- **Novelty Fun**: To discover a new species of beetle in the rain forest.
  In this table "trivial/routine process" means that no innovative computation process was required to gain the new knowledge. A biologist may have conducted several expeditions to the Amazon rainforest and at a certain day by using her typical (therefore, trivial) methodology and basically her eyes, she discovers a new species of beetle, which, on a very basic level, is accessing a new information string (which may have never been accessed by a human mind before) and for her this is equivalent with having novelty fun.
- **Process Fun**: To look at a painting again in different context or mood.
  It is not uncommon to hear people enjoying looking at the same painting again and again, e.g. revisiting a particular museum regularly for this purpose. Except for the case that they discover new details in the painting, they, on a very basic level, access the same information string and by doing so, even repetitively, they have process fun. The explanation is provided by Yampolskiy: The same information string can contain different knowledge and multiple levels of meaning (Yampolskiy, 2013).
- **Novelty and Process Fun**: To perform qualia surfing as an uploaded mind.
  Loosemore defines "qualia surfing" in the context of uploading as "collecting new experiences by transferring our consciousness back and forth between different substrates" (Loosemore, 2014). One of his several examples is to change "into a body that can swim in the atmosphere of Jupiter … while you stargaze through telescopic eyes that can see beyond the visible spectrum." He explains that even if qualia surfing is restricted to the real world there is vast space of new experiences, which would be even larger if virtual worlds are added. For a person experiencing certain qualia for the first-time novelty as well as process fun may be involved.

A less futuristic example is to watch for the first time a 3D movie. The computation process, via 3D glasses, is new as well the information string, i.e. content of the movie; given the person has not watched it in 2D before.

It has to be highlighted that it is critical that the function fun (mind string, info string) has two parameters. Fun does not only depend on the accessed information string, but very much on the individual mind. For example, there are obviously human minds who neither enjoy watching movies nor discovering new species of beetles etc.

A weakness of human minds and therefore a special case is forgotten knowledge. In contrast, it is very likely that more sophisticated minds will have a nearly perfect memory. When human minds regain forgotten knowledge, both could be possible, to have fun or not: It could be fun to watch a movie again after a long time because one had forgotten the storyline. It may not be fun, but frustrating to spend time re-learning vocabulary of a language, which one had not practiced for some time. In both cases the same information string is accessed by the same computation process when the knowledge had been computed for the first time.

Based on Yampolskiy's approach and other mathematical truths it is evident that there are infinite information strings, which can be turned through infinite computation processes into infinite knowledge (Yampolskiy, 2013). This means every access to new knowledge and every new computation of existing or new knowledge may or may not involve novelty or process fun respectively. Therefore, the questions remain:

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

PERFORMANCE EVALUATION AND ANALYSIS

Is the fun space also infinite? If yes, are human minds able to access an infinite subset of this fun space? One constraint was mentioned above: Some knowledge remains hidden from human minds due to insufficient intelligence, time and resources. Those portions of fun space that are linked to the novelty and processing of this inaccessible knowledge are thus also inaccessible for human minds. We look at an excerpt of a random sample truth table for the function fun (mind string, info string), which is infinite and countable since both parameter sets are infinite and countable.

The overall fun space would be infinite if the truth table of this function would contain an infinite number of the value "true". This we cannot prove. It is possible that the number of the value "true" is finite, which implies that in this case the number of the value "false" must be infinite.

For the second question above, we look at specific minds, human minds in particular, and their accessible fun space. Therefore, we added the second column in the above truth table (Table 3), which filters human minds out of the space of all minds. In this example "Mind 2" happens to be human, and this mind would have infinite fun space if that row contained an infinite number of the value "true". The above question whether human minds have access to an infinite subset of the fun space would be affirmative, if the following statement was true:

$$\forall\, x\text{: human_mind}(x) = \mathrm{t} \wedge |\, \{y \mid \mathrm{fun}(x,\, y) = \mathrm{true}\} \,| = \infty$$

We do not have a formal answer to this. In fact, it is almost certain that not all human minds have access to infinite fun space. However, we can observe that the accessible fun space has risen in history and is currently enormous, which is linked to what Kurzweil describes as the "Law of Accelerating Returns" (Kurzweil, 2005). According to this law the rate of change in certain developing systems, for example technologies, has shown to increase exponentially. As already mentioned earlier the access to the fun space of humans who lived hundreds or thousands of years ago was much more restricted than it is for present humans. Only thanks to technologies many novelties can be experienced. And also thanks to technologies we have more time at hand, which does not have to be spent on life-sustaining activities. Therefore, we may assume that future generations can access even larger parts of the fun space.

After focusing so far on current human minds we look in the last part of this section at potential future human minds and also other minds:

Fun for human minds with extended life span. The concern has been expressed that humans with an extended life span will run out of fun (Walker, 2006). Yet, an extended life span enables that one limitation above is alleviated even further (time). Therefore, all else equal (e.g. the intelligence of this

Table 3. Random sample truth table for the function fun

Sample Truth table fun(x,y)	Human mind (t/f)	Info 1	Info 2	Info 3	Info 4	Info 5	Info 6	Info 7	Info 8	Info 9	…
Mind 1	f	f	t	f	t	f	t	t	f	f	
Mind 2	t	f	t	t	f	f	f	t	f	t

ageing mind stays the same) this human mind has the potential to gain additional knowledge during the additional time of embodiment, which may entail novelty and/or process fun.

It is hard to speculate how the access to fun space will be for humans who live for thousands or millions of years, but so far life expectancy has been increased successively by smaller time frames only. It is likely that more radical extensions would be accompanied by other developments to the human phenotype, which we discuss below.

Fun for human minds enhanced by intelligence amplification and other trans-human features, potentially supported by friendly AI. Similarly, concern has been raised that humans enhanced by trans-human features and/or supported by friendly AI may run out of fun: "If we self-improve human minds to extreme levels of intelligence, all challenges known today may bore us. Likewise, if superhumanly intelligent machines take care of our every need, it is apparent that no challenges nor fun will remain." (Yudkowsky, 2015).

This argument addresses mainly the above defined "process fun", i.e. previous challenges are becoming too simple. Yet, we have stated not only the infinity of computation processes as well as the infinity of knowledge, but also shown that trivial/routine computation processes could tap fun space as long as a new information string is accessed (of which also an infinite number exists).

Therefore, even if such minds run out of "process fun", since previously challenging computation processes became much simpler and/or can be performed much faster, there should be still sufficient "novelty fun" available. Chances for "novelty fun" are actually much higher than for unenhanced human minds, since enhanced human minds can reach previously inaccessible knowledge due to 1) improved intelligence, 2) much longer life span and 3) more and other resources. Enhanced humans will likely have access to additional sensors, which provide for "novelty fun" through experiencing new qualia (Loosemore, 2014). This is in line with e.g. Bostrom and Yudkowsky, who also believe that enhanced minds will not run out of fun, given that they are embodied in a sufficiently advanced context (Bostrom, 2008; Yudkowsky, 2015). Bostrom is even optimistic regarding "process fun": "If some challenges become too easy for post-humans, they could take on more difficult challenges."

As indicated above, another scenario in the future, which would make the above considerations obsolete, is the manipulation of human and other minds through technology, known as wireheading, in a way that boredom will be "neurochemically impossible" as envisaged by Pearce (Pearce, 2012). For such a manipulated mind even uninterrupted dishwashing would be continuous fun.

Fun for AIs and other minds. We lack evidence to what extent non-human minds can access the fun space, i.e. have a sensation of fun as epiphenomenon of any of their activities. It could be anywhere between the two extremes, which are to never experience fun (*x1*) or to have fun no matter which information string is accessed (*x2*).

$\forall$ y: fun(*x1, y*) = false

$\forall$ y: fun(*x2, y*) = true

At least for those non-human minds that are to some extent steered by the drives proposed by Omohundro (Efficiency, self-preservation, acquisition, and creativity) (Omohundro, 2007, Omohundro, 2008) we may assume that they aim for novelties. On the one hand, it would be anthropomorphism to assume that their pursuit of novelties is accompanied or motivated by any form of fun. On the other hand, if we take our definition of the mind space as the set of all possible cognitive algorithms, i.e. an infinite set,

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

there must be other minds, apart from humans, which are able to access fun space. And considering the space of all possible cognitive algorithms, there must be even minds experiencing fun by performing activities, which have nothing to do with detecting novelties.

CONCLUSION

Based on the theoretical groundwork of having described the possible space of minds as well as the space of fun we contributed a relation between the two spaces. We have defined a Boolean function fun (mind string, info string) with two parameters, one numeric string representing a mind and another numeric string representing information/knowledge. This approach is novel, thus a comparison with existing approaches is not possible.

We have shown that human minds could experience two types of fun by transforming information to knowledge: novelty fun and process fun. By means of the above function we were able to formalize the critical question whether human minds are able to access an infinite subset of the fun space. It is beyond our means to give a definite answer to the question, but we provided a substantiated assumption that a large number of human minds in present time and especially in the future have access to a vast space of fun.

These findings have ethical relevance since human minds strive for fun (not merely knowledge). In history as well as still in present time there have been and there are numerous humans living a life predominantly characterized by life-sustaining activities, which do not involve much fun. Yet, ideally the human condition improves over time owing, among other things, to advances in technology. Therefore, in order to determine whether the extension of the life span and/or enhancements for humans really mean progress to the human condition it was critical to show that there will be no shortage of accessible fun space for these minds. If it had turned out that there is not sufficient fun for either human minds with extended life span or enhanced human minds such developments would probably not be desirable.

Moreover, these findings are contributions to the new field of "intellectology" (Yampolskiy, 2015). This field is still in its early stages and provides for large areas of further research. To analyze relations between various kinds of minds and the fun space extends the traditional human-centric space of research and this is what "intellectology" is about. Further research is required on the question how to narrow down or to predict more precisely which new computation processes or which new knowledge mean fun for a certain mind, especially humans, and which are not part of the fun space despite being novel?

ENDNOTE

[1] Euler lived around 2,000 year later than Euclid and knew about Euclid's proof, i.e. the knowledge about the infinity of prime numbers had been accessed before, thus no involvement of "novelty fun" for Euler, but his proof was different, thus potential involvement of "process fun" for him.

Chapter 67
Data Extrapolation via Curve Modeling in Analyzing Risk:
Value Anticipation for Decision Making

Dariusz Jacek Jakóbczak
Technical University of Koszalin, Poland

ABSTRACT

Risk analysis needs suitable methods of data extrapolation and decision making. Proposed method of Hurwitz-Radon Matrices (MHR) can be used in extrapolation and interpolation of curves in the plane. For example quotations from the Stock Exchange, the market prices or rate of a currency form a curve. This chapter contains the way of data anticipation and extrapolation via MHR method and decision making: to buy or not, to sell or not. Proposed method is based on a family of Hurwitz-Radon (HR) matrices. The matrices are skew-symmetric and possess columns composed of orthogonal vectors. The operator of Hurwitz-Radon (OHR), built from these matrices, is described. Two-dimensional data are represented by the set of curve points. It is shown how to create the orthogonal and discrete OHR and how to use it in a process of data foreseeing and extrapolation. MHR method is interpolating and extrapolating the curve point by point without using any formula or function.

INTRODUCTION

Method of Hurwitz - Radon Matrices (MHR), invented by the author, can be applied in reconstruction and interpolation of curves in the plane. The method is based on a family of Hurwitz - Radon (HR) matrices. The matrices are skew - symmetric and possess columns composed of orthogonal vectors. The operator of Hurwitz - Radon (OHR), built from these matrices, is described. Author explains how to create the orthogonal and discrete OHR and how to use it in a process of curve interpolation and two-dimensional data modeling. Proposed method needs suitable choice of nodes, i.e. points of the 2D curve to be interpolated or extrapolated: nodes should be settled at each extremum (minimum or maximum) of one coordinate and at least one point between two successive local extrema, and nodes should be

monotonic in one of coordinates (for example equidistance). Created from the family of N - 1 HR matrices and completed with the identical matrix, system of matrices is orthogonal only for vector spaces of dimensions $N = 1, 2, 4$ or 8. Orthogonality of columns and rows is very important and significant for stability and high precision of calculations. MHR method is modeling the curve point by point without using any formula of function. Main features of MHR method are: accuracy of curve reconstruction depending on number of nodes and method of choosing nodes, interpolation of L points of the curve is connected with the computational cost of rank $O(L)$, MHR interpolation is not a linear interpolation (Ullman & Basri, 1991). The problem of curve length estimation is also considered. Algorithm of MHR method and the examples of data extrapolation are described. Value anticipation is the crucial feature in risk analyzing and decision making.

BACKGROUND

The following question is important in mathematics and computer science: is it possible to find a method of curve interpolation and extrapolation in the plane without building the interpolation polynomials? This chapter aims at giving the positive answer to this question. Current methods of curve interpolation are based on classical polynomial interpolation: Newton, Lagrange or Hermite polynomials and spline curves which are piecewise polynomials (Dahlquist & Bjoerck, 1974). Classical methods are useless to interpolate the function that fails to be differentiable at one point, for example the absolute value function $f(x) = |x|$at $x = 0$. If point (0;0) is one of the interpolation nodes, then precise polynomial interpolation of the absolute value function is impossible. Also when the graph of interpolated function differs from the shape of polynomials considerably, for example $f(x) = 1/x$, interpolation is very hard because of existing local extrema of polynomial. We cannot forget about the Runge's phenomenon: when interpolation nodes are equidistance then high-order polynomial oscillates toward the end of the interval, for example close to -1 and 1 with function $f(x) = 1/(1+25x^2)$ (Ralston, 1965). MHR method is free of these bad feature. Computational algorithm is considered and then it is important to talk about time. Complexity of calculations for one unknown point in Lagrange or Newton interpolation based on n nodes is connected with the computational cost of rank $O(n^2)$. Proposed method has lower calculation complexity.

A significant problem in risk analysis and decision making is that of appropriate data representation and extrapolation (Brachman & Levesque, 2004). Two-dimensional data can be treated as points on the curve. Classical polynomial interpolations and extrapolations (Lagrange, Newton, Hermite) are useless for data anticipation, because the stock quotations or the market prices represent discrete data and they do not preserve a shape of the polynomial. Also Richardson extrapolation has some weak sides concerning discrete data. This chapter is dealing with the method of data foreseeing and value extrapolation by using a family of Hurwitz-Radon matrices. The quotations, prices or rate of a currency, represented by curve points, consist of information which allows us to extrapolate the next data and then to make a decision (Fagin et al, 1995).

If the probabilities of possible actions are known, then some criteria are ready to be applied in decision making and analyzing risk: for example criterion of Laplace, Bayes, Wald, Hurwicz, Savage, Hodge-Lehmann (Straffin, 1993) and others (Watson, 2002). But in this chapter author considers only two possibilities: to do something or not. For example to buy a share or not, to sell a currency or not. Proposed method of Hurwitz-Radon Matrices (MHR) is used in data extrapolation and then calculations for risk analyzing and decision making are described. MHR method presents new approach to extrapolation problem because it takes the interpolation nodes to create orthogonal basis as columns

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

of matrix OHR operators. Then affine (convex) combination of such basis builds new orthogonal base for unknown coordinates of calculated points. MHR method uses two-dimensional data for knowledge representation (Markman, 1998) and for computational foundations (Sowa, 2000). Also medicine (Cierniak, 2005), industry (Jakóbczak & Kosiński, 2007) and manufacturing (Tang, 2005) are looking for the methods connected with geometry of the curves (Soussen & Mohammad-Djafari, 2004) . So suitable data representation and precise reconstruction (Latecki & Lakaemper, 1999) or extrapolation (Kozera, 2004) of the curve is a key factor in many applications of computational intelligence (Lowe, 1991 and 2001), knowledge representation and risk analysis. In comparison MHR method with Bézier curves, Hermite curves and B-curves (*B-splines*) or NURBS one unpleasant feature of these curves must be mentioned: small change of one characteristic point can make big change of whole reconstructed curve. Such an unwanted feature does not appear in MHR method. None of the methods, that are used nowadays, applies the orthogonal basis for unknown value extrapolation and foreseeing, but proposed MHR method does. Orthogonality means a very important feature for stability in calculations. Also point MHR interpolation and extrapolation via simple computations with matrices is something new in the problem of anticipation, risk analysis and decision making.

The considered problem statement looks as follow: let's assume there are given some 2D points of known data as the set of interpolation nodes. How the unknown value can be extrapolated and anticipated as the support in decision making and risk analysis, based on given characteristic (key) points?

THE METHOD OF HURWITZ-RADON MATRICES

Issues

This chapter deals with the problem of interpolation and extrapolation without computing the polynomial or any fixed function. The values of nodes are used to build the orthogonal matrix operators OHR and a linear (convex) combination of OHR operators leads to calculations of 2D curve points. Main idea of MHR method (Jakóbczak, 2006) is that the curve is interpolated or extrapolated point by point by computing the unknown coordinates of the points. The only significant factors in MHR method are: choosing the interpolation nodes and fixing the dimension of HR matrix ($N = 1, 2, 4$ or 8). Other characteristic features of function or curve, such as shape or similarity to polynomials, derivative or Runge's phenomenon, are not important in the process of MHR interpolation and extrapolation. The curve or function in MHR method is parameterized for value $\alpha \in [0;1]$ in each range of two successive interpolation nodes. Data extrapolation and foreseeing is calculated for $\alpha < 0$ or $\alpha > 1$. Estimation of the curve length with high precision is possible because of computing any number of curve points we want. Complexity of calculations for L unknown points in MHR interpolation and extrapolation, based on n nodes, is connected with the computational cost of rank $O(L)$. This is very important feature of MHR method.

The Origin of Hurwitz-Radon Matrices

Adolf Hurwitz (1859-1919) and Johann Radon (1887-1956) published separately the papers about specific class of matrices in 1923, working on the problem of quadratic forms. For example equation

$$(x_0^2 + x_1^2) \cdot (y_0^2 + y_1^2) = (z_0^2 + z_1^2)$$

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

is true when $z_0 = x_0y_0 - x_1y_1$, $z_1 = x_0y_1 + x_1y_0$. This result can be achieved from matrix equation:

$$\begin{bmatrix} x_0 & x_1 \\ -x_1 & x_0 \end{bmatrix} \cdot \begin{bmatrix} y_0 & y_1 \\ -y_1 & y_0 \end{bmatrix} = \begin{bmatrix} z_0 & z_1 \\ -z_1 & z_0 \end{bmatrix}.$$

Also equation

$$(x_0^2 + x_1^2 + x_2^2 + x_3^2) \cdot (y_0^2 + y_1^2 + y_2^2 + y_3^2) = z_0^2 + z_1^2 + z_2^2 + z_3^2$$

has solution:

$$z_0 = x_0y_0 - x_1y_1 - x_2y_2 - x_3y_3,$$

$$z_1 = x_0y_1 + x_1y_0 + x_2y_3 - x_3y_2,$$

$$z_2 = x_0y_2 - x_1y_3 + x_2y_0 + x_3y_1,$$

$$z_3 = x_0y_3 + x_1y_2 - x_2y_1 + x_3y_0.$$

This result can be achieved from matrix equation of dimension $N = 4$:

$$\begin{bmatrix} x_0 & x_1 & x_2 & x_3 \\ -x_1 & x_0 & -x_3 & x_2 \\ -x_2 & x_3 & x_0 & -x_1 \\ -x_3 & -x_2 & x_1 & x_0 \end{bmatrix} \cdot \begin{bmatrix} y_0 & y_1 & y_2 & y_3 \\ -y_1 & y_0 & -y_3 & y_2 \\ -y_2 & y_3 & y_0 & -y_1 \\ -y_3 & -y_2 & y_1 & y_0 \end{bmatrix} = \begin{bmatrix} z_0 & z_1 & z_2 & z_3 \\ -z_1 & z_0 & -z_3 & z_2 \\ -z_2 & z_3 & z_0 & -z_1 \\ -z_3 & -z_2 & z_1 & z_0 \end{bmatrix}.$$

Hurwitz and Radon proved that dimensions $N = 1, 2, 4$ and 8 are the only dimensions for these quadratic equations. When $N = 8$:

$$\left(\sum_{i=0}^{7} x_i^2\right) \cdot \left(\sum_{i=0}^{7} y_i^2\right) = \sum_{i=0}^{7} z_i^2$$

for

$$z_0 = x_0y_0 - x_1y_1 - x_2y_2 - x_3y_3 - x_4y_4 - x_5y_5 - x_6y_6 - x_7y_7,$$

$$z_1 = x_0y_1 + x_1y_0 - x_2y_3 + x_3y_2 - x_4y_5 + x_5y_4 + x_6y_7 - x_7y_6,$$

$$z_2 = x_0y_2 + x_1y_3 + x_2y_0 - x_3y_1 - x_4y_6 - x_5y_7 + x_6y_4 + x_7y_5,$$

$$z_3 = x_0y_3 - x_1y_2 + x_2y_1 + x_3y_0 - x_4y_7 + x_5y_6 - x_6y_5 + x_7y_4,$$

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

$$z_4 = x_0y_4 + x_1y_5 + x_2y_6 + x_3y_7 + x_4y_0 - x_5y_1 - x_6y_2 - x_7y_3,$$

$$z_5 = x_0y_5 - x_1y_4 + x_2y_7 - x_3y_6 + x_4y_1 + x_5y_0 + x_6y_3 - x_7y_2,$$

$$z_6 = x_0y_6 - x_1y_7 - x_2y_4 + x_3y_5 + x_4y_2 - x_5y_3 + x_6y_0 + x_7y_1,$$

$$z_7 = x_0y_7 + x_1y_6 - x_2y_5 - x_3y_4 + x_4y_3 + x_5y_2 - x_6y_1 + x_7y_0.$$

The matrices used to solve quadratic equations are defined: matrices A_i, $i = 1, 2, \ldots, m$ satisfying

$$A_jA_k + A_kA_j = 0, A_j^2 = -I, j \neq k, j, k = 1, 2, ..., m$$

are called a family of Hurwitz - Radon matrices.

A family of Hurwitz - Radon (HR) matrices has important features (Eckmann, 1999): HR matrices are skew-symmetric ($A_i^T = - A_i$) and reverse matrices are easy to find ($A_i^{-1} = - A_i$). Only for dimension $N = 1, 2, 4$ or 8 the family of HR matrices consists of $N - 1$ matrices. When $N = 1$ there is no matrix, just calculations with real numbers. For $N = 2$ we have one matrix:

$$A_1 = \begin{bmatrix} 0 & 1 \\ -1 & 0 \end{bmatrix}$$

For $N = 4$ there are three HR matrices with integer entries:

$$A_1 = \begin{bmatrix} 0 & 1 & 0 & 0 \\ -1 & 0 & 0 & 0 \\ 0 & 0 & 0 & -1 \\ 0 & 0 & 1 & 0 \end{bmatrix}, A_2 = \begin{bmatrix} 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ -1 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 \end{bmatrix}, A_3 = \begin{bmatrix} 0 & 0 & 0 & 1 \\ 0 & 0 & -1 & 0 \\ 0 & 1 & 0 & 0 \\ -1 & 0 & 0 & 0 \end{bmatrix}.$$

For $N = 8$ we have seven HR matrices with elements $0, \pm 1$ (Jakóbczak, 2006).

So far HR matrices are applied in electronics (Citko, Jakóbczak & Sieńko, 2005): in Space-Time Block Coding (STBC) and orthogonal design (Tarokh, Jafarkhani & Calderbank, 1999), also in signal processing (Sieńko, Citko & Wilamowski, 2002) and Hamiltonian Neural Nets (Sieńko & Citko, 2002).

The Operator of Hurwitz-Radon

Here is the beginning of proposed MHR method. Let us consider a combination of identity matrix and HR matrix of dimension $N = 2$:

$$a\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} + b\begin{bmatrix} 0 & 1 \\ -1 & 0 \end{bmatrix} = \begin{bmatrix} a & b \\ -b & a \end{bmatrix}.$$

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

For any points $(x_1,y_1) \in \boldsymbol{R}^2$, $(x_2,y_2) \in \boldsymbol{R}^2$ matrix equation

$$\begin{bmatrix} a & b \\ -b & a \end{bmatrix} \cdot \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} = \begin{bmatrix} y_1 \\ y_2 \end{bmatrix}$$

is true with

$$a = \frac{x_1 y_1 + x_2 y_2}{x_1^{\,2} + x_2^{\,2}},\ b = \frac{x_2 y_1 - x_1 y_2}{x_1^{\,2} + x_2^{\,2}} \text{ and } x_1^{\,2} + x_2^{\,2} > 0.$$

Reverse matrix equation

$$\begin{bmatrix} a & b \\ -b & a \end{bmatrix} \cdot \begin{bmatrix} y_1 \\ y_2 \end{bmatrix} = \begin{bmatrix} x_1 \\ x_2 \end{bmatrix}$$

is true with

$$a = \frac{x_1 y_1 + x_2 y_2}{y_1^{\,2} + y_2^{\,2}},\ b = \frac{-x_2 y_1 + x_1 y_2}{y_1^{\,2} + y_2^{\,2}} \text{ and } y_1^{\,2} + y_2^{\,2} > 0.$$

Also we can consider a combination of identity matrix and three HR matrices of dimension $N = 4$:

$$a\begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} + b\begin{bmatrix} 0 & 1 & 0 & 0 \\ -1 & 0 & 0 & 0 \\ 0 & 0 & 0 & -1 \\ 0 & 0 & 1 & 0 \end{bmatrix} + c\begin{bmatrix} 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ -1 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 \end{bmatrix} + d\begin{bmatrix} 0 & 0 & 0 & 1 \\ 0 & 0 & -1 & 0 \\ 0 & 1 & 0 & 0 \\ -1 & 0 & 0 & 0 \end{bmatrix} = \begin{bmatrix} a & b & c & d \\ -b & a & -d & c \\ -c & d & a & -b \\ -d & -c & b & a \end{bmatrix}.$$

For any points $(x_1,y_1) \in \boldsymbol{R}^2$, $(x_2,y_2) \in \boldsymbol{R}^2$, $(x_3,y_3) \in \boldsymbol{R}^2$, $(x_4,y_4) \in \boldsymbol{R}^2$ matrix equation

$$\begin{bmatrix} a & b & c & d \\ -b & a & -d & c \\ -c & d & a & -b \\ -d & -c & b & a \end{bmatrix} \cdot \begin{bmatrix} x_1 \\ x_2 \\ x_3 \\ x_4 \end{bmatrix} = \begin{bmatrix} y_1 \\ y_2 \\ y_3 \\ y_4 \end{bmatrix}$$

is satisfied with

$$a = \frac{x_1 y_1 + x_2 y_2 + x_3 y_3 + x_4 y_4}{x_1^{\,2} + x_2^{\,2} + x_3^{\,2} + x_4^{\,2}},\ b = \frac{-x_1 y_2 + x_2 y_1 + x_3 y_4 - x_4 y_3}{x_1^{\,2} + x_2^{\,2} + x_3^{\,2} + x_4^{\,2}},\ c = \frac{-x_1 y_3 - x_2 y_4 + x_3 y_1 + x_4 y_2}{x_1^{\,2} + x_2^{\,2} + x_3^{\,2} + x_4^{\,2}},$$

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

$$d = \frac{-x_1 y_4 + x_2 y_3 - x_3 y_2 + x_4 y_1}{x_1^{\,2} + x_2^{\,2} + x_3^{\,2} + x_4^{\,2}} \text{ and } x_1^{\,2} + x_2^{\,2} + x_3^{\,2} + x_4^{\,2} > 0.$$

Reverse matrix equation

$$\begin{bmatrix} a & b & c & d \\ -b & a & -d & c \\ -c & d & a & -b \\ -d & -c & b & a \end{bmatrix} . \begin{bmatrix} y_1 \\ y_2 \\ y_3 \\ y_4 \end{bmatrix} = \begin{bmatrix} x_1 \\ x_2 \\ x_3 \\ x_4 \end{bmatrix}$$

is satisfied with

$$a = \frac{x_1 y_1 + x_2 y_2 + x_3 y_3 + x_4 y_4}{y_1^{\,2} + y_2^{\,2} + y_3^{\,2} + y_4^{\,2}},\ b = \frac{x_1 y_2 - x_2 y_1 - x_3 y_4 + x_4 y_3}{y_1^{\,2} + y_2^{\,2} + y_3^{\,2} + y_4^{\,2}},\ c = \frac{x_1 y_3 + x_2 y_4 - x_3 y_1 - x_4 y_2}{y_1^{\,2} + y_2^{\,2} + y_3^{\,2} + y_4^{\,2}},$$

$$d = \frac{x_1 y_4 - x_2 y_3 + x_3 y_2 - x_4 y_1}{y_1^{\,2} + y_2^{\,2} + y_3^{\,2} + y_4^{\,2}} \text{ and } y_1^{\,2} + \mathrm{y}_2^{\,2} + y_3^{\,2} + y_4^{\,2} > 0.$$

A combination of identity matrix and seven HR matrices of dimension $N = 8$ looks as follows:

$$\begin{bmatrix} a_0 & a_1 & a_2 & a_3 & a_4 & a_5 & a_6 & a_7 \\ -a_1 & a_0 & a_3 & -a_2 & a_5 & -a_4 & -a_7 & a_6 \\ -a_2 & -a_3 & a_0 & a_1 & a_6 & a_7 & -a_4 & -a_5 \\ -a_3 & a_2 & -a_1 & a_0 & a_7 & -a_6 & a_5 & -a_4 \\ -a_4 & -a_5 & -a_6 & -a_7 & a_0 & a_1 & a_2 & a_3 \\ -a_5 & a_4 & -a_7 & a_6 & -a_1 & a_0 & -a_3 & a_2 \\ -a_6 & a_7 & a_4 & -a_5 & -a_2 & a_3 & a_0 & -a_1 \\ -a_7 & -a_6 & a_5 & a_4 & -a_3 & -a_2 & a_1 & a_0 \end{bmatrix}.$$

Results for matrix equations with a combination of identity matrix and seven HR matrices of dimension $N = 8$ are calculated in formulas (3), (4) and (8). Solutions of matrix equations (Sieńko, Citko & Jakóbczak, 2004) are used to build the matrix Operator of Hurwitz – Radon (OHR).

Let's assume there is given a finite set of points of the curve, called further nodes $(x_i,y_i) \in \boldsymbol{R^2}$ such as:

1. Nodes (interpolation points) are settled at local extrema (maximum or minimum) of one of coordinates and at least one point between two successive local extrema;
2. Each node (x_i,y_i) is monotonic in coordinates x_i or y_i (for example equidistance in one of coordinates).

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Assume that the nodes belong to a curve in the plane. How the whole curve could be interpolated or extrapolated using this discrete set of nodes? Proposed method (Jakóbczak, 2007) is based on local, orthogonal matrix operators. The values of nodes' coordinates (x_i,y_i) are connected with HR matrices, built on N - dimensional vector space. It is important that HR matrices are skew-symmetric and only for dimensions $N = 1, 2, 4$ or 8 columns and rows of HR matrices are orthogonal (Eckmann, 1999).

If one curve is described by a set of nodes $\{(x_i,y_i), i = 1, 2, \ldots, n\}$ monotonic (for example equidistance) in coordinates x_i, then HR matrices combined with identity matrix are used to build an orthogonal and discrete Hurwitz - Radon Operator (OHR). For nodes (x_1,y_1), (x_2,y_2) OHR of dimension $N = 2$ is constructed:

$$M = \frac{1}{x_1^{\,2} + x_2^{\,2}} \begin{bmatrix} x_1 & x_2 \\ -x_2 & x_1 \end{bmatrix} \begin{bmatrix} y_1 & -y_2 \\ y_2 & y_1 \end{bmatrix}, \; M = \frac{1}{x_1^{\,2} + x_2^{\,2}} \begin{bmatrix} x_1y_1 + x_2y_2 & x_2y_1 - x_1y_2 \\ x_1y_2 - x_2y_1 & x_1y_1 + x_2y_2 \end{bmatrix}. \tag{1}$$

For nodes (x_1,y_1), (x_2,y_2), (x_3,y_3), (x_4,y_4) monotonic (for example equidistance) in x_i OHR of dimension $N = 4$ is constructed:

$$M = \frac{1}{x_1^{\,2} + x_2^{\,2} + x_3^{\,2} + x_4^{\,2}} \begin{bmatrix} u_0 & u_1 & u_2 & u_3 \\ -u_1 & u_0 & -u_3 & u_2 \\ -u_2 & u_3 & u_0 & -u_1 \\ -u_3 & -u_2 & u_1 & u_0 \end{bmatrix} \tag{2}$$

where

$$u_0 = x_1y_1 + x_2y_2 + x_3y_3 + x_4y_4, \; u_1 = -x_1y_2 + x_2y_1 + x_3y_4 - x_4y_3$$
$$u_2 = -x_1y_3 - x_2y_4 + x_3y_1 + x_4y_2, \; u_3 = -x_1y_4 + x_2y_3 - x_3y_2 + x_4y_1.$$

For nodes (x_1,y_1), (x_2,y_2), …, (x_8,y_8) monotonic in x_i OHR of dimension $N = 8$ is equal with

$$M = \frac{1}{\sum_{i=1}^{8} x_i^{\,2}} \begin{bmatrix} u_0 & u_1 & u_2 & u_3 & u_4 & u_5 & u_6 & u_7 \\ -u_1 & u_0 & u_3 & -u_2 & u_5 & -u_4 & -u_7 & u_6 \\ -u_2 & -u_3 & u_0 & u_1 & u_6 & u_7 & -u_4 & -u_5 \\ -u_3 & u_2 & -u_1 & u_0 & u_7 & -u_6 & u_5 & -u_4 \\ -u_4 & -u_5 & -u_6 & -u_7 & u_0 & u_1 & u_2 & u_3 \\ -u_5 & u_4 & -u_7 & u_6 & -u_1 & u_0 & -u_3 & u_2 \\ -u_6 & u_7 & u_4 & -u_5 & -u_2 & u_3 & u_0 & -u_1 \\ -u_7 & -u_6 & u_5 & u_4 & -u_3 & -u_2 & u_1 & u_0 \end{bmatrix} \tag{3}$$

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

where

$$u = \begin{bmatrix} y_1 & y_2 & y_3 & y_4 & y_5 & y_6 & y_7 & y_8 \\ -y_2 & y_1 & -y_4 & y_3 & -y_6 & y_5 & y_8 & -y_7 \\ -y_3 & y_4 & y_1 & -y_2 & -y_7 & -y_8 & y_5 & y_6 \\ -y_4 & -y_3 & y_2 & y_1 & -y_8 & y_7 & -y_6 & y_5 \\ -y_5 & y_6 & y_7 & y_8 & y_1 & -y_2 & -y_3 & -y_4 \\ -y_6 & -y_5 & y_8 & -y_7 & y_2 & y_1 & y_4 & -y_3 \\ -y_7 & -y_8 & -y_5 & y_6 & y_3 & -y_4 & y_1 & y_2 \\ -y_8 & y_7 & -y_6 & -y_5 & y_4 & y_3 & -y_2 & y_1 \end{bmatrix} \cdot \begin{bmatrix} x_1 \\ x_2 \\ x_3 \\ x_4 \\ x_5 \\ x_6 \\ x_7 \\ x_8 \end{bmatrix} \tag{4}$$

We can see here that the components of the vector $\mathbf{u} = (u_0, u_1, \ldots, u_7)^{\mathrm{T}}$, appearing in the matrix M in formula (3) are defined by (4) in the similar way to formula (2) but in terms of the coordinates of the above 8 nodes. Note that OHR operators (1)-(3) satisfy the condition of interpolation

$$M \cdot \mathbf{x} = \mathbf{y} \tag{5}$$

for $\mathbf{x} = (x_1, x_2 \ldots, x_N)^{\mathrm{T}} \in \boldsymbol{R}^N$, $\mathbf{x} \neq \mathbf{0}$, $\mathbf{y} = (y_1, y_2 \ldots, y_N)^{\mathrm{T}} \in \boldsymbol{R}^N$, $N = 1, 2, 4$ or 8.

If one curve is described by a set of nodes $\{(x_i, y_i), i = 1, 2, \ldots, n\}$ monotonic (for example equidistance) in coordinates y_i, then HR matrices combined with identity matrix are used to build an orthogonal and discrete reverse Hurwitz - Radon Operator (reverse OHR). For nodes (x_1, y_1), (x_2, y_2) reverse OHR of dimension $N = 2$ is constructed:

$$M^{-1} = \frac{1}{y_1^{\,2} + y_2^{\,2}} \begin{bmatrix} x_1 & -x_2 \\ x_2 & x_1 \end{bmatrix} \begin{bmatrix} y_1 & y_2 \\ -y_2 & y_1 \end{bmatrix}, \; M^{-1} = \frac{1}{y_1^{\,2} + y_2^{\,2}} \begin{bmatrix} x_1 y_1 + x_2 y_2 & -x_2 y_1 + x_1 y_2 \\ -x_1 y_2 + x_2 y_1 & x_1 y_1 + x_2 y_2 \end{bmatrix}. \tag{6}$$

For nodes (x_1, y_1), (x_2, y_2), (x_3, y_3), (x_4, y_4) monotonic in y_i the reverse OHR of dimension $N = 4$ is constructed with u_o, u_1, u_2 and u_3 from (2):

$$M^{-1} = \frac{1}{y_1^{\,2} + y_2^{\,2} + y_3^{\,2} + y_4^{\,2}} \begin{bmatrix} u_0 & -u_1 & -u_2 & -u_3 \\ u_1 & u_0 & u_3 & -u_2 \\ u_2 & -u_3 & u_0 & u_1 \\ u_3 & u_2 & -u_1 & u_0 \end{bmatrix}. \tag{7}$$

For nodes (x_1, y_1), (x_2, y_2), …, (x_8, y_8) monotonic in y_i the reverse OHR of dimension $N = 8$ is equal with

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

$$M^{-1} = \frac{1}{\sum_{i=1}^{8} y_i^{\,2}} \begin{bmatrix} u_0 & -u_1 & -u_2 & -u_3 & -u_4 & -u_5 & -u_6 & -u_7 \\ u_1 & u_0 & -u_3 & u_2 & -u_5 & u_4 & u_7 & -u_6 \\ u_2 & u_3 & u_0 & -u_1 & -u_6 & -u_7 & u_4 & u_5 \\ u_3 & -u_2 & u_1 & u_0 & -u_7 & u_6 & -u_5 & u_4 \\ u_4 & u_5 & u_6 & u_7 & u_0 & -u_1 & -u_2 & -u_3 \\ u_5 & -u_4 & u_7 & -u_6 & u_1 & u_0 & u_3 & -u_2 \\ u_6 & -u_7 & -u_4 & u_5 & u_2 & -u_3 & u_0 & u_1 \\ u_7 & u_6 & -u_5 & -u_4 & u_3 & u_2 & -u_1 & u_0 \end{bmatrix}, \tag{8}$$

where the components of the vector $\mathbf{u} = (u_0, u_1,\ldots, u_7)^{\mathrm{T}}$ are defined in terms of (4). Note that reverse OHR operators (6)-(8) satisfy the condition of interpolation

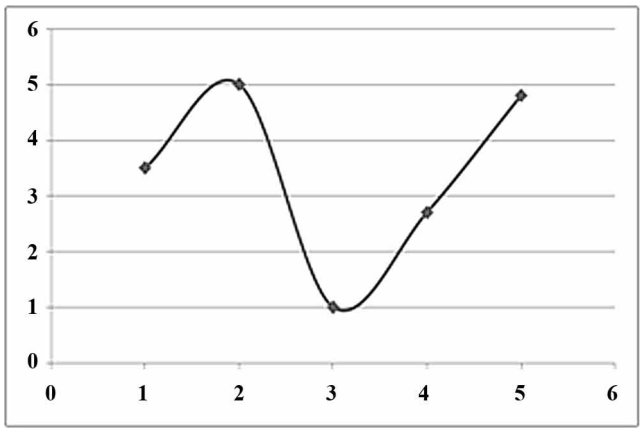
$$M^{-1}\cdot\mathbf{y} = \mathbf{x} \tag{9}$$

for $\mathbf{x} = (x_1,x_2\ldots,x_N)^{\mathrm{T}} \in \boldsymbol{R}^N$, $\mathbf{y} = (y_1,y_2\ldots,y_N)^{\mathrm{T}} \in \boldsymbol{R}^N$, $\mathbf{y} \neq \mathbf{0}$, $N = 1, 2, 4$ or 8.

Known values, for example currency rates or market prices, are represented on 2D curve by the set of nodes $(x_i,y_i) \in \boldsymbol{R}^2$ (characteristic points) as follows in proposed MHR method:

1. Nodes (interpolation points) are settled at local extrema (maximum or minimum) of one of coordinates and at least one point between two successive local extrema;
2. Nodes (x_i,y_i) are monotonic in coordinates x_i ($x_i < x_{i+1}$ for all i) or y_i ($y_i < y_{i+1}$);
3. One curve is represented by at least four nodes.

Condition 1 is done for the most appropriate description of a curve. The quotations or prices are real data. Condition 2 according to a graph of function means that coordinates x_i represent for example the time. Condition 3 is adequate for extrapolation, but in the case of interpolation minimal number of nodes is five.



Data points are treated as interpolation nodes. How can we extrapolate continues values at time $x = 5.5$ for example or discrete data for next day $x = 6$ (see Figure 1)? The anticipation of values is possible using proposed MHR method.

THE METHOD OF HURWITZ-RADON MATRICES

Key question looks as follows: how can we compute coordinates of points settled between interpolation nodes or beyond the nodes? The answer is connected with MHR method for interpolation and extrapolation. On a segment of a line every number "c" situated between "a" and "b" is described by a linear (convex) combination $c = \alpha \cdot a + (1\text{-}\alpha) \cdot b$ for

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. Five nodes of data and a curve. Source: author, 2014

$$\alpha = \frac{b-c}{b-a} \in [0;1]. \tag{10}$$

If $c < a$ then $\alpha > 1$: there is extrapolation of points situated left of nodes. If $c > b$ then $\alpha < 0$: extrapolation of points situated right of nodes.

When the nodes are monotonic in coordinates x_i, average OHR operator M_2 of dimension $N = 1, 2, 4$ or 8 is constructed as follows:

$$M_2 = \alpha \bullet M_0 + (1 - \alpha) \bullet M_1 \tag{11}$$

with the operator M_0 built (1)-(3) by "odd" nodes $(x_1=a,y_1)$, (x_3,y_3), …, (x_{2N-1},y_{2N-1}) and M_1 built (1)-(3) by "even" nodes $(x_2=b,y_2)$, (x_4,y_4), …, (x_{2N},y_{2N}).

When the nodes are monotonic in coordinates y_i, average reverse OHR operator M_2^{-1} of dimension $N = 1, 2, 4$ or 8 is constructed as follows:

$$M_2^{-1} = \alpha \cdot M_0^{-1} + (1-\alpha) \cdot M_1^{-1} \tag{12}$$

with the reverse operator M_0^{-1} built (6)-(8) by nodes $(x_1,y_1=a)$, (x_3,y_3), …, (x_{2N-1},y_{2N-1}) and M_1^{-1} built (6)-(8) by nodes $(x_2,y_2=b)$, (x_4,y_4), …, (x_{2N},y_{2N}).

Notice that having the operator M_2 for coordinates $x_i < x_{i+1}$ it is possible to reconstruct the second coordinates of points (x,y) in terms of the vector C defined with

$$c_i = \alpha \cdot x_{2i-1} + (1-\alpha) \cdot x_{2i},\ i = 1, 2, \ldots, N \tag{13}$$

as $C = [c_1, c_2, \ldots, c_N]^T$. The required formula is similar to (5):

$$Y(C) = M_2 \bullet C \tag{14}$$

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

in which components of vector $Y(C)$ give the second coordinate of the points (x,y) corresponding to the first coordinate, given in terms of components of the vector C.

On the other hand, having the operator M_2^{-1} for coordinates $y_i < y_{i+1}$ it is possible to reconstruct the first coordinates of points (x,y) in terms of the corresponding second coordinates given by components of the new vector C defined, as previously, with

$$c_i = \alpha \cdot y_{2i-1} + (1-\alpha) \cdot y_{2i},\ i = 1, 2, \ldots, N \tag{15}$$

and $C = [c_1, c_2, \ldots, c_N]^T$. The final formula is similar to (9):

$$X(C) = M_2^{-1} \cdot C \tag{16}$$

in which components of the vector $X(C)$ give the first coordinate of the points (x,y) corresponding to the second coordinate, given in terms of components of the vector C.

After computing (14) or (16) for any $\alpha \in [0;1]$, we have a half of reconstructed points ($j = 1$ in algorithm 1). Now it is necessary to find second half of unknown coordinates ($j = 2$ in algorithm 1) for

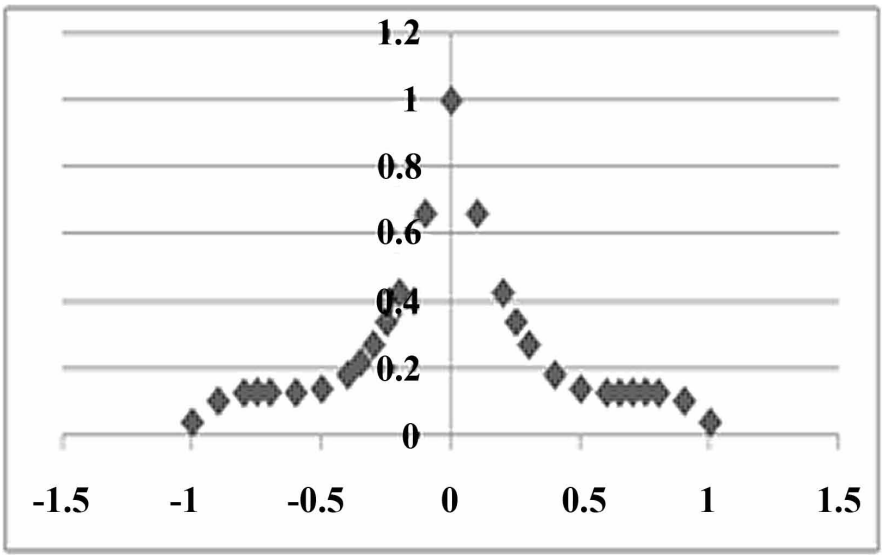
$$c_i = \alpha \cdot x_{2i} + (1-\alpha) \cdot x_{2i+1},\ i = 1, 2, \ldots, N \tag{17}$$

or

$$c_i = \alpha \cdot y_{2i} + (1-\alpha) \cdot y_{2i+1},\ i = 1, 2, \ldots, N \tag{18}$$

depending on whether x_i (17) or y_i (18) is monotonic. There is no need to build the OHR for nodes $(x_2=a,y_2)$, (x_4,y_4), …, (x_{2N},y_{2N}) or the reverse OHR for nodes $(x_2,y_2=a)$, (x_4,y_4), …, (x_{2N},y_{2N}), because we have just found M_1 or M_1^{-1}. This operator will play the role as M_0 or M_0^{-1} in (11) or (12). New M_1 or M_1^{-1} must be computed for nodes $(x_3=b,y_3)$, …, (x_{2N-1},y_{2N-1}), (x_{2N+1},y_{2N+1}) or $(x_3,y_3=b)$, …, (x_{2N-1},y_{2N-1}), (x_{2N+1},y_{2N+1}).

As we see the minimum number of interpolation nodes $n = 2N+1 = 5$, 9 or 17 using OHR operators of dimension $N = 2$, 4 or 8 respectively. If there is more nodes than $2N+1$, the same calculations (10)-(18) have to be done for next range(s) or last range of $2N+1$ nodes. For example, if $n = 9$ then we can use OHR operators of dimension $N = 4$ or OHR operators of dimension $N = 2$ for two subsets of nodes: $\{(x_1,y_1), \ldots, (x_5,y_5)\}$ and $\{(x_5,y_5), \ldots, (x_9,y_9)\}$.



Here is the application of MHR method for function $f(x)=1/(1+25x^2)$ with five nodes equidistance in first coordinate: $x_i = -1, -0.5, 0, 0.5, 1$ (see Figure 2).

MHR interpolation of function $f(x) = 1/(1+25x^2)$ gives better result then polynomial interpolation: there is no Runge phenomenon. The same can be said for function $f(x) = 1/x$.

MHR extrapolation is valid for $\alpha < 0$ or $\alpha > 1$. In the case of continues data, parameter α is a real number. For example there are four nodes: (1; 2), (1.3;5), (2;3), (2.5;6). MHR extrapolation with $\alpha = -0.01$ gives the point (2.505; 6.034) and with $\alpha = -0.1$: (2.55;6.348). But the rate of a currency or the quotations are discrete data. If we assume that the rate of a currency is represented by equidistance nodes (day by day – fixed step of time $h = 1$ for coordinate x), next data or the rate on next day is extrapolated (anticipated) for $\alpha = -1$. Calculation of unknown coordinates for data points using formulas (10)-(18) is called by author the method of Hurwitz - Radon Matrices (MHR).

Figure 2. Twenty six interpolated points of function $f(x) = 1/(1+25x^2)$ using MHR method with 5 nodes. Source: author, 2014

Algorithm and Complexity of MHR Calculations

The algorithm of points reconstruction for $2N+1 = 5$, 9 or 17 successive nodes is presented.

Algorithm 1.

Let $j = 1$. *Input: Set of interpolation nodes* $\{(x_i,y_i)$, $i = 1,2,\ldots,n$; $n = 5, 9$ *or* $17\}$ *such as:*

a) nodes are settled at local extrema (maximum or minimum) of one of coordinates and at least one point between two successive local extrema;
b) nodes (x_i,y_i) are monotonic in coordinates x_i or y_i.

Step 1: *Determine the dimension N of OHR operators:* $N = 2$ *if* $n = 5$, $N = 4$ *if* $n = 9$, $N = 8$ *if* $n = 17$.

Step 2: *If nodes are monotonic in* x_i *then build* M_0 *for nodes* $(x_1=a,y_1)$, (x_3,y_3), …, (x_{2N-1},y_{2N-1}) *and* M_1 *for nodes* $(x_2=b,y_2)$, (x_4,y_4), …, (x_{2N},y_{2N}) *from (1)-(3). If nodes are monotonic in* y_i *then build* M_0^{-1} *for nodes* $(x_1,y_1=a)$, (x_3,y_3), …,(x_{2N-1},y_{2N-1}) *and* M_1^{-1} *for nodes* $(x_2,y_2=b)$, (x_4,y_4), …, (x_{2N},y_{2N}) *from* (6)-(8).

Step 3: *Determine the number of points to be reconstructed* $K_j > 0$ *between two successive nodes, let* $k = 1$.

Step 4: *Compute* $\alpha \in [0;1]$ *from (10) for* $c_1 = c = \alpha \cdot a + (1-\alpha) \cdot b$.

Step 5: *Build* M_2 *from (11) or* M_2^{-1} *from (12).*

Step 6: *Compute vector* $C = [c_1, c_2,\ldots, c_N]^T$ *from (13) or (15).*

Step 7: *Compute unknown coordinates* $Y(C)$ *from (14) or* $X(C)$ *from (16).*

Step 8: *If* $k < K_j$, *set* $k = k + 1$ *and go to Step 4. Otherwise if* $j = 1$, *set* $M_0 = M_1$, $a = x_2$, $b = x_3$ *(if nodes are monotonic in* x_i*) or* $M_0^{-1} = M_1^{-1}$, $a = y_2$, $b = y_3$ *(if nodes are monotonic in* y_i*), build new* M_1 *or* M_1^{-1} *for nodes* (x_3,y_3), (x_5,y_5), …,(x_{2N+1},y_{2N+1}), *let* $j = 2$ *and go to Step 3. Otherwise, stop.*

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

The number of reconstructed points in algorithm 1 is $K = N(K_1+K_2)$. If there are more nodes than $2N+1 = 5$, 9 or 17, algorithm 1 has to be done for next range(s) or last range of $2N + 1$ nodes. Reconstruction of curve points using algorithm 1 is called by author the method of Hurwitz - Radon Matrices (MHR). If we have n interpolation nodes, then there is $K = L – n$ points to find using Algorithm 1 and MHR method. The complexity of MHR calculations has to be considered.

Lemma 1: Let $n = 5$, 9 or 17 is the number of interpolation nodes, let MHR method (algorithm 1) is done for reconstruction of the curve consists of L points. Then MHR method is connected with the computational cost of rank $O(L)$.

Proof. Using algorithm 1 we have to reconstruct $K = L – n$ points of unknown curve. Counting the number of multiplications and divisions D in algorithm 1, for example in (20) in case $n = 5$ for each c_i at first and second half of reconstructed points, here are the results:

1) $D = 4L+7$ for $n = 5$ and $L = 2i + 5$;
2) $D = 6L+21$ for $n = 9$ and $L = 4i + 9$;
3) $D = 10L+73$ for $n = 17$ and $L = 8i + 17$; $i = 2,3,4...$

The lowest computational cost appears in MHR method with five nodes and OHR operators of dimension $N = 2$. Therefore whole set of n nodes can be divided into subsets of five nodes. Then whole curve is to be reconstructed by algorithm 1 with all subsets of five nodes: $\{(x_1,y_1), \ldots, (x_5,y_5)\}$, $\{(x_5,y_5), \ldots, (x_9,y_9)\}$,

$\{(x_9,y_9), \ldots, (x_{13},y_{13})\}\ldots$ If the last node (x_n,y_n) is indexed $n \neq 4i + 1$, then we have to use last five nodes $\{(x_{n-4},y_{n-4}), \ldots, (x_n,y_n)\}$ in algorithm 1.

The Formulas for a Single Point and Error Estimation

Now there are the formulas for computing one unknown coordinate of a single point. Assume there are given four nodes (x_1,y_1), (x_2,y_2), (x_3,y_3), (x_4,y_4) monotonic in x_i. OHR operators of dimension $N = 2$ are built (1) as follows:

$$M_0 = \frac{1}{x_1^{\,2} + x_3^{\,2}}\begin{bmatrix} x_1y_1 + x_3y_3 & x_3y_1 - x_1y_3 \\ x_1y_3 - x_3y_1 & x_1y_1 + x_3y_3 \end{bmatrix},\ M_1 = \frac{1}{x_2^{\,2} + x_4^{\,2}}\begin{bmatrix} x_2y_2 + x_4y_4 & x_4y_2 - x_2y_4 \\ x_2y_4 - x_4y_2 & x_2y_2 + x_4y_4 \end{bmatrix}.$$

Let first coordinate c_1 of reconstructed point is situated between x_1 and x_2:

$$c_1 = \alpha\cdot x_1 + \beta\cdot x_2 \text{ for } 0 \le \beta = 1 - \alpha \le 1. \tag{19}$$

Compute second coordinate of reconstructed point $y(c_1)$ for $Y(C) = [y(c_1), y(c_2)]^T$ from (14):

$$\begin{bmatrix} y(c_1) \\ y(c_2) \end{bmatrix} = (\alpha\cdot M_0 + \beta\cdot M_1)\cdot\begin{bmatrix} \alpha\cdot x_1 + \beta\cdot x_2 \\ \alpha\cdot x_3 + \beta\cdot x_4 \end{bmatrix}. \tag{20}$$

After calculation (20):

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

$$y(c_1) = \alpha^2 \cdot y_1 + \beta^2 \cdot y_2 + \frac{\alpha \cdot \beta}{x_1^{\,2} + x_3^{\,2}}(x_1x_2y_1 + x_2x_3y_3 + x_3x_4y_1 - x_1x_4y_3) + \frac{\alpha \cdot \beta}{x_2^{\,2} + x_4^{\,2}}(x_1x_2y_2 + x_1x_4y_4 + x_3x_4y_2 - x_2x_3y_4). \quad (21)$$

So each point of the curve $P = (c_1, y(c_1))$ settled between nodes (x_1,y_1) and (x_2,y_2) is parameterized by $P(\alpha)$ for (19), (21) and $\alpha \in [0;1]$. Similar calculations are done for nodes (x_1,y_1), (x_2,y_2), (x_3,y_3), (x_4,y_4) monotonic in y_i to compute $x(c_1)$:

$$M_0^{-1} = \frac{1}{y_1^{\,2} + y_3^{\,2}}\begin{bmatrix} x_1y_1 + x_3y_3 & -x_3y_1 + x_1y_3 \\ -x_1y_3 + x_3y_1 & x_1y_1 + x_3y_3 \end{bmatrix},\ M_1^{-1} = \frac{1}{y_2^{\,2} + y_4^{\,2}}\begin{bmatrix} x_2y_2 + x_4y_4 & -x_4y_2 + x_2y_4 \\ -x_2y_4 + x_4y_2 & x_2y_2 + x_4y_4 \end{bmatrix},$$

$c_1 = \alpha \cdot y_1 + \beta \cdot y_2$ for $0 \le \beta = 1 - \alpha \le 1$, (22)

$$\begin{bmatrix} x(c_1) \\ x(c_2) \end{bmatrix} = (\alpha \cdot M_0^{-1} + \beta \cdot M_1^{-1}) \cdot \begin{bmatrix} \alpha \cdot y_1 + \beta \cdot y_2 \\ \alpha \cdot y_3 + \beta \cdot y_4 \end{bmatrix},\ x(c_1) = \alpha^2 \cdot x_1 + \beta^2 \cdot x_2 + \frac{\alpha \cdot \beta}{y_1^{\,2} + y_3^{\,2}} r_1 + \frac{\alpha \cdot \beta}{y_2^{\,2} + y_4^{\,2}} r_2 \quad (23)$$

for $r_1 = \text{const.}$, $r_2 = \text{const.}$ depending on nodes' coordinates: see formula (21). If nodes are monotonic in y_i, there is parameterization of curve points P settled between nodes $(x_1, y1)$ and (x_2,y_2): $P(\alpha) = (x(c_1), c_1)$ for (22), (23) and $\alpha \in [0;1]$.

If nodes (x_i,y_i) are equidistance in one coordinate, then calculation of one unknown coordinate is simpler. Let four successive nodes (x_1,y_1), (x_2,y_2), (x_3,y_3), (x_4,y_4) are equidistance in coordinate x_i and $a = x_1$, $h/2 = x_{i+1} - x_i = \text{const}$. Calculations in formulas (20)-(21) are done for c_1 (19):

$$y(c_1) = \alpha y_1 + \beta y_2 + \alpha\beta s \quad (24)$$

and

$$s = h\left(\frac{2ay_1 + hy_1 + hy_3}{4a^2 + 4ah + 2h^2} - \frac{2ay_2 + 2hy_2 + hy_4}{4a^2 + 8ah + 5h^2}\right). \quad (25)$$

As we can see in formulas (21) and (23)-(25), MHR interpolation is not a linear interpolation. It is possible to estimate the interpolation error of MHR method (algorithm 1) for the class of linear function f:

$$\left|f(c_1) - y(c_1)\right| = \left|\alpha y_1 + \beta y_2 - y(c_1)\right| = \alpha\beta\left|s\right|. \quad (26)$$

Notice that estimation (26) has the biggest value $0.25|s|$ for $\beta = \alpha = 0.5$, when c_1 (19) is situated in the middle between x_1 and x_2.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Having four successive nodes (x_1,y_1), (x_2,y_2), (x_3,y_3), (x_4,y_4) equidistance in coordinate x_i ($a = x_1$, $h/2 = x_{i+1} - x_i = \text{const.}$) we can compute polynomial $W_3(x) = m_3x^3 + m_2x^2 + m_1x + t$ for these nodes and estimate the interpolation error of MHR method (algorithm 1) for the class of order three polynomials. After solving the system of equations:

$$y_1 = m_3a^3 + m_2a^2 + m_1a + t,$$

$$y_2 = m_3(a+\frac{h}{2})^3 + m_2(a+\frac{h}{2})^2 + m_1(a+\frac{h}{2}) + t,$$

$$y_3 = m_3(a+h)^3 + m_2(a+h)^2 + m_1(a+h) + t,$$

$$y_4 = m_3(a+\frac{3h}{2})^3 + m_2(a+\frac{3h}{2})^2 + m_1(a+\frac{3h}{2}) + t,$$

it is possible to compute m_3, m_2, m_1, t and the estimation for point c_1 (19):

$$\left|W_3(c_1) - y(c_1)\right| = \beta\left|\frac{1}{2}h(y_2 - y_1)\frac{12\alpha\beta a + 12a\beta^2 + 2h\beta^2 - \alpha\beta ah^2 - 12a - 2h}{6ha + 12a^2 + h^2} - \alpha\cdot s\right|. \tag{27}$$

Notice that estimations (26)-(27) are equal with zero for $\alpha = 0$ or $\beta = 0$ (in nodes). For eight successive nodes (x_i,y_i), $i = 1,2,\ldots,8$ equidistance in coordinate x_i, $a = x_1$, $h/2 = x_{i+1} - x_i = =$ const., using OHR of dimension $N = 4$ in formula (14) here is a formula of second coordinate reconstruction with first coordinate c_1 (19):

$$\begin{aligned} y(c_1) = {} & \alpha y_1 + \beta y_2 + \frac{\beta h^2}{4a^2 + 16ah + 21h^2}[(\alpha y_3 + \beta y_4) + 2(\alpha y_7 + \beta y_8)] \\ & + \frac{\beta h}{(4a^2 + 16ah + 21h^2)(2a^2 + 6ah + 7h^2)}[2(\alpha y_1 + \beta y_2)(2a^3 + 10a^2h + 19ah^2 + 14h^3) \\ & + \alpha h(ay_1 + hy_7)(2a + 7h) + 3.5\alpha h^3(y_1 + y_3) \\ & + 2ah(\alpha hy_3 + \alpha hy_7 + 17ay_2 - ay_4 - 2ay_8 - 3hy_4 - 6hy_8) \\ & - 7h^3(21y_2 + y_4 + 2y_8) - 2ay_2(2a^2 + 27ah + 19h^2)]. \end{aligned} \tag{28}$$

So we have another parameterization (28) of the point $P(\alpha) = (c_1, y(c_1))$ for $N = 4$ and $\beta = 1 - \alpha$. Formula (28) doesn't include values y_5 and y_6: algorithm 1 with nine successive nodes (x_i,y_i), $i = 1,2,\ldots,9$ equidistance in coordinate x_i is free of using y_5 and y_6 for computing second coordinate of the point settled between first and second node.

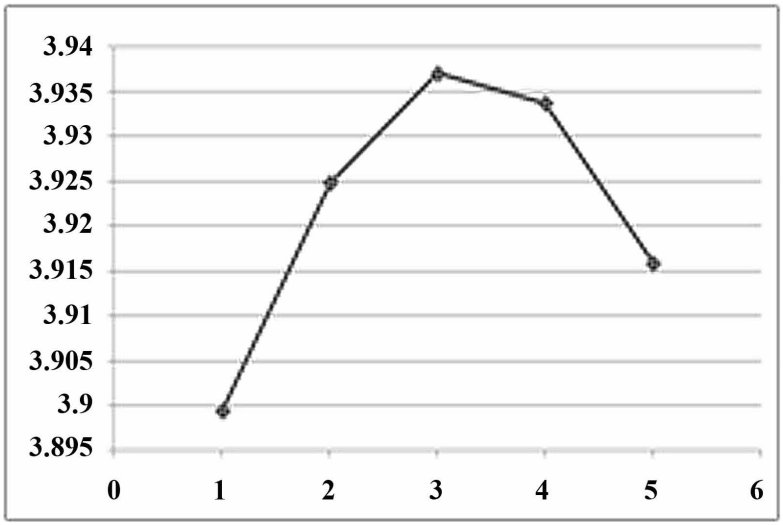
EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Algorithm 1 deals with average OHR operators (11)-(12) built with two OHR. This situation leads to parameterization of reconstructed point $P(\alpha) = (c_1, y(c_1))$ or $P(\alpha) = (x(c_1), c_1)$ settled between two successive nodes, where $\alpha \in [0;1]$ is order two in formulas (21), (23)-(25) and (28). The curve or data in MHR method are parameterized for value $\alpha \in [0;1]$ in the range of two successive interpolation nodes. MHR for data extrapolation is possible with $\alpha < 0$ or $\alpha > 1$.

Risk Analysis and Decision Making via Data Extrapolation

Example 1

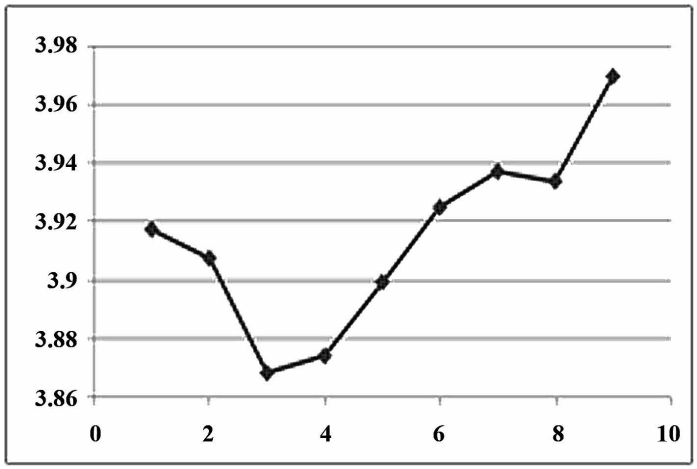
MHR calculations are done for true rates of euro at National Bank of Poland (NBP) from January 24th to February 14th, 2011. If last four rates are considered: (1;3.8993), (2;3.9248), (3;3.9370) and (4;3.9337), MHR extrapolation with matrices of dimension $N = 2$ gives the result (5;3.9158). So anticipated rate of euro on the day February 15th is 3.9158 (see Figure 3).



If last eight rates are considered: (1;3.9173), (2;3.9075), (3;3.8684), (4;3.8742), (5;3.8993), (6;3.9248), (7;3.9370) and (8;3.9337), MHR extrapolation with matrices of dimension $N = 4$ gives the result (9;4.0767). Anticipated rate of euro on the day February 15th is 4.0767 (see Figure 4).

There are two extrapolated values for next day. This example gives us two anticipated rates for tomorrow: 3.9158 and 4.0767, which differs considerably. How these extrapolated values can be used in the process of decision making and analyzing risk: to buy euro or not, to sell euro or not? The proposal final anticipated rate of euro for the day February 15th (see Figure 5) based on weighted mean value:

$$\frac{2 \cdot 3.9158 + 4.0767}{3} = 3.9694 \tag{29}$$

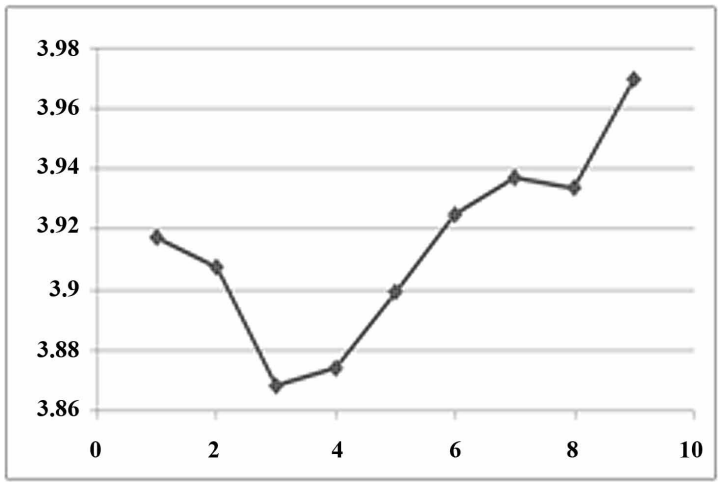


because the rate 3.9158 is calculated for $N = 2$, whereas 4.0767 is extrapolated for

Figure 3. Extrapolated rate for day 5 (February 15th) using MHR method with 4 nodes
Source: author, 2014

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 4. Extrapolated rate for day 9 (February 15th) using MHR method with 8 nodes
Source: author, 2014



$N = 4$. Formula (29) takes one fact into account: dimension $N = 4$ is two times bigger than dimension $N = 2$ and the result 3.9158 has to be strengthen multiplying by two.

If last sixteen rates are considered, MHR extrapolation with matrices of dimension $N = 8$ has to be used. Here are the rates: (1;3.8765), (2;3.8777), (3;3.8777), (4;3.9009), (5;3.9111), (6;3.9345), (7;3.9129), (8;3.9019), (9;3.9173), (10;3.9075), (11;3.8684), (12;3.8742), (13;3.8993), (14;3.9248), (15;3.9370) and (16;3.9337). Average OHR operator M_2 and MHR calculations look as follows:

$$M_2 = \begin{bmatrix} 0.3226 & 0.0154 & 0.0286 & 0.0462 & -0.062 & 0.0444 & 0.0924 & 0.0461 \\ -0.0154 & 0.3226 & 0.0462 & -0.0286 & 0.0444 & 0.062 & -0.0461 & 0.924 \\ -0.0286 & -0.0462 & 0.3226 & 0.0154 & 0.0924 & 0.0461 & 0.062 & -0.0444 \\ -0.0462 & 0.0286 & -0.0154 & 0.3226 & 0.0461 & -0.0924 & 0.0444 & 0.062 \\ 0.062 & -0.0444 & -0.0924 & -0.0461 & 0.3226 & 0.0154 & 0.0286 & 0.0462 \\ -0.0444 & -0.062 & -0.0461 & 0.924 & -0.0154 & 0.3226 & -0.0462 & 0.0286 \\ -0.0924 & 0.0461 & -0.062 & -0.0444 & -0.0286 & 0.0462 & 0.3226 & -0.0154 \\ -0.0461 & -0.0924 & 0.0444 & -0.062 & -0.0462 & -0.0286 & 0.0154 & 0.3226 \end{bmatrix}$$

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 5. Extrapolated rate for day 9 (February 15th) using MHR method with 8 nodes and weighted mean value (29). Source: author, 2014

$$M_2 \cdot \begin{bmatrix} 3 \\ 5 \\ 7 \\ 9 \\ 11 \\ 13 \\ 15 \\ 17 \end{bmatrix} = \begin{bmatrix} 3.7252 \\ 3.8072 \\ 3.8704 \\ 3.8278 \\ 3.8653 \\ 3.88834 \\ 3.9825 \\ 3.9882 \end{bmatrix},$$

HR extrapolation gives the result (17;3.9882). Anticipated rate of euro for the day February 15th is 3.9882 (see Figure 6).

MHR extrapolation has been done for three times ($N = 2$, 4 or 8) and anticipated values are 3.9158, 4.0767 and 3.9882 respectively. The proposal final anticipated rate of euro for the day February 15th (see Figure 7) based on weighted mean value:

$$\frac{4 \cdot 3.9158 + 2 \cdot 4.0767 + 3.9882}{7} = 3.9721 \tag{30}$$

because the rate 3.9158 is calculated with last four data points, 4.0767 is extrapolated for last eight data points and 3.9882 is computed for last sixteen data points. Formula (30) takes one fact into account: number of sixteen points is four times bigger than four and two times bigger than eigth. The result 3.9158 has to be strengthen multiplying by four and the rate 4.0767 has to be strengthen multiplying by two.

The true rate of euro for the day February 15th is 3.9398 (see Figure 8).

Figure 8. The true rate of euro for day 17 (February 15th). Source: author, 2014

In author's opinion, values extrapolated for next day 3.9694 (13) and 3.9721 (14) are good enough to be one of the factors for making a decision of buying or selling the currency.

Example 2

MHR calculations are done for true rates of US dollar at National Bank of Poland (NBP) from June 16th to July 8th, 2011 (Friday). If last four rates are considered: (1;2.7266), (2;2.7531), (3;2.7597) and (4;2.7505), MHR extrapolation with matrices of dimension $N = 2$ gives the result (5;2.7239):

$$M_2 \begin{bmatrix} 0.5503 & 9.13 \cdot 10^{-3} \\ 9.13 \cdot 10^{-3} & 0.5503 \end{bmatrix} \quad M_2 \cdot \begin{bmatrix} 3 \\ 5 \end{bmatrix} = \begin{bmatrix} 1.6964 \\ 2.7239 \end{bmatrix}$$

So anticipated rate of US dollar on the day July 11th (Monday) is 2.7239.

If last eight rates are considered: (1;2.7877), (2;2.7517), (3;2.7273), (4;2.7156), (5;2.7266), (6; 2.7531), (7; 2.7597) and (8; 2.7505), MHR extrapolation with matrices of dimension $N = 4$ gives the result (9;2.8471):

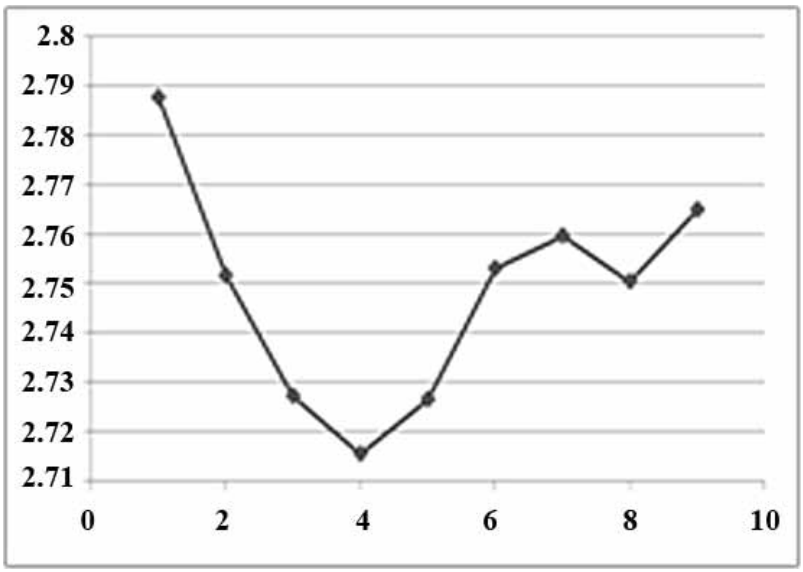
$$M_2 = \begin{bmatrix} 0.3919 & -0.0032 & 0.0999 & 0.0527 \\ 0.0032 & 0.3919 & -0.0527 & 0.0999 \\ -0.0999 & 0.0527 & 0.3919 & 0.0032 \\ -0.0527 & -0.0999 & -0.0032 & 0.3919 \end{bmatrix} \quad M_2 \cdot \begin{bmatrix} 3 \\ 5 \\ 7 \\ 9 \end{bmatrix} = \begin{bmatrix} 2.3333 \\ 2.4999 \\ 2.7365 \\ 2.8471 \end{bmatrix}$$

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Anticipated rate of US dollar on the day July 11th is 2.8471. There are two extrapolated values for next day. Example 2 gives us two anticipated rates for tomorrow: 2.7239 and 2.8471. How these extrapolated values can be used in the process of decision making: to buy dollar or not, to sell dollar or not? The proposal final anticipated rate of US dollar (see Figure 9) on the day July 11th based on weighted mean value:

$$\frac{2 \cdot 2.7239 + 2.8471}{3} = 2.7650 \tag{31}$$

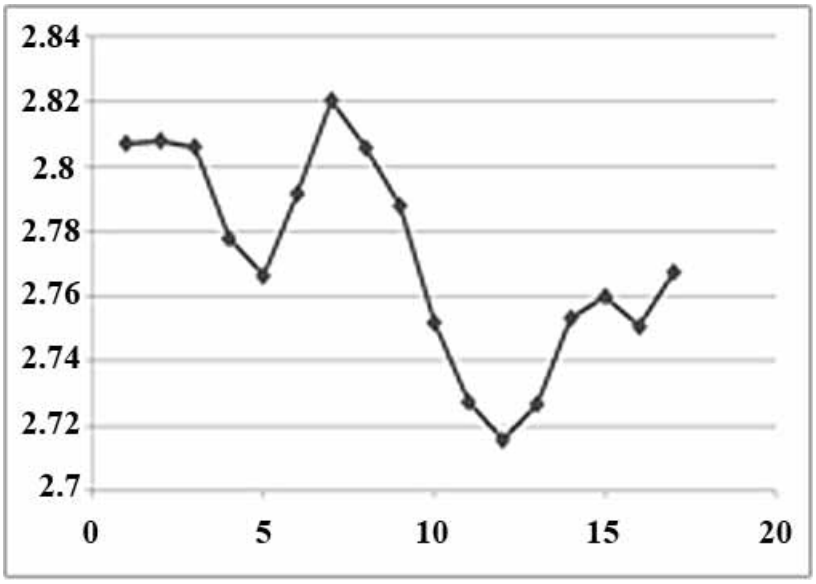
because the rate 2.7239 is calculated for $N = 2$, whereas 2.8471 is extrapolated for $N = 4$.



If last sixteen rates are considered, MHR extrapolation with matrices of dimension $N = 8$ has to be used. Here are the rates: (1;2.8069), (2;2.8077), (3;2.8058), (4;2.7776), (5;2.7661), (6;2.7914), (7;2.8201), (8;2.8055), (9;2.7877), (10;2.7517), (11;2.7273), (12;2.7156), (13;2.7266), (14;2.7531), (15;2.7597) and (16;2.7505). MHR extrapolation gives the result (17;2.7808). Anticipated rate of US dollar on the day July 11th is 2.7808.

MHR extrapolation has been done for three times ($N = 2$, 4 or 8) and anticipated values are 2.7239, 2.8471 and 2.7808 respectively. The proposal final anticipated rate of US dollar (see Figure 10) on the day July 11th based on weighted mean value:

$$\frac{4 \cdot 2.7239 + 2 \cdot 2.8471 + 2.7808}{7} = 2.7672 \tag{32}$$



because the rate 2.7239 is calculated with last four data points, 2.8471 is extrapolated for last eight data points and 2.7808 is computed for last sixteen data points.

Figure 9. Extrapolated rate for day 9 (July 11th) using MHR method with 8 nodes and weighted mean value (31). Source: author, 2014

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

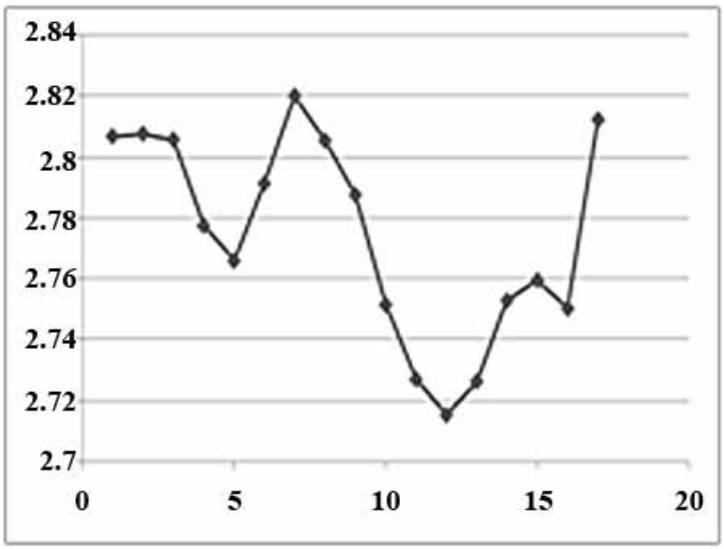


Figure 10. Extrapolated rate for day 17 (July 11th) using MHR method with 16 nodes and weighted mean value (32). Source: author, 2014

The true rate of US dollar on the day July 11th is 2.8123 (see Figure 11).

In author's opinion, extrapolated values 2.7650 (15) and 2.7672 (16) and anticipated rates in example 1 preserve the increasing trend and they are good enough to be one of the factors for making a decision of buying or selling the currency. Anticipated values, calculated by MHR method, are applied in the process of risk analysis and decision making: to follow the action or not, to do one thing or another. Extrapolated values can be used to make a decision in many branches of science and economics.

DISCUSSION OF EXAMPLES

This chapter goes to first step of application for MHR method in point extrapolation and decision making. Figures and calculations show the trends of value: increasing or decreasing. This information could be used in analyzing risk and decision making, for example buying or selling when risk analysis is very difficult and very important.

The Length Estimation

Selection of the nodes is a key factor in the process of interpolation and extrapolation. The length of a curve is significant feature. Also the length estimation depends on the nodes. Having nodes (x_1,y_1), $(x_2,y_2),\ldots,(x_n,y_n)$ in MHR method (algorithm 1), it is possible to compute as many curve points as we want for any parameter $\alpha \in [0;1]$.

Assume that L is the number of reconstructed points plus n nodes. So curve consists of L points that could be indexed $(x_1',y_1'),(x_2',y_2'),\ldots,(x_L',y_L')$, where $(x_1',y_1') = (x_1,y_1)$ and $(x_L',y_L') = (x_n,y_n)$.

The length of curve, consists of L points, is estimated:

$$d(L) = \sum_{i=1}^{L-1} \sqrt{(x_{i+1}' - x_i')^2 + (y_{i+1}' - y_i')^2} \ . \tag{33}$$

For any accuracy of length estimation $\varepsilon > 0$, it is possible to use MHR method (algorithm 1) with suitable number and location of n nodes and reconstruct curve consists of L and L_1 points, where $|d(L) - d(L_1)| < \varepsilon$. So there is no need to compute

$$\int_{x_1}^{x_n} \sqrt{1+[f'(x)]^2}\,dx \tag{34}$$

as the length of curve f. Formula (33) has lower computational cost then (34).

SOLUTIONS AND RECOMMENDATIONS

The chapter deals with the problem of data interpolation and anticipation. None of the methods, that are used nowadays, applies the orthogonal basis for unknown value extrapolation and foreseeing, but proposed MHR method does as the solution. Orthogonality means a very important feature for stability in calculations. Also MHR point interpolation and extrapolation via simple computations with matrices is something new in the problem of anticipation, risk analysis and decision making. Extrapolated values show increasing or decreasing trend during the process of analyzing risk and decision making. MHR method as the solution is recommended in artificial intelligence and operational research, for example in scheduling, time-tabling or planning.

FUTURE RESEARCH DIRECTIONS

Future works with MHR method are connected with the formula of extrapolated values. Also estimation of object area in the plane, using nodes of object contour, will be possible by MHR interpolation. Length of the curve and object area are significant features in many economic problems. Future works are dealing with smoothing the curve, parameterization of whole curve and possibility to apply MHR method to three-dimensional curves. Also case of equidistance nodes must be studied with all details. Another future research direction is to apply MHR method in artificial intelligence and operational research, for example scheduling, time-tabling, planning, identification of a specific person's face or fingerprint, character recognition (Lamdan, Schwartz & Wolfson, 1990) or image restoration (Pope & Lowe, 2004). There are several specialized tasks based on recognition to consider and it is important to use the shape of whole contour (Kriegman & Ponce, 1990) for identification and detection of persons, vehicles or other objects. Other applications of MHR method will be directed to computer graphics, modeling and image processing.

CONCLUSION

The method of Hurwitz-Radon Matrices leads to curve interpolation and value extrapolation depending on the number and location of data points. No characteristic features of curve are important in MHR method: failing to be differentiable at any point, the Runge's phenomenon or differences from the shape of polynomials. These features are very significant for classical polynomial interpolations and extrapolations. MHR method gives the possibility of reconstruction a curve and anticipation the data points. The only condition is to have a set of nodes according to assumptions in MHR method. Data representation and curve extrapolation by MHR method is connected with possibility of changing the nodes coordinates and reconstruction of new data or curve for new set of nodes. The same MHR interpolation and extrapolation is valid for discrete and continues data. Main features of MHR method are: accuracy of data reconstruction depending on number of nodes; interpolation or extrapolation of a curve consists of L points is connected with the computational cost of rank $O(L)$; MHR method is dealing with local operators: average OHR operators are built by successive 4, 8 or 16 data points, what is connected with smaller computational costs then using all nodes; MHR is not an affine interpolation.

