to touch but has been described with visual stimuli
5. In cortical myoclonus, patients may have both positive and negative myoclonus which may manifest independently or concomitantly
6. Prolonged cortical myoclonus that lasts for days or weeks is a rare form of focal epileptic status

Neuropathology

1. Focal cortical myoclonus is most often caused by an underlying lesion that produces hyperexcitability and includes:
 - a. Cerebral vascular pathologies (stroke, hemorrhage or malformation)
 - b. Post-hypoxic myoclonus (the Lance-Adams syndrome)
 - c. Progressive myoclonic epilepsies
 - d. Progressive myoclonic ataxias
 - e. Neurodegenerative diseases

Laboratory Evaluation

1. MRI:
 - a. Identifies the cortical pathology
 - b. EEG
 - c. Somatosensory evoked potentials
 - d. Evaluation of the neurodegenerative process
 - e. Molecular genetic analysis

*Negative Myoclonus (NM)***General Characteristics**

1. Is a sudden interruption of ongoing muscle contractions
2. It may be cortical or subcortical in origin

Clinical Manifestations

1. A non-specific shock-like involuntary jerky movement
2. If the trunk or lower extremities are involved the patient may fall
3. Epileptic negative myoclonus:
 - a. Interruption of tonic muscle activity
 - b. Time-locked to an epileptic EEG abnormality without evidence of antecedent positive myoclonus
 - c. It occurs in symptomatic and idiopathic epilepsy
 - d. It occurs in association with other types of seizures such as partial motor seizures (often of the Rolandic type), absence or atonic seizures

- e. It is never an isolated sign
- f. It may have a subcortical origin
- g. Lance-Adams syndrome:
 - i. Most often seen as a complication of successful cardiopulmonary resuscitation
 - ii. Associated with action myoclonus
 - iii. May affect the trunk and lower extremities that cause patients to fall
 - iv. May develop days or weeks after the event
 - v. There is no myoclonus at rest or during sleep
 - vi. There is no consistent correlation with EEG abnormalities
 - vii. PET evaluation demonstrates:
 1. Increased glucose metabolism in the pontine tegmentum, mesencephalon and ventrolateral thalamus
 2. SPECT analysis has demonstrated hypoperfusion of the temporal lobe
 3. Serotonin and GABA acid are thought to be the involved neurotransmitters
- h. Asterixis:
 - i. Subcortical origin
 - ii. Occurs in toxic metabolic encephalopathies
 - iii. Most often it is bilateral and rhythmic
 - iv. Unilateral asterixis has been described with thalamic and cortical lesions

*Subcortical Myoclonus***Non-Segmental Subcortical Myoclonus**

1. General characteristics:
 - a. Hyperekplexia and reticular reflex myoclonus are classic examples of brainstem myoclonus
 - b. Myoclonic dystonia and drug-induced myoclonus have no correlation with cortical myoclonic jerks and are therefore postulated to have a subcortical origin
2. Clinical manifestations of brainstem myoclonus:
 - a. Generalized jerks
 - b. Sensitivity to auditory stimuli
 - c. The two major types of brainstem myoclonus are:
 - i. The startle response that is physiologic or can be pathologic as in hyperekplexia
 - ii. Reticular reflex myoclonus

Physiologic Startle Response

1. Triggered by an unexpected stimulus
2. Sensitivity to somatosensory stimuli applied to the head, face and upper chest as well as visual stimuli
3. Places the body into a defensive position
4. EMG activity demonstrates an orderly spread of activity that starts in the sternocleidomastoid muscles and then engages the face, trunk and limbs (brainstem and spinal cord spread)
5. Proximal and distal muscles are involved synchronously and bilaterally that cause:
 - a. Brief, shock-like movements
 - b. Grimacing, arm abduction and flexion of the neck, trunk, elbows, hips and knees

Hyperkplexia

1. General Characteristics
 - a. Hyperkplexia may be caused by heterozygous, homozygous, or compound heterozygous mutation in the GLPA1 gene that maps to chromosome 5q33.1. Both AD and AR inheritance occurs
2. Clinical manifestations:
 - a. Congenital form:
 - i. Episodic and generalized stiffness after birth that subsides during the first years of life
 - ii. Apnea attacks
 - iii. Delayed speech
 - iv. Cognitive impairment
 - v. Excessive startle reflexes to unexpected stimuli (particularly auditory or tactile)
 - vi. Persistent startle attacks throughout life
 - vii. Increased incidence of umbilical hernia
 - b. Adult form:
 - i. Forced eye closure
 - ii. Rising of bent arms over the head
 - iii. Flexion of the neck, trunk, elbows, hips and knees
 - iv. Consciousness is maintained throughout the episode which distinguishes these episodes from seizures
 - v. Nocturnal myoclonus
 - vi. Falling with episodes
3. Neuropathology:
 - a. Loss of motor neuron inhibition due to mutation in the alpha 1 subunit of the glycine receptor
 - b. Other causes of hyperkplexia are brainstem encephalitis, vascular lesions and multiple sclerosis
4. Laboratory evaluation:
 - a. In some patients, EMG demonstrates contiguous activity at rest with normal motor unit action potentials which are abolished by diazepam (during episodes)
 - b. In one kindred, electrophysiological studies demonstrated a prominent C response 60–75 ms after median and peroneal nerve stimulation; it was hypothesized that hyperactivity of long-loop reflexes is responsible for the increased startle response

Brainstem Reticular Myoclonus

1. General characteristics:
 - a. A rare generalized myoclonus
2. Clinical manifestations:
 - a. Spontaneous myoclonus
 - b. Sensitivity to somatosensory stimuli applied to the distal limbs rather than the mantle or face
3. Neuropathology:
 - a. Post-hypoxic encephalopathy
 - b. Brainstem encephalitis
 - c. Ischemia
4. Laboratory evaluation:
 - a. MRI (patient was born after 35 weeks of gestation) with severe myoclonus

- i. High intensity lesions in the Rolandic area of the cortex, the thalamus, basal ganglia and brainstem
- ii. MRI in follow up at 1 month demonstrated great improvement of the pontine lesion as the patient was remitting from the myoclonus

Segmental Subcortical Myoclonus*Palatal Myoclonus***General Characteristics**

1. Essential palatal myoclonus (EPM) or symptomatic palatal myoclonus is classically thought to occur from a lesion in the Guillain-Mollaret triangle. The triangle comprises connections between the dentate nucleus, red nucleus and the inferior olivary nucleus

Clinical Manifestations

1. The palatal myoclonus is rhythmic (1–2 Hz) contractions of the tensor veli palatini muscle
2. An audible click may be heard by the patient from repetitive opening and closing of the eustachian tube in essential palatal myoclonus (EPM). It remits in sleep
3. In symptomatic palatal myoclonus:
 - a. There may not be clicking and it may persist during sleep
 - b. SPM occurs more frequently than EPM

Neuropathology

1. Lesions that cause symptomatic palatal myoclonus include:
 - a. Vascular disease (stroke)
 - b. Multiple sclerosis
 - c. Brainstem tumors
 - d. Progressive ataxia palatal tremor syndrome (PAPT)
 - i. May be sporadic or familial
 - ii. Marked brainstem and spinal cord atrophy
 - iii. No olivary hypertrophy
 - iv. Some familial patients with PAPT have adult onset Alexander disease from mutation of the GFAP (glial fibrillary acidic protein) gene
 - v. AD neuroferritinopathy due to ferritin light chain (NFL) gene mutation may cause palatal myoclonus
 - vi. Lesion-induced disease causes olivary hypertrophy

Laboratory Evaluation

1. MRI
 - a. Identifies structural lesions of Mollaret's triangle
 - b. Olivary hypertrophy

*Spinal Myoclonus***General Characteristics**

1. Most often secondary to a spinal cord structural lesion
2. Reflects the segmental organization of the spinal cord

Clinical Manifestations

1. May persist in sleep

2. Present at rest
3. May or may not be stimulus-sensitive
4. Affects one or a few contiguous myotomes
5. May occur irregularly or appear to be quasi-rhythmic

Neuropathology

1. Syringomyelia
2. Autoimmune causes of myelitis
3. Spinal cord trauma
4. Vascular malformations
5. Malignancy

Laboratory Evaluation

1. MRI:
 - a. Evaluates spinal cord structural lesions
2. EMG:
 - a. Motor unit action potential discharges of 1–2 per minute to 100–200 per minute
 - b. Myoclonic bursts may last up to 1000 ms

Propriospinal Myoclonus

General Characteristics

1. Propriospinal myoclonus affects spinal segments that are connected by propriospinal pathways rostrally and caudally from a spinal generator

Clinical Manifestations

1. Axial flexion jerks that involve the neck, trunk, and hips
2. It is initiated from a specific myelomere and then spreads to contiguous spinal segments rostrally and caudally
3. It most often occurs spontaneously but can be elicited by tapping the abdomen or eliciting deep tendon reflexes
4. It is exacerbated in the supine position
5. It may be exacerbated in sleep-wake transition

Neuropathology

1. Propriospinal myoclonus has been described with cervical and thoracic trauma, spinal cord tumor, and myelitis. In a significant number of patients, no clear etiology may be determined. It is often labeled as psychogenic

Laboratory Evaluation

1. MRI:
 - a. Specific spinal cord lesions; recently patients have been studied with diffusion tractography
2. EMG:
 - a. Polymyography which may delineate the generator muscle, the extent of propagation through propriospinal pathways, and slowed spinal conduction velocity from the latencies of the EMG bursts
3. Bereitschaftspotentials have been documented in some patients with a psychogenic etiology

Differential Diagnosis of Asterixis

1. Hepatic failure

2. Renal failure
3. Respiratory failure
4. Acidotic states:
 - a. Diabetic ketoacidosis
 - b. Poisoning (large anion gap)
5. Hyperosmolar states:
 - a. Usually a very high blood sugar (1500–2000 mg%); non-ketotic diabetic ketoacidosis
 - b. Severe hyperlipidemia

Differential Diagnosis of Spinal Myoclonus

1. Hyperosmolar states (most commonly non-ketotic diabetic ketoacidosis)
2. HZ infection
3. Trauma (spinal cord)
4. Paraneoplastic syndrome
5. HS
6. HIV
7. Spinal arteriovenous malformations
8. Arteriography of thoracic intercostal arteries

Differential Diagnosis of Propriospinal Myoclonus

1. Spinal cord tumor
2. Demyelinating disease
3. Viral myelitis
4. Alpha-interferon therapy (renal cell carcinoma)
5. Spinal anesthesia
6. Cervical hemangioblastoma

Peripheral Myoclonus

General Characteristics

1. Hemifacial spasm is the most common form

Clinical Manifestations

1. Rhythmic or quasi-rhythmic jerks

Neuropathology

1. Plexus, nerve or root lesions are causative; rarely described with anterior horn cell disease
2. Almost universal myoclonus with longstanding CRPS I and II (>1 year); associated neurogenic inflammation, edema, hyperalgesia to mechanical and thermal stimuli; frequently seen in a mirror distribution

Myoclonus Classification by Etiology

Physiologic Myoclonus

General Characteristics

1. Occurs in normal individuals

Clinical Manifestations of Sleep Myoclonus

1. Sleep is the most common cause of physiologic myoclonus

- a. Sudden jerks during sleep or sleep transition states
- b. Massive myoclonic jerks (hypnic)
- c. Partial jerks:
 - i. Multifocal
 - ii. Affects only distal musculature
- d. Hypnic jerks:
 - i. Affects the trunk and proximal extremities
 - ii. May be generalized
 - iii. May be noted prior to a major motor seizure
 1. May increase 1–2 weeks prior to a major motor tonic-clonic seizure
- e. Nocturnal myoclonus:
 - i. Repetitive stereotyped dorsiflexion of the toes and foot
 - ii. Flexion of the knees and hip
 - iii. May be associated with restless leg syndrome
 - iv. Occurs during non-REM sleep
 - v. Lasts 1.5–2.5 seconds
 - vi. Increased incidence in patients with daytime drowsiness or insomnia

Other Forms of Physiologic Myoclonus

1. Hiccough (diaphragmatic myoclonus)
2. Provoked by anxiety or exercise

Essential Myoclonus (Myoclonus Dystonia)

General Characteristics

1. Myoclonus is the sole manifestation or the major feature of the disorder
2. Patients suffer some disability
3. The myoclonus may be hereditary or sporadic

Clinical Manifestations (DYT11)

1. Inheritance is AD; 50% of patients have mutations in the epsilon-sarcoglycan gene that maps to chromosome 7q21
2. The disorder is most often inherited paternally with variable penetrance
3. Onset is in childhood
4. “Lightning jerks” (myoclonic) in association with mild dystonia
5. No other neurologic deficits
6. A subset of patients have anxiety, depression, and obsessive-compulsive disorder
7. Myoclonus and dystonia:
 - a. Affects the head, neck and arms
 - b. Rarely there is prominent leg involvement with falls
 - c. Dramatic response of the myoclonus to alcohol
 - d. Minimal stimulus sensitivity

Neuropathology

1. A putative subcortical myoclonus generator that involves the cerebellum
2. Subtle metabolic increases in the superior parietal cortex suggests this as the underpinning of the dystonic component (FDG)

Laboratory Evaluation

1. [¹⁸F]-fluorodeoxyglucose PET evaluation:
 - a. Increased metabolism in the inferior pons and posterior thalamus
 - b. Reduced metabolism in the ventromedial prefrontal cortex
 - c. Increased metabolism in the parasagittal cerebellum
2. Cortical somatosensory evoked potentials are normal

Epileptic Myoclonus

General Characteristics

1. Definition:
 - a. Disorders in which myoclonus occurs in the setting of epilepsy
2. Epileptic myoclonus may be positive or negative (lapse of postural tone)
3. Epileptic myoclonus is associated with generalized epileptiform EEG activity, but the myoclonus itself may be focal, segmental, or generalized
4. May occur as one component of the seizure or as its only manifestation
5. Myoclonus may be one seizure type among several in the individual patient

Clinical Manifestations

1. Older children and adolescents:
 - a. Photosensitive epileptic myoclonus
 - b. Myoclonic absences
 - c. May be associated with primary generalized epilepsy
2. Adults:
 - a. A proportion of adults with primary generalized epilepsy have morning myoclonic jerks
 - b. Myoclonus may be interictal in primary generalized epilepsy
 - c. Myoclonic jerks increase (particularly nocturnally) in 25% of patients prior to seizures
 - d. As a component of epilepsy:
 - i. Isolated epileptic myoclonic jerks
 - ii. Photosensitive myoclonus
 - iii. Stimulus-sensitive myoclonus
 - iv. Epilepsia partialis continua
 - e. Focal myoclonus can occur in lesional epilepsy from infection, vascular disease trauma, and tumor

Neuropathology (Causes of Myoclonic Epilepsy)

1. Childhood myoclonic epilepsy:
 - a. Infantile spasms
 - b. Lennox-Gastaut syndrome
 - c. Aicardi syndrome
 - d. Benign familial myoclonic epilepsy
 - e. Myoclonic epilepsy of Janz
2. Adult myoclonic epilepsy:
 - a. Progressive myoclonic epilepsy of Unverricht-Lundborg (ULD) (Baltic myoclonus)

- b. Lafora body disease
- c. Ceroid lipofuscinosis
- d. Tay-Sachs GM2 gangliosidosis
- e. Sialidosis
- f. Familial cortical tremor (benign autosomal dominant familial myoclonic epilepsy (BADFME))
- g. Mitochondrial disease
- h. DRPLA

Secondary Myoclonus

General Characteristics

1. Myoclonus that occurs in the setting of an underlying neurological or non-neurological disorder
2. The most common form of myoclonus
3. The major categories of etiology include:
 - a. Post-hypoxic
 - b. Drug-related
 - c. Toxic-metabolic
 - d. Lesions of the CNS (central nervous system)
 - e. Neurodegenerative disease
 - f. Hereditary metabolic diseases

Clinical Manifestations

1. Symptomatic myoclonus may be cortical, focal or multifocal, is sensitive to stimuli, and may be associated with asterixis and brainstem reticular myoclonus

Neuropathology

1. Metabolic abnormalities:
 - a. Renal failure
 - b. Hepatic failure
 - c. Respiratory failure
 - d. Electrolyte abnormalities
 - e. Acidosis or alkalosis
 - f. Hypoxia
 - g. Hyperosmolar states
2. Endocrine abnormalities:
 - a. Hashimoto's encephalopathy
 - b. Hyperthyroidism
 - c. Hypoglycemia
3. Vitamin deficiency:
 - a. Vitamin E deficiency
 - b. Thiamine deficiency
4. Myoclonus due to toxic-metabolic causes is most often associated with ataxia, seizures, and altered mental states
5. Toxins:
 - a. Alcohol and its withdrawal
 - b. Following dialysis (possible aluminum toxicity)
 - c. Methyl bromide
 - d. Gasoline sniffing (huffer's syndrome)
6. Post-anoxic myoclonus (Lance-Adams syndrome)
 - a. Severe hypoxia from cardiac arrest and resuscitation, respiratory arrest
 - b. May have delayed onset

- c. Myoclonus is most often cortical and multifocal, but may be associated with asterixis and reticular reflex myoclonus
- d. Action myoclonus
- e. Exaggerated startle reflex
- f. Seizure (some patients)
- g. Cognitive impairment (some patients)
7. Myoclonus of the progressive myoclonic epilepsies manifests as:
 - a. Multifocal involvement
 - b. Involves the distal extremities and face
 - c. Is provoked by posture or action
 - d. May be triggered by touch, noise, or light
 - e. Often has associated severe action myoclonus
8. Action myoclonus renal failure syndrome:
 - a. Caused by mutation of the SCARB2 gene that encodes liposomal integral membrane protein-2 (LIMP-2); inheritance is autosomal recessive (AR)
 - i. Onset is in early adulthood (age 17–26 years)
 - ii. Initial tremor that is followed by action myoclonus
 - iii. Infrequent seizures
 - iv. Cerebellar ataxia
 - v. Progression from proteinuria to renal failure
9. Progressive myoclonic ataxias (Ramsay Hunt syndrome)
 - a. Prominent myoclonus and ataxia
 - b. Seizures and cognitive impairment are less prominent
 - c. The progressive myoclonic ataxias include:
 - i. Celiac disease
 - ii. Some mitochondrial cytopathies
 - iii. Vitamin E deficiency
 - iv. Some patients with Unverricht-Lundborg disease
10. Neurodegenerative diseases:
 - a. Cortical myoclonus occurs in approximately 15% of patients with Lewy body disease and Parkinson's disease dementia
 - b. Multiple system atrophy:
 - i. May demonstrate small amplitude myoclonic movements of the outstretched fingers (polymyoclonus)
 - ii. The myoclonus is stimulus sensitive and increases with movement
 - iii. A cortical origin has been demonstrated by back-averaging
 - iv. May have "giant" somatosensory potentials
 - c. Myoclonus is demonstrated in 50% of patients with corticobasal degeneration:
 - i. It occurs in the affected arm
 - ii. Early in the course of the illness, it is repetitive and rhythmic in attempted movement or often with somatosensory stimulation. It may later occur spontaneously. There is associated apraxia, rigidity, dystonia, and the alien hand in the affected extremity
 - iii. It has a putative cortical origin

- d. Huntington's disease:
 - i. Myoclonus may occur in patients with a juvenile onset and in those with longer CAG repeats
- e. Alzheimer's disease may demonstrate multifocal myoclonus in its middle or late stages. In early-onset genetic forms it occurs earlier
- f. Myoclonus is prominent in sporadic, familial, and new variant Creutzfeldt-Jakob disease:
 - i. Early in the course of the disorder, myoclonus is limited and sporadic. Later in the illness it becomes generalized and rhythmic (0.6–1.5 Hz)
- g. Psychogenic myoclonus is characterized by:
 - i. Spontaneous occurrence or following a trauma
 - ii. It may be restricted to a few muscles or be generalized
 - iii. Distractible
 - iv. Inconsistent over time
 - v. Sudden onset and offset
 - vi. Day-to-day variability

Laboratory Evaluation

1. Routine evaluation:
 - a. Electrolytes, glucose, liver, renal and thyroid function
- b. MRI:
 - i. Brain and spinal cord imaging
- c. EEG:
- d. Additional evaluation depending upon the history and examination:
 - i. CSF
 - ii. Paraneoplastic antibody panel
 - iii. Genetic evaluation
 - iv. Enzyme activity assays

Neurophysiology

1. Electrophysiological tests are helpful in determining if the myoclonus is cortical, subcortical, or spinal
2. An EMG that determines duration, distribution, and stimulus sensitivity of the affected muscles
3. EEG-EMG back-averaging
4. Averaging and recording somatosensory evoked potentials (SSEPs)

Tic Disorders

General Characteristics

1. Definition: repetitive intermittent stereotypic movements that include the following features:
 - a. Sudden and rapid
 - b. Predominantly clonic
 - c. Temporarily suppressible for variable lengths of time
 - d. Preceded by a strong urge to make the specific movement
2. Spectrum of tics:
 - a. Simple blinks or jerks
 - b. Complex coordinated movements and vocalizations:
 - i. Clonic
 - ii. Choreic
 - iii. Dystonic

Clinical Manifestations

1. Simple motor tic: one group of muscles is involved
 - a. The movement often starts around the eyes or mouth, then spreads to the neck and shoulders, and then generalizes
 - b. The tic or simple movement may consist of:
 - i. Eye blinking
 - ii. Nose twitch
 - iii. Jerking extension of the head
 - iv. Shoulder shrug
2. Complex motor tic: a stereotypic series of movements that involves different groups of muscles; a coordinated series of movements that includes:
 - a. Neck turning, snorting and hand movements
 - b. Linguistically meaningful utterances
3. Chronic tic
4. Tonic or dystonic:
 - a. Slower in onset
 - b. Prolonged
5. Vocal tics:
 - a. Motor tics that involve respiratory, laryngeal, pharyngeal, oral and nasal musculature
 - b. Complex vocalizations:
 - i. Coprolalia
 - ii. Echolalia
6. Premonitory sensations:
 - a. Frequently present
 - b. Occur in the shoulder girdle, palms, midline abdomen, ventral thighs, feet, and eyes
 - c. The abnormal movement may relieve the provoking sensation. These are voluntary movements, whereas in other hyperkinetic movement disorders (the movements) are involuntary
 - d. Disturbed sleep patterns (some patients)
 - e. Tics are variably present during sleep

Neuropathology

1. In Gilles de la Tourette syndrome there may be caudate and putamen atrophy and cortical thinness
2. Most tic disorders have negative studies
3. Dopaminergic hypothesis is supported by:
 - a. DA receptor antagonists are effective in dampening tics
 - b. Tics are exaggerated by agents that enhance dopamine neurotransmission (for example, amphetamines)
4. Recent MRI (fMRI/PET) activation studies reveal:
 - a. Overactivation of prefrontal and premotor cortices including the supplementary motor cortex
 - b. Resting state functional connectivity studies reveal:
 - i. Abnormal connectivity of cortico-subcortical circuits
 - ii. Abnormalities in the limbic-cortico-basal ganglionic loops that include altered baseline neuronal activity patterns and specific tic-related movements
5. Deep brain stimulation has been utilized to stimulate the globus pallidus internus, the thalamic motor nuclei, and the nucleus accumbens with success

Laboratory Evaluation

1. MRI:
 - a. Specific deficits have been detected in GTS (detailed below)

Gilles de la Tourette Syndrome (GTS)*General Characteristics*

1. There are mutations in several genes that cause Gilles de la Tourette syndrome. Linkage to:
 - a. Chromosomes 3q, 4q, 5, 7p21, 7, 11 and 17q25 have been established

Clinical Manifestations

1. Childhood onset (usually prior to age 22)
2. Simple or complex motor tics
3. Vocalizations:
 - a. Sniffing, throat clearing, spitting
 - b. Complicated motor activity:
 - i. Jumping, kicking, bizarre gait
4. Coprolalia (obscene language)
5. Coprapraxia (obscene gesturing)
6. In severe GTS:
 - a. Elaborate sequential multiple complex movements
 - b. Echolalia and coprolalia
7. Mild GTS:
 - a. Tics are primarily in the face
 - b. Minor vocalizations
8. Associated disorders:
 - a. Attention deficit hyperactivity disorder
 - b. Obsessive compulsive disorders
 - c. Behavior disorders

Neuropathology

1. Structural changes of clinical phenotypes of GTS:
 - a. Determined by 3T high resolution T1-weighted images
 - b. Cortical thickness measurements
2. Patients with GTS and simple tics:
 - a. Cortical thinning was demonstrated in the primary motor cortex
3. Patients with GTS that manifested both simple and complex tics:
 - a. Cortical thinning extended into premotor, prefrontal and parietal areas
4. In patients with GTS and associated obsessive compulsive disorder:
 - a. Reduced cortical thickness in the anterior cingulate cortex
5. Altered hippocampal morphology
6. Decreased volume of the putamen and caudate nuclei have been reported
7. Local field potentials (3 patients that underwent DBS):
 - a. Thalamic synchronization and thalamocortical cross-coherence was noted in time-locked and prior to onset of spontaneous motor tics

8. Recording from 3 patients that were not time-locked to motor tics:
 - a. Increased intrathalamic coherences in the 1–8 Hz frequency band was noted
9. Spontaneous tics in GTS are preceded by repetitive coherent thalamocortical discharges
10. Thalamic recordings from patients with GTS reveal:
 - a. Power in low-frequency oscillations (2–15 Hz) is higher than power in high frequency oscillations (>45 Hz)
 - b. Activity in gamma band increases with patient improvement

Laboratory Evaluation

1. MRI:
 - a. As noted above
2. Functional:
 - a. Overactivation of prefrontal and premotor cortices including SMA
 - b. Abnormal connectivity of cortico-subcortical motor circuitry
3. CSF HVA:
 - a. Reduced baseline and turnover
 - b. D1 and D2 receptor binding:
 - i. Inconsistent bindings or minimal changes
 - c. Normal noradrenalin levels in the cortex and basal ganglia
4. MicroRNA (miR-H29) is underexpressed in GTS patients

Differential Diagnosis of Tic Disorders

1. Drugs:
 - a. Levodopa
 - b. Neuroleptics
 - c. Carbamazepine
 - d. Phenytoin
 - e. Lamotrigine
 - f. Phenobarbital
2. Basal ganglia diseases:
 - a. Neuroacanthocytosis
 - b. Encephalitis lethargica
 - c. Vascular disease
3. Toxins:
 - a. Carbon monoxide
 - b. Carbon disulfide
4. Trauma
5. Gilles de la Tourette syndrome
6. Obsessive compulsive disorders
7. Attention deficit disorder

Exaggerated Startle Reflexes*General Characteristics*

1. Syndromes with exaggerated startle can be divided into 3 major categories:
 - a. Hyperekplexia
 - b. Stimulus induced disorders
 - c. Neuropsychiatric disorders

Clinical Manifestations

1. Hyperekplexia:
 - a. An exaggerated motor startle reflex
 - b. Combined with stiffness
 - c. Mutations in the gene that encodes the glycine receptor
 - d. Preserved consciousness distinguishes it from startle epilepsy
 - e. Clonazepam responsiveness
2. The jumping Frenchmen of Maine:
 - a. Described in French Canadian lumbermen from the Moosehead Lake region of Maine; many come from the Bearce region of Quebec
 - b. The condition is often familial
 - c. A sudden sensory stimulus elicits an abnormal reaction while a sudden quick command elicits an appropriate response
 - d. The words of command would often be echoed (by the patient)
 - e. Onset ranges from 12–20 years of age
3. Latah:
 - a. A culture-specific startle syndrome described from Indonesia and Malaysia
 - b. Startle response with vocalizations and echolalia
 - c. Late behavioral response

Neuropathology

1. Two phases in the startle response have been described:
 - a. A short latency motor startle initiated from the lower brain stem (>100/120 ms)
 - b. A second phase:
 - i. Influenced by psychological factors (the “orienting reflex”)
 - ii. 100/120–1000 ms

Laboratory Evaluation

1. EMG:
 - a. Evaluates recruitment pattern latency and habituation
2. EEG:
 - a. Evaluates myoclonus

Painful Legs and Moving Toes Syndrome*General Characteristics*

1. Most often affects the lower extremities but may also be seen in the arm and fingers
2. Most often occurs in middle-aged women (66% in one large series)

Clinical Manifestations

1. Pain is more distressing to the patients than the chronic wiggling movement of the toes
2. Pain is most frequently described as neuropathic (lancinating, burning, tingling)
3. The initial movements start in one limb and then become bilateral

Neuropathology

1. Most often associated with a radiculopathy or at a peripheral nerve level that may induce a generator at the spinal cord or brain stem level from maladaptive neuroplasticity

Laboratory Evaluation

1. MRI:
 - a. Brain and spine to rule out a spinal lesion
2. EMG:
 - a. MUAP discharge is concomitant with digit movements. They are irregular or semi-rhythmic microphasic bursts with muscle contraction. Bursts duration (40 milliseconds to two seconds). The rates of motor unit discharge are from 1.5 to 30 Hz

Differential Diagnosis of Hyperkinetic Movement Disorders

The hyperkinetic movement disorders are the choreas, myoclonic disorders, tics, some dystonias and tremors. The diagnostic difficulty most often is not in distinguishing the categories, but in correctly diagnosing the entities within a specific category.

Huntington's disease is probably the most common hereditary chorea that will be encountered. The severity of the dementia, choreatic eye movements and lurching gait are dramatic. Family history at times is difficult to obtain, but when elicited is clearly autosomal dominant.

Sydenham's chorea is not hard to diagnose in childhood (although now rare in developed countries). As an adult it may be associated with old rheumatic heart disease, is often familial, and may not have an antibody response to streptococci. Rarely, it is associated in an adult with Jaccoud's arthritis. Autoimmune causes of basal ganglia disease both from infection and cancer are being increasingly defined in both children and adults. Benign familial chorea is not associated with cognitive decline and has a normal lifespan.

Medications, particularly D2 agonists, anticonvulsants, steroids and neuroleptics cause chorea. “Crack dancing” is not unusual. Patients that have chorea on birth control pills often returned with pregnancy. As noted earlier, many systemic diseases, particularly SLE with antiphospholipid antibodies, hyperthyroidism and metabolic derangements such as renal failure are associated with chorea.

Post-pump chorea and CHAP syndrome (choreoathetosis, orofacial dyskinesia, hypotonia and pseudobulbar palsy) declare themselves by the circumstances. However, hypoxia induced movement disorders may have a delayed onset.

Hereditary diseases in which chorea may be a component of the symptom complex all have striking seminal features exemplified by: Niemann-Pick type 2C (failure of vertical gaze), Pelizaeus-Merzbacher (Nystagmus), Wilson's disease (Kayser-Fleischer ring), Lesch-Nyhan syndrome (mutilated lower lip), ataxia telangiectasia (ataxia and scleral telangiectasia), the mitochondrial encephalopathies

(hearing loss, short stature, cardiomyopathy) and paroxysmal kinesigenic choreoathetosis (chorea and dystonia). Neuroacanthocytosis, Huntington's disease-like 2, PANK2 and Bassen-Kornzweig all have a complex of akinetic rigid features, tics, seizures and rarely vertical gaze deficits. DR-PLA also has a gamut of other movement disorders and seizures, cognitive dysfunction as well as acanthocytes on blood smear.

Hemichorea is most often seen with congenital disease of the striatum (severe hemiplegia) with atrophy of the affected side. Infarction of the thalamus (thalamoperforate artery), trauma, post-VIM thalamotomy for tremor, hemorrhages and tumor or vascular malformation are causative.

Hemiballismus is an instant diagnosis. The proximal flinging movements require the arm to be restrained (often under the belt). Usually it is secondary to infarction of the interpeduncular artery from the top of the basilar or occlusion of the P1 segment of the PCA that infarcts the thalamoperforate artery.

Tardive dyskinesias almost always have an oral lingual buccal component. The extremities, axial musculature and diaphragm may develop rhythmic movements over time. Akathisia, dystonic sustained movements (tardive dystonia) as well as facial dystonia, blepharospasm, mandibular dystonia and neck dystonia occur.

Neuroleptic induced oculogyric crisis (formerly common with von Economo's encephalitis) associated with myoclonus and tremor is encountered.

Abdominal dyskinesias usually occur after trauma and may be difficult to distinguish from propriospinal myoclonus. The clue is surgery in the former and exacerbation by the prone position and progressive waves of spreading axial myoclonus in the latter.

Athetosis is immediately recognized by its slow, sinuous writhing quality that primarily affects distal musculature. Pseudoathetosis is an updrift of the outstretched upper extremities with sinuous "piano playing" finger movements. It is usually seen in the context of congenital stroke, birth trauma, anoxia, kernicterus or Wilson's disease.

The dystonias are easily diagnosed because of the obvious abnormally held postures. The features that are peculiar to the diagnosis are sensory "tricks," dystonic spasms and unusual stereotyped maintained postures (dropped plantar flexed and inverted foot retrocollis or torticollis). Dystonic spasms and tremor may be confusing.

The dystonia of chronic regional pain syndrome (CRPS I and II) is very common, often associated with severe allodynia and neurogenic edema. It is invariably misdiagnosed.

Movement-specific, athletic and musicians' dystonias are easily diagnosed by their task-specific triggering movement, possibly caused by maladaptive neuroplasticity of the SMA, MC, or PMC. Rarely, peripheral surgery such as dissection in the neck causes axon rewiring or ephaptic conduction such that intended extension of the wrist results in hand flexion.

Spasmodic dysphonia is differentiated from lesions of components of the Xth nerve by its intermittent nature. These patients also demonstrate other neurologic abnormalities such as tremor.

The paroxysmal dyskinesias cannot be missed as a group due to their spectacular onset. Paroxysmal kinesigenic dyskinesia is composed of choreoathetosis, ballism and dystonic postures. Interruption of speech, rigidity and falls may be confusing. The attacks usually last for seconds to minutes.

Spontaneous paroxysmal non-kinesigenic dyskinesia is not initiated by movement and lasts from minutes to hours. This form of dyskinesia is triggered by stress, alcohol and caffeine. Specific paroxysmal dyskinesia is defined by initiating triggers, such as sleep or exercise and whether they are short lasting (less than five minutes). Paroxysmal ataxia and tremor has now been designated as a spinocerebellar degeneration (SCA7).

The differential diagnosis of myoclonus is wide. The setting in which it occurs most often determines the diagnostic possibilities. Hospital settings suggest metabolic or toxic etiologies. Renal failure and post-dialysis states often are accompanied by action myoclonus. Hyperosmolar states are most often from non-ketotic hyperglycemia. They cause segmented myoclonus. Hepatic insufficiency is accompanied by asterixis, lethargy and hyperreflexia. Mitochondrial disease that causes myoclonus should be suspected in a short patient with deafness, oculomotor paralysis, fatigue with minimal exercise and cardiomyopathy.

The Lance-Adams syndrome of post-hypoxic myoclonus, is more often seen with respiratory rather than cardiac arrest and should be suspected following any severe hypoxic episode. The intentional action myoclonus and postural kinetic components of the syndrome are seminal. It may be delayed up to two weeks following the anoxic event.

Most poisonings that cause myoclonus are accompanied by nausea, vomiting, and have a large serum anion gap.

The hereditary progressive myoclonic epilepsies are rare. Seizures and cognitive impairment predominate. Neuronal ceroid lipofuscinosis and Lafora body disease are most often seen in adults. Visual hallucinations and occipital lobe symptomatology occurs in 50% of patients with Lafora body disease. Cognitive impairment and severe ataxia are the seminal features of Ramsay Hunt syndrome.

Myoclonus may be a feature of all of the basal ganglia degenerations. Most present with akinetic rigid signs. Low blood pressure and cold hands suggest multiple system atrophy (MSA). Severe dysarthria, a wing-beating tremor and a Kayser-Fleischer corneal ring is pathognomonic of Wilson's disease. The "eye of the tiger" in the globus pallidus by IS MRI diagnostic of PANK2 (however, it may also be seen in other iron accumulation and neurodegenerative disorders).

Rapid dementia with myoclonus in an adult is Creutzfeldt-Jakob disease until proven otherwise. The 14-3-3 protein, elevation of neuron-specific enolase as well as a characteristic EEG support the diagnosis. PRNP is the only gene

in which mutations cause genetic prion disease. Late severe Alzheimer's disease may demonstrate myoclonus, but the loss of memory and general cognitive impairment have made the diagnosis long before myoclonus is prominent. Both Creutzfeldt-Jakob disease and Alzheimer's disease may have anterior horn cell involvement. Diffuse Lewy body disease may be associated with myoclonus, but visual hallucinations, transient episodes of altered mental status, falls and fluctuations in cognitive abilities are its most prominent manifestations.

Palatal myoclonus cannot be missed if the soft palate is examined. Rhythmic contractions of the platysma muscle, tensor veli palatini, clicking in the ears (opening and closing of the eustachian tubes) and ocular and diaphragmatic movements secure the diagnosis. Rhythmic palatal myoclonus is associated with torsional and rotary nystagmus, while pendular nystagmus is noted in the midline form.

The spinocerebellar ataxias, particularly SCA3/Machado-Joseph disease, have myoclonus as a minor component of the movement disorder. Bulging eyes and amyotrophy are prominent (in SCA3).

Propriospinal myoclonus is striking with axial and extremity arrhythmic jerks. The myoclonus of the abdomen is predominant.

Myoclonus diagnosed in the office is primarily a hereditary form, part of an ataxic syndrome or rarely a fragment of a seizure disorder.

Chapter 12

The Cerebral Cortex

Overview

Clinical anatomical correlations, studies with functional MRI, PET, SPECT and magnetoencephalography reveal that widely distributed brain networks form the basis of behavioral neurology. In essence, a lesion in varied areas of the brain may destroy a functional network which may then cause a specific deficit. Patterns or modes of distributed activity underlie functional connectivity. An eigenmode of functional connectivity, a covariance among regions or nodes, is the same as the eigenmodes of the underlying effective connectivity if it is restricted to symmetrical connections. The principal modes of functional connectivity correspond to dynamically unstable modes of effective connectivity that decay slowly and demonstrate long term memory. Dynamic instability underlies intrinsic brain networks. Cognitive flexibility and executive function require dynamic integration between brain areas. Should the previous sentence read as: The linking of brain regions (nodes) by their interactions (time-dependent edges or connections) groups brain region clusters together into densely interconnected structures (distributed networks) that change when a task is executed.

It is still clinically useful to assign major functions to specific anatomical areas of the brain with the understanding that this one area may be only one link in a distributed network. Another aspect of distributed networks is diaschisis of Von Monakow that must be borne in mind when performing pathological, anatomical and clinical correlations. This concept demonstrates that anatomical connections of a distributed network have metabolic and neurotransmitter concomitants that may cause a neurological deficit at a distance from the site of injury.

Electrical discharges from one area of the brain may damage homologous areas of the contralateral hemisphere or another component (node or edge) of the distributed network by:

1. Glutamate-NMDA excitotoxicity mechanisms
2. Induction of apoptosis from intracellular calcium dysregulation
3. Maladaptive neuroplasticity induced by immediate early response genes

In general, the anatomical, pathological and the clinical correlates of classic neurology have stood the test of time, but basic mechanisms have been more fully elaborated particularly on a molecular level.

Functional MRI has established the nodes and edges of the CNS connectome that comprise the major distributed networks that underlie higher cortical function and include:

1. The default mode network (DMN)
2. The salience network

3. Arousal and consciousness
4. Motor-sensory circuits
5. Executive function
6. Auditory and visual networks
7. Language networks
8. Memory and learning

Neurophysiological techniques such as EEG, magnetoencephalography and evoked potentials are able to evaluate spatial and time dimensions of a specific task.

PET radiotracers are able to evaluate the function of transmitter systems, microglial activation and neurochemical aggregate accumulation.

The Left Frontal Lobe

Executive function is a constellation of cognitive abilities that guide goal-oriented behavior and is comprised of working memory, inhibition, set shifting and fluency. These processes underlie planning and effective behavioral choices given specific options and are a major function of the left frontal lobe. Broca's aphasia and transcortical motor conduction aphasia occur with area 44 and superior Broca's area lesions. Immediately anterior to area 44 are the frontal operculum and the area triangularis. Lesions of this area cause a particular lack of facility with writing (out of proportion to hand weakness) and cortical negative variant grammatical mistakes.

Various apraxias occur with frontal lobe lesions. An apraxia is the inability to perform an isolated or sequential task in the face of normal motor, sensory and coordinative abilities. A specific motor function is first conceived and is denoted as an engram. The electrophysiological correlate is the *Bereitschaft* (readiness) potentials which are recorded over the prefrontal and supplementary motor cortices. They are then effected by the distributed motor circuitry of the cortico-pallido-thalamic cortical and cerebellar circuitries. Disorganization of simple or sequential engrams is the core of apraxia. Various apraxias are seen with left frontal lobe lesions. An ideomotor apraxia (the engram is encoded in area 6) is an inability to perform a single command such as saluting or using a comb. A patient with a callosal apraxia (right handed, left brain dominant) is unable to perform a simple task with the leg and hand. The command is decoded in Wernicke's area (posterior 1/3 of the superior temporal gyrus) and is projected to the left premotor area, crosses the corpus callosum (anteriorly) to synapse in the right prefrontal area which then engages the circuitry of the distributed motor loop. If the patient is able to perform the simple motor task, but does so with a lack of facility, it is a limb-kinetic apraxia (motor function has to be normal).

Major behavioral deficits of left frontal lobe lesions:

1. Poor planning
2. Poor behavioral choices
3. Poor executive function
4. Broca's aphasia

5. Acute mutism
6. Bilateral frontal opercular lesions
7. Anterior alien hand syndrome (intermanual conflict)
8. Callosal apraxia
9. Limb-kinetic apraxia – paracentral lobule
10. Writing apraxia (Exner's area)
11. Eyelid opening apraxia
12. Ideomotor apraxia
13. Constructional apraxia
14. Right-directional apraxia (hypokinesia)
15. Visual neglect of right hemispace
16. Imitation-utilization behavior (environmental-dependency)
17. Undue fatigue during the completion of a task
18. Paratonia (inability to change position once the extremity is placed)
19. Gait apraxia

Minor behavioral deficits:

1. Executing sequences
2. Inability to follow consecutive hand movements
3. Inability to copy facial movements
4. Difficulty following multiple commands
5. Inability to pair blink responses with voluntary saccades (the loop involved is from the posterior parietal cortex to the second frontal convolution)
6. Echopraxia
7. Sitting apraxia

The Primary Motor Cortex (M1)

Recent retrograde transneuronal transport of rabies virus from single muscles of rhesus monkeys has suggested a new organization of M1. The primary motor cortex is the major origin of descending motor commands for voluntary movement. The output from M1 of the corticospinal projections is from layer V. The corticospinal neurons are of two types. The axons from CST neurons that originate from the convexity of the precentral gyrus constitute approximately 5–10% of the CST neurons and synapse with interneurons of the intermediate zone of the spinal cord (Rexed layer VII). A proportion of these interneurons connects with motoneurons of Rexed layer IX and mediate a component of the descending command for movement. The major component of M1 cells that make direct contact with motoneurons of Rexed layer IX (termed corticomotoneuronal (CM)) cells take origin from the caudal portion of M1 in the anterior bank of the central sulcus. A few monosynaptic cells are also located in the rostral portion of M1 on the convexity of the precentral gyrus. Most single finger muscles are innervated by CM neurons from the caudal M1.

The new organization of M1 (as experimentally supported by tracing experiments in macaques) supports the view that M1 is subdivided into rostral and caudal zones that is based on the differential distribution of CM cells. The rostral zone

is on the crest of the precentral gyrus and the caudal zone is in the anterior bank of the CS. A great proportion of the CST neurons monosynaptically projects to interneurons of the ventral spinal cord. The CST neurons of the caudal region monosynaptically project to motoneurons in Rexed layer IX of the ventral spinal cord. In addition to distal forelimb muscles, shoulder and elbow musculature is also innervated by CST neurons from the caudal zone. The caudal zone directly synapses with motoneurons that control proximal and distal musculature. The direct monosynaptic connection from M1 to spinal motoneurons permits the development of more complex patterns of muscle activity and enhanced manual dexterity. The overlap of CM cells for different hand muscles and the muscles that control the elbow and shoulder enable the motor cortex to effect muscle synergies and multi-joint movement. The direct caudal zone connections are not present at birth and develop over the first months of life which parallels the development of new motor skills and the capacity for fractionated independent finger movement. Physiologic studies support a functional distinction between rostral and caudal subdivisions of M1. Neuronal activity in the rostral zone of M1 is correlated with the general direction and kinematics of hand movement while the caudal region controls the pattern of force production and the dynamics of the motor output. M1 has been shown to contain neurons that encode abstract movement parameters and others that discharge in concert with specific patterns of muscle activity.

The Premotor Cortex (PMC)

The premotor cortex is a complex mosaic of interconnected frontal lobe regions that are subdivided into lateral and medial components. The lateral component is located in Brodmann's area BA6 on the surface of the hemisphere rostral to the primary cortex M1. It has extensive reciprocal connections with M1 as well as axons that project through the corticobulbar and corticospinal tracts that modulate lower motor neurons of the brainstem and spinal cord. Approximately 30% of the axons in the CST originate from the PMC.

The structural distinctions between the PMC (area 6) and M1 (area 4) are:

1. Giant pyramidal cells (Betz cells) in layer V in M1 while there are fewer and smaller Betz cells in the PMC
2. The primary motor cortex is agranular; it lacks layer IV (that is composed of granular cells). Thus there is a transition between the agranular motor cortex (M1) and the six-layered PMC

The PMC is divided into four subregions based on cytoarchitecture, histochemistry and physiological properties. The studies delineating the specific anatomy and physiology of the PMC have been done in monkeys. If the correlation is congruent in humans is not known. The PMC utilizes projections and afferences from other cortical areas to select specific patterns of movement (an engram) that are appropriate for a

specific task. The neurophysiological correlate of this PMC function is the Bereitschafts- or readiness potentials that can be recorded over the PMC prior to movement. Their presence signifies voluntary intent for a specific movement.

Approximately 65% of neurons in the lateral premotor cortex are time locked to movement and increase their discharge frequency when the movement is made in a specific direction. The major connectivity of the PMC (BA6) is reciprocal with M1, the supplementary motor cortex (BA8, the medial component of the PMC), the superior and inferior parietal cortices and the prefrontal cortex (PFC). The premotor cortex has been divided into four fields, 2 dorsal and two ventral based on cytoarchitectonics based on experimental work in monkeys:

1. The premotor dorsal caudal field PMDc(F2):
 - a. A role in guiding and preparing movements
 - b. Neurons are active during preparation for the reach and during its execution
 - c. Respond most actively during one direction of reach
 - d. Stimulation of the area provokes a complex movement simulating reach
2. PMDr(F7):
 - a. This area may associate sensory stimuli with specific movements. It may also be associated with cortical control of eye movements
3. PMVc(F4):
 - a. This area is important for the sensory guidance of movement. Its neurons respond to tactile, visual and auditory stimuli. It may also be involved in object identification in peripersonal space (that immediately surrounding an individual)
4. PMVr(F5):
 - a. This region shapes the position of the hand during grasping and in interactions between the hand and the mouth

There are at least three representations of the hand in the motor cortex that are located in the primary motor cortex as well as one each in the ventral and dorsal PMC which suggests a specific function for each in control of hand movements.

It is presently thought that the lateral motor cortex is a mosaic of multiple subregions that includes M1 and several premotor fields that have specific functions. An alternative principle of organization for the primary motor cortex and the caudal portion of the premotor cortex is organization as a map of a behavioral repertoire in which different parts of the movement repertoire are located in different cortical subregions. Complex movements that require coordination among different body parts, the processing of complex variables, monitoring of objects in peripersonal space and control variables occur in the anterior portion of the motor map. The anterior motor map may also control complex movements that involve multisegments of the limb as the area also modulates the musculature of the neck and back which is a coordinating link between body parts. Simpler parts of the motor repertoire that controls the distal musculature are controlled by the primary motor cortex while more complex movements are initiated from the caudal premotor cortex.

The Medial Premotor Cortex (Supplementary Area BA8)

The supplementary motor cortex along with the lateral areas of the PMC are involved in selecting a specific movement or sequence of movements from a movement repertoire. Pathologic clinical correlations have demonstrated that the supplementary motor cortex is instrumental in coordinating muscle activation of both sides of the body, in speech, and the generation, temporal sequence and preparation of movements.

1. Motor function:
 - a. Initiates movements specified by internal cues. Experimental removal of this cortex in the monkey reduces self-initiated or spontaneous movement while the animal is able to execute movements in response to external cues
 - b. PET scans have demonstrated that activation of the SMA occurs in humans when subjects perform motor sequences from memory
 - c. Neuronal recordings demonstrate firing in the premotor cortex one to two seconds prior to the onset of self-paced movement
2. Aphasia (similar to Broca's)
3. Other motor functions:
 - a. Coordinating movements of both sides of the body during a task (walking, swing phase and stance phase)
 - b. Generation of engrams of movement
 - c. Temporal sequence of a motor task
 - d. Entrainment of motor sequences
 - e. Mirror movements may be seen with SMA lesions
 - f. Priming (encoding of consciously inaccessible knowledge)
 - g. Sequentially memory guided saccadic eye movements

The Major Motor Loops Derived from the Cortex

The major motor circuits arise from specific areas of the cerebral cortex, project to the basal ganglia and thalamus to return to their areas of origin in the frontal lobe. These circuits are characterized as:

1. Motor
2. Oculomotor
3. Prefrontal
4. Limbic

They have a segregated organization that facilitates parallel processing of cortical inputs through separate distributed networks. The separation of functional domains permits the targeting of specific nodes within a circuit without compromise of other circuit function. This is particularly true in the internal segment of the globus pallidus. Modulation of the subthalamic nucleus is less specific because of:

1. Its small size
2. The spatial proximity of its subdivisions
3. Wide dendritic fields
4. The overlap of adjacent terminal fields of corticothalamic projections

Movement disorders result from dysfunction within specific motor circuits. The motor circuit arises and terminates in cortical pre- and post-central motor areas that include M1, the premotor cortex (PMC), the cingulate motor area (CMA) and the supplementary motor area (SMA). These motor cortical areas project in a topographic organization to the motor portion of the striatum, putamen and post-commissural caudate nucleus and the motor component of the subthalamic nucleus (STN). The corticostriatal projections synapse on dendrites of striatal medium spiny projection neurons. Specific clusters of gamma-amino butyric acid (GABA-ergic) neurons connect the striatal motor nuclei to the external segment of the GPe, the internal segment of the GPi and the substantia nigra pars reticulata (SNr). The GPi and SNr are the primary output nuclei of the basal ganglia and project to the motor thalamus (VL_a, VL_m, VAp_c) and the brainstem. The topographic and parallel organization of connections is maintained from the cortex through the basal ganglia and thalamus.

The direct pathway from the striatum to GPi and SNr originates from medium spiny neurons that express D1-like receptors. The indirect pathway takes origin from striatal medium spiny neurons that synapse in the external segment of the globus pallidus (GPe) and express D2-like receptors. The external segment of GPe projects directly to GPi and via the STN. The hyperdirect pathway links frontal cortical areas to the STN. It is uncertain if this projection is from collaterals of corticobulbar and corticospinal fibers or takes origin from cortical neurons. The corticosubthalamic projection and that from the STN to the GPi constitute the hyperdirect pathway. This pathway facilitates cortical input to the STN and GPi at a faster latency than that which synapses in the striatum.

In the thalamus, projections of the motor circuit components synapse in the anterior ventrolateral thalamic nucleus, while projections from the associative circuit (primarily from SNr) synapse in the ventral anterior thalamic nucleus. The thalamic projections to the motor cortex fields (primarily glutamatergic) arise from the anterior ventrolateral and the ventral anterior thalamic nuclei to close the motor circuit. Clinical and experimental evidence indicate that the motor circuit has multiple non-overlapping parallel subcircuits centered on the delineated motor fields. There are collateral projections from both the pallidofugal and nigrothalamic (SNr) to the intralaminar nuclei. The centromedian nucleus (demonstrated in primates) receives afferents from the motor components of GPi and SNr which in turn project to the motor areas of the putamen and STN. The afferents to the parafascicular nucleus and its efferent output belong to the associative and limbic circuitry.

Axon collaterals of GPi and SNr synapse in the brainstem as well as the pedunculopontine nucleus and the superior colliculus. The pedunculopontine nucleus is heterogeneous and projects widely utilizing acetylcholine as its neurotransmitter to the thalamus, cerebellum and the brainstem. It has non-cholinergic projections to the SNpc, STN and globus pallidus as well as descending projections to the pons, medulla and

spinal cord. It is a component of the brainstem locomotor area and may be important for gait ignition. Experimental lesions in primates decrease spontaneous movement. There are subcortical anatomical and physiological interactions between the cerebellum and basal ganglia circuitries making a pure lesion of each unlikely. Dysfunction in either network may affect the other. Examples of this type of subcortical interaction have been hypothesized to occur in the rest tremor of Parkinson's disease and some forms of dystonia.

Functional interactions between the direct, indirect and hyperdirect motor circuitries determine the amplitude, speed, extent and duration of movement. The output of the GPi and SNr is inhibitory due to the release of GABA on brainstem and thalamic motor projection neurons. The activity of the direct and indirect motor circuitries facilitates or decreases movement respectively.

Cortical phasic activation of medium spiny neurons of the direct pathway directly decreases GABA-ergic output from the GPi and the SNr. Thus the thalamocortical motor projection neurons (utilizing glutamate) stimulate the motor neurons of M1, PMC and SMA that facilitates movement. Activation of the medium spiny neurons of the indirect pathway induces increased GABA-ergic output from the basal ganglia that suppresses glutamatergic stimulation of the motor cortex with consequent bradykinesia and reduced movement. The balance between activation of the direct and indirect circuitries determine the parameters of movement. It has been hypothesized that the hyperdirect pathway prevents premature reflexive responses to external stimuli by increasing inhibitory output to thalamocortical projection neurons. This mechanism would increase the time to select a more appropriate motor program. It may also play a role in switching from automatic and habitual motor programs to voluntary control.

A great deal of cortical and basal ganglion physiology is based on dopaminergic transmission. Corticostriatal transmission over the direct pathway is facilitated by dopamine release. It inhibits corticostriatal transmission over the indirect pathway. Its net effect, striatal dopamine release, would be a reduction of inhibitory basal ganglia output which would facilitate movement. Dopamine acts directly on receptors in the STN, the pallidum, thalamus and cortex that influence discharge patterns and rates in these nuclei and motor areas.

Phasic activation of dopamine receptors and medium spiny neurons induces long term potentiation or depression of corticothalamic neurotransmission which are mechanisms that are thought to be essential for reinforcement learning. The prefrontal associative cortex appears to be important for the learning of a motor task while the motor cortex executes the learned motor sequences.

Modulation of the motor circuit components of the STN, GPi and thalamus is effective for different movement disorders by disrupting abnormal projections from the basal ganglia which may allow intact portions of the motor circuit to function normally.

The Dorsolateral Prefrontal Cortex (DLPFC)

The DLPFC is generally thought to comprise the lateral part of Brodmann's areas BA9 and BA46 of the middle frontal gyrus. Some scientists have included BA8, BA9 and BA10. Its principal connections are the orbitofrontal cortex, the thalamus, the dorsal caudate nucleus, the hippocampal formation and primary and secondary association areas of the posterior temporal, parietal and occipital lobes. The DLPFC receives afferences from the dorsal visual stream. The ventrolateral prefrontal cortex receives visual afferences from the ventral pathway that identifies the characteristics of a visual stimulus.

A primary function of DLPFC is executive function that involves the higher cognitive processes of working memory, cognitive flexibility and planning. These functions had been extensively studied neuropsychologically utilizing the A-not-B task, the delayed response and object retrieval tests. The A-not-B/delayed response task requires the patient to find a hidden object after a time delay. This test utilizes working memory that is not required for memory of a single item (recognition memory). The DLPFC is required if two objects have to be compared from memory. Patients with DLPFC lesions are unable to identify objects they have seen after a time delay. Patients fail the Wisconsin card-sorting test as they are unable to maintain the current rule and organize their cards according to the previous correct rule. The DLPFC plays a major role in mood, emotional processing, and attentional processing of emotional information. The major functions of the DLPFC are in:

1. Decision evaluation:
 - a. The DLPFC is activated when subjects have to decide risk and moral attributes of a situation (how to distribute limited resources)
 - b. Cost benefit analysis of alternate choices
2. Working memory:
 - a. Working memory allows the individual to utilize transitory information to perform a task. It may be involved in computational mechanisms for monitoring and manipulating material
 - b. Analyzing visuospatial information to mentally represent coordinates within the spatial domain
3. Specialized DLPFC behavior functions include:
 - a. Act of deception and lying
 - b. Conflict-induced behavioral adjustments (what to do within conflicting rules that require action)
 - c. Associated with intelligence:
 - i. Involvement in deductive syllogistic reasoning
 - d. Threat-induced anxiety:
 - i. Theorized to be related to deficits in problem solving
 - e. Social cognition:
 - i. The DLPFC may be involved in:
 1. Inferring the intentions of other people
 2. Suppression of selfish behavior
 3. Commitment in a relationship

The DLPFC is important as a store of knowledge to solve problems that are immediate, to perform internally generated motor tasks and to perform motor functions that require multiple sequences. It is important in memory retrieval that is pivotal for working memory. The frontal eye fields are located in the DLPFC which initiate saccadic eye movements and are important for ocular fixation.

Major clinical behavior deficits in patients with DLPFC lesions

1. Pseudodepression syndrome:

- a. Psychomotor inhibition
- b. Indifference
- c. Lack of drive
- d. Decreased emotional reactivity

General clinical deficits with DLPFC lesions:

1. Decreased procedural learning
2. Decreased ability to index events in time
3. Failure to develop internal references
4. Apraxia:
 - a. Defective performance of purposive acts
5. Deficits in working memory
6. Deficits in awareness of near extrapersonal space:
 - a. Space that is within the grasp of the patient
7. Switching motor programs
8. Abulia
9. Post-stroke depression:
 - a. The severity of depression is related to the proximity of the lesion to the frontal pole
10. Release of approach behavior

Left Ventrolateral Prefrontal Cortex (VLPFC)

The ventrolateral prefrontal cortex is located in the inferior frontal gyrus that is bounded superiorly by the inferior frontal sulcus and inferiorly by the lateral sulcus. It includes Brodmann's area BA44, BA45 and BA47. It has anterior, mid and posterior subdivisions that have specific functional differences between the right and left VLPFC.

The left VLPFC is important in the cognitive control of memory. The anterior division (BA47; inferior frontal gyrus pars orbitalis) is involved with controlled access to stored conceptual representations. The mid VLPFC (BA45; inferior frontal gyrus pars triangularis) functions in a domain-general selection process that is involved in a post-retrieval process to resolve competition between active representations.

BA47 (left side) may also be involved in syntax processing in oral and sign language, musical syntax and semantic aspects of language.

Right Ventrolateral Prefrontal Cortex (VLPFC)

The right VLPFC is a functionally heterogeneous area. The prefrontal cortex in general has been shown to exert top-down

control of cognition in the execution of a desired task by utilizing multiple specific mechanisms. There are two prominent hypothesis of right VLPFC function:

1. The VLPFC putatively is involved in motor inhibition that stops or overrides a motor program. This function is supported by neuroimaging studies during tasks that require inhibition and clinical studies in patients with damage to the inferior portion of the right VLPFC that take longer than controls to override a motor task
2. It has also been proposed that the right VLPFC is a component of a right-lateralized ventral attention network that controls reflex reorienting. The area functions in concert with a region of the right temporoparietal junction (TPJ) and the inferior parietal lobule to reorient attention to stimuli that abruptly occur outside of the current focus of attention
3. The right VLPFC is active during the updating of action plans
4. The right middle VLPFC (BA45) is activated during decision uncertainty
5. The VLPFC is the termination of the ventral pathway of vision that is engaged in the determination of the characteristics of an object
6. The right VLPFC may be important in the mirror motor neuron system. These neurons respond both to the execution of an action and during the observation of performance of the same action. This system may be involved in imitation, empathy and social cognition. Neuroimaging studies have demonstrated bilateral activation of the VLPFC in concert with other regions during the observation of an action and imitation. The inferior frontal junction and the posterior and mid-VLPFC are prominently activated during these tasks. The orbital frontal cortex is Brodmann's areas BA10, BA11 and BA47. Anatomically it is usually considered to be synonymous with the ventromedial prefrontal cortex. It has widespread connections with primary and secondary association cortices, the limbic system and receives afferents from the magnocellular medial nucleus of the mediodorsal thalamus. It has extensive corticocortical connections with other prefrontal areas that include motor, limbic and sensory cortices. Its projections support a major role in the integration for executive motor control. All sensory cortices are reciprocally connected with the orbitofrontal cortex. There is extensive innervation from regions associated with olfaction and taste. Its somatosensory innervation from SI and SII is particularly dense in areas associated with innervation of the hand and trigeminal complex

The orbitofrontal cortex receives a rostral stream for auditory phonetic processing and a caudal stream that terminates just posterior to it in the periarculate prefrontal cortex that is associated with auditory-spatial processing. (There is overlap with OFC in this area.) Both the dorsal and ventral visual streams terminate in orbitofrontal cortical regions. There are dense reciprocal connections to the temporal pole, an area that

is important for integration of spatial and object processing. The OFC is reciprocally connected with limbic areas that include the granular, dysgranular and agranular insular cortex, the parahippocampal gyrus, the hippocampus, the amygdala and the hypothalamus.

Its striated projections are dense to the ventral reward-related areas. It has connectivity with thalamic and periaqueductal areas posited to be involved with autonomic functions.

Clinical pathologic and neuroimaging associated with specific tasks support a role for the OFC in decision selection, emotional control and reward expectation. Disruption of the striato-thalamo-orbitofrontal circuitry may be involved in drug addiction and substance abuse. Neural reward circuitry may also be involved with attention deficit hyperactivity disorder (ADHD). This circuitry is putatively involved in motivation, reward and impulsivity.

The medial component of the OFC is primarily connected to the hippocampus and associated areas of the cingulate, retrosplenial and entorhinal cortices, the anterior thalamus and the septal diagonal band of Broca. The lateral component of the OFC is characterized by its anterior section connectivity with the granular insula association cortex, mediodorsal thalamic nucleus, inferior parietal lobule and the dorsolateral PFC. Its most caudal sector has dense connections with the amygdala, midline thalamus, non-isocortical insula and the temporal pole.

