People nowadays base their behavior by making choices through word of mouth, media, public opinion, surveys, etc. One of the most prominent techniques of recommender systems is Collaborative filtering (CF), which utilizes the known preferences of several users to develop recommendation for other users. CF can introduce limitations like new-item problem, new-user problem or data sparsity, which can be mitigated by employing Statistical Relational Learning (SRLs). This review chapter presents a comprehensive scientific survey from the basic and traditional techniques to the-state-of-the-art of SRL algorithms implemented for collaborative filtering issues. Authors provide a comprehensive review of SRL for CF tasks and demonstrate strong evidence that SRL can be successfully implemented in the recommender systems domain. Finally, the chapter is concluded with a summarization of the key issues that SRLs tackle in the collaborative filtering area and suggest further open issues in order to advance in this field of research.

INTRODUCTION

With the dramatic spread of Internet, many connections and interactions have taken place in the networks. Therefore, information relying on people reactions has experienced a dramatic growth. Social Networks, which are named due to the crucial role of humans, are concentrated in the social relations that people have among them. In order to exploit these large amounts of data, it is required designing new algorithms and appropriate techniques for gathering valuable information. The field of expertise,

which deals with the aforementioned challenges, is Social Network Mining *(SNM).* Its major purpose is to extract information about network objects, behaviors and activities that cannot be yielded if the entities were to be examined individually.

A social network represents a social structure of entities known as nodes, which are related by one or more specific types of interdependency, such as friendship, common interests or same opinions. Social network analysis considers social relationships based on the network theory perspective; nodes represent people, whereas ties represent relations between them. Together they form a graph-based structure, which experiences significant complexity. Social networks can be categorized in four significant types due to various domains on which they operate:

1. **Citation Networks:** Deal with storing scientific papers, the relation of their subjects across their paper and corporate authors or joint paper reference
2. **SNS (Semantic Network Service) Websites**: Concern the organization of people and their related friends or professional contact for example: Facebook, LinkedIn, Instagram, twitter, etc
3. **Social Shopping Websites**: Related to e-commerce and opinion mining exploring products
4. **Social Media Websites**: Concern the suggestions about movies, music relying on user preference

Social Network Analysis has appeared to be one of the major techniques in social networks (Wasserman & Faust, 1994) intending to establish a model that can map entities and the relations between them. The probability of two entities to build a link between them may depend on the likelihood of having similar attributes. On the other hand, two entities that have developed a connection or link between them have good probability to have similar attributes.

One of the most compelling techniques of Social Network Analysis is the Statistical Relational Learning, which have emerged when traditional statistical approaches could not treat relational and complex data. Traditional approaches consider only independent and fully distributed data; therefore, they do not take into account dependent and complex relational structure of data. Furthermore, traditional Inductive Logic Programming (ILP) and relational learning do not model noisy data, hence do not perform in the presence of uncertainty. Nowadays, systems generate real world datasets, which represent multi–relational, heterogonous and semi structured data. Data mining systems deal everyday with noisy data and uncertainty. Hence, statistical relational learning approaches help to overcome these issues. Statistical relational learning can be implemented in different domains. One important task of the SRL is dealing with the recommender systems problem. Recommender systems are personalized information tools that generate recommendations, suggestions and predictions. They are employed in different areas where users might want suggestions in order to select among many various objects. For example, online portals of news provide headlines where the reader can focus. Moreover, in e-commerce perspective, online sites generally display a short list of the products in order for the user to have an overview of what the online shop provides. Subsequently, the user can select the product and explore it in more details either purchasing it.

A web page is linked with the web server, which contains a database with items available from the site. Due to the large number of items in the database, it is deemed appropriate to show the object list, which can be selected by the user. Recommender systems employ various algorithms in order to perform recommendation tasks. The algorithms aggregate items from like-minded users, thus by eliminating the item, which have been selected before and suggest the items, which have not been rated by the user. The most well-known algorithms deployed in recommender systems are collaborative filtering and content-

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

based filtering. Collaborative Filtering is concentrated on figuring out similar items; for each user that has rated items, the algorithm finds out the similar items, subsequently it aggregates and suggests them to the user.

This review chapter presents a comprehensive scientific survey from the basic and traditional techniques to the-state-of-the-art of SRL algorithms implemented for collaborative tasks. Authors throughout this chapter aim to disclose the most prominent methods and body of work related to Statistical Relational Learning combined with collaborative filtering techniques. These approaches combined together intend to alleviate the shortcomings of previous techniques. It is claimed that the research work can serve as a helpful roadmap for further researches and practice area.

The research chapter is structured as follows. First, it is provided an introduction to Statistical Relational Learning approaches (SRL). Along the chapter, the recommender systems are examined by focusing specifically at one of the most popular recommender system method: the collaborating filtering. In addition, authors have deepened their survey with the most significant research works that have combined SRL with Collaborating Filtering (CF). Finally, authors summarize and identify open issues in this area of research while providing significant findings for the aforementioned collaborative filtering systems.

BACKGROUND

Statistical Relational Learning

Statistical Relational Learning (SRL) is a new branch of machine learning for representing and learning a joint distribution over relational data (Getoor & Taskar, 2007). Getoor and Mihalkova (2011) have defined that Statistical Relational Learning are: "Methods that combine expressive knowledge representation formalisms such as relational and first-order logic with principled probabilistic and statistical approaches to inference and learning". There are some strong reasons why Statistical Relational Learning approaches have experienced a dramatic success and have become an emerging research area in the research community. SRLs constitute an important role in data mining. These algorithms are introduced with a set of candidate features and a model of selection process. The process of feature is decupled from modeling. Usually it can be performed manually. This comprises the most important challenge to the fully integrated application in real world practice where data is recorded in a relational way. Therefore, it is of paramount importance to employ statistical modeling techniques to explore richer data structures and to identify new and complex sources of evidence.

Statistical methods can effectively handle large quantities of noisy data. SRLs are widely exploited from the research community; this fact has given rise to a wide variety of different formalisms, models and probabilistic programming languages. Probability logic-based formalism determines probabilities in two kind of different methodologies: direct and indirect techniques. In the direct technique, probabilities are provided clearly for each probabilistic fact. In the indirect approach, formalisms are not associated to their probability. In this case, the probability is defined from an associated real-valued parameter.

As learning is a fundamental part of the SRL formalism-based system, authors have deemed appropriate to introduce herein two major problems that might be taken into account: parameter estimation and structure learning (Esposito et al., 2009). When the observed data are obtained from an unknown distribution or behavior, the aim is to make sense of this novel distribution. Usually both structure and model parameters must be learned. The parametric SRL approach concentrates on probabilistic model

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

with many finitely parameters by selecting a single model that outperforms the others. There are other nonparametric techniques, which employ probabilistic models with infinitely many parameters and multi-relational process models.

The major difference between traditional statistical approaches and statistical relational learning techniques is the fact that SRL deals with relational data while traditional models deal with propositional data. Therefore, data can be categorized as follows:

- **Propositional Data:** the data mining approaches systems mostly have focused on propositional data and rather in relational data. Propositional data (Khosravi & Bina, 2010) constitutes identically structured entities that are supposed to be independent.
- **Relational Data:** comprise different types of entities and each entity is distinguished by different attributes sets. They are complex and reflect better our real world large-scale systems where data are modeled in multiple related databases.

State-of-the-Art in Statistical Relational Learning

Probabilistic Graphical Models (PGMs) comprise joint probability distributions throughout graph tools and encode a complex distribution over high dimensional space (Chulyadyo & Leray, 2013). Regarding Probabilistic Graphical Models, nodes define the random variables in domain while edges define the probabilistic relationship among variables. Bayesian Networks and Markov Networks are two different classes of PGMs. While Bayesian networks incorporate directed acyclic graph and represent the joint probability distribution as a product of conditional probabilities, Markov Networks employ undirected graph by representing the joint probability distribution as a product of potentials.

Bayesian Networks (BNs)

The structure of a Bayesian Network (BN) (Kersting & De Raedt, 2007) is composed of directed acyclic graph and its nodes constitute a set of random variables. A Bayesian Network has a set of parameter values that determine the probability distribution of each node based on a conditional probability. The conditional probabilities are defined in a conditional probability table (Khosravi & Bina, 2010) for each variable. The assignment's joint probability is computed by multiplying the conditional probabilities of each node value assignment when it is provided the value assigment of its parent. Bayesian Logic Programming (BLPs) are models, which underlie the Bayesian Networks. They incorporate logic programmming. BLPs mitigate the propositional character of BNs, therefore, they are treated as one of the most succcesful model employed in SRL. The major principle of BLPs is to set one to one mapping between ground atoms in the least Herbrand model together with the random variables (Kersting & De Raedt, 2007). The least Herbrand model and its direct relation of influence embody the Bayesian Network. BPLs derive the same benefit of the Bayesian networks and the advantage of definite clause logic. BLPs can facilitate the graphical representation due to the strict separation. In addition, they can easily model any kind of Bayesian Network including those with pure Prolog program.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Probabilistic Relational Models (PRM)

Bayesian Networks have been very successful due to their simplicity. However, one of their major limitations is having difficulty in establishing and maintaining a model in large-scale systems. Complex systems are mostly made of repetitive patterns and they can be viewed in terms of object and relations. Bayesian model lacks the concept of objects and relations; in addition, it cannot model relational data. Hence, Bayesian model is intended to work with single tables of independent and identically distributed data. The task of converting relational real world data into flat propositional data may experience statistical skew and loss of significant data. In order to learn statistical models, PRMs were emerged as substitution of BNs for SRL.

Probabilistic Relational Models represent the first successful model belonging to the group of Statistical Relational Learning (SRLs). They represent a combination of frame-based systems with Bayesian Networks (Friedman et al., 1999). PRMs represent an extension of Bayesian Networks aiming to handle and explore relational data.

Markov Logic Networks (MLNs)

Markov Logic Networks have been one of the most successful techniques attempted to perform statistical relational learning. From the syntax perspective, they widen the first-order logic and establish weight for every formula. On the other hand, from the semantic point of view, they embody a probability distribution for possible worlds by incorporating formulas and their respective weights.

First-order knowledge base (KB) is a set of sentences or formulas in the first order logic (Genesereth & Nilsson, 1987). Formulas are created by incorporating four types of symbols: constants, variables, functions and predicates. A first-order KB is assumed to be a set of hard contraints on the set of possible worlds: if a world breaks just one formula, it is assigned to have zero probability. The motivation behind MLN was to mitigate these contraints. Thus, when a world has broken one formula in the knowledge base first-order, it has low probability, however, it is not impossiple to happen. Formulas are linked with weight in order to reveal the constraint strength.

Domingos and Richardson (2004) attempted to propose Markov logic as a unifying framework due to the need of facilitating knowledge transfer through tasks and approaches. Syntactically speaking, Markov logic can be differentiated from the first-order logic only from the formula to be weighted. In their research work, they exemplify the way certain distinct approaches like probabilistic relational model, knowledge-based construction and stochastic logic programs can be formulated into Markov Logic. Moreover, they have developed algorithms for learning and inference purposes.

Singla and Domingos (2005) have introduced a discriminative approach aiming to train MLN. Their research work intended to optimize the conditional likelihood of query predicates. They have carried out experiments regarding entity resolution and link prediction, which indicate the benefits of their approach if compared to the generative MLN training and even when compared to pure probabilistic models and logical ones.

Wong (2015) has addressed the limitation that Markov Logic Networks pose: the demand for substantial amount of training data. This downside leads to time consuming efforts from the human kind to develop and prepare the required training examples. This derives from the fact that MLN pertain to the supervised approaches. This paper attempts to come up with a semi-supervised mechanism for MLN. Researchers aim to maximize the likelihood function of the observation rather than maximizing the

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

likelihood function of the labeled training data; the latter is broadly used in the MLN supervised learning. Throughout various experiments, this novel approach appears to perform better than the existing frameworks, which exploit labeled training examples.

Relational Markov Networks (RMNs)

A Relational Markov Network identifies a conditional distribution over all entities labels given the relational structure and their content attributes (Taskar et al, 2002). It indicates the cliques, potentials and atributes of entities that are related. Hence, a single model specifies a logic and a relational distribution for any collection of instance. A relational clique template consists of cliques constructed in an instantiation. RMNs are mostly spread to many relational field of interest specifically in social networks. They give extensive information regarding people relations and certain links. Relational Markov Networks incorporate conjuctive database queries dubbed as clique template. Every possible state of cliques must have a feature aimed to reduce the complexity of dependecies. Markov logic undertakes first-order logic in order to describe features. Markov logic allows the presence of uncertainty against arbitrary relation and thus making RMNs more general. Generally, RMNs have been trained in a discriminative way.

An interesting piece of work regarding Relational Markov Network is proposed in (Taskar et al, 2002). Their work introduces a technique that establishes Markov Networks by addressing the shortcomings of undirected models. Undirected models do not impose acyclicity constraints and their limitations are well approppriate for discriminative training. Researchers have enhanced the conditional likelihood of the labels when features are provided. This work gives strong evidence of how to make use of approximate probabilistic inference for the collective classification task of entities related in multiple way with each other. Finally, they show that classification accuracy can be enhanced through incorporating these algorithms.

Assis Costa and Oliveira (2014) have tackled the problem integrating different data set in Linked Data Cloud, which comprises challenges due to incomplete and incosistent data containing outliers. Therefore, they have presented a novel method relying on the relational learning algorithms by incorporating statistical approximation techniques. They have viewed the problem as a relational machine learning task to be solved. This approach is founded in a sparse structure that has the significant capability to scale effectively large datasets.

RECOMMENDER SYSTEMS

A recommender system consists of a personalized information agent, which provides recommendations and suggestions for objects and items that one user might prefer (Burke, 2007). The difference between the recommender systems and information retrieval systems stands in the semantics of user interactions. A result from a recommender system is taken as a suggestion while in information retrieval systems the result is presented as the best match to the respective query. A recommender system varies from an information retrieval system even in terms of personalization and agent (Burke, 2007). A recommender system customizes its responses to a particular user according to user preferences. Rather than providing matches to user queries, it aims to embody an information agent. One compelling property of recommender systems is to alleviate the information overload by suggesting personalized recommendation for

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

each user due to user's previous likes and dislikes. There are many approaches proposed for recommendation systems. The recommendation method can be distingueshed based on the knowledge of the source. Previous research works have categorized recommender systems techniques as below (Burke, 2002):

- **Collaborative Techniques:** The recommender system operates by providing suggestions only via rating profiles of various users; they generate the items to the like-minded users by locating them with the same preference profile.
- **Content-Based Techniques:** The recommender system recommends an item to a user based upon a description of the item and the interest profile of the user (Pazzani & Billsus, 2007).
- **Knowledge Based:** The recommender system is based on knowledge, proposes items based on the inference about the preference of what a user needs (Burke, 2002).
- **Demographic Techniques:** This type of recommender systems works by generating recommendations through the demographic user profile. These methods have the capacity of indicating cross-genre niches and can withdraw the user to overcome and to try new items or products.

All of the four aforementioned techniques have their advantages and shortcomings; collaborative recommender systems have their own limitations, too. The most important challenges that collaborative techniques face when generating recommendations are:

- **New-User Problem:** In order to make sure that the generated recommendation is relevant to users, the system must learn the preference of user from the rating data that user generates by rating various items (Adomavicius & Tuzhilin, 2005). When the user is new, he does not have a rating preference, and the system is not able to recommend any items. This problem can be tackled by using strategies based on item popularity, item entropy, user personalization, etc (Rashid et al, 2002).
- **New-Item Problem:** This happens when an item cannot be recommended when no user has rated it before. Generally, new items face difficulties in being recommended to users. Collaborative systems only make use of the user's preference to develop recommendations. Hence, until a considerable number of users can rate the new item, the recommender system cannot develop a recommendation.
- **Sparsity:** Generally, the number of ratings obtained from users is much smaller than the ratings that must be predicted from the system. Recommender Systems do not perform well when the rating data of product is sparse. Mostly, users lack in rating items. Therefore, the matrix containing the user rating for each item is generally sparse. Hence, the systems have difficulty on finding out a set of users with similar rating. This challenge is of paramount importance when the system is in the first step of usage. It is crucial for systems to effectively predict rating from small number of samples.

Zhu et al., (2015) introduced an approach, which deals with recommender top-N queries in the relational databases. This methodology yields the top-N results for queries conducted by various users. Afterwards, the mechanism determines the linked keywords by computing respective weights of the related keyword. Thus, the approach proposed in this paper can be able to figure out new query words, which are connected to the prior queries and therefore can come up with a recommender query. The associated information of tuples is stored in a knowledge base database in order to evaluate and to

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

examine the recommender query. The advantage of this approach relies on the improving the classic ranking strategy in Information retrieval. The knowledge base, associated interchangeably as the index is the key component of this novel approach.

State-of-the-Art in Collaborative Filtering

The concept of collaborating filtering has derived from the real world domain. Recommendations from other users are highly considered by users. They base their behavior by making choices through word of mouth, reference letters, news, media, public opinion, surveys, guide, etc. Recommender systems facilitate and alleviate people digging through a large amount of information to find the most appropriate and useful information. Recommender systems can provide personalized recommendations through different types of algorithms, including content based filtering, demographic filtering, collaborative filtering, and hybrid filtering methods (Bobadilla et al., 2012). In content-based filtering systems, recommendations are provided to users based on the information related to items that other users have rated previously (Bobadilla et al., 2012). This technique is quite useful for making recommendations for instance that of an adventure movie based on other users who have bought similar category of movies. Demographic filtering techniques on the other hand make recommendations to users taking the positive ratings made by other users who have shared demographic information such as age, gender, qualifications etc. This might help provide recommendations to users based on demographic information and could help provide culturally appropriate information. Collaborative filtering methods allow providing recommendations to users based on how other users have rated items. Hybrid filtering methods allow recommender systems to provide recommendations through techniques based on both collaborative and demographic filtering methods (Bobadilla et al., 2012).

One of the most prominent approaches of recommender systems is collaborative filtering (CF), which uses the known preferences of several users in order to build predictions or valuable recommendations for other novel users. Collaborative filtering consists of various people collaborating in order to help each other to conduct filtering by taking notes of their reactions. The reactions are dubbed as annotations. In other words, collaborative filtering facilitates individuals in the decision making process based on the other people point of view. This method focuses on learning predictive models of user preferences, interests, attitudes, or various behaviors from community data.

The first recommender system dubbed as Tapestry (Goldberg et al., 1992) has introduced for the first time the keyword “collaborative filtering (CF)”. This phrase has been vastly used from the research community even though recommenders may not specifically collaborate with other preferences. The basic assumption of collaborating filtering is that if the user X and Y rate “n” items in the same way or have related preferences, they will behave alike even for new activities or items. CF consists of a user preferences database to predict further products or items that a new user might like.

Collaborating filtering incorporates many challenges that the research community must address. CF approaches are required to have the capability of managing highly sparse data, to scale with the large amount of users and items, to provide the appropriate and valuable recommendation and prediction in a short period. In contrast, content-based algorithms do not make use of any information or details about the items; items are handled as abstract entities. Therefore, collaborating filtering cannot predict items that have not been previously rated. On the other hand, content-based systems do not experience the issue dubbed as the cold-start problem because they benefit from the intrinsic item attributes. While collaborative filtering can develop recommendation to any pair of items as given an amount of sufficient

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

training data, content-based algorithms treat items with similar attribute as similar. Collaborative Filtering techniques are categorized in three kinds of major techniques, namely, memory-based collaborative filtering, model-based collaborative filtering, and hybrid collaborative filtering (Su & Khoshgoftaar, 2009).

Memory-based collaborative filtering employs the whole item-database of user for generating a prediction. Every user is part of a group of people having alike behaviors. A prediction can be elaborated by the system when identifying the neighbors of individuals of a novel user. Memory-based algorithms foretell the rating of items obtained by a user through aggregating the rating of other items generated by the same user or aggregate the other users' rating for the same item. These techniques make use of a similarity metric to figure out several fixed number of items rated by people that are more comparable to the specific item explored by the recommendation system. The most popular similarity metrics aiming to rate vectors are the Pearson correlation coefficient and the cosine-based similarity metric (Adomavicius & Tuzhilin, 2005). Memory-based CF algorithms are easy to implement and perform well for highly dense datasets. Major challenges of this technique are the dependence on user-ratings and their performance deterioration on sparse data. Another memory-based shortcoming is being heuristics-based; they entail extensive hand-tuning upon novel datasets. Moreover, they demand more memory than model-based techniques because of their requirement of accessing the whole dataset when developing recommendations.

Model-based collaborative filtering has been investigated to deal with the drawbacks that memory-based incorporates. The development of machine learning models can make the system learn to distinguish complex patterns by training the system and being able to intelligently predict items for collaborating filtering purposes. Model-based methods develop recommendations for rating by using parametric or semi-parametric model and training on the rating data.

Hybrid collaborative filtering combines CF with other recommender systems approaches just like content-based filtering systems to overcome the shortcoming of pure systems. Therefore, they enhance the performance and the prediction process. They are based on the external content that generally is not available and has increased complexity.

Herein the chapter, authors have explored the most significant pure and hybrid techniques of collaborating filtering. Employing both collaborating filtering and content-based techniques can help in alleviating many recommender system problems, rather than employing only one of respective methods.

Some researchers have pointed out that the first recommender system was Grundy (Rich, 1979), which advocated the utilization of stereotypes to build user models relying on limited information of each indvidual. These user models were exploited for recommending related books to each user and the recommendation appeared to be effective. The definition, collaborative filtering was used for the first time by Goldberg et al. (1992). They have founded an experimental mail system dubbed Tapestry developed at the Xerox Palo Alto Research Center. They assumed that filtering of information can be more effective when human beings are included in the process of filtering. Tapestry was based in both content-based and collaborative methods. It aimed to deal with any incoming stream of electronic documents. It was a framework composed of an indexer, document store, annotation store, filterer, little box, remailer, appraiser, and reader/browser. The reason why researchers developed tapestry relies on the dramatic growth of electronic mail usage. Users were faced with large incoming documents. In order to exploit this bundle of documents, mailing lists were created. The mailing list orientates users to select only those lists, which might have been of their interest. This filtering approach could be further ameliorated when users specified a filter that scans all lists. The major principle that Tapestry constitutes is that filtering can be more effective when humans engage in the filtering process.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

GroupLens (Resnick et.al, 1994) and Video Recommender (Hill et al, 1995) were the first recommender systems, which have incorporated collaborative filtering algorithms intended to automate predictions. The method proposed in Aggarwal et al. (1999) is based on the graph-theoretic approach and can estimate the nearest neighbor of user. There are works that have used person correlation coefficient to measure the similarity (Resnick et.al., 1994), however there are other cosine-based approaches (Breese et al., 1998) where the two users are considered as two vectors in a multi-dimensional space. The similarity between users can be estimated by calculating the cosine angle of two vectors.

Billsus and Pazzani (1998) have introduced a collaborative filtering technique where several machine learning methods just like Artificial Neural Networks are combined with feature extraction techniques. This technique outperformed the memory-based in terms of prediction accuracy and relevance. In Sarwar et al. (2001), the authors pointed out that item-based techniques can have better computation performance compared to traditional user-based collaborative methods. In addition, they appear to perform in comparable or better quality than best of user-based algorithms.

Many several algorithms have tackled the new user problem. Mainly they are based in the hybrid recommender systems. An interesting approach is introduced by Rashid et al. (2002), where various techniques are investigated to decide which is the best and relevant item for a new user. In order to avoid the new user problem, these approaches have made use of different scenarios like item entropy or user personalization.

In regards to the sparsity problem that collaborative techniques face, many significant methods have been explored. In order to mitigate the sparsity rating problem the collaborating system can utilize the information of the user profile to calculate user similarity. Pazzani (1999) have included gender, age, area code, education and employment information to develop effective recommendation and to enhance the problem of sparsity. In this case, this methodology of using not only user-rating, but other demographic information is dubbed as demographic filtering. The sparsity problem have been tackled from Huang et.al. (2004), too. They have mitigated the sparsity issue by carrying out the associative retrieval framework and related algorithms to explore transitive associations through their past feedback.

A significant piece of work was presented in Pennock et al. (2000). They have proposed a novel method named as Personality Diagnosis (PD). In this research work the probability whether users have the same "personality type" when having the same user preference profile for some specific items was calculated. The recommender system can make further predictions, if users like the new arrived items. The PD approach comprises some traditional similarity-weighting techniques where novel data can be included easily. Subsequently, personality diagnosis approach has a significant probabilistic interpretation, which may be utilized in order to analyze and interpret resulting predictions. They have undertaken the experimental phase by providing empirical results on the EachMovie dataset of user-ratings. Data of user profile have been collected by CiteSeer digital library. The Collaborating technique called PD can be viewed as hybrid method of memory-based and model-based algorithms. It has inherited the advantages of memory-based approaches by being fairy straight forward and recording all the data. In addition, it does not demand a compilation step in order to include new data. On the other hand, like other model-based approaches, its predictions are precise and the recommendations have a consequential interpretation. Every user's preference is treated as manifestation of their personality type. The personality type is materialized in a vector of the user's ratings in the database. After the system has obtained the active user's known ratings, authors have calculated the probability of having the same personality with every other user. PD makes better predictions than four other algorithms respectively two memory-based and two model-based approaches.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

An interesting approach regarding hybrid collaborative filtering was proposed in (Melville et al., 2002). They have introduced an elegant and effective approach in which was combined component of content and collaborative techniques. It was incorporated a content-based predictor in order to improve the existing user data and to generate personalized predictions via collaborative filtering. Their content-boosted collaborative filtering approach have given evidence to outperform the pure content-based predictor, the pure collaborative filter and even a naive hybrid approach. In order to mitigate the drawbacks of collaborating filtering algorithms, it was exploited content information of the items already rated. The content-based prediction is employed in order to convert the sparse matrix of user-ratings into a complete matrix. The framework was carried out in a domain of movie recommendation. They have utilized the user-movie rating from the EachMovie dataset (available from the Compaq Systems Research Center). The dataset is composed of a user-ratings data with the rating profile of each user and each movie. Regarding the methodology framework carried out in this research paper, they have compared their hybrid approach with a pure-based predictor and a naive hybrid approach. In order to perform comparison, it was incorporated a subset of rating data from the EachMovie dataset. Recommendation were developed for the withdrawn movie using the different predictors. The quality of the different recommendation algorithms was evaluated throughout the comparison of the predicted values for the withheld rating to the current ratings. They have addressed the sparsity problem by using the pseudo rating matrix, which embody a full user-rating matrix containing ratings for all movies. Therefore, it was aroused the probability of finding similar users with similar preference profile. Regarding the first-rater problem, the recommendation was developed using a content-based predictor for the user. Another body of work in the area of collaborative filtering was proposed by Canny (2002). This article has presented a novel collaborative method, which is intended to protect the privacy of user data. It has supported the Probabilistic Factor-analysis Model (PFM). In this approach the protection of data is carried out by a peer to peer protocol. Moreover, it deals with missing data and does not demand their default value. The novel approach exhibits advantages in speed and storage when compared to the preceding works. There are some significant contributions that this research paper has provided to the body of knowledge. First, this paper has presented the privacy-preserving scheme and explained the protocol generally. The second contribution consists of the new collaborative filtering that appears to be the most accurate CF comparing to the previous one, to their best knowledge. And the third is conducting testing and experiments in order to evaluate the accuracy, speed and storage.

Marlin et al. (2011) discussed the key problem in rating-based collaborative filtering: the possibility of a fundamental incompatibility among the features of recommender data sets and the supposition of valid estimation of statistical model experiencing missing data. In this research paper, it is explained and explored in depth the missing data process in the recommender systems and their influence in the standard statistical model estimation. The paper described components of recommender datasets linking them to the statistical theory of the model estimation. Authors have proposed a framework together with a set of modified evaluation protocols, which handle non-random missing data. Rating prediction provided by this paper, give strong evidence that their developed model can perform better than the standard models.

Big data have emerged substantially in our technology-based area, therefore some gaps and issues have emerged in the recommender systems. Liu & Li (2015) have addressed these issues by designing parallel recommendation algorithms, which constitute an enhanced parallel item-based collaborative filtering founded on Hadoop. Studies according to parallel recommender systems have not been explored in depth so far. The novel parallel item-based collaborative filtering introduced here aims to enhance the

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

performance of the recommendation due to introducing soft punishment on active users. The user-rating model is considered as a prediction model. Authors provide strong evidence that this novel parallel approach outperforms the previous algorithms in terms of speed and scalability.

In closing of Collaborating Filtering section, we must emphasize that because artificial data are usually not reliable due to the properties of CF tasks, it is more suitable to undertake live experiments with real world dataset.

STATISTICAL RELATIONAL LEARNING FOR COLLABORATIVE FILTERING

In this section, this research chapter will disclose herein the most prominent approaches, which combine various statistical relational learning methods in the collaborating filtering domain.

Latent structure of data has been taken into account in order to predict links that have been cumbersome to be analyzed from existing approaches. Hence, machine-learning research communities have examined the latent class model in combination with Bayesian nonparametric methods. Blei et al. (2003) discussed Latent Dirichlet Allocation (LDA), which constitutes a generative probabilistic model for collections of discrete data such as text corpora. LDA belongs to the three-level hierarchical Bayesian model where each item is modeled as a finite mixture over a corresponding set of topics. They introduce an efficient approximate inference technique based on variation methods and EM algorithm for empirical Bayesian parameter estimation. This approach is undertaken in document modeling, text classification and collaborative filtering. This chapter is interested to review collaborative filtering with LDA. Throughout their experimental phase, authors have made use of EachMovie collaborative filtering data. Regarding the collaborative filtering perspective, the model is trained on fully observed set of users. Then for each unobserved user, all movies are displayed except of the user's preferred one. The various algorithms are assessed due to the possibility that they assign to held-out movie. Furthermore, with a 1600 movies vocabulary, authors have found predictive perplexities, however the LDA model provides the best perplexities.

Miller et al. (2009) discussed a latent variable approach making use of Bayesian nonparametric techniques to infer the numbers of features at the same time when learning the respective entities with its corresponding feature. Each entity of the Bayesian nonparametric model has binary valued latent features that affect the relations depending on a set of known covariates. The authors claimed that their approach enables to simultaneously infer the number of the latent features and at the same time to infer the way these features influence observations. Their framework joins inferred features with known covariates aiming to predict the link prediction task. Previous existing class-based frameworks infer latent structure; consequently, proposed model is deemed more expressive than traditional methods and can utilize the output of previous approaches for initialization of its work. This chapter provides insightful evidence that their novel approach can perform well regarding link prediction tasks upon various dataset even on dataset that used to argue for class-based models. This approach exhibits expressiveness, therefore this lead to an enhancement of its performance in the datasets. Moreover, its advantage relies on its richer representations, which enable to mine patterns of interaction compared to class-based models.

Traditional collaborative filtering methods are based on the postulation that real-world data are stationary. Motivated by the sale prediction problem, Xiong et al (2010) introduced to the research community a factor-based algorithm that has the capability to take into consideration the time component when developing predictions. This paper has treated tensor factorization problem with a specific time dimen-

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

sion constraint. In addition, it conducted a fully baysian treatment in order to attain automatic model complexity control. Sampling procedure are performed in order for the system to learn the model. The novel approach dubbed as Bayesian Probabilistic Tensor Factorization (BPTF) is tested in real world data-ratings. Real relational data are in process of evolving and experience strong temporal patterns. This proposed framework is able to model time evolving relational data. This paper has tackled the overfitting problem by extending the approach with Bayesian algorithms. In regard to scalability function, authors have incorporated Markov Chain Monte Carlo (MCMC) process to perform the learning task.

Another domain where SRLs for collaborative filtering have been implemented is the Customer Relationship Management (CRM) field of interest. Customer modeling in CRM can be defined as a special case of a relational learning problem. Perlich and Hung (2010) have presented a connection between relational learning domain and CRM analysis particularly in customer classification and product recommendation. This work has been evaluated in seven-real world CRM datasets where empirical results have been gathered. This paper illustrated that relational learning techniques can be useful in addressing CRM modeling tasks. Authors have focused on predictive customer modeling underlying classification and probability estimation for cost-sensitive, decision-making and product recommendation. Relational learning can explore large-scale set of models, thus having the capability to capture predictable dependencies. This paper has modeled CRM with statistical relational learning techniques for product recommendation task. This tool was not meant to model all CRM, but it focused on performing exploration and capturing relevant information. The illustrated example in this paper was the bookstore dataset. They have utilized this dataset to examine the relational learning capability regarding the recommendation aspect. It is implemented the unified recommendation framework based on the extension of a relational learning, known as Probabilistic Relational Model (PRMs). In order to address the recommendation tasks, they have included a special existence attribute into the order table and obtained dependency frameworks relevant to order table attribute. The performance is evaluated with well-studied metrics including precision, recall F-measure and rank score.

Xu et al. (2010) have investigated complex social networks with Infinite Hidden Relational Models (IHRMs) for tasks of community detection, link prediction and product recommendation. A social network based IHRM employs edges associated with random variables. Probabilistic dependencies between these variables are determined based on the relational structure model. The hidden variables can transfer information in order to obtain non-local probabilistic dependencies. This model can serve for predicting entity attributes. In addition, it conducts a significant cluster analysis.

Statistical relational learning in the domain of collaborative filtering has been employed also to tackle the learning of trust. Rettinger et al. (2011) have pointed out that from a trustee perspective; trust is described as many relations happening among the agent to be trusted and the state of environment. They exemplify how to apply and learn context sensitive trust by employing SRL in the form of Dirichlet process model dubbed as Infinite Hidden Relational Trust Model (IHRTM). Several experiments are carried out in the user-ratings data from the eBay platform. Authors have demonstrated with empirical results that the trustee is enabled to specify the structure of the trust-situation by the inherent clustering process. Authors have highlighted that the employment of collaborative filtering combined with relational data can lead to an improvement of the trust assessment performance. Moreover, one other contribution of this framework is to enhance the cold start performance due to the learning and transferring knowledge faster. Dealing better with dynamic behavior in an open multi-agent system is another benefit that this approach provides, which is illustrated by records interaction generated from a scenario composed of two players.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

A method for modeling large-scale multi-relational dataset was discussed in Jenatton et al. (2012). Their framework represents a bilinear structure capturing several orders of data interaction. Furthermore, it shares latent factors through various relations. Authors have employed their approach on a standard tensor-factorization dataset. Their application across various experiments provides evidence that can efficiently learn semantically meaningful representations. The model for relational data is appropriate to be deployed in multi-relational graphs and in natural languages. Regarding the algorithmic approach, in order to speed up the optimization, they have utilized several scenarios. They have claimed that cannot treat the NLP application as a standard tensor factorization problem. The proposed framework is deemed probabilistic and can be a benefit for the accounting domain because of the uncertainty presence of data. The paper empirically has demonstrated that this approach outperforms the previous existing frameworks.

One of the most well-known SRL approaches, Probabilistic Relational Model (PRMs) have been employed for collaborative filtering in (Newton & Greiner, 2014). For experimental purposes, they have exploited the EachMovie dataset. First, they have learned standard PRM, then they have specified the hierarchical PRMs, which comprise an extension of standard PRM throughout refining classes into hierarchies. It is shown that this approach allows greater presence of context sensitivity compared to standard PRM, thus being more expressive. This piece of work provides strong evidence that PRMs can be effectively employed in the collaborative filtering area. They have discussed the performance of standard PRMs deployed in the EachMovie dataset and then compared it with the effectiveness of hierarchical PRMs (Getoor, 2002).

Chulyadyo and Leray (2014) proposed a novel method to establish a personalized recommendation model based on PRM incorporating user's preferences. The paper demonstrates that carrying out PRM for collaborative filtering can mitigate the cold start problem and thus making able to generate personalized recommendations. This work has emerged from the need of intelligent recommender system in professional community and in large-scale systems where the system does not have the user profile, which is composed of incomplete and inconsistent data. This work intends to serve as a help for users by showing their search queries listed by relevance. Previous techniques could not address the problem of real world applications that demanded personalized recommendation, therefore, lacking the user profile existence.

Yuan et al. (2015) have examined the importance of retrieving the contextual information of users. Contextual information stands for the time and the locations of various users. These key terms are applied in the micro-blogging services and location-based social networks domain. In this paper, authors deal with contextual recommendation tasks and contextual search. User mobility behavior is associated with four major questions: who visits, which place, what time and for what activity. Thus, addressing these topical issues demand for effective methods in examining the mobility behavior. The underlying approach introduces a nonparametric Bayesian model, which does not require any parameter tuning. When given one out of the four aspects, the mechanism itself can provide the remaining others. A variety of experiments demonstrates that the novel model is truly effective in unveiling user's spatial temporal topic. In this paper it is implemented a novel probabilistic generative model based on non-parametric Bayesian in order to represent the mobility behavior of users in terms of spatial, temporal and activity. The key contribution of this new model is to disclose spatial temporal matters for each user by making recommendations aware in terms of context and search.

SUMMARY

This chapter provided a comprehensive overview of the most compelling research papers that combine statistical relational learning for collaborative filtering tasks. Authors have conceptualized this research work by exploring first statistical relational learning and all the techniques that it comprises. Moreover, the chapter has explored the recommendation systems, its categorizations in three major approaches collaborative-based, content-based, knowledge-based, and demographic-based. Regarding collaborative techniques, the chapter has provided a profound classification, which include memory-based, model-based, and hybrid approaches. Authors have claimed that model-based techniques outperform memory-based. However, it is demonstrated in various previous researches that the hybridization of the two techniques can alleviate some limitation that each method imposes if they are employed purely. SRL have been combined for collaborative filtering purposes in recommender systems particularly for the product recommendation tasks. The most popular approaches for relational data are the PRM (an extension of Bayesian traditional Networks) and Rational Markov Networks (RMN).

In this survey work are introduced three tables, which summarize and categorize the whole research work that has been conducted throughout research chapter. Respectively, Table 1 describes the categorization of the statistical relational learning frameworks, Table 2 exhibits the classification and the state-of-the-art in collaborative filtering techniques, and finally the Table 3 refers to an overview of the research examples, which have combined techniques of statistical relational learning with collaborative filtering.

CONCLUSION AND FURTHER WORK

Collaborating Filtering incorporates many challenges that the research community must address. CF approaches are required to have the capability to manage highly sparse data, to scale with the large amount of users and items, to provide the appropriate and valuable recommendation and prediction in a short period, etc. Throughout the survey of SRL for CF approaches, it is demonstrated that carrying out PRM for collaborative filtering can mitigate the cold start problem and thus making able of generating personalized recommendations. Previous research works have addressed the sparsity problem by using the pseudo rating matrix, which enbody a full user-rating matrix containing ratings for all movies.

Table 1. Categorization of statistical relational learning techniques

	Types of Statistical Relational Learning Techniques		
	PRM	**MLN**	**BLN**
Class level model	Directed GM	Logical clauses	Bipartite directed
Parameter estimation	Machine Learning to fill CPT	Machine learning to Weights	Machine Learning to fill CPT
Structure learning	Score Based learning	ILP methods	ILP methods
Inference Graph	Bayesian network	Markov model	Bayesian network
Autocorrelation	Self-loops in class level model	Additional variables needed	It is not discussed in the research this feature

Sparsity rating problem can be addressed even by utilizing the information of the user profile to calculate user similarity. It is included gender, age, area code, education and employment information in order to develop effective recommendations and to overcome the problem of sparsity. In this case, this methodology of using not only user-ratings, but other demographic information is dubbed as demographic filtering. Regarding the first-rater problem, the recommendation must be developed using a content-based predictor for the user.The recommendation process has been further enhanced by generating effective prediction through using content-based prediction even for the other users. Several papers have illustrated that relational learning techniques can be useful in addressing CRM modeling tasks, too. In regards to collaborating filtering, it is emphasized that because artificial data are usually not reliable, it is more suitable to undertake live experiments with real world dataset.

In concluding this chapter, one open issue that can be suggested for future work is regarding the limitation that IHRTM impose on the process of not handling the trustees with strategies. An adaptive learning strategy can be implemented in the future. This is a domain that cannot be addressed by propositional machine learning algorithms; hence, statistical relational model would be appropriate for this problem. Finally, the combination of SRL for CF opens up new doors to many further applications in the future research. Open gaps can be tackled and future refinement of existing methods can be provided in order to advance in this new field of interest.

KEY TERMS AND DEFINITIONS

Collaborative Filtering: Collaborative filtering allows recommendations to users taking into account how other users have rated items. Collaborative filtering needs an extensive database containing exclusively the ratings made by users over the items (Bobadilla et al., 2012).

Content-Based Filtering: Content-based filtering systems allow recommender systems to provide recommendations to users based on the information related to items that other users have rated previously.

Data Mining: Data Mining is defined as the process of analyzing large information repositories for deriving and discovering useful patterns and identifying hidden relationships among the data (Siguenza-Guzman et al., 2015).

Hybrid Collaborative Filtering: Hybrid filtering methods allow recommender systems to provide recommendations through techniques based on both collaborative and demographic filtering methods (Bobadilla et al., 2012).

Recommender Systems: Recommender systems are software tools and techniques for suggesting items to users by considering their preferences in an automated fashion (Nilashi et al., 2013).

Social Network Mining (SNM): Its major purpose is to extract information about network objects, behaviors and activities that cannot be yielded if the entities were to be examined individually.

Chapter 34
An Artificial Intelligence–Based Vehicular System Simulator

Marvin T. Chan
University of Regina, Canada

Christine Chan
University of Regina, Canada

Jonathan T. Chan
University of Regina, Canada

Craig Gelowitz
University of Regina, Canada

ABSTRACT

This paper presents a vehicular system simulator, which enables the human player to race a car against three system-controlled cars in a three-dimensional road system. The objective of the vehicular system simulator is not to support defeating the opponent in a car race, but to provide the player with a challenging and enjoyable racing experience. Therefore, it is important that the system simulates human driving behavior and adopts cognitive computing. The paper discusses development of the vehicular system simulator using the artificial intelligence (AI) techniques that are supported in the game engine of Unity. The design and implementation of the vehicular system simulator are presented. The discussion includes some possible extensions of the current version of the system so that it can be adapted to be a simulation system for education purposes

1. INTRODUCTION

A vehicular system simulator provides a popular game environment. In a traditional game like chess, a situation is presented where "players engage in an artificial conflict, defined by rules, that results in a quantifiable outcome" Salen & Zimmerman (2004). Such artificial conflicts are often represented as a puzzle or a challenge, and having the puzzle solved or the challenge resolved provides a real-world purpose to the game players (Liu et al., 2011). These games are sometimes referred to as "serious" games (Wood & Reiners, 2012), but they have been increasingly replaced by electronic games, especially for the "game generation" (Prensky, 2001) of "digital natives". This younger generation of game players typically grew up playing games and, in contrast to the "digital immigrants" (Prensky, 2001) of the older

generation, they are adapt in "dealing with large amounts of information quickly even at the early ages, using alternative ways to get information, and finding solutions to their own problems through new communication paths" (Akilli, 2007).

The Artificial Intelligence (AI) field has witnessed a similar transition from the "classical AI games" such as Samuel's Checker Player (Samuel, 1967) and Waterman's Poker Player (Waterman, 1970) to the contemporary AI techniques adopted in electronic games. The goal of the game is no longer a quantifiable outcome of winning over the opponent as in the case of a checker or poker game. Instead, a contemporary game contains changing environments, multiple objectives, and dynamic aspects of the game that are revealed to the player as the game unfolds. The objective is to offer to the human player an enjoyable experience through his or her interaction with the game, and this does not involve any specific quantifiable outcome.

The vehicular system simulator has been developed as a racing game, called Racer, with the goal of offering to the player a challenging and enjoyable experience in a car race against a system-controlled car. Although the player's goal within the game is to win the race against the system-controlled car, the AI techniques adopted in the game are primarily designed to give the player an enjoyable time racing his or her car. In other words, the objective of winning by either side is not given the highest priority.

This paper proceeds as follows. Section 2 provides some background literature relevant to the work. Section 3 presents some components of the vehicular system simulator. Section 4 presents implementation of the vehicular system; Section 5 discusses some AI techniques adopted in the vehicular system simulator, their effects on system performance, and some exploration on feasibility of extending the current system into an educational software system useful for teaching transportation engineering concepts. Section 6 includes the conclusion and some ideas on future directions of the work.

2. BACKGROUND LITERATURE

Some research studies on cognitive vehicular systems are briefly summarized as follows. Xie & Xu (2015) provided an overview of the algorithms and technologies useful for extracting static properties of vehicles from videos so as to support criminal and traffic violations. With the rapid growth of the video surveillance technology, a large database of video and images has been created. The database can become an important resource for police in performing traffic events analysis: crucial information such as speed and license plate of vehicles can be extracted and examined. Yoshizawa & Iwasaki (2015) examined a type of driving behavior, called "aimless driving", which is responsible for a large number of fatal traffic accidents in Japan. The study investigates this "aimless driving" behavior by giving subjects non-visual secondary tasks of four difficulty levels while they watch pedestrians and their responses to objects in the road on which they travel are measured. The results indicated that even non-visual tasks influence eye movement and the subjects were not able to react well to objects on the road. Xu et al. (2014) studied the use of semantic technologies for annotating videos so as to enhance comprehensibility of the videos. Their work proposed a video annotation platform, which supports users by providing a search interface of annotated video resources. Some preliminary results indicated that applying semantic technologies for annotation of videos can enhance reusability, scalability, and extensibility of the video resource and support increased adoption of this resource for traffic events analysis.

Much research work that focuses on developing AI-controlled components of game systems called "bots" can be found. These "bots" approximate or emulate human game playing styles. Development of the "bots" often has been motivated by the belief that a human player's enjoyment in the gaming

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

experience will be higher if he or she can be led to believe that the opponents in the game are other human players. An example of this type of game is the popular multiplayer first person shooter game of Counter-Strike (Valve Corporation, 2016), in which the objective is to eliminate all players on the enemy or opponent team. This type of "bots" also appears in the early video game of PacMan, in which the computer-controlled ghosts in the maze are able to move towards the player-controlled characters because the former incorporated some path finding algorithms (DeNero & Klein, 2010). Some other AI algorithms commonly implemented in games include finite state machines, fuzzy state machines, and decision trees. Decision trees are often used to represent the decision making process involved in games like Checkers or Chess. Since a decision tree can specify a number of possible game states given a current state, and support a search process for a goal state, this approach is adopted so that the human player is defeated provided the AI-controlled game can identify the path to the goal state more efficiently than the human player.

Some other AI techniques used for building bots so that they would mimic or emulate human behavior can also be found. Khoo and Zubek (2002) adopted a behavior-based action selection technique in the software development kit (SDK) of Flexbot, which was used for developing the AI-controlled bot of Groo. This provided the basis for development of 32 bots, which can run simultaneously on a single machine. The human players who played against the bots believed the bots effectively emulated human behavior (Khoo & Zubek, 2002). Tatai and Gudwin (2003) discussed adopting semiotics in their development of a bot to assist or attack the human player in the game of Counter-Strike; their aim was to design the AI system in such a way that the human player is entertained and challenged and not simply defeated. Hence, the bot's performance is gauged not by its efficiency in killing its opponents, but by its "capability to emulate as close as possible all the activities commonly performed by a human player" (Tatai & Gudwin, 2003). Due to this consideration, the bot cannot be perceived by the human to be waiting because human players expect bots to be continuously working. In other words, the bot's reaction time was one of the key criteria in measuring its performance (Tatai & Gudwin, 2003).

In a vehicular system simulator, the user's expectation is to control the car by making small adjustments to the car's direction while driving because that is how a car is controlled in real life. Therefore, a vehicular system simulator must be able to make continuous adjustments to the car's direction as opposed to simply driving in a straight line and turning only when a curve in the road approaches. To ensure these expectations on human driving behavior can be satisfied, some AI techniques used for designing and implementing the vehicular system simulator will be discussed in the following sections.

3. VEHICULAR SYSTEM COMPONENTS

The vehicular system simulator consists of components that involved AI concepts and techniques; these are presented as follows.

3.1. The Road System

Two considerations were involved in design of the road system in the simulator: (1) how to design the road itself, and (2) how the navigation on the road can be realized. The road system provides the 3D graphical environment on which the cars travel, and the road consists of obstacles, curves, and corners which require careful navigation of the car. To guide the car's navigation on the road, the Unity engine

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. A screenshot of waypoints at key positions on the track

provides the waypoint system, which clearly specifies identifiable points on the road that support a car's navigation on the road. The waypoint system includes a set of waypoints and each waypoint is a coordinate in 3D space that represents a key position on the racetrack. In the vehicular system simulator, the waypoints are stored as a sorted list of positions in 3D space using the List generic class from the System.Collections.Generic namespace (Microsoft, 2016). This list of waypoints is read as input, and then the system iterates through the list until all the waypoints have been passed by the system-controlled car. The system only iterates to the next waypoint in the list when the system-controlled car is detected to be within a specified distance from its current waypoint. Figure 1 shows a screenshot of the waypoints on the track.

To turn the car towards its current waypoint, the system executes a series of vector calculations so as to define the amount of steering the car requires. The calculations are done using an initial vector based on the position of the current waypoint and the current position of the car. The calculations then generate an output vector that forms the basis for setting the steering and braking output levels of the car. However, due to the nonlinear relationship between the input and output vectors, the car could not be controlled using the output vector generated only, and the additional mechanism of the conditional monitoring system was also adopted.

Depending on the values of the initial calculated output vector produced from the waypoint system's vector calculations, the steering and braking output levels applied to the car are adjusted by the conditional monitoring system. When both the waypoint system and the conditional monitoring system were employed for controlling the car, it was able to drive smoothly on the road.

Instead of adding the conditional monitoring system, it was possible to augment the waypoint system with a user-defined nonlinear mathematical function so as to better control the car. However, this option was discarded because it may require complex mathematical manipulations.

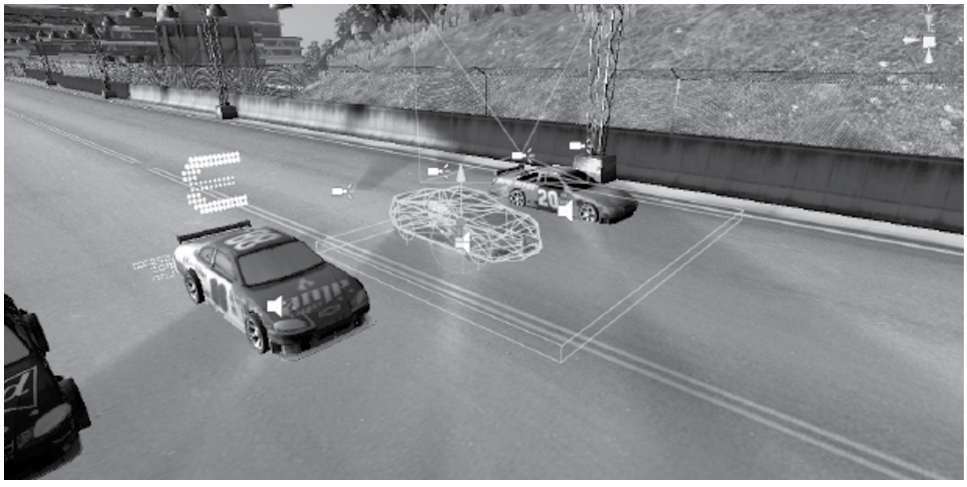
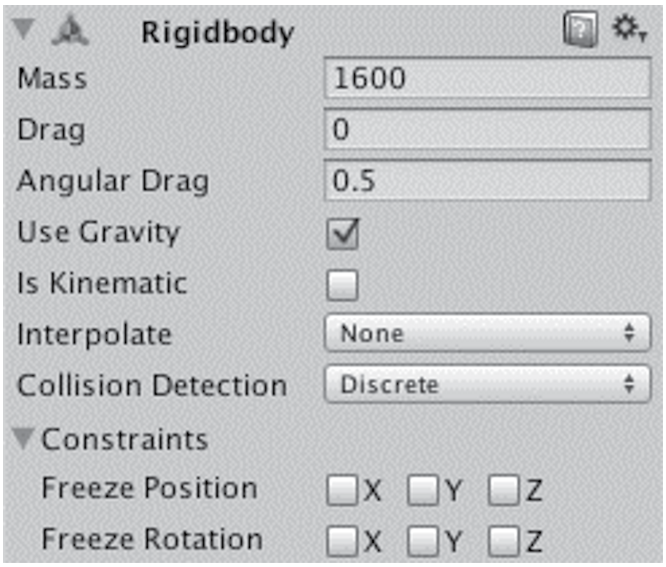
3.2. Artificial Environment Perception



To adequately steer the car away from obstacles on the road requires that the car can adjust to changing road conditions. In other words, the car needs to exhibit environmental perception. The Unity engine provides the mechanism of trigger detection that supports artificial environment perception. To implement trigger detection, a trigger detection area has to be first defined for a car, and then, when some other object enters into this trigger detection area, it can be detected. For example, if a wall comes into the trigger detection area, the vehicular system becomes aware of where the wall is with respect to the car. The system then adjusts the steering and braking levels of the car accordingly so as to steer the car away from the wall. Hence the trigger detection component is important for realizing artificial environment perceiption.