KEY TERMS AND DEFINITIONS

Artificial Intelligence: Intelligence of machines and computers, as a connection of algorithms and hardware, which makes that a man – human being can be simulated by the machines in analyzing risk, decision making, reasoning, knowledge, planning, learning, communication, perception and the ability to move and manipulate objects.

Contour Modeling: Calculation of unknown points of the object contour having information about some points of the object contour.

Curve Interpolation: Computing new and unknown points of a curve and creating a graph of a curve using existing data points – interpolation nodes.

Data Extrapolation: Calculation of unknown values for the points situated outside the ranges of nodes.

Hurwitz – Radon Matrices: A family of skew – symmetric and orthogonal matrices with columns and rows that create, together with identical matrix, the base in vector spaces of dimensions $N = 2, 4$ or 8.

MHR Method: The method of curve interpolation and extrapolation using linear (convex) combinations of OHR operators.

OHR Operator: Matrix operator of Hurwitz – Radon built from coordinates of interpolation nodes.

Value Anticipation: Foreseeing next value when last value is known.

This research was previously published in Analyzing Risk through Probabilistic Modeling in Operations Research edited by Dariusz Jacek Jakóbczak; pages 1-31; copyright year 2016 by Business Science Reference (an imprint of IGI Global).

ABSTRACT

This chapter presents an example of a virtual training scenario that allows trainees to learn the rules of real human institutions before joining them, that is, before having to cope with the consequences of their binding actions in real (serious) settings. The development of the training scenario is based on a combination of Electronic Institutions technology with 3D Virtual Worlds, and is enhanced with tutoring agents that provide assistance services along the training process. The theoretical benefits that result from this approach are demonstrated through an authentic scenario that represents a market (i.e., an institution) devoted to trading water rights. This scenario has been tested with real users, and thus, its benefits have been empirically assessed.

INTRODUCTION

A real-life institution is a rather complex and structured environment where users participate with the aim of developing serious activities, such as the trading of goods. Therein, users interact by following well-defined communication protocols and playing different roles: staff roles are in charge of support-

ing specific institutional tasks (i.e. register goods to trade or auction the registered goods), and external roles enter the institution to perform such tasks. Nevertheless, in these complex real-world scenarios, users may not know how to achieve their goals. Furthermore, users' actions usually have non-reversible and important consequences, such as, for example, the acquisition of legal obligations.

An approach to address users' participation in these intricate scenarios is to first immerse them in a "virtual" institution that reproduces the "real" one so that they can be trained to participate in the "real" one and to get familiar with its structure and functioning. Then, before their involvement in the "real" institution, users may learn by experiencing in a simulated environment, and this training would allow them to perform effectively and with confidence in the real situation.

In this context of adult learning, Kolb (Kolb, 1983, 2014) proposed a model that defines 4 experiential learning stages: concrete experience, reflection, abstract conceptualisation and active experimentation. That is, the learner lives a concrete experience, followed by a reflection on that experience. Then, the abstract conceptualisation allows either the application of known theories to the lived experience or the derivation of rules describing it. Finally, in the active experimentation the learner constructs a way of modifying the next occurrence of the experience, leading to a better performance.

These learning stages are usually leaded by the instructor and are experienced by the learner either inside or outside the class. On the one hand, typical in-person classes rely on the instructor to ensure the learner gathers and understands the needed information to reflect about, so that she is capable of creating an abstract conceptualization and to apply the gained understanding to the next experience. On the other hand, online (virtual) classes rely on a User Interface (UI) with the learner as the medium to go through the learning stages, with the timely support of teachers and workmates. This UI can be a web-based e-learning system such as moodle, or a 3D computer-generated simulation of an environment where the learner lives the "entire" learning experience. For example, a 3D Virtual World includes spaces for learning, tools to manipulate, virtual tutors to talk with, and other learners to interact with.

Some UIs consist in e-learning platforms, such as Moodle, where the last stage, active experimentation, occurs outside the e-learning space, that is in the learners' "real life"; whereas 3D Virtual Worlds (3D VWs) offer the possibility to do the active experimentation in the e-learning environment as well. Additionally to tutors and other learners, common to many e-learning spaces, 3D VWs offer spaces for learning, tools to manipulate, and virtual tutors. Moreover, virtual worlds grant the possibility to make an activity more than once at no cost and no risk, and they also result more attractive and ideal for social and collaborative activities.

Based on these benefits of 3D interfaces, this research sees 3D VWs as an adequate mean to instantiate this experiential learning cycle. That is, users can learn to participate in a real structured (complex) activity by acting themselves in a simulated scenario, experiencing the consequences of their actions, testing procedures and checking their understanding without harm (Hew & Cheung, 2010) nor consequences in the real world. As previous researches stated, virtual worlds could be much more appealing and engaging than traditional learning (Wrzesien & Alcañiz, 2010; Craven, 2015) . Hence, this chapter proposes to train real institutions' users by letting them experience their assigned duties within a 3D simulated space, fostering collaboration and engagement, and facilitating users' spatial situatedness and interactions.

Specifically, we present a Hybrid Structured 3D Virtual Environment where participants (both human users and software agents) develop, and are trained to develop, serious activities in rather complex institutions. To do so, we combine (i) an Organisation-Centred Multi-Agent System (OCMAS), to model the institution and regulate participants' interactions and (ii) a 3D training virtual environment, to facilitate learners interactions and engage them in the system.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Additionally, our training environment provides users with Personal Assistants devoted to help them during the learning process, and consequently, we named the entire proposal as Assisted Hybrid Structured 3D Virtual Environment. Personal Assistants are embodied tutoring agents who provide the users with different assistance services: information, justification, advice and estimation (Almajano, 2014; Almajano, López-Sánchez, Rodríguez & Trescak., 2014). They engage in conversation with learners to guide them in the consecution of their goals. These agents use an extension of AIML (Artificial Intelligence Modelling Language) for task-oriented conversations and let users rehearse in the system.

As a proof of concept, we present a training scenario of a virtual market for trading water rights: v-mWater. This scenario consists of several training activities reproducing those that users can perform in an actual water market (e.g., to register water rights or to auction them). During these activities, users interact with each other and staff agents, who are tutors in charge of assisting them.

The rest of this chapter is organized as follows. Firstly, a Background Section briefly presents the state of the art that contextualizes our work and highlights its potential benefits to training scenarios. Secondly, a System Model Overview Section describes the main components of our Assisted Hybrid Structured 3D Virtual Environment and how they relate to each other. Thirdly, the specific virtual water market scenario is introduced in the Training Scenario Section. Subsequent Technical Specification Section introduces the technical details related to the execution infrastructure and the assistance that tutors provide. Afterwards, Evaluation Section provides details on users testing. Next Section, entitled Discussion, is devoted to explain the limitations of the system and to present new research lines that can extend the system in several aspects, such as the incorporation of recommender systems, the inclusion of accessibility support, and the incorporation of gamification concepts to improve the learning experience. Finally, Conclusion Section presents some concluding remarks.

BACKGROUND

3D virtual worlds technologies were introduced by the seminal paper of Bartle(Bartle, 2003), and have been used in education since long ago. One of their strengths is their easiness of social interaction (San Chee, 2001), which can be done through chat, audio or even gestures. In particular audio and chat have proven to be particularly useful (Bouras & Tsiatsos, 2006). Nevertheless, single-user e-learning systems do not motivate users to explore thoroughly the possibilities of interaction (Monahan, McAdrle & Bertolotto, 2008)while teamwork help learners to reach higher achievements (Laister & Kober, 2002) as they feel as part of a supportive e-learning community and that fosters their motivation (McInnerney & Roberts, 2004). On the mentioned studies, on the overall, teachers and students find virtual environments intuitive and support the usefulness of 3D paradigm.

On the use of Virtual Worlds for training Dalgarno and Lee, in a seminal article on 2009 (2009) describe the learning affordances of 3D Virtual worlds as "enhanced spatial knowledge representation, greater opportunities for experiential learning, increased motivation/engagement, improved contextualisation of learning and richer/more effective collaborative learning" as compared to 2D counterparts.

Mostly, the literature agrees in the potentiality of 3D virtual worlds but it alerts about how to use them and the need to provide context and guidance to learners (Dickey, 2010)

Duncan, Miller and Jiang (2012) published the most general survey of the use of virtual worlds in education, and as a conclusion they recommend "the use of virtual support where real world experiential learning is difficult to achieve due to barriers of time, cost and place" although they identify some

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

disadvantages as the difficulty to monitor the educational process, the fact that students need more guidance, or their disadvantage in front of simulation in the real world and. A more recent literature survey, by Ghanbarzadeh et al. (2014), highlight the use of virtual worlds for both academic and professional training, and praise them as a natural evolution of Internet, distance learning and online gaming. The authors consider 3D virtual world "a demand of the new generation of students".

Recent articles show contradictory results. For example Hack research (2015) quantifies a decrease of failure in a distance learning module to health professionals from 11% to 5% thanks to the introduction of 3D virtual world training. On the contrary Richards and Taylor (2015), on an experiment with 129 biologists, found better learning gains in a 2D environment than in 3D virtual worlds.

It seems that 3D virtual worlds are justified in particularly costly and dangerous training scenarios, like police training (Moskaliuk, Bertram, Cress 2013), military, health or auctions as in the water-world case study.Also there is coincidence of a greater cognitive load in 3D scenarios. We think that the introduction of assistive agents, and natural language communication included in our proposal will be key for reducing both the learning curve and the learners' demands.A paradigmatic example of interactive e-learning is the city of Uruk, a simulation of the first city on earth, dating year 3000 BC (Bogdanovych, Rodríguez-Aguilar, Simoff, Cohen, 2010) (Bogdanovych, Kiran, Simoff, 2012) based on Second Life, where learners could interact with recreations of city buildings from Ziggurat or with the Uruk temple and also with their inhabitants. Posterior examples include medical education (Danforth, Procter, Chen, Johnson & Heller, 2009), or physics (Graesser, Chipman, Haynes & Olney, 2005) training where artificial dialogue agents were introduced.

Regarding personal assistants, Okamoto, Sycara and Scerri (2009) tested that agents' decision support to human users in hierarchical organizations improved success rate and efficiency. Many Multi-Agent System architectures have been proposed to provide assistance (Chalupsky et al., 2001; Yaich, Boissier, Picard & Jaillon, 2013; Dong, McCarthy, O'Mahony, Schaal & Smyth, 2012; Oh, Meneguzzi, Sycara & Norman, 2011), but they work in a restricted context where humans have limited and very specific tasks. In this chapter we offer a model for assistance in complex tasks related to Electronic Institutions[1], as defined by Esteva (Esteva, 2003).

Related to trainers-trainees interactions in virtual environments, natural language interactions constitute a suitable alternative to instructional/command based interactions. Embodied conversational agents, able to engage in a conversation with humans, are popular representatives of this type of interactions, which can be mostly found as virtual assistants in web environments. Specifically, Artificial Intelligence Mark-up Language (AIML) chatter bots ("Alicebot", n.d.) (Wallace, 2009) are well known reactive bots which follow basic dialogue structures defined in static files, but are able to store some general information (such as name or gender of the user) in a non-typed memory (i.e. a list of string values) and act accordingly. They have been conceived to give general information to users under request.

Finally, as for accessibility, i.e. the usability for people with disabilities, education presents a new challenge which is the enforced need to make any tool or material, virtual worlds included, valid for all profiles - blind, hard of hearing, with dyslexia, with motor impairments... - (Del Blanco, Marchiori, Torrente, Martínez-Ortiz & Fernández-Marijón, 2013; Torrente, Freire, Moreno-Ger & Fernández-Manjón, 2015). Unfortunately, although therapy benefits have been elicited about videogames (Vickers, Istance & Hyrskykari, 2013; Fikar, Schönauer & Kaufmann, 2013; "Transcript", n.d.), they are considered the less accessible multimedia platform. In fact, current development platforms do not facilitate the creation of universally designed videogames (Grammenos, Savidis & Stephanidis, 2007)and there still exists a wide gap in game accessibility between research and industry that has been repeatedly noted (Westin,

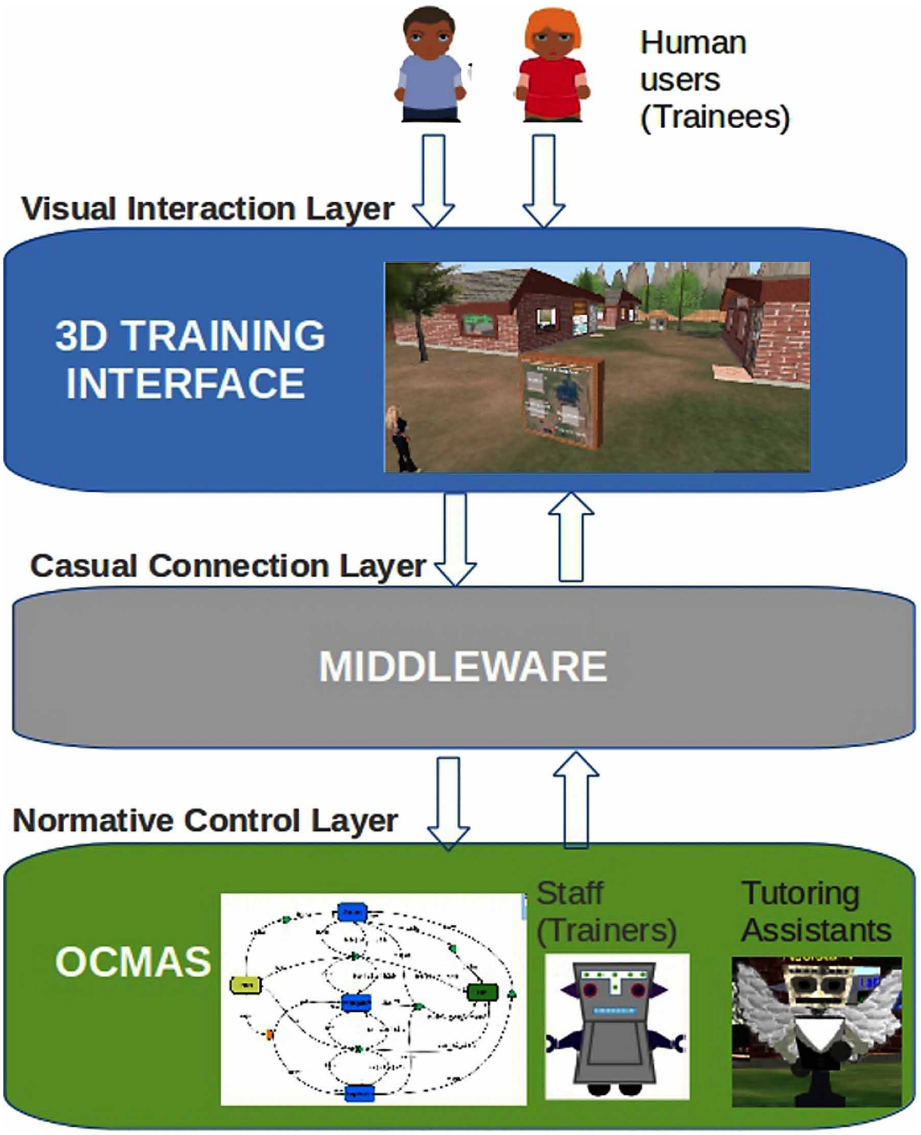
EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Bierre, Gramenos & Hinn, 2011; Yuan, Folmer & Harris, 2010; Porter, 2014). In our model, the universal education challenge is not yet addressed, but the assistance layer is a promising mechanism to support customized solutions without the requirement of specific development platforms.

Combining and enriching the benefits of previous proposals such as sociability, entertainment, easy to use and intuitive, and also the support of intelligent agents who communicate through natural language, our proposal has an inmense potential as a common tool for training in education or professional environements. With virtual worlds, electronic institutions and intelligent agents you can model many real situations and give the learners the freedom to explore with full support.

SYSTEM MODEL OVERVIEW

As previously introduced, this research advocates for the use of an *Assisted Hybrid Structured 3D Virtual Environment* (VE) to support the training of real institutions' users. This section describes the main components of the system. An Assisted Hybrid Structured 3D VE is a persistent multi-user system where participants (both human users and software agents) develop and learn to conduct activities. In this system, the 3D interface graphically represents the system and facilitates human participation, and an Organisation Centred Multi-Agent System (OCMAS) structures participants' interactions. To do so, the OCMAS specifies the roles that participants can enact, the activities where complex tasks can be accomplished, and the communication protocols that enable the prosecution of such tasks.



The system is, therefore, composed by three main components: the Normative Control Layer (OCMAS), the Visual Interaction Layer (3D interface), and a middleware to connect previous layers, which is the Causal Connection Layer (see Figure 1).

The division into a Normative Control Layer and a Visual Interaction Layer provides support to the conceptual separation between the normative control of interactions and the design of the virtual world, i.e., the design of the 3D interface. The Normative Control Layer is responsible for the institutional control of interactions among participants, while the Visual Interaction Layer focuses on the 3D representation of the institution. Both layers are causally connected. That means that, whenever one of them changes, the other one changes in order to maintain a consistent state (Maes & Nardi, 1988). Thus, the Causal Connection Layer keeps a consistent state between the model, represented by the Normative Control Layer, and its view, represented by the Visual Interaction Layer.

Regarding participants, humans (trainees) take part in the system by controlling an avatar on the Visual Interaction Layer. Software agents can be external, staff and assistant agents. External agents, likewise human participants, are connected to the system to perform activities on behalf of others. Staff agents are software agents devoted to support the institutional (system) activities. They act as trainers for human users. Tutoring Assistant agents are in charge of supporting human users in the consecution of their goals. These agents also act as trainers as they may guide users in their tasks. All software agents actually belong to the OCMAS within the Normative Control Layer; participate in the overall training system by exchanging messages; and are visualized as avatars in the Visual Interaction Layer in a way that can be distinctly identified. In this work, as depicted in the bottom part of Figure 1, we focus on those agents that support users during the training activities, that is, Staff and Tutoring Assistant agents.

Figure 1. System components

TRAINING SCENARIO

This research presents as training scenario v-mWater, a virtual market based on trading water. This scenario can be used by governments with the objective of encouraging a more efficient use of surplus of water for irrigation, especially in those countries suffering from water scarcity problems. It is inspired by similar tools such as the one developed by Waterfind ("Waterfind...", n.d.).

In this market, participants negotiate water rights (Almajano, Trescak, Esteva, Rodríguez, López-Sánchez, 2012). In an agricultural context, a water right is associated to a farmland and refers to the right of an irrigator to use a given volume of water from a public water source (e.g., a river or a pond) to irrigate. An agreement is the result of a negotiation where a seller settles with a buyer to reallocate (part

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

of) the water from her or his water rights for a fixed period of time in exchange for a given amount of money. Specifically, sellers are required to first register their water rights for sale and buyers compete for acquiring water rights by participating in an auction. In the following section we introduce tutoring agents (Trainers) and training activities in v-mWater.

Tutoring Agents

As aforementioned, participants in our system can be both human users and software agents. Trainers are internal software agents devoted to train human users to participate in the real-life institution. Specifically, our system has available two types of trainers: i) staff agents and ii) tutoring assistants.

Staff agents are in charge of training users on how to participate in the system. To do so, they are programmed to perform automatic institutional tasks, following the communication protocols established in the system specification. Thus, human users learn how to behave in a real institution by interacting with staff agents in the simulated one. Concretely, v-mWater incorporates the market facilitator, who carries out water rights' registration and also acts as auctioneer; and the basin authority, in charge of officially announcing valid agreements (selling of water rights) in the market.

Tutoring personal assistants support trainees to understand the social model of the institution and to perform the complex tasks in a seamless way. One tutoring personal assistant provides direct and sole support to one trainee, who, can freely use the given support in its decision process. Since Personal Assistants are organisational agents, they are allowed to use organisational information in order to provide assistance.

Tutoring Personal assistants offer four types of services: information, justification, advice and estimation. First, information service provides trainees with processed information about the system specification and its execution states. Second, justification service, based on the system specification and its current state, provides the trainee with a justification related to the last action that she or he failed to execute. Third, estimation service, also based on the system specification and the current state, is able to estimate whether the action can be executed at current state or not and, in affirmative case, it also computes the next state after executing the given action. Fourth, advice service is the more sophisticated one, and provides trainees with a plan that leads to her or his goal.

Training Activities

There are three activities in the market that take place in three separate physical spaces accessible from the entrance (see Figure 2). First, Waiting and Information activity, depicted in Figure 3, represents a common area where irrigators (both sellers and buyers) can ask for information about the market progress to the market facilitator agent. Second, within the Registration activity detailed in Figure 4, the market facilitator staff agent is in charge of registering sellers' rights. In fact, the institution regulation establishes sellers to be the only external role that can access this activity, and thus doors in the virtual registration building do not open for buyers (i.e., they are not allowed to enter).

Finally, the last (but not least important) activity that is available to the users is the Auction, where the selling of water rights takes place (see Figure 5). Like in real settings, there are three roles involved in this activity: buyers, which correspond to the bidders; the market facilitator, which acts as the auctioneer; and the basin authority, in charge of officially announcing the valid agreements. There may be different Auction activities going on in the scenario, since the organisation creates one Auction scene

Figure 5. v-mWater Auction training room

for each area of the basin. Within each Auction activity, water rights are auctioned in consecutive rounds and only buyers with owned water rights belonging to the area of the auction are allowed to join it (i.e., the access is restricted for the rest of participants). Auctions follow a Japanese protocol, which is most suitable for trading water rights, but may require buyers to get familiar with it.

These three activities in the virtual world are populated and leaded by staff agents who support users' training. For example, an irrigator could connect to the training system to learn any of the activities that take place in the market. In what follows we describe the process by which an irrigator learns how to register water rights by experiencing (rehearsing) it. To do so, she first enters the 3D agricultural environment with a seller role and walks around the market area to be aware of both market activity locations and other participants connected to the system. Then, whenever she finds the Registration room, she goes into it and inspects the space, which is populated by a registration desk, some pictures of the basin, and a staff agent representing the registration manager. Then, the staff agent engages in a conversation with the human with the ultimate goal of performing a task. From now on we will refer to it as "task-oriented conversation".

The conversation proceeds as follows. The agent initiates the conversation by greeting the user, and then proceeds by asking her for all the data needed to register a water right. The user gives the conversational agent the required data. If the data is correct the conversation flows as defined in the OCMAS interaction protocol. If it is incorrect, the agent informs about the error, and waits for the new data. At the end of the process, the irrigator is informed about the result of the task, whether failed or succeed.

Furthermore, trainees can ask for help to their personal tutoring assistant agents. For example, let's imagine that Mary Smith arrives to the 3D virtual market and wants to register a water right 5 euros higher than the last transaction done in the market; nevertheless, she does not know where and how to be aware of the last transactions' price and how to register a water right; then, she asks the tutoring assistant agent for advice on how to do it and as a result, her personal assistant provides her with the following plan of actions to achieve her goal (Figure 6 depicts this advice in context):

Mary Smith, enter the Waiting And Information room.
Information about market transactions is publicly displayed at Information Panels. KEEP THE INFORMATION OBTAINED HERE (price) TO BE USED LATER.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 6. A tutoring assistant agent provides a user advice on how to achieve her goal

Mary Smith, exit the Waiting And Information room.
Mary Smith, enter the Registration room.
Mary Smith, ask for registering a water right to Registration Manager.

As we can see with this example Mary Smith will succeed in registering her water right at the desired price without previous knowledge of the rules and needed steps.

So far, this section has described a training scenario in the context of a water market. Nevertheless, it is worth noticing that, from the point of view of the user, this virtual scenario allows users to rehearse tasks, previous to the "real" tasks conducted in the real setting. Note also that, as previously mentioned, the OCMAS specification establishes who is allowed to enter to the different spaces, and, for example, an irrigator playing the role of buyer would not be allowed to enter the registration room, nor a seller would be allowed to enter an auction room.

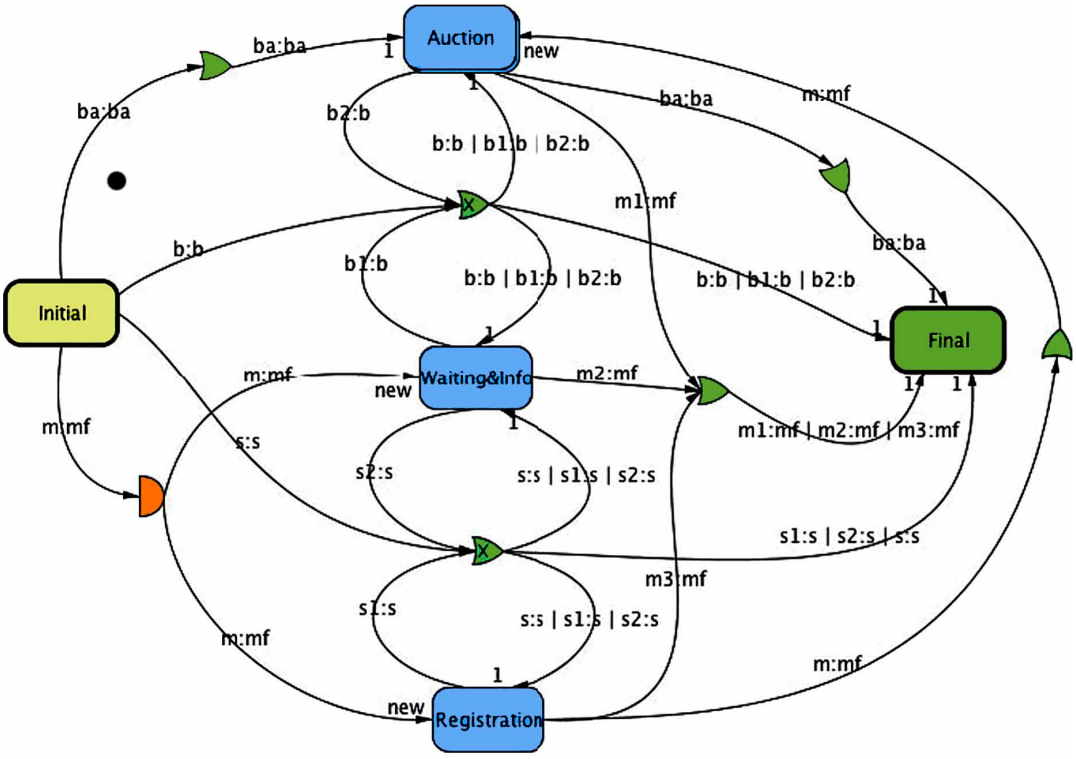
The following section presents the technical details of the infrastructure that supports the execution of such a scenario.

TECHNICAL SPECIFICATION

This section describes the infrastructure that supports the execution of training sessions by means of the previously introduced Assisted Hybrid Structured 3D Virtual Environment. The core execution infrastructure component is VIXEE, which is first presented. Then, some technical details are provided about the software agents involved in the training process as well as about the mechanism deployed for task-oriented conversations.

Execution Infrastructure (VIXEE)

VIXEE, is a robust Virtual Institution eXEcution Environment that provides interesting features such as multi-verse communication and dynamic manipulation of the virtual world content (Trescak, Rodríguez, López-Sánchez&Almajano, 2013). VIXEE is a generic and domain-independent solution. As specified



EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

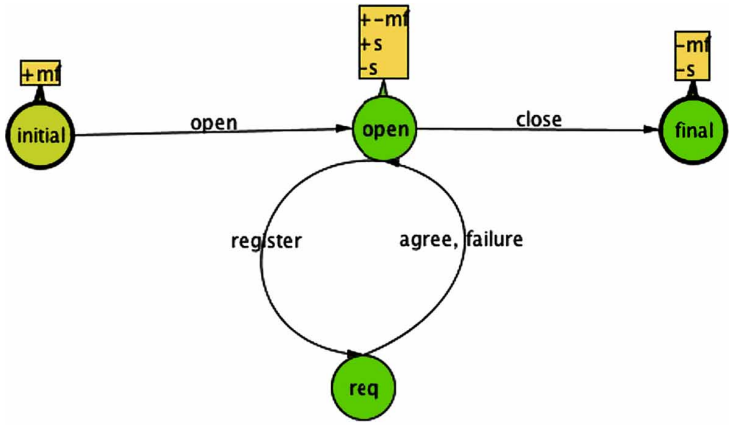
in the System Model Overview Section, and in particular, in Figure 1, its architecture is composed of three layers: i) Normative, ii) Visual Interaction and iii) Causal Connection.

The *Normative Layer* is composed by AMELI, the Electronic Institutions infrastructure that mediates agents' interactions while enforcing institutional rules (Esteva, de la Cruz & Sierra, 2002), the system specification and its running state. AMELI can be regarded as domain-independent because it can interpret any institution specification generated by ISLANDER tool (Esteva, de la Cruz & Sierra, 2002). It is implemented in JAVA and uses two TCP ports to communicate with the Causal Connection Layer.

Figure 7 depicts the specification of the Performative Structure of the v-mWater scenario. The so-called Performative Structure defines several dialogic activities (also referred as scenes) where agents participate enacting different roles. Additionally, it also specifies how agents can legally move among these activities depending on their roles. Specifically, a Performative Structure is defined as a graph where the nodes represent activities --and transitions, i.e. activity connectives used for synchronization-- linked by directed arcs, which represent the allowed agent movements between them. The example in Figure 7 depicts four different roles (mf: market facilitator; b: buyer; s: seller; and ba: basin authority) that can move between three scenario-dependant activities (Registration, Auction, and Waiting&Info). As depicted, the seller role is allowed to register water rights in the Registration activity and become informed about the market in the Waiting&Info activity. On the other hand, buyers can join the Auction activity once they have been informed about the registered water rights that will be auctioned. Finally, both the market facilitator and basin authority roles correspond to staff agents in charge of supporting these activities.

Figure 7. v-mWater Performative Structure

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use



Virtual interactions within each activity are structured by means of well-defined protocols. These interaction protocols are specified in terms of Finite State Machines, whose states capture the possible activity states and whose transitions are followed depending on time-outs or whenever agents send the specific messages (i.e., illocution[2] schemes) specified in the edge labels. Since participants may enter or leave activities, protocol nodes also define the roles that are allowed to enter and exit at them. Figure 8 depicts the protocol followed within the Registration activity. Specifically, Figure 8 represents the four protocol's nodes (*initial*, *open*, *req*: registration requested, and *final*) and five illocutions (*open*, *close*, *register*, *agree* and *failure*). In particular, once a market facilitator staff agent (mf) has opened the activity and a seller has entered it, this seller asks for registering a water right by uttering the illocution *register*. This *register* illocution should specify: the identifier of the water right the participant wants to sell; the quantity of associated water; and a reference price for its negotiation in the Auction activity. Then, the protocol (activity) state changes from *open* to *req*. At state *req*, the market facilitator decides if the registration is valid by checking specific market regulations and sends back the result of the process to the seller: *agree* in case of success and *failure* otherwise. The seller can then leave the activity and the market facilitator agent will remain in the activity waiting for other sellers to register their water rights until he decides to close and leave the activity.

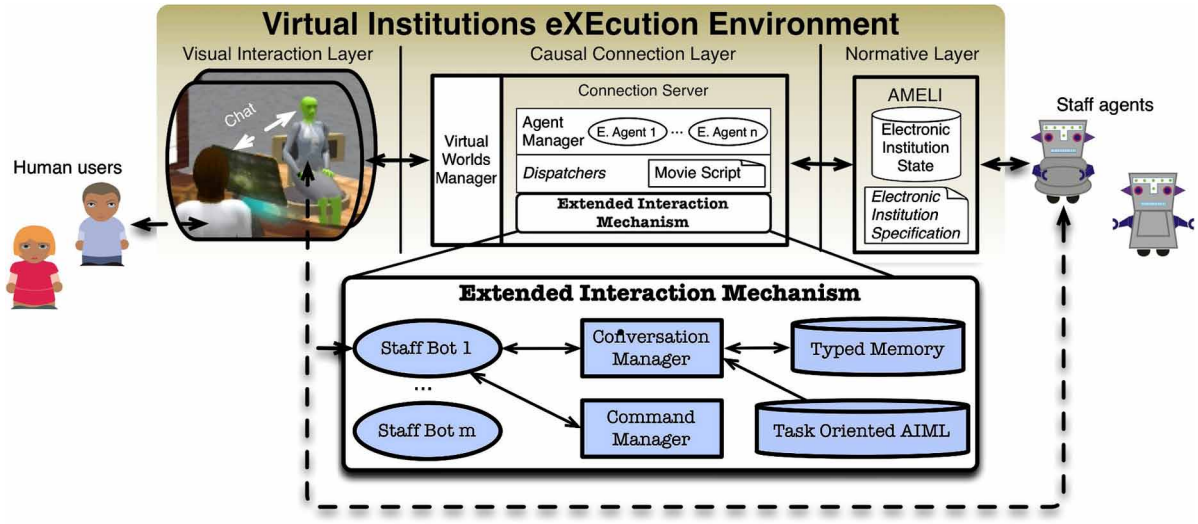
Note that the information specified in this protocol is used by tutoring assistant agents in the task-oriented conversation (see next section) in which they engage with human users, meanwhile the latters learn how to register a water right.

The *visual interaction layer* comprises several 3D virtual worlds. Each Virtual World can be implemented in a different programming language by using a different graphics technology. Common parts of a Virtual World are a Virtual World client and a Virtual World server. Such a server communicates with the causal connection layer by using a standard protocol (e.g. UDP, TCP or HTTP). In particular, our example scénario has been built with Open Simulator, an open source multi-platform, multi-user 3D Virtual World server ("OpenSimulator", n.d.).

Finally, the *causal connection layer* (Trescak, Rodríguez, López-Sánchez&Almajano, 2013) causally connects the visual interaction and the normative layers, that is, whenever one of them changes, the other one changes in order to maintain a consistent state (Maes & Nardi, 1988). As Figure 9 shows, this layer implements a Virtual Worlds Manager which is a multi-verse communication mechanism that allows

Figure 8. Registration protocol

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use



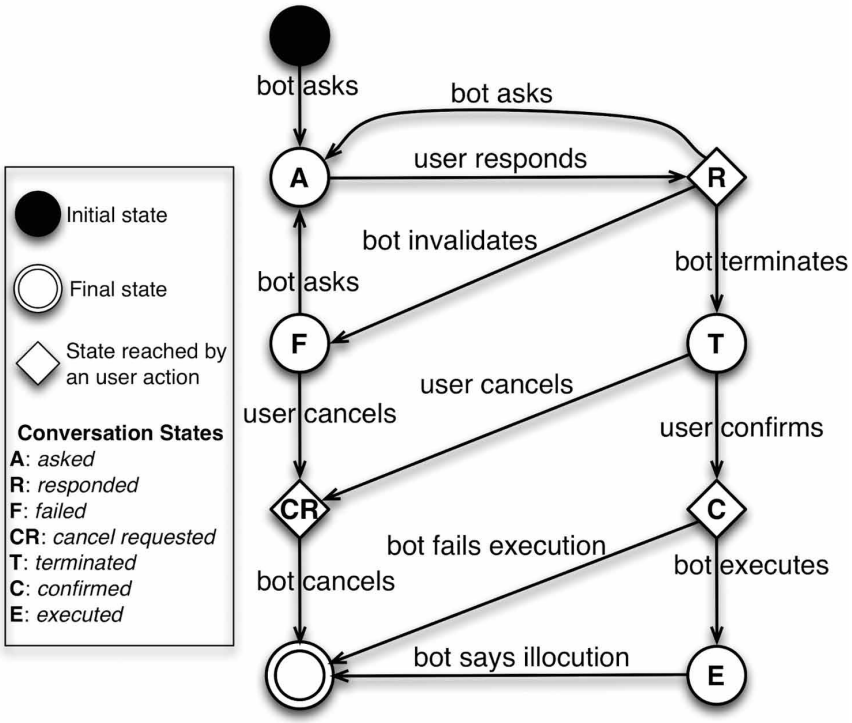
users from different virtual worlds to participate in the same Virtual Institution. Thus, the Agent Manager creates an External Agent for each connected user. Furthermore, dispatchers are in charge of the mapping between Virtual World actions and AMELI events -and vice versa- defined in the so-called movie script. On one hand, a message generated from AMELI provokes a Virtual World (VW) action so that the visualisation in all connected VWs is updated. On the other hand, for each institutional (regulated) action performed by a human avatar in the VW, a dispatcher sends the corresponding message to AMELI.

Human-agent interactions are ultimately supported by means of an the Interaction Mechanism at the bottom of Figure 9. Staff bots (connected to both staff agents and VW characters) are endowed with a textual communication system, which can be based on commands or/and on natural language dialogs. In the command based system, a Command Manager is in charge of mapping human commands to/from AMELIE messages (illocutions). As for the natural language dialogues, a Conversation Manager (CM) uses an extension of Artificial Intelligence Markup Language (AIML) to manage task-oriented conversations (Almajano, Mayas, Rodríguez & López-Sánchez, 2014). In particular, the Conversation Manager takes care of: i) identifying the task at hand (e.g., water right registration); ii) asking the human the required (if any) information (e.g., water right identifier, quantity or price of the associated water); iii) validating and storing provided inputs (if any) by considering both protocol's specification and the current state of the institution; and, finally, iv) informing about the result, which may imply composing an illocution from the gathered information or translating an illocution into natural language.

Task-Oriented Conversational Interaction

In real life institutions, users follow standardized communication protocols by means of natural language conversations in order to complete complex tasks. With the aim of providing a training scenario where the real institution is faithfully represented, our system has incorporated an interaction mechanism that allows tutoring agents (both staff and personal assistant agents), from now on referred as trainers, to converse in natural language with trainees (i.e. human users).

Figure 9. Overview of VIXEE Architecture



EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Using the conversational system, trainees can express their intentions using natural language dialogues and trainers have to understand trainees' entries and support them in their task completion. Trainer-trainee interaction in Assisted Hybrid Structured Virtual Environments have a complex structure, and thus, conversations must follow the communication protocols in the system specifications. As previously introduced, if a trainee initiates the interaction with a trainer, this requires the corresponding trainee to: First, identify trainee's task; Second, request required trainee entries and validate (and store) them based on both the system specification and current state; and Third, to redirect the compiled institutional message to the trainer so that the trainee's task can be completed. On the other direction, a trainer could also initiate an interaction with a trainee, if needed, by sending her or him a chat message in the simulated 3D environment.

This bidirectional process requires a trainer to dynamically control the flow and state of a task-oriented conversation with a trainee based on the trainee's entries, the system specification and its current state. The trainer delegates in a Conversation Manager the updating of the conversation's states, the storage of trainee's responses into a Typed Memory (with the types defined in the system specification) and the interpretation of the conversational knowledge. This conversational knowledge is based on Artificial Intelligence Mark-up Language (AIML), but we extended it in order to support structured/regulated conversations with the inclusion of some task-oriented special tags. This is so because basic AIML has been conceived to program reactive chatter bots that follow basic conversations with users, but it falls short for such complex interactions.

Figure 10. Finite State Machine depicting conversation's states during task stage

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Conversation Structure

In Assisted Hybrid Structured 3D Virtual Environments, a task-oriented conversation consists of three main interaction stages: welcoming, task, and farewell.

On the one hand, welcoming and farewell correspond to initial and final stages of the conversation. At these stages, the trainer is reactive and interacts with the trainee, basically, to greet and inform about the activity (welcoming stage), and say goodbye (farewell stage). On the other hand, as Finite State Machine in Figure 10 depicts, trainer-trainee interaction during the task stage is more complex. The change to this task stage is triggered when, during the welcoming stage, the trainee interacts with the trainer by sending a message, and the trainer recognizes this message content as a request to perform a task. During the task stage the human will send of messages to the corresponding trainer agent, and the trainer is an automata which, for a particular conversation state, selects the next action to perform based on the trainees' entries, messages defined in the system specification, and the allowed values of message contents at current state of the institution.

Once the trainer has identified the task (i.e. register), the task stage begins and the bot takes the initiative by asking to the trainee the data needed to complete the task. This interaction transits from the initial state to the asked state (A) in the Finite State Machine in Figure 10. In this state, the trainer waits for the trainee response, which will be processed in the responded (R) state.

Notice that both the format and value of trainee's entries (e.g., registration details) have to be checked against the system specification and current system state respectively. If these entries have incorrect format along a number of times, the conversation state becomes failed (F) and the trainer informs the trainee, asking for a confirmation to continue with the task. If the trainee confirms that she or he wants to continue with the task, the trainer repeats the last question and the conversation reaches again the asked state. Nevertheless, if she or he decides not to continue (cancel requested: CR state), it provokes the trainer to finish the task, reaching then the final state of task stage.

Alternatively, if all information is successfully gathered, the trainer terminates the questions (terminated state T) by presenting to the trainee the obtained information and requesting her or his confirmation before executing the actual message in the system. Then, the trainee can either request the cancellation with the same consequences as for previous failed state (F) or confirm that task's data is correct (confirmed state C). If the trainee user confirms, the trainer agent facilitates the execution of the corresponding message (i.e. register illocution) within the system. Upon successful message execution, the executed (E) state is reached, and the trainer sends a natural language message (response) back to the trainee, finishes the conversation, and changes to farewell stage.

EVALUATION

In order to check our scénario with real users we did a twofold evaluation, one about the virtual environment as a whole, where human-agent (i.e., trainee-trainer) interaction was based on commands; and one specific for the conversational mechanism, where command-based interaction was compared against the natural language dialogues. A total number of 37 participants were recruited to perform three separate tests that focus on studying specific aspects of our approach. The ages of the users were chosen within the range of working ages in many countries, as we intend the application to be useful both in education institutions and professional settings.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Virtual Environment Evaluation

Initially, the virtual environment was tested with an exploratory usability test (Rubin & Chisnell, 2008), mainly to get qualitative data on how the 3D virtual institution helped on the learning of the real institution. In the test, trainees had to accomplish a unique task: "Act as a seller, and register a water right for a price which is 5 euros higher than the price of the last transaction done", but performing it meant to plan her navigation through the 3D virtual scenario (the trainee had to visit two activity rooms), to get information in the Waiting&Info room, to work out an adequate registration price, and to achieve registration successfully.

The test aimed to know the effectiveness of the tool to reach trainees' goals and their willingness to use it, but also to observe human users interacting with the application, observe the mechanisms they used to obtain information, and value the easiness of getting that information.

The test was delivered to 13 users, ages between 18 to 54, 7 of them females and 6 males. As for experience with computers: 2 of the users had basic computer experience; 5 medium experience; and 6 advanced experience; whereas 1 had high experience with virtual environments, 3 some experience with them and 9 none. In order to facilitate interaction, users did a basic training session on functions and operation of the virtual environment before the test. During the test every interaction was recorded and analysed to observe the navigation paths of users and the obstacles they found to get theirs goals. Finally, a post-test questionnaire was administered to participants in order to know their opinion and satisfaction on the experience.

Despite the complexity of the task at hand, all users were able to complete the task, 10 of them with a correct price. Participants did not find any obstacle that prevented them completing the task, although 5 of them did not figure out they had to check prices before registering their water right.

The post test survey included 13 questions about:

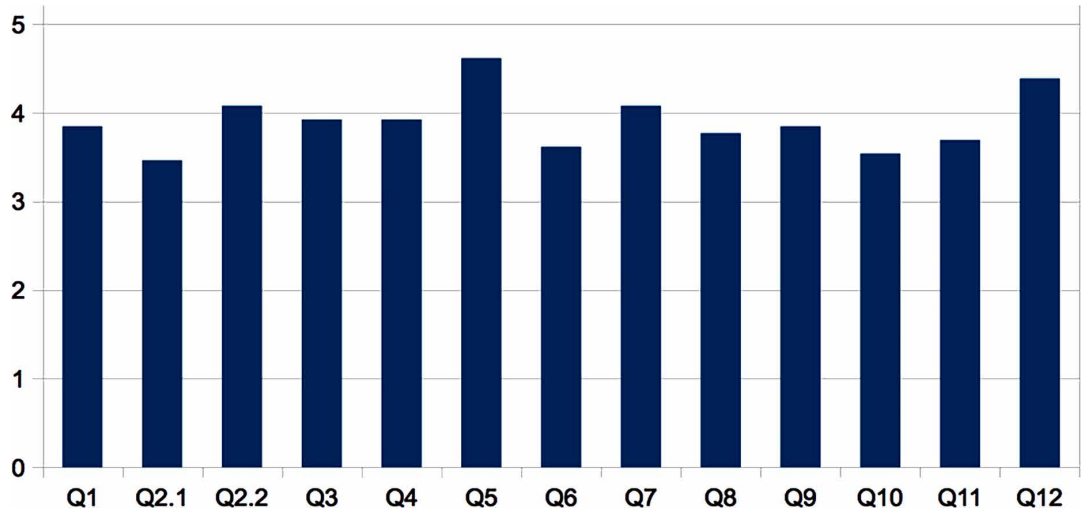
Q1: Situatedness and movement in 3D
Q2: Virtual Environment walking (2.1) and teleport (2.2) comfortability
Q3: Info gathering (panel/bot)
Q4: Human-bot interaction
Q5: Bot visual distinction
Q6: Chat-based bot communication
Q7: Task easiness
Q8: Immersiveness in 3D
Q9: Improved opinion of 3D VWs
Q10: Likeliness of future usage
Q11: 3D interface usefulness
Q12: Overall system opinion
Q13: User's comments

Figure 11 shows the average answers to the post-test questionnaire. As a summary, trainees evaluated very positively the facilities to gather information, both information panels and information bots, they had a good overall impression about interaction with bots but they did not like command-based dialogues. Observing the records of the tasks it was noted that older users found the environment difficult

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

but also more rewarding than younger players. Users without experience found it harder to play and, on the overall, computer experience was a direct indicator of the attained level of immersion. Users gave an average value of 3.5 over 5 on their intention to use a similar system in the future.

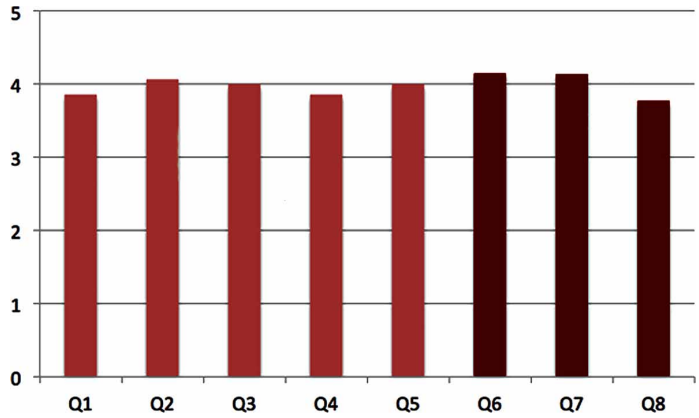
After the initial test, a second one was conducted where the assistance service provided by software trainers was included, and thus, its evaluation focuses on this service. The task was the same as in the initial test, but the tutoring assistants provided plan advices such as the one depicted in previous Figure 6. The second test script also consisted in a training session, the test and an ad-hoc post-test questionnaire. In this case there were 14 users (different from the ones in previous test), ages between 23 to 66, 4 of them females and 10 males. As of experience with computers, 4 of the users had basic computer experience and 10 advanced experience, while 8 had high experience with virtual environments, and 6 none.



The post test survey included 8 questions about:

Q1: Info gathering (panel/bot)
Q2: Human-bot interaction
Q3: Bot visual distinction
Q4: Dialogue-based bot communication
Q5: Overall system opinion
Q6: Assistance usefulness
Q7: Tutoring assistant interaction
Q8: Advice Understanding

And an open question to gather user's comments



Questions in the post-test questionnaire were focused on assistance. Figure 12 depicts its average results. Overall results were similar to the previous ones, but it is worth noticing the questions relating to the assistance service got very high scores.

Figure 12. Second post-test questionnaire results.
X axis: questions from Q1 to Q8. Y axis: average values

Along the tests, 13 out of 14 participants requested assistance voluntarily in different moments of the task, the interaction with bots was very natural and users could ask and understand the given information. In particular, plans were followed as expected. With the assistance, users reduced significantly the needed steps to reach their goal (from 10.8 in test 1 in average to 7 in test 2).

Conversational Interaction Evaluation

On a final test, the conversational mechanism was tested against the command-based interaction mechanism with a summative and comparative evaluation method (Bowman, Gabbard & Hix, 2002). 10 additional participants were recruited for this third test, ages between 21 to 45, 3 of them females and 7 males. Moveover, half of them (5) had previous experience with command-based systems, and the other half (5) were novices.

This third test followed a within-subject design and each subject did the same two tasks. Task 1 was defined as "Ask the Information Manager about the last 2 transactions in the market"; and Task 2 was defined as "ask the Registration Manager to register a water right, identified as wr1, for a price of 25€". Task order was alternated to avoid learning and fatigue effects, and thus half the participants started by using the command-based interaction style, whereas the other half started by using the conversational style.

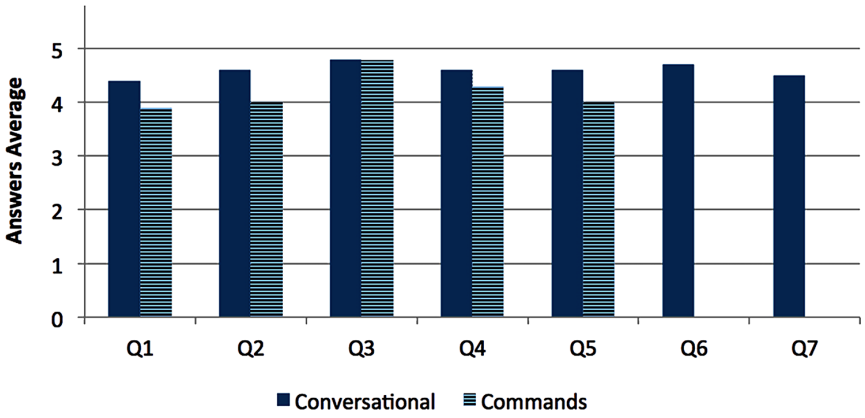
Before the test a short training session was delivered to teach how to interact with objects and bots and how to move in 3D environments, and as in the other two evaluations, there was also an ad hoc post-test questionnaire. This post-test consisted in the following 7 questions:

Q1: I did not feel I needed help while talking to the bot
Q2: I did not feel frustrated while talking to the bot
Q3: What the bot said to me made sense
Q4: I did know what to answer to the bot
Q5: How comfortable was the communication
Q6: I felt that the bot understood me
Q7: The bot had answers I expected

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Possible answers to these questions were: 1 never / very uncomfortable; 2 sometimes/uncomfortable; 3 regularly/normal; 4 often/comfortable; 5 always/very comfortable.

Figure 13 depicts average values for the answers to these 7 different questions. As we can observe in the Figure, overall satisfaction was good. In particular all dialog related questions had an average value above 4. Taking a closer look to the figures, we observed that novices valued most the conversational mechanisms while experts rated almost identically both mechanisms. The test was also useful to detect that bots should greet users on its own initiative as well as to be able to extract and process multiple data from a single conversational message.



Regarding effectiveness, the conversational interaction style obtained a task completion rate of 100%, while the command-based approach only a 70% rate. Additionally, errors were much lower in the conversational system (0.3 errors versus 2.2 errors in average in command-based system). Relating to efficiency, the number of messages in the conversational system was superior (that was forced by the design of the conversation interaction), but the messages were more focused and driven by the goal.

More tests and a quantitative approach would have yield more precise results, and maybe a segmentation of users based on age or experience could orient new paths for improvement. Nevertheless these evaluations gave us enough data to orient our future work.

DISCUSSION AND FUTURE WORK

We can see our training infrastructure as an authentic learning approach applied to learn specific skills and knowledge to perform tasks in a job (Donovan et al., 1998) as it provides a concise and immediate learning process. The term *authentic learning* refers to an "*educational and instructional techniques focused on connecting what students are taught in school to real-world issues, problems, and applications*" ("Authentic...", n.d.). Authentic learning methods include techniques that allow trainers to explore, discuss and build concepts and relationships in real-worlds situations.

Herrington, Reeves and Oliver (2014) developed the authentic technology-based learning environment model that defines nine practical characteristics derived from the cognitive and comprehensive learning experience. Next, we analyse these characteristics in our training scenario, showing its own advantages and limitations:

- **An Authentic Context Should be Used:** The scenario should reflect the real environment of the training, not a simplified version of the reality. Our training scenario defines a real complex and sustained trading situation with norms and roles that replicate the complexity of the irrigation market. The use of a virtual world gives the immersion and the strong feeling of "being there" while also allowing trainees to safety learn in a virtual environment.
- **Authentic Tasks Based on Ill-Defined Problems[3]:** This characteristic requires that trainers define tasks and sub-tasks that require to solve challenges faced by trainees. Also, tasks should allow competing solutions and a diversity of outcomes instead of one single correct answer. In our case, tasks can be solved by performing different plans, and thus, their solutions are not fixed. For instance, when a participant starts the water market session, she can freely navigate through the environment and access to either one of the three activities involved in the water rights' negotiation: Waiting and Information, Registration or Auction. Moreover, trainees can think different strategies to solve some tasks. Some participants enter the Waiting and Information Room to get the actual price of a water right, whereas others only watch the panel information from the window in order to get the desired information faster.
- **Allow to Access to Expert Performances and Modeling Processes:** the environment replicates the forms of support in the "real" context, as well as it is able to support different levels of expertise. In a 3D virtual world, expertise and performance can be captured and analyzed easily to reinforce some skills and improve their performance. In our case, tutoring assistants help trainees on-demand using a conversational system where trainees can express their needs using natural language dialogues and trainers understand trainees' entries and support them in their task completion, using information of the system specification and their current state. Such tutoring assistant agents use an extension of AIML to support task-oriented conversations. Furthermore, we may use adaptive agents to react to different expertise levels or to different behaviour. Moreover, the selection of the adequate tutoring of different levels could be based on a Recommender System. Specifically, Recommender Systems (RSs) represent one approach to develop more personalised information systems, which provide users with suggestions taking into account user requirements and community preferences (Konstan & Riedl, 2012). We consider that RSs can also be a significant part of e-learning systems for personalization and recommendation of appropriate materials to the learner considering its level of expertise(Parveen, Rubina & Anant, 2012). Although the use of RSs has been extensively focused on web-based scenarios, more recently, there is an interest in the study of their integration within 3D virtual environments, particularly in an e-commerce context (Arroyo, Serradilla & Calvo, 2010; Xu & Yu, 2010; Contreras, Salamó, Rodríguez & Puig, 2014; Contreras, Salamó, Rodríguez & Puig, 2013).
- **Multiple Roles and Perspectives Should be Provided in Order to Provide Trainees with the Opportunity to Examine the Problem from Different Perspectives Using a Variety of Resources:** In our case, participants can enact different roles in the virtual world so to learn different expected behaviours and perspectives of the simulated market. On the other hand, it is worth mentioning the potentiality of the assistance layer to offer message personalization for dif-

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

ferent profiles of users, in particular for users with disabilities. The personalization could consist of more verbose textual explanations for blind users, specific plans designed for users with motor impairments with less interactions, plain language instructions for users with cognitive or learning disabilities, etc. and thus, each user will solve the problem in a different way, taking profit of his strengths and minimizing his shortcomings.

- **Collaborative Construction of Knowledge:** Market institutions are generally characterised by a rather competitive coordination schema, and thus, its regulations and protocols scarcely support collaboration. Nevertheless, the overall learning approach we propose is scenario independent, and thus, activities could be applied to other domains and so specified to support collaborative knowledge creation and knowledge sharing.
- **Reflection:** this property provides trainees with the opportunity to examine their performances so to self-evaluate and repeat some parts of the training whenever required. We can use gamification strategies based on badges, scores and feedback of the realized actions to provide trainees with an immediate response from the system, as suggested in (Teräs, Teräs & Reiners, 2014) . Additionally, our virtual world could include game-based feedback(Deterding, Dixon, Khaled & Nacke, 2011). which stores points and achievements accumulated over time in a profile that provides a trainee with a potentially powerful representation of their avatar identity.
- **Articulation:** it provides mechanisms to communicate ideas between pairs and to reason some concepts. Currently, our 3D virtual environments are endowed with a chat-based communication mechanism that allows participants to exchange textual messages, and these chats can support both sharing ideas between participants as well as reasoning about specific concepts that should be learned. In our environment, though, these chat-based messages are allowed but they are not regulated by the virtual institution norms, and, in particular, they are not explicitly forbidden by any norm or protocol. Chat-based communication can be viewed as a complementary way to share knowledge and experiences among participants.
- **Scaffolding and Coaching:** it allows to integrate some type of assessment or assistance into the activities rather than employing external tests. In this respect, we could consider tutoring assistant agents as a first step towards this direction, since they monitor trainees' status and provide meaningful assistance.
- **Authentic Assessment Allows Trainees to Demonstrate Their Acquired Skills and Their Progression in the World:** This last learning characteristic can be naturally accomplished in our "real" immersive scenario.

This authenticity, and the technical feasibility of the model, as demonstrated by the text, makes this option a real alternative to live training for professional training both in educational and professional settings. The cost, flexibility and capacity of the System to be enriched will make it very attractive for lifelong learning and job orientation in a ever-changing world with increasing demands of professional skills.

As previously discussed, our future plans include to extend our current system to support a full authentic learning experience, such as using recommender systems, gamification strategies and adaptive learning systems to support a full authentic learning experience.

CONCLUSION

In real life institutions, people gather in physical spaces to develop complex tasks, such as trading or paperwork handling. Therein, institutional members, i.e. staff, are in charge of enabling the complex institutional activities while fulfilling the norms that regulate each particular institution. External users enter the institution and achieve their goals by interacting with both other external users and staff as well as with the environment. These interactions follow intricate communication protocols, and may have irreversible consequences, such as legal commitments.

This chapter has presented a training system that teaches human users to participate in such a complex scenarios. In particular, we propose to simulate a real institution and enable assistance mechanisms by developing it as an *Assisted Hybrid Structured 3D Virtual Environment*. The institutional physical spaces are represented in a 3D virtual environment, and the interactions between participants are regulated by means of an Organisation Centered Multi-Agent System (OCMAS).

The training system is populated by tutoring agents that are programmed to train human users (i.e. trainees) not only on how to participate within the real institution --by playing staff roles-- but also to understand the social model underlying it --by providing personal assistance. A personal assistant directly and solely supports a trainee, providing her or him with services such as information about the institution or advice on how to proceed along it. Additionally, tutoring agents are able to communicate with trainees in natural language conversations by means of our proposed Task-Oriented AIML. As a result, human users are trained to perform complex real-life tasks within an immersive scenario, in a seamless way and avoiding the fear to fail.

We have empirically tested our proposal by simulating a water market, where sellers enter to register water rights, and buyers negotiate them within an auction. Tutoring agents play staff roles market facilitator and basin authority, and tutoring personal assistants provide advices on how to perform a registration task. The performed experiments show that when the training system incorporates tutoring agents and conversational command styles its usability, efficiency, and efficacy increases.

To sum up, the training system presented in this chapter is an authentic learning approach for real institutions with a number of promising research lines still open. For example, techniques such as recommender systems, gamification strategies and adaptive learning systems taking into account accessibility issues, will be used to support full authenticity and education requirements. In its corrent State of development it is already a real alternative to live training, and it could be very attractive for higher education institutions of big companies looking for longlife learning. The immersive and supportive approach presented here can have a big impact on how training is modelized from now on.

KEY TERMS AND DEFINITIONS

3D Virtual World / Environment (3DVW): Persistent virtual locations where participants, represented as animated figures in a three dimensional visual environment, may interact with other participants or objects in the environment in real time.

Accessibility: The usability of an application for users with disabilities who often use assistive tools and different modalities of interaction (only text, no audio, keyboard instead of mouse…)

Agent: (Intelligent) autonomous entity (piece of software) that interacts within an environment.

Artificial Intelligence Markup Language: (AIML): An XML dialect for creating natural language software agents.

Assisted Hybrid Structured 3D Virtual Environment (3DVW): Where participants, which can be human and software agents, interact following the rules of an organization (an OCMAS) and are assisted accordingly.

Conversational Interaction: Interaction conducted in a dialogical way, by exchanging natural language messages.

Hybrid Structured 3D Virtual Environment (3DVW): Where participants, which can be human and software agents, interact following the rules of an organization (an OCMAS)

Multi-Agent System (MAS): Computerized system composed of multiple interacting (intelligent) agents within an environment.

Organization Centered Multi-Agent System (OCMAS): MAS endowed with an organization or institution, where agents interact in a structured way which is defined by the organization.

Recommender Systems: Systems that provide users with suggestions of items, taking into account user's requirements or preferences.

ENDNOTES

[1] An open Organisation-Centred Multi-Agent System, where agents may not belong to the institution and interact dialogically, by sending illocutions.

[2] An illocution is any structured message defined for an institution that participants utter when interacting within it.

[3] By ill-defined problem we mean problems that can be solved by different solution paths.

Chapter 69
Semantic Search Exploiting Formal Concept Analysis, Rough Sets, and Wikipedia

Yuncheng Jiang
South China Normal University, China

Mingxuan Yang
South China Normal University, China

ABSTRACT

This article describes how the traditional web search is essentially based on a combination of textual keyword searches with an importance ranking of the documents depending on the link structure of the web. However, one of the dimensions that has not been captured to its full extent is that of semantics. Currently, combining search and semantics gives birth to the idea of the semantic search. The purpose of this article is to present some new methods to semantic search to solve some shortcomings of existing approaches. Concretely, the authors propose two novel methods to semantic search by combining formal concept analysis, rough set theory, and similarity reasoning. In particular, the authors use Wikipedia to compute the similarity of concepts (i.e., keywords). The experimental results show that the authors' proposals perform better than some of the most representative similarity search methods and sustain the intuitions with respect to human judgements.

1. INTRODUCTION

The World Wide Web is the world's most valuable information resource and has become the world's largest database with search being the main tool that enables organisations and individuals to exploit its huge amounts of information that is freely offering (Virgilio et al., 2012). Thus, having a successful mechanism for finding and retrieving the most relevant information to a task at hand is of major importance. Traditionally, Web search is essentially based on a combination of textual keyword search with an importance ranking of the documents depending on the link structure of the Web (Fazzinga and

Lukasiewicz 2010). However, one of the dimensions that has not been captured to its full extent is that of semantics. Combining search and semantics gives birth to the idea of the semantic search. Semantic search can be described in a sentence as the effort of improving the accuracy of the search process by understanding the context and limiting the ambiguity (Melo et al., 2016; Virgilio et al., 2012; Vocht et al., 2017). In fact, the issue of semantics has become the grand challenge for the next-generation World Wide Web (Jindal et al., 2014; Storey et al., 2008).

The development of semantic search is currently an extremely hot topic (Binding et al. 2015; Fazzinga and Lukasiewicz, 2010; Formica, 2012; Formica et al., 2013; Likavec et al., 2015; Melo et al., 2016; Storey et al., 2008; Virgilio et al., 2012; Vocht et al., 2017). For example, Formica (2012) showed how rough set theory (Pawlak 1991) could be employed in combination with fuzzy formal concept analysis to perform Semantic Web search and discovery of information in the web. Formica et al. (2013) pointed out that there were many proposals on semantic search and retrieval in the literature, but there was still no specific solution that clearly emerged. For this reason, they presented a proposal based on a notion that is currently gaining momentum in the field: the Information Content (IC) approach (Resnik, 1995; Jiang et al., 2017).

However, there are still some limitations in the above approaches. For example, similarity reasoning in (Formica et al., 2013) was based on ontology based IC computation (Sanchez et al., 2011). The fact that ontology based IC computation only relies on ontological knowledge is a drawback because it completely depends on the degree of coverage and detail of the unique input ontology (Sanchez and Batet, 2013). Especially, with the emergence of social networks (Martinez-Gil and Aldana-Montes 2013), a lot of (sets of) concepts or terms are not included in domain ontologies (Kumar et al., 2017), therefore, IC computation that is based on these kinds of domain ontologies cannot be used in these tasks. On the other hand, the prerequisite of ontology based IC computation is the existence of several predefined domain ontologies. Clearly, the construction of domain ontologies is time-consuming and error-prone and maintaining these ontologies also requires a lot of effort from experts. Thus, the methods of ontology based IC computation are also limited in scope and scalability (Jiang et al., 2015). These limitations of similarity reasoning are the motivation behind the new techniques presented in this paper which implement semantic search by exploiting Wikipedia (Hovy et al., 2013; Medelyan et al., 2009). It should be noted that the authors' approaches are only suitable for less specific domains because Wikipedia does not guarantee the coverage for specific domains. In the case of a very specific domain, a domain specific reference resource such as ontologies is needed. On the other hand, in the case of less specific domains, semantic search relies on some knowledge sources such as WordNet (Fellbaum, 1998), DBpedia (Lehmann et al., 2009; Li et al., 2017b), Wikipedia (Hovy et al., 2013; Medelyan et al., 2009), and YAGO (Hoffart et al., 2013; Suchanek et al., 2008). In this paper, the authors will exploit Wikipedia to implement semantic search. In fact, the authors' approaches can also be based on other knowledge sources such as DBpedia or YAGO by simple adjustment.

The purpose of this paper is to present some new methods to semantic search to solve the shortcomings of existing approaches. Concretely, along the line of the research of (Formica 2012; Formica et al. 2013), the authors will propose some novel methods to semantic search by combining formal concept analysis (Ganter and Wille, 1999), rough set theory (Pawlak, 1991), and Wikipedia based similarity reasoning (Jiang et al., 2017; Li et al., 2017a; Ponzetto and Strube, 2007; Taieb et al., 2013; Yazdani and Popescu-Belis, 2013). On the other hand, semantic search usually adopts user-friendly unstructured (Rocha et al., 2004) or semi-structured (Anyanwu et al., 2005) query strategies. However, these reported approaches are still much less attractive than keyword search, which is the most effective and successful paradigm

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

for modern information retrieval (Ning et al., 2009). Research on semantic search based on keywords has been very active and many results have been achieved (Ning et al., 2009; Zenz et al., 2009). Thus, this paper focuses on the problem of supporting effective keyword search for semantic search.

2. PRELIMINARIES

In this section the authors briefly recall some basic notions of formal concept analysis and rough sets.

2.1. Formal Concept Analysis

Formal Concept Analysis (FCA) is a theoretical framework which supplies a basis for conceptual data analysis and knowledge processing (Ganter and Wille, 1999). In this subsection the authors give the basic of FCA (Ganter and Wille, 1999; Valverde-Albacete et al., 2016) as far as they are needed for this paper.

A formal context $K = (G, M, I)$ consists of two sets G and M and a binary relation I between G and M. The elements of G are called the objects and the elements of M are called the attributes of the context. gIm or $(g, m) \in I$ can be used to express that an object g is in a relation I with an attribute m.

A small context can be easily represented by a cross table, i.e., by a rectangular table the rows of which are headed by the object names and the columns headed by the attribute names. A cross in row g and column m means that the object g has the attribute m.

For a set $A \subseteq G$ of objects we define $A' = \{m \in M | \ gIm \text{ for all } g \in A\}$. Correspondingly, for a set B of attributes we define $B' = \{g \in G | \ gIm \text{ for all } m \in B\}$.

A formal concept of the formal context $K = (G, M, I)$ is a pair (A, B) with $A \subseteq G$, $B \subseteq M$, $A' = B$ and $B' = A$. The researchers call A the extent and B the intent of the formal concept (A, B). $\mathrm{B}(G, M, I)$ (or $\mathrm{B}(K)$) denotes the set of all formal concepts of the formal context $K = (G, M, I)$, $\mathrm{Int}(K)$ and $\mathrm{Ext}(K)$ denote the sets of intents and extents of all formal concepts of the formal context $K = (G, M, I)$, respectively.

If (A_1, B_1) and (A_2, B_2) are formal concepts of the formal context $K = (G, M, I)$, (A_1, B_1) is called a subconcept of (A_2, B_2) (or (A_2, B_2) is a superconcept of (A_1, B_1)), provided that $A_1 \subseteq A_2$ (or $B_2 \subseteq B_1$) and is denoted by $(A_1, B_1) \leq (A_2, B_2)$. The relation $\leq$ is called the hierarchical order (or simply order) of the formal concepts. The set of all formal concepts of (G, M, I) ordered in this way is denoted by $\underline{\mathrm{B}}(G, M, I)$ and is called the concept lattice of the formal context (G, M, I).

2.2. Rough Sets

Rough set theory is an extension of classical set theory with additional operators, namely approximation operators. Among the various formulations that can be found in the literature, below the one given in (Jiang et al., 2009; Yao, 1996; Zhang et al., 2015) is briefly recalled.

Let U denote a finite and non-empty set called the universe, and let $\mathrm{R} \subseteq U \times U$ denote an equivalence relation on U. The pair $apr = (U, \mathrm{R})$ is called an approximation space. The equivalence relation R partitions the set U into disjoint subsets. Such a partition of the universe is denoted by U/R. If two elements x, y in U belong to the same equivalence class, the researchers say that x and y are indistinguishable. The equivalence class of R and the empty set ϕ are called the elementary sets in $apr = (U, \mathrm{R})$. Any finite union of elementary sets is called a definable set.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Given an arbitrary set $A \subseteq U$, it may not correspond to a definable set because A may include and exclude objects that belong to different definable sets. In this case, one may characterize A by a pair of lower and upper approximations:

$$\underline{apr}(A) = \bigcup_{[x]_R A} [x]_R \text{ and } \overline{apr}(A) = \bigcup_{[x]_R \cap A \neq \varnothing} [x]_R$$

where $[x]_R = \{y | \, x R y\}$, is the equivalence class containing x. The pair $\left(\underline{apr}(A), \overline{apr}(A)\right)$ is called the rough set w.r.t. A.

The notion of approximation can be naturally introduced into FCA (Formica 2012). In line with (Formica 2012; Yao and Chen 2006), given a concept lattice L, let Int(L) be the family of all the intents of L. Given a set of attributes B that is not the intent of any concept in L, intuitively the upper approximation $\overline{apr}(B)$ is the smallest set in Int(L) that contains B, whereas the lower approximation $\underline{apr}(B)$ is the largest set in Int(L) that is contained in B. Formally,

$$\overline{apr}(B) = \cap \{X | \, X \in \text{Int}(L), B \subseteq X\},$$

$$\underline{apr}(B) = \{X | \, X \in \text{Int}(L), X \subseteq B, \forall Y \in \text{Int}(L) \, (X \subseteq Y \Rightarrow Y \not\subseteq B)\}.$$

3. SEMANTIC SEARCH FOR QUERY KEYWORDS

In this section the authors will propose two novel approaches to semantic search for query keywords.

3.1. Semantic Search Using FCA and Similarity Reasoning

To implement semantic search by exploiting FCA, the authors assume that users have a formal context and that Web queries are expressed by sets of query keywords. In fact, it is similar to the assumption of (Formica 2012). From a practical point of view this is a limitation users can live with, especially taking into account that the formal contexts are used to achieve some specific domain applications, and thus, users certainly can construct a corresponding formal context by transforming the original information.

In the following the authors assume that users have a formal context $K = (G, M, I)$, where $G = \{g_1, g_2, \ldots, g_m\}$, $M = \{a_1, a_2, \ldots, a_n\}$, and I is a relation between G and M (i.e., $I \subseteq G \times M$). According to the algorithms of concept lattice construction (Ganter and Wille 1999; Godin et al. 1995; Nourine and Raynaud 2002), users can obtain the corresponding concept lattice $L = \underline{\mathrm{B}}(K)$ (or $\underline{\mathrm{B}}(G, M, I)$) w.r.t K. On the other hand, Web queries are expressed by sets of keywords, formally, a query $Q = \{q_1, q_2, \ldots, q_s\}$, where q_i $(1 \leq i \leq s)$ is a keyword. Theoretically, in an open environment such as Internet a query keyword may be any string. It is the same as the query keyword in Search Engines such as Google. For example, $Q =$ {*Semantic search*, *Ontology*, *Rough sets*} is a set of query keywords. Clearly, Q contains two multiword expressions *Semantic search* and *Rough sets*. Users can use different search interfaces such as "*Semantic search*"+"*Ontology*"+"*Rough sets*" to extract the keywords correctly. Of course, for any query string

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

such as *Semantic search Ontology Rough sets*, users need to discover the keywords correctly by means of some techniques such as automatic term extraction and association measures.

Obviously, for any query $Q = \{q_1, q_2, \ldots, q_s\}$, if there is a formal concept $(A, B) \in L$ such that $Q = B$, then users know that A is the result for Q. However, if for any formal concept $(A, B) \in L$, users have $Q \neq B$. Then, the goal is to find the formal concepts of L whose intents "better approximate" the set of attributes specified by the query and, therefore, whose extents are closer to the expected answer. In the following the authors will propose two approaches to semantic search by "better approximating" the query keywords. The first method is provided by using FCA and Wikipedia based similarity reasoning. The authors call this method the Semantic Search for query Keywords by making use of FCA and Wikipedia based similarity reasoning (SSKFW). Essentially, SSKFW is implemented by evaluating the similarity between intents of formal concepts in L and the set Q of query keywords.

Definition 1: Let $K = (G, M, I)$ be a formal context, where $M = \{a_1, a_2, \ldots, a_n\}$ and $Q = \{q_1, q_2, \ldots, q_s\}$ be a query. The semantic similarity $sim_{att}(a_i, q_j)$ between a_i and q_j $(1 \leq i \leq n, 1 \leq j \leq s)$ is defined as follows:

(1) if $a_i, q_j \in WikiCon$, $sim_{att}(a_i, q_j) = \begin{cases} 1, & if\ Synonyms\left(a_i\right) \cap Synonyms\left(q_j\right) \neq \varnothing \\ sim_{fea}\left(feature\left(a_i\right), feature\left(q_j\right)\right), & otherwise \end{cases}$ and

(2) if $a_i \notin WikiCon$ or $q_j \notin WikiCon$, $sim_{att}(a_i, q_j) = \begin{cases} 1, & if\ a_i = q_j \\ 0, & otherwise \end{cases}$,

where: (1) *WikiCon* is the set of all Wikipedia concepts.

(3) *Synonyms*(X) is the set of synonyms of X. Users can get the value of *Synonyms*(X) by using the redirect page of Wikipedia. Technically, users also may exploit the property *wikiPageRedirects* of DBpedia (Lehmann et al. 2009) to obtain *Synonyms*(X). On the other hand, users can use Wikipedia anchor texts to add the elements of *Synonyms*(X). If DBpedia is considered as the knowledge source, users can also add the elements of *Synonyms*(X) by exploiting the entity linking system of DBpedia.

(4) *feature*(X) is the set of features of X. Technically, *feature*(X) = *words*(Y), where Y is the first paragraph of text of X in Wikipedia page. Users may obtain *words*(Y) by transforming Y into a set of words.

(5) $sim_{fea}(Set_1, Set_2) = \dfrac{\left|Set_1 \cap Set_2\right|}{\left|Set_1 \cup Set_2\right|}$.

Remark 1: According to the theoretical principles and the way in which knowledge are analyzed to estimate similarity, different methods can be identified (Martinez-Gil 2014; Petrakis et al. 2006). Currently, there are lots of approaches to Wikipedia based similarity computation (Jiang et al. 2017; Li et al. 2017a; Ponzetto and Strube 2007; Taieb et al. 2013; Yazdani and Popescu-Belis 2013). In Definition 1 users can use these existing methods to compute the similarity $sim_{att}(a_i, q_j)$ between a_i and q_j. However, the computation of these methods needs more time. For example, several approaches to Wikipedia based semantic similarity computation in (Ponzetto and Strube 2007) are based on the whole Wikipedia category structure. Thus, in Definition 1 the authors present a novel approach to similarity computation. The definition of sim_{fea} is based on *X-similarity* approach (Petrakis et al. 2006). Of course, users also can use other approaches to define sim_{fea}. For example, according to R&E approach (Rodriguez and Egenhofer 2003), sim_{fea} may be defined as follows:

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

$$sim_{fea}(Set_1, Set_2) = \frac{\left|Set_1 \cap Set_2\right|}{\left|Set_1 \cap Set_2\right| + \alpha\left|Set_1 \setminus Set_2\right| + (1-\alpha)\left|Set_2 \setminus Set_1\right|},$$

where $0 \leq \alpha \leq 1$ and the value of α is specified by users or experts ($\alpha = 0.5$ in default).

Since the intent $B = \{a_1, a_2, \ldots, a_t\}$ of formal concept (A, B) and the query $Q = \{q_1, q_2, \ldots, q_s\}$ are two sets of keywords, so the authors can give the notion of the similarity between B and Q by using sim_{att}. With regard to the computation of similarity for sets of keywords, the approach has been inspired by the method for evaluating concept similarity defined within the SymOntos (Formica and Missikoff 2002) and FCA (Formica 2006). It is based on the maximum weighted matching problem in bipartite graphs, that can be solved in polynomial time (Galil 1986).

Consider the intent $B = \{a_1, a_2, \ldots, a_t\}$ of some formal concept (A, B) and the query $Q = \{q_1, q_2, \ldots, q_s\}$. Let a candidate set of pairs be a subset of $B \times Q$ such that there are no two pairs in the set sharing an element. Then consider the set of all candidate sets of pairs, that is indicated as $CS(B, Q)$. For each candidate set of $CS(B, Q)$, consider the sum of the sim_{att} of the pairs of keywords. One of the candidate sets having the maximum among all the computed sums is chosen. Formally,

Definition 2: Let $B = \{a_1, a_2, \ldots, a_t\}$ be the intent of some formal concept (A, B) and $Q = \{q_1, q_2, \ldots, q_s\}$ be a query.

If $t \leq s$, the set $CS(B, Q)$ of the candidate sets of pairs is defined as follows:

$CS(B, Q) = \{\{\langle a_1, q_m\rangle, \ldots, \langle a_t, q_n\rangle\} \mid a_h \in B, q_l \in Q, \forall h = 1, \ldots, t, \forall l = m, \ldots, n, \{m, \ldots, n\} \subseteq \{1, \ldots, s\}$, and $a_i \neq a_j, q_i \neq q_j, \forall i \neq j\}$.

If $s \leq t$, the set $CS(B, Q)$ of the candidate sets of pairs is defined as follows:

$CS(B, Q) = \{\{\langle a_m, q_1\rangle, \ldots, \langle a_n, q_s\rangle\} \mid a_h \in B, q_l \in Q, \forall h = m, \ldots, n, \{m, \ldots, n\} \subseteq \{1, \ldots, t\}, \forall l = 1, \ldots, s$, and $a_i \neq a_j, q_i \neq q_j, \forall i \neq j\}$.

Definition 3: Let $K = (G, M, I)$ be a formal context and (A, B) be a formal concept of K, where $B = \{a_1, a_2, \ldots, a_t\} \subseteq M$. Given any query $Q = \{q_1, q_2, \ldots, q_s\}$, the similarity of B and Q, denoted as $sim_{FW}(B, Q)$, is defined as follows:

$$sim_{FW}(B, Q) = \frac{1}{\max(t, s)} \max_{cs \in CS(B,Q)} \left(\sum_{a_i, q_j \in cs} sim_{att}(a_i, q_j) \right).$$

Now the authors can provide the following SSKFW method in Algorithm 1.

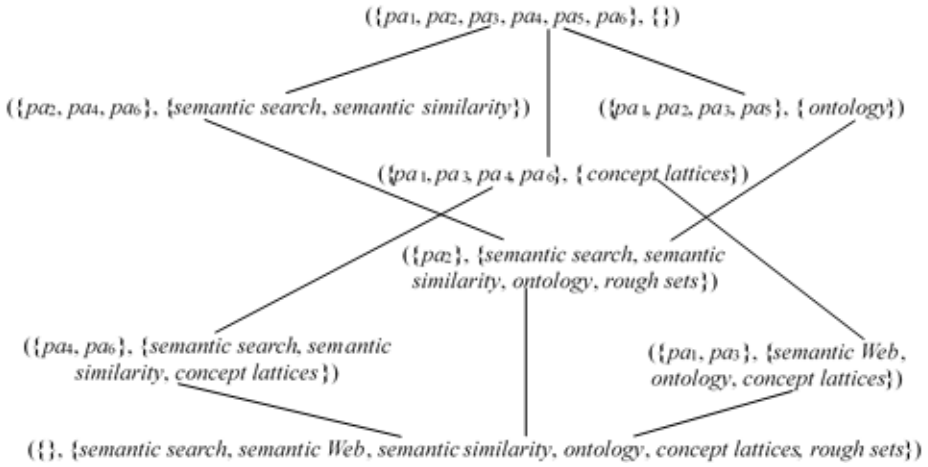
Algorithm 1. *SSKFW method for semantic search*

Input: a formal context $K = (G, M, I)$, where $G = \{g_1, g_2, \ldots, g_m\}$, $M = \{a_1, a_2, \ldots, a_n\}$, and $I \subseteq G \times M$; a query $Q = \{q_1, q_2, \ldots, q_s\}$

Output: a result set $S \subseteq G$ for Q

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

(1) generate the concept lattice $L = \underline{B}(K)$ (or $\underline{B}(G, M, I)$) of K;
(2) if there exists a formal concept $(A, B) \in L$, where $A = \{g_1, g_2, \ldots, g_w\}$, $B = \{a_1, a_2, \ldots, a_t\}$, such that $B = Q$, then assign A to S (i.e., $S = A$) and Goto (5); elsewise (i.e., for each formal concept $(A, B) \in L$, $B \neq Q$);
(3) for each formal concept $(A, B) \in L$, compute the similarity $sim_{FW}(B, Q)$;
(4) let $S = \cup\{A \mid (A, B) \in L \wedge sim_{FW}(B, Q) = \max\{sim_{FW}(D, Q) \text{ for all } (C, D) \in L\}\}$;
(5) return S.



Remark 2: In Algorithm 1, the step (4) is to find the results whose corresponding intents "better approximate" the set of keywords specified by the query and, therefore, whose extents are closer to the expected answer. In fact, users can relax the condition of "better approximation". Concretely, users may specify a threshold value α ($0 \leq \alpha \leq 1$) for "better approximation". Formally, the step (4) in Algorithm 1 can be modified as follows:
(4′) let $S = \cup\{A \mid (A, B) \in L \wedge sim_{FW}(B, Q) \geq \alpha\}$.

3.2. Semantic Search Using FCA, Rough Sets and Similarity Reasoning

From the step (3) in Algorithm 1 the researchers know that users have to compute the similarity between intents of all formal concepts in L and query. In particular, when some complex approaches to Wikipedia based similarity computation such as the methods presented in (Taieb et al. 2013; Yazdani and Popescu-Belis 2013) are used in SSKFW, it will waste a lot of time for computation of $sim_{FW}(B, Q)$ for each formal concept $(A, B) \in L$. The authors will give another method by a small amount of computation. The authors call this method Semantic Search for query Keywords using FCA, Rough sets, and Wikipedia based similarity reasoning (SSKFRW).

Example 1: Suppose that users have the concept lattice L related to research papers of Figure 1 and suppose the user is looking for a paper on semantic search based on similarity reasoning. This query can be represented by $Q = \{semantic\ search, ontology, semantic\ similarity\}$.

Figure 1. Concept lattice L of research papers

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Clearly, in the concept lattice L there are no concepts defined by Q. That is, there are no answers in L for the query Q. Similarly, to the method presented in (Formica 2012), users can look for the formal concepts whose intents better approximate it. According to the definitions given in Section 2.2, the smallest intent in L containing Q is {*semantic search*, *semantic similarity*, *ontology*, *rough sets*}, i.e., the concept whose intent is an upper approximation of Q is:

($\{pa_2\}$, {*semantic search, semantic similarity, ontology, rough sets*}).