Functionally the medial OFC is putatively involved in stimulus-reward selection and reinforcement of behavior. The lateral OFC is putatively involved in stimulus-outcome associations. The evaluation and possible reversal of behavior.

Activation and involvement of the lateral OFC occurs:

1. During the encoding of new expectations in regard to punishment and social reprisal
2. Approach avoidance contexts (suppressing negative emotions)
3. Conflict resolution:
 - a. Inappropriate anger and inappropriate response to anger in others
 - b. LOFC lesions have been associated with defensive personality traits
4. Machiavellian personality traits are seen if the medial OFC is activated with:
 - a. Monitoring, learning and memory of the reward value of reinforcers

In general, more complex or abstract reinforcers of value are represented more anteriorly in the OFC. There is a suggestion that the OFC mediates subjective hedonic experience.

The OFC is the termination of the olfactory cortex, the piriform cortex, amygdala and entorhinal cortex without a thalamic relay.

The OFC, nucleus accumbens and amygdala are thought to be major components influencing addictive behavior. A proposed mechanism is dopaminergic activation of reward circuits. The OFC may also be associated with compulsive,

repetitive behavior and drive via dysfunction of the striato-thalamo-orbitofrontal circuitry. The OFC projects to the nucleus accumbens via the mediodorsal nucleus of the thalamus that is thought to be important in reinforcing the effects of an administered drug of abuse. There are reciprocal nucleus accumbens projections to the OFC which also receives afferences from the dopaminergic ventral tegmental area (A10). The VTA has been posited with reinforcing the effect of drugs. Limbic regions of the hippocampus, cingulate gyrus, and amygdala project to the OFC which may function to integrate this information to modulate the response of limbic areas to the rewarding effects of drugs of abuse.

Addictive patients have deficits in orbitofrontal, striatal, and thalamic nuclei. It is posited that conscious mechanisms involve craving that is associated with loss of control and subconscious mechanisms that include anticipated conditioned responses to the addicting drug and impulsivity. Neuroimaging studies of cocaine withdrawal demonstrate increased glucose metabolism in the OFC that correlates to the degree of drug craving. During protracted withdrawal (3–4 months), there is decreased metabolism in the OFC of cocaine addicts as compared to healthy non-addicted subjects. There is a similar decreased metabolic activity in the OFC during withdrawal. This response is confounded due to the fact that detoxified alcoholics have lower levels of benzodiazepine receptors in the OFC (compared to healthy subjects) as well as decreased OFC metabolism in response to serotonergic and GABA-ergic stimulation. The role of these transmitter systems is not fully determined in cocaine addiction.

Other orbitofrontal cortex associated behaviors:

1. Pseudopsychopathic behavior
 - a. Disinhibition
 - b. Facetiousness
 - c. Sexual/perverted behaviors
 - d. Lack of concern for the effects of behavior
2. Bilateral lesions cause retrograde amnesia
3. Failure to break previously learned associations
4. Medial orbitofrontal lesions are associated with confabulation (similar to mediodorsal thalamic lesions that project to the OFC are seen with Korsakoff's syndrome)
5. Mania
6. Autonomic regulation of vagal tone

The Right Frontal Lobe

The distributed functions of the right frontal lobe are most involved with emotional control and inhibitory control of the limbic system. Deficits in the right frontal lobe are associated with disinhibition of personal behaviors, hygiene and sexual conduct. Patients frequently demonstrate "witzelsucht" (inappropriate jocularity) as well as impersistence.

Major right frontal lobe deficits:

1. Disinhibition:

- a. Personal behavior
 - b. Poor hygiene
 - c. Sexual dysfunction
 2. Inappropriate jocularity; "witzelsucht"; a drive to tell bad jokes
 3. Impersistence of a motor task
 4. Neglect of left hemisphere
 5. Stimulus familiarity and novelty abnormalities
 6. False recognition syndrome with confabulation
- Minor right frontal lobe deficits:
1. Understanding and mediating negative emotions
 2. Area 6 and 8 lesions are associated with simultanapraxia (inability to coordinate both sides of the body to accomplish a motor function)
 3. Right frontal eye fields direct bilateral search of the visual landscape
 4. Retrieving the temporal order of stimuli

The Parietal Lobe

The parietal lobe is central to somatosensory function. It contains the primary somatosensory cortex, Brodmann areas BA3, BA1 and BA2. It is somatotopically organized such that the lower extremity is at the top of the post-central gyrus and the mouth is inferior. The amount of primary somatosensory cortex representing a body part is proportional to the relative density of the cutaneous tactile receptors of that body part and the degree of sensitivity of that area. Thus the lip and hands have the largest representation.

BA3 is subdivided into areas 3a and 3b. 3a has pyramidal cells in layer V and layer IV is less granular than in 3b. Its cortical connections are with BA4, BA1 and BA5 and SII. It has a heavy muscle spindle input which responds during movement. It has some cutaneous sensitivity.

3b receives dense input from the major sensory nucleus of the thalamus (VPL). Its neurons respond to somatosensory stimuli (rarely to other stimuli), lesions impair somatic sensation and its electrical stimulation elicits somatic sensations. Its cortical connections are with BA1, BA2, BA3a, BA5 and SII. Its primary cutaneous afference is from rapidly adapting (RA1) and slowly adapting (SA) cutaneous receptors whose origin is from VPL. The projections from 3b to area 1 primarily are associated with texture information and that to area 2 relays information in regard to size and shape.

BA1 has granular layers III, IV and V which are less dense than in 3b. Its cortical connections are with BA2, BA3a, BA4, SII and reciprocally with 3b. Its afferences are from cutaneous RA1 and RA11 receptors whose origin is the VPL.

BA2 has a more dense granular IV than BA1. It receives projections from muscle and joints, some cutaneous receptors and contains direction sensitive, multidigit complex receptive fields. Its BA connections are with BA4, BA5, BA6, BA3a and SII. It provides feedback to 3b and 1.

Each of the four cytoarchitectonic regions contains a functionally distinct map of the peripheral body schema. Thala-

mic inputs project into layer IV that then project into other layers. S1 neurons are organized into vertical columns that have similar inputs and responses and extend through all of the cortical layers. Area 3a is at the top of the central sulcus followed in ascending order (towards the apex) by 3b, 1 and 2. The homunculus is organized somatotopically. The legs and trunk are at the top of the parietal convexity, the arm and leg are mid convexity, and the face is most inferior.

The functional organization of the posterior parietal cortex (PPC) has been extensively investigated in both humans and macaques both neurophysiologically and with functional MRI. The PPC contains specific clusters of neurons that are involved with goal-directed arm and eye movements needed for reaching, grasping and ocular fixation and saccadic eye movement. Functional MRI studies in patients have begun to delineate the role of the PPC in attention, planning, execution of movement and the control of rapid eye movements. The posterior parietal area is subdivided into the superior parietal lobule (Brodmann areas BA5 and BA7) and the inferior parietal lobule (BA39 and BA40) by the intraparietal sulcus (IPS). These areas integrate neural afferents from different sensory modalities to guide and control movements in space. They are arranged modularly, are reciprocally interconnected and comprise a series of neural circuits that involve both the frontal lobe and visual areas of the occipital cortex. The neurons of a specific IPS area encode the spatial coordinates of objects, the position of a body part in space, eye movement parameters and the shape, size and orientation of objects. The IPS is an anatomically constant sulcus in humans but has complex folding and branching patterns that have made it difficult to study in humans. The macaque monkey intraparietal sulcus has been studied on a cellular electrophysiological level and is thought to be relevant to its human counterpart.

Anterior parts of the IPS function in sensorimotor processing while its posterior parts are involved in visual information processing. Neurons in the IPS that are located in its medial bank are responsive to arm movements while those located in the lateral bank are involved with eye movements. Each area of the IPS receives and processes information from more than one sensory modality.

Anterior Intraparietal (AIP) Cortex

Clinical pathological correlation in patients with lesions of the anterior intraparietal cortex has demonstrated its importance for manipulating objects and grasping movements. PET studies in healthy subjects have shown that the anterior IPS is a component of a tactile shape-processing network that discriminates objects from changes in their 3D structure. Both areas in the anterior and posterior IPS are activated during the construction or recognition of 3D shapes by finger manipulation. The same area may be important for the discrimination of the orientation of a visual stimulus. The anterior

intraparietal cortex functions in tactile and visual object processing.

The Putative Ventral Intraparietal Area (VIP)

In macaques the VIP encodes polymodal motion processing primarily in head-centered coordinates. Visual, auditory and tactile motion detection and vestibular processing have been shown to activate modality-specific and supramodal areas of the VIP. These studies have demonstrated involvement of the PPC that supports this part of the parietal cortex as a component of a polymodal information-processing neural circuit. Lesion studies in patients demonstrate that the PPC is involved in the clinical phenomena of neglect or extinction that affects multiple modalities that are often organized in a head-centered frame of reference. It has been suggested that lesions of a putative human VIP may cause a component of visuospatial neglect.

The Putative Human Medial Intraparietal Area (IPA)

The human medial IPA is essential for visuomotor coordination of hand movements that require adjustment for dynamic grasp and the abrupt switches between grip apertures for different target sizes. Thus the medial intraparietal area is necessary for online-control and the correction of movement errors. Patients with optic ataxia (most often under-reaching the target) have lesions of the medial intraparietal cortex or contiguous areas. Functional MRI data support that the medial intraparietal cortex transforms visual coordinates into motor programs and is essential for the online control of goal-directed precision movements.

Putative Lateral Intraparietal Cortex (LIP)

In macaques LIP is located in the lateral wall of the IPS (intraparietal sulcus) and is a component of the saccadic network. It receives afferences from several areas of the visual cortex and projects to the frontal eye field (FEF) and the superior colliculus. These neurons discharge during the detection of a salient visual stimulus, during the delay period when the location of the stimulus is memorized and during the saccade to the intended location. Some studies demonstrate that the LIP is involved in the representation of the motor programs for saccadic movements. Other studies suggest that LIP neurons discharge at the locus of attention and therefore represent a salience map. This function may contribute to the maintenance of a spatially accurate representation of the visual field during eye movements.

Functional MRI studies in human subjects have shown that the IPS is involved in attention and the control of eye movements. Shifts in visuospatial attention activate the IPS as does detection of the target. In humans, the activation is in the medial rather than the lateral wall of IPS as occurs in the macaque.

The Putative CIP Area in Humans

Both PET and functional MRI studies demonstrate that posterior areas of the IPS are activated during the analysis of surface and pattern orientation. The human equivalent of CIP is located in the medial bank of the IPS and not lateral which is its location in the macaque.

The combined use of functional MRI and diffusion tensor imaging demonstrates that posterior IPS connects to retinotopically defined visual regions and the superior temporal gyrus while anterior IPS regions have higher connection probabilities to the prefrontal cortex. All IPS regions have interhemispheric connections to homologous areas of the contralateral hemisphere and connections to the thalamus and striatum.

Multiple visual maps exist within the intraparietal sulcus that are essential for encoding visuospatial information. Each hemisphere symmetrically represents contralateral visual space. The two major forms of hemispheric asymmetry occur in the parietal cortex ventrolateral to areas that are functional for visuotopic discrimination in the IPS. Attentional processes are localized in the right lateral parietal cortex primarily in the temporoparietal junction and long-term memory retrieval processes are localized to the cingulate gyrus of the left parietal cortex.

A frontoparietal attention network consisting of the IPS, the inferior parietal lobe and the dorsal premotor cortex that includes the frontal eyelids controls the selection of sensory targets by attention. The nodes of this network are connected by edges (sensory fibers) that form the superior longitudinal fasciculus.

The functional characteristics of the posterior parietal cortex include:

1. Feature-independent coding
2. Enhancement of activity by attention
3. Representation of task-related signals
4. The posterior parietal cortex comprises multiple reference frames that compute features and modality maps of the environment. It is postulated that the priority map integrates information from the sensory cortex with behavioral goals and expectations from the dorsolateral prefrontal and premotor cortex. The frontoparietal attention network has a decisive role in the selection of relevant environmental information
5. The PPC is activated in the planning and control of goal directed-action. Electrophysiologic studies in macaques have delineated reach-specific areas in the PPC. The reach modules (forearm and hand) in the human PPC area are the superior parietal cortex, the occipital cortex, the mid-posterior intraparietal cortex and the cingulate gyrus. A functional framework for the human PPC has been proposed and includes:
 - a. Encoding of reach goals in the posterior-medial PPC
 - b. Reach movement vectors are processed in anterior-lateral PPC areas

- c. Integration within a broader cortical framework for reach grasp and eye-hand coordination that enables the spatial information in the parietal reach region to influence eye control pathways

In summary, the posterior parietal cortex is essential for the production of planned movement. It receives afferents from sensory systems that localize the body in space (visual, somatosensory and auditory). Its major output is the frontal motor cortex, the dorsolateral prefrontal cortex, the secondary motor cortex and frontal eye fields. It is composed of a mosaic of small modules that guide the movements of the eyes, head, and extremities.

The primary deficits in patients from PPC injury are in:

1. Perception and memory of spatial relationships
2. Hand movements, particularly reaching and grasping
3. Control of saccadic eye movements
4. Attention
5. Hemispatial neglect

General Parietal Lobe Sensory Function (Similar in Each Hemisphere)

1. Two point discrimination
2. Localization of extremities and objects in near and far space (outside of the examiner's grasp)
3. Graphesthesia
4. Stereognosis
5. Point localization
6. Perceptual rivalry of double simultaneous stimuli. Non-perception of the damaged side
7. Posterior parietal cortex:
 - a. Reach and grasping (the modules in the intraparietal cortex)
8. Anterior intraparietal sulcal cortex:
 - a. Manipulation or active touch
9. Posterior superior parietal cortex:
 - a. Inability to utilize stereoscopic vision for hand movements
 - b. Optic ataxia (area 5)
10. Gesture representations:
 - a. Bilateral ventral medial parietal lobe
 - b. Inability to recognize objects (BA7)
11. Inferior parietal lobule:
 - a. Memory or recognition of spatial position
12. Medial parietal lobe:
 - a. Deficient sense of direction
13. Intraoral sensation (parietal operculum)

Right Parietal Lobe

1. Visuospatial processing
2. Asomatognosis (denial of a body part)
3. Denial of illness (anosognosia)
4. Asimultagnosia:

- a. Inability to synthesize parts of an object into a whole (eyes, ears and nose can be recognized but the patient cannot synthesize these individual parts to perceive a face)
- 5. Left visual inattention (hemineglect)
- 6. Aprsody:
 - a. Flat speech without the proper intonations appropriate for the circumstances
- 7. Constructional apraxia
- 8. Dressing apraxia
- 9. Pressure of speech
- 10. Inability to judge the directional orientation of lines (right posterior parietal areas)
- 11. Inability to discriminate faces
- 12. Right superior parietal cortex:
 - a. Poor visual-manual coordination
 - b. Optic apraxia
 - c. Inability to judge a previously bisected line
- 13. Responding to a question posed to an adjacent patient
- 14. Gourmand syndrome:
 - a. Eating disorder
- 15. Decreased short term memory
- 16. SII involvement:
 - a. Asymbolia for pain
 - b. The entire body is represented
 - c. Located at the foot of SI with the head dorsal and foot ventral
 - d. A sensation of heat that may rise and envelope the entire body (a seizure aura)
- 17. Topographic disorientation:
 - a. Right medial parietal lobe
- 18. Topographic amnesia:
 - a. Inability to remember shapes and locations
- 19. Alloesthesia
 - a. Touch on the abnormal side is transferred to a homologous position on the normal side
 - b. Impulse control disorder

Left Parietal Lobe Function

- 1. Gerstmann's syndrome:
 - a. Right-left confusion
 - b. Inability to cross the midline
 - c. Finger agnosia
 - d. Conduction aphasia
 - e. Dyslexia with or without agraphia
- 2. Bilateral deficits in point localization
- 3. Alexia without agraphia (BA39, 40 & 41)
- 4. Conduction aphasia:
 - a. Disconnection of Wernicke's and Broca's area
 - b. Damage to the arcuate fasciculus
- 5. Inferior left posterior parietal lobule:
 - a. Deficits in auditory verbal short term memory
- 6. Superior parietal lobule:
 - a. Appreciation of detail
- 7. Parietal-occipital function:

- a. Bálint's syndrome:
 - i. Most often the lesions are bilateral for the full blown syndrome
 - ii. Deficit in visual scanning
 - iii. Optic ataxia (undershooting an object on attempted grasp)
- 8. Color anomia
- 9. Anomic aphasia:
 - a. Lesion of the supramarginal gyrus
- 10. Posterior alien hand:
 - a. Posterior parietal areas 5 and 7
 - b. Ideational apraxia:
 - i. Inability to complete a sequence of commands
 - ii. Lesions of the supramarginal and L superior lobule

The Temporal Lobe

The temporal lobe's distributed functions include receptive speech that is involved in processing sensory input into language comprehension that occurs primarily in Wernicke's area and in the basal temporal language areas. The right temporal lobe processes visual memory. The middle temporal gyrus visual area is vital to recognition and tracking of moving objects. The dorsal visual stream of the parietal lobe is most important for delineating the salience and position of objects. Medial temporal lobe structures are pivotal for the registration and consolidation of short term memory. The temporal lobes are one of the anatomical substrates of personality in and of itself and due to its anatomical projections to the limbic system and frontal lobes (the uncinate fasciculus is a major projections tract).

The medial temporal lobe is critical for declarative memory or explicit memory which is conscious memory that is divided into semantic memory for facts and episodic memory for events. The hippocampus, perirhinal, parahippocampal and entorhinal neocortical areas are fundamental for this memory function. Areas of the prefrontal and visual cortices are also activated during explicit memory. The hippocampus is essential for the inscription of memory (the first thirty seconds) and the encoding of short term memory (those that last for less than 3 minutes). The lateral temporal lobe is involved in primary auditory perception as it contains the primary auditory cortex in the superior temporal gyrus.

The ventral visual stream terminates in the inferior temporal gyrus where object and complex stimuli such as faces (fusiform gyrus) and scenes (parahippocampal gyrus) are decoded.

The inferior temporal cortex has been extensively studied both electrophysiologically and with functional MRI. The inferior temporal cortex (ITC) contains multiple color-biased areas that are ventral to regions activated by face perceptions. Both color and face areas are located anteriorly in the ITC. The ITC areas comprise parallel and multi-stage processing networks that are organized as a coarse map of eccentricity

similar to the retinotopic map in the visual cortex. Peripheral representations of objects overlap with regions that respond to the place of the object. Some functional MRI experiments have suggested that the ITC is not retinotopically organized but reflects an organization based on size. Regions of ITC that are activated by images of large objects are separated from areas activated by images of small objects.

Activity in the face-selective fusiform cortex is enhanced by emotional (usually fearful) expressions.

Left Temporal Lobe

1. Wernicke's aphasia (BA22, BA23)
2. Rostral Pole (proper name anomia)
3. Sensory conduction aphasia
4. Short term memory loss
5. Basal temporal language area:
 - a. Receptive speech/anomia
 - b. Deficits in confrontational naming
6. Color anomia:
 - a. Medial temporal lobe
 - b. Fusiform gyrus
7. Temporal/occipital junction:
 - a. Dorsal
 - i. Pure alexia
8. Semantic memory:
 - a. Left inferior temporal gyrus
9. Superior temporal gyrus:
 - a. Consolidation of memory
10. Grammatical comprehension:
 - a. Anterior temporal lobe
11. Temporal parietal junction:
 - a. Object word naming

Right Temporal Lobe

1. Anterior temporal lobe:
 - a. Anxiety/panic attacks
 - b. Amnesia
 - c. Apraxia
 - d. Agitated delirium:
 - i. Superior and middle temporal gyrus
 - e. Aura of hunger
 - f. Priming for memory
 - g. Non-verbal amnesia
 - h. Pathologic crying
 - i. Right hippocampus:
 - i. Non-verbal task processing:
 1. Spatial information
 2. Less readily verbalizable visual stimuli
 - j. Parahippocampal gyrus:
 - i. Encoding of spatial information for long-term storage
 - k. Prosopagnosia:
 - i. Impairment in the recognition of faces and of unique individual facial features
 - l. Visual agnosia:
 - i. Impairment in the identification of familiar objects

Bilateral Temporal Lobe Dysfunction

General Characteristics

1. Causes of bilateral temporal lobe disease
 - a. The major pathologies are complex partial seizures that induce temporal lobe dysfunction contralateral to the seizure focus (excitotoxicity)
 - b. Head trauma
 - c. Temporal lobectomy:
 - i. The contralateral temporal lobe is defective
 - d. Herpes simplex (Klüver-Bucy syndrome)
 - e. Urbach-Wiethe disease
 - f. Irradiation of the pituitary
 - g. Pick's disease
 - h. Frontal temporal dementia
 - i. Korsakoff's syndrome

Clinical Manifestations

1. Deafness
2. Apathy and personality change
3. Impaired learning and memory
4. Amnesia

Neuropathology

1. Klüver-Bucy syndrome:
 - a. General characteristics:
 - i. It is most often incomplete
 - ii. A dangerous complication of lesioned temporal lobectomy
 - b. Clinical manifestations:
 - i. Most often associated with bilateral damage or removal of the temporal lobes that contain the amygdale
 - ii. Hypersexuality
 - iii. Hyperorality
 - iv. Hypermetamorphopsia (excessive explanation, attention and manipulation of visual stimulus)
 - v. Visual agnosia
 - vi. Apathy
 - vii. Severe memory deficits
 - c. Neuropathology:
 - i. Dependent on the pathologic process that affects the medial temporal lobe structures
 - d. Laboratory Evaluation:
 - i. MRI:
 1. Destruction of medial temporal lobe structure including the amygdala
 2. EEG
 3. Neuropsychological testing

Urbach-Wiethe Disease

General Characteristics

1. Lipoid proteinosis (Urbach-Wiethe disease) is caused by homozygous or compound heterozygous mutation in the ECM1 gene that maps to chromosome 1q21

2. It is autosomal recessive in inheritance
3. The extracellular matrix protein 1 (ECM1) gene encodes for a glycoprotein that appears to be involved in skin adhesions, epidermal differentiation, wound healing and scarring, endochondral bone formation, tumor biology, endothelial cell proliferation and angiogenesis

Clinical Manifestations

1. Dermatological:
 - a. Changes of the skin have onset in infancy with thickening of the skin and mucous membranes
 - b. Thickening of the vocal cords with hoarseness
 - c. Lesions and scars occur on the face and distal extremities from poor wound healing
 - d. The skin is dry and wrinkled, it may appear waxy
 - e. White or yellow infiltrates occur in the lips, buccal mucosa, tonsils, uvula and epiglottis
 - f. Beading of papules around the eyelids is common
 - g. Rare dermatological and other signs include:
 - i. Hair loss
 - ii. Parotitis
 - iii. Dental abnormalities
 - iv. Corneal ulceration
 - v. Focal macular degeneration

Neurological Manifestations

1. 50–70% of patients have calcification of the amygdala and the periamygdaloid gyri
2. Abnormal fear response
3. Complex partial seizures (temporal lobe origin)
4. Partial or complete Klüver-Bucy signs and symptoms

Neuropathology

1. Accumulation of hyaline-like material in the dermis and thickening of the skin basement membrane. The hyaline material is periodic acid-Schiff (PAS) positive
2. Calcium deposits within the amygdala blood vessels with gradual ischemic infarction
3. Staining of skin lesions with antitype I collagen antibodies or antitype VII collagen antibodies is positive at the dermoepidermal junction

Laboratory Evaluation

1. Genetic testing for identification of the ECM1 gene
2. Skin biopsy
3. MRI:
 - a. Calcification of the amygdala

Amygdala Seizures

Clinical Manifestations

1. Seizure semiology:
 - a. Freezing response
 - b. Autonomic response (paleness)
 - c. Lack of emotional expression

- d. Slow contralateral turning (may occasionally be ipsilateral turning)
- e. Automatism:
 - i. Lip smacking or chewing
2. Medial amygdala nuclear discharge:
 - a. Ictal fear
 - i. Abdominal location
 - ii. Free-floating; cannot be linked with an expected or past event
 - iii. Associated with excessive anxiety
 - iv. Feeling of impending doom

The Cingulate Cortex

The cingulate cortex includes the enteric cingulate gyrus, is located above the corpus callosum and extends into the cingulate sulcus. It is part of the limbic lobe. Its major afferences are from the thalamus and the neocortex and it projects to the entorhinal cortex via the cingulum. It is essential for emotional formation and processing, learning, memory, pain, motivation and emotional components of movement. It is on the medial surface of the hemisphere and is composed of Brodmann's areas BA23, BA24, BA26, BA29, BA30, BA31, BA32 and BA33. BA26, BA29 and BA30 are its retrosplenial components.

1. The anterior cingulate cortex:
 - a. Is composed of Brodmann's areas BA24, BA32 and BA33; its anterior continuation is located below the genu of the corpus callosum (BA25)
 - b. Cytoarchitectonically it is agranular
 - c. It is divided further into the pregenual anterior cingulate cortex that is near the genu and the mid-cingulate cortex

Clinical Manifestations

1. The pregenual regions are associated with affective experience
2. A major component of autonomic regulation
3. Electrical stimulation of the dorsal pregenual cortex elicits fear, pleasure and agitation
4. Electrical stimulation of BA24 and BA25 evokes:
 - a. Increases and decreases of respiratory rate and blood pressure
 - b. Mydriasis and piloerection
 - c. Facial flushing
 - d. Visceral responses (nausea, vomiting, epigastric sensations and bowel and bladder evacuation)

Neuropathology

1. Connections of the pregenual ACC that regulate autonomic activity include:
 - a. The nucleus solitarius
 - b. Dorsal motor nucleus of the vagus
 - c. Sympathetic thoracic intermediolateral column

- d. The periaqueductal gray
- e. Reciprocal connections with the amygdala
- f. The PACC (Posterior anterior cingulate cortex) is involved in emotionally relevant autonomic activity through its connections to BA25 that in turn activates brainstem autonomic nuclei

The Mid Cingulate Cortex (MCC)

General Characteristics

1. Has a major role in motor response selection derived from the motivational relevance of a particular situation

Clinical Manifestations

1. Attention for action response selection
2. Error detection
3. Anticipation
4. Working memory

Neuropathology

1. The MCC is composed of two subdivisions:
 - a. The dorsal MCC (dMCC) in the sulcal cortex that extends into the superior cingulate gyrus
 - b. An area on the surface of the cingulate gyrus
2. The dMCC:
 - a. Has large layer Vb neurons that project to the spinal cord, supplementary motor, primary motor and limbic cortices
 - b. Electrical stimulations of dMCC evokes:
 - i. Gestures; touching, kneading and rubbing the hands together; lip puckering or sucking
 - ii. These gestures can be modified by sensory input and at times voluntary control
 - iii. Blood flow studies have demonstrated modifiable changes in this area of the cingulate cortex by altering the reward qualities of particular outcomes

The MCC in addition to selection and regulation of motor actions and motivation also has a role in cognitive processes associated with divided attention.

The Posterior Cingulate Cortex (PCC)

General Characteristics

1. The PCC consists of BA23 and BAB1
2. It is granular

Clinical Manifestations

1. The PCC and retrosplenial cortex are involved in topographic and kinetic memory
2. Focal lesions (experimental lesions in macaques) impair memory of spatial positional relationships

Neuropathology

1. The afferents to the PCC are from the thalamus (lateral dorsal and anterior nuclei)
2. Direct afferents from the subiculum

3. BA23 projects to the dorsolateral prefrontal cortex (BA9), the anterior prefrontal cortex (BA10), the orbitofrontal cortex (BA11), the parahippocampal gyrus and the posterior part of the inferior parietal lobule, the presubiculum, the superior temporal sulcus and the retrosplenial area
4. Deep brain stimulation (DBS) of the subcallosal cingulate cortex (SCC) is now being assessed for treatment resistant depression. To date, it has been found to be efficacious for transient changes in mood, attention and social connectedness which have also been shown by DBS of the medial forebrain bundle and the nucleus accumbens. The effectiveness of DBS for treatment-resistant depression requires inclusion of:
 - a. The forceps minor of the anterior corpus callosum which connects the two ventromedial frontal cortices
5. The cingulum bundle that connects the ipsilateral subcallosal cingulate (SCC) to the rostral and dorsal anterior cingulate cortices
6. The uncinate fasciculus that connects the SCC to the ventromedial frontal cortex
7. The frontal-subcortical fibers connect the SCC to the basal ganglia, thalamus and brainstem. All components of the cingulate gyrus may be involved in vascular disease, head trauma, tumors and viral encephalitides. Immune-mediated processes particularly affecting NMDA and AMPA receptors, as well as anti-Hu paraneoplastic diseases frequently affect the cingulate gyrus. It frequently herniates under the tentorium during increased intracranial pressure from mass lesions and is a component of central brain herniation

Laboratory Evaluation

1. MRI:
 - a. Evaluates mass lesions and MRA evaluates the vascular supply to the gyrus
 - b. Antibody studies evaluate paraneoplastic processes and those that affect NMDA and AMPA receptors
 - c. EEG in confusional states

Summary of the Cingulated Cortex

The cingulate gyrus is an integral component of the limbic system. It is a major component of Papez' loop that consists of the mammillary bodies, the mamillothalamic tract, anterior ventral thalamic nuclei, cingulate gyrus, prefrontal cortex and hippocampus. Its distributed functions are associated with attention, motivation, the affectual components of movement, and the "suffering" component of pain. It has a major function in the control of the autonomic nervous system particularly in response to emotional states.

1. The ACC:
 - a. Affective states and the control of the ANS
2. MCC:
 - a. Selection of movement and motivation
 - b. Divided attention
3. PCC:
 - a. Topographic and topokinetic memory

The Occipital Lobe

Overview

The primary visual cortex is Brodmann's area BA17. It is located on the medial side of the occipital lobe within the calcarine sulcus. It is named the striate cortex due to a large stripe of myelin, the Stria of Gennari that is visible.

The primary visual cortex (V1) encodes the orientation, spatial frequency and chromatographic features of small receptive fields of the visual field. V1 projects to V2 and V4 of the visual ventral stream. The dorsal stream V3, MT (V5) and dorsomedial area also receives projections from V1. In general, the ventral stream processes visual information for object recognition while the dorsal stream is involved with object movement and its spatial location. Each visual area maintains a map of the visual field. "Low-level" representations of edges, color and lights are built into "high-level" of semantic representations that include the perceptions of objects, faces and environmental scenes.

The occipital lobe is central to all aspects of vision. Knowledge of occipital lobe function has been meticulously accrued from elegant physiological and anatomical studies in primates that have been buttressed by pathological correlation in patients and by recent functional imaging studies with PET, SPECT, functional MRI and neurophysiologic studies.

Stimulation of the calcarine cortex BA17 in awake patients evokes non-colored, non-moving flashes of light with occasional geometric designs. Stimulation more anteriorly in BA18 produces moving, colored geometric figures in the contralateral visual field. Stimulation in the junction of the temporo-parietal-occipital cortex causes visual distortion, phosphenes, photopsia (moving geometric patterns), complex visual hallucinations and palinopsia (visual perseveration). Occasionally a fixed visual hallucination may be seen or a positive bright yellow scotoma is noted with lesions in this area. Color naming may be lost with lesions of the fusiform gyrus and visual agnosia supervenes with bilateral lesions of the junction of the temporo-occipital cortex. Word blindness occurs with a left posterior cerebral artery occlusion that destroys the splenium of the corpus callosum which isolates Wernicke's area (for decoding graphemes) from the right occipital lobe (the left occipital lobe is infarcted). Visual memory may be disturbed with lesions of the inferior longitudinal fasciculus such that visual images cannot be compared with prior images stored in hippocampal circuitry. Metamorphopsia, unusual interest in all visual objects, occurs with lesions of the occipital-parietal cortex as well as lesions in the retina, chiasm, optic radiations and retrosplenial areas.

Disorders of Complex Visual Processing

Visual Agnosia

1. Definition: Visual agnosia is a disorder of higher behavior in which an alert, intelligent, non-aphasic patient with normal visual perception does not recognize a visual stimulus

2. There is specificity for the types of stimuli for which patients are impaired. They include:
 - a. Agnosia for objects
 - b. Propagnosia (faces)
 - c. Words ("pure word blindness")
 - d. Colors
 - e. Environment (including landmarks)
 - f. Simultagnosia (an inability to see more than one object at a time)
3. Functional imaging demonstrates that specific regions of the brain process different classes of visual stimuli
4. Specific visual information is segregated at the retinal level and different afferent visual input is processed in parallel. Color, angle, motion, depth orientation, and length are processed in different brain regions in parallel
5. "Boundary marking", a low-level visual process groups different stimuli that lead to visual forms. These processes are automatic, not requiring attention or effort and group visual characteristics that are essential for objective cognition
6. Visual attributes are processed in parallel but have to be integrated that is "binding" of visual feature information that is "visual attention."
7. Imaging studies support the fusiform gyri and the lateral occipital cortex as the anatomical substrate for the integrated feature representation and structural description systems
8. Familiar objects are recognized across a wide range of angles and perspectives that is termed the view normalization system

Visual Object Agnosia

These patients are unable to recognize the generic class to which an object belongs. A defect of visual naming is common as is alexia. Some patients with object agnosia may recognize the object when it is moved or rotated. These patients may complain of "unclear" or "blurred" vision, possibly related to a selective defect of low spatial frequency vision that impairs appreciation of static, low contrast stimuli. Moving, high contrast stimuli may be appreciated. Visual object agnosia patients have bilateral lesions in the ventral and mesial part of the occipital temporal visual areas that extend dorsally and laterally.

Disorders of Low-Level Vision

The primary deficit in these disorders is impairment of processing of different types of visual feature information.

Achromatopsia

Achromatopsia is an acquired impairment of color perception that manifests as an inability to distinguish color. It varies widely in its clinical expression from a mild loss of intensity or richness of color (e.g. "red desaturation"—red looks brownish) to a complete loss of color sense. If severe, patients may see the world as black or white or shades of gray. The de-

fect may affect only one visual field. Lesions generally involve the lingual or fusiform gyrus. It may be associated separately or associated with prosopagnosia, alexia, and superior visual field deficits. Rarely is it associated with visual object agnosia.

Motion perception deficit (akinetopsia) results from damage to cells that are biased to discharge by motion are localized in the retina, lateral geniculate body, primary visual cortex, and the MT (medial temporal gyrus). Pure disorders of motion perception are rare. One patient extensively studied with profound impaired motion perception suffered bilateral infarcts of the posterior portions of the middle temporal gyri that extended into the occipital lobe and adjacent subcortical white matter. Movement was not perceived as a continuous process – objects jumped from one position to the next. Moving objects would appear static.

Patients have been described in which object recognition is influenced by motion. This manifests as failure to recognize static stimuli (“static form agnosia”) but ability to recognize the object when it is moved. The posterior portion of the middle temporal gyrus (V5) is specialized for motion processing.

Visual Form Agnosia

Visual form agnosia has been postulated to be a deficit in the segregation of coherent regions of visual input. Patients are unable to discriminate shape although there is no impairment in cognitive function or the recognition in differences in luminance, wavelength, area or motion. The two patients described also had difficulties recognizing drawings, letters, or faces. MRI revealed bilateral lesions of the lateral occipital lobes.

Definition of Visual Attention

Simultanagnosia

Simultanagnosia is the inability to see more than one object at a time. Patients may also have difficulty with recognizing single objects. This impairment is usually a deficit in the ability to appreciate the entire visual stimulus. Dorsal simultanagnosia is associated with a visual field deficit and has been described with bilateral posterior parietal-occipital lesions. It has been postulated that this is an impairment of visual attention allocation that is required for the integration of visual feature information. These patients incorrectly combine visual features.

Deficits in the View Normalization System

These patients have difficulty identifying objects from different angles, perspectives or views. Several patients have been described with lesions of the posterior portion of the non-dominant hemisphere. It has been suggested that patients are unable to generate a representation of the object in its canonical principal axis.

Associative Agnosia

Associative agnosia refers to the failure to name an object although the patient may be able to copy it. Patients are able

to describe the object visually, but are unable to do so verbally or by touch. This differentiates the disorder from loss of knowledge of the object which is a semantic deficit. These patients have difficulty sorting complex non-object figures.

Prosopagnosia

Prosopagnosia is a visual agnosia characterized by an inability to recognize previously known human faces and to learn new ones. Recognition through other sensory channels is intact. These patients are unable to recognize stimuli that belong to a group that have numerous subcomponents. Patients can perform generic recognition. They recognize the class to which the stimulus belongs, but are unable to identify a specific member within the generic class. The deficit lies in the appropriate retrieval of contextual memory (one possible mechanism). Lesions associated with prosopagnosia are usually bilaterally in the temporo-occipital area although they have been described with lesions only in the right hemisphere. Functional MRI has delineated a region of the fusiform gyrus bilaterally designated as the “fusiform face area” that is activated by the presentation of faces. The argument is primarily whether prosopagnosia should be considered a cortical module for the processing of faces or is part of the visual recognition system that is biased for the stimulus properties that characterize faces. Additional deficits that have been described with prosopagnosia include achromatopsia, visual field loss, topographical memory loss and object agnosia. Most patients described have suffered emboli to the distal branches of the posterior cerebral arteries that may have occurred at different times. Some patients have had bilateral tumor involvement. It has also been described as an epileptic phenomenon.

Pure Alexia

Alexia without agraphia or “word blindness” is a disorder of visual pattern recognition. These patients can copy what they cannot read, have normal visual acuity and have normal recognition of non-verbal visual stimuli. They are unable to evoke the appropriate associated material when confronted with words. Speech, writing, auditory comprehension is normal.

The necessary lesions to cause the syndrome must disconnect both visual association cortices from the dominant language area. Lesions of the splenium of the corpus callosum cause interhemispheric disconnection and combined with a lesion of the left occipital cortex cause disconnection of visual association cortex with the language areas. A lesion of the tapetum, beneath the occipital horn can disrupt both callosal and left visual association fibers and thus cause pure alexia. Patients may have alexia and visual agnosia with additional right visual association cortex lesions.

Disorders of Spatial and Topographic Orientation

These patients demonstrate an acquired inability to locate a familiar room in their house, a common public building

and are unable to utilize verbal directions to locate a specific place. This type of deficit may occur secondary to unilateral hemispatial neglect or from a global amnesic syndrome. These specific defects underlie a lack of visuospatial memory whereby the architectural or topography detail cannot trigger the retrieval of stored memories that could be utilized to plan a route to the desired destination. Bilateral lesions of the inferior and superior visual association cortices especially the right occipital parietal area cause this deficit. Patients with prosopagnosia may have impaired ability to learn new topographic paradigms. These patients may also be unable to identify cities on a map, to draw a state or country and suffer geographical orientation deficits.

Disorders of Color Perception

There are acquired disorders of color perception that involve all or part of the visual field with preservation of formed vision. Patients with central achromatopsia lose color vision in a portion or all of their visual field. They report the deficit most often as a dulled or washed out but distinguishable color or as a complete loss of color so that the patient only sees objects as black or white. Patients otherwise see accurately in the colorless portion of their visual field. Patients with full visual field achromatopsia often have impairment in portions of their visual field with visual agnosia, and blindness for form. A lesion of the left inferior occipital temporal cortex may cause pure right hemi-achromatopsia alexia from damage to intra- and interhemispheric visual pathways within the left occipital cortex. These lesions are often embolic to the terminal branches of the posterior cerebral artery that supply the fusiform and lingual gyri.

Disorders of Color Naming

These patients can match colors, but are unable to name them. They are not aphasic and have no deficit of color perception. They have concomitant right homonymous hemianopsia, intact color perception in the left visual field and pure alexia. The lesion responsible for this color-naming deficit is in the left hemisphere between the occipital and temporal lobe. The right homonymous deficit is from a lesion in the geniculate body, optic radiation or visual cortex. Some patients demonstrate more difficulty in naming colors to confrontation than on pointing to them. In general, disorders of hue and color perception are associated with prosopagnosia and those of color naming are associated with alexia and word blindness. Some patients suffer the inability to associate a specific color with a specific object which is easily accomplished by patients with an isolated color naming defect.

Disorders of Spatial Analysis

Bálint's Syndrome

Bálint's syndrome is an acquired inability to perceive the visual field as a whole and to perform visually guided move-

ments, and to shift gaze to new stimuli in the visual fields. They have visual disorientation, optic ataxia, and apraxia. Visual disorientation and optic ataxia can occur concomitantly with one of the other two components of the syndrome.

Patients most often see only the macular component of the visual field, but even this fragment of the visual field moves erratically from quadrant to quadrant. These patients fail to orient to new stimuli that appear in the peripheral field unless the erratic movements of the macular component settles on it. They often have simultagnosia, the inability to report more than one or two components of a scene which may suddenly vanish as the center of vision shifts. Patients also complain that moving objects are difficult to see. Patients concomitantly suffer optic ataxia which is the inability to grasp an object using visual guidance. They can point to objects in their own body and to the origin of sounds. They frequently undershoot the grasp of the intended object. Patients have ocular apraxia and are unable to generate a saccade that will fix gaze on a new stimulus that enters the periphery of the visual field. Bálint's syndrome is most often encountered following damage to bilateral occipital parietal watershed regions between the anterior and posterior cerebral arteries and the middle cerebral artery. In the complete syndrome, there is frequent involvement of BA7, BA19 and BA39. Most lesions that cause Bálint's syndrome are in the parietal-occipital cortex. Patients that have visual disorientation in isolation have bilateral lesions of the supracalcarine cortex that spares the parietal cortex.

Area 7 of the parietal lobe contains cells that discharge to and direct gaze to new stimuli that appear in the peripheral visual field and are important for visually guided hand movements. The superior occipital striate and peristriate cortex are important for perception of the visual field as a whole. Patients with Bálint's syndrome have impaired perception of spatial information outside of their own body. They often cannot locate an object and cannot tell if an item is moved towards or away from them. Bálint's syndrome has been suggested as a type of double neglect. They may neglect both sides of a room, but can see a single object. In hemineglect from a right parietal lesion, there is inattention to the left side of visual environment as well as the left side of objects. They (Bálint's patients) see complete objects and neglect both sides of the room.

Deficits of Stereopsis

The ability to discriminate depth from binocular visual cues is stereopsis. Two-dimensional projections of these dimensional objects are projected to slightly different portions of the left and right retinas. This horizontal disparity provides the anatomic basis of stereopsis. There seems to be stereoptic function in each hemisphere. Both the striate and peristriate cortex have cells that respond to binocular stimuli. The disparities are processed by these cells which produces depth perception. The perception of depth and 3-dimensional structure can be performed with one eye from differences in object

size and motion parallax although not as accurately as that derived from bilateral disparities.

Course stereopsis is used to estimate stereoscopic motion in the environmental periphery. It provides the sense of localization in one's environment and is important for orientation in space while moving. Fine stereopsis is required for the completion of delicate motor tasks (i.e., threading a needle). Fine stereopsis requires good visual acuity in each eye to be able to detect small spatial differences. Coarse stereopsis is associated with the magnocellular visual pathway that processes low spatial frequency disparities and motion. Fine stereopsis is processed by the parvocellular pathway that processes high spatial frequency retinal disparities.

Cortical Blindness (Anton's Syndrome)

Most patients have suffered bilateral damage to both visual cortices and to the optic radiations.

They have:

1. Inability to see
2. Often are euphoric
3. Have normal pupillary responses
4. Deny blindness
5. Confabulate vision
6. Patients may be able to move around a room without hitting large objects possibly related to preserved islands of retinal rod vision

The Insular Cortex (IC)

General Characteristics

1. The insular cortex is a portion of the cerebral cortex located deep within the lateral sulcus. It is divided into two parts:
 - a. The anterior insula and the posterior insula
2. The cortical operculum overlies the insula which is formed from components of the frontal, temporal and parietal lobes
3. The anterior insula has an agranular cytoarchitecture while the posterior IC is granular
4. The anterior insular cortex contains von Economo neurons that are large bipolar neurons found only in the great apes and humans. They have a simple dendritic structure which has been posited to enable them to process information rapidly. They are selectively lost in the early stages of frontotemporal dementia that supports their involvement in empathy, social awareness and self-control
5. The anterior insula afferences are primarily from:
 - a. Basal ventral medial nucleus of the thalamus
 - b. The central nucleus of the amygdala with which it is reciprocally connected
6. The posterior insula:
 - a. Connects reciprocally with the secondary sensory cortex (SII)
7. Receives afferents from:

- a. Spinothalamic projections that activate the ventral posterior inferior thalamic nuclei (VPI)
- b. Posterior VPM
8. The efferents from the anterior insular cortex include:
 - a. The anterior amygdaloid area
 - b. The medial, cortical, accessory basal magnocellular, the medial basal and lateral amygdaloid nuclei
 - c. Temporal and occipital lobes, the operculum and orbitofrontal cortex and the triangular and opercular parts of the inferior frontal gyrus. Asymmetrical connections have been noted between the hemispheres
 - d. The efferents from the posterior insula include:
 - i. The dorsal region of the lateral nuclei of the amygdala
 - ii. Central amygdaloid nuclei

Clinical Manifestations

1. Interoceptive awareness:
 - a. Both the right frontal insular cortex and the anterior cingulate cortex have von Economo (spindle) neurons that are thought to be involved with empathy and self-aware emotional feelings. It has been suggested that these feelings are a consequence of the role of the insula in the homeostatic aspects of consciousness. In particular, functional MRI studies suggest that the right insula is involved in the interoceptive awareness of body states
 - b. The insular cortex is a major component of the afferent pain matrix
 - i. It is the only area of the brain that when stimulated causes pain
 - ii. The insula is activated when a patient looks at painful events and when the patient anticipates forthcoming pain and its degree
 - iii. The right anterior insula is activated by the degree of non-painful warmth or coldness, gastric dilatation and a full bladder
 - iv. The unpleasantness of dyspnea may be processed by the right insula cortex
 - c. The insula may be activated by vestibular sensation. Lesions of the anterior insula cortex have been described that cause loss of balance and vertigo
 - d. Non-interoceptive perceptions processed or modulated by the insula include:
 - i. Laughter and crying
 - ii. Empathy and compassion
 - iii. Aspects of language
 - e. Motor control: The insular cortex has been ascribed to have a role in:
 - i. Hand and eye movement
 - ii. Swallowing
 - iii. Gastric motility
 - iv. Speech articulation:
 1. Involved in the capacity to maintain long and complex sentences

- v. Motor learning
- vi. Possible role in stroke recovery
- vii. Increases heart rate and blood pressure at the onset of exercise
- f. Homeostasis:
 - i. The insula cortex is a major component of the autonomic nervous system by its regulation of sympathetic and parasympathetic projections. It is important in homeostatic functions such as taste, visceral sensations and autonomic control
- g. Sense of self:
 - i. The IC has a role in the perception of self-awareness, sense of agency and body ownership
- h. Social emotional state:
 - i. Emotional experience that the anterior insular cortex processes includes:
 - 1. The sense of disgust to smells, and at the sight of mutilation or contamination which is a possible link between external and internal experience
 - 2. It is activated by norm violations; empathy and orgasm
- i. Affect:
 - i. The insula cortex is part of the limbic system. It has a major role in body representation and emotional experience, particularly visceral states that are associated with emotional experience

The anterior insula processes olfactory, gustatory, visceral, autonomic, and limbic functions. The posterior insular cortex is involved with auditory, somatosensory and motor functions. Both anterior and posterior insular cortices process convergent and primary inputs that induce an emotionally relevant context for sensory experience.

Functional MRI protocols have demonstrated activation of the anterior insular cortex by feelings of romantic and maternal love, anger, fear, sadness, happiness, sexual arousal, disgust, aversion, unfairness and inequity, indignation, uncertainty, disbelief and trust.

Importantly, the insular cortex as noted above is important in the affectual aspects of pain, food and drug craving as well as addiction.

The insular cortex is involved in the processes that link interoception with emotional salience which generates a subjective representation of the body. The distributed loops for this salience function include:

1. The anterior insular cortex, the pregenual anterior cingulate cortex (BA33)
2. The anterior and posterior mid-cingulate cortex
3. A general salience system that processes:
 - a. Monitoring of the environment
 - b. Response selection
 - c. Motor functions that engage all of the insular cortex as well as the mid-cingulate cortex
4. Additionally, it is proposed that the right anterior insular cortex regulates the dorsal attention system that controls the salience of selective attention required to complete a

task; the salience of arousal mediated by the ventral attention system needed to maintain focus on the behavioral task

Neuropathology

1. The insular cortex is most often involved in:
 - a. Neurodegenerative disease (FTLD)
 - b. Stroke (MCA branches)
 - c. Glioma
 - d. Rare inflammatory conditions
 - e. Autoimmune processes exemplified by paraneoplastic diseases
2. Progressive non-fluent aphasia:
 - a. Associated with hypometabolism and atrophy of the left insular cortex
 - b. Occurs in Pick's disease, frontotemporal dementia, some forms of motor neuron disease, corticobasal degeneration and rarely Alzheimer's disease
3. Addiction:
 - a. Functional MRI protocols have demonstrated that during drug craving in addicts the insular cortex is activated. This activation has been demonstrated for cocaine, alcohol, opiates and nicotine
 - b. It has been postulated that the insula stores representations of the pleasurable interoceptive sensations of drug use which are activated by exposure to environmental cues of post-drug use. Thus the insula may be involved in memory of pleasurable interoceptive drug effects
 - c. Subjective certainty:
 - i. The strong feeling of certainty may be caused by dysfunction of the anterior insular cortex. Mismatches between the predicted state and actual state are no longer perceived with anterior insular cortex malfunction. This produces a state of emotional confidence (with no anxiety)

Laboratory Evaluation

1. MRI:
 - a. Structural lesions from stroke and tumor
 - b. Gadolinium enhancement with pathologies that disrupt the blood-brain barrier
2. EEG
3. Laboratory evaluation for autoimmune, paraneoplastic and medical conditions
4. Neuropsychological evaluation in the early stages of dementia (FTLD and Pick's disease)

Arousal

General Characteristics

1. Arousal is the physiological and psychological state of being fully alert. It requires activation of the reticular activating system in the brainstem whose projections extend throughout the cortex. The transmitters involved are norepinephrine, dopamine, histamine, acetylcholine and serotonin

- a. The acetylcholinergic system is located in the pons and basal forebrain. Stimulation of the system increases cortical activity and alertness. The four other basic neurotransmitter systems activate acetylcholinergic neurons

The origin of the noradrenergic system is the locus coeruleus that projects to the neocortex, limbic system and basal forebrain. There is a heavy projection of noradrenergic innervations to the posterior cortex and the basal forebrain that synapse with acetylcholine neurons. Noradrenergic discharge increases wakefulness and increases vigilance.

The origin of the dopaminergic system is the ventral tegmental areas of the midbrain (A9 of the SNpc) and A10 primarily. Dopaminergic neurons project to the nucleus accumbens, the striatum, forebrain, limbic system and the prefrontal cortex. The limbic system is essential for the regulation of mood. The central nuclei of the amygdala signals fear, and the prefrontal cortex regulates movements associated with an emotional context.

The origin of the serotonergic system is the raphe nuclei of the reticular formation. Activation of this system causes cortical arousal, elevated mood and amplified movement.

The tuberomammillary system is the origin of the histaminergic system that projects widely to the frontal cortex, thalamus and basal forebrain. It stimulates the release of acetylcholine into the cortex.

The interplay between the ascending reticular activating system and posterior thalamic nuclei and their projections are major determinants of wakefulness. The ascending reticular activating system originates in the lateral medulla. It receives projections from the spinothalamic tract and all major special senses. The dorsal pons, periaqueductal gray and intralaminar nuclei of the thalamus are major subcortical components. The intralaminar nuclei project bilaterally to the cortex. Each cortical area is activated by a reticular activating system projection.

Arousal is compromised by lesions in:

1. Lateral > medial reticular formation
2. Dorsal pons
3. Periaqueductal gray matter of the midbrain
4. Intralaminar thalamic nuclei
5. Bilateral involvement of the cerebral cortex is required for a depression of consciousness
 - a. There is full alertness with one functioning hemisphere
6. The ventrolateral preoptic area is a descending GABAergic pathway that dampens wakefulness and arousal. Acetylcholine and norepinephrine inhibit projections from the ventrolateral preoptic nuclei

Clinical Manifestations

1. Akinetic mutism is a state of disordered arousal in which the patient neither initiates nor responds easily to verbal stimulation. Patients lack spontaneous movements, speech, facial expression or gestures. They may retain visual tracking movements that appear to be purposeful.

They appear to be alert. These characteristics are manifested by patients with bilateral frontal lobe damage

2. Mesencephalic akinetic mutism is distinguished by drowsiness, hypersomnolence, vertical gaze palsy, ophthalmoplegia and decreased spontaneous speech and movement

Neuropathology

1. Frontal lobe damage:
 - a. Lesions may be in the basal forebrain of the frontal lobe bilaterally
 - b. Trauma
 - c. Anterior cerebral artery rupture with vasospasm
2. Thalamic damage:
 - a. Most often hemorrhage or venous thrombosis (inferior or superior sagittal sinus thrombosis)
 - b. Trauma with disruption of the intralaminar nuclei
 - c. Midbrain:
 - i. Pressure from cerebral herniation (diencephalic)
 - ii. Stroke (interpeduncular artery) and hemorrhage
 - d. Ablation or damage of the cingulate gyrus

Laboratory Evaluation

1. MRI:
 - a. To evaluate structural lesions
2. EEG
3. Metabolic and toxic screen
4. CSF evaluation to r/o infectious etiologies

Differential Diagnosis

1. Respiratory and cardiac arrest that induces cerebral hypoxia
2. Rare encephalitis lethargica
3. Meningitis
4. Hydrocephalus
5. Trauma (frontal lobe, midbrain and cingulate gyrus)
6. Aneurysm (primarily anterior communicating and basilar) and their repair from vasospasm
7. Tumors (frontal lobe gliomas that cross the corpus callosum; thalamic tumors)
8. Olfactory groove meningioma (severe frontal lobe pressure)
9. Third ventricular cyst (head bobbing in children)
10. Toxins
11. Delayed post-hypoxic leukoencephalopathy (often occurs two weeks after a successful cardiac resuscitation)
12. End stage Creutzfeldt-Jakob disease (mesencephalic involvement)

Abulia

General Characteristics

1. Abulic patients resemble those suffering from akinetic mutism but differ in that, with intense verbal stimulation, they may be induced to respond or move

Clinical Manifestations

1. Lack of initiation and the ability to sustain purposeful movement
2. Decreased spontaneous movement
3. Decreased spontaneous speech with increased response time to questions
4. Reduced emotional responsiveness and social interaction
5. Inability to swallow (patients hold food in their mouths for hours)

Neuropathology

1. Disruption of frontal circuits
2. Lesions that involve:
 - a. The basal ganglia. Approximately 15% of patients with basal ganglia lesions have diminished motivation
 - b. Capsular genu:
 - i. Damage to the thalamocortical projections that originate in the ventral anterior and medial dorsal nuclei
 - c. Damage to the anterior cingulate circuit which is important for initiation of behavior, motivation and goal orientation
 - d. Caudate nucleus lesions; most often the left caudate is involved with extension into the putamen
 - e. Pathologies with prominent abulia include:
 - i. Depression
 - ii. Schizophrenia
 - iii. Parkinson's disease
 - iv. Huntington's disease
 - v. Pick's disease
 - vi. PSP
 - vii. Traumatic brain injury
 - viii. Stroke

Laboratory Evaluation

1. MRI:
 - a. To rule out structural lesions
2. EEG
3. Neuropsychological evaluation

Unresponsive Wakefulness (UWS)*General Characteristics*

1. The older terminology for unresponsive wakefulness was the chronic vegetative state

Clinical Manifestations

1. Residual cortical processing in the absence of behavioral signs of consciousness
2. Patients are in a state of partial arousal rather than awareness
3. Patients are unresponsive to external stimuli
4. Patients may be able to track moving objects, but often maintain a fixed position
5. The sleep-wake cycle may be retained or they may be in a state of chronic wakefulness

6. Brainstem reflexes may be evident and include:
 - a. Grinding of teeth
 - b. Swallowing
 - c. Smiling, shedding tears, moaning or screaming without external stimulation

Neuropathology

1. Hypoxic ischemic injuries
2. Stroke particularly of the vertebrobasilar system
3. Intracranial hemorrhage (most often basal ganglia or thalamic with midbrain compression)
4. Severe increased intracranial pressure from any structural lesion
5. Systemic infections and sepsis
6. Traumatic brain injury
7. Hepatic encephalopathy
8. Adrenal and thyroid failure
9. Electrolyte disorders
10. Seizures:
 - a. Non-convulsive status epilepticus
 - b. Post-ictal state
11. Meningitis (bacterial, viral, fungal)
12. Toxins (uremia, ethanol, opiates, lead)
13. Metabolic disease (urea cycle disorders, Reye's syndrome, mitochondrial disease)
14. Degenerative diseases
15. Acute disseminated encephalomyelitis

Laboratory Evaluation

1. MRI:
 - a. To rule out structural lesions
2. EEG
3. Toxic and metabolic screen
4. Functional MRI to evaluate brain functional connectivity and responsiveness

The Minimally Conscious State (MCS)*General Characteristics*

1. Following coma a majority of patients transition to unresponsive wakefulness syndrome or a minimally conscious state
2. MCS demonstrates the presence of inconsistent, but behavioral signs of awareness of self or the environment
3. The MCS has been subcategorized into MCS+ and MCS- conditions

Clinical Manifestations

1. MCS+ patients:
 - a. Are able to follow commands
 - b. Have intelligible verbalization
 - c. Can respond to gestural or verbal yes/no responses
2. MCS- patients:
 - a. Non-linguistic signs of conscious awareness that include:
 - i. Visual pursuit
 - ii. Localization of painful stimuli
 - iii. Appropriate behavioral response to some stimuli

Elicited Behaviors That Establish the Diagnosis of MCS

1. Following commands
2. Gestural or verbal yes/no responses
3. Intelligible verbalization
4. Purposeful behavior elicited from appropriate environmental stimuli
5. Reaching for objects with correct relationship between object location and direction of the reach
6. Manipulation of objects in accordance with their size and shape
7. Pursuit eye movements or sustained fixation in response to salient stimuli

Neuropathology

1. All of the pathologies noted to cause the unconscious awareness syndrome. Especially prominent are:
 - a. Recovery from hypoxic-ischemic injury (cardiac and respiratory arrest)
 - b. Severe post-traumatic brain injury
 - c. Cerebral vascular disease that includes large artery occlusions of both anterior and vertebrobasilar circulations
 - d. Basal ganglion thalamic hemorrhages

Laboratory Evaluation

1. MRI/MRA:
 - a. To evaluate structural lesions and blood vessel patency
2. Functional MRI:
 - a. Resting state functional magnetic imaging:
 - i. Group level functional connectivity of the following systems:
 1. Default mode network
 2. Frontoparietal
 3. Salience
 4. Auditory
 5. Sensory motor
 6. Visual networks were evaluated in patients with minimally conscious state, unconscious awareness syndrome and comas
 7. Coma recovery scale-revised correlates with nodes of each network that supports their involvement in consciousness
 8. All networks had >80% discriminative capacity to separate patients in a minimally conscious state from those with unresponsive wakefulness syndrome (UWS)
 9. The auditory network was more functionally connected in patients in the MCS compared to unresponsive wakefulness
 10. Multisensory integration and top-down processing supported by auditory and visual cross-modal connectivity of the auditory and visual cortices are essential for the MCS
3. Event-related potentials:
 - a. The P3 component is related to attention and may predict awakening from coma

- b. The salient value of the patient's own name has been chosen as the self-referential stimulus to elicit the P3 response

Differential Diagnosis of Disorders of Arousal

1. Cerebral herniation
 - a. Cingulate gyrus herniation under the falx cerebri:
 - i. Compromises venous outflow which increases intracranial pressure and is a major cause of central (diencephalic herniation)
 - ii. The usual lesions are structural and are located above the tentorium (intracranial hemorrhage, brain tumors, traumatic brain injury with edema, subdural and epidural hematoma)
 - b. Transtentorial diencephalic herniation:
 - i. Compresses the midbrain RAS at the level of the periaqueductal gray
 - ii. Causes rupture of pontine and midline mesencephalic arteries and veins (Duret hemorrhages)
 - iii. Unilateral uncal herniation:
 1. Unilateral temporal lobe swelling from tumor, trauma or a vascular event
 2. IIIrd nerve palsy is an early sign
 - iv. Upward herniation:
 1. Posterior fossa lesions
 2. Most often seen in children with posterior fossa tumors
 3. Extraocular movement paralysis occurs prior to pupillary involvement
 - a. Compression of the collicular plate by the vermis
2. Thalamic/subthalamic infarction:
 - a. Top of the basilar artery embolus
3. Various vertebrobasilar infarctions (most often the basilar artery)
 - a. Basal forebrain lesions
 - i. Abulia
4. Locked-in syndrome:
 - a. The patient is unable to move or speak due to paralysis of somatic muscles
 - b. The patient is completely alert and aware
 - c. Is able to follow commands utilizing vertical eye movements
 - d. In total locked-in syndrome, the eyes are completely paralyzed
 - e. Many patients retain all sensory modalities
 - f. A few patients may retain the ability to use some facial musculature
 - g. Most often caused by infarction of the ventral pons
 - h. Rare causes include:
 - i. Central pontine myelinolysis
 - ii. Traumatic brain injury
 - iii. Neurotoxic snake venom
 - iv. Autoimmune demyelinating disease

5. Acute agitated delirium
 - a. Caudate nucleus infarction (R > L)
 - b. Bilateral temporal lobe dysfunction
 - c. Right-sided temporo-parieto-occipital lesions
 - d. Orbitofrontal lesions
6. Hyperalertness or insomnia:
 - a. IIIrd cranial nerve ventricular lesions
 - b. Anterior thalamic structural lesions and prion disease of the same nuclei
7. Sleep disturbances
 - a. Sleep apnea
 - b. Locus coeruleus lesions
 - c. Pedunculopontine lesions
8. Delirium:
 - a. Drugs
 - b. Toxins
 - c. Metabolic disorders
9. MCS (minimal conscious state)
10. UWS (unresponsive wakefulness syndrome)

Memory and Amnesia

Overview

The three major processes involved in the very complicated mechanisms that underlie memory are:

1. Encoding or registration:
 - a. Processing and combining of specific information
2. Storage:
 - a. The record of the encoded information in short- or long-term memory
 - b. Retrieval of the stored information in response to a cue

At the molecular level, protein synthesis is required for long-term memory, but not for task acquisition and short-term memory formation. Pharmacological and genetic studies have demonstrated the critical role of *de novo* gene expression and protein synthesis in long-term memory. The fundamental process that underlies memory formation is synaptic plasticity, the ability of synapses to strengthen (long-term potentiation) or weaken (long-term depression) their connections between neurons from activity-dependent stimuli. The maintenance of these changes in synaptic efficacy is triggered by *de novo* protein synthesis.