An alternative technique considered for implementing artificial environment perception was the ray-casting technique. Ray-casting involves drawing a ray or line from an object towards a specified direction, which in the case of the vehicular system simulator, is the direction the car is heading. This drawn line or ray can be used for determining whether a car is about to collide with another object. However, the ray-casting mechanism can only detect collisions in one direction. By comparison, the trigger detection mechanism can detect collisions in all directions, and therefore, the latter is adopted in the system. Figure 2 shows a screenshot of the trigger detection area defined for the system-controlled car.

3.3. Car Definition



The Unity game engine (trademark of Unity Technologies) provides some features that enable the car to be defined according to user preferences, and two of these are: (1) the rigid-body component, and (2) the wheel-collider component. The rigid-body component enables the user to modify properties of the rigid body object and how physical forces are exerted upon it. Using the rigid body interface, the user can modify the properties of a car such as its mass, drag, and angular drag, as well as its kinetic properties of velocity, angular velocity, rotation, and angular rotation. Figure 3 shows the rigid body interface, which enables users to define the values of the properties of a car.

Figure 2. A screenshot of the trigger detection area defined for the system-controlled car

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 3. A screenshot of the interface of the rigid-body component

The component of the wheel collider in Unity supports the high-level abstraction implementation of wheel-type objects. This component enables users to specify the various properties of a car that directly affects the frictions between the tires and a road, and hence, a car's ability to navigate on a road system. The user can control the values of the properties of forward and sideways frictions, which are critical for determining how a car drives on a road and in simulating its braking distance. Figure 4 shows the interface of the wheel collider component in Unity, which enables the user to provide input to the various properties of the wheel-collider component of a car.

The coefficient of sideways friction of the wheel collider component plays an important role in situations when the car may slip, overturn, or when it is travelling in super-elevation or in curvilinear motion. On the other hand, when simulating braking distance in rectilinear motion, the coefficient of forward friction is proportional to the forward friction stiffness value in the wheel collider component, which is user-defined. When simulating curvilinear motion, the coefficient of sideways friction is determined by the stiffness value in the parameter of sideways friction of the wheel collider component. Figure 5 is a screenshot of the wheel-collider on the wheels of a car object.

4. IMPLEMENTATION OF THE VEHICULAR SYSTEM

4.1. Unity Game Engine

The vehicular system simulator was built using the Unity game engine developed by Unity Technologies (2016). Unity is a game development engine combined with an integrated development environment (IDE) that is capable of creating applications for Windows, Mac OS X, Linux, as well as other mobile platforms (Unity Technologies, 2016). The Unity game engine can perform graphical rendering and physics calculations, thereby enabling developers to focus on positioning, scaling, and adding realistic physics to objects in the vehicular system.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

4.1.1. MonoDevelop

The Unity game engine works together with MonoDevelop for controlling the behavior of objects. MonoDevelop is an open source IDE developed by Xamarin and the Mono community (MonoDevelop Project, 2016), which is primarily used for development in the C# programming language. In the environment of MonoDevelop, developers can write scripts in C#, Javascript, or Boo to control the logic and behaviors of objects defined in Unity (2016). For example, to implement the braking system on the wheels of the player-controlled car, a script can be written that takes keyboard input from the user and applies the input value to the attribute of the velocity of the car's wheel defined in Unity. Hence, the combined tools of Unity and MonoDevelop enable developers to focus on the development of the system components and they can leave issues related to 3D graphics rendering and physics calculations to the combined platform.

4.2. Programming Languages and Data Structures

The primary programming language used for writing the scripts to control the behaviors of objects was C#, which has advantages because firstly, C# is object-oriented and class-based. Secondly, the language C# has a variety of libraries and frameworks built specifically for development with Unity. The libraries consists of many generic classes and interfaces such as the List, Stack, and Dictionary (Unity Technology, 2016). Thirdly, online documentation is available to support development.

4.3. Vehicular System Modules

The system consists of three main modules, which include: (1) the player-controlled car module, (2) the system-controlled car module, and (3) the environment module. They are discussed as follows.

The player-controlled car module consists of four sub modules: (1) the body, (2) the wheels, (3) the heads-up-display (HUD), and (4) the player controller script. The body of the car is the 3D model that the player sees in the system; this sub module consists of the colliders, which enable the car to collide with objects on the road. The wheels of the car contain wheel colliders, which enable the wheels to make contact with the road and drive the car forward. The wheels sub module contains a script, which is responsible for animating rotation of the wheels as the car travels on the road. The HUD component of the car is controlled by the HUD.cs script; this is responsible for displaying the current speed, position, and lap of the car. Finally, the sub module of the player-controller script, called PlayerCarController.cs, takes the user input from the keyboard and applies the appropriate steering, accelerating, and braking output levels to the player-controlled car.

The system-controlled car consists of four sub modules: (1) the body, (2) the wheels, (3) the trigger area, and (4) the controller script. The body and wheels of the system-controlled car are identical to the body and wheel components of the player-controlled car. The trigger area component of the car is controlled by the CarSensor.cs script; it detects when an obstacle such as a wall enters into the trigger area. When this happens, the system controller is informed and responds by adjusting its control of the car. The system controller script, called AICarController.cs, contains all the implemented artificial intelligence techniques and algorithms responsible for ensuring the system-controlled car can effectively race against the player-controlled car.

The environment module consists of two sub modules, which are the road system and the waypoints system. Both sub-modules have been presented earlier.

5. DISCUSSION

5.1. Development Tools

Development of the vehicular system simulator was supported by the implementation tools. The Unity game engine provides high-level abstraction programming tools and an intuitive user interface. The engine can support developers in implementation of AI concepts and enable them to ignore lower level development details such as graphics rendering and physics calculations. The combined tools of MonoDevelop and Unity supports the system implementation process because MonoDevelop consists of auto-correction features for many libraries and SDKs used in Unity. For example, the combined tools support the developer in implementation of the waypoint system because the Unity engine supports positioning waypoints in 3D space. Hence, the developer can use this technique of a waypoint system instead of more traditional AI techniques like the A* search method, which is also an effective path finding technique. For controlling the car, the system of conditional monitoring was adopted instead of developing the nonlinear mathematical function, mainly for the sake of simplicity. In terms of collision prevention, the trigger detection technique was used instead of ray-casting because the former is more effective than the latter in that the technique of ray-casting only supports artificial environment perception in one single direction per casted ray. By comparison, the trigger detection technique supports simultaneous perception in all directions surrounding the car. Moreover, the Unity engine has built-in high-level abstractions for trigger detection, which facilitates implementation.

A possible direction for future work is to extend the vehicular system into a simulation system for education purposes, and more specifically, for teaching transportation engineering concepts. The components developed in the system can be used for illustrating graphically many concepts in transportation engineering. For example, one such concept is “braking patterns”, which can include the concepts of: (a) normal braking, (b) accelerated braking, and (c) stonewall braking. Normal braking is the act of slowing down gradually when there is no immediate danger of collision while accelerated braking is the act of decelerating quickly in anticipation of an impending collision. Stonewall braking is the actual occurrence of a collision which forces the car to stop abruptly. The vehicular system simulator can illustrate visually these concepts by defining one or more than one car and their properties. In scenario (a), one car has to be defined, and its braking pattern can be implemented by defining the side friction parameter. Since in scenario (b), two cars are involved and the braking pattern of the first car affects that of the second one, two cars need to be defined. In scenario (c), a stationery object, such as a wall, and a car are involved.

All three of these braking patterns can be simulated using the implementation mechanisms of the car’s artificial environment perception system through the use of a trigger area. The trigger area detects how far away an obstacle is and hence, the distance of a potential collision. Based on the distance, the system can determine whether normal or accelerated braking is required. In addition, the trigger area detects the direction of the potential collision, so that the car can adjust its turn to steer away from the object. If the potential colliding object is a safe distance away, the driving system will apply normal braking to gradually decrease the car’s speed. However, if the colliding object is close to the car, accelerated braking will be applied to slow the car down more suddenly. The value of the side friction parameter can be adjusted to support braking while turning. If the car does come into collision with an object, the magnitude and direction of the force of the impact on the car can be detected and the information displayed to the user for further analysis. These sample features of the vehicular simulation system can all be useful for visual and real time presentation of concepts in transportation engineering.

5.2. Extension Into an Educational Simulation System

A possible direction for future work is to extend the vehicular system into a simulation system for education purposes, and more specifically, for teaching transportation engineering concepts. The incorporation of game or simulation systems for teaching transportation engineering has been the focus of research, and some sample works are presented as follows.

Chen & Levinson (2006) investigated the efficacy of using simulation for teaching the topic of transportation network growth by conducting an experiment at the Civil Engineering Department of the University of Minnesota. A network growth simulator program (SONG 1.0) was incorporated into a senior/graduate class in transportation system analysis. Instead of aiming to generate a perfect reproduction of the real world SONG 1.0 aims to help students explore the micro-world of transportation network systems so that they are stimulated and encouraged to come up with innovative ways of conceptualizing the network growth and planning process. The experimental results demonstrate that the use of SONG 1.0 effectively enhanced students' in-depth understanding about development of network patterns, which in turn helped to develop their skills in problem-solving and decision-making. Zhu *et al.* (2011) reported on a transportation planning software package called Agent-Based Demand and Assignment Model (ADAM). The agent-based modeling approach assumes that the aggregate urban travel demand arises from a multidimensional selection process, which includes choices related to residential and business locations, trip origins, trip destinations, routes, etc. All agents in the model are assumed to have individual characteristics, goals, and patterns of travel behaviors. The agents exchange information on their experiences and adjust their travel choices according to the available information. ADAM was incorporated as part of a teaching strategy, and evaluations showed that ADAM helped students in forming opinions, evaluating projects, and making judgments. Students who used ADAM reported an enhanced understanding of the concepts taught in the class, and students who prefer visual and active learning were found to benefit more than others. Kasaraneni (2009) presented a web-based game system that demonstrates driver-behaviors at signalized intersections. It was used as a supplementary tool in an introductory course on Transportation Engineering, and helped students understand decisions of drivers at the onset of the yellow signal based on existing traffic conditions. The game was implemented on the .NET Framework using Microsoft Visual C#, ASP, and Microsoft Access (all trademarks of Microsoft, U.S.A.). Based on collected data on student engagement in the course, it was found the game system helped students to better focus their attention. The creative instructional activities also provided students with hands-on experience of simulated real world scenarios. The game system discussed in Kasaraneni (2009) was further developed in Abbas & McNair (2014) with the objective of investigating game-aided pedagogy for improving engagement and learning outcomes of students in transportation engineering. The enhanced game system consists of three layers: (1) a web-based user interface to display simulated traffic flows, (2) a game control layer to implement logic controls based on the game context and user commands, and (3) a data source layer, which consists of the two databases of traffic snapshots and traffic scenarios. Assessment of student engagement and learning outcomes was conducted by means of questionnaires and statistical analysis on the collected data indicated the game enhanced learning outcomes.

The components developed in the vehicular system simulator presented in this paper can be ex-tended so that they support student interaction. For example, the consideration of a vehicle's braking distance is important for the design of a road system. The concepts involved can be categorized into linear or curvilinear motion of a vehicle, along a straight or curved road. If it is a curved road, the motion can be further divided into (1) horizontal curvilinear (i.e. on a flat curved road), or (2) vertical curvilinear (i.e.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

on a curved road that travels up and down hilly terrain). Typically, in a transportation engineering class, the concept of braking distance is explained by means of an equation, which expresses the relationships among the variables of initial velocity or speed, final speed, gravity, coefficient of friction between the road and the tires, and the grade of the road. For the last variable of the grade of a road, an uphill road has a positive grade value, and a downhill road has a negative grade value. The equation for braking distance is often used in road design, such that if a velocity of v_o is allowed on the road, then the road must be at least Db meters long so that cars can safely come to a stop. The equation for defining braking distance is given as follows (Papacostas & Prevedouros, 2001),

$$D_b = \frac{v_0^2 - v^2}{2g\left(f \pm G\right)}$$

where

D_b = braking distance,
$v0$ = initial velocity;
v = final velocity;
g = gravity;
f = coefficient of friction;
G = gradient (+ve = uphill, -ve = downhill).

This can be modeled in a simulation software system so that the student or user I supported in providing input values for the velocities, and the equation embedded in the system will determine the length of the road to ensure safe deceleration of a vehicle.

Some features in the current version of the vehicular system simulator can also be used for illustrating graphically concepts in transportation engineering. For example, one such concept is "braking patterns", which can include the concepts of: (a) normal braking, (b) accelerated braking, and (c) stone-wall braking. Normal braking is the act of slowing down gradually when there is no immediate danger of collision while accelerated braking is the act of decelerating quickly in anticipation of an impending collision. Stonewall braking is the actual occurrence of a collision which forces the car to stop abruptly. The vehicular system simulator can illustrate visually these concepts by defining one or more than one car and their properties. In scenario (a), one car has to be defined, and its braking pattern can be implemented by defining the side friction parameter. Since in scenario (b), two cars are involved and the braking pattern of the first car affects that of the second one, two cars need to be defined. In scenario (c), a stationery object, such as a wall, and a car are involved.

All three of these braking patterns can be simulated using the implementation mechanisms of the car's artificial environment perception system through the use of a trigger area. The trigger area detects how far away an obstacle is and hence, the distance of a potential collision. Based on the distance, the system can determine whether normal or accelerated braking is required. In addition, the trigger area detects the direction of the potential collision, so that the car can adjust its turn to steer away from the object. If the potential colliding object is a safe distance away, the driving system will apply normal braking to gradually decrease the car's speed. However, if the colliding object is close to the car, accelerated braking will be applied to slow the car down more suddenly. The value of the side friction parameter can be adjusted

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

to support braking while turning. If the car does come into collision with an object, the magnitude and direction of the force of the impact on the car can be detected and the information displayed to the user for further analysis. These sample features of the vehicular simulation system can all be useful for visual and real time presentation of concepts in transportation engineering.

6. CONCLUSION

The vehicular system simulator was tested by over twenty users, who all reported that they thoroughly enjoyed the experience of racing provided by the system. It was observed that there was approximately equal number of players who were able to win the race against the system-controlled cars. This suggests that not only did the system provide an entertaining gaming experience; it also provided a reasonably engaging and challenging gameplay.

Future work would involve incorporating other path finding techniques into the vehicular system simulator so that it can be more dynamic and exciting. While the waypoint system in the current version of the system is satisfactory, path finding methods such as the A* search method would enable the system-controlled car's path to be dynamically determined based on its current position. This would make it more difficult for the human players to predict the behavior of the system-controlled cars, and the unpredictable behavior would mean a more challenging racing experience for the user.

Furthermore, while this vehicular system simulator was designed for entertainment, the system can be extended to become a simulator system for education. By modifying some of the parameter values of the car, such as the braking coefficients and torque values, and by modifying the road system environment to resemble that of a municipal road system, the current version of the vehicular system can be adapted to become a simulation software for teaching transportation engineering concepts, for training learner-level drivers, or for familiarizing drivers with the roadway layouts and traffic laws of foreign or unknown cities.

Chapter 35
A Novel Architecture for Learner-Centric Curriculum Sequencing in Adaptive Intelligent Tutoring System

Ninni Singh

ABSTRACT

An ideal face-to-face tutor learner interaction aims to offer learning to the learner in a manner that best suits an individual learner's learning level and learning style. This ability of differentiated instruction has been built in Seis-Tutor Intelligent Tutoring system, developed to offer subject matter knowledge of 'Seismic Data Interpretation,' a field of geo-physics. The detailed architecture of learner-centric curriculum sequencing module, built to this effect, with its components, sub-components, their interconnected functioning, to generate exclusive learning path, have been described. An algorithm for learner-centric curriculum sequencing, a mathematical model and proposed implementation using a case study has been elaborated.

INTRODUCTION

Artificial intelligence is an advanced field of research. Its use in the field of education particularly in making teaching and learning more effective, has been significantly exploited in recent past. This has resulted in development of variety of educational computer artifacts. Further developments have caused origin of the field of intelligent tutoring. This field developed at the intersection of disciplines

of computer science, cognitive psychology and educational research has gained immense popularity in current times, particularly due to the development of Intelligent Tutoring Systems (ITS) (Nwana et al., 1990). These systems termed as cognitive tutors offer tutoring in a manner that best suits the learning preference of the learner. It is a program that not only behaves like a human tutor but also follows the rules and instructions based on the progress and behavior of the learner.

ITS is an intelligent computer system which solves the learner's problems by bestowing feedback and hints. It traces the learner's activity, assesses the learner's mastery on subject matter and seeks to understand the learner's psychological mind. Cognizing psychological mind of learner makes a tutoring system an "intelligent" tutoring system because it solves the learner issues and offers the tutoring content in a manner that learner can grasp easily and effectively. An ITS is distinctly different from a typical e-learning system, such as a web-based learning system, that facilitates a learner to explore a specific domain or course contents via internet. Like ITS, these systems do not adapt to the learner's learning needs and also do not offer learner-specific feedback and hints. ITS being adaptive in nature, has gained immense popularity in current times.

Now-a-days, adaptation and personalization are two important aspects of computer aided instruction systems. On web-based education systems, study material resources are available, but with their overloading and accessibility issues. Hence, it is difficult for a learner to achieve his/her learning goals in cyberspace. In an education system, categorization of learning material and related activities, to present to learner, in learner exclusive manner, targeted to achieve learning objectives, is termed as learning path. This learning path may vary from person to person depending of his/her profile. This is aimed to offer individualistic learning experience to each learner. This is because each individual imbibes knowledge at different speed. The knowledge of a particular learner may grow quite fast and for others the time taken may vary greatly. The response of an individual to learning material too, may be different. A given page may be difficult to understand for a beginner learner and be unimportant and dull for an advanced leaner (Gutiérrez, & Pardo, 2007).

BACKGROUND AND PRELIMINARIES

Very limited work is reported in learner path sequencing in intelligent tutoring systems. However, a reasonably sizable work on curriculum sequencing is reported in e-Learning systems, web-based hypermedia systems and Learning Management Systems. But our systematic review reveals that the ITS systems have remained unexplored in this context so far. Till now, the organization of learning material in intelligent tutoring system, is commonly based on heuristic rules, i.e. during construction of domain, programmer defines rules for all possible situations. This means that initially all learners are provided with same predefined curriculum, but as learners progress, the remedial actions on each activity of the learner are recommended, much the same way like the human tutors do. For example, ITS helps the learner to solve a particular question by providing necessary hints for the question (Brusilovsky, Schwarz, & Weber, 1996, Skinner et al., 1958, Wu et al., 1991).

Some work on curriculum sequencing in ITS is reported below: A depth first traversal algorithm was used in Knowledge-based systems, Hyperbook systems as a sequencing technique (Baldoni, Baroglio, & Patti, 2001).

Chen, (2011) proposed personalized and remedial e-Learning system (PDRLS), providing learning path for specific learners on the basis of their previous knowledge about the course. Firstly, experts describe the relationship among the concepts. Learner pretest plays a vital role in the identification of

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

learning path. For identifying learner previous knowledge structure, they used pathfinder network algorithm, which takes outcomes of pretest as input. At last they compare knowledge structures and generate the appropriate learning path.

Concept map is a way of organizing knowledge in form of courses, topics and subtopics, represented as squares, circles and connection between them indicating the degree of relativeness or relation. The idea of concept map is proposed by (Novak, & Cañas, 2008) on meaningful theory of Ausubel.

Xie, Zou, Wang, Wong, Rao, & Wang, (2017) proposed a technique, to resolve issue related to finding suitable learning path for a group of learners. Profile based framework was proposed for determining their learning path by considering various parameters (temporal boundaries and prototype based aggregation) related to learning.

Further, new approach using data mining techniques has also been explored. With the objective to discover new and meaningful knowledge data mining techniques such as prediction, association, classification have been used. Such systems monitor learner web usage as they navigate through the web pages. Hsieh, & Wang, (2010) proposed web-based learning system that works in two important steps. First is learning path recommendation and second, learning path construction. First, the system generates an initial learner course using data mining technique based on an apriori algorithm. Later learning path is constructed using formal concept analysis that determines the relationship between the course concepts and generates appropriate learning path.

Techniques like fuzzy rule matching have been used to discover association between learner's requirements and list of course materials based on web navigation pattern (Li, & Huang, 2006).

Another Karampiperis, & Sampson, (2004) experimentation has been use of the concept of ontologies and learning object metadata to address the adaptive learning object sequencing problem in intelligent learning management system. They also presented the decision framework for extracting the appropriate learning path according to steps of learner's navigation.

In recent past, nature-inspired and evolutionary algorithms have been used to solve adaptive curriculum sequencing problem. Classification problem of artificial neural network (ANN) Dron et al., (2002) has been used for selection of appropriate learning object.

Chen (2008) proposed a genetic based learning path sequencing method for generating learner tailored learning path. They used level of difficulty as well as concept relation degree parameters for the fitness functions.

Another approach was use of genetic algorithms in e-learning systems. Their proposed methodology is based on a pre-test, to collect incorrect learning concept of learners, then GA is employed to construct a near optimal learning path according to incorrect response patterns of pre-test.

Ant Colony Optimization (ACO), a bio-inspired artificial intelligence technique has also gained attention. The first ant system was proposed by Seridi, Sari, Khadir, & Sellami, (2006) and was successfully applied in solving traveling salesman problem. The optimization of learning path in educational hypermedia system is done in such a way that the structure of the learning material is represented by a graph with valued arcs whose weights are optimized by virtual ants (learners) that release virtual pheromones along their path. In Hong, Chen, Chang, & Chen, (2007) the adaptation of the learning path is done towards student's learning style and optimized using Ant's Algorithm. Bonabeau, Dorigo, & Theraulaz, (1999) introduced an approach to recommending the sequence of e-learning modules for distance learners based on self-organization theory. The architecture they named as 'educational wayfinding support' that supports the recording, processing and presentation of collective behavior designed to create a feedback loop, guiding learners on successful path towards learning goals based on ant-algorithm. Similar techniques

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

can be applied using a probabilistic graph where nodes are pedagogical items, arcs are hypertext links with their associated probabilities and students play the role of ants that traverse the graph (Dron et al., 2002, Weber, & Specht, 1997, Brusilovsky, Ritter, & Schwarz, 1997). Paraschool (Dahbi, Elkamoun, & Berraissoul, (2006), Van den Berg, Van Es, Tattersall, Janssen, Manderveld, Brouns, & Koper, (2005) applied the ACO heuristics to pedagogic material navigation problem, and Valigiani, Biojout, Jamont, Lutton, & Collet, (2005) experimented with an "ant-hill" method which laid the pheromone depending on how students validated an item (success or failure), so as to optimize learning path with different students that have different views. Style-based ant colony system (SACS) by Semet, Lutton, & Collet, (2003), Wang, Wang, & Huang, (2008) is based on group learning pattern and employed an extended ant-colony system approach. It is proposed to construct a user model for finding suitable learning path from graph-based path structure for solving most global optimal problem.

Sengupta, Sahu, & Dasgupta, (2012) also proposed an ant colony optimization approach to achieve adaptivity in sequencing of learning concept. In order to determine the relation among the concept they utilize the frequent graph pattern.

Kardan, Ebrahim, & Imani, (2014) proposed two stage robust learning path algorithm termed as ACO Map. In first stage, they determine the knowledge level of the learner based on the outcomes of pretest, in the second stage, they utilize the metaheuristic method, i.e. ant colony optimization, to generate a learning path which best suits the learner profile.

In ELM-ART ITS (Brusilovsky, Schwarz, & Weber, 1996) provides adaptive hypermedia and path sequencing which help learner to navigate through the learning material. The course content of this ITS is hosted on internet in hypertext form. It comprises of two main components: reference manual and textbook. Textbook has tree like hierarchical structure, which contains topics, subtopics, and related contents, while manual is available for reference to course content. ELM-ART provides navigation support through two hypermedia techniques, adaptive annotation and adaptive sorting. In adaptive annotation, visual artifacts like colors, icons of font are used to represent links, and in adaptive sorting, similarity between links is computed and most relevant links are presented first. The negative side of their proposed technique is that learner gets lost in this complex hyperspace.

In view of positive influence of intelligent and adaptive techniques in education systems, research teams have experimented with intelligent features in intelligent tutoring systems. One of the initial features explored in these systems is use of sequencing technologies (question sequencing, page sequencing, and curriculum sequencing, etc.). Subsequent features to follow are adaptive problem-solving support, navigation support, etc. Literature study reveals, intelligent technologies have been in experimentation and research since long. Presented below is a systematic cataloging of prevalent systems. Table 1 shows the integration of features of adaptive hypermedia and intelligent tutoring in web based tutoring systems. Table 2 elaborates web-based hypermedia systems that incorporate intelligent techniques. Table 3 illustrates web-based intelligent tutoring systems.

PROPOSED ARCHITECTURE AND METHODOLOGY

This section elaborates the work flow of proposed curriculum sequencing module built in Seis-Tutor intelligent tutoring system. Curriculum planning and its sequencing as per learner's learning style and level, are an easy and natural process exhibited by a human tutor. Planning and sequencing course content dynamically is one of the cognitive intelligences, exhibited by a human. To mimic this cognitive intel-

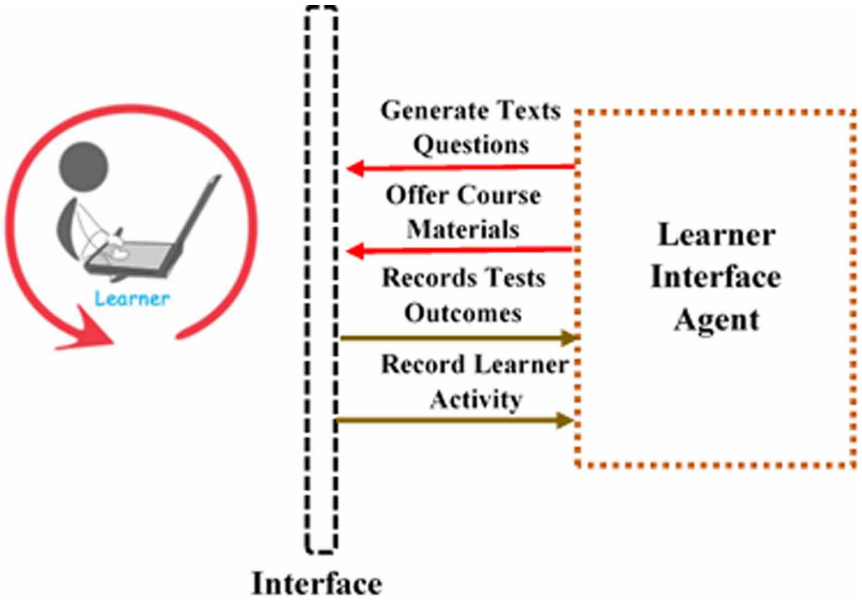
ligence of human by machine, is one of key research aspects discussed here. The proposed architecture of curriculum planning and sequencing module of SeisTutor in intelligent tutoring system has been described below.

Curriculum sequencing using evolutionary techniques has been proposed to make the tutoring adaptive to the learner. To better detail the functionality of Seis-Tutor, this part of the system is termed as 'Tutoring Engine'. The architecture of tutoring engine showing three agents and three databases is presented in Figure 1. The three agents are 'learner interface agent,' 'retrieval agent' and 'learning concept recommendation agent'. The three databases are 'learner account database,' 'learner performance database' and 'domain knowledge database'. The sub-components that carry out the actions within tutoring engine are the 'learner interface agent,' 'learning course generator,' 'retrieval of learning concept' and 'learning concept recommendation agent.'

Learner Interface Agent

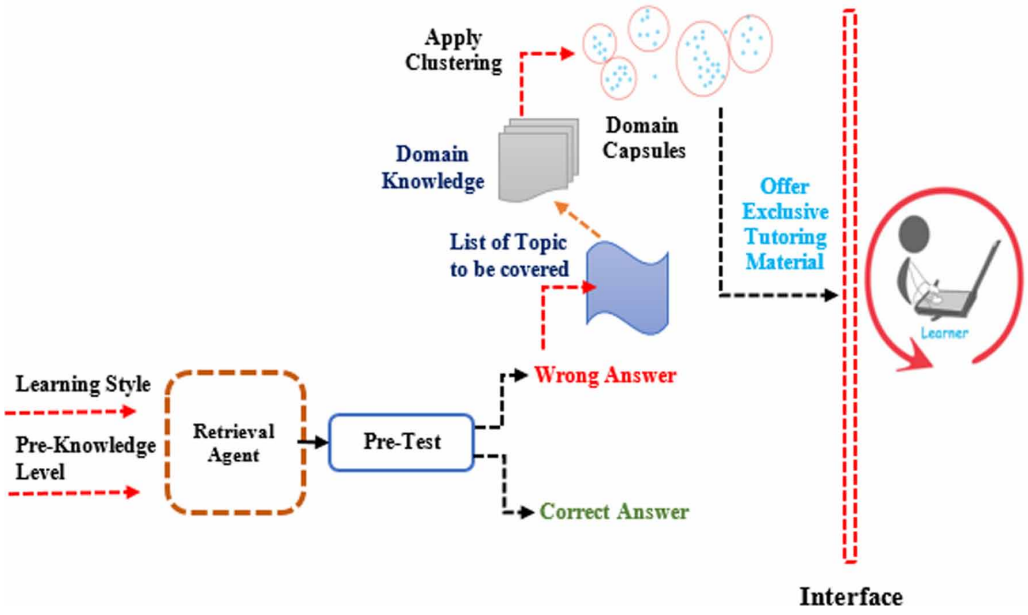


The objective of learner interface agent is to offer an adaptable learning interface to the learner to interact with the intelligent tutoring system. The aim of pretest module is to generate the test items that help the tutoring system to adjudge pre-knowledge level and learning preferences of the individual learner. It then allots a level and learning style to the learner. These are provided to learning course generator, which generates an exclusive tutoring strategy for the learner that is expressed or represented as exclusive learning path implemented through one of the soft computing techniques (see Figure 2).

Figure 1. Curriculum Sequencing architecture in Seis-Tutor

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. Learner Interface Agent work flow in Seis-Tutor



Retrieval Agent

After the identification of exclusive tutoring strategy, retrieval agent triggers its actions, i.e. it applies clustering technique on domain knowledge. The purpose of clustering technique is classification of the pool of course contents into clusters, each represented by a combination of pre-knowledge level and learning style, the repository so formed are termed as learner concept repository. The possible media formats for course content are presentation, document and video. Clustering these media has been implemented through K-Mean, hashing and unsupervised clustering technique. Based on the incorrect responses in the pretest, an appropriate curriculum sequence is determined. Curriculum sequence is represented in the form of a learning path. Retrieval agent examines responses of the learner and based on analyzed learner problems, through the ongoing learning process, Seis-Tutor determines appropriate learning path. Assuming the test comprises of one question each from each subtopic, and the response of the learner indicates that he/she has got some questions wrong, then his/her exclusive learning path will essentially comprise of those subtopics and in required detail, rather than those sub-topics, whose questions are answered correctly. An implementation has been built using, rule-based mechanism with production rules. Using these, exclusive learning path for a learner is chosen from a pool of available learning paths. Topics, sub-topics and related course content along with their association as defined by domain experts is maintained as part of the domain module of Seis-Tutor. Retrieval agent selects topics, subtopics, and course content from the learning concept repository and populates the learning path. Then the learning path is displayed through learner interface (see Figure 3).

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 3. Retrieval Agent work flow in Seis-Tutor

Learning Concept Recommendation Agent

The learning concept recommendation agent guides the learning process of the learner. It records the learning progress and performance data into the Learner Account Database (see Figure 4).

Flow of Control of Tutoring Engine

The section below presents the working of the tutoring engine. Firstly, the learner logs into the Seis-Tutor through learner interface, assisted by the learner interface agent. The learner interface agent authorizes, by checking for existence of learner profile in learner account database. If the learner is already registered, the agent loads the profile from learner account database and assists the learner to proceed with unfinished tutoring session, else considers learner as new to the system and administers pretest. The questions for pretest are taken from the pool maintained in learner performance database.

The pretest is made available to the learner through learner interface. The learner interface agent hands over the outcomes of pretest to the pretest module. The pretest module examines the pretest results, determines the pre-knowledge level and learning style of the individual learner and conveys to learner course generator. The learner course generator generates course

sequence based on adjudged pre-knowledge level and learning style of the learner. The exclusive learning strategy manifested as course (curriculum) sequence has been implemented using fuzzy soft computing techniques. This then is handed over for execution to the retrieval agent. Thus, an exclusive learning strategy is progressed for the learner and performance during ongoing tutoring is recorded. Accordingly, the learning path may undergo modification in real time, with an aim to provide best and exclusive learning experience (see Figure 5).

Table 4. Nomenclature

Symbol	Definition
T	Set of topics to be covered
Q	Set of questions asked in Pretest.
$Q_{Correct}$	Correct response
Q_{wrong}	Incorrect response
Topic	Topic to be covered
t_1	Introduction
t_2	Seismic Waves and their Types
t_3	Reflection Seismology
t_4	Source and Receivers
t_5	Analog and Digital recording
t_6	Seismic Interpretation Methods
t_7	Faults in Petroleum Provinces
t_8	Stress & Strain
t_9	Seismic Expression of Faults
t_{10}	Interpretation of Fault data and 3-D data
t_{11}	Velocity Interpretation
t_{12}	Hydrocarbon Indicators and Modeling

Mathematical Justification of Proposed Architecture for Curriculum Sequencing

See Table 4 for Nomenclature.

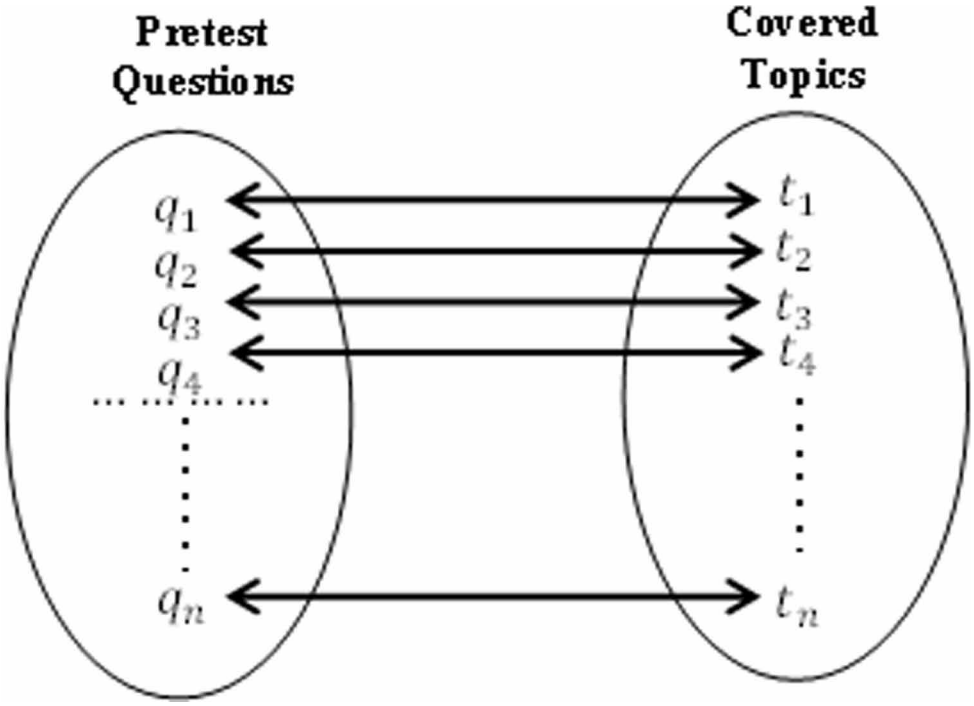
Let us consider T as the set of topics to be covered in the tutoring session.

$$T = \{t_1, t_2, t_3, \ldots\ldots, t_{12}\} \tag{1}$$

Let us consider Q is the set of questions asked in Pre-Knowledge level test (Pretest).

$$Q = \{q_1, q_2, q_3, \ldots\ldots, q_{12}\} \tag{2}$$

Then,



$$Q \in T \tag{3}$$

Equation (3) indicates that each question that was presented by the SeisTutor corresponds to the list of topics that were listed and detailed to be covered.

Note: The relation between questions and topics can be one-to-one and many-to-one, but just for the ease of representation one-to-one mapping has been presented in Figure 6.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 6. One-to-one mapping state

Let us consider $Q_{correct}$ as the set of questions answered correctly by the learner and Q_{wrong}, is the set of questions answered incorrectly.

$$Q_{correct} = \{c_1, c_2, c_3, \ldots\ldots, c_{12}\} \tag{4}$$

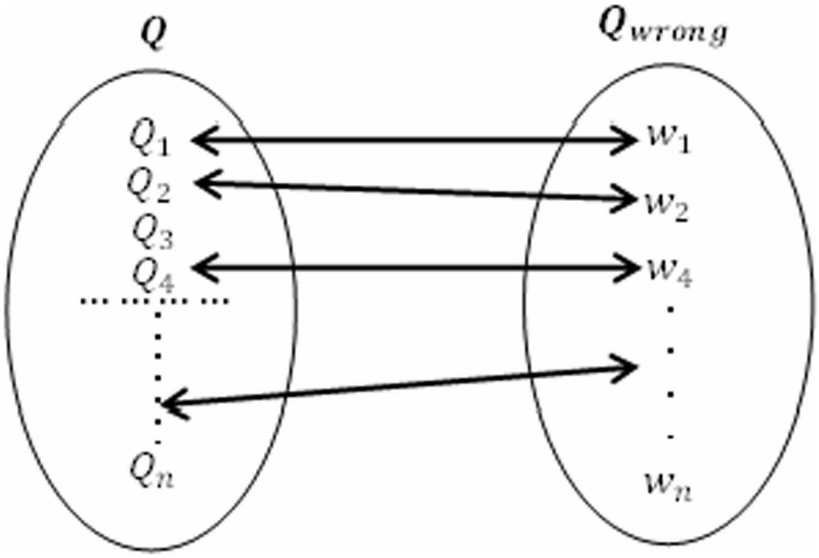
$$Q_{wrong} = \{w_1, w_2, w_3, \ldots\ldots, w_{12}\} \tag{5}$$

Let us consider learner gives correct responses to (Q) 20% of questions.

$$\text{As } Q_{correct} \in Q \text{ and } Q_{correct} \subseteq Q \tag{6}$$

$$Q_{correct} = \{c_3, c_6, c_{10}\} \tag{7}$$

Then 80% of questions Q belong to set of incorrect answered questions.



$$Q_{wrong} = (Q - Q_{correct}) \tag{8}$$

i.e.

$$Q_{wrong} = \{w_1, w_2, w_4, w_5, w_7, w_8, w_9, w_{11}, w_{12}\} \tag{9}$$

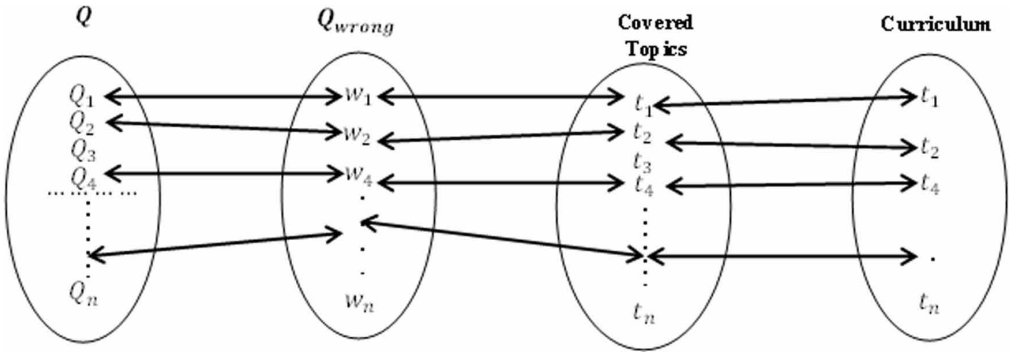
EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 7. One-to-one mapping between Pretest questions and incorrectly answered questions

Similarly, $Q_{wrong} \in Q$ and $Q_{wrong} \subseteq Q$ (10)

As Q_{wrong} Set consists of questions which are incorrectly answered from the question set Q (see Figure 7). Afore mentioned in equation (3) that $Q \in T$.

Thus, by following transitivity law of algebra, i.e. if Set $A \in B$, and Set $B \in C$, then $A \in C$ or $A \in B \in C$.



Thus, $Q_{wrong} \in Q \in T$ (11)

$$Topic = \left\{t_1, t_2, t_4, t_5, t_7, t_8, t_9, t_{11}, t_{12}\right\} \tag{12}$$

From equation (11), 12 exclusive curriculum design as developed in SeisTutor is mathematically proved. Same is illustrated by Figure 8.

Presented in Algorithm 1 illustrating step-wise implementation of learner-centric curriculum design based on outcomes of the pre-knowledge level test.

Figure 8. Curriculum designing

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Algorithm 1

Input: Outcomes of Pre-Knowledge level Test
Output: Exclusive curriculum design for the learner

Begin
1. Retrieve the answers opted by the leaner for the given set of questions Q in a variable $RT=\{R_1,R_2,R_3,\ldots\ldots,R_n\}$. Where RT is a set which enclose, learner's responses, Q is the set of asked questions, and $R_1,R_2,R_3,\ldots\ldots,R_n$ are respective learner responses.
2. Matching operation is performed between received results and the master copy of answers, which is stored the database. $MA=\{A_1,A_2,A_3,\ldots\ldots,A_n\}$. Where MA is a set which encloses correct responses and $A_1,A_2,A_3,\ldots\ldots,A_n$ are the respective correct answers.
3. Separate sets of correct responses $Q_{correct}$ and incorrect responses Q_{wrong} were created.
3.1. do
3.2. {
3.3. if($R_i==A_i$)
3.4. {
3.5. $Q_{correct}=Q_i$;
3.6. }
3.7. else
3.8. {
3.9. $Q_{wrong}=Q_i$;
3.10. }
3.11. $i++$;
3.12. } while ($i\leq n$);// where n is the number of questions asked in Pre-Knowledge pretest
4. Step 2 and 3 will repeat for all the response until while condition met.
5. Q_{wrong} Sets are taken into the consideration and perform a mapping operation between the topics covered and Q_{wrong} sets.
5.1. for ($k=1$; $k\leq n$; $k++$)
5.2. {
5.3. for ($l=1$; $l\leq n$; $l++$)
5.4. {
6. if ($Q_{wrong}==W_k==T_l$) // where W is a set which enclose the labels (that directly links to the topics) and $W = \{W_1, W_2, W_3,\ldots\ldots,W_n\}$ are the respective labels associated with the questions.
6.1.
6.2. {
6.3. Topic=T_l;
6.4. }
6.5. else
6.6. {
6.7. continue;
6.8. }
6.9. }
6.10. }.
7. Topic Set consists of the course collection which is exclusively designed for the learner by the SeisTutor.
End

EXPERIMENTAL ANALYSIS AND DISCUSSIONS

Seismic Data Interpretation

Subject matter identified for tutoring in the present work is 'Seismic Data Interpretation,' a sub-field of 'Geophysics'. The primary interest behind petroleum exploration is to uncover the geological substructure opportune for hydrocarbon aggregation. Geologists generally use seismic snaps to portray the earth substructure. Seismic snaps are manually interpreted by the seismologists by utilizing their own skill and expertise. This skill and branch of study is called 'Seismic Data Interpretation'. Due to the absence of formal rules of interpretation, geologists utilize their own experience (established over past years) and skills for interpretation and as a result same seismic image may be interpreted differently by different seismologists (Ahuja, & Diwan, 2012).

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

To provide a fair idea of implementation, case studies has been depicted in Table 5, Table 6 and Table 7.

Case Study 1: Mathematical Justification of Differentiation in Curriculum Design Based on Pre-Knowledge Level

Let us consider three learners identified to gain knowledge learn 'Seismic Data Interpretation' through SeisTutor. After formal registration, learner applicants enter Initial assessment phase. The learner is presented with a brief test administered under two categories, "*Pre-Knowledge test"* which adjudges the learner's profile under one of the three different levels (profiles) "Beginner", "Intermediate" and "Expert", and "*Learning style test*" encompassing specific questions to adjudge the learning style of the learner. It was observed that one applicant was allotted 'Beginner profile,' one of them the 'Intermediate profile' and rest of them the 'Expert profile'. Now as per proposed algorithm for curriculum design these three applicants received exclusive curriculum plans, different from each other.

Figure 9 illustrates the learner profile base differentiation. Figure 9 indicates the discrimination of learner profile based on PreTest score percentage. The learner whose Pretest score is less than or equal to 20% categorized as 'Beginner profile' in a similar manner whose Pretest score is between 20% and 40% categorized as 'Intermediate Profile' and whose Pretest score is between 20% and 60% above (categorized as 'Expert Profile.'

Figure 10 describes the closest relation between correct response and the designed curriculum. As beginner provided correct response for only three question thus the designed curriculum comprises additional topics whereas an expert applicant provide correct response to seven questions, thus the designed curriculum comprises less number of topics.

Case Study 2: Mathematical Justification of Differentiation in Curriculum Design Within Similar Pre-Knowledge Level

Let us consider three learners identified to gain knowledge on 'Seismic Data Interpretation' domain via SeisTutor. After formal registration, learner applicants enter Initial assessment phase. The learner is presented with a brief test administered under two categories, "Pre-Knowledge test" which adjudges the

Table 5. Case Study 1

Beginner	Intermediate	Expert
--) Assuming Pretest score of learner to be 20% (categorized as 'Beginner') by Equation (3) --) $\boldsymbol{Q_{correct}}$=$\{c_2, c_6, c_9\}$ by Equation (4) --)$\boldsymbol{Q_{wrong}}$=$\{w_1, w_3, w_4, w_5, w_7, w_8, w_{10}, w_{11}, w_{12}\}$ by Equation (12) --) ***Topic***= $\{t_1, t_3, t_4, t_5, t_7, t_8, t_{10}, t_{11}, t_{12}\}$	--) Assuming Pretest score of learner to be between 20% and 40% (categorized as 'Intermediate') **by Equation (3)** --) $Q_{correct}$=$\{c_6, c_5, c_9, c_{12}, c_7\}$ **by Equation (4)** --) Q_{wrong}=$\{w_1, w_2, w_4, w_6, w_{10}, w_8, w_{11}\}$ **by Equation (12)** --) *Topic*= $\{t_1, t_2, t_4, t_6, t_{10}, t_8, t_{11}\}$	--) Assuming Pretest score of learner to be between 20% and 60% (categorized as 'Expert') **by Equation (3)** --) $Q_{correct}$=$\{c_1, c_2, c_3, c_9, c_{12}, c_7, c_{10}\}$ **by Equation (4)** --) Q_{wrong}=$\{w_3, w_5, w_6, w_8, w_{11}\}$ **by Equation (12)** --) *Topic*= $\{t_3, t_5, t_6, t_8, t_{11}\}$ It can be observed that the curriculum plan for the 'Beginner' is $\{t_1, t_3, t_4, t_5, t_7, t_8, t_{10}, t_{11}, t_{12}\}$, whereas that by 'Expert' is $\{t_3, t_5, t_6, t_8, t_{11}\}$

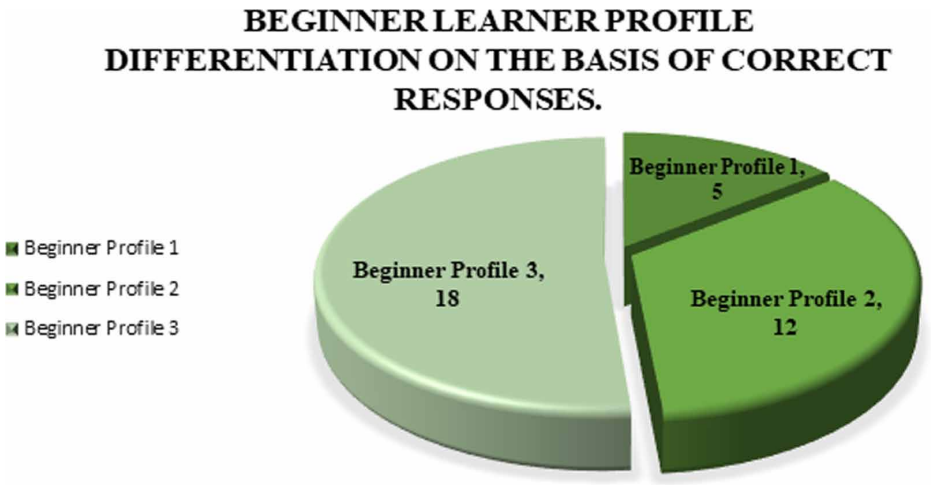
Table 6. Case Study 2

Beginner Profile 1	Beginner Profile 2	Beginner Profile 3
--) Assuming Pretest score of learner to be 5% (categorized as 'Beginner') by equation (3) --) $\boldsymbol{Q_{correct}}=\{c_2\}$. by equation (4) --) $\boldsymbol{Q_{wrong}}=\{w_1, w_3, w_4, w_5, w_6, w_7, w_8, w_9, w_{10}, w_{11}, w_{12}\}$. by equation (12) --) ***Topic***$= \{t_1, t_3, t_4, t_5, t_6, t_7, t_8, t_9, t_{10}, t_{11}, t_{12}\}$.	--) Assuming Pretest score of learner to be between 1% and 12% (categorized as 'Beginner') **by equation (3)** --) $Q_{correct}=\{c_3, c_5\}$. **by equation (4)** --) $Q_{wrong}=\{w_1, w_2, w_4, w_6, w_7, w_8, w_9, w_{10}, w_{11}, w_{12}\}$. **by equation (12)** **--)** $Topic= \{t_1, t_2, t_4, t_6, t_7, t_8, t_9, t_{10}, t_{11}, t_{12}\}$.	--) Assuming Pretest score of learner to be between 1% and 18% (categorized as 'Beginner') **by equation (3)** --) $Q_{correct}=\{c_4, c_9, c_{12}\}$. **by equation (4)** --) $Q_{wrong}=\{w_1, w_2, w_3, w_5, w_6, w_7, w_8, w_{10}, w_{11}\}$. **by equation (12)** --) $Topic= \{t_1, t_2, t_3, t_5, t_6, t_7, t_8, t_{10}, t_{11}\}$

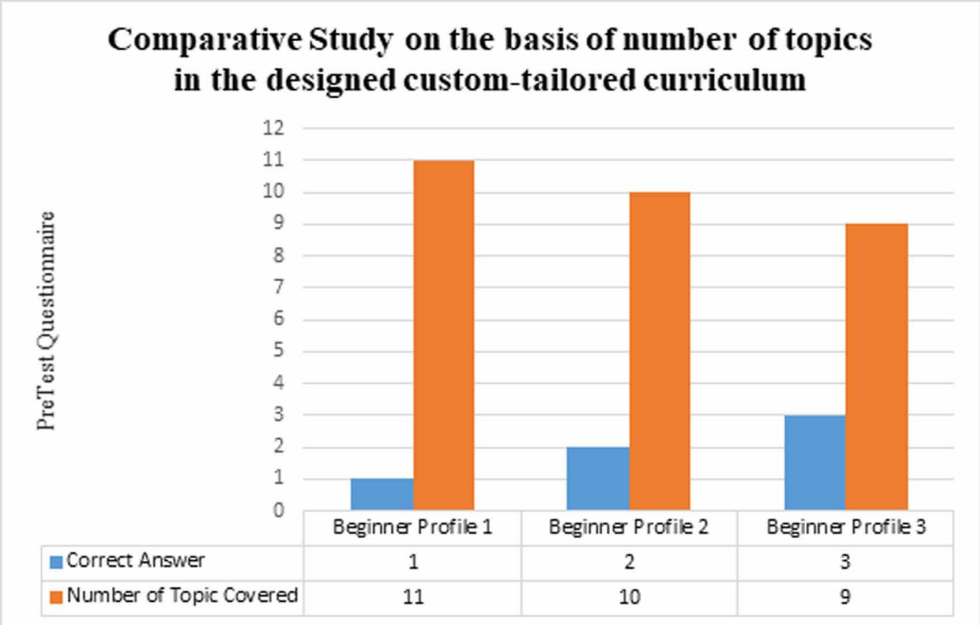
in Table 6, that each '*Beginner*' is offered exclusive curriculum different from each other. Now as per proposed algorithm for curriculum design these three applicants received exclusive curriculum plans, which are different from each other.