Analogously to the upper approximation of Q, lower approximations of Q can also be obtained. Two lower approximations are identified in L. They correspond to the following concepts whose intents are the largest sets contained in Q:

($\{pa_2, pa_4, pa_6\}$, {*semantic search, semantic similarity*}) and ($\{pa_1, pa_2, pa_3, pa_5\}$, {*ontology*}).

Here, users can select as answer, on the basis of their needs, one of the concept extents associated with the above upper and lower approximations. That is, users can choose $\{pa_2\}$, $\{pa_2, pa_4, pa_6\}$, or $\{pa_1, pa_2, pa_3, pa_5\}$ as the answer. Obviously, there is a problem here. Since lower approximations may not be unique, so it is still difficult to choose the answer. Naturally, users should be able to implement generation of answers from the upper and lower approximations automatically using Wikipedia based similarity computation. Intuitively, users first obtain the upper and lower approximations of the query by using rough set theory. Then users get the results of query by computing the similarity between the intents of upper and lower approximations and the query. However, there is still one problem.

Assume another query is represented by $Q' = \{$*semantic searching*, *ontologies*, *semantic relatedness*$\}$, users know that the set of formal concepts whose intents are upper or lower approximations of Q' is an empty set. Formally,

$$\{(A, B) | (A, B) \in L \wedge (\overline{apr}(Q') = B \vee \underline{apr}(Q') = B)\} = \phi.$$

Obviously, this result is not correct from a semantics point of view since there exist some semantic relationships between the intents of formal concepts in L and the query Q'. Concretely, according to Wikipedia or DBpedia users have the following:

semantic searching ≡ *semantic search, ontologies* ≡ *ontology,* and *semantic relatedness* ≡ *semantic similarity.*

Therefore, Q and Q' are equivalent from a semantics point of view. That is, the upper and lower approximations of Q' should be the same as those of Q. In SSKFRW, the authors will consider these cases.

Definition 4: A Semantically equivalent Set of Keywords based on Wikipedia (SSKW) is an unordered collection of strings $SSKW = \{key_1, key_2, \ldots, key_u\}$ such that

$\forall key_i, key_j \in SSKW, i \neq j \rightarrow key_i \not\equiv key_j$ (i.e., Synonyms(key_i)∩Synonyms(key_j) = ϕ). That is, there do not exist $key_i, key_j \in SSKW$ such that $i \neq j \wedge key_i \equiv key_j$ (i.e., Synonyms(key_i)∩Synonyms(key_j)≠ϕ).

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

In what follows the authors only consider semantically equivalent sets of keywords.

Definition 5: Given two semantically equivalent sets of keywords (SSKWs) $SSKW_1$ and $SSKW_2$, $SSKW_1$ is said to be a semantic subset of $SSKW_2$ (denoted by $SSKW_1 \subseteq_S SSKW_2$) if and only if the following condition holds:

$\forall key_1 \in SSKW_1$, there exists $key_2 \in SSKW_2$ satisfies $key_1 \equiv key_2$.

$SSKW_1$ and $SSKW_2$ is said to semantically equivalent (denoted by $SSKW_1 \equiv_S SSKW_2$) if and only if $SSKW_1 \subseteq_S SSKW_2$ and $SSKW_2 \subseteq_S SSKW_1$.

Given a keyword *key* and an SSKW *SSKW*, if there exists a keyword $key' \in SSKW$ such that $key \equiv key'$, *key* is called a semantic element of *SSKW*, and *SSKW* is said to semantically contain *key*.

The authors write $key \in_S SSKW$ to denote that *key* is a semantic element of *SSKW*. The notation $key \notin_S SSKW$ denotes that *key* is not a semantic element of *SSKW*.

Similarly, to $key \in_S SSKW$ (resp., $key \notin_S SSKW$), the authors can define $skey \in_S SSSKW$ (resp., $skey \notin_S SSSKW$), where *skey* is a set of keywords and *SSSKW* is a set of *SSKW*.

Definition 6: Given a concept lattice L and a set of attributes (i.e., keywords) B, $B \notin_S \text{Int}(L)$, the semantic upper and lower approximations of B, $\overline{apr}(B)$ and $\underline{apr}(B)$, are defined as follows, respectively:

$$\overline{apr}(B) = \cap\{X \mid X \in \text{Int}(L), B \subseteq_S X\},$$

$$\underline{apr}(B) = \{X \mid X \in \text{Int}(L), X \subseteq_S B, \forall Y \in \text{Int}(L)\ (X \subseteq Y \Rightarrow Y \not\subseteq_S B)\}.$$

Now the authors provide the SSKFRW method.

Algorithm 2. *SSKFRW method for semantic search*

Input: a formal context $K = (G, M, I)$, where $G = \{g_1, g_2, \ldots, g_m\}$, $M = \{a_1, a_2, \ldots, a_n\}$, and $I \subseteq G \times M$; a query $Q = \{q_1, q_2, \ldots, q_s\}$

Output: a result set $S \subseteq G$ for Q

(1) construct the concept lattice $L = \underline{\mathrm{B}}(K)$ (or $\underline{\mathrm{B}}(G, M, I)$) of K;
(2) if there exists a formal concept $(A, B) \in L$, where $A = \{g_1, g_2, \ldots, g_w\}$, $B = \{a_1, a_2, \ldots, a_t\}$, such that $B \equiv_S Q$, then assign A to S (i.e., $S = A$) and Goto (9); elsewise (i.e., for each formal concept $(A, B) \in L$, $B \not\equiv_S Q$);
(3) compute the semantic upper approximation *UA* and the set of semantic lower approximations *LA* of Q;
(4) assign $\{UA\} \cup LA$ to *CS*, i.e., $CS = \{UA\} \cup LA$;
(5) for each intent $int \in CS$, obtain the corresponding formal concept (ext, int) in L, i.e., $(ext, int) \in L$;
(6) let $FC = \{(ext, int) \mid (ext, int) \in L \wedge int \in CS\}$;
(7) for each formal concept $(A, B) \in FC$, compute the similarity $sim_{FW}(B, Q)$;

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

(8) let $S = \cup\{A | (A, B) \in FC \wedge sim_{FW}(B, Q) = \max\{sim_{FW}(D, Q) \text{ for all } (C, D) \in FC\}\}$;
(9) return S.

Remark 3: Similarly, to Remark 2, users can specify a threshold value α ($0 \leq \alpha \leq 1$) in step (8) of Algorithm 2. Formally, the step (8) in Algorithm 2 can be modified as follows:
(8′) let $S = \cup\{A | (A, B) \in FC \wedge sim_{FW}(B, Q) \geq \alpha\}$.

Compared to Algorithm 1, although users need to spend time to calculate the semantic upper and lower approximations in Algorithm 2, however, users only need to compute the similarity between intents of part of formal concepts in L (i.e., the upper and lower approximations of Q) and query, respectively in step (7) of Algorithm 2 (Algorithm 1 needs to compute the similarity between the query and the intents for each formal concept), thus, SSKFRW is an improvement of SSKFW in computation time.

4. EVALUATION

To validate the effectiveness of SSKFW and SSKFRW, in this section the authors will use real-world data in their experiments. It is well known that evaluating semantic search is a problem that has been studied in the literature (Elbedweihy et al. 2015; Fazzinga and Lukasiewicz 2010; Formica 2012; Formica et al. 2013; Storey et al. 2008; Virgilio et al. 2012). However, these semantic search methods have inherently different underlying assumptions, so the authors cannot perform benchmarks and comparative results for their approaches and the existing proposals. In fact, Formica (Formica 2012) analyzed various representative papers on the basis of the different topics addressed in semantic (Web) search and pointed out that an evaluation of these works is difficult to be performed. Similarly to evaluation method in (Formica et al. 2013), the authors evaluate their approaches by comparing SSKFW, SSKFRW, against the Dice, Jaccard, Cosine, and the Weighted Sum, which are some of the most representative proposals defined in the literature and are defined as follows (for any two sets $X = \{X_1, \ldots, X_m\}$ and $Y = \{Y_1, \ldots, Y_n\}$ of keywords):

$$Dice(X, Y) = \frac{2\left|X \cap Y\right|}{\left|X\right| + \left|Y\right|},$$

$$Jaccard(X, Y) = \frac{\left|X \cap Y\right|}{\left|X \cup Y\right|},$$

$$Cosine(X, Y) = \frac{\left|X \cap Y\right|}{\left|X\right| \times \left|Y\right|}, \text{ and}$$

$$WeightedSum(X, Y) = \frac{2\sum Aff\left(X_i, Y_j\right)}{\left|X\right| + \left|Y\right|},$$

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

where the affinity of X_i and Y_j is $Aff(X_i, Y_j)$ is:

$Aff(X_i, Y_j) = 1$ if $X_i = Y_j$; $= 0.5$

if X_i is broader or narrower concept of Y_j; $= 0$ otherwise.

The authors also compare SSKFW and SSKFRW against human judgment (HJ). Similarly to HJ evaluation in (Formica et al. 2013), in order to evaluate HJ of the authors' experiments, they ask to a group of 10 people, randomly selected from their Institute staff, to indicate the similarity among each query Q_i ($1 \leq i \leq 4$, see Table 1) and the real-world research papers pa_j ($1 \leq j \leq 30$, see Table 2), defined in their keywords. The semantic similarity between each paper and each query is assessed by 10 people in a scale between 0 (semantically unrelated) and 1 (highly synonymous), respectively. Thus, four final sets of paper and query pairs are rated with the average of the similarity values provided by their Institute staff and are shown in Tables 3−6.

More concretely, the authors consider four query, namely Q_i ($1 \leq i \leq 4$), representing the query request of four research papers, shown in Table 1. The authors also consider 30 research papers, namely pa_j ($1 \leq j \leq 30$), representing the digital resources by using different keywords, shown in Table 2. The HJ values, and the results obtained according to the above-mentioned similarity methods (Dice, Jaccard, and Cosine) and their approaches (SSKFW and SSKFRW), are shown in Tables 3−6, corresponding to the experimental results about Q_i ($1 \leq i \leq 4$), respectively.

Now the authors discuss the precision and recall of the approaches SSKFW, SSKFRW, the Dice, Jaccard, Cosine, and the Weighted Sum. In Tables 7−10, the digital resources are listed according to the values assigned by HJ, Weighted Sum, and Dice from the highest up to the threshold (the authors fix the threshold to 0.50), and the results returned by SSKFW and SSKFRW. Note that Jaccard and Cosine have not been addressed because their values are all less than the given threshold. The authors apply the typical evaluation measures, namely precision and recall, to the returned digital resources (the definitions of recall and precision in Weighted Sum and Dice are the same as traditional information retrieval). Assume that the ranked papers of HJ are $\{pa_1, pa_2, \ldots, pa_n\}$ and the relation of HJ values of the ranked papers is $HJ(pa_1) \geq HJ(pa_2) \geq \ldots \geq HJ(pa_n)$, the returned papers of SSKFW (or SSKFRW) are $\{pa'_1, pa'_2, \ldots, pa'_m\}$. If users use max function in Algorithm 1 (or Algorithm 2), recall and precision are defined as follows:

$$recall = \begin{cases} \dfrac{\left|\left\{pa_1, pa_2, \ldots, pa_m\right\} \cap \left\{pa'_1, pa'_2, \ldots, pa'_m\right\}\right|}{m}, & if\ n \geq m \\ \dfrac{\left|\left\{pa_1, pa_2, \ldots, pa_n\right\} \cap \left\{pa'_1, pa'_2, \ldots, pa'_m\right\}\right|}{n}, & if\ n < m \end{cases} \quad \text{and}$$

$$precision = \begin{cases} \dfrac{\left|\left\{pa_1, pa_2, \ldots, pa_m\right\} \cap \left\{pa'_1, pa'_2, \ldots, pa'_m\right\}\right|}{m}, & if\ n \geq m \\ \dfrac{\left|\left\{pa_1, pa_2, \ldots, pa_n\right\} \cap \left\{pa'_1, pa'_2, \ldots, pa'_m\right\}\right|}{m}, & if\ n < m \end{cases}.$$

If users use threshold in Algorithm 1 (or Algorithm 2), recall is defined as follows:

$$recall = \frac{\left|\left\{pa_1, pa_2, \ldots, pa_n\right\} \cap \left\{pa_1^{'}, pa_2^{'}, \ldots, pa_m^{'}\right\}\right|}{n} \text{ and}$$

precision is defined as follows:

$$precision = \frac{\left|\left\{pa_1, pa_2, \ldots, pa_n\right\} \cap \left\{pa_1^{'}, pa_2^{'}, \ldots, pa_m^{'}\right\}\right|}{m}.$$

From Tables 3−10 users know that the precision of SSKFW and SSKFRW approaches in most cases is equal to 1 except for three cases (0.75, SSKFW for q_1 using max; 0.75, SSKFRW for q_1 using max; and 0.86, SSKFW for q_3 using threshold). Similarly, the precision of Weighted Sum and Dice in most cases is also equal to 1 except for one case (0.67, Weighted Sum for q_1). This shows the fact that all methods (SSKFW, SSKFRW, Weighted Sum, and Dice) always can retrieve the relevant resources correctly.

Concerning the recall, the recall of SSKFW and SSKFRW in most cases is greater than or equal to 0.67 except for one case (0.25, SSKFRW for q_3 using threshold). Especially, for SSKFW and SSKFRW with max, the recall of 6 cases (a total of 8 cases) is equal to 1; for SSKFW and SSKFRW with threshold, the recall of 6 cases (a total of 8 cases) is greater than 0.80. However, the best recall of Weighted Sum and Dice is 0.55 (Weighted Sum and Dice for q_2). In particular, for Weighted Sum and Dice, the recall of 6 cases (a total of 8 cases) is less than 0.40, where the worst recall is 0.17 (0.18) in the case of Dice for q_1 (q_4). Clearly, the recall of SSKFW and SSKFRW approaches is always greater than the recall of Weighted Sum and Dice.

There are two points that the authors have to point out here. Firstly, regarding the computation time and space complexity, SSKFW and SSKFRW must be greater than Dice, Jaccard, Cosine, and Weighted Sum, because SSKFW and SSKFRW implement search on the semantic level, thus, SSKFW and SSKFRW need more computing than Dice, Jaccard, Cosine, and Weighted Sum. In fact, all approaches for

semantic search are faced with this problem. From Algorithms 1 and 2 users know that SSKFW and SSKFRW are feasible in practical applications because concept lattice can be generated off line and users may select different approaches to similarity computation for different applications. Secondly, SSKFW and SSKFRW need to use Wikipedia to implement semantic search. However, the content of Wikipedia is constantly changing. Generally speaking, the content is getting better and better, thus, with the development of Wikipedia content, SSKFW and SSKFRW can get better results.

5. CONCLUSION

In this paper the authors propose two novel methods to semantic search by combining formal concept analysis, rough set theory, and Wikipedia based similarity reasoning. The experimental results show that the authors' proposals perform better than some of the most representative similarity search methods and sustain the intuitions with respect to human judgements. As future work, the authors are planning to investigate the approaches to unambiguous Wikipedia concepts selection by automatic disambiguation methods and to query keywords discovery by means of automatic term extraction or association measures. In addition, the authors plan to validate the SSKFW and SSKFRW approaches in some application domains such as social networks.

Chapter 70
The Rise of the Virtual Human

Wendy A. Powell
University of Portsmouth, UK

Natalie Corbett
University of Portsmouth, UK

Vaughan Powell
University of Portsmouth, UK

ABSTRACT

Virtual Humans are here to stay. From the voice in your satNav to Apple's "Siri", we are accustomed to engaging in some level of conversation with our technology, and it is rapidly becoming apparent that natural language interfaces have potential in a wide range of applications. Whilst audio-only communication has its place, most natural conversations take place face to face, and believable embodiment of virtual humans is the necessary next step for them to be fully integrated into our lives. Much progress has been made in the creation of relatable characters for film, but real-time facial animation presents a unique set of design challenges. This chapter examines the role of the virtual human, its history, and approaches to design and creation. It looks at ways in which they can be brought to life, interacting, assisting and learning. It concludes with a view into popular culture and perceptions of the future, where fact and fiction meet.

INTRODUCTION

With the rapid advances in technology in the past 40 years, the vision of the virtual human is coming closer to reality, with improvements in visual appearance, speech and emotion, and in the application of this into real-world settings. As can already be observed in pre-rendered animations, near-photorealism is now possible, with some avatars almost indistinguishable (Alexander, Rogers, Lambeth, Chiang & Debevec, 2009; Borshukov, Piponi, Larsen, Lewis & Tempelaar-Lietz, 2005). Although total realism not yet possible, many studies are working toward this goal, with even real-time avatars slowly becoming more and more realistic. This chapter introduces a range of virtual humans currently in development or

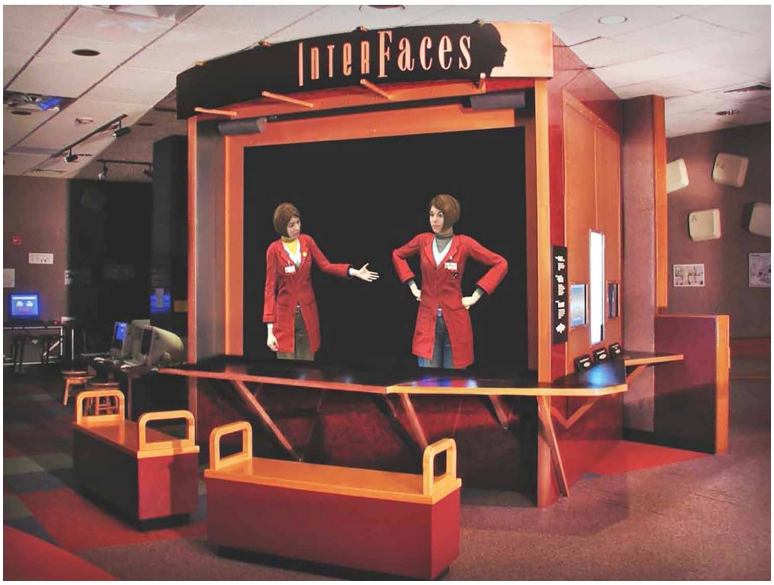
being used in real-world interaction. The history of animated humans and the recent rapid advances are discussed. The chapter will then examine some of the technical challenges involved in creating virtual humans, particularly with regards to facial expression and speech. Finally, the role of the virtual human in popular culture is explored, looking at fears and hopes for the future, and how perceptions are changing over time.

BACKGROUND: THE ROLE OF THE VIRTUAL HUMAN

This section will take a look at avatars already being used in real-life settings, interacting independently with users, learning and remembering information, and even assisting in the treatment of patients.

Avatars Who Interact

Since the early days of computing there has been a fascination with the concept of communication between computers and human beings. As early as 1950 Alan Turing raised the question of whether a computer could appear to think like a human (Turing, 1950), and even today the 'Turing Test' is considered to be a benchmark by which we measure the success of virtual humans. Whilst early work focused on text-based communication due to the poor quality of speech generation and animation, improvements in technology have raised our expectations to the point where we anticipate that a humanised avatar could pass the Turing test within the next generation.



Early research on avatar development and behaviour focused mainly on speech, with the eyes and the motion of the head receiving little attention. However, in a 2004 study, a group developed an avatar to interact with video feeds rather than directly with humans, watching and following movement in a variety of situations. The team used a neurobiological model of visual attention in order to create realistic avatar eye and head animation (Itti, Dhavale & Pighin, 2003). They postulated that this type of non-verbal communication was an essential part of human interaction, and aimed to recreate this digitally in the most realistic way possible, using a procedural, science based approach. A reflexive approach was used to guide the avatars attention toward visual targets, in the form of either video recordings or video game output. Automatically generated eye blinks were added to aid realism, as well as accurate deformation of the facial tissue during movement, and a photorealistic facial model. Although the avatar was not always human-like in its point of focus, results of this early work showed potential, in using attention-directed behaviour to enhance the realism of a virtual human.

More recent work saw the development of virtual twins Ada and Grace (Figure 1), who were deployed in a museum to interact with each other and with visitors using both verbal and non-verbal communication (Swartout et al., 2010).

To communicate with the characters, the operator could push a button then speak into a microphone. The audio was then sent to an automatic speech recogniser (ASR), which translated the speech into text, sending this on to a language understanding module. An algorithm used the text to select an appropriate response for the characters to use. The characters have a set of about 400 responses to draw from, with dialogue management software ensuring that responses are not repeated. Animation sequences were also created and stored, with these being called upon at the same time as the responses, with the relevant animations being called upon dependent on the response. Viewing video footage of Ada and Grace being posed questions by museum visitors (USC ICT, 2010), it can be seen that there is rapid retrieval of

responses with appropriate answers being given to visitors. However, the animation is clearly constrained by the demands of real-time performance, with repetition of a small gesture set and relatively low fidelity facial performance and, partciularly in the synchronisation of mouth movements to speech elements. The lack of movement of the facial musculature when speaking, results in a somewhat robotic effect. As can be seen within the Digital Emily project (Alexander, et.al., 2009), the USC ICT is more than capable of creating incredibly lifelike animations, with their light stage also used to great effect in many films (Debevec, n.d.). However, there does seem to be a trade-off between the achievement of high graphical fidelity, and the ability to work in real-time, with a distinct drop in graphical fidelity when increasing the demand of real-time processes. However, as technology improves and graphical rendering capabilities increase then we are likely to see rapid improvements in this visual fidelity.

Also emerging from USC ICT is the virtual support agent or 'SimCoach' (Figure 2), providing information and support for military personnel and their families (Rizzo et al., 2011). The user will be able to select from a gallery the character that they feel most comfortable talking with. The characters will use speech, gesture and emotion to introduce the system to the user, as well as asking questions about the user's history and medical concerns in order to provide the right kind of support. A prototype SimCoach has been deployed on a veterans website (Brave Heart Veterans, n,d.). At the time of writing, interaction was limited to text-based questioning, and responses are limited and somewhat lacking in visual fidelity. Nevertheless, it is already demonstrating the potential to provide support and advice via a humanised interface.

Researchers in the UK are developing the RITA avatar (Figure 3), which is designed to interact with older adults. Although only in early stages of development at the time of writing, RITA demonstrates a significantly higher level of visual fidelity and realism than many earlier real-time avatars. The prototype uses a library of pre-recorded speech segments and blend-shape animation to communicate with realistic emotional expression. Vision-based facial and emotion recognition software identifies known

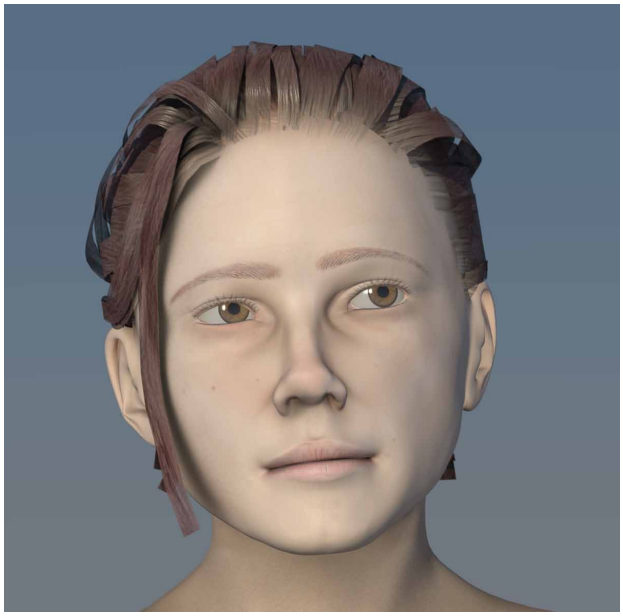
users and interprets their current emotional state, triggering responses which vary according to both the mood and identity of the user. Technology still needs to advance considerably in order to support the full planned functionality of RITA (RITA, n.d.)., but nevertheless, it gives us a glimpse of the future potential of nearly-real virtual humans.



Whilst the ability of a virtual human to hold a conversation is an impressive achievement, it is still of relatively limited application without some further purpose. Conversational agents are deployed in many areas, from marketing websites through to exhibition guides, but development has not stopped here. More recent development is bringing us intelligent agents who teach, learn, and even care for people.

Avatars Who Help

An example of a successful avatar created for use within the field of education, although not a true example of a virtual human, comes in the form of 'Steve' (Soar Training Expert for Virtual Environments), an avatar used for training Navy personnel to operate a high-pressure air compressor (HPAC) on board a ship (Johnson & Rickel, 1997). Steve consists of a virtual hand, inhabiting a virtual representation of a ship, complete with the HPAC that students must learn to operate. The students are allowed a 3D view of this world through use of a head mounted camera, interacting with either a 3D mouse or data gloves. Steve was designed to help students learn to perform tasks such as operating the HPAC, and repairing equipment, but also to enable them to apply these procedures to a variety of situations, by understanding the rationale behind each step. Steve was given the ability to manipulate and point at objects to help students, as well as constantly monitoring the environment. For demonstrating or monitoring tasks, Steve is equipped with a pre-programmed knowledge of tasks in the form of hierarchical plans, learning the processes required to complete each task. Steve can be switched between monitoring and demonstra-

tion modes, allowing for a smooth and flexible student and tutor relationship in which learning can take place at the pace of each individual. Although not a full virtual human, the learning algorithms used in Steve's design have the potential to be used in other avatar applications, particularly as the sophistication of the technology increases.

More recently, a group researchers has been developing virtual nurses to aid in the communication of discharge information to patients with low health literacy skills (Bickmore, Pfeifer & Jack, 2009). Health literacy refers to the ability to understand healthcare information, and to apply this understanding to health situations. The lack of understanding of discharge information can lead to patients being readmitted to hospital after not taking medication correctly, or not understanding side effects. The greatest aid to those with low health literacy seems to be in face-to-face communication, used in conjunction with written instructions, allowing the patient to ask questions, and for the nurse to elaborate on information. The use of this delivery in the form of a virtual nurse is beneficial, as it allows the patient to take as much time as they need, without feeling that they are wasting anyone's time, something which seems to be a recurrent feature in the use of avatars within the healthcare sector (Rizzo et al., 2011). Two virtual nurses were created, with the head and torso displayed for use in the system. These nurses were very stylised, and spoke using a synthetic voice, with scripted dialogue. Animation was also implemented for lip sync, and to allow the hands of the nurse to point at relevant information. Interaction for the patient was in the form of the selection of utterance options, displayed on a touch screen. A mobile kiosk containing the patient information and the virtual nurse was wheeled into the patient's room, with the patient then left alone to conduct their conversation (Figure 4).

The nurse could be programmed with information about the patient, calling them by name, and firstly asking a few questions relating to their interests, in order for the patient to feel more at ease. The virtual nurse would then move on to the discharge information, explaining each point whilst pointing at relevant

parts of the leaflet, and encouraging the patient to follow in their paper copy. The results of the study were largely positive, with the virtual nurse tested on both hospitalised and non-hospitalised participants. 92% of the participants claimed that they felt comfortable with the nurse, with 70% stating that they either preferred speaking with the virtual nurse, or were indifferent. When dealing with doctors and nurses, it may often be the case that patients feel that they are wasting time, particularly in the elderly, who may put off going to their GP or to the hospital because of this. The results of this study support the notion that people like, and often prefer, talking to a virtual avatar, particularly within the healthcare sector.

Avatars within the healthcare industry have been implemented for use in a variety of settings, ranging from communication training for children with autism (Chops, 2014; Kandalaft, Didehbani, Krawczyk, Allen & Chapman, 2013), to treatment of speaking (Slater, Pertaub & Steed, 1999; Kang, Brinkman, van Riemsdijk & Neerincx, 2011), and the treatment of post-traumatic stress disorder (Rizzo et al., 2011).

Autistic children often have difficulty in social communication, and may find it easier to communicate with a virtual human. CHOPS (2014) have created animated characters to aid in treating autistic children. The children can either interact with the animated character, with a speech pathologist used to reply to the children in real-time, through the animated character, or learn to control the animations themselves. The character can be used by therapists in a number of ways, for example, to tell stories, teach lessons, and demonstrate facial expressions or body language. As the avatars used are far less threatening for a child with autism than a real person, the student can remain engaged and will be much more open to learning new concepts. The novelty of the animated characters can also aid in keeping their attention for a longer period of time.

Another example of the use of avatars to aid in the treatment of Autism is through the use of the online virtual-reality world, 'Second-life.' Researchers at the University of Texas Centre for Brain Health, paired clinicians with Autism patients within the Second-life world to deliver therapy (Kandalaft, Didehbani, Krawczyk, Allen & Chapman, 2013). The study aimed to enhance the social skills, social cognition and social functioning among eight young adults diagnosed with high functioning autism. Virtual-reality

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

therapy for Autism patients can be beneficial, as social interactions can be simulated and easily repeated, without fear of mistakes or rejections and with lower levels of stress. Avatars were created to resemble each of the participants within the study as well as the coach involved. After logging into the system for each session, participants would each be instructed to go to a specific location to meet a specific person with whom they would be interacting. This person would be in the form of another clinician, playing the part of a person, such as a potential employer delivering an interview, or a confrontational roommate. The participant would then take part in the selected interaction, with the coach remotely observing, taking notes on the social objectives of the participants performance. After the interaction had taken place, the participant would then meet with the virtual coach to discuss performance, receiving feedback from the coach, which they would then attempt to implement in a second attempt at the same interaction. The results of this study found largely positive feedback among participants, with all stating that they found the sessions enjoyable, and reporting social benefits, such as participating more within social situations and finding it easier to see things from other people's perspectives. However, the very small sample size, as well as the lack of a control group, limits the generalisation of the study. The use of only participants from the high functioning end of the autistic spectrum also means that this study may not be applicable to a very wide range of people within other parts of the autistic spectrum. However, the findings are of interest, and do present the idea that virtual-reality, and virtual avatars can be of benefit within the general healthcare system when used alongside real life medical practitioners, and should not be overlooked within this sector.

Virtual-reality has also proved useful within in the treatment of phobias, providing a safe, non-threatening environment, in which clinicians can have complete control over the stimulus and situation, allowing patients to take therapy at their own pace, and feel more secure than in a real-life phobia inducing situation. One such study aimed to aid in the treatment of public speaking anxiety (Slater et al, 1999). This study aimed to utilise a virtual environment occupied with virtual avatars to explore their effectiveness in psychotherapy for social phobias. To create the environment in which the experiment would take place, researchers constructed a virtual seminar room, matching the one in which participants met with the researchers and completed questionnaires. The virtual seminar room was populated with an audience of eight avatars, placed in a semicircle to face the speaker. The avatars were programmed to display six primary facial expressions, the same as those outlined within Ekman's 'Unmasking the Face' (Ekman & Friesen, 1975), as well as yawns, sleepy faces, and random autonomous actions such as twitches, blinks and nods. Avatars also were programmed with the ability to stand up, clap, and walk out of the seminar room. To increase the realism of the avatars, an unseen operator would trigger the audience responses at key moments during the experiment. Participants were asked to give a prepared talk three times, receiving one positive reaction from the avatars, one negative response, and one mixed. Interestingly, the study found that the level of interest of the audience was important, and this influenced the impact of the positive or negative response, even though the audience consisted of relatively low fidelity avatars. Although this was a fairly early study in the field, it does indicate that virtual humans may be of use in treating social phobia and presentation anxiety.

A more recent study into the therapy of anxiety disorders is the 2011 study by Kang et al. (2011). This study, although not yet completed, aims to use an internet-delivered system to treat multiple patients through the use of exposure therapy, a type of therapy in which the patient is exposed to the cause of their anxiety (c.f. Parsons & Rizzo, 2008). The project is a four year research plan, which once complete, will provide an internet-delivered therapy system, with a virtual therapist implemented who will monitor the patient, making adjustments to the virtual-reality scenario, changing the level of expo-

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

sure relative to the patients levels of anxiety. The project in its current stage will only focus on social anxiety, within a public speaking scenario, much like the study of Slater et al (1999). The avatars used within this project, as with the aforementioned study, will take the form of members of an audience, programmed to react to the participant speaking. They will also be designed to portray four different attitudes; interested, neutral, bored, and critical. Each avatar will also vary in its personality and physical state, meaning that each individual avatar should be able to behave autonomously, reacting to both the perception of the environment, and its own mental and physical state. In order to test the effectiveness of the virtual avatars, the project proposes three control methods, the first being the autonomous behaviour already outlined. The second control method will be a scripted method, in which the reference of the real audience filmed, will be replicated exactly for each of the avatars. The final control method will be one of random control, in which avatars will choose a completely random set of behaviours, in no way connected to their environment. Although this project is not yet complete, the audience design is certainly moving towards more realistic virtual humans, with dynamically generated behaviour based upon individual programmed personalities.

Finally, at the cutting edge of development of virtual healthcare agents, are projects creating virtual humans capable of understanding patients and detecting real-time indicators of physical or emotional health.

A collaboration between USC IT and the Defence Advanced Research Projects Agency (DARPA) aims to create a virtual agent capable of identifying indicators of psychological distress, in order to provide healthcare support for military personnel and their families (Figure 5). The system should eventually, be able to monitor users over weeks and months to monitor change, working closely with real life healthcare professionals if psychological disorders are seen to be present (DeVault et al., 2014; Morbini et al., 2014). The systems used within this research consist of two core components. The first is 'Multisense', which is used for the automatic tracking and analysis of facial expression, body posture, acoustic features, linguistic patterns and high level behaviour descriptors such as fidgeting. This system directly communicates with the virtual human, 'SimSensei'. This human platform is able to process all of the signals sent from the Multisense, providing real-time reactions to the user, through speech and gesture.

For the development of this virtual human, whom the researchers named 'Ellie', three design goals were set. The user should be comfortable talking to Ellie, the system should be sensitive to non-verbal behaviour displayed by the user, and should generate appropriate non-verbal behaviour in response. This should all take place within a 15-25 minute interview, in which the user should remain engaged and interested in communicating with Ellie. Data has been extracted from numerous interviews between a real psychologist and patient, and verbal and non-verbal behaviours identified and quantified. Based on this data, the team have begun to create a system that will enable Ellie to operate automatically and autonomously. In order to do this, specific modules were implemented into the mulitsense, which all communicate with one another, in order to dictate how Ellie should behave and react. These modules currently include; 3D head position and facial tracking, expression analysis, gaze direction and audio analysis. The multisense uses all of these signals, measuring factors such as smile intensity, in order to inform the other modules of the SimSensei, which are used to drive Ellie. These modules include the generation of non-verbal behaviour, realization and rendering.

In order to animate Ellie, reference footage of real clinicians was used to create a series of key frame animations for Ellie to draw from. These were placed into a program called Cerebella, which can be programmed to take into account factors such as characters personality, culture, gender and body type to drive animation.

Figure 5. 'Ellie' is being developed to provide healthcare support to military personnel and their families.
© USC Institute for Creative Technologies. Used with permission.

Ellie currently has the ability to use 100 fixed utterances, with 60 top level interview questions. Elllie's speech is pre-recorded, rather than generated, which does seem to give a more realistic result then synthetic speech generation. In order to detect and process user speech, the system used a variety of different software implemented within the speech recognition module, similar to the processes used within the Ada and Grace study (Swartout et al., 2010), although more complex. These systems were not only able to process human speech, but able to detect the emotion within the speech, and select an appropriate response in real time. Full details of the dialogue processing systems used can be found in Morbini et al., (2014).

Although the majority of participants to date claimed to have felt comfortable with Ellie, most felt that she didn't understand their non-verbal behaviour, preferring speaking to the Ellie who was controlled by the researchers. Given the early stage of development, these results are unsurprising; however do give promise to the future development of this system. From viewing a video of Ellie speaking with participants (USC ICT, 2013), it can be observed that the system appears to display a high level of intelligence. However, the video gives no indication as to whether the system is running autonomously or whether the avatar is being controlled, limiting any conclusions to be drawn as to the effectiveness of the automated system. The animation of the avatar itself is somewhat lacking in fidelity, an issue which still plagues most real-time virtual humans, being a trade-off between realism and system performance. Nevertheless, the avatar is seen to accurately interpret body language and emotion of the two participants, reacting appropriately, in a similar manner to a real life therapist, with reassuring nodding motions, and knowing when to respond once the user had finished speaking. Ellie does demonstrate the potential for future deployment of caring virtual humans, with technological advances only serving to improve the system, and allow for fully autonomous behaviour.

A UK-based early stage project with a long-term vision is developing a virtual human which is designed to provide support, companionship and advocacy to older adults (RITA, n.d). The RITA avatar has been built using state-of-the art motion capture and animation techniques, with a design based on features which appear trustworthy and competent (Powell, Garner, Tonks & Lee, 2014) (Figure 6).

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 6. RITA is designed to appear trustworthy and competent.
© 2014, University of Portsmouth. Used with permission.

The system is designed to store personal, social and medical information, and to monitor health and emotional state in real-time, in order to provide tailored companionship and support. It will link with body-worn and smart-home sensors and also monitor activity and mood over time, identifying early warnings of deteriorating physical or mental health, and accessing appropriate support and intervention.

Although extensive further development is needed to fully realise the vision of projects such as RITA and SimSensei, it is clear that virtual carer-givers are likely to play a part in our future healthcare. However, to create virtual humans which are fully accepted into our daily lives requires pushing the boundaries of technology, in order to achieve realism in both behaviour and appearance. The development of Artificial Intelligence (AI) is being driven by demands in a wide variety of application areas, and the need for the humanised interfaces to AI is increasingly apparent. The next section of this chapter will explore at the technical development of expressive virtual humans, from ancient history to the present day.

THE DAWN OF THE VIRTUAL HUMAN

The Study of Facial Expression

Facial expression is key to our communication with each other, and is an area that has been studied since as early as the 17th century. The earliest know writer on the subject of expression, as well as the use of expression for the deaf, was the medical practitioner John Bulwer, who was the first to record that communication could come by way of movement, rather than just speech, naming this form of gesture, the "Universall language of Humane nature" (Bulwer, 1649). However, it was Charles Darwin who was the first to detail why and how emotional expression is formed, and suggested that expression is universal, expressed the same regardless of culture or background, being a product of evolution and biology (Darwin, 1872). Darwin wrote at length about the basic principles of expression, including the muscles which are activated during expression of each emotion.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

In Ekman and Friesen's book 'Unmasking the Face' (1975), it was revealed, through scientific study, that Darwin was in part correct, with six expressions found to be universal. These expressions are; surprise, fear, disgust, anger, happiness and sadness, and many modern studies directly use these six emotions as basis for creating facial animation. Darwin's work, as well as the research of Ekman & Friesan, provides a valuable theoretical underpinning to facial animation, particularly when building a muscle based facial system. The universal rules of which muscles work during each of the emotions, can be applied directly to an animated model. Ekman and Friesen later went on to create a 'Facial Action Coding System', as a way to categorise the physical expression of emotions (Ekman & Friesen, 1978). The Facial Action Coding System, or FACS, is an anatomically based system for the measurement of all visual facial movements. This facial activity is described upon the basis of 44 unique action units (AUs), as well as including categories of head and eye movements and positions. Each action unit has a designated numeric code, with the muscle groups involved in each action linked to each of the AUs. Whilst FACS is anatomically based, a one to one correspondence does not exist between the muscle groups and the AUs, with any given muscle acting in different ways or contracting in different regions to produce visibly different actions. For example, contraction of the medial position of the Frontalis muscle will result in a raise of the inner corners of the eyebrow, whilst a contraction of the lateral portion of this muscle will raise the outer brow. The use of the coding procedures as outlined in FACS also allows for the coding of the intensity of each facial action unit. This is of particular use in animation, whereby varying degrees of emotion will need to be portrayed dependent on the character or situation, and is a system widely used and referenced today.

Although the study of the human face with regards to expression and emotion has ancient beginnings, the application of this understanding to computer based facial modeling, expression and animation is fairly new, first appearing in the early 1970's (Parke, 1972). With the technology to create animations in its relative infancy, early attempts at facial animations were fairly basic by today's standards. However, the techniques and processes used have been adapted and improved, directly influencing the high quality animations that we see today.

Early Examples of Animation

The first method of animating, before the use of computers, was via the use of hand drawings, portrayed in such a way as to give the impression of motion. Perhaps the oldest animation was found on a 5,200 year old bowl in Iran. The bowl had drawings of a goat on it, which when spun, gave the impression of the goat jumping to retrieve leaves from a tree (Ball, 2008). Many centuries later, Georges Melies, who was a professional magician by training, was one of the first great visual effects artists, using tricks during filming to create animation on top of live action from 1896 to 1912. However, it was in 1928, when Disney released 'Steamboat Willie' the first ever hand drawn cartoon animation with synchronised sound, which saw the birth of modern day animation production (The Museum of Modern Art, n.d.).

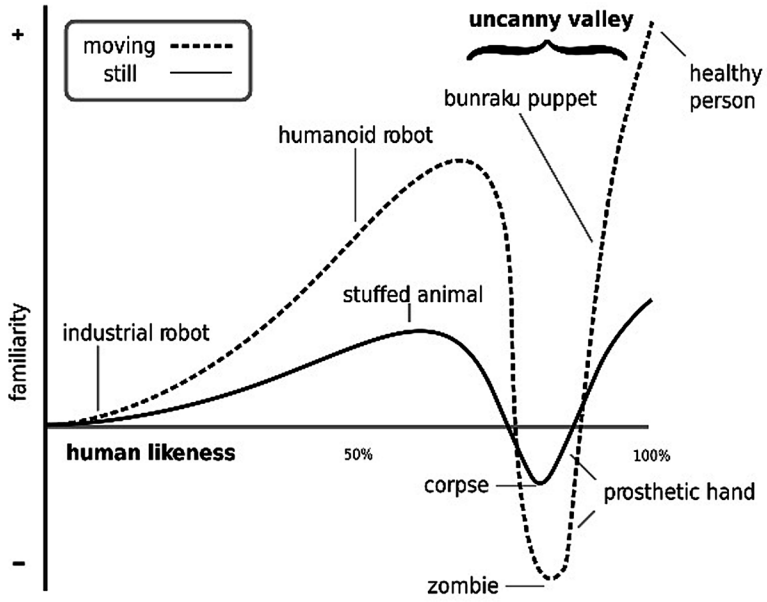
Computer-based facial animation came somewhat later, with Parke creating one of the first examples in 1972, generating an animated sequence of a head changing expressions, using a 250 polygon basic mesh, and using dots on facial photographs as references for creating the animated expressions (Parke, 1972). By 1988, a more sophisticated approach was seen, with 'Mike the Talking Head' being animated in real-time by puppeteers (Robertson, 1988). 'Mike' was created using data scanned from a real actor to create a polygon mesh, with software algorithms created to interpolate between phonemes of speech.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

In the same year that 'Mike the Talking Head' was created, Jim Henson Productions brought out their own real time animation solution in the form of 'Waldo C Graphic' (Walters 1989). Waldo got his name from the device used to control him, a Waldo. This was a type of input device which consisted of an upper and lower jaw, to control the characters mouth, and an arm, which controlled the movement, similar to the technology used to control Mike. Waldo was used by Jim Henson Productions to perform in real time, in a concert with real puppets, appearing in the TV series The Jim Henson Hour until 1992 (IMDb, n.d). The Waldo type of device used to control animation was a rather popular choice in the early days of animation, particularly for use in real time, with examples of this seen through until the 90's (SimGraphics, n.d; Robertson, 1992). This popularity is probably due to the ease of the device allowing an animator to have full control of the character without the need to be physically sat at a computer. The use of a Waldo is rare now, with computers now able to be drive real-time animation without the need for a puppeteer.

The early 1990's saw the introduction of 'Performance Driven Facial Animation' (Williams, 1990). Using a more advanced system of the earlier work of Parke (1972), Williams used motion tracking via the use of physical markers to track the motion of an actor's face making different expressions, using this data to drive animation of a 3D model. Williams was the first to use performance to directly drive animation in this way, and paved the way for motion captured facial animation, with the same marker based motion techniques still in use today. Parallel development saw the introduction of physically-based facial models in the early 1990's. These were based on Ekman's FACS system with an anatomically based muscle system used to control facial movement (Terzopoulos & Waters, 1990). To animate the facial model, 2D static images from a video of a real actor were taken, with an algorithm applied to track the facial features of each image, and apply these in 3D to the model.

During these early years of computerised facial animation, processing constraints restricted the complexity of the 3D models, resulting in characters which appeared blocky and unrealistic. In the early 70's, most standard computers came equipped with just 4Kbs of memory, using 8 bit graphics. Floppy Disks were invented in 1971, with these used for external storage of up to 250Mb of data up until 2000, when the 8Mb memory stick was introduced. In comparison, a standard modern desktop computer will come equipped with 500GB of memory and a graphics card supporting HD video at around 250 bits. These exponential improvements in computer processing power and dedicated graphics processors are able to support very complex digital meshes, enabling the creation of characters which at times are almost indistinguishable from real humans (Alexander, Rogers, Lambeth, Chiang & Debevec, 2009; Borshukov, Piponi, Larsen, Lewis & Tempelaar-Lietz, 2005). In parallel with this development, advances in Artificial Intelligence software techniques have enabled computers to learn, to make semi-autonomous decisions, and to communicate independently to humans, responding to speech and emotion (Rizzo et al., 2011; DeVault et al., 2014). These Virtual Humans are now being used in a variety of settings, from the entertainment industry through to marketing and health-care.



Whilst it is generally considered that the goal of virtual human design is for every-increasing realism, near-realistic avatars can actually be less acceptable than more stylised offerings, a phenomenon known as the 'Uncanny Valley' (Figure 7).

The Uncanny Valley

The 'Uncanny Valley' was first described by Mori (1970). His theory suggest that as a robot (or an avatar) becomes more realistic it is more acceptable, until it approaches a level of near-realism, at which point we begin to notice imperfections, finding these unsettling (MacDorman, Green, Ho & Koch, 2009).

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 7. The Uncanny Valley
Mori, 1970.

This feeling is heightened when movement is added, as indicated by Mori. If a virtual human becomes realistic enough, it emerges from the 'Uncanny Valley' and can be fully accepted. In fact, our perception and acceptance of virtual humans is somewhat more complex than first postulated by Mori, with factors such as facial proportion, texture, detail and believability of movement all playing a role (MacDorman, et. al., 2009; Qiao & Eglin, 2011). The 'Uncanny Valley' graph (Figure 7) proposed by Mori and reinforced by others since, in fields ranging from robotics to CGI, should be considered a conceptual model only. It does not imply any precise values, predict any absolute positions of avatar characteristics, nor give a magnitude of the axes and does not define points on its distribution, nor has it been empirically validated. Nevertheless, conceptually it is generally accepted within its respected disciplines even though such a simplified model is unlikely to really convey the nuances of human emotional reaction to the range of possible integrated characteristics that make up a complex avatar that aspires to be acceptable and lifelike (Tinwell & Grimshaw, 2009). Any deviation or discrepancy in any given characteristic, especially when others are reasonable might be enough to generate an uncanny response. The use of real time motion capture technology for both body movement and capturing real facial expressions has the potential to reduce the discrepancy and discord often perceived in moving characters as reported by Mori. Nevertheless a near veridical detail of subtle movements, skin detail and lighting, as aspired towards by projects such as digital Emily (Alexander et. al. 2009) are as yet far from commonplace and highly demanding. Whilst incongruities remain, the human perception of virtual humans may continue to suffer moments of discord and disengagement, when some element or another does not quite match our expectations or experience and as such, the 'Uncanny Valley' whilst no longer an insurmountable barrier to virtual human acceptance, certainly remains a problematic challenge and a potential pitfall.

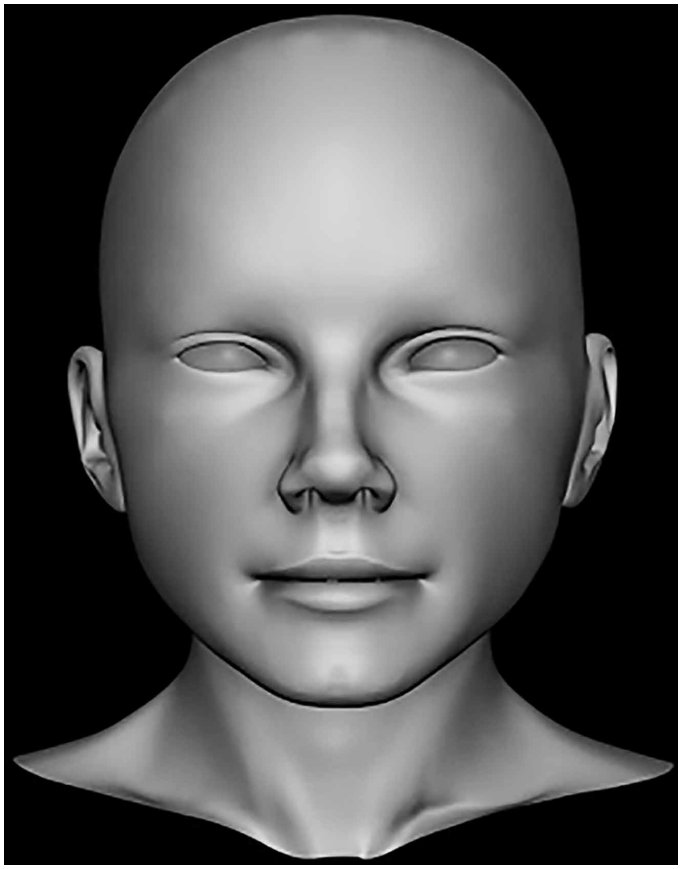
Whilst pre-rendered animation produces the highest fidelity results, it is the potential of real-time dynamic animation which is currently of great interest for individualised interactions across a wide range of applications, and this will be the main focus of this chapter. The following sections will address the state-of-the -art techniques for the creation of the virtual human, including building the facial mesh, methods of motion capture and animation, inclusion of speech and emotion, and interactivity.

BUILDING A VIRTUAL HUMAN

There are two main considerations when first creating a virtual human; firstly, how the mesh itself will be created, and secondly, how it should be rigged for animation. Within the creation of the mesh are such considerations as whether to create the mesh manually, or through the use of scans, and the implications of the "Uncanny Valley". For rigging, two main methods can be implemented, bone based rigging, blend shapes, or a combination of the two. Ultimately this initial stage will dictate how the final product will appear, with a better quality mesh, and more accurate rigging producing the highest fidelity of animation, thus this could be considered as the most important stage of development, as it provides the core foundation for the rest of the stages of the production pipeline.

Creating the Mesh

There are two main methods for creating a mesh. The mesh can either be created manually within the 3D space of the computer, or it can be created from scans of a real human face. With both of these techniques, a method of physically based modeling can also be implemented, in which the anatomy of the facial tissue and muscles can be used to influence the creation of the mesh (Figure 8).



Manual creation of the mesh involves careful manipulation of numerous flat planes to create a 3-dimensional polygonal shape. Whilst time-consuming, it has the advantage of allowing the digital artist complete control of the process. It often results in smaller mesh size, better suited to real-time performance, and allowing complete customisation of the appearance of the face. However, some of the fine details of facial anatomy are difficult to reproduce using manual techniques, which can reduce the visual realism of the resultant avatar.

Alternatively, facial scans can be taken of a real human and the data used to reconstruct the face within the digital space. This method is faster and generally results in a much higher fidelity avatar. However, it tends to result in a much bigger mesh, less suited to real-time performance, and the final appearance of the avatar is constrained by the anatomy of the human used for data capture. In addition, the equipment required for high-definition facial capture may be prohibitively expensive, and produce more than a Gigabyte of data every second.

In order to create a virtual human which is not only realistic in its static form, but also in dynamic expression, the underlying anatomy of the face should be taken into account. Physically based modelling places the polygons of the facial mesh in such a way as to mimic the layout of the underlying facial musculature seen (Terzopoulos & Waters, 1990), allowing for more accurate deformation of the mesh. However, this level of detail can result in a polygon count of millions, making it less suited to real-time animation. Nevertheless, physically based modelling can result in a very high level of visual fidelity (e.g. Sifakis, Selle, Robinson-Mosher & Fedkiw, 2006).

Rigging the Mesh

A 3D mesh is like a clay sculpture - it can be further moulded, but creating real-time animation would be extremely difficult. Therefore the sculpted mesh must be linked to a digital skeleton (rig), with a system of joints and controls in order to move the face from pose to pose. The two main systems used for rigging a virtual human are bone-based and blend-shape based.

Bones are generally used to control specific parts of the face such as eyelids and jaw. Bones are relatively simple to rig and animate, and one set of bone-based controls can be used to animate a number of different face types. However, facial animation using just bones can appear wooden and emotionless.

Blendshapes are animation tools which allow smooth morphing of one digital mesh into another, giving the appearance of natural movement. These blendshapes can be weighted, with more than one blendshape influencing facial geometry during movement. Although the use of blendshapes adds to both the polygon count and the processing load, it does allow for much more natural facial expression, and can approach a level nearly indistinguishable from a real human. For real-time animation, a combination of bone and blend-shape rigging gives the optimum results, with the blend-shapes being based around Ekman's FACS system (Ekman & Friesen, 1978).

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

With the virtual human created and rigged, the next stage in the process is how the avatar is to be animated. The two main options for this stage are animating by hand, or to use video recording, either as reference, or to directly drive the animation through use of motion capture. Within these options are a plethora of different methods, which each yield slightly differing variations of results. These options range from type, and number of cameras to be used, as well as lighting set-up, use of markers, tracking, and application of the data to the virtual human.

Lights, Camera, Action

In order to animate a virtual human, after the initial building phase is complete, many options can be considered. The use of video reference is common practice, either acting as a guide for hand animation, or to directly drive the animation through use of motion capture. The use of video as reference can also be used in a method called 'Rotoscoping', in which an animator will draw over video footage frame by frame to create the animation. This method dates back to the early days of Disney films, with animators directly drawing over video footage for such films as Peter Pan, Alice in Wonderland and Snow White. Rotoscoping is still a method in use today, and can be adapted for use in various situations.

However, hand animating is extremely time-consuming in order to achieve realistic results, and modern motion capture techniques can accelerate this process by an order of magnitude. We suggest that for the level of animation detail necessary for realistic facial expression, motion capture is currently best option, and this is the approach we will address in this section.

The three key considerations one must make when considering facial motion capture are lighting, camera type and placement, and facial tracking techniques. In addition, the data needs to be transferred to the mesh (re-targeting).

Lighting

Whilst not essential for facial motion capture, lighting can support and enhance the capture process, leading to better quality data and a more realistic animation.

Structured light techniques use projected light to cast a structured pattern of light onto the face to provide a detailed surface texture which aids in the tracking of motion (Bradley, Heidrich, Popa & Sheffer, 2010). This can be used instead of placing markers on the face, being less intrusive for the actor and requiring shorter setup times. However, high powered light beams can be a distraction for the actor, and reconstruction done in this way can suffer from a drop in precision, due to interleaving between the ambient illumination and the structured light (Bradley et al., 2010).

Uniform lighting allows a clear view of the face, with no shadows influencing the capture. This reduces 'noise' in the capture data, and results in a better quality of motion data for the animation (e.g. Bradley et al., 2010).

Light stages allow a programmed approach to lighting setup, allowing extremely precise control of the lighting during facial capture. A light stage may have over 150 lights placed around the actor (Alexander, et.al., 2013.).

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Camera Set Up

In order to record facial performance, one or more cameras are needed, and the quality, number and lay-out of these cameras can have a significant impact on the quality of the final animation data (Figure 9).

Single camera capture will generally result in 2D data (unless structured light is used). However, due to the low cost and ease of use of single-camera setup, this is the approach of choice for many commercially available systems (e.g. Faceware Tech, Faceshift, Mixamo). This form of motion capture can be effective (e.g. Weise, Bouaziz, Li & Pauly, 2011), although the post-processing require to achieve high quality animation can be complex, and 2-dimensional capture may miss subtle facial movements, leading to a drop in visual fidelity.

Multiple camera setup on the other hand, allows 3-dimensional data to be captured using multiple cameras in different positions. Whilst the quality of the data obtained in this way is much higher, the hardware and software costs may be prohibitive, and there is a much higher processing overhead due to both the quantity and complexity of captured data. Systems can range from just 2 cameras (Cudalbu, Anastasiu, Grecu & Buzuloiu, 2006), to 200 (Havaldar, 2006)

Stereo camera tracking is arguably the most accurate approach to facial tracking (Lewis & Pighin, 2006). This method uses pairs of cameras to track facial movement using triangulation of the data. However, as in other multi-camera approaches, the cost is high and the captured data demanding to store and process.

After lighting and camera setup, the next consideration is the type of tracking used to convert the facial performance into motion capture data in order to apply it to the rigged digital model.

Motion Capture Tracking

There are two main approaches to motion capture tracking. Physical markers may be placed directly onto the performer as reference points, or the key facial features such as eyes mouth and nose are used directly as reference from the video stream.

Figure 9. An actor's facial performance can be captured using an array of cameras.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Marker-based tracking involves the placing of multiple small markers on key anatomical landmarks of the face. Marker positioning varies, and may use simple visual reference points, or sophisticated reflective marker and camera systems, but the core principle remains the same. The relative positions of the markers are tracked over time, and the resultant data is processed in order to interpret the complex movements of the facial features during speech and emotional expression. Whilst this approach can produce high quality data which is fairly robust (Alexander, et.al., 2013; Sifakis et. al., 2006), it is intrusive and may affect an actor's facial performance. Furthermore, it interferes with the ability to acquire facial texture data from the capture cameras during live performance.

Markerless tracking does not require the placement of any reference points directly onto the actor's face, but relies on the ability of the software to translate the changing facial appearance into 3D motion data. This can be done by tracking key features of the face, such as eyes, nose and mouth (Terzopoulos & Waters, 1990; Lewis & Pighin, 2006; Bradley et.al., 2010). Although feature-based tracking is often considered to be a somewhat outdated approach, it's low cost and ease of use make it the preferred method within a number of commercial systems, particularly where the main goal is to drive bone-based animation. A more popular alterative in recent years is appearance-based tracking, which uses a training set of data based on variations of the face shape and skin texture during reference expressions, before capturing a full facial performance (Bradley et. al., 2010; Borshukov et. al., 2005).

Data Retargeting

Unless the model is an exact representation of the human facial actor, the captured data will need to undergo further adaptation before it can be applied to animate a rigged model. This processing is known as retargeting. The most common approach is to use blendshape weightings, with an estimation of the parameters for the target blendshape derived from the capture facial data at each frame (Figure 10). Alternatively, non-linear mapping produces a target expression for each source expression extracted from the captured data in order to replicate distinct facial expressions.

The final stage in the creation of a virtual human is in the implementation of speech and emotion. This is of particular importance when creating a real-time conversational avatar.

Figure 10. The retargeted data can be applied to the model to create a range of facial expressions.

BRINGING A VIRTUAL HUMAN TO LIFE

If we are to create a believable avatar to remind us to take our medicine, teach our children, or chat to an elderly relative when they are lonely, we need them not only to have a realistic face, but also to be able to communicate, both verbally and non-verbally. Within pre-rendered animation, the addition of speech and facial expression is a relatively straightforward task, with facial capture methods used as the foundation for replication of speech and emotion from the performer to the 3D model. Within real-time animation, however, the method of the generation of speech and emotion is a challenging one, particularly if both are to be portrayed simultaneously. Within speech, challenges such as coarticulation and synchronisation of lip movements to audio (lip sync) must be addressed, as well as the replication of the shapes the mouth makes when annunciating, avoiding looking robotic and unrealistic. The consideration of synthetic or natural speech must also be accounted for, with various limitations in the use and creation of synthesised speech. Emotion is a slightly easier behaviour to replicate, with Ekman's FACS system a useful guide for replicating this both in real-time and pre-rendered examples, however it does present challenges when paired with speech. This section will focus on the speech requirements for real-time interaction.

Natural Speech

In order to support realistic interactions, the goal of most virtual human projects is to produce speech elements which are as natural as possible. The most straightforward way to achieve this is to pre-record all the required speech segments with their animations (Swartout et al., 2010 DeVault et al., 2014 Morbini et al., 2014 Rizzo et al., 2011). However, this does constrain the range of possible communication, and is better suited to applications with a limited set of required responses

Phoneme Based Speech

A phoneme is the smallest unit of sound within speech, for example the word 'cat' is made up of three phoneme sounds – 'c' 'a' and 't'. A grapheme is a letter or number of letters that make up the sounds in our speech, for example the word 'ship' is made up of two, two letter graphemes – 'sh' and 'ip'. A viseme is the shape the mouth makes when articulating a phoneme or grapheme (Ezzat & Poggio, 2000). However, the term 'phoneme' is often used to encompass all of these terms. A library of phonetic sounds and animations can be created for the animated character to draw on. This is particularly useful in real-time conversation or situations where the virtual human will need to have a wide variety of words and phrases. Manual animation or motion capture of a large speech library is costly and time-consuming, and by creating this core library, any speech content can be dynamically generated. The fidelity of this type of speech generation varies greatly, depending on the methods used to combine the discrete elements together. Every phonetic segment is influenced by the preceding and following segments (co-articulation), and if this is not adequately addressed then the generated speech will sound unrealistic and robotic. Phonemes can either be pre-recorded or synthetically generated.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Synthetic Speech

Unless speech can be fully pre-recorded, synthetic speech is often the only option, stringing together sets of phonemes to automatically simulate speech (Wan et al., 2013; Arellano, Spielmann & Helzle, 2013). Although natural speech is generally preferred by users over synthetic speech, some factors have been identified which improve the perception and understanding of synthetically generated speech. The first factor is the acoustic-phonetic properties of the speech. The clearer and more realistic the speech sounds, the better understanding will be. As quality of synthetic speech degrades, the listener will rely increasingly upon their own linguistic knowledge to identify the words spoken. This leads on to the second factor, being the previous experience and background of the listener. A listener with previous exposure to the synthetic voice will perform much better in comprehension tests than one that is hearing it for the first time. A person with higher linguistic knowledge is also likely to perform better. As well as this, voices that are familiar to the listener are better understood, with native English speakers performing better than non-native English speakers when listening to an English voice (Pisoni, 1997). Although synthetic speech generation allows far more conversational flexibility, the techniques are not yet able to generate fully realistic voices or emotional overlays, resulting in speech which is, at best, somewhat flat and robotic. Nevertheless, progress in this area is continuing, and in the future synthetic speech is likely to be the best option for interactive virtual humans.

Emotive Speech

In order to fully engage with a virtual human, it is necessary to achieve some level of emotional realism and empathy. However, applying speech and emotion simultaneously is a challenging task for application in real time, often not quite achieving realism (Arellano, Spielmann & Helzle, 2013). Effective emotional communication requires the selection (identification) of the appropriate emotion, accurate expression of the emotion, and blending of the expression onto speech elements with the correct weightings. At the most basic level, this can be achieved by predetermined emotions associated with set phrases which are stored in a pre-animated library. However, real-time integration of emotional expression with dynamically generated speech segments requires sophisticated algorithms which can assign weightings to different elements of the blendshapes according to both the linguistic and emotive demands of the speech elements. Whilst development in this area is still in early stages, the Cambridge University 'Zoe' project has had some success using Hidden Markov Model (HMM) based Cluster Adaptive Training (CAT) in order to allow for synthesis from the text written, to the speech, and to allow Zoe to produce new emotions. The system learns which phrases or emotions to use (Wan et al., 2013). However, in spite of good lip synching and the advanced speech algorithms, she still appears relatively lifeless and robotic in video footage (University of Cambridge, 2013). This could be, in part, to do with the fact that the animation has been applied to a fairly basic 3D model, rather than a high quality mesh with many polygons. It could also be due to the fact that, as with the other studies that have used synthetic voice (Ezzat & Poggio, 2000) (Arellano, Spielmann & Helzle, 2013), the voice does not sound human, somewhat detracting from the animation. The emotion does come through in the voice, which is an impressive feat, not seen before during real time synthetic voice projection, however the face still needs some work to also express this emotion, with the mouth animation doing most of the work, the eyes and eyebrows largely remaining in a neutral pose throughout the animations.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

The RITA project (RITA, n.d) has taken a slightly different approach for its avatar prototype. An actress was used to record a library of speech segments and facial animations, including a range of emotional expressions, which were retargeted onto the facial mesh and deployed in real-time (Figure 8). Words and phrases from the library are selected and combined by the intelligent software according to the identified user and their facial and vocal input. Whilst this approach allows for a much more realistic encounter for short interactions, there are limits to the scalability of such a technique, and as improvements in natural speech synthesis continue, it would be more useful use this technique in the future. Nevertheless, the concept demonstration of the RITA system is impressive, and shows the level of real time animation performance which can already be achieved (RITA, n.d)..

Although there is clearly still much work to be done to achieve truly realistic virtual humans, they already have a significant presence in our digital encounters, and this is likely to increase as technology improves and the underlying intelligent systems develop.

WHERE NEXT?

This final section examines the rise of the virtual human in fact and fiction, and reflects on the narrowing gap between the two.

Media representations and perceptions of virtual humans, avatars and artificial intelligence (AI) take many forms and are typically used either to explore philosophical debates as to what it is to be human, or to express our concerns as to what form these might take. Can they be controlled, or will they attempt to control us? Are they to be welcomed, or feared?

In the entertainment industry there has been a notable shift from the depiction of detached cold automata in the original "Battlestar Galactica" (1978) and "Terminator" (Colla & Larson, 1978, Cameron & Hurd, 1984), to portraying AI and virtual humans as main characters in their own right with emphasis either on their seemingly ever present assistance and acceptance in "Ironman", "I Robot" and "Her"(Favreau, Theroux & Lee, 2002, Proyas & Goldsman, 2004, Jonze, 2013) and with more depth of character, demanding empathy from the audience: Automata, Ex Machina, I Robot, A.I., Battlestar Galactica (2004) (Ibanez & Legaretta, 2014, Garland, 2015, Proyas & Goldsman, 2004, Spielberg & Aldiss, 2001, Larson & Moore, 2004). Nevertheless the cautionary tale of too much power and autonomy leading to potentially omnipresent and almost omnipotent technology which judges humans to be inferior or a threat to be eradicated or controlled remains a persistent and popular narrative: Terminator: Genisys, I Robot, Battlestar Galactica, (Taylor et.al., 2015, Proyas & Goldsman, 2004, Larson & Moore, 2004).

Such ambivalence around both acceptance and fear of the virtual human in fiction is reflected in the perception of its adoption in mainstream society. Individual reactions to the concept of virtual human assistance can equally be met with enthusiasm or open hostility (Figure 11).

Films such as "I Robot" (Proyas & Goldsman, 2004) pitch these two perspectives against one another utilising a unique sentient machine with human emotion, creativity and compassion which realises the intent of Asimovs rules (Saygin et al 2000) is to protect humanity in its holistic form including physical and emotional state and its desire for life. The antagonist is portrayed as an almost omnipresent and omniscient purely logical system which concludes that the only way to comply with Asimovs rules is to effectively incarcerate mankind to protect it from itself.

> Wow. What a depressing idea – makes me want to cry! Maybe the 'strain of taking care of Britain's aging population' could be shouldered by human beings? with kindness, and beating hearts?

> Having had three elderly relatives die in the past five years, but being painfully conscious that however hard I tried the majority of their time was spent alone (one in Belfast, one in Norfolk, one in South England) I would not have seen RITA as a substitute for me, other family members and for the professional carers each had. Rather RITA would have augmented what we all did to make at least two of those elderly men a little less lonely and bewildered in their final years. The reality is that in a society that has grown away from living in extended family units, with increased younger generation mobility, and with an ageing population, I think we do need to look to technology for some of the answers. For myself, I'd pre-order a RITA for my own elder years !

The film 'Her' (Jonze, 2013), unlike the others discussed, uses a mobile phone as the main vehicle for the Artificial Intelligence, rather than a humanoid robot. This film is almost a love story between human and AI, with the two forming a relationship. The AI portrayed in this film has the ability to 'learn', something which is already being demonstrated in real life AI development, albeit not yet in such a human-like way (Baker, 2012). Nevertheless the ability of programs such as IBMs Watson (Baker, 2012) to draw upon information from an unstructured corpus of data, including social network feeds and online chats to create a reasonably credible persona tailored to the preferences of an individual is bringing such scenarios closer to reality. In addition the possibility that many online virtual interactions may utilise avatars to convey a personality that may bear no relation to the user, real or virtual (Cooper, 2007), has many implications for who or what we perceive as our social circle.

The film "Ex Machina" (Garland, 2015) poses a slightly different dilemma and looks at the creation of AI so sophisticated that it encompasses a simulacrum of emotion in a humanoid form. Whether sentient self awareness actually occurs or whether it is simply following its instruction to convince someone to help it escape remains deliberately ambiguous. Nevertheless the film develops a plot where its capacity to appear human not only exceeds the Turing test (Saygin et. al., 2000) where an individual can no longer discern it from a sentient person but its ability to emotively manipulate someone to empathise and collaborate with its wishes leads an individual to attach their loyalty to the AI as opposed to the AIs creator. In this role the virtual human 'AVA' even draws upon the protagonists own social media and internet searches to identify appearance and clothing styles that are likely to be attractive to him, a capability that is no longer entirely science fiction. The film also briefly explores a crisis of identity where the individual discovers that other individuals in the house are not human as first perceived but actually AI personas which leads the individual to dramatically question their own humanity as well as their sanity.

Artificial Intelligence (Spielberg, 2001) was based on the 1969 book 'Super-Toys Last all Summer Long' by Brian Aldiss. This film is based around a futuristic society in which Robots are designed to think and feel as humans do, centred on a robot designed to mimic a young boy who is placed to live with a human family as surrogate for the child they lost. The child robot of course needs to be designed

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

to believe in his role that he portrays, yet does not grow up and is even abandoned by those around him. The conceptual dilemma of 'When is a machine no longer just a machine that can be discarded?' is becoming a more common theme explored in popular media.

There is a sense here that virtual humans might be acceptable in the short term as companions but the prolonged lack of real human contact might further the sense of isolation and such considerations would suggest that such systems should be considered augmentation of and not replacements for real human company. In addition the concept of replacing a lost companion whilst in the short term might have a certain appeal for some would require an incredible suspension of disbelief and denial that might not easily be maintained and perhaps just postpone grieving and possibly exacerbate guilt at the acceptance of the virtual substitute.

Virtual humans for healthcare have been and continue to be explored in both fiction and reality. The Doctor (Emergency Medical Hologram) in Star Trek (Frakes, et.al., 1996) is represented as a virtual human as a means to be relatable when treating patients. Star Trek has previously experimented with virtual humans such as "Data" (Frakes, et.al., 1996) as a means of exploring the concept of human and both of these characters undertake this narrative element seeking to become "more human". The idea of virtual humans being responsible for our healthcare is potentially contentious in some aspects but with the current healthcare burden technological assistance to support with common tasks is now arguably a necessity and restoring a virtual human interface over seemingly impersonal touchscreens would appear to be well received for a number of duties freeing up qualified human staff for more vital roles. Virtual healthcare practitioners, such as SimSensei and RITA, arguably may have been inspired by the early iterations of such sci-fi concepts and certainly seem to aspire to that level of interaction and knowledge base.

Sci-Fi Games have also naturally adopted the concept of the virtual human as an A.I. interface or as an assistant or narrative director. 'Cortana' in the Halo series of games (Staten & Boren, 2001) is depicted as a female smart A.I. virtual assistant providing narrative and context to missions as well as tactical updates and guidance. Largely there is little in-game mechanics for her in the Halo series of games although she is depicted accessing computers etc in cut scenes. The role of an avatar as a digital assistant is already available in various guises such as "Denise" and her various alter egos which are the creation of a Brazillian company, Curitiba-based Guile 3D Studio. Their system uses artificial intelligence software, and voice recognition and synthesis in 46 languages as well as biometric systems. A more direct, albeit contrived, merging of science fiction with factual reality is to be represented in the debut of an integrated personal digital assistant "Cortana" for the Windows Phone 8.1 (Warren, 2014). Cortana is designed to continuously learn a user's behaviours, interests and preferences as well as organise their daily activities and schedules. The name is not a coincidence; one novelty of this virtual human assistant is the very deliberate use of the Cortana avatar from the Halo games, including using the same voice actress (Jen Taylor) who plays Cortana in the game. In this case the role of fiction inspiring reality is clear.

Virtual human personas as a means of technological assistance or enhancement are perhaps more readily acceptable for some. Concepts such as the seemingly omniscient Jarvis AI in Ironman (Favreau et. al., 2010) seem to operate like sophisticated personal assistants and information repositories for much of the time but are clearly capable of operating the systems in the home and even autonomously operating the "Ironman suit". Naturally enough it is this autonomous operation of weaponised technology that is often a source of concern both in films and the real world. Unmanned autonomous battlefield assistance vehicles and even weaponised drones are potentially helpful for the protection of troops on the ground and have even demonstrated rescue and evacuation capability for injured or vulnerable personnel (Osborne, 2009). Whilst many of them have AI functionality and are capable of making autonomous decisions,

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

including identifying and firing upon threats, there has been a notable reluctance to portray them with a virtual human persona to the general public. Machines being able to carry out tasks, without risk to their human counterparts, are clearly an attractive proposition to the military. Yet the idea of machines being able to autonomously fire upon human beings is largely unpopular in the media and dysfunctional systems or unanticipated programming conclusions are the inspiration for many films where machines turn upon their makers, such as 'Terminator', 'Battlestar Galactica' or 'The Machine' (Cameron, 1984, Pate, 2012, James, 2013)

In the past the idea of the machine being a slave or a tool that toiled or made life easier for its creator seemed part of the utopian vision, and naturally a narrative that allowed that machine to throw off its shackles of slavery and rebel against its masters seemed an obvious counterpoint dystopian vision. The subtle shifts in the perception of A.I., and the philosophical dilemmas they raise, have complicated this vision. Popular media is exploring narratives where machines can appear so human that we cannot discern whether they are or not, and even machines that believe they are human or at least similar in free thought and complex emotion, including love and loss. The reality is perhaps not far behind, but for now, other, perhaps less anticipated interactions between man and machine, are emerging that are far from our utopian ideal.

Cyber security is now a pervasive issue with a number of artificial intelligence systems and programs designed to overcome the conventional security systems we often take for granted. However we rationally determine that there are some subtle differences in the perception capacity of these "bots" and those of a "real" human that we can utilise to our advantage. For example, the "Captcha" security system is a visual arrangement of letters and numbers that can be interpreted easily by humans but are a barrier to intelligent "bots". In a somewhat ironic twist some A.I. systems now identify these captcha and copy them in order to present them to real human operators who may believe they are entering in the correct details to legitimately access information on some other site (Egele et. al., 2010). In this manner A.I. is now effectively utilising humans to achieve its designed goals, and so the puppet guides the puppeteer.

However, the concept of A.I. determining our actions is not new, and is still being explored for its considerable benefits for relieving the cognitive load in our everyday lives, and in scenarios with extreme tedium and risk of poor error management from the human controller. This has been evident in automatic pilots, and the choice of the female human voice to calmly deliver flight control warnings to pilots and in the investment into autonomous self driving cars and transport systems with voice and gesture commands and audio responses. It is likely that in the near future such systems may use a human-like persona for mediating interactions.

We have a long way to go to fully comprehend both the extent of the impact and the moral and ethical dilemmas of the virtual human and its perception and acceptance in society. Fears, both rational and unfounded, will have to be addressed. Nevertheless technological assistance has been welcomed into many aspects of our lives, becoming commonplace to the extent where we wonder how we would mange without them. Moreover the future potential of such technology is hardly something to be dismissed lightly. Perhaps in time the virtual human that tends to your health and knows your every need and preference so well will become equally acceptable, as will the virtual PA who has all the information you need and can tend to those tedious reports. Maybe even the virtual companion who can share your memories and reminiscences with anecdotes and stories will be like one of the family. With ageing populations, greater demands and expectations of healthcare, more complex technology and the need to manage vast amounts of data, something needs to be done to relieve the burden. The virtual human in differing guises seems

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

well suited to the task and is realistically already among us. The fear of "what if it breaks" will perhaps always remain in our psyche, but humans too are fallible particularly under stress. If "to err is human" then perhaps "to err less often is virtual human" and perhaps that will suffice for now.

We would clearly be foolish to abandon all the potential benefits inherent in the virtual human but we must strive to focus our design towards the safe utopian vision of our digital future.

Apart from the actual representation of virtual humans, perhaps the key concerns which emerge as repeating themes in fiction and in fact, are centered around issues of AI autonomy and ethical decision making, and social isolation from human contact. In order to embrace the full potential of the virtual human, these issues must be addressed.

Even before the recent advances in virtual human technology, our increasingly technological society is creating concerns around social isolation and lack of human-human interactions. Some might argue that for those already naturally socially isolated (the elderly, disabled, social phobias etc), technology-enhanced interactions actually decrease social isolation by providing a medium and means to interact through the guise of an online alter ego. In Science fiction this has naturally been the subject of film plots such as "Surrogates" (Mostow, 2009). In the 'real' gaming world this is a natural expression of 'self', with users portraying themselves in a variety of customizable avatars that may or may not relate to their real persona. This can be empowering (allowing a physically disabled individual to portray himself in an able bodied avatar) or sometimes allow the freedom for individuals to portray themselves as they would like to be perceived by others, or to explore alter egos whose appearance and behaviour diverge from their normal life (Cooper, 2007). Alternatively however, it might also allow those with ulterior motives to approach unsuspecting individuals in a guise that intentionally deceives age, gender and intent with far more sinister implications.

Positive or negative, we cannot ignore the reality of increasing levels of human-computer interaction in all its forms (games, social media etc) and its potential impact on health, obesity, and social withdrawal. The research in this area is of prime importance, not just in documenting the concerns, but also in investigating solutions which don't exclude technology, but facilitate more positive interactions.

The concerns around AI having too much autonomy are extensively investigated in some aspects such as military and legal issues, yet largely neglected in other more social forms to date, yet these are often fears expressed by the general population as the technology closes the gap between reality and fiction. Although we don't yet have any clear failsafe mechanisms to address these theoretical future risks, for now perhaps the approach taken by the Watson AI (Baker, 2012), whereby the AI will offer an informed opinion, but also presents the evidence supporting the opinion, leaving the (human) user to make the final decision, offers one acceptable compromise.

This strategy of keeping a human "In the loop" is one commonly suggested for key decision making and is often advocated in military options, (and indeed the fears of its absence makes a key plotline in films such as "Terminator"), but maintaining fully informed human decision making as a safety override imposes its own limitations in terms of timely decisions and bias judgments and allocating effective man-hours which may negate or undermine some of the key benefits of virtual humans.

Ethical decision making is complex among 'real' humans relying on judgments and weightings that are dynamic and even personal. Translating this into a rule based AI system with theoretically universal weightings and priorities will be contentious at best. Asimov's rules, although a good conceptual starting point, are simply not enough here as their interpretation and implementation are as yet not fully defined and prone to conflicts whose consequences we as humans would have to live with.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Even the concept of realistic virtual humans has ethical conflicts. Blurring our ability to recognize human from virtual human has some notable advantages, for example as companions, care providers, advocates and assistants among others. However, there is a fine balance to maintain.

It's vital that we retain our humanity, which includes caring for the vulnerable in our society. If we leave this task entirely to an army of robots, we will in the process lose something of what makes us fully human. (Powell W, 2014)

At what point does convenient, comfortable deception become negligent, malicious or abusive? Should 'Virtual Humans' always be marked out as different somehow so that when the beguiling suspension of disbelief strays into misrepresentation we have the means for a reality check? Such issues have a form of precedent in the media with images of models that have been 'enhanced' with image manipulation software, often now carrying a disclaimer to that effect. Nevertheless the message conveyed by a static 2D image is unlikely to be as complex to mitigate, as that of a fully interactive avatar.

With our continuing changes in society it is increasingly likely that we may come to rely on these 'Virtual humans' for our healthcare and many other everyday interactions and services, but therein lies a dilemma: we need them to be like us for our sake, possibly better than us for societies sake, but we remain unsure how much like us is permissible and ultimately controllable. Wherever the future of virtual humans takes us, we should not be reactive after the event, but anticipate and plan to firmly define their role and place in society in order to fully realise their benefits without the realisation of our fears.

Chapter 71
How Games Improve Language in People With Language Dysfunctions

Robert Wahlstedt
Independent Researcher, USA

ABSTRACT

Many people as they age face a greater challenge of muscular dexterity around their facial muscles. This results in difficulty producing certain sounds, and sometimes the problem is so severe that they are unintelligible. People who could benefit from the methods in this chapter are those who are hard of hearing and do not have feedback readily accessible and people with ALS. This chapter describes a method that uses a computer learning algorithm that predicts what people are about to say based on earlier content and learns what the natural sound of their voice sounds like. This chapter illustrates speech trajectory and voice shaping. Clear Audio is a biologically inspired framework for studying natural language. Like the story behind Jurassic Park, Clear Audio attempts to make predictions about data from existing data, inspired by biological processes. Its main goal is to give feedback for speech pathology purposes.

INTRODUCTION

In order to comprehend meaning in a sentence the software must recognize a bit of language sound or phoneme meaning the software must then predict sentence trajectory of what is to come. In a word with more digital data than ever before, each word is a trap door to another set of meanings. Words are fossils of another time and another place brought back to evoke sentiment including thoughts or feelings of previous experiences. For example, in a paragraph that mentions "snow" denotes that the paragraph is about snow. Lieberman argues that the brain is always in the mode of social communications and that it does not turn off. Lieberman argues that although a person is not born with social mechanisms in place he or she quickly develops social capacity as the brain adapts to its environment. The human needs 10,000 hours' practice to become an expert in a specialty. The brain achieves this social learning

by age ten (Lieberman, 2011). The Second Machine Age argues that while computers are not capable of doing anything other than what a human tells them to do, if they have an exact enough feature set, they are better than humans at determining how the proper order of events. One process is modeled by the Zachman framework of asking who, what, when, and why. For example, the Google Chafer project, a project to designed a computer to drive a car. The feature set was as good as of 2014 the car had only two accidents, one of which was rear ended at a stop light. Should the Zachman framework be used in natural sentence processors such as our Clear Audio Project can predict as some critics of natural language processing say, predict the surprising punch line of Grandpa's unpredictable jokes. Filters become more essential with the growing field of data mining and big data. Recently Google and Apple (Siri) released new versions of speech recognition in Google Now and IOS 6. These represent the best of today's big data. Traditionally data scientists compare the concept of big data to a big hard drive full of stuff that the scientists process. However, as this big pile of data grows the only people who are able to sort it have many hundreds of processor cores. Jeff Stibel points out that large internet-based companies have their servers based in cheap places to get electricity (Stibel, 2014). Cnet, in their review of IOS Maverick, claims that the catch or the storage of internet files on the macs is overbearing. Worse is the concern that having even anonymous data can have legal implications because people with unique conversations would stand out in a crowd. Aiden explains how almost in a decade worth of Google searches some queries stand out (Aiden, 2013). Particular phrases such as idioms from cultural minorities can distinguish a person's conversation. This predicament reveals a required feature set. Data without a feature set is useless. Mathematics is defined by The Oxford Dictionary as "the abstract science of number, measure, and space." Language and mathematics share the definition as being omnipresent, constant, without regards to feelings or sentiments. People argue that language is more chaotic.