Neuronal dendrites and spines contain polyribosomes, translation factors, and messenger RNA (mRNA). Protein synthesis is triggered at activated synapses. A complicated series of steps is involved in the process of mRNA translation, translational control primarily occurs as the rate-limiting initiation step rather than during elongation or termination. Gene-specific translational control occurs by phosphorylation of the protein initiating factor eIF2- α , which in turn is accomplished by eIF2- α kinases. EIF2- α phosphorylation is divergently activated during LTP or LTD which regulates the translation of specific sets of mRNA to strengthen or weaken synaptic efficacy.

Short-term memory is primarily referred to as working memory. It underlies recall for several seconds to a minute without recall. The store of short-term memory items is 4–5 items. Short-term memory uses an auditory more than a visual code.

Long-term memory is encoded semantically. A component of long-term memory is episodic memory, the encoding of specific events. Short-term memory is supported by neural circuits that include the dorsolateral prefrontal cortex, while long-term memory is more widely distributed throughout the brain. The hippocampus is required for learning new information and for the consolidation of information from short-term to long-term memory.

Declarative memory, also known as explicit memory, requires conscious recall. It is subdivided into semantic memory (principles and facts) and episodic memory (related to a particular context, the time and place of the event). Autobiographical memory, the personal events of one's life, is a subset of episodic memory.

Implicit or procedural memory is not conscious recall of information, but is based on implicit learning. It is primarily the memory of the process that underlies motor skills. It is dependent on the cerebellum and basal ganglia.

Isolated memory disorders in amnesia frequently occur following bilateral involvement of the medial temporal lobe and the CA1 region of the hippocampus, as well as the dorso-medial nucleus of the thalamus. Anterograde amnesia is the inability to learn new material, while retrograde amnesia is the inability to remember events prior to an injury. In some instances of retrograde amnesia, the memory loss can extend back for decades, while in other instances it may extend only for days or weeks. Both types of amnesia can manifest simultaneously. Patients may retain the ability to recall immediate information, and may still be able to form new memories. Most patients have difficulty learning new material, as well as with retrieval of stored information. They retain the ability to learn procedural knowledge. Many patients retain intellectual, linguistic, and social skills. In some patients, older memories are most resistant to amnesia.

In a core amnesic syndrome, patients suffer a global anterograde and retrograde memory deficit with occasional confabulation. Other cognitive functions, including attention and motivation, are intact.

Differential Diagnosis of Amnesia

Wernicke-Korsakoff's Syndrome

1. General characteristics:
 - a. Most often seen in a context of long-term alcohol abuse and malnutrition (stomach cancer, anorexia nervosa)
 - b. It is caused by vitamin B1 deficiency

Korsakoff's Syndrome

1. The acute onset of severe memory impairment without loss of other cognitive abilities

2. Clinical manifestations:
 - a. Anterograde amnesia
 - b. Variable retrograde amnesia
 - c. One of:
 - i. Aphasia
 - ii. Apraxia
 - iii. Agnosia
 - iv. Deficit in executive function
 3. Cognitive deficits:
 - a. Anxiety and difficulty with concentration
 - b. Confusion
 - c. Confabulation
 - d. Inability to focus
 - e. Deficits in cognitive estimation tasks
 - f. Confabulation
 - i. Spontaneous confabulation (incorrect memories that the patient may act on) is more common than provoked confabulation. It is posited that the patient cannot remember the spatial and contextual information of an event, and utilizes older or irrelevant memory traces to compensate for inaccessible information. Another hypothesis is that patients suffer executive dysfunction, in which they are unable to inhibit incorrect memories or to shift attention away from an incorrect response
 4. Neuropathology
 - a. Anatomically there are bilateral lesions of the mammillary bodies, the anterior column of the fornix, hypothalamic nuclei, the dorsal medial nuclei of the thalamus, the medial pulvinar, and lateral dorsal thalamic nuclei. The dorsal medial nuclei of the thalamus may be important for confabulation as well as memory
- iv. Hypothermia
 - v. Seizures
 - vi. Progressive hearing loss
 - vii. Photophobia
3. Neuropathology of WKS
 - a. Brain atrophy occurs in:
 - i. The mammillary bodies (they may also be enlarged in Leigh's myopathy); over time they atrophy
 - ii. Thalamus (mediodorsal nucleus)
 - iii. Hypothalamus
 - iv. Periaqueductal gray
 - v. The walls of the IIIrd ventricle and the floor of the IVth ventricle may be hemorrhagic
 - vi. The cerebellum and frontal lobe are involved
 4. Laboratory evaluation:
 - a. MRI: Evidence of cytotoxic edema in the mammillary bodies, mediodorsal thalamic nuclei, tectal plate and the periaqueductal region
 - b. Vitamin B1 assay

Post-Traumatic Amnesia

1. The amnesia may be retrograde, anterograde, or of mixed type
2. It is usually transient, but may be permanent, dependent on the degree of injury

Dissociative Amnesia

1. The inability to recall information following a stressful or traumatic event
2. Access to long-term memory is impaired due to psychological defense mechanisms
3. Patients retain the ability to learn new information, and with time there may be partial or complete recovery of memory

Transient Global Amnesia (TGA)

1. General characteristics
 - a. TGA's major defining elements are loss of short term memory and dysfunction in accessing older memories
2. Clinical characteristics:
 - a. Inability to encode new memories
 - b. The patient retains complete consciousness, has knowledge of self-identity, and maintains perceptual skills and a complex of learned behaviors
 - c. The degree of amnesia is severe, and the patient may be anxious during the attack. Memories for distant events may be affected to a degree
 - d. The attack is witnessed by a reliable observer who documents a clear loss of short-term memory (anterograde amnesia)
 - e. Consciousness is clear
 - f. There are no focal neurologic signs, such as seizure activity, during or after the episode
 - g. The attacks usually last between 2–8 hours, and resolve within 24 hours

Wernicke's Encephalopathy

1. General characteristics:
 - a. Most often there is an acute Wernicke's encephalopathy phase followed by chronic Korsakoff's syndrome
 - b. Wernicke's encephalopathy is caused by vitamin B1 deficiency
2. Clinical manifestations:
 - a. Confusion, apathy, inability to concentrate and decreased awareness of the environment
 - b. Mental status changes occur in approximately 80% of patients with Wernicke's encephalopathy
 - c. Approximately 30% of patients develop partial ophthalmoplegia. Caucasian patients are more frequently involved with ophthalmoplegia than black patients. Rarely there is disc swelling and abnormalities of the pupillary light reflex
 - d. Cerebellar and vestibular symptoms are seen as well as stance and gait abnormalities in 25% of patients
 - e. Variable features include:
 - i. Stupor
 - ii. Hypotension
 - iii. Severe tachycardia

- h. Perseveration, in which the patient repeats statements or questions, is common
- i. Patients may be disoriented in time and space
- j. Approximately 10% of patients appear emotional during an attack, with some expressing a fear of dying
- k. The majority of patients suffer no long-term effects, but there is a complete lack of recall for events during the attack; this is almost always anxiety provoking to the patient. Memory may be lost for events that occurred 1–2 hours prior to the attack
- l. Precipitating events can be documented in approximately 1/3 of patients. They include:
 - i. Vigorous exercise
 - ii. Sexual intercourse
 - iii. Swimming in cold water
 - iv. Emotionally traumatic or stressful events
 - v. Following medical procedures
- 3. Neuropathology
 - a. The hippocampus and amygdala are the primary sites of involvement
 - b. It has been posited that TGA may be caused by vascular insufficiency, a TIA (transient ischemic attack), a temporal lobe seizure, or migraine
- 4. Laboratory evaluation:
 - a. MRI:
 - i. Brain MRI with and without contrast, with 3 mm oblique axial hippocampal sections to rule out possible structural lesions
 - b. EEG:
 - i. Some patients have been posited to suffer transient epileptic amnesia
- 5. Differential diagnosis of transient global amnesia (TGA)
 - a. Vertebrobasilar TIA (ischemia of the hippocampus and amygdala)
 - b. Cardioembolic stroke (top of the basilar artery)
 - c. Complex partial seizures (temporal lobe origin) or focal frontal lobe seizure
 - d. Migraine variant
 - e. Posterior cerebral artery ischemia

Hypothalamic Tumors

- 1. Amnesic syndromes have been reported in cases of hypothalamic tumors, particularly in those surrounding the walls and floor of the IIIrd ventricle

Thalamic Lesions

- 1. Bilateral dorsomedial thalamotomies cause transient loss of the temporal organization and chronology of a patient's experience
- 2. Thalamic infarcts affecting the paramedian and dorsomedial nuclei are associated with severe anterograde and retrograde memory loss. Unilateral left thalamic lesions in the dorsomedial or anterior thalamic nuclei have been associated with anterograde amnesia, particularly for language

Basal Forebrain Lesions

- 1. Lesions affecting the septum, hypothalamus, and caudal orbitofrontal regions from tumor or anterior communicating aneurysmal rupture may cause severe amnesia. These pathologies damage the septal nuclei and the nucleus basalis of Meynert (NBM), which destroys the cholinergic innervation of the limbic and frontal cortex

Bilateral Fornix Lesions

- 1. Patients with tumors or bilateral injury may develop an amnesic syndrome

Cingulate Lesions

- 1. Bilateral cingulotomies are associated with transient memory disorders with confabulation similar to Korsakoff's syndrome. These patients may also suffer difficulty in ordering memories in a proper temporal sequence. Amnesic syndrome after callosal commissurotomy or posterior corpus callosum tumor may be due to posterior cingulate gyrus damage

Selective Amnesia from Unilateral Temporal Lobe Lesions

- 1. The recognition of recurring nonsense figures, faces, and maze learning may be difficult after right temporal lobe lesions. The recall of verbal material is disturbed after left temporal lobectomy. The right temporal lobe can recognize non-verbalizable tactile patterns better than the left after commissurotomy
- 2. These deficits clearly overlap with memory and learning deficits

Amnesia of Uncertain Anatomical Cause

- 1. Head trauma:
 - a. Long fiber bundles including the fornix are damaged by shearing forces
 - b. The temporal poles and the orbitofrontal cortex are often severely damaged
 - c. There is a correlation between the amount of damage in these areas with the severity of anterograde and retrograde amnesia

Electroconvulsive Therapy

- 1. Comparable to head injury
- 2. Unilateral ECT-material specific amnesic syndrome, much less severe memory deficits than bipolar techniques (often more effective)

Epilepsy

- 1. Some initial seizures may present as TGA
- 2. Transient epileptic amnesia:
 - a. Attacks are of short duration (<1 hour)
 - b. May recur

Drugs

- 1. Benzodiazepines cause a state similar to transient global amnesia (TGA)

2. Amytal induces “blackouts”
3. Scopolamine induces memory loss similar to amnesic syndromes (rarely used with deliveries)

Psychogenic Amnesia

1. This form of amnesia (dissociative) occurs after strong emotional or psychologic trauma
2. It may be associated with loss of personal identity: patients forget their names and their past, but memory for recent events is normal
3. Anxiety may not be apparent, although it may be accompanied by a fugue state that usually resolves in days to weeks

The Clinical Anatomy of Memory

Memory can be divided into three stages for clinical purposes:

1. Inscription:
 - a. This process takes place during the first 30 seconds, and occurs in the medial hippocampal structures. It has been posited to relate to reverberating circuits, and acetylcholine is the primary neurotransmitter
2. Consolidation:
 - a. The structures that are most important for this phase are:
 - i. The medial hippocampus (CA1 field)
 - ii. The mammillary bodies and the mammillothalamic tract
 - iii. The dorsomedial nucleus of the thalamus
 - b. Messenger RNA is synthesized in synaptic dendritic spines
 - c. The memory trace is vulnerable to intrusions
 - d. Long-term potentiation (LTP) with increased synaptic efficacy is accomplished; that may be the molecular base of the memory trace
 - e. Protein synthesis:
 - i. Long-term memory is related to protein synthesis
 - ii. Long-term potentiation and long-term depression (LTD) are basic mechanisms effected by gene activation
3. Retrieval:
 - a. The dorsolateral prefrontal cortex is important for activating and retrieving memory that has been consolidated
 - b. Cueing appears to affect the DLPFC

Forgetting may be due to LTD (long-term depression) of specific synapses, and due to the unfolding of the tertiary structure of specific synapses or proteins.

Benign Senescent Forgetfulness

1. The greatest difficulty is for names and details, although most events are easily recalled
2. Cueing improves performance
3. The deficit may be at the retrieval stage

Confusional States

1. Overview:
 - a. The definition of delirium or acute confusional state is an organically-caused decline from a previously attained baseline level of cognitive function. An acute confusional state is a change in mental status, the most important feature of which is failure of attention. Most often, there are no neurological signs other than a coarse tremor, myoclonus or asterixis. Vigilance is defective in intensity and selectivity. Attention either wanders aimlessly or is suddenly focused with inappropriate intensity, or an irrelevant stimulus becomes the source of distractibility. Thought and skilled movement are diminished by interference, impersistence, and perseveration. The stream of thought is interrupted by frequent intrusions of competing thoughts and sensations
 - b. The three cardinal features of a confusional state are:
 - i. Disturbance of vigilance and heightened distractibility
 - ii. Inability to maintain a coherent stream of thought
 - iii. Inability to carry out a sequence of goal-directed movements
 - c. Perceptual distortions lead to illusions and hallucinations. Patients are disoriented, have memory deficits, mild anomia, dysgraphia, dyscalculia, and constructional apraxia. Judgment is poor, insight is lacking, affect is labile with a curious tendency for facetious witticism. Some confusional states are apathetic while others cause extreme agitation. Confusional states fluctuate from hour to hour and are exacerbated at night
2. Clinical manifestations:
 - a. Inattention:
 - i. Distractibility and inability to shift and/or sustain attention
 - b. Disorientation:
 - i. Loss of awareness of the environment
 - ii. May occur in the sphere of time, place, or person
3. Deficits in memory occur and are associated with inattention. New long-term memories are not formed, but old memories may be retained
4. Higher cognitive deficits include deficits in:
 - a. Comprehension
 - b. Abstraction
 - c. Initiation/perseveration
 - d. Switching mental sets
 - e. Temporal sequencing and organization
 - f. Insight and judgment
5. Language dysfunction includes:
 - a. Anomic aphasia
 - b. Paraphasias
 - c. Decreased comprehension
 - d. Agraphia
 - e. Word finding
6. Disorganized thinking:
 - a. Tangentially, circumstantiality, and loose associations between elements of thought

7. Sleep abnormalities:
 - a. Disruption of the sleep-wake cycle, which may be seen prior to the episode
 - b. Sleep fragmentation
 - c. Reversal of the sleep-wake cycle, which is a reflection of abnormal circadian rhythm regulation
8. Motor activity:
 - a. Patients may be hypoactive, hyperactive, or show mixed symptomatology
 - b. Hypoactive patients are often misdiagnosed as suffering depression
 - c. Cognitive impairment and EEG slowing are seen with equal frequency in both hyperactive and hypoactive states
 - d. Psychiatric and psychotic symptomatology may be seen in both motor states
9. Psychiatric symptoms:
 - a. Psychotic symptoms occur in 50% of patients in delirium
 - b. Most patients who are in delirium do not have hallucinations or delusions
 - c. Thought content abnormalities include suspiciousness, overvalued ideation, and when severe, delusions which are often of impending danger or threat. Misperceptions include depersonalization and misidentification
 - d. Hallucinations and illusions are most often visual, although tactile and auditory ones have been reported
 - e. Affectual states fluctuate widely, so that a delirious patient may show fluctuations between terror and jocularity
 - f. The most common predisposing factors for delirium include:
 - i. Old age
 - ii. Cognitive impairment and dementia

Aphasia

Overview

Modern techniques of functional brain mapping with MRI and transcortical mapping during epilepsy and brain tumor surgery have demonstrated that the language-distributed networks are different than previously described.

Production of Speech

Prior to speech, the speaker must activate the knowledge of the sequence of consonants and vowel speech sounds (phonemes) of the word to be spoken. This function, prior to articulation, is phonologic retrieval and is accomplished by drawing upon a phonologic mental image of the sounds that make up the intended spoken words. Dysfunction of this retrieval function causes phonemic paraphasia in which there are errors in the phonemes of the intended words to be articulated or their sequence is incorrectly ordered. This type

of deficit is seen in both classic Wernicke's and conduction aphasia. This paraphasic dysfunction is a deficit of speech production rather than speech comprehension.

It has been demonstrated in healthy controls by fMRI, PET, and magnetoencephalography that Wernicke's area is important for phonologic retrieval. The anatomical substrates for this process are the posterior superior temporal gyrus, posterior middle temporal gyrus, and the supramarginal gyrus.

In studies of patients with conduction aphasia, it has been demonstrated that the left pSTG and left inferior parietal lobule are associated with phonemic paraphasia without loss of comprehension that is evidence that these areas are involved in prearticulatory phonologic retrieval which is an inability to retrieve an internal image of the phonemes. Similar clinical findings occur with logopenic primary progressive aphasia in which patients have inability to retrieve words, make phonemic paraphasias during speech but retain word comprehension. The major pathology of the condition is in the inferior parietal lobule and the posterior superior temporal gyrus. Clinical and experimental evidence supports the supposition that the pSTG and the supramarginal gyrus are essential for phonologic retrieval. Recent voxel-based pathologic lesion symptom mapping studies have demonstrated comprehension impairment from damage to the MTG, AG (angular gyrus), anterior STG and prefrontal cortex but not in the classic Wernicke's area of the pSTG or supramarginal gyrus (SMG). In addition, physiologic and mapping studies in patients with the semantic variant of primary progressive aphasia have pathology in the anterior areas of the temporal lobe. These patients have severe comprehension deficits with loss of the understanding of the meaning of words. This comprehension deficit can occur from damage to distributed speech networks that are not restricted to classic Wernicke's areas.

Present knowledge suggests that speech comprehension involves two specific stages. The first is a process in which auditory input is analyzed on a phonemic basis ("phonemic perception") in the STG, the superior temporal sulcus of both hemispheres. The STG region that is involved is anterior to that involved in speech production as well as being anterior to the classic Wernicke's area. The second stage of speech comprehension involves the retrieval of semantic information (the meaning of the words) of the auditory input. This function depends on a large distributed network that includes the AG, MTG, ventral temporal lobe, medial parietal cortex, medial prefrontal cortex, and the inferior lateral prefrontal areas. It is clear that many cortical areas are involved in speech comprehension but, surprisingly, the Wernicke's area is not.

Posterior Cortical Language Networks Derived from Lesion Analysis and Functional Mapping

1. Wernicke's area is essential for phonologic retrieval in which the phonemes and their temporal order of articulation are mentally represented. This process is necessary for:

- a. Repetition
 - b. Word retrieval
 - c. Naming
 - d. Reading aloud
2. Speech repetition requires input to the phonologic retrieval system from the auditory phonemic perception system (anterior temporal lobe). A similar mechanism underlies reading aloud. In this instance, the afference to the phonologic retrieval system is from a visual letter perception system located in the ventral occipital temporal area
 3. Spontaneous speech and naming is sequential:
 - a. A stage prior to phonologic retrieval in which a concept of the intended verbalization is formed
 - b. Word retrieval occurs by mapping of word meanings onto phonologic representations
 - c. The input to the phonologic retrieval system is from an internal word meaning (semantic) system
 - d. The distributed semantic processing network is located in the associative cortices of the temporal, parietal and frontal lobes
 4. Speech comprehension depends on mapping sequences of phonemes (auditory phonemic perception system) onto the semantic system

Lesion Analysis of Posterior Aphasic Syndromes

1. Damage of the phoneme perception system
 - a. Superior anterior temporal lobe
 - b. Pure word deafness
 - c. This syndrome occurs after bilateral lesions because both hemispheres are involved in phoneme perception
2. Lesions of the phonologic retrieval system
 - a. Midanterior temporal lobe
 - b. Causes phonemic paraphasia and anomia (impaired word retrieval)
 - c. In isolation this lesion causes:
 - i. Conduction aphasia
 - ii. Logopenic primary progressive aphasia
3. Lesions of the semantic network
 - a. Midtemporal gyrus
 - b. Posterior temporoparietal junction
 - c. Causes:
 - i. Transcortical sensory aphasia
 - ii. Semantic variant of primary progressive aphasia
 - iii. Comprehension deficits with intact automatic speech
 - iv. Anomia and empty speech that lacks meaningful content
4. Wernicke's aphasia is characterized by paraphasic speech and impaired comprehension due to damage to phonologic retrieval and to the semantic system

An alternate view of the anatomical basis of aphasia suggests that cortical areas can be roughly divided into dorsal and ventral pathways that mediate phonological and semantic processing respectively. The dorsal pathway extends from

the posterior superior temporal to the inferior frontal cortices. Semantic information is relayed in a ventral pathway that extends from the temporal pole to the basal occipito-temporal cortex that also includes anterior connections. Current theories support the hypothesis that the ventral stream processes acoustic-phonetic features of speech while the dorsal stream mediates interactions between auditory and articulatory-motor representations.

Classical Aphasia

Broca's Aphasia

General Characteristics

1. Diffusion tensor imaging has demonstrated an extended Broca's area that involves two new fascicles:
 - a. The operculo-premotor fascicle that connects the pars opercularis with the premotor area
 - b. The triangulo-orbicularis system that connects the pars triangularis with the pars orbitalis

Clinical Manifestations

1. The major components of Broca's aphasia are difficulty initiating and articulating speech
2. Non-fluency
3. An output of less than 20 words per minute
4. The phrases are short and have abnormal rhythm, inflection and timbre
5. The patient utilizes meaningful substantive words with a lack of syntactic language. This agrammatism is noted by a decreased use of prepositions, articles, grammatic modifiers and the use of endings which delineate plurals, possessives and tenses. Patients with anterior aphasia have a specific disturbance in use of syntactic aspects of language. Repetition is abnormal particularly for simple syntactic words and endings
6. Comprehension is abnormal particularly for syntactic function words such as the difference between in and on
7. Confrontation naming is abnormal but performance is improved with a phonetic or contextual cue
8. Reading comprehension is impaired due to failure to understand grammatically significant words
9. Writing is abnormal which is out of proportion to weakness and demonstrates omission of grammatical words and misspelling of substantive words
10. Persistent Broca's aphasia is frequently associated with an ideomotor apraxia of the left hand. A significant number of patients demonstrate apraxia in handling objects and for imitation of movement with the left arm and face

Neuropathology

1. The most common cause of expressive or Broca's aphasia is stroke. The prefrontal and frontal branches of the MCA are most commonly affected. Stem MCA occlusion causes both Broca's and Wernicke's aphasia due to decreased perfusion of both the inferior and superior divisions of the artery. Rarely vascular disease of the anterior

cerebral artery causes an anterior aphasia due to ischemia of the SMA

- Any structural lesion of the brain that damages BA44, BA45 and surrounding and connecting white matter pathways such as tumor, cerebral hemorrhage or trauma may cause an anterior aphasia

Laboratory Evaluation

- MRI/MRA:
 - To evaluate the structural integrity of Broca's area and surrounding white matter
 - The patency of MCA and ACA arteries and their origins
 - EEG
 - Neuropsychological language testing

Wernicke's Aphasia

General Characteristics

- Wernicke's aphasia renders a patient unable to understand spoken language due to damage of the classic left temporoparietal cortex (BA22). Auditory-verbal comprehension of written words and pictures may be partially spared
- Recent functional MRI studies have demonstrated a role for the anterior temporal lobes in multimodal semantic processing (phonemic and semantic systems)

Clinical Manifestations

- Patients demonstrate fluent verbal output and/or normal to increased rate of word production
- Normal prosody and phrase length
- Their primary difficulty is an inability to comprehend language which includes understanding their own spoken language
- Grammatical structure is nearly normal although there is a lack of substantive words
- There are characteristic verbal or semantic paraphasic errors (word substitutions), literal or phonemic paraphasias (consonant errors), and neologisms (non-existent) word errors
- In some patients comprehension of midline commands may be partially retained
- Naming ability is severely impaired
- Reading and writing are involved to varying degrees. Some patients are more "word deaf" than "word blind"
- Most patients lack insight into their deficit
- A hemiparesis is unusual; a superior quadrant defect may be present as well as an apraxia of imitation and object handling
- There is presence of speech and logorrhea (non-stop output of speech)
- Words that have affective associations may be retained (profanities)
- Non-dominant hemispheric Wernicke's area damage may be associated with errors in the perception of the pitch, rhythm and emotional tone of speech
- Patients that utilized sign language are affected similarly

Neuropathology

- The great majority of lesions that cause Wernicke's aphasia are from damage to Brodmann area BA22 in the posterior 1/3 of the superior temporal gyrus of the dominant hemisphere
- There is support for damage to the medial temporal lobe and underlying white matter as also important for receptive aphasia
- Damage to the posterior 1/3 of the superior gyrus of the temporal lobe also isolates this portion of the language core from the occipital, temporal and parietal cortex
- Vascular lesions are the primary cause of Wernicke's aphasia. These are primarily from involvement of the inferior division of the middle cerebral artery and particularly the temporal-occipital-parietal branch. If a Wernicke's aphasia is of sudden onset and appears in isolation it is most often associated with an embolus characteristically from atrial fibrillation. Disease of the ipsilesional carotid and middle cerebral artery may also be causative
- Any structural lesion of the posterior 1/3 of the superior temporal gyrus such as blunt trauma, tumor, arteriovenous malformation may cause this aphasia

Laboratory Evaluation

- MRI/MRA:
 - To evaluate the structural integrity of the temporal lobe and its vascular supply
- EKG and echocardiography to evaluate a cardiac source of embolus
- EEG

Conduction Aphasia

General Characteristics

- The classic concept of conduction aphasia was that of a disconnection between Wernicke's area for receptive speech and Broca's area for expressive speech
- Recent studies demonstrate that patients with conduction aphasia more often have lesions in the supramarginal gyrus or deep parietal cortex than the arcuate fasciculus
- Auditory-verbal short-term memory (AVSTM) and repetition appear to involve overlapping distributed networks

Clinical Manifestations

- Patients have intact auditory comprehension that is fluent (often with paraphasic errors)
- Speech repetition deficits that include:
 - Difficulty repeating phrases
 - The difficulty with repetition increases with phrase length and complexity
- Speech errors occur during spontaneous speech that include substituting or transposing sounds
- Patients are unaware of their errors of speech and have difficulties in correcting them
- Spontaneous speech is fluent and most often grammatically and syntactically correct

6. Error sequences are often incorrect approximations of known morphemes
7. Naming is impaired due to literal paraphasic substitutions
8. Reading aloud is performed poorly but comprehension is relatively well preserved
9. Writing demonstrates omissions, spelling errors and altered sequences of words and letters
10. Auditory-verbal short-term memory (AVSTM) may be impaired in conduction aphasia
 - a. AVSTM:
 - i. A memory store of verbal information that can be retrieved in a time period of seconds
 - ii. It requires phonological input processing with translation to speech output mechanisms but also requires a storage/rehearsal component
 - iii. Deficits of AVSTM are demonstrated by dysfunction in span tasks and the number of digits and words that can be repeated
 - iv. Impairment of delayed response tasks associated with dysfunction of the rehearsal component of AVSTM were found to have lesions of the pre-frontal cortex
 - v. Patients with lesion of the posterior temporoparietal areas had deficits in span tasks from disruption of the phonological store (also includes auditory rhyming and repetition)

Neuropathology

1. In most patients, anatomical correlation with detailed aphasia battery testing reveals that the lesion for conduction aphasia associated with left posterior temporoparietal cortical areas rather than the arcuate fasciculus
2. Repetition and the phonological store of information are associated with the left-mid-posterior STG and portions of the MTG and inferior parietal cortex
3. The phonological store component of AVSTM is also dependent on the left STG/IP (subserves digit and word span)
4. All pathologies, vascular, trauma, tumor or surgical that involve the posterior temporal and inferior parietal areas of the dominant hemisphere may cause conduction aphasia. There have been several patients described with intact arcuate fasciculi with conduction aphasia

Laboratory Evaluation

1. Functional MRI neuroimaging reveals:
 - a. Repetition/conduction aphasia is associated with lesions in the perisylvian cortex
2. Perfusion imaging and structural MRI demonstrate:
 - a. Impaired repetition is associated with:
 - i. Hypoperfusion in the left inferior supramarginal gyrus and temporoparietal areas
3. Summary of both structural and functional studies of conduction aphasia:

- a. Single word repetition is dependent on the left posterior STG and inferior parietal cortex
- b. Phonological store, measured by the word and digit span, is associated with the medial portion of the MTG/STG border that is adjacent to the underlying white matter and Heschl's gyrus

Transcortical Motor Aphasia

General Characteristics

1. Is usually caused by a stroke of the anterior superior frontal lobe

Clinical Manifestations

1. Difficulty in initiating speech
2. Patients stammer and may appear dysarthric
3. They may be able to repeat flawlessly but have difficulty with naming
4. They may have well preserved comprehension
5. They can read aloud and for comprehension, but writing is performed poorly
6. Patients may suffer a hemiparesis and may have an ideomotor apraxia of the left hand to verbal command
7. May have poor grammar (syntax) and narrative discourse that causes poor formation of complex sentences, the selection of appropriate words and the initiation of speech in conversation

Neuropathology

1. Most transcortical motor aphasias are caused by lesions in the superior frontal lobe convexity above Broca's area or in the supplementary motor area
2. Other pathologies include brain tumor, trauma and neurodegenerative diseases
3. Watershed area stroke between ACA/MCA territories

Laboratory Evaluation

1. MRI/MRA:
 - a. To evaluate for structural lesions and the vascular supply to the frontal lobe
 - b. Speech-language therapist for a comprehensive speech evaluation

Transcortical Sensory Aphasia

General Characteristics

1. This aphasia is similar to Wernicke's aphasia but patients can repeat

Clinical Manifestations

1. Patients demonstrate a normal or rapid rate of speech production, normal phrase length, rhythm of speech and prosody
2. Patients have a nominal aphasia and cannot read or write
3. Phonological processing is intact but lexical semantic processing is impaired
4. Patients can repeat complicated sentences but have impairments in comprehension of propositional speech

5. Paraphasias may be prominent
6. Patients may have an associated hemisensory and visual field deficit

Neuropathology

1. The usual brain area involved is the inferior left temporal lobe (left hemisphere speech dominant patient)
2. Transcortical sensory aphasia has also been described with damage to the angular gyrus, the second and third temporal gyrus or a MCA/PCA border zone infarction of the parietal-temporal junction
3. In addition to vascular disease, TCS aphasia may be caused by contusions and vascular malformations of the temporal lobe and tumors as well as neurodegenerative diseases

Laboratory Evaluation

1. MRI/MRA:
 - a. To evaluate the structural integrity of the left temporal lobe as well as the patency of the posterior cerebral artery
2. The Minnesota test for differential diagnosis which probes for weaknesses in auditory and visual components of aphasia as well as reading comprehension

Mixed Transcortical Aphasia and Isolation of the Speech Areas

General Characteristics

1. The majority of these patients suffer anterior and posterior vascular border zone ischemia or infarction

Clinical Manifestations

1. In border zone ischemia, patients often present with mixed transcortical motor and sensory aphasia that evolves to TCM, if anterior arteries, or TCS if posterior arteries, are predominately affected
2. If both MCA/ACA and MCA/PCA border zone infarctions are complete, patients have isolation of the speech areas. In this instance patients demonstrate:
 - a. Inability to initiate speech, name objects, follow commands, read or write
 - b. They can repeat a short phase

Neuropathology

1. Most patients have suffered a severe anoxic injury or prolonged cerebral hypotension
2. Carbon monoxide poisoning
3. A few patients have been reported with acute carotid occlusion, head trauma and severe cerebral edema

Laboratory Evaluation

1. MRI/MRA:
 - a. To evaluate for structural lesions in border zone distributions
 - b. Cardiac evaluation for ejection fraction and arrhythmia

Global Aphasia

General Characteristics

1. Global aphasia is non-fluent and severely affects both receptive and expressive components of speech

Clinical Manifestations

1. Most patients with global aphasia have suffered damage to the frontal and parietotemporal language areas from a carotid occlusion or stem middle cerebral artery embolism. They often appear mute at ictus (stunned)
2. These patients cannot initiate speech, follow commands, read, write, repeat or name
3. The impairment is present across all language modalities
4. The patient may be able to use one or two words that are a response to all questions
5. Patients are socially appropriate
6. Automatic speech has normal phonemia, phonetic and prosody
7. Patients may correctly utilize facial expression, gestures and intonation
8. Most patients suffer a concomitant right hemiparesis but some have been documented with minimal or no motor or sensory loss

Neuropathology

1. Most patients suffer severe left perisylvian lesions from occlusion of the stem of the middle cerebral artery that occludes both its superior and inferior divisions. Both thrombotic and embolic causes have been reported. Rarely, an anterior or superior trunk MCA occlusion can cause the syndrome acutely that rapidly evolves into a Broca's aphasia
2. Large hemispheric tumors (glioma) or severe head trauma as well as large hematomas from intracranial hemorrhage may cause the syndrome
3. Global aphasia without hemiparesis has been described with:
 - a. Single or multiple lesions
 - b. Subcortical lesions
 - c. Cardioembolic stroke
 - d. Internal carotid artery occlusion
 - e. Often there is rapid recovery

Laboratory Evaluation

1. MRI/MRA:
 - a. To detect embolic pattern of lesions and to evaluate the internal carotid and middle cerebral artery circulations
2. EKG and echocardiography to evaluate the heart as an embolic source
3. Medical evaluation to rule out systemic causes of arteritis that may also effect the cerebral arteries as exemplified by SLE and anti-nuclear antibody syndrome

Anomic Aphasia

General Characteristics

1. The most common aphasia

2. The three major types of anomia are:

- a. Word selection anomia
- b. Semantic anomia
- c. Disconnection anomia

Clinical Manifestations

1. Word selection anomia:

- a. The patient can explain how the object is used and can correctly identify the object within a group of other objects
- b. The patient is unable to name the object
- c. Some patients have selective anomia for particular types of objects
- d. In color anomia, the patient is able to distinguish among colors but is unable to identify them by name or the name of object's color. The patient is able to separate colors into categories

2. Semantic anomia:

- a. The meaning of words is lost
- b. The naming deficit is accompanied by a recognition deficit
- c. Patients are unable to select the target object from a group of objects even when given the object's name

3. Disconnection anomia:

- a. These patients may have modality-specific anomia in which the anomia is limited to a specific sensory modality
- b. There is disconnection between the sensory cortex and language areas
- c. Patients with disconnection anomia may also have associated callosal anomia. In this situation, corpus callosum disruption prevents the transfer of sensory information to language areas. The sensory information from the left hand is processed in the right somatosensory cortex which then cannot be transmitted to language areas of the left hemisphere. The patient is not able to identify objects in the left hand by touch

Neuropathology

1. A lesion of the left temporoparietal junction is most characteristic although anomic aphasia has been seen with dominant hemisphere frontal, temporal and parietal lesions. It has rarely been reported following right hemisphere and subcortical pathologies
2. Brain tumors may cause a slowly progressive anomic aphasia
3. Anomic aphasias may be seen in neurodegenerative diseases, traumatic brain injuries and with metabolic and toxic disorders. In the latter situation patients have evidence of an acute confusional state and writing may be more impaired than speaking
4. Pure anomic aphasia may occur with supramarginal gyrus lesions

Laboratory Evaluation

1. MRI/MRA:

- a. To evaluate lesion distribution or to delineate the patterns of cortical degeneration in neurodegenerative disorders

2. Speech evaluation

Subcortical Aphasia

General Characteristics

1. Three major subcortical areas have been associated with subcortical aphasia and include:

- a. Striatocapsular lesions
- b. White matter periventricular lesions
- c. Thalamic lesions

Clinical Manifestations

1. Striatocapsular and white matter periventricular lesions:

- a. Lack of speech fluency
- b. Paraphasias
- c. Minimal involvement of comprehension
- d. Naming is primarily intact
- e. Verbal output is slow and poorly articulated

2. Thalamic aphasia:

- a. Fluent speech
- b. Some have isolated naming deficits
- c. Comprehension deficits
- d. May have initial mutism or hypophonia

Neuropathology

1. Subcortical nuclei and areas that cause aphasia are the:

- a. Putamen
- b. Caudate
- c. External capsule
- d. Anterior internal capsule
- e. Thalamus

2. The language deficits following thalamic stroke have been postulated to occur from:

- a. Dysfunction of thalamocortical distributed networks directly which may secondarily cause mild diffuse hypoperfusion of the cortex
- b. Concurrent cortical hypoperfusion
- c. Diaschisis of cortical language areas
- d. The most prominent feature of striatocapsular aphasia is phonetic impairment of language, while in thalamic aphasia it is lexical semantic processing

3. The major pathology associated with subcortical aphasia is ischemia of the posterior cerebral artery particularly of the P1 segment that gives origin to the thalamogeniculate and interpeduncular arteries

4. Tumors, hemorrhage and traumatic brain injury that disrupt thalamic-cortical projections are also causative

Laboratory Evaluation

1. MRI/MRA:

- a. Delineation of the subcortical topography of the causative lesion
- b. DWI and PWI:
 - i. Aphasia is more correlated with PWI (perfusion weighted than diffusion weighted sequences)

Differential Diagnosis of Aphasia

1. Mutism:
 - a. A common entity misdiagnosed as aphasia is mutism which by definition is the total cessation of verbal output
 - b. The most common brain areas associated with mutism are frontal, supplementary motor, left thalamic, mesencephalic and the left posterior inferior portion of Broca's area
 - c. If a patient can write normal sentences when speech returns, speech will be normal with only a few aphasic errors
 - d. Stem occlusion of the MCA and SMA lesions often present with mutism prior to evolution into a specific aphasia
2. Dysarthria
 - a. Motor speech disturbances such as ataxia, hypo- or hyperkinetic speech, aphemia may be misinterpreted as an aphasia
 - b. Aphasia can only be diagnosed when a disturbance of language function is demonstrated by incorrect grammar usage or choice of words. Abnormal phonology, the learned rules for producing the sounds of specific language only occurs with aphasia
3. Aphemia
 - a. Aphemic patients have great difficulty with articulation:
 - i. They can express themselves in written language and fully comprehend written and spoken language
 - ii. Word choice and syntax are normal
 - b. Aphemia is a severe disorder of verbal output. Many patients are mute in the acute stage and demonstrate a transient right hemiparesis
 - c. As a patient recovers, speech is hypophonic and poorly articulated. The speech is grammatically correct but the prosodic quality is often altered
 - d. Neuropathology:
 - i. The usual lesions are small and affect the motor system for articulation: pars opercularis, inferior prerolandic gyrus and the white matter deep to these areas
 - ii. The usual pathology is ischemia of the articular speech areas supplied by the prefrontal branches of the MCA or A1 branches of the ACA
 - iii. Aphemia has been described with lesions of the medial frontal cortex, the supplementary motor area or the motor area of the cingulate gyrus
 - iv. Any structural lesions of these areas including tumor, traumatic brain injury or hemorrhage may cause aphemia
 - e. Laboratory evaluation:
 - i. MRI/MRA:
 1. Evaluations of the ACA and MCA territories
 2. Rule out any structural lesion of the appropriate areas
4. Pure word deafness
 - a. Patients with pure word deafness cannot comprehend spoken language but can identify non-verbal sounds
 - i. They are fluent, are able to read and write, but can neither comprehend spoken language or repeat it
 - b. Patients have been reported in which word deafness and Wernicke's syndrome occur concomitantly. These patients demonstrate a fluent aphasia in which there is a greater deficit in comprehension than in writing. The anatomic lesions that cause severe word deafness are damage to Heschl's gyrus and destruction of the radiations from the medial geniculate body as well as the callosal fibers from the contralateral superior temporal gyrus. This combination of lesions isolates the left hemisphere auditory association cortex from any auditory input
 - c. The second localization for this syndrome is bilateral damage to the anterior and midportion of the superior temporal gyrus
 - d. Non-verbal auditory agnosia, the inability to recognize non-verbal sounds, occurs with lesions of the right hemisphere. Cortical deafness occurs with bilateral damage to Heschl's gyrus and its connections. In this state, patients are aware of words and sounds but cannot interpret them
5. Auditory agnosia
6. Cortical deafness

Written Language Impairments***Agraphia****General Characteristics*

1. If patients suffer aphasia in spoken language writing is also affected
2. Agraphia by definition, is a loss of the ability to communicate through writing either due to motor dysfunction or an inability to spell
3. Central agraphia:
 - a. Involves language areas of the brain that causes difficulty with spelling or with spontaneous communication. It is accompanied by other language dysfunction
4. Peripheral agraphia:
 - a. There is dysfunction of motor and visuospatial modalities in addition to language dysfunction
5. Agraphia may be caused by dysfunction from:
 - a. Language processing
 - b. Spelling
 - c. Visual processing
 - d. Visuospatial orientation for graphic symbols
6. Motor planning
7. Motor control of handwriting

Clinical Manifestations of Central Agraphia

1. Central agraphia manifests with impairment in spoken language and with the motor and visualization abilities required for writing
2. Patients with agraphia in association with fluent aphasia:
 - a. Are able to write a normal quantity of well-formed letters
 - b. Lack the ability to write meaningful words
3. Patients with agraphia and non-fluent aphasia manifest:
 - a. An ability to write short sentences
 - b. Poorly executed handwriting that is produced with great difficulty
 - c. Syntax is poor and there are spelling mistakes
4. Alexia with agraphia patients manifest:
 - a. Difficulty with production and comprehension of written language
5. Deep agraphia:
 - a. Patients have difficulty with phonologic aspects of speech and with orthographic memory
 - b. Patients are unable to recognize words when spelled correctly or sound them out in preparation for spelling
 - c. Semantic errors are frequent
 - d. Patients have difficulty with abstract concepts and uncommon words (defect in orthographic memory)
 - e. There are reading and spoken language errors
6. Gerstmann's syndrome:
 - a. There is impairment with written language production in association with:
 - i. Finger agnosia
 - ii. Right-left confusion
 - iii. Acalculia
 - iv. Some patients have conduction aphasia
7. Global agraphia:
 - a. Impairs orthographic memory to a greater extent than occurs with deep agraphia
 - b. Severe spelling impairment. A patient may only be able to write a few meaningful words
 - c. Reading and spoken language are impaired
8. Lexical and structural agraphia:
 - a. This form of agraphia is caused by damage to orthographic memory
 - b. Patients are unable to visualize the spelling of a word but are capable of sounding them out
 - c. Patients have more difficulty spelling words without regular predictable spelling. Less impairment in the spelling of common words
 - d. Patients make mistakes with homophones (a word that is pronounced the same as another word but has a different meaning)
 - e. Grammar and sentence writing is maintained
9. Phonological agraphia:
 - a. The ability to sound out words is impaired but orthographical memory is not affected
 - b. Patients are better at spelling words than non-words

- c. More difficult for patients to spell prepositions than concrete nouns
10. Pure agraphia:
 - a. An impairment of written language without any other language or cognitive disorder

Peripheral Agraphia

1. Apraxia
 - a. Due to the disruption of the motor system
 - b. Patients manifest:
 - i. Slow, effortful and imprecise letter formation
 - ii. Retain the ability to spell aloud
 - iii. This form of agraphia is due to a loss of the engram (the motor plan) for the formation of letters
 - iv. It may or may not be associated with ideomotor apraxia
 - v. Motor disorders associated with agraphia are:
 1. Parkinson's disease:
 - a. Inability to sustain writing with gradual micrographia
 2. Cerebellar ataxias:
 - a. Large poorly formed letters
 3. Dystonia:
 - a. Writer's cramp
 4. Chorea:
 - a. Disjointed chaotic poorly formed letters
- c. Hysterical agraphia:
 - i. Caused by a conversion disorder
- d. Reiterative agraphia:
 - i. Letters, words or phrases are repeated in an abnormal fashion
 1. Examples are preservation, paragraphia and echographia
- e. Visuospatial agraphia:
 - i. Patients neglect the side of the written page
 - ii. Lines are slanted upward or downwards
 - iii. There is abnormal spacing between letters, syllables and words
 - iv. Deficits in the orientation and correct sequencing of writing
 - v. Visuospatial agraphia is often associated with left hemispatial neglect and constructional apraxia

Neuropathology

1. Clinical pathologic correlation as well as fMRI analysis of normal healthy controls and patients with agraphia reveals a primarily left-hemisphere network of 12 cortical and subcortical areas that are utilized with writing
2. Distinct functional areas have been delineated and include:
 - a. The middle frontal gyrus and the superior frontal sulcus
 - b. The left superior parietal cortex that includes the inferior parietal lobule, the superior parietal lobule and the intraparietal sulcus
 - c. The primary motor and sensory cortex

3. Primary writing-specific areas are:
 - a. Left superior frontal sulcus/middle frontal gyrus
 - b. Left intraparietal sulcus/superior parietal area
 - c. Right cerebellum
4. Areas that are activated with writing but are related to non-specific motor or linguistic processes include:
 - a. Primary motor and sensorimotor cortices
 - b. Supplementary motor area
 - c. Thalamus (posterior nucleus)
 - d. Putamen (left)
 - e. Linguistic processing:
 - i. Ventral premotor cortex
 - ii. Posterior/inferior temporal cortex
 - f. Left inferior frontal gyrus
 - g. Right posterior cerebellum
 - h. Right inferior parietal lobule
 - i. Left fusiform gyrus

Clinical Pathologic Correlations of Agraphia

1. Phonological agraphia:
 - a. Damage to perisylvian structure that include Broca's and Wernicke's area as well as the supramarginal gyrus
2. Lexical agraphia:
 - a. Damage to the left angular gyrus and/or posterior temporal cortex
3. Deep agraphia:
 - a. Damage to the left angular gyrus and posterior temporal cortex often posterior and inferior to perisylvian language areas
4. Gerstmann's syndrome:
 - a. Most often is caused by an angular gyrus lesion
5. Apraxic agraphia:
 - a. Most often is caused by lesions of the superior parietal or the premotor cortex (engram formation)
 - b. Cerebellar lesions have been reported as causative
 - c. Apraxic agraphia without an associated ideomotor apraxia has been reported from lesions:
 - i. Either parietal lobe
 - ii. The dominant frontal lobe
 - iii. The dominant thalamus
6. Visuospatial agraphia:
 - a. Most of the pathology is in the non-dominant hemisphere
 - b. Right frontal lobe damage causes motor deficits while damage to posterior parietal areas leads to spatial deficits
 - c. Vascular disease
 - d. Tumor
 - e. Head trauma

Laboratory Evaluation

1. MRI/MRA:
 - a. To evaluate the anatomic status of the areas defined for writing with their attendant blood supply
2. Functional magnetic resonance imaging:

- a. The left parietal (BA5) and premotor areas are activated when writing with the dominant hand
- b. The anterior aspect of the dorsal premotor cortex (BA6) may be the source of the engrams for writing

Alexia Without Agraphia

General Characteristics

1. Alexia without agraphia was the first disconnection syndrome described. It has also been designated as pure alexia or word blindness

Clinical Manifestations

1. Patients suffer an inability to comprehend written language
2. They are able to recognize words spelled aloud, graphesthetically produced words written on the palm or words constructed with blocks that are palpated
3. Most patients can recognize a few letters
4. There is often an associated right homonymous hemianopsia and impaired naming and understanding of color names in the face of normal color vision. A few patients have central achromatopsia
5. Associated anomia

Neuropathology

1. The usual lesion is occlusion of the left posterior cerebral artery with infarction of the left occipital lobe and the splenium of the corpus callosum which prevents transfer of visual information from the right occipital lobe to the left angular gyrus
 - a. Occlusion of the dominant middle cerebral artery or its distal branches may also lead to an acquired loss of the ability to read or write from infarction of the parietal lobe. These patients often have a concomitant mild hemiparesis, hemisensory loss, partial visual field deficit and anomia
2. Lesions of the posterior inferior frontal cortex of the dominant hemisphere may impair the ability to comprehend the syntactic structures such as function words and endings. These patients may understand substantive words but cannot recognize relational words. This defect is seen in both spoken and written language. Patients have difficulty in understanding sequences of semantically significant words
 - a. Some patients have a concomitant Broca's aphasia, right hemiparesis, and mild hemisensory loss. Paralexia refers to substitutions of words or syllables when reading aloud. Synonym substitutions of nouns for objects and an inability to read nonsense and function words. This type of dyslexia follows severe damage to the dominant hemisphere language areas and may be seen during recovery from complete alexia

Laboratory Evaluation

1. MRI/MRA:

- a. To evaluate these anatomically significant areas and their blood supply that may also be affected by tumor, cerebral trauma, hemorrhage as well as ischemia
2. Functional MRI demonstrates activation of the superior temporal gyrus, supramarginal gyrus, inferior frontal gyrus/operculum, precentral gyrus and insular cortex during reading
3. Diffusion tensor imaging reveals:
 - a. Lesions in the white matter tracts that connect these areas in patients with phonological alexia/agraphia

Syndromes of Calculating Impairment

Acalculia

General Characteristics

1. Acalculia is an acquired disability in which patients have difficulty performing simple mathematical functions
 - a. Dyscalculia is a developmental disorder during the acquisition of mathematical skills

Clinical Manifestations

1. The cognitive functions required for basic mathematical tasks include:
 - a. Every number represents a value
 - b. The recognition of a number's value with respect to other numbers
 - c. Understanding the number's location in a series of numbers
 - d. Association of a numerical symbol with its name
2. Aphasic acalculia:
 - a. The patient is not able to utilize numbers as a language entity
 - b. Patients are unable to comprehend or write numbers correctly or substitute one number for another
 - c. Aphasic acalculia is seen in most aphasic patients
3. Visual spatial acalculia:
 - a. The patient can compute, understands numbers and computational signs but is unable to place numbers in the correct position in space
 - b. Patients are unable to align numbers in columns or place decimal points which interferes with complex calculations although they can manipulate individual mathematical functions
 - c. The lesion affects the non-dominant hemisphere at the parieto-occipital junction
4. Anarithmia:
 - a. These patients are not able to manipulate numbers or compute
 - b. They can recognize and reproduce individual numbers, understand their value but cannot compute
 - c. The lesion most often is noted in the dominant posterior parietal cortex

Neuropathology

1. Lesions of the angular gyrus may cause greater impairment in memorized mathematical tasks such as multipli-

cation tables with relatively normal subtraction ability. Patients with lesions of the intraparietal sulcus have greater difficulty with subtraction than multiplication. It appears that specific regions of the parietal cortex are specialized for specific mathematical functions

Laboratory Evaluation

1. MRI/MRA:

- a. To evaluate for structural lesions particularly of the posterior parietal areas and the angular gyrus

Apraxia

General Characteristics

1. Apraxias are the inability to perform an individual or sequential function with intact motor, sensory and coordinative abilities
2. Different areas of the brain are specific for specific forms of apraxia
3. Apraxia is a disorder of motor planning (the development of an engram) for a specific movement

Clinical Manifestations

1. Ideomotor apraxia:

- a. Patients have an inability to plan or complete a single motor action that requires semantic memory
- b. They are able to explain how to perform the action but are unable to imagine it or carry it out
- c. The patient may retain the ability to perform the activity automatically

2. Ideational apraxia:

- a. Patients are unable to conceptualize and perform a multistep task
- b. There is loss of the ability to perform a learned task when given the appropriate tools
- c. Patients may not be able to initiate the sequence required to perform a task or abandon it in the middle
- d. Patients may have an inability to handle real objects even though they can mimic the use of the object

3. Constructional apraxia:

- a. Constructional apraxia is impairment in the ability to construct the copy of a visually presented object with blocks or by drawing. Patients must be able to perceive the elements of the object, their spatial relationships and possess the motor ability to perform the task
- b. Both left and right parietal lesions can cause a defect in constructional praxis, although right-sided lesions are more common. In right-sided lesions, the deficit is more severe as patients have left-sided neglect of the object to be copied
- c. Patients with left parietal lesions and constructional apraxia frequently have an associated fluent aphasia

4. Buccofacial or orofacial apraxia:

- a. The cardinal features of oral-buccal-lingual apraxia is the loss of the patient's voluntary ability to utilize muscles of mastication, swallowing and speech

- b. These muscles are innervated by the first four branchial arches
- c. Patients are unable or have difficulty with speech, swallowing, chewing and pursing their lips on command
- d. Coughing, sneezing and involuntary movements are preserved
- e. Oral motor apraxias may be seen with:
 - i. Landau-Kleffner syndrome
 - ii. Benign Rolandic epilepsy
 - iii. Anterior perisylvian lesions
 - iv. Foix-Chavany-Marie syndrome
 - a. Vascular bilateral insular infarctions
 - v. Frontotemporal dementia and other neurodegenerative diseases
- 5. Limb-kinetic apraxia:
 - a. Patients have difficulty making precise movements
- 6. Oculomotor apraxia:
 - a. Patients have difficulty in producing saccadic eye movements that direct gaze to specific targets on command. It is prominently seen in Bálint's syndrome
- 7. Dressing apraxia:
 - a. Patients are unable to dress themselves properly even when they are given the garment
 - b. The apraxia is rarely isolated and is often seen with neglect, Bálint's syndrome and in confused and demented patients
 - c. The responsible lesion is in the right occipitoparietal or bilateral occipitoparietal areas
- 8. Callosal apraxia:
 - a. Callosal apraxia is the inability to perform a simple command with the left hand although the right hand performs it easily
- 9. Gait apraxia:
 - a. Patients have trouble in initiating the swing component of gait, walk as if they are on eggs or have a foot grasp of the floor
 - b. Normal pressure hydrocephalus, lesions that affect the pedunculopontine nucleus or other components of locomotor centers as well as basal ganglia disease and lacunar stroke involvement of the corticospinal system are causative
- 10. Apraxia of speech:
 - a. Patients are unable to plan or program phonetic and prosodic speech
 - b. These patients suffer:
 - i. Inconsistent articulatory errors
 - ii. Unusual oral movements to prepare for articulation
 - iii. Produce errors with increased word and phrase length
 - iv. Difficulty with production of all of the sounds in a word
 - v. Vowels are easier to produce than consonants and single consonants are more easily produced than blends

- vi. Final components are easier to pronounce than those in the initial position
- c. Apraxia of speech is often seen with concomitant oral-buccal-lingual apraxia
- 11. Conceptual apraxia:
 - a. Patients lose the associative knowledge of tool action and may also not have an understanding of mechanical knowledge, which is the advantage tools offer
 - b. Frontal lobe degeneration is most often associated with conceptual praxis
- 12. Eyelid opening apraxia:
 - a. Patients are unable to open their eyelids on command
 - b. The apraxia may be seen in isolation or in conjunction with other neurologic features of neurodegenerative diseases
 - c. Most often seen with lesions of the superior frontal gyrus
 - d. Some demented patients think they are blind because they cannot open their eyes

Neuropathology

- 1. Specific apraxia by anatomical site:
 - a. Oral-buccal-lingual apraxia:
 - i. Insular cortex; if bilateral it may constitute the Foix-Chavany-Marie syndrome
 - b. Ideomotor apraxia:
 - i. Inferior parietal lobes; SMA; premotor cortex
L > R
 - c. Ideational apraxia:
 - i. Left posterior BA5 and BA7
 - d. Limb-kinetic apraxia:
 - i. BA6, inferior parietal lobe, SMA
 - e. Dressing apraxia:
 - i. Right parietal lobe
 - f. Constructional apraxia:
 - i. Right frontal and right parietal lobes
 - g. Eyelid opening apraxia:
 - i. Second frontal gyrus
 - h. Callosal or sympathetic apraxia:
 - i. Corpus callosum (usually anterior)
 - ii. Left and right prefrontal cortex
 - i. Gait apraxia:
 - i. Leg fibers surrounding the lateral ventricles; paracentral lobule
 - j. Conceptual apraxia:
 - i. Associative knowledge (tool action) the frontal lobe
 - ii. Mechanical knowledge of the tool (its advantage) the frontal lobe

The lesions causing apraxias are most often vascular, neurodegenerative disorders, normal pressure hydrocephalus, traumatic brain injuries and tumor

Laboratory Evaluation

- 1. Structural MRI studies reveal:

- a. Lesions in the left frontal, parietal and temporal lobes in patients with pantomime deficiency
2. Functional MRI:
 - a. Associates pantomimes with left parietal activation with or without concurrent frontal or temporal activations
 - b. Both lesion and functional studies demonstrate a left hemispheric frontal-temporal-parietal network that plays a key role in pantomiming object use

Distributed Brain Networks

Overview

Functional MRI (fMRI) imaging has been demonstrated to be exceptionally valuable in investigating human brain function. This functional neuroimaging procedure measures brain activity by detecting changes that are associated with cerebral blood flow in specific brain regions either at rest or during specific task related activities. fMRI utilizes blood-oxygen level dependent BOLD contrast that is based on the concept that local cerebral blood flow and neuronal activity are coupled. Thus if an area of the brain is activated its blood flow increases. The procedure utilizes the change in magnetization between oxygenated and deoxygenated blood. The change in MRI signal from neuronal activity is the hemodynamic response which lags the triggering neural event by 1 to 2 seconds. It has a peak rise in approximately 5 seconds after the activation. If there is continuous neuronal activity, the peak plateaus. Cessation of neuronal activity causes the BOLD signal to fall below the baseline level that is known as undershoot. The BOLD contrast signal primarily reflects neuronal input and integrative firing rather than the neuron's output discharge. The BOLD signal cannot distinguish between excitation or inhibitory activity in a network and thus the final signal is the summation of the network's activity. The BOLD signal may also be affected by sedation, anxiety, blood vessel physiology (ability to dilate) and medication that dilates blood vessels.

The Default Mode Network

The default mode network (DMN) consists of interacting brain regions (nodes) that are correlated with each other by white matter pathways (edges). It is active when the subject is not focused on a task-specific activity while the brain is at "wakeful rest". It is active during daydreaming, mind wandering, thinking of oneself or others, remembering the past, and planning for the future. In general, the network is deactivated during goal-oriented tasks but can be activated for social work, memory or autobiographical goals. It is negatively correlated with attention networks

Anatomy of the DMN

The DMN can be defined by placing the seed in the posterior cingulate cortex and analyzing which brain areas correlate

with it during the resting state. It has also been structurally defined by the nuclear areas that are deactivated during externally directed goal-directed tasks as compared to rest.

The major hubs of the DMN include:

1. The posterior cingulate cortex (PCC):
 - a. The ventral PCC activates with reflections of self, remembering the past, thinking about the future and spatial navigation
 - b. The dorsal PCC is activated during involuntary awareness and arousal
 - c. The precuneus may be activated by visual, sensorimotor and attentional input
2. Medial prefrontal cortex is activated by self-processing information, autobiographical memories and future goals and events. Its lower component is activated by emotional content and internally valued reward
3. Angular gyrus activation occurs with:
 - a. Episodic memory
 - b. Attention
 - c. Spatial cognition
4. Dorsal medial subsystem:
 - a. Activates when thinking about others
5. Dorsal medial prefrontal cortex activates with:
 - a. Inferring the purpose of others' actions
6. Temporoparietal junction:
 - a. Activates when reflecting on the beliefs of others
7. Lateral temporal cortex activates with the retrieval of social semantic and conceptual knowledge
8. Anterior temporal pole:
 - a. Activates when reflecting on abstract conceptual information
9. Medial temporal subsystem:
 - a. Activates with autobiographical memory and future goals
10. Hippocampus:
 - a. Activates with the formation of new memories and reflections of the past and imagining the future
11. Parahippocampus activation occurs with spatial scene recognition and its stimulation
12. Retrosplenial activation:
 - a. Spatial navigation
13. Posterior inferior parietal lobe activation occurs with:
 - a. Integration of auditory, visual and somatosensory afferences
 - b. Attention

Modulation of the DMN

1. Acupuncture:
 - a. Deactivation of limbic areas
2. Meditation:
 - a. Structural changes have been defined in posterior cingulate cortex and precuneus in intense practitioners
3. Sleeping and resting wakefulness:
 - a. Strong functional connectivity between nodes of the DMN

- b. Onset of sleep:
 - i. There is a decrease in connectivity between the DMN and task-positive networks
- c. REM sleep:
 - i. Questionable increase of nodal connectivity in the DMN
- d. Stages of N2 and N3 of NREM sleep
 - i. Decreases of connectivity between the posterior cingulate and medial prefrontal cortices
- e. Sleep deprivation;
 - i. Decrease of connectivity within the DMN
 - ii. Sleep loss may induce a decrease between the DMN and task-positive networks

Neuropathologies in Which There May Be Involvement of the DMN

- 1. Autism:
 - a. Failure to deactivate the DMN during cognitively demanding tasks
- 2. Schizophrenia:
 - a. Overactive DMN
- 3. Alzheimer's disease:
 - a. Preferential accumulation of amyloid-beta in the DMN
- 4. Severe long-term trauma and abuse:
 - a. Lower connectivity across the network
- 5. Post-Traumatic Stress Disorder:
 - a. Lower activation in the posterior cingulate gyrus
- 6. Depression and chronic pain:
 - a. Hyperconnectivity across the DMN

Task-Related Functional Networks

Cognitively demanding tasks consistently recruit the dorsal anterior cingulate cortex (dACC), the orbitofrontal insula (FI), the lateral prefrontal cortex and the lateral parietal cortex that has been termed the task-activation ensemble (others have termed it the task-activation network).

The lateral prefrontal cortex (PFC) and parietal areas coactivate with the dACC and FI during attention, working memory and response selection. They also activate during pain, uncertainty and threats to homeostasis. Thus, it has been questioned whether these areas are activated in a task-specific manner or to cognitive, homeostasis or emotional salience which are inherent in these tasks and require change in sympathetic tone. The salience network, primarily the dACC and the orbitofrontal insula (FI) are intimately involved in interoceptive-autonomic processing which coactivate during the affective aspects of pain, empathy for pain, metabolic stress, hunger, pleasurable touch and specific social situations. The dorsal medial thalamic nucleus may be an essential integrative node for the system. The ACC has been hypothesized to play a cognitive role by processing errors and conflict. It, along with the FI, has also been postulated to be specialized nodes for sympathetic control and interoception.