It can be observed that the applicants who belong to similar profiles have been offered distinct curriculum plan. Afore mentioned case study 2 illustrates the learner-centric curriculum plans for different learners of 'Beginner' profile.

Figure 11 illustrates the Beginner learner profile base differentiation. Figure 11 indicates the differentiation of Beginner learner profile based on PreTest score percentage. Here all the applicants belong to beginner profile, hence categorization is performed based on Pretest score. Beginner profile 1 learner Pretest score is 5%, Beginner profile 2 learner Pretest score is 12% and Beginner profile 3 learner Pretest score is 18%.

Figure 12 illustrates designed curriculum is custom-tailored within same level of learner.



As beginner profile 1 answered only one question thus the designed curriculum comprises more number of topics in a similar manner beginner profile 3 applicant answered three questions thus the designed curriculum comprises less number of topics compared to beginner profile 1.

Figure 11. Beginner learner profile discrimination

Figure 12. Compatitive study on designed Curriculum

Case Study 3: Mathematical Justification of Curriculum Design for Learner-Cold Start

Let us consider learners identified to gain knowledge on 'Seismic Data Interpretation' domain using SeisTutor. After formal registration, learner applicants enter Initial assessment phase. The learner is presented with a brief test administered under two categories, "Pre-Knowledge test" which adjudges the learner's profile as one of the three different levels (profiles) "Beginner", "Intermediate" and "Expert", and "Learning style test" encompassing specific questions to adjudge the learning style of the learner.

Considering that the applicant has no prior knowledge related to seismic data interpretation, therefore as a result in "Pre-Knowledge test," he or she may not be able to provide a single correct response and be "Beginner" profile. Now, as per the proposed algorithm for curriculum design each applicant receives exclusive curriculum plan, which is different from each other. But in this case, it is very difficult to recommend custom-tailored curriculum. This condition is widely named as "Cold Start Problem."

It can be observed that when the applicants are cold start learners then SeisTutor offers a default curriculum plan.

Research shows that learners follow a variety of mechanisms for gathering and delineating information. Further they have different preferences to understand and process information. These preferences are termed as 'learning styles'. Systematic review of literature reveals that, if learner preferences are pre-identified, then teaching and learning can be provided in a manner that learner learns more effectively. The effectiveness of an ITS depends upon generation of tutoring strategy (A combination of a learner level and a learning style represents a tutoring strategy) by the pedagogy model.

Curriculum sequencing is very vital in ITS, as well as in the classroom, due to its systematic approach, which is congenial to learning. Moreover curriculum sequencing, maps appropriate to a course

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 7. Case Study 3

Beginner Profile
Now, as per the proposed algorithm for curriculum design, these applicants receive default curriculum, because of poor performance in *Pre-Knowledge test"* . The curriculum recommendation system works on bugs found in the PreTest. As aforementioned in Equation (3) that each question that was presented by the SeisTutor corresponds to the list of topics that were listed and detailed to be covered. --) Assuming Pretest score of learner to be 0 (categorized as 'Beginner') by equation (3) --) $\boldsymbol{Q}_{correct}=\{NILL\}$ by equation (4) --) $\boldsymbol{Q}_{wrong}=\{w_1, w_2, w_3, w_4, w_5, w_6, w_7, w_8, w_9, w_{10}, w_{11}, w_{12}\}$ by equation (12) --) $\boldsymbol{Topic}= \{t_1, t_2, t_3, t_4, t_5, t_6, t_7, t_8, t_9, t_{10}, t_{11}, t_{12}\}$

outline, to be covered. As in classroom teaching, a tutor is expected to provide learning for all learners irrespective of their individual knowledge levels, or learning preferences, hence, a generalized course delivery plan is developed and put into practice. The major drawback of this mechanism is that the teacher is not familiar with the pre-knowledge level, thus he or she is able to bring only very limited variation a teaching style. Whereas, in ITS the aim is to overcome this drawback, to a great extent. Till date, the focus on ITS research, has been majorly on tutoring a learner, as per his/her learning preference, but very limited attention, has been paid on curriculum sequencing, which is the design of an exclusive learning path for that particular learner. Every learner before being admitted to a course holds some knowledge about the domain. Thus, there is a need to predetermine the knowledge level of the learner and based on that, sequence the learning material for the learner, by choosing items from the pool of courseware. The research shows that if the courses are tutored as per the learner pre-knowledge level and preferences, the overall learning gain and degree of engagement of the learner with ITS, are enhanced.

CONCLUSION

Architecture of curriculum sequencing module of adaptive intelligent tutoring system Seis-Tutor, developed for this purpose has been detailed. A human tutor very naturally uses cognitive intelligence to provide learner with appropriate course content, offered through a customized learning path. This ability has been built into Seis-Tutor and it generates an exclusive learning path for the learner. The aim of the exercise is to provide best learning experience and significant learning gain for the learner, comparable to ideal 'face-to-face human tutor learner' classroom interaction.

Chapter 36
Designing a Socially Open Narrative Generation System

Taisuke Akimoto
The University of Electro-Communications, Japan

Takashi Ogata
Iwate Prefectural University, Japan

ABSTRACT

The authors propose the design of a Socially Open Narrative Generation System (SONGS) that co-creates a collection of diverse narratives from a narrative generation program and people. This is a challenge of the social application of narrative generation technology used for vitalizing the social activity of producing and sharing narratives. The key idea is to connect and unify individual narrative productions by many agents, including a computer program and many humans, via a collection of narratives produced and accumulated by these agents. At the same time, SONGS is the practice of a computational approach to narratology as a model for the social process of narrative production. This chapter describes the key concepts and mechanism design of SONGS with several experimental programs.

INTRODUCTION

Narrative is a universal form of human knowledge and memory, and a strong way for people to communicate knowledge and information in their society. The computational modeling for narrative generation and understanding is a key topic for the next information society. Such modeling will contribute to the creation of human-friendly information technology and culture development. The fundamental interest of this study is to explore the possibilities of the social application of narrative generation technologies.

This chapter proposes the design of a Socially Open Narrative Generation System (SONGS) that will run on the Web as a space for co-creating a collection of diverse narratives from a narrative generation program and many humans. The ultimate goal of this study is to vitalize the social activity of producing and sharing narratives. Its long-term vision includes, in particular, the creation of a new type of platform

for expanding and supporting creative activity and a content industry with computational narrative creativity. At the same time, SONGS is the practice of a computational approach to narratology as a model for the social narrative production process.

The remaining part is organized as follows. First, the authors provide background information on intelligent information technologies for narrative. Second, the authors propose the basic design of SONGS. Third, in the subsequent two sections, the authors describe the two main components of the narrative generation and interface parts. Finally, the authors discuss future works and conclude the chapter.

BACKGROUND

This section takes two perspectives for providing background information. The first subsection reviews the history of the studies on narrative generation systems. For further information in this area, refer to the "Introduction" chapter of this book by Ogata or other surveys, such as Gervás (2009). The second subsection discusses the significance of narrative and narrativity for artificial intelligence (AI) and informatics.

Narrative Generation System

Narrative generation systems, or the computational modeling of narrative creativity, are a challenging AI topic. The fundamental objectives include the computer implementation of narrative creativity and elucidation of the human narrative ability or narrative nature. In the early stage, since approximately 1970s to 1990s, researchers attempted to apply AI methods to narrative generation models. These studies are broadly divided into three approaches. First, several researchers attempted to model the story generation process as the planning of character actions directed by goals, emotions, or other bases (Meehan, 1980; Okada & Endo, 1992; Riedl & Young, 2010). Second, the formulation of generative rules or schemes for narrative structures were addressed (Pemberton, 1989; Lang, 1999; Bringsjord & Ferrucci, 1999). These are mainly rooted in a cognitive model of the story scheme (Rumelhart, 1975). The third approach was derived from the framework of case-based reasoning (CBR) (Riesbeck & Schank, 1989). In this approach, narrative generation is formalized as the transformation or adaptation of a previous narrative or case to fit the current problem (Turner, 1994; Peinado & Gervás, 2005; Swanson & Gordon, 2012).

Since approximately 2000s, several researchers have introduced narratology—the theory of narrative mainly inspired by structuralism—to narrative generation studies. Ogata (2002, 2004a) proposed a research methodology called "expanded literary theory" that aims to create synergy between narrative generation technologies and narratology. Gervás, Lönneker-Rodman, Meister, and Peinado (2006) also discussed the importance of interdisciplinary approaches for both disciplines of AI and narratology. In this movement, the morphology of the folktale by Propp (1968) has been applied to several studies as a model or schematic knowledge of story composition (Ogata & Terano, 1991; Peinado & Gervás, 2005; Imabuchi & Ogata, 2012; Gervás, 2015). In addition, narratology provided a distinction between story—"[t]he [content] plane of [narrative]" (Prince, 2003, p. 93)—and discourse—"[t]he [expression] plane of [narrative]" (Prince, 2003, p. 21)—to narrative generation studies. Whereas most of the early systems focus primarily on the story aspect, several recent studies have applied the narrative discourse theory by Genette (1980) to the modeling of narrative discourse composition (Ogata, 2004b; Montfort, 2007; Bae, Cheong, & Young, 2011; Akimoto & Ogata, 2012, 2013).

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

For the past few years, Ogata and colleagues have been developing an integrated narrative generation system (INGS) where the three generative modules for story structure, discourse structure, and surface expression are connected (refer to the "Introduction" chapter by Ogata for further information). This includes three narratology-based mechanisms that apply the theories of Propp (1968), Genette (1980), and Jauss (1982) as central elements for the story and discourse generation (Akimoto & Ogata, 2014). Although INGS is in an ongoing process of the research project, this systematic framework provides a solid foundation for the narrative generation mechanism of SONGS.

Meanwhile, narrative generation studies have great application potential for advanced information technologies, but this is almost unexplored. A possibility is to expand the creative activities of people or society. Narrative or narrativity is a common and core element of various artistic or entertainment works, such as novels, film, drama, manga (comic), anime (animation), video games, and commercial films. Narrative generation technologies can create new forms of expression and a creation method for the narrative. Interactive narrative systems are already a major genre of narrative content that uses computer technologies (Riedl & Bulitko, 2013), but this is based only on a semi-automatic narrative generation, and most content is designed by the human creators. Because of technological difficulties, there are very few applied studies on fully automatic narrative generation. However, the authors propose two exploratory applied narrative generation systems: "KOSERUBE," which automatically generates multimedia narrative expressions in the style of a folk tale (Akimoto et al., 2013), and "Narrative Forest," which figuratively expresses the floating narrative generation process within the system using the image of growing trees (Akimoto, Ono, & Ogata, 2013).

Narrative as Information, Knowledge, and Intelligence

Narrativity is a fundamental nature of the human mind that forms memory or knowledge. From the psychological perspective, Bruner (1991) discussed that the human experience and cognition of the real world is based on narrativity and is formed as narratives. In addition, a narrative contextually integrates a variety of things or knowledge and effectively provides rich information to people. From such nature, narratives provide different values to people and society. People tell and receive narratives in various scenes of daily life. Narrative is commonly involved in various genres of art and entertainment. People develop knowledge or cultural literacy and cultivate sensitivity through the accumulation of such artistic experiences. Narrative is an effective and versatile communication tool for various business fields. Quesenbery and Brooks (2010) described practical methods of storytelling for improving the design processes of services or artifacts. Information technology has great potential to expand human activities in a broad range of fields.

Meanwhile, narrative is an essential research subject for the computational implementation of intelligence, a common goal of AI. Schank and colleagues have addressed the story nature of human intelligence and proposed several key AI frameworks, including Conceptual Dependency, script, plan, goal, and CBR (Schank & Abelson, 1977; Riesbeck & Schank, 1989; Schank, 1990). These ideas have significant influence on narrative generation studies.

Several researchers have addressed the construction of large-scale commonsensical knowledge bases mainly based on the concept of script. Singh, Barry, and Liu (2004) designed StoryNet as a database of scripts constructed through crowdsourcing. Chambers and Jurafsky (2010) presented a database of narrative schemas that consists of the semantic knowledge of events and their temporal relationships. This was constructed with their knowledge acquisition algorithms for learning narrative schemas from

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

texts (Chambers, Wang, & Jurafsky, 2007; Chambers & Jurafsky, 2008, 2009). This type of knowledge is applicable to various tasks of natural language processing, such as understanding and summarization, and also provides a basic knowledge for narrative generation. McIntyre and Lapata (2009) and Li, Lee-Urban, Appling, and Riedl (2012) proposed a story generation method based on script similar to chains of events. The case base in the CBR-based narrative generator is also narratives.

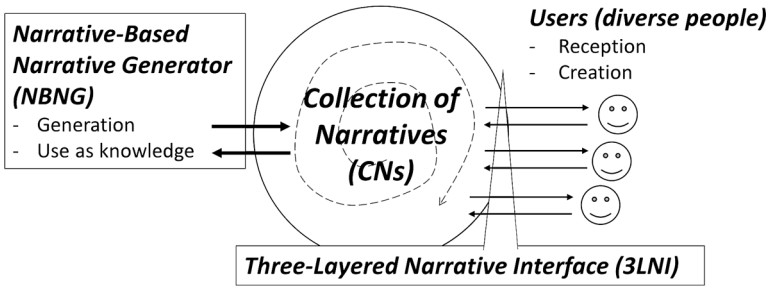
Another important research topic is to explore how narrative-based knowledge works in a cognitive system. Although CBR provides a reasonable model, in recent years, several researchers have addressed modeling narrative-centered cognitive architecture and knowledge systems (Szilas, 2015; Anderson, 2015). From the perspective of cognitive systems, a role of narrative creativity is to construct internal narratives as knowledge or episodic memory from external information.

Similar to the topics discussed above, narrative computational modeling is a crucial problem for future intelligent information technology. First, it will expand the creation and sharing of narratives in society. Second, it is necessary for true intelligent systems that construct knowledge through interaction with the real world, subjectively cognize things, create new narratives or knowledge, and effectively communicate with others.

BASIC DESIGN OF SONGS

Figure 1 shows the overall structure of SONGS, which co-creates a collection of narratives (CNs) through the continual interaction of produced narratives from a narrative generation program and many human users. The central idea of the narrative generation program is to model narrative generation as a cyclic process for composing new narratives in relation to previously generated narratives. The authors call this narrative-based narrative generator (NBNG). CNs provide NBNG with comprehensive knowledge for composing new narratives. In addition, SONGS involves an interface that opens CNs to individual humans (users). The design for SONGS assumes that users will access CNs based on their values or objectives, and appreciate contained narratives or create new ones by recomposing those that already exist. Moreover, user-created narratives are added to CNs. In order to allow such usage, the interface provides multiple perspectives on CNs, in particular:

1. Collective view on CNs for exploring valuable narratives,
2. Surface view on a narrative for appreciating it, and
3. Internal view on a narrative structure for creating a new narrative by recomposing the structure.



We call the interface that is based on the above framework a three-layered narrative interface (3LNI). The following four subsections describe the key concepts of SONGS.

Narratives as Comprehensive Knowledge for Narrative Generation

Narrative is a type of comprehensive knowledge structure that contains various types of information or knowledge. A narrative can contain a variety of things, including events, humans, objects, abstract concepts, time, space, and so on, within its contextual information or meaning. In addition, the composition of a narrative implicitly includes such abstract or ill-defined information as emotion, sense of value, and aesthetic, which are crucial aspects for generating valuable narratives for people.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. Overall structure of SONGS

By focusing on the above narrative nature, SONGS positions CNs as the central knowledge for producing new narratives. The basic principle of using narratives as generative knowledge is to formalize a narrative generation process as recomposition of an existing narrative through structural operations, such as decomposition, transformation, and synthesizing with other narratives.

The point that SONGS positions individual and concrete narratives as the central knowledge is different from a major approach that generalizes narrative structures as a set of abstract rules or schemes—e.g., schematic methods based on Propp's morphology of the folktale (Ogata & Terano, 1991; Imabuchi & Ogata, 2012; Gervás, 2015). However, such abstract knowledge is essentially acquired empirically and dynamically from many narratives, similar to Propp (1968) deriving his morphological knowledge from the analyses of approximately 100 Russian fairy tales. An essential question is to explore a unified framework of the individuality/concreteness and generality/abstractness of narrative knowledge.

On the other hand, NBNG is partially similar to CBR-based narrative generators. Riesbeck and Schank (1989) described the basic procedure of CBR as "[finding] those cases in memory that solved problems similar to the current problem, and [adapting] the previous solution or solutions to fit the current problem, taking into account any difference between the current and previous situations" (p. 25). CBR-based narrative generators basically follow this procedure. However, NBNG uses CNs in flexible ways as types of materials for composing new narratives. In addition, narrative generation in NBNG is directed not as problem solving, but as the production or exploration of some differences and novelty from prior narratives. This concept is discussed in the next subsection.

Narrative Generation in Relation to Prior Narratives

Because the macroscopic goal of SONGS is to accumulate a wealth of narratives through the continual generation cycle, the microscopic goal in each generation process is to produce a narrative that has some novelty or difference from prior narratives. Namely, the prior narratives are not only material knowledge for narrative generation, but basing points for creating new narratives. CNs have a higher-level structure for organizing the narratives, and by using it, NBNG systematically controls the narrative production.

A relationship among narrative works is a crucial aspect for the process of producing narratives in the real world. Several literary models of relative narrative production have discussed in the field of narratology. In early twentieth century, the movement of Russian formalism discussed a model for the evolution of literature as a continual cycle of "automatization" of human perception and alternation of the immanent laws of a particular genre (Tynyanov, 1982). Jauss (1982) presented a new idea concerning the history of literature. Although he respected the previous research regarding Russian formalism,

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

he criticized the literary theory of evolution as being dependent upon the dynamism of change in narrative techniques and descriptions. He sought to center his literary process model in the dynamism of the mutual relationship between a literary work/author and the readers. His idea involved modeling the literary history of various relationships between a reader's "horizon of expectation" and literary works, including those estrangements and the change of horizon through a continual reception process.

In another context, Kristeva (1980) described the theory of "intertextuality," arguing that a literary text is positioned as an organization and citation of related preceding texts, and also included subsequent works for the reader. There exist few studies that apply the concept of intertextuality to narrative generation methods. Nakashima and Ogata (2006) proposed several experimental programs that generate new stories through elemental substitution or associations of an input story.

Collective Narrative Generation

The co-creation in SONGS refers to the collective creation process as a continual chain reaction of narrative productions among different types of generative agents—i.e., NBNG and the users—via produced narratives or CNs. Narrative generation in SONGS is basically formalized as the recomposition or derivation of prior narratives. Computers where basic principles of narrative generation are programed can systematically produce a large number of different narratives in order to not be tied to commonsensical or stereotyped constraints on narratives. The distinct narrative creativity will bring inspiration or surprising ideas to the users. On the other hand, the cooperation of diverse users is important for both increasing the diversity of narratives and the generation ability of NBNG. How to attract and activate user creation activity is a key issue in designing SONGS.

Meanwhile, because SONGS aims to create new values for people or society, the problem is similar to the one for artifact design. Co-creation is an important approach in designing complex artifacts that involve pluralistic values related to various people (Fujita & Ota, 2015). Internet technology has expanded co-creation by many people. Tanaka (2011) introduced a novel design method called "Design as Re-Design." This refers to the continual upgrading and remixing of existing open data on the Web through "editing, reforming, or deriving" as a type of collective creation.

Collective creation is traditionally embedded in Japanese culture, and it is a distinguishing feature of contemporary subculture in Japan. Information technologies—e.g., online community spaces such as "Nico Nico Douga" (Niwango, n.d.) and "VOCALOID," a technology for singing voice synthesis (Yamaha, n.d.)—are increasing collective creation activity through "N-th order derivative creation" (Hamano, 2008). This activity is building a singular and rich culture. Co-creation is a valid approach for the problem of narrative generation, and SONGS aims to drive such type of activity by the computational narrative creativity.

Providing Diverse Values to Diverse People

The authors broadly categorize types of users as readers, those who appreciate narratives, and authors, those who use SONGS for creating original narratives. For instance, potential uses of SONGS include the following situations: a manga (comic) artist searches/makes primitive materials for his/her work, a commercial planer searches/makes ideas of scenario for advertising a product, an amateur author creates derivative works of computer-generated narratives, and a student learns multiple perspectives on a social issue from different narratives relevant to the issue.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

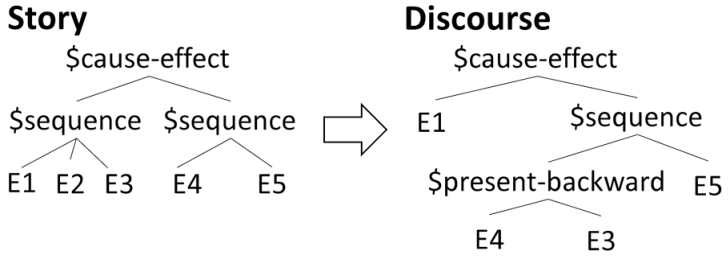
SONGS should provide some type of value to diverse users. The authors assume that narrative values include the following two aspects: giving some type of cognitive effect to readers—e.g., impression, surprise, and knowledge discovery—and giving some type of effect to the author's creation process or the result—e.g., inspiration, augmentation, extension, amplification, constraint, and inducing. In the above sense, narrative values vary depending on various factors, such as individual value, purpose or use situation, and historical or cultural background. Hence, it is difficult to computationally define and control narrative values.

The authors apply the computational design methodology called "Design as Search" introduced by Tanaka (2011) to the above problem. In the methodology, "design" refers to a process where the user searches or explores a preliminary modeled solution space for finding a solution that meets his/her need or purpose. In SONGS, the user searches valuable narratives from CNs. This is an application of the concept of "Design as Search." The system will be useful for individual users when there exist few valuable narratives for them, and they can find them. A central problem is designing an interface that allows the user to find valuable or desired narratives, including cases where the user has no explicit narrative needs. This is a common problem with general information retrieval. Although there is another method as a type of on-demand narrative generation, in many cases, users cannot represent their needs or have no clear narrative needs. In addition, it is difficult task to generate narrative that is suitable to the user's needs.

NBNG: NARRATIVE-BASED NARRATIVE GENERATOR

In designing NBNG, the authors start with by modifying and expanding a Jauss-based narrative discourse generation system proposed by Akimoto and Ogata (2012, 2013). A central idea of the system is to model a generative process of historical or continual literature changes based on the reception theory by Jauss (1982). Although the implemented system has many theoretical problems, the fundamental idea is applicable to NBNG. After an overview of the Jauss-based system, the authors describe the NBNG design.

Narrative Discourse Generation System



This subsection outlines the Jauss-based system based on Akimoto and Ogata (2012, 2013) and discusses the issues from the perspective of SONGS. The system was developed as a prototype version of the discourse generation part of INGS. The system generates a series of different "discourse" structures from an input "story" structure. A story represents the content information of a narrative. In particular, it represents the temporal sequence of events. A discourse means the structural aspect of how a story is expressed. Discourse generation refers to structural transformations from a story structure to a discourse one, and it is modeled based on the narrative discourse theory by Genette (1980). Jauss's theory is applied to the controlling model of continual discourse generation.

Modeling of Discourse Generation Based on Genette's Theory

Both story and discourse are described through the conceptual representation of a tree that consists of "events" and "relations." Figure 2 shows diagrams of story and discourse structures. An event is the basic unit of constituting a story or discourse, whereas a relation semantically combines the child nodes, i.e.,

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. Story and discourse structures

the events or sub-structures. In the figure, events and relations are indicated by "E*" and "$*", respectively. An event is represented with a case structure of verb concept. Figure 3 is an example of event representation. The system includes a simple natural language generator for transforming a conceptual representation to Japanese text. For instance, the event representation in Figure 3 is transformed into the sentence "蛇が皇女を誘拐した" ("a snake abducted a princess").

Structural transformation techniques, or "discourse techniques," are defined by applying the narrative discourse theory by Genette (1980). He categorized various classes of discourse structures through the analysis of a novel. His discourse classes consists of the following three broad categories: "tense," which concerns the relationship between the time of the story and that of the discourse; "mood," which concerns the modality for regulating narrative information; and "voice," which concerns the relationship among narration, story, and discourse. Each category is further divided into subcategories.

Through the computational formalizations of part of Genette's subcategories, the authors implemented the following 13 discourse techniques: "external analepsis," "complementary analepsis_ellipsis," "complementary analepsis_paralipsis," "repetitive analepsis," "external prolepsis," "complementary prolepsis_ellipsis," "complementary prolepsis_paralipsis," "repetitive prolepsis," "achronie," "pause," "implicit ellipsis," "repeating," and "paralipsis." In general terms, they include the following transformation types: temporal ordering of events, adding supplemental events for the story, omitting events, repeating events, and inserting descriptions of characters, objects, or locations. For instance, in the discourse structure of Figure 2, E2 is omitted by "implicit ellipsis" and E3 is reordered by "complementary analepsis_ellipsis."

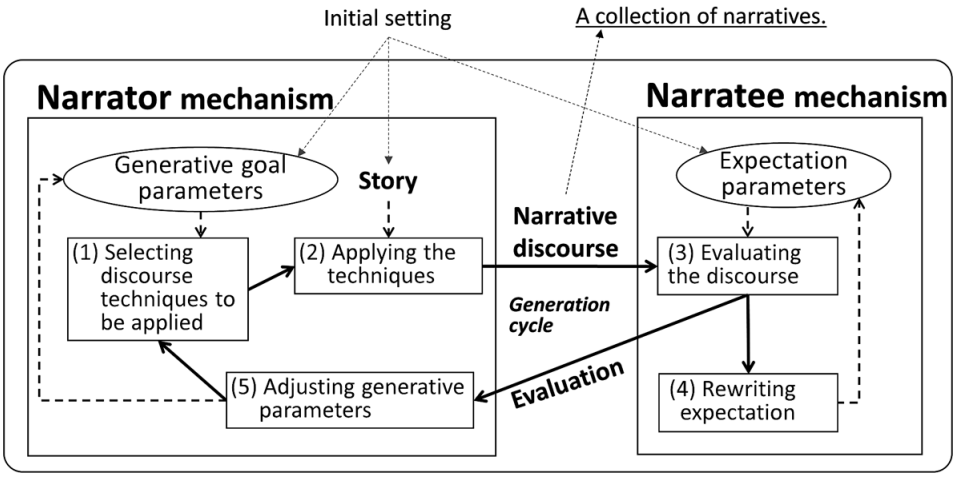
(*from* nil)
(*to* nil))

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

One or more discourse techniques can be used in combination with generating a discourse structure. Different discourse structures are generated depending on the selected techniques and target part—i.e., a node of the tree structure—of each technique. Because each target part is determined randomly with several conditions, output structures by the same combination of techniques have relatively small differences.



Continual Discourse Generation Based on Jauss's Reception Theory

Jauss (1982) developed seven theses for the essence of his reception theory. The authors focus mainly on theses II and III in modeling the continual generation process. Jauss's thesis II describes the "horizon of expectation" as being the reader's preliminary knowledge for ranking a literary work in the context of reading experience, and this can be acquired by known genres and exposure to famous literary works. In thesis III, Jauss proposes that readers understand literary artistic features as the distance between the work and their "horizon of expectation." If the distance is small, the work has strong recreational purpose and a familiar beauty. Those with large distances have various and distinguished influences for the reader: to one reader the work may be highly regarded creative work, but it could be a waste of time to another reader. The horizon can change so that the impression of a work becomes ordinary for a reader.

The authors modeled Jauss's historical view as an iterative mutual action, referred to as "generation cycle," between the two mechanisms of narrative generator, or "narrator," and evaluator, or "narratee." Figure 4 outlines the process flow. In the system, authors and readers in Jauss's theory respectively correspond to the narrator and narratee mechanisms. The notion of "horizon of expectation" is objectivized as the narratee's expectation represented as a set of parameters.

The input consists of a story, initial parameters of the narrator's generative goal and the narratee's expectation, total number of generating discourses, and other configurations. The parameters for the generative goal and expectation commonly consist of the following ten structural features: "supplement," "complexity," "suspense," "length," "hiding," "descriptiveness," "repetition," "diffuseness," "implication," and "temporal-independency." Each parameter takes a value of 1 (small), 2 (medium), or 3 (large). Through an iterative generation process, the system outputs a series of discourses. A text by the natural language generator and log data accompany each discourse.

Figure 4. Jauss-based narrative discourse generation system

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

The generation cycle continues according to the interaction between the narrator and narratee. First, the narrator generates discourse from the input story based on the generative goal. The narrator has a set of rules for controlling the application of discourse techniques based on the generative parameters. The narratee then evaluates the results by comparing his/her expectation parameters and the narrator's generative ones. In the next cycle, the narrator applies corrections according to the evaluation in order to achieve the narratee's satisfaction. The process, however, eventually reaches a point where the narratee becomes tired or his/her satisfaction begins to fall. When this happens, "deviation" occurs and the narrator abandons a portion of the old generative parameters and moves to the generation of a discourse with the new generative goal. The narratee's expectations also change according to the reconstruction.

System Behavior

The authors show an example of executing the system for 10,000 steps. In Figure 5, the upper and lower texts respectively show the input story and generated discourse by English translations of Japanese sentences by the natural language generator. The authors added explanations on the discourse structure in angle brackets.

In order to analyze all generated discourses, the authors defined metrics to quantify the structural features of each discourse, referred to as discourse feature values (DFVs) (see Table 1). These features correspond to the aforementioned ten parameters in the system. These metrics are incorporated in the above system, and DFVs for each generated discourse are automatically logged in the generation cycle. Figure 6 shows the transitions of each DFV from step 1 to 1000. There are two types of changing patterns: micro level changes based on the same generative parameters that occur in each step, and macro level changes caused by the narrator's deviations.

Issues

The central problem of the above model is that the narrator and narratee mechanisms are disconnected from accumulated discourses through the generation cycle. In each step, the narrator generates a discourse from the input story according to a set of absolute parameters represented in three-point scale.

Figure 5. Generation example

Natural language expression of the input story (English translation):
A snake abducted a princess at a garden. An older woman sang a grief-stricken song at the garden. Ivan resolved to search the princess at a town. Ivan departed from the town. Ivan battled with the snake at the snake's land. Ivan injured his arm by the snake at the snake's land. Ivan won against the snake at the snake's land. Ivan abducted the princess at the snake's land. Ivan departed from the snake's land. The snake flied at the snake's land. The snake chased Ivan at the snake's land. Ivan hid himself on the back of a rock at the snake's land. The princess knew Ivan's wound at the snake's land. Dwarfs built a palace at the town. Ivan lived at the palace. Ivan married with the princess at the palace.

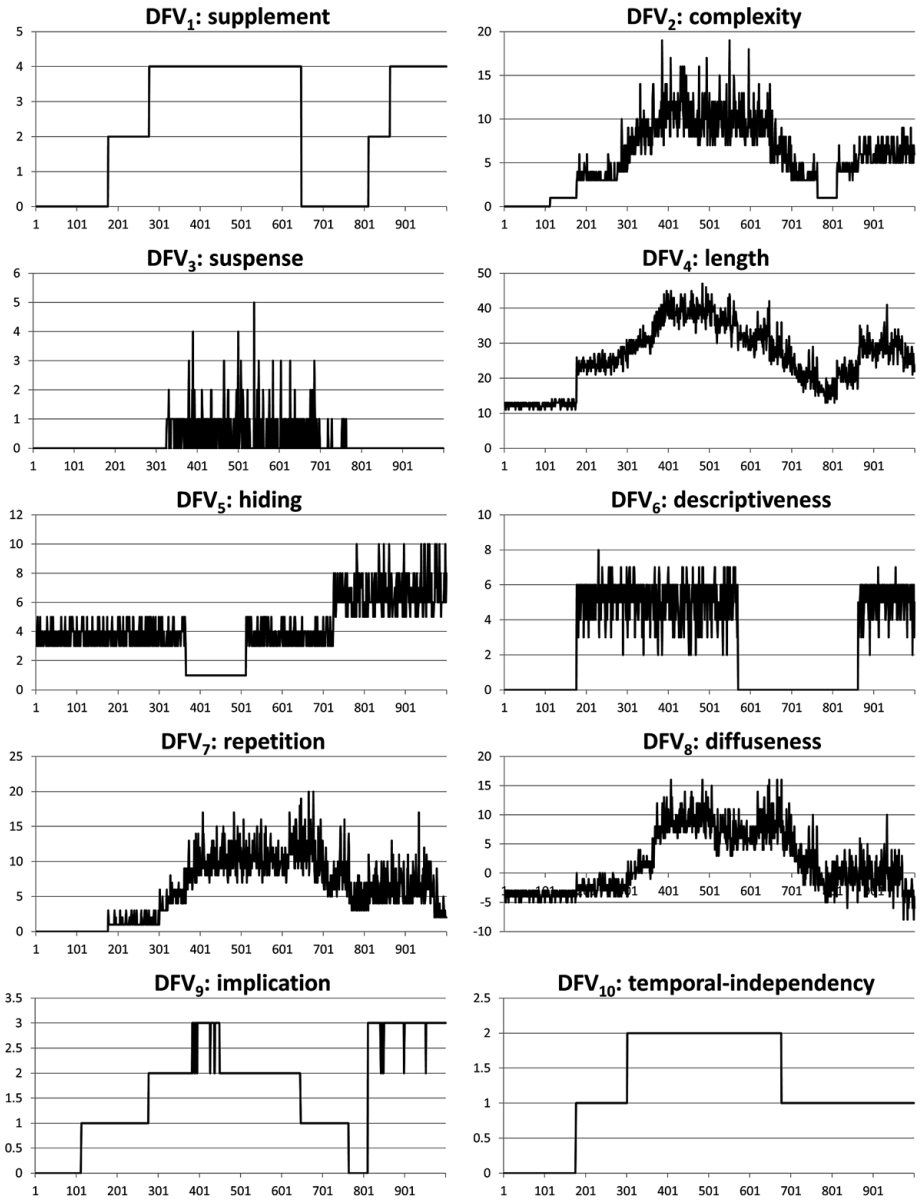
Natural language expression of a generated discourse (English translation):
A snake abducted a princess at a garden. [<future> The princess divorced with Ivan. The princess returned home from a palace.] An older woman sang a grief-stricken song at the garden. Ivan resolved to search the princess (at a town). Ivan departed from the town. [<future> Ivan won against the snake at the snake's land. [<future> Ivan lived at a palace.]] Ivan battled with the snake (at the snake's land). Ivan injured his arm by the snake. Ivan won against the snake. Ivan abducted the princess. The princess knew Ivan's wound. Dwarfs built a palace at the town. Ivan lived at the palace. Ivan married with the princess. [<backward> Ivan battled with the snake (at the snake's land). Ivan injured his arm by the snake. Ivan won against the snake.]

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 1. DFVs metrics

DFVs	Metrics
DFV_1: Supplement	Number of "events" positioned outside the story's temporal range that provide complementary information.
DFV_2: Complexity	Number of "relations" required to define temporal order transformations. A relation nested under one or more relations of temporal ordering is additionally weighted in proportion to the depth of nesting.
DFV_3: Suspense	Number of "events" moved from a backward position in the story and not accounted for before.
DFV_4: Length	Total number of "events" and "descriptions."
DFV_5: Hiding	Number of "events" contained in the story, but not accounted for in the discourse.
DFV_6: Descriptiveness	Number of "descriptions."
DFV_7: Repetition	Sum of the numbers of repetition of each "event."
DFV_8: Diffuseness	Subtraction of DFV_5 ("hiding") from DFV_7 ("repetition"), i.e., "diffuseness" is increased by "repetition" and decreased by "hiding."
DFV_9: Implication	Number of "relations" required to define the prospective temporal order transformation.
DFV_{10}: Temporal-independency	Number of "relations" using the "achronie" technique, which inserts events that do not have any temporal connection with the story.

Potential narratives to be generated are prelimited depending on finite combinations of parameters, independently of the past history of the system actions. Actually, the authors observed that the difference or novelty of the generated narrative from those prior, based on DFVs, decreases gradually through the generation cycle. Because the primary goal of NBNG is to continually increase narrative diversity, this model is not adequate for NBNG.



A root cause of the above problem is in the functional relationship between the narrator and narratee, i.e., the modeling of how the generation and reception interact in a continual narrative production process. The above system is implemented as the direct interaction of the generation and evaluation of the two agents. This is a personal interaction, rather than a social or historical process. However, the point of Jauss's theory is to provide the role of dynamically forming the "horizon of expectation" to the reception side (i.e., readers) and construct a literary history based on the historical change of the horizon. Namely, each work is historically positioned based on the relationship to the horizon at the time. In this manner, the reception side plays a central role in the construction of literary history. This idea is applicable to the model of production and organization of narratives in SONGS, but is missed in the above model. The authors designed a new model for NBNG mainly by modifying this problem.

Designing NBNG

A main modification from the previous model is to place the recipient side not as the direct evaluation mechanism for the narrative, but as the mechanism for organizing narratives in CNs. In particular, the recipient side attaches external attribute information to a generated narrative in order to position the narrative into the organization of CNs. On the other hand, the generation side generates new narratives with reference to CNs, based on a relative goal as difference from prior narratives. This way, an indirect interaction between the narrative generation and reception arise via CNs. In addition, the authors mainly apply the following modifications. First, the users are explicitly associated with the model. Second, the system treats the total process of narrative generation, not only discourse generation, but also story gen-

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

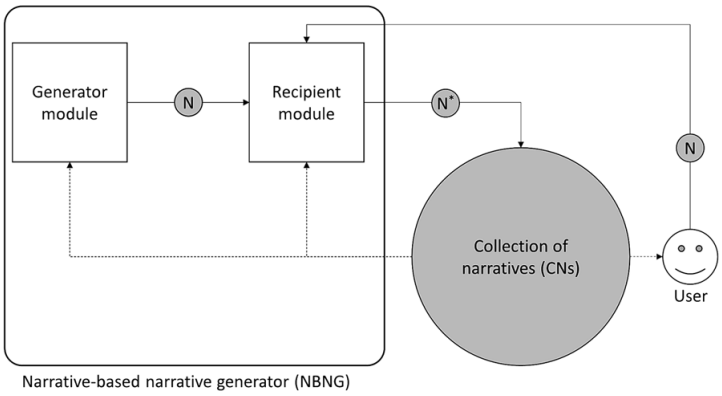


Figure 6. Change of generated discourses through generation cycle

eration. Third, the authors completely revise the terms from the previous model. In particular, because the mechanisms of narrative generation and reception in SONGS are positioned as being the outside agents of a narrative text, the authors change the names narrator—"[t]he one who narrates, as inscribed in the text" (Prince, 2003, p. 66)—and narratee—"[t]he one who is narrated to, as inscribed in the text" (Prince, 2003, p. 57)—to "generator" and "recipient," respectively. Figure 7 shows the overall architecture of NBNG, including the relationships to CNs and users. In the figure, "N" indicates a narrative and "N*" means a narrative accompanied by the external attribute information by the recipient. The rest of this section describes the main elements of NBNG.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

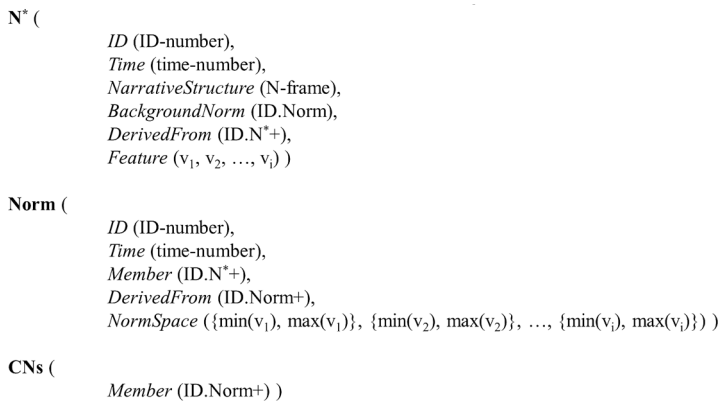
Figure 7. NBNG architecture

Narrative (N)

In CNs, each N corresponds to a conceptual representation as the formal description of content and structure of a given narrative. In the development of INGS, the authors defined a structural framework of narrative that consists of the three dimensions of story structure, discourse, and expression. A story represents the content information of a narrative and discourse is the structural aspect of how a story is expressed. A story is further divided into two types of structures: a temporal sequence of events and the background states. The latter corresponds to the structure of the story world that defines the information of characters, objects, and locations in a story.

According to the above framework, the authors defined a frame format, referred to as N-frame, for representing N in CNs (see Figure 8). Each italic element in the figure indicates a slot, a composing element of N. Namely, N is composed of conceptual representations of the story world (*StoryWorld*), chronologically structured events (*Story*), and discourse structure (*Discourse*). The representation method of each element is basically defined based on that in INGS. Note that in SONGS, the narrative expression generation is a function of the interface part.

Collection of Narratives (CNs)



CNs are organized based on the two substructures of "N*" and "Norm." Each element is defined by a frame format referred to as N*-frame, Norm-frame, and CNs-frame (see Figure 9). In the figure, each italic element indicates a slot, tailing plus ("+") means "one or more," and a period (".") between two elements means "of"—e.g., ID.N* means *ID* of N*.

Figure 8. N-frame

N (
StoryWorld (conceptual representation of story world),
Story (conceptual representation of chronologically structured events),
Discourse (conceptual representation of discourse structure))

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 9. N-frame, Norm-frame, and CNs-frame*

In N*-frame, the *NarrativeStructure* slot contains N, and other slots correspond to the external attributes. *ID* indicates the unique number for N. *Time* marks the actual date when N is generated. It means the temporal position on the timeline of the continual production process. *BackgroundNorm* indicates the Norm in which N* is placed. *DerivedFrom* links prior N(s) used in generating N. *Feature* takes a set of feature values of N. It is similar to DFVs for the Jauss-based system.

Each Norm forms a subset of N*s that have some commonality in their features. In other words, it is an intermediate unit of CNs that corresponds to the notion of "horizon of expectation" in Jauss's theory. A Norm is used as the basis for both processes of the generator's narrative production and the recipient's narrative positioning. Norms and CNs are automatically updated when a new N* is added to CNs. In Norm-frame, *ID* and *Time* respectively indicate the unique number and temporal position. *Member* lists the contained N*s. *DerivedFrom* links the prior Norm(s) from which the Norm is derived. *NormSpace* represents the ranges of the feature values in the member N*s. CNs are only a set of all Norms.

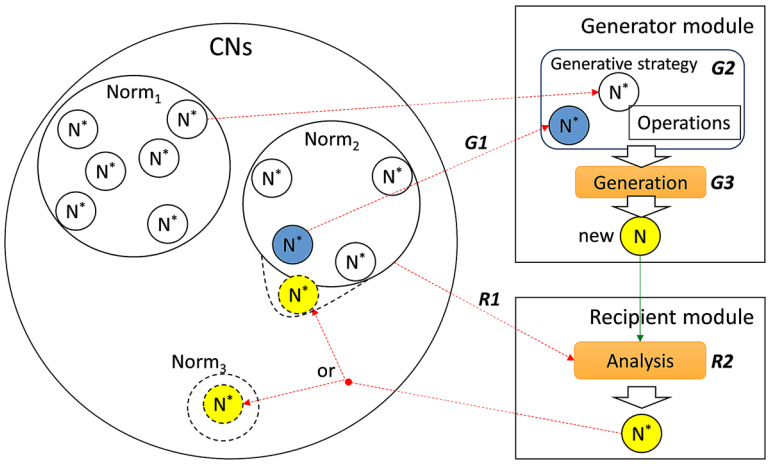
Overall, CNs are organized based on the following four formation principles:

- **Timeline:** N*s and Norms are placed on a timeline (*Time*).
- **Norm-Based Hierarchy:** CNs are hierarchically grouped by Norms, in particular, *Member* in Norms and CNs and *BackgroundNorm* in N*s.
- **Derivative Network:** N*s and Norms are respectively linked based on their derivative relationships, in particular, *DerivedFrom* in N*s and Norms.
- **Feature Space:** N*s and Norms are positioned in a feature space based on their feature values, in particular, *Feature* in N*s and *NormSpace* in Norms.

Process Flow

Figure 10 shows a total picture of the system actions through generator to recipient.

The generator produces a new N through the following procedure:



G1 - Setting a Basing N*: The generator selects N* for the basing point of generating a new N.

G2 - Planning a Generative Strategy: The generator makes a plan for how to recompose the basing N*.

First, with reference to the *BackgroundNorm* of the basing N*, the generator sets a basic objective

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 10. Total picture of system action

of either normative generation or deviation from the Norm. Deviation means an action to attempt to produce a new type of N by breaking the existing Norm. Based on the basic objective, the generator makes the following two choices: *what*, or target elements in the basing N*—i.e., constituents of *StoryWorld*, *Story*, and *Discourse*—and *how*, or operations for each target—e.g., transformation, deletion, addition, substitution, abstraction, concretization, and synthesizing with other N*s.

G3 - Generating N: The generator recomposes the basing N* in order to generate a new N based on the generative strategy.

The new N is sent to the recipient. In addition, the generator may send additional information to the recipient on background information of the generation process, i.e., the basing N* or *BackgroundNorm*. This helps the recipient to position N into CNs.

Next, the recipient composes N* through the following procedure:

R1 - Setting a basing Norm: The recipient selects a basing Norm in receiving the N based on the generator's additional information.

R2 - Composing N*: The recipient analyzes N and fills the slots of N*-frame. The values of *ID*, *Time*, and *NarrativeStructure* are simply determined. *DerivedFrom* is determined by the Generator's additional information. The values of *Feature* are calculated by analyzing the structure of N. *BackgroundNorm* is determined based on *Feature*. When N is located near the basing Norm or the inside, based on the features, it is incorporated in the basing Norm—i.e., *BackgroundNorm* is the basing Norm. Otherwise, N is regarded as a deviation from the basing Norm and is positioned as a new Norm—i.e., *BackgroundNorm* is a new Norm to be created. Finally the composed N* is sent to CNs.

After the process, CNs and Norms are updated. When N* is placed in an existing Norm, the latter is expanded. Otherwise, a new Norm is created. The above process is iteratively executed at a regular time interval—e.g., once a minute. On the other hand, the user also can create a new N.

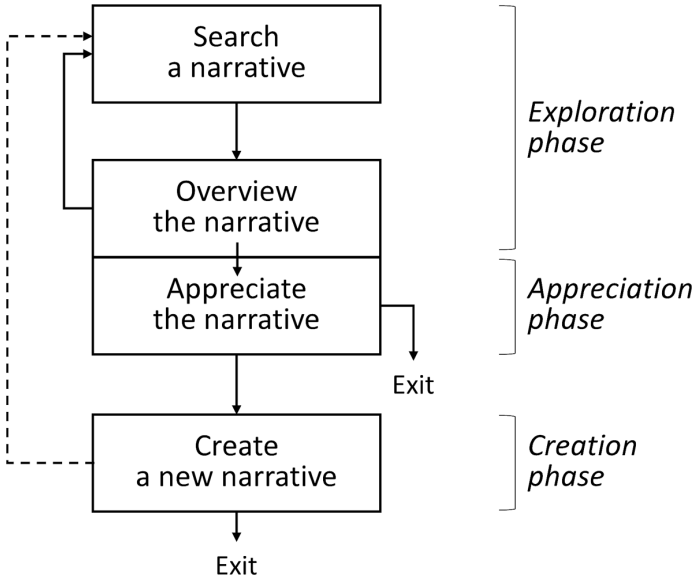
3LNI: THREE-LAYERED NARRATIVE INTERFACE



In this section, the authors propose the basic framework of 3LNI by considering a basic scenario for the use of SONGS. The central method is to visualize the following three aspects of CNs: organization of narratives, surface expressions of a narrative, and internal structures of a narrative. The authors also present a partial prototyping of 3LNI.

Basic Scenario of SONGS Usage

Figure 11 shows a basic scenario of user actions. This consists of the following three phases:

- **Exploration Phase:** First, users explore CNs to find a valuable narrative for their value or objective. In particular, users repeat the following two actions until a valuable narrative is found. First, the users search and select a narrative from CNs. Second, they overview the narrative in a short time. If the narrative seems valuable, the users proceed to the appreciation phase. Otherwise, they search another narrative.
- **Appreciation Phase:** The users closely read or see the selected narrative. This phase is always performed regardless of whether the user's objective is appreciation or creation. Subsequently, when the users have an objective or motivation of narrative creation, they proceed to the creation phase. Otherwise, the users exit from SONGS.
- **Creation Phase:** The users create an original narrative using the selected narrative as the material or draft. In the process, the users can obtain additional narratives or materials from CNs, as indicated by the dotted arrow line in Figure 11. Finally, the created narrative is added to CNs via the NBNG recipient module.

Figure 11. Basic scenario of SONGS usage

3LNI Framework

As the authors indicate in the above scenario, the interface needs to provide mainly the three functions of exploration, appreciation, and creation. The framework of 3LNI is designed to integrate these functions and the authors employ visualization—a well-known technique for providing human-friendly expressions in order to understand a huge amount of data or complex objects—for the central interface method. In particular, 3LNI divides and connects the following three perspectives on CNs: *CNs layer*, or collective view on whole and parts of CNs; *NE layer*, or surface view on a narrative expression; and *NS layer*, or internal view on a narrative structure. Via the above views, individual users share CNs, i.e., the object of co-creation, with NBNG and other users. Figure 12 shows the above concept of 3LNI.

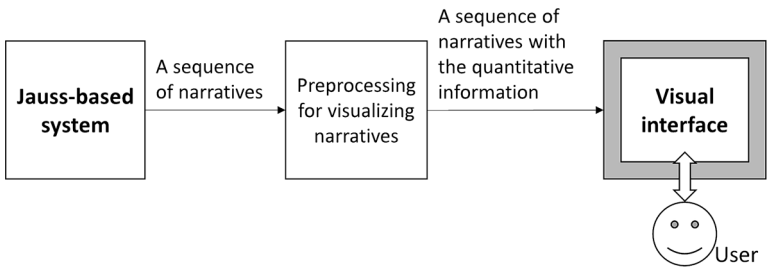
The basic functions of each layer are as follows:

- **CNs Layer (Collective View):** This visualizes the organization of CNs into a two-dimensional space. Narratives or norms are represented as visual objects in the space. This includes various visualization methods depending on the CNs aspect or formation principle that is focused, in particular, timeline, norm-based hierarchy, derivative network, or feature space. The user explores and selects narratives with this macroscopic perspective.
- **NE Layer (Surface View):** This provides the surface expressions of a narrative. Because each narrative in CNs corresponds to a conceptual representation, surface expressions are generated in this layer. Natural language is a basic expression form. However, a narrative potentially allows various expressions depending on media—e.g., natural language, still or moving image, and music—and styles of expression. The user appreciates a narrative selected from the CNs layer.
- **NS Layer (Internal View):** This visualizes the internal structure of a narrative from multiple perspectives of the story world (*StoryWorld*), organization of events (*Story*), and discourse structure (*Discourse*). In addition, this layer includes editing functions that allow the user to visually recompose a narrative structure. The user sees the internal structures of a narrative from an analytical perspective and creates a new narrative by recomposing the visualized narrative structure.