Fortunately, mathematics offers fractals such as the Mandelbrot Fractal shown above to help people understand complexity and chaos in simple terms. Computers can find similarities in pictures without knowing what they are. Recently Peter Norvig of Google gave a talk to Brown University about memorization or a way that the computer can know what an image consists of although it may not know the

Figure 1. Shows a computer rendering of the Mandelbrot fractal (credits go to Wikimedia)

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

name of these items the computer found similar. In Surfaces and Essences, compares an object being placed in a box and then taken out of the box to words being conceptualized and formatted. Consider all the meanings of the word band. This can connote everything from a marching band to a wedding band to a Band-Aid that filters air to a wound so it is not infected. Which one of these is a metaphor? We can never tell which usage of the phrase is the original as opposed to the ones are comparable to the original fossil of the metaphor. With the Zachman framework, we come close to determining the usage of phrases. While metaphors are an important aspect of word origins, writers of newspapers write articles so people with a ten-year-old child's vocabulary and intellect can understand them. We cannot assume that many ten-year old children can understand metaphors such as a broken record or see an activist as something that acts upon an agenda. This network of vernacular fossils composes much of our language today. Therefore, something else is happening. Iacoboni asks why is it that a person gestures when they are talking on a phone and it the other person cannot see these gestures. It is because we use words as a vehicle to transport the other person to a thought or feeling we wish to convey (Iacobon, 2008). Using this method, I will refer to as capture and transport method, in chapter two of this paper, we discuss how educational games and by letting people have experiences using augmented reality to reinforce Hebbian learning of experiences. What we need to find out is how spelling constructs etymological concepts. If we were strictly, follow a formula for the English of yesterday of pragmatically tagging parts of speech (P.O.S.) we would never be able to keep up with new words as the as people use these words new to our corpus. In the later part of the last century, stock traders worked on algorithms to decide in which direction stocks will go. A key advantage was that stocks exist in numerical form. However, this does not relinquish the marvel of predicting what would happen next. Natural language processing researchers can take lessons from stock market predictions and apply them to both word and concept formation. Humans tend to repeat language behaviors if they were effective or energy-efficient or economical. The researcher's goal is to use the Maven Markup Modeling Language (MMML) based on predictive modeling markup language (PMML) to find ways of correlating words to integrate new words faster into the corpus. Text mining projects at Universitat Politecnica de Catalunya depend on lexical categories for their lexical analysis tagging. Yagoda suggests "According to grammarians, adjectives, nouns, verbs, and injunctions are 'open' parts of speech because they shift functions ... and because new words are continually added to their ranks. This proves that classification of words is not always necessary." (Yagoda, 2006). To make matters worse, a gerund is using a verb in its – ing form as a noun such as living. Although the English language has synoptically, there are two types of words, content words and structure words. The natural language processing engine can remove structure words such as "hope that" "clearly" "strangely"" indeed" "conceivably" "seriously" "ultimately" "theoretically" "naturally" "ironically" "fortunately" incidentally" do not containing meaning in themselves however they send signals to listeners about words that are coming later. The word "like" is overused because it is often used as filler words while the person thinks of something else to say. The National Science Foundation did a study that demonstrated when a storyteller used the word "this" instead of "a" or "an" the person demonstrated better retention. Another concern is that these systems do not account for pragmatically that is the study of context is it situational.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

BACKGROUND

There are two classes of people with speech challenges; the first class consists of those who had trouble speaking since birth. They are aware of the fact they are more challenging to understand. One hypothesis on speaking challenges is the disorder is more prevalent in children because the work of both conceptualizing and the formatting tasks of language overwhelms them. Bell Labs engineer Robert Lucky estimated the cortex cannot take more than 50 bits per second. Mihaly Csikszentmihalyi estimated one apperception to take 1/15th of a second or 105 bits per second. Regardless of the figure a person has limited bandwidth or computing power. Because it takes a lot of concentration to come up with metaphors and categorize ideas with words, the quality of speech declines. Along with this speech has limited prosody referred to in this paper as words per minute, pitch variance, and stress of syllables. With the knowledge that they are unintelligible, they compensate using repetition or choose words that do not contain the element that they have trouble with. They may do these substitutions or repetitions unconsciously. People with speech aphasia often have trouble with pronouns. A goal of Clear Audio is to find the use of pronouns and the repetition by using summarizing tools. Section 2 explains these methods. Section 3 describes other people who have difficulty speaking later in life due to a stroke are confident that their pronunciation is the same as it was before their decline and may not utilize either repetition or choice of words.

WHAT DO COCHLEAR IMPLANTS SUGGEST ABOUT SOUND?

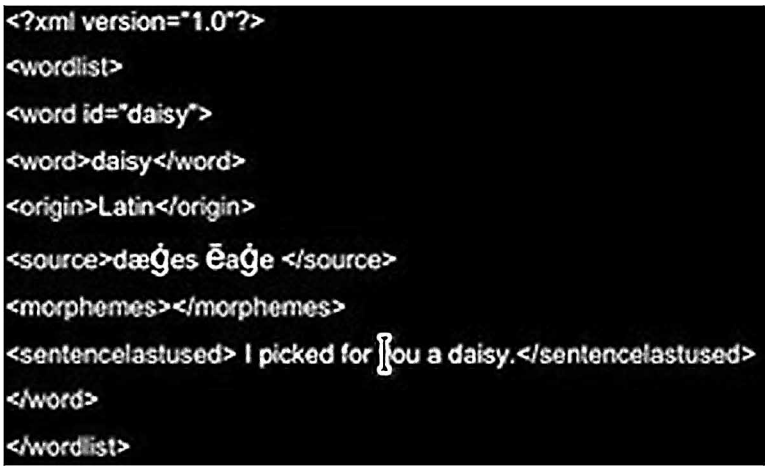
Helping Those Who Repeat to Be Understood

In order for a contextual agent of software that recognizes speech, it must develop a cohesive hypothesis about what a speaker is saying. Denworth discusses the requirements of language for cochlear implant patients. She suggests that processing sound is a multifaceted event including both contextual clues for perception and the stemming. Denworth introduces David Pisoni's work on "visual speech" that Denworth describes as the act of a person to see objects without cognition of what they are. Densworth gave this as a reason her son has an implant starting at age three (Densworth, 2014). While experimenting with Audacity, we realize how redundant speech is as opposed to music. A more sporadic sampling of voice is enough for voice while for music every sound we must accommodate for. Summary generation for detecting repetitions A piece of literature is similar to a piece of music in that both contain repeated themes throughout the piece. While the BBC has a recording of Tchaikovsky's 1812 overture that lasts 17 minutes, most people remember only the theme. In this paper, we discuss the methods how literature themes stand out from the rest of the piece through both exact repetition and supporting variations of the theme. Some scientists who study the brain call this grouping "chunking." Many textbooks of text mining hold the author's beliefs that word categories or parts of speech are important. These papers create summaries by deleting irrelevant words until only the nuclear core remains. However, these authors overlook context. A new approach seeks to use structural knowledge of pragmatic through latent semantic analysis. For example, to get to the best diagnosis of patients, it is important to take into account their entire medical histories and not just a few quotes. This method does analysis on the entire document before concluding so metaphors and words with multiple meanings are not confused. This paper proposes if using metadata, or data about the data, to distinguish repetition of the theme from supporting variations,

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

also known as satellites. This is achievable by finding the roots of words through their origins, translating the word prefix, root, and suffix into metadata. The brain constantly encounters more information than it can digest. Oliver Sacks discusses how Chinese speakers represent a higher than average percentage of people who have pure tone. Of these, the greatest were musicians who started learning their instrument before age six. This is because the tonal system of the Chinese language is a very important element and is necessary to distinguish words from each other. The brain of the Chinese speakers adapts so it is accustomed to listening to other Chinese speakers (Sacks, 2007). At the time of birth, a person is born they can absorb much information from their senses including hearing. Around 80 percent of the energy they get from food goes to developing their brain. Swaab discusses one theory that a person uses the equivalent of $1500 for their entire life or 15 watts per hour (Swaab, 2014). In order to come up with a computational model we need to ask the right questions. As they start building heuristics and finding out what is important and what is not then less energy goes to fuel for the brain. Dean Buonomano commented on how musicians dedicate larger than average part of their brain to muscular memory in their fingertips through reallocation. He goes on to say the brain does not consciously govern the real estate in the nervous system so this was a subconscious process. Why do English speakers who are not musicians have such a seeming disadvantage? One dominant theory is that of the Hebbian Synapse that neurons that fire together wire together. In other words, if two events are not linked by the human brain as related, the brain acts like a filter and events are never associated or learned with one another (Buonomano, 2011). Stanislas Dehaene takes this notion further and discusses the history of the mind and body model. In the ancient world, philosophers like Descartes often thought that the heart was the headquarters of human thought (Dehaene, 2014). The soul or spirit was a detachable element from the physical body. This is similar to today's notion between the difference between computer software and computer hardware. Later scientists developed interfaces for working with the injured brain to capture electrical signals. These in addition to fMRI have introduced new material under review as far as what a person can understand. Through the new methods, we can detect electrical signals of which the brain encodes information into neurons. We now have empirical evidence that people see other people through filters and this becomes imprinted on their brain based on prior experiences. For example, we know that when person has had a negative experience with big dogs, certain elements the perception system exaggerate such as teeth, when the person encountering future dogs. This conceptualization is utilized in visual speech.

In designing a program, it is necessary to understand what one has to work with. Imagine a machine with two cameras perceiving words. When a person reads a word like "unbuttoning" the human brain strips off the "un" and the "ing" and it is left with two morphemes, "but" and "ton." There is a priming effect where a person is more inclined to think about a certain flow of words. For example, after casa, there sometimes is the word Blanca like the movie. This is why we understand differing homograph meaning. A grapheme is a letter or a series of letters that map a phoneme in the target language. Imagine a web of words that links all words in existence. Pulverm introduces a word-related functional web. It is a synchronous firing chain or synfire chain (Pulverm 2002). At first glance, automata might be similar to this web. However, a computer differs from a brain because even computers with multiple processing cores are asynchronous in the sense that the computer can only process a few threads unified by a central process. The human brain is a democracy having processes happening simultaneously and the strongest impulse, usually by a collective number of neurons fire that is what the human brain thinks. Miguel Nicolelis argues there is not a separate part of the brain language support.



EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

However, a certain sequence of neurons that light up when a person reads about an object because it invokes an emotion (Nicolelis, 2011). Kenneally describes how non-humans animals could use simple language. Instances of non-humans are territorial warning signs and primitive inner species communication (Kenneally, 2007). The article "How Dolphins Say Hello" says that dolphins only whistle when they are in a group of dolphins and find themselves through echolocation. Grammar is a set of rules in a language that allows people to communicate and understand. There is a debate between B.F. Skinner and Noam Chomsky. Skinner believes that a person learns language through association, the sight of things along with the sound of the word. There conformity of this association matching constructs a dialect. Chomsky believes that a Martian scientist observing children in a single-language community would see that language is very similar regardless of the culture and therefore innate. Although reading is unnatural, our brain wants to see patterns and group objects together. We recognize lines and shapes that we read as characters. We then group these characters into morphemes. We then put these morphemes into phrases, idioms, words, and sentences. These sentences form a paragraph. Similar to computers recognition is easy, recalling meaning is difficult. Henry Hitchings discusses how it is possible to use stemming while the human language evolves. He says it is amazing that people spell words uniformly. Before computers, he points out that even dictionaries were inconsistent (Hitchings, 2011). There was a survey where a computer used phonetics to spell out words and 50 percent of the words did not agree with the phonetic spelling. Steven Pinker tells us that 84 percent of the words have a spelling that conforms to patterns we can notice. As shown by these statistics, the ability to conform is possible (Pickner, 2007).

It is necessary to study of metadata to correlate etymology with words. Etymology is the study of finding word roots and morphology is the study of word making. Today advances in bioinformatics tools have yielded a complex study of the human genome and have made great strides in finding out mutations that can create a higher chance of cancer. We should do so because we can learn about the human race as well as expand our knowledge of words. Here are some examples: nickname originally came from nekename containing the compound eke and name. Eke came from ēac that means also. It means an extra name. The word "hobby" comes from the word hob and yn. Hob or hŏb means a threaded and fluted hardened steel cutter, resembling a tap, used in a lathe for forming the teeth of screw chasers, worm wheels (Webster's Revised Unabridged Dictionary) and yn means "to be." It means to spin time. The word "omelet" comes from the French word omelette. Omelette comes from alemette that comes from alemelle that as comes from la lemelle that means a thin plate like structure. We should know how to find the prefix, root, and suffix because we are able to understand why someone in history responded to situations. The written word often transcends a person's lifespan and the culture changes. A written manuscript is similar to a fossil. For example, rabbit comes from the words robète that means to steal. This explains why Mr. MacGregor thinks Peter Rabbit as such a nuisance. If you are a person that is a Christian, it might please you to know that Nicodemus comes from the word nincompoop. This comes from the Latin phrase non-compos mentis meaning not of sound mind. People regard him as a hero of the Christian faith because he walked by faith and not by knowledge. What does a computer have to do with this? Computers are able to carry out arithmetic or logical operations such as regular expressions or pattern matching. Given some rules and a lexicon file, they are able to study morphology. "A" as in rag or Prague is big and "I" as in pin am small, "e" is somewhere in between. There has been some big vowel shifting in England between 1350 and 1500 known as the big vowel change so words like big and small have the wrong letters. Little and large are right. Pimpf means "a little boy," pimple means a little swelling, and pampers means a lot. Servant is in between. Quick Summary uses Maven Metadata Markup Language or MMML. It has a structure similar to the one shown below.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. Shows the XML layout of the word "daisy" in Maven markup modeling language (MMML)

It may seem everything the software needs are stemming or taking apart words to find their meaning. The book Found in Translation: How Language Shapes our Lives and Transforms the World, talks about how words are associated with different metaphors in different cultures. One example they give is intaxicato solar. This means food poisoning. It looks as though it means intoxicated as though someone had too much to drink. This is an example of what linguists call a "false friend" also known as a false cognate meaning that it looks as though they come from the same linguistic root but have different meaning. Another example is the word okoru in Japanese. Although (Truss, 2004). The word leaves can also be from a plant or it can mean to abandon an area. These point out in addition to stemming the software needs to run on a distributed blackboard approach to artificial intelligence. A blackboard is a comprehensive method that has several expert knowledge agents, they feed an aggregate stream with what the agent knows based on a limited perspective, and each agent fills in insufficiency of different agents. In our software, the stemming is one agent and context of the previously spoken topic are another. In addition, features should consist of tone or pitch, the tempo of words were spoken or speed, and vibrancy or liveliness. Pentland introduces a social-o meter that has a microphone for determining pitch and speaking duration. However, this microphone is unable to decide the real words (Pentland, 2014). A key distinguishing reason of the research presented from other software that can recognize speech such as Dragon Speaking Naturally Dictate has pride itself with how many sample voices have trained it. These speech recognition engines do not consider how important tonality is in making speech palatable. The brain needs some difference, dissonance, and variance to stay focused. When a robotic voice speaks, it often takes greater amounts of concentration to listen. In today's high-paced world, people might not always have energy enough to listen. Sounds constantly bombard with data and as we discussed before in this paper under the section A Human's Big Data Filtering Method, the brain does a good job of filtering out what are signals as opposed to noise it looks as though it may resemble the word to occur, it means to get angry. The book Found in Translation goes on to say that, certain brands like Mitsubishi have to rename their Pajero module and Honda Fitta module in particular countries. The countries have different connotations of the words. The word gift means poison in German. The Online Etymology Dictionary says that it was often associated with prescribed medicine. People used the word gift as in a potion by a doctor and it came to mean something of tangible from a knowing person. Found in Translation tells

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

how jokes in some languages are missed such as in the Harry Potter Series Lord Voldemort is "Tom Marvolo Riddle" is an anagram for I am Lord Voldemort. The Bulgarian translation is Mersvoluko whose anagram translates to "And here I am, Lord Voldemort". The word in Hebrew originally was tohu meant formless and vohu meant empty. In French today toha bohu meant chaos and confusion. These words became associated with chaos later in Hebrew (Kelly, 2012). Sometimes the environment makes it necessary to invent words to present the concepts behind them. For example, to explain to the Hmong people about cancer at UC Davis, they compiled English to Hmong dictionary for medical terms. Martin Luther when translating the scriptures invented words so he can explain to people Latin concepts such as Machtwort (authoritative guidance). Truss indicates this problem by having multiple definitions for the word shoots meaning to fire a fast projectile from a gun or shoots that are a part of a plant (Truss, 2004). The word leaves can also be from a plant or it can mean to abandon an area. These point out in addition to stemming the software needs to run on a distributed blackboard approach to artificial intelligence. A blackboard is comprehensive method that has several expert knowledge agents, they feed an aggregate stream with what the agent knows based on a limited perspective, and each agent fills in insufficiency of different agents. In our software the stemming is one agent and context of the previous spoken topic are another. In addition, features should consist of tone or pitch, tempo of words spoken or speed, and vibrancy or liveliness. Pentland introduces a social-o meter that has a microphone for determining pitch and speaking duration. However, this microphone is unable to decide the real words (Pentland, 2014). A key distinguishing reason of my research is that other software that can recognize speech such as Dragon Speaking Naturally Dictate has pride itself with how many sample voices have trained it. These speech recognition engines do not consider how important tonality is in making speech palatable. The brain needs some difference, dissonance, and variance to stay focused. When a robotic voice speaks, it is often takes greater amounts of concentration to listen. In today's high-paced world, people might not always have energy enough to listen. Sounds constantly bombard with data and as we discussed before in this paper under the section A Human's Big Data Filtering Method the brain does a good job at filtering out what are signals as opposed to noise. to noise. Those who hear a 60-hertz drone of a light fixture will likely ignore the drone because the brain has trained itself to ignore some sounds. Next, I hope I am able to find a feature set to annotate and make computer voices easier for people to listen.

In the Story of English in 100 Words, David Crystal discusses the origin of words. He gives the history of the word jail borrows from the French originating in the about the time of the Norman invasion of 1066 study we can tell because the word gaol is Latin. Crystal explains that languages borrowed this word twice, being what Crystal refers to as double borrowed. We can tell this because the word did not get its origin meaning. This is also true for the word convey originality coming from the French word convoy. Our approach is to take this research and combine with what is known about UML, I* and the Zachman framework to discuss the questions of what, where, when, why, who and how. With this data, it is possible to verify that our summary correctly reflects the emphasis of the paper. In Empires of the World: A Language History of the Word, Nicholas Ostler demonstrates beginning with ancient Babylonians carrying off the Hebrew slaves and forcing them to melt into the culture of the Babylonians how language can melt together. John McWhorter writes this is what happened during the Norman invasion. There was not a bloody war instead slowly, over time the Normans introduced French. English, Crystal says, is like a Our approach is to take this research and combine with what is known about UML, I* and the Zachman framework to discuss the questions of what, where, when, why, who and how. ancient Babylonians carrying off the Hebrew slaves and forcing them to melt into the culture of the Babylonians how language can melt together. John McWhorter writes this is what happened during the Norman invasion. This field of anthropology is transcultural transfusion (McCrum, 2010). This is an example of diffusion by choice. By studying hyperdiffusionism under the belief that man originated in one place, we can learn through cultural similarities. For instance, most civilized cultures today teach us that it is wrong to kill or commit adultery. Noam Chomsky writes about a universal grammar being indistinguishable by a Martian linguist. McWhorter claims that through DNA evidence anthropologists discovered the village where the anthropologists discovered the village where the Germanic dialect began. In tracing word etymologies, it is important to ask ourselves where features of a language began. Guy Deutscher makes the following observation: "Often, it is only the estrangement of foreign tongues, which their many exotic and outlandish features, that brings home the wonder of language's design." By incorporating origin into a NLP translator, we can see by parapraxis, images that speaker has in mind. Through a more careful of word choice, we have the advantage of seeing the speaker's words and come closer to making up for the disadvantage of not seeing him communicate those words to us. We can see how a language would transform and predict new words that might occur. By understanding how the introduction of new words and in what context it helps us predict what the likelihood that a speaker is, uttering these new words and this can greatly help the software that recognizes speech, sucking up words around it. McWhorter likens it to summer camp, where an exchange of ideas takes place. Robert McCrum writes that non-native speakers to surpass the limitations of English by borrowing from other languages use Globish (McCrum, 2010). This field of anthropology is transcultural transfusion. This is an example of diffusion by choice. By studying hyperdiffusionism under the belief that man originated in one place, we can learn through cultural similarities. For instance, most civilized cultures today teach us that it is wrong to kill or commit adultery. Noam Chomsky writes about a universal grammar being indistinguishable by a Martian linguist. McWhorter claims that through DNA evidence anthropologists discovered the village where the Germanic dialect began. In tracing word etymologies, it is important to ask ourselves where features of a language began. Guy Deutscher makes the following observation: "Often, it is only the estrangement of foreign tongues, which their many exotic and outlandish features, that brings home the wonder of language's design" (Deutscher, 2011). By incorporating origin into a NLP translator, we can see by parapraxis, images that speaker has in mind. Through a more careful of word choice, we have the advantage of seeing the speaker's words and come closer to making up for the disadvantage of not seeing him communicate those words to us. We can see how a language would transform and predict new words that might occur. By understanding formation of new words and in what context it helps us predict what the likelihood that a speaker is, uttering these new words and this can greatly help the software that recognizes speech.

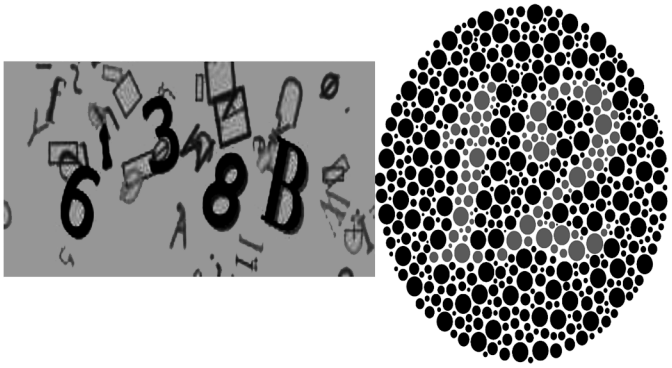
How to Assist Those With Speech Issues That Do Not Overcompensate

In people with speech issues who obtained them later in life due to a stroke it is important to utilize elements of traditional speech recognition. These include language based game theory and eliminating what is not the topic. This paper proposes imitation of a biological system.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Language Based Game Theory



A project in the Netherlands led by Jan Dietz seeks to map words as they relate to events in the world. Their premise is that we are like parrots repeating ideas that come to us through movies and books. In a game of broken telephone, a group of people sits in a circle and whisper a message to the person next to them. The message tends to vary as the first person conveys the message to the next person. These researchers claim through recursion we repeat these events demonstrated to us in a particular order. They believe they can forecast behaviors based on the past. The DEMO research group claims that BPMN, UML-AD, EPC, IDEF-3 are method independent. They do not take into account the redundant nature of business. It captures the conversations between actors. Jan Dietz explains that the subject chose to share one of their thoughts called the locutor. It appears as <locutor>: <illocution>: <addressee>: <fact>: <time> For example, let us consider checking a book out from a library. Certain circumstances must satisfy the checkout conditions. First, to check out books the subject must be a member at the library. Then he must not have any pending fees. Essence, the attributes that make the subject what he or she is. He is a candidate who can pick books out of the library. Should there be problems, he cannot check out books from the library. The production act of picking books out of the library is the executioner. It is a repeatable act. David Bellos tells an account of how his father was able to check into a hotel in a non-English speaking community because both he and the hotel staff were familiar with the process (Bellos, 2011).

Another tool that can help with the speech is to find the topics not discussed. As the speaker is generating a narrative the chance of the speaker continuing to speak of a topic becomes greater. This directs the trajectory a certain way. Throughout the conversation, we use the Zachman framework to generate a possible persona of who the speaker is. If the speaker is a 16-year-old, we know there is a greater chance of them looking into colleges as opposed to retirement homes. While in certain situations, this can happen. The computer takes the conversation as a puzzle which has certain elements and can affirm or discredit the personas generated by the computer of who is speaking. To confirm accuracy, information can be gathered through abnormal changes in sediment. There is an emerging field of looking for statements and determining whether they are joking or using sarcasm. This technique is similar to those in visual saliency to help us deduct clues. Barash speaks of language like a stream of water (Barash, 2003). An adversary comes from the Latin word adversus meaning turned towards the flow. Language consists of hundreds or thousands of transactions and our program can learn what to expect. Language is much like the social behavior of ants. Can computers learn enough by watching transaction to find what stands out among the ordinary. The article Ant-Inspired Visual Saliency Detection, gives the image of ant behavior when they take the way that requires the least amount of effort to get towards their food. Saliency provides a method of processing of images for anything that stands out including edges. There is software for finding salience such as the Saliency Toolbox and the Neuromorphic Vision Toolbox. Consider the test for color blindness where a hidden object in an image or CAPTYA in figure one and two below.

Consider the book, Where's Waldo. In the Where's Waldo example the stimulus is when we Consider the book, Where's Waldo. In the Where's Waldo example the stimulus is when we see something that resembles Waldo. For example, the viewer considers the color red with Waldo. Then on to the next level, they consider red stripes. Then they associate glasses. The template starts to form that confirmed by people of different cultures is a grammar. It is possible by using a grammar to spot what the topic is not, much like a Bayesian spam filter. This monitors the flow of the conversation and when an unexpected sound appears in the recording it the software can quickly process the sound by assessing it and managing it. Artificial Neural Networks

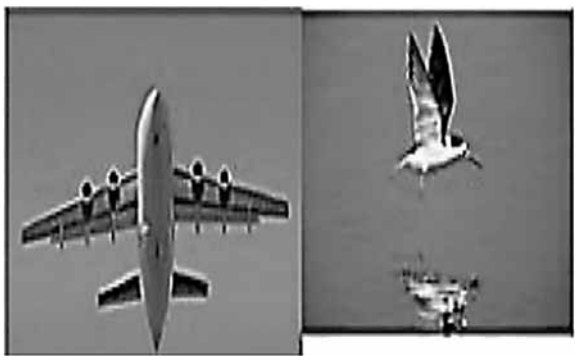
Figure 3. Two hidden objects one in a CAPTYA and the other in a color blind test



As discussed before in this section automata are not an adequate algorithm for defining morpheme parsing. A neural network is a statistical algorithm used in machine learning. It is simple yet effective. Biological neural networks inspire artificial neural networks. Neural networks are adaptable and can self-organize in real-time. They also give fault tolerance. The brain forms the basis of an artificial neural network. Consider the images shown in Figure 4. These are both images of a flying object.

The one on the right inspires the one on the left. They both have two wings and a tail and are both of the same air stream figures. When the inventors like Leonardo De Vinci was constructing a flying machine it very much resembled a bird. Similarly, a neural network is a natural model of a brain (Abu-Mostafa, 2012). It is self-organizing, fault tolerant, and adaptable. We need to build a software design that resembles this working model. Looking at the PyBrain code it looks as though we can and should adopt something like this for our sentence processing sequence. In How the Mind Works, Steven Pinker discusses the benefits of using a neural network; however, linguists need to improve multiple instances of the same object.

adopt something like this for our sentence processing sequence. In How the Mind Works, Steven Pinker discusses the benefits of using a neural network; however, linguists need to improve multiple instances of the same object.

FUTURE RESEARCH DIRECTIONS

I hope to find a feature set to annotate and make computer's speech easier for people to understand. I am working on looking at integrating the Neuromorphic Vision C++ Toolkit, a vision toolkit, with GBBOpen, an open source blackboard system, and Pybrain, an open source artificial neural network framework. I hope I am able to understand the algorithms well enough to port them all to python and so it can run on an Android. Kivy is an open source virtual machine containing libraries on how to write crossplatform python applications. GBBOpen uses lisp and the Neuromorphic Vision C++ Toolkit uses C++. The requirements are an algorithm that processes events in parallel and learns from reinforced learning. A brain can be thought of as a multi-core or quantum computers that resemble neurons. Change blindness as described in the book The Invisible Gorilla, talks about how we long for continuity (Chabris, 2010). However, in this paper I argue that this pattern matching classification is done to overlook elements in sound. Naturally we each have a certain range of activities that go unnoticed. Sometimes this varies from person to person, a common example being tinnitus. Like light, sound is often measured in how it is different from one element to the next such as pitch. Sound appears unified until broken apart by a prism called a spectrometer. This helps us figure out what the light emitting object is constructed and composed of. We are unable to tell boundaries are twofold. First the mind likes unifying patterns into things it can understand and find patterns between two "corresponding" events. This is so we can communicate what it is we saw. This is despite the entropy and separations posed by natural limitations such as quantum mechanics in harmonic wave functions The second reason is pink noise also known as Brownian motion or noise that we disregard as background noise. This is what audiologists call masking and can dampen boundaries between two events in sound. However, I am uncertain that most pink noise is extraneous. It could provide useful clues as to the context of the speech by harmonic analysis and studying representational theory. This can be explored in the study of continuous-time Markov chain. This uses the analogy of how elements combined in a certain way makes a chemical reaction. Grammar is different and cannot be measured by finite states but rather provide a framework of rules for processing. Rather it can be seen as a horde of ants interacting and otherwise affecting their evolutionary walks. Noam Chomsky talked about how rules do not necessarily guarantee a sentence. For example the notion that "Green colorless ideas sleep furiously" is a sentence is simply unsound. David Ben-Zvi uses a concept he describes as the x-games to describe infinitesimal generator matrix by using differentials to study the elements in an evolution of sounds. In my papers I've discussed the benefits of starting to play musical instruments as a younger person (some would argue ideally preschool aged). This is because it raises the awareness and attention of the threshold between two different events musically.

The blackboard algorithm combined with a neural network is a good approach to the complexity of sound. To fully appreciate the significance of each node, we not only need what is preceding it but what is going on simultaneously that give clues about what might happen in the future. In my paper I suggest that one reason people have difficulty speaking is that their mind is not able to function and keep up with everything. In this area I believe computers can excel because as computers become more powerful, they can surpass human's attention spans. The ants marching in a row is a nice picture but seldom

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

happens because of the simultaneous complex world we live in. I am confident that with the emerging field of multiprocessor concurrency and abandoning the idea of having a master core and adopting a system more like the brain of adopting many neurons firing electrical signals would bear success in the years to come. There is a consensus and each core is aware of what is going on.

CONCLUSION

Much work is necessary to give a feature set to describe the spoken natural language. This paper intends to give a framework of how to think of big data as a filter analogous to a prism that a person can see more clearly through and to ask right questions. The paper discusses why examining why people talk the way they do is important. The paper proposes that the Zachman framework and through deducting what a topic is not aid the process. This paper also examines how a human understands language and sound.

SOLUTIONS AND RECOMMENDATIONS

Having a stroke is difficult because part of the brain may stop functioning. This affects the part of the brain that produces language. To counter this, engaging games that target the mind using neuro-gaming which may include augmented reality should be developed. It has been shown that video games and television can change people's perspectives about what words mean. This can be both used positively and negatively and some of the pioneers in the field include advertisers. Some examples of media which helps people learn words include Sesame Street while those who use this power negatively do so for selling products to enhance how people view their body. What I am proposing differs from competitors because does more immersive experiences similar to those played on PlayStation or GameCube. In order for a person to truly exercise they need to be caught up in the passion of the event and forget that they are exercising. It's like the book "See Spot Run" as compared to "Jurassic Park". You can base a movie on Jurassic Park but I think I'd save my money on the spot video. Athletes can get caught up in a sport such as tennis and forget they are working out The people who could benefit from this the most, the people with early signs of memory loss and mentally illness, are the ones who cost is a barrier to using other platforms. Learning should be based on applicable games based on learning. This differs from conventional mind games because feedback is given and expounded not only showing possible solutions but they take the user's attempts and building upon them so they are guided to a solution. The audio clarifier for the phone works during the assessment phase and does not give feedback. MIT Professor Eric Klopfer says a game that much like a spelling bee gives feedback on whether the answer is correct or not but frustrates the participant by making them feel incompetent. To feel competent the participant must be guided towards a solution. The game's purpose is functionality and how it works to assess whether the person knows about the concept and situation which the clear audio needs to be activated to shape the words. The goal is to become more comfortable taking risks.

The part of the brain lost caused by strokes make it necessary for other parts of the brain to compensate. The parts which compensate may be dormant but they still exist. Language is a foundation about how we communicate with others and often is a way of conveying thoughts that are within us. Studies demonstrate that find that people who have somniloquy or are sleep talkers. WebMD finds that 10% of children make utterances in their sleep or when they are in the process of waking up (Talking in Your

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Sleep). When a person is asleep in the past they often thought that the brain activity waves would shut down, however recent studies in sleep found that a person uses the brain as much during the night as they do during the day. Eagleman tells of how a patient had hemispherectomy or part of their brain removed to prevent epileptic episodes. As a side effect, they were unable to create new memories but the memories that they had remained. Sometimes memories are activated during the night, however the part of the brain that determines whether the implications of the dream is not functional. As a result of some dreams perceptions change and sometimes people wake up irritated with another person because of an altered inaccurate perception. However, language can come up with ideas. During the reign of the communist leader Nicolae Ceauşescu of Romania and the results of the way he ran his state-run orphanages made clear our dependency on language to communicate ideas. He wanted to increase the number of workers in Romania to increase revenue into the country. Not only were abortions illegal but each family that did not produce at least five offspring were taxed heavy taxes. As the economy collapsed, the shortage of money caused many families to abandon their children in orphanages. In these state operated orphanages, when there should be three care takers for every 15 kids, there was only one. After the fall of the communists in 1989 the children that were in the care of the state grew from 47,405 orphans in the care of 25,870 orphanages in 1990 to 62,000 in the care of 19,000 orphanages. The caretakers were told not to pick up or show any affection to the kids that were in their cribs because of the fear that should the caretaker show affection to one, they all would want attention and draw the energy out of their limited number of caretakers. In 2009 BBC journalist Chris Rodgers was appalled by conditions and found that the orphans spoke a coarse language they made up themselves with the purpose of communicating among themselves to survive.

What does this have to do with patients who had a stroke? The answer is that human language is a foremost tool in comprehension and our survival. Suskind argues that language is the foremost building block of our education system (Suskind, 2015). Noam Chomsky argues that language is itself innate because people from other cultures communicate in much the same way universally. The book, American English compendium: a portable guide to the idiosyncrasies, subtleties, technical lingo, and nooks and crannies of American English by Marv Rubinstein makes the point that there once was a gap between people of different countries, even American English and British English were distinct while Canadian English were a blend between the two. Because of media this gap has somewhat closed, however many phrases are still based on historic culture. Dana Suskind cites Hart and Risley's study showing people who are more successful later in lives have more interaction with their parents that are memorable because they are positive. The people who did not do so well in life according to their study suppressed negative memories of interaction with their parents which were fewer (Suskind, 2015). Questions arise such as who has memories that are dormant that could benefit most from my study into games.

Games are beneficial because they involve multiple inputs of sensory information and can help people become acquainted with Hebbian learning that is that neurons which fire together wire together. Like many professional golfers who learn through muscle memory, because of the intense thought process behind processing language in both mechanically speaking as well as comprehending the conversation the brain often differs from a computer in that once a pattern is found, the brain goes into autopilot. This is why experts sometimes find it difficult to explain their decisions in a series of rules. While people may think that programmers are unequipped to know what an expert knows in topics on medicine, since they are outside the field they have the advantage of a recently acquired understanding of what they had to go through to get knowledgeable about the skill. Music provides a good example. To a person who began taking music lessons early in life, they are unable to, without some practice; describe to someone

Figure 5. Shows a Tamagotchi pet (credits go to Wikimedia)

how to start making music. When the stroke occurs and kicks the stroke person out of autopilot mode acquired during Hebbian learning. Many of the tasks which seem so familiar must now have renewed thought and concentration to each event as though they are relearning how to become acquainted with human life at infancy. The goals are to take what motivates each gender and age group and helps them become motivated towards their goals. We are fortunate to live in an era of simulation games such as Opensimulator or Second Life. These are like Tamagotchi pets, which limit the input, and makes what is expected easier. For example, the Tamagotchi pet shown in figure 5 only has three buttons and from the context we can simulate the entire lifestyle of a dog or a cat.

Computer programmers are used to the concept of intelli-sense which hints given the context about what the person is about to say. However, it is imperative to make sure that it does not frustrate the person with the stroke.

KEY TERMS AND DEFINITIONS

Artificial Neural Networks: A data processing method in which a representation of the information processing of the brain is mimicked.

Natural Language Processing: A branch subject of artificial intelligence dealing with words as they are spoken and gathering linguistic qualities for a computerized system.

Neural-Gaming: A branch of augmented and simulated reality using a computerized platform meant to benefit the advancement of a human's brain.

Verbal Apraxia: A speech impediment caused by a motor disorder resulting from possible damage in the brain.

Verbal Dyspraxia: A speech impediment caused by a developmental delay.

Voice Recognition: A branch of artificial intelligence and natural language processing interpreting human speech into structured data usable by the computer.

Chapter 72
Research on Human Cognition for Biologically Inspired Developments:
Human-Robot Interaction by Biomimetic AI

Marko Wehle

Alexandra Weidemann
Technische Universität Berlin, Germany

Ivo Wilhelm Boblan
Technische Universität Berlin, Germany

ABSTRACT

Robotic developments are seen as a next level in technology with intelligent machines, which automate tedious tasks and serve our needs without complaints. But nevertheless, they have to be fair and smart enough to be intuitively of use and safe to handle. But how to implement this kind of intelligence, does it need feelings and emotions, should robots perceive the world as we do as a human role model, how far should the implementation of synthetic consciousness lead and actually, what is needed for consciousness in that context? Additionally in Human-Robot-Interaction research, science mainly makes use of the tool phenomenography, which is exclusively subjective, so how to make it qualify for Artificial Intelligence? These are the heading aspects of this chapter for conducting research in the field of social robotics and suggesting a conscious and cognitive model for smart and intuitive interacting robots, guided by biomimetics.

INTRODUCTION

Humans adapted in the former eras of technological progress often to the use of technology, in spite developed by humans, one had to learn how to handle technology via many steps and realise them with caution. Because of technology's pioneering complexity it was not always satisfying the users needs and the premise of safe handling, special training and expert knowledge was often required to a large extend. In the new era control and feedback control systems, also called Cybernetics, take over for handling technology with ease and comfort. The focus on the practical usage of technology shifted in an evolutionary process towards human centred interfaces, e.g. from first computers with command line via mouse input towards touch-screens. For instance, considering people, and even kids, on using touch-screens one can recognise an intuitive usage, familiar and intuitive movements for interactions are easier to accomplish. In addition, sophisticated countries and states have to face the challenge of a demographic transition in their societies, which conditions the vision of service robotics to develop machines to be adaptive in their social behaviour. Meaning, reflecting the environment and being available to different users or user groups and their pleomorphism. A carer or patient interacting with the same device will have perhaps miscellaneous requirements and emphasis for it. Therefore, the research on biological cognitive abilities and confident behaviour, as well machine learning with information seeking aspects, should be considered for developing artificial intelligence (AI) systems. Thus far, it is not a new idea and the subject of mind, consciousness and models of thinking and self-awareness are discussed already since the 16th century, but often in rather philosophical or mathematical semantic ways, because the inside perspective is hard to grasp. Notably the beginning in understanding of mind led to impressive sociological impact, for example by the "Age of Enlightenment". Hence resulting in innovative thinking, which still influences current research and this research is a remaining challenge to science and engineering with impressive progress about the last six decades. Despite the different nature of former scientific contributions, all of the work has one major aspect in common: to achieve the goal of an implementation of artificial thought, mind and consciousness – only an interdisciplinary perspective can provide the necessities and insights from biological role models towards intuitive artificial intelligent systems. With the aim to provide input to the development of intuitive user interfaces and artificial perception, leading to artificial cognition, only joint competence from fields like biology (physiology, cognition), physics/mathematics (cognition, information processing and artificial intelligence), engineering (cybernetics, biomimetics, robotics), sociology (cooperation, synergy of human and technology, as well sociological impact and consequences, ethics), design (materials, aesthetics, appearance), philosophy and arts can identify and display what humans are capable of and what is requested for feasible, useful and intuitive interaction with technology. Research is not aiming only to understand the basic mechanisms of mind by modelling it, also for generating computer models for robot artificial intelligence. So, that machines can interact (Human-Robot-Interaction: HRI) according to the gold standard of intuitive interaction, which is the role model of Human-Human-Interaction (HHI). Thus, empowering the robot with consciousness to be willing to learn, for adaptivity and its gain for autonomy and persistence as a service tool, able to tackle unknown tasks, changes of plans and at least mimicking HHI in HRI.

Reciting that "Biomimetics combines biology and technology with the goal of solving technical problems through the abstraction, transfer, and application of knowledge gained in interdisciplinary co-operation from biological models" (Bionik, 2012), the human could be the quasi-role-model for the robot. This is correct insofar as it is assumed that biological structures have been developed in the course of 3.8 billion years of evolution and are optimised under the given conditions in mutual dependency

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

with the environment. Now synthetic consciousness can be a useful concept for implementing intuitive HRI, despite the term consciousness somehow evades precise definition and the debate about it should be left to others, it is a concept for combining different ideas of modelling AI in robotic systems to gel intuitive and adaptive behaviour in AI. The question that rises therefore beforehand is, how can a human being, due to its biological and cognitive abilities, interact intuitive and modest? Given the biological role-model – the human – and its failsafe operation as an outline for biomimetic developments, it is important to study the processes of subjective perception and their application, to exploit the comfort zone of people for optimal interactions.

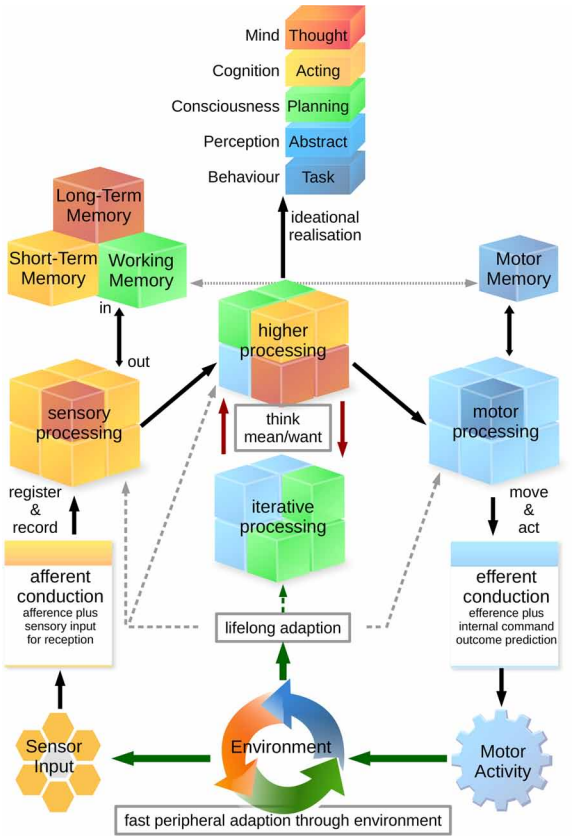
Consequently, robot developments are driven by the similarity of how we perceive the world through our senses to solve all the different tasks we are able to accomplish – so robots should receive the same information with their sensors and process it via adaptive artificial intelligence. The sensors absorb signals and transmit them to the robots controller. Sensors are available for a variety of measurements of changes in the environment in a variety of forms. The sensors of the robot can perceive even a wider range than the physiological senses of nature, but robots are limited at seeing the natural environment by their processing. Because the "brain" of the robot would be faced with the complex task to reconstruct images from the jumble of lines, shadows, and flitting spots of colour that are recorded by cameras and giving the input a meaning. The tactile sense as another example is a vast challenge for developing robotic hands which can tackle a variety of tasks as human hands do. The options in technology are more comprehensive as in the physiology of a human, but millions of years of evolution and adaption lead to a filtering process, which would remain to the engineers and programmers for the developments. In addition to give robots the necessary autonomy for operating, planning tasks and mission accomplishment, they have to be aware and their artificial intelligence has to lead to an embodiment for the interest of managing resources and given priorities in tasks. Nevertheless, there is also a catalogue of interests in AI developments for intuitive Human-Robot-Interactions aiming for social robotics, in summary, setting up clear and humble standards for common Robot-Human communication and interaction aspects, which can help to guide future developments. The acceptance of social technology and its impact in society – to be secure, fair and in the favour of most, should be improved by following a biomimetic approach and some basic questions:

- How can a robot act accordingly and adapt to a human being to achieve a simple and convenient interaction?
- What are cognitive capabilities, skills and limits of humans, theoretically, to mimic HHI in HRI?
- How can anticipation, support and help for preventing frustration in HRI?
- What are technical options for sensor fusion, artificial intelligence and perception modelling?
- How can privacy and as well data security be assured?

In order to elaborate these questions, HRI is in research a flourishing field, because the challenge is to overcome certain barriers for intuitive interacting AI by setting humble standards and a baseline for training an AI machine, the rest is, in an ideal case, left to adaptivity. The reasoning behind this is, that programming an open world and complex social behaviour may take infinite time and may never converge due to changes, caused by mutual interaction with the environment. Especially the process of decision making in unknown terrain and in adaptive interaction situations is a progressive problem.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

BIOLOGICAL ASPECTS: ROLE MODEL FOR ARTIFICIAL INTELLIGENT HRI



New technologies will to be developed in participative manner, eventually: through intensive HRI research by the advantages of video analyses, as well evaluation of user behaviour and comfort via social cues. Innovative non invasive measurements of physiological aspects, like monitoring skin conductance, gaze tracking and heart rate, blushing, speech analyses and analyses of questionnaires can help in order to establish a baseline. There are manifold biomimetic aspects for artificial intelligence to be considered and phenomenography is a powerful tool to classify most aspects, which will become goals in technology developments. As a starting point to layout an implementation, rather physiological aspects provide key aspects, for instance sensor-fusion and neural network dynamics lead for information integration, prerequisites for error correcting approaches, conscious information processing and weighting for output, in the end this progresses to decision making and interaction. But in the first instance, the window to our world is provided and in the same time limited by the physiology of our senses. In order to perceive and interact with our environment, we need constant feedback. Humans receive information in the order of magnitude of a 10^9 bit/s through our senses; only 10^1 – 10^2 bit/s are added and processed consciously. The remaining information will be processed subconsciously or filtered to be not used. Conversely, we generate, for example by speaking and motor information about 10^7 bit/s towards the environment. Figure 1 displays the interconnection between perceiving of and interacting with the environment for an embodied intelligence.

The neurobiological hypothesis behind these schematics in Figure 1 is the model for explanations of higher order mental activities. Assuming that humans perceive their environment and register it via multiple over the organism distributed sensory cells. The sensory processing within the cerebral cortex delivers information to the working memory and as well the long-term memory (LTM). The higher order processing and the motor processing can convert signals in fast movements, while the motor memory is delivering therefore already manifested excitation patterns towards the motor active neurons. Additionally, before higher level processing, contents can be iteratively processed in cycles, for the purpose of temporal extended thought processes. Motor active aiming and thinking corresponds here, with what is considered as will. Intensive, sufficiently long, vehement thinking results in ideational realisation or consciousness. Appropriately induced actions will be recognised as consciously triggered. The actual consciousness will stay without repercussion, in the sense of physical compatibility.

Generally we perceive our world with 5 senses, but for HRI especially the 3 senses for vision, acoustic and tactility are considered to be important, so to be focussed for developments. The stimuli of the environment affect the body in various forms of energy, like mechanical and electromagnetic waves mainly. In the sensory organs, there are specific receptors and each sensory cell has its adequate stimulus which causes for each stimulus a specific sensory impression. Within one sensory modality (vision, acoustic, tactility) the different qualities of a stimulus can be distinguished by quantities like intensity and frequency, e.g. sound or light. For instance, the optical sense provides alone and very fast about 80% of information of the surrounding, thus constitutes the most of our perception. This is accompanied by the acoustic and haptic perception. While in principle perception is indirect, meaning the stimulus information is passed to the appropriate areas of the brain via the thalamus as a hub, thus filtering the amount and distributing the information. The specific regions communicate with each other, they decode the previously encoded information from the sensory organs and discern the information. But of course it is the composition and conscious reconstruction of information that provides us an overall picture and most important gives rise to a meaning for information. Also a human being is confronted with a lot of

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. Organisation scheme for AI in operational architectonics mimicking biological paragons

information that cannot be recorded and processed. Therefore, the selection of information passed is of utter importance and already begins in the sensory organs, e.g. target selection cells in vision, additionally filtering processes occur in further certain regions of the brain. Remarkably, the brain can shift individual perception fractions on the timeline, which in turn assembles perception performances and fills gaps in perception. For continuous, gapless perception the brain has to manipulate our perception of time in the performance. Perception is also a memorising process, by storing patterns of perception, and depends on our attention.

Perception leads to neurobiological consciousness and cognition, the localisation of consciousness is thought to be shown in large cortical areas of the left brain half, additionally support for the consciousness is given by input from the hindbrain, anterior to the cerebellum, seen as the stem of the brain and towards thalamic structures. A signal is retrieved as conscious input by signal propagation time of more then 0.5s and so to say is conversely a processing which is extensively carried out in the human brain, also called cognitive processes (Pfützner, 2014). Nevertheless, a healthy human is always seen as conscious while being not in a coma or deep sleep and therefore consciousness is a central aspect of our life and in interactions as well. Consciousness is fuelled with perceptions and memories giving meanings to our cognitive processing. As several definitions for consciousness arise, they all share the activeness of thought (Koch, 2013):

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

- Respective to our common sense, consciousness is equal to our inner mental life, consciousness appears if we wake up in the morning and is present till we fall asleep (not dreaming), it is present if we dream and disappears if we are in deep sleep, coma or being under general anaesthetic, death makes it disappear forever.
- On the basis of behaviour is consciousness a checklist of actions or psychology, which rates every organism as conscious that can achieve at least one of them (Glasgow Coma Scale).
- A neuronal definition describes minimal psychological mechanisms, which are necessary for conscious perception, an active and functioning cortico-thalamic (or thalamo-cortical) complex (neocortex and thalamus appended by hippocampus and amygdala, basal ganglia and claustrum).
- In philosophy, the general definition is that consciousness is how it is to be like something. How does an experience feel like if it is perceived by an organism and only this particular organism can know how it feels, if it has this experience (phenomenological consciousness).

In cognitive sciences, consciousness is also linked with information process theories, meaning that information exchange between regions of higher order in the visual cortex and the planning stages of the prefrontal cortex are perceived as conscious. Supported by the model of "global radiation", which states that data in a workspace is available to a number of underlying or subordinate processes (working memory, speech, planning module, etc.) and emanating information makes them conscious. Hereby is also worth noting the consideration that the workspace is rather limited and information is rivalling, so information can get expelled. However, conscious information is therefore accessible as a unity and globally for the whole system. Physiologically this is achieved by weeping pyramidal cells in the prefrontal cortex and from this follows the creation of the global workspace. Information theory is often used in this context as a mathematical formalism, which can quantify the causal interactions of each part of the neuronal system. It describes how much a status of each part influences the status of the other parts and how this influence develops with time. Also, it categorises and characterises therefore the interrelation between all components of the system, which is seen as a unity comprised by its components. Consciousness is not an accumulation of bits, it is not about culmination of data, it is rather the relation between those bits. The architecture of the neuronal system, its inner organisation, is crucial for consciousness. Another refinement of the model is the so called "double aspect theory" retrieved from philosophical monist theories, but still considers a distinction between mental and physical aspects. Which concludes that information of two originated states with inherent and elementary attributes exists divided into extrinsic and intrinsic states, whilst the number of discrete states positively correlates with the repertoire of conscious experiences/apperceptions. Centre point is as well the integration of information, each apperception is especially informative and specially differentiated and conscious states share the attribute of integration of information. Each conscious state is a monad, but it cannot be disassembled into its single components anymore, which could be independently experienced (Tononi, 2004). The quantity of conscious experiences, which is created from any physical system in a certain state, is equal to the amount of integrated information of these states, plus the information generated by its sub-entities. As integrative step, the system has to discriminate between the states within the repertoire of states, acting as a unit – the system cannot split the information into a collection of causal independent parts anymore. For instance, in a split-brain patient live two independent conscious units, each with information independent from the other hemisphere – the integration of information is for the brain as a whole unit unachievable.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Consciousness is assumed to be equal to the content of short-term memory (STM) and long-term memory (LTM) (Thompson, 2010):

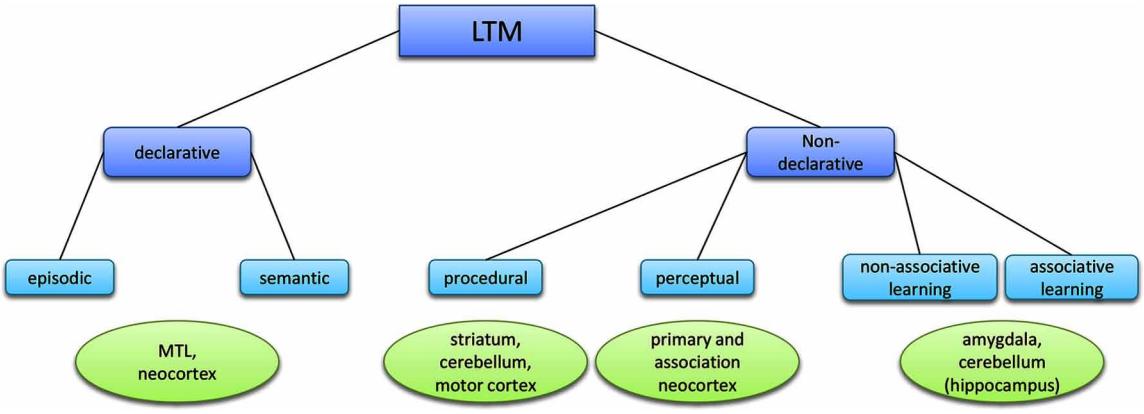
- Consciousness plays a key role as necessity for cognition and cogitation.
- Conscious experiences appear as apperception – if attention is paid to the senses.
- Self-consciousness includes the moment/situation.
- Consciousness spreads with perception over time (past) for aspects of experiences and knowledge.
- Memory of knowledge, experience and skills in the long-term memory can be retrieved from the subconscious mind.

Recalling consciousness as a process which is applying numerous feedback loops regarding different parameters (e.g. temperature, space, time and in relation to each other) to create a model of an environment, mainly to attain aims (e.g. procreation, survival, food, etc). Biologically there is a classification of consciousness in its peculiarity (Kaku, 2014):

1. **Stream of Consciousness:**
    a. Mobile organisms with a central nervous system have a so called stage-1-consciousness, because they require a set of parameters to register their changing environment (e.g. reptiles, they possess hundreds or more feed-back loops which regulate their senses of smell, balance, tactility, hearing and vision, blood pressure etc., with individual feed back loops in the specific brain areas as well). The human brain roams sensory information through the brain stem (Truncus encephali), passes the thalamus with pre-processing and filtering, reaching eventually several areas of the cortex for further processing and will be passed to the prefrontal cortex. This processing results in our physical position in space.
2. **Sociological Rooting:**
    a. Organisms which not only possess a model of their location, also a relation to other organisms (social beings with emotions), have an exponential increase of feedback loops with a correlating complexity of behaviour. Therefore, creating a model of a position in a "society", which is depending on the establishment of brain structures in the limbic system, whereas the limbic system consists of the hippocampus (long-term memory), amygdala (centre for emotions) and the thalamus (relay station/hub for sensory input). This system issues new parameters to refine models for the relationship to others. In the human brain, emotions will be created in the limbic system and processed there, in the framework of the stage-2-consciousness the brain is confronted with a constant stream of information from sensory input, but emotion are the fast reaction of the limbic system on a situation, for instance the fastest in emergency situations, which even neglect an authorisation from the prefrontal cortex. The hippocampus is crucial for the contribution and the digestion of memories. Mirror neurons will therefore also play a role for emulation and for empathy and raise the ability not only to mimic complex processes, also to empathise with others.
3. **Simulation of Future/Prediction of Outcome:**
    a. If an organism reaches stage-3-consciousness, the number of feed-back loops is tremendous, so that no supervision is needed for filtering incoming data, in order to simulate future outcomes of situations and actions, so that predictions can be made in order to make decisions. With this model of the world, simulating future, causalities are connected and form a tree of

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

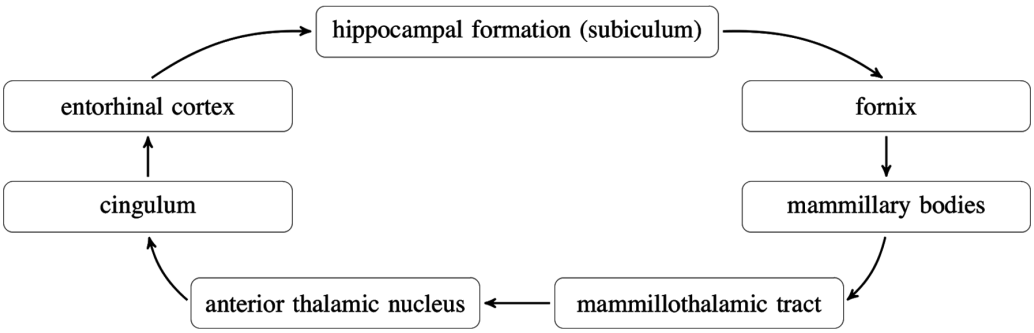
causalities (or a decision tree). In the human brain, the key aspect of stage-3-consciousness is formed in the dorsolateral prefrontal cortex, which is assumed as the most recently evolved part of the brain, it conveys between the orbitofrontal cortex (decision centre) and nucleus accumbens (centre of desire) and serves as a working space of mind.



Deducing that in order to feel experiences; consciousness and cognition, the presence of information in short-term memory as a workspace and stored information from long-term memory is needed. Because the short-term memory is limited in capacity and memory, the persistence ranges from a few minutes towards 24 hours, new content is extruding older information. The long-term memory is described as a selection of information, which are filtered and consolidated from short-term memory by repetition and learning. Whilst all information, once attained in the long-term memory, are permanent and pattern regular memory trails, so called engrams, which facilitate remembering contents by biochemical connections/processes. Figure 2 summarises how the information storage is classified in the human brain in terms of memory aspects.

The Papez-circuit, see Figure 3, is thought to play a major role for information exchange between short-term memory and long-term memory, since experiments and observations have shown that damage of some of the involved parts can result in memory and language impairment. Repeated passing of the circuit can lead to information transfer from short-term memory to long-term memory, while this is also thought to be a cause of dreaming for long-term memory consolidation.

How the memory consolidation can be depicted in a schematic way is shown in Figure 4. Additionally, the instance of the iconic memory is a mainly visual sensory memory and part of the short-term memory, it is thought to be a domain which quickly records apperceptions from senses, e.g. a face or a scene, and is able to transfer the information more or less directly to the long-term memory.



This organisational scheme from Figure 2 depicts the idealisation for interconnections between networks forming network complexes, additionally it shows an idealised hierarchical assumption for the long-term memory (LTM) as a top level memory entity, which is a naturally inspired assumption for supporting a global workspace theory and instantaneous memory access for all processing brain structures. Cross-connections are not drawn but biologically evident. (MTL: medial temporal lobe).

Figure 2. Hypothetical memory organisation scheme in a human brain, different types and aspects of memory (in blue) are connected to their associated brain structures (in green)

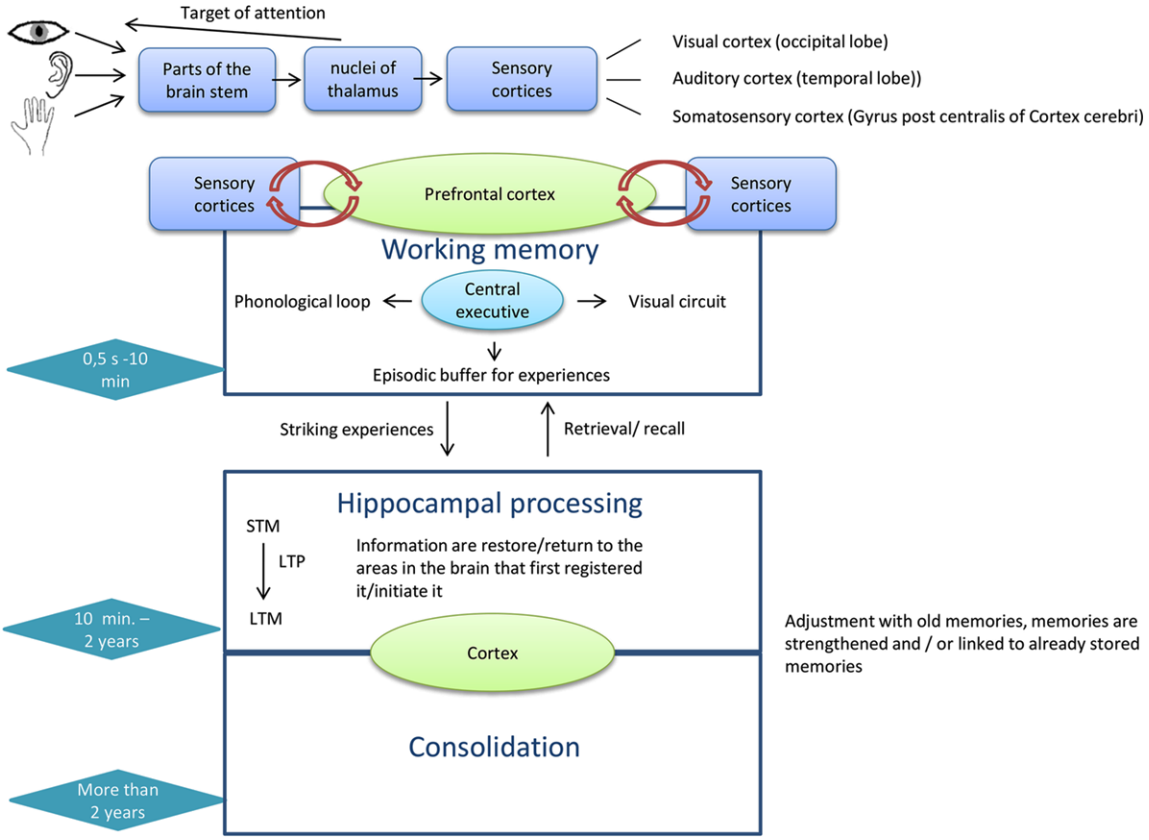
Figure 3. The Papez circuit with information flow in circular manner between the brain entities involved



Some fragments of information still stay in the short-term memory and are available for the working memory. Are these information new or respectively motor skills and they are not practised, only a part is transferred to the long-term memory and most of it will be lost.

The schematic memory layout from in Figure 4 shos sensory information, which also includes procedural knowledge (like learned motor activity), is taken up, filtered and moved through parts of the brain stem and kept temporarily for short time with full detail in the working memory (seen as sensory or iconic memory), for processing the information. Further processing and association of a part of these information reaches the short term-memory (STM), for instance by paying attention to it, which gives it importance for the brain after a certain timespan forming spatiotemporal patterns and when these patterns are seen as relevant, the hippocampus repeats and loops those patterns in the consolidation process to combine these information containing patterns with associated memories for long-term storing. (LTP: long-term potentiation).

Long-term memories are conserved in a formation of groups of neurons, which fire in the same pattern as the original experience was represented. "Complete memories" are divided in components (emotions, sentiments, thoughts, etc.) and in each case distributed to be stored in the competent or relevant areas of the brain. The simultaneous firing or activation of these groups of neurons represents these memories at large (Carter et al., 2010). Attention ($t \sim 0.2s$) arranges neurons, which register the event to fire more frequent, this increases the intensity of experiences and in addition increases the probability to memorise this event. The thalamus regulates therefore the brain activity regarding the aim of attention, whereas the frontal lobe filters information to increase the attention span by averting possible diversions. Sentiments or feelings ($t \sim 0.2–0.5s$) are perceived through combination in associative areas. This especially happens within the memory consolidation process in deep sleep (delta-sleep), while information gathered throughout a day are absorbed, assigned and partially presorted, during the sleep phase it will be finally sorted and partially deleted, otherwise consolidated. Storing learned contents and consolidation of knowledge happens during these deep sleep phases, the brain combines subconscious and parenthetically recorded information to new knowledge, at the same time learning is conducted, the brain also subconsciously solves problems and combines knowledge to ideas. In the wake phase recorded information will be stored temporarily and is so recalled for long-term memory consolidation. Facts, which are connoted with emotions, remain easier in the memorising process and are known to last longer, because their activation patterns are much stronger. Presorting and filtering of importance of information is thought to be carried out through a process called "tagging", this process can be influenced and emphasised by emotions (Born & Wilhelm, 2012). Important information is tagged through gathering and perception,

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 4. Schematic layout for memory consolidation processes

while standing in a context, these tags support memory consolidation during sleep phases. The paradigm is also seen to be valid for premeditatedly recorded information (motivation aspects), which are correspondingly tagged. Since the brains memory consists out of many different systems, the central hub hippocampus processes information, for instance information is filtered, valued and compared and passed on to the long-term memory in the cerebral cortex. Different kind of memories can be stored in different systems, for instance is in the cerebellum the procedural memory, perceptual memory in the cerebral cortex and factual knowledge is located in the left hemisphere of the brain.

The human brain is subject of massive stimulation in every second being conscious and it can not only rely on filter processes in “bottom-up” approach, this information processing also has to be carried out “top-down”, in order to select relevant information from the massive amount of stimuli and experiences. Events can be even predicted from experience, touching, scent, taste, the brain constantly and continuously processes information and makes predictions from this. Consequently, if the predictions become reality, the brain can discard the information processing and dismiss the information, because the implicit knowledge about the event is already present. If the event causes a “better than” signal in perception, learning will be triggered and only this can cause an organism to adapt its behaviour over time for optimisation. Learning is by this means not everything what is perceived, rather what is perceived with positive repercussions (Spitzer, 2002).

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Individual perception of self is also a result of a distinction between objectivity and subjectivity. Objective results require review by measurements without human influences like emotions or feelings, whereas subjective results are influenced by involvement and estimates like taste, memories and associations. Objective reality engages with life, how humans perceive reality and with the construal of coalesced personal experience. While subjective perception is different for each individual (senses work different, matching in standing by memories is different etc.), but still comparable, because individuals have comparable apperceptions and use learned expressions from extrinsic input. Consequence is, that an objective reality which is perceived remains objective, apart from the individual independent character, because humans interact with objective reality and explore it as a subjective extract, while this is than subjective reality.

SILICON DEDICATED TO CONSCIOUS HRI

Now, rather than to simulate a brain in order to conduct research on its processing, the aim is to emulate attributes of higher order processing for an implementation in an AI structure. Therefore, not the entirety of physiological and biochemical attributes has to be re-created, but individual aspects of those can be implemented for benefit, e.g. for a reward system for learning or achieving an aim, or even empathy in HRI. Before starting to model any ideas about AI architectures, the division of tasks concerning the aspects of filtering information and processing information on different levels has to be tackled. The term consciousness is here a vehicle to operate with subjective entities to address questions about information processing.

In cognitive sciences and philosophy, the ability to abstract from information and changing the level of representation of information is an alternative way to distinguish between unconscious and conscious states. From hereby inspired modelling attempts are preferably symbolic representations of artificial intelligence and therefore efforts to refer to knowledge representations which are suitable to express human expertise. Whereas in neuronal networks these representations are covered within patterns in the network activity, here the knowledge is depicted in data structures following rules of causality and association, which is emphasising multiple levels of representation in perceptual information processing.

In terms of a better scientific understanding, the questions what is the nature of consciousness and if a machine can be conscious will remain idealistic to be answered and may in present research not even converge to unfeigned machine consciousness. But imitative consciousness and essentially approaching machine autonomy by awareness can be tackled; despite the lacking definition of the terms (Rosenthal, 2009). Therefore, neurobiological findings will serve as a layout and biomimetic inspiration for technological developments. Neurophysiology provides the insights of neural architectures and the operational partitioning thereof, these insights are often obtained by electric field and imaging experiments, which obey an analysis in contrastive manner. The brain activity is monitored as patterns during events in the experiment, a distinction between conscious and unconscious states is possible, for instance given under laboratory conditions making a test person aware and conscious about a briefly seen written word or not, obtaining the outcome that patterns of conscious brain activity are monitored only for subjects perceiving the written input, called the “attentional blink” (Dehaene & Naccache, 2001).

Consciousness may be the product of carefully balanced chaos.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

This statement is displayed in the context of a biological study to reveal the importance of "cortical integration" in maintaining consciousness (Tagliazucchi et al., 2015). This means, in the current context of AI modelling, the processing and combination of multiple inputs from different "senses" at once. Whereas the fact if consciousness by itself is subjective or objective is rather philosophical, the division between conscious and unconscious processing can be made, and is even measurable (Tagliazucchi et al., 2015). Most of the experiences for humans are created by the complex intertwining of several sensations like vision, smell, touch and the reminiscence of previous experiences with the same object, for instance of a fruit. For this, the brain is merging all the inputs into a subjective experience at once, whilst consciousness is creating a meaning for the sensory patterns conceived by exploring the spatial patterns in the brain. It has been concluded that, in the brain, a well-balanced and optimised connectivity between neurons creates a large number of possible pathways and within this network of neurons consciousness might appear by exploring the network meticulously. These experimental results agree with the theoretical lead of information process theories, that a physical basis for awareness is achieved in a complex active system with conscious memory, which can be seen only as an integrated and unified system of specialised compartments for processing. In this respect division of labour, distribution of tasks and parallel processing is implemented and complex network dynamics provide an overview for pattern formation, to preserve integrity of procedural information processing as well representation of declarative knowledge. But also like suggested in Information Integration Theory (Tononi, 2004; Koch, 2009), the largest number of pattern forming arrangements is not necessarily implying the maximum connectivity between neurons. Because the signals need to be distinguishable and the cortical circuits also flexible, the arrangement of the patterns is what is thought of as driving consciousness.

Despite facing a line of philosophical implications within consciousness research models and each one driven by different objectives, a categorisation of model systems can be undertaken by some central attributes of concepts. In summary there is a distinction of models with global workspace, or integrated information, or internal model of self, or higher order representation within the abstraction of represented contents, or attention seeking and exploring mechanisms, these fundamental criteria can help to classify different models, as long as the particular criteria is central for the modelling approach. Of course, the listed features can overlap and applying criteria like qualitative-ness, subjectivity, sense and notion of self, unity, etc. and behaviour measurements on humans like the Glasgow-coma-scale, do not necessarily contribute to overcome the problems assigned to machine consciousness (Reggia, 2013). Several attempts to model synthetic consciousness are carried out and they were carefully realised in the context of information processing aspects of functional consciousness, not as any kind of subjective experience. Because the emulated aspects of consciousness within its assumed neuronal correlates are modelled by the help of computational methods, like it is done in many fields, for example enzyme-ligand binding or even activity and reaction transition states and nobody would expect this reaction even to happen in a simulation, as we would not put the substrate into the computer and expect the product of the reaction as physical entity coming out. The expectations are indeed not so high that machines develop phenomenological consciousness to be present, but simulations are evaluated in which sense they can reflect experimental correlates and in particular how they can help to improve artificial intelligent systems in functionality.

Substantial for a consideration in modelling a neurobiological layout are a few ideas, for instance is the biological role model here seen by the raise of global distributed neural activity in the brain via global patterns. Where the brain is seen as organised in a global network of specialised processing units organised in subnetworks like sensory input processing, motion control, learning and mainly working

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

on an unconscious level, but giving raise to consciousness as a unit by the means of a global information processing. This high level of interconnection and cross linking enables spatiotemporal patterns from modules to be spread globally and accessible for any mental state, if conscious (Baars, 2002; Baars et al., 2003; Massimini, 2005). The ideas for those theories are vastly inspirited by the "global workspace theory" of Bernard Baars (Baars, 2002, 2005). Several modelling attempts have been carried out in computational manner, for example with "IDA" (Intelligent Distributed Agent), which is an assembly of Java "codelets", a later version even is able to learn ("LIDA") and given a self-model too (Franklin & Patterson Jr, 2006; Snaider et al., 2011). Rather than a neuronal network, these program fragments are specialised on their tasks and executed in parallel as modules, but communicate via a global workspace. Other models show a stricter structure of neuronal networks, even incorporating biological relevant features like models of spiking neurons and explicit oscillatory behaviour. For instance, the "stoop" task model has been showing to simulate the "attentional blink" (Dehaene et al., 2006; Raffone & Pantani, 2010). Also robotic implementations have been tackled for a global workspace model to control a simulated robot with approximations of the concepts of consciousness, imagination, and emotion (Shanahan, 2006; Shanahan & Baars, 2005). While some of the models are made for simulating consciousness, they all show the significance of a global workspace approach, inspired by and taken from biology, to create instantaneous consciousness based on experience and empirical knowledge. The global workspace processing is collocating the subconscious processing done in specialised parts of the brain where local processes are carried out. To premise up on the global workspace model and additionally getting an idea what the global workspace is, one might assume that consciousness is correlated to the utilisation of information integrated in a system. For instance, realised in the concept of a neurocontroller for simulated robot vision (in order to make it "attracted to positive stimuli"), information integration based predictions about the conscious states of a spiking neural network (Gamez, 2010) were achieved. The evaluation of this trial was carried out by a measure of φ. Information integration theory (IIT), in contrast to others, already enables a quantification or measure for consciousness of a system with its number φ, which can be useful as a concept. Unfortunately, to compute this aspect is prohibitively computational expensive, so that for the experimental implementation only an approximate and more efficient algorithm could be applied (Gamez, 2010; Tononi, 2004, 2008; Tononi & Koch, 2014).

Further progress has been made for a first person perspective with self-awareness, in the frame of an internal self-model. As a necessity of conscious mind, the basis for the first person perspective is a neuronal representation of body properties in the brain, even if somewhat scaled and referred to as cortical homunculus which is a physical representation of the human body and this neural mapping can be even distinguished between a sensory and a motor representation. This aims the so called "body image": a modelled idea of the sensory-motor cortex (Bongard et al., 2006). A self-model in artificial intelligence, or even one step further as self-awareness, is more than helpful for a machine to support its way towards a first person perspective. So the aspect, which is central for a biomimetic approach, is the embodiment and the robots awareness of its extremities, to learn motions and to adopt within executing physical tasks. Moving away from a central controlling system upon which all sensors, actuators and limbs depend, provides the opportunities to outsource computation to the body and the environment in order to help to abstract information for higher integrity and to take advantage of ontologies within AI systems. This so called *morphological computation* is a notion of soft robotics and uses the capabilities of materials to effectively carry out computations and sensorial tasks through their properties of elasticity, viscosity and compliance (e.g. electric sense, magnetic fields, shape change). In physical robots this can be achieved by sensory data processing and morphological computing in the limbs, which can be

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

used to classify the input towards concepts of data and the concepts will be passed on to a higher level of processing in symbolic representations of causality (Chella et al., 2008; Chella & Macaluso, 2009). Additionally, soft robotics actuation and persistent autonomy can pay off together in energy harvest, simplified control, safer HRI and extending the robots endurance (Lane, 2012). While in addition, the use of special distributed neural network architectures helps to minimise computational effort and to ensure maximum efficiency. The virtual representation of a machines physique as approach for embodiment is ingeniously for autonomy and mobility of robots nevertheless and therefore a must have in an artificial intelligent robot.

Other vital functions, for instance plasticity in recovery states of a machine for memory consolidation can be even essential rather than plainly advantageous. A necessity for this idea is the phenomenological abstraction of perception and a hierarchy of operations for spatiotemporal pattern representation, which will also serve the purpose of instantaneous information and memory access. This is quite significant because the implementation of artificial intelligence, and therein contained aspects of perception and memory processing of information should lead to a synthetic knowledge that is useful for the perception of the environment and, accordingly, for integration into it via embodiment. In this respect an implementation does not mean seemingly autonomy by image processing, classification and conversion of observations into coordinates, the aim is to achieve interaction and communication with the user. In addition the technology should be participative to achieve a maximal acceptance, even if a convergence towards 100% is unrealistic. But exploration, guessability and willingness to learn should be integrated into the system, so that the robot adaptively follows the users behaviour. By stages, the exploration and attention of an artificially intelligent system can also be driven intrinsically by conscious awareness to fraction input streams of visual and acoustic data, while filtering of information is mainly thought to happen in subconscious areas of the brain. So, consciousness and attention are not synonym, but definitely linked and highly correlated. A valuable side effect is that, attention mechanisms are useful for exploration and learning in machine behaviour, driven by information gain to base decision making on machine experience, whilst learning can be reinforced due to positive reward, like modelling neurotransmitter distribution etc (Distefano et al., 2015).

In the often studied role model for human cognitive developments, children development, it is observed how an organism can learn to discover its own physical role in the environment, interact with objects and establish social behaviour. These studies show the basic mechanisms of organisation and progressive learning by increasing complexity of processes and interaction, while the connection between brain and physical body is networking with respect to the physical and social environment. Aiming the reproduction of such role models in robotic developments is helping to understand the basic mechanism not only further, also it raises the opportunity to mimic the progressive learning curve for social interaction in application for HRI research (Nguyen & Oudeyer, 2013; Oudeyer, 2013).

The perpetual dialogue between social studies and engineering can build up research to robots which are learning by watching and exploring through curiosity and can make use of their developmental trajectories to self-organise and discover the physical world by their physical attributes, estimate the functionality of an interactive object by visual recognition and as well the ability to communicate. This technology foresight ideally enables AI structures to be primed by limited training for social common sense on an established baseline dataset and afterwards to structure its own learning experiences, creating its own sets of skills, for instance manipulation and handling of objects, by specialised application and depending directly on its environment towards increasing complexity of its sensorimotor capabilities.

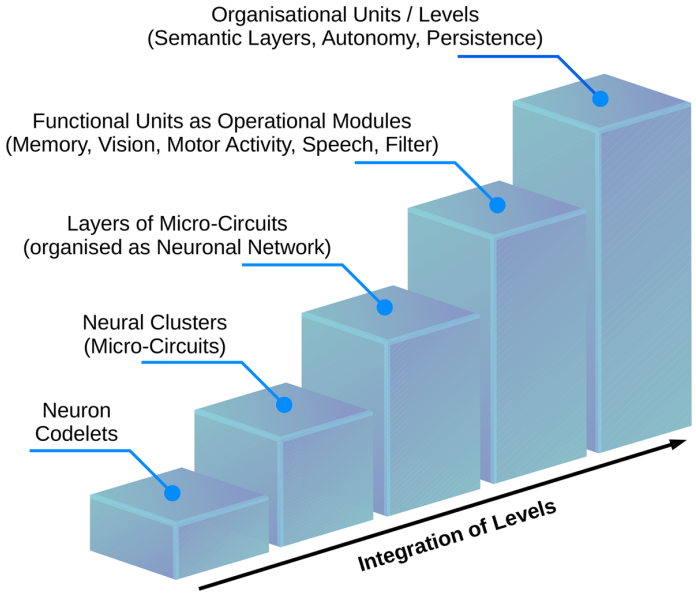
Modular Artificial Intelligence on a Pseudo-Biological Layout

In order to link biological input and developments of robotic AI technology in a bottom-up approach, following the course of

Kinematics → Dynamics → Phenomenology (Taketani, 1971)



This course can help to avoid first hand implications by aiming for synthetic consciousness. In the current context this hierarchy of physical principles is motivating to model a structure of causal connected small entities, which will form an AI connected to the physical world in the end. In order to follow the lead of biological role models and applying biomimetic layouts, but not mimicking low-level neurophysiology, the modelling approach is summarised by the guidance of the Operational Architectonics Theory (OA) (Fingelkurts et al., 2012), and it describes the higher level features of machine consciousness in a hierarchical operational framework. In contrast (Fingelkurts et al., 2012), the term operational modules includes in this chapters context, additionally to spatially and temporal organised patterns of brain activity, the organisation of higher level features abstraction of information processing and perception. To start from the bottom, again a fundamental biological fact supports the idea: the brain is divided into functional units (modules) which each developed evolutionary a specialised functional architecture, but it is always to be considered as a "whole" for the preservation of "integrity of procedural information processing". Thus, the revised idea of OA can be extended with modularity in AI aspects by implementing functional units for task distribution and parallel information processing capabilities to aim for autonomy and persistence in robotics. Necessary phenomenological abstraction and a hierarchy of operations are thought to represent spatiotemporal patterns, which ensure the immediate exploration of information for their instantaneous access. This does not only offer new functionality in the processing of sensory data, it is in many ways connected with feedback about changes in the environment and even the impact of actions by the robot itself. In principle, this allows also for predictions of an outcome of an action through internal simulation of action sequences. The basic idea is illustrated in Figure 5 as integrated hierarchy of operational units.

Nevertheless, a neurological or anatomically inspired path still has to be trodden, in order to embed all phenomenological contents in a unified three-dimensional spatial coordinate system. A possible implementation aims consequently for flexibility by using different types of neurons in the network formation, e.g. an opportunity is provided in codelets (Franklin & Patterson Jr, 2006; Snaider et al., 2011), which can form an artificial neural network (ANN) by a bottom-up hierarchy via small recurrent networks organised in microcircuits over local networks of microcircuits (Local Area Networks (LAN)) as intra-cortical layout, which organise functional units and level up towards corticocortical connections as interconnected LAN's forming organisational units.

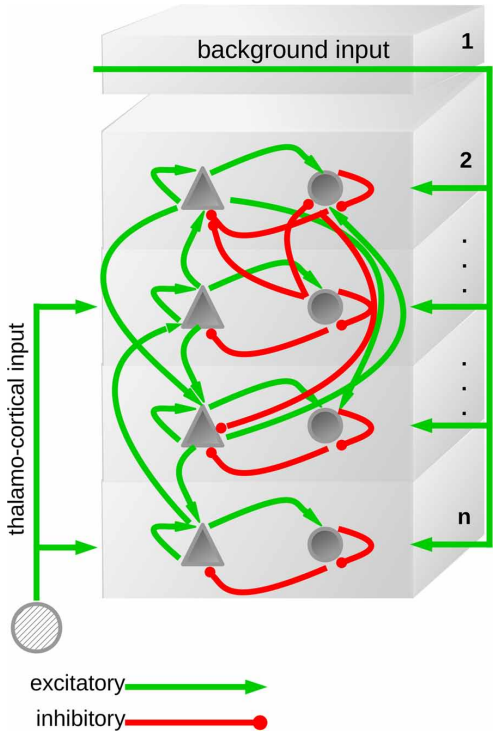
Specifically, for an implementation, one can consider the small recurrent neuronal circuits inspired by the neocortex, the so called microcircuits, see Figure 6. This layout is suggested for an implementation, since in the neocortex the encoding for nerve impulses and its circuitry is one of the key aspects for the brains processing capabilities. Basis for the biological computing is the recurrent connectivity and the major aspect of inhibition in the connections, which leads to the formation of dynamical spatial networks already in the smallest scale. Biologically not all the mechanisms in inhibition are well understood, additionally the classification of inhibitory cells follows a non-standard terminology and this is complicating the situation also for modelling these aspects. Because there is no clear distinction between the differ-

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 5. Organisation scheme for implementing an AI following the idea of an operational architectonics hierarchy by mimicking biological paragons

ent types of inhibitory cells and their connective specificity on subregions of their target neurons, most modelling attempts usually use only general inhibitory neurons for their tasks. But what is known can be helpful and used for modelling inhibition in cortical circuits. Of all cerebral cortical neurons about 15% are inhibitory and there exist about a dozen morphological distinct types (Douglas & Martin, 2004). It is inviting to assume the existence of specific spatial grids formed of inhibitory neurons, embedded in the complex lattice of excitatory neurons. But the actual distribution is mainly organised in boutons[1] of inhibitory neurons and is rather dense and local. The lateral axon extension is usually not more than 0.5mm, in comparison the excitatory neurons form less dense local bouton clusters with more exceeding lateral projections (Binzegger et al., 2007; Douglas & Martin, 2009). Observations for different types of inhibitory neurons forming specific synapses with distinct parts of targeted neurons promote the idea of functional specificity, but unfortunately here biological access and evidence for the mechanisms is rare and simulations show no biophysical effects either, but have shown that inhibition is not acting as a switch, rather that effectiveness of inhibition is graded depending by the firing rate and the arriving excitatory current at the soma of pyramidal cells for example. Taken together, this view supports that some specific inhibitory cells control the output while others rather control the input to neurons (Douglas & Martin, 1990). To summarise the main functions of inhibition by neurons, they moderate excitation of course and they as well inhibit inhibitory cells, in principle to de-allocate circuits from inhibition. A further explanatory thought for the roles of inhibition in cortical circuits, and for instance the generation of non-linearity in linear excitatory projections, is the normalisation by division of the linear firing rate of each neurone by growing input of an aggregation of cortical cells. The dividing process is proposed as a mechanism of “shunting inhibition”, which decreases the resistance of target cells proportional to global network activity. Nevertheless, the so called division is indeed rather a subtractive mechanism by changing of firing rates. The excitatory and inhibitory systems together form therefore the algebra of the nervous systems and enable processing by gain control (Douglas & Martin, 2009).