The executive control network is fundamental for operations that require:

- 1. Directed attention to pertinent stimuli
- 2. Behavioral choices
- 3. Contextual cues
- 4. Homeostatic demands

This network contains sites for:

- 1. Sustained attention and working memory (the DLPFC and lateral parietal cortex)
- 2. Response selection (dorsomedial frontal/preSMA cortex)
- 3. Response suppression (ventrolateral prefrontal cortex)

Neural Orientation

Neural oscillation in the CNS refers to repetitive or rhythmic neural activity driven by mechanisms within individual neurons or by interactions between neurons. Oscillations in individual neurons are produced by changes in membrane potential which then cause oscillatory activation of postsynaptic neurons. Macroscopic oscillations, those are at the level of the nuclei, represent synchronized activity of large numbers of neurons, and can be seen on the electroencephalogram. Oscillations between groups of neurons are often produced by feedback loops that cause synchronization of the firing patterns. Synchronization between neuronal aggregates may have oscillations at a different firing frequency than that of their component individual neurons.

The function of neural oscillations includes:

- 1. Feature binding
- 2. Information transfer
- 3. The generation of rhythmic motor patterns

Oscillations are seen at all levels of the neuraxis and include:

- 1. Spike trains
- 2. Local field potentials
- 3. EEG (large scale oscillations)

They are characterized by their frequency, amplitude, and phase. Amplitude changes in large-scale oscillations are due to changes in synchronization within a neuronal aggregate (local synchronization). Neural oscillations and their synchronization across distributed loops (often concordant with areas of activation delineated by fMRI) are essential for many cognitive functions that include:

- 1. Information transfer
- 2. Perception
- 3. Memory
- 4. Motor control

EEG signals (measure of large oscillations) reveal oscillatory activity in specific frequency bands that include:

- 1. Alpha activity:
 - a. 8–13 HZ
 - b. Detected from the occipital lobe
 - c. During periods of relaxed wakefulness
 - d. Increased when the eyes are closed
- 2. Delta band:
 - a. 1–4 Hz
- 3. Theta band:
 - a. 4–8 Hz

4. Beta band
 - a. 13–30 Hz
5. Gamma band:
 - a. 30–70 Hz

b. Gamma activity has been linked to cognitive processing. Neural oscillations are linked to cognitive states that include sleep, awareness and levels of consciousness. Single cell readings in patients, primarily in those undergoing surgery for epilepsy or brain tumors, have demonstrated that neurons fire at particular frequencies and are termed resonators. Spike firing patterns have been associated with information coding. Neuronal aggregates that fire synchronously produce oscillations in local field potentials.

Multiple action potentials in neurons in sequence produce spike trains that have been posited to be the basis of neural coding and information transfer in the CNS. Spike train patterns are varied and include rhythmic spiking and bursting as well as oscillatory activity. Activity patterns of neuronal spiking are classified as class I or class II.

1. Class I neurons:
 - a. Generate action potentials with low frequency band that depends on input strength
2. Class II neurons:
 - a. Generate action potentials in a frequency band relatively independently of input strength
 - b. They demonstrate subthreshold oscillations in membrane potential

Neuronal aggregates (a nucleus or group of nuclei) generate oscillatory activity by synaptic interactions that synchronize different neuronal firing patterns. The rhythmic change in electrical potential produced by summated action potentials further summates. These synchronized firing patterns produce a synchronized afference into other distributed nuclei that cause large amplitude oscillations of local field potential. They are evaluated (large oscillations by EEG or magnetoencephalography activity) and are the reflection of the synchronized activity of millions of neurons that have similar spatial orientation. Inhibitory neurons generate a narrow window for excitation and rhythmic modulation of the firing rate of excitatory neurons and are essential for generating synchrony in neuronal aggregates.

Neuronal oscillation is fundamental to the function of distributed neural circuitry. Brain areas are bidirectionally coupled that form feedback loops. Positive feedback loops cause oscillatory activity whose frequency is related to delay time between neuronal aggregate interactions.

The mechanisms that determine oscillatory activity are determined by:

1. Neuronal properties that determine membrane potential oscillations
 - a. Voltage-gated ion channels
2. Network properties that affect the timing of spike trains, coupling strength, time delay, and sign (excitation or inhibition) determine if the spike trains of interacting neurons will be synchronized. The coherent activity of multiple modality brain activity connected by dynamic links between brain areas is essential for cognitive function

3. Neuromodulation of oscillatory activity is accomplished by neurotransmitters. The concentration of specific neurotransmitters regulates the amount of oscillatory activity in a distributed network. This is primarily affected by the diffuse brain projections for norepinephrine, acetylcholine, and serotonin. These transmitter systems effect wakefulness and arousal and influence the amplitude of different brain waves

Task-specific functional MRI and analysis of the oscillations and coherence of distributed networks are rapidly changing many concepts of the physiologic organization and function of the cerebral cortex.

Chapter 13

Dementia

Overview

Most dementing illnesses have specific clinical patterns of deterioration, destroy particular areas of the brain in a sequential pattern and are associated with seminal clinical features that permit a clinical classification. They are now being categorized on a molecular, biological, genetic and neuropathological basis.

The prevailing theories of brain function emphasize modularity and connectivity that processes information flow across large-scale distributed networks. Modularity is specialized processing within specific brain regions while connectivity describes the correlation of the major hubs of networks. It is clear that long term potentiation (LTP) and long term depression (LTD) are major mechanisms that determine synaptic efficacy for learning and memory. In the former (LTP), specific integrated loops and neurons are strengthened whereas in the latter these neurons are suppressed and their neurons cannot fire. Neurotransmitter systems that include acetylcholine are essential for memory and many other aspects of cortical function. The interplay of GABA-ergic and acetylcholinergic systems at the thalamic level is important for maintaining consciousness and directed attention. Dopamine has a major role in basal ganglia function at all levels and most probably with affect and subcortical dementia. Serotonin has been shown to be pivotal in many aspects of emotional expression and pain. Thus, dementing processes that destroy neurotransmitter systems in the brainstem have far-reaching neurological manifestations.

A fundamental aspect of all dementing processes appears to be the loss of synapses as well as neurons. Synaptic loss may be the best correlate of the severity of dementia and may be an early manifestation. Synaptogenesis and maintenance of formed synapses may depend on activity dependent neuroplasticity, neurotrophic factors and connectivity. Synaptic "pruning" (loss of dendrites) is prominent in many of the childhood and early adult storage diseases that eventuate in severe dementia.

The intense interest in the formation of nuclear and cytoplasmic inclusions points to the role of protein metabolism in dementing illnesses. The exact mechanism of cellular death when inclusions accumulate is not known but is hypothesized to include failure of axonal transport, apoptosis, the malformed protein response, and damage from free radicals.

The electrical correlates of normal brain function and that which occurs with dementing illness is now being unraveled. The EEG is often slow in dementing disorders. The ability to make cortical negative variants (readiness potentials) gives some insight into the brain's functional activity. The recent discovery of specific brain oscillations for attentiveness (beta

oscillations) and gamma oscillations (active during perception) suggest a mechanism for information transfer between different distributed loops. Magnetoencephalography allows for precise localization of a brain electrical event in real time. Its major use at present is to localize epileptic foci. It appears to take 0.5 msec to process a stimulus to a perception. This figure has been derived from an analysis of cortical negative variant potentials and thalamically generated gamma waves.

Functional MRI, PET and SPECT all localize an area of activity during a specific event, but do not identify its sign (inhibitory or excitatory) or localize its precise origin, the synapse or neuron. Most metabolic activity occurs at the synapse (estimated to be 85%).

The fundamental characteristics of a dementing illness are:

1. The cognitive impairment is acquired
2. The impairment involves multiple domains of cognitive function
3. There is no impairment of arousal
4. There is deterioration of previously acquired intellectual abilities of sufficient severity to interfere with social or occupational function
5. There is memory impairment with at least one other aspect of cognitive behavior
6. The disturbances of higher cognitive functions include:
 - a. Aphasia
 - b. Apraxia
 - c. Agnosia
7. Often personality change
8. There is no intoxication or delirium

Core Clinical Features of Cortical Dementias

1. Neuropsychological deficits:
 - a. Memory impairment:
 - i. Recall is not aided by cues
 - ii. Decreased retention
2. Cognitive domain deterioration:
 - a. Aphasia
 - b. Apraxia
 - c. Agnosia
 - d. Poor visuospatial abilities
 - e. Decreased executive function
3. Speed of cognitive function:
 - a. Normal
4. Psychiatric manifestations:
 - a. Depression (all)
 - b. Hallucinations (synucleinopathies)
 - c. Day to day variability (LBD); Lewy body dementia
 - d. Delusions (all)
 - e. Apathy (all)
5. Motor abnormalities:
 - a. Depends on the specific dementing illness; often specific:
 - i. Asymmetry (CBG); Cortical basal ganglia

- ii. Parkinsonism (akinetic rigidity > tremor)
 - 1. PDD (Parkinson's disease dementia)
 - 2. CBG
- iii. Loss of vertical gaze:
 - 1. PSP (Progressive supranuclear palsy)
- 6. Severity and progression:
 - a. Dependent on the specific dementing illness
 - b. Significant inter- and intrafamilial variance in genetic disorders
 - c. Variability is the rule in sporadic disease

Core Clinical Manifestations of Subcortical Dementia

- 1. Neuropsychological deficits:
 - a. Frontal memory impairment:
 - i. Recall aided by cues
 - ii. Decreased verbal fluency and recall
- 2. Speed of cognitive function:
 - a. Slow
- 3. Psychiatric manifestations:
 - a. Apathy
 - b. Depression
- 4. Motor abnormalities:
 - a. Dysarthria
 - b. Extrapyrmidal signs
- 5. Severity and progression:
 - a. Mild to moderate
 - b. May be intermittent if the disorder is due to specific structural lesions

Primary Dementing Illness

- 1. Definition:
 - a. The primary characteristics of dementia will be a feature of the clinical presentation of the dementing illness
- 2. Differential diagnosis of primary degenerative dementing disease:
 - a. Alzheimer's disease
 - b. Frontotemporal dementia and variants
 - c. Dementia with Lewy bodies (LBD)
 - d. Multiple system atrophies (MSA)
 - e. Progressive supranuclear palsy (PSP)
 - f. Corticobasal ganglia degeneration (CBG)
 - g. Wilson's disease
 - h. Huntington's disease
 - i. Pantothenate kinase deficiency
 - j. Familial Creutzfeldt-Jakob disease
 - k. Pick's disease
 - l. Posterior dementia with medial temporal sclerosis

Alzheimer's Disease

General Characteristics

- 1. Epidemiology:
 - a. Incidence of 5–8/thousand person years

- b. Approximately every five years after the age of 65 the risk doubles
- c. Women have a higher risk of developing the disease than men particularly in the age group of older than 85
- d. It is estimated that the prevalence rate will triple and the absolute number of patients will quadruple by the year 2050

Genetic Factors Associated with Alzheimer's Disease

- 1. Approximately 1–5% of patients:
 - a. Most of autosomal dominant familial AD is caused by mutations in 3 genes:
 - i. Amyloid precursor protein
 - ii. Presenilin-1 and presenilin-2
 - b. Most of the mutations in these genes increase the production of AB42 (amyloid-beta 1–42), (the major component of senile plaques)
 - c. Some mutations alter the ratio between AB42 and AB40 without increasing AB42 concentrations
- 2. Most patients with AD are sporadic with some genetic risk factors
 - a. The most studied genetic risk factor is inheritance of the E4 allele of the apolipoprotein E (ApoE). Approximately 40–80% of patients with AD have at least one ApoE E4 allele which increases risk 3 times in heterozygotes and 15 times in homozygotes
 - b. Mutations in genes that may affect risk are:
 - i. CASS4
 - ii. CELF1
 - iii. FERMT2
 - iv. HLA-DRB5
 - v. INPP5D
 - vi. MEF2C
 - vii. NME8
 - viii. PTK2B
 - ix. SORL1
 - x. ZCWPW1
 - xi. SIC24A4
 - xii. CLU
 - xiii. PICALM
 - xiv. BIN1
 - xv. MS4A
 - xvi. ABCA7
 - xvii. EPHA1
 - xviii. CR1
 - xix. CD2AP
 - c. Mutations in the TREM2 gene are associated with 3 to 5 times higher risk of developing the disease

ApoE4 Gene: Major Genetic Risk Factor for Late Onset AD General Characteristics

- 1. Located on the proximal long arm of chromosome 19:
 - a. Risk factor for late onset AD
- 2. ApoE is important for
 - a. Lipid transport

- b. Metabolism
- c. Targeting and clearance of amyloid-beta peptide
- 3. ApoE allele frequency:
 - a. E2/E2 – 1%
 - b. E3/E3 – 60%
 - c. E4/E4 – 3%
 - d. E2/E3 – 12%
 - e. E2/E4 – 2%
 - f. E3/E4 – 20%
- 4. E4 allele:
 - a. Noted in 40% of patients with late onset AD
 - b. If patient is homozygous for the E4 allele, he has a 90% chance of AD by age 80
 - c. The E4 allele bestows an earlier onset of sporadic AD
 - d. The E4 allele is found at its normal frequency in early onset familial AD
 - e. 50% of ALZ patients do not have an E4 allele
 - f. Pathology associated with ApoE:
 - i. Senile plaques (found within the plaques)
 - ii. Amyloid angiopathy
 - iii. Neurofibrillary tangles
 - iv. Binds to amyloid-beta fibrils which increases AB (amyloid-beta) aggregation

Clinical Manifestations

- 1. Minimal cognitive impairment:
 - a. May appear up to a decade prior to the onset of dementia and manifests as:
 - i. Short term memory loss
 - ii. Difficulty learning new information
 - iii. Deficits in executive function that are featured by loss of attentiveness, decreased mental flexibility, loss of abstraction, impairment of semantic memory (the memory of meaning and concept relationships in language)
 - iv. Apathy, depression, irritability and loss of awareness of memory deficits. If memory deficits are predominant, this form of minimal cognitive impairment is termed amnesic MCI
- 2. Early AD:
 - a. Most often, there is increasing impairment of short term memory and learning
 - b. Variable features:
 - i. Language deficits
 - ii. Apraxia, agnosia, and loss of executive function
 - iii. Episodic memory, semantic memory (facts learned) and implicit memory (motor engrams) may be less affected than that for new information
 - c. Language deficits:
 - i. Decreased vocabulary and fluency both in oral and written language

Moderately Advanced AD

- 1. Continued mental deterioration that starts to hinder the patient's ability to perform the usual activities of daily living

- 2. Language deficits accelerate:
 - a. The patient is unable to recall vocabulary that causes word substitutions (paraphasia)
 - b. Progressive loss of the ability to read and write
- 3. Deterioration of complex motor sequences
- 4. Behavioral and neuropsychiatric changes become evident; approximately 30% of patients develop illusionary misidentifications, and delusional symptoms, anosognosia develops

Advanced Alzheimer's Disease

- 1. Language deteriorates to single phrases or words: some patients develop a complete loss of speech
- 2. Apathy and exhaustion are common
- 3. Sarcopenia (loss of muscle mass) and a bedridden state with complete dependency on caregivers

Cognitive Defects in Alzheimer's Disease

- 1. Attention:
 - a. Definition:
 - i. The ability to select specific information to process
 - ii. Limitation of selective attention:
 - 1. Divided attention:
 - a. Inability to process multiple sources of information as efficiently as one source
 - b. Focused attention:
 - i. Difficulty in blocking irrelevant information
 - iii. AD Patients:
 - 1. Difficulty in dividing attention
 - 2. Better at focusing attention
 - 3. Difficulty in disengaging from an attended stimulus
 - iv. Alertness in AD patients:
 - 1. Phasic changes:
 - a. The time to process an expected input increases
 - 2. Tonic changes:
 - a. Slow decline in performance during a long and repetitive task
 - v. Language deficits:
 - 1. Failure of semantic speech (the production and comprehension of the meaning of words):
 - a. Inability to find the appropriate word
 - b. Comprehension of complex sentences
 - c. Inability to search semantic categories
 - d. Poor production of a semantic association to a given stimulus
 - e. Minimal difficulty with syntax; speech is grammatically correct
 - vi. Memory:
 - 1. Severe disruption of memory
 - 2. Deficiencies in encoding new information
 - 3. Memory for distant events (remote) memory:

- a. Less disrupted
- b. Demonstrates a temporal gradient (recall of distant information better than more information that is recent)
- 4. Implicit memory is relatively preserved in some studies but has been found to be deficient in others

Neuropsychiatric Manifestations of Alzheimer's Disease

1. Behavioral changes in Alzheimer's disease:
 - a. Psychoses
 - b. Agitation
 - c. Depression
 - d. Anxiety
 - e. Personality changes
 - f. Neurovegetative changes
2. Distribution of behavior changes:
 - a. Apathy – 72%
 - b. Agitation – 60%
 - c. Delusion – 22%
 - d. Hallucinations – 10%
 - e. Anxiety – 48%
3. Neuropsychological detection of preclinical Alzheimer's disease:
 - a. Deficits on confrontation naming
 - b. Deficits in abstract reasoning and executive function
 - c. Decreased memory encoding
 - d. Delayed recall (list learning task)

Alzheimer's Disease Variants

1. Alzheimer's with extrapyramidal features:
 - a. Faster rate of decline
 - b. Earlier neuropsychiatric manifestations
2. Alzheimer's disease variant with visual complaints:
 - a. Present with Bálint's syndrome
 - b. Complex visual complaints
 - c. Decreased occipital cortex and visual association area hypometabolism (PET scanning)

Amyloid Precursor Protein Mutation (APP)

General Characteristics

1. APP is an integral membrane protein expressed in many tissues and enriched in neuronal synapses
2. It has been postulated to play a role in the regulation of synapse formation, neural plasticity, and ion export
3. It is the precursor molecule that when proteolyzed generates amyloid-beta (AB) a 37–49 amino acid peptide. The amyloid fibrillar form of the protein is a major component of the amyloid plaques of AD
4. Mutation of the gene for APP maps to chromosome 21. Mutations in the critical regions of the protein, that which generates amyloid-beta, causes susceptibility to AD. Several mutations outside of the AB region increase the production of AB and are associated with familial AD

5. The APP gene encodes a 695–770 aa precursor protein:
 - a. The gene has 19 exons
 - b. Exon 16/17 codes AB (amyloid-beta)
 - c. Amyloid-beta (39–43 aa) is processed to pathologic amyloid fibrils
 - d. Specific mutations:
 - i. Exon 17 (3 mutations); codon 717
 - ii. The most common mutation is APP 717 (Val 717-Leu) > Val/Phe > Val 717/Gly
 - iii. There is a double mutation of exon 16 at codon 670–671
 - iv. In early onset AD:
 1. Mutations flank the amyloid
 2. Beta sequence
 3. Mutations within the sequence cause hemorrhage
 - v. APP's post-translational modifications include: glycosylation, phosphorylation, sialylation, tyrosine sulfation and proteolytic cleavage that generate peptide fragments:
 1. Alpha-secretase and beta-secretase cleave the protein that releases membrane-anchored carboxy-terminal fragments that may induce apoptosis
 2. Gamma-secretase cleaves the protein within the membrane-spanning domain after beta-secretase generates the amyloid-beta fragment

Clinical Manifestations

1. Early onset AD
2. Clinical features of the 717 codon mutations (Val/Glycine):
 - a. Myoclonus
 - b. Hypertensive cardiovascular disease
 - c. Heart disease
3. 717 Val/Ile mutation:
 - a. Klüver-Bucy-like syndrome (without the hypermetamorphopsia or hypersexuality)
 - b. NPH (normal pressure hydrocephalus)
 - c. Auditory hallucinations
4. Some mutations in APP gene are protective for AD by decreasing the production of AB, reducing amyloidogenic processing of APP or decreasing AB aggregation. A recent example is the A673T mutation in the APP gene

Presenilin-1

General Characteristics

1. Mutations in the presenilin-1 gene (PSEN1) that maps to chromosome 14 is one of the core proteins in the presenilin complex that causes autosomal dominant early onset AD
2. The protein may regulate proteolytic processes intracellularly one of which involves gamma-secretase that cleaves APP
3. Neuronal cultures derived from presenilin-1 deficient mouse embryos demonstrate that:

- a. Cleavage by alpha- and beta-secretase is normal
- b. Cleavage by gamma-secretase of the transmembrane domain of APP is absent
4. The presenilins may be involved in the cleavage of the Notch receptor that may also regulate gamma-secretase activity
5. The protein is located within nerve cells, the Golgi apparatus, and the endoplasmic reticulum

Clinical Manifestations

1. Age at onset of AD is between (35–55 years)
2. Progressive aphasia
3. Myoclonus
4. Generalized seizures
5. Penetrance is complete by age 60
6. Extrapyrimal signs
7. The range of onset varies within families
8. Duration of the disease is short 5.8–6.8 years

Variant of AD with Spastic Paraparesis

General Characteristics

1. Deletion of exon 1 of PSEN1

Clinical Manifestations

1. Described in a Finnish kindred
2. Spastic paraparesis
3. Onset 40–60 years of age; mean of 51 years of age
4. Memory impairment
5. Decreased hand coordination
6. Dysarthria

Neuropathology

1. “Cotton wool” plaques
2. The plaques are immunoreactive for amyloid-beta
3. No congophilic cores

Neuroimaging

1. MRI:
 - a. Temporal and hippocampal formation atrophy
2. PET:
 - a. Bilateral temporoparietal hypometabolism

Presenilin-2

General Characteristics

1. Mutations of the presenilin-2 gene (PSEN2) map to chromosome 1
2. As with presenilin-1, PSEN2 is postulated to regulate APP processing through its effect on gamma-secretase or by cleavage of the Notch receptor
3. The PSEN2 gene has 67% homology to PSEN1; the most common mutation is on chromosome 1:227073304 A > T

Clinical Manifestations

1. Early onset AD

2. Volga German population
3. Age of onset is 54.9 ± 8 years
4. Variation of age of onset is between 40–75 years
5. Two patients >80 years of age have been described with no clinical signs
6. Penetrance is usually >95%
7. Duration of illness is approximately 7.6 years: mean age of death is 64 years of age
8. Disease onset is characterized by memory deficits and other cortical cognitive dysfunction
9. Disease course is slower than other familial AD mutations particularly PSENs
10. Rare pyramidal or parkinsonian features
11. Approximately 30% of patients had seizures and 33% suffered hallucinations, delusions or other psychiatric manifestations

Neuropathology

1. Gross atrophy of the medial temporal and parietal lobes with lesser atrophy of the frontal cortex and cingulate gyrus
2. Early loss of synapses and neurons in the cerebral cortex and subcortical nuclei
3. As the disease progresses there is degeneration of the locus coeruleus
4. Loss of cholinergic neurons in the nucleus basalis of Meynert of the substantia innominata
5. Intraneuronal neurofibrillary tangles (NFTs) associated with neuritic plaques and dystrophic neurites:
 - a. Filamentous insoluble inclusions
 - b. Located in the cell body
 - c. Extend into the dendrites but not the distal axons
6. NFT tangles:
 - a. The major component is the hyperphosphorylated microtubule associated protein tau:
 - i. Tau normally binds to tubulin to stabilize microtubules
 - ii. When hyperphosphorylated it aggregates and interferes with cellular function
 - iii. Ghost tangles represent insoluble residues in dead neurons
 - iv. Evolution of NFT spread:
 1. The earliest area of involvement is the entorhinal cortex; it next spreads to the limbic cortex and lastly the cortex
 - v. The amyloid plaques:
 1. The amyloid plaques are extracellular and diffuse initially
 2. At later stages, they are cored
 3. The cores are 50–200 nm in diameter
 4. Cored plaques:
 - a. Are surrounded by dystrophic neurites
 - b. Reactive glial inflammatory response
 - c. Plaque core:

- i. 70% of the proteinaceous material is amyloid-beta (derived from the enzymatic cleavage of APP)
 - ii. Abnormal organelles
 - iii. Tau protein
 - iv. Apolipoprotein E (ApoE)
- d. Synaptic alterations:
 - i. Decreased presynaptic terminal density
 - ii. Disconnected neurons
 - iii. Synaptic pruning
- e. Cerebral amyloid angiopathy (CAA):
 - i. A feature of AD
 - ii. Can occur separately
 - iii. Associated with hemorrhagic stroke:
 - 1. AD Dutch disease
 - iv. ApoE allele may predispose to angiopathy in contradistinction to ApoE4 that is associated with AD
- f. Granulovacuolar degeneration:
 - i. Mainly confined to the hippocampus
 - ii. Vacuoles are found in pyramidal cells that contain a single granule:
 - 1. Reactive with antineurofilament antibodies
- g. Plaques and tangles are noted in normal aging:
 - i. They are less widely distributed and much fewer in numbers; amyloid can be abundant

Risk Factors for Alzheimer's Disease

1. Genetic forms of early onset disease with autosomal dominant inheritance (APP, PSEN1 and 2):
 - a. Associated genetic mutations (19 genes)
 - b. E4 allele
2. Age is the major risk factor
3. Geographic distribution:
 - a. Similar incidence worldwide
4. Women are more affected than men
5. Prevalence putatively related to educational background
6. Weak associations:
 - a. Head injury (repeated)
 - b. Parental age at birth
7. Age-associated cognitive decline:
 - a. Brain atrophy:
 - i. In normal controls, it is 0.4% per year
 - ii. In Alzheimer's disease, it is 2.4% per year
 - b. The deficits in age-associated cognitive decline are only in one cognitive domain
 - c. The deficit is greater than six months in duration
 - d. The deficits are greater than one standard deviation below values for age-matched controls
 - e. ApoE4 has no relation with cognitive decline of aging

Distribution of Pathologic Amyloid Plaques

1. Amygdala

2. Hippocampus:
 - a. Dentate gyrus (molecular layer)
 - b. Ca1 and Ca3 subregions
 - c. Subiculum
3. Layer III and V of the entorhinal cortex
4. Layer II contains NFTs
5. Temporoparietal neocortex > frontal lobe
6. Laminar degeneration of the posterior cingulate cortex
7. Histologic diagnosis of AD requires both neuritic amyloid plaques and NFTs in the neocortex
8. Lewy bodies may be seen

Possible Mechanism of Alzheimer's Disease

1. The amyloid hypothesis:
 - a. The accumulation of amyloid-beta peptides is the pathologic trigger that destroys neurons. Amyloid fibrils possibly are the toxic form of the protein that accumulates and causes:
 - i. Abnormally folded amyloid-beta protein (proteopathy)
 - ii. Disrupted calcium homeostasis
 - iii. Induction of apoptosis
 - iv. Accumulates in mitochondria (mitopathy)
 - v. Decreases glucose utilization
 - vi. Increased inflammatory response with abnormal proinflammatory cytokines and chemokines
 - vii. Alterations in neurotrophic factor physiology
2. Abnormal aggregation of tau protein:
 - a. Hyperphosphorylation of tau that aggregates and creates neurofibrillary tangles that disrupt the neuron's cytoarchitecture and internal transport processes

Laboratory Evaluation

1. Neuropsychological testing
2. Comprehensive medical evaluation to rule out B12 and folate deficiency, endocrine disorders, syphilis, liver and renal failure, electrolyte disorders

Neuroimaging

1. Characterizes the pattern of cerebral atrophy and its progression in Alzheimer's disease
2. Alzheimer's disease disrupts functional connectivity of intrinsic brain networks most prominently in the default mode network
3. MRI:
 - a. Medial temporal lobe atrophy is more important than small vessel disease in predicting minimal cognitive impairment
 - b. MRI tractography confirms that structural connectivity across almost all nodes of intrinsic brain networks are disrupted in AD
4. PiB PET is being utilized along with Florbetapir to demonstrate the distribution of amyloid deposition in the brain
5. The cingulum-angular bundle is disrupted
6. Thinning of the precuneus
7. Alterations in the uncinate fasciculus

Dementia with Lewy Bodies*General Characteristics*

1. Lewy body dementia is a progressive degenerative dementia characterized by an accumulation of alpha-synuclein and ubiquitin protein in the brain
2. There are alpha-synuclein plaques in greater numbers throughout the cortex than expected for age

Clinical Manifestations

1. Initial deficits:
 - a. Deficits of frontal subcortical abilities
 - b. Decreased visuospatial skills
2. Later in the course of the illness
 - a. Memory deficits
3. Core components of the disorder:
 - a. Fluctuating cognitive function with pronounced variation in attention
 - b. Recurrent visual hallucinations
 - i. Formed; detached
 - c. Parkinsonism
 - i. Bradykinesia and rigidity
 - ii. Rare tremor
 - iii. Poor response to L-dopa
 - d. Associated features
 - i. Repeated falls
 - ii. Syncope and transient loss of consciousness
 - iii. Neuroleptic hypersensitivity
 - iv. Delusions (other than visual) that are often paranoid
 - v. Urinary incontinence occurs later than cognitive decline
 - vi. REM sleep disorder
 - vii. Depression
 - viii. Sleep-disordered breathing
 - ix. Difficulty swallowing
 - x. Visual hallucinations include:
 1. Perceptions of non-existent people or animals
 - xi. Delusions:
 1. Reduplicative paramnesia
 2. Elaborate misperceptions
 3. Patients may have insight into the illness
 - xii. Double vision
 - xiii. Stroke-like episodes

Neuropathology

1. The major antigenic components of Lewy bodies include:
 - a. Presynaptic protein alpha-synuclein
 - b. Neurofilament proteins
 - c. Ubiquitin
2. Cortical Lewy bodies:
 - a. Lack a clearly definable central core and distinct peripheral corona

- b. The inclusions are formed from aggregated masses of intermediate neurofilaments
3. The number of cortical LB is variably correlated with the severity of the dementia:
 - a. Temporal lobe Lewy bodies correlate with visual hallucinations
4. Cortical Lewy bodies occur:
 - a. Cingulate gyrus
 - b. Entorhinal cortex
 - c. Insular cortex
 - d. Frontal cortex
 - e. Amygdala
5. The pathology of Lewy body disease is often concomitant with Alzheimer's disease
6. Neurofibrillary tangles are not common in DLB
7. There is loss of dopaminergic neurons in the substantia nigra as well as loss of acetylcholine producing neurons of the nucleus basalis of Meynert in the substantia innominata

Laboratory Evaluation

1. Structural tensor and diffusion tensor imaging of DLB disease reveals:
 - a. Anterior thalamic radiation (ATR) and the cingulum-cingulate gyrus are altered in DLB disease
 - b. Secondary axonal degeneration within the anterior thalamic radiations are due to microstructural damage within the medial dorsal thalamic nucleus
 - c. White matter alterations are seen in the uncinate fasciculus
 - d. It is posited that the structural connectivity disruptions in DLB disease is linked to gray matter neuronal loss rather than direct white matter injury
 - e. The ATR is altered in DLB disease and not in AD
 - i. The tract connects the dorsomedial thalamic nucleus to the prefrontal cortex
 - f. Degeneration is noted in the inferior longitudinal fasciculus (a ventral associative connection that transmits visual afferences to the temporal lobe; possible relationship to the hallucinations seen in DLB disease)
 - g. There is disruption of the supracallosal white matter bundle in DLB but not in AD
 - i. These white matter tracts wrap around the corpus callosum from the medial frontal cortex and anterior cingulate cortex to the dorsal posterior cingulate cortex. They are posited to regulate attentional focus. The loss of these white matter bundles may be linked to neuronal loss in posterior cortical regions

Frontotemporal Dementia*General Characteristics*

1. Frontotemporal lobar degeneration (FTLD) is heterogeneous and includes tauopathies

2. FTD may account for 20% of early onset dementia; the process affects men and women equally
3. The FTDs are heterogeneous clinically, pathologically and genetically
4. They are characterized by:
 - a. Behavioral variants (bvFTD)
 - b. Language impairment:
 - i. Semantic dementia
 - ii. Progressive non-fluent aphasia

Clinical Manifestations

1. In general patients with FTD have normal:
 - a. Perception
 - b. Visuospatial skills
 - c. Memory
 - d. Praxis
2. In the later stages of FTD clinical phenotypes may overlap. Patients have variable binge eating and compulsive behaviors
 - a. The neural substrates for the abnormal eating behavior are posited to include:
 - i. Right ventral insula
 - ii. Striatum
 - iii. Orbitofrontal cortex
 - b. Executive functions of planning, and organization and sequencing deteriorate
 - c. Clinical phenotypes may overlap

Neuropathology

1. The three major subtypes of FTD are:
 - a. FTD-tau
 - b. FTD-TDP
 - c. FTD-FUS
2. Behavioral variant FTD has the most severe atrophy and is associated with corticobasal ganglia degeneration, Pick's disease and TDP pathology

Laboratory Evaluation

1. MRI:
 - a. Frontal lobe and/or temporal lobe atrophy
 - b. Atrophy can be bilateral and asymmetric
2. FDG-PET:
 - a. Frontal and/or anterior temporal hypometabolism (differentiates it from Alzheimer's disease). AD demonstrates biparietal hypometabolism
3. A ventromedial prefrontal cortex distributed loop is primarily affected
 - a. The degeneration initially involves the orbitofrontal cortex and ventromedial cortex and spreads to the dorsolateral cortex and temporal lobe

Neuropsychological Testing

1. The Iowa gambling task:
 - a. Evaluates decision making; the assessment of the values of available choices

- b. Evoked emotion (somatic marker) is associated with outcomes that form experience which biases future decision making during specific behaviors
- c. This behavior is posited to be a function of the orbitofrontal cortex
2. Faux Pas Recognition Test:
 - a. Deficits in self-monitoring (an inability to evaluate one's behavior in specific situations)

Behavioral Variant Frontotemporal Dementia (bvFTD)

1. The deficits of behavior and social interaction include:
 - a. Early onset
 - b. They are out of proportion to the memory deficit
 - c. Loss of personal hygiene and deficient grooming
 - d. Loss of social graces
 - e. Disinhibition
 - f. Impulsivity
 - g. Hyperorality and hyperphagia
 - h. Depression, psychosis and stereotyped behavior
2. Criteria for behavioral variant frontotemporal dementia (bvFTD):
 - a. Disinhibition
 - b. Apathy/inertia
 - c. Loss of sympathy/empathy
 - d. Perseverative/compulsive behavior
 - e. Hyperorality
 - f. Dysexecutive neuropsychological profile
 - g. For a possible diagnosis of bvFTD the patient must present with at least three of the designated features

Semantic Dementia (SD) Variant of FTD

General Characteristics

1. Semantic dementia is associated with loss of semantic memory in both verbal and non-verbal domains
2. Primarily associated with temporal lobe atrophy (L > R)

Clinical Manifestations

1. Presents often with word finding difficulty
2. Fluent aphasia
3. Anomia
4. Inability to comprehend the meaning of words
5. Inability to match semantically related pictures or objects (an associative visual agnosia)
6. Rarely, a selective deficit in reading unusual words that has atypical spelling-to-sound correlations (surface dyslexia)

Neuropathology

1. Most patients have ubiquitin-positive, TDP-43-positive and tau-negative inclusions
2. Rare pathologies seen in SD are AD pathology and tau-positive Pick's disease

Laboratory Evaluation

1. MRI:
 - a. Atrophy of the L > R temporal lobes that includes:

- i. Anterior > posterior topology
 - ii. Inferior > superior involvement
- 2. FDG-PET:
 - a. Alterations (hypometabolism) of the temporal poles and amygdalate
 - i. Decreased metabolism in areas that have been associated with semantic information processing and social cognition
- 3. Neuropsychological testing:
 - a. Patients have severe deficits with semantic knowledge (the meaning of words) as demonstrated by:
 - i. The Warrington Concrete and Abstract Word Synonym Test
 - ii. The Pyramids and Palm Trees task in which patients demonstrate picture naming deficits (semantic errors) and category fluency

Progressive Non-Fluent Aphasia (PNFA) Variant of FTD

General Characteristics

1. Initial language deficit is in the absence of other cognitive abnormalities

Clinical Manifestations

1. The left hemisphere is primarily affected
2. The primary characteristics of the disorder are with speech production that is manifested by:
 - a. Hesitant, stuttering, effortful speech output
 - b. Speech apraxia
 - c. Stuttering
 - d. Anomia
 - e. Sound errors in speech that produce a phonemic paraphasia
 - f. Agrammatism (deficits of syntax, sequence and wrong tense)
3. Over time, speech output progressively decreases to mutism (some patients)
4. Later in the disease:
 - a. Deficits in reading, writing and speech comprehension occur
 - b. Behavioral abnormalities are seen

Neuropathology

1. Presence of misfolded, insoluble and hyperphosphorylated tau proteins in neurons and glia in the frontotemporal distributed network for phonological and syntactical speech processing

Laboratory Evaluation

1. MRI:
 - a. Severe left perisylvian atrophy
2. FDG-PET:
 - a. Decreased metabolism in the frontotemporal distributed networks for speech
3. Neuropsychology:
 - a. Speech evaluation

Major Tau Mutations

Overview

Tau is the major microtubule-associated protein (MAP) of neurons. Its major functions are the assembly and stabilization of microtubules (MTs) that are essential for morphogenesis and axonal transport. Neuronal and glial inclusions of abnormal tau fibrils cause neuronal death, brain atrophy and dementia. The genetic tauopathies with mutations of the tau gene impair the ability of tau to bind microtubules and alter the normal ratio of tau isoforms that causes fibril formation. Tau may also have a role in DNA protection and genome stability. Some mutations cause oligomeric rather than fibrillar aggregates. The primary neuropathological signatures of tauopathies are the deposition of misfolded, insoluble hyperphosphorylated tau proteins.

The primary tauopathies are:

1. FTD (behavioral, SD and PNFA)
2. Progressive supranuclear palsy
3. Corticobasal syndrome (CBS)

The major Mendelian genes linked to FTD are those coding for microtubule-associated protein tau (MAPT), progranulin (GRN) and chromosome 9 open reading frame 72 (C9orf72).

Other uncommon mutations that have been associated with FTD include:

1. Inclusion body myopathy with Paget's disease of bone (UCP gene)
2. Charged multivesicular body protein 2B (CHMP2B gene)
3. Fused in sarcoma (FUS gene)
4. Dynactin (DCTN1)
5. Sequestosome 1 (SQSTM1)
6. Colony-stimulating factor 1 receptor (CSF1R)
7. Triggering receptor expressed in myeloid cells (TREM2)
8. Ubiquilin-2 (UBQLN2)
9. Heterogeneous nuclear ribonucleoprotein (A2B1)

FTD-tau represents approximately 30–40% of FTD patients that are found in MAPT gene mutations as well as in Pick's disease, PSP and corticobasal degeneration. TAR DNA-binding protein 43 (TDP-43) are the inclusions originally identified as ubiquitin-positive and are now identified as FTD-TDP. The majority of FTD with ALS also have TDP-43 inclusions. Approximately 10% of FTD patients that are negative for tau or TDP-43 inclusions have FUS inclusions. Some patients with FUS have immunostaining for TATA-binding protein-associated factor 15 (TAF-15) and Ewing sarcoma protein (EWS).

MAPT Mutations

General Characteristics

1. The MAPT gene maps to chromosome 17; approximately 44 mutations have been identified in the gene to date
2. Alternate splicing of mRNA in exons 2,3 and 10 of the MAPT gene produces 6 isoforms of the protein

3. The exclusion or inclusion of exon 10 produces 3 isoforms with four repeats (4R) or three isoforms with three repeats each (3R). The repeats are in the microtubule-binding domains of the tau protein
4. The 4R repeat produces more microtubule assembly
5. Mutations are missense in exons 9–13 which determines tau effectiveness in microtubule stabilization
6. Intronic and coding mutations modify the splicing of exon 10 at the mRNA level that changes the 3R/4R tau isoform ratio
7. The frequency of MAPT mutations is 0–3% in sporadic patients to 5–20% in familial FTD patients

Clinical Manifestations

1. Mutations produce a heterogeneous clinical phenotype with high penetrance
2. Disease onset is variable between 45–65 years of age with a mean of 55; rarely it may present at age 20–30; its presentation is approximately 10 years earlier than in patients with the progranulin mutation (GRN)
3. The mean disease duration is 9 years (range 5–20 years)
4. Primarily there is a dementia or Parkinsonian phenotype
5. The most common type is bvFTD with loss of inhibition, social behavioral deficits and obsessive-compulsive disorder
6. Patients may later develop Parkinsonism that usually develops concomitantly with the behavioral disorder; a few patients have a primarily Parkinsonian disorder which can be seen with PSP or CBG
7. Parkinsonism is characterized by bradykinesia, postural instability and axial and appendicular rigidity; there is no resting tremor
8. Variable features include:
 - a. Supranuclear gaze palsy
 - b. Upper and lower motor neuron signs
 - c. Dystonia
 - d. Myoclonus
 - e. Postural and action tremor
 - f. Apraxia of eyelid opening and closing
 - g. Dysarthria and dysphagia
9. Patients with the N279K mutation may present with an asymmetric resting tremor and Parkinsonism
10. Language impairment may occur but is not seen at presentation
11. There is no clear correlation between type of mutation and clinical phenotype
12. Rarely there may be memory impairment

Neuropathology

1. Temporal lobe atrophy is the most frequent loss of neural tissue, but may be associated with basal ganglia and brainstem tissue loss
2. MAPT mutations involving exon 10 are associated with medial temporal lobe atrophy while those in the coding region cause lateral temporal lobe atrophy

Laboratory Evaluation

1. MRI:
 - a. Heterogeneous pattern of cortical atrophy with predominant frontal and temporal lobe atrophy
 - b. Atrophy is most prominent in the anterior medial temporal lobes
 - c. Cortical atrophy is most often symmetrical
 - d. Atrophy of the basal ganglia and brainstem is seen particularly in patients with parkinsonism
2. F¹⁸ fluorodeoxyglucose (FDG-PET):
 - a. Hypometabolism of the frontal and temporal lobes
3. Functional connectivity studies reveal:
 - a. Alterations in connectivity of the DMN between the precuneus and the lateral temporal lobe and the medial prefrontal cortex
 - b. Decreased fractional anisotropy (FA) and increased radial diffusivity bilaterally in the uncinate fasciculus
 - c. Decreased FA in the forceps minor

Progranulin (GRN) Mutations

General Characteristics

1. GRN mutations (approximately 70 delineated to date) account for approximately 20% of familial and 5% of sporadic FTD patients
2. Progranulin:
 - a. Is a secreted growth factor expressed in neurons and glial cells
 - b. It has a role in biological processes that include:
 - i. Cellular and tissue development
 - ii. Inflammation
 - iii. Wound healing
 - iv. Cancer
 - v. Neurotrophic properties
 - vi. It is proteolytically processed into peptides (granulins) whose function is largely unknown
 - vii. Mutations cause disease by haploinsufficiency
 - viii. Its expression is modulated by variants in the TMEM106B and by SORT1 gene as well as by microRNAs

Clinical Manifestations

1. Phenotypic expression is highly variable even in families with the same mutation
2. Age at onset varies from 35 to 89 years with an average of 65 years of age. Penetrance is 90% by the age of 70 years
3. The initial presentation is often with the behavioral variant FTD symptomatology primarily apathy and social withdrawal
4. Aphasic disorder similar to PNFA (progressive non-fluent aphasia)
5. 40% of patients have extrapyramidal features
 - a. Limb apraxia
 - b. Asymmetrical parkinsonism
 - c. Dystonia

6. In approximately 25% of patients there are hallucinations
7. In 10–30% of patients there can be a significant memory deficit
8. A subgroup of patients demonstrates dyscalculia, visuospatial deficits and limb apraxia
9. A few patients have had ALS and complete GRN deficiency has been shown to cause neuronal ceroid lipofuscinosis

Neuropathology

1. GRN mutations are associated with FTD-TDP pathology and is also seen in a subgroup of ALS patients and those with FTD-MND (motor neuron disease)

Laboratory Evaluation

1. MRI:
 - a. Asymmetrical atrophy of the hemispheres
 - b. Involvement of the inferior frontal, temporal and inferior parietal lobes
 - c. Involvement of the parietal lobes that is unusual in other FTD
 - d. Long intrahemispheric association white matter pathways are involved
 - e. Carriers may demonstrate deep subcortical gray matter atrophy in the:
 - i. Caudate nucleus
 - ii. Bilateral thalami
 - iii. Rare cerebellar atrophy
2. Annualized rates of whole brain atrophy and ventricular enlargement are greatest in GRN > sporadic FTD > C9orf72 > MAPT
3. SPECT evaluation:
 - a. Hypoperfusion of the hippocampus and the cingulate gyrus

C9orf72 Mutations

General Characteristics

1. The GGGGCC hexanucleotide repeat is located in a non-coding region of the C9orf72 gene that maps to chromosome 9p21
2. The mutation has been posited to cause haploinsufficiency due to loss of gene expression
3. A gain of function mechanism due to secondary RNA toxicity caused by sequestration of RNA-binding proteins has been proposed
4. The number of repeat expansions varies from several hundreds to thousands of copies whereas control subjects have 2–24 repeats. There is no clear evidence of anticipation

Clinical Manifestations

1. The pathogenic hexanucleotide expansion has been described in:
 - a. 37% of familial ALS
 - b. 6% of sporadic ALS
 - c. 21% of familial FTD

- d. 6% of sporadic FTD
2. Age at onset is variable and ranges from 27–83 years (mean of 50 years of age); penetrance is 90% at age 70
3. Disease duration ranges from 1–22 years
4. The most common presentation is FTD then ALS or both
5. Most common subtype of FTD is the behavioral variant with rarer NFPA
6. As has been seen in GRN and MAPT patients, deficits of episodic memory at onset of the illness have been reported as have extrapyramidal and cerebellar dysfunction
7. During the course of the illness the majority of patients develop behavioral, language and motor deficits

Neuropathology

1. TDP-43 immunoreactive inclusions are found in the cerebral cortex, hippocampus, basal ganglia, substantia nigra, and the lower motor neurons of the brainstem and spinal cord
2. There are TDP-43-negative, p62-positive inclusions with characteristic star-like morphology in the cerebellum, hippocampus and frontal cortex
3. The inclusions with p62 have been posited to consist of dipeptide repeat (DPR) proteins that are the result of bidirectional translation of the non-coding GGGGCC expansion repeat by non-ATG-initiated translation (RAN translation). The DPR proteins have been detected in the neocortex, hippocampus, cerebellum and to a lesser degree in motor neurons
4. It has been posited that DPR aggregation due to RAN translation is the pathologic trigger for TDP-43 accumulation

Laboratory Evaluation

1. MRI:
 - a. Symmetrical, bilateral, cortical and subcortical atrophy; the frontotemporal areas are most severely affected
 - b. VBM analysis:
 - i. Atrophy of frontal, insular, temporal, parietal cortex
 - ii. Thalamus and cerebellar atrophy
2. FDG-PET and SPECT imaging:
 - a. Frontal, temporal, parietal and subcortical deficits
 - b. White matter atrophy of long intrahemispheric commissural and corticospinal tracts have been demonstrated with diffusion tractography
 - c. Seed-based intrinsic connectivity demonstrates deficits in the salience and sensorimotor networks; the behavioral symptoms have been shown to correlate with salience and DMN deficits
 - d. Presymptomatic imaging signature may be seen in carriers

VCP Mutations

General Characteristics

1. Missense mutations in the VCP gene that maps to chromosome 19p13.3 cause autosomal dominant inclusion body

- myopathy with Paget's disease of bone and FTD (IBMPD)
- The Valosin-containing protein (also referred to as p97) is an ATPase and is associated with:
 - Protein degradation
 - Membrane fusion
 - Transcriptional activation
 - Apoptosis
 - Molecular chaperoning
 - The frequency of VCP mutations in FTD is approximately 1.6%; approximately 80% of VCP mutation carriers have a positive family history

Clinical Manifestations

- The disorder's onset is approximately age 40
- The presentation is muscle weakness (proximal) in approximately 80% of patients
- Approximately 60% of patients develop adult-onset Paget's disease of bone
- FTD develops later in the course of the disease (55–60 years of age) and affects about 30% of patients
- Rarely there are:
 - Psychiatric disorders
 - Dementia-only phenotype
 - Early language deficits
 - Semantic impairment
 - MND with FTD

Laboratory Evaluation

- MRI:
 - Prominent frontal lobe atrophy
 - Some patients have demonstrated:
 - Asymmetric focal atrophy in the anterior and temporal lobes
- FDG-PET:
 - Glucose hypometabolism of the bilateral frontotemporoparietal regions

TARDBP Mutations

General Characteristics

- TDP-43 is a ribonucleoprotein encoded by the TARDBP gene that maps to chromosome 1
- Putative functions include:
 - Regulation of transcription
 - Messenger RNA splicing
 - Exon skipping
 - MicroRNA biogenesis
- A possible mechanism for its involvement in neurodegenerative disorders is:
 - Its redistribution from the nucleus to the cytoplasm
 - Sequestrations into inclusions that are composed of abnormally phosphorylated and c-terminally truncated TDP-43 fragments
- Mutations in the TARDBP gene occur in 2–3% of ALS patients in both familial and sporadic forms of the disease

Clinical Manifestations

- FTD with MND:
 - Significant motor neuron involvement
 - FTD-MND with extrapyramidal signs
 - FTD with supranuclear palsy
- 16 patients with pure FTD without motor neuron involvement have been reported to date:
 - bvFTD > PNFA with age of onset from 29–77 years

Neuropathology

- TDP-43 inclusions may be seen in GRN, VCP and C9orf72 mutation patients
- Pathologic TDP-43:
 - Is hyperphosphorylated and cleaved and is the major pathogenic protein in ubiquitin-positive, tau and alpha-synuclein-negative FTD (previously called FTL-D-U)
 - It has also been reported (in addition to above described genetic forms of the disease) in:
 - Chronic traumatic encephalopathy
 - Subset of Alzheimer's disease

Neuroimaging

- MRI: Temporal lobe atrophy

CHMP2B Mutations

General Characteristics

- A heterozygous mutation in the CHMPB2 gene (chromatin-modifying protein/charged multivesicular body proteins) that maps to chromosome 8p11.2 was identified in causing FTD in a large Danish kindred. Gene transversions and truncating mutations have also been reported as causative. The Danish kindred had autosomal dominant inheritance
- The encoded proteins are components of ESCRT-III (endosomal sorting complex required for transport III)
- The complex of which CHMP is a component is involved in degradation of surface receptor proteins and the formation of endocytic multivesicular bodies

Clinical Manifestations

- Onset in the Danish kindred is 55 years of age (range of 46–65 years)
- Primarily bvFTD symptomatology
- Associated with:
 - Late onset Parkinsonism
 - Dystonia
 - Myoclonus
 - Pyramidal signs
- Missense mutations have been associated with FTD-ALS

Neuropathology

- Ubiquitin p62-positive, TDP-43/FUS-negative neuronal inclusions (FTLD-U)
- Endosomal pathology has been reported in mutation-positive patient brains

3. Endosomal pathology has been detailed in patient fibroblasts; experimental studies suggest disruption of endosome-lysosome fusion in which the mutant CHMP2B protein constitutively binds to MVB and prevents recruitment of Rab7 that disrupts fusion
4. Specific lower motor neuron variant of ALS with CHMP2B mutation microarray analysis reveals:
 - a. Downregulation of genes involved in axonal transport
 - b. Autophagy induction
 - c. Protein translation
5. One patient with ALS had:
 - a. Intraneuronal inclusions immunopositive for ubiquitin and p62/sequestosome 1 (SQSTM1)-reactive inclusions in oligodendroglia of the motor cortex

Laboratory Evaluation

1. MRI:
 - a. In presymptomatic carriers of the CHMP2B mutation:
 - i. Cortical thinning of the frontal and occipital lobe and the L temporal lobes
 - ii. Increased atrophy rates bilaterally in the inferior temporal cortex, the superior frontal cortex, and the insular cortex
 - b. Structural neuroimaging with CT and MRI:
 - i. Generalized cortical and central atrophy
 - ii. Enlargement of lateral ventricles
 - iii. No white matter changes
2. H₂ O₁₅-PET evaluation of regional cerebral blood flow in symptomatic patients revealed:
 - a. Decreased flow in frontal, parietal and temporal lobes

FUS Mutations

General Characteristics

1. Mutations in the FUS gene that maps to chromosome 16 gives rise to familial ALS and FTD
2. FUS belongs to the FET family of DNA/RNA-binding proteins that bind to overlapping RNA targets
3. It has been posited that the protein is involved with:
 - a. Cell proliferation
 - b. Transcription regulation
 - c. DNA repair
 - d. RNA and microRNA processing

Clinical Manifestations

1. ALS:
 - a. Average age at onset is approximately 44 years of age
 - b. Rarely onset is reported in adolescence
 - c. Approximately 90% of patients die within 3½ years (more rapid demise than with SOD1 or TARDBP)
 - d. Approximately 1/3 of patients have a bulbar onset
 - e. Four mutations in FUS have been associated with FTD. Most mutations are sporadic

Neuropathology

1. In ALS-FUS there is concordant accumulation of other FET proteins into FUS-positive inclusions
2. TAF-15 and EWS proteins are identified in FUS-positive cytoplasmic inclusions in patients with FTD
3. Cell line experiments demonstrate that:
 - a. Wild type FUS is cleaved post-translationally which produces various sized fragments that are localized to the nucleus
 - b. Mutant FUS forms inclusion bodies in the cytoplasm in 5–13% of cells. The proposed pathologic inclusions were similar to stress granules (enclose mRNA and RNA-binding proteins) during various forms of cellular stress. The stress granules have been posited to cause cellular toxicity

Neuroimaging

1. MRI:
 - a. Loss of volume in the anterior temporal lobes, amygdala, anterior hippocampus, anterior insular cortex and anterior cingulate cortex
 - b. Bilateral anterior striatal atrophy severe in the head of the caudate that may differentiate FUS-FTD from FTD-tau and FTD-TDP

TREM2 Mutations

General Characteristics

1. Homozygous loss of function mutations in the TREM2 gene (triggering receptor expressed on myeloid cells 2) that maps to chromosome 6p21 has been associated with an autosomal recessive form of early onset dementia

Clinical Manifestations

1. Bone cysts and fractures (polycystic lipomembranous osteoplasia)
2. Onset in the third decade with pain and swelling of the ankles and wrists; fractures caused by minor trauma
3. By the fourth decade patients develop:
 - a. Memory deficits
 - b. Euphoria
 - c. Loss of social inhibitions
 - d. Impotence
 - e. Increased deep tendon reflexes
 - f. Dysphasia
 - g. Death occurs between ages 35–45
 - h. The late manifestation of the disease resembles Alzheimer's disease
 - i. Variable features in other described kindreds include:
 - i. Myoclonic twitches
 - ii. Seizures
 - iii. Disorder of intestinal motility
 - iv. Leukemia
 - j. Homozygous and compound heterozygous TREM2 (exon 2) mutations have been identified in families that demonstrate:

- i. No bone involvement
- ii. Early age at onset (20–50 years of age)
- iii. Behavioral change
- iv. Extrapyrarnidal features
- v. Hippocampal deficits
- vi. Seizures
- k. TYROBP (also known as DAP12) that maps to chromosome 19q13.12 causes polycystic lipomembranous osteodysplasia with sclerosing leukoencephalopathy (PLOS):
 - i. Most patients have been seen in Finland and Japan
 - ii. These patients have earlier bone fractures than those with TREM2 mutations

Neuropathology

1. Cystic rarefactions in the epiphyses of bones
2. The cysts are noted in phalanges, metacarpals, carpals, metatarsals, patella and the ends of long bones
3. Sclerosis and demyelination of white matter
4. Abnormalities of blood vessels in the brains and bone characterized by thickened and reduplicated basement membranes and abnormal endothelial cells
5. TREM2 interacts with DAP12 in microglia:
 - a. The interaction triggers phagocytosis of amyloid-beta peptide and apoptotic neurons without inflammation
 - b. The mutations in TREM2 interfere with phagocytosis and have been posited to increase the risk of Alzheimer's disease because of failure to clear amyloid-beta peptide

Laboratory Evaluation

1. X-rays that demonstrate cystic rarefaction of the epiphyseal regions of bones
2. Neuroencephalography in the early described patients demonstrated cortical atrophy and dilated ventricles
3. MRI:
 - a. Extensive white matter lesions; frontotemporal atrophy
 - b. An American family of Czechoslovakian ancestry had basal ganglia calcifications
4. Genetic analysis:
 - a. The CQ33X, R47H and the T66M mutations in TREM2 are associated with the disease

Dynactin Mutations

General Characteristics

1. Mutations in the DCTN1 gene that maps to chromosome 2p13.1 have been associated with FTD, motor neuron disease/ALS as well as distal hereditary motor neuropathy type VIIB and Perry syndrome
2. The gene encodes p150 (glued) a large dynactin complex polypeptide that:
 - a. Binds directly to microtubules and cytoplasmic dynein, a motor protein
 - b. Dynactin is required for cytoplasmic-driven movement of organelles along microtubules
 - c. The binding of dynactin to dynein is essential for vesicle motility along microtubules

Clinical Manifestations

1. A few families have demonstrated FTD and MND/ALS
2. Distal hereditary motor neuropathy with vocal cord paralysis
3. Perry syndrome:
 - a. Parkinsonism (occurs early in the course)
 - b. Hypoventilation (occurs late in the course)
 - c. Depression (and apathy)
 - d. Weight loss (late in the course)
 - e. The mean age of onset is 48 years of age and disease duration is approximately 5 years
 - f. Defined DCTN mutations in some families with PSP

Neuropathology

1. Neuronal loss in the substantia nigra (without Lewy bodies)
2. Some neuronal loss is seen in the locus coeruleus, caudate/putamen, hypothalamus, periaqueductal area, dorsal raphe nuclei and the brain stem reticular formation
3. Loss of respiratory neurons in the ventrolateral medullary and dorsal raphe areas
4. Immunohistochemistry:
 - a. Ubiquitin and transactive response DNA-binding protein 43 (TDP-43)-positive neuronal inclusions, dystrophic neurites, glial cytoplasmic inclusions and axonal spheroids. TDP-43 inclusions are predominant in the extrapyramidal system and are similar to those in FTD-4 and ALS

Laboratory Evaluation

1. Structural MRI:
 - a. Most often normal
2. FDG-PET:
 - a. Reduced metabolic rate in lateral prefrontal temporal areas
3. Dopaminergic pathway functional imaging (18-fluodopa (FDG-PET))
 - a. Reduced striatal uptake
4. 4 patients in one Japanese family:
 - a. Decreased cardiac uptake of I-metaiodobenzylguanidine scintigram

Frontotemporal Lobe Variants

Logopenic Progressive Aphasia (LPA)

General Characteristics

1. A language variant of Alzheimer's disease overlaps with LPA
2. There is controversy in regard to the entity as some clinicians feel that LPA and posterior cortical atrophy are clinical presentation of sporadic early onset Alzheimer's disease

Clinical Manifestations

1. A progressive non-fluent aphasia that is characterized by:

- a. Slow rate of speech
- b. Difficulty with word retrieval
- c. Impaired repetition
- d. Poor auditory short-term memory
- e. Maintained single word comprehension and semantic associations
- f. Differential points that distinguish the disorder:
 - i. Slow output of words; much faster in semantic dementia
 - ii. No agrammatism and articulation difficulties that are seen in PNFA
- g. ApoE4 is not a risk factor for LPA or posterior cortical atrophy that distinguish them from Alzheimer's disease

Neuropathology

1. Brain atrophy is more posterior than that of semantic dementia and Alzheimer's disease
2. White matter abnormalities are most severe in the tempoparietal areas of the dorsal language network

Laboratory Evaluation

1. MRI:
 - a. Atrophy of the left posterior, superior and temporal regions
 - b. Atrophy of the inferior parietal lobe
 - c. Hypoperfusion of the structurally affected areas

Corticobasal Ganglia Degeneration

General Characteristics

1. The prevalence of CBGD is 4.9 to 7.3 patients per 100,000 people
2. Slight predominance of women

Clinical Manifestations

1. Onset is usually between 50–70 years of age; may be sudden
2. Average disease duration is 6 years
3. Symptoms and signs are typically asymmetric
4. Parkinsonism:
 - a. Usually present in one extremity and is always asymmetric; the non-dominant arm may be more frequently affected
5. Rigidity, bradykinesia, shuffling gait
6. Alien hand syndrome:
 - a. Affects approximately 60% of patients
 - b. The alien hand is most often of the posterior variety in which the arm and hand move sinuously. The arm may be elevated and appears to act on its own. It may follow the physician's hand (seen in other dementia as well). Rarely patients complain of sensory symptoms in the hand
7. Apraxia:
 - a. The inability to repeat or mimic a particular movement with or without objects. If the apraxia occurs in the lower extremity, it may impair walking

- b. Limb kinetic apraxia may impair fine movements of the hand and fingers
8. Aphasia:
 - a. The aphasia is of the non-fluent, progressive type
 9. Psychiatric disorders may have bvFTD characteristics along with depression and instability
 10. Cortical parietal sensory loss (almost always asymmetric)
 11. Rare myoclonus and dystonia

Neuropathology

1. Astroglial inclusions that may appear as astrocytic plaques (blurred margins from the astrocyte) primarily
2. Encountered in the anterior frontal and premotor areas
3. Abnormal accumulation in astrocytes and glial cells of tau protein (a tauopathy)
4. Ballooning of neurons
5. Diagnosis can only be secured at post-mortem

Laboratory Evaluation

1. MRI:
 - a. Posterior parietal and frontal cortical atrophy that is asymmetrical
 - b. Corpus callosum atrophy
2. fMRI:
 - a. Reduced connectivity of the parietal cortex, sensorimotor and supplementary motor cortex
3. SPECT evaluation:
 - a. Hypoperfusion of the posterior frontal and parietal lobes
 - b. Variable perfusion deficits have been noted in the thalamus, temporal cortex, basal ganglia and frontocerebellar connections
4. Imaging of the dopamine system with PET:
 - a. Diminished dopamine uptake in the caudate and putamen

Differential Diagnosis

1. PSP
2. Parkinson's disease
3. Alzheimer's disease
4. Lewy body dementia
5. FTD

Frontotemporal Dementia with PSP

General Characteristics

1. The prevalence of PSP is approximately 4–6 per 100,000 people; it is the second most common form of parkinsonism after PD
2. Men and women are affected equally
3. The progression is insidious with a mean survival time of 5.6 years