Figure 12. 3LNI basic concept

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

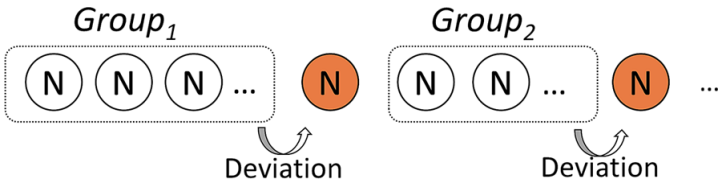
In the exploration phase, the user mainly employs the CNs layer to search a narrative, and the NE layer to overview it. In addition, the NS layer may provide multifaceted summaries of a narrative structure and help the user understand it quickly. Meanwhile, keyword retrieval is a popular method for searching information or content. However, the authors assume that, in many cases, the user has no clear requirement for narratives or cannot adequately represent the requirement through language. The authors will apply keyword retrieval methods as a subsidiary function for the exploration phase in the CNs layer.



The above design positions the user creation phase in the NS layer. Although it is possible to design the creation phase at the surface expression level or NE layer, in order to share user-created narratives with NBNG, surface narratives must be transformed into a conceptual representation. This is a very difficult task for a computer. In addition, editing narrative expressions requires significant time and effort from the user. Hence, designing editing functions in the NS layer is a key issue for smoothly circulating the collective creation process between NBNG and users.

VISUAL INTERFACE FOR COMPUTER-GENERATED NARRATIVES

As a preceding idea for 3LNI, Akimoto and Ogata (2015a) proposed a visual interface for exploring narratives generated by the Jauss-based narrative discourse generation system introduced in the section "Narrative Discourse Generation System." The design concept partially overlaps the 3LNI framework. This subsection outlines the implemented visual interface in order to provide the readers with a concrete image of a part of 3LNI. The basic idea of the interface is to arrange and visualize many narratives into a two-dimensional space that allows users to explore and browse narratives based on their values or objectives. Figure 13 shows the relationship between the Jauss-based system and the visual interface.



The composition of a series of narratives produced by the Jauss-based system is summarized in Figure 14. Such composition consists of a number of groups or subsets of narratives respectively formed by the same set of generative parameters. Namely, each group contains one or more narratives with similar features. In terms of the SONGS design, the entire set of narratives and groups correspond to CNs and norms, respectively. The number of narratives in each group is indefinite, but loosely controlled depending on the initial configurations of the Jauss-based system. A new group is produced via the narrator's deviation process that changes a parameter value. In Figure 14, "N" refers to a set of discourse structure, the natural language expression, and DFVs. Although the design of 3LNI includes the function of narrative expression generation in the NE layer, in this version, this is embedded in the Jauss-based system.

Figure 13. Process flow through narrative generation to visual interface

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 14. Composition of a series of generated narratives

The preprocessing part in Figure 13 calculates the statistics—minimum, maximum, and average for each DFV—of each narrative group and the entire set of narratives. The visual interface uses the group-based hierarchy and feature spaces to organize the narratives into a two-dimensional space. In particular, this consists of the following three perspectives:

V1: This plots the visual objects of the groups.
V2: This plots the visual objects of the narratives in a group.
V3: This represents a narrative by a natural language text and diagram of the structure.

In terms of the 3LNI framework, V1 and V2 correspond to the CNs layer, and V3 includes the NE and NS layers. Each perspective corresponds to an interface window, and these are mutually connected via the visual objects. Figures 15–17 show screenshots of each window for a series of 10,000 generated narratives with 271 groups. The input story is equal to that shown in Figure 5. In V1 and V2, two of the DFVs are used to arrange the discourses into a two-dimensional space. We indicate the features of the horizontal and vertical axes as DFV_x and DFV_y, respectively. Choosing different features for these axes results in different narrative arrangements. In Figures 15 and 16, DFV_x and DFV_y are DFV_4 (length) and DFV_2 (complexity), respectively. The user can change DFV_x and DFV_y using the "up"/"down" and "left"/"right" arrow keys, respectively.

In the V1 window, each group is represented by a blue rectangle with the group number. In the space, the left/lower ends and right/upper ends correspond to the minimum and maximum of DFV_x/DFV_y in the entire set of narratives, respectively. The area of a rectangle represents the ranges of DFV_x and DFV_y in the corresponding group. The users can move to the V2 window by clicking the left mouse button on a group number.

In the V2 window, each discourse is represented by a small yellow circle. The center of the space—i.e., the intersection of the horizontal and vertical axis lines—corresponds to the average of each DFV_x and DFV_y. Discourse objects are positioned based on their distance from the center, i.e., the averages. In addition, the deviated discourse is positioned as a small red circle. The user can move to the V3 window by clicking the left mouse button on a small circle. When the user clicks the right mouse button on a small circle, a sub-window for the miniature window L3 is displayed. In Figure 16, a sub-window of $Discourse_{3507}$ is shown. The user can return to the V1 window by clicking the "back" button.

The V3 window expresses a narrative using Japanese text and a diagram of the structure. The text in Figure 17 corresponds to the English expression of the generation example in Figure 5. The diagram represents the discourse structure using a graph. Each node (numbered circle) corresponds to an event, and the edges show the flow of the narration (for more detail, refer to Akimoto and Ogata (2015a)). The user can save the narrative text to a file by clicking the "save" button and return to the V2 window by clicking the "back" button.

FUTURE RESEARCH DIRECTIONS

This chapter presented the core concepts and basic mechanism design of SONGS. The next challenge is to concretize the system design through the constructive cycle of experimental developments and the verifications or considerations of mechanisms. A main focus is to design a method for strategically

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 17. V3 window of narrative$_{3507}$

triggering various types of creative interactions between NBNG and human users. At the same time, it is important to discuss a macroscopic vision on the social impact of SONGS for determining the correct direction of system development. In the following subsections, first, the authors describe a plan for designing interaction between NBNG and human users. Second, the authors draw several long-term visions toward relating SONGS to the real world.

Toward Interaction Design between Generative Program and People

In order to produce a wealth of CNs, SONGS needs to be able to originate various types or modes of creative interactions between the generative program (i.e., NBNG) and many humans in the collective creation process. For this, it is important to design not only the mechanism of the program side, but also the behavior of the human side. If the program's narratives have an expansionary effect on human narrative creations—e.g., increasing the diversity of created narratives or triggering unique ideas—this will be a positive aspect of SONGS. In contrast, if the program's narratives do not give rise to such positive phenomena, the authors should consider the causes and redesign the system.

From the above perspective, the authors have conducted an experiment to investigate the effects of computer-generated narratives on human narrative creation using a narrative generation system that consists of the Jauss-based system and visual interface, i.e., preceding versions of NBNG and 3LNI (for details of the experiment, refer to Akimoto and Ogata (2015b)). In the experiment, 14 human subjects were divided into two groups: A and B. Each subject in group A used the system and created a variety of scenarios by obtaining narrative texts on the interface and then editing them to make them unique. Each subject in group B performed the same creation task, but without using this system. The authors then analyzed the structures of created scenarios and compared the differences between the scenarios

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

created by both groups. From the experiment results, the authors found a type of creation mode where humans strengthen the weakness of structural organization of computer-generated narratives. From a cognitive perspective, it seems that blanks or disconnections from the flow of a narrative text generated by the program strongly induce human creation in order to cause the narrative to be organized logically. This way, many scenarios were created that have unique storylines. A direction of future development is to design functions of the NS layer of 3LNI that allow this type of creation. However, the authors also need to consider strategies for triggering more diverse modes of the human creation processes.

Toward Relating SONGS to Real World

Next the authors take a long-term view and discuss possible impacts of SONGS to the real world. First, the central goal of SONGS is to activate creative activity and content industry in the real world. In order to consider this possibility, the authors discuss the relationship between the characteristics of the Japanese content industry based on Koyama (2009) and those of the SONGS design. Koyama described the characteristics and strengths of the Japanese-style content industry model by comparing with the Hollywood style. According to Koyama, the characteristics of the Hollywood style model can be summarized as follows: Groups of many professionals mass-produce huge works and maximize the benefits that arise from "hits." In this type of model, because the professionals excessively pursue the maximization of benefits while avoiding risks, diversity of subjects or narratives in the works tend to decrease. In contrast, the Japanese style model has the following characteristics: a) the boundary between professionals and amateurs is vague and there are many and diverse creators, b) the boundary of creators and consumers is vague and derivative, or collective creation activity is lively, c) the market consists mostly of small to medium-scaled works, d) there is a high degree of freedom for creation/expression activity, and so on. The unique and diverse creative culture in Japan is underpinned by these types of characteristics.

These characteristics of the Japanese style model are, at a fundamental level, largely similar to the design concepts of SONGS. In addition, SONGS drives the co-creative cycle through the computer program with a distinguishing narrative creativity. It has the potential of creating a new platform for expanding the creative culture and content industry. In order to obtain several users and gain powerful influence on the real world, it is naturally important to enhance the system's basic performance, such as the quality of produced contents, interface usability, degree of freedom for user creation, etc. The accumulation of steady efforts to achieve these is required.

Another possibility or secondary application of SONGS is for CNs to be a type of knowledge resource for intelligent information technologies in various fields. As described in the background section, narrative or story-based knowledge is focused as an important aspect of intelligence. Because each narrative in CNs consists of conceptual information by formal descriptions, CNs have high availability for computers or AI systems. For instance, lately, humanoid robots or AI applications have been active in various fields, such as entertainment, nursing care, education, etc. CNs can help the dialogue or storytelling tasks of such AI systems in various situations by providing diverse narratives. In addition, narrative knowledge or creativity is necessary for human-like intelligent machines. For instance, CNs or NBNG can be applicable to robots that compose high-level future goals or action plans, similar to the way in which humans makes decisions or life plans based on their narrative knowledge, such as past experiences, history, and so on.

CONCLUSION

In this chapter, the authors proposed a design of SONGS that continually co-creates a wealth of narratives between a narrative generation program and many human users. This is based on the following four design concepts:

- SONGS uses narratives as comprehensive knowledge for producing new narratives.
- SONGS controls the continual narrative production process with relation to prior narratives.
- The generative program and many humans collectively produce narratives through the interaction of produced narratives.
- SONGS provides diverse narratives for people with diverse values or objectives.

In the next study stage, through experimental developments, the authors will elaborate the designs of NBNG for the narrative generation engine, and 3LNI for the visual interface. An important basis for the narrative co-creation is to formalize the narrative structure and its operations. The authors will apply their fundamental study of INGS to the modeling of structural representation and operations of narrative in SONGS. Although this chapter focused on a particular system, the basic framework or idea can be applicable to other creative activities of structural artifacts, such as music, architecture, and graphic arts. SONGS can be a form of connection between computational creativity and the real world.

KEY TERMS AND DEFINITIONS

3LNI: Three-layered narrative interface, the user interface for accessing CNs. 3LNI provides multiple perspectives on CNs: collective, surface, and internal.

CNs: Collection of narratives. Narratives produced in SONGS are accumulated in this part and shared by the narrative generation program (NBNG) and human users.

Co-Creation: Cooperative process for producing novel and valuable artifacts or information through mutual action among two or more agents.

Computational Creativity: Research field that addresses computer-based modeling, design, simulation, and implementation of creativity. Research subjects include various creative areas, such as arts, entertainment, artifacts, content, ideas, and knowledge.

Narrative: Product that represents one or more events by some media for humans, or some formal descriptions for computers. In our study, a narrative is constructed as the totality of a story, discourse, and expression.

Narrative Discourse: The structural aspect of how a story is expressed. In our study, a discourse is represented not as surface expression, but as a formal description.

Narrative Expression: Surface expression of a narrative by a medium such as natural language, still or moving image, and music, or their combination.

Narrative Generation System: Computer program that produces some types of narratives.

NBNG: Narrative-based narrative generator, the generative program in SONGS. The narrative generation is modeled as a cyclic process for composing new narratives in relation to previously generated narratives in CNs.

Story: The content information of a narrative, in particular, a chronologically ordered sequence of events.

Story World: The background world information of a story, including characters, objects, places or spaces, timelines, etc.

This research was previously published in Computational and Cognitive Approaches to Narratology edited by Takashi Ogata and Taisuke Akimoto; pages 91-117; copyright year 2016 by Information Science Reference (an imprint of IGI Global).

Chapter 37
Conceptual Graphs Based Approach for Subjective Answers Evaluation

Goonjan Jain
Jawaharlal Nehru University, India

D.K. Lobiyal
Jawaharlal Nehru University, India

ABSTRACT

Automated evaluation systems for objective type tests already exist. However, it is challenging to make an automated evaluation system for subjective type tests. Therefore, focus of this paper is on evaluation of simple text based subjective answers using Natural Language Processing techniques. A student's answer is evaluated by comparing it with a model answer of the question. Model answers cannot exactly match with the students' answers due to variability in writing. Therefore, researchers create conceptual graphs for both student as well as model answer and compute similarity between these graphs using techniques of graph similarity measures. Based on the similarity, marks are assigned to an answer. Lastly, in this manuscript authors compare the results obtained by human graders and the proposed system using Pearson correlation coefficient. Also, comparison has been drawn between the results of proposed system with other existing evaluation systems. The experimental evaluation of the proposed system shows promising results.

INTRODUCTION

Tests are an indispensable part of our education system and are used to gauge student's knowledge. Two basic categories of tests are Objective and Subjective tests. Objective tests require student to only select a correct response from several alternatives or utmost to supply a word or short phrase to answer a question. On the contrary, subjective tests require test taker to form an original answer based on their own understanding of topic.

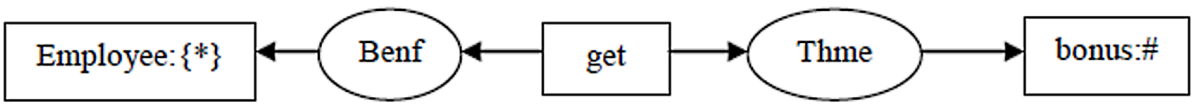
Subjective tests are useful in measuring educational objectives such as analysis, and synthesis. They permit freedom of response that in turn allow students to present their ideas and knowledge they have in the subject area covered by the question. With this, subjective tests also promote development of problem solving skills and eliminate guessing.

Despite the unique benefits of subjective tests, their automation is very limited when compared with automation of objective tests. Major reason for this is that there are downfalls when it comes to marking subjective exams electronically. They have lots of complexities like, different ways of answering the same question; some question requires diagrams or equations. Some questions require answer in more than one word and length of answer may even vary from individual to individual. On the contrary, it is simple and efficient to mark objective item tests because a computer can easily process multiple choice responses.



In this paper, authors propose a unique automatic grading system that can assign grades to short subjective answers provided by student. The system does so by using a model or template answer as a reference. Proposed technique is unique in itself because none of the existing techniques leverages semantics of the text to evaluate it. This limitation significantly hampers effectiveness of technique as questions can be answered in many ways based on candidate's understanding, strength of vocabulary and expressive nature. In addition to this, considering only syntax and morphology will not be sufficient to accurately mark a subjective answer. A correct answer can take many shapes as long as its semantic and syntactic structure is correct. Therefore, it is very important to understand the way the answers are paraphrased for representing the importance of words. This can be achieved by understanding semantics of text and the authors have employed Conceptual Graphs for this.

"Conceptual Graphs (CG) are a system of logic which is based on the existential graphs, the semantic networks of artificial intelligence. Conceptual graphs are described as the logical form that state relationships between concepts and thus represents a meaning." (Sowa, 1984) They were originally developed as a representation that could help in understanding the meaning of natural language text. They have been successful in capturing the nuances in natural language along with the ability to be implemented in computer software. Conceptual Graph is a knowledge representation technique that expresses meaning in a precise, readable and computationally tractable way and therefore is an efficient tool for information and knowledge processing.

The CGs are labelled graphs and have two types of nodes – concept and relation nodes. A concept node is a discrete unit of perception and represents entities, attributes, states, and events (Sowa, 1984). There are two types of fields in a concept node - type and referent. The type field specifies the class of entity represented by the concept and an instance of the concept type is identified by a referent. The interconnection of concept nodes is shown by relation nodes. Each conceptual relation has n arcs which are linked to some concept. Every conceptual relation has a relation type and a valence which tells the number of arcs belonging to the relation. Consider an example sentence "Employees get the bonus". The CG representation for this sentence is shown in Figure 1.

Since CGs are a good way to capture semantics of text, authors have used an NLP approach along with conceptual graphs to understand the semantics of students' answers and then evaluate it.

Figure 1. Conceptual Graph Representation for Sentence "Employees Get the Bonus"

Next section presents a brief description of some of the approaches that have been proposed for automatic evaluation of subjective answers. It also summarizes the work that has been done in the field of conceptual graphs. Detailed design and implementation methodology of proposed work is explained in the following section. The results of evaluation of proposed work by undertaking various experiments and its comparison with other available methods are reported in later section. Finally, the work has been concluded along with its possible future extensions.

RELATED WORKS

Work has been done in automatic scoring of answers in recent years which is evident from development of various systems like TCT (Larkey, 1998), Intelligent Essay Assessor (Foltz, Laham, & Landauer, 1999), Automark (Mitchell et al., 2002), C-rater (Leacock, Chodorow, 2003), OXFORDUCLES (Sukkarieh, Pulman, & Raikes, 2003), JESS (Ishioka, Kameda, 2004) etc. Various techniques have been employed by these systems like Latent Semantic Analysis (LSA) or any variant of it, text mining, Natural Language Processing (NLP), Information Extraction (IE), keyword analysis, BLEU algorithm or a hybrid of any of the above.

Auto-assessor developed in year 2011 by Laurie and Maiga uses NLP techniques. Both the student's answer and correct answer are reduced to their canonical forms and these forms are compared with each other to determine their level of equivalency and accordingly scores are awarded for student's response. Ade-Ibijola et al. (2012) developed Expert System for Essay Scoring (ES4ES) for scoring free text answers. It uses a built-in Inference Engine designed with Shallow Natural Language Processing Techniques using Tokenization, Statistical Keyword Analysis and Domain-Specific Dictionary. It further uses a Fuzzy-Scoring Model to assess student's answers to open-ended questions and thus computes the relative correctness of student's answers to model answers. A system developed by A. Dhokrat et al... in 2012 generates a sequence state transition for candidate's answer which is then compared with the model answer. Exact match or at least 50% match in key terms marks the answer to be correct. Papri Chakraborty (2012) in proposed that an answer is considered to be correct if it is syntactically and morphologically same as the model answer. A. Kaur et al. in 2013 proposed an approach that converts reference and student's answers into a graphical form and then matches their nodes and labels by applying different similarity measures. These measures include partial and full string match and use of WordNet measures like Similar_to, Is_apart_of, Subset_of or Superset_of or Derived_from, Opposite_of etc. B. Kaiche et al. (2014) proposed a method for automatic evaluation of multiple sentence descriptive answers by using an algorithm based on Pattern Matching Technique. In 2014, Patil et al. proposed a system to evaluate multiple sentences answer by determining the semantic meaning of the answer. Tutor identifies the keywords from correct answer with their respective weights. Both students' and correct answers are processed and then these answers are compared word-by-word along with the POS tag and word position. Willis (2015) developed a system called *Amati* that develops a set of automatic marking rules which can be applied to larger question sets as well as for automatic marking. A unique superlative model has been proposed by Jayshankar et al. in 2016 that improves the accuracy by using word clouts.

Since the inception of Conceptual Graphs by Sowa in 1984, they have been highly used in different fields and for different purposes. Their capability to capture the semantics of natural language text makes them usable in varied domains. Various methods have been proposed by researchers for automatic generation of CG from natural language text. Sowa (1986) himself attempted one. In his work, he describes

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

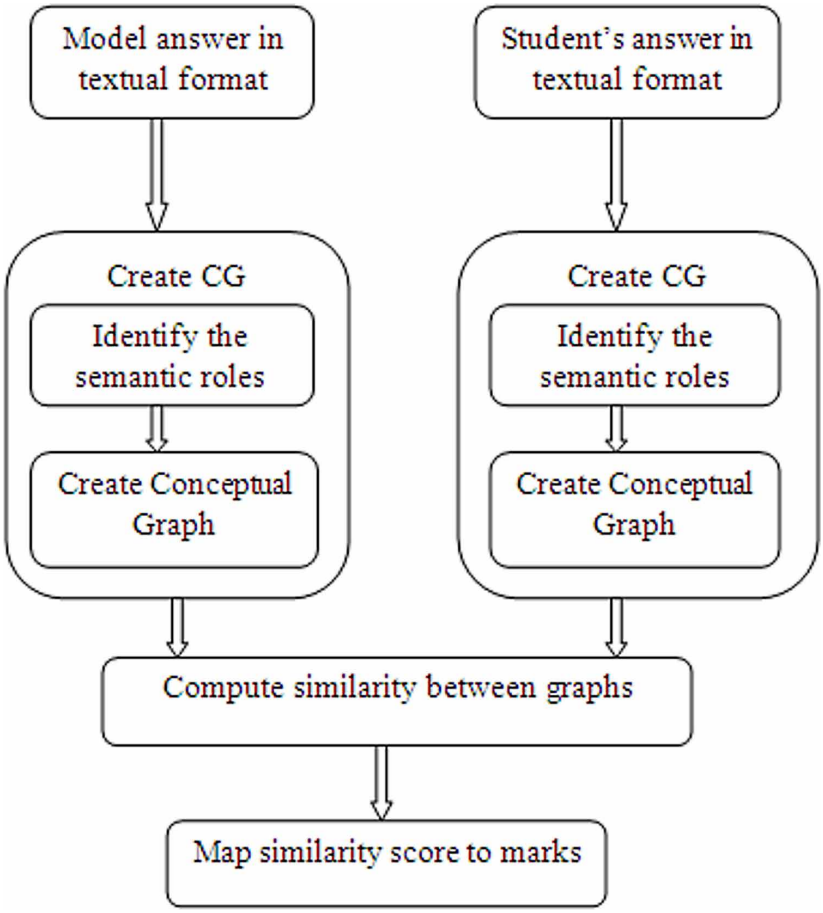
a semantic interpreter where it accesses a lexicon of canonical graphs for each word of input and joins them to generate conceptual graph. In his book titled *Knowledge Representation*, Sowa (1999) explained logical representation of knowledge and various computational issues related to knowledge representation. This book concerns about knowledge representation using logic which includes vocabulary, syntax, semantics and rules of inference using conceptual graphs. Shih-Yao Yang, Von-Wun Soo in 2012 proposed to extract CG from plain text in patent claims by combining techniques such as finite state machines, POS tags, domain ontology and dependency tree. F. Rotella et al. (2013) proposed automated learning of CG with respect to missing or partial knowledge that does not allow extracting a full conceptual graph and only provides sparse fragments thereof.

A number of researchers have proposed computationally tractable CG matching algorithms. M.Montes et al. (2000) used variation of Dice Coefficient that took bipartite nature of CG into consideration to compare CGs. Montes et al. (2001) proposed another method for flexible comparison of CGs. They improved the flexibility by considering synonymy and subtype/supertype relationships between concepts and relations. Another matching algorithm based on Conceptual sub-graph weight self-adjustment was proposed by Zeng et al. in 2014. To compute the Conceptual Graph similarity, it gives homologous weight to subgraphs based on the proportion of how much information a subgraph contains in the whole Conceptual Graph.

DESIGN AND IMPLEMENTATION OF THE PROPOSED SYSTEM

In the proposed method, researchers find confidence level for a given answer by comparing student's answer to model answer and therefore check text relatedness between the two answers. As a first step, researchers perform preprocessing of the student's answer to correct spelling mistakes before performing other tasks. The model answer available is also processed using similar NLP tools. To understand semantics of answers, candidate's and model answers are represented in CG notation. CGs are compared by taking their corresponding structures into consideration and eventually producing an output in a form that shows semantic closeness between the candidate's answer and given model answer.

Proposed method is shown diagrammatically in Figure 2. The proposed method consists of mainly two tasks:



1. Create Conceptual Graphs for model and student answer.
2. Find similarity between these graphs using conceptual graph similarity measure and assign marks accordingly.

Creation of Conceptual Graph

The authors have used NLP techniques to create CG representation of text. A sentence is considered to be consisting of many fragments or syntactic patterns. These segments are related to each other through relationships identified by verbs. Therefore, to construct a CG for a sentence, program has to identify the syntactic patterns of a sentence and the semantic roles that each word in the sentence plays with respect to every identified verb. The proposed system uses an external Semantic Role Labeling (SRL) tagger to tag words of a sentence with corresponding semantic roles. In the process of identifying semantic roles, tagger performs syntactic parsing of a sentence and identifies constituents or syntactic patterns that constitute the sentence.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. Flowchart of the Proposed System

The process of creating a CG from a text is as follows:

1. Use SRL tool to tag each word of the sentence with their corresponding semantic roles.
2. Create a CG for this semantic role tagged sentence.

Various SRL tools are freely available like Mate Tools[1], SEMAFOR[2], SENNA[3], ClearNLP[4] etc. to tag semantic roles in a sentence. In the proposed work, authors have used *"SENNA- Semantic Extraction using a Neural Network Architecture"* for tagging sentences with semantic roles.

SENNA is a software which outputs a host of Natural Language Processing (NLP) predictions: part-of-speech (POS) tags, chunks (CHK), name entity recognition (NER), semantic role labels (SRL) and syntactic parsing (PSG) (Collobert et al., 2011; Collobert, 2011). A sentence is taken as input and the algorithm gives semantic roles for each word of the input sentence for every identified verb. Several stages of processing are involved in SRL systems. In the first stage, a parse tree is produced and then parse tree nodes that represent the arguments of a given verb are identified, and finally these nodes are classified in to the corresponding SRL tags. *Chunking* (*CHK)* labels segments of a sentence with syntactic constituents such as noun or verb phrases (NP or VP) (Collobert et al., 2011). IOBES (inside, other,

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

beginning, end, and single) encoding scheme has been adopted to mark chunk boundaries, i.e., identify location of the current word in the chunk. It associates a single tag with each input token. To mark a verb phrase containing a single word, it uses tag "*S-VP*". Tags "*B-VP*", "*I-VP*", and "*E-VP*" mark the first, intermediate and last words of the verb phrase. Tag "*O*" marks those words that are not members of a chunk. Before transforming a sentence into its CG, anaphora resolution is performed.

A sentence is transformed into its CG representation through following steps:

- Build CG representation for every syntactic constituent of a sentence.
- Link together all the conceptual graphs representing the constituents to form a single graph, thus, representing the complete sentence. (Hensman, 2004; Hensman et al., 2004)

First step is to build a conceptual graph for every constituent or phrase. Here, assumption is to represent each token in a sentence by a separate concept, therefore all nouns, verbs, adjectives and adverbs are represented using individual concepts. Determiners, numbers etc. are used as referents of the relevant concept. However, this work does not consider referents while creating CGs (Hensman, 2004; Hensman et al.., 2004). Not using referents for CG also keeps the system domain independent as the system need not maintain any ontology or knowledge base. For a sentence like "Tommy likes milk" the CG is Tommy:Dog <- like -> milk. So, the system needs to maintain an ontology where it knows that Tommy is a dog.

Algorithm 1 depict steps to be followed for creation of CG of a sentence already processed through SENNA. If CHK-tag = '*S*', a concept with the corresponding token as concept type is created. If CHK-tag = '*B*', it marks the beginning of a new chunk, hence, look forward in the following lines till corresponding '*E*' tag is found which marks end of the chunk or phrase. While traversing through a chunk, track of POS labels of each token is kept and concatenated with each other as they make the phrase structure of the identified chunk. Finally, concepts based on the involved syntactic pattern are created. Some of the syntactic patterns for noun phrases are shown in Table 1.

Algorithm 1. Creation of Conceptual Graph

```
Input: Text file containing syntactic information of a sentence in a tabular
format
Output: Conceptual Graph for a sentence
1.        begin
2.        while file is not empty
3.                 begin while
4.                         if CHK-tag ='S' and CHK = "PP"
5.                                Do nothing
6.                         else if CHK-tag = 'S'
7.                                Create a concept for the corresponding to-
ken
8                         else if CHK-tag = 'B'
9.                                 Traverse the file till corresponding 'E'
tag is found and based on the phrase structure formed by corresponding POS
tags create a CG
```

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

```
10.         end while
11.         for each of the CGs created
12.                 Locate the semantic role of the head node and link the head
node to the verb concept using the identified semantic role
13. end
```

Each of the syntactic patterns needs different processing. For example, for pattern (3), concepts that represent noun token and adjective token are created and then linked using an attribute (*attr*) relation. Determiners in a sentence provide information on the type of referents. However, referents are not considered while creating CGs in this work. Following this notation, for pattern (4), a single concept for noun without any referent is created.

In case of prepositions, they mark the beginning of semantic role played by rest of the relevant phrases in the sentence for the identified verb. Therefore, if for a token, CHK-tag = '*S*' and CHK = "*PP*", no concept is created for it.

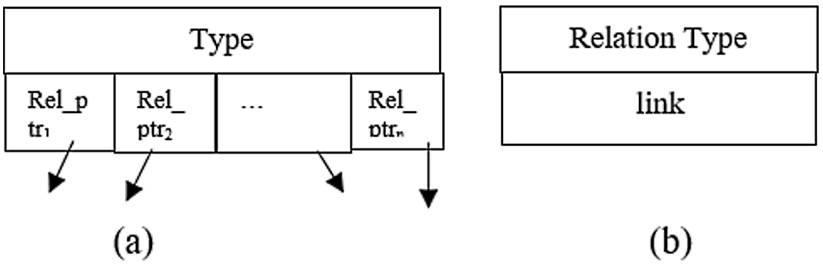
After separate graphs for each constituent is constructed, they are linked together to get a complete conceptual graph for the sentence. As each of these constituents describes one or another aspect of the verb, therefore their CGs are linked to the concept representing the verb. The concept representing head of the constituent is linked to the verb concept with an appropriate relation.

Compute Similarity of Conceptual Graphs

To evaluate candidate's answer, firstly the proposed method compares CGs of candidate's answer and model answer and then based on the closeness amongst graphs, marks are calculated.

The researchers have used the method proposed by Montes et al. (2000) to compute similarity of CGs. The algorithm for comparison of CG representations of two sentences is implemented in two main steps:

1. Find intersections (I_1, I_2 …) of the given two conceptual graphs to identify the common elements.
2. Measure similarity between the two graphs as the relative size of each one of their intersection graphs.



The value of similarity score varies between 0 to 1, where 0 indicates that given two graphs are totally dissimilar and 1 indicates that the two CGs are semantically equivalent.

Table 1. Some of the Syntactic Patterns Headed by Noun Phrase (NP)

[1] [9] NP ->NP PP (1)
[2] NP -> NNP (NNP ...)(or NNPS) (2)
[3] NP -> JJ NN (3)
[4] NP -> DT NN (4)
[5] NP -> NN (5)
[6] NP -> NNS (6)
[7] NP -> DT JJ NN (7)

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 3. Structure of (a) CONCEPT and (b) RELATION Nodes

Intersection of Two Conceptual Graphs

The intersection graph contains all concept nodes common in both the graphs and relation nodes appearing in both the graphs that relate the same concept nodes. In general, intersection of graphs may consist of more than one subgraph. In such a case, similarity measure is applied to each of them separately, and the highest value is taken as the similarity value.

To implement intersection of CGs, create two kinds of nodes – CONCEPT and RELATION nodes. CONCEPT node consists of a *type* field which stores the concept type of the concept and an array of pointers *(rel_ptr$_0$, rel_ptr$_1$ … rel_ptr$_n$)* to RELATION nodes that link concept to relations. In this work, authors are not taking referent field into consideration. Further, RELATION node consists of a *relation type* field and a *link* pointer which connects relation node to a concept node, assuming only binary relations (see Figure 3).

Algorithm 2. Intersection of Conceptual Graphs

Input: Student's answer CG and model answer CG.
Output: Intersection subgraphs of two inputted graphs.
Algorithm starts with the root node of student's CG

Step 1: Compare a concept from student's graph with all the concepts in model graph. If a match is found, continue with step 2 else goto step 4.
Step 2: Create a new concept. Compare the corresponding preceding concept as well as the relation joining the two concepts of student graph as well as already initiated intersection subgraph. If they are same, then link the newly created concept to the existing intersection subgraph.
Step 3: Else initiate a new intersection subgraph with the newly created concept.
Step 4: Repeat steps 1 to 4 with the next concept in student's graph till no more concept in student graph is left for comparison.

Similarity Measure of Conceptual Graphs

In the second step, correspondence between graphs is measured. Since conceptual graphs are bipartite in nature, the similarity *s* is calculated as a combination of conceptual similarity, and relational similarity (Montes et al., 2000).

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

1. The conceptual similarity, s_c, measures degree of similarity between concepts in both sentences.
2. The relational similarity, s_r, measures similarity of information communicated by these concepts in the two sentences.

The conceptual similarity s_c provides the number of concepts that are common in both the graphs. This is calculated by using an expression analogous to Dice coefficient (Dice, 1945):

$$s_c = \frac{2n\left(G_i\right)}{n\left(G_s\right)+n\left(G_m\right)} \tag{1}$$

where $n(G_s)$, $n(G_m)$ and $n(G_i)$ are the number of concept nodes contained in student's, model and intersected conceptual graphs respectively. The value of this expression lies between 0 and 1. Value is 0 when the given graphs have no concept in common between them and is equal to 1 when the two graphs have identical set of concepts. Method to count the number of concepts in a graph is given in Algorithm 3.

Algorithm 3. Count Number of Concept Nodes in a CG

Input: Nodei - initial concept node of a CG. No_of_concepts - initially 0.
Output: No_of_concepts - number of concepts in a graph

```
CountConcepts(CONCEPT *Node_c)
begin
        if  Node_c is not NULL
                No_of_concepts++
                Recursively call CountConcepts for all concepts related via
relation pointers rel_ptr in Node_c
end
```

To identify relationship between contexts of common concepts, relational similarity s_r is calculated. This measure provides the similarity of information communicated in both sentences about these concepts and is calculated using Equation 2.

$$s_r = \frac{2 * m\left(G_i\right)}{m_{G_i}\left(G_s\right)+m_{G_i}\left(G_m\right)} \tag{2}$$

where $m(G_i)$ is the number of relation nodes in conceptual graph G_i, and $m_{Gi}(G_s)$, $m_{Gi}(G_m)$ is the number of edges in G_s and G_m which have at least one end belonging to G_i respectively. To implement this measure, mathematical method to calculate the value of $m_Y(G)$ for a subgraph $Y \subseteq G$ is used as Equation 3:

$$m_Y\left(G\right) = \sum_{c \in Y} deg_G c - m\left(Y\right) \tag{3}$$

where $\deg_G c$ is the degree of a concept node c which is equal to the number of edges connected to c in the conceptual graph G.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Algorithm 4 and 5 describe methods to find the number of relation nodes in a graph and the degree of a concept node in a CG respectively.

Algorithm 4. Count Number of Relation Nodes in a Conceptual Graph

Input: $Node_j$ – initial concept node of a CG. No_of_relations – initially 0
Output: No_of_relations - number of relations in a graph

```
CountRelations(CONCEPT *Node_r)
begin
        if Node_j is not NULL
                for all non-null relation pointers rel_ptr in Node_r
                                No_of_relations ++
                                Recursively call CountRelations for all con-
cepts related via relation pointers rel_ptr in Node_r
End
```

Algorithm 5. Find Degree of a Concept Node in a Conceptual Graph

This algorithm finds degree of a concept which is sum of incoming and outgoing edges in a concept.

```
Input:          CONCEPT Node_d - node whose degree is to be calculated. concept_
degree -  initially 0
Output: concept_degree- degree of a concept node in a graph
CountDegree(CONCEPT *Node_d)
begin
        if Node_d has an incoming edge
                        Concept_degree++
                for all non-null relation pointers rel_ptr in Node_d
                        Concept_degree++
end
```

The cumulative similarity measure *s* is defined as

$$s = s_c * (a + b * s_r) \tag{4}$$

Coefficients *a* and *b* are smoothing coefficients to level the effect of s_r on cumulative measure, *s*. The values of coefficients *a* and *b* depends on the structure of the graphs G_s and G_m. Value of *a* is calculated using the following formula:

$$a = \frac{2n\left(G_i\right)}{2n\left(G_i\right) + m_{G_i}\left(G_s\right) + m_{G_i}\left(G_m\right)} \tag{5}$$

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

where $n(G_i)$ is the number of concept nodes in intersection graph *Gi* and $m_{G_i}(G_s) + m_{G_i}(G_m)$ is the number of relation nodes in G_s and G_m that are connected to the concept nodes appearing in G_i. Value of b is given as below:

$$b = 1 - a \tag{6}$$

Once the intersection of graphs is computed, then using Equations 1 to 6, similarity score between CGs is calculated.

Calculation of Marks

After calculation of similarity values for all the intersection subgraphs, the highest value amongst them is taken as the similarity score of the original graphs. Marks are assigned based on this similarity score using the equation given2 below:

Marks assigned = Total marks allocated * similarity score (7)

ILLUSTRATIVE EXAMPLE

The above method can be explained through examples where model answer and candidate's answers are taken as input. For an example:

Question: Why are leg bones so large compared to other bones in the human body?
Model answer: The leg bones need to be large because the leg bones carry a lot of weight.
Candidate Answer 1 (C1): Because leg bones have to hold up a lot of weight so they have to be big.
Candidate Answer 2 (C2): They support your body.
Candidate Answer 3 (C3): The leg bones help stand up. They hold the most weight.

To evaluate candidate's answer, first step is to run these sentences through SENNA – SRL tagger. Conceptual Graphs for all these sentences is generated using Algorithm 1. The generated CGs are shown in Figure 4, Figure 5a, Figure 6a and Figure 7a for model and candidates' answers respectively. To calculate the resemblance between these graphs, intersection of graphs is computed as per Algorithm 2 and the intersected graph is shown in Figure 5b, Figure 6b and Figure 7b respectively.

Similarity values calculated using Equations 1 to 6 are given in Table 2. After similarity is measured, marks are calculated using Equation 7 assuming total marks assigned to the question be 10.

EXPERIMENTS AND EXPERIMENTAL RESULTS

To evaluate performance of the proposed approach, number of experiments are conducted. In this section, (i) evaluation metrics, (ii) experimental setup and procedure, and (iii) experimental results, are described.

Figure 6. a) CG for Candidate Answer, C2 b) CG of Intersection of Model Answer and C2

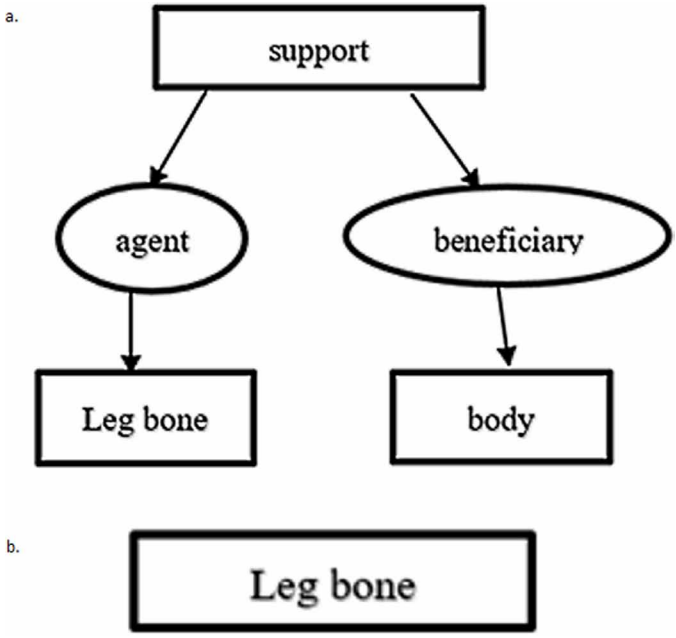

Table 2. Similarity Values Between the Graphs

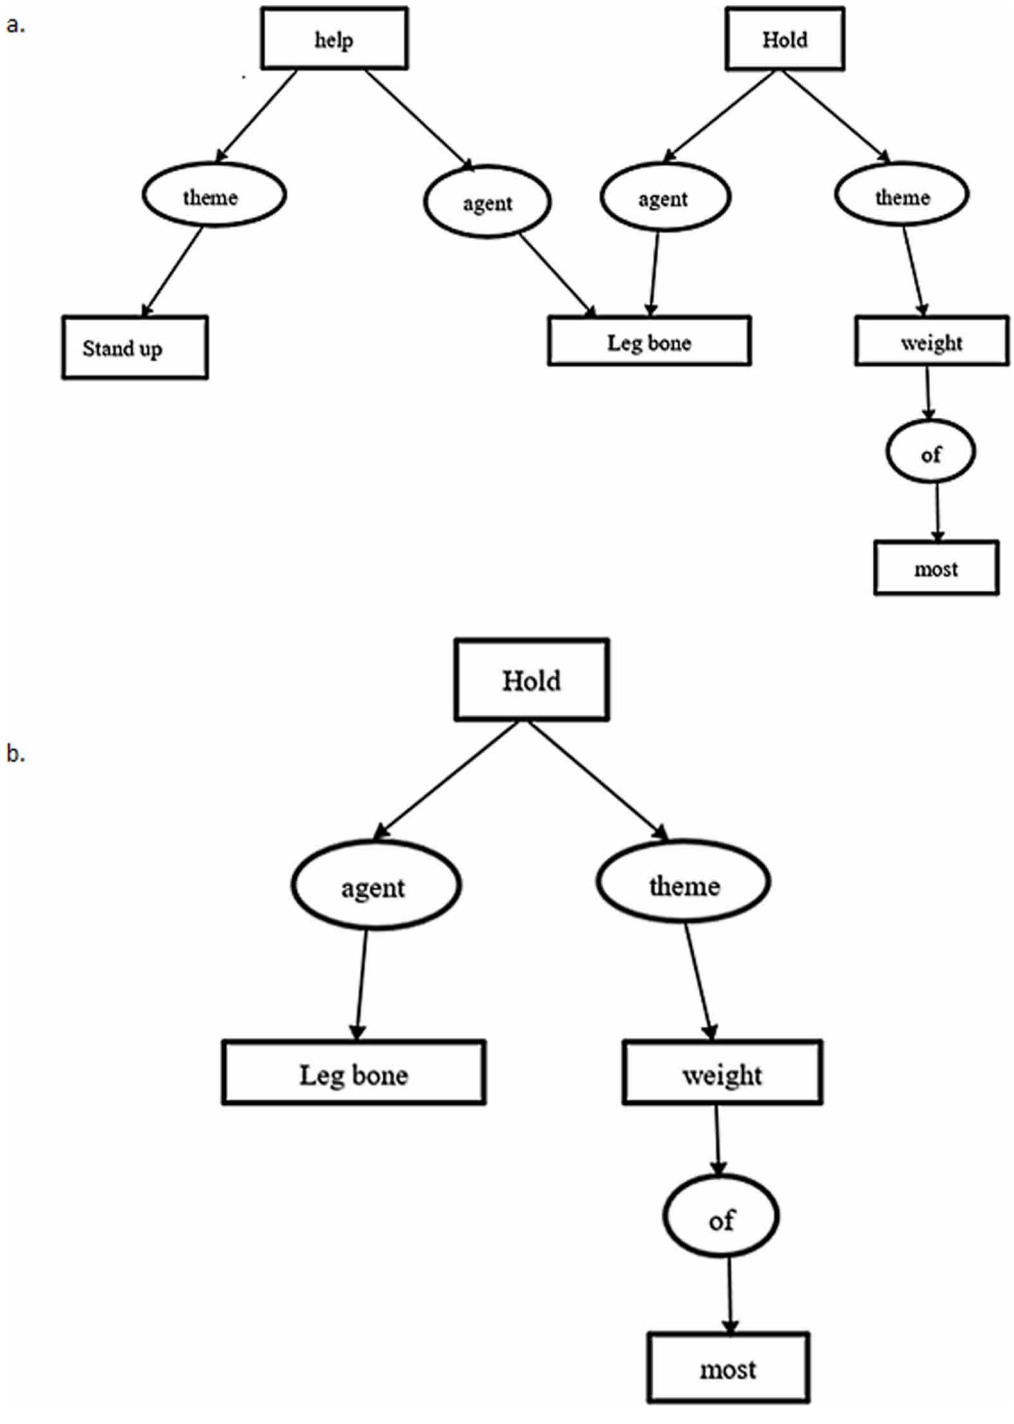
Candidate Answer	s_c	s_r	A	b	s	Obtained Marks
C1	1.00	1.00	.67	.33	1	10 (correct)
C2	.4	.67	.57	.43	.34	3.4 (incorrect)
C3	.57	.85	.53	.47	.53	5.3 (correct)

Evaluation Metrics



To evaluate performance of this system, authors compare the degree of agreement between human assessment and assessment of this proposed system using inter-rater agreement. Pearson Correlation Coefficient[3] has been used to evaluate the performance of proposed system.

"Pearson Correlation Coefficient is a statistical measure of the strength of linear relationship between two variables". It measures the standard correlation, that is, how much the human assessor scores or true scores (X) are related with the scores assigned by the system (Y). It is calculated by using Equation 8 below. The value of this measure lies between +1 and -1 inclusive where +1 signifies total positive correlation, 0 means no correlation and -1 shows total negative correlation.

$$Correlation\left(X,Y\right)=\frac{Covariance\left(X,Y\right)}{Standard\,Deviation\left(X\right)*Standard\,Deviation\left(Y\right)} \tag{8}$$

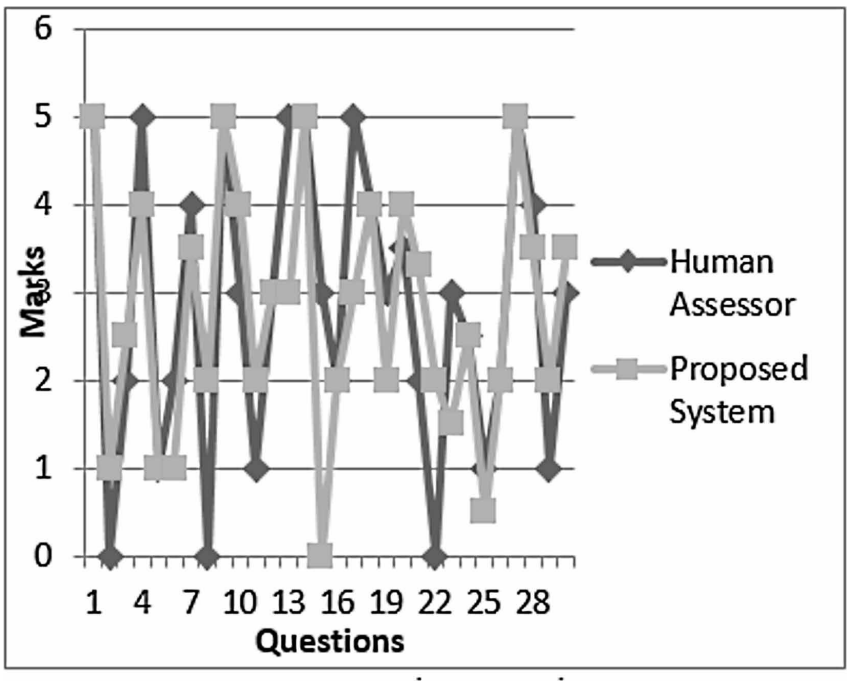
Experimental Setup and Procedure



The proposed algorithm has been implemented in C language. Empirical approach is considered for evaluating the system where users compose input for the developed system.

Initially, all experiments have been carried out with students belonging to same standard in primary school. A questionnaire was prepared consisting of 30 questions belonging to different topics. All questions carried equal weightage of 5 marks each. This questionnaire was distributed among 24 students and they were asked to answer these questions in a single sentence. Model answers for these questions were generated with the help of subject experts. The students' responses were then assessed by the newly developed assessment system as well as by human assessors. Marks were obtained from both assessments. Analysis of obtained marks showed that proposed system fully agreed with human graders about 44.7% of the time.

Experimental Results

The evaluations are run using Pearson's correlation coefficient filling one vector with marks assigned by human assessor and other with the marks generated by proposed assessment system. The correlation between the marks from human assessor and proposed system is measured and its value is $r = 0.73$ which suggests a strong positive correlation, i.e. higher score by human assessor is associated with higher score by the proposed system. A graphical description of this correlation is presented in Figure 8.

Figure 8. Plot Between Human Assessor Scores and Proposed Assessment System Score Using 30 Test Samples

Table 3. Overview of Reviewed Automatic Assessment Systems

System	Techniques	Evaluation	Language
Proposed System	NLP	Corr: 0.73	English
C-Rater	NLP	Agr: 0.83	English
E-Rater	NLP and VSM	Agr: 0.87	English
Automark	IE	Corr: 0.93	English
ES4ES	IE	Corr: 0.71	English

The overlapping points on the graph indicate the number of times the marks assigned by a teacher were exactly the same as the marks assigned by the system. Next, authors compare the performance of the proposed system with the existing 4 different automated assessment systems also. Table 3 gives overview of the techniques, evaluations results and language used of the reviewed automatic assessment systems.

SemEval-2013 – Task 7: The Joint Student Response Analysis and 8th Recognizing Textual Entailment Challenge

Effectiveness of proposed system is checked by performing student response analysis on SemEval-2013 Task 7 test data set. The data for competition was taken from Student Response Analysis corpus (Dzikovska et al... 2012) This corpus consists of two subsets: Beetle data (Dzikovska et al... 2010) and SciEntsBank data (Nielsen et al... 2008). With the aim to support those systems that generalize across problems and domains, three distinct test sets viz. Unseen Answers (UA), Unseen Questions (UQ) and Unseen Domain (UD) were created (Dzikovska et al... 2013).

Researchers performed experiments on 2-way test set i.e. proposed system marks answer as either correct or incorrect which is an umbrella term for partially_correct_incomlplete, contradictory, irrelevant and non-domain. Experiments undertaken established that answers with grades between 0 to 0.4 are incorrect and between 0.4 to 1 are marked correct. Experiments were performed on all three categories of test sets (UA, UQ and UD) on SciEntsBank data set and results obtained are shown in Figure 9. Results are tabulated in percentage of answers that were correctly marked as correct and incorrect in all three test sets. The results in Figure 9a demonstrates that system works fairly well with all the three test sets.

Comparison of proposed system with original SemEval-2013 competition results is shown in Figure 9b. The evaluation metric used was macro-average that is the average value of each metric i.e. recall, precision and F1 across classes without taking class size into consideration. It is defined as $1/N_c \sum_c \text{metric}(c)$, where N_c is the number of classes which in our case is 2. It is evident that this algorithm performs well and is quite competitive with other approaches. Though proposed system is a good performer in UA and UQ category but is one of the top performer in UD category. The reason for good performance in UD is the approach followed where proposed method does not rely on any ontology or knowledge base for CG creation and thus is domain independent. This gives the system an edge over other presented systems. A list of some of the examples taken from SemEval-2013 test sets is tabulated in Table 4 along with the evaluation results obtained using the proposed system.