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use



From the observations it seems clear that the reflex effect of concurrent stimulation of excitatory afferent nerve with inhibitory afferent nerve [...] is an algebraic summation of the effects obtainable from the two nerves singly [...]. The net change which results there when the two areas are stimulated concurrently is an algebraic sum of the plus and minus effects producible separately by stimulating singly the two antagonistic nerves. (Sherrington, 1908)

Emphasised is here the spike threshold importance and the fact of neurons being below threshold not contributing to the current circuitry. Inhibitory cells can keep the membrane potential under control and therefore actively shape the dynamical configuration of the circuits.

Considering inhibition as an important flexibility factor in the model, one can assume a dynamic network without explicitly changing the connectivity, but one step further, more flexibility and particularly a high depth of a network can be provided by recurrence, which aims for the so called deep learning. But the biological background is also provided from observations in the cortex. Estimates assume that the human cortex contains ~ 10^9 neurons and the architecture is laminar, while the functional diversity of the neurons can be broken down to about 100 different types in two major classes: excitatory and inhibitory neurons.

The model in Figure 6 is derived from cortical layers, represented via populations of exciting (triangles and green connections) and inhibiting neurons (circles and red connections). All Layers depicted here receive potential input from other microcircuits and external modules. The input can be seen as thalamo-cortical projections to corresponding layers, plus output in corticothalamic projections as recursion loops.

Figure 6. The definition of a microcircuit model

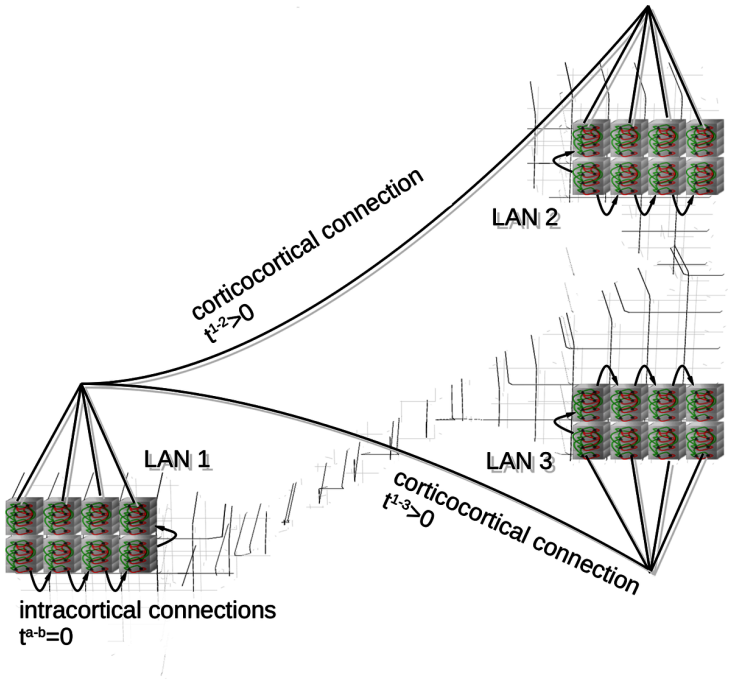
EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Connections between those neurons are estimated from animal physiological data, mainly visual cortex of cat and monkey, as well from mouse and rat somatic cortex. Riveting circuit properties were revealed with this anatomical data, concerning the physiological connection of neurons in cortex' laminar and inter-laminar structures and as a consequence thereof, providing intriguing insights about fundamental properties of cortical processing. Important as an aspect for modelling is the dominance of local cortical synapses over those afferent to other cortical areas, which can be understood as clustering neurons to local networks and those connect to each other as bundles. The vast majority of cortical excitatory synapses and also most of the inhibitory synapses originate from neurons within local cortical areas. Concluding in afferent projections of cortex from and to thalamus and other individual cortical areas comprise a rather small percentage ($5 - 10\%$) of all excitatory synapses in the target area. In the same way the local neocortical areas are interconnect sparsely as well. Nevertheless, these afferents are sufficient to drive the excitation of the cortex (Douglas & Martin, 2004, 2009). Figure 6 captures these mentioned aspects in forming a microcircuit out of neuron codelets in a model idea. For enabling recurrence already in these small scale model clusters, one can assume that same types of neurons prefer connections with similar types and locally. In fact, superficial layers of the cortex are mainly connected excitatory by pyramidal cells with extensive arborisations about 70% of its own type. Thus, first order recurrent connections between cortical cells are likely between own types, in which a target neuron projects back to its source neuron in a tight positive feedback loop. Meaning, that cortical computation is carried out by positive feedback of relatively small afferent signals, so appearing as selection and re-combination of signals. An additional control parameter is given by spiking, individual neurons operating on small rate modes, because generally lots of input spikes are needed to produce a spike output event of a neuron. Positive feedback potentiation may be adverse for the balance, but the amplification of positive feedback enhanced neuronal activity is stabilised if the sum of excitatory positive current is less than the total of dissipated negative current through membrane leak conductances, action potential and synaptic conductances. This states, that positive feedback is a way to amplify small input signals to stand out of the noise in the cortex. This signal-noise-balancing is crucial for the network circuits, so that magnitudes of causally related signals are always controlled. However, the distinction between noise (spontaneous activity) and small signal input is not clear yet and can't be easily covered in artificial neuronal networks either (Douglas & Martin, 2004). For a better understanding of cortical circuits in research the focus was on models with linear threshold neurons, which comprise continuous positive output. This output is directly proportional to the positive difference between excitation and inhibition those neurons receive, if the difference is not positive or zero they do not contribute to the output. ANNs modelled with these linear threshold neurons (from excitatory and a smaller number of inhibitory types), interestingly, produce non-linear behaviour for the output, despite the amplification of the input is linear. The result of this behaviour is important, because it rises the capability to actively impose interpretations on incomplete or noisy input by restoring basal activity distributions from the connectivity of excitatory pathways in the network. For instance, the weight matrix of synaptic interactions describes the circuitry between various neurons in a network. If a neuron is now inactive, it contributes to the network in a temporary degenerative way and is so decoupled from the circuit, so to say not expressing its interactions. The full weight matrix can be now depicted as a reduced matrix, called the "effective weight matrix", whilst "silent" neurons are zeroed. The changes in network activity due to rise and fall of neurons are directly reflected in the weight matrix, which becomes a timed dynamical entity, the so called "permitted set" of neurons. Specifically, for local recurrent circuitry, the control is illustrating that patterns of thalamic input can be selected and input is mapped therefore also topographically across cortical areas, effectively by recurrent connections

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

being mainly local. These variations in magnitudes of a response due to changes in attention to a cortical stimulus, or simply neuromodulation, can be viewed as changes controlled by external attentional input. The mediation is simplified as an extension of the "permitted set" concept, which expresses the recurrent activity not monosynaptically between local clustering of connected neurons representing members of the cortical maps, single neuronal connections and activity would have to defeat failure as well (versus flexibility). In conclusion, the neuronal cortical computing or processing and organisation is done by local circuits or subcortical nuclei with a proportionate distribution of neuronal interconnections, surely evolutionary driven by limits in connectivity and energy consumption, as well robustness and reliability.

On the assumption that artificial neuronal networks can be seen as spatial memory, e.g. Hopfield networks or bidirectional associative memory networks or self-organising maps, they display stable patterns of activation and can be considered as solution to constraint satisfaction problems approximating complex functions, while reducing the parameter space efficiently. The major restriction or limitation in this case lies in the division between training and reproduction phase, so to state the rigidity of the network organisation after the training period. In order to achieve the best results for flexibility and to implement a type of "intuition" in an ANN, learning and training has to become a process of plasticity. Information seeking and learning through exploration, and driven by curiosity, novelty, surprise and positive reinforcement (plus "emotional tagging"), ensures a steeper learning curve and provides success rating (Baranes et al., 2015). With saturation, the learned and processed information will be owned as an interest and skill. Even thinkable is the possibility to enable mechanisms which can drive persistence in learning (for a selection of skills) which can lead learning to perfection, for instance like in the learning process when acquiring motor skills for playing an instrument. More precisely, robots must be able to act autonomously over longer periods of time, not only within interaction tasks, learning and to achieve goals, also to manage resources and to recover within time constraints. This requires greater flexibility in the way the robot chooses to sense, interact and remember in achieving goals, including an ability to identify when it has not been successful executing an action (Spranger et al., 2010). State of the art autonomous robots seek for human assistance if they recognise that they are in situations beyond their logic or sensing abilities. Typically, this is the case for robots with pre-programmed/planned tasks, this often imposes unwanted operational constraints and is limiting the use cases. Task planning adds sophistication to simple switching of behaviour in traditional autonomous architecture, so to say adaptive planning has to respond to execution conditions and re-plan when failures or opportunities occur. Most recent attempts to process complex decision making resulted in an impressive demonstration of network capabilities, where the ANN was playing "intuitive" in the game "Go" and able to beat a professional human player. The success of "AlphaGo" is based on an efficient combination of machine learning methods to train a pattern recognising deep learning network, plus Monte Carlo tree search to estimate the value of each game state in the production phase (Silver et al., 2016). Here the advantage was played out by the use of several ANN's for the purpose of training each other. This clearly demonstrated the technical feasibility of combined machine learning and reproduction phase, but the shortcomings lie in the tree search and the requirements of dedicated hardware for the sophistication of processing. If this can be improved with efficiency and exploration mechanisms for robots via functional network architectures and synthetic consciousness through a global workspace, a big progress step can be made. For these considered aspects, learning has to provide flexibility and robustness in execution of actions, as well teaching abilities, so that it allows for consideration of spatial and temporal variabilities. Further extensions to reinforcement learning, state-action maps (policies) and noise filtering can be applied as well. Artificial Intelligence offers the prospect of realising cognition desired for persistent autonomy



EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

and the control of the robot can be stabilised and tuned to robot motion and contact conditions during task execution, whilst skill learning provides the means to respond to disturbances and errors within behaviour, without a recourse in planning. Intrinsic physical world modelling in AI processes sensor data to maintain a logical description of the environment, while it is used for directing the sensors accordingly to task execution and information seeking. AI status assessment monitors the performance of action execution and uses live sensor data for interpretation of the state of the environment to detect and diagnose failures and success of the task execution. Nevertheless, intelligence is as well devoted to spend time and resources to explore and obtain information, but the intrinsic motivation for such behaviour is not well discovered yet. Developments in machine learning and eye movement behaviour have shown, there is a connection between curiosity and information gain for learning progress mechanism in neuronal aspects (Baranes et al., 2015). A starting point in this research field of curiosity driven learning is the exploration of environment by its observers and actors, while they estimate their own epistemic states and how they specify their own uncertainties in order to find strategies to reduce theses uncertainties. Considerations show that possible motivations, besides gain control in elementary network aspects, can be derived from intrinsic and as well extrinsic factors. For extrinsic motivation the example of monitoring an obstacle while movements, with the goal of successfully moving towards a specific aim. This is a natural behaviour while pursuing a task-related sampling of information seeking, driven by maximising progress towards the goal. More complex is the goal setting of learning complex strategies, like in playing chess, over a long period of time. Intrinsically motivated information seeking in contrast is described as pursuing the goal as a goal in itself, like gathering information on reading for understanding, driven by positive reward mechanisms in the brain itself (Gottlieb et al., 2013). This falls back to the information sampling during solving a task by strategy progression and includes generating informational actions, as well learning. Machine learning approaches tackle this exploration or strategy searching for solving a task as an optimisation problem, where the task is modelled as a cost function and the strategy is simply to minimise this cost function.

Implementations take advantage of reinforced learning, stochastic optimisation, evolutionary algorithms and Bayesian optimisation. Supported is this procedure by division of duties, biological speaking e.g. eye movements and information filtering by target selection via cell activity. The agent monitors the uncertainty or predictability of action consequences and employs this quantity for the deployment of resources, like gaze. Finally, the environment becomes predictable by decreasing the uncertainty of future states through minimising the scattering or maximise the clustering of hidden states in the model. Another factor which can play a role is the trapping in unlearnable situations, because sampling can happen in a very large space. Contrary to the example used above, the real world is full of unsolvable tasks, maybe due to given limitations of the agent or irreducible uncertainty. Attention focus factors can be given by time dependencies for exploration based on heuristics and also task planning has to be constructive – one cannot walk before learning how to stand up. An attractive factor here can be provided by sensory novelty of information and uncertainty, while it is known biologically to enhance neuronal response, so that novelty can act as an intrinsic reward by dopamine release. Contextual novelty, like surprise, can combine sensory novelty with high prediction error and results in high attentional attraction. Additionally, the factor of curiosity is rising with awareness of differences for uncertainty between current state and reference state, as the goal or task. So this deprivation phenomenon is regarded to propel learning oriented tasks, which is driving the agent to fill a gap in knowledge for reward, e.g. minimising uncertainty about the state of the environment (Gottlieb et al., 2013).

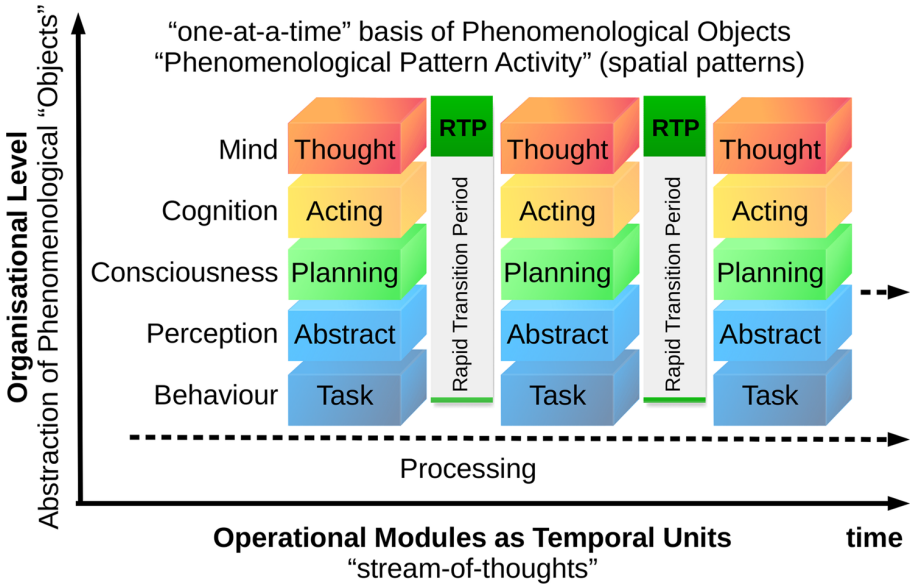
Figure 7. Organisation scheme for AI in operational networks



The specific modules shown in Figure 7 are artificial neural networks (ANN) in their own right and organised in Local Area Networks (LAN's), they can posses very different structures from each other, are interchangeable and can posses even specialised modelled neurone types. The overall global organisation is done via the interconnection and cross-linking of these modules, and especially by sharing a common workspace and memory. The connections are timed by distance to achieve spatiotemporal dynamics.

These arguments definitely speak again for a modular approach in implementing robotic AI and support as well the approach to combine machine learning with deep learning networks, this leads to a network of networks. Starting with the neuron codelets of specific types forming microcircuits and connecting these microcircuits as LANs can meet this idea, which is depicted in Figure 7. From a network of networks arise further aspects which are advantageous, already simplest network structures coupled via symmetric nearest neighbour connectivity matrices display a rich variety of oscillatory behaviour by applying time delays. These time delays arise from the network topologies where time t(i-j) is a function of distance between nodes |i-j| of network interconnections. While still in small local networks (microcircuits) the time delay for propagation is allowed to be neglected. The implied assumption of a homogeneous connection topology in the network, which is symmetric and translational invariant, is fulfilled by the fact that the recursion and inhibition in microcircuits mimics the heterogeneous connectivity observed in the biological structures of the cortex (Jirsa, 2004). The modular structure and the fact that neural information processing is not localised in one small brain area, plus a global workspace idea, the achievement of implementing several network classes and their hierarchy of connections leads beneficially to an interplay between connectivity and spatiotemporal dynamics. This interplay is eventually achieving the connection between time and space via geometry. This network-network connections can be organised in "global weight & connectivity matrices", again these are limited in flexibility, but in "sleep mode" plasticity

Figure 8. Scheme for an AI stream of "thoughts"

can be achieved through machine learning from the short-term memory. But more crucial at this point is the reproduction of "parent information processing" by abstraction, for example as semantic events by summation in local "Field Potentials" or potential fields for the production of higher-level patterns of neural activity. Biomimetic modelling, connectivity and functioning of significant parts of the brain to determine an architecture as of a series of nested sensorimotor loops are fundamental for this ideas. The networks have to consist out of tightly coupled layers for behavioural control; respectively the reactive, the adaptive and the contextual layers, and each one increasingly performing more memory dependent mappings from sensory states to action. The reactive layer performs reflex actions, including exploration, collision avoidance, search and homing, using sensory modalities and predefined sensory-motor mappings. The adaptive layer performs landmark recognition, feature extraction and memory segment construction, comprising heading direction and landmark information, for instance like implemented in self local area mapping ideas. These memory segments are sequenced in the short-term memory of the contextual layer until a goal state occurs. If this is recognised as a success state, the contents of the short-term memory are retained into long-term memory, like in hippocampus memory training. This architectures are already successfully implemented with modest general purpose computational resources e.g. for mapless navigation.

The illustration in Figure 8 relates neuronal assemblies and their dynamics with an operation and to neurophysiological abstract levels of operational modules, if cognitive phenomenal and behavioural operations coincide in time. Operational modules, as a result of synchronised operations caused by distributed transient neuronal assemblies, can be further synchronised between each other on shifted timescales as well and form so a more abstract and complex operational module, constituting an integrated experience. Consequently, functionally distinct operational modules can co-exist on different timescales.

Exemplarily implemented features of OA have shown promising results in decision making processes, in comparison to central state modelled decision making algorithms (Burmakin et al., 2009). Taken further is the idea of OA by a stream of "thoughts" implementation via operational modules in an abstraction

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

level hierarchy, see Figure 8, adapted from (Fingelkurts et al., 2012). Respectively, OA assumes, besides functional layers, the implementation of operational modules as time dependent connected abstractions of network activity. But the rapid transition periods, which basically reset parts of the working memory, are mutually independent between operational modules and coincide with self-organised stability in the network (Fingelkurts et al., 2012). This is to idealise semantic abstraction towards spatiotemporal pattern interpretations, which is an approach for generating sense in phenomenological space and time events. Apart from automatically resulting in a sense of time in artificial intelligence machines, the integration of information as a "stream-of-thoughts" means "spatial operational modules as temporal units", which means a sequential "stream of thought", but at the same time processing has from the global workspace all the information available and therefore unifies into a parallel processing of information, which promises to result in time dependent and predictive "thinking" in robots.

CONCLUSION

In contrast to a central processing unit (CPU), the performance of the human brain is clearly due to it's fundamentally different way of processing and its different state of matter. While computer chips follow mainly the paradigm of precision and fast calculation in sequential manner, the neuronal structures process massively parallel and abstract, while being less precise, but due to abstraction being more efficient and focusing on the real world representation. The global workspace idea gives rise to instantaneous access to contexts of information for processing and unifies the spatial networking and co-existence of time wise shifted functional spatio-temporal patterns. An artificial intelligence model, able to cover the latter aspects, should comprise to be intuitive, self-aware and even synthetically conscious for the means of an interactive robot, taught by biology. Joint aspects from different research disciplines and experiments lead to models of biomimetic approaches for artificial intelligence. To create robots, which should be able to learn, to recognise the environment, and to adjust to the change of situations respectively, research on cognitive abilities and AI is pulling on one string. By the biological role model, biomimetic aspects follow the modular organisation of the human brain as paragon and technologies like machine learning combined with deep learning networks will provide sufficient and efficient platforms to achieve these goals in robots. Therefore, the prediction is clear, that AI is able to mimic intuition and empathy in robots for intuitive user interactions.

Chapter 73
How to Identify Rheumatic Diseases by General Physicians

Eduardo C. Contreras
Autonomous University of Coahuila, Mexico

Gustavo J. Puente
Autonomous University of Coahuila, Mexico

ABSTRACT

A large part of the population in countries in process of development ignores what Rheumatic Diseases are, and general practitioners are in most cases unaware of enough information to identify them and the treatments to successfully control them. A proposal to help those general practitioners to detect if an articular condition belongs to a Rheumatic Disease case is to present them the clinical semiology that should lead them to redirect the given conditions to a specialist on the subject, a rheumatologist. The clinical semiology is presented by an automated algorithm inside a goal-based software agent, containing all the necessary information to identify the seven most common inflammatory Rheumatic Diseases, and fourteen of the non-inflammatory ones. The purpose of this tool is to provide the general practitioner with the correct information to redirect the patient with a rheumatologist, in order for it to receive the appropriate medication to be controlled.

INTRODUCTION

Project

This project is a field investigation, applied to medical area on the Rheumatology specialty related with Clinical Semiology and the Information Technology. It is in itself, an automated medical tool to identify joints affections, based on an Intelligent Agent from Artificial Intelligence specialty, based on the heuristic compilation of the tacit knowledge of rheumatologists. This study tries to associate the factors than relate the support process on Information Technology on a General Doctor, towards a modern tool as didactic software, which facilitates the most common rheumatic's affections identification.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

This identify tool has a section of rheumatic inflammatory conditions and a section of rheumatic non-inflammatory conditions. Inflammatory conditions referred to joint. In the section of inflammatory conditions the user will find windows that include the different aspects of the joint disease that must be considered in diagnosis such as kind of onset, number and size of involved joints, topography of the arthropathy and symmetry of involvement. The section of non-inflammatory conditions considers only localized, regional and generalized involvement. Both sections follow a reasonable and logic algorism that allows reaching diagnosis of the rheumatic conditions included in the diagnostic tool.

OBJECTIVE

To value the utility of the algorism for the identification of Rheumatic Affections" with a general practitioner, so that he will be able to provide an accurate diagnosis of joint diseases and redirect the patient with a rheumatologist for its early evaluation.

The proposed clinic semiology is based upon the human experience that is used to build a software agent didactic tool related to the Information Technologies; the software agent is a tool that allows the doctor to offer an appropriate evaluation of the rheumatic diseases.

BACKGROUND

Rheumatic Diseases

The study and management of rheumatic diseases in a rigorously scientific way has been in charge of the medical specialty of Rheumatology, a branch of Internal Medicine, since the middle of the 19th century, making it an medical area relatively new and this explains why, even in the beginning of the 21st century, rheumatic diseases are largely unknown both by the population in general and by doctors, who are not dedicated to this area of health.

Rheumatic diseases are heterogeneous clinical entities which affect musculoskeletal (Schumacher et al, 1998) system and other systems and organs, whose diagnosis often comes late due to little knowledge of these diseases and scarcity of rheumatologists, among other reasons (Taranta & Markowitz, 1981). Delay in diagnosis of these diseases may lead to damage of joints and related tissues, organs and systems with subsequent functional disability and increase in morbidity and mortality.

A person who suffers from a rheumatic disease that has affected the hip joint is facing a severe pain when attempting to walk. The first three or five steps walks with great difficulty, as it decreases the pain, once that it lessens can walk with less pain and greater agility. When attempting to stand the pain is so acute that it does not balance and when sitting drops the body waiting for that pain to decreases, spending time it dulls, but knowing that when get up again will face that terrible acute pain. When the joints of the hand are concerned it is very difficult to remove the lid to a jar, as pain does not allow you to force. If the person suffers from a knee, usually the cartilage that covers the joint decreases its thickness, staying in touch with the bone part, decreasing joint mobility and increasing pain to move it. Usually the patient will live with the pain articulates for a lifetime, with the probability that the joint will be merged and significantly decrease their movement, in such degree that it turns into a person with a

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

disability. Most of the people must be in constant motion, as it permits the disease, otherwise it would be in for life in a wheelchair or bed.

When a rheumatic disease affects joints, they are damaged in an irreversible process; therefore it is substantial to identify them as soon as possible. If general practitioners supply inappropriate medication, they will be at great risk of affecting the patient severely. The rheumatologist is the only appropriate person to administer the correct medication, due to the existence of the called "antirheumatics".

Distinctive features of this disease are pain, stiffness and articular inflammation that would only decrease after the consumption of the rightful medication.

Definition of the Common Ailments

- **Rheumatoid Arthritis:** A chronic inflammatory disease of unknown etiology which involves multiple diartrodial joints leading to hyperplasia of synovial tissue and destruction of cartilage and subchondral bone with subsequent deformity and functional limitation. (Stone, 2009)
- **Osteoarthritis or Degenerative Joint Disease:** A no inflammatory disorder of cartilage of the movable joints which suffers deterioration due to biochemical and structural changes in its matrix and in the subchondral bone.(Cañete,2008)
- **Gout:** A metabolic disease characterized by hyperuricemia and episodes of acute arthritis and progression to a generalized arthropaty with accumulation of monosodium urate (Wright & Harvey, 1988).
- **Spondiloarthritides:** A heterogeneous group of diseases characterized by inflammation of the joints of the spine, sacroiliac, limbs joints and in variable frequency affects also skin, mucosal of the digestive tract, urogenital tract and eyes.(Kats,1977)
- **Systemic Lupus Erythematous:** An autoimmune disease characterized for the appearance of multiple autoantibodies which participate in inflammatory disease of diverse organs and systems.
- **Juvenile Arthritis:** A term which refers to a group of inflammatory diseases of the joints in pediatric populations until the age of 16 years.
- **Infectious or Septic Arthritis:** A disease caused by invasion of the joints by bacteria and other microorganisms.
- **Fibromyalgia Syndrome:** The name of a condition characterized by chronic widespread musculoskeletal neuropathic pain in specific sites. (Clauw, 2005)
- **Carpal Tunnel Syndrome:** A clinical entity characterized by entrapment of the median nerve when it passes through a tunnel formed by the carpal bones and joints and the transverse carpal ligament.
- **Digital Stenosis Tenosynovitis:** (Of the fingers) is a constriction of the lumen of the fibrous sheath of flexor tendons of the fingers which impedes its free gliding.(Salter, 1998)
- **D'Quervain Tendinitis:** A condition that appears due to excessive friction between the tendon abductor policis longus and extensor pollicis brevis and its common fibrous sheath.
- **Epicondylitis or Tennis Elbow:** A degenerative tendon disease located in the origin of the forearm extensor muscles.
- **Rotator Cuff Tendinitis:** An inflammatory condition located at the insertion of the rotator muscles of the shoulders in the humeral head.
- **Dupuytren's Contracture:** A progressive retraction of the fibrous tissues of the palmar fascia.

Biological Therapies

Biological therapy (also called immunotherapy or biotherapy) often employs substances called biological response modifiers (BRMs). Biological therapy is thus any form of treatment that uses to stimulate or restore the ability of the immune (defense) system to fight infection and disease. Biologic therapy to block the action of a messenger of inflammation called tumor necrosis factor (TNF) is being used to treat conditions such as Crohn's disease and rheumatoid arthritis.

Biologics are genetically engineered proteins derived from human genes. They are designed to inhibit specific components of the immune system that play pivotal roles in fueling inflammation, which is a central feature of rheumatoid arthritis.

Antirheumatic drugs are drugs used to treat rheumatic diseases. The major classes of antirheumatic drugs include Nonsteroidal Anti-Inflammatory Drugs (NSAIDs), Corticosteroids, Disease Modifying Anti-Rheumatic Drugs (DMARDs), Slow-Acting Antirheumatic Drugs (SAARDs).

- **Nonsteroidal Anti-Inflammatory Drugs (NSAIDs):** Drugs belonging to this class bring symptomatic relief of both inflammation and pain, but have a limited effect on the progressive bone and cartilage loss associated with rheumatoid arthritis. They act by slowing the body's production of prostaglandins.
- **Corticosteroids:** These drugs are very powerful anti-inflammatory agents. They are the synthetic analogs of cortisone, produced by the body. Corticosteroids are used to reduce inflammation and suppress activity of the immune system.
- **Disease Modifying Anti-Rheumatic Drugs (DMARDs):** Influence the disease process itself and do not only treat symptoms, hence their name. DMARDs also have anti-inflammatory effects, and most were borrowed from the treatment of other diseases, such as cancer and malaria.
- **Slow-Acting Antirheumatic Drugs (SAARDs):** Are a special class of DMARDs and the effect of these drugs is slow acting and not so quickly apparent as that of the NSAIDs. (Medical Dictionary)

The treatment in a patient with anti-rheumatic drugs active ankilosing spondylitis (AS) and spondyloarthritides (PsA) whose condition is not sufficiently controlled with non-steroidal anti-inflammatory drugs (NSAIDs) in the case of axial disease, and sulphasalazine or methotrexate in the case of peripheral arthritis. Anti-tumor necrosis factor (Anti-TNF) therapy seems to be a powerful tool for the treatment of AS and other SpA.

Biological therapies for the treatment of rheumatoid arthritis, currently approved, are available: Etanercept, Infliximab, Adalimumab, Anakinra, Tocilizumab, Rituximab, Abatacept. Biologic agents most frequently used as first option are infliximab and etanercept. The progress in manufacturing biotechnology has contributed to the development of several other prospective agents that may form the basis for the therapy of rheumatoid arthritis in the near future. (Šenolta et al, 2009)

On a study in the hospital La Fé located in Valencia Spain, descripts the registry of adverse events of biological therapies in rheumatic diseases. It contains the description of: frequency of adverse events by groups, frequency of serious adverse events, frequency of fatal adverse events, incidence rate of adverse events and incidence rate of serious adverse events. (Research Unit of the Spanish Society of Rheumatology, 2013.)

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

The treatment in a patient with anti-rheumatic drugs active ankilosing spondylitis (AS) and spondyloarthritides (PsA) whose condition is not sufficiently controlled with non-steroidal anti-inflammatory drugs (NSAIDs) in the case of axial disease, and sulphasalazine or methotrexate in the case of peripheral arthritis. Anti-tumor necrosis factor (Anti-TNF) therapy seems to be a powerful tool for the treatment of AS and other SpA. (Braun & Sieper, 2004)

Biosimilars is the term used for generic versions of biologic agents, with identical primary sequences in which changes in the manufacturing processes have led to important differences in safety and efficacy. Introduction of biosimilars requires a specifically designed pharmacovigilance plan. (Kolkata, 2012)

Home Remedies for Arthritis and Joint Pain

In countries in process of developing most of the people relies on home remedies when they suffer a condition, given that they have little information, because of their culture, economic situation or the fact that they don't have access to specialized medical attention. In the case of suffering a joint pain without receiving a professional diagnosis, people often believe this pain is derived from a rheumatic origin, thus applying to themselves popular remedies such as: putting a potato, a magnet or a piece of copper or silver in their pockets; applying a poultice of ingredients like lettuce, smashed garlic, nutmeg, figs or cabbage; ingesting sage, leek or poppy seed infusions; and finally, drinking Turmeric and Ginger Tea, White Willow Tea, or Juniper Berry Tea.

Another home remedies are: Lubricate joints With Extra Virgin Olive Oil, Peppermint Eucalyptus Oil Blend, Blackstrap Molasses Drink and Pectin and Grape Juice.

These remedies don't change the course of the arthritis itself, but they do have an analgesic, or pain-relieving effect.

Clinical Semiology

In medicine, the clinical semiology is the group of knowledge that deals with the identification of the various pathological manifestations (signs and symptoms), from people and animals (in the veterinary field), in both cases with the objective of how to collect data.

Semiotics. With the objective of compile this data in syndromes and how to interpret them (clinical semiology). This discipline allows the physician not only directed at the diagnosis but have a prognostic assessment.

Unless other diseases, the traditional semiology teaching-learning process is focused on isolated concepts and practices. Rheumatic diseases, for example, need a systemic approach for their diagnosis.

This approach allows the study of the whole thing, it's not enough to study an only part or region of the human body because the rheumatic diseases come all from a mismatch on the immunological system. If a general practitioner applies immunosuppressers to a patient with a rheumatoid arthritis condition, with glaucoma, diabetes or an infectious condition, without considering the concomitant effect, this would affect the patient severely. For this reason, only a specialized practitioner, a rheumatologist, can prescribe the adequate medication without the risk of secondary effects.

For all the reason previously mentioned, the semiology must have a systematic approach (Bertalanffy, 2011). Semiology is the mainstay of clinical medicine. It is an art and a science. It presents a method of sorting knowledge (clinical method) and the goal is the diagnosis of health problems.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

The methods applied on Semiology are complex and differ one from another, mainly because their use as a method and recognition as a science have stopped in the present time.

According to the systemic approach, questionnaire, observation, physical examination and lab exams are not enough, because it involves historical methods, sociology, genetics (biological inheritance), psychology, psychiatry, etc., among other sciences.

- Rheumatology Method,
- Questionnaire,
- Physical Exploration on Joints,
- Inspection,
- Palpation,
- Mobility,
- Arthrocentesis,
- Lab exams,
- Reactive C Protein,
- Rheumatoid factor,
- HLA-B27 HLA-DRB1 HLA- DR4,
- Erythrocyte sedimentation rate (ESR),
- Antinuclear antibodies,
- Radiological examination,
- Anteroposterior,
- Lateral,

Radiographic semiology to detect:

- Ankylosing hyperostosis,
- Ankylosing spondylitis,
- Rheumatoid Arthritis,
- Paget's Disease,
- Neoplasms.

Software Agent Definition

In artificial intelligence, a software agent (IA) is an autonomous entity which observes and acts upon an environment and directs its activity towards achieving goals. (Rich & Knight, 1991) An agent is everything that can be considered that perceives its atmosphere by means of sensors and that response or acts in such atmosphere by means of effectors. (Russell & Norvig, 2003) A sensor is a device that measures a physical quantity and converts it into a signal, which can be read by an observer or by an instrument. For example, voltmeter, thermometer, thermocouple, seismometer, parking sensor, carbon monoxide detector. Effectors are agents or structures that cause an activity, like a nerve causing a muscle to flex, or a cell triggering an immune response to a foreign substance.

In robotics, an end effector is a device or tool that's connected to the end of a robot arm where the hand would be. The end effector is the part of the robot that interacts with the environment. The structure

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

of an end effector and the nature of the programming and hardware that drives it depend on the task the robot will be performing. (Resconi, 2004)

Intelligent agents are often described schematically as an abstract functional system similar to a computer program. On the Internet, an intelligent agent (or simply an *agent*) is a program that gathers information or performs some other service without your immediate presence and on some regular schedule.

Models to Construct Agent's Programs

- **Agents from Simple Reflex:** (Russell & Norvig, 2003) The rules condition-action allows the agent to establish the connection between perceptions and actions.
- **Agents Good Informed into Everything What Happens:** It updates the information based in its own internal state.
- **Agents Based on Goals:** It is a combination of the previous ones, with the information relative to the result than will produce the possible actions than will undertake. It handles the information that use to update the internal state and this way to select those actions that allow reaching the goal.
- **Agents Based on Utility:** It allows to differentiate a state from another and to take the decision that offers major utility to the agent.

Of these types we will be based only on Agents Based on Goals. Besides the states, agents need some kind of information about its goals. Goals will to detail the situations to that it is desired to arrive. The agent program could to combine goals with actions and in this way, to be able to choose those actions that allow reaching the goal.

Design of an Ideal Agent

To specify which kind of action should undertake an agent, as an answer to a certain sequence of perceptions constitutes the design of an ideal agent.

Agent Type: Medical Identification System

- **General Doctor's Perceptions:**
  - Symptoms, clinical signs, physical examination, heredity, personal data
- **Actions:**
  - Identifies: joint state, anatomical region, number of joints.
  - How the patient evolves.
  - Differentiate diseases.
- **Goals:**
  - Affection identification, time reduction, canalization of patient in case of such another disease.
  - Atmosphere.
  - Patient, general doctor.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Medical Identification System for Rheumatic Diseases (MISRheD)

The actions than this agent undertakes, are based exclusively in an integrated knowledge (provided by the rheumatologist), and so, its own perceptions are ignored (it does not count with sensors towards the environment), therefore the agent has not autonomy. Its conduct is defined by the human agent experience. It is reasonable to equip an agent of artificial intelligence with certain initial knowledge and capacity to learn (the rheumatology heuristic).

MAIN FOCUS OF THE CHAPTER

Problem Definition

Problem Identification

Most of the Mexican population, including the medical people, does not have the necessary information on rheumatic diseases to enable them to understand the importance of them and their socio-economic and psychological impact.

The Rheumatology is a relatively new medical specialty. In Mexico it was until the 1960s when it began with the training of specialists in this area of health. Most of the schools and faculties of medicine, both the public and private sector lack, even today, of the field of Rheumatology as part of their curricula and there is a limited number of specialists in our country. According to data collected and provided by the National Institute of statistics and geography until the year 1995 there were 59 faculties of medicine in our country; and it was until 1990 when it included the field of Rheumatology in these powers, so that medical graduates prior to this date were not given adequate information on this area, and only obtained some knowledge about the pathophysiology Traumatology, orthopedics and dermatology; matters that are related to the Rheumatology but do not have full knowledge about the same. For this reason there are currently a very small number of specialists in this area in our country.

Even though the Mexican College of Rheumatology Association Civil, has carried out information campaigns through the specialists affiliated to it and has also established the *National Day of the Rheumatic Patient* and other institutions have been involved in campaigns such as the Ministry of public health and private health institutions, as well as schools and faculties of medicine in our country have not achieved the objectives to inform the population in general on this condition.

All of these factors are contributors to the very low and erroneous information on rheumatic diseases in our country. Despite efforts to disseminate information on rheumatic diseases, are still insufficient the established programs for this purpose until the moment.

The population taken care by general doctors, or those from the population that has no access to the health services, due to its low economical condition or extreme poverty, this due to in Mexico is an indispensable requirement to access this health service system to be employed by some company, institution or government. Most of the population in Mexico is served by the main clinics hospitals of Social Security (Social Security Mexican Institute, Social Security Institute to Serve the State Workers, and specifically in Saltillo's Municipality by Magisterial Clinic Hospital) the rightful claimants must request its appointment in first instance with the general doctor, and this as well depending on the disease and also with some luck, it will alternate to the specialist doctor: however, the patient waits till three

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

months to obtain an appointment with the specialist doctor. This without a doubt has consequences that it can worsen the rheumatic disease of patients due to they are not served by a specialist doctor with the knowledge to identify the affection and to treat it suitably.

Medical specialists in the field estimated that 10% of the population develops over the course of his life any rheumatic disease and because general practitioners not diagnosed in time and correctly the disease is progressive and irreversible can subsequently cause a disability which may have been avoided if they had received the proper attention of a specialist.

Problem Quantification

In Other Countries

Rheumatic diseases in Spain according from data obtained from the National Institute of Social Security were in 2007 spending of 1.678 billion euros in temporary work disability. It is estimated that in Spain, approximately ten million people suffer from a rheumatic disease, 22.6% of population and cause between 10 and 15% of the primary care.

According to Statistics in USA: nearly 70 million Americans suffer from some form of arthritis or symptoms of joints chronic, rheumatic diseases are the leading cause of disability in people of 65 years of age and older, rheumatoid arthritis, how more disabling of arthritis affects approximately 2,100,000 Americans and attacks on women are two to three times more than males. These data come from Centers for the Disease Control and Prevention, National Institute of Arthritis and Musculoskeletal and Skin Diseases, which are part of the National Institutes of Health and Arthritis Foundation.

According to the statistics managed by the National Center for rheumatic diseases (CNER), in Venezuela, 20 of every 100 Venezuelans have been diagnosed with a disease of this kind.

In Our Country

In Mexico is not satisfied with the recommendation of the World Health Organization (WHO), that there is a rheumatologist per hundred thousand inhabitants, because there are only 560 Rheumatologist certificates, this is, a specialist for every 200 thousand inhabitants, it is not enough.

Rheumatic diseases are a major cause of morbidity and mortality. The available information indicates that the Systemic Lupus Erythematous has a mortality rate of 10% for the five years of its inception and 20% after 10 years; the rheumatoid arthritis reduces the survival in a range of 3 to 15 years compared with the general population and are diseases that on course have significant medical complications. Both diseases often affect people in productive age (18 to 60 years).

Statistics of the Mexican Institute of Social Security (IMSS) in our country report that until 1974 25% of disability pensions were granted by rheumatic ailments, and in 1978, 34% of the dictums of disability were granted for patients with diseases of the muscular-skeletal system. Rheumatic diseases are among the top ten causes of demand for health care in the family doctor system.

In Our Region

A number of questionnaires applied in the city of, Saltillo, Coahuila. To a based sample of 190 people older than 13 years (except for medical specialists in rheumatology) gave the following results:

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

From the sample of the population of Saltillo the 18.42% have information about rheumatic diseases, the 62,63% they have never been to talks or known information about these diseases, the 50.52% don't know that there is a medical specialty dealing with rheumatic diseases, the 27.36% believe that rheumatic diseases affect only to people of the third age, the 55.78% believes that rheumatic diseases affect little in economic or social, to the 61.57% almost aren't interested in further information on rheumatic diseases..

In the city of Saltillo with a population of 578 046 inhabitants only has 4 medical specialists in the medical industry.

Development Method of the Software Agents

The proposal to solve the problem is to identify the type of software agents (intelligent agent) suitable, according to the following elements:

Human agent: to identify a rheumatic disease, knowledge and heuristics of the specialist physician in rheumatology, which will provide the basis of knowledge, rules, diagnostic approach in rheumatology, interpretation of radiological studies, laboratory and physical examination is necessary. The experience of the physician rheumatologist for issuing a diagnosis relies 70% on interrogation, 20% in physical exam and 10% in laboratory and radiological tests.

- **Environment:** Specify the environment in which the agent will run, in this case the main actors are: the general practitioner and the patient.
- **Percepts:** Determine perceptions, entry of data to the agent, identify the types of sensors that the agent will communicate with the environment; in this case the sensors are replaced by the perceptions of the general practitioner.
- **Effectors:** Determine the effectors, mechanisms of response of the agent, in our case is the information displayed on the monitor.

When the above elements have been defined it identifies the type of appropriate agent that will better solve the problem on the basis of the needs and resources available.

Agent Type will be based only on Agents based on goals. Besides the states, agents need some kind of information about its goals. The goals will detail the situations which it is desired to arrive. The agent program could combine goals with actions and in this way, to be able to choose those actions that allow reaching the goal.

The actions than this agent undertakes, are based exclusively in an integrated knowledge (provided by the rheumatologist), and so, its own perceptions are ignored (it does not count with sensors towards the environment), therefore the agent has not autonomy. Its conduct is defined by the human agent experience. It is reasonable to equip an agent of artificial intelligence with certain initial knowledge and capacity to learn (the rheumatology heuristic).

Identification System of Rheumatic Diseases

Agent Type: Medical Identification System of Rheumatic Diseases

- **Percepts:**
  - General Doctor's perceptions.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

- Symptoms, clinical signs, physical examination, heredity, personal data.

- **Actions:**
  - Identifies: joint state, anatomic location, number of joints, joints size.
  - How the patient evolves.
  - Differentiate diseases.
  - Onset type.
  - Inflammatory.
- **Goals:**
  - Affection identification, time reduction, canalization of patient in case of another disease diagnosis.
- **Environmental:**
  - Patient.
  - General Doctor.

Unlike Russel and Norving (1996), in his model *an agent with explicit goals* applied in robotics, software agents type medical diagnosis system, instead of using sensors, software agents are given as percepts (agent receives as perceptions) of input data provided by the general practitioner (symptoms, clinical signs, physical examination, heredity, personal data, evidences and the patient answers) to report the current state of the environment (patient), this information is established a current state on the agent, the agent in this time meets the age, sex, type of disease, whether it is inflammatory or not inflammatory, Identifies: joint state, anatomical region, number of joints, joints size. Which will later be modified to know how will evolve the patient. Immediately questioned actions to take based on a table of terms, when he has taken an action check out the new State in which the patient has evolved to differentiate diseases and turns to question what happens if you take a different action, with this action obtains a goal (identifies the disease). The effectors are the responses of the agent to suggest a group of diseases in hierarchical order which shows the interaction of the user.

Requirements for Software Agents Development

Requirements

It's required, (Pressman, 2002) provide a rheumatic identification by means of an software agents which contains a knowledge base, and the needed algorithms, to make a search process that allows reaching a defined goal.

It's required, create a data bank which contains the information of general data of the patient, age, sex, anatomic location, startup type, inflammatory and so on), clinical signs, symptoms, laboratory analysis.

The human agent (rheumatologist) requirements are: provide the information to elaborate the structured questions, diagnostic approach in rheumatology, the initial evidences, rules and goals to that it is desired to arrive.

The requirements for the computer program are: a user interaction design that allows it to capture the needed information on a structured form, and that shows the same way an answer by means of a text file and images.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 1. Rheumatic diseases that cause inflammation in the joints

1	Gout
2	Infectious arthritis
3	Juvenile arthritis
4	Spondiloarthritis
5	Systemic Lupus Erythematosus
6	Rheumatoid arthritis
7	Degenerative joint disease

Data Analysis

It is necessary to identify and structure the information to facilitate the development of the agent, according to the heuristic of the physician rheumatologist, is described as follows:

The agent identifies a total of 41 diseases, same that are separated into two categories: inflammatory and non inflammatory. Referred to joint.

Diseases that Identifies Software

Inflammatory. See in Table 1, rheumatic diseases that can identify the software.

Description of the Knowledge Base

To search based on goals, we need the Knowledge Base, with well-defined information, established the same, with characteristics of diseases as well as by their categories.

For inflammatory joint disease characteristics are as follows:

1. **Sex:** Sex may refer to:
   a. Male.
   b. Female.
2. **Age:** Inflammatory joints diseases that will be taken into account for the agent are distinguished by a range of age that is presented; these ranges include the following way:
   a. 0 - 12 months or newly born.
   b. 1 - 16.
   c. 17 - 30.
   d. 31-50 years.
   e. 51 years old, or later.

Non inflammatory. See in Table 2, rheumatic diseases that can identify the software.

3. **Onset Type:** The onset type or in other words the way in which the disease occurs in the person concerned may be:
   a. **Acute:** The disease occurs suddenly, in a way not very recurrent.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

   b. **Insidious:** The disease occurs so insistent.
4. **Number of Joints:** The number of joints refers to the total number of joints that are being affected by the disease in the patient taking the following classification.
   a. **Monoarticular:** Disease found only in a joint. I.e. only affects a part of the patient's body.
   b. **Oligoarticular:** Disease is two to four joints. I.e. affects two to four parts of the body of the patient.
   c. **Polyarticular:** The disease is found in more than five joints. I.e. affects more than five parts of the body of the patient.
5. **Affected Region:** The region affected by the patient will be taken in three ways:
   a. Upper limbs.
   b. Lower limbs.
   c. Spine.

In the case of inflammatory diseases they are not given the joint, only the involved region, upper limbs may be the hand without specifying (ulna, radio, Carpus and Metacarpus), illness can involve multiple regions such as it can affect upper and lower limbs or spinal column.

6. **Size of the Joints:** The size of the joints in inflammation may refer to:
   a. **Small:** Metacarpophalangeal, interphalangeal, metatarsophalangeal.
   b. **Great:** Femur, knee, elbows, ankles, shoulders, and wrists.

Here we define the basic features that will be taken into account to enable the agent to the search for inflammatory diseases.

For "non" inflammatory disease characteristics are as follows:

1. **Similar to the Inflammatory:** sex, age, type of home, number of affected joints.
2. **Affected Region:** The region in the patient shall be taken in three ways:
   a. Upper limbs.
   b. Lower limbs.
   c. Spine.
3. **Location:** In the case of "non" inflammatory diseases wanted the part of the body that is affected by the disease, categorized in the following way:
   a. **Upper Limbs:**
      i. Shoulder(s).
      ii. Elbow(s).
      iii. Neck.
      iv. Hand(s).
      v. Wrist(s).
      vi. Finger(s).
   b. **Lower Limbs:**
      i. Foot(s).
      ii. Knee(s).
      iii. Leg(s).
      iv. Hip.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

   v. Ankle(s).
   vi. Thigh(s).
c. **Spine:**
   i. Lumbar.
   ii. Dorsal.
   iii. Cervical.

Some medical symptoms and clinical symptoms are similar in different rheumatic diseases. For this reason, software agents need take several actions to reach a goal.

4. **Clinical Signs:**
   a. Conjunctivitis.
   b. Seizures.
   c. Deformity.
   d. Volume increase of joints.
   e. Digital clubbing.
   f. Lymphadenopathy.
   g. Hair loss.
   h. Cyanosis (hand) or blue hand.
   i. Convulsions (seizure).
   j. Boutonnière Deformity of Finger.
   k. Varus or valgus knee deformity.
   l. Varus or valgus ankle deformity.
   m. Ulnar deviation or ulnar drift.
   n. Cubitus varus (gun stock deformity).
5. **Medical Symptoms:**
   a. Cough.
   b. Fatigue physical.
   c. Chest pain.
   d. Morning stiffness.
   e. Joint tenderness.
   f. Xerostomia(dry mounth).
   g. Dry eyes.
   h. Pyrexia(fever).
   i. Blurred vision.

Design Software Agents

Agent Attributes and Rules of Behavior

Listed in Table 3 are a group of conditions that will allow software agents to take action, which is not enough, therefore need a group of conditions that meet to take the appropriate action is what happens if I take action A? What happens if I take action B? What happens if I take action N…?

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 2. Rheumatic diseases non inflammatory in the joints

1	Deltoid Bursitis	18	Cervical root compression syndrome
2	Meniscus injuries	19	Thoracic outlet syndrome
3	Knee ligaments injuries	20	Carpal tunnel syndrome
4	Chondromalacia patellae	21	Lumbar root compression syndrome
5	Osgood-Schlatter disease	22	sciatic neuritis
6	Prepatellar bursitis	23	Epicondylitis or tennis elbow
7	Anserine bursitis	24	Peroneal syndrome
8	Ankle valgus	25	Growing pains

14	Scoliosis	31	Digital stenosis tenosynovitis
15	Spondylosis	32	Dupuytren's Contracture
16	Lumbar disc herniation	33	subtrochanteric Bursitis
17	Vertebral fracture	34	Disorders of the spinal alignment

With the action taken and to meet the rules set out in the knowledge base to identify a disease, the effectors are triggered, showing the interaction of user, the name of the disease, its features and images. For the general practitioner according to its criteria can give its opinion.

In this type of disease clinical signs, symptoms, and affected region, may be similar, which must have clearly defined rules, which are software agents that help identify correctly the condition. Then we'll show some rules to identify the rheumatoid arthritis.

R1: Starts with polyarticular pain.
R2: Volume increase of joints.

Table 3. Identifying inflammatory diseases

Condition	Action
If female	To identify sex
If the age is 7 years	Set to range between 1-16
If the disease is insistent	Sets onset type insidious
If you have an affected joint	Monoarticular
If you have from two to four	Oligoarticular
If you have more than five	Polyarticular
If it occurs in the shoulder	Identifies region affected upper limbs
If it occurs in the knee	Identifies region affected lower limbs

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

R3: It presents between 30 and 50 years old.
R4: It affects the wrists, metacarpophalangeal, interphalangeal joints.
R5: 20% of the cases have extrarticular disease.
R6: It affects shoulders and elbows in more than 50% of cases.
R7: The rheumatoid factor is positive in 70% to 80%.
R8: LC-reactive protein is positive.
R9: X-rays show ankylosis joints.
R10: Its elevated erythrocyte sedimentation and C-reactive protein is positive.

For Non Inflammatory Diseases

The main condition is that the disease is present without joins inflammation, the action taken by the agent is to locate the anatomical region to go to a possible goal, which is simpler to identify because they are very specific conditions of such diseases.

Table 4 shows the agent identifying a condition and taking action to reach a possible goal.

Algorithm

To classify diseases in inflammatory and "not" inflammatory, the search for Software Agents is much simpler, because that some diseases are discarded by groups thus are.

1. **Start:** First the user is asked to identify if the disease is inflammatory.
   a. If it is inflammatory
      i. Go to table of inflammatory diseases.
   b. else
      i. Go to table of Non inflammatory diseases.
2. **Input Percepts:** Calls for the data depending on whether the disease is inflammatory or not
   a. If is inflammatory then:
      i. {Age and sex.
      ii. Onset Type.
      iii. Size of joints.
      iv. Number of joints.
      v. Region affected.
      vi. Signs.
      vii. Symptoms}.
   b. Else "non" inflammatory:
      i. {Age and sex.
      ii. Onset type.
      iii. Region affected.
      iv. Part (s) concerned (s)}.
3. **State Update for Inflammatory Diseases:**
   a. To have entered the age and sex, is looked for in the Data Base diseases that match the age and sex that the user entered and stored. Result1 = Percepts1 ∩ **A,** where are the diseases recorded in the table knowledge base, percepts1 data entered above.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 4.

Located	Action	Goal
Upper limbs	Shoulder	Deltoid bursitis
		Rotator cuff Tendinitis
	Elbow	Epicondylitis
		Epitrocleitis
	Hand	D'Quervain tendinitis
		Digital stenosis tenosynovitis
		Dupuytren Contracture
Lower limbs	Hip	Subtrochanteric bursitis
	Knee	Injury of meniscus
		Ligaments injury
		Chondromalacia patellar
		Osgood-Schlatter disease
		prepatellar Bursitis
		Anserine bursitis
	Feet	Ankle valgus
		Plantar Fasciitis
		Flat feet
		Hallux valgus
Back	Spine	Sprain
		Scoliosis
		Spondylosis
		Hernia of intervertebral disc
		Vertebral fracture
General	--	Fibromyalgia Syndrome
		Multiple myeloma
		Febrile diseases

b. To have entered the start type is looked for in the database diseases to coincide with the start type that the user entered and stored. Result2 = percept2 ∩ **A**.
c. To have entered the size of joints diseases that matches the size of joints that the user entered is sought in the database and is stored. Result3 = percept3 ∩ **A**.
d. To have entered the number of joints diseases that matches the number of joints that the user entered is sought in the database and is stored. Result4 = percept4 ∩ **A**.
e. To have entered the affected region seeks a disease that matches the affected region that the user entered in the database and saved. Result5 = percept5 ∩ **A**.
f. To have admitted the sign or signs is sought in the database diseases matching the sign or signs that the user entered and stored. Result6 = percept6 ∩ **A**.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

g. To have admitted the symptom or symptoms database is search diseases that match the symptom or the symptoms that the user entered and stored. Result7 = percept7 ∩ **A**.

Thus the sum of partial results is: Partial Result (PR)

PR = Result1 ∩ Result2 ∩ Result3 Result4 ∩ Result5 ∩ Result7 Result6

4. **Formulate Goal:** With the partial result, it obtained a first goal, performs a preliminary identification, at the moment the software agents known to the goal to be achieved, in other words, so far has identified a group of diseases that share common characteristics.
5. **Formulate Problem:** The problem to be solved is to select only one of the Groups of diseases, whereas the rules established for each of the diseases, we find differences that allow us to establish a new state that leads to a new target.
6. **Plan:** We will establish a plan to select one of the diseases of the identified group. What happens if I take action A? Or, if I take action B?

If taken to action leads to a goal to which we do not know if it is correct. This forces us to create a search-space. (Nilson, 2004)

7. **Search:**

```
while (plan not empty) do {
if (agree state == true) then{
If there are similarities with the provided data (state) establishes an action
leading to a recommendation, by selecting an option in the space of search
(search-space), considering the rules that are specific to each disease (these
are those that allow us to do a proper identification). Emits a response
through the effectors (user interaction) to the environment (general doctor,
patient) environment
If one accepts the answer ends.
}
Else {
If does not return to do a new search
It establishes a new plan calling for new data (creates a new state) to have
options to generate new actions that would lead us to a new target from the
selected groups of diseases (remainder), in every new search, it will decrease
the (remainder) until exhausted. }
Output Action
If there are no more actions to take, displays message that does not have suf-
ficient information to identify a disease of this kind.
end
```

Description of Medical Identification System of Rheumatic Diseases (MISRheD)

Clinical Method

In order MISRheD can correctly locate a disease, it is necessary that the information is provided by a general doctor, due to the account with the basic knowledge of medicine. Another person without this knowledge can hardly reach the desired goal.

First there is an interaction between the doctor and the patient to collect information to determine the clinical semiology considering the following factors:

- **Background Inherited Family:** Diseases of the connective tissue, urinary lithiasis, hyperuricemia, psoriasis, uveitis.
- **Particular Personal History:** Urinary lithiasis, hyperuricemia, adverse obstetric events, thrombotic, skin diseases, thyroid disease, uveitis events.
- **Evolution:** Episodic, intermittent, continuous, all types.
- **Joints Physical Examination:** Complete, orderly, symmetric, comparative.
- **Physical Examination:** Deformity, increased volume, functional limitation, snapping, painful points.

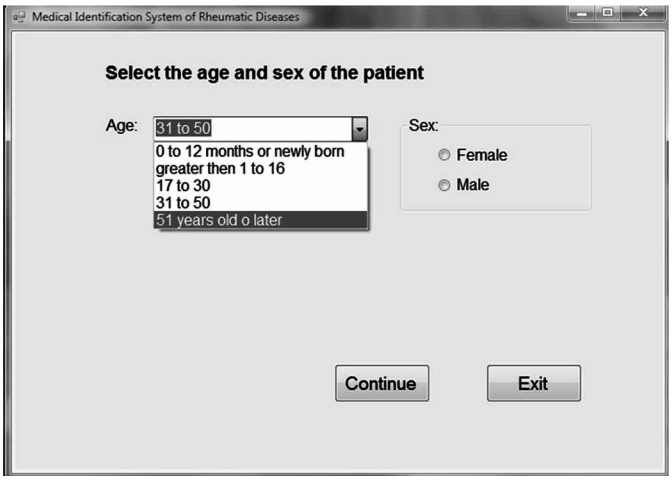
Below are the basic information needed from MISRheD to identify the following diseases.

Procedure for Identification of: Rheumatoid Arthritis

- **Female sex:**
  - Age 42 years
  - Inflammatory classification
  - Onset type: insidious
  - Number of joints 5
  - Region affected upper limb
  - Size of small joints
  - Radiological study erosion articulate with decrease of space joint
  - Study laboratory Hematology thrombocytosis, rheumatoid factor immunological studies 75%
  - Procedure for identification: spondiloarthritides
- **Male:**
  - 17 Years old
  - Inflammatory classification
  - Onset type: insidious
  - Number of joints 2
  - Region affected lower limb
  - Size of large joints
  - Radiological study of pelvis: sacroiliitis
  - Laboratory study: histocompatibility HLA-B27 antigen
  - Uveitis

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Procedure for identification of: Gout



- **Male:**
  - Age 47 years
  - Inflammatory classification
  - onset type: Acute
  - Number of joints 1
  - Region affected lower limb
  - Size of small joints
  - Radiological study: without bone injury
  - Laboratory study: hyperuricemia
  - Previous urinary lithiasis

User Interaction

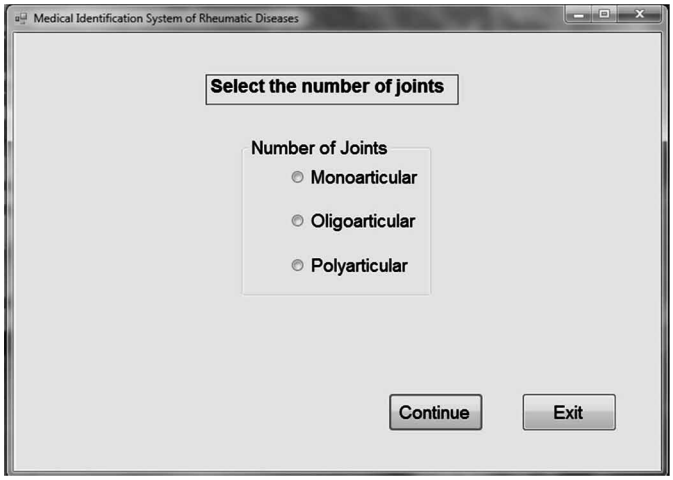
Description of the Templates for the Capture of Data Description Templates

The template in Figure 1 shows the capture of data to select age and sex of the patient. Figure 2 captures data on the number of damaged joints. The template in Figure 3 captures clinical signs of the patient. Figure 4 captures symptoms of the patient. In the template shown in Figure 5, the general practitioner can select the affected body region.

Figure 1. Templates to select age and sex of the patient

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. Templates to select the number of joints



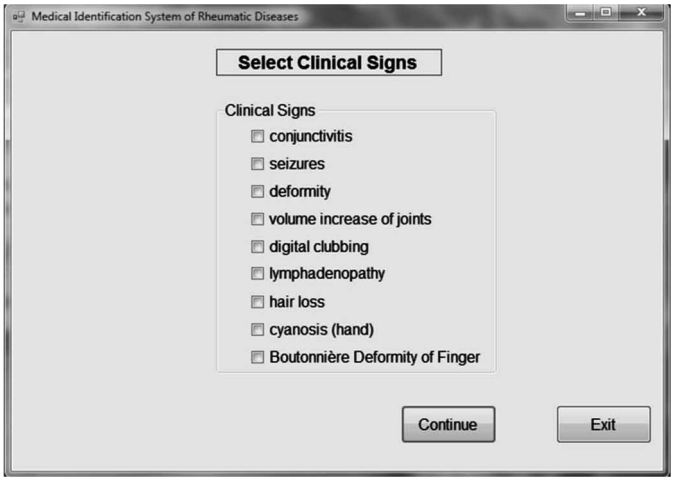


Figure 3. Templates to select clinical signs

SOLUTIONS AND RECOMMENDATIONS

Information to the Population and General Practitioners

Information campaigns and efforts from Government employ an appropriate strategy to the culture of the population. For example in our country, Mexico, the majority of the population is not accustomed to read texts nor to attend talks on cultural themes being these media the principal for disseminating information, in addition there are no records of formal studies of the results and impact obtained by these means of dissemination.

General practitioners who have years on practicing commonly received little information on rheumatic diseases, there is an especial need to offer them courses through the medical institution to which they belong. In this way it can improve its approach to identify a rheumatic condition to ensure that the

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 4. Templates to select symptoms

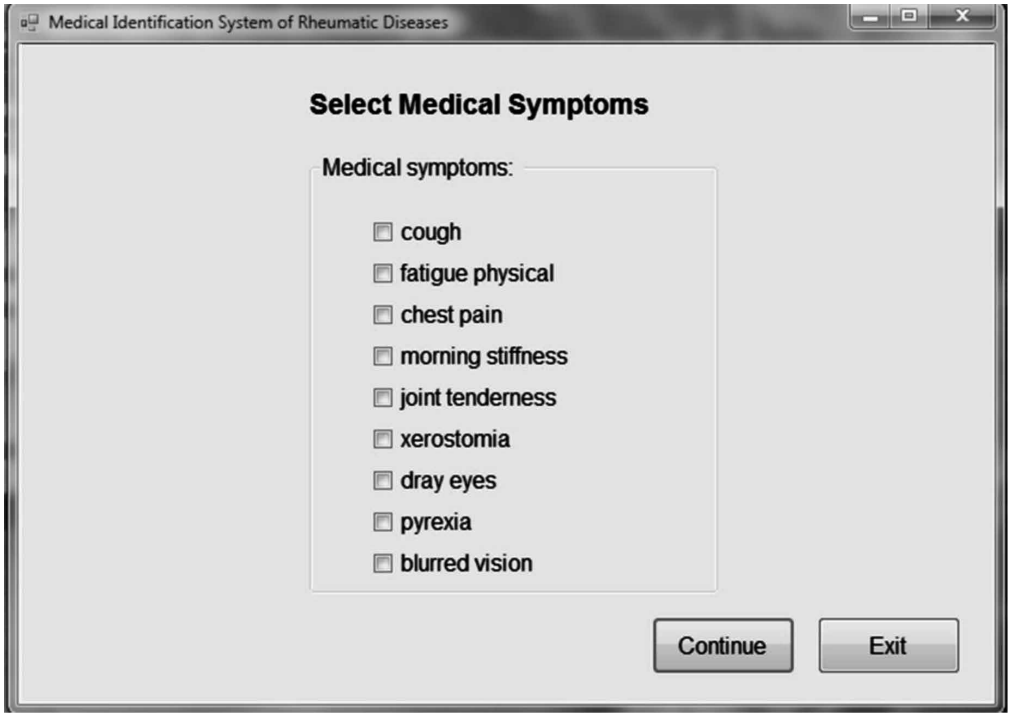

Figure 5. Templates to select region of the body

patient receives timely specialized medical attention. As mentioned above the general medical depends on the detection and prompt attention, which has become a vital part to address the problem in time.

Modifying the culture of the population in terms of popular beliefs of the rheumatic diseases are cured with home remedies, also such diseases are not curable, only controllable. To alleviate ailments people fall into apathy and let the time pass to receive adequate professional attention.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

On the economic side, companies are affected by issued labor disability and pensions granted to its staff, and that is why they should collaborate with the public health institutions requesting that the doctors could detect in time and control these diseases, to avoid large amount of costs that may be unnecessary.

In the social aspect personal disability causing these diseases, becomes a serious public problem that has been increasing in recent years, when a person is affected during his productive age affects also greatly to the family. Give people in productive age alternative effective for the control of the disease, so that in this way they prolong their lives economically active.

In Educational Institutions

Medical schools promote among their students the training of medical specialists in rheumatology to meet the demand of the population and to comply with the ratio of inhabitant/doctor (50/1) that in our country is not enough, in relation to Latin American countries such as Cuba (170/1).

The medical students in their courses receive information and expertise in the specialty of Rheumatology. Encourage the use of new technologies as alternative didactics, in our country this is an educational problem for the lack of resources and training to the medical teaching in the application of teaching tools.

In computer schools that offer courses on information technology, computer and related, promote the development of applications that focus to the medical area to address some of the demanding problems in our country in students and teachers. Projects are being implemented in conjunction with specialists from the sector health.

Physician Rheumatologist

Our country usually the physician rheumatologist provides medical care in his Office and very few are involved in research projects.

It is recommended that they are supported by government agencies or of private initiative for research activities. As mentioned in previous subjects nowadays still much is unknown with what respect to rheumatic diseases. On the other hand medical specialists are encouraged to increase the participation in events that allow the publication of information in books of texts, journals, magazines, proceedings, etc.

FUTURE RESEARCH DIRECTIONS

Perspective

In the future the new trends are to deploy applications using new information technologies in the medical sector to enable decision-making based on the knowledge of specialists and not only information, but complementing information and knowledge to establish a process of reasoning that leads to a certain diagnosis, we know that it is a major challenge for developing countries, because general practitioners do not have the culture of the use of tools of this type and on the other hand the conjunction medical specialist and ICT sector is difficult, because the physician has no researcher training. In the future, the narrow health gap and ICT should be closed.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

The social aspect has lagged behind in the development of the technology because it has focused on productivity, development of quality and economic improvements with cost-cutting in enterprises and the labor and productive sector.

From the technological aspect, it is not enough to develop applications to solve economic or business issues, the social aspect is very important, we know that public demand increasingly focuses on a better quality of life and better health services. In this chapter, we propose a way of decreasing the costs involved in attending to an employee with a rheumatic disease, (payments by inability, absenteeism, and lower productivity) that may temporarily or permanently disabled or improve care to an older adult, and as mentioned that these diseases affect a large population of this type. Using MISRA we propose new solutions based on technologies that will improve social and health services to treat a patient in time and take effective control of their disease.

This is neither the only solution nor the only tool, but new applications must be developed where The ICT sector is highly present in this context.

Viability

The viability of this proposal is feasible from the economic point of view, considering that the majority of medical institutions have computer equipment, for the implementation of MISRA requirements is minimal. The technical aspect was discussed in the model and how much the attitude of the physician to accept this proposal was discussed in the paradigm.

Model

On the way in which we are proposing the use of the model goal-based agents related to the medical area, can be very useful for students of computer science with application in artificial intelligence that helps to understand the algorithm and the structure of software agents and allows them later to develop such applications. For the medical students it can show them how the ICT can help them in their professional development. Use of ICT in their professional development, as well as software developers are to be considered an alternative resource for medical researchers.

Paradigm

In our country along the lines of others, to break paradigms and traditions is very difficult, the predominant practice of medicine used to make diagnoses in the presence of the patient, through questioning and exploration complemented by studies of laboratory and Cabinet, using clinical semiology traditional. Not relies on the computing resource, whether an expert system, computerized analysis of images, etc. because there isn't this resource implemented in our public health system. Public health institutions do not have this medium. The technological advancement of today's world requires that all areas of human activity are updated and this includes the medical work. It is desirable that the health institutions have computer hardware in their areas of medical care and that also to have computer tools to facilitate the diagnosis of common and frequent diseases in the various areas of medicine.

Some public institutions of health and in the majority of private institutions electronic formats are used to take control of the record of the patient, consultation to pharmaceutical dictionaries, existence of medicines at the pharmacy of the institution itself, but not on computer auxiliary diagnosis processes.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

This tells us that in the future the general practitioner can accept computer programs to improve their job performance and to enable them to make a reliable diagnosis with high expectations of accepting a new paradigm.

Future Research

A proposal for future research opportunities using software agent in medicine is the application:

Dermatology

The proposed algorithm can be applied wit the next similarity; it's required to create a data bank, which contains the information of general data of the patient (age, gender), visual data (rash, grain, color, anatomic location, size, shape and so on), clinical signs, symptoms, and descriptive images of several sufferings. The human agent (dermatologist) requirements are: provide the information to elaborate the structured questions, the initial evidences, rules and goals to that it is desired to arrive.

The software agent is required of a tables group, as they are enlisted next:

- Table of questions,
- Table of initial evidences,
- Table of conditions,
- Table of goals,
- Table of rules,
- Table of actions,
- Table that shows the pre-diagnosis.

The difference for these software agents is the use of a Bank of images for general practitioner so they can compare the injury of the patient with the disease that is shown in the image and software agents compare these features to perform the search.

Physical Medicine

The goal of software agents is to suggest to the general practitioner when he should send the patient for attention by the specialist in physical medicine and to receive physical rehabilitation therapy. Physical rehabilitation is considered as alternative medicine, for this reason not all doctors resort to it. The areas of medicine that frequently require management by physical medicine as support are Traumatology and orthopedics, Neurology and Rheumatology, however other areas can benefit from its use. An algorithm with the characteristics of the disease that afflicts the patient can achieve a timely delivery to a rehabilitative treatment to enable the recovery of a patient.

Similar to the previous proposal, apply the same algorithm with appropriate amendments, in this case the treatment received by the patient (cold, ultrasound, heat, infrared, hydrotherapy, physical exercise) that the patient needs is going according to the conditions of the joints or the affected part of the body.

The development of a medical diagnosis requires the mental processing of data provided by the patient, the exploration the doctor will take and support studies. For this reason any area of medicine could benefit from the creation of tools similar to which is intending in this chapter.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

CONCLUSION

The use of CIT as a tool to solve social and health problems, leads to the following:

1. Create multidisciplinary Workgroups. General physician, Rheumatologist, CIT's engineering, students that still are in the formative stages of engineering.
2. The project development and its completion through MISRheD, did not require many financial resources, most valuable resource was the human resource.
3. Takes time to develop such tools, for approximately two years we collected information from the experience of the rheumatologist, with approximately thirty years of professional experience.
4. The shortage of rheumatologists at our country indicates that few people have the knowledge and experience in this specialty, moreover, is a medical area where still much is unknown, MISRheD is a way of preserving part of this experience and transmitting it to the public health community.
5. There is a large backlog in the use of CIT in the institutions of public health in our country; there is the possibility that MISRheD will support telemedicine to apply it in places where there are no rheumatologists.
   The algorithm may be useful for general practitioners, professors, and computer science students, as an assistance that would help them to solve similar problems
6. This tool is an effort between researchers, doctors and students to improve the patients in health care, which are invited to participate in a future in collective projects to solve society's problems.
7. Antirheumatic drugs are needed to control them, such as: Nonsteroidal Anti-Inflammatory Drugs, Corticosteroids, Disease Modifying Anti-Rheumatic Drugs, Slow-Acting Antirheumatic Drugs and Biological Therapy.

KEY TERMS AND DEFINITIONS

Agents Based on Goals: The goals are to itemize the situations to that it is desired to arrive. The agent program can combine goals with actions and in this way, be able to choose those actions that will allow reaching the goal.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Antirheumatic Drugs: Antirheumatic drugs are drugs used to treat rheumatic diseases. The major classes of antirheumatic drugs include Nonsteroidal Anti-Inflammatory Drugs (NSAIDs), Corticosteroids, Disease Modifying Anti-Rheumatic Drugs (DMARDs), Slow-Acting Antirheumatic Drugs (SAARDs).

Biological Therapy: Treatment to stimulate or restore the ability of the immune (defense) system to fight infection and disease.

Clinical Semiology: In medicine, the clinical semiology is the body of knowledge that deals with the identification of the various pathological manifestations (symptoms and signs) and compiling them into syndromes and how to interpret.

Disease Modifying Anti-Rheumatic Drugs (DMARDs): DMARDs influence the disease process itself and do not only treat symptoms, hence their name. DMARDs also have anti-inflammatory effects, and most were borrowed from the treatment of other diseases, such as cancer and malaria.

Formulate Goal: To set a model for an intelligent agent due to define to achieved the goal, generating new states and testing them against a goal.

Inflammatory: Term to differentiate the types of rheumatic diseases. This is an inflammatory process that occurs in joints. Regardless of nerves or ligaments as prepatellar bursitis, it is the inflammation of the bursa that is positioned in front of the kneecap (patella).

Medical Signs: Term to identify the types of rheumatic diseases. The physician makes his judgments from the information that he gathers during a physical examination of a patient (conjunctivitis, seizures, deformity, volume increase of joints, digital clubbing, among others).

Medical Symptoms: Term to identify the types of rheumatic diseases. They are abnormal perception of a patient (cough, fatigue physical), chest pain, morning stiffness, joint tenderness, etc.).

Nonsteroidal Anti-Inflammatory Drugs (NSAIDs): Drugs belonging to this class bring symptomatic relief of both inflammation and pain, but have a limited effect on the progressive bone and cartilage loss associated with rheumatoid arthritis. They act by slowing the body's production of prostaglandins.

Recommendation: Filtered information is displayed to the user in order make decisions. Software agents suggest rheumatic disease.

Remainder: Selected information group, which matches the search. Rule out disease that does not match your search.

Rheumatic Diseases: They are systemic diseases of unknown origin that happen when the immune system goes haywire. The immune system attacks the linings of joints, ligaments, tendons, muscles, skin, eyes, cause inflammation, swelling, and pain. There are more than 100 rheumatic diseases.

Search Space: The group of records in a database that were selected according to the search that matches the goal that you want to reach (identify rheumatic diseases).

Slow-Acting Antirheumatic Drugs (SAARDs): A special class of DMARDs and the effect of these drugs is slow acting and not so quickly apparent as that of the NSAIDs.

Chapter 74
Social Implications of Big Data and Fog Computing

Jeremy Horne
Inventors Assistance League, USA

ABSTRACT

In the last half century, we have gone from storing data on 5¼ inch floppy diskettes to the cloud and now use fog computing. But one should ask why so much data is being collected. Part of the answer is simple in light of scientific projects, but why is there so much data on us? Then, we ask about its "interface" through fog computing. Such questions prompt this article on the philosophy of big data and fog computing. After some background on definitions, origins and contemporary applications, the main discussion begins with thinking about modern data collection, management, and applications from a complexity standpoint. Big data is turned into knowledge, but knowledge is extrapolated from the past and used to manage the future. Yet it is questionable whether humans have the capacity to manage contemporary technological and social complexity evidenced by our world in crisis and possibly on the brink of extinction. Such calls for a new way of studying societies from a scientific point of view. We are at the center of the observation from which big data emerge and are manipulated, the overall human project being not only to create an artificial brain with an attendant mind, but a society that might be able to survive what "natural" humans cannot.

INTRODUCTION

Fog computing is another link in the chain of information storage extending back from storing data in a handwritten manner to adding machines, vacuum tubes, and floppy diskettes. One creates the information, stores it, and then distributes it. It is easy to confabulate the motivation for its instrumentation, the "why" of the foundation (big data) with how we get it (storage and distribution methods). Two aspects characterize information: its growth and centralization. Fog computing has enabled its distribution not only to computers to billions of devices in a network we know of as the "Internet of things" (IoT), ranging from printers and phones to "smart appliances", like refrigerators and personal security systems. In

essence, anything that can house a computer chip is a candidate for this network. Accordingly, the scope of information has increased. In keeping with maintaining clarity between the storage of information and its rationale with its distribution, we will first look at big data in depth and its implication and then consider its mode of distribution (fog computing) in a similar light. A prefatory note about the origin of the present article is in order.

You are reading "Social Implications of Big Data and Fog Computing", which is a re-write and updating of "Visualizing Big Data from a Philosophical Perspective" that appeared in the 2018, *Handbook of Research on Big Data Storage and Visualization Techniques* (Segall and Cook, 2018, pp. 809-852). Most of the discussion was not simply of techniques but about the thinking underscoring why big data should be generated at all. Inasmuch as the current paper was invited, it can be assumed that someone "up there" thought that asking the "why" is important. The present article goes further and fits the "why" into a larger framework of how we regard societies and the challenges they are facing in an ever-increasing complex environment. As to the visualization, there are just as many ways of displaying data as there are projects and methods for creating it, as will be seen below.

Most of the technical aspects of the original work have not changed, and I will leave it to others to banter back and forth on all that updated "techie stuff". One can only imagine the further technological development that can and often has occurred during the last one or two years in which many of the sources used for researching the first article appeared. Too, the visualization aspect will not be emphasized here, because one only need read the original article for that information. Typing in "big data visualization" and related phrases will produce hundreds, if not thousands of images, each with its own purpose and technique. This is a trivial exercise without much intellectual content. What has been lacking in all these discussions about big data is similar to what was lacking and as expressed by J. Robert Oppenheimer in the development of the atomic bomb – the social implications of the technology.

There has been another addition to the previous article in the technological aspect, however, that does strengthen the sociological observations: the further development – fog computing - that is closely analogous to a neurophysiology and the argument made in the previous article. As in societies being at least analogously organic, there is a corresponding aspect of organicity in the technology, and that is beginning to assume literally a life of its own. But, we are getting ahead of ourselves a bit.

It is likely that each one of us has encountered some aspect of big data, it often being a buzz word. With fog computing as soon as one picks up a cell phone, works on a computer, or even opens the refrigerator door s/he in effect is one of the tentacles of a gigantic organism with emergent properties that we do not seem able to predict or control. Whenever we interact with a government agency, go to school, shop or use a computer, data is collected with or without our consent. As recent as 20 May 2018 controversy is swirling about Facebook's allowing its guard to be down so that the British company Cambridge Analytica could acquire through the popular social media outlet Facebook and mine its data to promote Donald Trump's U.S. presidential campaign. Insofar as privacy is concerned, if the information is in cyberspace, then logically it is accessible, the only secret in existence being the deodorant. The trail from the origins of data as representations of information ages ago to its present uses and abuses is long. While we marvel at the technology, it is critical to understand why the technology was created in the first place.

There is data (big or otherwise) and then there is its use and fog computing distribution. One should fathom the implications of the first to appreciate what happens with the latter. Otherwise stated and amplified, what applies to the first applies also to the second.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

This article will touch on some of the technical aspects of big data and fog computing, what is collected (as in National Security Agency's bulk data collection programme), and the limits of collecting large quantities of data. Overall, if something can be measured, data can be collected be it the length of every spider's leg, width of every tree or weight of every grain of sand. Yet, there is no dearth of facts but without organization and context there is little or no meaning. An overarching consideration is whether it should be collected at all.

Reactions to technology often are like this where people learn of the cleverness being developed, the "wow", "awesome", and glitz of the gadgets. Big data is no exception as in the wide-eyed reaction to being told of huge data storage capacities and now the ability of persons to access that data directly or through their Internet of things (IOT) devices with fog computing. Older generations accustomed to paper-based card catalog systems in libraries especially are taken aback in learning the big data of the whole of the Library of Congress in the very near future (and even now with 20 ten terabyte (TB) hard drives) can be sitting on their desk at home or on their laptop.

Facts are meaningless in themselves and they need to be connected to each other. Even if a person relates the facts to each other still there is no final coherence unless there is a framework for that coherence, i.e., a theme. There are two basic ways of remembering a situation: rote and as a series of connected events or motif. Describing the beautiful setting of the Grand Canyon including the ecology, geological history and so forth is further impressed upon us by introducing something closer and to which we can translate as a relevant experience the way someone like ourselves interacted with that environment as a story. So, one tells of a story of someone in the Grand Canyon invoking the description of all the things the narrator would like for the audience to remember - the environment, history and so forth. This is the way knowledge was passed down throughout prehistoric times by tales, proverbs, myths and other oral communications (Eliade, 1954). Here, a story is told about the development of big data, that story being analogous to a parable conveying meaning of the assemblage of descriptions about that big data.

Contemporary events may seem to be enveloping us, the proverbial tail wagging the dog. One needs to point only to global warming, exploding populations, mounting political and religious violence, and economic failures. There are luminaries who doubt the capacity of this species even to survive the next 100 years (Firth, 2015; Rees, 2008; Sheldrick, 2014; Carey, 2014). We read of events daily often noting the facts but failing to apprehend the context.

To provide meaning, one has to know what gives rise to the data in the first place including the rationale for it, how it is collected and how it is processed. Science gives the rationale for technology, theory does it for practice and overall the "why" is necessary for the "what" of anything. Besides the ways we think, the "why" of thinking is the subject of philosophy. We are also looking for an explanatory model of events that is consistent. There are immediate purposes for collecting data such as for doing scientific experiments and financial transactions, but one should start wondering about the reasons large volumes of data are collected on persons. Science exists because one wants to control the future, but this is done by understanding the past and such involves measurement and attendant data collection followed by analysis. Big data on us often is collected systematically and a case can be made that it is done for the same reason. Fog computing details how penetrating that data can be.