Clinical Manifestations

1. Onset is most often in the seventh decade of life

2. The early symptom in approximately 2/3 of patients is loss of balance with frequent falls
3. Supranuclear gaze palsy:
 - a. Patients often complain early of inability to read because they can't look down
 - b. Downward saccades may be worse than upward saccades
 - c. The supranuclear palsy can be easily overcome by vestibular input (oculocephalic maneuvers)
 - d. "Square wave jerks" are seen when a patient fixes at a distance (saccadic in appearance with no smooth phase)
 - e. Difficulty with convergence that may cause diplopia with down gaze
4. Bradykinesia
5. Axial dystonia and rigidity
6. Pseudobulbar palsy
7. Postural instability with characteristic falling backwards
8. Apathy and emotional blunting
9. Slow mental processing
10. Reduced verbal fluency
11. Neck dystonia (the head is held in extension; in other akinetic rigid parkinsonian syndromes the head is flexed)
12. Deep nasolabial folds
13. PSP has been categorized into 3 subtypes:
 - a. Richardson syndrome
 - b. PSP-parkinsonism
 - c. PSP-pure akinesia with gait freezing
14. Cognitive deficits and cortical atrophy are most severe in the Richardson subtype (clinical PSP)

Neuropathology

1. Most PSP is sporadic; less than 1% of PSP patients have an affected family member
2. A variant of the gene for tau, the H1 haplotype located on chromosome 17 has been delineated in several families
3. PSP patients have:
 - a. Abnormal neuronal and glial neurofibrillary tangles and neuropil threads that are:
 - i. Composed of hyperphosphorylated microtubule-associated protein tau primarily in the 4 repeat isoforms
 - ii. Tufted astrocytes
 - iii. Oligodendroglial coiled bodies
 - iv. Swollen "ballooned" neurons primarily in paralimbic areas but not as dense in number as seen in CBG degeneration
 - v. Neurotransmitter deficits occur in the dopaminergic, cholinergic, GABA-ergic and serotonergic systems
 - vi. Mitochondrial dysfunction may occur, leading to oxidative stress that promotes the formation of tau filaments

Laboratory Evaluation

1. MRI:
 - a. Atrophy of premotor and supplementary motor areas
 - b. Sparing of the inferior frontal lobe
2. PET imaging:
 - a. Several new selective in-vivo PET imaging ligands have been developed which include
 - i. [18F]THK523, [18F]Thk5117, [18F]THK5105, and [18F]THK5351
 - ii. [18F]AV1451(T807) and [11C]PBB3 are being intensely evaluated in regard to the rate of tau formation in neurodegenerative diseases

Frontotemporal Dementia and Parkinsonism Linked to Chromosome 17 (FTDP-17)

General Characteristics

1. Over the last several decades dominant forms of FTD were delineated whose major features are:
 - a. CBG-like
 - b. PSP-like
 - c. Associated with amyotrophy in some patients
2. The different delineations of these disorders were defined as:
 - a. Familial Pick's disease
 - b. Disinhibition dementia parkinsonian complex
 - c. Familial progressive subcortical gliosis
 - d. Familial presenile dementia with tangles
 - e. Autosomal dominant parkinsonism
 - f. Dementia with pallidopontonigral degeneration
 - g. Multiple system tauopathy with presenile dementia
 - h. FTD-17 is divided into:
 - i. Dementia-dominant
 - ii. Parkinsonian type
3. The majority of FTD-17 patients have mutations in the tau gene that occur within the microtubule binding domain. Most known mutations in non-coding regions affect the splicing of exon10 which alters the proportion of tau isoforms (ratio of 3 to 4 repeats) or to the ability of tau to bind to microtubules
4. There are FTDP-17 kindreds in which there are no tau mutations or pathology. Their phenotype is similar to that of patients with tau mutations. The genetic linkage is to the same region of chromosome 17q21 that contains the tau gene. This suggests that there are mutations in intronic sequences, regulatory regions of tau or other causative genes that have not been delineated

Clinical Manifestations

1. Onset is usually insidious
2. Behavioral and personality disorders that include:
 - a. Disinhibition
 - b. Apathy
 - c. Compulsive behavior
 - d. Drug addiction
 - e. Aggressiveness

3. Cognitive deficits:
 - a. Progressive speech difficulty primarily manifest as non-fluent or aphasia
 - b. Disorder of executive function
 - c. Over time patients develop loss of memory, orientation and visuospatial abilities as well as echolalia, palilalia and vocal and verbal perseveration
 - d. Dementia and mutism are apparent in end stage disease
4. Motor signs and symptoms:
 - a. Parkinsonism can be the first manifestation of the disease, although in some kindreds it occurs late in the disease. It is manifested by:
 - i. Symmetry
 - ii. Bradykinesia
 - iii. Postural instability
 - iv. Rigidity of axial and appendicular musculature
 - v. Usually no resting tremor
5. Poor or no response to levodopa
6. Variable features include:
 - a. Dystonia
 - b. Supranuclear gaze palsy
 - c. Myoclonus
 - d. Postural and action tremor
 - e. Eyelid opening and closing apraxia (frontal lobe involvement)
 - f. Dysphagia and dysarthria
 - g. Upper and lower motor neuron signs
7. Dementia predominant phenotype:
 - a. Is the more common phenotype
 - b. Seen in families with mutations in exon 1, 9, 11, 12, 13 and 10
8. The Parkinson-Plus predominant phenotype:
 - a. Manifests in families with intronic and exonic mutations in exon 10 that causes overproduction of 4R tau isoform

Neuropathology

1. Aggregation of recombinant tau in the presence of polyanions from the pool that is unbound to microtubules
2. The disruption of alternative splicing of exon 10 biases the tau ratio in the form of 4R:3R repeat sequences
3. In families without tau mutations:
 - a. Ubiquitin-positive, tau-negative intranuclear neuronal inclusions are seen in layer II of the cerebral cortex and the dentate gyrus of the hippocampus

Laboratory Evaluation

1. CT and MRI:
 - a. Dilation of the ventricular system
 - b. Frontal, temporal and parietal cortical atrophy
 - c. MRI T2-weighted sequences may demonstrate iron in mesencephalic nuclei
 - d. Some kindreds have asymmetrical cortical atrophy
2. SPECT:
 - a. Perfusion abnormalities in affected areas

3. I¹⁸ FDG-PET:
 - a. Reduced frontal-parietal-temporal uptake patterns
4. [¹⁸F]-fluoro-L-dopa (6FD) and [¹¹C]-raclopride tracer demonstrate greater caudate involvement than in the putamen which distinguishes it from idiopathic PD
5. EEG:
 - a. Diffuse slowing as the disease progresses
 - i. Patients with the P3015 mutation have sharp waves, spikes and epileptic discharges
6. EMG:
 - a. Electromyography may demonstrate neurogenic changes; nerve conduction velocities are normal

Differential Diagnosis of FTDP-17

1. Pick's disease
2. PSP
3. Corticobasal syndrome
4. Parkinson-plus syndrome
5. Dementia with Lewy bodies (DLB)
6. Parkinson's disease
7. MSA-P

Disinhibition-Dementia-Parkinsonian Amyotrophy Complex (DDPAC)

General Characteristics

1. AD; chromosome 17q21

Clinical Manifestations

1. Mean age at onset is 45 years
2. Disinhibition
3. Features of Klüver-Bucy syndrome
4. Schizophrenic behavior
5. Social withdrawal
6. Initial preservation of orientation, processing speed and ability to calculate
7. Hyperphagia
8. Later in the course of the disorder:
 - a. Perseveration
 - b. Constructional apraxia
 - c. Decreased speech output
 - d. Inability to calculate
 - e. Parkinsonism
 - f. Fasciculations and muscle wasting

Neuropathology

1. Anatomic areas of involvement:
 - a. Anterior temporal lobes
 - b. Entorhinal and cingulate cortex
 - c. Amygdala
 - d. Piriform cortex
2. Histopathology:
 - a. Circumscribed laminar spongiosis:
 - i. Limbic areas
 - ii. Association cortices
 - b. Neural intracytoplasmic inclusions

- i. Phosphorylated neurofilament lattice-like formations with ubiquitin
- ii. Located in the brainstem nuclei, hypothalamus, and basal ganglia
- iii. Negative for amyloid
- iv. Oligodendroglial cytoplasmic inclusions similar to those seen with multiple system atrophy

Neuroimaging

1. MRI:
 - a. Ventricular enlargement
 - b. Atrophy of the anterior temporal lobes, cingulate gyrus, and amygdala

Pallidopontonigral Degeneration (PPND)

General Characteristics

1. Missense mutations in exon 10 of the tau gene that maps to chromosome 17
2. Encodes a tau isoform with 4R repeats

Clinical Manifestations

1. Stage I (begins >30 years):
 - a. Mild dementia and parkinsonism
2. Stage II:
 - a. Moderate parkinsonism
 - b. Dementia
 - c. Dysarthria
 - d. Pyramidal tract signs
 - e. Extraocular muscle involvement
 - f. Sensory defects
3. Stage III:
 - a. Severe parkinsonism
 - b. Dementia
 - c. Dysphagia
4. Stage IV:
 - a. Terminal manifestations
 - b. Perseverative vocalizations
 - c. Frontal lobe release signs
 - d. Exceptionally progressive course
 - e. Symptom onset and death occur in the fifth decade

Neuropathology

1. Neuronal and glial tau inclusions
2. Hyperphosphorylated tau
3. Severe neuronal loss with gliosis in the substantia nigra, pontine tegmentum, and globus pallidus with less involvement of the caudate and putamen nuclei
4. Absent plaques, tangles and Lewy bodies

Laboratory Evaluation

1. [¹⁸F] 6-fluoro-L-dopa (6FD) positron emission tomographic studies reveal:
 - a. Markedly decreased striatal uptake of 6FD
 - b. Severe presynaptic dopaminergic dysfunction with intact striatal D2 receptors (RAC and 6FD scans)

Familial Progressive Subcortical Gliosis (FPSG)

General Characteristics

1. Autosomal dominant Parkinsonism that maps to chromosome 17

Clinical Manifestations

1. Onset in the presenium
2. Slowly progressive course
3. Early clinical features:
 - a. Personality change
 - b. Depression
 - c. Disinhibition
 - d. Degeneration of social graces
 - e. Memory impairment
 - f. Psychotic symptoms
4. Late clinical manifestations:
 - a. Progressive dementia
 - b. Verbal stereotypies
 - c. Decreased speech production
 - d. Features of Klüver–Bucy syndrome
5. Terminal clinical manifestations:
 - a. Profound dementia
 - b. Mutism
 - c. Dysphagia
 - d. Extrapyramidal signs

Neuropathology

1. Tau mutations:
 - a. Overexpression of the soluble form repeat tau isoform
 - b. Neuronal and glial tau accumulation
2. Generalized cerebral atrophy:
 - a. The frontal and temporal lobes are the most severely affected
 - b. Fibrillary astrocytosis of the subcortical white matter
 - c. Subpial and deep layers of the frontal and temporal lobes are affected most prominently
 - d. Laminar spongiosis in lamina II and III
 - e. Axonal spheroids with the 5q32 mutations

Laboratory Evaluation

1. There is a radiologic phenotypic spectrum as many patients reported do not have mutations in the MAPT gene
2. MRI:
 - a. Ventriculomegaly
 - b. Frontotemporal cortical atrophy
3. Patients with hereditary diffuse leukoencephalopathy with spheroids (HDLS) is caused by heterozygous mutation in the CSF1R gene on chromosome 5q32:
 - a. Localized white matter involvement of deep, subcortical and periventricular areas
 - b. Bilateral asymmetric lesions
 - c. Most prominent in frontal and parietal areas
 - d. Cortical atrophy
 - e. Involvement of the corpus callosum
 - f. Corticospinal tracts are involved late in the course of the illness
 - g. Minimal gray matter involvement

Hereditary Dysphasic Disinhibition Dementia (HDDD)**General Characteristics**

1. Autosomal dominant inheritance
2. Maps to chromosome 17q21-22

Clinical Manifestations

1. Global dementia
2. Disproportionate dysphasia
3. Behavioral frontotemporal symptoms

Neuropathology

1. Neuronal loss in layer II of the cortex
2. Cortical astrocytosis
3. Status spongiosus
4. Asymmetric atrophy of frontotemporal areas (left side)

Neuroimaging

1. MRI:
 - a. Left-sided > than right atrophy of frontotemporal areas

Progressive Language Disorder Due to Lobar Atrophy of FTD

The language variant of FTD becomes apparent when there is a gradual deterioration of speech and semantic abilities while other cognitive domains are relatively intact. FTD-related primary progressive aphasia (PPA) is divided into a non-fluent and agrammatic form (nfvPPA) and a semantic variant (svPPA). In nfvPPA there is progressive atrophy of the left inferior frontal regions and opercular and insular cortex. In svPPA there is bilateral atrophy of the anterior temporal lobes that is more severe on the left side.

The logopenic variant of PPA demonstrates atrophy that extends from frontotemporal areas into the parietal lobe and has Alzheimer's disease pathology. However, approximately 1/3 of patients with lvPPA have both clinical and pathologic characteristics of FTD.

There are many complicating features in determining phenotype and pathology in FTD patients with language disturbance.

These include:

1. The clinical phenotype changes as the disorder evolves
2. There are mixed clinical features at presentation; a common example being patients with PPA and bvFTD symptomatology
3. FTD syndromes overlap with:
 - a. Motor neuron disease
 - b. Corticobasal ganglia degeneration
 - c. PSP
4. Patients with nfvPPA demonstrate the extrapyramidal features of CBD and PSP within the first two years of language impairment
5. In general, lobar PPA is most often associated with FTD-tau, while nfvPPA is related to FTD-ubiquitinated (FTD-U) as is bvFTD

Non-Fluent/Agrammatic Variant of PPA**Clinical Manifestations**

1. The earliest disability is anomia and word finding
2. Early fluent speech evolves to effortful speech production due to articulatory deficits
3. Early difficulty with sentence construction and syntax
4. Agrammatic speech due to a shortage of verbs associated with phonological mistakes
5. Failure of subject-verb concordance
6. Apraxia of speech with motor planning and sequencing deficits that lead to:
 - a. Stuttering
 - b. Inability to repeat strings of syllables
 - c. Abnormal prosody, slow rate of speech production and decreased complexity of speech
 - d. As the disease progresses:
 - i. Difficulty with writing is greater than reading deficits that are primarily phonetic
 - ii. Patients have maintained comprehension but agrammatism interferes with comprehension of complex syntactic sentences and sequential commands

The Semantic Variant of PPA

1. The most homogeneous of the PPAs
2. There is progressive loss of semantic knowledge, the meaning of words, particularly in the comprehension of single words and naming
3. Patients utilize circumlocutions, overuse pronouns, verbs and high frequency nouns
4. Patients are able to repeat multisyllabic words
5. As the disease progresses patients demonstrate:
 - a. Disinhibited speech output
 - b. Stereotypic thematic perseverations
 - c. Inability to listen
 - d. Due to severe lexical-semantic impairment, patients become mute
 - e. As opposed to Alzheimer's disease, in svPPA patients do not benefit from cuing because there is no knowledge of the word's meaning rather than an inability to access it

Logopenic Variant of PPA**Clinical Manifestations**

1. Initially it is characterized by slow speech, difficulty with word finding and phonemic paraphasias
2. There is no agrammatism, articulatory difficulty or expressive aprosodia
3. Patients do not utilize telegraphic speech with missing function words and morphemes
4. Confrontation naming is only moderately affected
5. Single word comprehension is preserved but patients are impaired in repeating or comprehending sentences and long phrases

6. A phonological short-term memory deficit has been posited as the underlying deficit of lvPPA
7. Patients with lvPPA may have concomitant episodic memory deficit and acalculia

Pick's Disease

General Characteristics

1. Autosomal dominant inheritance in some patients
2. Mutations in the tau gene (MAPT) that maps to chromosome 17q21-22

Clinical Manifestations

1. Early personality changes
2. Deterioration of social skills
3. Early non-fluent aphasia:
 - a. Echolalia
 - b. Isolated word-finding difficulty
 - c. Relative sparing of auditory comprehension
4. Disinhibition, euphoria, and apathy at onset
5. Klüver-Bucy symptomatology in some patients
6. Variable signs of cortical dementia:
 - a. Aphasia (non-fluent)
 - b. Apraxia of speech:
 - i. Articulatory difficulty without language breakdown
 - ii. Lesion of the left pars operculum rather than pars triangularis
 - iii. Buccofacial apraxia and dysarthria
7. Absence of ideomotor apraxia
8. Absence of gait abnormalities at onset
9. Memory is usually preserved

Neuropathology

1. Pick bodies and Pick cells stain with anti-tau and anti-ubiquitin antibodies
2. In atypical Pick's disease these cells are absent
3. Pick bodies are located in the dentate gyrus, the pyramidal cells of the CA1 area and the subiculum of the hippocampus
4. The neocortex in layers II and IV; layers III and V demonstrate severe neuronal loss but have few Pick bodies
5. The caudate, putamen, globus pallidus and locus coeruleus and the lateral tuberal nucleus of the hypothalamus may be severely involved
6. The dentate nucleus is often involved but the substantia nigra is usually spared
7. Pick bodies usually demonstrate the 3R isoform of tau that are shaped with a round body that includes an indentation in the region that faces the nucleus
8. Pick bodies have a variety of other proteins that include the N-terminal of amyloid precursor protein, ubiquitin, Alz-50, neurofilament proteins, clathrin, synaptophysin and neuronal surface glycoside (A2B5)
9. Ballooned neurons

Neuroimaging

1. MRI:

- a. Frontal and temporal lobe atrophy often more severe on the left side
- b. Decreased volume of the caudate head

Frontal Lobe Dementia with Motor Neuron Disease

General Characteristics

1. Approximately 5% of patients with ALS inherit the illness
2. Some kindreds have members with ALS, FTD, and ALS-FTD
3. Genetic mutations causing FTD-ALS include:
 - a. The GGGGCC hexanucleotide repeat in C9orf72:
 - i. <23 repeats correspond with the wild-type allele; >30 repeats express the disease
 - ii. This expansion is seen in 12% of familial FTD and 22.5% of FALS
 - iii. European populations demonstrate a prevalence rate of 46% in familial ALS, 21% in sporadic ALS and 29% in familial FTD
 - b. Mutations in the TARDBP gene that maps to chromosome 1p36.22
 - c. Mutations in UBQLN2 have recently been shown to cause X-linked dominantly inherited ALS/FTD
 - d. DDPAC is linked to a tau gene mutation (MAPT) on chromosome 17q21

Clinical Manifestations

1. C9orf72:
 - a. Patients differ from typical FTD patients due to psychiatric symptoms that include:
 - i. Delusions, paranoia and irrational thoughts

Neuropathology (C9orf72)

1. TDP-43 inclusions
2. p62 positive cytoplasmic inclusions are found in the hippocampus and cerebellum
3. TDP-43 inclusions vary depending upon clinical phenotype:
 - a. Patients with pure ALS have TDP-43 inclusions primarily in the spinal cord
 - b. In those with pure FTD the pathology is in the cortex
 - c. Those with FTD/ALS have pathology in both the cortex and the spinal cord
 - d. TDP pathology may also be found in the cerebellum, parietal and occipital lobes
 - e. TDP-43 levels are higher in the CSF in patients with ALS or FTD than in controls
4. MND and parkinsonism the DDPAC variant:
 - a. Tau inclusions
5. UBQLN2 gene mutation (X-linked dominant ALS/FTD):
 - a. The pathology is ubiquitin-2 protein inclusions in the brain and spinal cord due to impaired degradation of ubiquitinated proteins
6. SOD-1 mutations cause approximately 20% of familial ALS:
 - a. Ubiquitin positive inclusions are found in the brain and spinal cord that are not TDP-43 positive

Clinical Manifestations

1. Characteristic upper and lower motor neuron manifestations
2. Onset of symptoms is between 50–60 years of age
3. Slightly more common in men than women
4. The motor neuron signs and symptoms may precede, occur concomitantly or follow the cortical features of FTD. Most often, cognitive deficits precede motor manifestations
5. The interval between cognitive changes and motor signs may be months to several years (mean of 2 years)
6. Bulbar onset may be more frequent than in ALS
7. A subset of patients has greater upper extremity involvement than lower
8. Behavioral changes are primarily in personality that is manifested by euphoria, indifference or apathy
9. Language deficits have components of non-fluent and semantic aphasia
10. Disease progression and death occur earlier than with ALS or FTD alone

Laboratory Evaluation

1. EEG may be normal or demonstrate background or focal slowing
2. Voxel-based MRI morphometry:
 - a. Atrophy in frontotemporal regions
3. SPECT:
 - a. Reduced uptake in the frontal lobes

Differential Diagnosis of the Tauopathies

1. FTD-17 Parkinsonism
2. Variants of FTD-17:
 - a. DDPAC (dementia depression disinhibition amyotrophy complex)
 - b. PPND (pedunculopallidal pontine nigral degeneration)
 - c. FSCG (familial subcortical gliosis)
 - d. HDDD (hereditary dysphasic disinhibition dementia)
 - e. FTDP-17 (missense mutations):
 - i. Splicing variants in exon 9, 10, 12
 - ii. 3 intronic mutations (regulate the alternative splicing of exon 10)
 - f. Primary progressive aphasia:
 - i. Semantic variant
 - ii. Non-fluent variant
 - iii. Logopenic variant
3. CBGD (corticobasal ganglionic variant)
4. PSP
5. Parkinson's disease ALS dementia complex of Guam
6. Head trauma

Post-Encephalitic Parkinsonism*General Characteristics*

1. Post-encephalitic parkinsonism or encephalitis lethargica appeared suddenly in 1916–1917 and continued to 1926.

Approximately one half a million patients were infected throughout the world. Approximately 1/3 patients died, 1/3 developed post-encephalitic disease and 1/3 completely recovered

2. Sporadic patients continue to be seen but it is not clear if these patients share the same etiology as those of the original pandemic
3. Recent studies support the hypothesis that encephalitis lethargica (EL) is an autoimmune disorder based on:
 - a. The clinical presentation
 - b. Intrathecal oligoclonal bands
 - c. Antibodies against basal ganglia antigens
 - d. There is indirect evidence that the disorder may be due to a specific enterovirus

Clinical Manifestations

1. The acute stage:
 - a. Somnolent or manic behavior
 - b. Mask-like facies
 - c. Rigidity
 - d. Tremor (not the pill-rolling type of classic Parkinson's disease)
 - e. Rarely, post-encephalitic Parkinsonism (PEP) developed without the acute stage
2. Chronic stage:
 - a. Akinetic rigidity
 - b. Oculogyric crisis
 - c. Ophthalmoplegia
 - d. Autonomic crises:
 - i. Blood pressure fluctuations
 - ii. Hyperhydrosis
 - iii. Pupillary dilatation
 - e. Central respiratory irregularities
 - f. Prolonged somnolence

Neuropathology

1. Possible enterovirus etiology; the autoimmune features described being secondary
2. Small virus particles have been identified in the cytoplasm and nucleus of neurons from classical and modern cases of EL. They have also been described in one patient with PEP
3. Severe neuronal loss and gliosis in brainstem nuclei, particularly the substantia nigra
4. Tau-positive neurofibrillary tangles: absent alpha-synuclein and TDP-43 inclusions

Laboratory Evaluation

1. CSF leukocytosis
2. Anti-BG antibodies
3. MRI:
 - a. Structural abnormalities of the cortex and basal ganglia
 - b. ¹⁸F-FDG PET:
 - i. Basal ganglia hypermetabolism

FTD*Clinical Manifestations*

1. bvFTD (behavior variant)
2. avPPA (the agrammatic variant)
3. svPPA (the semantic variant)
4. Genetic causes of FTD:
 - a. MAPT mutations:
 - i. GRN (progranulin)
 - ii. C9orf72
 - iii. VCP (valosin-containing protein)
 - iv. TARDBP (transactive response DNA-binding protein-43)
 - v. CHMP2B (charged, multivesicular body protein 2B)
 - vi. FUS
 - vii. DCTN1
 - viii. TREM2
5. Variant FTD:
 - a. DDPAC
 - b. PPND
 - c. FSCG
 - d. HDDD

Niemann-Pick Disease Type C*General Characteristics*

1. Niemann-Pick type C is caused by mutations in the NPC1 gene (95% of patients) and mutations in the NPC2 genes. The former is type C1 and the latter C2. The NPC1 gene maps to chromosome 18q11-q12
2. Niemann-Pick types C1 and C2 have a similar phenotype whose functions encompass the egress of lipids primarily cholesterol from late endosomes or lysosomes
3. The protein encoded by NPC1 is found in membranes within cells and moves cholesterol and lipids intracellularly. The protein functions as a transporter; the protein encoded by NPC2 concomitantly functions with NPC1 in cellular transport of unesterified cholesterol and glycosphingolipids

Clinical Manifestations

1. The clinical phenotype has a wide spectrum that includes:
 - a. Juvenile or adult patients who primarily present with neurologic or psychiatric signs and symptoms
 - b. Cerebellar ataxia (76%)
 - c. Vertical supranuclear ophthalmoplegia (75%)
 - d. Movement disorder (58%)
 - e. Cognitive deficits (61%)
 - f. Affective and psychiatric disorder (45%)
 - g. Splenomegaly occurs in 45% of adult patients
 - h. Variable symptoms and signs include:
 - i. Sleep inversion
 - ii. Partial or generalized seizures
 - iii. Gelastic epilepsy
 - iv. Progressive dementia

- v. Psychosis
- vi. Dystonia
- vii. Spasticity

Neuropathology

1. Accumulation of free or unesterified cholesterol in lysosomes that leads to deficiencies of cholesterol in neuronal membranes and for steroid synthesis
2. Tau-positive tangles and neuropil threads are detected in the midbrain and cerebral cortex

Laboratory Evaluation

1. Filipin test:
 - a. The demonstration of lysosomal cholesterol storage in cultured fibroblasts
2. Genetic analysis
3. MRI:
 - a. Periventricular white matter signal hyperintensities
 - b. Cortical atrophy
 - c. Mild cerebellar atrophy

Parkinson Dementia Complex of Guam (PDC)*General Characteristics*

1. The highest prevalence is in Guam, New Guinea and the Kii Peninsula of Japan:
 - a. Recently the incidence and prevalence rates have dramatically declined
2. There is evidence that mutation in the TRPM7 gene that maps to chromosome 15q21/2 may be causative:
 - a. It encodes a member of the transient receptor potential cation channel family:
 - i. PARK7 – a similar phenotype is caused by a double homozygous mutation in the DJI gene

Clinical Manifestations

1. A linear retinal pigment epitheliopathy is present in 50% of patients with ALS/PDC but in only 15% of asymptomatic Chamorro individuals. The retinopathy is also described in patients from the Kii peninsula of Japan
2. The Muro district of the southern coast of Japan is endemic for Kii ALS/PDC, also known as Muro disease
3. Parkinsonism-dementia complex:
 - a. Progressive parkinsonism
 - b. Dementia
 - c. Levodopa-unresponsive
4. The core neuropsychological features of patients with ALS/PDC from the Kii peninsula include:
 - a. Abulia
 - b. Apathy
 - c. Bradyphrenia
 - d. Hallucinations
 - e. Amnesia
5. Lytico (ALS) in patients from Guam and the Western Pacific Islands:

- a. Patient to patient variability
- b. Severe muscle atrophy
- c. Bulbar involvement
- d. Diaphragm and respiratory muscle involvement
- 6. Dementia (Chamorro patients) is progressive:
 - a. Severe emotional lability:
 - i. Mania
 - ii. Aggressive outbursts
 - b. A few patients are not cognitively compromised throughout their illness
- 7. Late in the course of the illness, they develop an akinetic-rigid state. Some patients have tremor; some patients are unable to close their mouths

Neuropathology

- 1. It is a complex and genetically heterogeneous disorder:
 - a. Muro disease (Kii peninsula) has four subtypes that include:
 - i. Sporadic ALS
 - ii. ALS/PDC with tauopathy
 - iii. ALS with C9 or 67y gene mutations
 - iv. ALS with optineurin genetic mutations
 - b. Neurofibrillary tangles (NFT) in the brain and loss of anterior horn neurons and corticospinal tract destruction in the spinal cord
 - c. NFTs in the temporal, frontal lobe and brainstem
 - d. Tau protein consisted of 3R and 4R isoforms

Laboratory Evaluation

- 1. Kii ALS/PDC patients:
 - a. SPECT:
 - i. Decreased blood flow of the frontal and temporal lobes
 - b. CT/MRI:
 - i. Atrophy of the frontal and temporal lobes

The Differential Diagnosis of Tauopathies with Parkinsonism

- 1. PSP
- 2. Corticobasal degeneration
- 3. Frontotemporal dementia and variants
- 4. Pick's disease
- 5. Niemann-Pick disease type C
- 6. Post-encephalitic Parkinsonism
- 7. ALS/PDC of Guam
- 8. FTD-17 (variants):
 - a. DDPAC
 - b. PPND
 - c. FSCG
 - d. HDDD
- 9. Generic MAPT (tau) mutations:
 - a. GRN
 - b. C9orf72
 - c. TARDP
 - d. UCP
 - e. FUS

- f. DCTN1
- g. CHMPB2
- h. TREM2
- 10. Mutations in the LRRK2 gene
- 11. Chronic traumatic encephalopathy

Prion Disease

Overview

A prion is an infectious protein that is the cause of the transmissible spongiform encephalopathies. It is a protein that is able to fold in structurally distinct forms and one of which is transmissible to other prion proteins. Thus, prions are able to self-propagate and transmit their conformation to other prions. Prions are misfolded protein molecules that induce normally folded proteins into a misfolded prion form. They contain no DNA or RNA. All prion diseases in humans affect the brain and neural structures. In its most general form, a prion protein is a template that shapes the misfolding of proteins into a prion form. Prions cause amyloid to fold in which its target protein polymerizes into aggregates of tightly packed beta-sheets. These amyloid aggregates are composed of fibrils that extend at their ends that replicate by breakage, the newly formed ends initiating growth.

The incubation of a prion disease depends on the exponential growth rate associated with its replication that is dependent on its linear growth and the breakage of aggregates. Prion propagation requires normally folded proteins for misfolding and propagation. Prion aggregates are very stable and are resistant to denaturation by chemical and physical agents. The normal form of prion protein is denoted as PrP^c. The "c" refers to cellular PrP. The infectious form is termed PrP^{sc}, the "Sc" denotes "scrapie" that is the prototypic prion disease discovered in sheep. PrP^c is a normal protein found on cell membranes. Its structure includes:

- 1. 209 amino acids
 - 2. One disulfide bond
 - 3. An alpha-helical structure
 - 4. There are several topological forms
 - 5. The protein cannot be separated by centrifugation
- Prion function is complex and not completely defined. It has been found to:
- 1. Bind copper (11) ions
 - 2. It is digested by proteinase K
 - 3. Possible role in long term memory
 - 4. Hippocampal LTP
 - 5. Can be cleaned from the cell surface by phosphoinositide phospholipase (PI-PLC) that disrupts the glycol phosphatidyl inositol (GPI) anchor
 - 6. Posited to be a component of cell-cell adhesion and intracellular signaling

Infectious PrP^{sc} that converts normal PrP^c into the infectious form by changing its conformation always causes disease. This isoform has a higher amount of β -sheet structure rather

than the α -helix conformation. The aggregation of the abnormal isoforms forms the structured amyloid fibers of the prion plaque. Free protein attaches to the end of each fiber that forms the template for growth. In general, PrP molecules with the identical amino acid sequence to the infectious PrP^{Sc} isoform are incorporated into the lengthening fiber.

The conformational change of PrP^C may occur spontaneously, from dominant mutations in the prion protein (PRNP) gene that encodes PrP^C or from infection by PrP^{Sc}. The exponential growth rate results from the combination of fibril growth and breakage that is dependent on the square root of the PrP^C concentration.

The exact mechanism underlying prion diseases has not been identified. A prion can be formed by the combination of PrP^C, polyadenylic acid and lipids in a protein misfolding cyclic amplification (PMCA) reaction. The pathology is vacuole formation in neurons that leads to spongiform degeneration in the affected parts of the CNS. All inherited cases of prion diseases are caused by mutations in the PRNP gene that causes their encoded proteins to fold into pathogenic prion.

The cause of prion disease to date may be sporadic, genetic, infectious and in some instances a combination of these mechanisms. The human prion disorders are:

1. Creutzfeldt-Jakob disease (CJD)
2. Gerstmann-Sträussler-Scheinker syndrome (GSS)
3. Kuru
4. Fatal familial insomnia (FFI)
5. Variable protease-sensitive prionopathy (VPSPr)

All of the disorders involve the conformational change of normal cellular prion protein (PrP^C) into the misfolded scrapie prion protein (PrP^{Sc}).

Creutzfeldt-Jakob Disease

General Characteristics

1. The classification of CJD includes:
 - a. Sporadic CJD (sCJD):
 - i. In approximately 85% of patients
 - b. Familial CJD (fCJD):
 - i. Accounts for most of the remaining 15% of patients
 - c. Variant CJD (vCJD):
 - i. Caused by the consumption of contaminated beef (now rare)
 - d. Iatrogenic:
 - i. Contamination from an infected patient primarily acquired during a medical procedure that have included:
 1. Blood transfusion
 2. The use of human-derived pituitary growth hormone
 3. Corneal transplants
 4. Gonadotropin hormone therapy
 5. Contaminated EEG needles

Clinical Manifestations

1. The first symptom is usually a rapidly progressive dementia characterized by:

- a. Anxiety, depression, paranoia
- b. Obsessive-compulsive behavior
- c. Psychosis
2. As the disease progresses:
 - a. Speech impairment (dysarthria)
 - b. Ataxia
 - c. Gait deterioration
 - d. Rigidity
 - e. Seizures
 - f. Myoclonus
3. Sporadic disease may be extremely rapid with death within weeks; most patients succumbing six months following the onset of symptoms
4. Approximately 15% of patients may survive for 2 or more years

Neuropathology

1. Spongiform degeneration in gray matter
2. The presence of vacuoles of one to 50 micrometers in the neuropil of all six cortical layers of the cerebral cortex
3. Some patients have diffuse involvement of the cerebellar molecular layer
4. Vacuoles may appear glassy or eosinophilic
5. Severe neuronal loss and gliosis in affected areas
6. In approximately 1/3 of patients with sporadic CJD, PrP^{Sc} can be detected in skeletal muscle and/or the spleen

Laboratory Evaluation

1. CSF analysis for 14-3-3 protein
2. Neuron-specific enolase (NSE) may be elevated and reaches more significance if associated with high 14-3-3 protein
3. Surround optical fiber immunoassay (SOFIA) is being validated
4. Nasal bushing method that detects PrP in olfactory epithelial cells is being validated
5. EEG:
 - a. Periodic sharp waves

Neuroimaging

1. MRI:
 - a. DWI images are most sensitive:
 - i. Approximately 25% of patients demonstrate cortical hyperintensity only
 - ii. In 68% of patients, there are cortical and subcortical lesions (hyperintensity)
 - iii. High signal intensity in the caudate and putamen bilaterally on T2-weighted sequences
 - iv. Posterior thalamic involvement on sagittal T2 sequences

Variant CJD

General Characteristics

1. VCJD is associated with the ingestion of beef contaminated with bovine spongiform encephalopathy (BSE)

- Most patients have been diagnosed in the United Kingdom; the risk of contracting the disorder is low. No cases of vCJD ("mad cow disease") have been reported in the USA

Clinical Manifestations

- Age of onset primarily young adults (mean 28 years)
- Median duration of the disorder is 13–14 months
- Psychiatric and behavioral symptomatology
- Painful dysesthesia
- Delayed neurological signs

Neuropathology

- Marked accumulation of protease-resistant prion protein
- Abnormal prion is found in lymphoid tissue
- Presence of amyloid plaques in the brain

Laboratory Evaluation

- EEG:
 - Periodic sharp waves may be absent

Neuroimaging

- MRI:
 - Pulvinar sign (bilateral high signal intensity) on Flair sequences is seen in >75% of patients
 - DWI high signal in the caudate and putamen may be absent

Mutations in the PrP Gene

General Characteristics

- PRPN gene maps to chromosome 20
- The mutations cause conformational changes in the PrP^c protein:
 - A shift from the normal alpha-helix to a beta-sheet
 - Affects the degree of glycosylation of the PrP^c protein
- The secondary and tertiary structure of PrP^{sc} determines:
 - The size of the protein
 - Differences (clinical)
 - Different mutations cause different pathologic changes:
 - Spongiosis
 - Amyloidosis
 - Neurofibrillary degeneration
 - Congophilic angiopathy
 - Gliosis
 - Neuronal loss
 - The tertiary structure of the PrP^{sc} newly formed conformational structure causes the different pathologies
 - Prion proteins PrP^{sc} are:
 - Neurotoxic
 - Fibrillogenic
 - In a beta-sheet secondary structure
 - Protease resistant

Classification of the Classic Form of Prion Disorders by the Underlying PrP Polymorphism at Codon 129

General Characteristics

- PrP^{sc} type I:
 - Methionine at codon 129:
 - The usual CJD presentation of rapidly progressive dementia associated with myoclonus (CJD – m/m1)
- PrP^{sc} type II:
 - The size of the protease-resistant core is 21kD
 - CJD m/m2:
 - A longer disease duration and lack of myoclonus
 - Met/Val at codon 129:
 - Related to the variant with Kuru plagues (CJD – m/v)
 - Val/Val at codon 129
 - Ataxia and late dementia (CJD – V/V)
 - CJD with M/V and V/V polymorphism at 129:
 - Less pathology on the neocortex
 - Involve primarily the deep nuclei and the cerebellum

Neuropathology

- Cortical atrophy
- Spongiosis:
 - Vacuoles within the neuropil that contain membrane fragments
 - Gliosis
 - Neuronal loss
 - Abnormal amyloid fibrils
 - Pathologic changes are due to a different degree and combination of:
 - PrP^{sc} fragment size
 - Tertiary structure of the protein
 - Type I/II PrP^{sc} coexist 33% of the time

Pathologic Distribution of Involvement by Polymorphism at Codon 129

- Met/Met at codon 129:
 - Mild accumulation of aggregates
 - Occipital lobe
 - Low PrP^{sc} load
 - Few focal PrP^{sc} amyloid deposits
 - No amyloid plaques
- Met/Val at codon 129:
 - Multiple lesions throughout the brain
 - The parahippocampal gyrus is particularly involved
 - Numerous amyloid plaques
- Val/Val at codon 129:
 - Younger at onset (<55 years of age)
 - Longer disease duration (mean of 11.5 years)
 - The hippocampal formation and basal ganglia are severely involved
 - Focal non-amyloid deposits

- e. Rare amyloid plaques
- 4. Unusual mutations:
 - a. E 200k or V 210I mutations are associated with familial CJD
 - b. 178 ASP to ASN mutations are associated with fatal familial insomnia (FFI) and familial CJD
 - c. Missense mutations at codon 102 (P 102 L):
 - i. Clinical manifestations:
 - 1. Cerebellar ataxia and dementia
 - d. Polymorphism at codon 129 and 219:
 - i. Clinical manifestations:
 - 1. Babinski signs are noted early
 - 2. Leg pain and dysesthesia:
 - a. Loss of ankle reflexes
 - 3. Some patients:
 - a. Axonal neuropathy
 - b. Motor neuron disease
 - ii. Neuropathology:
 - 1. PrP^{sc} amyloid plaque deposition:
 - a. Cerebral and cerebellar cortex
 - b. Involvement of anterior and posterior spinal horns
 - c. Deep basal ganglia nuclear involvement
 - d. Involvement of the dentate gyrus
 - e. Missense mutation of codon 105 (P 105 L):
 - i. Clinical features:
 - 1. Spastic paraparesis
 - 2. Dementia
 - 3. Age at onset 38–50 years
 - 4. Severe gait disturbance
 - 5. Involuntary movements

Gerstmann-Sträussler-Scheinker Syndrome

General Characteristics

1. The incidence is not known but is estimated to be 1–10 individuals per 100 million of the population
2. Familial patients show autosomal dominant inheritance
3. A mutation in the PRNP gene that maps to chromosome 20 causes a change in codon 102 (proline to leucine) that causes the disorder in most patients

Clinical Manifestations

1. Onset is from age 20–60 with dysarthria and ataxia
2. Over time dementia is evident
3. Memory loss may be the presenting symptom
4. Variable features include:
 - a. Extrapyrimal and pyramidal signs
 - b. May mimic a spinocerebellar degeneration early in its course
 - c. Myoclonus (less common than in classic CJD disease)
 - d. Nystagmus
 - e. Blindness and deafness (rare)

Neuropathology

1. Widespread deposition of amyloid plaques (multicentric)

Laboratory Evaluation

1. Genetic evaluation to detect the mutated gene

Neuroimaging

1. MRI:
 - a. High signal in the basal ganglia on T2-weighted sequences

Fatal Familial Insomnia (FFI)

General Characteristics

1. FFI is linked to a GAC to AAC point mutation at codon 178 of the PRNP gene that causes a substitution of asparagine for aspartic acid
2. This mutation is associated with the methionine polymorphism at codon 129 in the mutant allele
3. The mutation is at codon 178 but the phenotype is CJD unless there is a methionine at codon 129

Clinical Manifestations

1. The age at onset is highly variable between 18 to 60 years with an average age of 50
2. Patients succumb usually between 7 and 36 months after the onset of symptoms
3. Phenotypic expression is variable in families
4. The disease has been divided into 4 stages:
 - a. Stage I:
 - i. Increasing insomnia that causes or is associated with panic attacks, paranoia and phobias. This period lasts for approximately four months
 - b. Stage II:
 - i. Hallucinations occur with the panic attacks that last for approximately 5 months
 - c. Stage III:
 - i. Complete insomnia associated with weight loss that lasts for approximately 3 months
 - d. Stage IV:
 - i. Dementia with muteness. This stage lasts for 6 months
 - e. Associated signs and symptoms:
 - i. Hyperhidrosis
 - ii. Pinpoint pupils (miosis)
 - iii. Impotence
 - iv. Sudden menopause
 - v. Increased blood pressure and heart rate
 - vi. Constipation
 - vii. Extremity movement as if the patient is dreaming
 - viii. Myoclonus
 - ix. Dysarthria
 - x. Ataxia
 - xi. Severe memory impairment

Neuropathology

1. Neuronal loss and gliosis in:
 - a. Anterior ventral nuclei of the thalamus
 - b. Mediodorsal thalamic nuclei
 - c. Pulvinar

2. Morphometric analysis reveals a 60% loss of neurons in limbic-paralimbic, intralaminar and reticular nuclei
3. Atrophy of the inferior olive with neuronal loss and gliosis
4. Some spongiform change in cortical areas

Laboratory Evaluation

1. Tonsillar biopsy demonstrates PrP^{sc}
2. Increased levels of protein 14-3-3 in the CSF
3. EEG:
 - a. Patients do not advance past stage I sleep
4. FDG-PET:
 - a. Thalamic hypometabolism is usual even in presymptomatic stages
 - b. In a Korean kindred:
 - i. Decreased glucose metabolism of the midbrain and the hypothalamus
 - c. Other studies have reported hypometabolism in the thalamus, caudate and some cortical areas
 - d. Structured MRI was negative in this Korean kindred

Kuru

General Characteristics

1. Primarily a disorder of the Fore people of Papua New Guinea transmitted by ritual cannibalism
2. The incubation period is from 5–20 years

Clinical Manifestations

1. The disorder has been divided into 3 clinical stages:
 - a. Stage I (ambulant stage):
 - i. Unsteady gait and stance
 - ii. Incoordination
 - iii. Dysarthria
 - iv. Hypotonia
 - b. Stage II:
 - i. Inability to walk without support
 - ii. Severe ataxia with action tremor
 - iii. Emotional lability with associated depression
 - iv. Uncontrolled spontaneous laughter
 - v. Retained deep tendon reflexes
 - c. Stage III:
 - i. The patient is unable to sit
 - ii. Increased ataxia
 - iii. Mute
 - iv. Incontinent of bowel and bladder
 - v. Dysphagia
 - vi. Infection is often the cause of death

Neuropathology

1. Susceptibility to the disorder is associated with homozygosity for methionine at codon 129 of the PRPN gene. Heterozygosity is protective
2. The G127V polymorphism was found to be a resistance factor during the Kuru epidemic
3. Spongiform encephalopathy

Neuroimaging

1. MRI: Not defined

Focal Cortical Degenerations with Dementia

Frontal Lobe

1. Predominantly left hemisphere:
 - a. nfFTD (non-fluent)
 - b. IFTD (logopenic)
 - c. Hereditary disinhibition dysphasic dementia
2. Frontal and temporal lobe atrophy:
 - a. FTD:
 - i. bvFTD (behavioral variant)
 - ii. svFTD (semantic variant; primarily temporal lobe involvement)
 - iii. IFTD (logopenic variant)
 - b. FTD-17:
 - i. DDPAC
 - ii. PPND
 - iii. FSCG
 - iv. HDDD
 - c. Genetic MAPT gene (tau) mutations:
 - i. GRN
 - ii. C9orf72
 - iii. TARDP
 - iv. UCP
 - v. CHMPB2
 - vi. FUS
 - vii. TREM2
 - viii. DCTN1
 - d. Frontal lobe degenerations with ALS:
 - i. C9orf72
 - ii. TARDP43
 - iii. UBQLN2
 - iv. DDPAC – chromosome 17q21
 - e. Frontal lobe degeneration with primary lateral sclerosis
 - i. Corticobasal ganglionic degeneration (SI degeneration)
 - ii. Parietal Pick's disease
 - iii. Posterior cortical atrophy:
 1. Alzheimer's disease
 2. Hereditary subcortical gliosis
 3. Heidenhain variant of CJD
 4. Posterior lobar atrophy

Thalamic Dementia

1. Associated with MND
2. Familial multisystem atrophy (MSA)
3. Familial fatal insomnia (FFI)
4. Thalamic degeneration of Shulman

Hereditary Dementias

1. Alzheimer's disease:
 - a. Amyloid precursor protein (codon mutations); chromosome 21

- i. 717
 - ii. 670
 - iii. 691
 - iv. Val 717
 - v. Val 717 (phe)
- b. Presenilin-1 (chromosome 14)
- c. Presenilin-2 (chromosome 1)
- d. Trisomy 21
- e. APOE ϵ 4 (chromosome 19)
- f. Congophilic angiopathy with hemorrhage
 - i. Mutations of codon 693 and 692
2. Tauopathies:
 - a. FTD and variants
 - b. MAPT (tau) mutations
 - c. CBG degeneration
 - d. PSP
 - e. FTD-17 and variants
3. Prion diseases:
 - a. Creutzfeldt-Jakob disease (chromosome 20) Variant
 - b. CJD subtypes:
 - i. Heidenhain (occipital lobe)
 - ii. Gerstmann-Sträussler-Scheinker (cerebellum)
 - iii. Kuru
 - iv. Fatal familial insomnia
 - v. Variant CJD
4. FTD and variants:
 - a. bvFTD
 - b. mFTD
 - c. l FTD
 - d. FTD-17 and variants:
 - i. DDPAC
 - ii. PPND
 - iii. HSCG
 - iv. HDDD
 - e. MAPT gene mutations
 - f. FTD mutations on chromosome 9 and 13
5. Pick's complex
6. Diffuse NF tangles with calcification:
 - a. Chromosome 21
 - b. Codon 717 (val to gly mutation)
7. Huntington's disease (chromosome 4)
8. Wilson's disease (chromosome 13q 4.3)
9. Pantothenate kinase deficiency (chromosome 20p12.3-p13)
10. Multiple system atrophy:
 - a. Olivopontocerebellar atrophy
 - b. SCA3 (Machado-Joseph disease) chromosome 14q32.12
 - c. DRPLA-ATN1 gene on chromosome 12p13.31
11. Parkinsonism ALS dementia complex of Guam (X-linked)

Familial British Dementia

General Characteristics

1. FBD is caused by heterozygous mutation in the ITM2B gene that maps to chromosome 13q14.2

Clinical Manifestations

1. Onset is between 40–60 years of age
2. Early signs of spasticity
3. As the disease progresses there is severe leg rigidity
4. Progressive tetraparesis
5. No cerebellar dysfunction
6. Cognitive deterioration is progressive with impaired memory and ability
7. Survival may be up to 13 years from disease onset
8. Familial Danish dementia is similar clinically and also maps to chromosome 13q14.2 with mutation of the ITM2 β gene

Neuropathology (Autopsy of One Patient)

1. Widespread demyelination in the brain around hyalinized blood vessels
2. Distinct densely woven tangles of fibers and microglia
3. Minimal neuronal loss most marked in Purkinje cells
4. The corpus callosum, brainstem and cerebellar white matter tracts are involved and U-fibers are spared
5. Hyalinization of small blood vessels in the white matter
6. Amyloid deposition in both FBD and familial Danish Dementia
7. Complement system and proinflammatory activation products are detected
8. Activation of both the classic and alternative complement system from amyloid peptides occurs in both disorders

Neuroimaging

1. MRI:
 - a. Periventricular, white matter pathways of the brainstem and cerebellum demonstrate hyperintense signals on T2-weighted MRI sequences
 - b. U-fibers are intact

Dementias in Association with Basal Ganglia Degeneration

1. Huntington's disease
2. Wilson's disease
3. Pantothenate Kinase deficiency
4. Parkinson's disease
5. Multiple system atrophy-P
6. FTDP-17:
 - a. DDPAC
 - b. PPND
7. CBG degeneration
8. PSP
9. Pick's disease

Dementia in Association with Inherited Cerebellar Degeneration

Cerebrotendinous Xanthomatosis (CTX)

General Characteristics

1. CTX is a rare AR lipid storage disorder caused by mutations in the CYP27A1 gene that maps to chromosome 2q35

2. The gene encodes the mitochondrial enzyme sterol 27-hydroxylase that is involved in bile acid synthesis
3. The mutation causes a decreased synthesis of bile acid, an increased production of cholesterol with the accumulation of cholesterol in tissues
4. The prevalence of CTX is approximately 1/50,000 in Caucasians

Clinical Manifestations

1. The age of onset is 19 years (mean)
2. The initial manifestations are seizures and Parkinsonism
3. The manifestations have been divided into
 - a. Classic form:
 - i. Cerebellar dysfunction and supratentorial symptoms
 - ii. Chronic myelopathy
 - iii. Variable features include:
 1. Cognitive impairment
 2. Dementia
 3. Psychiatric and behavioral disorders
 4. Pyramidal signs
 5. Progressive ataxia
 6. Dystonia
 7. Palatal myoclonus
 8. Peripheral neuropathy
 9. Mild myopathic change by biopsy
 - iv. Ocular system:
 1. Childhood onset of cataracts
 2. Paleness of the optic disc
 - v. Systemic manifestations:
 1. Premature atherosclerosis
 2. Cardiovascular disease
 3. Osteoporosis
 4. 50% of patients have severe diarrhea

Neuropathology

1. Histopathology of the tendon xanthomas reveal multiple dispersed lipid crystal clefts
2. Cholesterol deposits in the white matter of the cerebellum and cerebral peduncles
3. Cerebral and cerebellar atrophy

Laboratory Evaluation

1. High serum cholestanol and low serum cholesterol (some patients)
2. MRI:
 - a. Bilateral symmetrical increased signals on T2-weighted sequences in the white matter of:
 - i. The cerebellum
 - ii. Periventricular areas
 - iii. Basal ganglia
 - iv. Dentate nuclei
 - v. Brainstem nuclei
 - b. Cerebral and cerebellar atrophy

Dentatorubral Pallidoluysian Atrophy (DRPLA)

General Characteristics

1. DRPLA is caused by an expanded trinucleotide repeat in the AN1 gene that maps to chromosome 12p13.31. Inheritance is autosomal dominant
2. Haw River syndrome and DRPLA are caused by the same expanded repeat of the ATN1 gene although they have slightly different clinical manifestations

Clinical Manifestations

1. Onset is between 5 and 55 years of age
2. Myoclonus
3. Epilepsy
4. Cerebellar ataxia
5. Choreaethetosis
6. Dementia
7. Patients usually succumb in their forties
8. Rare in Western countries and more common in Japan
9. Haw River syndrome clinical manifestations:
 - a. Onset is between 15–30 years of age (5 generation kindred studied in the Haw River region of NC USA)
 - b. Ataxia
 - c. Seizures
 - d. Choreiform movements
 - e. Progressive dementia
 - f. Death is often after 15–25 years of illness
 - g. Phenotype differences between Haw River syndrome and DRPLA are:
 - i. No myoclonic seizures in the Haw River syndrome

Neuropathology of DRPLA

1. Combined degeneration of the dentatorubral and pallidoluysian systems
2. Neuronal intranuclear inclusions; intracytoplasmic inclusions are found in the dentate nucleus
3. Neuropathology of Haw River patients:
 - a. Demyelination of the subcortical white matter
 - b. Basal ganglia calcifications
 - c. Neuroaxonal dystrophy

Neuroimaging

1. MRI:
 - a. Cortical, brainstem and cerebellar atrophy
 - b. Atrophy of the globus pallidus and dentate nuclei
 - c. Delayed myelination in some patients
 - d. Microcalcification of the globus pallidus in some Haw River patients

Olivopontocerebellar Atrophy

General Characteristics

1. OPCA occurs in several neurodegenerative syndromes that are inherited and non-inherited ataxias that include SCA3, MSA-C and in some patients with prion disease (Gerstmann-Sträussler-Scheinker variant)

Clinical Manifestations

1. Cerebellar ataxia predominates
2. Autonomic dysfunction
3. Mild Parkinsonism
4. Cranial nerve involvement (Fick-Winkler variant)
5. Inspiratory stridor
6. Dorsal column involvement (Menzel variant)
7. Some patients develop late onset dementia

Neuropathology

1. Atrophy of the cerebellar cortex and vermis, pons, and inferior olives
2. Purkinje cell loss
3. Glial cytoplasmic inclusions in the dentate nucleus
4. Neuronal intranuclear inclusions

Neuroimaging

1. MRI:
 - a. Vermian atrophy
 - b. Cruciate atrophy of the pons (atrophy of pontine nuclei and fibers of the middle cerebellar peduncles; the “hot cross bun sign”)
 - c. 30% of patients have cerebral atrophy
 - d. Atrophy does not correlate with either duration of illness or the severity of ataxia

Machado-Joseph Disease (MJD)**General Characteristics**

1. MJD, also known as spinocerebellar atrophy 3, is caused by a CAG trinucleotide expansion in the ataxin-3 gene that maps to chromosome 14q32.12. Inheritance is autosomal dominant
2. The gene encodes an abnormal polyglutamine (poly Q) repeat in the ataxin-3 protein
3. The length of the repeat correlates with both the severity of the disorder and age of onset (anticipation)
4. The ataxin-3 protein functions in the:
 - a. Chaperone system
 - b. Ubiquitin-proteasome system
 - c. Aggregation autophagy

Clinical Manifestations

1. Variable age at onset; adult onset is most frequent
2. There is pronounced phenotypic heterogeneity
3. The core clinical features include:
 - a. Gait ataxia
 - b. External ophthalmoplegia
 - c. Nystagmus
 - d. Bulging eyes
4. Variable manifestations:
 - a. Dementia
 - b. Generalized muscle and joint pain
 - c. Amyotrophy
 - d. Early onset Parkinsonism
 - e. Axonal sensory and motor neuropathy (in patients with fewer CAG repeats)
 - f. Restless leg syndrome

Neuropathology

1. The SCA3 pathogenic form of ataxin-3 (ataxin-3(exp)) impairs the clearance of misfolded protein that are either dependent or independent of its deubiquitinase activity. The result is an accumulation of misfolded protein that leads to neuronal death in the cerebellum
2. Demyelination of spinocerebellar tracts and the dorsal columns
3. Loss of neurons in the pons
4. The severity and loss of Purkinje and olivary cells is variable in different kindreds
5. The subthalamopallidal system may be affected

Laboratory Evaluation

1. EMG:
 - a. Sensorimotor neuropathy (some kindreds)

Neuroimaging

1. MRI:
 - a. Enlargement of the IVth ventricle
 - b. Diffusion MRI imaging with voxel-based morphometry demonstrates:
 - i. Loss of both gray and white matter in the cerebellar hemispheres, brainstem, pons and lateral thalamus

Differential Diagnosis of Cerebellar Diseases with Associated Dementia

1. Ataxia telangiectasia
2. Friedreich's ataxia
3. Marinesco-Sjögren's disease
4. MSA-C
5. SCA3 (Machado-Joseph disease)
6. Cerebroxanthomatosis (CTX)
7. OPCA
8. DRPLA

Thalamic Dementia**General Characteristics**

1. Thalamic dementia is most often caused by cerebral vascular disease that infarcts the anterior and medial thalamic nuclei but also occurs with lesions of the paramedian, intralaminar and pulvinar nuclei. The left thalamus may be particularly important for cognitive function

Clinical Manifestations

1. Onset in middle age
2. Progressive intellectual deterioration
3. Personality change
4. Bizarre behavior
5. Movement disorder

Neuropathology

1. The dorsomedial nucleus is usually the most severely affected
2. Associated involvement of:

- a. Cortex, brainstem, basal ganglia cerebellum, and white matter
- 3. Many patients have neuronal loss and gliosis in the anterior thalamic nuclei; often the lesions are bilateral
- 4. The cortical neuronal loss is of the linear spongy type

Neuroimaging

1. MRI:
 - a. Infarction of the artery of Percheron with paramedian nuclear involvement
 - b. Dural arteriovenous fistula with venous hypertension due to excessive drainage into the Vein of Galen that causes edema of paramedian nuclei bilaterally
2. T2-Weighted and FLAIR sequences demonstrate lesions in the Papez circuit as well as the anterior thalamic nuclei, intralaminar nuclei and the pulvinar

Differential Diagnosis of Thalamic Dementia with Neuronal Loss and Astrogliosis

1. Friedreich's ataxia
2. Some spinocerebellar degenerations
3. Multiple system atrophy
4. Membranous lipodystrophy
5. Creutzfeldt-Jakob disease
6. Fatal familial insomnia
7. Isolated thalamic degeneration of Shulman

Cerebral Amyloid Angiopathy

Overview

In cerebral amyloid angiopathy, amyloid deposits form in the walls of CNS blood vessels and are not related to systemic forms of amyloidosis. Congophilic angiopathy (CAA) can occur sporadically in elderly patients or in familial kindreds such as the Flemish, Iowa, Icelandic, and Dutch variants. It causes deposition of A-beta amyloid in both the leptomeningeal and cerebral blood vessels. The Flemish variant is different as there are associated dense-core plaques in the parenchyma of the brain.

A-beta amyloid is cleared from the brain by four mechanisms:

1. Endocytosis by astrocytes and the microglia
2. Enzymatic degradation by neprilysin or insulin
3. Cleared through the blood-brain barrier
4. Drained along periarterial spaces. The mechanisms involved in the deposition of A-beta amyloid in sporadic CAA are unclear

In the genetic form of CAA, it is posited that the basic mechanism of CAA is overproduction rather than inadequate clearance.