Baseline Majority	.362	.367	.367

Table 4. List of Some Examples Marked Using Proposed System

Question	Reference/Model Answer	Student Answer	Answer Accuracy as per test set	Marks and Result (Correct/ Incorrect)
You used several methods to separate and identify the substances in mock rocks. How did you separate the salt from the water?	The water was evaporated, leaving the salt.	We evaporated the water.	Correct	.94 (correct)
		Get all the water out.	Incorrect	.31(Incorrect)
You can tell if a rock contains calcite by putting it into a cold acid (like vinegar). Describe what you would observe if you did the acid test on a rock that contains this substance	Many tiny bubbles will rise from the calcite when the calcite contacts the cold acid.	If you see bubbles coming from the rock it contains calcite.	Correct	.82 (correct)
		It would fizzle.	Correct	0 (Incorrect)
You used 3 scratch tools in class to test minerals for hardness: your fingernail, a penny, and a paperclip. If a mineral can be scratched by a penny, you can be sure that a (paperclip) will also scratch it. Explain how you know that tool would scratch the mineral.	A paperclip is harder than a penny, so if a penny can scratch a mineral, a paperclip can also scratch the mineral.	Because the paperclip is an easier item to scratch a rock or mineral than a penny.	Incorrect	.14 (Incorrect)
		I knew that because the paperclip is harder than the penny.	Correct	.86 (correct)
What happens to earth materials during erosion?	Earth materials are worn away and moved during erosion.	They all settle to the bottom.	Incorrect	0 (Incorrect)
		During erosion earth materials break away and flow away.	Correct	.66 (correct)
Why does the level of the water in the straw go up when the bottle-and-straw thermometer is heated?	Water expands when water is heated.	Because hot water expands and cold water contracts.	Correct	.61 (correct)
		The hot water heats the thermometer.	Incorrect	.42 (correct)

CONCLUSION

Computer Based Assessment has been an interesting research area since 1970's. It helps in the evaluation of student's performance without bias and wastage of time. Automatic evaluation of descriptive answers would be beneficial for schools and universities as well as it provides ease to evaluators. The algorithm proposes a solution for automating the evaluation process of simple textual descriptive answers. The overall performance of this system was found to be 0.73. Major constraint of proposed system is that it is not considering answers that include mathematical formulas, diagrams, and examples.

Since the current work is a modest attempt to develop a CG based evaluation system, there is definitely a good scope for future research work in this area.

One of the possible works is to have an exhaustive analysis for similarity matching by assigning weightage to each term or word to have a better understanding of the relevance of each word in the answer. This may thus help in better evaluation of answers. The proposed algorithm can be modified for evaluation of complex, compound and multiple sentences answers.

Chapter 38
Wild Architecture:
Explaining Cognition via Self-Sustaining Systems

Vincent T. Cialdella
Illinois State University, USA

Emilio J. C. Lobato
Illinois State University, USA

J. Scott Jordan
Illinois State University, USA

ABSTRACT

In this chapter, the authors focus on cognitive architectures that are developed with the intent to explain human cognition. The authors first describe the mission of cybernetics and early cognitive architectures and recount the popular criticism that these perspectives fail to provide genuine explanations of cognition. Moving forward, the authors propose that there are three pervasive problems that modern cognitive architectures must address: the problem of consciousness, the problem of embodiment, and the problem of representation. Wild Systems Theory (Jordan, 2013) conceptualizes biological cognition as a feature of self-sustaining embodied context that manifests itself at multiple, nested, time-scales. In this manner, Wild Systems Theory is presented as a particularly useful framework for coherently addressing the problems of consciousness, embodiment, and representation.

INTRODUCTION

For some time now, one of the leading assumptions in the development of cognitive architectures has been Marr's (1982) tri-level theory of explanation; the idea that the proper approach in developing a cognitive architecture (and thus explaining cognition) is to

1. Determine the computations necessary to completing a cognitive task (e.g., sorting a list of numbers from lowest to highest),
2. Generate a representation of the inputs, outputs, and algorithms an information-processing system would need to complete the task, and
3. Actually build (i.e., implement) a system capable of executing the algorithms.

The purpose of the present paper is to examine issues that have proven challenging to Marr's implementation approach to explaining cognition. Three particular challenges are the issues of consciousness, embodiment, and representation. After examining these challenges, we will present an approach to describing cognitive architectures (Wild Systems Theory—WST, Jordan, 20213) that addresses each challenge, while simultaneously shifting the focus of modeling from looking to biology for inspiration, to looking at a more fundamental property that biological systems share with many other types of systems, including chemical, psychological, and cultural—specifically, the ability of certain far from equilibrium systems to generate catalysts that feedback into and sustain the processes that produced them; what Kauffman (1995) refers to as 'autocatalytic' systems, and what Jordan (2013) refers to as self-sustaining, or *wild* systems.

PROBLEMS WITH "IMPLENTATION AS EXPLANATION"

While Marr's (1982) approach to developing cognitive architectures has inspired research that has given rise to a host of new technologies, there are those who have expressed doubts regarding his assertion that implementation constitutes explanation. In his seminal paper, *Quantitative analysis of purposive systems: Some spadework at the foundation of scientific psychology*, William T. Powers (1973) expressed his belief that psychologists were working under the confused assumption that control-theoretic concepts had been developed to explain the behavior of organisms. According to Powers, control-theoretic concepts were developed so that engineers could develop systems capable of doing what organisms do; namely, maintain ordered states with their environment by offsetting environmental disturbances to those ordered states. Powers referred to this ability to maintain ordered states as *input control*, and he further stated that in order for engineers to be able to build input control systems, they had to develop a conceptual scheme that captured the dynamics of organismic input control in a way that allowed the dynamics to be transformed into functioning, artificial, input-control systems, what have come to be known as servomechanisms. Thus, the conceptual scheme created by engineers includes phrases such as reference signal, which represents the state the system is to sustain. For example, when one dials in a room temperature on a thermostat, one is basically specifying the reference signal for the system. Or, said another way, one is setting the input level the system should keep constant. In order to keep its input at a pre-specified level, the system must be able to counteract environmental events that move the input (i.e., sensed temperature) away from the value of the reference signal. For example, when one opens a window and allows cold air into the room, the air temperature will change. If it varies from the pre-specified level, the system must be able to offset such disturbance. The system's ability to generate disturbance-offsetting events is referred to as output. In the case of the thermostat, the system's output is the turning on of the furnace. As the system continues to generate output (e.g., the furnace stays on) the difference between the input and the reference signal decreases. From the perspective of an engineer, who is actually trying to build such a system, this means the system has to be able to compare its current

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

input state (i.e., sensed room temperature) to its reference signal. Engineers refer to the system component that accomplishes this function as a comparator. They also refer to the result of the comparison as an error signal. Collectively then, servomechanisms are constructed such that the error signal drives the system's disturbance-offsetting outputs (i.e., the difference between the sensed temperature and the reference signal determines when and for how long the furnace is active). As a result of this architecture, the error signal actually serves to negate itself (i.e., make itself become zero), and this explains why engineers also refer to servomechanisms as negative-feedback control systems.

The reason for analyzing the nature of servomechanistic concepts so thoroughly was to underline Powers' (1973) point that concepts such as *reference signal*, *disturbance*, *input*, *output*, *comparator*, *error-signal*, and *negative-feedback* were created by engineers so they could create systems capable of doing what organisms do (i.e., maintain ordered relationships). That is, the concepts were created for the purpose of *implementation*, not *explanation*. Implicit in Powers' argument is a take on the relationship between implementation and explanation that is counter to Marrs' (1982) position.

From Cybernetics to Cognitive Architecture

Following the cybernetic movement referred to by Powers (1973), cognitive psychologists began to work toward developing computational systems (i.e., architectures) meant to model human cognition. While some architectures were and are developed with the sole intention of enabling artificially intelligent behavior, others were and are developed in the hopes of explaining the architecture that underlies human cognition. Thus, as was the case in Powers' (1973) critique of the cybernetics movement, there are those whose approach to developing cognitive architectures entails two related, but distinct, goals: the technological goal and the explanatory goal. The former refers to the practicality of using artificial systems to complete tasks that require human level competence or, perhaps, a level of performance that goes beyond the limitations of humans (Duch, Oentaryo, & Pasquier, 2008). Cognitive scientists operating within the field of Artificial Intelligence (AI) are particularly interested in building systems that can realize the same cognitive functions that are achieved by humans. To some extent, the focus on modeling and building cognitive systems renders this approach an engineering perspective on cognition. On the other hand, the explanatory goal refers to the possibility of using what was learned while building an artificial cognitive system to explain the achievements of natural cognitive systems such as humans. That is, success in building an artificially cognitive system might be taken as an indication that human cognition is actualized by the same mechanisms that were used to produce artificial cognition (Anderson et al., 2004).

According to contemporary AI researchers, *cognitive architecture* can be described as the invariant properties that underlie cognition (Douglass & Mittal, 2013). While contexts inevitably vary, the principles by which a system engages the world exhibit consistency; that is, they are invariant. This consistency may be attributed to the system's stable architecture. Examples of cognitive architectures include Soar (Laird, 2008; Laird, Newell, & Rosenbloom, 1987), LIDA (Baars & Franklin, 2009; Franklin et al., 2013), and ACT-R (Anderson, 1996; Anderson et al., 2004). While these architectures may, to some extent, exhibit similarities, they diverge in their implementation, the authors' motivations and goals for their architectures, and the phenomena to which they are commonly applied. Laird (2012) described this divergence in reasons for development: Some developers design their architectures specifically with a more technical, engineering focus in order to support the development of agents, whereas others are designed with the goal of explaining cognition. In addition to their variable purpose, architectures also

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

differ in their fundamental assumptions about cognition; they may differ in the mechanisms by which they learn, the way in which knowledge is represented, or even the types of knowledge that can be represented.

To be sure, it is often the case that the same architecture is used to pursue both the technical and the explanatory goal. In the past, Soar has been used to model human behavior (Lewis, 1993; Miller & Laird, 1996), but the developers are now predominantly concerned with demonstrating its real-time functionality in artificial systems (Laird, 2012; Langley, Laird, & Rogers, 2009). In this sense, the developers are largely interested in achieving the technological goal of AI. In contrast with Soar, a majority of work in ACT-R seems to reflect an interest in the explanatory goal of AI. Although it has seen applied use in intelligent tutors (Koedinger, Anderson, Hadley, & Mark, 1997) and robotics (Trafton et al., 2013), ACT-R has largely been used to model a wide variety of data obtained from work in experimental psychology (e.g., Halbrügge, Quade, Engelbrecht, 2015; Wirzberger & Russewinkel, 2015). Despite the use of some architectures to achieve both technical and explanatory goals, we now focus on one particular architecture (i.e., ACT-R) and the issues that have arisen as research have attempted to use it as an explanation of cognition.

ACT-R as Explanation

The ACT-R architecture (Anderson et al., 2004) is composed of a number of components called modules, which each handle different types of information. Examples of ACT-R modules include an intentional module that maintains goal states and intentions, a declarative module that handles the retrieval of information from memory, a visual module that supports information about entities in the visual field, and a manual module that affords control over hands. Each module contains a buffer that maintains information relevant to the task currently being addressed. Two kinds of knowledge are represented in ACT-R: declarative knowledge and procedural knowledge. Declarative knowledge is represented using *chunks*: knowledge units that accommodate key-value pairs. Procedural knowledge is represented using *productions*: condition-action rules.

During run-time, buffers of each module can be manipulated by way of a central production system that recognizes when the chunk in a buffer meets certain conditions. When a pattern is matched, the production system can make changes to that buffer or the buffers of other modules. Buffers are updated by the productions that 'fire' when their conditions are met. For example, if a chunk in the visual buffer matches conditions specified in a production, the model might alter the chunk in the manual buffer to make a request to move the hands toward an identified object. In ACT-R, only one production can fire at a time. To resolve this conflict, a utility calculation determines which production will be most likely to achieve the current goal and consequently fire. Apart from the inter-module communication that is afforded through the central production system, these modules operate independently of one another.

According to ACT-R's implementers, the ACT-R architecture affords the development of software agents as well as a unified theory of human cognition (Anderson et al., 2004). That is, the authors strive toward the explanatory goal of cognitive architectures. As any good theory of human cognition should, the theory is used to explain a large body of data obtained in experimental psychology. In a comprehensive presentation of the ACT-R theory and related empirical work, Anderson and colleagues (2004) presented data from a number of behavioral and neuroimaging studies to identify the neural correlates of various ACT-R modules by tracking how and when information is updated in buffers while engaging in tasks. Since then, ACT-R models have been used in concert with fMRI data to localize the updating of working memory and the retrieval of declarative memory by using the activity of ACT-R's modules

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

as a predictor of neural activity in a regression analysis (Borst & Anderson, 2013). Another study has simulated the process of learning a new song, demonstrating robust primacy and recency effects that are similar to those observed in human subjects (Chikhaoui et al., 2009). Results from modeling efforts have also motivated the development of richer theoretical accounts of associative memory (Thomson, Pyke, Trafton, & Hiatt, 2015).

In other experiments, researchers have measured participants' ability to estimate the amount of time that has passed while multitasking. Comparing these results with ACT-R models has highlighted the importance of considering the influences of multiple contextual factors (Moon & Anderson, 2013). Researchers investigating action control while driving an automobile have evaluated the performance of novice and experienced drivers by using ACT-R to model the influence of driving experience on collision avoidance and lateral control skills (Cao, Qin, Jin, Zhao, & Shen, 2014; Cao, Qin, Zhao, & Shen, 2015). Additionally, comparison of models with human reaction-time data in a task-switching paradigm has generated possible, concrete accounts of psychological constructs such as flow (Altmann, & Trafton, 2007). In sum, by comparing the data exhibited by ACT-R models to the data collected from human participants, researchers are not only afforded the ability to generate possible explanations of observed phenomena but are also able to enhance their theoretical perspective.

Despite ACT-R's ability to computationally model experimental human data, there are those who express concerns regarding its ability to constitute an explanation of human cognition. For example, it is recognized (e.g., Bösser, 1987, 2013) that there exists more than one set of values for chunking parameters in Soar that can fit a single data set. This also applies to the parameterization in ACT-R. Others have criticized the practice of parameter estimation on the grounds that any pattern of data can be fit (Roberts & Pashler, 2000), and these criticisms have been appropriately responded to (see Anderson et al., 2004). Johnson-Laird expresses further suspicions regarding the explanatory capabilities of models:

The reason for the suspicion is complex. In part it derives from the fact that any large-scale program intended to model cognition inevitably incorporates components that lack psychological plausibility.… Certain aspects of any such program must be at best principled and deliberate simplifications or at worst ad hoc patches intended merely to enable the program to work. The remedy… is not to abandon computer programs, but to make a clear distinction between a program and the theory that it is intended to model. (1980, p. 110, emphasis in original)

Choices about what should be modeled (e.g., the types of knowledge) and how to model it will necessarily reflect the constraints and affordances of the technology that are made available to the developers. In order to obtain a functioning model, decisions might be made during implementation so as to accommodate for technological limitations. For this reason, as Johnson-Laird advises, one should be wary of equating a description (i.e., the model) with the explanation (i.e., the theory).

To be sure, the authors of ACT-R do not present their architecture as *the* truth about human cognition. Anderson and colleagues note, "just because such architectures aspire to account for the integration of cognition, they should not be interpreted as claiming to have the complete truth about the nature of the mind" (2004, p. 1057). Instead, the hallmark of cognitive architectures is their ability to force researchers to think about how all these various, independently studied functions can all be brought together under one cohesive framework. Focusing on the architecture of cognition draws attention to the problems that are neglected when theorists fail to concern themselves with the implementation of cognition.

CONTEMPORARY ISSUES WITH IMPLEMENTATION

Contemporary attempts to explain human cognition via implemented architectures have begun to place more emphasis on the biological substrate of human cognition (Franklin, Strain, McCall, & Baars, 2013). The BICA (Biologically Inspired Cognitive Architectures) movement, as represented by the journal of the same name, describes its mission as follows: "The focus of the journal is on the integration of many research efforts in addressing the challenge of creating a real-life computational equivalent of the human mind." Along the way, BICA researchers have also had to address the issue of whether the goal is to implement an architecture that can produce the same output as a biological organism, or is the goal to implement an architecture that serves to explain biological cognition? If the goal is the former, then issues with implementation are predominantly pragmatic. Specifically, the challenge of implementation largely, if not entirely, concerns finding the algorithms that will provide the right kind of output. If the goal, however, is explanatory, then all of the issues in the behavioral, cognitive, and social sciences necessarily become issues for instantiating a particular model of cognition. In the following sections, we outline three general topics that we feel need to be addressed by any explanatory cognitive architecture. These topics are consciousness, embodiment, and representation.

The Problem of Consciousness

A more recent cognitive architecture has been developed in response to the pursuit of biologically inspired artificial intelligence systems: the Learning Intelligent Distribution Agent (LIDA; Franklin et al., 2007). LIDA was developed to implement the Global Workspace Theory (GWT) of consciousness to integrate both conscious and unconscious aspects of biological, in particular human, cognition (Baars & Franklin, 2009). GWT proposes that cognition results from the culmination of many specialized and distributed processes within the brain. Conscious cognition is enabled and constrained by unconscious cognitive processes, in particular perceptual processes, which are recursively influenced by the focal content of conscious cognition feeding back to these unconscious processes (for review, see Baars, 1988). What LIDA attempts to do is to computationally model and implement GWT. Specifically, the LIDA model focuses on the notion of cognition as resulting from cognitive cycles, which are rapid sensory samplings by the cognitive agent of the environment (both external and internal) to update the agent's representation of the environment. During this rapid sampling process, the agent's unconscious processing determines what aspects of the environment are sufficiently salient enough to draw conscious attention toward, which is then fed back to the lower-level processes so that subsequent appropriate action selection and execution can occur.

The developers of the LIDA model have also recently proposed LIDA as a referent architecture for the broader community of scholars interested in artificial intelligence by outlining the conceptual commitments of the model (Franklin et al., 2013). The major draw of doing so is that LIDA, which is an outgrowth of GWT, is committed to the importance of consciousness as a necessary component of cognition, in contrast to other architectures like ACT-R or Soar (Chella, 2013; Franklin et al., 2013).

The Problem of Embodiment

Curiously, the authors of the LIDA model, in explicating the conceptual commitments of the system, express a commitment to embodiment as significant for their model without necessarily insisting on physical, robotic implementation (Franklin et al., 2013). This is due to their broad interpretation of embodied cognition as

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

just the structural coupling of the agent with its environment. Their view is that general intelligence is a sufficiently abstract enough entity to not necessitate robotic instantiation, and embodiment still occurs as long as the agent and environment are coupled in some way (Franklin, 1997; Franklin et al., 2013). Commenting on this curiosity of a disembodied form of embodiment, Wiltshire and colleagues (2013) noted that physical embodiment of an AGI model such as LIDA would enhance the capacities of the model. Morphology prescribes and constrains an agent's ability to perturb and interact with its environment (Anderson, 2003), particularly with regards to more complex and dynamic forms of agent-environment interactions such as social cognition. Architectures that aim to be used for the development of artificially intelligent agents might be more successful if they were to directly address the complexity of embodied cognition.

To be sure, this is easier said than done. The complexity of the embodied cognition perspective is partially due to the lack of a firm or precise description of what constitutes a body (Anderson, 2003). The most radical claim of the embodied cognition perspective is that "the brain is not the sole cognitive resource we have available to use to solve problems" (Wilson & Golonka, 2013, p. 1). As dramatic as that claim is, which itself cannot be understated currently, the claim does require further elaboration on what constitutes a body. This issue is addressed only indirectly, by describing what bodies do, such as "move and act in rich real-world surroundings" (Clark, 1998, p. 506) or describing the role of the body in constraining the form that behavior takes via an organism's perceptual-motor capabilities (Anderson, 2003; Varela, Thompson, & Rosch, 1991; Wilson & Golonka, 2013).

The Problem of Representation

In addition to consciousness and embodiment, another on-going critique of the cognitive architecture literature is its total reliance on the notion of "representation." Common to most such criticisms is a commitment to some form or another of dynamical systems theory and the assertion that the work of cognition is to be found in the self-organizing, synergetic, circular causality of continuous interactions between brain, body and world (Clark, 1997; Jordan, 2003; Kelso, 1995; O'Regan & Noe, 2001; Tschacher & Dauwalder, 2003; Thelen & Smith, 1994; van Rooij, Bongers & Haselager, 2002; Varella, Thompson & Rosch, 1991; van Gelder, 1998). A classic example of a self-organizing system is a convection roll. If one applies heat to a pan of cool oil, a rather complex system of convection rolls will emerge as the heated oil rises to the top and the cooler oil sinks to the bottom.

The resulting convection rolls are what physicists call a collective or cooperative effect, which arises without any external instructions… Such spontaneous pattern formation is exactly what we mean by self-organization: the system organized itself, but there is no 'self', no agent inside the system doing the organizing. (Kelso, 1995, pp. 7-8)

Van Gelder (1998) strongly rejects the computationalist notion that behavior is controlled (i.e., regulated) by internal structures such as codes and plans. Instead, he proposes it is possible for a system to give rise to regulatory behavior solely on the basis of self-organizing dynamics. He presents the Watt Governor as an example.

A Watt Governor is a mechanism that keeps the velocity of a fan constant. It does so because the velocity of the fan's flywheel influences itself recursively. That is, the faster the flywheel moves, the more it slows itself down. This is because the movements of the flywheel cause two weighted arms, attached to the

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

flywheel via a spindle, to rise as the flywheel moves faster. These movements cause a valve, connected to a steam-engine driving the flywheel movement, to close, thereby reducing the amount of steam released which, in turn, slows the flywheel and allows the weighted arms to lower. Because of the constant, mutual influence all the components have on one another, fan velocity can be held fairly constant. Van Gelder proposes the Watt Governor as a prime example of regulated behavior emerging out of purely self-organizing processes. At no point in the Watt Governor systems is there a 'code', a 'representation', or information being processed. As a result, he argues it should be possible to model cognitive systems solely in terms of self-organizing dynamics. (Jordan & Ghin, 2007. P. 183-184)

Jaeger (1998) later criticized theorists who asserted that dynamical systems such as the Watt Governor constituted the proper way to explain cognition. Specifically, he believed that the current state of mathematics in dynamical systems theory was not sophisticated enough to effectively model organisms:

First, DST principles like attractors and bifurcations are not of much help in wild systems with fast stochastic input varying on the system's own characteristic time scale. Second…DST handles high-dimensional domains by reducing them to low-dimensional descriptions…this reduction to some collective parameters is helpful in some respects but still poses a limit to the study of high-dimensional systems. (1998, p. 643-644, emphasis added)

Collectively, critiques of the ability of currently available cognitive architectures to explain cognition imply that while modeling efforts such as those in the ACT-R and LIDA communities have demonstrated considerable progress toward the technological goal of AI, the extent to which the efforts display progress toward the explanatory goal remains unclear. That is, such efforts surely have the potential to yield artificial systems that can do what we do, but successful modeling does not necessarily demonstrate that these artificial systems do what we do *in the way that we do it*. At their core, cognitive architectures engage cognition as a purely computational process. This conception of biological cognition has existed for decades (e.g., Miller, Galanter, & Pribram, 1960), arising in part from a desire to broaden psychological science as more than strict behaviorism. However, this assumption of cognition as computation is not universally accepted (e.g., Gibson, 1979), and there exist useful and productive lines of research that incorporate non-computational explanatory mechanisms in their theorizing of human cognition, either as true alternatives to purely computational models of information processing (e.g., Marsh, Richardson, & Schmidt, 2009) or as additional components into pluralistic frameworks that propose both computational and non-computational mechanisms to explain aspects of human cognition (e.g., Wiltshire et al., 2014; see also Gallagher, 2015). It is our contention that progress in the development of cognitive architectures that are intended to explain human cognition, rather than "simply" mimic the output of human cognition, would benefit greatly from attempting to model such non-computational components. In particular, we propose that the Wild Systems Theory (WST) put forward by Jordan (2013) serves as an especially useful framework for such an endeavor. In the following section, we will present and describe WST as a way to conceptualize human cognition that may aid in the development of a biologically inspired cognitive architecture that supports intelligence by means similar to those which result in natural cognitive systems.

WILD ARCHITECTURE

Jordan and Day (2015) describe organisms as multi-scale self-sustaining systems. This means that the work that organisms do is self-sustaining, or autocatalytic. That is, the work produces products that further promote the work. Put simply, an autocatalytic reaction between chemicals *A* and *B* will produce a catalyst for the *A*-*B* reaction (Kauffman, 1995). Such reactions continue to occur by the nature of their self-sustaining work. As networks of autocatalytic reactions are sustained, the stability maintained by this level of autocatalysis enables the emergence of larger-scale autocatalytic processes. When one level of autocatalytic order is achieved, another can emerge. One might conceptualize living systems as large-scale organizations of autocatalytic processes or multi-scale systems of self-sustaining work. The tree-climbing behavior of a monkey (i.e., the work) to obtain a banana will yield energy in the form of food that will further promote the energy-obtaining work of the monkey. Importantly, within each organism, self-sustaining work is occurring at multiple time scales simultaneously (Jordan, 2013). The monkey exhibits self-sustaining work at the behavioral level while the organs, tissues, and cells exhibit self-sustaining work at various different biochemical levels and time scales.

As these living systems emerge, they alter their environment by the nature of their autocatalytic work, providing a new context in which other self-sustaining systems can emerge. For example, the emergence of plants afforded the emergence of a life form that harvests plants for energy, and the emergence of herbivores afforded the emergence of a life form that harvests herbivores for energy. Given that organisms emerge out of the context in which they are embedded, the work they do necessarily reflects the kind of energy transformation that is required for self-sustainment in that context; the fuel source dictates the consumer (Jordan & Ghin, 2006). An organism (i.e., a self-sustaining energy transformer) sustains itself using the energy that is made available in its environment. Conceptualizing organisms in this way, nature is illustrated as a self-organizing energy-transformation hierarchy in which each organism alters its context such that it can continue to sustain itself and consequently creates a context in which another organism can obtain, transform, and dissipate the newly available energy. At each level, energy transformation is not what a system *does*; it is what a living system *is*.

Following from the notion that the fuel source dictates the consumer, Jordan and Day (2015) argue that all organisms constitute embodiments of their context. That is, organisms embody the dynamics in which they emerged and in which they continue to sustain themselves. As an example of an embodied context, the herbivore embodies the contextual constraints that determine what kind of work must be done for an organism to sustain itself in an environment furnished with plants. A carnivore embodies the constraints of its context, namely that it must be able to catch a moving energy source in order to sustain itself. For the carnivore, this requires anticipation of where the prey *will be* rather than where the prey *is* in order to be successful.

Jordan and Day (2015) contend that this anticipatory form of aboutness (i.e., embodiment) is what one might refer to as mind. However, it is important to note that there is a fundamental similarity between the abstract, anticipatory aboutness that we experience as a mental life and the aboutness of a plant. Both emerge out of the constraints that determine the work that must be done for an organism to sustain itself in a context. It just so happens that, because of the constraints of the context that fostered the emergence of humans, humans embodied the dynamics of temporally distal events. This allows humans to live rather anticipatory lives in which we can organize ourselves about abstract events such as ‘tomorrow’ (Jordan & Vinson, 2012).

What Does WST Afford AI Research?

From the WST perspective, one is afforded a new way of describing what it is that intelligent behavior entails: multi-scale, self-sustaining energy transformation. In architectures like ACT-R, wherein the basic mechanisms work in concert to produce a rich combination of symbolic and sub-symbolic knowledge (through the acquisition and curation of knowledge units), Wild Systems Theory (WST) proposes that knowledge exists at every scale of work because every level is about the context in which that order is maintained. In this way, knowledge is not something that intelligent agents *have*; it is what they *are*. This leads to two related statements that could be taken as invariant principles for a biologically inspired, artificial cognitive system: (1) behavior embodies contextual constraints and affordances; a system's work reflects the kind of energy transformation that is necessary for sustainment in that context, and (2) the system consists of multiple levels (e.g., sub-personal; personal; supra-individual; see Bohl & van den Bos, 2012; Wiltshire et al., 2014) of self-sustaining work; each level of order is achieved and maintained by work that adheres to principle (1). We argue that these two statements coherently capture what it is that intelligent systems are: multi-scale, self-sustaining embodiments of context. Thus, adherence to these principles effectively integrates all of human behavior (and cognition).

In order to better clarify how we believe the notion of multi-scale, self-sustaining embodiment of context provides a biologically inspired approach to cognition and cognitive architecture, we need to more thoroughly describe how the architecture of self-sustaining systems qualifies as "cognitive." Take, for example, a rock. A rock can be considered an embodiment of its context. That is, animals, plants, and rocks could all be considered instantiations of the demands or forces that their environments exert on them. In this sense, the rock is much like animals and plants; the rock also constitutes embodied context. So what makes the embodied context of living organisms different from the embodied context of a rock? Jordan and Vinson (2012) assert that the internal dynamics of an organism are coupled to the dynamics of the organism as a whole such that changes occurring at the micro scale bring about events at the macro scale that recursively affect the micro scale and serve to sustain both the micro and macro scales of organization. For example, energy depletion at the cellular level will influence behaviors at the organismic level to increase the amount of available energy at the cellular level. This recursion enables the sustainment of the internal and whole-organism dynamics. Like organisms, the rock is an embodiment of its context (i.e., the constant tension between the strong and weak atomic forces, electromagnetism, and gravity), but the micro-macro coupling does not serve to sustain the order achieved at either the micro or macro scale. In WST, it is the self-sustaining recursion of the micro-macro coupling that distinguishes the embodied context of organisms from that of rocks and affords a particularly interesting means of being 'about' the world. It is through this self-sustaining work that organisms maintain relationships with their environment. Rocks, desks, and computers do not share this feature with organisms. From this, we argue that the WST framework provides a unique avenue for addressing the problems of consciousness, embodiment, and representation that still challenge the development of cognitive architectures.

WST and Consciousness

Some researchers are not only interested in the processes that give rise to intelligent behavior, but are also interested in identifying those properties that afford a phenomenal consciousness (Reggia, 2013). Such an investigation first requires an adequate description of what consciousness is. Following from the conceptualization of organisms as self-sustaining embodiments of context, Jordan and Ghin (2006)

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

propose that consciousness is the 'aboutness' inherent in self-sustaining embodied context. That is, if a self-sustaining system constitutes an embodiment of its context, it follows that system is naturally and necessarily *about* its context. The authors consider the aboutness of a single-celled organism a "proto-consciousness" because it is the evolutionary precursor to human, embodied aboutness. This suggests that phenomenal consciousness is achieved by humans through their work's natural property of being *about* sustaining a relationship with the world. Accordingly, any system—natural or artificial—that has self-sustaining embodied aboutness would have what we call consciousness.

The problem of implementing consciousness is important to a few AI researchers (e.g., Baars, 1998; Baars & Franklin, 2009). Alternatively, others might operate under the assumption that one can ignore the "Hard Problem" of consciousness (Chalmers, 1995) and solely address the comparatively "easy" work of building an artificial system that can perceive, deliberate, and act. Such an approach could go on doing its work and create artificial systems that behave intelligently without a phenomenal consciousness. By contrast, from the perspective of WST, the problem of artificial cognition and the problem of artificial consciousness are, essentially, one and the same. In other words, if one produces an artificial system that is intelligent by the same means as organisms, one necessarily has implemented a phenomenal consciousness because the system would constitute the self-sustaining kind of embodied aboutness. To be sure, the distinction between the first perspective and WST is not intended as a criticism of the former but, rather, as an opportunity to clarify the difference between creating an artificial system that can do what we do and creating an artificial system that can do what we do *in the way that we do it*. In WST, consciousness is necessary for cognition because it is what we are (i.e., self-sustaining embodied aboutness).

WST and Embodiment

Hypothetically, one can attach arms and legs to a modern computer and program various behaviors into this robot. On the condition that its battery is nearly depleted, the robot might act so as to recharge its battery by navigating to a charging station. To be sure, one can refer to such behavior as self-sustaining. However, we would not grant this system the same self-sustaining, embodied aboutness that we ascribe to organisms. While the behavior of such a robot is self-sustaining at the organismic level, the stability at every other level of scale is taken for granted and is relatively independent of the self-sustaining work of the system as a whole. The chassis, for example, does not generate dynamics that sustain its work or serve to sustain the work of the robot. On the other hand, human neuromuscular architecture works to sustain its own integrity while simultaneously sustaining the integrity of the human. Changes that occur at the level of our neuromuscular architecture give rise to changes at the level of the organism, which, in turn, influences the neuromuscular architecture. This recursion simultaneously sustains the work of the neuromuscular architecture and the human organism, preserving their stability. Such self-sustaining micro-macro coupling would not be observed in the self-charging robot as described. One might say that the robot we described merely *has the ability* to recharge its own battery (i.e., obtain energy) while obtaining energy (i.e., self-sustainment) is what organisms *are*.

In sum, the human body is not merely a "container" for cognition. A body is yet another scale of self-sustaining work that emerges from and is sustained by all the levels of work of which it is constituted. In addition, the various levels of self-sustaining work that constitute a body are simultaneously embodiments of the contextual constraints that need to be addressed in order to afford sustainment. As a result, the human body can be coherently conceptualized as an amalgamation of internal and external

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

dynamical constraints, such as the multi-scale constraints that have to be addressed in order to propel oneself toward an energy source. Accordingly, unlike other embodiment perspectives which emphasize the importance of the body but fall short of defining exactly what a body is (Anderson, 2003), WST addresses the issue of embodiment by unifying bodies and cognition under the conceptual framework of self-sustaining systems.

Furthermore, this perspective clarifies exactly why bodies matter for cognition. Put simply, the body is an ever-present context for the brain and serves as a definable border between the entity and the external environment, albeit a border that is amenable to change (the development from a tadpole into a frog or the growth of a human newborn into an adult human as examples of typical changes to bodies' borders; loss of a limb due to an accident, surgery, or predation as an example of atypical changes to a body's border). The nature of the body as a defined border allows for cognition and behavior to reflect the simultaneous incorporation of or approach towards parts of the environment that facilitate self-sustainment as well as the rejection or avoidance of parts of the environment that destabilize self-sustainment. The self-sustaining work of a body is among the vast constellation of contextual constraints that a brain has to embody in order to sustain itself and the body to which it is recursively coupled. In short, bodies matter to brains because brains, as embodiments of context, are inherently *about* bodies.

WST and Representation

We have noted that there are those who abstain from the use of representation in describing the work of cognitive systems (e.g., Van Gelder, 1998). Specifically, researchers committed to a dynamical account of cognition tend not to refer to internal states with causal powers and, instead, view cognition as a self-organizing process spanning brain, body, and world. While WST does not refer to representations, it does not deny that cognition is constituted of content-bearing internal states. In fact, given the conception of cognitive systems as embodiments of contexts, cognition necessarily entails content (Jordan & Ghin, 2006). The internal dynamics of an organism must be about the contexts in which they are sustained, and for this reason, the internal dynamics of the organism are inherently meaningful. In other words, the internal work of an organism naturally refers to its context (i.e., it is an internalization of the contingent constraints). By replacing the notion of representation with the notion of *self-sustaining embodied context*, WST provides a means of addressing how the internal can be related to the external: "In short, the *inside* is an embodiment of the *outside*. Thus, there is no need to ask how internal states map onto external states….synchronies between internal and external events constitute resonances" (Jordan & Ghin, 2006, p. 58). The use of the word resonance—instead of representation—highlights the dynamic, interdependent relationship of the internal and external. The benefit of approaching the problem of representation from the perspective of WST is that one does not need to ask how cognitive systems represent their environments. Ultimately, self-sustaining systems entail embodied content. To clarify, from this perspective, representation is ubiquitous. Representation (i.e., embodiment) is not unique to brain dynamics or the putatively cognitive processes. It is a feature of all embodiments of contexts as they all effectively "represent" their contexts. The multi-scale self-sustaining processes that constitute a human body represent the phylogenetic, cultural, and ontogenetic contexts in which the body emerged and in which it sustains itself (Jordan & Vinson, 2012). As an embodiment of its context, it naturally and necessarily is *about* its contexts. In other words, one might say that the human body maintains "internal" states that reflect the contingent constraints. What distinguishes brains from other embodiments of context is the time scale at which they can reorganize themselves or change what they are "representing." The

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

importance of treating representation as a natural characteristic of embodied contexts is that it leads to the realization that bodies, like cognitions, are information-laden because they are saturated with *aboutness*. Strictly speaking, information is not unique to brains or cognitive systems; all embodiments of context entail information. Another way to say this is that self-sustaining embodiments are inherently semiotic systems (Emmeche, 2002; Jordan, 2008)

CONCLUSION

The description of Wild Systems Theory (Jordan, 2013; Jordan & Day, 2015) introduced an alternative way to conceptualize what it is that intelligent behavior entails. While other approaches (e.g., Soar, LIDA, and ACT-R) have made considerable progress toward developing architectures that enable intelligent behavior, Wild Systems Theory provides a glimpse at the fundamental principles that might support artificial intelligence if one is interested in creating systems that exhibit intelligent behavior *in the same way* as natural cognitive systems. In this chapter, we have set the foundation for the development of a biologically inspired cognitive architecture—a Wild architecture—one that is grounded in the notion of self-sustaining embodiment of context. Further, the proposal of consciousness as a property of self-sustaining systems sheds light on the nature of artificial systems that might potentially constitute phenomenal consciousness.

Chapter 39
Predictive Analysis of Emotions for Improving Customer Services

Vinay Kumar Jain
Jaypee University of Engineering and Technology, India

Shishir Kumar
Jaypee University of Engineering and Technology, India

ABSTRACT

Human emotions plays an important role in everyday communication. Emotions are formed by the combination of cues such as relative actions, facial expressions, and gestures and reactions. Emotions are also present in written texts like in social media, chats, customer reviews. By getting inspired by works done in the domain of sentiment analysis, this chapter explores advances to automatic detection of emotions in text which help in Improving Customer Services. This chapter presents a framework for automatic detection of emotions in customer reviews based on different emotions theories in the fields of psychology and linguistics. This framework uses advanced Machine Learning (ML) techniques with Natural Language Processing (NLP) methods for better understanding of emotion detection and recognition in customer reviews. The text under study comprises data collected from leading Indian e-commerce portals like Flipkart, Snapdeal and Amazon, which contains text rich in emotions. The advantages and application based emotion detection framework has been incorporated with suitable examples.

INTRODUCTION

Language is the most important tool for communication and help to convey information in a society. Language provides suitable means to express emotions in several forms. Natural Language Processing techniques are used to identify meaningful inferences content in text. Multiple applications related to information retrievals such as topic-based modeling, text categorization, question-answering systems, has been focused on the information contained in the data (Jain & Kumar, 2015).

During the last few decades around the world, the growth of the internet has increased the communication levels and internet users widely used multiple platforms to post their opinions online. In current scenario, people increasingly use micro-blogging platforms and social networking sites, to share and retrieve relevant information in real-time which contains opinions and sentiments (Chesley et al.,2006). Intelligent computational tools have been used to extract meaningful inferences and help companies to utilize this information for their productivity.

The e-shopping websites provides the feature where a customer can give feedback in the form of review to the product he purchased. There are massive amount of reviews available for every product in multiple e-commerce portals. A simple example related to customer review related to smart phone has been presented in Figure 1. Most of the users view the rating given to the product and read some of the reviews before decision making. The ratings are not enough to decide whether a product is feasible to buy or not. Therefore getting a conclusion from reviews is manually a tough task.

Much of the current work for analysis of customer reviews has been focused on polarity orientation of textual data. Limited work has been done in the direction of type of emotions present in written text by the customers. Recognizing emotions that has been expressed by customer reviews could provide the general intention of customer towards products and services. This chapter presented an emotion detection based system to provide benefit to the customer in decision making before the purchase of product or services. The Emotions categories in customer reviews definitely help companies to enhance their marketing strategy in a better way. .

The methods related to automatic emotion detection can be useful in many real-time applications with the help of human psychological techniques (Dung and Cao,2012). In recent years, the growth of e-commerce has brought a boom in the business market. The concept of online shopping has become one of the biggest successful businesses. With the availability of products on the websites, the interest of public has grown towards online shopping. Whenever any user is interested in purchasing a product online, the user completely depends on the reviews that have been given for a particular product. This review can be oral or written. On internet most of the emphasis is given on written review that a product receives, and this helps the user to make a decision whether to buy a product or not. So, it is necessary to build a system that finds out the emotions present every review by users so that they can but the product It also helps the company owners to determine whether the product they launched in the market is been accepted by users or not. In concern of social media or the customer reviews data it has more complications due different geographical location. A wide variety of work has been carried out in the field of sentiment analysis and opinion mining but limited work has been carried out in the field emotion detection and recognition. This chapter presents a framework for automatic detection of emotions in customer reviews using different emotions theories in the fields of linguistics and psychology. This framework uses Machine Learning methods and Natural Language Processing (NLP) and for better understanding of emotions present in customer reviews. A simple example of customer reviews which contains emotion bearing words has been presented in Figure 1.

BACKGROUND

Emotional states have multiple cognitive bases which are formed by number of factors. The scope of this chapter is limited to provide important features relevant to recognize emotion and the process of determining the emotional orientation of customer reviews. Emotion present in multiple languages or

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. A sample of reviews collected from E-commerce website

Very nice phone in terms of looks, weight, but the Flyme OS is little tricky and not at all user friendly, If you can bear the same you may go for it rest of all is fine..

Nice phone. camera, battery backup, look etc all are perfect at this price range.

hangs, touch is too bad at end of screen...never trust this model... above all where is the support...amazon just washed it by hands return policy over so can't make replacement !! Who will repair or replace !!

Ultimate mobile phone,have used HTC, SAMSUNG, APPLE and MOTOROLA but this one is not behind them in any way.

This is very fast and all mobile future very different then other mobile I love miezu

All features is gud in this phone but i have only one problem that i can't use 2g network only 3g and wifi is working

I have also a k3 and a mi 4i.performance wise k3 is best.but in camera look sound mi is best meizu is gd in performance touch experience design.....thanks

simply in a language can be expressed in several ways and understanding of this expression can be interpreted differently by different readers.

During the last few decades, Computational techniques such as Natural language processing, Artificial Intelligence (AI), Machine learning has been used to develop intelligent systems that interpreted human emotions (Jain et al., 2016). Several real-time processes have been modeled to develop effective intelligent systems by providing learning, perception and reasoning. Development of affective interfaces is an important research area in emotions. Affective interfaces are the system which provides emotional inputs; emotional responses using this facilitate online communication with the help of animated affective agents. These affective interfaces provide better user experience in following areas such as Computer-Mediated Communication (CMC) and Human-Computer Interaction (HCI). Text-to-Speech (TTS) synthesis systems are also used these interface for developing real-time systems.

Recognizing the polarity of sentiment present in written text such as in social media posts, blogs and forums is the most popular in sentiment and opinion mining domain (Pang and Lee, 2008) .Among the less paying attention area related to sentiment is the identification of emotions present in customer reviews and social media data. Computational techniques related to emotion analysis present in text mainly deals with their emotion modalities and emotion-annotated data (Jain et al., 2016).However, only limited work has been done in developing automatic emotion recognition system which benefits customer and e-commerce companies in decision-making. The focus of this chapter is to give advantages of recognizing emotions present in customer reviews which provide an insight related to customer's intentions.

THEORIES OF EMOTION

Theories of emotion mainly categorized in terms of the context within which the explanation is developed. There are different emotion theories are used in physiology and other relevant fields (Cowie et al.,2011).Recently, researchers have investigated a number of aspects related to human emotions in multiple domains. Authors categorized emotions terms in multiple emotion classes based on emotion-bearing words which are accepted across the world (Picard, et al [4]).

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Multiple milestone work has been carried out by researchers to provide right judgment related to emotion categories (Tomkins 1962; Plutchik 1980; Izard 1977; Ortony et. al., 1988; Raghavan, 2007 and Ekman, 1992). Emotion categories recognized by the different researchers has been presented in Table 1.

According to the popular emotion theory (Rasa theory) given by Bharta Muni, emotions are the primary gastric juices which represent every part of the world into the sentiments (Raghavan,2007). Rasa emotional theory is based on the Natyashastra (the Textbook on Drama) and given by Bharata Muni. According to Natyashastra(Raghavan,2007)., there are eight rasas corresponding to Bhava (mood). Ekman(Ekman,1992) has defined six basic emotions on the basis of distinctive facial expressions which are universally accepted has been presented in Table 1.

Watson and Tellegen in 1985 has presented a compressive theory i.e The Circumplex Theory of Affect which identifies two main classes as positive and negative affects which range from high to low(Watson and Tellegen, 1985). Osgood's in 1957 has proposed theory of Semantic Differentiation. (Osgood et al., 1957).In this theory words are assigned by emotive meanings using three factors such as activity factor, evaluative factor and potency factor.

Clore et al., proposed number of words which convey emotion explicitly, while other are depending on the context (Clore et al.1987). The classification of affective words into two classes 'indirect affective words' (implicit) and 'direct affective words' (explicit) has been performed by Strapparava and Valitutti (Strapparava and Valitutti, 2006).The chapter has utilized both these types of words given by Strapparava and Valitutti (Strapparava and Valitutti,2006).

EMOTION RECOGNITION

Emotion recognition in text is just one the numerous dimensions of the task of making the computers make sense of and respond to emotions. Emotion represents a complex, subjective experience which involves thinking, excitement, feeling and activation. This can be seen using native languages, physiological changes, and behavioral changes. The word "affect" is often used alternatively with "emotion" in the literature. Human emotion can be sensed from such cues as facial expression, gestures, speech and text. Research in emotion has focused on all these aspects (Cowie et al.,2011).

Table 1. Emotion categories or classes identified by authors

Muni (Raghavan,2007).,	Tomkins (1962)	Izard (1977)	Plutchik (1980)	Ortony et.al. (1988)	Ekman (1992)
		Disgust

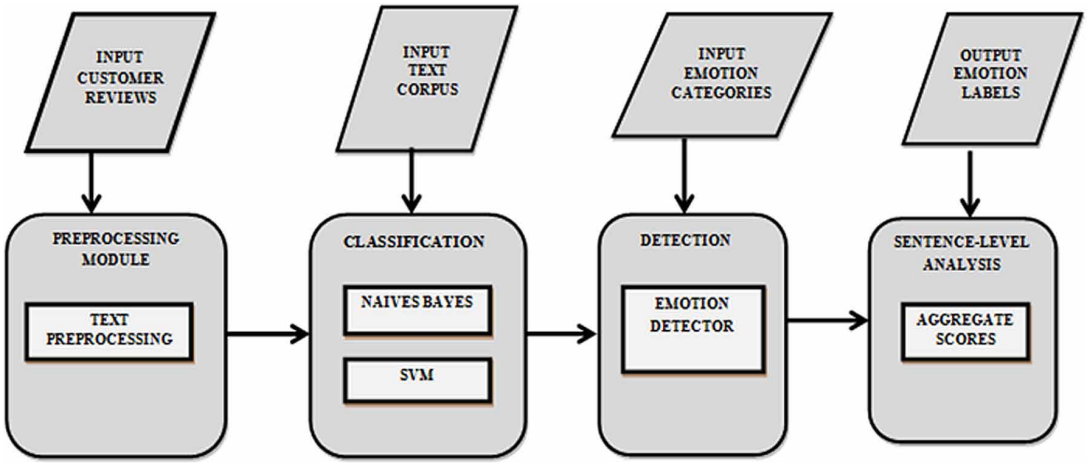
		Interest			

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Emotion detection has been focused on the sentence-level analysis or document level analysis for learning emotions in customer reviews. Emotional words are used as keywords to identifying emotion in input sentences. Osgood used multidimensional scaling to visualize the affective words for calculating similarity ratings between them. Three dimensions were used by Osgood which includes "evaluation", "potency" and "activity", where evaluation can be used to measure how much a word can refer to a pleasant or an unpleasant event (Osgood et al., 1957).

Read et al. have carried out appraisal annotation of a corpus of book reviews; a genre that provides ample instances of the various kinds of appraisal classes (Read et al.2007). They found that out of the three subsystems of the Appraisal Framework, the attitude subsystem's instances (which include emotion expressions) were the easiest to identify. Mihalcea and Strapparava present results in favor of automatic recognition of humor in texts (Mihalcea and Strapparava, 2005). They perform experiments to identify humorous one-liners, which are one-line sentences generally characterized by simple syntax and use of rhetoric which gives them a humorous connotation. Neviarouskaya et al. propose a system for augmenting online conversations with a graphical representation of the user, which displays emotions and social behavior in accordance with the text (Neviarouskaya et al,2007). This system performs automatic estimation of affect in text on the basis of symbolic cues such as emoticons, popularly used IM (Instant Messaging) abbreviations, as well as word, phrase, and sentence-level analysis of text.

Ghazi et al. proposed a multiple levels of hierarchy classification to classify emotions words (Ghazi et al., 2010). Strapparava et al. has developed a linguistic resource to lexically represent affective knowledge named WordNet – Affect (Strapparava et al., 2006). The WorldNet-Affect contains affective words and available freely as open-source lexical recourses. Wang et al [63] proposed a novel approach to detect emotion from Chinese language. The algorithm proposed was segment based fine grained emotion detection model that is a supervised learning approach.



Lie Dey proposed a system for extracting emotions from the data collected from chat messenger (Dey et al.,2014). The author built a lexicon of emotion conveying words to extract emotions from the data sets. Shaheen et al. had proposed a framework for classification of emotions based on generalized concepts extracted from the English sentences (Shaheen et al.,2014). Perikos and Hatzilygeroudis developed a system that can automatically recognize emotions in natural languages (Perikos and Hatzilygeroudis, 2013). They used Tree tagger and Stanford Parser. They also used WordNet Affect lexical resource in order to spot the emotional words. They then analyzed emotional words dependencies in order to specify the strength of emotional word's strength and also determined overall sentence emotional statues that are based on dependency graph of sentence.

EMOTIONS DETECTION FRAMEWORK

The objective of this framework is to provide an insight to the process of automatically recognize emotions from customer reviews. Experimental study using appropriate corpus of text (customer reviews) has been presented using this framework for emotion recognition. Research in automatic text-based emotion analysis is limited due to unavailability emotion-annotated data for written text. To solve this problem, data has been collected from the top Indian online e-commerce websites like Snapdeal, Flipkart and Amazon under multiple categories such as LED television, smart phones, laptops, tablets, cameras.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. An overview of emotion detection framework

Emotion detection in text is referring to as a classification problem. In this process multiple nominal labels are assigned to a text or sentence from a group of emotion labels. Figure 2 presents an overview of emotion detection framework for customer reviews data analysis. Presented framework for emotion detection for customer reviews has followed the methodology given as:

Let $\boldsymbol{c}$ is a customer review corresponding to a product or services and $\boldsymbol{k}$ is an emotion label. Let $\boldsymbol{e}$ be a set of $\boldsymbol{n}$ probable emotion categories where $\boldsymbol{e} = \{\boldsymbol{e}_1, \boldsymbol{e}_2, \boldsymbol{e}_3 \ldots\ldots\ldots \boldsymbol{e}_n\}$. The classification process has been used to label $\boldsymbol{c}$ with the finest promising emotion label $\boldsymbol{k}$, where $\boldsymbol{k} \in \{\boldsymbol{e}_1, \boldsymbol{e}_2, \boldsymbol{e}_3 \ldots\ldots\ldots \boldsymbol{e}_n, \text{neutral}\}$.

The framework of emotion detection is divided into four modules:

Pre-Processing Module

In this module customer's reviews data has been pre-processed to remove unwanted noise present in the data. Segmentation and Tokenization has been applied in first step. Sentence segmentation has been applied to form sentence chunks. Tokenization is has been applied to break stream of text up into multiple forms such as phrases, symbols, words, or other meaningful elements called tokens..In second step stop words removal process has been applied to filter out unnecessary words. Stemming is done on tokenized input.