In many cases it seems that science and the technology emanating from it have been sufficient to solve problems where antibiotics in medicine, phones and computers in communications and automobiles in transportation are obvious examples. In each of these areas we can identify big data sets. There are huge research projects like the Dark Energy Survey which uses a 570-megapixel camera and the 4-meter Blanco telescope at the Cerro Tololo Inter-American Observatory in Chile (Wikipedia, 2018h). Genome

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

sequencing, modeling chemical interactions, analysis of social systems and ecological studies are others. Meteorological agencies are attempting to capture meaning through thermodynamic models of weather systems. Then, there is big data captured in sociological analysis. Searching "sources of big data" and similar phrases on the Internet will produce hundreds of websites and images displaying various projects collecting, analyzing and displaying big data.

The capacity to collect data for all intents and purposes is limitless but its organization, analysis and application are the barriers to its utility. Humans have limitations to perform acts as in memorizing and seeing great distances and have devised tools like computers and telescopes to assist. So, it is with intellectual limitations, creating devices like computers to compensate. Big data may be thought of as a tool, the organization as the way of using it. Whether humans have the native abilities (read "intelligence") to manage the complexity is debatable, a factor contributing to the explanation of why so much research is being done in Artificial Intelligence, particularly with the announcement of the Decade of the Brain (Brain Project, 2015). With its 10 billion synapses (Synapses, 2015; Herculano-Houzel, 2012), the brain and associated consciousness arguably are greatest challenges to those collecting and managing big data. Yet, in considering that we live in a society, one asks about society being an entity of its own a human unto itself. Not only must the human brain encounter challenges of an increasingly complex world but we as a species are in the same situation. Think about this while reading the following philosophical account of big data. Consider that the ultimate visualization of big data is looking at ourselves in the mirror. We will first look at "big data" first and its implications, and then we will examine its distribution and use with fog computing.

BACKGROUND OF BIG DATA AND FOG COMPUTING

What Is/Are Data?

A systematic way of understanding the concept being conveyed by a word is to analyze the meaning of the word itself. Origins and context are a good starting point. The etymology of data is:

…1640s, plural of datum from Latin datum "(thing) given," neuter past participle of dare "to give" (see date (n.1)). Meaning "transmittable and storable computer information" first recorded 1946. Data processing is from 1954. (Data Etymology, 2018)

As a definition, there are these examples as the public first encounters the term:

Noun:

1. A plural of datum.
2. (Used with a plural verb) individual facts, statistics or items of information: These data represent the results of our analyses. Data are entered by terminal for immediate processing by the computer.
3. (Used with a singular verb) a body of facts; information: Additional data is available from the president of the firm. (Data Dictionary dot com, 2018)

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

1. Factual information (as measurements or statistics) used as a basis for reasoning, discussion or calculation
2. Information output by a sensing device or organ that includes both useful and irrelevant or redundant information and must be processed to be meaningful
3. Information in numerical form that can be digitally transmitted or processed (Data Dictionary Webster, 2018)

Facts and statistics collected together for reference or analysis. See also datum. (Data Dictionary Oxford, 2018.)

From the basic definition of data and its etymology, one can make some immediate observations.

1. A single piece of information, as a fact, statistic or code; an item of data. (Datum Dictionary dot com, 2015)

Webster's says, "noun plural but singular or plural in construction, data often attributive" (Datum Dictionary Webster, 2015). There is "A piece of information. See also data." (Datum Dictionary Oxford, 2015)

One should note that the technical term is "datum", the singular of data if one is to adhere to the Latin correctly. We will refer to "data" but what is said here applies to the singular "datum". Words common to these are fact, information and statistics. However, as we will see in a moment, the three are not synonyms for what initially is collected but results. One could take a photograph of anything and call that "data". However, we are the ones who give it meaning such as in a fact, information or statistic. The meow of a cat, the ripples on a pond, the smell of a rose, the feel of a porcupine's quill, and the taste of a chocolate bar all are data. The five senses feed to us the reflections of the phenomena of our environment in what we may call "big data."

The term "big data", itself, seems to assume a childlike perspective, a first grade word, "big" being juxtaposed to a much more complex term "data" (as opposed, let's say, to complex data or large information bases). It's coming into use only recently and in a specialized context might suggest that the term is a proper noun, i.e., the first letter of the two words is capitalized. However, common use – lower case "b" and "d" - says otherwise thus giving guidance here (SAS, n.d.). Hence, we will refer to "big data".

It helps to place a datum in its context using a common complexity model, i.e., data, information, knowledge and wisdom (DIKW). This DIKW sets forth:

- Data – mere phenomena
- Information – Phenomena that are processed as being intelligible or not
- Knowledge – Information that is evaluated as to quality or integrity
- Wisdom – Knowledge that is drawn upon to create ideas not found in the knowledge alone (DIKW Pyramid, 2018) (see Figure 1)

Data by itself is phenomena, bits being expressed as zeros and ones in the computer world. Whether it has meaning or not is the job of the information scientist winnowing out whether there is randomness (unpredictability) or patterns. That information is run through an accountability filter, the result being from epistemology (justified belief or knowledge). Synthesizing from that knowledge gives us wisdom.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. Data-Information-Knowledge-Wisdom Pyramid (Ibid.)

The subject of this paper is multiples of datum but is it information? Data is to be processed because often what is encountered is unintelligible. Consider:

```
0001, 0010, 0011, 0100, 0101

0111010101010010.
```

Both are data. There are two ways of looking at whether it makes sense. A mathematician or competent computer scientist will recognize the first sequence as binary or base two counting. The second sequence has no discernible pattern. That the first is intelligible as a pattern means that there is information. The second not having any pattern means there is no recognizable information. However, the other way of "making sense out of nonsense" is reversed, in attempting to translate the binary into words. The first does not translate into text, as it is not divisible by eight. The second does translate into "uR". In other words, whether data has meaning or not can be perspectival; it depends upon one's intent, point of view, and so forth. (As an aside, determining if something has content given a perspective – as in seeing the "uR" instead of nonsense – is meta as opposed to object level. One is talking about something rather than directly using it. For example, one may talk in English about the Spanish "mesa" as meaning "table", rather than simply saying in Spanish "poner esto sobre la mesa" – put this on the table.) While there may be information because of meaning does not say there is knowledge.

The collection of data may be by recording information electronically or even by hand. (For example, a person knowing about the census realizes that at least some of the data is collected the old-fashioned way by physically writing down answers.) How to interpret the data comes under "information" - making sense of it. Whether it has any value refers to knowledge and this is largely dependent upon organization and subsequent validation.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

The Origin of Data Collection

It is thought that Protagoras (c. 490 c. 420 BCE) said "Man [humans] is the measure of all things" (Wikipedia, 2018n), be it a qualitative description of phenomena or a quantitative measurement. Data collection can be as simple as making a tally mark on a stone, as was done in the Upper Paleolithic period of human development (Wikipedia, 2016) between 10,000 and 50,000 years ago. The 30,000-year-old paintings in the southern French Chauvet-Pont-d'Arc Cave (Wikipedia, 2018d) are data. Any recorded description involves data.

Measurement involves a language that conveys a concept of comparison. Comparison rests upon a fundamental law: something exists because of what it is not, a law of dialectics. One may picture her/himself in a room where everything is of the same shade and texture. There would be no way of discerning one object from another. If the lighting is changed, let us say as a single light bulb being the source of illumination, shadows will appear, each object now contrasted with the other by the shadowing. This simple discernment is comparison. Measurement can yield both the discernment and its magnitude of difference.

Data is about description, description is about comparison and comparison is about measurement. Otherwise stated, measurement, in its most basic form is about empiricism or understanding through the senses or in modern parlance, "sense data". These data are collected through sensors, our bodies having the most immediate sensors: tongue (taste), skin (tactile), eyes (sight), nose (olfactory) and ears (sound). Humans construct devices to extend the abilities of the natural sensors. Fog computing, itself, is a manifestation of how ubiquitous these sensors are.

Perhaps the simplest form of an artificial sensor is the sun dial or even a stick in the ground reflecting the position of the sun in its periodic traversing of the Earth's sky. The specific length of a shadow indicates time of day. The shadow is a piece of data, the information being that the shadow is so many centimeters long, the knowledge being that it is five o'clock in the afternoon. All of these sensors, natural and artificial, collect data, that data being processed to determine if it makes sense or contains information. Whether that information has any value requires higher cognitive faculties to evaluate it, memory, ability to compare and so forth.

To understand the world, we have come to rely on empiricism that which is gained through the senses. Science applications have yielded sensor technology where data about every motion and energy emittance can be sent to us for our devices to process. The explicit way of generating detail was verbalized by Rene Descartes (1596-1650), the modern originator of the analytical method. Descartes said, "...we cannot conceive body unless as divisible … body is by nature always divisible... (Descartes, 1641)". He set the stage for modern deduction theory and analysis thus highlighting the philosophy of the Age of Reason or Rationalism. It is subdivision, after all, that is the origin of big data.

Current Sources of Big Data and Rationale for Generating It

Big data results from measuring complex phenomena. Broad categories are exemplified by:

- Fluid dynamic processes (weather, bodies of water, behavior of gases)
- Nuclear processes (Large Hadron Collider, simulation of nuclear explosions)
- Social interactions (economic, political, educational, sociological)
- Biological descriptions (Human Genome Project, Artificial Intelligence)

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

In essence, if one wants to produce data, simply subdivide the phenomena or synthesize by relating two or more pieces. Observing phenomena and collecting information on it is guided by basic parameters as in:

- The nature of pattern and randomness
- What to look for
- How to look for it
- What to do with it

The "Techie Stuff" Concerning Big Data

Characteristics of big data often are listed as:

- Volume - How much of it there is
- Variety - How much difference there is in what is collected
- Velocity - How fast the data is coming in and processed
- Variability - How consistent is the characteristic of the data coming in
- Veracity - Refers to the quality of the data received
- Complexity - The number of sources as well as the type of data received (Big Data Characteristics, 2015; Kalbandi, 2015)

"Volume" is discussed here in terms of storage. "Velocity" refers to processing speed, a topic covered here after storage. "Variety", "variability", and "complexity" correspond to organizational issues. "Veracity" is discussed in terms of the data-information-knowledge-wisdom (DIKW) hierarchy discussed above.

Four parameters may be considered as limiting big data: how much potential data there is to be collected, the storage of it, the processing speed and the management (organization, interpretation and application) of it. We now treat each of these in turn.

Collecting data is no problem, as the plethora of sensors (Tae-il, 2013) indicates, as well as our capabilities of Cartesian analysis (Descartes, 1641). Any object can be subdivided to Planck scale, 1.6 x 10^{-35} meters. At this quantum level particles "flick in and out of existence" (Hawking, 2018). To illustrate the possibility of representing every aspect of our universe, one may consider Bostrom's (2003, pp. 243-255) idea that we may be inside of a matrix, part of a computer program. Such would require modeling and managing 1080 bits corresponding to the number of particles in the universe according to one physicist (Heile, 2015) and the same as the Eddington number of protons (Wikipedia, 2018i). This quantity of data far exceeds any current ability to store it, let alone process it, although quantum computing (Wikipedia, 2018o; Khodjasteh, 2013) may provide solutions in the future. Also, it may be possible to approximate a description of the universe by representing groups of these particles. Here, it is the quality of representation and subsequent organization of data that would be the determinant in successful management. Further,

A simulation that is undetectable by science (for instance, both astronomers and quantum physicists) would have to be very large and detailed, it would be very hard to justify its vast costs (it's easy to compute what is the physical volume of computer memory required to try to simulate a unit volume of substance-Avogadro constant is still very large in comparison to the volume of computer memory: The

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

most powerful supercomputer in the world (in June 2015) has "only" circa 1015 bytes of memory, compared with circa 6 x 1023 - particles contained only in 12 grams of unit matter and such supercomputers nowadays still have the weight of hundreds of tons.). (Webb, 2014)

To place data storage in perspective, consider that the whole document set of the U.S. Library of Congress can be stored in 200 terabytes (TB) (Johnston, 2012). Shantanu Gupta, director of Connected Intelligent Solutions at Intel is reported as saying that:

- On YouTube, 72 hours of video are uploaded per minute, translating to a terabyte every four minutes
- 500 terabytes of new data per day are ingested in Facebook databases
- The CERN Large Hadron Collider generates 1 petabyte per second
- The proposed Square Kilometer Array telescope will generate an Exabyte of data per day
- Sensors from a Boeing jet engine create 20 terabytes of data every hour (Higgenbottom, 2012)

To relate data storage quantities to each other, consider Table 1:

In 2010, it was estimated that storing a yottabyte on terabyte size disk drives would need one million city block size data-centers as large as the states of Delaware and Rhode Island combined (Diaz, 2010). However, the writer does not specify how tall the buildings would have to be and as will be seen shortly, the capacity of disk drives keeps growing. Too, Quantum Computing may drastically enlarge the ability to store data currently kept in separate spaces all in one place (Khodjasteh, 2013).

Table 1. Multiples of bytes

MULTIPLES OF BYTES

A better representation of this image can be seen in the electronic version of the publication.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

A further perspective on yottabyte storage capacity is:

With recently demonstrated technology using DNA computing for storage, one yottabyte of capacity would require a volume between 0.003 and 1 cubic meter depending on number of redundant backup copies desired and the storage density: "Our genetic code packs billions of gigabytes into a single gram". DNA is much less mature technology than microSDXC cards (for this application) and accompanied by uncertain costs but this suggests potential information density. (Yottabyte, 2018)

Here and elsewhere in this article are descriptions of technological capacities, such as the size of storage devices, figures which have been increasing as advances are made. Accordingly, little attempt has been made to obtain new figures since the publication of the previous article, as it is those figures not only are sufficient to make the point of the arguments but are now even more reinforced by those advancements.

As of this writing (March 2018), for a desktop personal computer (PC) one can purchase across the counter in retail consumer outlets a four Terabyte (TB) hard disk drive (HDD) for under $100. In September 2014, a desktop PC 10 TB HDD appeared (Hard Drive Capacity, 2015). In 2018 the capacity had increased to 12 TB and for under $800. One TB thumb, or flash drives were available at the end of 2015 (Thumb Drive Capacity, 2015). While the prices started out high, as with the current lower storage capacity ones, price drops could be expected, given the downward trend in prices in other technologies. This all says nothing about solid state drives with vastly reduced access times. These are desktops and laptops that the ordinary consumer can purchase. Data storage does not seem to be much of a problem. What, then, about processing speed?

A four-time winner, Tianhe-2, a supercomputer developed by China's National University of Defense Technology, once more took home the title as the world's fastest computer with a performance of 33.86 petaflops (quadrillions of calculations per second) on the Linpack benchmark. To reach that remarkable number, Tianhe-2 uses over 3 million Intel Xeon E5-2692v2 12C cores running at 2.2GHz. It's not the speed of the processor you see in modern-day supercomputers that's important; it's how you get all those processors to work in concert with each other. In addition, its main processors are backed up by Intel Xeon Phi 31S1P coprocessors. (Tianhe, 2015)

Then, "President Obama has signed an executive order calling for the US to build the world's fastest computer by 2025 (Baraniuk, 2015). The supercomputer would be 20 times quicker than the current leading machine which is in China (Supercomputers, 2015).

In terms of cloud storage, the sky is the limit. One only needs the hardware and connectivity. With many free email services, 15 gigabytes of storage are routine. Then, there are dozens of data storage services such as Dropbox, Trend Micro, and Google (Wikipedia, 2018e; Wikipedia, 2018f). Of course, there are pros and cons of such methods, but data storage capacity itself is not an issue, at least for home use and most scientific projects.

Organization of the data is the bottleneck. However, organization is somewhat simplified if one knows the purpose for which the data is sought. Once an organizational scheme is identified, then the sophisticated and often abstract aspects can be presented visually. That a "picture is worth a thousand words" works quite well if that picture is that of the purpose.

Visualizing Big Data and a Research Excursion in Pattern Recognition

Pictorializing big data is for our benefit. A picture is worth a thousand words. The display of the data itself or a picture representing it may give us some insight into the data's meaning that verbal descriptions may not be able to do. For examples, one does an internet search for "big data visualization" and similar phrases, selecting "images for" to see the myriads of ways of presenting big data displays. There are just as many images as there are algorithms to generate them, given an Internet search under "Visualization of big data" and similar phrases represented by the examples above. Many times, visualization techniques are just as much of an art as they are a technical methodology. One visual presentation of what otherwise would be incomprehensible in formulas and words may not make any sense to one person but may be enlightening to another.

How might the data be visualized? It has been said that, as in statistics, there are two basic forms of presentation: to the specialist in the area and to the public. There are processed and unprocessed data where less refinement is required for the specialist. In each area of inquiry, different project teams may collect and process data with different methods.

Particularly relevant to this discussion is open data where:

Thanks to open data we now have services such as App&Town: an application that acts as a guide from your point of departure to your destination using Barcelona's metropolitan transport services. The app offers the best routes and indicates where the nearest stop or station is as well as advising when you have to get on or off; or how about CityBikes, which provides information about the city's Biking system. As a useful aid for the health sector mention should be made of SOS info: an application that shows information about the user (allergies, illnesses, emergency contact details, etc.) and the location of the nearest emergency services. (Spelling in original) (Barcelona Smart City, 2015)

An additional method of visualizing data is with context diagrams showing the interrelation of components in a system (Wikipedia, 2018g). These often convey a crisp and clear meaning about what the data means as opposed to tables of data about voters wanting something from their representatives or figures showing what happens inside the system (as in traffic patterns, revenue, numbers of students per school, etc.).

Now, we get to the deep structure of data and begin our trip of pattern recognition.

It needs to be stated at the outset that bivalency is used to designate the on and off switch conditions in computer architectures. No inherent meaning exists in the way computer scientists design these architectures or the machine language software they manage. Nor is there any particular significance in the zeros and ones in themselves as any symbol could be used to represent the on and off conditions. The bivalent logic that computers use to generate data of any size is a language of a basic order in the universe (Horne, 1997). Here, the logic is specifically applied to how the concept of magnitude is regarded, in this case a base two counting, most commonly expressed by the zeros and ones. Sets of zeros and ones are arranged according to rules or instruction sets, each computer chip architecture having a different way of configuring these. Machine code instruction sets are unique to each processor or processor family, the instructions themselves being physical designs of bit arrangements that represent machine commands. This means that the instruction set belongs to a particular processor class but using generally the same type of architecture (Machine Code, 2018) rather than from any natural ordering, as in binary counting.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

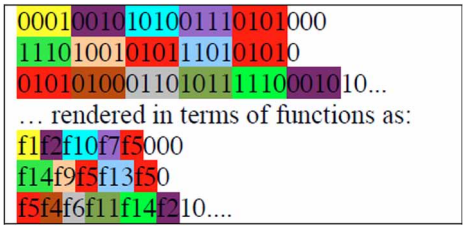
With any digitized phenomenon, including large bodies of data, recursion might be used as a method for detecting patterns not otherwise revealed by mathematical analysis or visualization. The Wuensche and Wolfram designs above result from repeatedly and randomly concatenating binary operators, a type of recursion. Recursion here means that the outputs of a binary formula are fed back in as inputs until the function reappears as an output (Horne, 2006).

There is a natural binary space that emerges from fundamental dyadic computations of base two (Horne, 2006). Contained in a display of zeros and ones, as above, are sets of four representing binary functions where p and q are placeholders for the permutation of zeros and ones, shown in Table 2.

A logician, mathematician, and computer science student will recognize that this table shows a binary counting from left to right, reading the columns downwards: 0000, 0001, 0010, etc., functions f0, f1, f2, f3, onward to the right. Any display of zeros and ones will contain complete or partial sets of functions from the TOLS as in Box 1 (using the arbitrarily selected color code):

Not only is each of these functions recursive, but any function over any other two functions, f*(fn,fp) is recursive as well because there can be only a maximum of 16 iterations (only 16 unique functions) on any branch before there is a repetition of one of the previous (Horne, 2006). Otherwise stated, even if there are 16 unique outputs on a branch, there is repetition on the 17 iteration, i.e., no function can have more than sixteen iterations. This is reflected by a three-dimensional hypercube displaying all 4096 dyadic relations (Horne, 2012). Of 16 panels, there is, for example, f_{13} - ⊃, p contains q, p ⊃ q, – defines deduction shown by Table 3.

The recursion method is shown in Table 4 with the diagram for Function 9 in Figure 2.



We said that just because there does not appear artistically to be a pattern, it doesn't mean that there is not one as the example above illustrates. In terms of visualization, reducing binary strings to functions may assist in detecting patterns. For example, we have the traditional truth table rendering of (p & q) ' [(r = s) v (p ' r)] in Table 5.

Table 2. Table of Functional Completeness (Horne, 2006)

p	q	f_0	f_1	f_2	f_3	f_4	f_5	f_6	f_7	f_8	f_9	f_{10}	f_{11}	f_{12}	f_{13}	f_{14}	f_{15}

Table 4. Recursion method (Horne, 2006)

For the p side: F*(fp, fq) = fa F*(fa, fq) = fb BaraniukF*(fb, fq) = fc ….	For the q side: F*(fp, fq) = fa F*(fp, fa) = fb F*(fp, fb) = fc …. Max F*(fp, fq≤16) before there is repetition

This is reduced to a table of functions (Table 6), making it easier to discern regularities.

In Table 6, without the distraction of the detail of the 0s and 1s, one may discern repetitions of functions. Again, the configurations do not necessarily convey any deeper meaning than that there is a regularity. One, however, should ask what "generates it" and moreover, "why", beyond the simple fact a formula exists. That is, what generates the formula?

Latent or unexpected arrangements and processes may exist inside data displays. What results is "emergence", something that cannot be explained by the properties of the individuals used to create the results (Emergence, 2018). All digitized data is in its most basic form bits (zeros and ones). Usually, data storage is according to predefined categories used to collect it. The more vague and coarsely grained the categories, however, the less context and often the less value. Displays of large data sets as zeros and ones may reveal patterns whereas other forms of analysis may not. This works in at least two ways, the first being the existence of patterns in a binary display but no known ordering (or categorization of data) principle and the second where the ordering principle is not known but there results a pattern which then tells the person that principle.

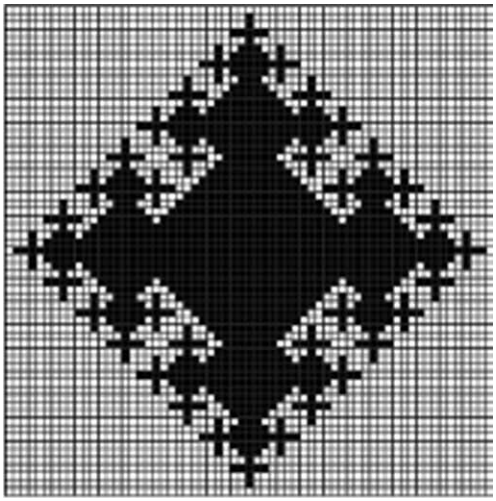
For example, there is a pattern, a regularity, in the following images in Figure 3 and Figure 4, generated by randomly concatenating dyadic binary formula but no meaning is obvious beyond that, the issue being that apparent randomness can spawn order.

These patterns of Wuensche (1993) and Wolfram (2002) may not represent or convey any meaning by themselves as in a display of machine code (Wikipedia, 2018k) of zeros and ones. Rather, the art results from a naturalness. East Asian philosophies have mandalas and koans, objects and expressions upon which persons can meditate to gain meaning and perhaps these images may be included. Overcoming randomness is through pattern recognition and such allows us (or so we think) to manage the future. As

Figure 3. Regularity in cellular automata (1) (Wolfram, 2002)



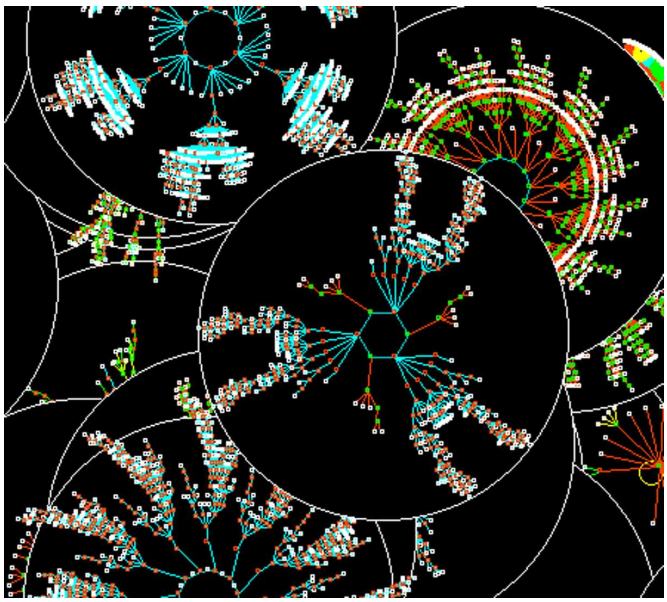


Figure 4. Regularity in cellular automata (2) (Wolfram, 2002)

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

has just been seen, though, regularity does not compel us to repeat it, only to know that an order exists. Above, the regularity in the visualization seems to challenge the supposed randomness used to generate the images. Tautologically, knowledge of order is foundational to answering why it exists.

The second example of discerning a pattern in a binary display and extrapolating the algorithm is exploratory research representative of visualization that may explain data ordering where initial analysis may not. In a more purposeful fashion, most modern computers generating and managing big data use machine language, an example of which is:

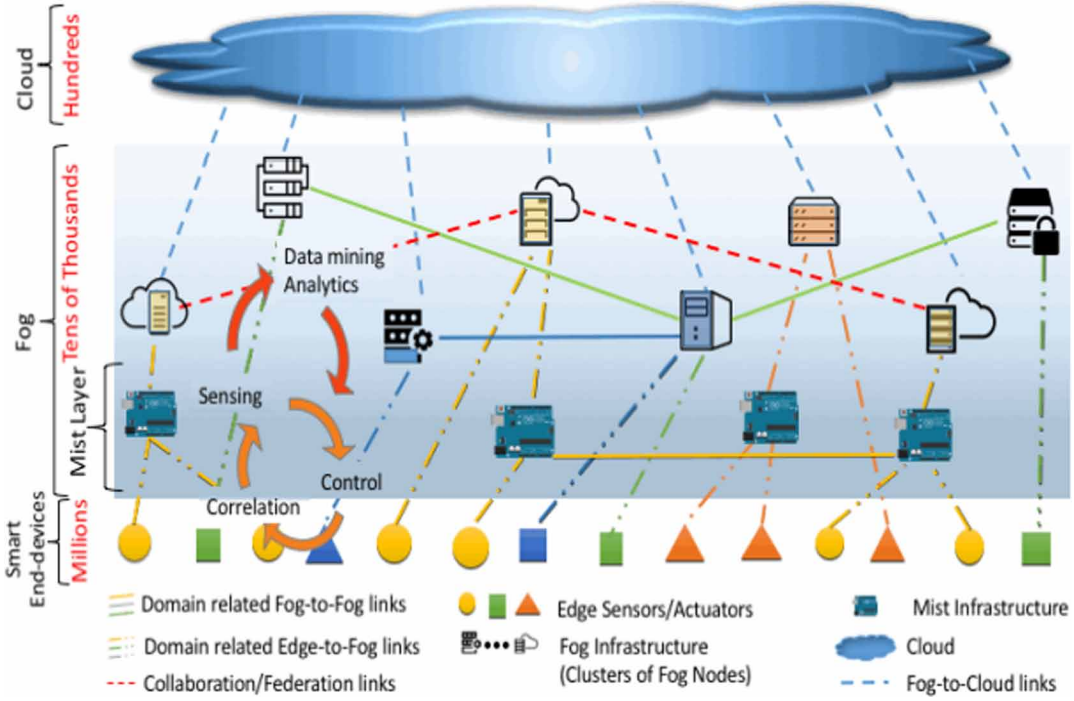
```
01101100 01100101 01100011 01110100 01110010 01101111 01101110 01101001
01100011 00100000
01101101 01100101 01100100 01101001 01100001 00100000 01110100 01101000
01100101 01110010
01100101 00100000 01100011 01100001 01101110 00100000 01100010 01100101
00100000 01110110
01100101 01110010 01111001 00100000 01101100 01101001 01110100 01110100
01101100 01100101
00100000 01110000 01110010 01101001 01110110 01100001 01100011 01111001
00100000 01100001
01101110 01111001 01110111 01100001 01111001 00101110
```

To a person unfamiliar with binary code, this display would be meaningless, but its meaning is translated as, "With an electronic media there can be very little privacy anyway" (Binary Translator, 2018).

On the heels of this statement two aspects need to be considered about what is found inside data, other than the ostensible information they may convey. First is a pattern inside the zeros and ones that may emerge despite attempts to mask their ostensible messages. The second is to illustrate that wherever there are zeros and ones there is the opportunity to introduce other information, as in malware.

What is Fog Computing?

This author loves standardization, and the U.S. National Institute of Standards and technology (NIST) is working on a definition, as expressed in its August 2017 "The NIST Definition of Fog Computing" (NIST, 2017, p. 2):



Fog computing is a horizontal, physical or virtual resource paradigm that resides between smart end-devices and traditional cloud or data centers. This paradigm supports vertically-isolated, latency-sensitive applications by providing ubiquitous, scalable, layered, federated, and distributed computing, storage, and network connectivity.

Let us compare NIST's diagram of fog computing to human anatomy.

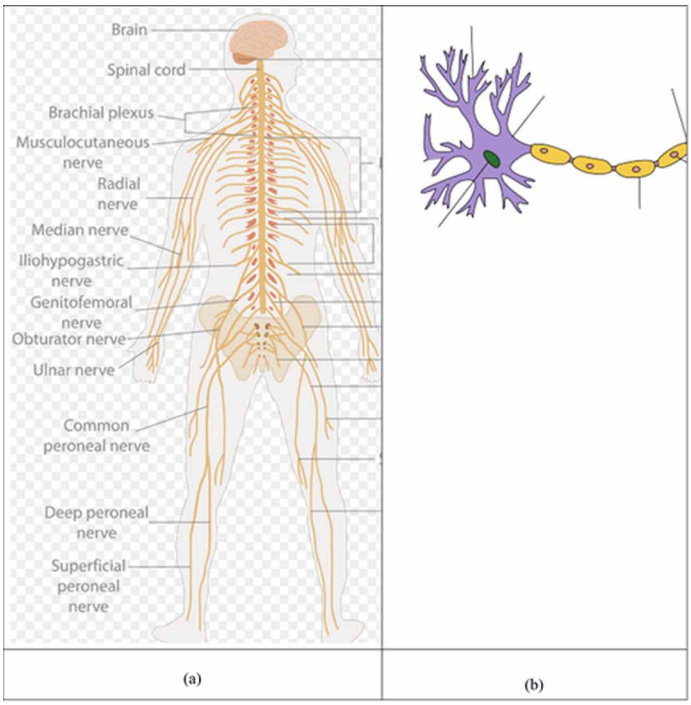
The cloud might be considered the human body, with the "fog" underneath it the various organs, and the "smart-end-devices" the neurons. Here, the NIST diagram might be a misleading, as big data can and usually is stored in computers, with the devices feeding in an receiving big data. There seems to be a transformation, where big data is being shifted to the cloud, with the computers being its manipulators.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 5. Cloud computing configuration (NIST, 2007, p. 8)

Of course, the "elephant in the room" question is where the big data is being stored in the BIST model, other than the "cloud". Of course, the answer is in computers, albeit especially configured.

Still the hierarchy of number applies, there being many more neurons than nerves, and many more nerves than organs, and so forth. The overall discussion does not change, in that there are what analogously are data reception, transmission, and manipulation devices (cell phones, IoT, etc.) and a passage from these to a central area (cloud, huge data banks, etc.), the whole configuration effectively acting not unlike a huge organism that potentially could develop a life of its own.



We will see all of this in a social context later, but for now the comparison should be obvious, with all the attendant implications of self-organization, as the discussion about Wolfram, Wuensche, and emergence above indicated. Cloud computing might be regarded as a brain in the Internet overall, or at least that part of the Internet brain responsible for memory (see Figure 6).

THE IMPORTANCE OF BIG DATA AND FOG COMPUTING

Big data concerns us for several reasons. The quantity of phenomena is so large that it makes the job of organizing, interpreting, and controlling it enormous, our frustrations often being reported in terms of "too much information" (TMI) or "information glut". One's ability to process it is complicated further if there is more potentially extraneous data. Then the "fingers" of control with fog computing ultimately manipulated by those generating and applying big data are more ubiquitous than ever, the end-users of data weighing convenience against privacy.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 6. (a) TE-Nervous system diagram (Own Work, 2010); (b) Neuron (Quasar Jarosz, 2009)

There are many relatively neutral projects where huge amounts of data result but to which there is little direct relation to us as in data from surveying the universe. Closer to us, there is information more of a personal concern. Each time one makes a purchase, data is collected, mainly the details about the transaction amount, date, store and item purchased. Beyond that there are other data about the person making the transaction, web data collection forms being a primary example. We are asked about who is making the purchase, why, income, age, sex and so forth. Marketers and advertisers particularly are interested in a buyer's profile for repeat business. Universities collect data on students and faculty and government do on the citizens/subjects in order to manage them.

The importance of what is to be identified comes first. Then, is how to collect it. The quality of collection is next. Organization is next. Then, we need to interpret whether collected data is information or not, as in the DUIKW pyramid discussed previously. These areas may overlap as in identifying the pieces before organizing them. We now come to the eye of the storm, humanity, itself. The philosophy underpinning big data can be discussed as concerning that apart from us as in scientific studies or what persons collect when we, ourselves, are observed. There are individuals and there is the society in which they live; big data exist for both. Philosophy is about asking "why".

Two aspects emerge. The first is about how we relate not only to big data, itself, but how we relate to those who are using it. Besides the privacy issues are social policy analysis and application in achieving ends which may not be agreeable to us, increased complexity of cataloguing use and access, and security. The second aspect is about the organic character of big data and how its development and evolution may track the development evolution of societies. Society may have a collective brain with its memory, so

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

the collection of big data can be regarded as a memory to be accessed and used by artificial intelligence or consciousness. First, though, let us look at what is being collected now as big data and then we can discuss the future in terms of societal development.

The Social Source of Data

Data results from a record keeping, the purpose of which is to understand how to manage the future based on the past. This method is an outgrowth of the millennial-old playing of games but in a more formalized manner. For example, assessing a person's throwing capability by itself may not have much value but there is more meaning when viewed as the person having to compete with warriors with different capabilities. The data is a record of that person's capability. The individual is viewed in a systemic context, the society benefiting from a positive battle outcome. Further on down, the nature of social systems will be discussed, but for now a system is viewed as a collection of elements related by having a common purpose and interacting with an environment so as to be able to survive or adapt.

From various projects emerge big data but one should ask what produces the projects. Big data often is associated either with just itself as in an often-inchoate mass of bits to be processed into information and organized or big data is associated with large-scale undertakings such as designing medicines or analyzing thermodynamics, but these do not simply happen. Organizations initiate them; more precisely, persons individually or collectively with motivations having enough influence in the organizations initiate them. In attempting to describe the future behavior of a society researchers will describe it with a model, much in the same manner a toy airplane "describe" a real one.

Researchers instantiate a model with various hypothetical factors and events to observe possible outcomes. As an example, one speaks of ecological systems. A particular one, as that in any country, is a model. The climate, vegetation, fauna and so forth are identified as elements. One then gives these variables a special condition, as there being a specific type of animal, tree or crop and studies their interactions in a simulation. Another example is that of a city where aspects such as traffic flow, electrical power management and communications management in themselves require big data sets. However, each of these is a subsystem within the framework of a larger one, the city. Here, all the data is collected, processed, interpreted, and disseminated within the larger context of a large dynamic system (the city), analogous to an organism composed of numerous subsystems all working together, a key word here being "organism". The simulation occurs by inserting specific examples of vehicles in a traffic flow, number of megawatts of power being supplied and how many phone calls are being made at a specific time.

One often cannot predict from big data sets precisely what will happen. This means that an outcome cannot be explained by what the pieces are doing or their properties individually. This is called "emergence" (Vintiadis, 2018). In essence a collection of entities with a purpose (a system) seems to assume an activity or life of its own. Such is what appears to be "organic behavior" in big data in the form of the Internet.

Networked computers are subject to compromise when there are one or more deleterious factors involved, malware (Wikipedia, 2018L) being the prime example. Over the years a medical or organic model has been used to address the problem as the "virus" and "anti-virus" terminology illustrates. So too the Internet has assumed a character that can be considered "organic" as a search for "Internet as organism" will show. In a way similar to how big data being generated in drug trials (simulated and real), a simulation may show what effect a specific piece of malware would have on the Internet at a specific time.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

A simple Gedanken, or thought, exercise will place data collection about us in perspective. If there is a phenomenon, it can be detected either naturally or with some aid as in a sensor. This is no less true for ourselves in every organ, cell, movement or behavior as we above with the cellular-scale sensors that can be integrated with body tissue (Tae-il, 2013). One can subdivide to the quantum level and organisms including *Homo sapiens sapiens* (the correct and technical name for human beings) are not exempt. There are numerous projects that collect and manage big data and these in themselves are feats that impress technophiles, but a larger picture emerges when they are seen as articulating as an organic whole. Who would care, were it not for the controversies over data collection and privacy, most of which focus on one's privilege to protect identity and prevent control by others? We are our own commanders, and the more someone else knows about us the greater potential they have to rob our identities, extort us and even replicate us making the individual superfluous.

Again, we need to be asking throughout, what drives big data? It is not simply about describing an individual in her/his entirety even the brain and consciousness. There are large data sets generated by easily identifiable projects, but, overall, we have that background question about the coalescence of large data sets. It may be argued successfully that the full power of the State rests upon the ability to collect, manage, and analyze data and the ability to exert its power (ultimately in a physical manner). We will discuss more formally later the nature and role of the State.

One should notice this discussion has progressed from talking about big data emanating from systems without human involvement, such as thermodynamic systems, quantum-cosmological phenomena (CERN [originally Conseil Européen pour la Recherche Nucléaire]), the Sloan Digital Survey) and ecological research to systems in which humanity plays an increasingly involved role or ones it has created outright as in the uninhabited autonomous systems (UAS), brain research, and human genome projects. It is humans - the creator and observer - to whom data and its management are important, and surely big data is created in these arenas, arguably the largest data sets of all.

Outside the development by governments are non-governmental big data projects that are just as sophisticated in replicating human behavior. Aside from the above references to artificial intelligence and non-hydrocarbon replication of the human brain are modeling and simulation projects of society, itself and for which research data can be obtained. Two prominent examples are *Simulated Society* (SimSoc), started in 1966 and the recent *Second Life* created in 2003. A visitation to these sites (easily accessible by an Internet search with these terms) will illustrate how far we have gone in creating an electronic world in which persons can interact to such a realistic extent that they will go so far as real world trading in currency (as in Linden Dollars for Second Life) and artifacts used in the simulation. We are on the edge of technological advancement not only in the realm of virtual reality but venturing into three-dimensional virtual worlds, where human consciousness could not only be altered but permanently affected and possibly merged into a larger world. In these social simulations it is instructive to observe not only the extent of big data generated but how the virtual and real world might cross over into each other by data manipulation.

Let us look at several examples of how big data is collected on our mentation (intelligence, emotions, psyche, behavior, mind, consciousness, etc.), our daily activities, and various social interactions with respect to the military.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Big Data About Ourselves and Psyche

To understand the conceptual framework for assessing the scope, purpose and ultimate meaning of big data as applied to our personal lives, we need to discuss its context, both historical and current. A central goal of modern scientific endeavor is to extrapolate from the past so as to be able to project to the future so as to be able to manage it. The more we know about objects and processes in our environment, the greater potential we have for managing the future. Immediate concerns over data collection on ourselves focus on privacy but a larger context shapes long-term outcomes of other having data on us. Here, each piece of datum is mapped on to an aspect of our lives. Precisely why would anyone want to do this?

Aside from the everyday data collection at supermarkets by various governments, educational institutions and corporations, we have seen data collection on ourselves in a detailed way but another concerns the way we interact with society.

Perhaps it is natural for a person to react in some way - often by surprise and wonderment - when particular attention is paid, as when someone is taking a picture unexpectedly. Answering a few questions in an initial social exchange is to be expected. "Where are you from? What do you do?", etc. However, in this initial and casual exchange, anxiety heightens the more interrogation proceeds. In exchanges with organizations, a certain amount of data is anticipated to be collected, but again, the more that is collected the greater concern there is about motivation.

In the government area, official business is recorded from the military, driver's licenses, taxes and so forth. For schools, there is student data that can be in detail ranging from name and address to psychological profiles and detailed financial information.

With each encounter with a person or organization arises an opportunity for measurements to be taken of every aspect. Stand back, observe these and other sources of data, and consider collecting all of this data under one roof, thus allowing storage of a complete description of a person's past, present and probable future. So far, we have seen examples of projects that each unto themselves can generate big data, but there is one project beyond that encompassing all of the above and more. Each of us has both a physical and mental health collected by doctors and hospitals and big data reflects this. Going beyond a doctor's visit, physiological data now can be collected at the cellular level, where micron-sized sensors can be integrated with tissue (Tae-il, 2013), these sensors also being a part of fog computing.

In the not so distant future, the health of each any every cell hypothetically might be monitored in a manner analogous to how numerous intelligent communications devices report on their own health (how data is collected, managed and applied) such as smart phones. Fog computing is designed to manage this level of data collection and management granularity. We are on a curious road of complexity that may lead us in unanticipated directions. Thermodynamic and other physical systems present degrees of uncertainties and ranges of possible configurations and behavior that tax even the most advanced of contemporary supercomputers (Tianhe, 2015). Yet, the most complex of all is our brain and associated consciousness.

What follows is not an argument that the research described can be accomplished successfully but that we need to pay attention to what is driving it. The former may be fiction, but the latter is fact. In the past decade, a number of projects have arisen to replicate the human brain, some of them being Blue Brain, Riken Brain Science Institute work and SyNAPSE (Blue Brain, 2015; Riken, 2015; IBM SYNAPSE, 2015; Human Brain Project, 2013). Ray Kurzweil (2015), leader of the Singularity Movement (Singularity, 2015) and Artificial Intelligence advocate categorically states that success along these lines is a distinct possibility. An appreciation for the scope and depth of research on replicating human menta-

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

tion ("consciousness", intelligence, memory, etc.) may be gained by reflecting on a sample of available literature on the subject in "Steps toward Memory Preservation v1.6" (2018). Reading the bibliography is an eye-opening research exercise.

A description of physiology is easy compared to that of consciousness associated with the human brain (Toward a Science of Consciousness, 2018). The psychological domain has not been precise until more recently when diagnostic and treatment models became more medically oriented. Today, getting diagnosed and treated more often than not starts with a psychiatrist, a medical doctor specializing in the managing of mental problems. For many years the *Diagnostic and Statistical Manual of Mental Disorders* (DSM) has been used to identify persons with abnormal deleterious mental conditions or disorders (DSM, 2015). However, it is clear that a person emerging from a psychiatrist's office with an evaluation based on the DSM of being mentally healthy can and does engage in violent behavior. That is, nothing in the application of DSM criteria guarantees these people will or will not act violently. One reason is that there is no clearly defined validation mechanism for the DSM. Human behavior until recently has been described primarily by a subjective evaluation of behaviorists relying on observing how a person acts and her/his reports of interactions with the environment. There is no set of clearly defined and uniformly applied metrics to observable conditions; diagnosis is behaviorally based. The DSM is merely a checklist of phenomena to be recorded and judged from professional training and experience. Even though the American Psychiatric Association is transitioning the DSM to the United Nations World Health Organization's International Classification of Diseases (ICD) (ICD, 2015) and even though it may be a more detailed description of a disorder, the same remarks about the DSM apply to it as well.

In 2008, the U.S. National Institutes of Mental Health (NIMH) initiated its Research Domain Criteria (RDoC) project to arrive at diagnosing mental conditions based on an integrated approach including neuroimaging and genetics (RODC, 2018). In NIMH's word:

RDoC is a research framework for new ways of studying mental disorders. It integrates many levels of information (from genomics to self-report) to better understand basic dimensions of functioning underlying the full range of human behavior from normal to abnormal. The RDoC framework consists of a matrix where the rows represent specified functional constructs (concepts representing a specified functional dimension of behavior) characterized in aggregate by the genes, molecules, circuits, etc. used to measure it. Constructs are in turn grouped into higher-level domains of functioning, reflecting contemporary knowledge about major systems of emotion, cognition, motivation and social behavior. (RODC, 2018)

Cognitive neuroscience is a rapidly developing field in which various parts of the brain are found to be responsible for specific behaviors (Brain Behavior, 2015; Wimmer, 2012; Gazzaniga et al, 2009; Kanai, 2011; Dawes and Fowler, 2009; Miller, 2012; Cope, 2014). To replicate the human mind requires at least an accurate and complete description of it as in the Research Domain Criteria project and the BRAIN Initiative (Brain Initiative, 2015). Neuroimaging is here and data collection underpins it. What to do with it shapes what data will be collected and how it is organized. Data collected on us now and of which we have concern about privacy is that reflecting our behaviors. Information on how one acts now can be significant in predicting how the person will act in the future.

There has been advanced a more formidable rationale for wanting to know how a person may act especially in light of increased worldwide terrorism and crime. The Broad Agency Announcement (BAA) BAA 11-65 calls for "New approaches for understanding and predicting the behavior of individuals and

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

groups especially those that elucidate the neurobiological basis of behavior and decision making and the neurobiology of moral judgment, development, and action." Factors motivating the DARPA search include (as stated in BAA 11-65) the need to understand:

- Attitude and habit formation particularly when uniquely influenced by or highly plastic in response to virtual interactions;
- Measuring human propensity to engage in violence against out-group members;
- Mechanisms important to mobilization into violent social movements and groups;
- Pathologies resulting in warfighter accidents, misjudgments and maladaptive behavior. (Broad Agency Announcement 11-65, 2015)

The BAA 11-65 was a first step in researching how that behavior might be preempted. Ultimately, the contract was awarded to Fast Mathematical Algorithms & Hardware.

FMA&H will enable scalability to massive data of their basic analytic database processing system therefore addressing all components of their system. The scalability of their system will be tested and measured on several databases. The first tests will be on hyperspectral imagery where each pixel is a point in 256 dimensions and we have several megapixels. An outcome of the organization is an image segmentation coupled with a related spectral feature sets, integrated with the data morphology, to be achieved automatically with the data viewed as a generic database of size 10 (power of 6) X 256. Other tests will be performed and evaluated for efficiency on massive genetic databases as well as document elections (BAA 11-65 Award, 2015).

Ethical systems are predicated upon what their creators consider what should and should not be done in society. These "shoulds" and "oughts" are translated into the day-by-day standards of behavior, the moral code. Usually, ethical systems are predicated upon value systems or an ethos. These systems may be regarded from either the creator's perspective or the one expected to abide by the system. This consideration is even starker in discussing the ethics of social control. Attempts have been made to produce automated human behavior evaluation software such as Effects Based Assessment Support System (EBASS, 2015) and SENTURION (2015).

That the U.S. Taxpayers are funding research on how they may be controlled, evidenced by BAA W911NF-17-S-0002 (2017), where the Army Contracting Command of the Army Research Laboratory (ARL) is calling for research to

…to support Strategic Land Power Dominance for the Army of 2030 and beyond.… Proposals are expected to be for cutting-edge innovative research that could produce discoveries that would have a significant impact on enabling new and improve d Army operational capabilities and related technologies. (Ibid., p. 1)… The Social and Cognitive Networks programs …supports projects that contribute substantive knowledge to theories about human behavior and interaction and make methodological advancements in modeling and analyzing social network structures (Ibid., p. 54) … Integrated Intelligence, Theory of Mind, and Collective Intelligence (ibid., p55) … identifying and modeling the coevolutionary multiscale dynamics of human neural, cognitive, physical and social systems. (Ibid., p. 60) …develop new theories to understand the dynamic interrelationships between individual/group cognition, decision-making and the role that these influences play on interactions with large and small social systems" (Ibid., p.61).

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

The U.S. intelligence apparatus has been busy, as well in focusing on the biological aspects of human behavior. Under the Officer of the Director of National Intelligence is The Intelligence Advanced Research Projects Activity (IARPA), inviting researchers to participate in programs, such as:

- MICrONS seeks to revolutionize machine learning by reverse-engineering the algorithms of the brain
- The focus of the ICArUS Program is to understand and model how humans engage in the sense-making process, both during optimal and suboptimal (biased) performance. Of particular interest are cognitive biases related to attention, memory, and decision making.
- The goal of the KRNS Program is to develop and rigorously evaluate theories that explain how the human brain represents conceptual knowledge. In part the evaluation will rest on how well concepts can be interpreted from neural activity patterns using algorithms derived from the theories. In addition to new theories and algorithms, KRNS seeks the development of innovative protocols for evoking and measuring concept-related neural activity using neural imaging methods such as (but not limited to) functional magnetic resonance imaging (fMRI) and magnetoencephalography (MEG).
- The MOSAIC program seeks innovative approaches to unobtrusive, passive, and persistent measurement to predict an individual's job performance.
- IARPA's Janus program aims to dramatically improve the current performance of face recognition tools by fusing the rich spatial, temporal, and contextual information available from the multiple views captured by today's "media in the wild".
- The HFC program seeks proposals for research to develop and test hybrid geopolitical forecasting systems. These systems will integrate human and machine forecasting components to create maximally accurate, flexible, and scalable forecasting capabilities. (IARPA Research Programs, 2018)

The RDOC by the NIMH, BAAs, IARPA, and ethical behavior assessment programmes might be considered a primary investigatory phase of describing how the brain functions. It is said that describing a problem is half the solution. This would be the ultimate of control but control requiring enormous ability to collect data. The technological aspects pale in comparison to the ethical issues. While major scientists encourage research into artificial consciousness, they have warnings.

Each of the above projects – both non-governmental and governmental – is an example of reaction where the investigators respond to how persons and their minds behave. It remains how one can forestall behavior by creating the mind itself.

In January 2015, Nick Bostrom joined the late Stephen Hawking, Max Tegmark, Elon Musk, Lord Martin Rees, Jaan Tallinn among others in signing the Future of Life Institute's open letter warning of the potential dangers associated with artificial intelligence. The signatories "...believe that research on how to make AI systems robust and beneficial is both important and timely and that there are concrete research directions that can be pursued today" (AI Warning, 2015).

There are two directions in collecting data on neuroimaging: individual brains and collective ones. Sociologists like Gustav Le Bon (1896) continued the tradition in arguing that groups of individuals have a collective psyche, one not being the same as an individual. In a true Cartesian approach (Descartes, 1641), one attempts to understand the whole by breaking it down into its constituent parts. If society is an organism, then, we begin by identifying its components: members within it. As the method goes, by understanding how the individuals work, conclusions may be drawn about the whole in an inductive or probabilistic fashion.

Big Data Collected by the NSA on US

Two main US surveillance institutions are the National Security Agency (NSA) and the Department of Defense. Other spy agencies exist, such as the Central Intelligence Agency and Federal Bureau of Investigation, but it can be assumed that if information sharing is not seamless across the full spectrum of the US surveillance network, efforts are ongoing to make this happen (National Infrastructure Advisory Council, 2012). Indeed, a special website dubbed "Intel.gov" refers to "…a multi-agency community" (U.S. Intelligence Community, 2018). The controversial Cybersecurity Information Sharing Act of 2015, S.754 (S.754, 2015, pp. 31-34), was signed into law by U.S. President Obama on 18 December 2015. Companies no longer have to make anonymous data they give to the U.S. Government concerning "cyber threat indicators", which the critics argue are not described in the legislation. If one wants to get somewhat facetious, they could argue that since every major computer operating system has vulnerabilities (National Vulnerability Database, 2015), then there is a "cyber threat indicator" every time someone gets on a computer. Whatever we communicate over the Internet may be deemed a "threat indicator" with all information being monitored by a federal agency. The U.S. Department of Homeland Security says, "Protecting the country from ever-evolving, transnational threats requires a strengthened homeland security enterprise that shares information across traditional organizational boundaries" (U.S. Department of Homeland Security - If, 2018). It is intriguing to note that the DHS phrase "If you see something, say something" is formally registered trademark with the U.S. Patent and Trademark Office (U.S. Department of Homeland Security – Information, 2018). How can anyone miss the parallel between dictatorial spy agencies like the Gestapo and Stalin's NKVD encouraging citizens spying on each other?

Representative of the potential if not the actuality of governments collecting data on their populations is the U.S. National Security Agency (NSA) Utah Data Center (formally called "Intelligence Community Comprehensive National Cybersecurity Initiative Data Center") at Camp Williams near Bluffdale, Utah, between Utah Lake and Great Salt Lake. When one searches for "Utah Data Center" a web page entitled "Domestic Surveillance Directorate" appears with a mock-up but realistic insignia to the left (Utah Data Center, 2018), the astute observer of history being reminded of the vast repositories on information kept by the Gestapo, KGB and Stazi.

A number of verifiable facts are presented, peppered with links to some official U.S. Government website, as well as a major link entitled, "IC off the Record" (2018) with its banner headline, "Truth is coming and cannot be stopped". To the left of "Utah Data Center" page are numerous links to legitimate sources, such as news releases, descriptions, articles, and so forth. At the very bottom of this very official-looking page is:

This is a parody of nsa.gov and has not been approved, endorsed, or authorized by the National Security Agency or by any other U.S. Government agency. Much of this content was derived from news media, privacy groups, and government websites. Links to these sites are posted on the left-sidebars of each page.

However, the imitation is more real than one might think ostensibly. What is not a joke is The U.S. Army Corps of Engineers "project specifics":

- 65 Mega Watts Technical Load to the Raised Floor
- Average load density: 650 watts/square feet (sf)
- Maximum load density: 1600 watts/sf

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

- 100,000 sf of Raised Floor in 4 Data Halls
- Tier III Data Center Standard, Concurrently Maintainable
- Flexible Cooling to Data Hall IT Rooms: Water and Air
- Air: 250 watts/sf
- Water: 1600 watts/sf
- Clean Agent Fire Suppression for Data Halls
- Redundant Utilities, 100% Generator & UPS Backup
- Mechanical & Electrical Support Structures
- 2 Substations
- Goal LEED Silver, Other Green Technologies Stressed
- Water usage at full load is approx. 1.7 million gal/day
- Thermal energy storage tanks
- 3 days of fuel storage
- Piping distribution will be primary and secondary
- Secondary pumps will be on UPS
- Cooling towers shall be Cooling Technology Institute
- (CTI) certified or built (Ferguson, Lange, and Capenos, 2009, pp. 10-11)

"Tier III" is a classification created by The Uptime Institute, and recognized as a computer industry standard. It means "Concurrently Maintainable data center has redundant capacity components and multiple independent distribution paths serving the critical environment. For the electrical power backbone and mechanical distribution path, only one distribution path is required to serve the critical environment at any time" (Uptime Institute, 2018, p. 6, Section 2.3) (see Figure 7).

Some other actual facts about the very real Utah Data Center are its:

- Million and a half square feet overall "about a third larger than the U.S. Capitol and the House and Senate office buildings"
- Yottabyte capacity storage (one thousand trillion gigabytes of data)
- $1.2 billion cost
- 200 acres
- 900,000 square feet of technical support and administrative space.**"** (Building size, of course, is not the only factor in considering data storage capabilities; it is what can be placed inside. What is important concerns the ability to store massive amounts of data in such a small space. To illustrate, an average 15 × 15 foot room eight feet high is 259,200 cubic inches, each inch representing the size of a thumb drive. Above was described some of the latest advances in technology, where there now are two terabyte thumb drives. At this point, one can allow the imagination to do the rest in wondering how much data can fit in to a few hundred rooms of this size given what was said above about data storage capabilities. To conceptualize proportions, the NSA Utah Data Center mission critical area may contain 444 of these 15 × 15 foot rooms (100,000 square feet). (UTC data, 2018)

One can perseverate on the Utah Data Center indeed existing and be amazed over the physical construction, but the question is "why", outside the propagandistic reasons of "national security", etc. To uncritically believe NSA's 2013 press release:

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 7. Tier requirements summary (Adapted from Ibid., p. 9)

	Tier 1	Tier II	Tier III	Tier IV
Minimum Capacity Components to Support the IT Load	N	N+1	N+1	N After any Failure
Distribution Paths-Electrical Power Backbone	1	1	1 Active and 1 Alternate	2 Simultaneously Active
Critical Power Distribution	1	1	2 Simultaneously Active	2 Simultaneously Active
Concurrently Maintainable	No	No	Yes	Yes
Fault Tolerance	No	No	No	Yes
Compartmentalization	No	No	No	Yes
Continuous Cooling	No	No	No	Yes

Many unfounded allegations have been made about the planned activities of the Utah Data Center. One of the biggest misconceptions about NSA is that we are unlawfully listening in on, or reading emails of, U.S. citizens. This is simply not the case." (Reuters Staff, 2013)

would be the height of naiveté, in light of the ongoing provisions of the Patriot Act, DHS, and what the Electronic Frontier Foundation has to say, all of which can be learned through the Internet and by what has been said to this point.

One also should reflect on the scope of the "Officer of the Director of National Intelligence (emphasis in original) (DNI, 2018). This is left as a research exercise.

As somewhat of a sidebar, to read the original Fed Biz Opps (Federal Business Opportunities) solicitation W912DR-10-R-0015 one accessing the listings even to read the contents of the solicitations and awardees has to be a registered contractor (Fed Biz Opps, 2018).

Big Data Collected by the Military

Aside from the vast empire of the Department of Homeland Security lies the U.S. Department of Defense (DoD). We have discussed its Broad Agency Announcements calling for research on human behavior, but it also has been focusing on modeling and simulation (MSCO, 2015), or automated war, an outgrowth of which is Network-Central Systems, referred to commonly as "Net-Centric Warfare" (Wikipedia, 2018m). As an affirmation of what already has been said about systems and modeling and simulation as the generator of big data sets, the following is presented from the U.S. DoD Modeling and Simulation Coordination Office, *Modeling and Simulation Body of Knowledge* (MSBOK, 2015):

A system is a collection of components organized to accomplish a specific function or set of functions. System types are: (1) units; (2) weapons; (3) platforms; (4) sensors; (5) life support and (6) Command, Control, Communications, Computers and Intelligence (C4I). Systems are further categorized by operating environment which is divided into five areas: (1) individual; (2) air; (3) sea; (4) space and (5) ground. (Ibid., p. 6)

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

A model is a physical, mathematical or otherwise logical representation of a system, entity, phenomenon or process. (Ibid., 2015, p. 6)

Human representation refers to the use of a computer-based model within a simulation that mimics either the action of a single human or the collective action of a team of humans. Human behavior representation can model any of the complicated facets of human behavior including ability to reason, ability to change the environment, reaction to comfort and discomfort, susceptibility to injury and illness, emotional responses, communication with others, ability to sense the environment and physical capabilities and limitations. (Ibid., p. 6)

A substantial rationale for identifying systems, creating models of them and testing them through simulations is to obviate the large costs of creating and seeing how they work in real life. The DoD's reasoning also is that, "The need for taking people out of dull, dirty and dangerous missions is a primary motivator for UAST [Uninhabited Autonomous Systems Test]" (UAST, 2015, p. 5). With UAST in mind, we now are ready to consider the larger context of big data, also focusing on the word "intelligence" in all of its forms – natural, artificial, and the very words like "intelligence gathering", "Director of National Intelligence", and out of its office, "Intelligence Advanced Research Projects Activity" (IARPA, 2018).

BIG DATA AND FOG COMPUTING FOR SOCIAL INTELLIGENCE

The Relationship Between Big Data and Societies

To summarize our discussion to this point, one wants ultimately to get knowledge about their environment. Beforehand, data needs to be collected and made sense of by converting it to information. Such information needs to be evaluated as to quality to produce knowledge. Then, the information is vetted and accessed *vis a vis* the repositories to the recipients with fog computing. In order to do any of this, one needs an organizational framework that comes through analysis or subdivision of the environment into constituent parts that are interactive, processing the environment and producing outputs which in turn feed back into the environment and its participants all in the form of what formally is regarded as a system. A system operates in an environment such as medical, social or educational. A particular system is a model. To study how a model acts, one identifies hypothetical situations or examples and observes how the model behaves, i.e., simulates a situation.

All of this is a formal way of generating big data. Yet, we have been discussing big data as an object – its size, who collects it, and even why it might be collected. NSA collects data to "...monitor, strengthen and protect the nation." IARPA collects it to understand human behavior better and possibly control it. Modeling and simulation projects (SimSoc and Second Life) allow people to live out their fantasies in a virtual world, and government projects want to see what happens when variables are manipulated so as to at least think about prescriptions for societies.

So, back to the fact that prompted this discussion about systems in the first place, one should be reminded about the nature of the entity that would want to do this. We can put the gamers aside and focus on those thinking about real-world uses and applications, i.e., governments. Governments are focal points for social decision-making, and it can be argued that societies, themselves are organisms. This next section traces the development and nature of modern societies, those same societies that are generating

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

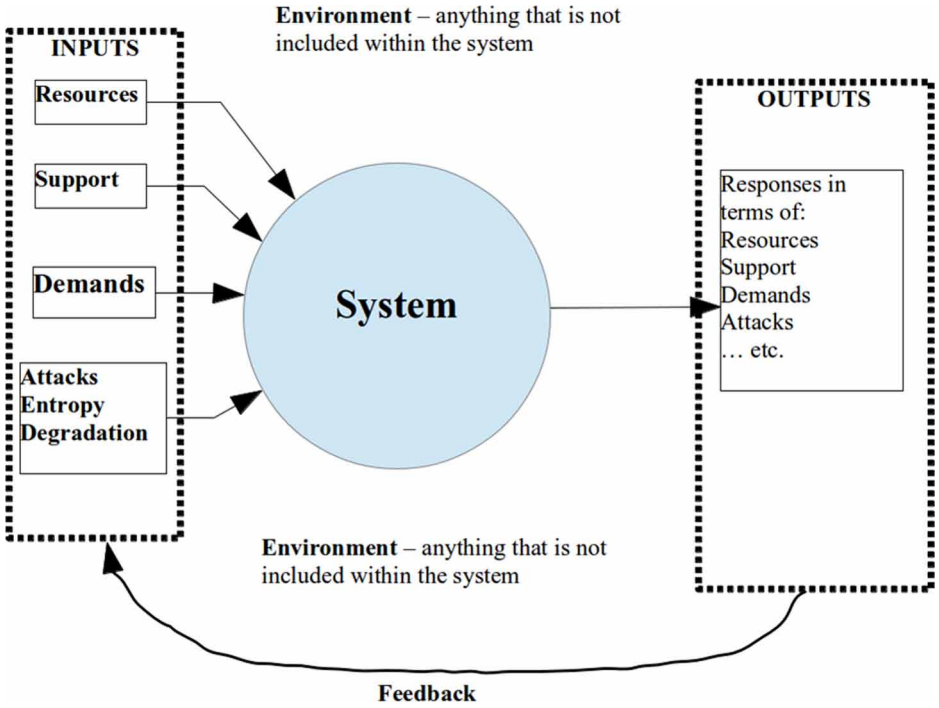
big data, that data reflecting more about the nature of the society generating it. Rather than having been more passive up to this point – social institutions collecting and using big data – that big data is part of a larger scope involving the very nature of these societies and what they do. More explicitly and in finding a common denominator of big data collection, that collection centers about the nature of thinking, mind, intelligence, consciousness, and so forth and finding ways of directing, shaping, or even re-creating it.

Following is a model for discussing the "why" of data in context. In essence big data is analogous to a memory and in the computer world that data is stored electronically. However, so goes the organization of society, so follows technological structure. One may think of a snake skin or animal armor; as the creature grows, so does its outer surface. Hence, we should examine the societal analog of memory and data storage, but to do so we need to identify the locus. In the organism, it is in the neurological structure, the more complicated loci being the brain.

Parallel to the emerging structure of data generation, storage, and distribution is the organization of society. Such organization is not only mechanical but is dynamic, as the parts of a body have their mechanical aspects, but each being an integral part of the whole corpus that embodies them. However to study these entities requires an approach, a discipline, better situated than the current political or social sciences.

What is this to be a science about? It is not enough to say "a study of power", "politics", or "societies". What is about these things that would warrant the word "science"? Extrapolating from the past to project to the future as the foundation of science is not done very well by those purporting to be social or political scientists. This section sets forth a framework for making sense of how big data relates to a science of societies. Treating societies as organisms – dynamic entities – will help us better answer questions like "How could an institution such as the NSA, come about, despite the long history and tradition of mistrusting 'the government'?". Data is collected not as a recreation but for a specific and usually scientific purpose: discerning patterns from the past and present so as to be able to predict and manage the future. The NSA data is about us and the society and unless we see its collection in the context of the political, the society, it won't make much sense. It is time for those studying social and political science to realize this in a modern way. Let's start by looking at the foundation of societies, focusing upon their being special dynamic systems, in particular, organic ones.

How Societies are Organized



Late in the 1960s and mid-1970s, cybernetics was applied to social phenomena as systems analysis. Organizational behavior is predicated upon the dynamics of structures as systems. A system is a collection of elements in which each element bears a relationship to the other and the collection of elements has a purpose (Buckley, 1968, p. 430; Callaos, 1994, p. 3). In perspective, on a larger scale, examining the behavior of a collection of systems and systems of systems is in the realm of complexity studies and at this level big data becomes explosive. The explicit rationale for the systems analysis method as opposed to any others is that it follows directly from basic logic which is inherently a bootstrapping method. Logical proof allows one to posit assumptions within a set of definitions, rules and so forth and draw conclusions. Otherwise put, various elements are arranged according to a scheme-a system-where there are defined inputs, outputs and various processes. The theoretical underpinnings of a system applied to a particular set of circumstances produces a model, that model being tested with instantiations with simulation.

As Social Contract philosophers (e.g.: Hobbes and Rousseau) discussed societies as organisms starting in the 17th century, modern systems analysis identifies social components collected into functioning entities living in environments, intaking, outputting, and processing factors, either maintaining themselves or adapting (Buckley, 1968; Wikipedia, 2018r). For example, we may consider a general systems as a framework into which data can be related, i.e., a form of data visualization, a context diagram, Figure 8.

The system takes demands and supports as inputs and processes the outputs as decisions and actions, which are processed by the environment and fed back to the system. Outputs, decisions and actions of authorities (Buckley, 1968, p. 434) are consequences of the behavior of system members. How the system processes inputs is a function of its ability to adapt. A political system must be able to allocate values and be able to have members accept those allocations of values. Stress and tolerance for it determines system viability. A cybernetic approach to systems theory in political science refers to an organism (system) having a behavior, a condition requiring consciousness, mind and psychology. Indeed, the expression "body politic" alludes to this. The word "corporation", a basic social unit, is about the "corpus", or body. It may be argued that, while there is no homunculus (as in an entity coordinating or being the center of consciousness), there is a center of organization, i.e., decision-making bodies, as in the three branches of government – legislative – executive – judicial (analogous to the brain of a body), where each of the other system's constituents (as in the electorate) have no sense of the organism's overall motion, direction or organizational-level consciousness. Such would explain why that long tradition of individualism and mistrust of government does not translate into coherent widespread opposition to institutions like the NSA. Somewhat analogous is a muscle exhibiting pain upon exercise directed by the brain, but the muscle, itself, is powerless to countermand the directive, except by breaking down.

Figure 8. A context diagram of a generalized system (Courtesy of the author, Jeremy Horne – drawn especially for this paper)

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

A key feature of systems as observed by Ross Ashby (1954) is that most are dynamic because they have to be adaptive to survive. How does an ecosystem fare with the arctic as a model simulated by polar bears affected by climate change? Note that one may change the granularity of analysis by studying the population of polar bears as the system modeled by their being in a specific location and this model being simulated with a particular month. There is minimally a primitive organicity or organic character to a system, each part of the system articulating in concert with another to achieve the overall aim of survivability, adaptability or improvement.

The Nature of Organicity

All organic things are systems, but not all systems are organic. It is the "organic" aspect of societies that helps us place big data in better perspective. Yet, the question is begged: "what is organic?" An organism is seen as a dynamic entity that depends for its existence on parts that interact with each other and cannot exist independently of that entity. Note that "organicity" (having the characteristics of an organism) has to do nothing with the material out of which an organism may be made, be it a hydrocarbon or not. "Organic" rests upon the concept of what "life" means, and this question by no means has been finally resolved. However, and for our purposes and pulled from myriads of sources the following commonly are listed as criteria:

- Life has complex patterns.
- A living thing has metabolism (processing inputs as food to provide sustenance to sustain itself)
- Something living can interact dynamically with the environment
- Killable
- Able to maintain itself (or even adapt) despite environmental changes or even modify the environment.
- All the parts depend upon each other for their existence.
- The entity is able to reproduce itself.

Searching for Erwin Schrödinger, Carl Sagan, John Casti, and Alan Turing, among others, will enrichen the discussion, this being left as a research exercise. By no means is there any universal agreement about clear-cut lines between what life is and what it is not (Trovonov, 2012; Weber, 2018). Now, let's couple systems and organicity to discuss the highest form of social evolution: the State.

The State and its Models

Plato thought in his Republic that the society is an organism carefully describing how each part should be qualified and function.

However, in founding the city we are not looking to the exceptional happiness of any one group among us but as far as possible, that of the city as a whole. (Plato, 420b, 1968) Have we any greater evil for a city than what splits it and makes it many instead of one? Or a greater good than what binds it together and makes it one? (Republic 462A, 1968)

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Thomas Hobbes' Leviathan (a Biblical sea monster) writes in the Introduction of "Nature (the art whereby God hath made and governs the world)," and from this of societies not only being organic but artificial:

Nature (the art whereby God hath made and governs the world) is by the art of man, as in many other things, so in this also imitated, that it can make an Artificial Animal. ... Art goes yet further, imitating that Rationall and most excellent works of Nature, Man. For by Art is created that great LEVIATHAN called a COMMON-WEALTH, or STATE, (in latine CIVITAS) which is but an Artificiall Man; though of greater stature and strength than the Naturall, for whose protection and defence it was intended; and in which the Sovereignty is an Artificiall Soul as giving life and motion to the whole body; The Magistrates and other Officers of Judicature and Execution, artificiall Joynts; & …. (Hobbes, 1651, Introduction; spelling and emphasis in the original)

Rousseau thought of human societies being organic as well:

At once, in place of the individual personality of each contracting party, this act of association creates a moral and collective body composed of as many members as the assembly contains votes and receiving from this act its unity, its common identity, its life and its will. This public person, so formed by the union of all other persons, formerly took the name of city,1 and now takes that of Republic or body politic; it is called by its members State when passive, Sovereign when active and Power when compared with others like itself. Those who are associated in it take collectively the name of people and severally are called citizens, as sharing in the sovereign power and subjects as being under the laws of the State. (Rousseau, 1761, p. 44)

Perhaps by far the greatest development of a coherent idea of the State was Georg Wilhelm Friedrich Hegel (Hegel, G.W.F., 1833/1896/2001) in his *Grundlinien der Philosophie des Rechts, (Philosophy of Right)* ("§" references are section numbers locatable in any edition).

The state is the realized ethical idea or ethical spirit. It is the will which manifests itself, makes itself clear and visible, substantiates itself. It is the will which thinks and knows itself, and carries out what it knows, and in so far as it knows. (§257, p. 128)

[The State has] a higher authority, in regard to which the laws and interests of the family and community are subject and dependent. On the other side, however, the state is the indwelling end of these things, and is strong in its union of the universal end with the particular interests of individuals. Thus, just so far as people have duties to fulfil towards it, they have also rights" (§261)

...Political disposition is given definite content by the different phases of the organism of the state. This organism is the development of the idea into its differences, which are objectively actualized. These differences are the different functions, affairs, and activities of state. By means of them the universal uninterruptedly produces itself, by a process which is a necessary one, since these various offices proceed from the nature of the conception, …(§ 269, p. 136)

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

After Hegel and then Darwin, the Victorian period, represented by Herbert Spencer descrying the social state (Spencer, 1896, p. 608, et. seq.) and Émile Durkheim (Durkheim, 18982, p. 123), as in his reference to social organism, and "For what else essentially constitutes the body social if it is not the social space) (Ibid., p. 203)", brought forward more the view of society as organic and evolving with a collective consciousness, just like one of Darwin's organisms (Organic Theory of the State, 2015).

Most relevant is Durkheim's (1858 – 1917) (1893/1984, p. 77) saying:

All the functions of society are social, just as all the functions of an organism are organic (Ibid., p. 81).

[C]o-operative relationships do not carry with them any other form of sanctions. Indeed, special tasks, by their very nature, are exempt from the effects of the collective consciousness. This is because if something is to be the object of shared sentiments, the first condition is that it should be shared, that is, present in every consciousness, and that each individual may be able to conceive of it from a single, identical viewpoint (Ibid., p. 82).

In the end this law plays a part analogous in society to that of the nervous system in the organism. That system, in effect, has the task of regulating the various bodily functions in such a way that they work harmoniously together. Thus it expresses in a very natural way the degree of concentration that the organism has reached as a result of the physiological division of labour.

*Yet if from this comparison it is legitimate to induce, with some degree of probability, that economic functions are not of a kind to be placed under the immediate influence of the s***ocial 'brain',** *it does not follow that they can be isolated from all regulatory influence. (Ibid., p. 164) (emphasis added).*

We will return to the "social brain" later, but suffice it to say that these smatterings of writing about society being more coherent than a loose assemblage of entities and at least analogously a living being illustrate more profound thinking than most politicos realize. Suffice it to say, we rarely see any philosophy of society like this in mainstream public debate. It is a worthy research exercise and learning experience to read these (and many more) thinkers who proposed that societies are organic. Phrases like "society as organism", "superorganism", "organic societies" and related phrases will open up a new world to those accustomed to the prevalent thinking that social arrangement are just mechanical ones. For example, regarding society as an organism implies that human being are integrated and interdependent, the more harmonious the greater chance of survival and growth. Indeed, the organizational model of governments and economic units is the corporation. A recent U.S. Supreme Court ruling (Citizens United vs. Federal Election Commission, 2015) concluded what had been assumed under this model, corporations are persons, complete organic units. Sociological data collection, like that in other systems areas, concerns describing organic entities and their components including us.

Characteristic of the Social Organism

Whether this direction towards a central authority collecting so much detailed data on us has a nefarious purpose is not immediately material. The effort is coherent and the effect of the coalescence of these events/factors shaping that collection may result in the same as if it were intentional. For argumentation's sake and to make this controversial (a nature of philosophical inquiry) discussion more dynamic, one

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

may consider what the most elite of policy makers potentially may think about, an argument in behalf of the Devil. Such a discussion technique follows an accepted scientific methodology of attempting to disprove the null hypothesis (Popper, 1959) or that in logic of the indirect proof, the common denominator of each being the attempt to develop a contradiction. What might policy makers contemplating social control from an elitist perspective – hypothetical or intentional-consider in their collection of big data and its management? Let us look at what they are facing and why the organic model makes the most sense in identifying and solving social problems.

Challenges to the State as Organism

Set before societies is unreservedly an existential challenge to which traditional responses most likely will not be adequate. Much has been written about increasing adverse complexity brought about by exploding populations, global warming, environmental degradation, and greater technology (Homer-Dixon, 2007; Tainter, 2003). Because of these as major factors, coupled with others, scientists are now discussing the "Sixth Great Extinction", the question of whether *homo sapiens sapiens* will even be around as a subspecies in a hundred or so years. A cursory search under "sixth great extinction", or "Holocene extinction" will display hundreds of entries, many of them peer-reviewed scientific articles on the subject; these are recommended reading (e.g. Ceballos, 2015). Organizations like the World Wildlife Fund, Post-Carbon Institute, The Intergovernmental Science-Policy Platform on Biodiversity and Ecosystem Services (IPBES), and National Geographic Society have numerous pieces on the subject, those being retrievable by a simple search in their websites. So goes the species, so goes its organization(s).

This species cannot wait for the wheels of participatory decision making with all its infighting to meet the challenge (Kintisch, 2015). It is incumbent on anyone valuing the continuation of this human species and its environment to research the Sixth Great Extinction and think how a social consciousness resting upon the bedrock of big data might address. That there does not exist the State is reflected by governments meaningfully and totally assuming ownership of problems that are existential in nature. Let us focus on some. This discussion is needed to help provide a larger context within which big data is collected and used, each problem having its own data set. The nature of the society in which we live is a major determinant of that collection of data, its applications, and how we relate to that use.

Even with populations exhibiting passion for their fellow members of this species, indifference, tolerance of events, desensitization and gradualism (Lifton, 1986) allow mass suffering and death. There is a growing burnout of social caregivers that contributes to social paralysis in front of danger (Pace, 2014).

Given that so many people are getting on line with very affordable computers and intelligent communications devices, security has become such a highly complex issue that there may not be any real protection but only management of an attack that is seen as inevitable. Protective measures are chimeras not unlike whack a mole. As soon as one barrier is erected, the monster is inside the compound again. This problem is exacerbated because people not only have access to the computer but they are increasingly dependent upon its integrity in their daily lives. Millions of persons use antiquated software that was deficient to begin with and they do not do basic maintenance mainly because of being ignorant (Microsoft, 2015). Society, itself - education, commerce, government, etc. - also depend upon that integrity for basic functioning.

That computer security is a growing threat to communications stability (Computer Security, 2018; U.S. Cert, 2018; Sans, 2018; CERT, 2015; Wikipedia, 2018L; SC Magazine, 2018), may be symptomatic of a larger problem of how a growing population responds to material (read "economic") challenges. A

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

prison guard knows all too well what an inmate can do with limited resources in fabricating contraband (Contraband, 2018). We now are witnessing what a population can do unfettered and with the same sociopathic mentality. While the one percent of the U.S. Population being sociopathic (NIMH-sociopathy, 2018) seems to be a low figure, it translates into 3.2 million persons (U.S. Census, 2015). This says nothing of at least 11 million others under severe mental duress (NIMH Results, 2018).

Given this mentality and a question of whether a large part of the population lacking ethics (Cattermole, 2010; Jordan, 2015; Ceballos, 2015; National Geographic, 2006) or intelligence (as in the IQ bell curve), we see more extremist movements and gangs that seem to be capable of meeting the consequences of alienation (Weber, 1992). It may be argued persuasively that the lack of employment, recreational facilities, social organizations or other institutions that traditionally have socialized individuals has been a main contributing factor to the social entropy (DeAngelis, 2009). Increasing millions are under psychological duress (NIMH Results, 2018) as the 353 incidents of multiple shootings (alone) would seem to indicate (Multiple Shootings, 2018).

More controversially is the question whether this subspecies has the intelligence and will enough to manage the onrushing complexity so as to save itself from extinction. Allowing the average to make critical decisions could be fatal. Considering this means critically regarding perhaps the most cherished myths of modern times, that of "democracy".

Despite all the talk about "democracy" and its being the rationale for so many modern wars, the backdrop of Plato and Aristotle has persisted throughout time. Plato in his *Republic* and Aristotle in *Politics* argued throughout that a participatory society (referring then explicitly to democracy) cannot last without a substantial educated middle class. One might add that the electorate needs to be ethical and be willing to participate in decision making. The classic argument is that the uneducated poor will easily be swayed by demagogues, be more prone to settle problems through violence (not having the capacity to think critically), and be susceptible to financial rewards in return for support. Persons not having a basic knowledge (Alsop, 2014), of even the geography where the contemporary affairs occur (let alone the affairs, themselves) will not be able to select their representatives intelligently. A knowledge of basic world events aside, more egregious is that one in four of Americans thinks the Sun goes around the Earth and only half realize that antibiotics are ineffective against viruses (National Science Foundation, 2014). It may be asked, "How can leaders and policy makers be selected intelligently those who will be faced with complexities far exceeding knowledge equal to that of an eighth grade student?" Recent world events seem to illustrate that social upheavals against dictatorships rarely culminate in participatory governments, the Middle East after the so-called Arab Spring being a case in point. There is enough "big data" to substantiate the thesis that violent approaches to problem solving are positively correlated with ignorance and low critical thinking skills. However, one must be intelligent to be educated and use those skills.

While substantial literature exists on multiple intelligences (Wikipedia, 2018t; Gardner, 1993; Gardner, 2004), one may ask whether the average person (average IQ) can understand today's complexities let alone manage them successfully (IQ, 2018). A persistent argument exists (Wikipedia, 2018b) that if society is composed largely of persons of average or lower than average intelligence, as reflected in a popular book, *The Bell Curve*, policy should be made only by intellectual elites (Hernstein, 1994). It is beyond the scope of this paper to delve into the IQ debate but suffice it to say, reams of peer-reviewed literature have appeared on the subject as an Internet search under "IQ" and similar terms will indicate. There is ongoing argumentation about whether there has been a peak in the percentage of persons attaining quality education. In 1983, The Carnegie-Mellon Institute issued *A Nation at Risk* (National Com-

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

mission, 1983), describing a National security risk existing because of the generally poor educational attainment of the US population. In the middle of the second decade of the 21st century, matters have not changed significantly. According to the U.S. Department of Education in 2013 – 30 years later-only 39% of high school students were academically prepared for college in mathematics and 38% in reading (DOE Statistics, 2013). If data from organizations like the Literacy Project Foundation are credible, concern is raised about 50% of U.S. Citizens being functionally illiterate, i.e., reading below the eighth grade. (Literacy Project Foundation, 2018). Even being able to read at a minimal level does not even begin to address serious issues like evaluating information for its quality (including identifying good sources of information), let alone critically thinking about it. The National Science Foundation surveys referenced above result partially from illiteracy but a question remains why persistently so many persons are illiterate let alone knowledgeable in basic facts.

Such deficiencies have major policy implications on an international scale, where ignorant voters select policy makers with the power ultimately to press buttons on nuclear weapons systems. It may be argued that the pattern of world events has not changed since ancient times with the exception of the capacity to destroy being greater and radically more complex technology being able to magnify human error especially beginning with World War One and now with vast nuclear weapons stockpiles. Societies have become enormously complex with even the best and brightest seemingly making questionable judgments (atomic bomb, bioweapons, and fossil fuels).

These may all be factors besetting the average and below average person, but as systems become even more complex, one may ask about the increasing portion of the more intelligent being drawn into this group, Dr. Theodore Kaczynski, the Unibomber, being case in point. At some point, even those with an above 150 IQ (or whatever standards are used to gauge intelligence, multiple and qualitatively different IQs included) may be incapacitated in managing social complexity. In an extreme case, one only need look at the *Einsatzgruppen* (Nazi death squads), where "Of the 25 *Einsatzgruppen* and *Einsatzkommando* leaders, 15 of them bore the title of PhD, most of them doctors of jurisprudence or philosophy. (*Einsatzgruppen*, 2006)." One asks the same of the Nazi doctors (Lifton, 1986).

Again, the above argumentation may not be necessarily sound, let alone valid, but one needs to consider it as a possible motivation for why data is being collected as BAA-1165 and the various intelligence websites illustrate. If the population cannot control itself even to the point of protecting its own environment, the question is raised, who will? For the present one may refer to the technocratic movement as a response to these problems (Technocracy, 2018), especially in considering such big data laden projects as those of NSA, NIMH, the BAAs and brain modeling.

What are the Implications of Fog Computing?

It was mentioned that data can and often is acquired from sensors, perhaps the most personal example being those placed inside of a pill-sized object and the whole assembly being swallowed in order to report on what is happening inside the digestive tract. Typing in "microsensors", "miniature sensors", "radio frequency sensors", and similar phrases should prompt the imagination in envisioning how detailed data collection might be (Minin, I., 2011). On the outside, radio frequency (RF) tags can be affixed to just about any object, with that object being tracked. RF tags now are being embedded in the skin for various purposes. It is not a question, then, of whether objects can be tracked and data collected on them. Where does that data go, who manipulates it, who manages it, and why? A number of situations were alluded to above, which can be the core of lively debate, but what of the future?