The Boston Criteria for the Diagnosis of Cerebral Amyloid Angiopathy (CAA)

1. Definite CAA:

- a. Post-mortem examination reveals lobar, cortical or subcortical hemorrhage and evidence of severe CAA
- 2. Probable CAA:
 - a. The clinical data and pathologic biopsy or evacuated tissue demonstrate the characteristics of definite CAA and some degree of vascular amyloid deposition
- 3. Probable CAA:
 - a. Clinical data and MRI findings demonstrate multiple hematomas (lobar primarily) in a patient older than 60
- 4. Possible CAA:
 - a. The patient is >60 years of age, MRI reveals a single lobar, cortical or cortico-subcortical hemorrhage without another cause; multiple hemorrhages with a possible, but not definite cause or some hemorrhage in an atypical location

Dementia in Familial Cerebral Amyloid Angiopathies

Hereditary Cerebral Hemorrhage with Amyloidosis-Icelandic Type (HCHWA-I)

General Characteristics

1. HCHWA-Icelandic type is caused by mutation in the cystatin C gene that maps to chromosome 20p11.21
2. The gene encodes a protein that is similar to a human protein termed gamma-trace or cystatin C

Clinical Manifestations

1. Recurrent primarily lobar cerebral hemorrhage with focal deficits
2. Slowly progressive dementia secondary to parenchymal destruction

Neuropathology

1. Amyloid is deposited in the walls of arteries and arterioles in:
 - a. Leptomeninges
 - b. Cerebral cortex
 - c. Deep gray and white matter
 - d. Brainstem
 - e. Cerebellum
2. Repeated hemorrhage in these areas but predilection for the cortex
3. No parenchymal amyloid plaques or neurofibrillary tangles
4. Cystatin-C amyloid may be found in lymphoid tissue, spleen, salivary glands and seminal vesicles

Laboratory Evaluation

1. Low CSF cystatin C
2. Molecular genetic analysis

Neuroimaging

1. MRI:
 - a. Lobar microbleeds
 - b. Lobar hemorrhages

Hereditary Cerebral Hemorrhage with Amyloidosis (Dutch Type)

General Characteristics

1. APP-related cerebral amyloid angiopathy (CAA) Dutch type is caused by mutation in the APP gene that maps to chromosome 21q21.3
2. It is found in Dutch, Italian, Iowa (kindred), Flemish, Arctic variants
3. It is the most common form of CAA

Clinical Manifestations

1. Acute cerebral hemorrhage that occurs between 45–60 years of age
2. Approximately 2/3 of patients succumb and the remainder develop focal deficits and dementia
3. Rarely dementia is a presenting feature of the disease
4. TIA's may occur

Neuropathology

1. Vascular amyloid deposits are related to the beta-protein that is associated with Alzheimer's disease and Down syndrome
2. Small vessels may have thickened or split walls due to hyaline congophilic material
3. Abnormal vessels are in the leptomeninges and the cerebral and cerebellar cortex
4. Amyloid-beta 40 is seen in the cortical capillaries while amyloid-beta 42 is deposited in the neuropil of gray matter
5. In general, hemorrhage and infarcts are noted in the temporal and occipital lobes
6. Amyloid is deposited in arteries and arterioles:
 - a. Leptomeninges
 - b. Cerebrum and cerebellum
 - c. Cerebral cortex:
 - i. As diffuse A-beta Amyloid plaques
 - ii. Little neuritic pathology
7. An Iowa and Spanish kindred demonstrated:
 - a. Spanish kindred:
 - i. Tram-track bilateral occipital calcification
 - ii. Leukoencephalopathy
 - iii. Bilateral external carotid artery dysplasia
 - iv. EM evaluation of brain biopsy:
 1. Multilayered round microcalcifications in the basal lamina
8. It has been suggested that more than 15 amyloid-beta severely stenotic blood vessels in 5 frontal cortical sections are sufficient to cause dementia in the Dutch Variant

Neuroimaging

1. MRI:
 - a. Primarily cortical microbleeds with lobar hemorrhage
 - b. Rare variants (Spanish and Iowa kindreds):
 - i. Occipital lobe calcifications
 - ii. Leukoencephalopathy
 - iii. Bilateral external carotid artery dysplasia

Point Mutation of the APP gene at Codon 618

General Characteristics

1. The G to C transversion at codon 618 that encodes the extracellular portion of APP 695, produces an amino acid substitution of glutamine instead of glutamic acid

Clinical Manifestations

1. Symptoms develop in the fifth decade
2. Progressive dementia
3. Spastic paralysis
4. Ataxia
5. Memory impairment is rare
6. Stroke-like episodes are uncommon

Neuropathology

1. Atrophy of cerebral and cerebellar hemispheres
2. Cystic infarcts of the deep white matter
3. Arteries demonstrate:
 - a. Fibrotic thickening and obstruction
 - b. Fragmentation of the elastic lamina
 - c. Periarteriolar microhemorrhage
4. Ischemic neurons are found in the:
 - a. Cerebral cortex and white matter
 - b. Thalamus
 - c. Cerebellum
5. Non-neuritic amyloid plaques occur in the:
 - a. Cerebral and cerebellar cortex
6. Neurofibrillary tangles are demonstrated in the hippocampus and amygdala

Neuroimaging

1. MRI:
 - a. Atrophy of the cerebral and cerebellar hemispheres
 - b. Cortical microbleeds
 - c. Multiple simultaneous lobar hemorrhages

Familial Amyloid Angiopathy with Deafness and Ocular Hemorrhage (Danish type)

General Characteristics

1. Danish familial dementia is caused by mutation in the ITM2 gene that maps to chromosome 13q14.2
2. Possible function as an intracellular signaling molecule
3. The gene is also the site of mutation in familial British dementia (FBD)

Clinical Manifestations

1. Cataracts early in life (posterior polar)
2. Deafness by age 30–50 years of age
3. By the fifth and sixth decades patients manifest:
 - a. Ataxia
 - b. Dementia
 - c. Rare ocular hemorrhages
 - d. Rare stroke-like episodes
 - e. Paranoid psychosis
 - f. Most patients succumb in the fifth to sixth decade

Neuropathology

1. Diffuse brain atrophy
2. The cerebral cortex, cerebellum and white matter are affected
3. Thin and demyelinated cranial nerves
4. Amyloid angiopathy in:
 - a. Cerebrum
 - b. Choroid plexus
 - c. Cerebellum
 - d. Spinal cord
 - e. Retina
 - f. The amyloid is deposited in the endothelial and basement membrane
5. Neuritic plaques and neurofibrillary tangles are present in the hippocampus

Laboratory Evaluation

1. Proteins of the complement system and their proinflammatory activation products are found in the CNS
2. Genetic analysis for the mutation in the ITM2 gene

Familial British Dementia (FBD)**General Characteristics**

1. FBD is caused by heterozygous mutation in the ITM2 gene that maps to chromosome 13q142
2. A point mutation at the stop codon of ITM2B generates an ABR1 peptide that is deposited as amyloid fibrils

Clinical Manifestations

1. Onset is between 40–60 years of age
2. Early spasticity
3. Muscle rigidity is seen late in the course of the illness (legs are maintained in extension)
4. Truncal ataxia
5. Positive Romberg sign
6. Progressive loss of cognitive function

Neuropathology (Autopsy of 1 Patient)

1. Widespread demyelination most marked around small hyalinized blood vessels
2. Minimal neuronal loss except for Purkinje cells
3. Neurofibrillary tangles in the hippocampal formation but less than that found in Alzheimer's disease
4. Severely thinned corpus callosum; spared U-fibers
5. Hyalinization of small vessels in the white matter and pia
6. Congophilia in perivascular plaques
7. Parenchymal plaques and cerebrovascular amyloid aggregates in both FDD and FBD contain complement activation products of both the classic and alternative pathways

Neuroimaging

1. MRI (1 patient):
 - a. Periventricular white matter abnormal signal; sparing of U-fibers
 - b. Abnormal signal intensity in the brainstem and cerebellar white matter

Laboratory Evaluation

1. Slightly increased CSF protein

Differential Diagnosis of the Familial Amyloid Angiopathies

1. Alzheimer's disease (sporadic and familial)
2. Point mutation of the amyloid precursor protein at codon 618
3. Amyloidosis – Icelandic type
4. Amyloidosis – Dutch type with variants
5. Flemish amyloidosis
6. Familial Danish amyloidosis
7. Familial British amyloidosis
8. Gerstmann-Sträussler-Scheinker syndrome
9. Familial cerebral amyloid angiopathy with non-neuritic plaque formation

Secondary Dementia**General Characteristics**

1. A secondary dementia is a form of dementia that develops as a peripheral manifestation of a pre-existing mental illness or organic condition. Thus secondary dementias are those caused by or closely related to some other recognizable disease
2. Mild cognitive impairment (MCI) is a transitional stage between normal aging (usually age-associated memory impairment) and dementia. It is now clear that both neuropathological changes and subtle cognitive deficits are present up to two decades prior to the onset of dementia in many neurodegenerative diseases. Patients with MCI are at a greater risk of developing dementia than normal cognitively functioning individuals. The clinical criteria of MCI are:
 - a. Subjective cognitive changes corroborated by an informant
 - b. Impairment in one or more cognitive domains that are compatible with age and educational level
 - c. Normal activities of daily living are attained
 - d. Absence of dementia; the cognitive difficulties are mild with no significant social or occupational impairment

Vascular Dementia**Overview**

Cognitive impairment caused by vascular disease includes subclinical brain injury, silent brain infarction (SBI) and both large and small vessel stroke, as well as cerebral hemorrhage. MRI neuroimaging reveals a prevalence of covert small-vessel disease in the elderly population of 21% for silent lacunes and 95% for incidental white matter hyperintensities, both of which are associated with an increased risk of stroke and dementia. Pathologically, large cortical infarcts, lacunar infarcts, subcortical white matter disease, strategic subcortical infarcts, and hemorrhages all cause cognitive im-

pairment. Vascular lesions are frequently found in association with Alzheimer's disease and may lower the threshold for its clinical expression.

Cognitive syndromes associated with vascular disease have two core features:

1. Demonstration of the cognitive disorder by neuropsychological testing
2. History of clinical stroke or presence of vascular disease by neuroimaging

A memory deficit is not required for the diagnosis of vascular cognitive impairment or vascular dementia.

Research classification systems suggest that vascular cognitive impairment (VCI) includes a spectrum of cognitive main deficits that may be biased more to executive dysfunction than memory loss. The most severe form of VCI causes vascular dementia (VaD).

The most important cerebral vascular pathology that causes cognitive impairment is infarction. Macroscopic chronic infarctions occur in approximately 1/3 of older individuals. Microscopic infarctions, small vessel disease, and white matter lesions on MRI are vastly more common in community-based epidemiologic studies. As a general rule, larger loss of parenchymal brain tissue and an increased number of macroscopic infarcts are associated with vascular cognitive impairment. It has been suggested that loss of 100 mg of tissue is associated with dementia but it clearly has been evident with loss of much smaller brain volumes. There is not a good correlation between volume loss, the number of infarcts and cognitive impairment. This has generated the concept of strategic infarction whereby lesions in specific locations such as the thalamus, cingulate gyrus, and basal ganglia rather than other nuclear areas are more likely to cause dementia. Recent work with functional MRI (fMRI) suggests that specific distributed loops with hubs, small or large world connections, support specific brain oscillations required for attention, memory, and executive function. A small infarction that disrupts a specific distributed loop may have a major effect on cognition. The phenotypic and pathologic spectrum of vascular disease is wide and includes:

1. Primary vessel disease:
 - a. Arteriolosclerosis
 - b. Lipohyalinosis
 - c. Atherosclerosis
 - d. Cerebral angiopathy
 - e. Cerebral microbleeds

Primary vessel disease may be associated with strategic infarction (the disruption of specific distributed loops), diffuse tissue damage (white matter pathway damage), or functional deficits from hypoperfusion.

In most hospitals, present MRI resolution detects macroscopic infarcts of approximately 3 mm but is incapable of resolving microscopic infarcts and arteriolosclerosis. White matter degeneration and microbleeds are associated with VCI and Alzheimer's disease; pathologically both are related to lipohyalinosis. Hippocampal atrophy may also be caused by

Alzheimer's disease or ischemia. There is a complex interplay between vascular and Alzheimer's disease in determining the manifestations of VCI, dementia and Alzheimer's disease.

The neurovascular unit is altered in both Alzheimer's disease and vascular cognitive impairment. In both disorders, microvessels have thickened basement membranes, are tortuous and reduced in density. Arterioles undergo lipohyalinosis (hyaline degeneration). Periventricular white matter demonstrates microglial activation and astrogliosis due to the expression of hypoxia-inducible genes. Accumulation of amyloid-beta in the media of cortical arterioles in both congophilic angiopathy (cerebral amyloid angiopathy) and Alzheimer's disease is a cause of microbleeds and lobar hemorrhage (basal ganglia microbleeds are from hypertension).

A β (amyloid-beta) found in Alzheimer's disease and CAA (cerebral amyloid angiopathy) causes:

1. Suppression of endothelium-dependent responses such as functional hyperemia and autoregulation
2. Vasoconstriction
3. Increased constrictor tone of smooth muscle (Alzheimer's disease)

The key pathogenic factors in the neurovascular dysfunction seen in vascular cognitive impairment are oxidative stress and inflammation. The free radicals generated under ischemic conditions are thought to be produced from inefficiencies in oxidative phosphorylation and by nicotinamide adenine dinucleotide phosphate oxidase. Free radicals activate redox-sensitive proinflammatory transcription factors; endothelial dysfunction induced by oxidative stress releases vascular endothelial growth factor (VEGF) and prostanooids that increase vascular permeability, protein extravasation and cytokine production and release. Further pathology is caused by inflammatory process enhancement of oxidative stress that upregulates reactive oxygen species producing enzymes and downregulates antioxidant defenses.

The A β (amyloid-beta) clearance receptor (low-density lipoprotein receptor-related protein-1), is downregulated in Alzheimer's disease blood vessels that allows amyloid-beta accumulates around blood vessels and exacerbates their dysfunction. Oxidative stress and the inflammatory cascade are deleterious for the proliferation, migration, and differentiation of oligodendrocyte progenitor cells, which impairs white matter repair.

Recent clinical and experimental evidence support a significant role of the neurovascular unit in VCI and may exacerbate Alzheimer's disease by:

1. Altering the regulation of the local blood supply
2. Disrupting the kinetics of the blood-brain barrier
3. Decreasing the trophic support of neurotrophic factors

There is a strong correlation between age and the structure and physiology of large extra- and intracranial vessels. The selected parameters for investigation have included carotid wall thickening and aortic stiffness that putatively measure athero- and arteriosclerosis, respectively. There is a strong

correlation between the parameters of vascular aging and cognitive impairment and silent cerebral small vessel disease. There is linkage between large artery dysfunction and cerebral small vessel disease that are independent of both age and cardiovascular risk factors.

Midlife hypertension is a clear risk factor for later cognitive impairment and vascular dementia. Systolic increased blood pressure appears to be a more consistent biomarker of cognitive impairment than diastolic variability and failure of the nocturnal dip of systolic pressure. A history of hypertension and total cholesterol level are also biomarkers of vascular cognitive impairment.

Associated disorders of vascular dementia include:

1. Coronary and peripheral arterial disease
2. Atrial fibrillation
3. Renal disease, and
4. Cardiac failure

Dementia from Strategic Vascular Lesions

General Characteristics

1. In some patients mental impairments are the presenting or only manifestation of stroke:
 - a. Approximately 15% of strokes may have minimal or transient motor or sensory symptoms and signs
 - b. Small cortical or subcortical infarcts that are asymptomatic but disrupt important distributed networks that subserve executive function, attention and language, may be silent

Clinical Manifestations

1. Middle cerebral artery:
 - a. Acute confusional states occur more frequently with R > L hemisphere infarction
 - b. Confusional state may occur from infarction of the:
 - i. Middle frontal gyrus
 - ii. Middle temporal gyrus
 - iii. Inferior parietal lobule
 - iv. Head of the left caudate nucleus
 - v. Right temporoparietal occipital cortex
 - c. Global deficits of selective attention causes confusion with associated clinical deficits of:
 - i. Attention to relevant stimuli
 - ii. Distractibility
 - iii. Normal arousal
 - iv. Lack of concern for the illness
 - v. Disorientation
 - vi. Anomia
 - vii. Inability to maintain coherent thought
 - viii. Restless, agitated, and at times aggressive behavior
 - ix. Most acute confusional states last days to weeks; rarely they are permanent
 - x. Disruption of distributed language loops, attentional loops, and components of the DMN (default mode network) lead to vascular dementia

2. Anterior cerebral artery:

- a. ACA branch occlusions that cause dementia include the:
 - i. Frontopolar artery
 - ii. Callosomarginal artery
- iii. Neuroanatomical structures that are involved are:
 1. The orbital cortex
 2. Medial frontal cortex (a major hub of the DMN)
3. Clinical signs:
 - a. Mental inertia (abulia)
 - b. Indifference and apathy
 - c. Emotional blunting
 - d. Infarcts cause subtle deficits of:
 - i. Divergent thinking
 - ii. Temporal organization
 - iii. Executive and planning strategies
4. Behavior may be triggered by environmental stimuli:
 - a. Imitation behavior
 - b. Utilization behavior

3. Posterior Cerebral Artery

- a. Infarction of the posterior cerebral artery causes ischemia to a varying degree in:
 - i. Mediotemporal areas (P₁)
 - ii. Midline mesencephalon (interpeduncular artery)
 - iii. Thalamic nuclei (DM and anterior):
 1. Thalamogeniculate arteries
 - iv. Occipital/temporo/parietal junction:
 1. TPO branch of the inferior division of the DCA
- b. Occipital lobe lesions and behavior:
 - i. Color vision (lingual and fusiform gyri)
 - ii. Color naming
 - iii. Alexia without agraphia (visual field deficit in the left occipital lobe with concomitant damage of the corpus callosum)
 - iv. Visual distortions and hallucinations (perceived in the hemianopic or entire VF)
 - v. Bilateral lesions of the occipital lobe cause:
 1. Visual agnosia
 2. Cortical blindness
- c. Medial temporal lobe infarction:
 - i. Severe amnesic deficit:
 1. Often bilateral involvement
 2. Severe hippocampal formation damage
 3. Rarely occurs in isolation: usually a consequence of anoxia due to the ischemia of cardiac arrest or severe hypotension during prolonged heart or abdominal surgery

Subcortical Infarction and Dementia

General Characteristics

1. Thalamic vascular disease
2. Interpeduncular artery infarction from involvement of top of the basilar artery (usually embolic)

3. A single arterial stem that supplies both paramedian thalamic nuclei (the thalamic peduncle of Percheron)
4. Small artery infarction from penetrators of the posterior communicating artery

Clinical Manifestations

1. Bilateral involvement (midline thalamic nuclei)
 - a. Disturbance of consciousness acutely
 - b. Eye movement deficits (eyes looking down at the tip of the nose) and other vertical gaze palsies
2. Unilateral thalamic infarction (DM, anterior nuclei)
 - a. Inattention
 - b. Motor neglect
 - c. Anterograde amnesia
 - d. Left-sided lesions (aphasia):
 - i. Fluent paraphasic speech
 - ii. Perseverative speech
 - iii. Anomia
 - iv. Spared repetition
 - e. Right-sided lesions:
 - i. Hemineglect of the left side of the body and personal and extrapersonal space (VPL nucleus with the parietal projection)

Neuropathology

1. Infarction of thalamic nuclei:
 - a. The intralaminar nuclei: deficits of arousal and attention
 - b. Medial dorsal nuclei: short-term memory loss
 - c. Anteroventral nuclei: disruption of Papez circuit of the anterior limbic system:
 - i. Personality change
 - ii. Episodic memory loss
 - iii. Insomnia and sleep-wake cycle alterations

Caudate Lesions

General Characteristics

1. Disruption of caudate frontal lobe projections

Clinical Manifestations

1. Left caudate head:
 - a. Acute agitation (R caudate > left)
 - b. Thalamic type of aphasia
 - c. Frontal lobe syndrome

Neuropathology

1. Infarction of the thalamoperforate artery (origin is P2 segment of the PCA)

Multi-Infarct Dementia

General Characteristics

1. The most common form of multi-infarct dementia is that from small vessel disease that most often occurs without a specific clinical deficit and is manifest by:

- a. White matter hyperintensities throughout the brain
- b. Lacunar infarction
- c. Supra- and infratentorial microbleeds
- d. Enlarged perivascular spaces
- e. Microinfarction of arterioles

Clinical Manifestations

1. Patients are usually older than 50 years of age: men > women
2. Episodic lacunar infarctions with focal deficits that include:
 - a. Hemiparesis
 - b. Hemisensory deficit
 - c. Rarely aphasia
 - d. Dysarthria
 - e. Confusion
 - f. Ataxia
 - g. Diplopia
 - h. Dizziness
3. Cognitive deficits may occur early or late in the course, depending on the disruption of the specific distributed loop that is affected
4. In general, there are usually minimal residual deficits from each episode
5. Cognitive deficits include:
 - a. Slowed psychomotor processing
 - b. Decreased attention
 - c. Decreased concentration
 - d. Poor memory
 - e. Inertia
 - f. Loss of executive function
6. Prior to cognitive decline there is:
 - a. Gait disturbance
 - b. Urinary incontinence
7. Variable neurologic signs include:
 - a. Pyramidal tract dysfunction
 - b. Spasticity
 - c. Parkinsonism
 - d. Pseudobulbar palsy
 - e. Hypomimia
 - f. Instability of gait
8. Accumulation of cortical lesions cause:
 - a. Aphasia
 - b. Visuospatial deficits
 - c. Various apraxias:
 - i. Ideomotor (frontal lobe)
 - ii. Limb kinetic (both frontal and parietal lobe)
 - iii. Ideational (parietal lobe)
 - iv. Oral buccal and speech apraxia (supplementary motor area and frontal lobe)
 - v. Eye opening and closing apraxia:
 1. Frontal lobe (second frontal convolution)
 - vi. Sympathetic apraxia (anterior corpus callosum) – inability to follow commands with the left hand
 - vii. Both cortical and subcortical deficits:

1. May have an abrupt onset
2. Stepwise deterioration
3. Association with nocturnal confusion
4. Depression and inertia
5. Fluctuating course
- viii. Concomitant medical associations in most patients:
 1. HCVD
 2. CHF
 3. Diabetes mellitus
 4. Intermittent claudication
 5. Angina
 6. Myocardial infarction
 7. Generalized vascular disease
 8. Valvular heart disease (less frequently)
 9. Chronic kidney disease
 10. Atrial fibrillation
 11. Prior stroke

Neuropathology

1. Microbleeds
 - a. In the basal ganglia due to hypertensive vascular disease
 - b. Lobar cortical distribution due to CAA
2. CAA
3. Increased perivascular spaces
4. Lacunar infarction (“état lacunaire”) if severe
5. Associated hypertensive changes in large vessels
6. Generalized atherosclerosis
7. Numerous microscopic infarcts in the cortex have been associated with cortical granular atrophy
8. Territorial infarction of large vessels with atherosclerosis and arteriolar sclerosis
9. Ventricular enlargement
10. Hippocampal atrophy:
 - a. Alzheimer’s disease > frequency than vascular disease
11. Loss of 50–100 grams of brain tissue has been correlated with vascular dementia

Laboratory Evaluation

1. Carotid intima-media thickness
2. Arterial stiffness (arteriosclerosis): Carotid-femoral pulse wave velocity is increased with stiffened atherosclerotic vessels
3. Associated:
 - a. Hyperglycemia
 - b. Insulin resistance
 - c. Metabolic syndrome
 - d. Diabetes
 - e. Lipids: midlife total cholesterol is a risk factor
 - f. Inflammation: plasma levels of inflammatory proteins:
 - i. α 1-antichymotrypsin
 - ii. C-reactive protein
 - iii. Increased interleukin-6

Neuroimaging

1. MRI techniques:
 - a. FLAIR
 - b. Diffusion tensor
 - c. Magnetization transfer
 - d. NMR spectroscopy
2. Infarction in multiple cortical areas (topographical distribution)
3. Lacunar infarction of the basal ganglia, thalamus, internal capsule, and centrum semiovale
4. FLAIR or T2-weighted sequences white matter hyperintensities around the ventricles (“ventricular capping”)
5. Strategic infarcts
6. White matter hyperintensities throughout the brain on FLAIR or T2-weighted sequences

Inherited Vascular Diseases Associated with Dementia

Small Vessel Syndromes

1. CADASIL:
 - a. Missense mutations of the Notch 3 gene
 - b. Deposition of granular eosinophilic aggregation in the arteriolar media
2. CAA:
 - a. Mutations or duplication of the APP amyloid-beta precursor protein gene
3. Autosomal dominant retinal vasculopathy with cerebral leukodystrophy due to frame shift deletions in the exonuclease TREX1 gene
4. Cerebral autosomal recessive arteriopathy with subcortical infarcts and leukoencephalopathy from missense or nonsense mutations of the transforming growth factor β 1 repressor HTRA1 gene
5. COL4A1 type IV collagen subunit gene mutations are associated with:
 - a. Congenital porencephaly
 - b. Leukoencephalopathy
 - c. Intracerebral hemorrhage
6. HCHWA (Icelandic); cystatin c gene
7. HCHWA (Danish) – ITM2B gene
8. HCHWA (British) – ITM2B gene
9. HERNs – TREX1 gene
10. Moyamoya – RNF213 gene
11. Fibromuscular dysplasia:
 - a. Autosomal dominant inheritance
 - b. Approximately 10% of patients have an affected relative
12. Pseudoxanthoma elasticum:
 - a. ABCC6
 - b. XYLT1 – modifier of severity
 - c. XYLT2 – modifier of severity
13. Homocystinuria:
 - a. Autosomal recessive inheritance
 - b. Homozygous or compound heterozygous mutation in the cystathionine beta synthase gene (CBS)

Binswanger Disease*General Characteristics*

1. Subcortical arterioleukoencephalopathy of the Binswanger type that may be associated with confluent white matter lesions
2. Diffuse white matter damage of vascular etiology

Clinical Manifestations

1. Patients are between 50–70 years of age
2. Males and females are equally affected
3. Subacute neurologic symptoms and signs
4. Progressive longstanding dementia
5. Most prevalent in hypertensive patients
6. Occipital lobe preponderance

Neuropathology of White Matter Disease

1. Triad of demyelination, axonal loss, and lacunar infarction is the pathology of WML (white matter lesions) that when confluent, constitute “leukoaraiosis”
2. This pathologic process is located in:
 - a. The periventricular white matter
 - b. Subcortical white matter
3. It has a wide phenotypic expression from dilation of the Virchow-Robin spaces to diffuse myelin pallor (demyelination) and microinfarction that spares subcortical U-fibers (connect adjacent convolutions)
4. The lesions are putatively caused by microvascular changes of arteriosclerosis, hyalinosis, and focal fibrinoid necrosis, with or without occlusion of small penetrating arterioles
5. White matter lesions are putatively also caused by chronic ischemia due to hypoperfusion and disruption of the blood-brain barrier
6. The process is often associated with atherosclerosis of large cerebral blood vessels
7. The myelin changes are most severe in:
 - a. Frontal, occipital and parietal lobes
 - b. The distribution is most often bilateral and symmetrical
8. Lacunes are often seen in the deep gray matter of the pons, caudate, putamen, centrum semiovale and internal capsule
9. Minor degree of cortical infarction

Neuroimaging

1. MRI:
 - a. Lateral ventricular enlargements are prominent posteriorly
 - b. Diffuse and at times WML that are confluent
 - c. Cortical atrophy

Cerebral Microbleeds (CMB)*General Characteristics*

1. CMBs are defined histologically as blood extravasation into the perivascular and/or Virchow-Robin space without disruption of the surrounding brain parenchyma. They may also be very small intracerebral hemorrhages of <5 mm in diameter

2. Hemosiderin-laden macrophages and hemosiderin deposits within the perivascular space indicate post-resolved microbleeds

Clinical Manifestations

1. If predominate in the basal ganglia they are most often due to prolonged hypertension. Hemorrhage in this distribution is associated with severe neurological deficits of hemiparesis, hemisensory deficits associated with aphasia if left-sided and visuospatial deficits with hemineglect if right-sided
2. Cortical microbleeds in a lobar distribution in patients older than 60 years of age are most often due to congophilic angiopathy:
 - a. Minimal focal neurologic deficit depending on location
 - b. No alteration of mental status
 - c. May be multiple

Neuropathology

1. Arterioles that have ruptured walls demonstrate:
 - a. Thickened acellular walls
 - b. A deficient muscular layer with AB1-40 deposition
2. Hemosiderin-laden macrophages and deposition of hemosiderin within perivascular spaces
3. Activation of surrounding microglial cells, late complement activation and apoptosis

Neuroimaging

1. MRI:
 - a. Most effectively detected with gradient echo sequences
 - b. Only a few CMB may be clinically significant
 - c. Lack of a signal on GE sequences (due to cancellation effects of hemosiderin) in lesions <5 mm are characteristic
 - d. A gliotic lesion with a surrounding hemosiderin ring located superficially in the cortex in a lobar distribution is characteristic of CAA

Normal Pressure Hydrocephalus*General Characteristics*

1. The incidence (estimated from a Norwegian population) is 5.5/100,000 of the population
2. Normal pressure hydrocephalus is now separated into idiopathic NPH and secondary NPH
3. Possibility 1% of dementia

Clinical Manifestations

1. Occurs most frequently in the sixth and seventh decade
2. Gait disturbance:
 - a. Initiation difficulties
 - b. “Foot grasp” of the floor
3. Subcortical type dementia:
 - a. Slow information processing
 - b. Decreased attention
 - c. Poor concentration

- d. Poor abstract thought
- e. Memory is relatively well preserved
- f. Falling backwards
- g. Urinary incontinence (precipitate micturition; deficit of inhibition from the paracentral lobule)

Neuropathology

1. Ventricular enlargement causes:
 - a. Stretch of the long descending corticospinal leg fibers that are periventricular (increased reflexes; gait apraxia)
2. Bladder fibers:
 - a. Paracentral lobule bladder inhibitory afferents to the frontal lobe become dysfunctional
3. Distributed loops associated with executive functions are affected:
 - a. Cortico-cortical-fibers
 - b. Transcallosal fibers
4. Normal brain weight
5. Well preserved cortical ribbon
6. Minimally thinned corpus callosum
7. Mild pallor of periventricular white matter
8. Concomitant features:
 - a. Vascular pathology
 - b. Amyloid plaques; neurofibrillary tangles
 - c. Hypertension
 - d. Peripheral vascular disease
 - e. Posterior circulation insufficiency
 - f. Arrhythmia, valvular disease, congestive heart failure, myocardial infarction aortocoronary bypass
 - g. Secondary NPH:
 - i. Predisposes to obstruction of CSF flow or reabsorption from:
 1. Subarachnoid hemorrhage
 2. Head injury
 3. Meningitis
 4. Aqueductal stenosis
 5. Syringomyelia

Neuroimaging

1. MRI:
 - a. Severely dilated lateral and IIIrd ventricles
 - b. Absence of significant cortical atrophy
 - c. Dilated temporal horns out of proportion to dilatation of the other ventricles
 - d. Transventricular edema
 - e. MRI Aqueductal flow:
 - i. Aqueductal flow values are elevated which is seen in idiopathic NPH
 - ii. Persistent ventricular stasis on radioisotope cisternography (in the lateral ventricles)

Metabolic Disease Associated with Dementia

Uremia

General Characteristics

1. Associated, HCVD and anemia

2. Blood uremia nitrogen >60 mg/dl
3. Parathyroid hormone may be involved in the cognitive deficits

Clinical Manifestations

1. Cognitive deficits in all spheres
2. Memory deficits
3. Process fluctuates
4. Usually a slowly progressive course that fluctuates
5. Associated with:
 - a. Dysarthria
 - b. Myoclonus
 - c. Seizures
 - d. Dysphagia
 - e. Asterixis
6. Dialysis patients:
 - a. Uremic encephalopathy
 - b. Dialysis disequilibrium disorder
 - c. Associated:
 - i. Atherosclerosis
 - ii. Stroke
 - iii. Peripheral neuropathy
 - iv. Restless leg syndrome

Neuropathology

1. Subclinical hemorrhage is seen in 1–3% of patients
2. Generalized and variable neuronal loss
3. Perivascular necrosis and demyelination
4. Neuroanatomical areas of involvement:
 - a. Cerebral cortex
 - b. Subcortical brainstem nuclei
 - c. Cerebellum
5. Alzheimer type 2 astrocytes are prominent
6. Calcification of large and medium-sized blood vessels
7. Infarctions of both large and medium-sized cerebral vessels as well as widespread small vessel disease

Neuroimaging

1. MRI:
 - a. Uremic encephalopathy may cause irreversible posterior leukoencephalopathy
 - b. Basal ganglia involvement is rare
 - c. Supratentorial white matter involvement is rare
 - d. Calcification of extracranial blood vessels is common and often severe
 - e. Bilateral cytotoxic edema in the centrum semiovale

Laboratory Evaluation

1. Increased blood urea nitrogen and creatinine
2. Increased parathyroid hormone
3. Acidosis
4. X-ray of bones demonstrate severe osteoporosis
5. EEG:
 - a. Paroxysmal sharp waves and polyspikes

Hepatic Encephalopathy (HE)

General Characteristics

1. Hepatic encephalopathy (HE) may be minimal or overt and occurs with liver disease or portosystemic shunting
2. Overt HE presents with a wide phenotype from mild confusion to coma
 - a. Minimal hepatic encephalopathy may cause neurocognitive impairment in patients with cirrhosis and portal-systemic shunting that have a normal neurologic and psychiatric examination

Clinical Manifestations

1. Acquired hepatolenticular degeneration:
 - a. Occurs in patients that have had several episodes of hepatic encephalopathy; usually in cirrhotic patients
 - b. Subcortical type dementia
 - c. Falling backwards
 - d. Parkinsonism
 - e. Severe dysarthria
 - f. Choreoathetosis

Neuropathology

1. Patchy cortical laminar involvement with pseudolaminar necrosis
2. Polymicrocavitation at the corticomedullary junction and in the striatum
3. Diffuse Alzheimer type 2 astrocytosis
4. Neuronal loss in the cortex, cerebellum and basal ganglia
5. Ammonia has a central role in both hepatic encephalopathy and minimal hepatic encephalopathy; it is felt that other processes contribute to the neurocognitive deficits that include:
 - a. Infection
 - b. Oxidative stress
 - c. Manganese accumulation
 - d. Intestinal bacterial overgrowth
 - e. Benzodiazepine-like toxins

Laboratory Evaluation

1. Elevated systemic and CSF ammonia
2. EEG:
 - a. Triphasic waves

Neuroimaging

1. MRI:
 - a. High signal intensity in the globus pallidus in T1-weighted images (most often posited to increased tissue concentrations of manganese)
 - b. In some patients the hypothalamus and pituitary gland have shown high signal intensity
2. MR Spectroscopy (proton):
 - a. Elevated glutamine/glutamate peaks
 - b. Decreased myoinositol and choline signals

Thyroid Failure with Dementia

General Characteristics

1. Hypothyroidism is one of the most important causes of treatable dementias
2. Psychosis is occasionally an associated manifestation and is termed myxedema madness
3. Other specific forms of thyroid disease with dementia are:
 - a. Hashimoto's encephalopathy
 - b. Apathetic hyperthyroidism

Clinical Manifestations of Myxedema

1. Lethargy and bradyphrenia
2. Psychotic behavior that ranges from depression to severe agitation
3. Most often in a setting of severe long standing hypothyroidism
4. Subcortical dementia
5. Associated neurologic signs and symptoms:
 - a. Proximal myopathy
 - b. Ataxia (Purkinje cell loss)
 - c. Hearing loss
 - d. Rarely facial pain (mucopolysaccharide deposition in the Vth nerve)
 - e. Bilateral carpal and tarsal tunnel syndromes
 - f. Sensorimotor neuropathy
 - g. Delayed relaxation phase of reflexes
 - h. Scleromyxedema:
 - i. Generalized popular eruption
 - ii. Dermal fibroblast proliferation
 - iii. High fever
 - iv. Seizures
 - v. Coma

Hashimoto's Thyroiditis

General Characteristics

1. Hashimoto's encephalopathy is an encephalopathy that is posited to be autoimmune and associated with high titers of antithyroid peroxidase antibodies
2. It is more common in women than men and may be seen in pediatric, adult and elderly patients

Clinical Manifestations

1. Often a relapsing and remitting course that includes:
 - a. Seizures
 - b. Stroke-like episodes
 - c. Neuropsychiatric disorders
 - d. Myoclonus
 - e. Progressive cognitive decline
 - f. Response to corticosteroids
 - g. Peak incidence is between 45–65 years of age

Neuropathology

1. The disorder depends on an immune defect in a genetically susceptible patient triggered by environmental factors

2. Gradual atrophy of thyroid tissue due to lymphocytic cell invasion
3. Follicular atrophy
4. Oncocytic metaplasia of follicular cells

Laboratory Evaluation

1. Elevated antibody titers against thyroid tissue that include:
 - a. Anti-TPO (thyroperoxidase)
 - b. Anti-Tg (anti-thyroglobulin)
 - c. Rarely TSH-stimulation blocking antibody (TSBAbs)
 - d. The antibody titers often correlate with an increased inflammatory reaction in the thyroid parenchyma and resultant hypothyroidism
 - e. Inflammatory cytokines are detected in thyroid follicular cells
 - f. Increased CSF protein
 - g. EEG:
 - i. Severe slowing

Hypothalamic-Pituitary Disorders

General Characteristics

1. Usually associated with symptoms due to endocrine dysfunction prior to neurological features

Clinical Manifestations

1. Adrenal failure:
 - a. Personality change
 - b. Apathy
 - c. Cognitive impairment
 - d. Severe fatigue (asthenia)
 - e. Flexed posture
 - f. Thin muscles
 - g. Abnormal body mass index and decreased growth velocity in children

Neuropathology (Causes)

1. Craniopharyngioma
2. Optic pathway glioma
3. Suprasellar arachnoid cyst
4. Germ cell tumor
5. Astrocytoma

Neuroimaging

1. MRI:
 - a. To evaluate intracranial lesions

Laboratory Evaluation

1. Increased potassium concentration and decreased sodium concentration in the serum
2. Depressed thyroid and gonadal hormones; decreased growth hormone
3. ACTH and cortisol levels are low

Adrenal Insufficiency

General Characteristics

1. Primal adrenal insufficiency:
 - a. 80% are secondary to autoimmune mechanisms
2. Secondary adrenal insufficiency:
 - a. Most common cause in the West is exogenous steroid use (in general at least 3 weeks of >25 mg hydrocortisone/day with an inadequate taper)
3. Tertiary adrenal insufficiency:
 - a. Due to hypothalamic disease and decrease in corticotrophin releasing hormone (CRH)

Clinical Manifestations

1. Medical signs and symptoms:
 - a. Hypoglycemia
 - b. Weight loss
 - c. Dehydration
 - d. Hypotension
 - e. Nausea, vomiting
 - f. Diarrhea
 - g. Associated goiter and vitiligo
 - h. Hyperpigmentation of buccal mucosa, scars and skin creases
2. Decreased cognition is most often due to concomitant thyroid or electrolyte disturbances

Neuropathology

1. Adrenal dysgenesis:
 - a. Mutations of the SF1 transcription factor
 - b. Congenital adrenal hypoplasia (CAH) due to DAX-1 gene mutations
 - c. Mutation of the ACTH receptor gene or Triple A gene
 - d. DAX-1 may be a component of concomitant gene mutations that include glycerol kinase deficiency
2. Impaired synthesis:
 - a. Smith-Lemli-Opitz syndrome and abetalipoproteinemia impair the delivery of cholesterol from which cortisol is synthesized
 - b. 21-hydroxylase, 11 β -hydroxylase, 17 β -hydroxylase, 3 β -hydroxysteroid dehydrogenase and lipoid CAH congenital adrenal hypoplasia (due to STAR and DNA mutations) are the major enzymatic deficiencies that cause failure of synthesis
3. Destruction of the adrenal gland:
 - a. Autoimmune adrenalitis (immune impairment of 21-hydroxylase) can be isolated or occurs with autoimmune polyendocrine syndrome type 1 or 2
 - b. Adrenoleukodystrophy
 - c. Waterhouse-Friderichsen syndrome
 - d. Antiphospholipid syndrome
 - e. Tuberculosis, coccidioidomycosis and histoplasmosis
 - f. Amyloidosis

Laboratory Evaluation

1. Serum cortisol, ACTH, aldosterone, renin, potassium and sodium concentration

2. CT of the adrenal gland
3. MRI of the pituitary
4. ACTH simulation test
5. 21-hydroxylase autoantibody test for Addison's disease

Hyperthyroidism

General Characteristics

1. Thyrotoxicosis is caused by the secretion of excess thyroid hormone from any cause
2. Grave's disease causes 50–80% of hyperthyroidism in the USA; possibly 1% of the population is affected

Clinical Manifestations

1. May be asymptomatic
2. Increased heat rate
3. Hyperhidrosis
4. Thinning of the skin
5. Brittle hair
6. Increased bowel movements
7. Weight loss
8. Menstrual cycle abnormalities
9. Heat intolerance
10. Neurologic complications:
 - a. Anxiety and depression
 - b. Proximal myopathy
 - c. Sleep disruption
 - d. Tremor
 - e. Cognitive impairment (inattention)
 - f. Panic attacks
 - g. Panic and paranoia (rare)
 - h. Periodic paralysis (primarily Asian patients)
 - i. Associated with myasthenia gravis
11. Ophthalmopathy:
 - a. Pathologic lid retraction
 - b. Exophthalmos
 - c. Extraocular muscle weakness
 - d. Eye muscle swelling
 - e. Lid lag and failure of convergence

Neuropathology

1. Thyroid inflammation (Hashimoto's leading to hypothyroidism) and subacute (De Quervain's) inflammation
2. Exogenous consumption
3. Amiodarone (can cause hyper- or hypothyroidism)
4. Post-partum thyroiditis
5. A struma ovarii
6. Excess iodine consumption (kelp algae)
7. Pituitary edema with increased TSH

Laboratory Evaluation

1. TSH (low)
2. Increased T3 and T4
3. Anti-TSH-receptor antibody in Grave's disease; anti-thyroid peroxidase antibodies in Hashimoto's disease
4. Thyroid scintigraphy

Hyperparathyroidism

General Characteristics

The neurologic manifestations of parathyroid disease are associated with serum calcium levels:

1. Hyperparathyroidism is caused by excessive PTH (parathyroid secretion in respect to calcium homeostasis)
2. Familial forms of the disease are caused by mutations in:
 - a. MEN gene for type 1 disease and RET gene for MEN (multiple endocrine neoplasia) type 2 disease
 - b. Calcium-sensing receptor gene for familial hypocalcemic hypercalcemia
 - c. Parafibromin (HRP2 oncosuppressor gene) for PHPT-jaw tumor and carcinoma
 - d. 80% of patients have sporadic adenomas most commonly found with mutation of the menin gene for activation of the PRAD1 oncogene
 - e. Rarely HRPT2 and CASR gene mutations

Clinical Manifestations

1. Bone involvement is more prominent at skeletal sites that have an increased concentration of cortical tissue; trabecular skeletal sites are relatively spared
2. General medical signs and symptoms are primarily due to hypercalcemia and include:
 - a. Fatigue
 - b. Anorexia
 - c. Thirst
 - d. Polyuria
 - e. Kidney stones
 - f. Constipation
 - g. Peptic ulcer

Neurologic Manifestations

1. Psychiatric disorders
2. Patients with bipolar disorder on long term lithium may become hyperparathyroidotic (usually caused by a single adenoma)
3. Muscular weakness (proximal)
4. Cognitive impairment with encephalopathy
5. Bone pain
6. Muscle soreness
7. Secondary hyperparathyroidism:
 - a. Due to hypocalcemia from vitamin D deficiency (decreased calcium absorption from the intestine)
8. Chronic renal disease:
 - a. Failure to convert vitamin D to its active form (occurs in the kidney)

Neurologic Manifestations of Hypocalcemia

1. Cognitive impairment
2. Neuromuscular irritability:
 - a. Chvostek's and Trousseau's sign
 - b. Hyperactive reflexes
3. Seizures
4. Asterixis
5. Basal ganglia dysfunction

Neurologic Manifestations of Hypercalcemia

1. Lethargy progressing to stupor
2. Early stages poor cognitive function primarily that of a subcortical dementia
3. Associated neurologic features:
 - a. Absent reflexes
 - b. Absent bowel sounds
 - c. Very rare pseudo ALS syndrome
 - i. Fasciculating tongue
 - ii. Proximal muscle weakness
 - iii. Hyperactive reflexes
 - iv. Associated with primary hyperparathyroidism

Neuropathology

1. Primarily hyperparathyroidism is caused by oversecretion of PTH from:
 - a. Parathyroid adenoma
 - b. Parathyroid hyperplasia
 - c. Rarely as a component of multiple endocrine neoplasia (MEN) syndrome
2. Secondary hyperparathyroidism:
 - a. Vitamin D deficiency
 - b. Malabsorption (from the intestine)
 - c. Chronic renal failure

Laboratory Evaluation

1. Parathyroid immunoassay:
 - a. PTH is elevated or inappropriately normal in the face of an elevated calcium concentration
2. Increased serum calcium levels with abnormally low serum phosphate due to decreased renal tubular phosphate reabsorption
 - a. In secondary hyperparathyroidism the phosphate may be elevated due to renal disease
3. Alkaline phosphatase is usually elevated in primary hyperparathyroidism
4. Parathyroid scan

Diabetes*General Characteristics*

1. Astrocytes convert glucose into lactate and transfer it to neurons that is essential for neuronal metabolism, the formation of synapses, dendrites and the expression of genes that are involved in memory
2. Severe hyperglycemia is associated with alterations in osmotic pressure and diabetic ketoacidosis may cause cerebral edema

Clinical Manifestations

1. Cognitive impairment and dementia have recently been posited to be complications of diabetes mellitus
2. Obesity and insulin resistance may increase the risk of both vascular dementia and possibly Alzheimer's disease

Neuropathology

1. Chronic hyperglycemia and hyperinsulinemia cause the formation of advanced glycation end products (AGEs) that cause overproduction of reactive oxygen species
2. Insulin is neurotrophic at normal concentrations but at higher concentrations may impair amyloid-beta clearance from alterations in insulin degrading enzyme availability. This is posited to be a component of the A β amyloid clearing mechanism. Glucose has a much higher affinity for the enzyme
3. Hyperglycemia and hyperinsulinemia may accelerate brain aging by:
 - a. Microangiopathy
 - b. Induction of tau hyperphosphorylation
 - c. Amyloid oligomerization
4. Diabetic patients have a higher propensity to develop leukoaraiosis that is associated with cognitive impairment
5. Pathologic hyperglycemia may induce:
 - a. Mitochondrial production of free radicals
 - b. Oxidative stress
 - c. Activation of neuronal apoptosis
 - d. Increased proinflammatory cytokines may be produced during insulin resistance that may cross the BBB to induce inflammation
 - e. Glycogen-synthetase kinase (GSK-3) is increased in diabetes and is a component of the regulation of tau phosphorylation and A β peptide production

Laboratory Evaluation

1. Hyperglycemia and insulin resistance
2. High metabolic index

Neuroimaging

1. MRI:
 - a. Large and small vessel atherosclerosis
 - b. Microangiopathy
 - c. Leukoaraiosis

Episodic Hypoglycemia*General Characteristics*

1. Hypoglycemia is most often encountered in patients with poorly controlled diabetes mellitus that are utilizing insulin
2. Extremely rarely it is caused by an insulinoma
3. Hypoglycemia occurs in a setting of hepatic and renal insufficiency, starvation and rarely with suicide attempts (medical personnel)

Clinical Manifestations

1. Multiple episodes of seizures and coma lead to the neurological sequelae
2. Gradual deterioration of cognitive function
3. Associated with:
 - a. Motor neuropathy
 - b. Ataxia
 - c. Involuntary movements

Neuropathology

1. Neuroanatomical areas of neuronal loss:
 - a. Neocortex layers III–VI
 - b. Purkinje cells
 - c. Globus pallidus internus
 - d. Anterior horn cells

Laboratory Evaluation

1. Episodic hypoglycorrhachia (CSF) with blood sugar concentration of less than 30 mg/dl

Neuroimaging

1. MRI (head):
 - a. To rule out bacterial, fungal or tuberculosis meningitis

Differential Diagnosis of Hypoglycorrhachia in Adult Patients (Tertiary Center)

1. Bacterial meningitis:
 - a. Most often in patients following neurosurgical procedures
2. Stroke and hemorrhage
3. Carcinomatosis
4. Lymphoma and leukemia
5. Immunosuppressed patients more likely to have fungal meningitis
6. Sarcoidosis
7. Viral meningitis:
 - a. Herpes simplex
 - b. Mumps
 - c. Enterovirus
8. GLUT1 deficiency
9. Neurosyphilis:
 - a. May not affect the CSF sugar

Cushing's Syndrome*General Characteristics*

1. Definition:
 - a. Cushing's disease or pituitary dependent Cushing's syndrome is caused by a corticotroph pituitary tumor and accounts for approximately 70% of chronic endogenous hypercortisolism
 - b. Cushing's disease is caused by increased secretion of cortisol from the adrenal glands due to excessive ACTH stimulation from a pituitary tumor. The usual tumor is a pituitary adenoma
 - c. Microadenomas account for 90% of patients; macroadenomas account for 10%; rarely pituitary carcinoma is causative
 - d. The incidence of CD is 1.2 to 2.41 million of the population/year
 - e. CD is three times more prevalent in women than men

Clinical Manifestations

1. Medical complications:

- a. Weight gain with central obesity
- b. Fatigue
- c. Proximal myopathy
- d. Thin skin with purple striae
- e. Medical comorbidities:
 - i. Arterial hypertension
 - ii. DM
 - iii. Dyslipidemia
 - iv. Osteoporosis
 - v. Depression
 - vi. Impaired sexual function in men
 - vii. Menstrual irregularities in women
2. Neurocognitive disorders:
 - a. Neurocognitive impairment occurs in:
 - i. The memory domain
 - ii. Visual and spatial abilities
 - iii. Executive function
 - iv. Verbal learning
 - v. Language domains

Neuropathology

1. Decreased brain and hippocampal volume
2. Nuclei involved in cognitive functions have a high density of glucocorticoid receptors
3. Endogenous Cushing's syndrome is caused by:
 - a. Pituitary adenoma that causes excess adrenocorticotrophic hormone secretion
 - b. Increased secretion of corticotropin releasing hormone (CRH)
 - c. Adrenocortical tumors or hyperplasia
4. Exogenous Cushing's syndrome:
 - a. Iatrogenic steroid administration

Lysosomal Storage Disorders and Dementia***Overview***

There are more than 50 lysosomal storage disorders primarily arising from abnormal function of lysosomal enzymes. They are caused by genetic mutations which cause a decreased or lack of activity of proteins that belong to four functional groups:

1. Acid lysosomal hydrolases that degrade macromolecules
2. Proteins that are involved in lysosomal transport
3. Proteins that deliver enzymes into lysosomes
4. Activation of lysosomes

These deficiencies cause complete or partial failure of degradation of macromolecules which accumulate in lysosomes with consequent physiologic and pathologic dysfunction in cells, tissues and organs. The lysosomal storage diseases are autosomal recessive with 3 exceptions: 1. Fabry's disease and Hunter's disease (mucopolysaccharidosis type II) that are X-linked recessive diseases and 2. Danon disease which is an X-linked dominant disorder.

Lysosomal function is a component of the endosomal-lysosomal system. This system accomplishes the internalization, recycling, transport and decomposition of cellular and extracellular molecules as well as dissociating receptor ligand bonds. The lysosome is the major component of endocytic and phagocytic enzymes that are found in both endosomes and lysosomes but are more effective in the latter due to its greater acidity.

Lysosomal enzymes are synthesized in the rough endoplasmic reticulum, are N-glycosylated and enter the Golgi compartment and, through a series of actions, acquire the M6P ligand. The receptor protein complex then enters the late endosomes where the final steps of proteolysis, folding and aggregation occur.

Adult Lysosomal Disorders with Dementia

GM1 Gangliosidosis

General Characteristics

1. GM1-Gangliosidosis is autosomal recessive and is caused by mutations in the GLB1 gene that maps to chromosome 3p22.3
2. The 3 major variants are:
 - a. Infantile form (Type I)
 - b. Late infantile form (Type II)
 - c. Adult onset (Type III)
3. Mutations in both the infantile and adult forms interfere with the phosphorylation of precursor beta-galactosidase. The precursor is secreted instead of being compartmentalized into lysosomes and processed further

Clinical Manifestations (Adult Form)

1. Onset may be in the first decade (3–30 years of age)
2. Slowly progressive
3. Dystonia
4. Spasticity
5. Ataxia
6. Myoclonus
7. Cognitive impairment
8. No visual involvement

Neuropathology

1. Minimal storage of gangliosides in the cerebral cortex
2. Atrophy of the caudate, putamen and globus pallidus (neuronal loss with gliosis)
3. Meganeurite formation is noted in the basal ganglia and pyramidal neurons of the cortex
4. The stored ganglioside is PAS-positive
5. No vacuolated lymphocytes

Laboratory Evaluation

1. Vacuolated lymphocytes are described in Type I but not in Type III

Neuroimaging

1. MRI:

- a. Progressive atrophy in the cerebrum and cerebellum
2. Quantitative MRS:
 - a. Deficit of N-acetyl aspartate in both late infantile and juvenile patients

GM2 Gangliosidosis

General Characteristics

1. The GM2 gangliosidosis are three related genetic diseases that are caused by a deficiency of the enzyme beta-hexosaminidase. They are:
 - a. Tay-Sachs disease:
 - i. Mutation of the HEXA gene that maps to chromosome 15q23 and causes a deficiency of hexosaminidase A
 - b. Sandhoff disease:
 - i. Mutations in chromosome 5 of the HEXB gene
 - ii. Encodes the lysosomal enzymes beta-N-acetyl hexosaminidase A & B
 - c. AB variant:
 - i. Mutations in the GM2A gene cause this variant that maps to chromosome 5
 - ii. Encodes an enzyme cofactor in the GM2 activator that is essential for the function of beta-hexosaminidase A

Clinical Manifestations

1. Infantile form (all types have similar signs)
 - a. Onset at 3–6 months of age with developmental delay
 - b. Cognitive impairment
 - c. Macrocephaly
 - d. Exaggerated startle response
 - e. Blindness
 - f. Cherry red spot in the retina
 - g. Seizures
2. Juvenile onset:
 - a. Spinocerebellar symptoms

Hexosaminidase A Deficiency in Adults (Type B)

General Characteristics

1. Mutations in the alpha-subunit that causes failure of association with the beta-subunit
2. Low hexosaminidase A activity

Clinical Manifestations

1. Slowly progressive deterioration from early childhood
2. Cognitive impairment
3. Ataxia
4. Dysarthria
5. Recurrent psychotic episodes
6. No seizures
7. The most common presentation is motor neuron disease
8. No ocular abnormalities
9. Peripheral neuropathy

Neuropathology

1. Large increase of GM2 ganglioside in neurons

- a. Less storage in the cortex of ganglioside than is seen in the infantile or juvenile forms
- b. Storage in the brainstem, cerebellum, basal ganglia and the spinal cord
- c. Concomitant lipofuscin storage

Laboratory Evaluation

1. Molecular genetic testing (MGT)
2. Absent to near absent HEXA enzymatic activity in the serum

Kufs Disease

General Characteristics

1. Kufs disease is an adult onset neuronal ceroid lipofuscinosis that is genetically heterogeneous
2. Mutations in the gene CLN6:
 - a. Autosomal recessive inheritance
 - b. Maps to chromosome 15q23
3. The type A phenotype of mutation in CLN6 gene causes progressive myoclonic epilepsy while type B is associated with dementia and motor dysfunction
4. Recent exome sequencing has revealed homozygous and compound heterozygous missense mutations in the CTSF gene that maps to chromosome 11q13.2
 - a. Encodes cathepsin F, a lysosomal cysteine protease
5. Mutations in the DNA JC5 gene that maps to chromosome 20q13.33 and causes dominant Kufs disease

Clinical Manifestations

1. The phenotype of CTSF/CLN3 of Kufs disease type B
 - a. Onset in the second and third decades
2. Cerebellar syndrome with tremor
3. Ataxia and dysarthria
4. Tonic-clonic seizure
5. Progressive cognitive impairment

Neuropathology

1. Diffuse cerebral atrophy
2. Neuronal loss and astrogliosis most severe in the cerebral cortex and cerebellum
3. Autofluorescent material in the cytoplasm of neurons in the cortex, thalamus, striatum, brainstem nuclei and Purkinje cells
4. Deposition in meganeurites of the basolateral amygdaloid complex
5. Storage may be in layers III–VI of the cerebral cortex
6. No vacuolated lymphocytes

Laboratory Evaluation

1. Sequence analysis reveals the CLN6 gene maps to chromosome 15q21-q23

Neuroimaging

1. MRI:

- a. Kufs disease type B (CTSF)
 - i. Brain volume reduction
 - ii. Periventricular deep white matter hyperintensities
 - iii. Atrophy of the corpus callosum
- b. Similar MRI alterations are seen in adult-onset neuroceroid lipofuscinosis due to mutation in DNAJ CS, CLN6 and CLN5 and patients with mutations in GRN

Niemann-Pick Disease

General Characteristics

1. Niemann-Pick disease type A is caused by mutation in the sphingomyelin phosphodiesterase-1 gene that maps to chromosome 11p15.4
2. Niemann-Pick disease type B is allelic
3. Both types A and B are caused by a deficiency of acid sphingomyelinase

Clinical Manifestations

1. Persistent early jaundice with an enlarged abdomen
2. Developmental delay
3. Hepatosplenomegaly
4. Related physical growth and mental development delay
5. Neurologic features:
 - a. Hypotonia
 - b. Rigidity
 - c. Severe cognitive impairment
 - d. Demise by 3 years of age
 - e. Cherry red spot
 - f. Corneal opacification and brown discoloration of the anterior lens capsule
6. Clinical features of Niemann-Pick Type B
 - a. Thrombocytopenia (most patients)
 - b. Leukopenia and anemia less common
 - c. Decreased HDL cholesterol
 - d. Decline in pulmonary function

Neuropathology

1. Sphingomyelin accumulates in:
 - a. Reticuloendothelial cells throughout the body
 - b. Increased sphingomyelin is found in the bone marrow, skin and amniotic cells
2. Slight brain atrophy in NP type A; the brains of type B patients are normal
3. Neuronal and glial ballooning
4. Gliosis and storage cells in the white matter
5. Foamy histiocytes that contain cholesterol esters are found in the globus pallidus, substantia nigra, and the dentate nucleus
6. Niemann-Pick cells (a foamy storage cell) are found in most organs
7. Ganglion cells of the CNS are affected

Laboratory Evaluation

1. Molecular genetic testing to identify the gene mutation
2. Cell culture that demonstrates increased sphingomyelin in bone marrow or skin cells

Adult Form of Niemann-Pick Disease Type C (NP-C)*General Characteristics*

1. NP-C is a neurovisceral lysosomal storage disease with an estimated incidence of 1/120,000 live births
2. NP-C has autosomal recessive inheritance and is caused by mutations in the NPC1 gene that maps to chromosome 18q11.2 (in 95% of families) or mutations in the NPC2 gene (occurs in 5% of families) and is mapped to chromosome 14q24.3
3. Niemann-Pick disease type D (the Nova Scotia type) is caused by mutation in the NPC1 gene
4. The exact function of the encoded proteins from the mutants is not known. It is posited that they are involved in post-lysosomal and late endosomal transport of cholesterol

Clinical Manifestations

1. Clinical features of NP-C are varied
2. The age of onset varies from the perinatal period to the seventh decade. The average age of onset in the adult form is 59 years of age
3. Systemic disease, if present, precedes the onset of neurologic signs and symptoms. Systemic symptoms may be absent or slight in 15% of patients
4. Cerebellar ataxia
5. Dysarthria and dysphagia
6. Progressive dementia
7. Vertical supranuclear gaze palsy
8. Dystonia occurs in 25% of patients
9. Cataplexy (with or without narcolepsy) often laughter induced
10. Seizures
11. Isolated splenomegaly and lung involvement
12. A psychiatric presentation may be isolated for years prior to the onset of motor and cognitive impairment and includes:
 - a. Schizophrenia-like psychosis with paranoid delusions
 - b. Depression
 - c. Bipolar disorder
 - d. Obsessive-compulsive behavior
 - e. Behavioral problems
 - f. Visual hallucinations and confusion
 - g. Symptom fluctuation
 - h. Aggravation by neuroleptic drugs
13. The adult form is dominated by cerebellar and extrapyramidal rather than pyramidal signs

Neuropathology

1. Impaired utilization and processing of endocytosed cholesterol is a major component in the pathogenesis
2. Sphingomyelin accumulation is related to lysosomal storage
3. Cholesterol accumulation in the late endosomal/lysosomal compartment may impair the trafficking of late endosomal proteins Rab 9 and mannose-6-phosphate receptors

4. Generalized neuronal and glial ballooning
5. Foamy histiocytes containing cholesterol esters are found in the globus pallidus, substantia nigra and dentate nucleus

Laboratory Evaluation

1. Molecular genetic testing that identifies the mutations
2. Low HDL-cholesterol is a frequent but not a diagnostic finding
3. Chitotriosidase activity is mildly elevated
4. Impaired intracellular cholesterol transport is a diagnostic test for NP-C usually accomplished with skin fibroblast culture. The filipin test is the most sensitive and specific assay. It is a compound that forms specific complexes with unesterified cholesterol. Fluorescent microscopic examination of NP-C positive cells reveals positive cholesterol filled perinuclear vesicles
5. Foam cells and sea-blue histiocytes may be present in the bone marrow

Neuroimaging

1. MRI:
 - a. The callosal area and its mean thickness are reduced most severely in the genu, posterior body, isthmus and anterior splenium
 - b. Lower corpus callosum fractional anisotropy, volume and cross-sectional area correlate with clinical symptomatology

Gaucher's Disease*General Characteristics*

1. Gaucher's disease Type III is the subacute form of neuronopathic Gaucher's disease. Type II is caused by a homozygous or compound heterozygous mutation in the GBA gene that maps to chromosome 1q22
2. The gene encodes acid beta-glucosidase

Clinical Manifestations

1. Phenotypic subgroups of Type III Gaucher's disease
 - a. Type IIIA:
 - i. Myoclonus and dementia
 - b. Type IIIB:
 - i. Early onset of isolated horizontal supranuclear gaze palsy with aggressive systemic disease
 - c. Seizures occur
 - d. Norrbotten type:
 - i. Described from the Norrbotten province of Sweden
 - ii. Onset was 2.5 years of age (8 months to 14.5 years)
 - iii. Severe phenotypic variability and course among patients
 - iv. Affected patients have short stature, normal intelligence and seizures (some patients). There is later development of abnormal eye movements
 - e. Bone pain due to vascular changes in the metaphysics of long bones
 - f. Collapse of vertebral bodies with spinal cord compression
 - g. Parkinsonism and mood disorder

Neuropathology

1. Gaucher cells are seen perivascularly
2. Neuronal loss in cortex layers III and V, the cerebellum and basal ganglia
3. Gaucher cell:
 - a. 20–100 μ m in size
 - b. Cytoplasmic fibular material is PAS-positive

Laboratory Evaluation

1. Anemia, leucopenia and thrombocytopenia are seen in the Norrbotten variant
2. Deficit in enzymatic activity of glucocerebrosidase in circulating leukocytes
3. Molecular genetic analysis; patients with the L444P mutation in the GBA gene have a high incidence of neuralgic disease

Metachromatic Leukodystrophy*General Characteristics*

1. Metachromatic leukodystrophy is caused by mutation in the arylsulfatase A gene (ARSA) that maps to chromosome 22q13
2. There are 5 allelic forms of MLD that include:
 - a. Late infantile
 - b. Juvenile
 - c. Adult
 - d. Partial cerebroside sulfate deficiency
 - e. Pseudo arylsulfatase A deficiency
3. There are 2 non-allelic forms:
 - a. MLD due to saposin 13 deficiency
 - b. Multiple sulfatase deficiency

Clinical Manifestations of the Adult Form

1. Symptoms begin after age 16 years of age. Most adult patients have onset between 20–30 years of age
2. Patients present with a subtle organic brain syndrome:
 - a. Impaired concentration
 - b. Memory dysfunction
 - c. Schizophrenic behavior
 - d. Emotional liability
3. Rare seizures
4. Spasticity
5. Unusual movements
6. Increased reflexes
7. A rare presentation may occur without psychiatric symptoms
8. Variant of arylsulfatase A gene mutation:
 - a. D281Y in an adult patient
 - b. Slowly progressive psychiatric and cognitive decline
9. Pseudodeficiency of arylsulfatase A:
 - a. Mutations occur within the gene
 - b. No disease produced
 - c. Two patients have been reported with abnormal neurological findings that have arylsulfatase A deficiency

Neuropathology

1. Loss of myelin throughout the brain
2. Neuronal deposition of sulfatide in:
 - a. The basal ganglia
 - b. Dentate nucleus
 - c. Brainstem nuclei
 - d. Spinal cord neurons
 - e. μ fibers are spared
3. Loss of myelinated fibers in peripheral nerves
4. Sulfatides are in macrophages and Schwann cells

Laboratory Evaluation

1. Molecular genetic evaluation to determine the mutation
2. EMG:
 - a. Demyelinating neuropathy
 - b. The gallbladder may be non-functional

Neuroimaging

1. MRI:
 - a. Symmetric signal abnormalities of the periventricular and centrum ovale that spares fibers
 - b. Regional measurement of cortical atrophy:
 - i. The cingulate and frontal lobes are most affected in the adult form (measured by age-related volumetry)
 - ii. Frontal white matter involvement correlates with decreased cingulate, insular and frontal lobe cortical thickness
 - iii. Cerebellar atrophy is most pronounced in patients with an adult presentation
 - iv. Thalamic volumetric loss is present early in the disease