Classification Module

Automatic classification of emotional sentences need a feature sets. The most appropriate features that distinguish emotional expressions from non-emotional ones are the emotion words. To recognize these words in the sentences or customer reviews, publicly available lexical resources are available such as – WorldNet-Affect (Strapparava and Valitutti, et al., 2006).Researchers have identified various categories of basic and secondary emotions. Ekman six basic emotions is one of the most popular models in various domains (Ekamn, 1992). Detection of emotional orientation of text has been performed naïve approach by determining emotion words, such as "happy", "terrified", and "amazed" in customer reviews. The clear advantage of this approach is that it requires no training data.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 2. Description of emotion word list that has been extracted from WordNet affect

Emotion Category	#synsets	Sample Words
Happiness	227	joy, love, rejoicing, glee, happiness, euphoria, enthusiasm, admiration, cheerful, content, happy, merrily
Sadness	123	sorrow, misery, woe, gloom, grief, depression, heartbreak, mournful, hapless, guilty, sadly, remorsefully, repent, bored
Anger	127	wrath, fury, rage, angry, annoyed, pissed, mad, sore, livid, displeasingly, aggressive, hateful, hostile, malice, spite, resentfully
Disgust	19	repulsion, nauseous, foul, abhorrent, fed_up, abominably, revolt, sicken
Surprise	28	wonder, fantastic, marvelous, baffle, bewilder, astonishing, awestruck, stupefy, dumbfound, staggering
Fear	82	scary, fright, panic, terror, chilling, frightful, terrible, intimidate, dread, anxiously, apprehension

Emotion Detection Module

After the classification of emotional words from the customer reviews a baseline system called as emotion detector has been used to counts the number of emotion words of each category in a sentence, and then assigns the category with the largest number of words to the sentence. Ties were resolved by choosing the emotion label based on a random predefined ordering of emotion classes. A sentence containing no emotion word of any type was assigned the *no-emotion* category. Emotion detector gives an insight of overall category present in Table 2 of a particular customer review of a product.

Sentence-Level Analysis

Sentence-level analysis provides aggregate score of emotion present in all the product categories with emotion levels of customer review. This provides emotion related to specific brand and categories.

IMPORTANCE OF EMOTIONS DETECTION

Emotion Detection in customer reviews is important for e-commerce industries because it identifies meaningful ways to improve their operations and marketing strategy for their products and services. This can be accounted by measuring the public's emotions on products, services, and advertisements. E-commerce companies can use emotion detection framework for prediction of their services based on diffusion of innovation theories. This framework is also helpful in new product launch in the market by examine public emotion towards the product or services. According to marketing survey agencies, customer reviews provides new battleground for brands. E-commerce companies focused to build loyalty with product buyers, which help to grow and expand their business. New emerging platforms based on social media provide rich source of information about the product or services. Emotion detection framework can help companies in measuring public feeling related to products and services.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

ADVANTAGES OF EMOTION DETECTION

E-commerce companies always focused to build long term relation with their customers. Customer services such as product delivery timing, response to their query etc are mainly focused by e-commerce companies. The e-commerce should always aware their customer response about product or services they sale on their portal. Emotion detection framework can easily give real-time information about customer's mood and feelings. Emotion detection play an important role to gain advantages over other techniques or policies and helps companies in improving their market strategy. Following are the key benefits provided by emotion detection framework:

1. **Accessibility:** Emotion detection framework provides real-time emotions 24X7.
2. **Gain Business Intelligence:** This framework provides meaningful inference which help business to take rapid decisions.
3. **Quickly Identify the Tonality:** Framework provides real-time trends related to products and services with emotion spikes based on emotion models.
4. **Easily Built Engagement Platform:** Measurement of effectiveness of promotional offers and viral advertisements can easily be understood with the help of this emotion detection. This will help in better engagement with customer to build up long relationship.
5. **Beat Competition:** Track competitor responses help in improvement of action plan over time.
6. **Alerts Service:** Alerts can be set up for the brands to be notified of specific emotion labels and rapid decision cans be easily taken out.
7. **Improve Customer Service:** The major advantages of this framework help in improving customer services which is the major challenge for e-commerce companies in current scenario.

CONCLUSION

This chapter describes the potential of real –time emotion detection system based on customer reviews present in e-commerce portals. This framework can help in providing solutions to number of problems related to businesses and marketing. This chapter present an emotion detection framework based on Ekman emotion model. Methods and technique are presented help in knowing customers emotions with help of product reviews. This framework gives important and valuable knowledge towards improvement in departments such as customer management, customer relations & marketing, product management and corporate management.

The emotion detection framework presented in this chapter can be pursued further in several domains. One of the tasks is to consider emotion intensity for classification. Explore the relation between emotion classes and emotion intensity.

Chapter 40
A Fuzzy Logic Based Synonym Resolution Approach for Automated Information Retrieval

Mamta Kathuria

YMCA University of Science and Technology, India

Neelam Duhan
YMCA University of Science and Technology, India

ABSTRACT

Precise semantic similarity measurement between words is vital from the viewpoint of many automated applications in the areas of word sense disambiguation, machine translation, information retrieval and data clustering, etc. Rapid growth of the automated resources and their diversified novel applications has further reinforced this requirement. However, accurate measurement of semantic similarity is a daunting task due to inherent ambiguities of the natural language, spread of web documents across various domains, localities and dialects. All these issues render to the inadequacy of the manually maintained semantic similarity resources (i.e. dictionaries). This article uses context sets of the words under consideration in multiple corpora to compute semantic similarity and provides credible and verifiable semantic similarity results directly usable for automated applications in the intelligent manner using fuzzy inference mechanism. It can also be used to strengthen the existing lexical resources by augmenting the context set and properly defined extent of semantic similarity.

INTRODUCTION

With the passage of time, human dependency has increased manifold on the automated resources. These resources depend upon the underlying inference mechanism and stored data for their decisions/actions. Unlike humans, these resources are devoid of their own intelligence and analytical capability. Therefore, it is necessary that these systems be embedded with the resources which are totally free from ambiguity so that their decisions/actions are reliable and credible. As and when an automated system has to deal with an inherently ambiguous environment such as Natural Language Processing(NLP), there are two options available to the designer to increase the reliability and credibility of the system:

1. To deal directly with the ambiguity at the inference level by designing the knowledge base with the help of tools like fuzzy logic which have the ability to handle the ambiguity to an extent and provide a coarse (not that precise) automated solution;
2. To make the underlying data less ambiguous and more suitable for automated applications.

In an automated system, which works in an inherently ambiguous environment, both the approaches may be required but an effort in the direction of second approach shall reduce the requirement of first approach making the system more precise.

One of the most frequently used automated systems in the present-day environment is *web search engine,* commonly referred to as search engine. It tries to provide a set of documents semantically related to the query submitted by the user in the natural language. For getting better results, the search needs to be widened by using terms semantically similar to input query. This leads to the requirement of unambiguous, efficient lexical resources providing precise semantic similarity information directly usable by the automated systems. The heterogeneity in web literature owing to its global spread over geographical boundaries, languages, dialects combined with other inherent ambiguities in the natural language makes this task quite difficult which is beyond the grasp of manually maintained dictionaries. To overcome this drawback, the current literature provides several empirical methods based upon web page count and text snippets count as discussed in literature survey presented in this paper. These methods basically fail to take into account the exact context of the word pair usage due to following reasons:

- Occurrence of a pair of words within the same page does not ensure the similarity of their contexts;
- Sometimes the size of the snippets is increased to ensure the larger number of instances which may result in the loss of context.

To ensure the better efficiency and credibility of these web based automated systems such as search engines, it is necessary that the underlying lexical resources be automation friendly and as less ambiguous as possible. An information retrieval system based upon the crude semantic similarity taken from online lexical sources like WordNet (2005), etc., without considering the context, leads to fetching of large number of undesired pages which otherwise may not be that useful. Therefore, there is a need to tune these lexical resources in such a manner that the derived synonyms are also provided with the following:

- Their respective applicable context set;
- Properly defined extent of semantic similarity.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

It shall help the automated systems in choosing an appropriate synonym set.

The proposed work accomplishes the above-mentioned goals by defining a credible synonym resolution process. The work intends to pave the way for the design of next generation lexical resources and shall be helpful in the areas of natural language processing, information retrieval, web mining, word sense disambiguation and automated machine translation.

The paper has been organized as follows: The introduction section of the paper is followed by the literature survey section. After taking a look on the available literature, the objectives of the proposed work have been defined. Thereafter, the details of the proposed work have been discussed. After discussing the proposed work, results have been presented and analysed. Last section concludes the work with possible future extensions.

LITERATURE SURVEY

The inadequacy of the manually created lexical resources has been long felt due to their inability to cater various diversified domains of knowledge area such as engineering, medical, music and finance etc. Moreover, mostly their updation is also based upon the perception of very few people. With the growth of web over multifaceted heterogeneous environments spread over variety of domains, people, nationalities, dialects etc., the limitations of these resources are being strongly felt than ever. Moreover, the need for meaningful query expansion has gained more and more prominence wherein the lexical resources are unable to provide the requisite support to the web search engines. This issue can only be addressed through proper semantic resolution which in turn requires knowledge about exact estimate of the semantic similarity between the terms. The growth of the web has pushed the research in the area of precise semantic similarity measurement to help web users in getting the accurate results through proper semantic interpretation of their queries. In this section, a look at these contributions is being taken.

Rada, Mili, Bicknell, Blettner (1989) proposed a method of semantic similarity by taking into consideration the taxonomy of words. Shorter the path in taxonomy, more similar the words are.

Resnik (1995) proposed semantic similarity measurement between two concepts using Brown Corpus (1991) and WordNet(2005). The proposed method finds the similarity between the two concepts C1 and C2 on the basis of a third concept C that subsumes both the concepts and is the biggest of all such possible concepts.

Li, Bandar & Mclean (2003) proposed a semantic similarity measure based on various features such as path length, depth and local density of the taxonomy. They combined these structural features of the taxonomy along with the information model.

A double-checking model using text snippets was suggested by Chen, Lin & Wei (2006) for measuring semantic similarity between two words. For computing the similarity between words P and Q, occurrences of word P are counted in the snippets for word Q and similarly the occurrences of word Q are counted in the snippets for word P. Then, the corresponding values are used to calculate the similarity between P and Q by using Co-occurrence based Double-Checking (CODC) measure as defined below:

$$CODC\left(P,Q\right)=\begin{cases}0, & if\ f\left(P\,@\,Q\right)=0\\ exp\left(log\left[\dfrac{f\left(P\,@\,Q\right)}{H\left(P\right)}\times\dfrac{f\left(Q\,@\,P\right)}{H\left(Q\right)}\right]^{\alpha}\right) & otherwise\end{cases} \tag{1}$$

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

where f(P@Q) is the number of occurrences of P in the top-ranking snippets of Google corresponding to query Q, H(P) denotes the page count for query P, and α is a constant which was experimentally set to the value 0.15 by the authors. The drawback of the method is its dependency on the ranking method adopted by a search engine in use. It happens because a search engine considers publication date and link structure along with semantic similarity while ranking the search results corresponding to the user query.

Initial efforts to make a decision about semantic similarity based upon web content were relying upon page count. In these cases, page count of the word pair (say P and Q) is taken into consideration for computation of semantic similarity. Here, H(P) and H(Q) indicate the page counts for word P and Q respectively and H(P∩Q) denotes the page count for conjunctive query 'P AND Q'. Based upon the page count, various indices have been proposed, which are as follows:

$$WebJaccard\left(P,Q\right)=\begin{cases}0, & if\,H\left(P\cap Q\right)\le c\\ \dfrac{H\left(P\cap Q\right)}{H\left(P\right)+H\left(Q\right)-\left(H\left(P\cap Q\right)\right.}, & otherwise\end{cases} \tag{2}$$

This coefficient is set to zero if page count H(P∩Q) for the conjunctive query is less than a predefined threshold c:

$$WebOverlap\left(P,Q\right)=\begin{cases}0, & if\,H\left(P\cap Q\right)\le c\\ \dfrac{H\left(P\cap Q\right)}{\min(H\left(P\right),\,H\left(Q\right))}, & otherwise\end{cases} \tag{3}$$

$$WebDice\left(P,Q\right)=\begin{cases}0, & if\,H\left(P\cap Q\right)\le c\\ \dfrac{2H\left(P\cap Q\right)}{H\left(P\right)+H\left(Q\right)}, & otherwise\end{cases} \tag{4}$$

The fourth measure WebPMI (Pointwise Mutual Information) reflects the independence between two probabilistic events and is defined as:

$$WebPMI\left(P,Q\right)=\begin{cases}0, & if\,H\left(P\cap Q\right)\le c\\ log_2\left(\dfrac{H\left(P\cap Q\right)\big/N}{H\left(P\right)\big/N\cdot H\left(Q\right)\big/N}\right), & otherwise\end{cases} \tag{5}$$

where N is the number of documents being indexed by the search engine. Probabilities are assessed based on maximum likelihood principle.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

With the advancement in search engine technology, new empirical methods were defined in the light of search results. Cilibrasi & Vitanyi (2007) defined a semantic similarity measure called Normalized Google Distance (NGD) based upon page count provided by the search engine. The NGD measure can be defined as given in Equation (6):

$$NGD\left(P,Q\right)=\frac{\max\left\{\log H\left(P\right),\log H\left(Q\right)\right\}-\log H\left(P,Q\right)}{\log N-\min\{\log H\left(P\right),\log H\left(Q\right)\}} \tag{6}$$

All these methods consider the co-occurrence of words without taking into account the context of the words in which they occur on the page.

Bollegala, Matsuo, and Ishizuka (2011) proposed an empirical method to measure semantic similarity between two words based on page counts and text snippets retrieved from a search engine in response to the said words. They identified several semantic relations between given words by the using pattern extraction and pattern clustering algorithms. They also used Support Vector Machine (SVM) based supervised learning model for deciding the appropriate boundaries of classification.

Specia, Jauhar, & Mihalcea(2012) provided a mechanism for Lexical Simplification which involves the replacement of words and phrases through their simpler variants using complexity analysis, substitute lookup and context-based ranking.

Jurgens, Mohammad, Turney & Holyoak(2012) have focussed on relational similarity such as entity:sound (dog:bark, cat:meow), cause:effect (virus:flu) etc. for the purpose of semantic similarity resolution.

Pilehvar, Jurgens, & Navigli, (2013) have presented a unified approach for finding semantic similarity that operates at multiple levels from comparing word senses to comparing text documents. The method leverages a common probabilistic representation over word senses in order to compare different types of linguistic data. This unified representation shows state-of-the-art performance on three tasks: semantic textual similarity, word similarity and word sense coarsening.

Severyn, Nicosia, & Mchitti (2013) have taken up the task of semantic textual similarity (STS) using a large number of pair-wise similarity features. Their model includes: encoding of input texts into relational syntactic structures, use of tree kernels to handle feature engineering, combining both structural and feature vector representations in a single scoring model using Support Vector Regression (SVR). The contribution of the work is quite significant in the area of semantic textual similarity.

Adhikesavan (2015) has proposed a method which takes into account association rule mining, classification, clustering and information available on the web for measuring the similarity between words/ sentences. The hallmark of the proposed scheme is that it can be adapted for different domains. The author evaluates the results using various datasets which shows its performance over other competing methods.

Recski, Iklódi, Pajkossy and Kornai (2016) have proposed a hybrid system that measures the semantic similarity between a set of word pairs using WordNet and concept dictionary. The concept dictionary with its ability to encode semantic relations between words using concept graphs improves the performance of the system which is not otherwise possible using standard tools like Wordnet. The drawback of the approach is inability to find the semantic relation between phrases.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Ranjbar, Mashhadirajab and Shamsfard (2017) have proposed a method for evaluating semantic similarity between the words of Persian language on the basis of corpus and knowledge based methods. The corpus based method uses Word2Vec and knowledge based method uses FarsNet (lexical ontology). The drawback of the work is that it uses only one corpus and its application is limited to Persian Language only.

Hakami, Hayashi and Bollegala (2017) have proposed a bilinear operator called PairDiff to compute the vector offset between the corresponding word embeddings. The effectiveness of the operator has been checked empirically on several benchmark data sets. However, the work lacks a critical theoretical evaluation.

Elekes, Schäler and Böhm (2017) have analysed the statistical distribution of similarity values systematically using two series of experiments. First experiment examines the distribution of similarity values depending upon different embedding-model algorithms and parameters. In the second one, they have tried to show that intuitive similarity thresholds do not exist. They have been able to show that though word embedding models have yielded meaningful results in many cases yet it is necessary to examine when exactly similarity values in word embedding models are meaningful.

Falho, Rodrigues, Coheur and Quaresma (2017) in their work have studied Semantic Textual Similarity and Multilingual Word Similarity for English and Spanish languages using a rich set of features. Their goal is to move from lexical to semantic features on the basis of Abstract Meaning Representation and SMATCH measure by combining *WordNet* information with Word Embeddings. The hallmark/ drawback of the approach is its simplicity/ naiveness.

Bjerva and Östling (2017) in their work have assessed the semantic similarity between sentences which can be in same or different languages. They have employed multilingual word representations for similar words of different languages which are semantically close to each other. The languages used are English, Spanish, Arabic, and Turkish. The hallmark of the scheme is that the semantic similarity can be inferred even for languages for which no annotated data exists. The drawback of the proposal is that the system fails to deliver requisite performance on the shared task test sets.

After having a critical look on the literature, the following drawbacks have been identified:

- Mere page count based methods are quite crude;
- A text snippet may be quite long;
- Word taxonomy may depend upon various heterogeneous aspects;
- Processes like concept identification and relation identification are perception dependent;
- Word embedding models are not that consistent and their applicability depends upon case to case basis.

These challenges have been the motivating factors for the proposed work. The next section defines the objective of the proposed work.

OBJECTIVE OF THE PROPOSED WORK

The main objective of the work is to propose a synonym resolution method based upon the immediate context of the word under consideration in various corpora. The outcome of the work includes context set identification for a word and computation of an index indicating the extent of semantic similarity

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

between a pair of words based upon the similarity of their context set. The lists of the contexts for the word under consideration were obtained from various corpora by using their respective search utilities. The computed index was then fuzzified in order to design a Fuzzy Rule Base (FRB) for the purpose of automation in the web search engines and other such applications.

PROPOSED WORK

In the area of the information retrieval, the semantic aspect of the query is quite vital. As and when a user submits a query to the search engine, he/she expects to retrieve a set of documents which are semantically related to the query submitted. To accomplish this, it is required that users' query be expanded to cover more and more expressions which are semantically same. A normal keyword based information retrieval system is unable to use the concept of semantic similarity thereby missing the major chunk of otherwise relevant pages. To overcome this drawback, it is necessary that query be expanded through meaningful semantic extensions using appropriate choice of concepts/words. This appropriate choice requires the precise knowledge about semantic similarity between original word in the query and the word to be substituted. But the precise measurement of the semantic similarity is a challenging task as most of words in a natural language have context dependent meaning. A search engine, if it does not take into consideration the context of query and directly uses the online sources, may fetch large number of undesired pages which are otherwise not required. Keeping this need in view, a new approach is being presented in this paper which tunes the lexical resources wherein the derived synonyms of a word are also provided with their applicable context. The work will help the automated systems like search engines in extending the query through appropriate choice of context based synonyms. Moreover, the extent of semantic similarity has also been defined to help the automated tools in choosing the appropriate list of synonyms in the order of semantic similarity index till the requisite numbers of pages are provided to the user. Thus, the goal of the present work is synonym resolution wherein, for a given word, a lexical resource would be enriched with:

- Its applicable contexts set i.e. set of contexts to which the word is applicable;
- A set of synonyms of the words along with intersection context set i.e. the set of contexts which is applicable to both (the word and the corresponding synonyms);
- A similarity index indicating the extent of similarity which will help the automated tool in making the decision about the order of substitution. Larger the index, more is the priority for substitution. A cut off value may also be decided beyond which the substitution is not desirable.

To enable the automated tool in making the intelligent decision on the basis of the additional information created in the work, the similarity index has been fuzzified through the design of appropriate fuzzy sets. This will help the information retrieval system in following manner:

- Minor differences arising out of computation due to the choice of search engine, set of documents, dialects etc. are eliminated as two close values would normally be residing in the same fuzzy set;
- The fuzzy sets created in such a manner can be used for intelligent decision making by creating a Fuzzy Rule Base that can be run on an appropriate fuzzy inference engine.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Now, to accomplish the proposed work, the following Algorithm 1 has been designed.

Algorithm 1. Fuzzy_rule_base (w, n sets of corpus)

Input: The word w whose rule base is to be created, n sets of word corpus
Output: The fuzzy rule base of the input word

Step 1: *Choose a candidate word for finding semantic similarity, say w*
Step 2: *Choose a set of n corpora.*
Step 3: *For each corpus i, identify set of contexts for w,* C_i
Step 4: *Compute* $C_{pw} = C_1 \cup C_2 \cup \ldots \cup C_n$ *// Possible list of contexts for w*
Step 5: *Compute* $C_{cw} = C_1 \cup C_2 \cup \ldots \cup C_n$ *// List of most commonly used contexts for w*
Step 6: *Augment* C_{pw} *and* C_{cw} *in lexicon alongwith the word w.*
Step 7: *Let S be the set of synonyms for w obtained from a lexical resource, say WordNet.*
Step 8: *for each x∈S, Compute Cpx and Ccx using step 3-5 //List of possible and commonly used contexts for x respectively*
Step 9: *Compute similarity index between w and x using WebJaccard, WebOverlap and WebDice type co-occurrence measure. Here, the context set cardinality is used instead of page count.*

Modified_WebJaccard (w, x)= $|C_{pw} \cap C_{px}| / |(C_{pw} + C_{px} - C_{pw} \cap C_{px})|$
Modified_WebOverlap(w,x)= $C_{pw} \cap C_{px} / min(C_{pw}, C_{px})$
Modified_WebDice(w,x)= $2*C_{pw} \cap C_{px} / (C_{pw} + C_{px})$

Step10: *Normalize the computed co-occurrence to a range* $[r_1, r_2]$.
Step11: *Use* $[r_1, r_2]$ *as domain of discourse to create fuzzy sets expressing the extent of similarity between the words w and x. Let the fuzzy sets be: not_similar, poorly_similar, medium_similar, highly_similar, extremely_similar.*
Step12: *Create an appropriate Fuzzy Rule Base (FRB) to implement the computed similarity in automated manner.*
Step 13: *Use FRB for query expansion and information retrieval.*
Step 14: *Stop*

Explanation and Implementation of Proposed Algorithm

To identify the contexts related to a word, four corpora were chosen namely Coca Corpus (1990), BNC Corpus (1980), Wikipedia Corpus(2006) and GloWbE Corpus(2005). The reason for choosing the above corpora is their ability to allow search on the basis of word, phrase, part of speech and synonyms.

The details of these corpora have been provided in Table 1.

The proposed algorithm was implemented using a very commonly used word beautiful. The reason for choosing the word beautiful is because of its commonness and availability of its large number of synonyms applicable to different varieties of contexts. Its available synonyms were found using the lexical resource *WordNet* thereby creating the set *S*. For the purpose of context identification, the size of text window was taken as 2 (two) because a shorter window ensures that proper relevance of the context. Moreover, since the word is of adjective type, this window size is quite appropriate. For other types of words, the size of the window can be changed. The computation of possible set of contexts C_{pw} and commonly used contexts C_{cw} using multiple corpora ensures the elimination of bias that may occur with a particular corpus. To apply the algorithm, few synonyms of beautiful were taken namely: Pretty, Lovely, Gorgeous, Glorious, Good_looking and Stunning.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 1. Details of Corpora used in this work

Corpus	Wide Range of Genres (e.g.)	No. of Words	Type of Documents
Coca Corpus	spoken, fiction, popular magazines, newspapers, and academic texts.	520 million words	Text
BNC Corpus	spoken, fiction, magazines, newspapers, and academic)	100 million words	Text
Wikipedia Corpus	4.4 million documents related to microbiology, economics, basketball, Buddhism, or thousands of other topics.	1.9 billion	Text
GloWbE Corpus	Any type of data related to newspaper, magazines and academic.	1.9 billion	Text

The extracted list of synonyms is checked for similarity with the input adjective word. The different corpora (four) are used to identify the contexts related to a given word and its synonyms. Then list of all possible contexts are taken out by considering the union of contexts taken from all the four corpora. The list of most commonly used contexts is taken out by considering the intersection of contexts using these corpora. In the literature, WebJaccard, WebOverlap and WebDice are different types of standard indices used to compute similarity index between input word and its synonymous on the basis of page-count. All these indices have been modified in our algorithm to use the context set cardinality instead of page count. It is for this reason that they have been named as Modified_WebJaccard, Modified_WebOverlap and Modified_WebDice respectively.

The computed index results have been normalized to the range [0,100] through the use of a normalization factor. The purpose of normalization is to create a relative standing between the various candidate synonyms through a standard level of parity like percentage. The so computed normalized index can also be used as the membership indicator in the corresponding fuzzy set. The range [0,100] is then used as a domain of discourse to create fuzzy sets expressing the extent of similarity between two words through linguistic expressions. The fuzzy set framework created in such a manner leads to the creation of a Fuzzy Rule Base (FRB) that can be used for automated query expansion and information retrieval through the usage of computed normalized similarity index.

The major issue in this context was the calculation of normalization factor. The empirical calculation of this factor may slightly vary with the perception of the designer. In our case, it is considered that two different words are almost similar (assuming that they cannot be exactly similar) at the level of 100 if their context set is at least 80% same as that of the smaller context set and sizes of their context sets don't differ by 25%. Of course, the designer of the automated system can choose different values as suited to their application and the precision requirement. To illustrate the normalization process, let us take two words w_1 and w_2 with cardinality of their context sets $|C_{w1}|$ and $|C_{w2}|$:

Let $|C_{w1}| = 100$, $|C_{w2}| = 125$ // Difference in cardinality of context set being 25%

$|C_{w1} \cap C_{w2}| = 80$ // Context set matching is 80% of the smaller context set

$|C_{w1} \cup C_{w2}| = |C_{w1}| + |C_{w2}| - |C_{w1} \cap C_{w2}| = 145$

Expected normalized similarity value=100

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

This data leads to values of different indices as follows:

Modified_ WebJaccard= 0.55

Modified_ WebOverlap as 80/100=0.80

Modified_ WebDice as 160/225=0.71

The normalization factor under the circumstances for these indices will be 100/0.55=181.81 (182), 100/0.80=125 and 100/0.71= 140.84(141) respectively subject to maximum of 100. The so computed normalization factor has been used in the Tables 3-9 of this paper to computer the normalized similarity index.

Given below are possible and commonly used context sets for the example word 'beautiful' and its synonyms.

- **List of possible contexts for word Beautiful C_{pw}** { area, art, baby, bay, beach, black, blonde, blue, body, book, boy, bride, building, children, church, city, cloth, color, country, countryside, creature, dark, daughter, day, dreamer, dress, evening, eyes, face, family, female, fish, flower, game, garden, girl, hair, head, home, house, image, island, job, lady, lake, landscape, liar, life, little, maiden, man, mind, morning, mother, mountain, movement, music, name, natural, new, night, object, old, park, part, person, photo, picture, piece, place, post, princess, red, river, room, scenery, setting, sight, singing, skin, smile, song, soul, sound, south, spring, story, stranger, summer, surrounding, temple, thing, town, valley, view, village, voice, way, weather, wedding, white, wife, woman, word, work, world, young}=107
- **List of Commonly used contexts for word beautiful C_{cw}**{baby, beach, city, country, daughter, day, face, flower, garden, girl, lady, person, place, scenery, thing, view, voice, wife, woman, young} = 20
- **List of Commonly used contexts for word Pretty C_{CX1}** {girl, woman, face, picture}=4
- **List of possible contexts for word Pretty C_{PX1}**{ baby, blonde, boy, busy, child, cloth, committee, dress, eyes, face, garden, girl, guardian, horse, lady, light, maid, picture, pink, poison, sight, soldier, solid, song, sweet, thing, village, visitor, woman}=29
- **List of Commonly used contexts for word Lovely C_{CX2}**{bone, children, city, couple, daughter, day, eyes, face, family, garden, girl, guy, lady, man, night, person, place, sight, song, story, thing, voice, wife, woman}=24
- **List of possible contexts for word Lovely C_{PX2}**{afternoon, angel, area, article, ballad, bank, blog, blue, body, bone, book, boy, bride, bunch, butcher, carrot, children, city, cloth, color, colour, country, countryside, county, couple, daughter, day, dinner, dog, dream, dress, egg, evening, eyes, face, family, feather, feeling, flower, food, friend, garden, gift, girl, green, guy, hair, head, holiday, horse, hotel, house, idea, idol, image, kid, lady, land, lane, light, little, lock, lunch, man, meal, moment, music, name, night, old, party, person, photo, picture, piece, place, princess, reader, red, rita, room, rose, seat, setting, shade, sight, smell, smile, song, sound, spot, story, stuff, summer, surprise, tea, thing, thought, time, town, valley, view, voice, war, way, weather, white, wife, woman, word, world, young}=112

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

- **List of Commonly used contexts for word Magnificent C_{CX3}**{achievement, bird, building, city, collection, display, example, garden, house, job, old, performance, piece, scenery, sight, view, work}=17
- **List of possible contexts for word Magnificent C_{PX3}**{ achievement, amberson, animal, architecture, art, away, backdrop, baroque, bastard, beach, beast, beauty, bird, black, blue, body, book, bridge, bronze, building, but, butcher, career, castle, cathedral, century, church, city, cliff, collection, contribution, coral, country, countryside, courage, court, creation, creature, day, desolation, dining, display, dog, dress, effort, entrance, event, example, experience, figure, five, four-poster, fraud, frigatebird, funeral, game, garden, gift, goal, golden, gothic, grey, hall, head, history, home, horse, hotel, house, job, journey, lake, landscape, library, life, man, mansion, marble, medieval, mile, montague, monument, moody, mountain, muraco, natural, new, obsession, old, opportunity, palace, panorama, park, performance, physique, piece, place, player, record, red, renaissance, response, ring, room, scale, scenery, season, second, set, setting, seven, show, sight, site, six, sound, specimen, spectacle, stained, state, stone, structure, sunset, surrounding, temple, thing, tomb, tree, victory, view, villa, vista, voice, way, white, woman, wooden, work, world, yankee, young}=141
- **List of Commonly used contexts for word Good_Looking C_{CX4}**{ boy, couple, dog, face, fellow, female, girl, guy, man, person, woman}=11
- **List of possible contexts for word Good_Looking C_{PX4}**{ actor, african-american, american, animal, babe, baby, bastard, bird, black, blog, bloke, blonde, boat, body, boss, boy, breed, british, broad, brother, brunette, cabin, car, castored, chap, character, chestnut, chick, child, children, cloth, club, college, color, cook, cookware, corpse, couple, crowd, curve, daddy, danish, date, design, desk, detective, diagram, dish, doctor, document, dog, dreamer, drew, duck, dude, duke, european, face, family, feature, fellow, female, field, fighter, film, folk, football, foreigner, frame, friend, game, gentleman, girl, glass, graphics, group, guard, gun, guy, hair, handset, head, horse, husband, image, kid, lady, living, male, man, manuscript, mary, movie, musician, officer, one, pair, patient, person, phone, photo, pig, playboy, product, professional, series, shot, stranger, sunshine, surgery, teacher, teenager, victory, view, voice, waiter, weather, white, woman, year, young, youth}=122
- **List of Commonly used contexts for word Glorious C_{CX5}** { battle, career, celebration, city, day, death, era, food, future, history, land, life, light, moment, night, revolution, summer, sun, thing, tradition, victory, voice, year}=23
- **List of possible contexts for word Glorious $C_{PX5\{}$** abandon, achievement, adventure, afternoon, age, amateur, appearing, army, ascension, battle, beach, bloom, blue, body, book, burden, career, cause, celebration, century, chance, chapter, church, city, climax, color, colour, company, country, countryside, day, dead, death, deed, display, empire, end, era, experience, eyes, fire, first, food, freedom, future, garden, goal, god, gospel, green, hair, heritage, high, history, human, king, land, leader, life, light, lord, love, memory, mess, minute, mission, moment, month, morning, mother, mud, music, mystery, name, nation, night, noise, opportunity, order, past, path, peace, period, place, player, power, prospect, red, return, revolution, ring, role, run, scenery, season, sense, sight, song, sound, spring, success, summer, sun, sunrise, sunset, sunshine, thing, time, tradition, victory, view, virgin, voice, war, way, weather, week, work, world, year, youth}=121
- **List of Commonly used contexts for word Stunning C_{CX6}**{ array, beauty, collection, landscape, performance, photograph, piece, scenery}=8

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

- **List of possible contexts for word Stunning C_{PX6}**{ about, accomplishment, ace, achievement, admission, album, amount, announcement, arcade, architecture, array, art, artwork, attack, beach, beauty, black, blonde, blue, book, cast, central, claim, clarity, coast, collapse, collection, color, conclusion, contrast, costume, countryside, creation, dark, day, debut, decision, defeat, design, detail, development, discovery, display, dot, double, dress, effect, election, end, evening, example, exhibition, fact, fall, fashion, film, fish, form, garden, girl, goal, good, graphics, guitar, hat, home, illusion, image, impact, lake, landscape, lap, light, line, location, look, loss, military, moment, mountain, move, natural, news, number, opening, panoramic, performance, photo, photograph, picture, piece, place, portrait, presentation, record, result, reversal, scenery, sea, season, series, set, sight, solo, souvenir, speed, start, statement, story, strike, success, surrounding, thing, turn, variety, victory, video, view, visual, voice, volley, white, woman, work, young}=125

RESULTS

Table 2 represents the computation of various indices based upon the extracted information. Results have been normalized using the normalization factors described earlier in this paper. The computed results have been compared with *UMBC* toolkit (2004), [A Similarity ToolKit] in Tables 3 to Table 9. The toolkit uses statistical method that is based on Latent Semantic Analysis (LSA) and distributional similarity. The whole process is automated and can be trained using different corpora. The technique used in this toolkit assumes that the semantics of a phrase is compositional on its component words. The concept and relation similarity can be found for noun, verb, adjective and adverb using either refined Stanford Webbase corpus (2007) or LDC English Gigaword corpus (2003).

The computed results show quite an agreement with the toolkit and the errors due to various factors owing to the usual ambiguity of the natural language justify the need for fuzzification. The domain of discourse for the fuzzy sets is [0,100] and the chosen fuzzy sets are:

NS: Not_Similar
PrS: Poorly_Similar
SS: Somewhat_Similar
QS: Quite_Similar
PfS: Perfectly Similar

Now, one can choose an appropriate index and use it for fuzzification. Our preferred choice is Modified WebJaccard as it into account both union and intersection aspect. The membership graph of various fuzzy sets is shown in Figure 1.

The design of fuzzy sets follows the fuzzy rule base (FRB) needed for automated decision making. The design of fuzzy sets and the FRB is illustrative and designer of the system can chose modify them as per the requirement.

Fuzzy Rule Base

If the similarity index is *perfectly similar* use W2 in place W1 for word sense disambiguation, web page classification and query expansion.
If the similarity index is *quite similar* use W2 in place W1 for query expansion and web page classification.
If the similarity index is *somewhat similar* use W2 in place W1 in query expansion.
If the similarity index is *poorly similar* use W2 in place W1 for query expansion after checking the context.
If the similarity index is *not similar* don't use W2 in place W1.

Figure 1. Membership graph of various Fuzzy sets

Format of Next Generation Lexical Resources

In the last, the desired format of next generation lexical resources has been shown.

The lexical resource will look as follows.

Modified Lexical Resource

<chosen Word>: <Set of possible contexts>
<Set of most commonly used contexts>
<Synonym-1>:<similarity index>
< common context set>
<Synonym-2>:<similarity index>
< common context set>
……..
……..
……...
<Synonym-k>:<similarity index>
< common context set>

CONCLUSION AND FUTURE SCOPE

The paper presents an efficient and effective approach for finding semantic similarity between words depending upon their contexts. To ensure the neutrality of the approach, multiple corpora have been taken. The similarity index has been computed on the basis of commonality of the contexts. Various benchmark indices have been used to find the similarity index and the results have been normalized. The obtained results can be used for enrichment of lexical resources. The results obtained have been compared with a standard toolkit for the purpose of authentication.

The proposed work provides a basic framework that can be carried out on various options at different levels such as with the choice of larger number of corpora, making better choices for corpora, changing the benchmark for basic index computation, calculation of normalization factor, choice of fuzzy sets and their domain of discourse, redefining of fuzzy rule base etc. paving the way for better synonym resolution for automated systems and enrichment of lexical resources.

Chapter 41
Finding the Semantic Relationship Between Wikipedia Articles Based on a Useful Entry Relationship

Lin-Chih Chen
National Dong Hwa University, Tawian

ABSTRACT

Wikipedia is the largest online Internet encyclopedia, and everyone can create and edit different articles. On the one hand, because it contains huge amounts of articles and there are many different language versions, it often faces synonymous and polysemy problems. On the other hand, since some of the similar Wikipedia articles may have the same topic of discussion, it needs a suitable way to identify effectively the semantic relationships between articles. This paper first uses three well-known semantic analysis models LSA, PLSA, and LDA as evaluation benchmarks. Then, it uses the entry relationship between Wikipedia articles to design its model. According to the experimental results and analysis, its model has high performance and low cost characteristics compared with other models. The advantages of its model are as follows: (1) it is a good model for finding the semantic relationships between Wikipedia articles; (2) it is suitable for dealing with huge amounts of documentation.

1. INTRODUCTION

World Wide Web (hereinafter referred to as the Web) is a distributed information-sharing platform that allows a wide range of users to share their information via the Internet. Starting with Web 1.0, users only need to use the relevant HTML syntax to create a static web page and publish the page to the web server host. Web 1.0 only provides limited one-way interaction between hosts and users (Singh, Bebi, & Gulati, 2011). That is, users cannot share their ideas directly and immediately with other users by using Web 1.0.

From traditional Web 1.0 to modern Web 2.0, users can use various information and communication platforms to achieve the two-way interaction between users. Until today, there are many well-known Web 2.0 platforms, such as Facebook, Twitter, YouTube, and Wikipedia, which provide users with an environment to comment, review and share ideas with other users. According to Best (2006), Web 2.0's main features compared to Web 1.0 include a rich user experience, user participation, dynamic content, metadata, Web standards, and scalability.

A widely-used Web 2.0 platform is Wikipedia, which is a free access to the collaborative Internet encyclopedia, where everyone can create and edit their articles or entries. The advantages of Wikipedia compared to other traditional encyclopedias include the following: (1) it contains almost all the possible topics in different subjects (Garcia & Ng, 2006), (2) it can respond quickly to any new event (Jokinen & Wilcock, 2012), (3) it offers various different language versions of the encyclopedia for different users (Hale, 2014).

When users search in Wikipedia, they often need to find semantic relationships that may occur between search terms. In general, users often need to consider the synonymy and polysemous relationships between search terms to help them select the most suitable Wikipedia entry. This is important because most users are difficult to distinguish between synonyms and polysemy entries in Wikipedia's 37 million entries (CBS, 2015).

Semantic analysis models are widely used to identify semantic relationships between terms (Egozi, Markovitch, & Gabrilovich, 2011; Ji, Jing, Wang, & Su, 2012; Liu, Zhang, Chang, & Sun, 2011; Lu, Mei, & Zhai, 2011; Lu, Peng, & Ip, 2010). In recent years, some well-known semantic analysis models have emerged, such as Latent Semantic Analysis (LSA) (Landauer, Foltz, & Laham, 1998), Probabilistic LSA (PLSA) (Hofmann, 2001), and Latent Dirichlet Allocation (LDA) (Blei, Ng, & Jordan, 2003) to find possible semantic relationships between terms. However, these models lack the mechanism to find efficiently the semantic relationships between Wikipedia entries. This is also important because similar entries in Wikipedia may have the same discussion topic. Thus, in this paper, we use a new entry relationship to identify hidden semantic relationships that exist between Wikipedia articles.

The rest of this paper is organized as follows. First, in section 2, we briefly review some of the literature related to this paper. Next, in section 3, we introduce all the semantic analysis models used in this paper. Then, in section 4, we analyze and discuss the relevant experimental results. Finally, in section 5, we conclude this paper and discuss future research directions.

2. LITERATURE REVIEW

In this section, we briefly review some of the research literature related to this paper, including Wikipedia applications and semantic analysis models. In this section, we provide two tables for readers to read and compare related literature.

2.1. Wikipedia Applications

Many researchers have tried to use Wikipedia as the main source of research to solve many different information retrieval problems. Table 1 shows some recent studies on Wikipedia applications. Milne and Witten (2013) created a Wikipedia miner toolkit that allows users to combine the semantics of Wikipedia into their applications. The benefit of the toolkit is that it can efficiently classify different elements of

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Wikipedia, such as articles, labels, and links. The classification methods used in the toolkit include articles and labels comparators, labels and links disambiguators, and links detectors. Wu and Weld (2010) proposed an open information extraction system to build training data. They deal with the unbounded number of relationships found on the web by using the heuristic match between the Wikipedia infobox attribute values and the corresponding sentences. Through this training data, the system can find the possible semantic relationships from the natural language text. Lehmann et al. (2015) presented a DBpedia project that provides query and search capabilities to a wide range of communities. The project extracts some important structured data from Wikipedia through the following extractors: mapping-based infobox, raw infobox, a feature, and statistics. Hahn et al. (2010) proposed a Wikipedia search mechanism that enables users to ask complex questions about Wikipedia knowledge. The mechanism first sends the query to DBpedia to produce the facet value for each potential Wikipedia article. It then uses the sparse tree to store the facet value, which is used to search for related questions. Ciglan and Nørvåg (2010) proposed a WikiPop system to detect trends that are popular topics related to the user's interest. The system first uses a Wikipedia link graph and a graph-based recommendation algorithm to identify some related topics. It then uses the page view statistics to filter out the most popular related topics.

2.2. Semantic Analysis Models

Currently, the most famous semantic analysis models are LSA (Landauer et al., 1998), PLSA (Hofmann, 2001) and LDA (Blei et al., 2003), respectively. We compare and analyze these models based on the methods, advantages and disadvantages, and the concept of problem solving, as shown in Table 2.

LSA first uses the Singular Value Decomposition (SVD) to separate the topic matrix from the original term-document matrix. Then, it uses a dimension reduction technique to filter out some noisy topics from the topic matrix. Its advantage is that it can effectively deal with synonyms by using the dimension reduction technique (Dumais, 2004). On the contrary, its disadvantage is that it cannot effectively deal with the problem of polysemy because SVD is a one-to-one mapping technique from a specific term to a specific document (Landauer, McNamara, Dennis, & Kintsch, 2013). Many researchers have used LSA to solve different Information Retrieval (IR) problems. For the evaluation of short free text answers, some researchers (Klein, Kyrilov, & Tokman, 2011; Lintean, Moldovan, Rus, & McNamara, 2010) attempted

Table 1. Summary of Wikipedia applications

Researcher	Application	Approach	Advantage
Milne and Witten (2013)	Wikipedia miner toolkit	Articles and labels comparators, labels and links disambiguators, and links detectors	It can efficiently classify different elements of Wikipedia
Wu and Weld (2010)	Open information extraction system	The heuristic match between the Wikipedia infobox attribute values and the corresponding sentences	It can deal with the unbounded number of relationships
Lehmann et al. (2015)	DBpedia project	Mapping-based infobox, raw infobox, feature, and statistics	It provides query and search capabilities to a wide range of communities
Hahn et al. (2010)	Wikipedia search mechanism	DBpedia & sparse tree	It allows complex questions in Wikipedia
Ciglan and Nørvåg (2010)	WikiPop system	Link graph, recommended algorithm, page view statistics	It can detect popular topics related to the user

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 2. Discussion on different semantic analysis models

Model	Method	Advantage (A) and Disadvantage (D)	Problem Solving
LSA	SVD & Dimension reduction	A: Synonymy D: Polysemy	Evaluate short free text answers, Document summarization, Plagiarism detection in source code
PLSA	EM algorithm	A: Synonymy and Polysemy D: Long estimated time	Location prediction service, sports video summaries, Detect sound events
LDA	Dirichlet distribution & Gibbs algorithm	A: Unsupervised learning model D: Small or normal distribution of data	Automatic classification bug reporting, Search for multimedia content, Image annotation

to use LSA to automatically assess whether the answer was correct. For the summary of user-generated documents, the researchers (Ozsoy, Alpaslan, & Cicekli, 2011; Yeh, Keb, Yang, & Meng, 2005) used LSA to sort all the documents to achieve the purpose of document summarization. For the problem of plagiarism detection in source code, Cosma and Joy (2012) tried to use LSA to determine whether the source code was plagiarized.

PLSA uses the iterative Expectation Maximization (EM) algorithm to estimate the probability values for all cells in the term-document matrix. The EM algorithm first estimates the expected value of all latent topics based on the probabilities of the observed parameters. It then updates the probabilities of the observed parameters by maximizing the objective function. Compared with LSA, its advantage is that it can further deal with the problem of polysemy, because the EM algorithm is a statistical estimation technique that can simultaneously estimate multiple parameters (Fernandez-Beltran & Pla, 2015; Siddiqui, Mishra, & Verma, 2015). On the contrary, its disadvantage is that it takes a long-estimated time, because the EM algorithm is a time-consuming algorithm (Brahmane & Amune, 2014; Hsieh et al., 2015; Li, Li, & Li, 2013). In the past, many researchers have succeeded in using PLSA to solve various IR problems. To improve the location prediction service, McInerney et al. (2012) used PLSA to predict the mobility patterns of some new users. For sports video summaries and searches, Xu et al. (2008) first analyzed the broadcast video to get the relevant text, and then used PLSA to detect possible sporting events. Mesaros et al. (2011) used two stages to detect the sound events of human activity. In the first stage, PLSA finds the relationship between events. In the second stage, PLSA updates the probability of the event based on the history of the event.

LDA first uses the Dirichlet probability distribution to establish the probability distribution of the relevant parameters. Then it uses the Gibbs sampling algorithm to estimate the final probability of the relevant parameters. Its advantage is that it can easily find the relevant term for each topic, because it is a generation model based on unsupervised learning (Blei, 2012). On the contrary, its disadvantage is that it is not suitable for dealing with a small amount or normal distribution of data (Wang & Blei, 2013). In the past, many researchers used LDA to solve different IR problems. To automatically classify many bug reports, Somasundaram and Murphy (2012) used LDA to help users to streamline the process of resolving bugs. To help users search for multimedia content, Krestel et al. (2009) used LDA to recommend related multimedia tags to users. To achieve effective image annotation, Liénou et al. (2010) first searched for all pattern relationships between different image frames. It then applied the LDA to annotate automatically the image according to the pattern relationship.

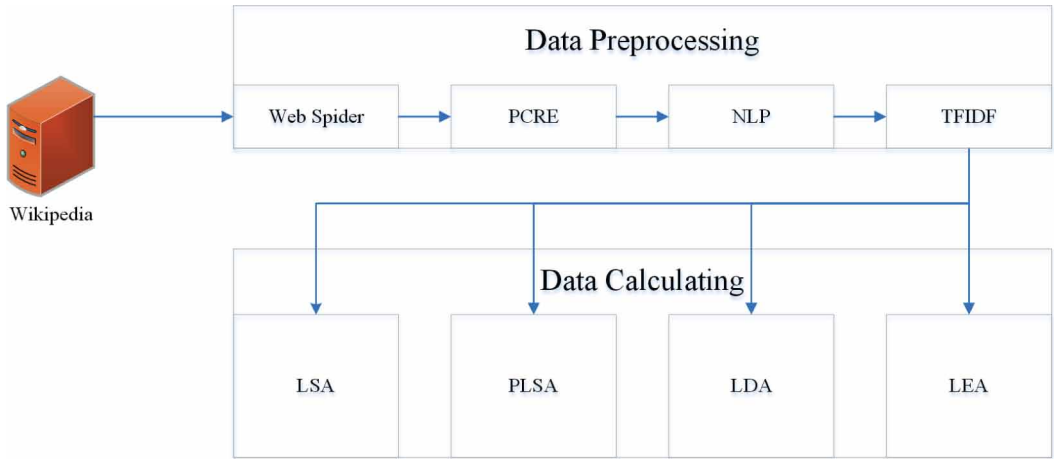
3. RESEARCH METHOD

In this section, we briefly introduce our system, as shown in Figure 1. It contains two major stages to produce relevant experimental data. In the Data Preprocessing stage, we first use the Web Spider to crawl the Search Engine Results Page (SERP) from Wikipedia to get the data source for this study. Since SERP is an unstructured document, we then use Perl Compatible Regular Expressions (PCRE) and Natural Language Processing (NLP) to convert unstructured SERP documents into structured documents. Since the input of the semantic analysis model is the term-document matrix, we finally use the Term Frequency Inverse Document Frequency (TFIDF) to convert all structured documents into the term-document matrix. In the Data Calculating stage, we first use the LSA, PLSA, and LDA models as our benchmark. We then develop a Latent Entry Analysis (LEA) model to find the latent semantic relationship between Wikipedia articles.



3.1. Data Preprocessing Stage

At this stage, we first developed a Web Spider technique for crawling multiple SERPs from Wikipedia at the same time. In theory, through our technique, the crawling time of multiple SERPs is the same as a single SERP when network latency and bandwidth are not considered.

Since SERP is an unstructured document (Gärtner, Rauber, & Berger, 2014; Naughton, Stokes, & Carthy, 2010), we next use PCRE technique (Hazel, 2017) to do pattern matching for all collected unstructured documents to get important analysis elements such as page title, URL, and description.

Then, we use some NLP techniques to avoid unnecessary characters or words that appear in structured documents. In this study, we use the following NLP techniques: stemming, removing stop words, removing non-word symbols. To avoid the problem that different words have the same root to reduce the performance of IR, we use the snowball stemming algorithm (Porter, 2015) to convert the word to its root. To avoid common and meaningless words in structured documents, we use 671 stop words suggested by Google (2015) to filter out stop words that may degrade IR performance. For the same reason, we also remove all non-word symbols, such as punctuation, special characters, spaces, and HTML tags.

Figure 1. The flow chart of this study

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

We finally use the TFIDF method to convert all structured documents into the term-document matrix, which is the input for different semantic analysis models. The conversion process is shown in Equation 1 and subsequent text:

$$TD\left(d,t\right)=\frac{N\left(d,t\right)}{N\left(d\right)}\log\left(\frac{\left|D\right|}{df\left(t\right)}\right) \tag{1}$$

where $TD(d,t)$ represents the weight that the term t appears in document d; $N(d,t)$ indicates the number of occurrences of t in d; $N(d)$ represents the total number of terms in d; $|D|$ represents the total number of structured documents; $df(t)$ is the number of documents where t appears.

3.2. Data Calculating Stage

At this stage, we first discuss the concepts of LSA, PLSA, and LDA, and then describe our LEA model.

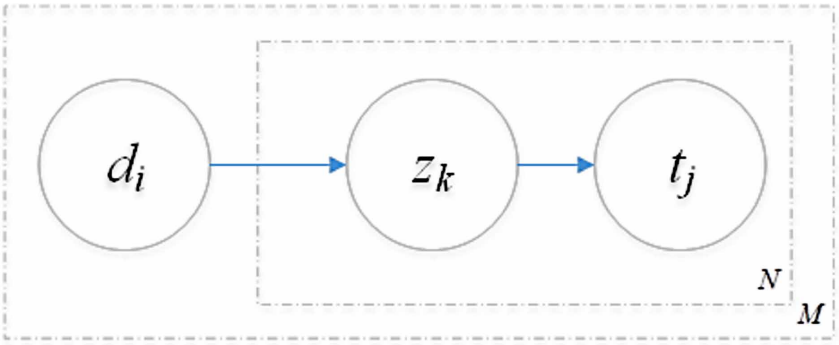
3.2.1. LSA

LSA first uses the SVD technique to decompose the original term-document matrix into three new matrices, as shown in Equation 2 and subsequent text; where S is the topic semantic space, T is the term space corresponding to S, D is the document space corresponding to S, and D^{tr} is the transpose of matrix D:

$$TD(d,t) = TSD^{tr} \tag{2}$$

It then uses the dimension reduction technique to filter out the noise information in S. That is, to obtain the noise-free semantic space S', we preserve the K largest eigenvalues in S and treat the rest as noise. It finally produces the term-document matrix with noise-free topics by the product of the T, S' and D^{tr} matrices.