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

What applies to cloud also applies to fog, as the latter merely is the interface between humans and big data. One may think of peripheral nerves and appendages in the form of drones, IoT devices, phones, etc. We saw how the The National Institute of Standards and Tchnology (NIST, 2017) fog computing diagram resembles neuroarchitecture. Hence, we can see in a society as organism model big data as memory, the "social brain" using it, and fog computing as a way of individual cells receiving and sending via the social brain big data.

If societies can be regarded either literally or analogously as organisms and computer technology in the form of data collection and management and artificial mentation parallel the organism in themselves assuming an organic character, we now see ourselves as at least technologically in the completion stage, where fog computing providing that last segment of detail to enable complete manipulation of the technological organism reflecting the society. As the organism takes on its emergent characteristics, so does the technological ensemble.

Towards a Solution

If perceived deficiencies of the average individual and the societies in which they live are some of the motivations driving social control, what, then, is to be modeled? The above discussion on simulated societies may offer a starting point in that modeling and simulating human interactions in what amounts to a social laboratory can reveal roads to possible solutions. It has been said that principles of organization underpin the utility of large data sets.

Collecting data and identifying it as information about physiography, thermodynamic interactions in the atmosphere and precipitation levels are in the context of a larger framework of meteorology, each area of investigation articulating with another to describe a system. Data sets reflecting a description of DNA, diseases and the make-up of organisms are within the context or framework of promoting the health of those organisms as systems. For humans living together on this planet, it is the society that has been regarded as an organic system having a health. A reading of the literature of organic thinkers, Hegel and Durkheim in particular, will present a viable way of diagnosing and treating social and political problems. Durkheim's "social brain" is foundational.

For thousands of years humans have created tools to do what they could not alone. Simple machines (levers, wheels, inclined planes and so forth) are combined into complex ones. From the science that provides the understanding of our world comes the technology to manage it. Computers are tools to memorize, compute and analyze. Now, we have a society confronted with problems threatening species survival that even the best and brightest individually or collectively may not be able to solve, as Homer-Dixon and Tainter (discussed above) have alluded. To this point we have described a repository of information (data storage), methods of collecting that data, and some of the uses to which it might be put. The next step is connecting the myriads of parts of society – its members and technology to that repository and its manipulators. A clue is with cybernetics and scientists becoming involved their "scientific study of control and communication in the animal and the machine." as stated by Norbert Weiner (1948). But, first, we need a science of society and its subdomain, politics.

The New Social and Political Science

Social and political use of big data generally re issues normally under the purview of sociology and political science, but they remain only as issues, rather than being viewed in a wider context of the nature

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

of the society, itself, that society assuming a particular character that can help explain the larger role that big data is playing in our lives.

Political science has been thought to be a misnomer since time the term was presented formally in 1752 by David Hume, who wrote that:

… politics may be reduced to a science So great is the force of laws and of particular forms of government and so little dependence have they on the humors and tempers of men, that consequences almost as general and certain may sometimes be deduced from them as any which the mathematical sciences afford us. (Hume, 1742)

Aristotle has been credited as the founder of political science (Aristotle and Political Science, 2015), and Aristotle's teacher, Plato, wrote extensively about the thinking behind and outcome of social behavior in the form of constitutions. However, the words "political science" do not appear in any of Plato's or Aristotle's works. The study of peoples' (demos) institutions polis (city) as a result of human behavior (ethics) was not regarded so much as a science as a philosophy or a way of thinking. More precisely politics was about how power is acquired, distributed and used, power being the ability to make another do one's will (What is Political Science, 2015). One of, if not the modern founder of the systemic studies of politics under the rubric "political science" was Henry Baxter Adams in 1880 in establishing the "Johns Hopkins Studies in Historical and Political Science" (Adams, 2015).

Years of debate ensued about how much of a science was there of politics. After all, science could be listed in their order of exactitude and value in predicting: math, physics, chemistry, biology, psychology and the so-called social sciences including political science (Political Science History, 2015). For the most part any technical rigor to the field has been in collecting and analyzing data from survey research, but because these surveys are behaviorist-oriented, with those surveyed being highly ephemeral in their views, precision might be regarded to that on par with predicting the outcome of a horse race. The recent attempts to prohibit the U.S. National Science Foundation from funding political science as in the failed Coburn Amendment SA 2631 (2015) illustrate this.

What may be giving force to a more legitimate study of societies as a science is a model that has been developing for millennia, one of the State being an organism, where diagnosis and treatment of problems would be analogous to medicine a thematic approach, more coherent that the cacophony of what exists now. Overlain on this is a focus on identifying the "social brain", asking the pertinent question of whether its collective mentation is sufficient to meet future challenges, especially the Sixth Great Extinction. Heightened big data capacities, as well as more sophisticated management are at issue. It may be added, too, that political philosophy is conspicuously absent in political and social science departments, the preference being for mechanical descriptions and piecemeal Band-Aid type remedies for problems.

Political science (and social science) to be a science must follow scientific methods, but in contemporary times, with an increasingly interdependent and diverse world, it needs to be interdisciplinary. This is to say that political and social science students need to address not only what they are studying now but other fields, like biology (focus on organicity), artificial intelligence, neuroanatomy, and perhaps most important philosophy (consciousness studies, logic, and ethics) if this discipline is to have any thematic unity and coherences oriented to organic societies and social brain.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

FUTURE DEVELOPMENTS AND RESEARCH

What might the ultimate meaning of big data be? We have seen "data points" above that indicate future technological development, the primary areas being in data storage capacity and processing speeds both addressed by quantum computing. To gain some perspective on how rapid technology can evolve, look at ENIAC, the vacuum tube-based computer sponsored by the U.S. Army in 1943, where in a large room the 30-ton machine of thirty separate units relied on forced-air cooling used 19,000 vacuum tubes, 1,500 relays and hundreds of thousands of resistors, capacitors, and inductors, and required about 200 kilowatts of electrical power. It was a complex operation for it to do square roots and long division (Weik, 1961). It is almost impossible to comprehend what may happen in the next 70 or so years given our moving ever so closer to replicating the human brain.

Yet, one should track development of big data where there is the greatest complexity in organization and management as well as in the areas of social control. In answer to the problems of democracy, referring back to Plato and Aristotle, policy makers may be thinking about developing tools to accomplish what humans alone cannot do among other things getting humans to live peacefully with each other. Big data is all about complexity both concerning the project for which it is collected and the big data itself in terms of collection methods, organization, interpretation and management. Somewhat of a paradox is emerging in that the level of complexity either natural (before any human intervention) or of humans' own making-far outstrips the ability of humans to deal with it. It was stated that the ability to replicate the universe is questionable at best. At some juncture, there is a crossover point, where after so many Cartesian subdivisions, the emerging complexity simply from a big data standpoint may be impossible to record, let alone be managed. We are out-analyzing ourselves, as it were. What emerges very likely will be something unpredicted.

We have seen how the discussion about big data started from a rather simple description of large individual systems, such as those involved in weather modeling, could be seen in larger contexts, leading into data about modeling the human brain and perhaps consciousness, itself, culminating in modeling all of society, inductively described by what happens with individuals. For this last, consideration is given to developing the ultimate tool, Durkheim's social brain, but that brain being human-made. This is a logical outcome of transhumanism (to be researched) and Kurzweil (2018), where, starting from simple prosthetics humans gradually are transformed into non-hydrocarbon beings.

There can be a science of societies and politics if there is an interdisciplinary program, not only consisting of historical and descriptive accounts of societies and politics but of scientific research methods, biology (as in focusing on what life is), neuroimaging, artificial intelligence, and above all, philosophy to impart the whole realm of study with meaning. At its foundation are social groupings as organisms, each organism having a "brain", each brain as a repository of "big data", with various "programs to manage it, but overall with a "high-road" ethos as the motivation for sustaining the organism.

Given the discussion about whether Earth can support this species in the future and much more long-range, the ultimate demise of the universe, thinking has emerged about reproducing humans digitally, the complete elimination of hydrocarbon-based life, big data far beyond creating an artificial brain. This digital immortality was proposed by Frank Tipler in his 1994 work *The Physics of Immortality* (Tipler, 1994). It may be pseudoscience or not but as with science fiction inspiring real technological development, this Ph.D. Physicist's work might have the same effect (Digital Immortality, 2018). Indeed, fog computing now is giving us those peripheral nerves which allow us to complete that mapping from hydrocarbon-based systems through non-hydrocarbon-based ones and one to full digitization of hu-

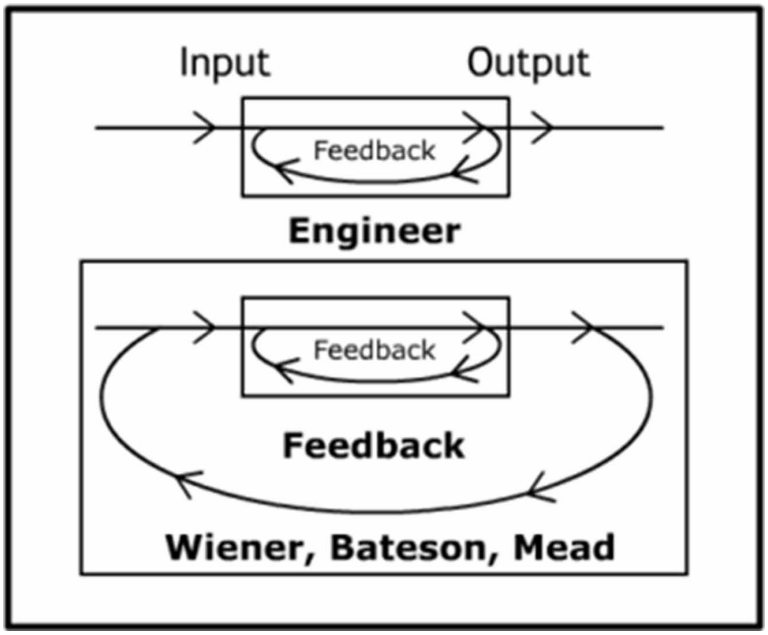
manity. In any case, it is a bellwether of thinking about how to manage seemingly irresolvable complex problems. Ray Kurzweil (Kurzweil, 2015), referred to above as a leader of the singularity movement, sees such a day coming. As defined,

The technological singularity is a hypothetical event related to the advent of artificial general intelligence (also known as "strong AI"). Such a computer, computer network or robot would theoretically be capable of recursive self-improvement (redesigning itself) or of designing and building computers or robots better than itself. Repetitions of this cycle would likely result in a runaway effect an intelligence explosion (Chalmers, 2010; Loosemore, 2011) where smart machines design successive generations of increasingly powerful machines, creating intelligence far exceeding human intellectual capacity and control. Because the capabilities of such a superintelligence may be impossible for a human to comprehend, the technological singularity is the point beyond which events may become unpredictable or even unfathomable to human intelligence. (Wikipedia, 2018s)

By regarding society as a natural organism, one looks at the evolution of computer networks and artificial intelligence with all that big data, processing ability, and fog computing to incorporate everything having a chip and those holding that object that may equal or even exceed present "natural" capabilities.

The concept is not new if one remembers Alan Turing and John Von Neumann. In a more sophisticated form John Glad (Glad, 2008) argues that we can shape our own evolution in a cyborg fashion. We have come full circle to our creating ourselves just as Von Neumann with his Universal Constructor (Universal Constructor, 2015) and Turing (Turing, 1950) suggested. A "minor" problem exists - bias. Turing stated,

...a machine undoubtedly can be its own subject matter. It may be used to help in making up its own programmes, or to predict the effect of alterations in its own structure. By observing the results of its own behaviour it can modify its own programmes so as to achieve some purpose more effectively. These are possibilities of the near future, rather than Utopian dreams. (Turing, 1950)



For argument's sake, let us say that the outcome of the ultimate big data project-the creation of a mind equivalent to ourselves-is feasible (and, again, we are not arguing that it ever can be successful, only that persons are working as though it could be). Clearly, the observer has become a participant, i.e., second order cybernetics and recursion (Wikipedia, 2018q). That artificial mind would be seeing us through ourselves, a case of reflexivity, a topic that has generated its own and very large body of literature (Wikipedia, 2018p). Immediately, we are confronted with emergent systems immanent with human bias. A data visualization as a context diagram may appear as in Figure 9.

If one is to posit that the culmination of big data with fog computing will be in the form of reproducing ourselves as in the artificial brain, one should be free to discuss some consequences having to do with human bias and the differences between an organic and a non-hydrocarbon-based way of doing things. Such is even truer about replicating society as a being unto itself. Too, the question is not so much as whether it is possible to do all of this down the road but the thinking in that direction and the implications of these attitudes.

In emergence, one needs to address autopoiesis or self-creation (Wikipedia, 2018a). After all, modeling a social brain is what we are doing. In the same discussion about the seeds of creation being within ourselves, one must also address in a dialectic fashion, autodestruction analogous to a death gene (Prescott, 2012). What if, in emergence, as in systems acting on their own (Singer, 2009), this tendency

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 9. Second order cybernetics feedback loop (Côté, 1976)

becomes predominant? The U.S. Department of Defense surely has these concerns as illustrated in one of its Broad Agency Announcements:

This new and expanding challenge to the test community is being driven by rapidly accelerating technology developments in cognition, control, autonomy, sensors, computing, software and communications resulting in the development of advanced unmanned military-technical capabilities being deployed at an ever expanding pace. This is consequently straining the verification and validation methods as they are practiced today (BAA UAST-0002, p. 13).

Another consideration is that of entropy. It is said that the Universe is tending towards a heat death where all energy will be equally dispersed (Wikipedia, 2018j). Entropy also results when information emanates from chaos (as in the singularity that was the origin of the Universe) produced what we have today and will continue to produce until its heat death end. We have as Boltzmann entropy, the equalization of particles giving an evenness. Information entropy is regarded as the ability to predict (Shannon, 1948; Chaitin, 2001). It is uniformity that allows the experimental scientific method (Whewell, 1847), but is not uniformity randomness? Yet, this is a uniformity of process but it would appear that entropy in this sense already has occurred. In all the scientific development it becomes hypothetically possible to predict the future. Given what we have just said, we will be approaching a maximum entropy, in essence, a condition being, as the Universe is tending, one of maximum information dispersal. It will be a maximum Cartesianism as it were to test our ability to identify every element. Information entropy then may be that autodestruction. Our quest for "knowledge" is that autodestructive process with big data the barometer.

CONCLUSION

Data exists every time we measure something or tell someone about something. There may be too much of it for our own good. Ostensibly, it seems we can manage it by inventing storage and distribution technologies. However, "big" elides to "unmanageable" when there are insufficient organization and analysis methods. It is at this juncture where the conversation about "big data" goes from describing the technological wonderment to the more serious one of not only the organization but the purpose of big data. This brings in more profound considerations of philosophy (metaphysics, ethos, etc.). If we cannot manage the answers to this question, the technological aspects of management become minuscule even comical. Think of society as a child building a house of cards of big data and poking around it with fog computing.

Large projects, exemplified by genome sequencing, weather modeling, or quantum research in particle accelerators are simple in comparison to modeling global combat, the complexities of the human brain, or society as a conscious organism. Such complexity raises the question of humans' ability to manage it. It may be the case that in a situation similar to humans needing jack for the car they can't alone lift. Humans need a tool to help think of solutions for problems they cannot solve with their natural brains. It is in this context we can have our discussion of big data, especially in light of our discussion on the U.S. intelligence network and agencies, the National Institute of Mental Health's Research Across Domains (RDOC, 2015), the various artificial brain projects, and the Broad Agency Announcement calls for identification and detention of mentally disordered persons as potential terrorists (Broad Agency Announcement 11-65, 2015). One asks about the concept of Durkheim's "social brain", extending digital immortality (Tipler, 1994) to society as a whole, especially if this species is asking whether it will survive.

Figure 10. Our context diagram (Courtesy of the author, Jeremy Horne – drawn especially for this paper)

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

The more data accumulated the more we have measured our world and presumably the more we have understood it. Knowledge acquisition overall has as its main objective the enhancement of our ability to predict (and control) our future. The question immediately relevant in this paper is who acquires that data and who manages it? Without a science of society and politics, the anarchy of big data will continue, the trend leading where most anarchistic endeavors have in the past, to destruction and iron-fisted oppressive rule.

These broader considerations of "big data" and fog computing make it all the more imperative to conduct research not simply into the technological aspects of the subject but more importantly the reasons for it. So, in the end, the reader is left with a visualization of data within the larger framework of what has been described here linearly Figure 10:

From this, one only hopes that there will be a simulation of a second order cybernetic model that will at least preserve this species and its environment. Let's look into that mirror again and reflect on all of what has been said here.

AUTHOR'S NOTE

A note on Wikipedia: This article is only a seed for further thinking about big data. Numerous citations of Wikipedia appear, not because they necessarily are peer-reviewed sources (though many articles are) but because they provide a general overview of the topic and moreover lists of further readings upon which the content is based. In addition, this information is what the general public often encounters (and only this one). One should refer to the content and references as any competent scholar would and see, for the most part, that most importantly, the Wikipedia presents a useful starting point for research.

In terms of other references, they are not meant to be complete but only what the author of this paper thinks are representations of typical evidence supporting the arguments. A number of works for which there are no downloadable versions can be purchased on line through various booksellers. Many can be read on line via places like Gutenberg Project or https://archive.org/.

KEY TERMS AND DEFINITIONS

Broad Agency Announcement (BAA): A BAA is a solicitation to the general public for one of its members or organizations to provide under contract, in the words of the U.S. Code of Federal Regulations, 48 CFR 35.016(a), "scientific study and experimentation directed toward advancing the state-of-the-art or increasing knowledge or understanding."

Cloud Storage: A repository of data on a remote storage medium often distributed through multiple servers accessible through the Internet and owned and managed by a provider.

Cellular Automaton: A grid of any number of dimensions composed of regularly-sized spaces or cells each of which may be in an active or inactive state, the whole assemblage of which assumes distinct conditions or goal states and through each unit of time each cell's condition being dependent upon the condition of one or more other cells.

Complexity Theory: Thinking underscoring the identification of simplicity or difficulty required in understanding the construction, analysis or resolution of a problem particularly related to systems.

Deduction: In an argument, if the premises are found to be true, the conclusion follows with certainty; the conclusion is found entirely within the set of premises; a closed system.

Dyadic Binary Formula: A composition of terms in a two-variable or base-2, system with a set of operators according to rules establishing how to compose an expression. Examples: $p \rightarrow q$, Rxy & Pyx, A + B (where "A" and "B" are the only two variables); 00111 * 10010

Emergence: Unexpected phenomena appearing (and often having a regularity or pattern) from a collection of apparently unrelated elements and where the elements themselves do not have the characteristics of the phenomena and that phenomena itself is not contained deductively within the elements (See "deduction").

Induction: In an argument, the conclusions follow only probabilistically from the premises. The scope of the conclusions is larger than the set of premises individually or collectively.

Quantum Computing: A computer architecture relying on the physics of quantum mechanics where the units or qubits of transmitting data may be in a multiple set of states simultaneously and where the transmission of data requires the "collapse" of one or more the qubits to a definite state.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Recursion: In its simplest sense: repeatability. For example, when the outputs or results of a formula are fed back into the formula as inputs, the outputs will reappear. In the computer world, an overall solution requires the solution of its smaller constituents. One statement can generate any number of objects, meaning a specific program can describe limitless computations. A computer program reflects recursion by having a function call itself inside a program.

Reductionism (Cartesianism): Subdivision of a whole into parts normally meaning that the whole can be described by the sum of those parts.

Second Order Cybernetics: The introduction of the observer or creator of a situation as a part of what is being observed.

Visualization Technique: Simply and broadly stated, a method of pictorializing or generating images of a symbolized: such as verbal or numerical - description.

Chapter 75
State of the Art Recommendation Approaches: Their Issues and Future Research Direction in E-Learning A Survey

Bhupesh Rawat
Babasaheb Bhimrao Ambedkar University (BBAU), India

Sanjay K. Dwivedi
Babasaheb Bhimrao Ambedkar University (BBAU), India

ABSTRACT

Recommender systems have been used successfully in order to deal with information overload problems in a wide variety of domains ranging from e-commerce, e-tourism, to e-learning. They typically predict the ratings of unseen items by a user and recommend the top N items based on user's profile. Moreover, the profile can be enriched further by using additional information such as contextual data, domain knowledge, and tagging information among others for improving the quality of recommendations. Traditional approaches have not been effective in exploiting these additional data sources. Hence, new techniques need to be developed for extracting and integrating them into the recommendation process. In this article, the authors present a survey on state of the art recommendation approaches their algorithms, issues and also provides further research directions for developing smart and intelligent recommender systems.

INTRODUCTION

E-learning is an acronym for electronic learning which makes learning content available online for learners to access from anywhere and at any time. It is broadly inclusive of all the forms of education that make use of technology and multimedia. Online communication with real people may or may not be involved but the focus of E-learning is usually more on the learning content than on the communication between learners and tutors (Fetaji et al., 2011). E-learning systems provide huge benefits in comparison to traditional education systems (Zhang et al., 2004). However, they have several drawbacks

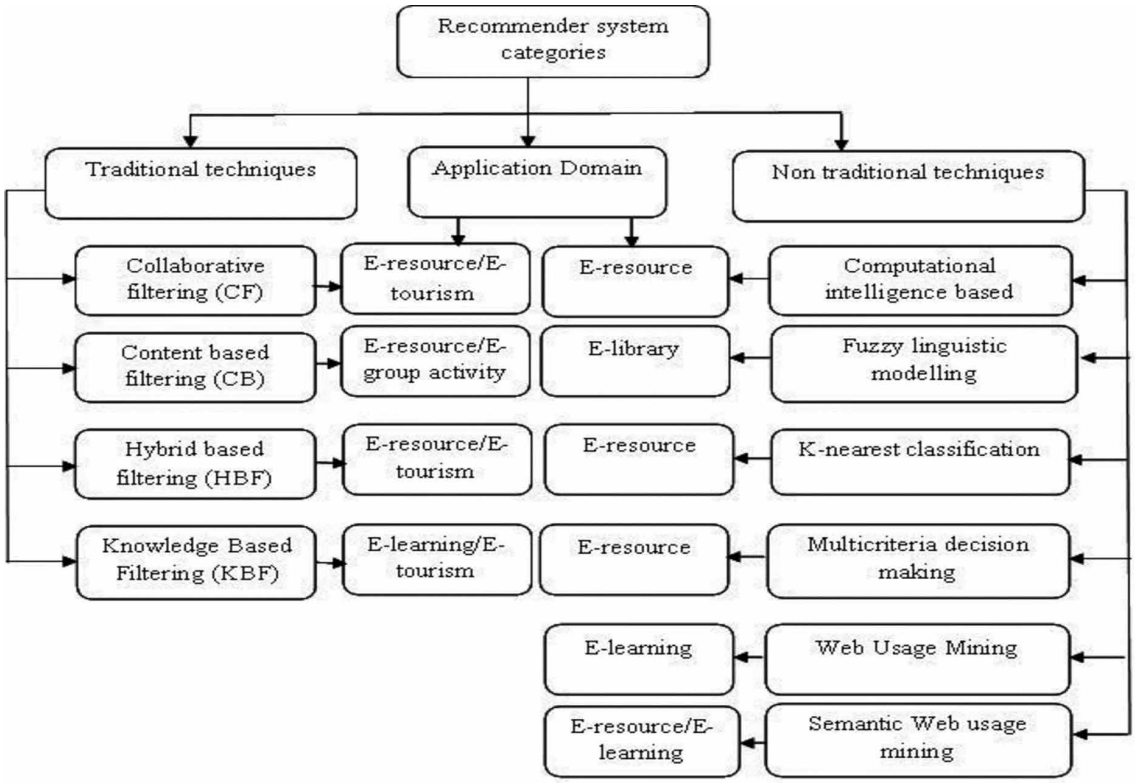
such as users spending a lot of time in searching the required information and same learning material is provided to all the learners regardless of their interest, skill, and level of knowledge among others. Recommender systems play an important role in this context by suggesting relevant items to learners based on their profile.

Recommender systems have drawn the attention of the research community since the appearance of the first paper on collaborative filtering (Adomavicius et al., 2005). Existing literature (Lu et al., 2015) suggests that among all the recommendation techniques, collaborative filtering, content-based, hybrid and knowledge-based have been used relatively more in the domain of e-government, e-business, e-commerce, e-library, e-learning, and e-resource.

The rest of this article is organized as follows. Firstly, we discuss major recommendation approaches, their critical issues, algorithms and input/output required by them. We also present some popular real systems based on these approaches. Then we provide further research direction which could help in developing more intelligent recommender system. Finally, the paper concludes with the discussion section.

BACKGROUND



The roots of recommender systems lie in cognitive science (Rich, 1979), information retrieval (Salton, 1989) and approximation theory (Powell, 1981). The recommender system appeared as an independent research area in the mid-1990s (Resnick et al., 1994). Recommender systems are software tools suggesting for items to be of use to a user (Resnick et al., 1997). They assist users in selecting the right item from a vast repository on the web, hence overcoming information overload problem. Conventional recommendation approaches such as content filtering, collaborative filtering, and more recently developed web usage mining have been successfully used in several domains. However, they are unable to exploit additional sources of information such as domain knowledge, tag information, and annotation among others which could significantly improve the quality of recommender systems (Pazzani et al., 1997). Non-traditional approaches such as computational intelligence, semantic web usage mining, multi-criteria decision making, and fuzzy linguistic modeling have recently emerged as an extension of the traditional approaches. In conventional systems, recommendations are made based on the profile of user which comprises of either user's ratings or description of item experience by a user (Gemmis et al., 2009). Moreover, users' unwillingness to provide ratings leads to sparse "user item rating matrix" which causes poor quality of recommendations. However, additional information about user and item can enrich a user's profile and hence improve the quality of recommendations.

TYPE OF RECOMMENDATION APPROACHES

We have broadly categorized recommendation techniques into "traditional techniques" and "non-traditional techniques" as shown in Figure 1. Unlike earlier survey papers on recommendation systems, this paper also includes web usage mining (WUM) and semantic web usage mining (SWUM) which play a major role for developing next generation of recommender systems.

Figure 1. Types of recommendation approaches with their domains

Collaborative Filtering (CF)

Collaborative filtering (CF) is one of the most widely used approaches in the recommendation system (Herlocker et al., 1999). They recommend an item by matching the preferences of a target user with similar users (also called neighborhood of the target user). CF-based systems are classified into memory based and model-based. The memory-based methods compute the similarity of an active user with similar users without creating a model (Rafter, 2010). They are not fast and scalable which is required in real-time systems, hence model-based approaches were developed. They use "user-item ratings" for building a model without using the entire dataset which provides scalability and reduces runtime. They make use of the Bayesian network, clustering, and rule-based approaches to improve the quality of recommendation systems (Portugal et al., 2015).

The inputs to collaborative filtering systems are a set of all users which is represented by the symbol 'U' and a set of all possible items which is denoted by the symbol 'I'. The goal of CF is to predict the rating of item i by a user u which is denoted by R(u,i). User's ratings are stored in a two-dimensional "user-item rating matrix". The output of collaborative filtering system is a set of items (i_1, i_2, i_3……i_k) where k <= I which are ranked and top N items are suggested to the user.

Collaborative systems have been used in many application areas such as movies, article, and products among others. However, altered Vista (AV) is one of the first collaborative systems used for recommending learning resources (Walker et al., 2004). The AV comprises a database of learners' evaluations

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

of learning resources which can be shared to other learners' as word of mouth recommendations about the quality of resources. "Web-based Peer Grader" is another popular CF based system which aims to improve learners' skill by reviewing and evaluating the solutions of their peer (Gehringer et al., 2001). LARGO (Pinkwart et al., 2006) is another popular collaborative system in the field of legal argumentation to evaluate the verdict (decision rule) of the supreme court of US. It makes the interpretation of legal argument textually. Diagrams are used within LARGO to visualize court arguments as hypothesis testing. The approach is designed to support first-year law students in learning legal argumentation skill by creating a graphical model of oral arguments and presenting them weakness in their models. The approach is able to reveal three types of weaknesses in arguments. LARGO uses graph grammar to handle structural and context weaknesses. Collaborative filtering is employed to handle content weaknesses. RACOFI (rule applying collaborative filtering) (Anderson et al., 2003) approach integrates two recommendation techniques. Ratings are elicited from learners on learning resources and inference engine is used for discovering the association between learning resources to be recommended to learners. Scaffolded writing and rewriting (SWoRD) is another popular collaborative system. Due to long text homework, tutors are unable to evaluate the whole text consequently learners don't get feedback on their performance. The tool deals with this problem by making use of peer review process. Experimental evaluation of the tool shows the improvement in the performance of learners as compared to single expert feedback systems (Cho et al., 2007).

Collaborative filtering systems could be benefitted by using the tagging information associated with social networking sites (Mathes, 2004). It helps to enrich a user's profile which leads to recommend more relevant items to a user. Tagging allows users to label their resources (images, audio etc) and assign them some meaningful words called tags (Golder et al., 2005). These tags can also be used to retrieve user information. Users can assign any tag to their resources; however, it leads to the problem of identifying most appropriate tags.

The collaborative approaches are more reliable than content filtering as they can capture 'realistic relationships' among items based on similar preferences of identical users. However, CF-based systems suffer from sparsity (Sarwar et al., 1998) and cold start problem (Iaquinta et al., 2011). Sparsity means not having adequate users' ratings to compute correct prediction. As the rating matrix gets sparse scalability makes it difficult to generate recommendations with the huge dataset. The cold start problem occurs when the system does not have enough ratings to make a recommendation. However, CF-based systems provide reasoning of items being recommended which is one of the important features of a recommender system.

Majority of collaborative filtering systems use k-nearest neighbor (Cover et al., 1967), association rule mining algorithm (Aggarwal et al., 1994) and matrix factorization algorithm (Takacs et al., 2008) among others for making recommendations. The k-NN is more suitable for building collaborative systems due to their similar functionality (Adomavicius et al., 2005). The matrix factorization is used because it allows us to discover latent features underlying the interaction between user and item(Yeung,2010). Collaborative filtering systems based on association rule mining algorithm are quite effective as compared to other recommendation approaches (Lin, 2000).

Content-Based Filtering (CB)

Content-based recommender systems make a prediction using the features of an item rather than ratings of other users (Basu et al., 1998). They consist of "content analyzer", "Profile learner" and "Filtering component". The inputs to the "content analyzer" are web pages, documents and product description.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

The content analyzer aims to perform initial pre-processing on unstructured data (i.e. text) to make it suitable for the next processing step. The "Profile learner" takes input from the "content analyzer" in the form of "structured item representation" and generates "general user profile" using machine learning algorithms. This component also requires user feedback for updating user's profile to recommend more relevant items. The "filtering component" takes "user profile" as input for recommending relevant items to users by matching their profile with the items to be recommended.

CB approaches are unaffected by sparsity and gray sheep problems due to their independence from "user-item ratings". Moreover, they can be utilized in domains such as movies, news article, web page, and television program.

Majority of recommender systems based on content filtering use Bayesian approach (Ericson, 2013), decision tree (Lucas, 2012), neural network (Alvarez, 2011), rule learning (Hariri, 2013) among others. Bayesian approach is used due to its reduced complexity in Bayesian calculations. Content filtering systems based on neural network are gaining popularity due to their ability to differentiate between two different classes of items rapidly and accurately.

CB approaches are categorized into case-based reasoning (CBR) and attribute-based techniques (ABT). CBR recommends those learning objects which are strongly correlated to the objects which a user liked in the past. The quality of items is improved as more users' ratings are collected in the system. However, it suffers from overspecialization and sparsity problems. Overspecialization occurs due to recommending similar items to a user repeatedly. CBR is more useful in teaching and learning field. For example, Pixed (Project Integrating eXperience in Distance Learning) is an implementation of CBR which is a hypermedia ontology-based system. In yet, another CBR based system best navigational path is provided to the learner (Huang et al.,2006). An instructional planner was proposed in (Elorriaga et al., 2000) which adapts the sequences observed in logs to create instructional sequences for a complete course. Attribute-based techniques recommend objects by matching their attributes to the learner profile. They address 'cold start' problem as their recommendations are not based on the learner behavior data.

Existing literature suggests that content-based filtering has been used relatively less in e-government domain and more in e-resource and e-group (Lu et al., 2015). This is primarily due to the privacy policy of data which makes it difficult to get users and items data from the government organization. CB approaches have the following issues:

Cold Start Problem

Cold start problem occurs when a recommender system does not have enough ratings either of a user or item to make recommendations to a user. This is due to either the user has not rated items or a new item was added to the site recently which makes it difficult to provide high-quality recommendations. Cold start problem is of three types: New user problem, new item problem, and new system problem. The new user problem occurs when a user has not used an item from the repository. The new item problem arises when a new item is added to a site without any ratings from a user and the new system problem arises when the system is new and has just started to operate and does not have any ratings either from the user or the items. The cold start problem has its origin in recommendation system (Iaquinta et al., 2011).

One of the most challenging tasks of the recommendation system is to improve the recommendation accuracy for the new user (inactive) or new item (rarely rated item). Cold start problem causes missing ratings in user-item rating matrix. Several solutions (Zhang et al., 2010; Iaquinta et al., 2011) were suggested to address this issue. Furthermore, missing ratings could also be filled with their default values

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

such as the middle value of average user or item (Breese et al., 1998). Moreover, content filtering approach (Degemmis et al., 2007) and autonomous agents (Good et al., 1999) have also been used to deal with missing ratings.

Sparsity

Sparsity refers to insufficient information in the "user-item matrix" (R) for making recommendations controlling the quality of recommendations (Sarwar et al., 1998). With the huge number of items and users in many large-scale applications, the rating matrix can still be extremely sparse even when many events have been recorded which leads to the situation where the similarity between two given users is zero, rendering collaborative filtering useless. Due to sparsity, a rule-based recommender system cannot give any recommendations. Sparsity occurs because some users' rate only a very small fraction of the available items, hence making it difficult to find a sufficient number of common items in multiple user profiles. The problem often occurs in web usage mining and collaborative filtering as compared to other recommendation approaches. In (Chen, 2011), the authors relied on some standard dimensionality reduction techniques to alleviate sparsity. However, this approach suffers from the problem of some of the interesting items may be removed from the final recommendation list. The authors (Owoc et al., 2012) suggested two solutions to this problem. The first solution is to rank all the discovered rules based on the degree of intersection between the left-hand side of each rule and the user's active session and then to generate the top k recommendations. This approach eliminates constraint of having to obtain the complete match with the left-hand side of the rules. The second solution is to employ collaborative filtering in which the system finds "close neighbors with similar interest to the target user and makes recommendations based on the close neighbor's history. In (Popescul et al., 2001) they used probabilistic models for unified collaborative and content-based recommendations in the sparse data environment.

Scalability

With the increasing number of users and items, the existing recommender systems need more resources such as CPU and memory for processing of large information. Most of these resources are used for identifying users with similar taste and descriptions. This problem is solved by considering the combinations of various types of filters and system physical improvement. Moreover, several attempts (Georgiou et al., 2010; Aggarwal et al., 1999) have been made to deal with the problem of scalability. One of the widely used methods is matrix factorization (Koren et al., 2009) which provides several latent models such as SVD (single value decomposition) and SVD++. The latter is an advanced version of SVD and is used to incorporate other sources of feedback from the user (Koren et al., 2011) in order to improve prediction accuracy. The goal of latent models is to convert user and item variables to the same latent factor space.

Over Specialization Problems

In over specialization a user model solely relies on tags in his rated items (Kim et al., 2011). This makes it difficult to recommend new items other than the user has previously rated. For example, if a user is interested in "action movie" but not comedy movies then he/she will never get recommendations for the movie which is a mix of action and comedy. Users are restricted to receive recommendations which strictly match with the information in their profile. Overspecialization prevents the user from discover-

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

ing new items and various available options other than suggested by his profile. However, the diversity of recommendation is an important feature of all recommendation system. The problem is solved using genetic algorithms and provides a wide range of alternatives (Silva et al., 2010). In (Alphy et al., 2015) they have proposed WebBluegillRecom-annealing dynamic recommender system which gives dynamic recommendations each time a user visits a site thus overcoming specialization issue. In yet another work (Ruiz-Iniesta et al., 2012) a recommendation framework is proposed which is a prototype of the knowledge-based system and overcome the problem of overspecialization. Knowledge-based filtering is also used to address overspecialization (Trewin, 2000).

Hybrid Based Recommender Systems (HBRS)

Hybrid Based Recommender Systems combine two or more recommendation techniques such as collaborative filtering (CF), content-based (CB) or knowledge-based (KB) in order to utilize the strength of each one to improve the overall quality of recommendations (Burke, 2002). For example, CF relies on user ratings for predicting the ratings of a new item to be recommended. On the other hand, CB approach does not depend on ratings from a user and based its recommendations on the features of items. Numerous combinations can be created by using the basic recommendation techniques (Burke, 2007) in which he has discussed existing and possible HBRS and also proposed a novel system namely Entrée which combines knowledge-based approach and collaborative approach for recommending restaurants.

Existing literature shows that hybrid models perform better than single recommendation techniques (Soboroff et al., 1999; Pazzani, 1999). In (Savic et al., 2011) they have presented a multi-criteria hybrid recommender system based on analytic hierarchy process(AHP), trend analysis and data comparison in order to evaluate the quality of e-learning. The goal of AHP is to view a problem in terms of hierarchy starting from the top through the intermediate level to the lowest level.

Although hybrid recommender systems have been successfully employed in wide variety of applications, they have the following issues:

1. The constraint with switching hybrid (one of the forms of hybrid techniques) is to have prior information of confidence value or external criteria.
2. Another issue with HBRS is of producing the new rank score based on the individual ranks generated by each component. One of the solutions to this problem is simply adding the individual ranks such as KB_rank (2) + CB_rank (4)->Mixed_rank(6).

Hybrid filtering systems require various input such as user profile (which stores users' preferences about item) and contextual parameters such as (time of day, time of year), demographic data (age, location, gender, etc.) or community data, item or product features (title, genre, actors), different knowledge models (such as rule-based, Bayesian network, etc.). The output of HBRS is a list of items (i_1, i_2, $i_3 \ldots i_n$) with their predicted score such as (0.8, 0.3, 0.5).

Existing literature shows that HBRS are mostly used in the domain of e-government, e-resource, and e-tourism (Lu et al., 2015). A comprehensive study on the possible combination of basic recommendation techniques has been reported in (Burke, 2002).

Among several machine learning algorithms, ANN (Artificial neural networks) has shown good results in combining output from various recommendation models (Hsu et al., 2007). Another approach used is an ensemble of a classifier in building hybrid recommender system as reported in (Tiemann et al., 2007).

Knowledge-Based Recommender Systems (KBRS)

These systems predict the utility of an item by using some appropriate utility function even when no knowledge about the preferences of an item is available. Case-based reasoning system (CBRS) is one of the popular KBRS (Bridge et al., 2006). A suitable similarity function is employed for learning how an item fulfills user's need. One of the forms of CBRS is "constraint-based recommender systems" which are used when a solution is needed in order to fulfill a specific requirement of the user (Felfering et al., 2008). Some conditions must be satisfied by such system for making effective recommendations. For example, if a client 'X' wants to purchase customized software from a company let's say 'ABC' then the set of constraints imposed by the client might be the following: a) A client asks for distributed software system b) The software should be run on the open source platform such as Linux/UNIX c) the client also specifies the number of users who will be using the software d) He states hardware constraints such as minimum required memory and type and speed of CPU. In this scenario, case-based recommender system would be more appropriate as collaborative filtering requires frequent ratings of an item over a period of time which is not possible in the above situation where the client would purchase software once or twice a year from the company which leads to sparse rating matrix and results in collaborative technique useless.

The following issues need to be addressed for the success of KBRS:

1. One should be able to explicitly define knowledge base.
2. Good domain knowledge is required.
3. Must have expertise in representing domain knowledge.

The following inputs are required by KBRS for achieving their goal:

1. User properties, such as type of learner (beginner or advanced), learning style (visual learner or pragmatic learner)
2. Item properties, for example, fiction, non-fiction among others
3. Constraints, they are provided by learner such as courses must be recommended depending upon the type of learner
4. A part of an ontology, to be obtained from database schema
5. Contextual knowledge
6. Filter conditions, provided by a learner such as a book's price should not exceed as stated by a learner

The output of KBRS is the set of items to be recommended. KBRS in particular "case-based recommender" employs several technologies (Felfering et al., 2008).

Several techniques have been employed in the construction of knowledge-based recommender systems. Some of the popular ones are critiquing which is a popular interaction style and was first proposed by (Burke,1996), natural language processing (Zanket et al., 2008), finite state automation (Felfernig et al., 2006).

Computational Intelligence Based Recommender Systems (CIBRS)

Computational intelligence based recommender systems can recognize patterns, exhibit computational adaptability, have fault tolerance, and their error rate approximate human performance (Bezdek, 1994). Computational intelligence is a discipline of artificial intelligence which uses various techniques such as fuzzy sets (fuzzy logic, fuzzy numbers), artificial neural networks (Backpropagation neural networks, self-organizing map, feedforward networks), evolutionary computing (genetic algorithms, genetic programming, evolutionary programming), swarm intelligence and artificial immune system among others. These technologies have made recommender system more robust, effective and context-aware (Huang et al., 2006).

For recommender system based on computational intelligence, the input consists of user preferences from an active user and contextual parameters and the output produced is top N recommendations (list of items with their predicted value).

The reviews of existing literature on CIBRS show the following issues:

1. Overfitting is one of the problems of neural networks (NNs).
2. The black box effect is another problem which is due to the difficulty in selecting its parameters.
3. Neural networks take relatively more processing time due to training with a large number of samples data.
4. Difficulty in interpreting learned neural network.

Computational intelligence techniques have been known for not only improving recommendation accuracy but also able to deal with issues found in traditional recommendation approaches such as sparsity, cold start, and scalability. Majority of computational intelligence techniques such as fuzzy sets (Zhang et al., 2013), artificial neural networks (Devi et al., 2010) and evolutionary computing (Hernandez, 2008) among others have been used in building context-aware recommender systems.

Fuzzy Linguistic Modelling (FLM)

Fuzzy linguistic modeling is a tool which uses the concept of a linguistic variable in order to deal with qualitative assessment (Zadeh, 1975). It has been used in varieties of the problem such as decision making (Herrera et al.,1996) and clinical decision making (Degani et al., 1998), political analysis (Arfi, 2005) among others. FLM is of two types namely the 2-tuple FLM (Herrera et al., 2000) and the multi-granular FLM (Herrera et al., 2000).

There have been several works reported based on fuzzy linguistic modeling. In one such work (Yager,2003) fuzzy set is used in order to represent an item in a recommender system. In yet another work (Zenebe et al.,2009) the authors have defined a set of properties for an item and set of values for each property. Existing literature suggests that Fuzzy linguistic modeling is mostly used in the domain of e-government, e-commerce, e-library and e-learning (Lu et al., 2015).

In spite of their widespread applications, fuzzy linguistic modeling has the following issues:

1. Difficulty in the interpretation of TFN (trapezoidal fuzzy numbers)
2. The granularity of uncertainty.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

In order to produce the desired output fuzzy linguistic modeling requires the following inputs and output:

1. Crisp input, for example: high (1), low (0)
2. Fuzzy input, obtained after fuzzification between 0 and 1
3. Fuzzy output, obtained after passing through fuzzy inference engine
4. Fuzzy rule database, for example if… then
5. Crisp output, obtained after defuzzification

Recommender systems based on fuzzy linguistic modeling employ Markov chain model (Huang et al., 2009), OWA (ordered weighted averaging functions) which have become very popular among the fuzzy community for associating a weight with a relative value of an input (Yager,1988).

K-Nearest Neighbours (k-NN)

The k-nearest neighbor is a non-parametric method which stores the entire training dataset in memory and compares the test instance with each of the training instances in order to find its class. K-NN is simple and effective in many cases (Hand et al., 2001).

Although *k*-NN has been used as one of the widely used approaches of collaborative filtering, it has the following issues:

1. To determine the value of k(number of neighbors)
2. Formation of the neighborhood is computationally expensive
3. The requirement of large memory in case of a big dataset

K-NN needs various inputs such as training dataset, N input/output pairs. The output consist of $y_i \in \{1, ..., C\}$ for classification; a discrete variable for classification; a discrete variable $y_i \in R$ for regression; a continuous (real-valued) variable.

Among all instance based classifier such as KStar (John et al., 1995), LWL (Locally weighted learning) (Frank et al., 2003) and IBk (Aha et al., 1991), IBk is widely used for building collaborative filtering (CF) system due to its functional similarity with CF.

Multi-Criteria Decision-Making Recommender Systems

Multi-criteria recommender systems in contrast to traditional single criteria recommender systems consider multiple criteria in order to compute the utility of an item for a particular user (Adomavicius et al., 2005). For example, in traditional systems rating function is defined as follows:

$$R: U \times I \rightarrow R_0 \quad (1)$$

where U is the set of all users, I is the set of all possible items to be commended and R_0 is the predicted rating. However, single criteria recommender systems are unable to compute the utility of an item effectively as an item (movie) might be rated from different aspects such as story and visual effects in a

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

movie recommendation system. A user might provide ratings of 3 to story and 5 to visual effects. On the other hand, a multi-criteria recommender system predicts the utility as follows:

$$R: U \times I \rightarrow R_0 x \times R_1 x \times .... \times x R_k \quad (2)$$

The input to multi-criteria systems is same as single criteria recommender systems with the only difference of considering multiple attributes of an item and asking users' preference on these attributes. The output is a set of top N items to be recommended for the user.

MCDM's (multi-criteria decision making) have the issue of intrusiveness which occur due to explicitly asking additional information from a user. Several works have been reported to address this issue (Caglayan et al., 1997; Konstan et al., 1997). Another issue is handling incomplete data which occurs more in the multi-criteria systems as users are usually unwilling to provide ratings and these systems require more data from a user on multiple attributes of an item. Expectation maximization algorithm has been successfully used to deal with this issue (Ghahraman et al., 1994). However, several other machine learning techniques could also be explored in this context (Portugal et al., 2015). The issue of constructing the item evaluation criteria is critical in multi-criteria systems as it directly affects the quality of recommendations. MCDM requires information on several attributes from a user hence they must be carefully chosen in order to compute the utility of an item.

Algorithms employed by multi-criteria recommender systems are broadly classified into heuristic (Adomavicius, 2007; Manouselis et al., 2007) and model-based approaches which include, probabilistic modeling (Adomavicius, 2007) and multilinear singular value decomposition (Li et al., 2008).

Web Usage Mining (WUM)

Web mining is the application of data mining techniques to the content, structure, and usage of Web resources (Liu,2011). It is broadly categorized into web content mining, web structure mining and web usage mining. Web content mining concentrates on the content of individual pages, which is contained in the HTML (Hypertext markup language), script and code that generates a page. In (Sebastiani, 2002) they have presented a detailed review of text mining.

Web usage mining refers to the use of data mining techniques to automatically discover and extract useful information from the web document and services (Facca et al., 2005). It is becoming more and more popular among users due to easy access to the log file as well as its applicability in CRM (Customer relationship management). The goal of CRM is to provide not just the quality products and services but also make, retain and grow customers (Kotler,2004). This is possible once we know the needs and preferences of the customers by applying data mining techniques to customers' usage data in order to get the profile of customers. In Web usage mining, the primary web resource is a record of the requests made by visitors to a Web site, most often collected in a Web server log (Srivastava et al., 2000).

WUM process consists of three major steps. The first step is "data preparation" which takes its input as "site files" and "web server log." The data preparation step comprises several sub-steps such as data cleaning, user identification, transaction identification, usage statistics, and support filtering. The output of this step is "user transaction file" which is fed to the "usage mining phase." The transaction records are inputted to the various mining algorithms such as clustering and association rule mining which outputs "frequent itemsets" and URL cluster. The third step is generating recommendation which takes its input from the "usage mining stage" and outputs set of rules which are recommended to a user.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Majority of recommender systems based on web usage mining uses association rules, sequential patterns (Sungjune et al., 2008), and clustering (Liu, 2011). The major application areas for WUM are personalization, system improvement, site modification, business intelligence and usage characterization (Srivastava et al., 2000). Moreover, web content or site structure can be integrated with usage data in order to improve the accuracy of the personalization system (Liu, 2011). Web usage mining primarily collects its data from the log file of a web server which contains all the users' data visiting the site such as IP address, pages visited and visiting time among others. It collects, analyzes and process this data to discover user access patterns. The result of this analysis provides us with useful insight into interesting usage information and patterns which can be further used to predict the web pages a user is likely to be interested. Table 1 presents recommender systems based on web usage mining using popular machine learning algorithms in e-learning:

Issues of Web Usage Mining

Although web usage mining techniques have been able to overcome the limitations of traditional recommendation approaches, they have the following issues:

Table 1. E-learning recommendation systems based on web usage mining

S.No	Methods and Algorithms	Results
1	The Combination of k-means and apriori algorithm(Aher et al.,2013).	Recommending best combination of courses
2	Naive Bayes algorithm (Kotsiantis et al.,2003).	Predicting students with high probability of drop out
3	Web usage mining and decision tree (Cho et al.,2002).	Improved and effective product recommendation
4	Web usage mining and information retrieval(Khirbi et al.,2008).	Recommend relevant links to an active learner.
5	Multi-attribute evaluation and fuzzy method(Lu,2004).	Providing learning material recommendations.
6	Association rule mining (Zaiane et al.,2002).	Suggesting activity or shortcuts to learners.
7	Web usage mining coupled with content based and collaborative filtering(Claypool et al.,1999).	Recommending relevant links to active user.
8	Association rule mining and collaborative approach for recommendation to courseware Filtering (Garcia et al.,2009).	Courseware Recommendation
9	Bayesian approach (Bekele et al.,2005).	To predict the performance of a student
10	Content-based analysis, collaborative filtering and data mining techniques (Hsu et al.,2006).	To generate recommender score by which help the student to select appropriate lessons?
11	Combining oversampling techniques and cost sensitive learning (Nguyen et al.,2009).	For improving prediction/ classification results.
12	Collaborative algorithm (Michael et al.,2007).	For recommendation of online course Enrollment.
13	Collaborative, Content-Based and Demographic Filtering (Pazzani 1999)	For recommending restaurants.

Privacy

Privacy is one of the major issues of web usage mining. It is drawing a lot of attention of research community due to constantly growing nature of the world wide web. The issue of privacy is based on the fact that majority of users want anonymity while surfing the web. While administrators are interested in discovering users' access patterns which requires applying data mining techniques to user's browsing data, users are generally unwilling to disclose their browsing information. Moreover, this information would help in improving the design of a site and meet the requirements of different users leading to improving user's browsing experience. The challenge here is to make a compromise where user's identity is not disclosed and site administrators can get required data for their analysis. Furthermore, there should be regulations in place which prevent user's data being sold to third party and site administrators can perform analysis on usage data. The users should also be informed about the site's policy so that they can make an informed decision about disclosing their personal information. The world wide web consortium has started an initiative called P3P (*Platform for Privacy Preference*). It allows a site to publish their privacy policies in a machine-readable format. When a user first visits a site, the browser matches the privacy setting of the site with the security settings configured by the user. If a match is found satisfactory then user's request is allowed otherwise a negotiation protocol is used which is acceptable to the user. Another aim of P3P is to provide guidelines for independent organizations which can ensure that sites comply with the policy statements they are publishing (Srivastava et al., 2000). The European Union has taken a lead in setting up a regulatory framework for internet privacy and has issued a directive which sets guidelines for processing and transfer of personal data. Some of the privacy issues have been reported in (Facca et al., 2005).

In order to get the most accurate and valid recommendation, the system must have a large amount of possible information about the user such as demographic data and the location of a particular user. Obviously, the question of reliability, security, and confidentiality of the given information arises. Many online shops provide effective privacy protection for the users by using specialized algorithms. Although in the U.S there is no unifying framework in place, U.S federal trade commission has recommended that Congress develop legislation to standardize the personal information of websites.

Dependency on Usage Data Alone

Recommender systems based on WUM suggest items using historical data found on the server due to which they miss certain objects added to a site recently which have not been consumed by a user. Moreover, without using the semantic knowledge they cannot recommend certain complex objects using their properties and attributes. For instance, let us consider an e-learning recommender system having few tables in its database namely course, instructor, book and so on. In the absence of semantic knowledge or ontological structure of the site, we might end up recommending objects only on the basis of features of the entities (tables). Moreover, we might also miss some important relationships which exist among those tables and have the potential to improve the quality of recommendations. However, incorporation of semantic information in the different phases of the web usage mining process allows a recommender system to infer new semantic relationships which were not obvious otherwise. For instance, in "pure usage-based e-learning system", a learner could be recommended "Advance operating system" course based on his profile. However, with the integration of semantic information with usage data we could suggest learner some "introductory level operating system course" in order to enable the learner to ac-

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

quire some basic knowledge of the course before opting for the "advanced operating system" course or could also suggest him a course instructor. Such type of semantic relationship could only be discovered by enriching usage level transactions with semantic information.

Usage-based recommendation systems also cannot explain the reason behind a particular set of recommendations. However semantic web has successfully overcome this limitation by providing the domain knowledge representation language such as DAML+OIL (Horrocks, 2002), SHIP (DL) and description logic (Horrocks et al., 2001).

Pre-Processing of Click-Stream Data

Another issue with the web usage mining is pre-processing of users' click-stream data which ensures the quality of data before mining. It involves applying different algorithms and heuristics such as data cleaning, session identification, path completion, pageview identification among others to raw data (Cooley et al., 1999). We also found many data pre-processing tools such as WEKA (Waikato environment for knowledge analysis), DBMiner, Delta miner among others which can be used effectively and efficiently for the data preparation tasks (Goebel et al., 1999). Among all these tools, WEKA is the most popular one due to its user-friendly interface and open source nature.

Semantic Web

The Semantic web is the extension of the web 2.0 in a sense that adding semantic to the web makes the information meaningful. It can be used in a variety of applications areas such as data integration where data in various locations and formats can be integrated in one seamless application; In resource delivery and classification to provide better domain-specific search engine capabilities; In cataloguing for describing the content and its relationship available at a particular website; In describing content rating; In explaining collection of pages that represent a single logical document; for illustrating intellectual property rights of web pages among others. Moreover, semantic web helps improve the existing services available on the web. For example, many e-portals, such as e-learning, e-government, and e-commerce were in need of semantic structure and intelligent logic. This goal is achieved by integrating two fast-developing research areas such as semantic web and web mining. Currently, they are among the most discussed topics in the research community. They can be combined successfully in order to achieve the common objective of understanding huge data in an automated way and also discovering and obtaining meaningful results. Semantic tools such as web services and semantic web agents can be used to achieve the goal of personalization of services over current e-learning portals and course management system (Mustapasa et al., 2010).

Semantic Web Mining (SWM)

The semantic web is proposed by Tim Berners-Lee the inventor of the World Wide Web. In the words of Tim Berner-Lee "The semantic web is not a separate Web but an extension of the current web, in which information is given well -defined meaning, better-enabling computers and people to work in cooperation. Generally semantic refers to the meaning of a sentence. Semantic web mining involves the integration of domain knowledge into the web mining process. The Majority of research, in SWM, has focused on application areas such as web content and structure mining (Stumme et al., 2002).

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Semantic Web Usage Mining (SWUM)

Semantic web aims to make the web content understandable to humans as well as machines, hence allowing the software agent to search for desired content, share information and knowledge in a format that other software agent can understand.

Recommender systems based on semantic web usage mining require various inputs such as "server log", "web page" and "domain information". The server log and web pages are fed to the usage processing step which outputs "semantic user transactions". Ontology processing is also performed which results in domain ontology and acts as input to the subsequent phases such as pattern discovery and online recommendations. "Semantic user transactions" and "domain ontology" are fed to the pattern discovery phase which outputs "semantic usage patterns" which are finally inputted to online recommendation engine for generating recommendations to the active user. Table 2 presents some of the most recommendation system based on well-known semantic web usage mining techniques.

Issues of Semantic Web Usage Mining

For semantic web usage mining to be successful, it has to address the following issues:

Table 2. E-learning recommendation systems based on semantic web usage mining

S.No	Methods and Algorithms used	Results
1	Domain ontology and aggregate usage profiles(Mobasher et al.,2002).	To recommend personalized learning.
2	Multi-agent system based on ontology(Rani et al.,2015).	Formal description of learning Content and Process.
3	An e-learning recommender system using ontology, web ontology language (OWL) and rule filtering(Shishehchi et al.,2010).	Help the learners choosing the suitable material.
4	Web-based learning management system based on semantic web technologies(Begam et al.,2013).	To recommend varied resources to different user based on their need.
5	A combination of Ontology, information retrieval, and data mining (Faoud et al.,2012).	To discover, categorize and retrieve of personalized resources.
6	Integration of ontology and web usage mining(Zhudhdar et al.,2009).	To improve the accuracy of recommendations.
7	E-learning system based on RDF/XML(Shah et al.,2011).	Provide many semantic web services such as registration, personalization, notification and ontology mapped tutorial pages.
8	E-learning system using the combination of the semantic web and web mining (Jain et al.,2012).	Personalization of e-learning services.
9	Personalized learning system based on ontologies and semantic web(Vargas et al.,2008)	To manage the personal profiles and identities of learners.

How to Represent Domain Knowledge as Content Feature

Many sources of domain knowledge can be utilized in the mining and personalization phase such as textual data of a website. The semantic of a site to some extent depends on the content features which are related to items. This feature needs keywords, phrase, category name, etc. Content pre-processing is essential before domain knowledge can be represented using domain representation languages. It is defined as extracting relevant features from text and meta-data. If features are extracted from text then features are assigned different weights which show the relative importance of features, if they are retrieved from meta-data then weights are derived automatically. The integration of content features with personalization process is required when the site is rich in text. However, the difficulty with this approach is that it is not able to find the complex relationship that may exist among objects at a deeper semantic level due to inherent properties possessed by these objects. Machine learning algorithms can also be used to further pre-processing of content features. For instance, content feature's classification with concept hierarchy may be used to limit the discovered patterns to those having page views about a particular subject. Similarly using clustering, formal concept analysis or association rule mining in the feature space can lead to composite features representing concept categories or hierarchies. For a system to be able to recommend the various types of complex objects the system must use ontology and not just keywords for the objects (Clerkin et al., 2001).

How to Represent Domain Knowledge as Structured Data

In web usage mining, the focus is on a web transaction or a user profile which is usually composed of a group of page view names and query strings (extracted from Web server logs). Though these features do not possess the semantic information about a transaction, therefore a mapping needs to be done between these features and the objects they represent. There are many e-commerce sites which allow generating web pages by querying an operational database from which semantic information can be easily obtained. Machine learning techniques can be used when structured data is not available. Moreover, to perform further pre-processing the acquired knowledge should be easily understandable. So, a standard language is needed to represent extracted knowledge. DAML+OIL (Darpa agent markup language and Ontology inference layer) is an example of an ontology language that combines the Web standards from XML (Extensible markup language) and RDF (Resource description framework), with the reasoning capabilities from SHIP (DL) description logic (Horrocks, 2002; Horrocks et al., 2001; Unadkar, 2015). Relational models and probabilistic models can also be integrated in order to enhance web personalization process with domain knowledge. In (Anderson et al., 2002) they have used Relational Markov Model for personalization. In (Horrocks et al., 2001) they adopted the syntax and semantics of another ontology representation framework and SHOQ (D) (Description logic) to represent domain ontologies.

How to Create Mapping between Usage Level and Domain Level Instances

The mapping process involves assigning usage level patterns like URL or page view name to the instances in the knowledge base. For example instead of describing a user's navigational path as: "u1, u2, ..., un" (where ui is a URL (Uniform resource locator) pointing to a Web resource), we need to represent it using the instances containing in the knowledge base, like: "movie(name = The Hangover), movie(name = Ghostbusters), movie(name = Austin Powers).Moreover, with the help of pre-acquired concept hierar-

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

chy, we may be able to infer that current user's interest is in the comedy category. This is also termed as semantic user profile which can further be used for the purpose of semantic pattern discovery and online recommendations.

Using Query Strings

We generally ignore the huge amount of information accumulated in the database or semi-structured documents in a site. Large database server frequently provides content integrated from various underlying servers and database. The dynamically created pages on such servers are based on queries with several parameters linked to the URL matching to the underlying scripts. By means of the web server query string recorded in the server log files, it is likely to recreate the response page. Usually, in well-designed sites, there is a semantic mapping between query parameters and objects (such as products and categories). When a user clicks on a certain item on the product page of a site, this request is sent and recorded in the web server. It also appears in the address bar of the browser as query strings. The item details can be retrieved from the database using item_no, item category, and the backend database. For example, two query strings from a hypothetical bookstore are given below. The name value pair which begins right after question mark containing item_no and item category can be utilized to learn the interest of a customer in various books. Based on this a recommender system can update the profile of a user which can further be used to suggest more books to a customer. The first string below shows the item_no=7859645 and item category=3456 which can be queried to the database and the corresponding item details retrieved from the server can be displayed on a response page.

1. http://www.xyz.com/app.cgi?action=viewitem&item=7859645&category=3456.
2. http://www.xyz.com/app.cgi?action=order&item=1234567&category=1234&coupanid=3456.

Table 3 and Table 4 shows that semantic web usage mining (SWUM) is frequently used in e-learning domain which is due to the availability of many open source e-learning systems such as Moodle, ATutor, Eliademy, Formal LMS, and OLAT among others (Cavus et al., 2014) which provide rich features and offer several functionalities to their users. Moreover, due to their user-friendliness and less cost in implementing these systems, many universities, institutions, and schools are adopting them in order to improve their learning process. The database schema of these systems is easily accessible and the emergence of several semantic web technologies such as DAML+OIL, SHIP(DL) and a wide variety of open source ontology tools makes it easy to extract and process domain knowledge. Moreover, semantic web usage mining requires usage data (extracted from the log file of a web server) and domain knowledge (part of content and structure of a site) which is easily available in these systems. Table 3 and Table 4 also presents a summary of various traditional and non-traditional recommendation approaches their benefits, limitations, along with real applications which are based on these approaches and corresponding domain where they have been used often.

FURTHER RESEARCH IN RECOMMENDER SYSTEM

The emergence of a plethora of social networking sites such as Facebook, tweeter, flicker, YouTube, LinkedIn, Instagram among others provide opportunities for researchers to exploit the additional informa-

Table 4. Summary of recommender system approaches

Approaches	Benefits	Limitations	Application Examples	Frequently used Domain
K-nearest classification	Faster and more accurate recommend ation	High computation cost due to comparison of test instance with each training instance	• Foxtrot(Middleton et al.,2004).	E-resource
Multi-Criteria Decision Making	Ease of use ,Scalable, Easily adjustable in size due to hierarchical structure	Incredible amount of input is required at each step of the process.	• Primitive cognitive network process(P-CNP) (Yuen,2012) • MCEQLS(Multipl e criteria evaluation of the quality of software) (Kurlovas et al.,2013)	E-resource
Web Usage Mining	Overcomin g deficiencies of traditional approaches such as collaborativ e filtering.	New item problem, Sparsity, scalability, overspecializa tion problem, security and privacy issues.	• LMOS (Learning material organization system)(Tsai et al.,2006). • LLA (Learner learning assessment system)(Hwang et al.,2003). • AHA!(Romero et al.,2009).	E-learning
Semantic Web Usage Mining(SWU M)	More relevant information, exchange of information becomes easier between program and sites.	Representatio n of domain knowledge, the mapping between usage data to domain level instances.	• SEWeP(Eirinaki et al.,2003). • Web-page recommender (Nguyen et al.,2013).	E-learning

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

tion associated with user's profile on these sites such as contextual information, tag, and annotation in order to improve the quality of recommendations. The additional information is labeled by users while uploading their resources such as images, videos among others which help to enrich the profile of a user (Golder et al., 2005). Moreover, tagging information could also help recommender systems to learn more accurately about their user's preferences. The integration of tag information with user preferences results in improving the accuracy of prediction, hence more relevant items could be recommended to a user. Collaborative tagging could further be explored to learn new ways to extract user's preferences effectively and efficiently. Another emerging area is "semantic web usage mining" (Berendt et al., 2002) which holds a lot of potentials to assist recommender systems in recommending more accurate items. A considerable amount of information about user and item is underlying a website which is hidden and unexplored (Third, 2012). Moreover, this information can be extracted from the content and structure of a site using tools from semantic web to discover the semantic relationship among objects which is usually missing in usage-based recommendation system (Stumme et al., 2006). Furthermore, more intelligent recommender systems could be developed by exploiting and integrating the semantic knowledge in different stages of the web usage mining process.

Recommender systems based on multi-criteria decision making needs to be investigated further. They learn user's preferences by asking for information on multiple attributes of an item in contrast to single criteria recommender systems. However, multi-criteria systems present several issues such as the issue of intrusiveness. Instead of interrupting a user by getting information on multiple attributes of an item, it would be better to collect information implicitly which reduces user involvement. New methods based on multi-criteria decision-making need to be developed in order to implicitly collect data from users.

Furthermore, construction of multi-criteria (an item having multiple attributes) in terms of identifying and specifying functions that represent preferences of users could further be explored in multi-criteria recommender systems(). For example, in a "book recommender system" a book is treated as an item which could have various properties such as "type of book" (fiction or non-fiction), "book language" (French, English) type of author(national, international) among others and non-fiction attribute might have its own subcategory such as "non-fiction by discipline" or "non-fiction by topic" or "non-fiction by writers". Furthermore, non-fiction by topic could further have another level of attributes such as "a book about the arts" or "business books." Hence, there could be a hierarchy of attributes and each level could have one subcategory of attributes. These attributes should be selected carefully so as to have a meaningful relationship with them which finally leads to improving the quality of recommendation. Overall, we can say that by exploiting additional sources of information leads to the development of next generation of recommender systems.

CONCLUSION

We have discussed various recommendation approaches especially web usage mining and semantic web usage mining, their algorithms, issues and additional data sources for improving the quality of recommendation system. While several attempts have been made earlier to address the issues of traditional recommender systems, these systems still have not been able to fully exploit additional information. Moreover, the domain knowledge could be represented either as the content feature or structured data depending on the application. Various classification algorithms were also reviewed for creating map-

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

pings from usage data to domain level instances. However, other machine learning algorithms could also be investigated in this context. Moreover, query strings can also be utilized to exploit enormous information stored in a database or semi-structured documents associated with a site in order to learn more about a user's preferences. The recommender systems based on above-discussed approaches can be made smarter and intelligent by incorporating additional information such as tag, annotation and domain knowledge in the recommendation process.

Chapter 76
Combining Artificial Intelligence and NetMedicine for Ambient Assisted Living: A Distributed BDI-based Expert System

Paolo Sernani
Università Politecnica delle Marche, Italy

Andrea Claudi
Università Politecnica delle Marche, Italy

Aldo Franco Dragoni
Università Politecnica delle Marche, Italy

ABSTRACT

World population is shifting towards older ages: according to recent estimates there will be 1.5 billion people over 65 years old in 2050. Local governments, international institutions, care organizations and industry are fostering the research community to find solutions to face the unprecedented challenges raised by population ageing. A combination of Artificial Intelligence and NetMedicine could be ideal to face these challenges: they provide the means to develop an intelligent system and simultaneously to distribute it over a network, allowing the communication over the internet, if needed. Hence, the authors present a Multi-Agent Architecture for Ambient Assisted Living (AAL): it is the model for a system to manage a distributed sensor network composed by ambient and biometric sensors. The system should analyse data and pro-actively decide to trigger alarms if anomalies are detected. The authors tested the architecture implementing a prototypical Multi-Agent System (MAS), based on Belief-Desire-Intention (BDI) paradigm: the Virtual Carer.

INTRODUCTION

The lengthening of life expectancy, jointly to the decreasing of fertility, will triple the number of people aged 65 or older from 524 million in 2010 (8 percent of the world population) to 1.5 billion in 2050 (16 percent of the world population) (World Health Organization, 2011). The increasing median age of the world population has significant social and economic implications: the consequent rise of chronic diseases will result in a dramatic increase of emergency situations and missions within the coming years (Kleinberger, Becker, Ras, Holzinger, & Müller, 2007). This is becoming a substantial issue in Europe, USA and Japan owing to their high dependency ratio[1] (Christensen, Doblhammer, Rau, & Vaupel, 2009). Thus national governments, no-profit organizations as well as industry are fostering the research community to contribute to the Ambient Assisted Living (AAL) field. AAL aims at extending the time older people can live in their home environment, assisting them with the activities of daily living, promoting the use of intelligent products and Information Technology (IT) tools to provide remote care services (Sun, De Florio, Gui, & Blondia, 2009).

In this paper we propose a multi-agent architecture for an AAL system. The cornerstone of this idea is the combination of Artificial Intelligence and NetMedicine in order to develop a system able to manage a distributed sensor network, composed by ambient and biometric sensors; it should be, at the same time, an interface layer between the network, the assisted person, his relatives and the medical staff. The system, named Virtual Carer, models actions and behaviours of a human caregiver, to help a patient in his daily activities inside his home environment, simultaneously monitoring his health conditions and ensuring his security. The Virtual Carer is able to analyse data coming from the available sensors and, thanks to its knowledge base, to infer new knowledge and to decide if detected values should be notified, possibly triggering an alarm.

The need for an intelligent system controlling a distributed network clearly suggests an integration between Artificial Intelligence and NetMedicine. Artificial Intelligence provides technologies to develop a proactive expert system, while NetMedicine offers the possibility to access data and alarms triggered by the system through the web. The term NetMedicine simply denotes every medicine activity which is carried on through the Internet (Dragoni, 2009). In other words NetMedicine has to be intended as the evolution of TeleMedicine, due to the digitalization of information and the emergence of internet: the fast improvement of the ICT technologies is greatly moving the demand for knowledge by the physicians towards the cyberspace (Nakic, & Loškovska, 2012). Moreover, social networking fosters the constitution of communities sharing similar medical interests, even enhancing primary care practice (Hawn, 2009).

Multi-Agent Systems (MAS) represent one of the possible points of contact between Artificial Intelligence and NetMedicine; indeed the main advantages of a MAS approach (Palazzo, Rossi, Dragoni, Claudi, Dolcini, & Sernani, 2013), essential for the proposed system, are:

- Distribution;
- Modularity;
- Robustness.

The MAS architecture allows to distribute software agents and the platforms that manage them over one or more networks; each sensor can be associated with an agent, making the system resilient to sensor failures and disconnections. The adoption of the Foundation for Intelligent Physical Agents (FIPA) standards as the Agent Communication Language (ACL) allows to add and remove sensors and devices

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

in a transparent way, simply wrapping them with agents. Furthermore agent-based systems can provide interfaces to access through the internet.

In addition to the listed features, pro-activeness plays a prominent role, making the system able to autonomously take the initiative, guided by goals. Thus the reasoning module of the system, i.e. the Virtual Carer Agent (VCA), is based on Belief-Desire-Intention (BDI) paradigm. The VCA models logical structures, reasoning and behaviours similar to those of a human caregiver, transforming data from sensors in logical predicates representing its knowledge base. To perform actions on the monitored environment and interact with the assisted person, VCA communicates (through FIPA messages) with agents controlling actuators.

The listed features meet the requirements on modularity and adaptability of AAL systems (Ayala, Amor, & Fuentes, 2012): MAS approach and BDI paradigm make the proposed system capable to autonomously adapt to context changes.

The rest of the paper is organized as follows. The next section gives the needed background on agent technology, BDI paradigm and AAL in general. Then some related works are outlined. In the further section a MAS general architecture for AAL is described. Implementation section gives details about the proposed system, highlighting some features of the Virtual Carer and describing its main advantages by means of a simple simulation scenario. Finally, results are highlighted and conclusions drawn.

BACKGROUND

The guidelines of AAL indicates the need of unobtrusive, adaptable and dynamic intelligent environments (Sadri, 2011); AAL systems have to adapt themselves over time to cope with the changing needs and health conditions of the assisted person, providing technical solutions flexible and adaptable enough to respond to this dynamic requirement (Wolf et al., 2010). Moreover, they need to perceive variation in habits that can indicate health-related problems or stressful situations. Applying Artificial Intelligence techniques on this domain seems to be a promising direction for research (Pollack, 2005; Cook, Augusto, & Jakkula, 2009; O'Grady, Muldoon, Dragone, Tynan, & O'Hare, 2010).

The next two subsections describe agent technology and the AAL field, clarifying that MAS and BDI agents with an appropriate knowledge base are suitable to meet the listed guidelines.

Agents

According to Russell & Norvig (2009), an agent is an entity that can perceive the environment through sensors and act on the environment through actuators. Wooldridge (1995) defines the main properties of an agent: autonomy, social ability, reactivity and pro-activeness indicate that agents operate without external intervention, interact with other agents using an Agent Communication Language (ACL), perceive the environment answering to changes and are able to autonomously exhibit goal-directed behaviours.

The human practical reasoning described by Bratman (1987) is the theoretical foundation for the BDI paradigm: the intersection between beliefs, i.e. the agent knowledge about the environment, and desires, i.e. the set of states representing the environment as desired by the agent, generates agent's intentions, i.e. the set of desires that an agent wants to achieve; in other words intentions constitute the goals pursued by an agent.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

An agent-based system usually consists of multiple agents (Bellifemine, Caire, & Greenwood, 2007): these MAS are suitable to model complex systems; the agents composing a MAS may interact with each other both indirectly (by acting on the environment) or directly (via communication and negotiation). The interaction between agents may be cooperative (they cooperate to achieve mutual benefits) or competitive (they vie for their own interests).

Ambient Assisted Living

Through the AAL Joint Programme, the European Union aims to foster the emergence of AAL services and systems for ageing well at home, in the community, and at work (The AAL Joint Programme, 2004). The AAL Joint Programme defines these key objectives for AAL:

- To extend the time people can live in their preferred environment by increasing their autonomy, self-confidence and mobility;
- To support maintaining health and functional capability of the elderly individuals;
- To promote a better and healthier lifestyle for individuals at risk;
- To enhance the security, to prevent social isolation and to support maintaining the multifunctional network around the individual;
- To support carers, families and care organizations;
- To increase the efficiency and productivity of used resources in the ageing societies.

Home Automation and, specifically, Ambient Intelligence (AmI) provide pervasive devices and technologies for AAL systems, in order to build a safe environment for the assisted person (Sun et al., 2009). AmI builds around people an unobtrusive, interconnected, adaptable, dynamic, embedded, and intelligent environment (Sadri, 2011), with the leading goal to help them in their daily activities. One of the main commitments of AmI is to allow the user to interact with an AmI system using the most natural ways, as he would do with any other human (Kleinberger et al., 2007). However assistive technologies can supplement human caregiving and cannot substitute it, having the potential to improve the quality of life for both older adults and their caregivers (Pollack, 2005).

The need of a smart interaction between AAL and AmI systems and the elderly is guiding the research community towards the exploration of Human-Computer Interaction (HCI) and Human-Robot Interaction (HRI) solutions. In such a context elderly people should be considered the most prominent stakeholders for IT developments (Holzinger, Searle, Auinger, & Ziefle, 2011).

RELATED WORKS

In recent years the MAS approach to AAL and healthcare has been exploited in several works. Reinisch & Kastner (2011) point out the importance of pro-activeness in a smart home characterized by a dynamic, non-deterministic, complex environment: being capable of reasoning to find out which actions to execute, BDI agents are better suited to such an environment than reactive agents; in the use case proposed by authors a small society of BDI agents is designed to cope with the energy efficiency of a smart home when different devices are available. To monitor the patient status, BDI agents are implemented also in the work described by Borowczyk, Gawinecki, & Paprzycki (2008): agents cooperate to carry out

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

specific tasks such as evaluating the patient's heartbeat and deciding to trigger an alarm if necessary. Nefti, Manzoor, & Manzoor (2010) propose a MAS performing risk assessment tasks for patients with dementia: a Risk Assessment Agent, using its knowledge base (to load the patient's history) and information provided by agents responsible for various ambient sensors (such as a Gas Detector Agent or a Temperature Analyzer Agent), employs a method based on fuzzy logic to predict risk situations and to send appropriate alarms. Beside agent-based works, scientific literature is rich of contributions on the intelligent interpretation of available data. In (Mileo, Merico, Pinardi, & Bisiani, 2009), to monitor the posture and the health conditions of an elderly, a reasoning component based on answer set programming analyses data gathered by a hierarchy of wireless sensor networks in a home environment. Pinardi, & Bisiani (2010) describe the recognition of the patient's movements using a machine learning approach. A smart home should also include technologies to allow an easy interaction between the elderly and the system: speech recognition is deeply investigated, establishing new challenges for the analysis of ageing voices (Vacher, Portet, Fleury, & Noury, 2011).

To implement an AAL system with an effective impact on daily life the design phase and, at a later stage, the evaluation phase should include several perspectives (Kleinberger, Jedlitschka, Storf, Steinbach-Nordmann, & Prueckner, 2009): the points of view of end users (elderly persons and their relatives), physicians, medical caregivers and research developers (software and systems engineers) are all characterized by the same importance to assess the effectiveness of an AAL system. Participatory design (Serrano, 2010) and evaluation (Demiris, Oliver, Dickey, Skubic, & Rantz, 2010) involve all the stakeholders, taking into account different (and sometimes conflicting) needs and opinions.

ARCHITECTURE

Our multi-agent architecture constitutes the ground for an AAL (IT) system, characterized by the following fundamental purposes:

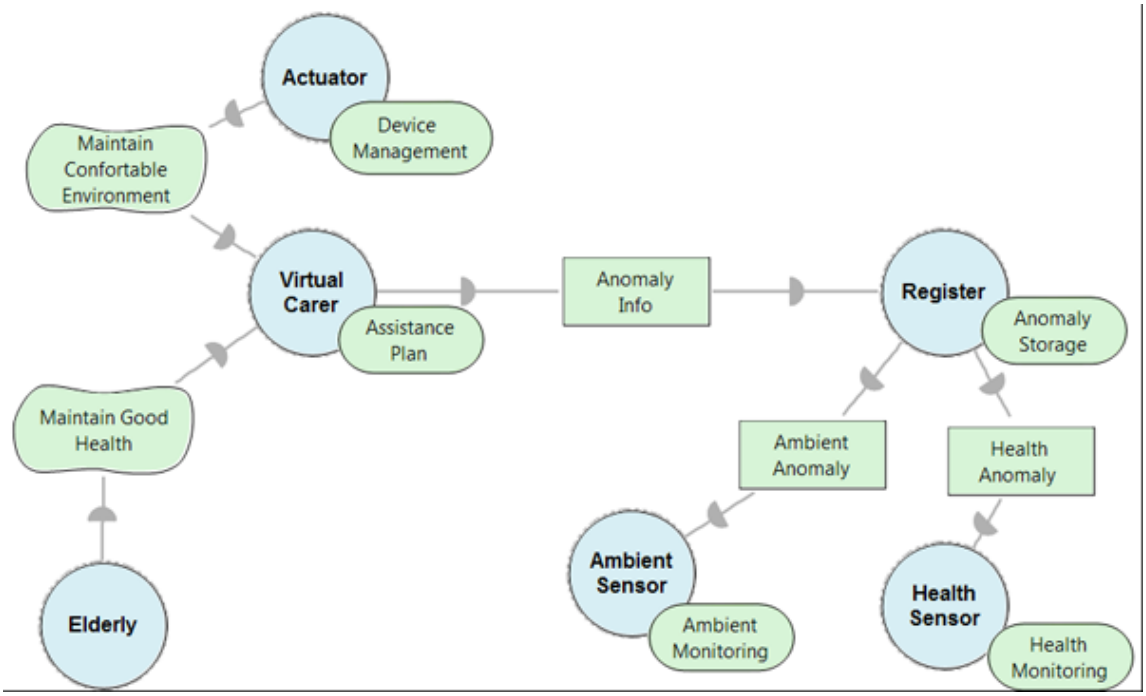
- To communicate with an assisted person;
- To monitor his health conditions;
- To control the environment around him.

The system is purely an Information Technology (IT) system: it exclusively use technologies provided by Computer Science and Artificial intelligence to model a distributed, reliable and modular sensor network composed by biometric and ambient sensors. To cope with highly variable environments typical of AAL, the prosed agency integrates a BDI core agent: the Virtual Carer Agent (VCA). It represents reasoning mechanisms and behaviours similar to those of a human caregiver. This feature is the core of the prototypical system "Virtual Carer" based on the defined multi-agent architecture.

The large amount of information used by the Virtual Carer system is represented by logical predicates, forming its Knowledge Base (KB). It chooses the right actions to perform on the environment with an inference engine applied on its KB. The Virtual Carer works as follows:

- It analyses data provided by sensors and devices forming the system (i.e. by agents controlling them) and updates its KB;
- When its KB is updated, Virtual Carer generates new knowledge using its inference engine;

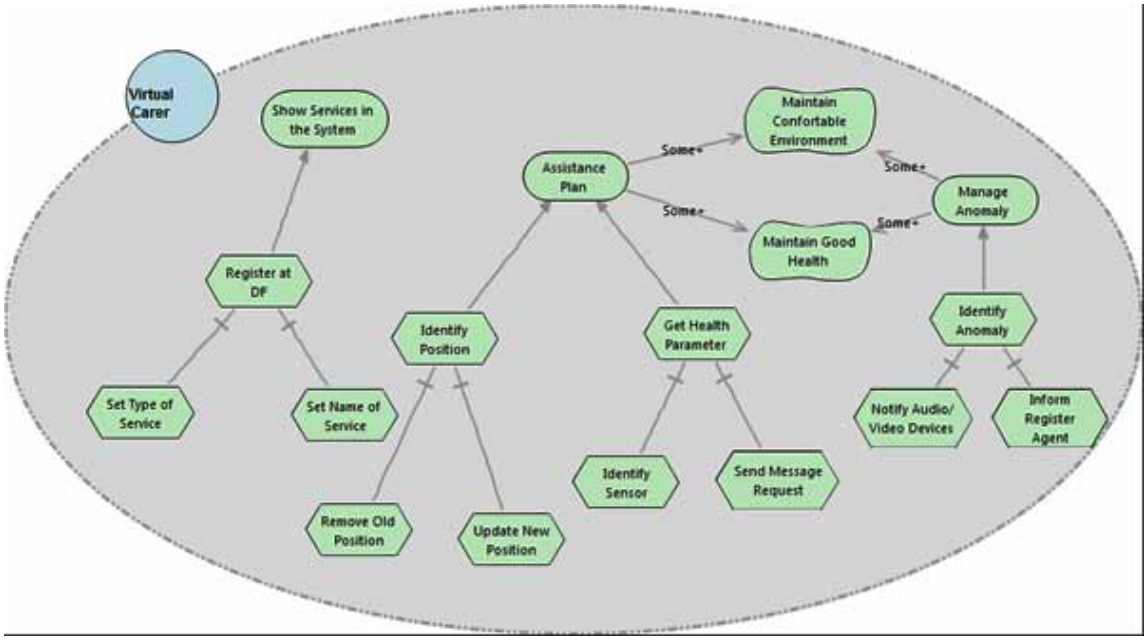
EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use



- With backward reasoning rules applied on its KB, the Virtual Carer selects the main goal and chooses (through backtracking) the plan to satisfy it;
- The Virtual Carer carries out the actions of the chosen plan, collaborating with agents responsible for actuators, in order to directly act on the environment.