Krabbe's Leukodystrophy*General Characteristics*

1. Krabbe's disease is caused by homozygous or compound heterozygous mutations in the galactosylceramidase gene (GALC) that maps to chromosome 14q31.3
2. It is an autosomal recessive lysosomal disease that affects the myelin of both the peripheral and CNS
3. The disorder presents as:
 - a. An infantile form
 - b. Late onset disorder
4. The gene encodes galactosylceramide beta-galactosidase

Clinical Manifestations (Late Onset Form)

1. May have very late onset (up to 84 years of age)
2. Gait abnormality
3. Progressive spasticity (tetraparesis)
4. Visual dysfunction
5. Cognitive impairment (50% of patients)
6. No seizures
7. Optic disc pallor
8. Pes cavus

Neuropathology

1. Gross loss of CNS myelin
2. Astrocytic gliosis
3. Globoid macrophages that generally surround blood vessels
4. In late onset patients the appearance of globoid cells may be delayed
5. Globoid cells are PAS-positive
6. The cortex may be relatively normal
7. Loss of neurons in the dentate nucleus and the inferior olives
8. Straight or curved tubule crystalloid inclusions in Krabbe's globoid cells

Laboratory Evaluation

1. Neurophysiologic studies:
 - a. 20% of patients have slow nerve conduction studies
 - b. Brainstem auditory evoked potential abnormalities are seen in 40% of patients
 - c. Approximately 1/3 of patients have an abnormal EEG
 - d. Molecular genetic evaluation to determine the mutation
 - e. Globoid cells in brain tissue, derived from monocytes-macrophage stem cells from the bone marrow that contain psychosine and galactosylceramide
 - f. Enzyme assay of leukocytes or fibroblasts
 - g. Increased CSF protein

Neuroimaging

1. MRI:
 - a. Involvement of parieto-occipital periventricular white matter

Mucopolysaccharidosis*General Characteristics (Adult Form)*

1. The mucopolysaccharidoses are disorders in which there is a deficiency of enzymes that metabolize glycosaminoglycans (CAGs) which are long chains of sugar carbohydrates
2. The lysosomal enzyme deficits result in storage of glycosaminoglycans within liposomes of most tissues
3. There may be early death or survival into adulthood in all forms

Clinical Manifestations (Adult Form)

1. Severe and mild disease for all the various forms
2. Hepatosplenomegaly
3. Coarse features
4. Mild to severe cognitive impairment
5. Skeletal changes that may cause spinal cord compression
6. Corneal clouding in type I, IV, VI and VII
7. Carpal tunnel syndrome
8. Cardiomyopathy
9. Aortic and mitral valve incompetence
10. Normal intelligence in Scheie, Morquio and Maroteaux-Lamy disease

11. Sanfilippo

- a. Severe behavioral disturbance
- b. No skeletal abnormalities

*Adult Forms of Mucopolysaccharidoses with Dementia***General Characteristics**

1. Hurler syndrome
 - a. The mutated gene is IDUA that maps to chromosome 4p16.3. The mutations are homozygous or compound heterozygous
 - b. The encoded enzyme is alpha-L-iduronidase
2. There is a wide range of phenotypic expression with 3 subtypes:
 - a. Hurler (MPS 1H)
 - b. Scheie (MPS IS)
 - c. Hurler-Scheie (MPS IH/5)
 - d. Hurler and Scheie are the most severe and least affected (respectively) with Hurler-Scheie being the intermediate phenotype

Clinical Manifestations

1. Children appear normal at birth and develop clinical symptomatology during early life
2. Coarse faces
3. Corneal clouding
4. Cognitive impairment
5. Hernias
6. Dysostosis multiplex
7. Hepatomegaly
8. Nervous system
 - a. Developmental delay
 - b. Chronic hearing loss
 - c. Head circumference at or above the 95th percentile

Neuropathology

1. Dura and leptomeninges may be thickened
2. Perivascular areas contain foamy cells
3. There may be severe neuronal storage of glycosaminoglycan throughout the brain
4. Associated with increased neuronal lipopigment

Laboratory Evaluation

1. Molecular diagnosis
2. Quantitative dimethylmethylene blue test for determination of heparin sulfate and dermatan sulfate in the urine

Neuroimaging

1. MRI: (children)
 - a. Cystic low signal lesions on T1-weighted sequences and high signal intensity lesions on T2-weighted sequences perivascularly
 - b. Myelination delay
 - c. Cerebral atrophy
 - d. Enlarged ventricles

Hunter's Syndrome*General Characteristics*

1. Hunter's syndrome is caused by mutation in the IDS gene that maps to chromosome Xq28
2. The gene encodes the liposomal enzyme iduronate sulfatase
3. It is a multisystem disorder

Clinical Manifestations

1. Airway obstruction
2. Skeletal deformities
3. Cardiomyopathy
4. Most patients succumb by the second decade although some survive into the fifth and sixth decade
5. Two major phenotypes:
 - a. Severe phenotype MPS IIA:
 - i. Progressive cognitive decline
 - ii. Systemic involvement with death by age 15
 - b. Mild form (MPS IIB):
 - i. Survival into adulthood
 - ii. Mild cognitive impairment
 - c. Lack of corneal clouding
 - d. Mild dysostosis (adult form)
 - e. Aortic regurgitation
6. Variable features:
 - a. Patients with a complete deletion of the IDS locus:
 - i. Atypical phenotype that includes:
 1. Ptosis
 2. Obstructive sleep apnea
 3. Seizures

Neuropathology

1. Storage of glycosaminoglycans within liposomes of most tissues and organs
2. Neuronal glycosaminoglycans storage; minimal cortical storage in mild cognitively impaired patients
3. Neuronal storage throughout the brain
4. Hepatic fibrosis

Laboratory Evaluation

1. Molecular genetic evaluation to detect the mutation
2. Urinary excretion of heparin and dermatan sulfates

Sanfilippo Syndrome Type IIIA*General Characteristics*

1. Mucopolysaccharidosis type IIIA is caused by homozygous or compound heterozygous mutations in the SGSH gene that maps to chromosome 17q25.3
2. There are 4 types of MPS III due to deficiencies of different enzymes:
 - a. Heparin N-sulfatase (type A)
 - b. Alpha-N-acetylglucosaminidase (type B)
 - c. Acetyl CoA: alpha-glucosaminide N-acetyl transferase (type C)
 - d. N-acetylglucosamine 6-sulfatase (type D)

Clinical Manifestations

1. Wide phenotype variability with delineation of a severe, intermediate and mild forms
2. Intermediate and mild types live into adulthood
3. Attenuated adult form:
 - a. Achieve speech and ability to walk
 - b. Behavioral disorder
 - c. Seizures
 - d. Upper airway infections
 - e. Death occurs usually by 18 years of age
 - f. Spasticity

Neuropathology

1. The accumulated glycosaminoglycan is heparin sulfate

Laboratory Evaluation

1. Molecular genetic analysis to determine the gene mutation
2. Urinary excretion of heparin sulfate
3. Radiologic evaluation of the extremities:
 - a. Persistent biconvexity of the vertebral bodies
 - b. Thick calvaria

Morquio Syndrome (IVB)*General Characteristics*

1. Mucopolysaccharidosis type IVB is caused by mutation of the GLB1 gene that maps to chromosome 3p22.3
2. Incidence of both type IVA and IVB in one patient per 75,000 of the population
3. The gene encodes beta-galactosidase
4. Inheritance is autosomal recessive
5. Mucopolysaccharidosis type IVA is caused by mutation of the GALN gene that maps to chromosome 16q24.3 and has overlapping phenotypic features with type IVB
6. MPS IVB is an autosomal recessive disorder

Clinical Manifestations

1. Normal intelligence
2. No central nervous system involvement
3. Spondyloepiphyseal dysplasia
4. Corneal clouding
5. Short stature

Neuropathology

1. No CNS involvement
2. Accumulated keratan sulfate

Laboratory Evaluation

1. Bone X-rays
 - a. Flattening of the vertebral bodies and femoral heads
 - b. Coxa valga
 - c. Absence or hypoplasia of the odontoid process
 - d. Abnormal metacarpal epiphyses
 - e. Narrowed phalanges
2. Molecular genetic evaluation
3. Deficient B-galactosidase in leukocytes
4. Increased urinary sulfate excretions

Maroteaux-Lamy Syndrome (MPS VI)*General Characteristics*

1. Maroteaux-Lamy syndrome is caused by homozygous or compound heterozygous mutation in the ARSB gene that maps to chromosome 5q14
2. The gene encodes arylsulfatase B

Clinical Manifestations

1. Severe skeletal dysplasia
2. Short stature
3. Kyphosis
4. Heart defects
5. Hepatosplenomegaly
6. Corneal clouding
7. Usually normal intelligence
8. Facial dysmorphism
9. Spinal cord compression (some patients with severe kyphosis)
10. Joint contractures

Neuropathology

1. Ligamentum flavum hypertrophy due to deposition of glycosaminoglycans with spinal stenosis at multiple levels
2. Demyelination of optic nerves (reported in some patients)

Laboratory Evaluation

1. Alder granulations may be present in neutrophils (reddish violet granulation by Wright stain)
2. Residual N-acetylgalactosamine 4-sulfatase in cultured fibroblasts
3. Increased urinary excretion of chondroitin sulfate

Neuraminidase Deficiency*Sialidosis Type I**General Characteristics*

1. Sialidosis type I is caused by homozygous or compound heterozygous mutation in the NEV gene that maps to chromosome 6p21.33
2. Inheritance is autosomal recessive
3. There is storage of sialylated glycopeptides and oligosaccharides due to a deficiency of neuraminidase
4. Type I has a less severe phenotype, it is also referred to as cherry red spot-myoclonus syndrome

Clinical Manifestations

1. Presentation is often in the second to third decade
2. Bilateral cherry red spots in the macula
3. Progressive visual loss
4. Myoclonus (cherry red spot myoclonus)
5. Corneal clouding
6. Punctuate opacities of the lens
7. Red-green color blindness
8. Ataxia
9. No hepatosplenomegaly
10. Cystic long bone changes
11. Alternating periodic nystagmus
12. Usually normal intelligence

Neuropathology

1. Minimal neuronal storage in the cortex
2. Some vacuolation of neurons in:
 - a. Cortex
 - b. Basal ganglia
 - c. Thalamus
3. PAS-positive foam cells in the marrow

Laboratory Evaluation

1. Urinary excretion of N-acetylneuraminic acid covalently linked to oligosaccharides or glycoprotein
2. Molecular genetic evaluation to detect the mutation

*Sialidosis Type II**General Characteristics*

1. Sialidosis type II is caused by mutations of the NEV1 gene that maps to chromosome 6p21.33
2. It is a more severe phenotype than type I

Clinical Manifestations

1. Earlier onset than type I, autosomal recessive inheritance
2. Coarse facial features
3. Pectus carinatum
4. Thoracic kyphosis
5. Progressive loss of vision
6. Corneal cloudiness
7. Bilateral macular cherry red spots
8. Deafness
9. Ataxia
10. Joint contracture
11. Cortical myoclonus

Neuropathology

1. Neuronal storage:
 - a. Brainstem
 - b. Anterior horn cells
 - c. Nucleus basalis of Meynert (substantia innominata)
2. Rectal biopsy
 - a. Lamellar inclusion bodies
3. Foam cells in the marrow

Laboratory Evaluation

1. Molecular genetic analysis
2. Cytoplasmic vacuolization of peripheral lymphocytes
3. Enzyme assay of cultured fibroblasts
 - a. Decreased oligosaccharide sialidase activity
4. Increased urinary excretion of N-acetylneuraminic acid covalently linked to oligosaccharides or glycoproteins
5. Radiography:
 - a. Dysostosis multiplex
 - i. Vertebral anomalies

Galactosialidosis (GSL)*General Characteristics*

1. Galactosialidosis is caused by mutation in the CTSA gene that maps to chromosome 20q.13.2

2. Inheritance is autosomal recessive
3. The gene encodes cathepsin A
4. It is a lysosomal storage disease that has a combined deficiency of beta-galactosidase and neuraminidase due to a defect in protein: cathepsin A
5. 3 subtypes have been delineated:
 - a. Early infantile
 - b. Late infantile
 - i. Both subtypes associated with early demise
 - c. Juvenile/adult type
6. The majority of patients are Japanese and have the juvenile/adult form of the disorder

Clinical Manifestations (Adult Subtype)

1. Wide phenotype spectrum
2. Variable levels of cognitive impairment
3. Angiokeratoma
4. Ataxia
5. Myoclonus
6. Cherry red macular lesions
7. Coarse facies
8. Skeletal dysplasia

Neuropathology

1. In this disorder, there is a dramatic increase of degradation of beta-galactosidase from a half-life of 10 days to 1 day
2. The increased degradation of both neuraminidase and beta-galactosidase is due to a deficiency in a glycoprotein that is posited to be necessary for activation or protection of the two enzymes
3. Atrophic brain
4. Loss of cortical neurons
5. Lipofuscin is accumulated in layers III, V and VI of the cortex
6. Demyelination in the CNS
7. Vacuolated lymphocytes
8. Foamy cells in the bone marrow
9. Stored material resembles membrane cytoplasmic bodies

Laboratory Evaluation

1. Molecular genetic analysis
2. Vacuolated lymphocytes in the peripheral blood and foamy cells in the bone marrow
3. Enzyme analysis of cultured fibroblasts
4. Electron microscopy of skin biopsy and peripheral blood lymphocytes demonstrate:
 - a. Membrane-bound fibrillogranular inclusions
5. Sialyloligosaccharides in the urine

Mucopolipidosis II

General Characteristics

1. MLD (mucopolipidosis II) alpha/beta, also known as I-cell disease is caused by a homozygous or compound heterozygous mutation in the GNPTAB gene that maps to chromosome 12q28.2

2. Inheritance is autosomal recessive
3. The gene codes for N-acetylglucosamine-1-phosphotransferase

Clinical Manifestations

1. Similar phenotype to Hurler syndrome
2. Cognitive impairment
3. Skull and skeletal deformities:
 - a. Congenital dislocation of the hip
4. Thoracic deformities
5. Hernia
6. Short stature
7. Restricted joint movement
8. Clear cornea
9. Intrauterine fracture
10. Inter- and intrafamilial variability
11. Cardiomegaly
12. Developmental delay

Neuropathology

1. Mutations of the N-acetylglucosamine-1-phosphotransferase complex from defects in the alpha and beta subunits leads to decreased mannose-6-phosphate synthesis. This is the marker on the oligomannosyl type glycan side chains of lysosomal enzymes which targets them to the lysosomes of connective tissue cells
2. This is a disorder of lysosome function rather than of storage of undegraded materials
3. Abnormal inclusions in fibroblasts in some patients

Laboratory Evaluation

1. Skeletal X-rays:
 - a. Osteopenia and dysostosis multiplex
 - i. Diaphyseal widening
 - ii. Shortening of the tubular bones
 - iii. Long tubal and ischial bones (some patients)
 - iv. First and second lumbar vertebral abnormalities
2. Molecular genetic analysis that documents mutations in the GNPTAB gene
3. Cytoplasmic inclusions
4. Increased oligosaccharide urinary excretion

Neuroimaging

1. MRI:
 - a. Brain atrophy in some patients

Mucopolipidosis III Alpha/Beta

General Characteristics

1. Mucopolipidosis III alpha/beta (pseudo-Hurler polydystrophy) is caused by mutation in the GNPTAB gene that maps to chromosome 12q23.2
2. The gene encodes the alpha/beta subunit precursor gene of GlcNAc-phosphotransferase
3. The mucopolipidosis III variant MLIII gamma is due to the GNPTG gene that encodes the gamma subunit
4. Inheritance is autosomal recessive

Clinical Manifestations

1. A less severe phenotype than the allelic disorder mucopolysaccharidosis type II alpha/beta
2. Development of dystrophic features similar to Hurler syndrome
3. Severely stiff joints
4. Flexion contraction in the fingers and toes; reduced mobility of the ankles, wrists, elbows, hips, shoulders and spine
5. Rare corneal clouding
6. Carpal tunnel syndrome
7. Mild cognitive deficits
8. Developmental delay

Neuropathology

1. The disorder is caused by a defect in lysosomal enzyme phosphorylation and localization
2. Empty vacuoles in bone marrow cells
3. Increased glycosaminoglycan of skin lesions; coarse collagen fibers that consist of type I, III, and VI collagen
4. Myelination is normal in both CNS and PNS
5. Primarily a mesenchymal disease

Laboratory Evaluation

1. Radiographic features:
 - a. Dysostosis multiplex
 - b. Trabecular osteopenia
 - c. Subperiosteal bone resorption
 - d. Increased biochemical indices of increased bone turnover
2. Elevated serum levels of lysosomal enzymes
3. Molecular genetic analysis

Mucopolysaccharidosis III Gamma (MDL III)*General Characteristics*

1. MLD III is inherited as an autosomal recessive disorder
2. MLD III gamma is caused by mutation in the gene GNPTG that maps to chromosome 16p13.3
3. The gene encodes the gamma subunit of N-acetylglucosamine-1-phosphotransferase

Clinical Manifestations

1. Childhood onset
2. Joint stiffness with pain in the shoulders, hips and fingers
3. Gradual coarsening of facial features
4. Cardiorespiratory complications:
 - a. Restrictive lung disease
 - b. Thickening and insufficiency of the mitral and aortic valves
 - c. Left ventricular hypertrophy
5. Mild cognitive impairment in some patients
6. No organomegaly
7. Genu valgum

Neuropathology

1. Recent studies posit that the gamma subunit is important in the maintenance of alpha and beta subunits in the GlcNAc-6-phosphotransferase complex

Laboratory Evaluation

1. Skeletal radiographs:
 - a. Hypoplastic iliac bones
 - b. Dysplasia of the proximal femoral epiphyses that causes coxa valga
 - c. Diaphyses of metacarpal and phalanges are shortened
 - d. Widening of the costochondral junction of the ribs
 - e. Generalized platyspondyly
2. Increased activity of lysosomal hydrolases in the serum
3. Molecular genetic analysis to delineate the mutation in GNPTG

Mucopolysaccharidosis IV*General Characteristics*

1. Mucopolysaccharidosis type IV is caused by homozygous or compound heterozygous mutation in the MCOLN1 gene that maps to chromosome 19p13
2. It encodes the lysosomal Ca(2+) efflux channel TRPML1 (transient receptor potential mucolipin 1 (MCOLN1))
3. Inheritance is autosomal recessive
4. The lysosomal hydrolases in MLIV are normal. The defect is one of transport along the lysosomal pathway that affects membrane sorting or the late steps of endocytosis. Recent evidence supports a mechanism in which the target of rapamycin (TOR) targets and inactivates the TRPML1 channel which alters autophagy
5. 80% of patients with the disorder are of Ashkenazi Jewish descent

Clinical Manifestations

1. No skeletal abnormalities
2. Developmental delay
3. Severe cognitive impairment
4. Less severe juvenile and adult patients:
 - a. Corneal clouding (some patients)
 - b. Cognitive impairment
 - c. Ataxia
 - d. Hepatosplenomegaly (some patients)
5. Variable features:
 - a. Achlorhydria
 - b. Mucosal inflammation and atrophy in the stomach

Neuropathology

1. Autophagic alteration due to aberrant regulation of the lysosomal Ca(2+) efflux channel TRPML1
2. Hypoplasia of the corpus callosum (absent rostrum, dysplastic or absent splenium)
3. Demyelination of white matter
4. Atrophy of the cerebrum and cerebellum in long standing diseased patients

5. Electron microscopy of skin biopsies:
 - a. Membranous cytoplasmic bodies in Schwann cells, blood vessel walls, smooth muscle fibers and sweat glands
6. Neuronal storage of PAS-positive granules in both the CNS and PNS
7. Membranous cytoplasmic bodies in endothelial cells of blood vessels

Laboratory Evaluation

1. Retinal pigment abnormalities (some patients) in the macula and retinal vessel attenuation consistent with VEP and ERP documented retinal dystrophy
2. Abnormal fibroblast inclusions may be noted in conjunctival biopsy

Mannosidosis Alpha B

General Characteristics

1. Alpha-mannosidosis is caused by homozygous or compound heterozygous mutation in the MAN2B1 gene that maps to chromosome 19p13.13
2. The new classification:
 - a. Type I:
 - i. The least severe phenotype
 - ii. Onset after age 10
 - iii. No skeletal abnormalities
 - iv. Slow progression
 - b. Type II:
 - i. Onset prior to age 10
 - ii. Skeletal abnormalities
 - iii. Slow progression
 - iv. Ataxia by age 20
 - c. Type III:
 - i. The severest phenotype
 - ii. Onset is early infancy
 - iii. Skeletal abnormalities
 - iv. Death from neurologic CNS deficits or myopathy

Clinical Manifestations (Type I)

1. Onset after age 10; often the second decade of life
2. Cognitive impairment
3. Deafness
4. Pectus carinatum
5. Thoracolumbar gibbus
6. Lens opacities
7. Gingival hypertrophy
8. Ataxia
9. Recurrent infections
10. Retinal degeneration

Neuropathology (Type II and III)

1. Vacuolization of neurons in:
 - a. Cerebral cortex
 - b. Brainstem
 - c. Spinal cord
 - d. Vacuoles in astrocytes and endothelial cells
 - e. Diffuse gliosis and loss of myelin

Laboratory Evaluation

1. MRI (Type I):
 - a. Cerebellar atrophy and periventricular hyperintensity on T2-weighted sequences
 - b. Molecular genetic analysis to delineate the gene mutation
 - c. Alpha-mannosidase activity is decreased in patient lymphoblasts
 - d. Increased urinary excretion of oligosaccharides
 - e. Vacuolated lymphocytes in the peripheral blood

Beta Mannosidosis

General Characteristics

1. Beta-mannosidosis (MANSB) is caused by homozygous or compound heterozygous mutation in the beta-mannoside gene (MANB) that maps to chromosome 4q24
2. The gene encodes beta-mannosidase
3. Inheritance is autosomal recessive

Clinical Manifestations

1. Severe cognitive impairment in most patients
2. Deafness
3. Mild dysmorphic features (some)
4. Angiokeratoma (some patients)
5. Peripheral neuropathy (1 patient)

Neuropathology

1. Gross vacuolization is seen in many cell types
2. Fibroblasts show vacuolization by electron microscopy

Laboratory Evaluation

1. Molecular genetic analysis to delineate the mutation
2. Vacuolated lymphocytes are not seen
3. Direct enzyme assay of fibroblasts

Fucosidosis

General Characteristics

1. Fucosidosis is caused by homozygous or compound heterozygous mutation of the FUCA1 gene that maps to chromosome 1p36.11
2. The gene encodes alpha-L-fucosidase
3. Inheritance is autosomal recessive

Clinical Manifestations

1. There are two types:
 - a. Infantile severe form with death during the first decade (Type 1)
 - b. Type 2 with a less severe phenotype
2. Adult clinical manifestations:
 - a. Facial dysmorphism similar to the mucopolysaccharidosis
 - b. Angiokeratomas
 - c. Cognitive impairment
 - d. Vascular tortuosities in the conjunctiva and retina
 - e. Dysostosis multiplex
 - f. Hypohidrosis and poor temperature regulation

Neuropathology

1. Enlarged or small brain
2. Neural ballooning in all brain structures; olivary nucleus, thalamus, and dentate nuclei in particular
3. Granulovacuolar storage in all organs
4. Foam cells in the bone marrow
5. White matter may demonstrate loss of myelin and gliosis
6. Rosenthal fibers may be seen
7. Marked vacuolation in vascular endothelial cells, fibroblasts and sweat glands
8. Lamellar inclusions and empty occlusions are seen in neurons, astrocytes and Schwann cells

Laboratory Evaluation

1. Molecular genetic analysis to delineate the mutation
2. Decreased ability to degrade fucose-containing blood group H and Lewis substances. Lewis A and B antigens are high in both red cells and saliva
3. Enzyme evaluation in cultured fibroblasts
4. Vacuolated lymphocytes in the blood

Aspartylglucosaminuria*General Characteristics*

1. Aspartylglucosaminuria is caused by mutation in the AGA gene that maps to chromosome 4q34.3
2. The disorder is classified as one of Finnish disease heritage and is autosomal recessive

Clinical Manifestations

1. Common in Finland
2. Severe cognitive impairment
3. Sagging coarse skin (particularly in the cheeks)
4. Joint laxity
5. Short stature
6. Dysostosis multiplex
7. Rare hepatosplenomegaly
8. Macroglossia
9. Excitable psychotic behavior in adults
10. Spondylosis/spondylolisthesis (3 adolescents)
11. Angiokeratoma (some patients)
12. Bacterial infections

Neuropathology

1. No consistent macroscopic changes in the brain
2. Cranial hyperostosis
3. Some patients have thickened and crenated mitral valves
4. Neuronal cytoplasm is filled with vacuoles in:
 - a. The cerebral cortex
 - b. Basal ganglia
 - c. Less evident in the brainstem
5. Neurons and glial cells contain increased lipofuscin

Laboratory Evaluation

1. Molecular genetic analysis to delineate the mutation
2. Urinary excretion of aspartylglucosamine

3. Body fluid and tissue accumulation of glycoasparagines that are glycoconjugates with an aspartylglucosamine moiety at the reducing end
4. Vacuolated lymphocytes

Sialuria*General Characteristics*

1. Sialuria is caused by heterozygous mutation of the GNE gene that maps to chromosome 9p13.3. It is autosomal dominant
2. The gene encodes uridine diphosphate-N-acetylglucosamine 2-epimerase (UDP-GlcNAc 2-epimerase)
3. Putative defective feedback inhibition of an enzyme that is involved in sialic acid synthesis

Clinical Manifestations

1. Occurs primarily in Finland
2. Onset most often in infancy
3. Severe cognitive impairment
4. Adults most often have an IQ of less than 30
5. Spasticity
6. Ataxia
7. Athetosis
8. Mild coarse facies
9. Hepatosplenomegaly
10. Developmental delay

Neuropathology

1. Gyral atrophy of the cerebral cortex; atrophy of cerebellar folia
2. Loss of cortical neurons, astrocytosis and increased lipofuscin
3. Occasional NFT (neurofibrillary tangles)
4. The thalamus, basal ganglia and spinal cord are involved to a varying degree
5. Lysosomal storage of free sialic acid
6. The metabolic defect has been posited to be a loss of sensitivity of the rate-limiting enzyme uridine diphosphate-N-acetylglucosamine 2-epimerase (UDP-GlcNAc) to feedback inhibition by cmp-NANA (in fibroblast cultured cells from patients)

Laboratory Evaluation

1. Massive excretion of free sialic acid in the urine
2. Molecular genetic analysis to delineate the mutation

Neuroimaging

1. MRI:
 - a. Reduction of white matter; normal cortical ribbon; thin corpus callosum

Fabry's Disease*General Characteristics*

1. Fabry's disease is caused by mutations in the GLA gene that maps to Xq22.1 which encodes alpha-galactosidase A

2. The enzyme defect leads to the accumulation of globotriaosylceramide and other related glycosphingolipids in cellular lysosomes
3. Heterozygous female patients have severe medical complications

Clinical Manifestations

1. Systemic:
 - a. Angiokeratoma corporis diffusum:
 - i. Punctate reddish purplish telangiectasia primarily in a bathing suit distribution
 - ii. Mucous membranes
 - iii. Rarely, they are absent
 - b. Proteinuria to renal insufficiency
 - c. Hypertrophic cardiomyopathy; mitral insufficiency
 - d. A variant:
 - i. Left ventricular hypertrophy with or without renal failure that develops in the sixth decade
 - e. Minor to major manifestations occur in female heterozygotes
 - f. Autonomic dysfunction:
 - i. Decreased sweating (may lead to severe hyperthermia)
 - ii. Decreased saliva and tear formation
 - iii. Decreased intestinal motility
 - g. Retinal, conjunctival and corneal abnormalities
 - h. Sensorineural hearing loss
 - i. Neurologic complications:
 - i. Mental deterioration from renal failure, cardiomyopathy and stroke
 - ii. Burning pain and paresthesia of the extremities (small fiber neuropathy)
 - iii. Small and large vessel stroke
 - iv. Severe hyperthermia

Neuropathology

1. Accumulation of globotriaosylceramide in the plasma and cellular lysosomes of vessels, peripheral small diameter nerve fibers and visceral organs
2. Foam cells are present in bone marrow aspirates
3. Accumulation of globotriaosylceramide and related glycosphingolipids in the:
 - a. Amygdala
 - b. Hypothalamus
 - c. Brain stem
 - d. Anterior horn cells
 - e. Brain pathology is related to the vascular pathology that leads to primarily small vessel infarcts
 - f. Involvement of the leptomeninges
 - g. Small fiber peripheral nerve involvement
 - h. Corneal involvement
 - i. Whorl-like corneal dystrophy:
 1. Corneal involvement is equal in males and females (a marker for female heterozygotes)
 - ii. Atabrine and amiodarone cause similar changes

Laboratory Evaluation

1. Molecular genetic analysis to delineate the gene mutation
2. Increased serum myeloperoxidase (MPO) levels in male patients
3. Defects in thyroid, gonadal, adrenal and growth hormone/insulin-like growth factor-1 (higher circulating TSH and ACTH circulating levels)
4. Marked increase of plasma lyso-Gb3 in hemizygotes at a young age; female heterozygotes demonstrate mild lyso-Gb3 increase in the plasma
5. Deficient activity of alpha-galactosidase in leukocytes in both affected males and heterozygote females
6. Urinary trihexoside assay
7. Biopsy demonstrates PAS-positive deposits in the walls of blood vessels which also stain with Luxol fast blue

Neuroimaging

1. MRI:
 - a. Ectasia of large cerebral arteries; particularly in the basilar artery
 - b. White matter hyperintensities throughout the cerebrum
 - c. Small vessel > large vessel infarction

Schindler Disease

General Characteristics

1. Schindler disease types I and III are caused by homozygous or compound heterozygous mutation in the alpha-N-acetylgalactosaminidase gene (NAGA) that maps to chromosome 22q13
2. There are three subtypes:
 - a. Type I:
 - i. An infantile onset neuroaxonal dystrophy
 - b. Type II (Kanzaki disease):
 - i. Adult-onset with angiokeratoma corporis diffusum and mild cognitive impairment
 - c. Type III:
 - i. Intermediate form with a less severe phenotype than Type I
 - ii. Inheritance is autosomal recessive
 - iii. The gene encodes alpha-N-acetylgalactosaminidase

Clinical Manifestations

1. Type I (infants/children):
 - a. Infantile onset neuroaxonal dystrophy
 - b. Pyramidal tract signs
 - c. Hypotonia
 - d. Myoclonus
 - e. Early visual impairment
 - f. Severe cognitive impairment
 - g. Seizures
2. Clinical manifestations of the adult form of the disorder Kanzaki disease:
 - a. Onset in the second or third decade

- b. Mild cognitive impairment
- c. Hearing loss (sensorineural)
- d. Peripheral neuropathy
- e. Angiokeratoma
- f. Facial dysmorphisms:
 - i. Enlarged tip of the nose
 - ii. Depressed bridge of the nose
 - iii. Thick lips
 - iv. Lymphedema

Neuropathology

1. Type I:
 - a. Neocortical and peripheral autonomic axons reveal:
 - i. Tubulovesicular and lamelliform membranous arrays
 - ii. Acellular clefts
 - iii. Electron-dense axoplasmic matrix
 - iv. Spheroids are detected by light and electron microscopy in terminal axons of gray matter consistent with an infantile form of axonal dystrophy
 - v. Vacuolization of fibroblasts in type 2

Laboratory Evaluation

1. Molecular genetic analysis to identify the mutation in the NACA gene
2. Decreased alpha-NAGA activity in cultured leukocytes, fibroblasts and in the plasma
3. Abnormal urinary oligosaccharide pattern

Neuroimaging

1. MRI (children):
 - a. Atrophy of the cerebellum, brainstem and cervical spinal cord

Type II Glycogenosis (Acid Maltase Deficiency)

General Characteristics

1. Glycogen storage disease 2 (GSD2) is caused by homozygous or compound heterozygous mutation in the GAA gene that maps to chromosome 17q25.3
2. The gene encodes acid alpha-1-4 glucosidase

Clinical Manifestations of Adult Onset Glycogen Storage Disease 2

1. Proximal muscle weakness
2. Severe involvement of the diaphragm which is manifest early in the course of the disease
 - a. Severe dyspnea in the supine position
 - b. Nocturnal dyspnea
 - c. Mechanical ventilation is required in severely affected patients
3. Lingual weakness and scapuloperoneal phenotype have been reported
4. Ectasia of cerebral blood vessels as well as Wolff-Parkinson-White syndrome and second-degree atrioventricular block has been reported

5. Many adult onset patients report mild muscular symptoms during childhood although muscle signs in adults occur primarily in the 3rd decade

Neuropathology

1. Glycogen is enclosed in lysosomal membranes rather than in the cytoplasm as is characteristic of other glycogen storage disorders
2. The mutation is posited to affect the production or degradation of the enzyme rather than its catalytic properties
3. Severe vacuolization of skeletal muscle, liver and vascular smooth muscle is noted
4. There is glycogen deposition in vascular smooth muscle
5. Skeletal muscle:
 - a. Is affected in both the infantile and late onset forms
 - b. Vacuoles are filled with soluble B particle glycogen
 - c. Type 2 muscle fibers are more affected than type 1
6. There is no neuronal glycogen storage in the adult form of the disorder

Laboratory Evaluation

1. Peripheral blood lymphocytes have discrete cytoplasmic vacuoles
2. Molecular genetic analysis to delineate the mutation in the GAA gene
3. Enzyme activity can be assessed from skin fibroblast cultures
4. Elevated CK (creatine kinase)
5. Alpha-glucosidase activity can be assessed in dried blood spots
6. Diminished plasma methylation capacity and elevation of insulin that lead to a chronic catabolic state

Farber's Disease

General Characteristics

1. Farber lipogranulomatosis is caused by homozygous or compound heterozygous mutation in the ASAHL gene that maps to chromosome 8p22
2. The protein encoded is acid ceramidase; inheritance is autosomal recessive
3. Acid ceramidase is also referred to as N-acylsphingosine amidohydrolase which catalyzes the synthesis and degradation of ceramide

Clinical Manifestations

1. There are 6 clinical subtypes
2. Patients with type 3 may live to the end of the second decade
3. Infantile form:
 - a. Onset is in the early months of life
 - b. Painful swelling of joints
 - c. Subcutaneous nodules over the affected joints
 - d. Hoarse cry (laryngeal involvement)
 - e. Feeding difficulty

- f. Irritability
- g. Hepatosplenomegaly in some patients
- h. Patients with type 2 and 3 have the longest survival
- i. Cognitive impairment is noted in the more severe patients
- j. Macular cherry red spot may be seen in some infantile patients

Neuropathology

1. Neuronal storage:
 - a. Swollen neurons and glia with non-sulfonated acid mucopolysaccharide
 - b. Brainstem
 - c. Basal ganglia
 - d. Anterior horn cells
 - e. Cortical neurons and those of the GI tract are involved to a lesser degree
2. Subcutaneous nodules
 - a. Formed by collections of foam cells
3. Zebra-like bodies are detected in neurons

Laboratory Evaluation

1. Molecular genetic analysis to identify the mutation in the *ASAHI* gene
2. Direct assay of skin fibroblasts demonstrates ceramidase deficiency
3. Lymph nodes demonstrate histiocytic infiltration that does not involve sinusoids which is typical for proliferative histiocytic disease

Wolman's Disease/Cholesteryl Ester Storage Disease

General Characteristics

1. Lysosomal acid lipase deficiency is caused by homozygous or compound heterozygous mutation of the *LIPA* gene that maps to chromosome 10q23.31
2. Inheritance is autosomal recessive
3. There are two phenotypes:
 - a. Wolman's disease
 - b. Cholesteryl ester storage disease (CESD)

Clinical Manifestations

1. Wolman's disease:
 - a. Diarrhea, vomiting, failure to thrive in infancy
 - b. Hepatosplenomegaly
 - c. Anemia and fever
 - d. Adrenal calcification
 - e. Death usually by 1 year

Neuropathology

1. Massive infiltration of the liver, spleen and other organs by:
 - a. Macrophages filled with cholesteryl esters and triglycerides
2. Less severe involvement of the skin, retina and CNS

Laboratory Evaluation

1. Foam cells occur in the bone marrow
2. Vacuolated lymphocytes in the peripheral blood
3. Diffuse punctuate calcification of the adrenal glands
4. Molecular genetic analysis to delineate the mutation in the *LIPA* gene
5. Enzyme activity can be quantified in cultured fibroblasts. It is reduced approximately 200 fold in Wolman's disease

Cholesteryl Ester Storage Disease

General Characteristics

1. CESD is caused by homozygous or compound heterozygous mutation in the lysosomal acid lipase gene (*LIPA*) that maps to chromosome 10q23.31. Inheritance is autosomal recessive
2. Primarily a visceral disease

Clinical Manifestations

1. Later onset than Wolman's disease
2. Wide phenotypic spectrum
3. Hepatitis-like illness
4. Pulmonary vascular obstruction in some patients
5. Atherosclerosis with cardiovascular complications
6. Liver disease:
 - a. Altered liver function with jaundice
 - b. Steatosis, fibrosis and cirrhosis
 - c. Secondary hypersplenism
 - d. Malabsorption

Neuropathology

1. Failure of intracellular hydrolysis of cholesteryl esters and triglycerides primarily in hepatocytes and macrophages that causes accumulation of these lipids in lysosomes
2. Some fibrillary gliosis of white matter, although the brain demonstrates no gross changes
3. Calcification of the deeper layer of the adrenal gland
4. Lipid-laden foamy cells of the mononuclear phagocyte system

Laboratory Evaluation

1. Molecular genetic analysis to demonstrate the mutation in the *LIPA* gene
2. Serum lipid profile:
 - a. High total serum concentrations of cholesterol
 - b. Increased serum low-density lipoprotein and triglycerides
 - c. Low serum concentration of high-density lipoprotein
3. Deficient LAL enzyme activity can be measured in peripheral blood leukocytes, fibroblasts and dried blood spots

Cystinosis

General Characteristics

1. Nephrotic cystinosis is caused by mutation in the cystinosis gene (*CTSN*) that maps to chromosome 17p13.2
2. It differs from other lysosomal diseases because acid hydrolysis is not a mechanism in the accumulation of cystine
3. The protein encoded is cystinosin, a cystine transporter

Clinical Manifestations

1. Infant nephropathic form:
 - a. Failure to thrive
 - b. Fanconi syndrome
 - c. Photophobia due to crystals within the conjunctiva and cornea
 - d. Depigmentation of the retina
 - i. Slight decrease in visual acuity
 - e. Fair complexion and light hair
 - f. Hypothyroidism by age 10
 - g. Many patients succumb in the first decade
2. Intermediate form:
 - a. Later onset of renal disease
 - b. Survival to age 30
3. Benign cystinosis:
 - a. No renal involvement
 - b. Corneal and retinal changes
4. Long term survivors (usually on dialysis)
 - a. Photophobia from both corneal and conjunctival deposition of cystine refractile material
 - b. Patchy retinopathy
 - c. Cognitive impairment
 - d. Myopathy (severe)
 - e. Oral motor dysfunction
 - f. Decreased tongue and lip strength; deficits in swallowing
 - g. Children with nephropathic cystinosis:
 - i. Inability to produce the normal amount of sweat:
 1. Heat intolerance
 2. Flushing
 3. Hyperthermia
 - h. Decreased pulmonary function at 21–40 years of age
 - i. CNS calcifications at 21–40 years of age
 - j. Retinal blindness, diabetes mellitus and hypogonadism between 18–40 years of age

Neuropathology

1. Cystinosis deficient proximal tubular epithelial cells have:
 - a. Abnormal shape and distribution of the endolysosomal compartments
 - b. Impaired endocytosis
 - c. Decreased surface expression of multiligand receptors
 - d. Delayed lysosomal cargo processing
2. Multifocal cystic neuronal and spongy change in the cerebrum (autopsy of a 28 year old)
3. Necrosis of the internal capsule and brachium pontis
4. Deposition of cystine crystals that is widespread and is mainly within the mononuclear phagocytic system

Laboratory Evaluation

1. Moderate to severe visual field constriction
2. Decreased rod-and-cone electroretinographic responses
3. Molecular genetic analysis to delineate the mutation in the CTNS gene

4. Increased concentration of free cystine in the leukocytes of patients
5. CT evaluation:
 - a. Cerebral atrophy

Differential Diagnosis of Lysosomal Storage Disease

Most of the lysosomal storage diseases have an adult form that will manifest seminal neurological features. They are rare and will be intermingled with other dementing illnesses that make their diagnosis difficult.

Outstanding neurological features that suggest these disorders are:

1. Facial dysmorphism
2. Corneal clouding
3. Cherry red spot in the retina
4. Spasticity
5. Skeletal dysplasia (dysostosis multiplex)
6. Myoclonic epilepsy
7. Adrenal dysfunction or calcification
8. Angiokeratoma
9. Cardiac valve dysfunction

GM1 gangliosidosis has the combination of dystonia, ataxia and spasticity. The adult form of GM2 (hexosaminidase A) deficiency presents as anterior horn cell disease. Behavioral and psychiatric episodes may be prominent. Niemann-Pick (sphingomyelinase) type C is striking due to the vertical gaze ophthalmoparesis that is seen. Gaucher's disease in adults is often suspected due to long bone changes, myoclonic epilepsy and bleeding. Metachromatic leukodystrophy should be suspected in an adolescent or young adult with psychiatric problems and spasticity.

Facial coarseness, corneal clouding, skeletal dysostosis with normal intelligence suggests Morquio, Schie or Maroteaux-Lamy disease. Deficiencies of neuraminidase (sialidosis I and II) are suggested by cherry red spot myoclonic epilepsy, cystic long bone changes, skeletal dysostosis and deafness. Galactosidases have myoclonic seizures and cherry red spots in the retina but angiokeratoma of the skin in addition. Abnormal joint mobility with corneal clouding, suggest mucopolidosis II and III. Angiokeratoma of the skin are distinctive and are seen in fucosidosis, sialidosis, galactosialidosis, and alpha-N-acetylglucosaminidase deficiency. Fabry's disease is the most commonly encountered disorder with this physical finding and demonstrates angiokeratoma in the bathing suit distribution. A common early complaint of these patients is burning hands and feet from small fiber neuropathy. They are heat sensitive due to hypohidrosis. Strokes at an early age and renal involvement are prominent.

The mucosulfatidoses have ichthyosis, retinitis pigmentosa, and corneal clouding.

Wolman's disease (patients die by one year most often) and cholesteryl ester storage disease are associated with calcification of the adrenal glands. The latter is also associated with accelerated atherosclerosis.

Adult Krabbe's disease has the unusual combination of spasticity and features of a demyelinating neuropathy with MRI involvement of the parietal lobe.

Kufs disease (neural ceroid lipofuscinosis) is suspected in a middle-aged patient with myoclonic epilepsy, dementia, and ataxia.

Differential Diagnosis of Lysosomal Storage Disorders Presenting as an Adult or Persisting into Adulthood

1. Metachromatic leukodystrophy
2. Krabbe's disease
3. Fabry's disease
4. Niemann-Pick disease
5. GM1 (gangliosidosis)
6. GM2 (gangliosidosis)
7. Gaucher's disease
8. Mucopolysaccharidoses
9. Salla disease
10. Cholesteryl ester storage disease

Peroxisomal Disorders

Overview

Peroxisomes are oxidative organelles found in the cytoplasm in most mammalian cells. They utilize molecular oxygen in oxidative reactions that generates hydrogen peroxide. They contain peroxidase (catalase) which, in conjunction with H₂O₂, oxidizes substrates.

Peroxisomal enzymes catalyze anabolic and catabolic reactions that include:

1. Plasmalogen synthesis, which are the most abundant phospholipids in myelin
2. Beta oxidation of very long chain fatty acids (VLCFA), the products of which are used in the biosynthesis of cholesterol and bile acids
3. Glyoxylate transamination
4. Pipecolic acid oxidation
5. Glutamic acid oxidation
6. Phytanic acid α -oxidation
7. Dolichol synthesis
8. Alcohol dehydrogenase

The peroxisome consists of a single membrane that encloses its matrix. It is a lipid bilayer with embedded peroxisome membrane proteins. The peroxisomal membrane proteins and matrix enzymes are encoded by nuclear genes that are synthesized and then imported into the peroxisome. Peroxisomal proteins involved in biogenesis are called peroxins and are encoded by PEX genes. The peroxisomal disorders are caused by:

1. Single enzyme deficiency
2. Biogenic disorders (defects in their assembly) PBDs

The peroxisomal biogenetic disorders (PBD) are associated with deficiencies of multiple peroxisomal enzymes and often

a decrease of peroxisomal number. Most peroxisomal disorders are associated with migration deficits, myelin alterations and neuronal degeneration. The non-neurological abnormalities are dysmorphisms, liver dysfunction and skeletal deficits. Laboratory diagnostic features are elevated VLCFAs and decreased RBC plasmalogens. The only peroxisomal disorder that does not have autosomal recessive inheritance is X-linked adrenoleukodystrophy.

Several mutations of each gene may occur and mutations of different genes may cause a similar phenotype.

Peroxisome Single Enzyme Defects of Adolescence and Adulthood

X-linked Adrenoleukodystrophy

General Characteristics

1. X-linked adrenoleukodystrophy is caused by mutation in the ABCD1 gene that maps to chromosome Xq28
2. The ABCD1 gene encodes the peroxisomal transporter ATP-binding cassette subfamily D member 1
 - a. The transporter imports very long chain fatty acid (VLCFA) esters across the peroxisomal membrane. Mutation of the ABCD1 gene impairs VLCFA degradation with their consequent accumulation in different lipids and body tissues
3. Approximately 95% of patients inherit the ABCD1 pathogenic variant from one parent while 4% of patients have a de novo mutation
4. Affected male patients transmit the disorder to all of their daughters and none of their sons. Females who inherit the pathologic variant are carriers and usually are only mildly affected. Males that inherit the mutated gene are affected
5. The three major phenotypes in affected males are:
 - a. Childhood cerebral form
 - b. Adrenal myeloneuropathy
 - c. Addison's disease (in isolation)
6. Subtypes occur within families and within kindreds
7. Manifesting female carriers occur in approximately 20% of patients (carriers)

Clinical Manifestations

1. Childhood cerebral form:
 - a. Onset between four and eight years of age
 - b. Progressive cognitive impairment
 - c. Attention deficit hyperactivity symptoms
 - d. Decreased vision, hearing and motor abilities
 - e. Severe disability within two years
2. Adolescent form:
 - a. Onset from 11–21 years of age
 - b. Dementia
 - c. Hearing loss
 - d. Visual deficits
 - e. Pyramidal tract signs and symptoms
 - f. Extrapyrmidal dysfunction
 - g. Cerebellar signs

- h. Adrenal insufficiency manifested by:
 - i. Increased pigmentation
 - ii. Episodic vomiting and diarrhea
 - iii. Hypotension
 - iv. Severe weakness and fatigue
- 3. Adult cerebral type:
 - a. Schizophrenia-like symptoms
 - b. Dementia
 - c. Spasticity
 - d. Aphasia
 - e. Auditory and visual deficits
 - f. Patients may or may not have adrenal insufficiency
- 4. Adrenal insufficiency without neurologic symptoms:
 - a. Patients have a high risk of late neurologic disease
 - b. Oldest patient described with Addison's disease is 78
- 5. Asymptomatic carriers of the genetic deficit with elevated VLCFA:
 - a. High risk of later neurologic symptoms and signs
 - b. Oldest patients are males between 60–70 years of age
- 6. Adrenoleukodystrophy female heterozygotes:
 - a. Female carriers of the gene defect may develop neurologic symptoms
 - b. Non-random X-chromosome inactivation that favors expression of the mutant allele is the postulated mechanism
 - c. The usual phenotype is that of adrenomyeloneuropathy (AMN)
 - d. Onset is in the fourth decade
 - e. Mild signs
 - f. Slowly progressive course

Adrenomyeloneuropathy

General Characteristics

1. Affects approximately 40–45% of patients with X-linked adrenoleukodystrophy

Clinical Manifestations

1. Onset is between 20–40 years of age
2. Slowly progressive
3. Approximately 50% of patients have cerebral involvement
4. Often presents with clumsiness and leg stiffness
5. Spastic paraplegia
6. Impotence and incontinence
7. Sparing of the upper arms
8. Adrenal insufficiency occurs in 60–70% of patients
9. Adrenal symptoms may precede neurological signs and symptoms
10. In 10–20% of patients brain involvement is rapidly progressive that causes severe behavioral disorders and cognitive impairment

Isolated Addison's Disease

General Characteristics

1. Affects approximately 10% of X-linked ALD

Clinical Manifestations

1. Males may present with signs of adrenal insufficiency from age 2 years to adulthood. The most common age at presentation is 7.5 years
2. Most often patients present with vomiting and/or severe weakness. Occasionally the presentation is coma
3. There is variable hyperpigmentation of the skin (particularly skin creases and scars)
4. Males whose initial presentation is adrenal insufficiency develop signs of AMN by middle age
5. Adrenal function is abnormal in approximately 90% of symptomatic boys and 70% of men with AMN
6. Adrenal function is usually normal in female carriers

Variable Presentations with X-Linked Adrenoleukodystrophy

General Characteristics

1. Unusual presentations are seen in approximately 5–10% of patients with X-linked adrenoleukodystrophy

Clinical Manifestations

1. Age four to 10 years but occasionally in adolescents and adults:
 - a. Headache
 - b. Increased intracranial pressure (pseudotumor cerebri)
 - c. Hemiparesis
 - d. Visual field deficits
 - e. Aphasia
 - f. Focal neurological deficits
2. Adult patients:
 - a. Progressive behavioral disorder
 - b. Dementia with spastic paraparesis
 - c. Neurogenic bladder
 - d. Gastrointestinal dysmotility
 - e. Progressive incoordination and ataxia
 - f. Impotence without associated other neurologic or endocrine deficits; usually in at risk males with a positive family history
 - g. No neurologic or endocrine dysfunction
 - h. Cerebellobrainstem dominant form of X-linked ALD
 - i. Presentation is characteristic of multiple system atrophy
3. The Zellweger spectrum is the most severe part of the X-linked ALD clinical spectrum and is composed of:
 - a. Zellweger cerebrohepatorenal syndrome (ZS)
 - b. Neonatal adrenoleukodystrophy (NALD)
 - c. Infantile Refsum's disease
4. These entities are due to mutations of PEX genes that cause abnormalities of peroxisome biogenesis

Pathology of X-Linked ALD

1. Diffuse myelin loss, lipid laden histiocytes and perivascular lymphocytic infiltrates
2. VLCFA accumulation has been postulated to activate microglia which enhance inflammatory demyelination
3. Cellular inclusions are trilamellar membranes that contain VLCFA cholesterol esters

4. A caudal rostral progression of the leukodystrophy
5. The occipital parietal and temporal lobes are most severely involved
6. Bilateral symmetrical lesions
7. Severe demyelination of:
 - a. Optic nerves
 - b. Fornix
 - c. Hippocampal commissure
 - d. Posterior cingulum
 - e. Corpus callosum
 - f. Internal capsule
 - g. Partial sparing of the subcortical arcuate fibers
8. The brainstem and spinal cord are less affected:
 - a. Involvement of descending tracts only
9. Neuropathology of AMN:
 - a. Brainstem (minimally involved)
 - b. Cerebellum (moderate involvement)
 - c. Lumbar corticospinal tracts (demyelinated)
 - d. Cervical fasciculus opacities
 - e. Dorsal spinocerebellar tracts (demyelinated)
 - f. Advancing demyelination
 - i. Axons are spared
 - ii. PAS-positive macrophages
 - g. Peripheral nerves:
 - i. Loss of large and small diameter fibers
 - h. Adrenal glands are atrophic
 - i. Electron microscopy:
 - i. Trilaminar bodies
 - ii. These inclusions may also be found in nerves, conjunctiva and skin

Laboratory Evaluation

1. Molecular genetic analysis to detect the hemizygous ABCD1 pathogenic variant
2. The plasma concentration of very long chain fatty acids (VLCFA) is abnormal in males with X-linked ALD
 - a. The parameters that are analyzed are:
 - i. Concentration of C26:0 fatty acids
 - ii. Ratio of C24:0 to C22:0 fatty acids
 - iii. Ratio of C26:0 to C22:0 fatty acids

Neuroimaging

1. MRI:
 - a. Symmetric enhanced T2 signal in the parieto-occipital area with contrast enhancement at the margin in approximately 86% of patients
 - b. The corpus callosum is involved
 - c. Minimal if any involvement of the arcuate fibers
 - d. Primarily posterior involvement of the cerebrum

Unusual Leukodystrophies That May Be Seen in Adulthood with Dementia

Pelizaeus-Merzbacher Disease (PMD)

General Characteristics

1. PMD is caused by mutation in the PLP1 gene that maps to chromosome Xq22

2. The gene encodes proteolipid protein-1
3. There is wide genetic heterogeneity in the hypomyelinating leukodystrophies (> than 12 delineated genes at present)
4. There are 3 types of PMD:
 - a. A classic infantile form:
 - i. Onset in infancy and death in late adolescence or early adulthood
 - b. Connatal type
 - i. Fatal in infancy or childhood
 - c. Transitional type
 - i. Intermediate in severity

Clinical Manifestations

1. Onset of nystagmus in infancy (horizontal with a torsional rotary component)
2. Stridor early in life (some patients)
3. Developmental delay
4. Ataxia
5. Seizures (some patients)
6. Optic atrophy by age 5 (some patients)
7. Death may occur at any age up to the fifth decade
8. Heterozygous females may be symptomatic

Neuropathology

1. Various proteolipid protein 1 mutations that include duplications, point mutations and deletions cause oligodendrocytic dysfunction that underlies PMD
2. The phenotypic spectrum is determined by the type of proteolipid mutation. Duplications usually have a milder classic form compared with missense mutations associated with the connatal type
3. The greatest risk in females is with nonsense or null mutations
4. Atrophic brain
5. Cerebellar atrophy
6. Loss of myelin with a tigroid pattern of residual myelin
7. Decreased numbers of oligodendroglia
8. Increased astrocytes

Laboratory Evaluation

1. Abnormal brainstem auditory potentials
2. Molecular genetic analysis to delineate the mutation of the PLP1 gene

Neuroimaging

1. MRI:
 - a. Macrogyria
 - b. Lack of myelination
 - c. Iron deposition in the basal ganglia
 - d. Brain and cerebellar atrophy
2. Magnetic resonance spectroscopy
 - a. Increased concentrations of N-acetyl-aspartate
 - b. N-acetylaspartylglutamate, glutamine, myoinositol, creatine and phosphocreatine in affected white matter

3. Decreased choline-containing compounds
4. The white matter analysis is consistent with:
 - a. Increased neuroaxonal dystrophy
 - b. Astrogliosis
 - c. Decreased oligodendroglia
 - d. Hypomyelination
5. MRI of obligate carriers:
 - a. Periventricular and subcortical white matter hyperintensities

Pelizaeus-Merzbacher-Like Disease (PMLD)

General Characteristics

1. PMD-like disease is caused by homozygous or compound heterozygous mutation of the GJC2 gene that maps to chromosome 1q42.13
2. The gene encodes the gap function protein connexin 47 (CX47)
3. Inheritance is autosomal recessive
4. The protein is highly expressed in oligodendrocytes

Clinical Manifestations

1. Nystagmus
2. Developmental delay
3. Progressive spasticity
4. Ataxia
5. A CJC2 missense mutation causes a milder phenotype
 - a. AR spastic paraplegia type 44
6. Usually less cognitive and motor deficits than classic PMD although one variant is very severe and resembles congenital PMD

Neuropathology

1. Similar to PMD

Laboratory Evaluation (GJC2 Mutation)

1. Brainstem auditory evoked potentials deficits are less severe than in patients with classic PMD
2. Waves III, IV and V (generated in the pons and midbrain) are recordable in PMD-like disease but are usually absent in PMD
3. Delay in visual and somatosensory evoked potential conduction
4. Mild peripheral nerve conduction delay in some patients with PMD-like disorder and is normal in classic PMD
5. Molecular genetic analysis to delineate the mutation in the GJC2 gene

Neuroimaging

1. MRI
 - a. Similar to classic PMD

Alexander's Disease

General Characteristics

1. Alexander's disease is caused by heterozygous mutation in the gene GFAP that maps to chromosome 17q21.31
2. The gene encodes fibrillary acidic protein

3. There are infantile, juvenile and adult forms of the disease
4. Inheritance is autosomal dominant

Clinical Manifestations

1. Infant form:
 - a. Megalencephaly
 - b. Failure to thrive
 - c. Developmental delay
 - d. Seizures
 - e. Ataxia
2. Juvenile form:
 - a. A phenotypic spectrum
 - b. Some patients are asymptomatic
 - c. Onset between 5 and 9 years of age
 - d. Linear growth failure
 - e. Excessive sleepiness
 - f. Vomiting
 - g. Bulbar or pseudobulbar signs
 - h. Spasticity
 - i. Cognitive impairment
 - j. Megalencephaly
 - k. Seizure
 - l. Ataxia
3. Adult form:
 - a. Onset is in the third and fourth decade
 - b. Varied phenotype
 - c. Sleep disturbance (since childhood)
 - d. Dysautonomia
 - e. Bulbar signs
 - f. Brainstem cranial nerve dysfunction
 - g. Cognitive impairment
 - h. Ataxia
 - i. No macrocephaly
 - j. One reported kindred:
 - i. Progressive kyphosis
 - ii. Short neck
 - iii. High-arched palate
 - k. Focal brainstem involvement (some patients)
 - l. Palatal myoclonus

Neuropathology

1. Histologic findings:
 - a. Rosenthal fibers (elongated tapered rods that may be 30 microns in length) that are diffusely scattered throughout the cortex and white matter
 - b. Rosenthal fibers are:
 - i. Subpial
 - ii. Around blood vessels
 - iii. Subependymal areas
 - iv. Contain GFAP and alpha-beta-crystalline
 - v. Primarily located in astrocytes
2. Demyelination (rarefaction)
3. Hydrocephalus (some patients)
4. Differential diagnosis of Rosenthal fibers
 - a. Astrocytoma
 - b. Optic nerve glioma
 - c. Chronic reactive gliosis

Neuroimaging**1. MRI:**

- a. Extensive symmetric white matter hyperintensities that are predominantly in the frontal lobe
2. Basal ganglia and thalamic signal abnormalities
3. Brainstem lesions with atrophy
4. Lesions may enhance
5. Atypical MRI evaluation:
 - a. Predominantly posterior fossa lesions
 - b. Tumor-like brainstem lesions
 - c. Asymmetric frontal lobe involvement
 - d. Basal ganglia lesions
 - e. Predominant atrophy and signal changes in the medulla and spinal cord

Laboratory Evaluation

1. Molecular genetic analysis to delineate the mutation in the GFAP gene

Hereditary Diffuse Leukoencephalopathy with Spheroids (HDLS)**General Characteristics**

1. HDLS is due to mutations in the colony-stimulating factor-1 receptor gene (CSF-1R) that maps to chromosome 5q32
2. Missense and splice site mutations have been delineated in the tyrosine kinase domain
3. A frameshift mutation that causes nonsense-mediated mRNA decay has been described

Clinical Manifestations

1. Approximately 22% of patients are of Japanese ethnicity
2. Mean age of onset is 45 years (range 18 to 78 years)
3. Cognitive decline
4. Behavioral disorders
5. Pyramidal signs
6. Parkinsonism
7. Seizures
8. Ataxia (rare)

Neuropathology

1. Loss of myelin and microglial activation
2. Macrophage infiltration of the parenchyma
3. Axonal swellings and spheroids

Laboratory Evaluation

1. Electron microscopy:
 - a. Axonal swelling in the CNS and skin nerves
 - b. Pigment containing macrophages
2. Molecular genetic analysis to delineate the mutation in the CSF-1R gene

Neuroimaging**1. MRI:**

- a. Bilateral confluent white matter hyperintense signal on T2-weighted sequences in the cerebrum

Adult-Onset Autosomal Dominant Leukodystrophy (ADLD)**General Characteristics**

1. ADLD is caused by heterozygous tandem genomic duplication that causes an extra copy of the lamin B1 gene that maps to chromosome 5q23.2

Clinical Manifestations

1. Onset in the 5th and 6th decades
2. Cognitive impairment is usually mild
3. Autonomic failure is often a presenting feature and includes:
 - a. Postural hypotension
 - b. Neurogenic bladder
 - c. Impotence
 - d. Rectal incontinence
 - e. Heat intolerance (some patients)
4. Spasticity
5. Ataxia (cerebellar type)
6. Clinical exacerbation often triggered by mild head trauma or viral infection
7. Personality change and depression
8. Ataxic gait
9. REM sleep behavior disorder (one patient)
10. Autonomic dysfunction that either precedes or is concomitant with gait and coordinative deficits
11. Motor deficits ascend from spastic paraplegia to tetraplegia and pseudobulbar palsy by the seventh decade

Neuropathology

1. Frontal and parietal lobes are preferentially affected
2. Demyelination occurs from the lateral margins of the corpus callosum that diminishes in severity to the occipital lobes
3. Vacuolar changes in the white matter
4. U-fibers are not affected

Neuroimaging**1. MRI:**

- a. MRI alterations of the brain and spinal cord may precede clinical symptoms
- b. Symmetric atrophy of the white matter of the frontal lobes, centrum semiovale and cerebellum
- c. Spared U-fibers and optic radiations
- d. Spinal cord involvement best appreciated on T2-weighted transverse sequences

Vanishing White Matter Disease**General Characteristics**

1. Leukoencephalopathy with vanishing white matter is caused by homozygous or compound heterozygous mutations in any of 5 genes that encode subunits of the translation initiation factor gene EIF2B that maps to:

- a. E1F2B1 – chromosome 12q24
- b. E1F2B2 – chromosome 14q24
- c. E1F2B3 – chromosome 1p34
- d. E1F2B4 – chromosome 2p23
- e. E1F2B5 – chromosome 3q27
2. The adult form of the disease is due to mutation in E1F2B3
3. Inheritance is autosomal recessive