3.2.2. PLSA



The PLSA uses the aspect model (Hofmann, 1999), which is a latent variable model for estimating unknown variables based on some known variables, to estimate the latent probabilities between terms and documents. The aspect model is shown in Figure 2. In this model, PLSA uses the iterative EM algorithm and the Maximum Likelihood Estimation (MLE) method to estimate the probability that the term appears in the document.

PLSA first selects a specific topic z_k on a given document d_i and then selects a specific term t_j on a given topic z_k. The symbols for PLSA are defined as follows: M is the number of documents, N is the number of terms, $d_i \in \{d_1,\ldots,d_M\}$ is a specific document, $t_j \in \{t_1,\ldots,t_N\}$ is a specific term, $z_k \in \{z_1,\ldots,z_K\}$ represents an observed topic variable.

Based on the aspect model, it uses the following equation to estimate the probability that the term t_j appears in document d_i, $p(d_i,t_j)$, where $p(d_i)$ is the probability of document d_i, $P(X|Y)$ is the conditional probability of X for a given Y occurrence:

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. PLSA's aspect model

$$p\left(d_i,t_j\right)=p\left(d_i\right)\sum_k p\left(t_j|z_k\right)p\left(z_k|d_i\right)=\sum_k p\left(t_j|z_k\right)p\left(z_k\right)p(d_i\mid z_k) \tag{3}$$

To estimate the relevant parameters, PLSA uses the iterative EM algorithm and the MLE method to compute the result of $p(d_i,t_j)$. In the MLE method, it uses the following likelihood function as the objective function, where $n(d_i,t_j)$ represents the weight that the term t_j appears in document d_i:

$$L\left(d_i,t_j\right)=\sum_i\sum_j n\left(d_i,t_j\right)\log p\left(d_i,t_j\right) \tag{4}$$

To maximize the objective function, it uses the EM algorithm to estimate the probability of the relevant parameters. In the E step, the algorithm uses the probability of the observed parameter to estimate the expected value of the hidden topic parameter, as shown in the following equation:

$$p\left(z_k|d_i,t_j\right)=\frac{p\left(d_i|z_k\right)p\left(z_k\right)p(t_j\mid z_k)}{\sum_k p\left(d_i|z_k\right)p\left(z_k\right)p(t_j\mid z_k)} \tag{5}$$

In the M step, the algorithm first uses the result of the E step to maximize the value of the objective function and then updates the probability of the observed parameter in Equation 3, as shown in the following three equations:

$$p\left(t_j|z_k\right)=\frac{\sum_j n\left(d_i,t_j\right)p(z_k\mid d_i,t_j)}{\sum_j\sum_i n\left(d_i,t_j\right)p(z_k\mid d_i,t_j)} \tag{6}$$

$$p\left(z_k\right)=\frac{\sum_j\sum_i n\left(d_i,t_j\right)p(z_k\mid d_i,t_j)}{\sum_j\sum_i n\left(d_i,t_j\right)} \tag{7}$$

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

$$p\left(d_i|z_k\right)=\frac{\sum_i n\left(d_i,t_j\right)p(z_k\mid d_i,t_j)}{\sum_j\sum_i n\left(d_i,t_j\right)p(z_k\mid d_i,t_j)} \tag{8}$$

3.2.3. LDA

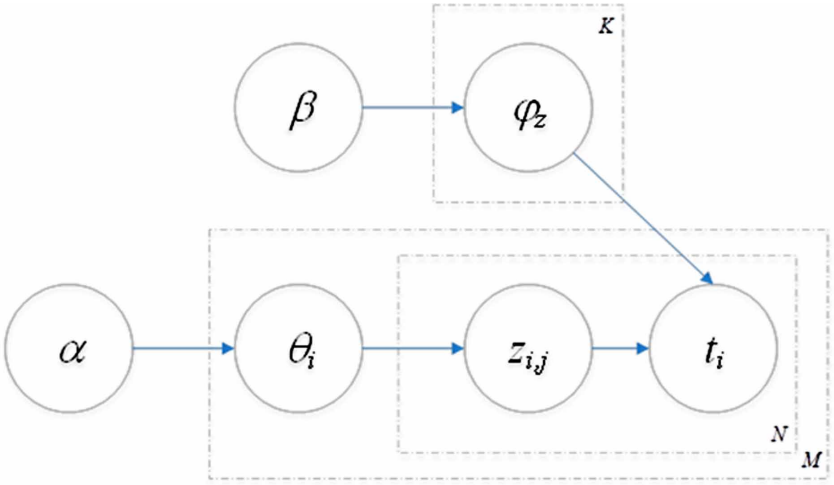
The LDA uses an aspect model as shown in Figure 3 to represent the probability distribution between the term and the document. Compared with LSA, its advantage is that it is a probability model with explanatory topics. The relevant parameters for LDA are shown below:

- α denotes the parameters of the Dirichlet distribution prior on the topic-document distributions;
- β denotes the parameters of the Dirichlet distribution prior on the term-topic distributions;
- *K* is the number of topics;
- *M* is the number of documents;
- *N* is the number of terms;
- θ_i denotes the topic distribution of document *i*, which is corresponding to the conjugate distribution of parameter α in the Dirichlet distribution;
- φ_z denotes the terms distribution of topic *z*, which is corresponding to the conjugate distribution of parameter β in the Dirichlet distribution;
- $z_{i,j}$ denotes the topic of document *i* containing term *j*, which is corresponding to the conjugate distribution of parameter θ_i in the multinomial distribution;
- t_i denotes the specific term in document *i*, which is corresponding to the conjugate distribution of parameter φ_z in the multinomial distribution.

The LDA first estimates the conditional probability of the *K*-dimensional Dirichlet variable θ when given the parameter α($\theta_k\geq 0$ and $\alpha_k\geq 0$), as shown in the following equation; where α is the *K*-vector with element α_k, and (*x*) is the Gamma function:

$$p\left(\theta|\alpha\right)=\frac{\left(\sum_k \alpha_k\right)}{\prod_k\left(\alpha_k\right)}\theta_1^{\alpha_1-1}\ldots\theta_K^{\alpha_K-1} \tag{9}$$

It next estimates the joint distribution probability for all observed and unobserved parameters when given the observed parameters α and β, as shown in the following equation:



$$p\left(t_i,z_{i,j},\theta_i,\varphi_z|\alpha,\beta\right)=\prod_j p(\theta_i\mid\alpha)p\left(z_{i,j}|\theta_i\right)p\left(t_i|\varphi_z\right)p(\varphi_z\mid\beta) \tag{10}$$

It then estimates the MLE of the term distribution of the document by integrating over θ_i and φ_z, as shown in the following equation:

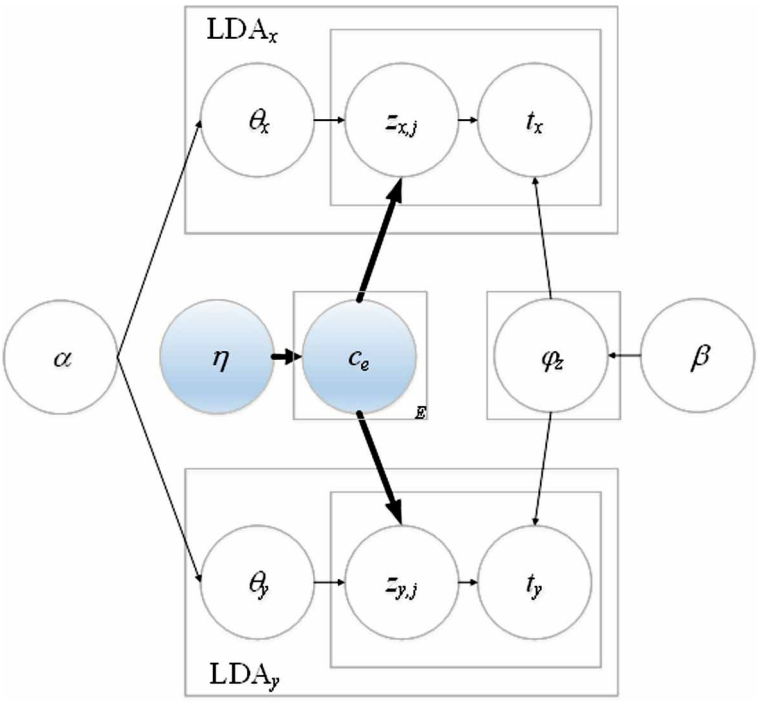
$$p\left(t_i|\alpha,\beta\right)=\int_{\theta_i}\int_{\varphi_z} p\left(t_i,z_{i,j},\theta_i,\varphi_z|\alpha,\beta\right)d\varphi_z d\theta_i \tag{11}$$

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 3. LDA's aspect model

It finally uses the Gibbs sampling algorithm (Speh, Muhic, & Rupnik, 2013) to estimate the probability of α and β from the collected documents. Compared with PLSA, its advantage is to reduce significantly the required calculation time, because it uses Gibbs sampling algorithm rather than EM algorithm to estimate the probability of different parameters (Speh et al., 2013).

3.2.4. LEA



According to section 2.2, LSA can effectively deal with synonyms, but its lack of processing polysemy. PLSA can properly handle synonymous and polysemy problems, but its computation time is time-consuming. LDA can handle synonymous and polysemy problems, and the computation time is relatively fast. However, it is not suitable for dealing with documents of normal distribution, such as Wikipedia, because Wikipedia often has a hidden semantic relationship between different articles. In this paper, we propose the LEA model to present the entry relationship between Wikipedia articles.

LEA first needs to find a model to describe the relationship between terms and topics on a particular document. According to the LDA description, it is a suitable model to estimate the probability of term-topic and topic-document when given a specific document. Therefore, to establish a document link relationship between documents, we need two LDA models, LDA_x and LDA_y, to represent the LDA model of the x and y documents. To connect the two LDA models, in our LEA model, we additionally include an entry relationship parameter η and generate a binary link variable c_e. Figure 4 is the LEA model with the entry relationship between documents x and y. The relevant parameters for LEA are shown below:

- η is the parameters of the Dirichlet distribution prior on the topic-link distributions;
- c_e denotes the topic distribution of entry e, which is corresponding to the conjugate distribution of parameter η in the Dirichlet distribution;
- E denotes the number of entry relationships.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 4. LEA's aspect model

For any pair of documents, the LEA uses the topic-link relationship η between two documents to estimate how a topic affects the entry relationship. For all collected documents, LEA uses the weighted average of all ηs to estimate how different topics affect the entry relationship.

We now discuss the LEA model's estimation equation in detail. It first estimates the joint distribution probability of all observed and unobserved parameters when given the observed parameters α, β and η, as shown in the following equation:

$$p\left(t_i, z_{i,j}, \theta_i, \varphi_z, c_e | \alpha, \beta,\right) = \prod_j \left(\prod_{i \epsilon \{x,y\}} p(\theta_i \mid \alpha \right) p\left(z_{i,j} | \theta_i\right) p\left(t_i | \varphi_z\right) p\left(z_{i,j} \mid c_e\right) p\left(\varphi_z \mid \beta\right) p\left(c_l \mid\right) \tag{12}$$

It then estimates the MLE of the term distribution of all documents by integrating over θ_i, φ_z and c_e, as shown in the following equation:

$$p\left(t_i | \alpha, \beta,\right) = \int_{\theta_i} \int_{\varphi_z} \int_{c_e} p\left(t_i, z_{i,j}, \theta_i, \varphi_z, c_e | \alpha, \beta,\right) dc_e d\varphi_z d\theta_i \tag{13}$$

Table 3 is a comparison of different semantic analysis models. LSA uses SVD and dimension reduction to filter out noisy topics from raw data. Through dimension reduction, it can effectively identify synonyms between terms. PLSA uses the EM algorithm and the MLE method to estimate the relevant parameters. It can further identify the polysemy between terms because the EM algorithm can simultane-

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

ously estimate multiple parameters. LDA and LEA use Gibbs sampling algorithm and MLE method to estimate the relevant parameters. The difference between these two models is that they have a different focus. In LDA, it focuses on the topic between terms because of its two important parameters, α (topic-document) and β (term-topic), all focused on topic processing. In LEA, it focuses on how to identify effectively the entry relationship between documents. Through our model, we can easily cluster similar documents with the same discussion topic into a cluster. For speed considerations, LSA is the fastest because it does not use any iterative method to estimate the relevant parameters. In contrast, PLSA is the slowest because the calculation time of the EM algorithm is exponentially increasing as the number of terms and documents increases (Chen, 2012). LDA and LEA are significantly faster than PLSA because the two models use the Gibbs sampling algorithm instead of the EM algorithm to estimate the relevant parameters. In the next section, we will perform some experiments to compare the performance and cost of different semantic analysis models.

4. EXPERIMENTAL ANALYSIS AND RESULTS

In this experiment, the experimental data was selected from the top 100 visited articles in Wikipedia from 2012 to 2014. By looking at all the entries, we only keep one when there are duplicate entries in different years. The number of views for each entry is the sum of the number of visits in different years. Table 4 is the most popular 20 entries on Wikipedia. In this study, we selected 206 entries as experimental data for this study. All experimental data are shown at http://goo.gl/wn5aHZ.

For the Data Preprocessing stage in Figure 1, we use the PHP scripting language to produce the term-document matrix from Wikipedia. For the Data Calculating stage, we use the MATLAB programming language to simulate different models. To compare the performance of different models, we need some

Table 3. Comparison of different semantic analysis models

Model	Method	Speed	Focus
	Estimation Equation		
LSA	SVD & dimension reduction	Fastest	Synonyms between terms
	$TD(d,t) = TSD^{tr}$		
PLSA	EM & MLE	Slowest	Polysemy between terms
	$p(d_i,t_j) = \sum_k p(t_j \mid z_k)p(z_k)p(d_i \mid z_k)$		
LDA	Gibbs & MLE	Fast	Topics between terms
	$p(t_i,z_{i,j},\theta_i,\phi_z \mid \alpha,\beta) = \prod_j p(\theta_i \mid \alpha)p(z_{i,j} \mid \theta_i)p(t_i \mid \phi_z)p(\phi_z \mid \beta)$ $p(t_i \mid \alpha,\beta) = \int_{\theta_i}\int_{\phi_z} p(t_i,z_{i,j},\theta_i,\phi_z \mid \alpha,\beta)d\phi_z d\theta_i$		
LEA	Gibbs & MLE	Fast	Entry relationship between documents
	$p(t_i,z_{i,j},\theta_i,\phi_z,c_e \mid \alpha,\beta,\eta) = \prod_j(\prod_{i\in\{x,y\}} p(\theta_i \mid \alpha)p(z_{i,j} \mid \theta_i)p(t_i \mid \phi_z)p(z_{i,j} \mid c_e))p(\phi_z \mid \beta)p(c_l \mid \eta)$ $p(t_i \mid \alpha,\beta,\eta) = \int_{\theta_i}\int_{\phi_z}\int_{c_e} p(t_i,z_{i,j},\theta_i,\phi_z,c_e \mid \alpha,\beta,\eta)dc_e d\phi_z d\theta_i$

similarity functions to evaluate the similarity between two terms or document vectors in the matrix. The similarity function can be any vector similarity function. The most common similarity functions are COSine similarity (COS) and CORrelation coefficient (COR) (Hofmann, 2003; Nguyen & Bai, 2011; Tan, Steinbach, & Kumar, 2005). Therefore, in this study, we use these two similarity functions to evaluate the performance of different models.

The number of topics will affect the performance of different models. On the one hand, more topics may lead to degradation of performance; on the other hand, fewer topics may lead to reduced discrimination between documents. Therefore, how to set properly the appropriate number of topics becomes an important job. According to Hoffman et al. (2008), we set the number of topics from 5 to 50 to evaluate the performance of different models.

We first enter the query "mobile phone jb" to Wikipedia to explain carefully synonyms and polysemy how to affect the performance of different models. Table 5 shows an example of COS and COR produced by the results of the different models. According to the table, we found that the terms "mobile phone", "cell phone," and "hand phone" have synonymous features. Similarly, the terms "jb" and "jailbreak" (or "jelly bean") also have synonymous features because "jailbreak" or "jelly bean" are abbreviated "jb". In addition, the term "jb" is also a polysemy because it has at least two different meanings "jailbreak" and "jelly bean". Based on the results of the table, we found that the COS and COR of PLSA, LDA and LEA were significantly better than LSA in terms of the evaluation of terms or document vectors. This means

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

that all models can find the semantic relationships that exist between "mobile phone", "cell phone", and "hand phone". However, LSA lacks the ability to find the semantic relationship between "jb" and the two polysemous terms. That is, all models can handle synonyms properly, but LSA's ability to handle polysemy is poor. The reason is that after SVD processing, the row vector in the matrix can only represent a term, so LSA cannot effectively deal with the polysemy between terms (Ishida & Ohta, 2002). Other models use the aspect model to estimate simultaneously the joint probability of terms and documents. By using the probabilistic approach, it can clearly classify the types and meanings of different terms, so these probabilistic models can properly handle the problem of polysemy.

Next, we perform an extended experiment on a large-scale dataset. For the 206 entries above, we crawl these entries and perform the Data Preprocessing stage to produce the term-document matrix needed for the different models. In this extended experiment, we also use COS and COR to measure the performance of different models. For this data set, we use a computer with Intel Core 2 Duo T9600 and 2GB memory to simulate the performance and computation time needed for different models.

The relevant experimental parameters in this study are described below. First, we use all the Wikipedia articles that match to the selected 206 entries as all the documents in the term-document matrix. Next, we analyze the links in all the documents and use the text matching to all the links as all the terms in the term-document matrix. The number of terms contained in all documents is between about 100

and 200. The reason why there are so many terms in each document is that we selected the popular entries in Wikipedia. Then, we use the TFIDF method to calculate the weight of each cell in the original term-document matrix. Finally, as shown in Figure 1, the original term-document matrix is used for the source of different models and the experimental results are evaluated by calculation of different models.

The result of the different models consists of a term-document matrix with term (row) vectors and document (column) vectors. To verify the effect of different models on terms and documents, we need to calculate the similarity between row and column vectors separately. First, we discuss the effect of different models on terms (row vectors). Figures 5 and 6 show the average similarity between the different term vectors for different models. Each dot in the figures is the average of the similarity between the different term vectors under a given number of topics. According to the results in the figures, COS and COR will decrease as the number of topics increases. The best and worst models are LEA and LSA, respectively. When the number of topics is greater than 5, the cosine similarity of LSA has a significant downward trend, but the trend of other models is not as obvious as it is. This means that LSA is not suitable for handling multiple topics at the same time. According to the results shown in the figures, the performance of PLSA is close to LDA, but it needs much computation time to achieve this solution as described below. This means that PLSA is not suitable for handling huge amounts of documentation. Since the underlying model of the LEA is LDA, the LEA can significantly reduce the computational time as LDA. This means that LEA and LDA are suitable models for handling huge amounts of documentation. Compared with LDA, COS and COR of our model are superior to LDA in Wikipedia article processing. This means that when we use the LDA model in Wikipedia articles and consider the entry relationship between articles, it can further improve performance.

(b) Correlation Coefficient between Terms for different models

Next, we discuss the effect of different models on documents (column vectors). Figures 7 and 8 show the average similarity between the different document vectors for different models. Each dot in the figures is the average of the similarity between the different document vectors under a given number of topics. Based on the results in the figures, we found the average similarity of LSA, PLSA, and LDA has lower performance compared to LEA. This means that the ability of these models to understand document similarity in Wikipedia articles is consistent low. The reason for this is that these models do not consider the entry relationships between documents that often appear in Wikipedia articles. LEA uses the entry relationships between documents to find the semantic relationships that exist between Wikipedia articles. This means that we can easily cluster similar documents with the same discussion topic to the same cluster through the entry relationship. For example, in Table 5, documents d_1, d_2, and d_3 have the same discussion topic ("mobile phone"). With LEA's entry relationship, we can cluster d_1, d_2, and d_3 documents to the same cluster and further improve the average similarity between document vectors.

To understand the source of the differences in experimental data, we then use SPSS 14.0 for Windows to analyze the results of the two experiments. Considering COS and COR of LSA, PLSA, LDA and LEA, we use a statistical method, Analysis of Variance (ANOVA), to show that $F_{(K=5)} = 112.871$, $F_{(K=10)} = 430.771$, $F_{(K=15)} = 555.322$, $F_{(K=20)} = 723.694$, $F_{(K=25)} = 884.042$, $F_{(K=30)} = 903.743$, $F_{(K=35)} = 901.851$, $F_{(K=40)} = 929.021$, $F_{(K=45)} = 928.332$, $F_{(K=50)} = 932.991$ (Table 6) are greater than $F_{0.001}(3,3292) = 5.435$ (F-distribution). This provides a strong evidence to reject the null hypothesis, that is, there is a significant difference in the performance of COS and COR for different models. To compare the differences between the different models, we performed the pairwise comparisons of Fisher's Least Significant

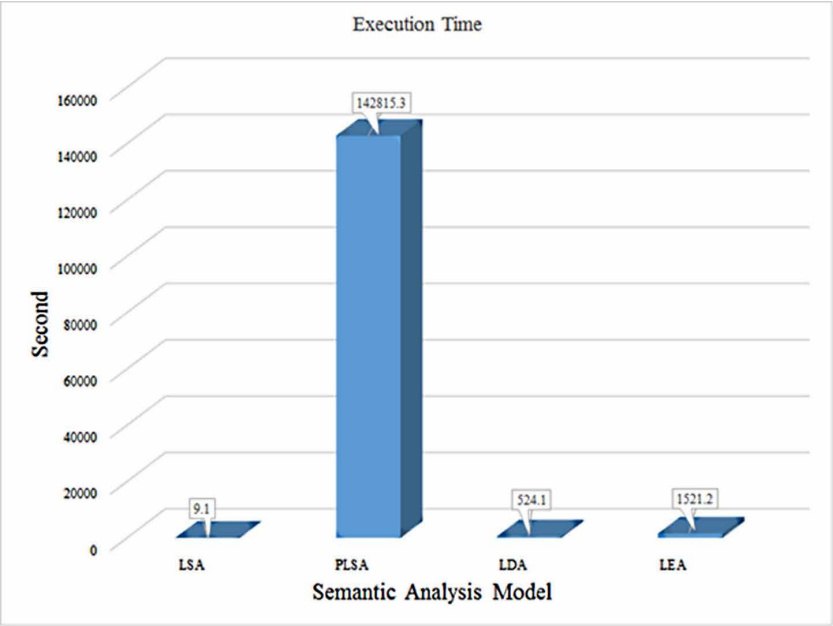
Difference (LSD) at 1% significance level. Since the result of the LSD is lengthy and tedious, we put the complete statistical results at http://goo.gl/EGjJfC. As shown in the LSD results, we found that LEA (LSA) is better (worse) than other models.



Finally, we analyze the computation time (cost) needed by the different models to verify that PLSA is not suitable for handling huge amounts of documentation. Figure 9 is the computation time required for the different models. Compared with other models, LSA has the fastest calculation time because it does not use any iterative method to estimate the relevant parameters. However, its performance is

Figure 9. Computation time for different models

the worst because it lacks the ability to handle polysemy. According to the results of the figure, PLSA spent 142815.3 seconds to run the EM algorithm. This means that PLSA needs much computation time to estimate the relevant parameters compared to other models. This is because its computation time exponentially increases as the number of terms and documents increases (Chen, 2012). The advantage of LDA and LEA compared to PLSA is that they can significantly reduce computational time because they use the Gibbs sampling algorithm instead of the EM algorithm to estimate the relevant parameters.

5. CONCLUSION AND FUTURE WORK

In this paper, we use the entry relationship between Wikipedia articles to design our semantic analysis model. The first advantage of our model is that it can effectively identify the semantic relationship between Wikipedia entries. According to the relevant experimental results, the performance of our model is significantly better than other models. The second advantage of our model is that it can significantly reduce the computational time so that our model is suitable for handling huge amounts of documents.

In the future, we plan to add a time series relationship to our model so that we can perform further clustering for documents that have similar update times. Through this relationship, we can clearly distinguish between iPhone 6 and iPhone 6S, because these two types of iPhone phones have different release date.

ABSTRACT

In the context of a citizen lab, this article describes how a vanguard of activists, designers, scholars and participation practitioners were involved in a participatory prototyping process. CoGovern was designed as an online participation tool whose focus is to incorporate citizen preferences in local policy making. It is aimed at supporting informed and transparent participatory processes while reducing the ability of sponsoring authorities to "cherry-pick" policy proposals and avoid providing explanations. This article proposes a decision-making process that incorporates artificial intelligence techniques into a collective decision process and whose result is mainly based on standard optimization techniques rather than vote-counting.

1. INTRODUCTION

The field of democratic innovations (Fung & Wright, 2001; Smith, 2009) is currently crowded with digital tools aimed at facilitating deliberative and participatory processes. Frequently, these tools emerge within activism environments characterised by a high level of civic engagement and political interest. In particular, most of these environments largely embrace the principles promoted by those social movements in defense of free and open source software such as opensource.org. More recent initiatives also promulgate the coproduction of knowledge between the general public and the scientific community such as Citizen Science (Socientize Consortium, 2013).

This article stems from one of those spaces: MediaLab Prado, a Citizen Lab located in Madrid (Spain). This experimental Lab organized a Workshop for Collective Intelligence on Democracy whose main purpose was to prototype digital tools addressing the challenges posed by citizen participation in the age of social media.

We address some of these challenges by focusing on two main questions: How can digital tools be designed in order to make participatory processes more transparent and accountable? Can artificial intelligence enhance participatory processes in an objective and publicly auditable manner, without deviating from participants' interests?

Firstly, this paper seeks to reflect how a vanguard of activists, designers, scholars and practitioners currently envision what – according to them – will be one of the most common forms of citizen participation in the coming years. Secondly, it proposes the basis for the future development of *CoGovern,* an online citizen participation tool whose focus is to incorporate citizen preferences in local policy-making. Thirdly, our tool proposal aims to ensure informed and transparent participatory processes to avoid that sponsoring authorities cherry-pick policy proposals and omit to provide explanations. And finally, for these purposes, this article proposes a decision-making process which incorporates artificial intelligence (AI) techniques in order to align citizen preferences, budgetary constraints and priorities, or strategic objectives about what policies and investments should be chosen for implementation.

The result has been the initial design of *CoGovern,* a prototype web application in which citizen participation is grounded in information fusion (Torra, V. & Narukawa, Y., 2007), argumentation theories (Awad, E. et al., 2015), and standard optimization techniques. In other words, the main substantive contribution is to propose a decision-making process in which the outputs – normally participatory policy proposals – are selected using optimization techniques. The central argument is that a proposal selection method based on the best possible combination, according to previously agreed and weighted criteria, instead of the traditional vote-counting system, can enhance participatory decision making.

The article proceeds as follows. The next section presents the sociological and technological research background. In particular, it introduces artificial intelligence techniques that can be applied to decision support in the context of political participatory processes. Next, we present the methodological approach which is based on a collective intelligence (CI) experiment; more specifically, a case study about a Citizen Lab is described. Subsequent section presents the resulting prototype design by focusing on its graphical design, functionalities, and automated decision making. Lastly, some implications of these types of participatory tools and future research paths are discussed.

2. INTRODUCING AI IN PARTICIPATORY DECISION-MAKING PROCESSES

Political sociology often distinguishes three decision-making models in democratic regimes: representative, participatory, and technocratic (Bengtsson & Christensen, 2014). The major difference between them resides in the actors responsible for the decision making. Thus, in the representative model, a group of elected politicians are in charge of making decisions, whereas that is the responsibility of citizens and experts in the participatory and technocratic models, respectively. Recent public opinion research argues that most citizens prefer decision-making processes that involve both elected politicians and ordinary people; however, people believe that decisions are solely taken by elected politicians (Allen et al. 2015; Font et al. 2015, 2017).

On the contrary, in *Stealth Democracy*, Hibbing and Theiss-Morse (2002) question the existence of a real demand for more participation. They argue that people actually prefer not to participate but decisions to be taken "efficiently, objectively and without commotion and disagreement" (2002:143). Other participation criticisms revolve issues such as the lack of efficiency and the perception that participatory processes are highly time consuming. This article addresses this tension between a desire for more opportunities to participate and a demand of political processes to be more objective and efficient. Overall, our aim is to work towards convergence of diverting positions rather than their confrontation.

Despite this ambivalence results on citizen process preferences, "the participatory turn" has become rooted in political agendas (Bherer et al., 2016). As a result, during the last decades, participatory experiences have widespread around the world putting the stress on different aspects such as: prioritization of the aggregative component (e.g. voting) vs. deliberation; interested groups participation vs. open participation; top-down vs. bottom-up; or consultative vs. "more" binding processes.

However, over the past years, a new generation of participatory institutions is announced, mostly characterized by the use of the new information and communication technologies (ICTs). It is still early to assess whether the spread use of the ICTs entails a entirely new generation of participatory institutions. Nevertheless, what is certain is that, at least, they introduce new demarcation lines when designing participatory processes. For instance, according to Dahlberg's classification (2011), we can find four main categories of e-democracy tools: counter-publics, autonomous Marxists, liberal consumer and deliberative. Whilst the first would seek shaping groups of activists to perform contestatory actions, the second would be oriented towards the networking and self-organization outside the capitalist system (see also Chadwick, 2009:21). On the other hand, those under the category of liberal consumer would be oriented towards making requests and receiving support for them. Some scholars (London, 1995; Bohman, 1998) critically name these spaces as a "Marketplace of ideas" competing between them and introducing game elements (gamification) (Secchi & Spada, 2017). In contrast, those under the category of Deliberative would include argumentation systems to transform particular interests or concerns into common and consensual ones through the rational model of deliberation (Dahlberg, 2011). *CoGovern*, our participatory tool proposal, lies within this last category.

One of the most important changes that these new tools have introduced is the fact of increasing the number and diversity of participants. Although dilemmas on some key issues, such as anonymity and the digital divide, remain unsolved, large participation allows to build streamlined participatory processes as well as to scaling-up. However, this comes at a cost, since it also increases the complexity of the decision-making process. Taking into account this and other challenges facing participatory democracy, this article develops a theoretical decision-making process which incorporates AI techniques. In particular, it proposes a selection method of citizens proposals which determines the best possible combination (of

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

proposals) rather than conducting the traditional vote-counting ranking. But, can AI expected always to enhance participatory processes? We must be prudent about the most suitable application scope of AI when considering democratic processes, since there are many AI techniques, and we cannot foresee all the consequences of introducing general AI in our everyday political life. On the contrary, this article focuses on a specific aspect that can certainly benefit from the incorporation of a particular AI technique: the objective proposals' selection in participatory processes based on optimization techniques.

Nowadays, it is most often the case that authorities sponsor participatory processes to gather citizens preferences about what policies are needed and, once the consultation is finished, they might: (i) just cherry-pick a subset of proposals without giving any reasoned explanation; or (ii) prioritize the proposals in decreasing order of citizen support (normally gathered through voting), and choose the first ones in the ranking[1] so as to implement them as long as the budget lasts. Nevertheless, technology can enrich the whole participatory process. In particular, there are some areas of AI related to information aggregation, argumentation, and optimisation that can be applied. On the one hand, information aggregation (Torra & Narukawa, 2007) and argumentation (Awad et al., 2015) can be applied to opinion gathering. On the other hand, optimisation techniques (Hwang & Masud, 2012) are particularly suited for choosing the best subset of citizen proposals once their characteristics are quantified and selection criteria are clearly stated.

Regarding opinion gathering, voting is the hegemonic mechanism in democratic societies. It is simple and scales-up well. Thus, citizens are familiar with it and it allows the participation of a large number of citizens. Nevertheless, most times decisions are taken in a biased or even uninformed way. Ideally, arguments in favor and against a proposal should be thoughtfully pondered before voting for it. Forums in online participatory processes try to leverage these shortages, but they are unstructured and they just work well for small groups. Argumentation theory (Awad et al., 2015) is a research area concerned with reaching agreements through logical reasoning that consider supporting or/and attacking arguments. Most research work on argumentation is kept at a theoretical level; however, Deliberatorium, an on-line tool for collaborative deliberation (Klein, 2012) constitutes a remarkable exception. Moreover, aggregation operators, such as Weighted Ordered Weighted Aggregation operators (WOWA) (Torra & Narukawa, 2007), constitute mathematical methods that combine information in a richer and more general manner than standard methods such as the average or the mean computation.

As for choosing the best subset of proposals, optimisation methods have been long applied to economic contexts so to maximise the benefit in the selection. Combinatorial auctions (Cramton et al., 2006) for trading bundles of products in markets constitute a representative example. Most commonly, benefit is associated to monetary aspects, but in fact it can be computed with respect to several criteria, as long as they are quantified. The optimisation problems that consider different criteria simultaneously constitute the so-called multi-objective optimisation problems, and linear programming (Hwang & Masud, 2012) is a computational technique designed to solve them (i.e., to maximise the compound benefit). These methods compute the best solution (or, in other words, optimizes an objective function) that satisfies some additional restrictions.

In the subsequent sections of the article, we develop a method through which citizens can rate participatory proposals and also provide arguments in favour or against other citizens' arguments. Furthermore, proposals are selected by means of standard optimisation methods (Hwang & Masud, 2012). Specifically, proposals are chosen for implementation based on a set of criteria: citizen support, budget constraints, and, as we will detail later on, proposal alignment with pre-agreed priorities or strategic objectives.[2] In this manner, decisions are publicly known to be the best ones according to the previously established criteria. To the best of our knowledge, participatory processes do not use any of these methods to select

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

proposals. Our central argument is that these methods enhance transparency and effectiveness in citizen participation because it makes transparent the functioning rules before starting the participatory process. Thus, *CoGovern* prevents arbitrary actions by the authorities such as *cherry-picking* and, on the other hand, selects the best possible combination of proposals, taking into account citizen support, budget constraints, and a proposal's convergence with priorities or strategic objectives.

3. COLLECTIVE INTELLIGENCE AS A METHODOLOGICAL APPROACH: THE CASE OF A CITIZEN LAB

This section presents the methodological approach adopted in this article. For this purpose, it begins by explaining the starting point of this project. Second, it introduces the role played by a Collective Intelligence experiment (an international workshop) in its development.

3.1. Starting Point for the Project

The *CoGovern* project stems from a previous research named *Information fusion for norm consensus in virtual communities* (Serramia, 2016) developed at the University of Barcelona (UB) and the Artificial Intelligence Research Institute (IIIA-CSIC). This project was oriented to facilitate that members from a virtual community were able to decide their own community rules. Briefly, it aims to enable large-scale debates for collective decision making. The main idea is that users can express their support to a presented norm proposal by exposing arguments in favour and against it, as well as scoring (in a 1-5 points scale) each one of the arguments made by other users. By doing so, an argumentative structure (the so-called norm argument map) is naturally created. Aggregation methods are then used to, first, assess the collective support for each argument and, second, compute the collective support for the whole proposed norm. Two pilot tests were performed in order to evaluate the functionality of the norm argument map. Tests encompassed, respectively, 11 (Rodriguez-Aguilar et al., 2016) and 17 (Garcia-Heveling, 2017) people debating on norms within a prototyped football social network. Most users were male university students who reported having participated in virtual communities before. The average age was 25.5 years old. During the tests users debated normally about a few norms (they created and rated up to 76 arguments per norm); afterwards, a satisfaction survey asked them if resulting aggregated ratings were reasonable. In a scale from 1 to 5, the answers' mean was 3.36 respectively, which can be considered as a positive preliminary result if we take into account the usability deficiencies of our prototype.

Considering these modest tests as a starting point, the research team from UB and IIIA decided to look into the field of participatory processes to broaden the application of their research. Thus, in contrast with other projects in alpha or production stages[3], *CoGovern* is in a incipient stage whose goal is to clearly define both the project and the scope of its applications. This stage would correspond to a conceptualization phase encompassing the Envision and Speculate phases defined by Mario Špundak (2014).

3.2. Collective Intelligence at Medialab Prado

The project aforementioned (Serramia, 2016) was presented to the call for "Collective Intelligence for Democracy" by Medialab Prado. This call consisted on a two weeks international workshop aimed at exploring new ideas to design innovative participation tools. Medialab Prado is a Citizen Lab (Mazé, 2014;

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Hillgren et al., 2011; Seravalli, 2011) where individuals from different backgrounds – scientists, policy makers, lay citizens, programmers or designers – work together to solve complex social problems through participatory prototyping (Brodersen et al., 2008) and co-design. The interaction of these elements is what is known as collective intelligence. Following Chadwick, the core idea is that a distributed network of creators and contributors, the majority of them amateurs, can, using simple online tools, produce information goods that may outperform those produced by so-called authoritative, concentrated sources (2009, p. 21).

This international workshop applied work dynamics that come from the "hackathon" logic. According to Gerard Briscoe (2014), hackathon settings involve people working intensively during a limited period of time. The main goal is to generate ideas rather than develop fully operational tools. Documentation becomes crucial for these events, since it allows to have a registry of all the process which is fundamental to continue the work in the future. Another important factor of this methodology is the relationship established between the participants. *CoGovern* involved two main actors: project coordinators (who applied to the call by Medialab Prado) and external collaborators (who chose the project according to their preferences). The involvement degree between these two roles was balanced in order to guarantee an open participation (Manzini & Coad, 2015; Manzini & Rizzo; Lee, 2008). Finally, *CoGovern* team was composed by a wide range of profiles including architects, political scientists, designers and social workers of different ages and nationalities (Latin America and Spain).[4] This diversity caused the participation to respond to different interests and expectations.

Once the coordinator exposed the initial project, the collaborators concluded that there were already other tools addressing deliberative processes through aggregation methods, and only a few included some specific artificial intelligence techniques (see Table 1 in discussion section). Thus, an initial conceptual mapping was developed in order to find out some gaps in the existing participatory and deliberative tools. After comparing a number of digital tools, the team decided to focus on three dimensions: 1. how citizens can participate and express their preferences; 2. to what extent the decisions taken are binding; and 3. the existence of monitoring mechanisms to follow-up the decisions approved. Afterwards, the work team was divided into groups to work these dimensions focusing specially on the design of the different interface's sections: 1. participation: how to create proposals and how to structure and aggregate argumentation; 2. decisions (outputs): show how the final list of proposals that have been selected according to pre-established priorities, citizen support and budget; and 3. follow-up (outcomes): tracking the fate of the proposals (implementation, modification or cancellation). Finally, the resulting preliminary prototype conceptualization and design was presented (and discussed with other groups and participants) at the closing event of the workshop.

4. CO-GOVERN: A PARTICIPATORY TOOL PROPOSAL

Figure 1 details the overall participatory process in *CoGovern,* which can be described in terms of the following stages:

1. To release the functioning rules: Initially, the authority releases the necessary information to fully understand the process so to be aware of the "rules of game": informing about the prioritization criteria: i) citizen support; ii) budgetary aspects; and iii) alignment with a set of priorities or strategic goals. An information sharing event can help to disseminate and clarify the participatory process as well as to learn how the online tool works.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

2. To create proposals: Upon login, city residents and government can create proposals that are classified by administrative areas in case of a process in which different sectorial actions are aimed to be carried out. Users can also obtain information on the other proposals.
3. To deliberate and vote: A key feature of *CoGovern* is that it supports citizens to vote for and/or deliberate about proposals at their own convenience. The deliberative interface (Figure 2) shows the distribution of votes (it also offers the possibility of voting), as well as pro and cons arguments. Citizens can both provide new arguments and express their agreement, neutrality, or disagreement in relation to their peers' arguments. Argument information is aggregated[5] and added to the general voting by modifying the level of citizen support of each proposal.
4. To filter and fully specify proposals: After reviewing the contributions made by citizens, authorities' technical staff filter out illegal proposals and introduce both the cost and their strategic alignment (since most probably proposals will vary in their support to stated priorities or strategic goals) for the remaining proposals. Moreover, technicians are also required to specify those incompatibility relationships that hold between proposals. Such incompatibilities correspond to objective –and documentable– impediments for proposals to be simultaneously selected. Thus, for example, two proposals of alternative urban interventions designed for the same location are infeasible. This specification relates to the recommendations of the Participatory Budget Partners in UK,[6] that state that this indispensable technical input "might include reference to existing or planned spending proposals, to avoid duplication in allocating resources."
5. To select proposals: Once the data is gathered –citizen support (after computing voting and argumentative support), costs and strategic alignment– the proposals are selected according to an algorithm publicly known beforehand. Next subsection details how this selection process is automated.
6. To visualize the results: Users can inspect each proposal. Figure 3 depicts its state (selected or not) and its alignment with the considered criteria (citizen support; budgetary constraints, and alignment with pre-established priorities or strategic objectives) by means of colored bars.
7. To follow up selected proposals: Selected proposals are ordered according to its implementation degree. Users can also monitor their implementation schedule, deviations from the initial budgeting, and companies in charge. Once the project is completed, a report with all the information (Figure 4) will become available.

4.1. How Does Artificial Intelligence Operates in CoGovern?

Leaving aside the number of proposals to deal with, choosing the best combination of proposals constitutes a complex task, since selected proposals must satisfy incompatibility constraints and balance different criteria. Thus, for instance, it could be the case that the proposal with highest citizen support turns out to be so expensive that it alone depletes the overall available budget so that there is no budget left for implementing other interesting proposals. Alternatively, it could also be the case that the chosen proposals are not aligned with the administrative strategic objectives. For example, if promoting social cohesion is very important for the authorities, then a proposal dividing two neighborhoods should not be prioritised. This is so because co-governance is about seeking agreements between citizens and authorities, deciding upon those sets of proposals that are good enough for all the actors involved in the process. Overall, it is fundamental for transparency and accountability that the selection process is properly publicized, that it is objective, and that it encompasses rules for balancing different criteria that are clear from the very beginning, before the deliberation process starts.

Making explicit the selection process requires some details to be released. Firstly, the overall available budget is needed not only to know how much can be spent but also to characterize proposals accurately. Secondly, since several criteria are taken into account (citizen support, budgetary constraints, and alignment with priorities or strategic objectives), we need to know if all of them are considered to be equally important or if there are some preferences over some of them. If this is the case (e.g., citizen support is considered to be more important than cost) then the actual weights have to be clearly stated. Similarly, it is also necessary that priorities or strategic objectives are prioritized among them, so that they are presented in an orderly manner. Finally, in addition to the specific characteristics of each proposal, such as citizen support or implementation cost, it is also necessary that proposal incompatibilities are clearly displayed so that whenever a proposal is chosen, all participants understand that those other proposals that are incompatible with it cannot be possibly chosen.

Once this information becomes clear, it is possible to compute the best subset of proposals to implement. This selection process can be automatized by applying optimization techniques. More specifically, we propose to specify an optimization problem that seeks to maximize 1. the number of proposals; 2. the citizen support; 3. the support to administrative strategic objectives; whilst minimizing cost. Optimization problems can be encoded as linear programs that can be automatically solved by means of state-of-the-art solvers (i.e., optimization code libraries). In particular, considering a set of proposals P, we encode the problem by defining a set of binary decision variables $\{x_1,..x_{|P|}\}$ where each x_i e$\{0,1\}$ encodes the decision of whether proposal p_i will be selected (thus taking value 1) by the system or not (i.e., $x_i = 0$). Therefore, solving the problem amounts to solving the following linear program:

$$\max \sum_{i=1}^{|P|} x_i$$

$$\max \sum_{i=1}^{|P|} s\left(p_i\right) \cdot x_i,$$

being $s(p_i)$ a function that provides the support obtained by each proposal p_i

$$\min \sum_{i=1}^{|P|} c\left(p_i\right) \cdot x_i$$

being $c(p_i)$ a function reporting the cost of each proposal p_i

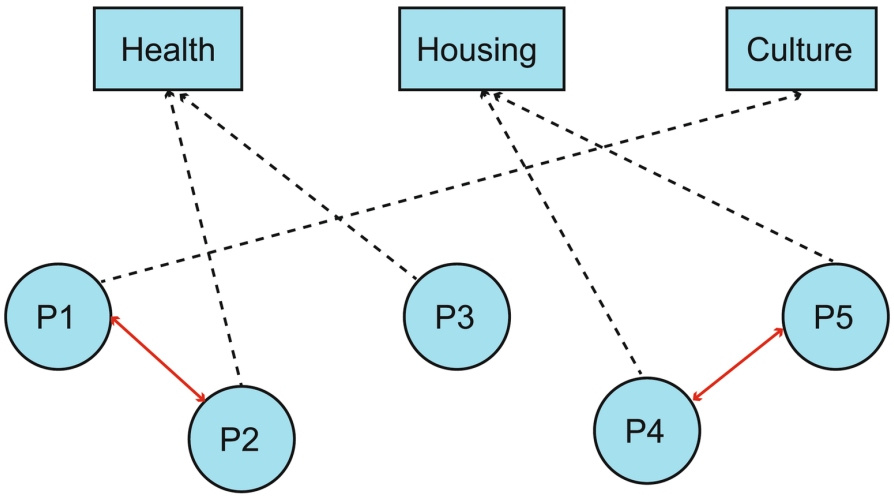
$$\max \sum_{i=1}^{|P|} v_p\left(p_i\right) \cdot x_i$$

being $v_p(p_i)$ a function that considers some values associated to the ordered strategic objectives so that, if we assume there are |O| strategic objectives, then we have $v_1 > \ldots > v_{|O|}$, where each v_i corresponds to the i-th strategic objective. Then, using an intermediate function f that specifies, for each proposal p_i, the strategic objectives it is aligned with, we compute $v_p(p_i) = \sum_{j \in f\left(p_i\right)} v_j$

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

We can cast this problem specification as a single objective optimization problem that can be solved by the following linear program (refer to Lopez-Sanchez et al., 2017 for a more comprehensive and detailed explanation):

$$\max\left[\frac{w_r}{|P|}\cdot\sum_{i=1}^{|P|}x_i+\frac{w_s}{S_{max}}\cdot\sum_{i=1}^{|P|}s\left(p_i\right)\cdot x_i+\frac{w_v}{V_{max}}\cdot\sum_{i=1}^{|P|}v_p\left(p_i\right)\cdot x_i+\boldsymbol{w}_c\cdot\left(y-\frac{1}{b}\cdot\sum_{i=1}^{|P|}c\left(p_i\right)\cdot x_i\right)\right] \quad (1)$$



Subject to a number of constraints encoding maximum budget, incompatibility relationships or the importance awarded to criteria.

Figure 5 illustrates the resolution of this problem with an example: Imagine decision makers have the following priorities: 1. Promote health; 2. Provide access to affordable housing; and 3. Promote culture. We consider they are ordered in decreasing order of importance (that is, health is the most important priority, and it gets a value v_1=3 whereas culture is the least preferred one with value $v_3 = 1$). Additionally, we consider five different proposals promoting some of these values and described in Table 1. Notice that, as depicted in Figure 5, p_1 and p_2 are exclusive (i.e., they cannot be simultaneously chosen). This is so because they would be built in the same plot of land. Similarly, p_4 and p_5 are exclusive because urban architects constitute a scarce resource that can only work on a single urban plan at a time.

Last column in Table 1 shows how the standard way of choosing proposals would order them by just considering citizen support.

Considering a maximum budget of 5 million (b=5), the result would be to choose p_5 which has the highest support ($s(p_5)$ =0.9) and requires most budget ($c(p_5)$ =4). Unfortunately, next proposal in order (p_4, with 0.8 of support) cannot be included because it is incompatible with p_5. Subsequent proposal (p_2) cannot be included either because it costs 2 million and its addition to p_5 would exceed the maximum budget b=5. An alternative may be to add next proposal in the ordered list that would fit the available budget (i.e., p_1, which costs 1M). Thus, if we choose p_5 and p_1 we do not exceed the total budget.

Figure 5. Example of proposals (circles) and priorities (rectangles). Dashed (black) lines relate proposals to the priorities they promote. Solid (red) lines relate incompatible proposals

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 1. Proposals example. Source: own elaboration

Proposal p_i	Description	Citizen Support $s(p_i)$	Cost $c(p_i)$	Strategic Objective $f(p_i)$	Standard Ranking
p_1	Build a library.	0.6	1	culture $f(p_1) = 3$	4
p_2	Build a new medical assistance center	0.7	2	health $f(p_2) = 1$	3
p_3	Improve ambulance services	0.4	1	health $f(p_3) = 1$	5
p_4	Rehabilitation of a deteriorated neighbourhood	0.8	2	housing $f(p_4) = 2$	2
p_5	Promotion of a new neighbourhood	0.9	4	housing $f(p_5) = 2$	1

Alternatively, we propose to consider the optimisation mechanism previously introduced that does not only consider citizen support, but it also combines both the cost and the priorities within a single evaluation function. In this case, any state-of-the-art solver such as CPLEX (CPLEX 2009), Gurobi (Gurobi) or GLPK (Makhorin, 2000) that is provided with the linear program encoded in Equation 1 would produce as a solution the combination composed by proposals p_2, p_3, and p_4, since it corresponds to the best possible proposal combination.

5. DISCUSSION

This article introduces a proposal for a digital tool for citizen participation. But, in which contexts and spaces can it be applied? Transferability and institutionalization have been central in the tool's design. The former is the capacity of a tool of democratic innovation to "operate in different political contexts, understood in relation to scale, political system or type of issue" (Smith, 2009:13), whereas institutionalizing means "moving from sporadic, episodic experiments toward embedded and routinized and easily replicable structures within government that last beyond the initial enthusiasm" (Russon-Gilman, 2016, p. 119). Taking into account these two principles three main decisions were made during the participatory prototyping process in order to shape the participatory device proposed in this article.

Firstly, the online tool proposed was conceived for two widespread types of participatory processes: participatory budgeting and strategic planning. Through participatory budgeting, authorities allocate a portion of the municipal budget for citizens to decide how to invest it. As for strategic planning, it projects the main lines of action in mid and long terms and seeks to fulfill governance objectives. Both participatory processes can be done on-line. Nevertheless, we should be prudent about the rapid spread of ICTs in participatory democracy. For example, some engaged citizens can perceive a loss of civic rewards as consequence of the digitalization of the participation. In this sense, Russon-Gilman alerts about "how ITCs could alter the character of deliberation and substantive participation within Participatory Budgeting (2016:129-130;138)". Obviously, a face-to-face deliberation cannot be equated to a process based on online argumentation. However, in our opinion, both have pro and cons. On one hand, argumentation allows a greater systematization, although the threat of the digital divide is still an issue. On the other hand, face-to-face deliberation has its own biases since some citizens are not able or willing to attend assemblies due to a lack of time, their different participatory styles, or simply, their fear to speak in public. The solution of the dilemma between online and offline participation seems to be an hybridization. For example, although proposals in participatory budgeting processes are uploaded

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

and voted through on-line applications, currently, some authorities (such as in Getafe, Spain) also offer technical support for those in need at designated physical locations (e.g., civic centres).

Secondly, the approach proposed in *CoGovern* highlights the importance of the convergence between citizens and authorities' perspectives. This recommendation is also shared by the Participatory Budgeting Partners in UK, among others. Nevertheless, it is worth noticing that alignment can lead to an excessive framing and, consequently, some groups may consider this type of participation too constrained. Therefore, before starting the participatory process it becomes key to explain that this alignment pretends to guarantee a high level of political compromise, which is essential for a successful implementation of the results of participatory processes. Moreover, it should be noted that priorities or strategic objectives, and their respective weights, may well be previously agreed between authorities and the community. In fact, this is in line with the principle of transferability which implies a certain degree of flexibility within and adaptation to specific contexts. For example, since 2016 the participatory budgeting of the city of Paris prioritizes projects made on deprived or sensitive areas, reserving 30% of the allocated project. *CoGovern* is much more open and simply makes explicit all the priorities or strategic objectives that will be considered in the selection process.