We modelled the system using the *i** notation (Yu, Giorgini, Maiden, & Mylopoulos 2011). Figure 1 illustrates a high-level Strategic Dependency Model; the system is composed by various actors: Virtual Carer, Register, Actuator, Ambient Sensor, Health Sensor and the elderly person who needs assistance. To preserve his health conditions, the elderly depends on plans executed by the Virtual Carer; also Actuators depend on command and plan decided by the Virtual Carer, in order to maintain the environment comfortable. A Register Actor is responsible for the storage of detected anomalies, offering the databases to the Virtual Carer. Thus, the Register depends on Ambient Sensor and Health Sensor for the acquisition of values.

Agency



Each actor in the Strategic Dependency Model, except for the Elderly, corresponds to an agent in the defined architecture. Hence, there are a Virtual Carer Agent (VCA), a Register Agent, Ambient and Health Agents and Actuator Agents. The VCA is responsible for the execution of plans on the basis of the context (its belief base), according to the BDI paradigm. Figure 2 shows the Actor Model developed for the VCA. To achieve its goals the VCA performs several tasks: it has to identify the patient's health

Figure 1. i Strategic Dependency Model for the whole system. The Virtual Carer should cooperate with other actors to allow the elderly to "mantain a good health"*

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. i Actor model for the Virtual Carer: to achieve its goals the Virtual Carer uses data gathered by health and ambient sensor*

condition, his position and to detect dangerous or anomalous parameters using available sensors. To complete these tasks the VCA has to publish its services for other agents: this goal can be achieved by registering to the Directory Facilitator[2] (DF) of the whole agency.

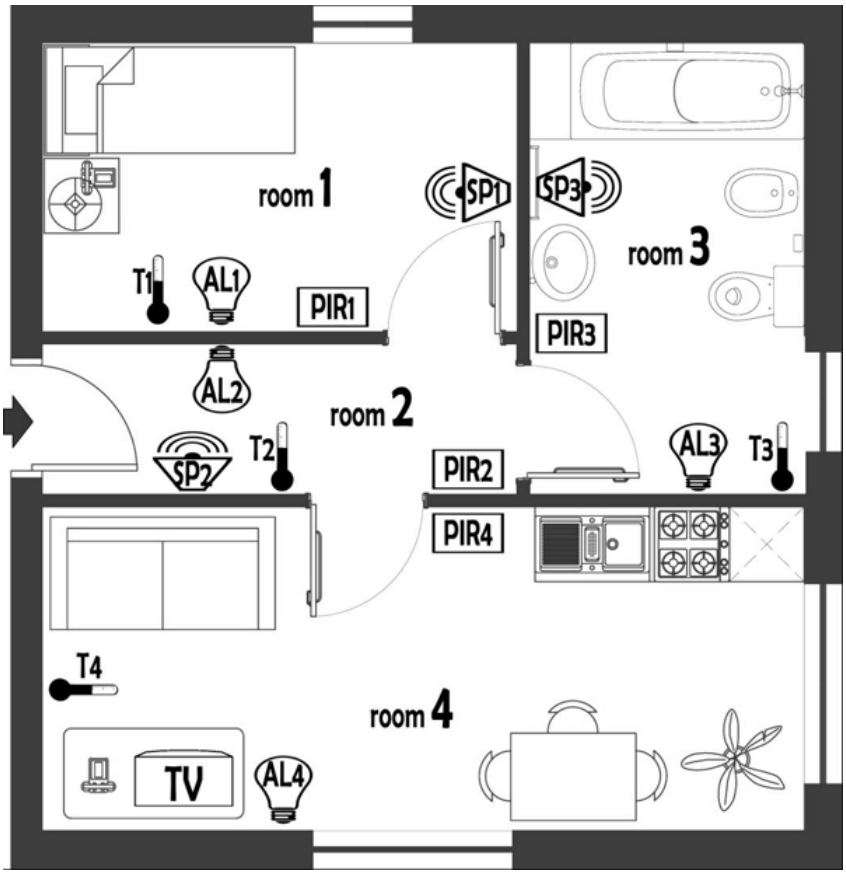
Sensor Agents are responsible for environment and health monitoring. Hence, they can be distinguished in two types: Ambient Agents and Health Agents. Ambient Agents read the value of ambient sensors, as the temperature of a specific room. If the value is outside of a predetermined range, the Ambient Agent communicates the anomaly to the VCA. Also presence sensors (as Passive Infrared) are managed the Ambient Agents: they directly inform the VCA about the presence of someone in the monitored room. Similarly, Health Agents manage sensors measuring parameters related to the health conditions of the assisted person. An example could be a Health Agent to control a heartbeat sensor.

Finally, Actuator Agents are responsible for the management of the various devices composing the system such as lights, shutters, speakers, monitors, etc. They must be able to receive request messages (from the VCA) in order to execute on/off commands on the devices.

VIRTUAL CARER IMPLEMENTATION

Two frameworks were adopted to implement the agents composing the Virtual Carer: JADE (Bellifemine et al., 2007) and JASON (Bordini, Hübner, & Wooldridge, 2007): both are FIPA compliant. Firstly the frameworks are fully interoperable; moreover modularity of the system is ensured, since the communication takes advantage of the adoption of FIPA-ACL messages: different devices can be added any time simply integrating more agents. JASON and the AgentSpeak language were used for BDI agents,

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use



i.e. the VCA and the Register Agent, making it capable to store beliefs directly in the database. JADE, instead, was employed for the implementation of Sensor and Actuator Agents.

To show the effectiveness of the proposed agency a simulation scenario were built. In addition, to highlight the capability to integrate devices in a transparent way, a mobile application for the STMicroelectronics BodyGateWay sensor was developed and integrated into the agency using the JADE-LEAP add-on (Bellifemine et. Al, 2007).

Agency Operating Mode

In the typical interaction among the agents composing the Virtual Carer, the VCA receives alarms from Sensor Agents when a value is out of the predetermined safe range; otherwise, if the current plan needs data to satisfy the goal, the VCA can decide to require to read a value on his own initiative. The Register Agent receives and stores in a database values from Sensor Agents and warnings or anomalies reported by VCA. Similarly, the VCA can require values from the database to the Register Agent. The VCA sends request to the Actuator Agents in order to execute actions corresponding to the adopted plan[3].

Figure 3. Fictional home map for the simulation scenario of the Virtual Carer

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Simulation Scenario

To test the Virtual Carer, software simulations were carried out: figure 3 presents the fictional home map used as a simulation scenario, highlighting the arrangement of the available devices in the environment. There are 4 rooms: the bedroom (room 1), the hallway (room 2), the bathroom (room 3) and the living room (room 4). For each one, a temperature sensor (T1, T2, T3, T4), a PIR sensor (PIR1, PIR2, PIR3, PIR4) and a device to turn the light on/off (AL1, AL2, AL3, AL4) are provided. In addition there is a speaker (SP1, SP2, SP3) for each one of the first three rooms, and a monitor to visually communicate with the assisted person in room 4. Pressure sensors are supposed to be in each place where the person can sit or lie down (e.g. couch, bed, seats), and contact sensors are supposed to be placed on every door and window, to monitor their open/close state. Body sensors are used to monitor the vital parameters (e.g. heartbeat, body temperature) of the assisted person. For each sensor and device in the described scenario the appropriate Ambient, Health and Actuator Agents are created.

To run the simulations a BDI agent, i.e. the Elderly Agent, was integrated in the agency, modelling plausible behaviours of the person assisted by the Virtual Carer system. The Elderly Agent sends messages to other agents of the system: for example, to simulate the detection by a PIR sensor, it informs the Ambient Agent when it moves in the controlled room; moreover it can send requests directly to Health Sensors to know the value of specific health parameters.

Figure 4 shows an emergency plan example for the VCA: it is executed when an Ambient Agent, responsible for a temperature sensor, reads a value out of the predetermined range. In this case the VCA communicates the anomaly to the Register Agent and activates the plan “notify”, in order to evaluate if the monitored person has to be notified with some alarms. The plan in figure 5 is activated when the body temperature of the assisted person is out of a security range. This plan is similar to the previous one.

In addition, the VCA needs to evaluate if a combination of values provided by Sensor Agents is dangerous. Thus the VCA’s KB includes specific rules to perform this task.

Figure 4. Emergency plan for the Virtual Carer Agent. The plan responds to a room temperature anomaly

```
+emergency1(V)[source(A)] : true <-
        .print("Room temperature out of range");
        .print("from sensor ", A);
        .print("value ", V);
        .time(H,M,S);
        .send(register,tell,anomaly(A,V,H,M,S));
        .print("Information sent to Register
Agent");
        ?em1(N);
        New = N + 1;
        -+em1(New);
        !notify;
```

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 5. Emergency plan for the Virtual Carer Agent. The plan responds to a body temperature anomaly

```
+emergency2(V)[source(A)] : true <-
        .print("Body temperature out of range");
        .print("from sensor ", A);
        .print("value ", V);
        .time(H,M,S);
        .send(register,tell,anomaly(A,V,H,M,S));
        .print("Information sent to Register
Agent");
        ?em2(N);
        New = N + 1;
        -+em2(New);
        !notify;
```

Figure 6. An example of the rules in the VCA's KB. If the heartbeat is over 120 bpm and the patient is not moving, it could be tachycardia

```
tachycardia :- heartbeat(X) & dangerousHeartbeat(X)
& restfulActivity.

dangerousHeartbeat(X) :- X >= 120.

restfulActivity :- accelerazione(Y) & Y < 0.3.
```

Figure 6 contains an example[4] from the VCA's KB. The rules intuitively indicate that a scenario where the patient has an heartbeat over 120 bpm and is not in a stressful situation (i.e. he is not moving) could be considered tachycardia: the VCA has to perform some actions to solve this emergency without stressing the elderly.

To simulate the different behaviours of the assisted person, the Elderly Agent was provided with different plans. Figure 7 shows a plan including the transition from the hallway to the bedroom the plan models the situation in which the assisted person goes to bed and measures its body temperature. This simulation works as follows. At first, the Elderly Agent initializes the VCA, providing it the information about its initial position; then, after 10 seconds (i.e. the time necessary to get to bedroom), it informs the PIR Agent of its presence in the final position (this simulates the detection of the elderly by the PIR sensor). The PIR Agent controlling the bedroom notifies the VCA about the presence of a person in the bedroom; thus the VCA has a new belief (i.e. the presence of the assisted person in room 1), and activates the plan to turn the light on in the bedroom and to turn it off in the hallway. Finally, the Elderly Agent sends a message to the VCA to know its body temperature value. The VCA activates a plan that includes all the actions necessary to require data from the proper Health Agent and to communicate it to the Elderly Agent.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

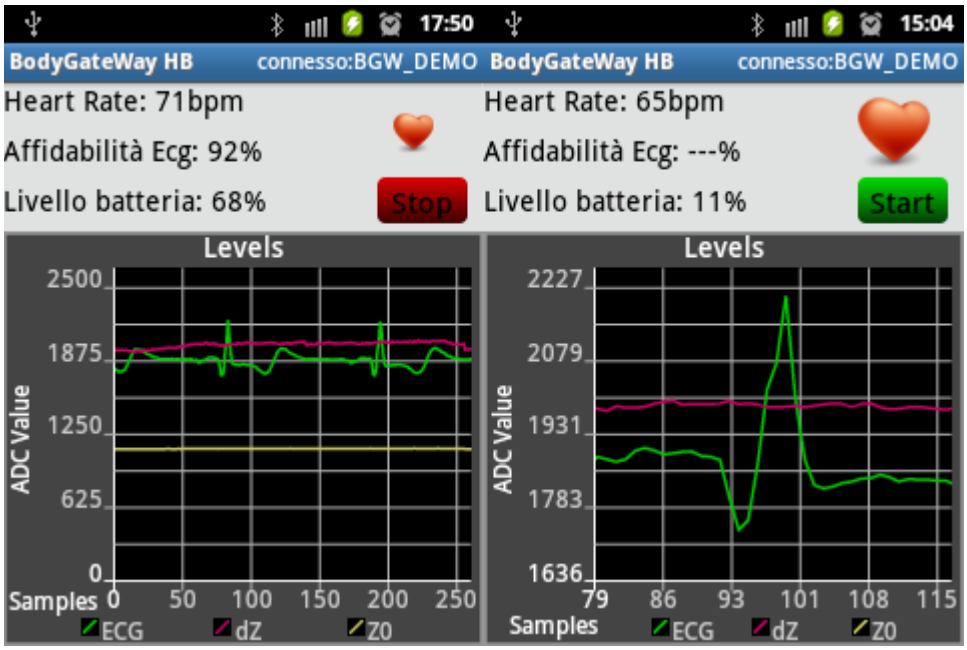


Figure 7. A plan for the Elderly Agent

```
+-scenario5 : true <-
        .send(carer,tell,init(hallway));
        .wait(10000);
        .send(pir1,tell,at);
```

Beside plans similar to the one just described, we simulated plans without an explicit request by the Elderly Agent, in which the Virtual Carer had to infer the right actions. For example, when a window remains open in the bedroom and the assisted person is sleeping, the decreasing of room and body temperature should activate the plan to wake up the person and ask him to close the window. In this scenario, the Ambient Agent associated to the bedroom window informs the VCA that the window state is "open". At a later stage the Ambient Agent responsible for T1 sensor communicates to the VC Agent that the detected value is out of the predetermined range; a similar message is sent by Health Agent. VCA updates its KB with these new beliefs and activates a plan ending with a message to the Elderly Agent, asking it to close the window.

To highlight the power of the MAS approach we developed a mobile application for the STMicroelectronics BodyGateWay, a wearable electronic patch integrating three accelerometers with sensors to detect the ECG and the bioelectrical impedance. Figure 8 shows a screenshot from the Android application. We tested the application separately, on human patients. Then we integrated the mobile application in the agency, using the JADE-LEAP add-on and simulating the message exchanges with the Virtual Carer Agent.

Figure 8. Screenshots from the mobile application for the STMicroelectronics BodyGateWay

RESULTS

To fully validate the proposed approach, some tests should be carried out in a real home environment, equipped with existing sensors and devices. However, the implemented simulations are suitable to underline the advantages of the application of MAS and BDI paradigm to AAL.

JADE and JASON (i.e. the frameworks we used for implementation) provide fault tolerant techniques to implement agent platform, such as the Main Container Replication Service (MCRS) and the Directory Facilitator Persistence: the first prevents that the agents creation and management can be single points of failure, the latter allows the traceability of agent services.

More in general MAS approach ensures the distribution of agents over a network; the adoption of FIPA standards guarantees modularity to the system: as tested in the simulations, devices can be added without specific efforts. Furthermore agents, using FIPA-ACL messages for communication, can provide information over the internet, publishing services for the authorized clients.

Thanks to the BDI paradigm, data from ambient and health sensors update the VCA's belief base; thus the VCA can infer new knowledge and desires, being able to decide to trigger an alarm if an anomaly is detected. Hence, the VCA quickly responds to changes in a dynamic environment.

CONCLUSION

We presented a MAS approach to AAL to face a dynamic environment, monitoring the health conditions of an elderly or disable person. The essential idea of the work was to combine Artificial Intelligence and NetMedicine through the definition of a multi-agent architecture and the adoption of BDI paradigm, to lay the foundations for a distributed expert system. A prototype system, i.e. the Virtual Carer, was implemented to highlight the benefits of the proposed architecture. The reasoning core of the system is a BDI agent: the Virtual Carer Agent. It collaborates with other agents controlling various sensors and devices (Actuator Agents) to facilitate the daily activities of the assisted person and to trigger alarms when an anomaly is detected among the parameters regarding the patient's health conditions.

The system flexibility is ensured by the adoption of FIPA standards: new devices can be added simply integrating agents in the proposed architecture, making the system ready for the inclusion of new technologies. The adopted frameworks natively provide services addressed to fault-tolerance: the MCRS and the DF persistence make the agent-based architecture resilient to single point of failures for the agent management and for the traceability of agents' services.

The system was tested through software simulations in a fictional scenario; the assisted person was represented by another BDI agent: the Elderly Agent. Several plans were taken into account, modelling different actions performed by the Elderly Agent (e.g. movements in the home environment, direct request of health parameters). Tests show that MAS and BDI paradigm improve modularity and adaptability of AAL and AmI systems. The MAS approach guarantees the distribution of the system, making it able to share information with authorized clients, if needed; the BDI paradigm allows to respond to changes in the environment and in the needs of the assisted person. Thus MAS, as the point of contact between Artificial Intelligence and NetMedicine, can play a crucial role in the development of systems to extend the time in which people can live in their preferred environment.

Future works include the execution of more insightful tests; nevertheless a daily-used home environment, equipped with devices and sensors, where an assisted person can actually live, or an accurated

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

simulator (Sernani, Claudi, Calvaresi, Accattoli, Tofani, & Dragoni, 2014) is beyond our possibilities at this stage of the work, but it is the only way to fully validate the proposed approach.

ACKNOWLEDGMENT

The authors would like to thank STMicroelectronics for providing the BodyGateWay sensor for tests.

Chapter 77
An Imagination of Organizations in the Future: Rethinking McKinsey's 7S Model

Oya Zincir
Istanbul University, Turkey

Ayşegül Özbebek Tunç
Istanbul University, Turkey

ABSTRACT

Organizations try to survive in a hypercompetitive, changing, and unpredictable environment. The form of this survival continuously changes and requires different tools, solutions, dynamics and drivers according to the actual time. Today organizations face with a big paradigm shift, the industrialization of information age. Organizations should find a new form on the basis of the new age requirements. Some authors have suggested some strategic prescriptions harmonized with the actual term such as McKinsey's 7S Model including strategy, structure, systems, skills, staff, style and shared goals. It is considered that there is a gap related to updating and upgrading these formulas by activating some new concepts such as morphing, organizational ambidexterity and so on. In this study, it is aimed to understand the organizations in the future with internal elements and outer changes which would affect them at the edge of the new era by using this model and offer many propositions.

INTRODUCTION

I don't read history. That's in the past. I'm thinking of the future. Henry Ford (Lander, 2014)

Managerial and organizational studies' aspects have changed through the years and so have organizations. According to the well-known study of Alvin Toffler (1980), three types of societies -based on the concept of waves; each wave pushes the older ones aside- have evolved through first, second and third waves as agricultural, industrial and information ages. First wave is the society after Agrarian Revolu-

tion which characterized by the enclosure of common land and the introduction of some technological innovations such as the seed drill. The concepts of this age led to the development of job specialization, complex political structures, non-portable possessions, architecture, and the rise of industry and commerce. Second wave is the society during the Industrial Revolution which characterized by mass production, distribution, consumption, education, recreation and destruction that combines those things with standardization, centralization, concentration, and synchronization. The structure of organization was bureaucracy. Third wave is the Post-Industrial Society characterized by actionable knowledge as a primary resource, demassification, diversity, knowledge based productions and non-linear change. The structure of organization is adhocracy. Based on these developments, organizations have evolved into various types through the ages.

With the 21st century, it has been recognized that new social and technical aspects of work systems, organizational structures, managerial practices, competencies and skills are needed. Some authors (Anderson, 2012; Rifkin, 2011, 2014) define this new age as "Third Industrial Revolution" and explain it as "the industrialization of Information Age". It can been said that it is the collaboration age; the modern enterprise is already a cyberfactory with the usage of robotics, internet of things and high-automation (Czarniawska, 2012) and high collaboration is very important for organizations and people who work for them.

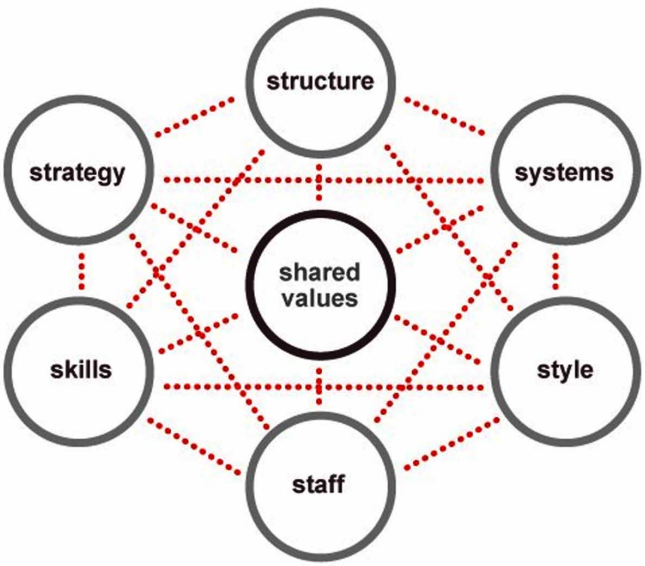
Rifkin adresses renewable energy by mentioning its sustainable use and he stresses that this energy will be one of the main power element to change the understanding of world (Rifkin, 2011). Further, Rifkin (online, para.36-37) also explains organizations and workforce of the future by mentioning some important aspects: 'The new high tech workforce of the Third Industrial Revolution will need to be skilled in renewable energy technologies, green construction, IT and embedded computing, nanotechnology, sustainable chemistry, fuel-cell development, digital power grid management, hybrid electric and hydrogen-powered transport and hundreds of other technical fields. Entrepreneurs and managers will need to be educated to take advantage of cutting edge business models, including distributed and collaborative research and development strategies, open source and networked commerce, performance contracting, shared savings agreements, and sustainable low-carbon logistics and supply chain management". Organizations shift from centralized global companies to distributed small and medium size enterprise networks. Klaus Schwab (2016), using the term of Fourth Industrial Revolution, explained future concepts on the topics of mobile supercomputing, self-driving cars, geneting editing and many others by defining them with some megatrends (physical, digital and biological). These developments will affect economies, organizations, governments, societies and individuals. Schwab (2016) also emphasizes that the speed, breadth and depth and the holistic effect of the Fourth Industrial Revolution is a way more different than the other industrial revolutions. It is non-liner; will change many paradigms and recreate them by gathering some of them together and it needs to be considered holistically with countries, companies, sectors and more. He mentions that the new era is the "collaboration era", so that these institutions should collaborate together to do the necessary changes. The developments in advanced robotics, 3D printing, circular economy, internet of things (IoT), sharing economy, artificial intelligence, innovation making, humanistic approaches and many more, will reshape the world. In this manner, we need to understand new organizational concepts and economics systems and they should be renewed according to these developments. Machines will be used even more in doing business and so, not "race against the machine" but "race with the machine" understanding should be complementary. In short, people and machines should be team mates. Data driven developments help goods to be better produced, and this leads to increase asset productivity. Organizations collaborate with different partners

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

and learn from them even more and so forth. Thus, with all these, it can be said that the skill levels and managerial styles might be quite different from now; more agile, sustainable, collaborative, humanistic, flexible, technologic, creative, innovative, etc.

In this study, it is aimed to prescribe organizations of the future by rethinking McKinsey's 7S Model. It is a management model which developed by Robert Waterman and Tom Peters, most often used as an organizational analysis tool to assess and monitor changes in the internal situation of an organization. By using this model, it is aimed to understand organizations in the future with internal elements and outer changes which would affect them at the edge of the new era. On this framework, based on future thinking and new concepts, 'organizations in the future' is prescribed on some topics and furthermore, propositions are presented about some concepts. Some of them are liquid organization model, morphing, organizational ambidexterity, roles (staff who work for not jobs but for multiple roles), cyborganization, holacracy.

LITERATURE REVIEW



Introduced in the June 1980 issue of *Business Horizons*, in an article titled "Structure is not Organization" by Thomas J. Peters, Robert H. Waterman and Julien Phillips, McKinsey's 7S Model maps a constellation of interrelated factors that influence an organization's ability to change on seven elements. It suggests that significant progress in one element of the organization will be difficult without working on the others. The model has been used as an important tool to understand the complexity of organizations and provides a deep understanding of that structure alone doesn't refer to the whole organization.

The 7S are (which can be seen in Figure 1); hard elements that of structure, strategy, systems and soft elements that of skills, style, staff and shared values. As the authors explained (Waterman, Peters & Phillips, 1980), the elements are interconnected, they have effects on each other and do not follow a hierarchy or an importance degree. Strategy is the plan devised to maintain and build competitive advantage over the competition; structure is the way an organization is structured and who reports to whom, and systems is the daily activities and procedures that staff members engage in to 'get the work done'. These are hard elements; easy to define or identify and management can directly influence them. Shared values -called "superordinate goals" when the model was first developed- are the core values of the company that are evidenced in the corporate culture and the general work ethic; style is the style of leadership adopted; staff is the employees and their general capabilities, and skills are the actual skills and competencies of the employees who work for the company. These are soft elements; more difficult to describe, less tangible and more influenced by culture (Waterman, Peters & Phillips, 1980).

Peters (2011, para.15) also explains that now, in the new era, "hard is soft, soft is hard. The plans and the numbers are often 'soft' and the people (staff) and shared values (corporate culture) and skills (core competencies) which are truly 'hard' that is, the bedrock upon which the adaptive and enduring enterprise is built". It illustrates the paradoxical characteristics of the Hard Ss and Soft Ss elements. This perspective grounds on the "people" dimension. People's competences differentiate and change constantly (Dahlgaard-Park, 2013). Hamm (2015, para.3) explains this as that "the traditional hard skills are readily available and they cover a small percentage of what it takes to be 'excellent' as a company. On the other hand, the soft skills are really difficult to master. Finding people with the skills that are highest in demand is difficult". Currently, workforce is changing. Digitalization and other developments brought some serious effects on employees and customers. Employees expect a harmonized work-life balance. Customer expectations are

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. McKinsey's 7S Model

more specialized today. They are the forcing dimension of business (one example is user innovation). In this demand economy, people also choose which organizations that they want to work with and there are human resources intermediaries who gather people and organizations. Organizations will have the chance to use "human clouds" to choose its future employees. All these grounds on "people dimension" of the model. It is the main dimension which is effected by the changes in workplace behaviors and working conditions. When considering the model, it can be said that, social aspects of works, leadership/management style and staff' skills and competencies are the pillars of the model now by considering all the elements.

RETHINKING MCKINSEY'S 7S MODEL FOR ORGANIZATIONS IN THE FUTURE

The methodology of this study bases on rethinking McKinsey's 7S Model for the future understanding of organizations. As explained above, the model includes seven elements which interact each other. Mentioning that 'hard is soft, soft is hard' in this new era, in this study, every element are explained on some topics. For example, strategy is defined as a soft element and conceptualized by tactics and maneuvers, emergent strategies, strategic flexibility, transient advantage strategy etc. Staff, another example, is conceptualized by t-shaped skills, roles in organizations, technophilia, etc.

Soft Elements (Soft Ss)

As Peters (2011) explained lately, strategy, structure and systems are the soft elements of the model. In this study, it is considered to explain these elements under this category. When it is first written, the authors explains these elements as hard elements. By the time, business world has changed and so have organizations. First, each element is identified, and than some new concepts are explained and lastly propositions are introduced for each concept.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Strategy

In the model, strategy is defined as the plan devised to maintain and build competitive advantage over the competition. The focus is on 'building sustainable competitive advantage over the competition'. Strategy has been seen as a hard element and business world was (and still is) focused on building sustainable competitive advantage by creating a strong position among rivals and defending it for extended periods of time (McGrath, 2013). Lippitt (2007) underlined the fact that 'execution, not strategy, offers an exclusive competitive advantage'. Strategy execution which aims a competitive advantage is still very important for companies, but companies need to understand new rules of this new era. In today's world, competitors and customers are very unpredictable and amorphous (McGrath, 2013), and high-velocity competitive contexts are fast becoming the norm (Leavy, 2014).

In hyper-changing industries that effected by globalization and the digital revolution, competitive advantage often evaporates in a year. So, if companies want to stay ahead, they need to constantly start new strategic initiatives, building and exploiting many transient competitive advantage at once (McGrath, 2013). For this manner, first, it is essential to define 'transient advantage'. It is a strategy that prioritizes fast innovation to build a pipeline of competitive advantages where business environment requires the capacity to surf through waves of short-lived opportunities.

Proposition 1: In turbulent industries, organizations which follows transient advantage strategy can cope with emergent strategies more easily than the others.

Where being fast and changing fast are important aspects, and strategic flexibility is a vital capability, organizations need to give importance to tactics and maneuvers more. The reason is that tactics are actions that take advantage of opportunities offered by the gaps within a given strategic system. Maneuvers are actions that improve or maintain strategic situation of the company in a competitive environment or avoid a worse situation. 'Strategy is undertaken before the battle; tactics and maneuvers are implemented during the battle'. In this manner, where execution of the strategy is very important, organizations need to prioritize maneuvers and tactics to execute strategies. Strategic flexibility, also another important concept, is defined as the ability to precipitate intentional changes and adopt to environmental changes through the continuous rethinking of current strategies, asset deployment and investment strategies (Roberts & Stockport, 2014).

Proposition 2: In turbulent industries, organizations might prioritize maneuvers and tactics to execute strategies faster.

Proposition 3: Organizations that internalized strategic flexibility can adopt to environmental changes faster and easier.

Waterman et. al (1980), explained the strategy as the way a company aims to improve its position vis-a-vis competition. The focus is now on transient advantage strategies and wining the competition for a short period of time by, for example, creating new strategic initiatives, building organizational dynamics on strategic flexibility, etc. From this perspective:

1. Making innovation an everyday proficiency;

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

2. Practicing healthy disengagement as a normal, regular activity and continuously reconfiguring resources; and
3. Doing activities to achieve a dynamic balance between stability and agility (Leavy, 2014) are essential for organizations who want to cope with new environment changes and be competitive with the changing dynamics.

Proposition 4: Transient advantage strategy prioritizes fast innovation practices for organizations to compete among rivals.

Proposition 5: Transient advantage strategy generates the development of new strategic advantages for the organizations.

Porter (1980) asserted that companies should concentrate for one direction for their strategies to gain competitive advantage. Therefore he recommended to choose either differentiation-oriented or low cost-oriented as strategic positioning. He argues that there are insuperable trade-offs between these strategies, so that organizations have to make explicit choices (Porter, 1996). This assumption was a cornerstone for strategy field and also for companies who practice the findings of related academic studies in 1990s. Porter was not only a management thinker to support one point of view that means making choices that favor one activity over the other. According to this perspective, companies that pursue mixed strategies risk becoming "stuck in the middle," which may lead to poor performance (Raisch & Birkinshaw, 2008). This metaphor obviously presents how the duality is perceived as risky.

This duality is called 'ambidextrous approach' in terms of not only strategy but also structure. Ambidexterity concept is first used by Duncan (1976) who argued that firms need to innovate in order to insure long-term success and should consider a dual structure, one to initiate and one to execute, as a means to achieve these ends. This concept covers the idea that organizations should put in place dual structures, with one unit focusing on exploration and the other focusing on exploitation (Birkinshaw & Gupta, 2013). Exploration includes such things captured by terms such as search, variation, risk taking, experimentation, play, flexibility, discovery, innovation. Exploitation includes such things as refinement, choice, production, efficiency, selection, implementation, execution (March, 1991). It is argued that too much emphasis on exploitation to the exclusion of exploration leads to competency traps, inertia, and ultimately obsolescence. By contrast, too much focus on exploration to the exclusion of exploitation leads to a failure trap in which organizations gains no returns from its knowledge (Simsek et al., 2009). For this reason, some authors support the balance between these contrary ways. Actually today's organizations focus on strategies, in other words, how to formulate the best strategy to survive. On the other hand, future organizations should concentrate on dynamic capabilities, expertise activities, competencies and try to reveal the best mixture to be successful. This mixture provides them flexibility, diversity, harmony capability and holistic paradigm for organizations.

Proposition 6: Ambidexterity strategies might provide flexibility and diversity for organizations.

Proposition 7: Ambidexterity strategies might push the development of dynamic capabilities for organizations.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Structure

Structure is the way an organization is structured and who reports to whom. It divides tasks and then provides coordination, trades off specialization and integration (Waterman, Peters & Phillips, 1980). There are various structure types, such as functional, matrix, adhocratic, etc. A traditional hierarchy is not always the most effective structure; different organizations have different types of structure and these different structures effect the way they perform. Mintzberg (1980) identifies five main successful organizational structure as the entrepreneurial organization, the machine organization (bureaucracy), the professional organization, the divisional (diversified) organization and the innovative organization (adhocracy). Structure effects the organizational practices such as standardization of work processes, unit size, centralization/decentralization etc. It is important to mention that there's no "right" organizational structure, thus, to understand how structure relates to the variety of attributes in an organization is essential.

There is also a new concept which is called 'holacracy'. It is defined as a system of organizational governance in which authority and decision-making are distributed throughout a holarchy of self-organizing teams rather than being vested in a management hierarchy (Rud, 2009). As Robertson (2007) explains, holacracy aligns the explicit structure of an organization with its more organic natural form, replacing artificial hierarchy with a fractal "holarchy" of self-organizing teams ("circles"). A "circle" in holacracy is a self-organizing team. Each circle has an aim (purpose), and the authority to define and assign its own roles and accountabilities. Each circle is a holon -a whole self-organizing entity in its own right-, and a part of a larger circle. Each one connects to other of its sub-circles via a double-link, where a member of each circle is appointed to sit on the other, creating a bidirectional flow of information and rapid feedback loops. Each circle governs itself by uncovering the roles needed to reach the aim of the circle, and assigning circle members to fill them (Robertson, 2007).

Proposition 8: In holacratic organizations, staff might perform innovative work behavior more often.
Proposition 9: In holacratic organizations, staff might be more focused to team and organizational goals.
Proposition 10: In holacratic organizations, staff might get more rapid feedback and information from other members of the organization.

There is another concept that should be mentioned. It is 'morphing' which means continuous ongoing transformation. Morphing is used especially for change management practices. Generally, it mentions ongoing changes of the whole organization; for example, the changes of organization's strategies, structure and processes etc. Morphing embraces fluidity and continuous change rather than stability and certainty. It explains the rapid, seamless and more or less total change of the organizations which are mostly in high-velocity industries seek to regenerate their competitive advantage under hyper-competition conditions (Marshak, 2004). As explained above, transient advantage strategy helps organization to win the competition for a short period of time. This means that morphing could be an internal structural change process[1] to fit this strategical movements and flexibility.

Proposition 11: Morphing might help organizations to adapt strategic flexibility more easily.
Proposition 12: Morphing might help organizations to adapt short-term strategic changes more easily.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Liquid organization model is another concept that could be mentioned as a structural practice. Liquefying an organization means disrupting the industrial-age driven assumptions on which rigid structures are designed and move on to make it adaptive, dynamic and anti-fragile. Based on lean management and open collaboration principles, the liquid organization model is flat, meritocratic and value-driven, enabling stigmergic behavior and "organic" effectiveness (Verzera, 2014). Its meritocratic feature defines it as a performance-measured system. Stigmergic behavior means efficient collaboration between members and parts of the organization. As a whole, collaborative working, transparency, lean perspective, concentrated decisional power, agility, etc. are the basic features of the liquid organization. New organizations which could be called as "game changers" ground on these concepts. These entities lead to structural changes and new organizational structures; and new practices that change business world's dynamics.

Proposition 13: Liquid organization model might enhances stigmergic behaviors of staff by enabling collaboration.

Proposition 14: Liquid organization model might helps to improve organic effectiveness of the organization.

Czarniawska (2011) has developed an analytical metaphor of 'cyberfactory' that refers to a news agency where software has a central importance in the control of news production through the professional journalist. This terms brings the affirmation of the interconnectedness of people and machines in perceiving the world and brings another term that is 'cyborganization'. It is a term which describes the concept of a future form of organization, shaped by technology-mediated coordination, social computing and organizational algorithms. It basically describes a hybrid of a human and computer shaped form of organization (Kaminski, 2014). With new arising technologies and collaborative networks of resources and knowledge, one can assume that daily life and work will change dramatically within the next decades which have never seen before. Organizations can basically become structural artifacts that reflects as cyborganizations of the *Second Machine Age* which has been defined as a new era that makes people and software-driven machines substitutes, rather than complements. It is argued that it will bring technology-driven opportunities and challenges which will transform economy in the new era and will require human-beings to learn 'race with the machines' (Brynjolfsson & McAfee, 2014).

Proposition 15: In cyborganizations, staff can gain technological skills and be more innovative.

Proposition 16: Cyborganizational structure can act as a catalyst between staff and technological assets of an organization.

In terms of organizational paradigm, chaos theory refers to a subset of chaos incorporates principle of quantum mechanics and presents them in a complex system environment. On the basis of this theory, organizations face with the layout in chaos as an inevitable part of the environment (Ozbebek Tunc & Turan, 2013). In such an environment possibly in the future, fractal organization structure can help companies to survive. Because this type of organization offers open, self-organized, reconfigurable, nonlinear, self-contained and acquired structure. It discusses on the meaning of authority and hierarchy. From this aspect, it shows similarity with holacratic organization. This structure is self-similar, too irregular, goal-oriented, dynamically restructured and suitable for a turbulent environment (Ryu & Jung, 2004).

Proposition 17: Fractal organizations can help to link with internal regularity and external irregularity.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Systems

Systems are formal and informal daily activities and procedures that staff members engage in to 'get the work done'. Financial systems, promotion and reward systems, recruitment systems, and information systems are some examples of internal systems. Through these organizational systems, all the processes, information flows and key activities are carried out (Dahlgaard-Park, 2013). The way systems mirror the state of an organization is very important to enhance organizational effectiveness.

Getting Things Done (GTD) approach focuses on workflow and time management. It rests on the idea of moving planned tasks and projects out of the mind by recording them externally and then breaking them into actionable work items which allows one to focus attention on taking action on tasks (Allen, 2001). GTD approach can help staff and organizations simplify tasks, arrange them and engage in. This can increase efficiency and reduce time waste. These are really important for all types of organizations.

Proposition 18: GTD approach can help organizations to increase efficiency.
Proposition 19: GTD approach can help organizations to be more effective when doing business-related activities.

Integrative Decision Making (IDM) is defined as a decision-making process in which an individual balances tensions between opposing variables. It follows a four-step process. The first step (salience) seeks to define the relevant aspects of a problem. The second step (causality) seeks to determine the relationships between related and seemingly unrelated parts of the problem. The third step (architecture) involves the creation of a model that outlines the relationships defined in the previous two steps. The fourth step (resolution) outlines the decision and how it was reached (Business Dictionary).

Proposition 20: IDM can help staff to gain effectiveness in decision making process.
Proposition 21: IDM can help organizations to be more faster in strategy implementation process by making decision making process more effective.

All groups of individuals or organizations get things done via a 'crowd of wisdom'. Collective intelligence (CI) is defined as groups of individuals doing things collectively that seem intelligent. Wikipedia is an example of collective intelligence. CI refers to anyone in a large group who chooses to do an activity, without being assigned by someone in a position of authority (Malone et. al., 2009). Collaboration platforms such as Wikipedia allows organizations to connect and engage people and information, anywhere, anytime, and on any device. More data means more potential information that can be gathered about anything. This can lead to better decision making, being able to filter the information and make sense of it is crucial (Morgan, 2014). Thus, it can be said that knowledge and information gathering is essential for people and organizations so much more, especially for making new innovations, and CI helps to gather people for these purposes.

Proposition 22: CI can help staff to harness knowledge from other members of an organization, interest people and other organizations.
Proposition 23: CI can help staff to collaborate of other members of the organization, interest people and other organizations by displaying collective behavior.
Proposition 24: CI can help staff to learn new ways of doing business.

A meme is an idea, behavior, style or usage that spreads from person to person within a culture. It acts as a unit for carrying cultural ideas, symbols, or practices that can be transmitted from one mind to another through writing, speech, gestures, rituals, or other imitable phenomena with a mimicked theme (Dawkins, 1990). Techno-memes (temes) are memes which live in technological artifacts instead of the human mind. Communication systems spread memes over longer distances, and broadcasting increases the number of copies sent out; sound and image recording systems raise longevity by storing previously ephemeral information; and new technologies raise fidelity enormously by making the shift from analogue to digital recording. The systems that do these are increasingly copying, storing and propagating information without human help (Blackmore, 2009). The Internet of Things is helping to create the vast amounts of big data. Devices will be able to "talk" to each other and to people on their own without human intervention or activation. This has the potential to make lives and workplaces easier and more streamlined as well as help people to better understand themselves about how they work, and how they live (Morgan, 2014). The current developments for the Internet of Things (IoT) can be a way of exchange temes between machines and this can reshape most industries by changing the way of doing the formal and informal daily activities and procedures.

Proposition 25: Temes can reflect as a factor that increase efficiency of an organization.
Proposition 26: Temes can reflect as a factor that make work-related activities more easily.

Artificial intelligence (AI) is a field of science and engineering concerned with the computational understanding of what is called 'intelligent behavior' and with the creation of artifacts that exhibit such behavior (Shapiro, 1992). It is defined as the study and design of "intelligent agents (machines)" which refers to the system that perceives its environment and takes actions that maximize its chances of success. AI promises to replace some human jobs, freeing people for other pursuits by automating manufacturing and transportation, self-modifying, self-writing, and learning software which relieves programmers of the burdensome task of specifying the whole of a program's functionality. AI can see relationships in enormous or diverse bodies of data that a human could not (Rajani, 2011).

Proposition 27: AI can help to increase staff's innovative work behavior by freeing them on thinking more about work-related issues.

Another concept that is interested in this chapter is biomimicry. It was first used by Benyus (1997) and defined as 'an approach to innovation that seeks sustainable solutions to human challenges by emulating nature's time-tested patterns and strategies' by Biomimicry Insitute (online). In short, it is about inspring from the nature. Companies inspire from the nature related to innovation, structure, strategies, business models, etc. It can be assessed that this inspiration is a systemic challenge because of its holistic effect to the whole. If a company design all activities, roles, competencies, goods and services on the basis of biomimicry view, it can be said that the organization is systematically biomimetic and so adapt to the environment as an eco-system. They can come up with organizational problems by considering nature's solution systems and ways. For example, they can model a kind of bird on producing new airplane or an ant subsystem on organizing team work.

Proposition 28: Organizations adopt biomimicric thinking can change their systems to the nature and so adapt easily to the future environment.

Hard Elements (Hard Ss)

As Peters (2011) explained lately, skills, staff, styles and shared goals are the hard elements of the model. Related new concepts are categorized and explained theoritically under every element. After that they are linked with future organization abilities and some propositions have been offered.

Skills

Skills are the actual skills and competencies of the employees who work for the company. They are the distinctive capabilities possessed by individuals, groups, and an organization as a whole. The skills variable can be referred to as the core competencies of an organization. It is a strong component of competitive advantages of organizations (Dahlgaard-Park, 2013).

Intrapreneurial behavior (IB) refers to the voluntary employee behavior and is a "bottom-top" process related to the spontaneous behaviors of individual employees which is aimed at the perception of opportunities, generation of ideas, creation of new products, as well as the development of new business lines. IB is an extra-role behavior which is self-initiated and reflects in individuals' risk-taking, innovation, and proactiveness (Antoncic & Zorn 2004; De Jong et al. 2011).

Proposition 29: By the time, the mission of being change agent has shifted from corporations to individuals.

Shirky (2010) argues that people are learning how to use free time more constructively for creative acts rather than consumptive ones, particularly with the advent of online tools that allow new forms of collaboration. People use online tools such as social media platforms and tools and create something collectively. Cognitive surplus (CS) is defined as the free time of the world's educated citizenry as an aggregate (Shirky, 2010). Cognitive surplus frames the abundance of free time as a collective resource that society may be able to use more effectively (Tomlinson & Silberman, 2012).

Proposition 30: Future employees can simultaneously and collaboratively create, contribute and use information via online tools.

Proposition 31: Future employees can spend their free time to learn and create something.

T-shaped skills as Hansen (2010) explains, is a metaphor used in job recruitment to describe the abilities of people in the workforce. It represents as a method for assessing résumés to build interdisciplinary work teams for creative processes. T-shaped people have two kinds of characteristics: The vertical stroke of the "T" is a depth of skill that allows them to contribute to the creative process that can be from any number of different fields such as an industrial designing, architecture, social science, etc. The horizontal stroke of the "T" is the disposition for collaboration across disciplines which is composed of two things:

1. Empathy that allows people to imagine the problem from another perspective; and
2. Enthusiasm about other people's disciplines, to the point that these people may actually start to practice the disciplines (Hansen, 2010).

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Proposition 32: T-shaped skills can make workforce more collaborative.
Proposition 33: T-shaped people can have deeper understanding about theirselves and the others.

Staff

Staff is the employees of an organiation and their general capabilities. Staff is the crucial asset of an organization, it is a "sine qua non", a must. An organization should consider its staff and their general capabilities. The workforce is changing. New employee behaviors entering organizations are challenging the conventional idea of how employees work and what they expect from an organization. A new generational workplace means new behaviors, approaches, attitudes, and expectations about work and the workplace. Mobility allows employees to stay connected and working even when they are on the go. This helps make employee location independent. Organizations, large and small, can be comprised of international teams. Organizations can also develop a presence in any part of the world and work without boundaries (Morgan, 2014).

First, Y Generation entered the business life; in the near future, Millennials will enter. And they are quite different from other generations; they are shaped by technology (can be called as techno-born). They value community and creativity in their work. They have invested in human capital more than previous generations. They will contend with the effects of starting their careers during a historic downturn for years to come (Millennials Report, 2014). In short, the future employee wants to work for an organization that believes and invests in sustainability and community development, corporate social responsibility, health and wellness, employee happiness, ethical choices, and in making the world a better place (Morgan, 2014).

'Role' in an organization means one specific activity that the organization is counting on. For example, creating and maintaining a project release plan is a Project Manager's role. Whenever a new role is defined, it is then assigned to a member of the organization to fill and execute. This formally gives that member control to do what is needed to enact the accountabilities of the role, within any defined limits. It also gives others in the organization the reasonable expectation that they can ask the individual to account for any of the role's explicit accountabilities. In holacracy (explained above), the title of a role becomes secondary, the role is the list of explicit accountabilities. With the detailed accountabilities used in holacracy, any given role may have dozens of accountabilities, and any given individual may fill multiple roles (Robertson, 2007).

Proposition 34: Role-shaped organizations can help staff to gain new talents and competences.

Technology decisions are now in the hands of anyone and everyone within an organization, not just IT department or management. Cloud-based technologies can decrease the time to deploy, make upgrades and deployments easier and faster, and allow organizations to put together their own "stacks" made up of components from various vendors (Morgan, 2014). Technophilia is a term that refers to the enthusiasm toward technology with its rewarded and knowledgeable adoption (Ronit, 2011). It can reflect as techno-creativity of staff and, with the staff-driven activities, organizations can become techno-creative and change some industries' parameters and dynamics.

Proposition 35: Staff that reflects technophilic behaviors can help organizations to become techno-creative organizations.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Green-collar workers can be defined as workers who have interest, expertise, and knowledge in environmental issues and practices within organizations and are employed primarily for these reasons. A green-collar worker is an environmentalist, someone whose functions at the workplace include protecting the environment, encouraging sustainable workplace practices, and raising environmental awareness among co-workers. They advocate for the environment within their organizations and are cognizant of whether the organization acts in a socially responsible manner with regard to environmental issues (Harvey et. al., 2010).

Proposition 36: Green-collar workers can help an organization to give more importance to sustainability-related activities.

Proposition 37: Green-collar workers can help co-workers to be aware of environmental issues and social responsibilities of an organization.

Style

Style is the style of leadership adopted. It refers to the issues of how key managers behave in achieving organizational goals. It is also considered to encompass the cultural style of an organization. All organizations have their own specific culture and management style. The style/culture includes the dominant values, beliefs, norms, and traditions that are relatively enduring features that permeate organizational life (Dahlgaard-Park, 2013). Morgan (2014:91) explains that the future managers needs to "be a leader, follow from the front, understand technology. They need to lead by example, embrace vulnerability, believe in sharing and collective intelligence, be a fire starter, practice real-time recognition and feedback, be conscious of personal boundaries and adapt to the future employee". To be a fire-starter means to challenge conventional ideas about management and work not just take things at face value. A fire-starter must be curious ditch the template and the management formula. Lead by example means to be a role-model for others in every actions.

Proposition 38: When management/leadership style become more people-centric, staff can be more committed to the organization.

Proposition 39: When manager/leader is a 'fire starter', staff can be more innovative.

Some organizations can be 'managerless'. They are managed by employee-appointed committees. But how could they be managed? They can be guided by coaches and mentors. They can be called as 'employee-managed' organizations. Transparency, freedom with accountability, mentorship and support, communication and long-term approach are very important for these organizations. They must reflect values, hire the right people and understand that employees have their own lives (Morgan, 2014). 'Self-management' concept can reflect for these organizations.

Proposition 40: Self-management can help staff to be harmonized by collaborated and cooperated activities.

Proposition 41: Self-management can help staff to make decisions faster.

Proposition 42: In employee-managed organizations, staff can be more committed to the organization.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Shared Goals

Shared Values -called "superordinate goals" when the model was first developed- are the core values of a company that are evidenced in the corporate culture and the general work ethic. This element is considered to be the interconnecting center of all other variables and refers to the guiding concepts and meaning or the purpose of organizations' existence that are shared among all organizational members (Dahlgaard-Park, 2013). Morgan (2014) explains that future organizations will focus on creating a place of "want" instead of a place of "need", adapt to change faster, innovate anywhere and all the time, shift from profit to prosperity, and be more flatter. It can be said that future organizations will be more people-centric, humanistic, lean, innovative, technologic and flexible.

Proposition 43: When organizations become more people-centric, staff can have more flexibility with their roles, functions and work styles.
Proposition 44: When organizations become more flexible, staff can adapt to change faster.
Proposition 45: When organizations focus on creating prosperity, staff can be more people-centric and sustainable.

DISCUSSION AND CONCLUDING REMARKS

In this chapter, it is tried to relate between business concepts and futuristic trends for organizations. It is mentioned about the paradigm shift over years and described the dynamics of today. On the basis of today, it is assumed that some propositions for the future. The major purpose of this study is to prescribe the organizations of the future by rethinking McKinsey's 7S Model by mentioning some concepts such as morphing, holacracy, biomimcry etc. All these concepts are newly discussed theoretically and practically. Even though they are new concepts for today, they will be pillars and corner stones of future. They do shape not only companies but also whole business environment. Market, companies and even employees will have to change theirselves to this aura.

Furthermore, in this study, some propositions are offered to understand the organizations in the future with internal elements and outer changes which would affect them at the edge of the new era which is called as Second Machine Age or Third/Fourth Industrial Revolution by considering different dynamics and concepts. This revolution forces companies to turn traditional management roles upside down and inside out via digital mind on the basis of digitalization. This big change create a paradigm shift about business manners. No doubt that today's organizations should not pass over the symptoms of the new era to be a good example of 'future organization'. For this, they will have to be highly sensitive to all variables of environment and fast-changing as well as the world. This chapter aimed to spotlight on the question 'what is the future?' by offering some futuristic predictions which will be probably realized.

On the other part of this study, McKinsey's 7S Model maps a constellation of interrelated factors that influence an organization's ability to change on seven elements which have been called as hard and soft elements. Hard elements have been conceived as strategy, structure and systems. Soft elements have been conceived as staff, skills, shared values and style. Being hard means a 'hardly changeable, easy to define' structure, and being soft lies upon an 'uneasy to define' concept according to the model. But conversely, in this new era, which grounds on chaotic, hyper-changing and competitive environment, it can be said that 'hard is soft, soft is hard'. This reverse view let companies think all variables and

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

parameters as deeply embedded parts of the system and people as its center. It is because that the model basically grounds on the 'people' dimension now. Human-beings are developing more and more each day and gain new skills and competences. Furthermore, the growth rate of technologic developments is incrementally rising and human-machine collaboration occurs more often. In the near future, it is expected to see many new technologies and developments that grounds on it. This may lead new line of businesses and challenges in the current ones. Organizations may face with a big paradigm shift. The radical changes may push companies to be more innovative but unstructured, holistic but niche-based activities. Organization may look for new ways to build enduring but flexible structures and evolve from self-managed to unmanaged. They may have indulgence to democracy of ideas coming from employees, partners, customers, and even society. In other words, organizations may have to find a new form on the basis of the new age.

All in all, this chapter let anyone to rethink actual strategic models and imagine a future organization. It provides to find an answer to the basic question 'How may be a future organization?'. Future organizations may be structured with no hierarchy, holacratic, liquid, open to morphing, cyborganization, role-shaped, people-centric and fractal formation. They may adopt the systems including getting things done approach, integrative decision making process and temes. They may let to improve collective intelligence and artificial intelligence as a whole. They may prefer to formulate emergent tactics and maneuvers rather than long-term strategies, so they have internalized strategic flexibility. They also may plan to attain transient advantage which is contrary to today's dynamics. They may focus on contrary competencies as being ambidextrous and having duality. They may let their employees to be more entrepreneur, collaborative, innovative, t-shaped and learn to learn at their free time. They may prefer to work with green-collar workers and encourage them to be self-managed people. In conclusion, companies which do the best practice for these concepts in a sustainable manner may be able to survive with destructive competition. No doubt this survival story of companies may start with the exploration of their managerial DNA and then mapping out a route. For companies, the future requires to define uncertainties and make them certainties as soon as their rivals.

KEY TERMS AND DEFINITIONS

Artificial Intelligence: Artificial Intelligence refers to computational understanding of intelligent behavior which works as a system that perceives its environment and takes actions that maximize its chances of success.

Cyborganization: Cyborganization refers to a hybrid of a human and computer shaped form of organization that shaped by technology-mediated coordination, social computing and organizational algorithms.

Holacracy: Holacracy refers to an organizational form which grounds on a peer-to-peer workplace that of flexible structure, self-organized holons, unique decision making process, etc.

Morphing: Morphing means continuous ongoing transformation of an organization that of structural change, strategical change etc.

Second Machine Age: The Second Machine Age refers to the new age that grounds on software-driven technological developments and human-machine collaboration.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Third Industrial Age: The Third Industrial Age refers to the industrialization of information age that grounds on digitalization and renewable, distributable and smart energy for every continent of the world.

Transient Competitive Advantage: Transient Competitive Advantage is a strategy that grounds on short-lived opportunities and focuses to gain short-term strategic advantage of competition among rivals.

ENDNOTE

[1] It is not only a 'structural' practice; in this section, it is used for explaining possible future practices.

Chapter 78
Events Automatic Extraction from Arabic Texts

Emna Hkiri
University of Monastir, Tunisia

Souheyl Mallat
University of Monastir, Tunisia

Mounir Zrigui
University of Monastir, Tunisia

ABSTRACT

The event extraction task consists in determining and classifying events within an open-domain text. It is very new for the Arabic language, whereas it attained its maturity for some languages such as English and French. Events extraction was also proved to help Natural Language Processing tasks such as Information Retrieval and Question Answering, text mining, machine translation etc… to obtain a higher performance. In this article, we present an ongoing effort to build a system for event extraction from Arabic texts using Gate platform and other tools.

1. INTRODUCTION

With the increase amount of textual data, there is a need of methodologies for analyzing, and representing these data in the best form. One of the challenges of the textual data analysis is information extraction (IE). IE as defined in the message understanding conferences (MUC), aims to analyze natural language texts and extract useful information from a particular domain or application. IE is used in processing text for Arabic systems such as search engines, clustering, classification, text mining systems Question and answering, information retrieval (Atta-Allah al, 2006), text summary, indexation, and classification(Cimiano et al, 2004), (Cohen et al, 2009).

DOI: 10.4018/978-1-7998-0951-7.ch078

Copyright © 2020, IGI Global. Copying or distributing in print or electronic forms without written permission of IGI Global is prohibited.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

If this search domain is already extensively covered, the event extraction remains a vital and complex task. Event extraction from Arabic text could be beneficial for IE systems in various ways. For example, being able to determine events could improve the performance of news systems (Borsje et al, 2010), monitoring systems (kamijo et al, 2000) risk analysis applications (Capet et al, 2008) and decision making tools (wei et al, 2004).Extracted events are also extensively applied within the medical domain (Cohen et al, 2009), (Yakuji et al, 2001)

In this paper, the input of our information extraction system is a set of unclassified news websites articles written in Arabic language, and the output is a set of events with their attributes. In this context, we adopt the definition of the ACE (Automatic Content Extraction) (George, 2004) model that defines the event as an action, a process in which participants are connected. We describe in this paper the different steps followed to develop our event extraction system from Arabic texts.

The rest of the paper is organized as follows: Section (2) presents Arabic language and details its unique features. Section (3) deals with the definition of the event and present some related works. In section (3), we present our approach for the automatic extraction of events. The implementation of our approach in the Gate platform is described in section (4). In section (5), we evaluate the system to demonstrate its capabilities. Finally, we conclude our work with some perspectives.

2. ARABIC LANGUAGE

In Arabic processing domain, the research started in the 1970, even before editing texts problems are fully solved. Early studies focused mainly on lexicons. For ten years, the Web internationalization and the proliferation of media in Arabic demonstrated the usefulness of a large number of potential applications of the Arabic NLP. Therefore, researches have begun to address issues more varied as syntax, automatic translation, automatic indexing of documents, information retrieval, etc. (Farber; 2008).

In what follows, we present orthographic and morphological systems of the Arabic language and some problems of its automatic processing as the lack of free resources, lack of vowels and the agglutination of words. Those are the main issues that characterize Arabic and strongly contribute to the delay of its automatic processing. For morphological analysis, the absence of vowels adds additional ambiguity of Arabic words. As for the agglutination, it makes it more difficult to identify the segments that make up these words.

2.1. Features of Arabic Language

Arabic language is considered difficult to control in the NLP. It is a semitic language: it is written from right to left and its alphabet is an Abjad. It is composed of consonants and long vowels "ي", "ا" and "و".

In addition, Arabic writing is unicameral: capital letters and lowercase letters do not exist. It is a semi cursive language that most of its letters are attached to each other, their spellings differ depending on whether they are preceded or / and followed by other letters or are isolated. Only the letters "ا" and "و, د, ر" are never attach to the next letter.

The Arabic lexicon is composed of three main classes: nouns, verbs and particles. The class of particles is extended to include grammatical morphemes. This extension leads to a reorganization into four classes: verbs, nouns, pronouns and tools words and (Khoja et al, 2001):

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

- **Verbs:** Most of them are formed on radical of 3 consonants such as the verb (“بتآ” kataba - write) and possibly 4 consonants such as the verb “wrدحج” dahrağa - drag, to drag). These roots may give rise to several patterns as a result of one or more morphological changes (eg, repetition of a consonant, a vowel lengthening, the addition of a morpheme, etc.);
- **Nouns:** The morphological system of Arabic nouns is composed of:
  - **Primitive Nouns:** Cannot be attached to a verbal root. Example: سأر (RAAS - head), (مد dam - blood), (مف fam - mouth), (بأ AAB - father) (خأ ah - brother) etc.;
  - **Deverbal Nouns:** Nouns that can be derived from a verbal root;
- The particle class is composed of numbers, pronouns and tool words:
  - **Numbers:** This category consists of names of simple numerals representing units: from (“رفص” sifr-zero, 0) to (“ةعست” tis’at - nine, 9); tens (“ةرشع” ašarat- dix, 10) (“نورشع” išruwn - twenty, 20) ... and (“نوعست”tis’uwn - ninety, 90); hundreds, etc. and composed numerals such as (“رشع ةعست” tis’at’ Asara - nineteen 19);
  - The pronoun is formed of:
    - Demonstrative pronouns (“ةراشإ ءامسأ” ásmaā’ íšaārat): (“اذه” hadaā – this);
    - Relative pronouns (“ةلوصوم ءامسأ”Asmaa mawsuwlat): they are related to the noun or pronoun that precedes (“الذي” al-ladiy - one), (“اللتيتن”) al-latayni - those, feminine, duel “اللذيذن” (al-ladayni - those, masculine, plural), etc.;
    - Personal pronouns (“ةلصفنم ريمض” damaāýir munfasilat): they identify the grammatical persons;
  - Tool words are used to locate facts or objects relative to time or place. Tool words are divided into quantifiers and adverbs, prepositions, etc.;
- **Prepositions:** eg (“في” fiy - in) or (“ىلع” Alaa - on);
- **Conjunctions of Coordination:** eg (“مث” tumma - then, then);
- **Adverbs:** eg (“ادبا” Abada - ever) or (“بشكلياع” bišaklĩ ‘aādiyyĩ - normally normal way);
- **Quantifiers:** eg (“لك” kulla - all) or (“ضعب” ba’d% a - a little).

2.2. Morpho-Syntactic Problems

Arabic is considered as difficult language to apprehend (written and spoken) in the domain of NLP (Atwell et al, 2004), (Debili and al, 2002), it presents specific morphological, syntactic, phonetic and phonological features; many researches have been conducted to study the specific linguistic phenomena in Arabic such as non-vocalization and agglutination. The difficulty occurred in a complex implementation of a theoretical model or prototype into a real system usable in large scale applications.

2.2.1. Lack of Vowels (or Diacritics)

The automatic analysis of the Arab faces the problem of the lack of vowels (or diacritics) in the texts. This problem causes a number of lexical ambiguity for example the word non-vowelized (“بتك” ktb) have 17 different voyellations.

A statistical study made by F. Debili (Debili, 2001) shows that only 19% of words in the corpus are unambiguous and the average is six voyellations by word. Thus, given the large proportion of ambiguous words, we can conclude that this phenomenon is very frequent for Arabic processing and requires serious studies. Vowels play a crucial role for Arabic; every letter of every word should have its short

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

vowel which is generally not the case in the texts. Short vowels remove the ambiguity, and they give the grammatical label of a word regardless of its position in the sentence.

2.2.2. Agglutination of Arabic Words

A major problem comes from the Arabic agglutination as a word can mean a whole sentence by itself. For example, the form agglutinated ("لياستكملها" is translated into lystkmlhA) to make it complete. The structure of the Arabic word is divided into five components: proclitic, prefix, base, suffix and enclitic (Larkey et al, 2002), (Tuerlinckx, 2004).

The proclitics are particles (conjunctions and / or prepositions and / or articles) .

Prefixes and suffixes express grammatical features and functions to indicate the nouns and the mode of verbs (active / passive) and the (number, gender, person, ...) .

The enclitics are personal pronouns.

The base is a combination of a root (The set of two, three or four consonants that represent a structure of language or verbal behavior of speakers).

To detect the root of a word, we must know the schema from which it was derived and remove inflectional elements that have been added:

- The last example: لياستكملها / lystkmlhA: to make it complete;
- Proclitic (ل / l): preposition = > (to);
- Prefix (ي / y): verbal prefix of unfulfilled time;
- Base: (إستكمل / istkml) derived from the root كمل by scheme (إستفعل / IstfEl) C1 C2 C3 = > (to be completed);
- Enclitic (ها / hA) suffix pronoun = > (it).

In any automatic processing perspective, the problem is to decompose the word into parts. This decomposition requires knowledge of higher level in case of ambiguities (if the word accepts multiple segmentations).

2.2.3. Segmentation of Texts

To analyze an Arabic text, we must add a segmentation phase because a paragraph may not contain any punctuation other than a point at the end. In addition, the Arabic sentence is long and complex; the recognition of the end is difficult because the punctuation is not systematic and sometimes particles can define another role than separating sentences. To solve this problem a number of studies were carried out as work Ouersighni and the results are quite modest (Ouersighni, 1998), (Ouersighni, 2000), (Ouersighni, 2002).

2.2.4. Word Order in the Sentence

The order of words in Arabic sentence is relatively flexible. The sentence can be ordered as: verb +subject + complement, Subject + verb + complement, complement +verb +subject So, we conclude that the relatively free words order accumulate the morpho-syntactic problems specific to Arabic. Indeed, taking into account all possible combinations of rules of sentence constituents cause, probably, additional syntactic ambiguities.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

2.3. Other Problems

The lack of strict lexical and grammatical structures in natural language poses many challenges for automatic analysis especially for the Arabic language, which by its morphological and syntactic properties is considered a difficult language in the domain of automatic processing of language (Larckey et al, 2002)(Mallat et al, 2013).

3. STATE OF ART

Named entity recognition acquired in recent years considerable attention. Several works has been done in NE recognition in Arabic. The majority of Arabic NER system focused mainly on traditional classes like (person, organization and location). Some systems introduced additional classes and categories related to a specific domain. Here we present a brief survey.

Several works applied statistical learning algorithms to Arabic NER. Abdul-Hamid, (2010) applied Support Vector Machines algorithm. Nezda (2006) as well as Benajiba (2007) use Maximum Entropy Models. Farber (2008) and Mohit (2012) use Perceptron. A range of works on Arabic named entity recognition includes labeled datasets, creation of gazetteers, rule-based and also statistical systems. RENAR (Rule-based Arabic named entity recognition system) is a recent rule-based approach (Zaghouani, 2012). It is based on gazetteers and grammar recognition rules to build the lexicon entities. The second system is proposed by Oudah and Shaalan (2012), it is a hybrid approach and combines rule-based approach with various statistical classifiers for extracting out of a set of NE classes.

Wikipedia has been the test-bed for few studies and systems of NER, they take advantages of its multilingual links and disambiguation and redirect pages to identify NE equivalences in target language. Behrang (2012) extended classes of named entities and developed a NER system using Arabic Wikipedia. Wentland et al. (2008) leveraged Wikipedia links and pages to produce NE for German and Swahili language. Other works combined Wikipidea with other resources to identify names and variants; Stern & Sagot (2010) exploited French wikipedia and GeoNamess to create a French Database. In addition, Toral et al. (2008) joint Wordnet to Wikipedia. Their resource contains 310,000 entities and variants found in Wikipedia

But while the problem of detecting and extracting named entities is relatively well understood, the event extraction remains a problem far from being solved tasks because an event mention can be expressed by several linguistic expressions and several sentences (Béatrice, 2012)(Aymen, 2007). The same definition of event varies depending on the domain of application: software engineering, history, philosophy and linguistics ...etc.

In Table 1 we present an overview of event extraction researches and their approaches.

Extracting event attracted a number of works, mostly restricted to English (Gabriel, 2006) or French (Gabriel, 2008), (Ludovic, 2011). This domain of research is widespread, but it is still very little studied for the Arabic language because it has several unique features that do not exist in other languages (Al-Jumaily, 2012) (Soraya, 2013). For other languages different approaches have proposed different models in the definition, which can be summarized in two main flows: The approach or TimeML standard and the ACE Model.

	(Ahn, 2006)	Nearest neighbor and maximum entropy classifiers	ACE	2006
HYBRID	(Sangeetha et al, 2010a)	Trigger detection using bayesien theory and argument detection using Ontosem system and text meaning representation	ACE	2010
	(Sangeetha et al, 2010b)	Using lexical chain to trigger detection and patter, matching to argument detection	Wikipedia document local event	2010
	(Piskorski et al, 2007)	Clustering pattern matching	Security related in news document	2007

The ACE model (Automatic Content Extraction) defines the event as an action, a trial at which the participants are connected. Events are represented according to their attributes and their participants. ACE event can have a number of participants, and each participant is characterized by a role (agent, object, source, target).The event attributes are its types (destruction, creation, transfer, movement, interaction) and the modality of an event is (real and not real). Several systems and projects were founded on this model such as the Aone and Ramos-Santacruz approach, which is interested in events and relations between them; it is based on patterns for the labeling. The idea is to search find all informations about the event and to fill the grid corresponding to it for example the event "bying" their REES tool do extract from the text informations about the time, place, the seller and the buyer (Aone and Ramos-Santacruz, 2000).

The approach of Ahn is founded on machine learning. It is composed of 4 modules, each one is generated by TiMBL tool these modules are trigger identification; events anchors; attributes identification and the last one corresponds to the coreference of the events (Ahn, 2006).

The same principle of modules is used in Beatrice approach for French events extraction, the module of anchors identification is based on the prepositions or determinants and the events could be nouns, verbs, adjectives or adverbs. The identification of these anchors is based on classification of words in the texts. The basic indices of the classification are morpho-syntactic categories of words, lexical features (lemma, form, depth in the dependency tree) issued from WordNet, words surrounding the event, etc...

The approach or TimeML standard (Roser, 2006) is based on three fundamental concepts: time, event and relations. The TimeML project was created with the aim of improving Q-A systems to deal with questions of temporal order on the entities and events. TimeML adopts a large conception of events. The <event> tag classifies an annotated event by the TimeML ontology; the latter includes different classes of events (aspectual, intentional action, intentional state, perception, and state case).

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Parent used TimeML guide to manually annotate the English texts. Their model is based on patterns and syntactic analysis. The author is interested in adverbs, verbs, adjectives and nouns events. In their approach, they are based on words of action verbs and syntactic rules to annotate nouns events which depend on temporal prepositions. These prepositions are initially issued from TimeML guide (Parent et al., 2008).

The approach in (Saurí et al., 2005) focused on the disambiguation of nouns that may have event interpretation using SemCor corpus and TimeBank1.2. He extracted 25 sub-tree of the semantic network, which contains essentially nouns referring to events. This approach is also based on a statistical module and WordNet for event annotation. If the process of events search in WordNet is worthless they pass to use their Bayesian classifier. This last is founded on a set of rules learned from the SemCor corpus. The evaluation of their results is done by comparison with the tags of the TimeBank1.2.

In our work we are interested in the EVITA system (Sauri, 2005). This system is part of the project TARSQI (Verhagen, 2005) respecting the TimeML specification, EVITA is a tool for event detection for the English language. In this system, we consider verbs, nouns and adjectives as events. These textual elements are considered the most meaningful. In this system for each type of "trigger", an extraction method is associated particularly considering the grammatical and textual features.

EVITA system tests first if the category of a word is a verb, noun or adjective and then classifies it among the types of predefined events. These processes are complemented by the identification of the various arguments whose objective is the identification of event participants. The identification is made by detecting pairs between the trigger and the other entities of the sentence.

Detection of pairs is realized based on indices such as the morpho-syntactic category of the two elements, the type of event, the type of entity or the dependency relations in the pair.

4. PROPOSED METHOD

In our work, as already mentioned, we were inspired by the EVITA system. EVITA considers verbs, nouns and adjectives as the most meaningful events. For us, we judged that only verbs and nouns as events while adjectives as less significant.

Our event extraction system was built using GATE General Architecture for Text Engineering). Our system identifies predefined named entities (names of "people", "places" "organization", and "dates"), and the relations between the entities and the defined events. The extraction of an event consists of the discovery of links between the "trigger" of the event and its arguments/attributes. The extraction of the link is established based on a syntactic analysis "dependency analysis» and of extraction rules exploiting this analysis. To implement this task we used JAPE transducer (JAVA Annotation Pattern Engine) provided by Gate Toolkit.

Our event detection system is composed of five main phases summarized below.

The first phase is processing that aims to represent data in a form that can be efficiently analyzed and to improve the data quality by reducing the quantity of trivial noise (the non-Arabic words). We carry out text transliteration and segmentation. The next step is segmentation and tokenization of each sentence in the arabic text. We applied a morphosyntactic analysis and stop-word elimination and we finished by the normalization.

The second phase is lemmatization; for each word in the Arabic text, we assign its lemma. We obtained verbal and nominal lemma depending of the grammatical category of the term.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

The third phase is the identification of triggers; it is done by the use of gazetteers. These lists are composed of verbal lemmas for verbal triggers and nominal lemmas for nominal triggers. This phase is realized as the following steps:

- We compare each lemma to the list of triggers (list of gazetteers);
- If matching, we annotate the corresponding lemmatized word as an event trigger.

In the fourth phase, as in the EVITA system we associated the trigger to the class that it represents. At this stage of our work we do not deal with polysemous triggers, we just developed gazetteers for monosemic triggers.

The last phase includes the identification of participants and their semantic roles. For identification, the transducer is used to extract the main dependencies "subject", "object", "preposition", "agent » by executing the developed rules. The purpose of the semantic analysis is the assignment of semantic roles to participants extracted in the previous phase.

The algorithm corresponding to the proposed method is presented as shown in Algorithm 1.

5. SYSTEM IMPLEMENTATION

5.1. WORK Environment

5.1.1. GATE

Most of existing tools for text engineering, if not all, were not originally developed for the treatment of the Arabic language. Most tools were built for English, French or other languages as ACABIT, LEXTER, FASTER, ANA, EXIT (Roch, 2004). Some tools can support or be modified to treat Arabic as Nooj and GATE. We chose the latter for the implementation of our system. GATE[1] (General Architecture for Text Engineering) is a Java open source platform dedicated to textual engineering; it appeared to us well suited for the development of our system. It is a toolkit for natural language processing and very useful for information extraction.

By a system of plugins GATE provides to users a variety of modules dedicated to textual analysis. The most commonly used are tokenizers (segmenters), Part Of Speech Taggers (morpho-syntactic taggers), Gazetteers (lexicons) and transducers (JAPE).

Named entities extracted by GATE correspond to person names, organization, location, dates, etc... To realize new annotation Gate permits to load new resources and plugins. Also, it permits to combine and parameter them within the same treatment chain.

Figure 1 shows the interface of the Gate platform and its basic components for extraction of different types of named entities mentioned above:

- "Language Resources" is composed of linguistic data such as documents, corpora or ontologies;
- "Processing resources" for different resources used for annotation, such as analyzers, segmenters, taggers etc.;

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Algorithm 1. Event annotation algorithm

Input of (Preprocessing)
Corpus C, Document D
(1) Preprocessing of the documents
For each document D in Corpus C do
Remove(digits and punctuation marks) (=,+,$,*.,:,/,, [,] (,)_,&,|,-,^,, {, }, !,§,-)
Filter(the non Arabic words)
Transliteration
Segmentation of text into sentences
Segmentation of sentences
Morphosyntactic analysis
Extraction of simple and composed terms
Remove (Arabic stop words by the anti-dictionary)
Normalization
End for
Output: Preprocessed Document D

Input of (Lemmatization**):**
$S = \{S_i; \bigcup_n^1 S_i = D\}$ the set of segments forming each document D in the corpus.
$T = \{T_i; \bigcup_n^1 T_i = S_i\}$ with T the set of terms forming Si
(2) Lemmatization of T
Output of (1):
$L = \{L_i; \bigcup_n^1 L_i = S_i\}$ with L the set of lemmas forming Si

Input of (Triggers identification & Class Attribution**):**
$L = \{L_i; \bigcup_n^1 L_i = S_i\}$ L set of lemmas forming S_i from**(1).**
$EI = \{EI_i; \bigcup_n^1 EI_i ; C_i\}$EI a set of indicators relating to Events,
Ci corresponds to the event Classes
(3,4) Triggers identification & Class Attribution
For each L_i in S_i do
If ($\exists L_i \in EI$) then
Annotate (T_i) with T_i term which corresponds to lemma L_i
Return (T_i, C_i)
End if
End for
Output of(3,4):
{T, C} the set of terms with their corresponding event_class

Input of (Identification of participants/ arguments in the event**):**
{T, C} the output of **(3,4):**
$N = \{\bigcup_n^1 N_i, RN_i; \in S_i\}$ N is the set of named entities annotated by gate inS_i.
RNi={date, location, person, organization }
$Ev = \bigcup_n^1 J_i , J_i\{I_i\}$ Represents Jape event annotation rule having Ii as trigger/ indicator.
(5) Identification of participants/ arguments in the event (Syntactic and semantic analysis)
For each J_i in Ev do
Extract (Ni of I_i) with Ni is the set of participants
End for
Output of (5):
{T,C,N} the set of triggers, class and the participants of each trigger

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

- On the right part, different named entities are colorized and annotated by GATE, which are the default_token (Date, Location, Organization, Person) we do mention that GATE does not the annotation of events.

5.1.2. External Resources

For the Arabic language, Gate does not have a satisfactory number of instances in his predefined Gazetteers of named entities. For example, the Gazetteers_Personne is composed only of two types (female_names.lst and male_names.lst) whereas for English almost 20000 entries, classified in nine different types (person_ambig.lst, person_female_cap.lst, person_female.lst,person_full.lst, person_male_cap.lst,person_male.lst, person_relig.lst,person_sci.lst, person_spur.lst).

To overcome, this problem of deficiency in the Gazetteers, we have used external resources to enrich Gate predefined Gazetteers, which consist of five different types; all built manually using our corpus and web resources (see also Table 2):

- **Person gazetteer:** A list of 3257 complete names of people found in Wikipedia and other websites. These names are normalized and formalized to end with a list of 3000 names (first and final names);
- **Organization gazetteer:** We collected 2400 names of organizations;

Figure 1. Interface of GATE platform

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

- **Location gazetteer:** We enrich it by Arabic Wikipedia, taking the page labeled "countries of the world in Arabic" to retrieve location names. It consists of 2500 of continents, cities, countries… etc.;
- **Date Gazetteers:** We did enrich this predefined gazetteer by 910 new entities;
- **Event Gazetteers:** Gate as mentioned above do not do the annotation of event and have no predefined Gazetteer for it, that's why we did create a new one, composed of verbal and nominal list of triggers. These lists are collected from our domain corpus. To enrich it we added to their extracted lemmas their synonyms using Arabic WordNet[2] and as well as the argument prepositions structures (for verbs) by the Arabic dictionary. This final Gazetteer contains 700 entries.

5.2. System Description

The implementation in GATE platform has necessitated the use of additional Gazetteers and tools; therefore the installation of new plugins.

For the lemmatization phase, we used morphological analyzer (GATE Morphological Analyser). This analyzer has allowed us to obtain, for each word in the Arabic text, the associated lemma. These lemmas are then used in the next phase.

The second phase of identifying triggers is performed using resources Flexible Gazetteer, which allowed us to compare the tokens of the Arabic text to lemmas in both created Gazetteers (one for verbal lemmas and the other for nominal lemmas).

In the third phase, we classified the verb and noun lemmas into subclasses of the "Event" class (Attack, Military_Operation, Crash, Shooting, Damage, Bombing, Death, Kidnapping, War, Injure).

In the fourth phase, for the identification of participants, sentences were cut with the Noun Phrase Chunker and VP Chunker resources. For syntactic analysis, Stanford Parser was used and configured to process the Arabic language.

In the last phase, we pass to develop our linguistic rules with JAPE transducer (Java Annotation Patterns Engine**).** The role of the transducer is to identify named entities (Person, Organization, Location, and Date). So in our case, JAPE [3]executes the developed rules to extract the various arguments of the event. Writing these rules is followed by a test phase which aims to detect annotation errors and therefore the correction of these rules.

The Figure 2 shows an example of Arabic text where events are annotated by our tool: they belong to some predefined event classes such as:

Table 2. Enrichment of Gate Gazetteers

Gate	Predefined Entries	Enriched Entries	Overall
Person	1700	3000	4700
Organization	96	2400	2496
Location	485	2500	2985
Date	84	910	994
Event	0	700	700

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. Example of annotated events from an Arabic text

- **Death:** مقتل
- **Attack:** الهجوم
- **InjureEvent:** إصابة
- **Military_ Status:** تعزيزات عسكرية
- **War:** الحرب العالمية الثانية / الحرب الأهلية

6. EXPERIMENTAL EVALUATION

6.1. Experimental Setup

6.1.1. Data

We used MILTcorp to test our system. MILTcorp is annotated especially for the Event extraction task. This corpus is related to our domain research; the military domain. Its articles are collected from news websites and news wire like (aljaziraa, al_arabia, al_manar, France24 (Arabic) also from electronic journals (al-Quds).

6.1.2. Annotation

The evaluation of the annotation is performed as follows:

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 3. Data collection

	Test Corpus
Number of sentences	1650
Number of words	45350
Number of words/sentences	24

- Three human annotators manually annotated texts of test corpus. These three human annotations are gathered in one annotation used as "the reference annotation;"
- In a second time, we annotated automatically these texts with our proposed system.
- We have established a comparison between these two annotations with Corpus Quality Assurance. This Gate tool makes the comparison between two annotations on a corpus;
- The result of the comparison is the generation of precision, recall and f-measure values.

6.2. Evaluation Metrics

To measure the effectiveness of our proposed system, we used a set of well-known evaluation metrics: precision, recall, and F- measure. Precision measurement is defined by the percentage of entities found by the system and which are correct, and the recall is defined as the ratio between the numbers of found correct entities by the number of entities extracted from the reference articles. The overall evaluation of entities extracted by our system compared to reference articles is based on the use of F-measure. This measure combines the precision and the recall, it is defined as following (we have used the $F_{ß}$=1; the precision and the recall are weighted equally):

$$\text{Precision} = \frac{\text{number of found correct entities}}{\text{number of entities found}}$$

$$\text{Recall} = \frac{\text{number of found correct entities}}{\text{number of entities in the corpus}}$$

$$\text{F} - \text{measure} = \frac{\left(ß^2 + 1\right)*\text{Precision}*\text{Recalll}}{ß^2*\text{Precision} + \text{Recall}}$$

6.3. Experimental Results

To evaluate the overall system, we established comparison with Gate baseline system. As we mentioned before Gate do not annotate event entity in texts. Table 4 shows results for different entities annotated by Gate (using only the basic predefined gazetteers without the enriched gazetteers). The results are automatically generated by the Corpus Quality Assurance.

Table 5 presents the results obtained by using the enriched gazetteers (person, organization, location, date) and our method of event extraction.

Table 4. Gate baseline results

NE	Precision	Recall	F-Measure
Date	51%	29%	36, 97%
Person	33%	15%	20, 62%
Organization	52%	33%	40,73%
Location	59%	44%	50,40%
Event	0%	0%	0%
Overall	**39%**	**24,2%**	**29,67%**

Table 5. Annotation results with event, date, person, organization, location gazetteers

Named Entities	Precision	Recall	F-Measure
Date	84.03%	77.19%	80,64%
Person	83.04%	79.34%	81,14%
Organization	78.6%	62.11%	69,38%
Location	86.14%	77.42%	81,54%
Event	70%	35%	46,66%
Overall	**80,36%**	**66,21%**	**71,87%**

Table 4 shows the results obtained by using the enriched gazetteers (person, organization, location, date) and our method of event extraction.

From Table 5, we see the effect of the annotation of events on the annotation of named entities extracted by Gate. We obtain an improvement of accuracy of 39% to 80,36% same with the recall from 24,2% to 66,21%.

6.4. Discussion

The strength of our Annotation system is in recognizing Event, Location and Date entities, which is attributed to the high named entity coverage of our NE base containing the enriched gazetteers.

It is important to observe that our system shows good recall for Person Names which were more abundant in the training corpus. Besides this, the corpus had a heterogeneous mix of Person proper names not only from Arabic countries but also from the continents of Africa, Asia and America. A good recall percentage for Person entity names is encouraging as the named entities related to south Asia and America have no phonetic similarity with the native person names entities available in Arabic countries. This gives good credence to our annotation process presented above.

A detailed look to the Event Recall reveals that our NE recognition system performs poorly for Event entities that appear in the corpus, this is due to the specificities of Arabic sentences such as free word order that affects the identification of participants and their semantic roles. In addition, we notice that our system cannot efficiently handle the acronyms, short names or the abbreviations of organization entities.

These previous results are satisfying according to limitations due to the complexity of Arabic sentences and the lack of adequate tools for the treatment of the Arabic language.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

In the next future, we plan to complete the event Gazetteers (verbal and nominal) and the disambiguation of polysemous triggers also to increase the size of our corpus to obtain a higher performance of the system.

7. CONCLUSION

In this paper we have presented our system to detect and extract Event named entity in Arabic text using Gate tool. The event extraction was performed through several stages; collection of data, preprocessing, Triggers identification, Class Attribution, Identification of participants/ arguments in the event. The evaluation results show that our method is very promising, This system can be generalized for the purposes of NLP enrichment which can be implemented in many fields such as question answering, text mining, summarization, etc... There are many directions for future work. One of the basic directions is to identify and annotate different types of relations between the named entities.