Clinical Manifestations

1. Classic phenotype:
 - a. Onset is between 1 and 5 years of life
 - b. Cerebellar ataxia
 - c. Spasticity
 - d. Slowly progressive course
 - e. Neurologic deterioration may be exacerbated by fever, infection, mild head trauma
2. Adult onset type:
 - a. A milder and insidious cause
 - b. Behavior disorders
 - c. Dementia
 - d. Seizures
 - e. Complicated migraine
 - f. Less frequent stress-related neurological deterioration
 - g. Ovarian failure is common and may precede neurological signs and symptoms
 - h. Female mutation carriers may manifest ovarian failure by primary or secondary amenorrhea associated with elevated gonadotropin levels at less than 40 years of age
 - i. Spastic paraparesis
 - j. Optic atrophy (some patients)

Neuropathology

1. Cystic degeneration of cerebral white matter with reactive changes
2. Primary axonopathy rather than demyelination
3. Hypomyelination, demyelination and gliosis
4. Decreased quantity of myelin specific proteins and lipids

Laboratory Evaluation

1. Molecular genetic analysis to delineate the mutation in the E1F2B gene subunit

Neuroimaging

1. MRI:
 - a. Symmetric involvement of cerebral hemispheric white matter
 - b. Some component of the white matter has a signal intensity similar to CSF on proton-density, T2 and T1-weighted sequences
 - c. Mild to severe vermian atrophy
2. MRS (magnetic resonance spectroscopy):
 - a. Decrease of all normal signals
 - b. Presence of lactate and glucose

Vascular Leukoencephalopathy Mapping to Chromosome 20q13

General Characteristics

1. This vasculopathy has been investigated in two sisters and 21 members of their kindred
2. The causative gene has been mapped to chromosome 20q13

Clinical Manifestations (5 Patients)

1. Gait disturbance
2. Transient movement disorders
3. Cognitive impairment
4. Stroke

Neuropathology

1. Cerebral arteriopathy that affects preterminal arterioles

Neuroimaging

1. MRI:
 - a. Symmetric white matter hyperintensities that increased with age

Differential Diagnosis of Adult-Onset Genetic Leukoencephalopathies

1. Vascular forms:
 - a. CADASIL
 - b. CARASIL
 - c. COL4A1
 - d. Retinal vasculopathy with cerebral leukodystrophy (RVCL)
 - e. Polycystic lipomembranous osteodysplasia with sclerosing leukoencephalopathy (PLOS)
 - f. Cerebroretinal microangiopathy with cysts and calcifications (CRMCC); primarily infantile onset with vascular based myelin damage
2. Autosomal dominant forms of adult-onset leukoencephalopathy:
 - a. Hereditary diffuse leukoencephalopathy with spheroids (HDLS)
 - b. Autosomal dominant adult-onset leukoencephalopathy (ALDL)
 - c. CADASIL
 - d. Alexander's disease
3. Autosomal recessive forms of adult-onset leukoencephalopathy:
 - a. CARASIL
 - b. Vanishing white matter (VWM) with leukoencephalopathy
 - c. Nasu-Hakola disease
 - d. Metachromatic leukodystrophy
4. X-chromosome-linked disorders
 - a. Fragile X-associated tremor and ataxia syndrome (FXTAS)
 - b. Adrenoleukodystrophy

Differential Diagnosis of Genetic Inborn Errors of Metabolism That Present into Adulthood and May Manifest Cognitive Impairment

1. Lysosomal disorders:
 - a. Metachromatic leukodystrophy
 - b. Krabbe's disease
 - c. Fabry's disease
 - d. Niemann-Pick disease
 - e. GM1 gangliosidosis
 - f. GM2 gangliosidosis
 - g. Gaucher's disease
 - h. Mucopolysaccharidoses
 - i. Salla disease
2. Peroxisomal disorders
 - a. Adrenoleukodystrophy
 - b. Adrenomyeloneuropathy
3. Mitochondrial disorders:
 - a. MELAS
 - b. MERRF
 - c. Leigh's syndrome
 - d. PEO
 - e. MNGIE
 - f. Kearns-Sayre syndrome
 - g. POLG
 - h. Diabetes with deafness
4. Urea cycle disorders
5. Organic acidemias:
 - a. Phenylketonuria
 - b. Methylmalonic acidemia
 - c. Propionic acidemia
 - d. 3-methylglutaconic aciduria
 - e. 2-hydroxyglutaric aciduria
6. Cytoskeletal or transporter molecular defects
 - a. Alexander's disease
 - b. Pelizaeus-Merzbacher disease
 - c. Wilson's disease
 - d. Huntington's disease
7. Disorders of iron accumulation
8. Unusual and rare disorders:
 - a. Megalencephalic leukoencephalopathy with subcortical cysts (Van der Knaap disease)
 - b. Polymerase-III gene defect ("4H syndrome")
 - c. Childhood ataxia with central nervous system hypomyelination (vanishing white matter disease)
 - d. Cockayne syndrome

Toxic and Physical Disorders with Dementia

General Characteristics

1. Aluminum toxicity usually seen in patients with impaired renal function

Clinical Manifestations

1. No longer thought to be significant in Alzheimer's disease
2. Dialysis encephalopathy:
 - a. Possibly associated with osteomalacia

- b. An increased concentration of aluminum has been documented in hemodialysis patients from hemodialysis solutions with high levels of aluminum

Neuropathology

1. Mechanism of action:
 - a. Increases oxidative stress
 - b. Increases the phosphorylation of heavy and medium neurofilament subunits
 - c. Induces cross linking between neurofilaments
 - d. Posited inhibition of enzyme activity and decreased protein synthesis

Laboratory Evaluation

1. Aluminum brain concentration should be lower than 2 ug/g
2. Secondary hyperparathyroidism
3. Anemia
4. Aluminum in the bone marrow confirms the diagnosis

Alcohol and Dementia

General Characteristics

1. There has been a reported increase rate of alcohol abuse in older people and increased consumption in women
2. There are two main forms of alcohol-associated cognitive disorders
 - a. Alcohol-related dementia (ARD)
 - b. Alcohol-induced persisting amnesic syndrome (Wernicke-Korsakoff syndrome)
3. Neuropathological and neuroimaging studies demonstrate that excessive and prolonged alcohol abuse leads to structural and functional brain damage
4. The controversy has been: is there a direct alcohol-induced dementia or is it the associated thiamine deficiency or other nutritional deficiencies
5. Alcohol-related dementia patients:
 - a. Most often are male
 - b. Have comorbid mental and medical complications such as liver and gastrointestinal disorders
 - c. Diagnosed often by hospital admissions
 - d. Are socially isolated and unmarried
6. Wernicke-Korsakoff patients (WKS):
 - a. Most patients have alcohol abuse difficulties but there are multiple non-alcohol medical causes
 - b. Prevalence rates are between 1–2% (post-mortem studies) of the general population and approximately 10% of severe alcohol abuse patients in Western countries

Clinical Manifestations

1. Alcohol-related dementia
 - a. Direct intoxication:
 - i. Impairs almost all cognitive function
 - ii. Alcohol in excess often leads to stupor and respiratory depression
 - b. Acute withdrawal in severe alcohol abuse patients causes:

- i. Tremor
- ii. Hallucinations (small green insects)
- iii. Seizures
- iv. Severe agitation, paranoia and fear
- v. Fluctuating levels of consciousness
- vi. In a setting of severe autonomic dysregulation
- c. Neuropsychological evaluation:
 - i. Language is spared (as opposed to many other forms of dementia)
 - ii. Some deficits on semantic tasks that include:
 - 1. Confrontational naming
 - 2. Category fluency
 - 3. General knowledge
 - 4. Verbal recognition
 - 5. Delayed recall
 - iii. Deficits in visuospatial tasks:
 - 1. Decreased working memory, executive function and motor speed
 - 2. Clinical profile supports both cortical and sub-cortical deficits
- 2. Other non-alcoholic causes of WKS include:
 - a. Starvation diets
 - b. Prolonged IV treatment without thiamine supplementation
 - c. HIV (AIDS)
 - d. Gastric stapling
 - e. Renal dialysis
 - f. Prolonged vomiting

Neuropsychology of Wernicke-Korsakoff Syndrome

- 1. Profound anterograde amnesia
- 2. Impaired recall (better for remote time period events)
- 3. Implicit and procedural memory are more intact
- 4. Impaired executive function
- 5. Visuospatial deficits
- 6. Decreased working memory

Classic Wernicke-Korsakoff Syndrome

- 1. Ophthalmoplegia
- 2. Nystagmus
- 3. Ataxia
- 4. Encephalopathy

Core Clinical Manifestations of Korsakoff's Psychosis

- 1. Amnesic state
- 2. Deficits in memory:
 - a. Anterograde episodic memory deficit
 - b. Normal semantic memory
 - c. Relatively intact non-declarative memory
 - d. Normal intelligence and implicit and procedural memory
 - e. Retrograde amnesia may be severe (years or decades)
 - f. Confabulation (minority of patients)

Neuropathology

- 1. Alcohol-related dementia:

- a. Approximately 80% of patients with chronic alcoholism have some degree of brain pathology
- b. White matter loss occurs in the:
 - i. Prefrontal cortex
 - ii. Corpus callosum
 - iii. Cerebellum
- c. Neuronal Loss:
 - i. Superior frontal association cortex
 - ii. Hypothalamus
 - iii. Cerebellum (particularly the anterior vermis)
- d. Partial recovery of white matter deficits can occur with abstinence that correlates with clinical improvement
- e. Although controversial, lesions of the mammillothalamic tract and the mediodorsal thalamic nuclei are most closely correlated with the memory deficit (evidence from thalamic infarction primarily)
- f. Possible mechanisms of neuronal degeneration include:
 - i. Glutamate excitotoxicity
 - ii. Oxidative stress
 - iii. Decreased neurogenesis
 - iv. Possibly associated with thiamine deficiency
 - v. Pathology of Wernicke's encephalopathy
 - 1. Neuronal loss and hemorrhagic lesions in the mammillary bodies, paraventricular and periaqueductal gray matter
 - 2. Wernicke's encephalopathy can include Korsakoff's syndrome if there is concomitant thalamic and hippocampal circuit disruption
 - 3. Korsakoff's psychosis
 - a. The medial dorsal nucleus is severely affected: subnucleus > lateral dorsal > medial pulvinar

Neuroimaging

- 1. MRI:
 - a. Structural changes, volume loss of frontal association areas
 - b. Small mammillary bodies (loss of signal T1 and T2) weighted sequences due to paramagnetic effects due to hemosiderin
 - c. Anterior vermian loss (lingua, culmen, and centralis lobules)
 - d. Frontal lobe volume loss
 - e. Functional MRI: (Patient with WK)
 - i. No hippocampal activation during encoding or recognition memory tasks
 - ii. Decreased activation of the ventrolateral prefrontal cortex
 - f. Elevated serum transketolase

Marchiafava-Bignami Disease

General Characteristics

- 1. Marchiafava-Bignami disease is most often associated with chronic severe alcohol abuse. It can occur in the absence of alcohol particularly in malnourished patients

Clinical Manifestations

1. Acute:
 - a. Seizures
 - b. Disorder of consciousness
2. Chronic:
 - a. Progressive dementia
 - b. Interhemispheric disconnection syndrome

Neuropathology

1. Necrotizing and cystic lesions of
 - a. Corpus callosum
 - b. Optic chiasm
 - c. Centrum semiovale
 - d. Middle cerebellar peduncle
 - e. Demyelination with axonal sparing
2. Other diseases that cause similar findings include:
 - a. Cyanide poisoning
 - b. Sepsis
 - c. Malnutrition and vitamin B deficiency
 - d. Sickle cell disease
 - e. Plasmodium infection

Neuroimaging

1. MRI:
 - a. Hyperintensity of the corpus callosum on FLAIR sequences
 - b. Frontal white matter may be concomitantly involved
 - c. Positive lesions demonstrated by diffusion-weighted-imaging
 - d. Atrophic corpus callosum in the chronic state; bleeding may occur in the subacute state
 - e. Extracallosal lesions occur in:
 - i. Frontal cortex
 - ii. White matter
 - iii. Putamen

Methyl Alcohol Poisoning*General Characteristics*

1. Methanol is a component of household products that include:
 - a. Paint remover
 - b. Windshield washer fluid
 - c. The usual patient exposure follows ingestion by alcoholics who filter it through various substances
 - d. Methanol is metabolized to formic acid

Clinical Manifestations

1. Acute intoxication:
 - a. Formic acid is six times more toxic than methanol
 - b. Symptoms usually begin within 30 minutes but occasionally they are delayed up to a day
 - c. Systemic symptoms:
 - i. Nausea and vomiting
 - ii. Headache

- iii. Abdominal pain
- iv. Dyspnea and cyanosis
- d. Neurologic signs and symptoms:
 - i. Edema of the optic discs (bloody)
 - ii. Loss of visual acuity
- iii. Acute coma
- iv. Parkinsonism (survivors)
- v. Dementia (survivors)
- vi. Focal neurologic signs from bilateral putaminal hemorrhage

Neuropathology

1. Edema and petechial hemorrhage throughout the brain
2. Loss of retinal ganglia cells
3. Hemorrhagic necrosis and hemorrhagic leukoencephalopathy
4. Bilateral necrosis of the putamen with cystic change
5. Gliosis and axon loss of the optic nerves
6. Bilateral necrosis of the putamen may also be seen in:
 - a. Carbon monoxide poisoning
 - b. Ethylene glycol poisoning (antifreeze; eluted from car radiators utilized during the manufacture of "moon shine")

Neuroimaging

1. MRI:
 - a. Swollen optic discs with bilateral putaminal and/or other brain hemorrhage
 - b. Severe metabolic acidosis with large anion gap
 - c. Serum drug level of methanol
 - i. <20 mg/dl may cause severe poisoning
 - ii. 8 g (10 ml, 10%) and 10 g (30 ml, 40%) of washer fluid may cause blindness and death

Volatile Solvents or Drugs of Abuse with Consequent Cognitive Impairment*General Characteristics*

1. Volatile solvents that are components of fuels, paints and thinners have worldwide usage and are often inhaled in high concentrations to produce an altered mental status
2. Solvents have an effect on channels and neural circuits that are involved in reward and cognition
3. Classification of abused solvents
 - a. Aromatic hydrocarbons
 - i. Industrial uses:
 1. Adhesives
 2. Spray paint
 3. Paint thinner
 4. Leather tanning
 5. Some disinfectants
 6. Petroleum
 7. Cleaner
 8. Octane booster
 - ii. Halocarbons:

1. Trichloroethylene (TCY):
 - a. Degreasing agent
 - b. Coffee decaffeination
 2. 1,1,1 Trichloroethylene (TCE):
 - a. Film cleaner
 - b. Correction fluid
 3. Tetrachloroethylene (PERC):
 - a. Dry Cleaning
 - b. Degreasing
 4. n-Propyl Bromide (NPB):
 - a. Metal cleaner
 - b. Adhesive
 - iii. Aliphatic
 1. Propane
 2. Domestic and industrial fuel
 - iv. Hydrocarbons
 1. Butane
 - a. Lighter fluid
 2. n-Hexane
 - a. Adhesive
 3. Iso-octane
 - a. Automotive fuel
 4. Chemical properties
 - a. Low vapor pressure and high volatility at room temperature that encourages their use as a euphorogenic inhaled agent:
 - i. Nitrous oxide:
 1. An adjunct anesthetic to promote relaxation
 2. Is utilized in aerosol propellants
 3. Street name is "laughing gas" or "whippets"
 - ii. Mechanism of action
 1. Increased GABA-ergic and opioidergic transmission
 2. Inhibition of NMDA glutamate receptors
 3. Possible nitric oxide-like actions
 - iii. Alkyl nitrites
 1. Street name is "poppers"
 2. String vasodilators most commonly used for ischemic heart disease
 3. Epidemiology
 - a. Volatile solvents are a major source of abuse and are the most commonly used class of abused inhalants
 - b. The majority of solvents contain a mixture of chemical volatile agents
 - c. Toluene is the dominant chemical in glues and paint thinners, is popular and is strongly psychoactive
 4. These agents have a major effect on the mesocortical and mesolimbic systems
3. Approximately 11% of chronic users demonstrate signs of withdrawal with cessation of use
4. Most patients report euphoria or "drunkenness" feelings with use, drug seeking as well as craving and restlessness
5. Psychotic symptoms with use include:
 - a. Emotional volatility
 - b. Hallucinations
 - c. Delusions
6. Cognitive impairment occurs with chronic use and includes
 - a. Loss of short term memory
 - b. Attention deficits
 - c. Response inhibition
 - d. Executive function
 - e. Comorbidity with:
 - i. Mood disorders
 - ii. Major depression
 - iii. Antisocial personality disorder
 - f. Dementia
 - g. Long term toluene abuse symptoms and signs include:
 - i. Cognitive impairment
 - ii. Short term memory loss
 - iii. Ataxia
 - iv. Nystagmus
 - v. Tremor
 - vi. Hearing loss that is also seen with styrene and trichloroethylene (often associated with Vth nerve involvement concomitantly)
 - h. A common mixture of abused solvents include
 - i. Toluene
 - ii. Styrene
 - iii. Trichloroethylene
 - iv. Xylene
 - i. Cognitive impairment and dementia may precede other neurological signs

Neuropathology

1. Loss of white matter throughout the brain
2. It is estimated that approximately 3% of the vapor concentration reaches the brain, the majority is excreted through the lungs or is metabolized
3. Cerebral atrophy
4. Ventricular enlargement
5. Cerebellar and brainstem atrophy
 - a. More cerebellar atrophy with toluene than other solvents
6. Trilaminar inclusions may be detected within PAS-positive macrophages
7. VLCFAs may accumulate in white matter
8. U-fibers may be involved
9. Toluene and possibly all volatile solvents act as CNS depressants
 - a. Potency and sites of action differ between solvent type
10. Toluene, benzene, m-xylene, ethylbenzene and 1,1,1-trichloroethene (TCE)

Clinical Manifestations

1. Chronic solvent use can lead to substance abuse disorder (DSM-IV)
2. 10% of patients develop tolerance to solvents

- a. Reversibly inhibit NMDA receptors (Glu N1/2B.Glu N1/2A)
- b. Toluene, TCE and trichloroethylene (TCY) increase GABA and glycine receptor function
 - i. Chronic use induces NMDA increased currents and decreased GABA-ergic activity
- 11. Toluene's major action is putatively increasing intracellular calcium concentration in both glutamatergic and GABA-ergic neurons
- 12. Toluene also affects:
 - a. Nicotinic acetylcholine receptors (inhibition)
 - b. Enhances 5-HT₃ serotonin receptors (as do TCE, TCY and ethanol)
 - i. Enhancement of 5-HT₃ receptor function may increase dopamine in the NAc which may underlie its rewarding properties
- 13. Anesthetics, toluene, TCE and tetrachloroethylene (PERC) inhibit voltage-sensitive calcium and sodium channels
- 14. Putatively toluene and other volatile substances
 - a. Affect fast synaptic transmission
- 15. The prefrontal cortex is inhibited by solvents which
 - a. Enhances DA neuronal activity
 - b. Disinhibits the mesolimbic DA circuit which leads to their psychoactive and reinforcing properties

Neuroimaging

- 1. MRI:
 - a. Diffuse cerebral and cerebellar atrophy
 - b. Ventricular enlargement

Differential Diagnosis of Drugs and Toxins That Impair Cognition

- 1. Arsenic
- 2. Barbiturates
- 3. Hypnotic sedatives
- 4. MPTP
- 5. Chemotherapeutic agents
- 6. Lead

Neoplasms Causing Dementia

General Characteristics

- 1. Dementia may occur with both malignant and benign tumors
- 2. Dementia is determined primarily by the site of the neoplasm
- 3. Slow growing tumors most frequently cause diagnostic confusion

Clinical Manifestations

- 1. Location

- a. Midline
 - i. Colloid cysts
 - 1. Severe positional headache
 - ii. Pinealoma
 - 1. Eye movement defects (failure of vertical gaze)
 - 2. Hearing loss (compression of the inferior colliculus)
 - 3. Aqueductal stenosis with hydrocephalus
 - iii. Pituitary tumors
 - 1. Panhypopituitarism
 - 2. Chiasmatic visual field defects
 - 3. Hydrocephalus
 - 4. Dementia is primarily from thyroid failure
 - 5. Midline thalamic glioma
 - a. Somnolence
 - b. Aphasia
 - c. Memory loss and cognitive impairment
 - d. Fluctuating levels of consciousness

Subfrontal Frontal Lobe Meningioma

- 1. Subfrontal tumors (planum sphenoidale)
 - a. Pressure and irritation of the limbic orbitofrontal cortex
 - b. Seizures
 - c. Personality change and behavioral disorders
 - d. Rarely Foster-Kennedy syndrome
 - e. Subcortical dementia
- 2. Dorsolateral prefrontal cortex
 - a. Frontal lobe syndrome:
 - i. Poor memory retrieval
 - ii. Deficits of planning, execution and attention
- 3. Global decrease of cognitive function

Glioblastoma Multiforme

- 1. Bilateral frontal lobe involvement:
 - a. Crosses to the contralateral side through the corpus callosum
 - b. Frontal lobe syndrome
 - c. Seizure
 - d. Focal neurologic signs
 - i. Contralateral hemiparesis
 - ii. Ideomotor, limbkinetic and callosal apraxia
 - e. Abulia

Lymphoma

- 1. Primarily noted in AIDS patients
- 2. Crosses the midline through the corpus callosum
- 3. More necrotic on MRI than the usual lymphoma
- 4. Frontal lobe syndrome

Paraneoplastic Syndromes with Dementia

General Characteristics

- 1. Primarily immune-mediated

- a. Both cell surface and intracellular epitopes
- b. Small cell carcinoma of the lung is the most frequent tumor, but breast, GI, ovary and blood dysplasias are also common

Clinical Manifestations

- 1. Limbic encephalitis
- 2. Bilateral involvement of the hippocampal formation, parahippocampal gyrus, cingulate gyrus
- 3. Memory loss
- 4. Personality and behavioral change
- 5. Seizures

Neuropathology (Limbic Encephalitis)

- 1. Neuronal loss:
 - a. Hippocampus
 - b. Cingulate gyrus
- 2. Lymphocytic perivascular cuffing

Laboratory Evaluation

- 1. Antibody serum analysis for paraneoplastic epitopes particularly anti-Hu, anti-NMDA, anti-AMPA
- 2. Increased lymphocyte pleocytosis and CFS protein

Neuroimaging

- 1. MRI:
 - a. Increased signal intensity on T-2 weighted sequences bilaterally in the medial temporal lobe, insular and cingulate cortex that are most often gadolinium enhancing

Chronic Traumatic Encephalopathy as a Cause of Dementia (CTE)

General Characteristics

- 1. Definition:
 - a. CTE is a progressive neurodegenerative disease most often seen in association with the contact athletics, military combat, and trauma
 - b. Clinical symptoms most often begin after a latent period of years (decades)
 - c. The chronic neurodegeneration may be initiated from minor brain trauma

Clinical Manifestations

- 1. Early clinical investigation of boxers detailed a symptom complex that resulted from repeated sublethal head trauma that was characterized by:
 - a. An unsteady gait
 - b. Impaired cognition
 - c. Bradykinesia
 - d. Hesitant speech
 - e. Tremor of the hands and head
 - f. The complex was defined as “dementia pugilistica”

- g. Further clinical studies demonstrate:

- i. Subcortical dementia
- ii. Ataxia
- iii. Pyramidal tract dysfunction
- iv. Pseudobulbar palsy:
 - 1. Increased gag reflex
 - 2. Bilateral corticospinal dysfunction
 - 3. Emotional lability (laughing without mirth and crying without tears)
- v. Dysarthria
- vi. Shuffling gait
- vii. Hypopituitarism:
 - 1. Common after moderate to severe traumatic brain injury

Neuropathology

- 1. General features:
 - a. Cerebral atrophy
 - b. Enlarged lateral and third ventricles
 - c. Thinning of the corpus callosum
 - d. Fenestration of the cavum septum pellucidum
 - e. Cerebellar scarring
- 2. Histology
 - a. Neuronal loss in the cerebellar tonsils and substantia nigra
 - b. Neurofibrillary tangles in the substantia nigra and cerebral cortex
- 3. Topographic and cellular pattern of tau neurofibrillary pathology:
 - a. Neurofibrillary tangles (NFT) are predominant in layer II and upper IIIrd of neocortical areas (also seen in post-encephalitic Parkinsonism and Guamanian amyotrophic lateral sclerosis (ALS) Parkinsonism dementia)
 - b. This distribution supports the involvement of short distance, forward projecting cortico-cortical neurons
 - c. The size of individual NFTs is larger in CTE than in Alzheimer's disease
 - d. Neurites are more spindle-shaped than in Alzheimer's disease
 - e. The phosphorylated tau is perivascular and concentrated in the depths of the sulci
 - f. Medial temporal lobe p-tau is not an early manifestation of CTE
 - g. There is immune-reactivity to both three and four repeat tau
 - h. Subpial regions are affected early in CTE
 - i. There is astrocytic tau pathology

Stage I Chronic Traumatic Encephalopathy

- 1. Isolated perivascular foci of p-tau-NFTs, neuritic threads and astrocytic tangles
- 2. Tau pathology is formed at the depths of the sulci in:
 - a. Superior, dorsolateral and inferior frontal cortices

- b. P-tau-positive astrocytes are in the subpial region overlying the perivascular foci
- c. P-tau pathology occurs in the locus coeruleus
- 3. Approximately 50% of patients have TDP-43 inclusions in the subcortical frontal white matter and fornix
- 4. Gliosis of white matter at the apex of gyri and at the junction between the deep layers of the cortex and white matter
- 5. Hemosiderin accumulation may be seen in arterioles and venules in proximity to perivascular p-tau pathology

Stage II Chronic Traumatic Encephalopathy

- 1. Mild enlargement of the frontal horns of the lateral ventricles and IIIrd ventricle
- 2. Pallor of the substantia nigra and the locus coeruleus
- 3. Multifoci of tau pathology in the depths of the sulci in the:
 - a. Superior, dorsolateral, lateral and inferior frontal, anterior inferior cortices
 - b. Temporal, parietal, insular and septal cortices
 - c. Similar microscopic location as is seen in stage I
- 4. NFTs spread to superficial layers of adjacent cerebral cortex that extends into the gyral crest
- 5. NFTs are detected in the substantia innominata
- 6. Mild neurofibrillary degeneration is seen in the substantia nigra, dorsal and median raphe and the thalamus
- 7. TDP-43 pathology occurs in a large proportion of patients in a similar distribution to tau pathology
- 8. There is no AB pathology and no substantial NFT pathology in medial temporal lobe structures

Stage III Chronic Traumatic Encephalopathy

- 1. Decreased brain weight, atrophy of the frontal and temporal lobes
- 2. Enlarged lateral and IIIrd ventricles
- 3. Cavum septum and septal fenestrations are common
- 4. Pallor of the locus coeruleus and substantia nigra
- 5. Atrophy of the mammillary bodies, thalamus and hypothalamus
- 6. Thinning of the corpus callosum
- 7. NFTs are seen diffusely in the frontal, temporal and parietal cortices
- 8. They are concentrated around blood vessels at the depths of sulci
- 9. Involvement of similar cortices as seen in stage II
- 10. Involvement of the hippocampus, entorhinal cortex, amygdala, nucleus basalis of Meynert and locus coeruleus with extensive NFTs in the hypothalamus, mammillary bodies, substantia nigra, dorsal and median raphe nuclei
- 11. In approximately 1/3 of patients NFTs are seen in the dentate nucleus of the cerebellum and in the spinal cord
- 12. The majority of patients have TDP-43 positive neuritis and inclusions in the cerebral cortex, medial temporal lobe, thalamus and brainstem
- 13. In less than 20% of patients there is AB deposition that is sparse and diffusely distributed

Stage IV Chronic Traumatic Encephalopathy

- 1. The brain weight is decreased and there is marked atrophy of the frontal and temporal lobes, the medial temporal lobe and anterior thalamus
- 2. Generalized white matter atrophy
- 3. Disproportionate thinning of the posterior corpus callosum
- 4. Severe spongiosis of the layer 2 of the cerebral cortex
- 5. Widespread myelin loss and astrocytosis of the cerebral hemispheres
- 6. Severe tau deposition throughout all structures involved in the earlier stages
- 7. Heavy density of NFTs in the hippocampal formation which is sclerotic and almost devoid of neurons
- 8. The cerebellum is involved with tau pathology in the dentate nucleus granule cell layer
- 9. The medulla demonstrates tau pathology in the medial lemniscus and inferior olives
- 10. TDP-43 deposition is widespread and dense with dot-like and thread-like inclusions in neurites and neuronal cytoplasm

Pathogenesis of Traumatic Brain Injury

- 1. The mechanism of traumatic brain injury neurodegeneration is not known, but posited causes include:
 - a. Axonal injury
 - b. Tau hyperphosphorylation
 - c. Misfolding and aggregation of proteins
 - d. Cytoskeletal disruption
 - e. Deficiency of axonal transport
 - f. Acute traumatic brain injury (TBI):
 - i. The brain is subjected to shear stress that:
 - 1. Elongates and injures axons
 - 2. Damages small blood vessels and astrocytes
- 2. Traumatic axonal injury causes:
 - a. Changes in axolemmal permeability
 - b. Ionic shifts with a large influx of calcium
 - c. Release of caspases and calpains that triggers:
 - i. Misfolding, truncation and phosphorylation of multiple proteins that include tau and TDP-43
 - ii. Disruption and degeneration of microtubules and neurofilaments that interrupts axonal transport
- 3. Repetitive injury with accumulation of misfolded proteins or p-tau aggregates is posited to:
 - a. Overwhelm clearance mechanisms
 - b. P-tau spreads transsynaptically and interneuronally by possible template mechanisms and cerebrospinal fluid clearance pathways
 - c. Inflammation and microhemorrhage from damage to small blood vessels

Neuroimaging

- 1. MRI:
 - a. Grade I diffuse axonal injury (DAI):

- i. Wide-spread axonal damage in the:
 1. Corpus callosum
 2. Cerebral hemisphere white matter
 3. Brainstem
 - b. Grade II DAI:
 - i. All of the abnormalities noted in grade I DAI
 - ii. Focal abnormalities of the corpus callosum with small hemorrhage (a tissue tear hemorrhage)
 - c. Grade III DAI:
 - i. All of the findings of grade II DAI
 - ii. Axonal abnormalities in the rostral brainstem
2. fMRI:
 - a. A frontal vulnerability in mTBI:
 - i. Decreased activity in the MFG, ACC (anterior cingulate cortex and right precentral gyrus)
 - ii. Bilateral decreased activity in the DLPFC (dorsolateral prefrontal cortex)
3. Magnetic Resonance Spectroscopy:
 - a. Reduced n-acetylaspartate (NAA) in white matter:
 - i. Disruption of neuronal integrity
 - ii. Alterations in cellular energy metabolism
 - b. Increased white matter choline:
 - i. Repair and inflammation of myelin
 - c. Altered metabolic integrity in the splenium of the corpus callosum is associated with reduced functional interhemispheric connectivity
4. Positron emission tomography (PET):
 - a. Decreased cerebral glucose metabolic rate in gray matter
5. Disrupted modular organization of resting state functional networks has been demonstrated in blast traumatic brain injury
6. Diffusion weighted imaging:
 - a. Demonstrates an anterior to posterior loss of white matter anisotropy

Vasculitic and Microangiopathic Forms of Dementia

General Characteristics

1. Deficits occur in:
 - a. Cranial nerves
 - b. Peripheral nerves
 - c. Spinal cord
 - d. Large or small vessel stroke
 - e. Often multiorgan involvement
 - f. Systemic signs and symptoms
2. Rarer presentations:
 - a. Depressed consciousness
 - b. Confusional state
 - c. Dementia

SLE

General Characteristics

1. Dementia occurs often with acute exacerbations and increased disease activity

Clinical Manifestations

1. Large and small cerebral infarcts may lead to multi-infarct dementia
2. Strokes in young adults
3. Libman-Sacks endocarditis (verrucous subvalvular fibrin deposits) that are associated with emboli

Neuropathology

1. Lupus anticoagulant and anticardiolipin antibodies are detected in the serum
2. Single- and double-stranded anti-DNA antibodies are detected in the serum
3. Prolonged PTT, false positive syphilis serology, and thrombocytopenia suggest an ACL antibody state
4. Increased sed rate and C-reactive protein are seen during exacerbations
5. CSF:
 - a. Increased protein, lymphocytic pleocytosis and IgG
 - b. Decreased complement
6. Neuroimaging:
 - a. Large and small vessel topographic strokes
 - b. Atrophy
 - c. Normal MRI in some patients

Polyarteritis Nodosa

General Characteristics

1. CNS involvement:
 - a. 20% of patients
 - b. Involvement of large intra- and extracranial vessels and intracranial arterioles

Clinical Manifestations

1. Global encephalopathy
2. Multifocal deficits
3. Dementia
4. Seizures
5. Large vessels stroke (rare)
6. Stupor and coma

Neuropathology

1. Necrotizing vasculitis in small- and medium-sized muscular arteries
2. Segmental arterial lesions
3. Endothelial proliferation
4. Polymorphonuclear and mononuclear cell infiltration of blood vessel walls
5. The kidneys may be severely involved in some patients with consequent severe HCVD

Laboratory Evaluation

1. Elevation of acute phase reactants (approximately 50% of patients)
2. A percentage of patients have:
 - a. Hemoglobin <12 grams/dl

- b. WBC > 12,000/ μm^3
- c. CRP > 5 mg/dl
- d. Thrombocytosis > 400,000/ μl
- e. Sedimentation rate > 40 mm/hr
- f. Positive rheumatoid factor, anti-nuclear antibody, ANCA antibody concentrations in the serum
- g. Elevated C3 complement
- h. HBs-Ag positivity

Neuroimaging

1. MRA:
 - a. Microaneurysms in a segmental pattern of medium-sized blood vessels
 - b. Cerebral arteries often have a beaded appearance with variable degrees of stenosis and occlusion with or without contrast enhancement in their walls
2. MRI:
 - a. Small ischemic change to topographical infarction, hemorrhage and white matter edema

Primary Arteritis of the CNS (PACNS)

General Characteristics

1. An idiopathic inflammatory process that only affects CNS vasculature
2. There is no systemic inflammatory response

Clinical Manifestations

1. Affects adults in the fifth to eighth decade
2. A subacute cognitive decline
3. Seizures
4. Focal neurological deficits
5. Headache
6. Impaired consciousness (with acute exacerbations)
7. Rare cranial neuropathy
8. Spinal cord infarction (rare)
 - a. Amnesic syndrome

Neuropathology

1. Confirmed PACNS patients have been reported in association with:
 - a. Hodgkin's disease
 - b. Amyloid angiopathy
 - c. Graft-versus-host disease
2. Primarily a leptomeningeal and cortical vasculitis which involves small and medium leptomeningeal and cortical arteries
3. Granulomatous angiitis with Langhans giant cells, or a necrotizing lymphocytic vasculitis
4. Inflammation leads to occlusion of the involved blood vessel with consequent thrombosis and infarction in its territory

Laboratory Evaluation

1. Entities to be excluded prior to the diagnosis include:
 - a. Infections

- b. Neoplasm
 - c. Drug exposure
 - d. Vasospastic disorders
 - e. Systemic vasculitis
 - f. Vasculopathies
2. No blood studies are diagnostic
 3. CSF evaluation:
 - a. CSF is abnormal in 80–90% of patients with PACNS
 - b. Modest lymphocytic pleocytosis with an elevated protein

Neuroimaging

1. MRI:
 - a. Bilateral infarcts in the cortex, deep white matter and leptomeninges with or without contrast enhancement
 - b. High resolution multicontrast wall and lumen MRI (inflammatory lesions encompass the circumference of the arterial wall)
2. Angiography:
 - a. Beading
 - b. Absence or cut off of one or more vessels

Giant Cell Arteritis (GCA)

General Characteristics

1. Giant cell arteritis is an inflammatory vasculopathy that occurs in medium and large arteries
2. The affected vascular beds are the:
 - a. External carotid branches, most often the temporal and occipital arteries
 - b. Ophthalmic, vertebral, distal subclavian and axillary arteries and the thoracic aorta
 - c. Often occurs in association with polymyalgia rheumatic (PMR)
 - i. Approximately 50% of patients with giant cell arteritis present with PMR before, concomitant with, or after the diagnosis of GCA

Clinical Manifestation

1. Peak incidence for GCA is between 70–80 years of age
2. Severe headache (often a burning scalp with mechanoallodynia and hyperalgesia)
3. Unilateral blindness:
 - a. Infarction of the posterior ciliary arteries that form a watershed with the central retinal artery at the optic disc
4. Rarely there is involvement of the carotid, vertebral arteries and the arch of the aorta
5. Brainstem, the cerebellum and rarely the spinal cord may be involved
6. Ischemic optic neuropathy causes vision loss in 10–15% of patients
7. Vascular dementia

Neuropathology

1. Dendritic cells of the vessel wall initiate the pathological cascade by recruiting T-cells and macrophages that form a granulomatous infiltrate

2. Vascular lesions of inflamed temporal arteries contain:
 - a. Inflammatory cytokines and mediators which include:
 - i. Interleukin-12-type; helper T-cells (Th1); interferons of the gamma axis
 - ii. Interleukin-6 and T-cell (Th17) and the interleukin-21 axis (which can be suppressed by glucocorticoids)
3. Effect of cytokines that are released into the arterial wall:
 - a. Activate inflammatory cells which target:
 - i. Endothelial cells
 - ii. Vascular smooth muscle cells
 - iii. Fibroblasts
 - b. The above cellular events lead to intimal hyperplasia and vessel obstruction
4. Remodeling of the vascular wall is produced by:
 - a. Matrix metalloproteinases
 - b. Vascular endothelial growth factor
 - c. Platelet-derived growth factor

Laboratory Evaluation

1. Marked elevation of the erythrocyte sedimentation rate (usually between 80–120 mm/hr) and the level of C-reactive protein
2. Anemia and thrombocytosis
3. Elevated IL-6
4. Color Doppler:
 - a. Visualizes superficial arteries but has limited value in deep blood vessels:
 - i. Vessel wall edema produces a halo sign
5. Temporal artery biopsy is the definitive test

Neuroimaging

1. MRA:
 - a. Evaluation of the aortic arch and its branches to rule out stenosis, dissection or aneurysm
 - b. Inflammation of the vessel wall is suggested by intramural delayed enhancement and thickening

Thrombotic Thrombocytopenic Purpura

General Characteristics

1. Familial thrombotic purpura is caused by mutation in the ADAMTS12 gene that maps to chromosome 9q342
2. It encodes the von Willebrand factor (VWF)-cleaving protease (VWFPCP)
3. In the majority of patients it is acquired in which antibodies against ADAMTS13 are detected in the patient's serum that decreases ADAMTS13 enzyme activity (often less than 5%)
4. ADAMTS13 is a metalloproteinase that cleaves the von Willebrand factor (VWF) into small fragments. Decreased enzyme activity, VWF multimers induce platelet accumulation and activation that induces microangiopathic hemolytic anemia and thrombocytopenia

Clinical Manifestations (Acquired Form)

1. Acute confusion state
2. Psychosis
3. Seizures
4. Purpuric skin lesions
5. Fever
6. Rare vascular dementia

Neuropathology

1. The enlarged multimers of VWF resemble huge VWF proteins that are secreted by human endothelial cells
2. The multimers effect adhesion of platelets to the subendothelium if there is vascular damage
3. The inhibitors against the metalloproteinase ADAMTS13 are IgG antibodies
4. Terminal arterioles and capillaries are occluded by hyaline thrombi that are primarily composed of platelets
5. There is no perivascular inflammation or endothelial desquamation

Laboratory Evaluation

1. Peripheral blood smear:
 - a. Schistocytes
 - b. Platelet count of $<30,000/\text{mm}^3$
 - c. High reticulocyte count
2. High indirect bilirubin and LDH levels
3. Low haptoglobin
4. Direct antiglobulin test is negative
5. Decrease in ADAMTS13 activity is less than 10% of a normal value with anti-ADAMTS13 antibodies

Differential Diagnosis of Acquired TTP

1. Congenital TTP (Upshaw-Shulman syndrome)
2. Atypical hemolytic uremic syndrome
3. Disseminated intravascular coagulation (DIC)
4. Antiphospholipid syndrome
5. Cobalamin deficiency
6. During pregnancy the HELLP syndrome
7. Evans syndrome

Central Nervous System Angioendotheliosis

General Characteristics

1. Neoplastic angioendotheliosis often affects the systemic vasculature and is rapidly fatal
2. CNS involvement may be insidious

Clinical Manifestations

1. Subacute dementia over months
2. Focal neurologic deficits
3. Renal involvement
4. Skin ulcerations

Neuropathology

1. Small infarctions

2. Medium-sized arterial involvement
3. Intravascular proliferation of atypical cells with proliferation of blood vessels
4. Electron microscopy:
 - a. Weibel-Palade bodies and factor VIII-related antigen in intravascular and extravascular neoplastic cells

Laboratory Evaluation

1. CT evaluation:
 - a. Diffuse lucencies compatible with ischemic lesions
 - b. The predominance of the lesions are in the white matter
2. Angiographic abnormalities are in medium-sized arteries
3. Some patients have an elevated sedimentation rate and modest renal impairment

Infectious Causes of Dementia

HIV

General Characteristics

1. After infection, the HIV virus rapidly enters the brain and induces widespread inflammation and neuronal damage that leads to cognitive impairment
2. Cognitive impairment occurs in 35–70% of patients with HIV-1 infection regardless of treatment or non-treatment
3. Combination antiretroviral therapy has decreased the prevalence of HIV-associated dementia (HAD) but milder forms of HIV-associated neurocognitive disorders (HAND) remain a major problem
4. At present, there are no diagnostic tests or specific biomarkers that can specifically diagnose HAND
5. Virus may be detected in the CSF within 7–10 days of infection
6. Severe immunosuppression is concomitant with cognitive impairment
7. Viremia reaches peak levels within 21–28 days after infection and is accompanied by a massive loss of CD4+T cells and an excessive increase in proinflammatory cytokines
8. Abnormalities of the caudate nucleus and the hippocampus may be appreciated with structural MRI and fMRI evaluation within 4–12 months
9. Atrophy in the basal ganglia is correlated with duration of the infection
10. There is evidence that ongoing brain damage occurs during systemic viral suppression that supports the hypothesis of a viral reservoir in the brain that may preclude total viral eradication

Clinical Manifestations

1. Deficits occur in:
 - a. Gross motor ability (timed gait)
 - b. Fine motor function (grooved pegboard)
 - c. Language (WRAT 4 reading)

- d. Verbal learning (Hopkins Verbal Learning Test)
- e. Verbal memory (HVLT-R, delayed recall)
- f. Speed of processing (Trail making-A, digit symbol)
- g. Attention and working memory (paced auditory serial addition task)
- h. Executive function (verbal fluency, Stroop and trail making-B)

The Frascati Criteria for Neurocognitive Disorders in HIV Patients

1. Impairment of cognitive function in at least two domains:
 - a. Usually the impairment is in multiple domains
 - b. Particularly severe deficits in:
 - i. New information learning
 - ii. Slow information processing
 - iii. Attention and concentration
 - c. Ascertainment of deficits by neuropsychological testing with at least two domains that are two standard deviations or more below the mean
2. The cognitive impairment interferes with activities of daily living
3. There is no delirium
4. There is no pre-existing cause for the dementia

Neuropathology

1. Diffuse white matter changes
2. Macrophage invasion, multinucleated cells and reactive gliosis in the affected areas
3. Neuronal loss in the basal ganglia and subcortical gray matter as well as the cerebral cortex
4. Associated pathologic processes:
 - a. Lymphoma
 - b. Progressive multifocal leukoencephalopathy (PML)
 - c. Infections:
 - i. Toxoplasmosis
 - ii. Tuberculosis
 - iii. Syphilis
 - iv. Cryptococcosis
 - v. Herpes simplex
 - vi. Herpes Zoster
 - vii. Epstein-Barr Virus
5. Infected macrophages in the meninges, subarachnoid space and parenchyma induce inflammatory cascades that involve:
 - a. Cytokines (TNF α and IL-6)
 - b. Chemokines (fractalkine and MCP-1)
 - c. Viral proteins:
 - i. Metalloproteinases may modulate the neurotoxicity of HIV viral proteins and are elevated throughout the course of the infection

Laboratory Evaluation

1. Positive serum, ELISA test
2. Confirmatory Western blot
3. Viral Load Test (primarily to monitor treatment):

- a. Reverse transcriptase (PCR)
- b. Branched DNA (test)
- c. Nucleic acid sequence based amplification assay (NASBA)
- 4. CSF:
 - a. Lymphocytic pleocytosis
 - b. Moderately elevated protein
 - c. Task switching paradigm:
 - i. HIV-infected patients were slower than controls in adapting to the task demand
 - ii. The deficits are correlated to less activation in the dorsal area of the anterior cingulate cortex
 - d. Neurovascular coupling may be abnormal in HIV-infected patients, which makes BOLD investigations less reliable as an index of neuronal activity
- ii. The regulatory region of the JCV archetype consists of one 98-bp element, whereas the regulatory region of pathogenic PML prototype have tandem repeats of a 98-bp element
- iii. Each individual patient has a unique regulator rearrangement. This attribute of the virus supports a mechanism in which the pathogenic prototype emerges within the host from the original commonly acquired JCV archetype, and is not a newly acquired infection from the environment
- f. The distinct PML risk populations include:
 - i. The HIV-positive population:
 - 1. 1 per 1000 person years in the post-cART era
 - 2. The mortality rate with cART treatment:
 - a. Approximately 30% after 1 year and 50–60% after 2 years
 - 3. The population of HIV+ patients with a low CD4+T-cell count are at a higher risk of developing PML
 - ii. The second largest risk population is patients with hematological malignancies, that account for approximately 10% of PML patients:
 - 1. Most of these patients succumb very rapidly
 - iii. The third largest population at risk is patients taking natalizumab for relapsing-remitting multiple sclerosis. The risk is estimated to be 3.96 per 1000 patients:
 - 1. The risk is primarily in patients with anti-JCV antibody and increases to 5.3 per 1000 patients after 2–4 years of treatment
 - 2. Prior immunosuppression increases the risk
 - iv. Other disease associations include:
 - 1. Organ transplantation
 - 2. Solid malignancies
 - 3. Sarcoidosis
 - 4. Autoimmune diseases

Neuroimaging

- 1. Functional MRI:
 - a. fMRI studies during attention and working memory in HIV-infected patients reveals:
 - i. Greater activation within the frontal and parietal cortices during performance of the paradigms
 - ii. HIV patients demonstrated less activation in the primary sensory cortices
- 2. Structural MRI:
 - a. Global atrophy of both gray and white matter
 - b. Basal ganglionic atrophy
 - c. Diffuse white matter increased signal on T2-weighted sequences (primarily periventricularly)
- 3. Magnetoencephalography:
 - a. HIV-infected patients exhibit reduced neural synchronization in the 6–12 Hz frequency range across the dorsolateral prefrontal cortex, frontal eye fields and posterior cingulate gyrus:
 - i. This frequency band includes a component of the 4–7 Hz and alpha bands that have been associated with working memory and visual attention
 - ii. Alpha-frequency activity may be critical for network coordination during cognitive processing

Progressive Multifocal Leukoencephalopathy

General Characteristics

- 1. JCV is a polyomavirus:
 - a. Genetically related to BK virus (BKV) and simian virus 40 (SV40) that is composed of a 15–13 Kb double-stranded DNA enclosed in a capsid that lacks a lipoprotein envelope
 - b. Probable oral-fecal route of transmission
 - c. Most individuals are infected by age 30–40
 - d. The JCV archetype is not pathogenic although it is spread through the community
 - e. The pathogenic prototype variant:
 - i. Differs from the archetype in the non-coding region of the viral DNA

Clinical Manifestations

- 1. Cognitive impairment
- 2. Ataxia
- 3. Hemiparesis
- 4. Hemianopia and central visual loss
- 5. Rare brainstem signs and symptoms
- 6. A few patients have a remission and a long survival

Neuropathology

- 1. The parieto-occipital lobes are most commonly affected
- 2. Serpiginous coalescent white matter lesions
- 3. Large bizarre multi-nucleated oligodendrocytes with intranuclear lesions
- 4. The subcortical white matter is primarily affected
- 5. Oligodendrites are destroyed
- 6. Bizarre astrocytes

Laboratory Evaluation

- 1. JC virus DNA is in the spinal fluid

2. Anti-JCV antibodies are in the serum
3. Rarely a brain biopsy is needed for diagnosis

Neuroimaging

1. MRI:
 - a. The cortical white matter of the parieto-occipital and frontal lobes are most often affected
 - b. Lesions may be seen anywhere in the brain and include:
 - i. Basal ganglia
 - ii. External capsule
 - iii. Brainstem
 - iv. Cerebellum
 - c. Periventricular white matter is also frequently involved
 - d. Lesions have a scalloped lateral margin when they involve the subcortical white matter
 - e. Lesions are hypointense and well-demarcated on T1-weighted sequences
 - f. Lesions typically do not enhance or have mass effect; rarely there is slight enhancement

Subacute Sclerosing Panencephalitis (SSPE)

General Characteristics

1. SSPE is a chronic encephalitis after measles virus infection
2. The prevalence of disease varies with vaccination rates
3. Measles can induce a “slow virus” infection that occurs years after the initial exposure
4. It remains a common cause of progressive myoclonus with cognitive impairment in regions with incomplete measles immunization

Clinical Manifestations

1. Childhood form:
 - a. The age of presentation is usually between 8–11 years
 - b. The onset is between 2–10 years after measles infection
 - c. Cognitive impairment
 - d. Progressive myoclonus
 - e. School failure (often the earliest cognitive sign)
 - f. Visuospatial impairment
 - g. Apraxias
2. Adult-onset SSPE:
 - a. May have atypical features
 - b. Presentation is at a mean age of 25.4 years (range of 20–35 years)
 - c. Higher proportion of a negative measles infection history than in children
 - d. These patients may be infected at a younger age (<3 years old) or at an older age (>9 years of age)
 - e. Long intervals from exposure to the virus and the onset of SSPE that ranges from 14–22 years
 - f. None of the patients follow a measles vaccination
 - g. Visual symptoms are prominent
 - h. Fewer patients have behavioral disorders

- i. Possibly a higher rate of remission although the course is progressive and fatal
- j. Motor manifestations include:
 - i. Myoclonus
 - ii. Spastic hemiparesis
 - iii. Bradykinesia
 - iv. Rigidity

Neuropathology

1. There is predominant cortical occipital lobe involvement, although the thalamus and putamen are affected
2. Dawson’s inclusion bodies:
 - a. Cowdry A bodies
 - b. Large intranuclear inclusions with a halo
 - c. Diffuse white matter demyelination

Laboratory Evaluation

1. Positive measles antibody titers
2. EEG:
 - a. Diffuse high-amplitude bursts of periodic slow-wave complexes every 3 to 5 seconds
3. CSF:
 - a. Positive IgG index > 7%/dl
 - b. Slightly elevated protein
 - c. No pleocytosis; may have a few lymphocytes

Neuroimaging

1. MRI:
 - a. Patchy areas of hyperintense signal on FLAIR sequences in periventricular areas and throughout white matter

Chronic Rubella Encephalitis

General Characteristics

1. Usually occurs after a congenital infection, although it may follow an acquired infection in an adult

Clinical Manifestations

1. Progressive rubella panencephalitis most often occurs in a child with congenital rubella
2. Most often manifests between 8–19 years of age
3. Child develops:
 - a. Progressive spasticity
 - b. Cognitive impairment
 - c. Ataxia
 - d. Seizures (rarely myoclonic)
 - e. There is no myoclonus
 - f. Retinopathy with optic atrophy in some patients

Neuropathology

1. Neuronal loss in the cortex, cerebellum and brainstem
2. Perivascular lymphocytic infiltration
3. Myelin destruction with axon sparing
4. Similar to the pathology of SSPE but without intracellular inclusion bodies

Laboratory Evaluation

1. Enzyme immunoassay of the serum for IgM; elevated rubella antibody titers in the serum and CSF

Neuroimaging

1. MRI:
 - a. Early cerebellar lesions
 - b. Ventricular enlargement
 - c. DWI with hyperintense ovoid lesions in the splenium of the corpus callosum

Neurosyphilis*General Characteristics*

1. The number of new patients with syphilis per year is approximately 20,000 in the USA
2. The highest rates occur among men who have sex with men; approximately 50% of new patients have a concomitant HIV infection

Clinical Manifestations

1. Neurological signs and symptoms may occur 15–20 years after the original infection
2. Cognitive impairment includes:
 - a. Memory loss
 - b. Apathy
 - c. An expansive paranoid state
 - d. Dysphasia
 - e. Apraxias
 - f. General paresis
3. Associated neurological features:
 - a. Seizures
 - b. Dysarthria
 - c. Tremor
 - d. “Trombone” tongue tremor (the tongue protrudes rhythmically)
 - e. Hypertonia
 - f. Vth nerve involvement with mid-face numbness
 - g. Paretic pupil with optic atrophy
 - h. Argyll Robertson pupil
 - i. Brainstem strokes
 - j. Gummas with focal features
4. Clinical manifestations of neurosyphilis in AIDS patients
 - a. There is a telescoped pattern of infection:
 - i. Primary and meningoencephalitic pattern may develop concomitantly
 - ii. Neurosyphilis may develop although the primary infection was adequately treated
 - b. Ocular involvement is prominent
 - c. Syphilitic meningitis is common
 - d. Gummatous arteritis occurs
 - e. A fulminant necrotizing hyperinfection (during an anergic state) has been delineated as “quaternary” syphilis

Neuropathology

1. Meningovascular syphilis:
 - a. Diffuse or localized to the base of the brain

- b. Lymphocytes and plasma cells associated with fibrous tissue form perivascular infiltrates around small blood vessels
- c. The inflammatory process may extend into the cranial and spinal nerves
- d. Associated hydrocephalus from the meningeal fibrosis
- e. Gummas:
 - i. Infrequently occur in the meninges
 - ii. Usual locations are:
 1. The cerebral convexity
 2. Less commonly found in the cerebral peduncles, hypothalamus and spinal cord
 3. Most often they attach to the dura mater and are embedded in the brain parenchyma
 - iii. Histology of gummas:
 1. Central gummatous necrosis in which there are dead cells and reticulin
 2. The core is surrounded by densely cellular epithelial cells, fibroblasts, and scattered multinucleated giant cells
 3. Syphilitic meningitis may be confined to the spinal cord; vascular involvement may cause transverse myelitis
4. Huebner’s arteritis:
 - a. Is the vascular component of meningovascular syphilis
 - i. An endarteritis obliterans
5. Parenchymatous neurosyphilis:
 - a. General paresis (paretic dementia)
 - b. Tabes dorsalis
 - i. Selective degeneration of posterior spinal nerve roots with dorsal root ganglia involvement
 - ii. Demyelination and shrinkage of the posterior columns
 - iii. Rarely the degeneration is more severe in cervical nerve roots
 - c. Parenchymal syphilis:
 - i. A severely shrunken atrophic brain with a thick and opaque pia-arachnoid
 - ii. Severe frontal gyral atrophy
 - iii. Ventricular enlargement
 - iv. Extensive granular ependymitis
 - d. Loss of the laminar pattern of the cerebral cortex
 - e. Loss of neurons in the cortex with astrocytic and microglial proliferation (cells are hypertrophied and rod-like)
 - f. Perivascular lymphocytic cuffing of blood vessels
 - g. Plasma cells in both the cortex and the meninges

Laboratory Evaluation

1. The VDRL (Venereal Disease Research Laboratory test) is the gold standard

2. Other serum and blood tests include:
 - a. Fluorescent treponemal antibody absorption test (FTA-ABS)
 - b. Rapid plasma reagin (RPR)
 - c. Treponema pallidum particle agglutination assay (TPPA)

Neuroimaging

1. MRI:
 - a. Patients with neuropsychiatric symptoms have:
 - i. Diffuse cerebral atrophy
 - ii. Parenchymal mesial temporal signal change
 - iii. Signal changes in basifrontal areas
 - iv. Topographical infarction
 - v. Non-specific white matter changes
 - vi. Cerebral gummas
 - b. Patients with meningovascular syphilis have:
 - i. Diffuse cerebral atrophy
 - ii. Topographical infarction
 - iii. Signal changes in the medial temporal lobe
 - iv. Sulcal exudates
 - c. Diagnostic pattern for cerebral neurosyphilis:
 - i. Cerebral gummas:
 1. Dural-based that are similar to meningioma
 2. Medial temporal lobe lesions that may be misdiagnosed as herpes encephalitis

Whipple's Disease

General Characteristics

1. A systemic disorder caused by the bacterium *Tropheryma whipplei*
2. Its classic presentation is with diarrhea, abdominal pain and weight loss
3. Involvement of other systems include:
 - a. The lymphatic system
 - b. Heart
 - c. Large joints
 - d. Central nervous system
4. Rarely, it may involve the brain without systemic involvement, and in association with a negative small bowel biopsy

Clinical Manifestations

1. Neurologic manifestations:
 - a. Onset is usually in men in the 4th-6th decades (87% of patients)
 - b. Neurologic signs and symptoms may occur without associated systemic features
 - c. Neurologic involvement may be silent (only found at autopsy)
 - d. Dementia
 - e. Myorhythmia (side to side jaw movement)
 - f. Ophthalmoplegia
 - g. Ataxia

- h. Hypothalamic syndrome
2. Systemic manifestations:
 - a. Lymphadenopathy
 - b. Hyperpigmentation
 - c. Large joint arthritis (asymmetric)
 - d. Steatorrhea with malabsorption and weight loss
 - e. May occur concomitantly with AIDS

Neuropathology

1. *T. whipplei* is an actinomycete that is most common in farmers and patients that are exposed to soil and animals
2. CD11b cells are deficient in patients
 - a. Have a role in the activation of macrophages that destroy intracellular bacteria
3. PAS-positive macrophages in the lamina propria that contain non-acid fast gram-positive bacilli
4. Disseminated lesions throughout the CNS that are noted in:
 - a. Subpial regions of the cortex
 - b. Basal ganglia
 - c. Hypothalamus
 - d. Dentate nuclei of the cerebellum
 - e. Brainstem nuclei
5. Small infarcts (less than 5 mm) are scattered throughout the brain

Laboratory Evaluation

1. Jejunal biopsy that identifies the gram-positive bacilli
2. PCR-based assay that may be utilized on blood, vitreous fluid, synovial fluid and CSF

Neuroimaging

1. MRI:
 - a. Multiple nodular enhancing lesions
 - b. Solitary mass lesion

Lyme's Disease Encephalopathy and Dementia

General Characteristics

1. Lyme's disease is caused by the *Borrelia* bacteria, a spirochete
2. Transmission to humans is from the bite of infected ticks of the *Ixodes* genus. The tick usually has to be attached for 36 to 48 hours
3. In the USA (and North America), the bacterium involved is *Borrelia burgdorferi*. In Europe and Asia it is *Borrelia afzelii* and *Borrelia garinii*
4. Nervous system involvement occurs in approximately 8% of patients affected with *B. burgdorferi*

Clinical Manifestations

1. There are 3 stages of the disease:
 - a. Stage 1:
 - i. Erythema marginatum of the skin associated with arthralgias

- b. Stage 2:
 - i. Occurs weeks or months after the initial infection
 - ii. Onset of neurologic and cardiac involvement occurs in this stage
 - iii. The neurologic signs include:
 - 1. Meningitis
 - 2. Cranial nerve involvement (bilateral or unilateral VIIth nerve palsy)
 - 3. Radiculoneuritis
- c. Stage 3:
 - i. Occurs several years after the infection
 - 1. Arthritis
 - 2. Cognitive impairment (rare and controversial)
- d. Patients with *B. garinii* > *B. afzelii*
 - i. Radicular pain
 - ii. Meningeal signs
 - iii. Less dizziness

Neuropathology

- 1. Nerve biopsy:
 - a. Perivascular lymphocytic infiltration around small endoneurial, perineurial, and epineurial blood vessels
 - b. Axonal degeneration
- 2. Lymphocytic meningitis

Laboratory Evaluation

- 1. The serological laboratory tests most widely used are the Western blot and ELISA:
 - a. The Western blot IgM has a specificity of 94%
 - b. ELISA has a sensitivity of 70%
- 2. CSF:
 - a. Lymphocytic pleocytosis

Neuroimaging

- 1. MRI:
 - a. Late stage disease:
 - i. Some patients demonstrate periventricular white matter hyperintense signals
 - ii. Ventricular enlargement
 - iii. Cortical atrophy

Cysticercosis

General Characteristics

- 1. The most common helminth with CNS involvement
- 2. A significant problem in immigrants from Mexico, Central and South America to the USA
- 3. Seen in approximately 1–3% of post-mortem studies in Mexico
- 4. The infection is caused by the larval stage of the pig tapeworm *Taenia solium*

Clinical Manifestations

- 1. Seizures

- 2. Acute and focal neurological signs
- 3. Increased intracranial pressure
- 4. Hydrocephalus
- 5. Meningeal form
- 6. Involves the diaphragm
- 7. Muscle enlargement from inflammation
- 8. Chronic dementia from the severe lesion load

Neuropathology

- 1. Most cysts are parenchymal; they vary from one to several hundred
 - a. Parenchymal cysts are usually 5–20 mm in diameter
 - b. Racemose cysts in the subarachnoid space may be as large as 6 cm
- c. There are intraventricular cysts
- d. Cysts are located:
 - i. Cortex
 - ii. Deep gray matter
 - iii. White matter
 - iv. Cerebellum
 - v. Meninges
 - vi. Ventricles
- e. Racemose cysts may occlude the internal carotid artery or burst within the ventricle, causing meningitis

Laboratory Evaluation

- 1. Antibodies to cysticerci are demonstrated by Enzyme Linked Immunoelctrotransfer Blot (serum)
- 2. ELISA for CSF samples

Neuroimaging

- 1. MRI:
 - a. Calcified and non-calcified cysts throughout the brain (dense in the cortex and basal ganglia)
 - b. Meningeal and ventricular involvement in some patients
 - c. Racemose cysts in the IVth ventricle

Chronic Infections Associated with Dementia

- 1. Tuberculosis
- 2. Neurosyphilis
- 3. Cryptococcus
- 4. Histoplasmosis
- 5. Coccidioidomycosis
- 6. Toxoplasmosis
- 7. Candida
- 8. HIV
- 9. Herpes zoster
- 10. CMV
- 11. Lyme's disease
- 12. Cysticercosis
- 13. SSPE (post-infection/measles)
- 14. Rubella panencephalitis (post-infection)
- 15. Herpes simplex