Thirdly, previous research -focused on democratic innovations- had already put the proposal selection problem on the table (Smith, 2009: 93; Font et al., 2017). These studies found out preliminary evidence about the existence of cherry-picking practices by authorities in the context of local participatory processes in Spain. This article has shown how this specific aspect within institutional participatory processes can benefit from certain AI techniques. However, it must be brought into discussion some considerations about the expansion of the use of algorithms for social purposes. Mattelart & Multigner (2007) – when referring to Gottfried Wilhelm Leibniz – alerted us to the use of algorithms for speculative purposes and their relation to modern capitalism. More recently, critical voices have related its use with the idea of cybercontrol. It is therefore imperative to seek new ways to make use of, visualize, and build the "algorithmic environment" (Álvaro, 2014). Can algorithms contribute to the social progress through its integration in social projects? Through codesign (Fuller, 2003), *CoGovern* has shown an attempt to bring the "algorithmic environment" closer to the society so as to be able to participate in its formulation. Enabling the dialogue between citizens, rulers and experts is an unavoidable task. It is a need, therefore, to create more spaces, such as citizens labs, in which citizens are confronted with the complexity of the institutions and technical issues, and institutions and experts adopt a sincere intent to (co)govern together with the people.

6. RELATED AND FUTURE WORK

This article proposes *CoGovern* as an online participation tool focused on incorporating citizen preferences to local policy making by means of artificial intelligence techniques. Thus, an unavoidable question has to do with what new elements has *CoGovern* brought into the landscape of participatory and deliberative tools. During the international workshop previously mentioned, invited experts introduced some of the most relevant participatory tools. Table 2 below summarizes the principal similarities and differences between these tools and *CoCovern*.

First, in relation to the main *goals* pursued by these different tools, *CoGovern* and *Decide Madrid* are both oriented to incorporate city residents preferences into policy decision-making processes at local level. The rest of tools, with the exception of the French tool *Parlement et Citoyens* (P&C), do not seek

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 2. Comparison of different participatory tools. Source: own elaboration

Tools	Goals	Types of users	Online argumentation	How do citizens decide?	Monitoring	AI
CoGovern	Incorporate citizens preferences in policy decision-making processes.	City residents	Yes (pro and cons arguments)	Arguments / voting	Yes	Yes (optimal proposal selection)
Loomio	Help small groups make decisions through inclusion	Small groups	Yes (messages)	Arguments / voting	No	No
Baoqu	Solve complex discussions	Large groups	Yes (comments)	Groups of 5 to 25 users in subsequent levels that require qualified majority	No	No
Decide Madrid	Create proposals, deliberate and vote	City residents	Yes (comments)	Popular referendum	Feasibility reports	No
Appgree	Create representativeness of a whole through small groups	Large groups	No (answers to questions)	Representative voting for answers	No	(Demorank)
Quoners	Help groups decide on what they agree (or disagree) with	Large and small groups	Yes (pro and cons arguments)	Vote for multiple answers	No	No
Consider.it	Create a discussion forum: participants opinions grouped in favor or against any topic	Large groups	Yes (pro and cons arguments)	No voting (decision based on opinions)	No	(Doctoral research)
Parlement et Citoyens	Tool that allows citizens and deputies to collaboratively draft legislative proposals	Large groups	Yes (pro and cons arguments)	Arguments / voting	No	No

to influence political decisions. P&C allows citizens and deputies to collaboratively draft legislative proposals, therefore, it represents an interesting attempt to scaling-up in terms of political influence beyond local contexts. Second, regarding the *types of users,* three main groups were identified: small groups, large groups, and citizens residents. Small groups refer to, for example, co-workers, family, friends or activists, whilst large groups lack specific shared interests, locations, or strong ties. In contrast, citizens residents refer to the whole set of people officially registered in a particular city. *CoGovern*, therefore, falls clearly into the latter group in which is included *Decide Madrid* as well as other tools developed by local administrations (not included in the table), such as *Decidim Barcelona, Participa Getafe* and *Budget Participatif* in Paris. Third, as for argument functionalities, although all the tools considered here allow participants to include additional information supporting decisions, most of them are treated as comments. Just *CoGovern*, quoners, consider.it, and P&C do structure them as arguments in favour and against. Fourth, regarding *how do citizens decide,* some of them combine the use of online argumentation and voting systems. That is the case of *CoGovern*, *Loomio* and *P&C*. In *consider.it*, by contrast, decisions are not taken through traditional voting, since the aim is to aggregate opinions (not votes). On the other hand, in *Decide-Madrid,* those proposals that have received support from at least 1% of the whole population in Madrid can be voted online or in polling stations during "the referendum week". *Appgree* and *Quoners* offer different modalities of voting whereas *Baoqu* develops a scalable system for massive deliberation based on agreements in small groups which scales up to higher decisions levels. Fifth, the existence of *monitoring systems* to trace the fate of proposals is especially relevant for our goal of increasing transparency and accountability. As table 1 shows, current tools lack in this respect. Lastly, the most innovative aspect in *CoGovern* is the usage of *AI* in the decision-making process, which seems

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

to be in early development stages for current tools. *Appgre* and *Consider.it* are the tools that include more sophisticated computation or research. Nevertheless, rather than taking decisions, *Appgree* uses an algorithm (DemoRank) to randomly choose a small group of people as representative of the whole, whilst *Consider.it* graphically clusters people based on their opinions.

The future research of the *CoGovern* tool focuses mainly on developing the prototype until reaching an alpha phase, which will allow us to test it with groups of citizens and policymakers to detect which parts can be improved when analyzing the user experience. Specifically, as was done at the beginning of the project (see point 3.1), we should check the degree of satisfaction between citizens and policymakers with both the usability of the tool and the proposals selection method presented in this article. In relation to the latter, we plan to present the outcome of the decision (list of proposals) as a comparison of the traditional model of vote-counting and the optimization proposed by *CoGovern* in order to evaluate the user's reaction.

Beyond implementation of the current proposal, we also plan to include improvements such as the enrichment of the argumentation, so that pro and con arguments can also be counter-argumented (although simplicity forces us to prevent further counter-argurments). Finally, another future objective concerns having the rules of the game as transparent as possible, since the proposals selection process constitutes the most sensitive feature of *CoGovern*. In this sense, we consider it fundamental that we be able to communicate in a very intuitive manner about the internal functioning of the tool. To that end, we plan to explore visual metaphors to help explain not only the results of the selection process but also how decisions were taken.

ENDNOTES

1. Rare exceptions, such as the one in Paris described in the discussion section, do also consider additional constraints that impose ad-hoc priorities.
2. As explained in the discussion, GoGovern has been designed to be applied mainly in two well-known types of participatory processes: participatory budgeting and strategic planning. Most often, we refer to priorities in the former and to strategic objectives in the latter, which may be more accurate.
3. Alpha projects: projects in demo phase that require a last revision to better define its functionalities. Projects in state of production: projects that are in the final phase of its development.
4. CoGovern project members, in alphabetical order: Nella Charms, Jennifer Clavijo, Ana Doria, José Luís Fernández-Martínez, Maite Lopez-Sanchez, Lizeth Ramírez, Juan A. Rodríguez-Aguilar, Jairo Salazar, Dionisio Sánchez, Marcelo Sánchez, Sayuri Susuki, and Berenice Zambrano.
5. By means of WOWA operators (see Serramia et al. 2016 and Torra & Narukawa, 2007)

Chapter 43
Exploring the Conceptual Nature of e-Business Projects

Benjamin Matthies
South Westphalia University of Applied Sciences, Germany

André Coners
South Westphalia University of Applied Sciences, Germany

ABSTRACT

E-business projects (eBPs) can be described as endeavors which transform traditional business functions into digital and mostly automated, inter-organizational e-business functions. Although studies exist which already increased the understanding of such endeavors, there is still no conceptualization that defines eBPs as their own kind of project, summarizing and categorizing all of their characteristic topics, problem areas, and tasks. This study attempts to close this gap by exploring the conceptual nature of eBPs. A large number of practical project reports was evaluated, using a latent semantic analysis for the exploratory summarization of the textual database. As a result, the study provides a comprehensive theoretical conceptualization including 12 core concepts and 74 specific sub-concepts, structured within the context of a system development life cycle. Such a project conceptualization provides a contribution to the practical management of eBPs, as well as a theoretical framework for further establishing eBPs as a unique project type.

1. INTRODUCTION

Transforming a company into a successful e-business has become one of the central strategic goals of modern corporate management (Ash & Burn, 2003; Chen, 2001; Gloor, 2012; Lientz & Rea, 2009). Such e-business transformations are basically about developing and implementing Internet-based technologies in order to pursue modern e-business models (Barua et al., 2001; Pateli & Giaglis, 2004; Wang et al., 2012). During this process, traditional business functions (such as sales, purchasing, and logistics) are expanded by integrating digital and inter-organizational e-business functions (such as e-commerce, e-procurement, or network-based supply chain management), typically resulting in fundamental changes

to the corporate value creation chain (Burn & Ash, 2001; Combe, 2012; Jackson & Harris, 2003). Therefore, these types of endeavors – so-called e-business projects (eBPs) – are particularly complex, and do not end after the purely technical implementation of new information technologies and systems. Instead, they rather initiate and accompany comprehensive corporate transformations, which extend beyond the technical aspects of typical IT projects in several ways (Chuang & Shaw, 2005). The consequences of eBPs require companies, for example, to align their corporate strategies profoundly before integrating e-business functions into the changing value creation; to coordinate the integration of new communication channels which change the way companies interact with customers; to collaborate with new stakeholders in inter-organizational alliances, to deal with new and often extensive data volumes; and, last but not least, to fundamentally redesign their business processes and the way employees execute their work (Balakian et al., 2002; Marca, 2006; Stoehr, 2002). This large number of diverse commercial, organizational, and technical considerations – which are often interdependent – ultimately results in an increased degree of complexity in such projects (Baccarini, 1996). As a consequence, even though eBPs basically encompass the implementation of e-business technologies, they can be described as comprehensive and externally-oriented business projects rather than as technical, internally-oriented IT projects. Accordingly, project management strategies, processes, and practices must be adjusted to match such complex undertakings (Phan & Vogel, 2012; Stoehr, 2002).

Because of their complexity, it is not uncommon for ambitious eBPs to fail (McLaughlin, 2009). As a result, research has shown an increased interest in exploring eBPs as a specific and unique type of project (see, e.g., Basu & Muylle, 2013; Clarke & Doherty, 2004; Lee et al., 2007; Phan, 2003; Phan & Vogel, 2012). Such studies deal with questions concerning, for example, which characteristics define eBPs, which specific challenges they encompass, and, of course, how to meet these. Nevertheless, although previous studies have significantly increased our understanding of eBPs, there is still no overall conceptualization – such as, for instance, the many conceptualizations that exist for general information systems development projects (see, e.g., Keil et al., 2000; Xia & Lee, 2005) – that structures eBPs as their own kind of project, summarizing and categorizing all of their characteristic topics, problem areas, and tasks. Such a project conceptualization could be of assistance in coming to understand the complexity of eBPs and, ultimately, to manage it (Gregory & Piccinini, 2013). In this regard, a conceptualization of eBPs would provide a basic content-based structure for their practical project management (e.g., during requirements analyses) and theoretical explorations (e.g., during success factors research).

This study addresses the research gap described and attempts to illustrate the complexity of eBPs through a comprehensive theoretical conceptualization. In this context, the study focuses on the following core question: Which specific topics, problem areas, and tasks characterize eBPs as a complex and unique type of project? Such a thematic project conceptualization is a recommended contribution for project management (Winter et al., 2006). In this respect, the contributions of this study differ from previous studies in two ways: (1) Unlike previous studies, this study is based on an evaluation of a large number of eBPs ($N = 355$). A collection of practical project reports will serve as a database for this purpose. An automated latent semantic analysis (LSA) will be used for the exploratory summarization of the primarily textual contents (> 2,000 pages). (2) For the first time, this study characterizes eBPs using a comprehensive thematic conceptualization including 12 core concepts and a total of 74 detailed sub-concepts. These thematic concepts are embedded in the context of a typical system development life cycle (SDLC), giving the conceptualization a founding framework. Finally, subsequent discussions work out and illustrate the conceptual nature of eBPs.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

The research goal of this study may therefore be summarized as:

The development of a comprehensive thematic conceptualization of e-business projects based on a summary evaluation of practical project reports.

This article is structured as follows: Section 2 will discuss the basic characteristics of eBPs, presenting associated studies. Section 3 will introduce the methodology of the study, describing the technique of LSA and its application for the evaluation of project documentations. Section 4 will present the developed conceptualization of eBPs and discuss its thematic concepts. Section 5 will deal with its implications for practice and research, as well as with potential limitations of the study. Section 6 will provide a concluding summary and a short overview.

2. CHARACTERISTICS OF E-BUSINESS PROJECTS

Stoehr (2002) describes the nature of e-business projects (eBPs) as follows: "The similarity among all e-business projects is that their objective is to build up an e-business solution that centers around the internet" (p. 2). In this context, an e-business solution can be described as a development of digitally enabled information technologies and inter-organizational systems in order to pursue modern e-business models with mostly automated e-business functions (Pateli & Giaglis, 2004; Wang et al., 2012). The effects of eBPs therefore extend beyond the purely technical implementation of information technologies and systems, and typically imply a significant shift in corporate value creation and organizational structures and processes (Chuang & Shaw, 2005; Combe, 2012; Jackson & Harris, 2003). In order to gain a deeper understanding of the nature of eBPs, the authors explored the literature focusing on studies which examined and described eBPs from a more comprehensive perspective. The authors were able to find several scientific studies that have already tried to characterize eBPs as a complex and unique type of project (see Table 1)[1], providing discussions of their specific features. In general, the following central characteristics and associated challenges can be summarized on the basis of these studies:

- eBPs often radically change the business model of a company (Gordijn & Akkermans, 2001; Pateli & Giaglis, 2004). These changes are not restricted to exploiting new markets and sales channels, but relate also the entire value-creation chains (Amit & Zott, 2001; Burn & Ash, 2001). Therefore, eBPs require integrating the e-business solution into existing business functions in a specific manner, expanding them purposefully (Phan & Vogel, 2012). This is why developing an appropriately well-founded e-business strategy in advance, and aligning it with general company goals, is considered a central cornerstone for the success of eBPs (see, e.g., McLaughlin, 2009; van Grembergen & Amelinckx, 2002).
- eBPs generally have a strong external influence on their customers, especially on the way companies communicate and interact with them. This is why a customer-oriented focus is often emphasized as an important factor in conceptualizing and implementing e-business solutions (see, e.g., Phan, 2002).
- eBPs implement modern information and communications technologies (ICT) and inter-organizational systems (IOS), which are the foundation for facilitating collaborative, typically automated business processes between multiple networks and stakeholders (Chuang & Shaw, 2005; Shaw,

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

2003; Wang et al., 2012). eBPs therefore require intensive cooperation with diverse, mostly external, partners (see, e.g., Clarke & Doherty, 2004), as well as a high degree of standardization in order to harmonize their actions (see, e.g., Phan, 2009; Zhao et al., 2007).

- eBPs imply significant changes to business processes and to the way employees perform their work (Jackson & Harris, 2003). Therefore, an effective change management (Burn & Ash, 2001) and the targeted development of new responsibilities and skills are often emphasized tasks in eBPs (see, e.g., Phan, 2002; Tiwana & McLean, 2003).
- eBPs are often confronted by innovative but, at the same time, untested and continually changing technologies (Chang, 2010). As a consequence, eBPs also often have far shorter technical cycle times than traditional IT projects (Mehler-Bicher, 2002). These circumstances demand remarkable flexibility and creativity from project teams, due to potential technical or content-based variations (Daniel & Wilson, 2003; Lee et al., 2007).
- eBPs offer great potential for innovation, on both technical and business levels. This is why technical capabilities are relevant here, as well as a profound understanding of the business domain, the customer, the organization, and business processes. Consequently, the need for interdisciplinary project teams is a much-discussed requirement (see, e.g., Lee et al., 2015).

Earlier studies of eBPs have two things in common (see Table 1). First, previous studies were based almost exclusively on individual case studies and/or survey studies. No study has yet offered a broad analysis of multiple practical eBPs. Second, previous studies describe a fairly abstract picture of eBPs, focusing on the general meta-level. They mainly discuss characteristic challenges or recommend central success factors for managing eBPs. No study has yet provided a comprehensive picture of eBPs, in the sense of a full taxonomy including all thematic facets, specific problem areas, and tasks. This is an obvious gap in research, especially in view of the fact that such theoretical conceptualizations have existed for quite some time, in multiple variations, for other project types such as general information systems development projects (Keil et al., 2000; Xia & Lee, 2005) or enterprise resource planning (ERP)-system implementations (see, e.g., Somers & Nelson, 2004, Barki et al., 2005). Therefore, the current study attempts to close this gap by summarizing the conceptual nature of eBPs in a comprehensive theoretical conceptualization.

3. METHODOLOGY AND APPLICATION

3.1. Latent Semantic Analysis

Latent semantic analysis (LSA) will be used as the method for the exploratory evaluation of documented eBPs. LSA is an automated content analysis technique that allows comprehensive summaries of large volumes of texts (for an introduction, see, e.g., Deerwester et al., 1990; Dumais et al., 2004; Landauer et al., 1998). The basic idea behind LSA is that any document collection consists of certain contexts (e.g. individual documents, paragraphs, or sentences), as well as of words associated with these contexts. A structural analysis of these words, meaning their existence or non-existence in the individual contexts, allows the creation of statistical patterns of strongly-correlated words (i.e., words often used together in documents) as well as strongly-correlated contexts (such as documents that contain comparable sets of words). In this respect, the method of LSA is based on a factor analysis with the goal of reducing

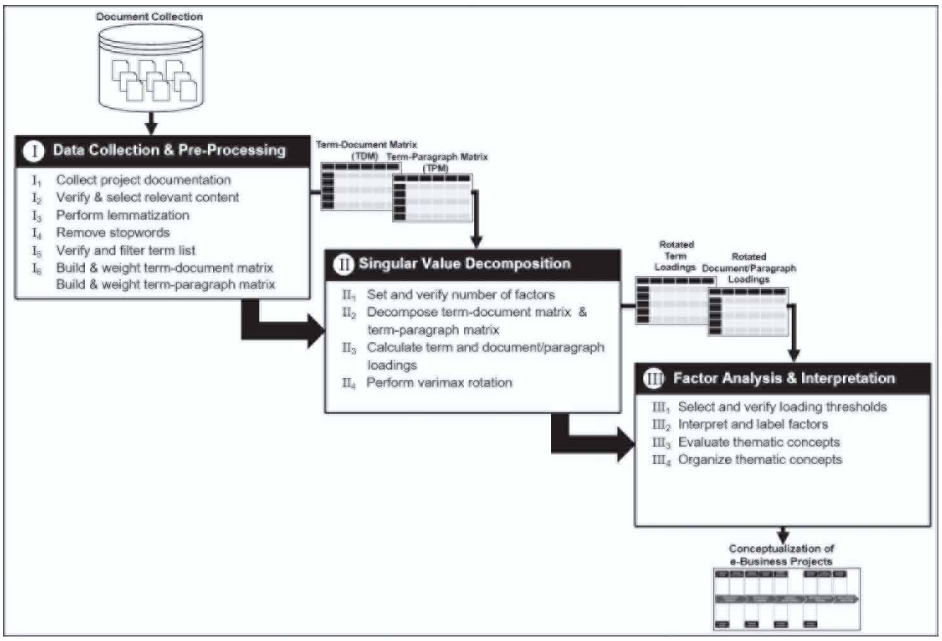
the dimensionality of a large textual database through singular value decomposition (SVD). Basically, SVD works by separating the textual database into matrices with two groups of variables: on the one hand, eigenvalues of the individual contexts (i.e., documents, paragraphs, or sentences) and on the other, eigenvalues of individual words (i.e., terms). SVD then uses these values to calculate a set of factors which stand for groups of correlated words and correlated contexts with similar content. These extracted latent semantic factors, then, represent specific word usage patterns which can be interpreted as the thematic concepts inherent in the underlying document collection (Landauer, 2007; Valle-Lisboa & Mizraji, 2007). See Appendix B for a simplified illustration of the analytical procedure used in LSA.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

In recent years, the application of automated content analysis techniques received growing attention in research for exploring large amounts of textual data (see Derbotoli et al., 2016). In particular, LSA offers this study three methodological advantages (see also Indulska et al., 2012; Evangelopoulos et al., 2012). First, it allows large collections of texts to be processed with a reasonable effort. Another advantage is the exploratory potential of LSA, since no manual, pre-defined analytic framework, for instance with pre-defined (a priori) variables or categories, is required. Third, the aforementioned advantages also help reduce negative human influence on the analysis, such as subjectivity or a lack of care in analytically coding texts. For these reasons, LSA is particularly well-suited for the purpose of this study: LSA facilitates an efficient, exploratory, and reliable identification of thematic concepts in a large collection of practical project reports.



3.2. Data Source and Data Collection

This study uses practical project reports as a data source for exploring characteristic thematic concepts in eBPs. Project documentations are generally a rich source of textual codified project experiences (Disterer, 2002; Schindler & Eppler, 2003). In this context, such documentations usually describe five dimensions of project knowledge (see Zhao & Zuo, 2011): business domain knowledge (What characterizes the project from a business domain perspective?); project product knowledge (What characterizes the project with regard to the project outcome itself?); project engineering (technical) knowledge (What characterizes the project from a technical perspective?); organization management knowledge (What characterizes the project with regard to the management of organizations and relationships?); and project management knowledge (What characterizes the project with regard to its management?). Due to this comprehensive amount of codified knowledge, analysis of practical project reports is an approach which has already been used multiple times to explore thematic concepts (see, e.g., Choudhary et al., 2009; Herbst et al., 2014; Lormans et al., 2008). This approach is especially useful for examining a new phenomenon in practice for which little theoretical foundation currently exists (Benbasat et al., 1987).

This study uses a collection totaling 355 documentations of practical eBPs, compiled from collections of two specific initiatives. These are, first, the Sectoral e-Business Watch initiative[2] ($N = 271$), funded by the European Commission, which investigated the influence of e-business on companies, industries, and economies by assembling a comprehensive collection of practical project reports. Second, the study uses the database of the eXperience Online initiative[3] ($N = 84$), which also specializes in e-business and contains a comprehensive collection of project reports. These reports contain a retrospective summarization of the whole projects and should therefore represent a rich source of information for the purpose of this study. The reports cover a broad thematic range of eBPs, including, among others, e-commerce, e-procurement, and e-learning. The project reports generally follow a standardized format, describing the project background, the e-business solution implemented, the project procedure and success, and the lessons drawn from the project. The initiatives verified the quality, authenticity, and credibility of these documents. The reports were created between 2004 and 2012, mainly contain textual descriptions and vary between 4-13 pages written in English.

Figure 1. Analytical Process of the Latent Semantic Analysis

3.3. Analytical Process and Application

LSA is typically executed in a three-step process (see Müller et al., 2014; Sidorova et al., 2008): beginning with data collection and preparation, followed by statistical analysis of SVD, and ending in the final interpretation and definition of thematic concepts. This study completes two independent yet complementary analyses as a part of this process:

1. A more general analysis on a meta-level, which finally extracts a total of 12 thematic core concepts.
2. A more detailed analysis on a meso-level, which finally extracts a total of 74 specific sub-concepts.

The associated analytical process is summarized in the context diagram below (see Figure 1), and its application is explained more specifically in the following sections. All procedures described have been completed using Provalis Research´s QDA Miner and its text mining extension, WordStat 7.1.

3.3.1. Data Collection and Pre-Processing

During the first phase, an appropriate document collection was assembled and the textual database was prepared to derive an analyzable database.

(I_1) Collect project documentation: In the first step, a collection of documents potentially relevant for the purpose of analysis needed to be assembled. This study is based on a collection of 355 documented eBPs described in Section 3.2. All project reports were downloaded from the online databases and

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

transferred into a unified plain text format. No duplicates were found. Ultimately, a total of 2,019 pages (an average of 5.7 pages per report, min. 4 and max. 18 pages) were available.

(I_2) Verify & select relevant content: In the next step, relevant document contents were manually preselected and verified for relevance. During this review, irrelevant sections (e.g., company profiles, references, copyrights, annotation) were excluded from the following analysis, since irrelevant textual data could falsify the statistical calculations.

(I_3) Perform lemmatization: The specified document collection resulted in a database including a total of 18,308 unique words (or terms). To reduce the various forms of the same word, a lemmatization was conducted (as suggested by Evangelopoulos et al., 2012). This procedure unified grammatical variations of a word to their base or dictionary form (so-called lemmas) using comprehensive thesauruses (e.g., "analyzing," "analyzes," and "analyzed" to the base form, "analyze"). In this way the database was reduced to a term list of 13,341 remaining unique terms.

(I_4) Remove stopwords: In the next step, particular stopwords were removed from the database, meaning terms that do not carry any particular meaning and are therefore trivial (e.g., "and," "or," "in"). This reduced the term list to 11,584 remaining terms. For this purpose, the publicly available stopword list provided by Provalis Research was used. Additionally, terms with an occurrence frequency of fewer than 2 in the total document collection were excluded (as suggested by Sidorova et al., 2008), since such individual terms do not contribute to discovering patterns. In this way, the term list was further reduced to a total of 5,141 unique terms.

(I_5) Verify and filter term list: The term list was then manually reviewed in order to correct spelling errors, harmonize varying spellings, and filter out further irrelevant terms. This term filtering process is a critical aspect in the course of an LSA (Evangelopoulos et al., 2012). Here, two different term lists for two different analyses were specified (see Phase III). The first is a more comprehensive term list from which only additional trivial terms irrelevant for the topic to be analyzed were manually removed (e.g., "approximately," "obvious," "monthly," or "November"). Two independent analysts executed this filtering process in parallel after determining basic coding rules. In this case, special focus lay on nouns (e.g., "project"), verbs (e.g., "planning"), and adjectives (e.g., "expensive"). Pronouns, adverbs, and prepositions were removed due to their limited informative value (Baeza-Yates & Ribeiro-Neto, 1999). Subsequently, each filtered term list could be reviewed and compared for agreement in order to determine the inter-coder reliability. The agreement was 78%, indicating a generally acceptable level of reliability (Landis & Koch, 1977). The discovered differences were then discussed and corrected according to consensus. The resulting list of 2,423 unique terms formed the first database for the detailed analysis of thematic sub-concepts. The second term list was then reduced to an even more specific one, including a total of 806 central key terms. This term list was further specified through frequency filtering, meaning that only those terms were included which appeared in a minimum of 20% of the document collection (71 project reports). Iterative evaluations of the generated term lists and early analysis results were used for evaluating the suitability of this frequency threshold. The generated term list, including widespread, i.e., central key terms, formed the second database for the analysis of dominant core concepts within the document collection.

(I_6) Build & weight term-document/term-paragraph matrix: In the next step, a structured and quantitatively analyzable database could be created. This is typically a matrix in which the selected terms (in the rows), including their frequencies (in the cells), are organized in their respective contexts (in the columns). The segmentation of the context determines how the thematic concepts to be extracted

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

are distributed across the documents or document collection. If, for instance, the goal is to extract the dominant concepts within a whole document collection, it makes sense to segment the database according to complete documents. If, however, the goal is to identify more specific concepts – of which there may be many in an extensive document – it makes sense to use a finer segmentation based on individual paragraphs of the document. For this reason, both a term-document matrix (TDM) with 806 central terms as well as a term-paragraph matrix (TPM) with 2,423 terms were created for the two different analyses of this study. The TDM allowed the extraction of dominant core concepts (co-occurring terms) within the context of the overall document collection, while the TPM allowed the extraction of specific sub-concepts expressed within the context of individual document paragraphs (see also task III_4). The analysis of the TPM added specific insights to the study, since this analysis extracts co-occurrences of terms on paragraph level, thereby allowing the identification of more specific tasks and problems regularly discussed in specific passages of the reports.

TF-IDF indices were then calculated to create a more representative weighting of individual terms (see also Appendix B), in which the absolute frequency of a term in a document (TF = term frequency) was multiplied with the inverse frequency of the term in the overall document collection (IDF = inverse document frequency). This calculation therefore takes into account both the frequency of a term and its prevalence in the document collection, providing an index of representative weightings. Concretely, this means that the weight of very frequent, i.e., common, terms is reduced, and rarer terms are given more weight. The TDM and TPM weighted in this manner provided the analyzable database for the ensuing SVD in Phase II.

3.3.2. Singular Value Decomposition

During the second phase, the TDM and TPM were processed using the singular value decomposition (SVD) and specific factor loadings for individual terms and for their contexts (i.e., documents or paragraphs) were calculated.

(II_1) Set and verify number of factors: First, it was necessary to determine a specific number of latent semantic factors to be calculated. This means a determination of the dimensionality of the analysis was required. A small number of factors (a higher degree of aggregation) is more likely to bring general thematic concepts to light, while a larger number of factors (a lower degree of aggregation) will produce more detailed thematic concepts. However, it is generally difficult to determine an optimum number of factors. Here, Evangelopoulos et al. (2012) recommend the sensitive and iterative testing of alternative numbers of factors that result in a collection of meaningful concepts. Additionally, scree tests are suitable for reviewing the empirical foundation for the number of factors, in order to explain the variation included in a data set. As previously mentioned, this study is based on two different and complementary analyses. The first is a more general analysis, based on a TDM with 806 terms, intended to extract central core concepts. A 14-factor solution was evaluated for this purpose. The second is a more specific analysis, based on a TPM with 2,423 terms, intended to extract detailed sub-concepts. An 80-factor solution was evaluated for this purpose. In both analyses, iterative test runs determined that a larger number of factors would not reveal any

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

new meaningful concepts, and that a smaller number of factors would cause the loss of relevant concepts. Subsequent scree tests also confirmed the number of factors from an empirical perspective.

(II_2) Decompose term-document/term-paragraph matrix: Based on the factors determined, the TDM or TPM were divided into a unique matrix of term eigenvalues, a matrix of document or paragraph eigenvalues, and a diagonal matrix of singular values (see also Appendix B). These matrices formed the basis for determining individual term or document/paragraph loadings.

(II_3) Calculate term and document/paragraph loadings: The loadings for terms, documents, and/or paragraphs were then determined. Assigning specific high-loading terms and documents/paragraphs to individual factors allowed then the discovery of the specific thematic concepts in the document collection.

(II_4) Perform varimax rotation: To simplify the ensuing interpretation of latent semantic factors, in particular the composition of their associated high-loading terms, a varimax rotation was performed (as suggested by Sidorova et al., 2008). This is a statistical process for more strongly emphasizing variations of a term loading which simplifies the demarcation of high-loading terms or low-loading terms. The rotated term and document/paragraph factor loadings formed the basis for the ensuing analysis and interpretation of factors in Phase III.

3.3.3. Factor Analysis and Interpretation

In the third phase, specific high-loading terms for each factor were determined before two analysts interpreted the resulting bundle of words as thematic concepts and organized them into a comprehensive conceptualization.

(III_1) Select and verify loading thresholds: Before finally deriving the individual semantic factors, the threshold above which a term should be assigned to a factor had to be determined. The optimum level for this loading threshold is the subject of some discussion in the literature. With regard to this question, Evangelopoulos et al. (2012) recommend testing a varying threshold, then determining whether the resulting factors lead to meaningful results. Following this suggestion, loading thresholds of 0.58 (14-factor solution) and 0.21 (80-factor solution) were determined for the two analyses in this study.

(III_2) Interpret and label factors: The meanings of the individual latent semantic factors were then interpreted by reviewing their associated high-loading terms. Interpretations were completed in parallel by two independent analysts. The agreement of the respective interpretations showed an acceptable inter-coder reliability of 84%. Discrepancies were discussed and corrected by mutual consensus. In this context the analysts were able, for example, to interpret the correlated words "security," "transaction," "transmission," "data," and "protect," as the sub-concept, transaction security (F80_2). Another example is the core concept, e-business requirements (F14_7), composed, among others, from the high-loading terms "innovation," "requirement," "condition," "satisfaction," "quality," and "safety." In this process, the interpretation of unclear terms was supported by an accompanying keyword-in-context analysis (KWIC), which represents the words within their sentences, supporting an assessment of their meaning. Within the framework of the 14-factor solution, the analysts were able to identify a total of 12 central core concepts, since two factors seemed to duplicates and could be interpreted as the same topic (F14_1+3; F14_6+9). Within the frame-

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

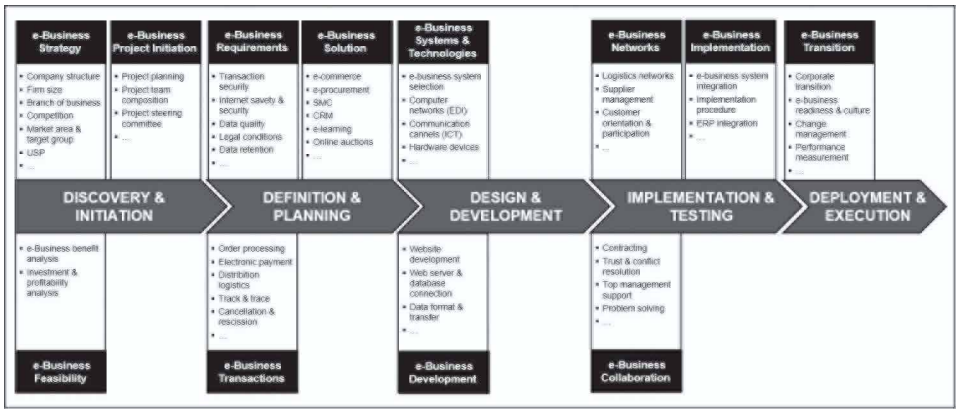
work of the 80-factor solution, the analysts were able to identify a total of 74 sub-concepts, since 4 concepts appeared twice (e.g., F80_9+31; F80_20+46), and 2 concepts could not be interpreted clearly (F80_28+40).

(III_3) Evaluate thematic concepts: The resulting concepts were then evaluated by an experienced domain expert for their meaningfulness and plausibility (as suggested by Evangelopoulos et al., 2012).

(III_4) Organize thematic concepts: The extracted concepts were then organized into a structured thematic conceptualization. The basic phases of a system development life cycle (SDLC; see Langer, 2004) provided the founding framework for this. These five phases delineate the typical context of an eBP, indicating the roles and interdependencies of the individual thematic concepts in a project process over time. First, the 12 core concepts were organized along these phases, providing main themes that characterize eBPs on a meta-level. In the following step, the specific 74 sub-concepts were then subordinated to these core concepts. These sub-concepts represent more specific tasks and problems on a meso-level. The analysts completed this organization using relevant literature related to the e-business discipline (see also Section 4). An illustrative example: the specific sub-concept communication channels (F80_53) was subordinated to the core concept e-business systems & technologies (F14_11) since it stands for a specific issue in the context of this main theme. Finally, the result was therefore a thematic conceptualization of eBPs, consisting of 5 project phases, 12 core concepts, and a total of 74 detailed sub-concepts (see also Figure 2 and Table 2 in Section 4).

4. RESULTS

4.1. Conceptualization of e-Business Projects



The following sections present and reflect on the developed conceptualization of eBPs (see Figure 2 and Table 2). This conceptualization describes the thematic complexity of eBPs on two different levels:

- 12 core concepts describe the central topical areas of eBPs.
- 74 detailed sub-concepts describe the detailed problem areas or tasks in eBPs.

Additionally, the basic phases of a system development life cycle (SDLC) provide structure and context. These phases of the SDLC are particularly appropriate for representing common eBPS, because they not only comprise technological areas of interest, but also organizational and business process re-engineering issues typically implied by such projects (Langer, 2004). The first project phase, Discover & Initiate, encompasses the underlying e-business strategy for eBPs, as well as the feasibility study on which project decisions are based. Furthermore, this phase involves the subsequent initiation of an eBP. Definition & Planning encompasses the conception of e-business solutions to be developed, the evaluation of associated requirements, as well as the analysis of involved business transactions, which may be either affected or created by the e-business solution. Design & Development encompasses the technical issues for realizing an e-business solution, such as an evaluation of existing e-business systems and technologies, as well as their ultimate technical conception and development. Implementation & Testing encompasses the implementation of e-business solutions in existing business operations, as well as their

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. Conceptualization of e-Business Projects

coordination and harmonization with cooperating networks. Deployment & Execution encompasses the issues of an organizational transition into a functioning e-business, such as change management and the creation of a company-wide e-business culture.

The following sections will discuss more closely the five project phases and their respective thematic concepts. Moreover, related literature will be referred to (see also Table 3 in Appendix A) in order to reflect on the individual concepts and their meaning more theoretically, thereby deepening the understanding of eBPs.

4.2. Discovery and Initiation

During the first project phase, discovery & initiation, the purpose, goals, and scope of the project are defined. In particular, this phase is concerned foremost with delineating the company background relevant for decision making and for developing an e-business strategy (F14_12). An investigation of the advantageousness and practicability of the envisioned eBP is also part of this phase, in the sense of an e-business feasibility study (F14_8). Building on these considerations, the e-business project initiation (F14_4) can be conducted.

e-Business Strategy (F14_12): Transforming a company into a modern e-business can have a wide-reaching influence on its general business model as well as on its strategic corporate goals (Barua et al., 2001; Chen, 2001; Gloor, 2012). Therefore, an e-business solution should not be initiated blindly or without reflection; instead, it must be integrated into existing business practices in a controlled and directed manner. McLaughlin (2009, p. 48) summarizes this issue aptly: "[S]imply building an e-business system does not guarantee its success." This is why researchers in previous studies have regularly emphasized the importance of providing a profound e-business strategy to guide the e-business endeavors, a strategy which is aligned to the company's background and overall corporate goals (see, e.g., McLaughlin, 2009; Tiwana & McLean, 2003; van Grembergen & Amelinckx, 2002). Such a strategy further calls upon a company to clearly define what it wants to achieve through the project and – perhaps much more importantly – what it does not need to achieve (Phan & Vogel, 2012). In this respect, the e-business strategy is the basic framework which defines the project's purpose, goals, and scope.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

The core concept, e-business strategy, encompasses such basic considerations of the company's situation, which may restrict the strategic framework of the e-business transformation in some instances. Several sub-concepts could be identified in this regard. For instance, the sub-concept, company size (F80_54), which may restrict the scope of an implemented e-business solution (Gengatharen & Standing, 2005; Taylor & Murphy, 2004). A company's structure (F80_12) may also influence the complexity of system and technology implementation (e.g., due to the number of locations and to decentralized functions). Further sub-concepts describe the general competitive situation, which should also be taken into consideration, including the branch of business (F80_59), the competitive environment (F80_7), as well as the market area and target group (F80_80). Finally, on the basis of such considerations, companies can then develop an appropriate e-business strategy (F80_37), as well as the unique selling proposition (F80_50) they aspire to.

e-Business Feasibility (F14_8): Companies should not integrate e-business solutions without critical reflection, but should weigh their advantages and disadvantages, opportunities, and risks carefully (Feng & Hong-Dan, 2010; Mehler-Bicher, 2002; Shu-Hang et al., 2007). On the one hand, the decision about e-business investments requires a rational evaluation of costs and benefits, and thus an objective consideration of the added value (Kleist, 2003; van Grembergen & Amelinckx, 2002). On the other hand, this not only concerns evaluating common economic indicators (revenue growth, for instance), but also evaluating IT-related aspects such as the continued development of operational efficiency (KLeist, 2003).

The core concept of e-business feasibility, therefore, encompasses an evaluation of the profitability of an investment into an e-business solution (F80_25). This means a review of whether the planned cost reductions or revenue growth justify the sometimes substantial investments in technology and organizational change (Kleist, 2003). Additionally, the sub-concept of e-business benefits (F80_24) was identified, describing the operational advantages, such as business process automation and efficiency increases (see, e.g., Ash & Burn, 2003), implied by the e-business solution.

e-Business Project Initiation (F14_4): On the basis of the antecedent considerations, the eBP can then be specified and initiated. The planning of eBPs involves, in particular, the concrete definition of a project assignment, meaning the goals the project is considered to achieve (Basu & Muylle, 2007). Furthermore, the responsibilities and allocated resources are defined (Chuang & Shaw, 2005; Fong et al., 2002). This also encompasses the formation of a project team, which generally should include professionals with interdisciplinary expertise (Lee et al., 2015).

The core concept, e-business project initiation, describes the aforementioned issues and encompasses related sub-concepts revealed, such as the initial planning of project goals, timeframes, costs (F80_47), the setting up of a project steering committee (F80_1), as well as the compilation of an appropriate operational project team (F80_30).

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

4.3. Definition and Planning

The project phase, definition & planning, is focused foremost on making the e-business solution (F14_1+3) to be developed as concrete as possible. Additionally, this phase involves considerations concerning the related e-business requirements (F14_7) and e-business transactions (F14_5).

e-Business Solution (F14_1+3): The e-business solution to be developed and implemented forms the core of any eBP (Balakian et al., 2002; Stoehr, 2002). E-business solutions, in this context, can be described as means for the expansion of traditional business functions through various digital and network-based e-business functions (Shaw, 2003; Shaw, 2000; Wang et al., 2012). The core concept of e-business solutions (F14_1+3) encompasses different forms of such e-business functions, including e-commerce (F80_61) and online marketing (F80_31), e-procurement (F80_56), network-based supply chain management (F80_57), customer relationship management (F80_36), e-learning (F80_69), e-auctions (F80_48), production management (F80_46), mobile business (F80_72), and online media & entertainment (F80_16). Furthermore, several enabling or supporting tasks and functions of an e-business solution were identified as sub-concepts, such as a help desk and incident management (F80_64), a product & service portfolio designed for e-business (F80_8), and document management (F80_7) and license management (F80_51). Securing the intellectual rights to e-business solutions that have been developed (e.g., technical innovations or brands) is another concept revealed in the course of this study (F80_36).

e-Business Transactions (F14_5): e-business solutions facilitate and/or require the development of automated and inter-organizational transactions (Wang et al., 2012). These transactions, meaning especially their operational effects, need to be profoundly harmonized with existing transactions (Phan & Vogel, 2012). In this context, the core concept, e-business transactions, describes such automated business processes facilitated through e-business solutions, in particular through the following sub-concepts: order processing (F80_4+33), distribution logistics (F80_58), electronic payment (F80_14), cancellation & recession (F80_68), authentication processes of users and customers (F80_3+75), outbound and inbound transactions (F80_67), and tracking & tracing of consignments (F80_70).

e-Business Requirements (F14_7): The developers of e-business solutions may be confronted with several requirements, in technical, business-related, or also legal contexts (see, e.g., Gilioli-Rotondaro, 2002; Gordijn & Akkermans, 2001; Jones et al., 2000). The core concept, e-business requirements, summarizes such demands and expectations, relevant, for example, within the framework of a requirements analysis (see Moertini et al., 2014; Shu-Hang et al., 2007). In the course of this study, several sub-concepts could be identified with respect to such requirements, such as internet security and safety (F80_26+72), transaction security (F80_2), the encryption of information (F80_11), a user-friendly interface (F80_32), and data quality requirements (F80_63). Legal conditions (F80_43) may imply additional, sometimes restrictive demands in eBPs, for instance in relation to the requirements of internet fraud prevention (F80_34) or data retention regulations (F80_42).

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

4.4. Design and Development

The project phase, design & development, describes technical aspects for facilitating an e-business solution. This includes considerations of both e-business systems & technologies (F14_11) and the technical realization of the envisioned concepts within the framework of an e-business development (F14_14).

e-Business Systems & Technologies (F14_11): From a technical standpoint, e-business is based on integrating information and communication technologies (ICT) and inter-organizational e-business systems (Wang et al., 2012). For the technical realization of the envisioned e-business functions, various solutions from different suppliers are available to companies. In this context, the core concept, e-business systems & technologies, represents a summarization of such technical solutions and involves a fundamental consideration of how to understand and evaluate this technical diversity. Several corresponding sub-concepts could be subsumed under this topic, such as the concepts describing e-business systems (F80_21), hardware & software technologies (F80_66), hardware devices (F80_22), and communication channels (F80_53). Considerations of specialized systems such as recommender systems (F80_45) may also play a role in this context.

e-Business Development (F14_14): Sooner or later, every eBP will include the technical development of e-business systems and technologies (see Phan, 2009; Phan &Vogel, 2012). In this respect, the core concept, e-business development, summarizes the issues associated with such a technical development of e-business solutions. This includes, for instance, developing websites (F80_49), connecting these to web servers and databanks (F80_5), integrating one's own systems into larger computer networks (F80_38), or developing company-specific business rules (F80_74). Handling and exchanging data – often large amounts of new data – are general challenges in eBPs (Wang et al., 2012; Zhao et al., 2007). This includes aspects of a standardized data format and data transfer (F80_29), data collection (F80_13), data replication and storage (F80_52), as well as real-time data exchange and data synchronization (F80_6).

4.5. Implementation and Testing

The project phase, implementation & testing, includes the operational introduction and start-up of e-business technologies and systems. Besides the actual e-business implementation (F14_10) into operating practices, this also requires interaction and coordination with a large number of stakeholders in e-business networks (F14_6+9), as well as the accompanying need for cooperative e-business collaboration (F14_13).

e-Business Networks (F14_6+9): Implementing e-business technologies opens up new forms of network-based cooperation. As Chang (2010) says: "Company value chains are transformed into horizontally integrated components" (p. 104). This means that e-business integrates mutually dependent partnerships along the whole value-creation chain. Thus, the very nature of e-business already implies that companies implementing an e-business solution have to interact with various stakeholders in such network-based environments (Clarke & Doherty, 2004; Zhao et al., 2007).

The core concept of an e-business network encompasses alliances and stakeholders with whom cooperation and coordination may be required in an eBP. For example, an eBP may require close collaboration with a company's suppliers (F80_15), in particular with e-procurement implementations (see Barua et

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

al., 2001; Chuang & Shaw, 2005; Krasner, 2000). Additionally, close coordination with larger logistics networks (F80_79) and their players may be necessary (see Boone & Ganeshan, 2007). Furthermore, customers are also important stakeholders (F80_18), and involving them early on is essential for ensuring that an eBP is consistently customer-oriented (Gilioli-Rotondaro, 2002).

e-Business Collaboration (F14_13): As already mentioned, implementing e-business solutions is always accompanied by intensive interaction with partners in inter-organizational alliances (Chang, 2010). Acting in these (external) partnerships, some of which may include heterogeneous or new stakeholders, can represent a complex organizational challenge in eBPs (Burn & Ash, 2001; Jackson & Harris, 2003). In this regard, Chang (2010) emphasizes the importance of an effective collaboration in such a dependent relationship, which requires, for example, the existence of mechanisms to facilitate a reliable collaboration, as well as the existence of mutual trust and personal commitment (see, e.g., OECD, 2005, for a description of a so-called "trust infrastructure" in e-business).

Against this backdrop, the core concept, e-business collaboration, encompasses the various tasks and capabilities required for acting in such a complex project environment. This includes sub-concepts describing an effective, prompt problem-solving (F80_79), the ability to overcome larger conflicts and to ensure binding cooperation based on trust (F80_10), and contracting (F80_76), which is an issue for determining binding obligations in a supplier cooperation (Boone & Ganeshan, 2007). Furthermore, an absolute support from the top management (F80_39) is another important prerequisite in such strategically-relevant cooperation, for instance in executing decisions (Phan, 2009; Phan & Vogel, 2012).

e-Business Implementation (F14_10): Implementing e-business systems and technologies implies operational consequences for business processes and the way employees work (see Burn & Ash, 2001; Jackson & Harris, 2003). The core concept, e-business implementation, encompasses such issues related to the well-planned introduction of new e-business solutions and the seamless transfer from traditional business functions to new and automated e-business functions. This core concept encompasses sub-concepts such as the operational integration of e-business systems (F80_20+46), the selected implementation procedure (F80_19), for example, piloting, as well as the harmonization with existing ERP-systems (F80_60). A good employee coordination (F80_44) is also an issue to mention in such complex organizational interventions, since this can often have a major influence on work content and processes.

4.6. Deployment and Execution

The project phase, deployment & execution, encompasses the consequences of the organizational transformation that companies are often confronted with after the implementation of e-business solutions, summarized in the core concept, e-business transition (F14_2).

e-Business Transition (F14_2): eBPs imply business-related and organizational transformations (see Barua et al., 2001; Burn & Ash, 2001; Gloor, 2012; Jackson & Harris, 2003). Kalakota et al. (1999) describes this aptly: "the creation and implementation of an e-business project is inextricably linked to the management of change" (p. 60). Therefore, an eBP does not just stop at a pure technical implementation of e-business systems and technologies, but also includes the sensitive transition

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

of traditional business practices into networked, automated business practices, and thus into a functioning e-business. In general, this results in the necessity to fundamentally rework prior business processes as part of a business process reengineering (Earl, 2000). This step may also include both questioning the breadth and depth of services offered by the company as well as externally pooling and potentially outsourcing company functions (Phan & Vogel, 2012). Of course, such fundamental structural and procedural upheavals require a high level of readiness for change from employees. As a result, e-business transitions require employees to be introduced to new processes and responsibilities so that they can acquire the knowledge they need (Daniel & Wilson, 2003; Lee et al., 2007; Tiwana & McLean, 2003). This is why the literature regularly emphasizes the importance of sound change management and trainings in the context of eBPs (see Burn & Ash, 2001). Finally, both measuring general e-business values and assessing the specific performance of e-business solutions are also frequently discussed challenges (see Kleist, 2003; Lesjak & Vehovar, 2005; van Grembergen & Amelinckx, 2002).

The core concept, e-business transition, encompasses a variety of issues involved in handling this type of organizational transformation. In this context, sub-concepts could be identified which describe the business process reengineering (F80_55) and the organizational transition into networked, automated business practices (F80_33), as well as considerations relating to the outsourcing of business functions (F80_65). Further sub-concepts describe the issues of an e-business culture and readiness (F80_27) and a change management, including employee training (F80_41), as well issues of measuring the attained performance of e-business (F80_78).

5. DISCUSSION

5.1. Contributions

This study provides two contributions: one methodological, and the other content-based. From a methodological perspective, this study is the first to use an examination of a large number of practical eBPs. The information potential of practical project documentations has been exploited for this purpose. For their explorative summary, latent semantic analysis (LSA) has proven itself an effective and efficient solution for extracting concrete thematic concepts from this extensive textual database.

From the content-related perspective, this study is the first to deliver a comprehensive thematic conceptualization that contributes to characterizing eBPs as a unique type of project. The dimensionality of this conceptualization, including 12 core concepts and 74 detailed sub-concepts, as well as its fundamental contextualization within the framework of a system development life cycle (SDLC), contributes to managing the thematic complexity in eBPs on various levels.

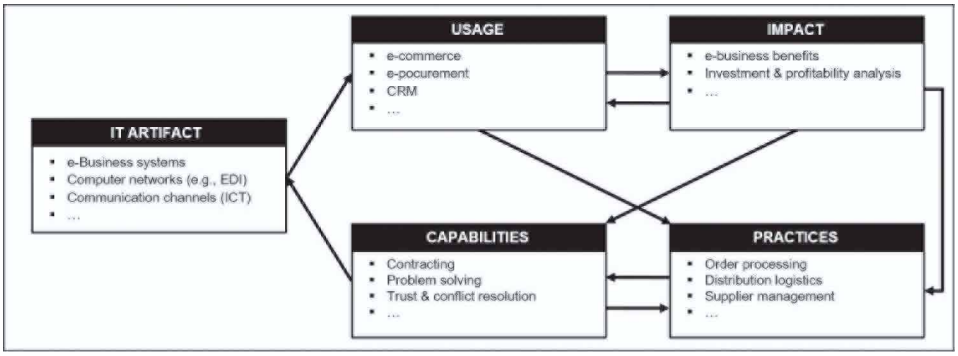
5.2. Implications for Practice

The conceptualization of eBPs can be of concrete practical use in three different ways. First, the conceptualization represents a comprehensive summary of the topics potentially relevant for planning eBPs. In particular, as part of a requirement analysis (see Mehler-Bicher, 2002; Shu-Hang et al., 2007), this type of thematic reference can provide structured leads on the problem fields and tasks that need to be taken into account. Secondly, the conceptualization provides a thematic structure for knowledge management within the framework of eBPs. This is true both for structured reflection on and documentation of finished projects in the sense of a post-project review (see Disterer, 2002), as well as for storing collected project knowledge in structured knowledge databases. In particular, the domain-specific knowledge of eBPs could be explicitly modeled in respective ontology-based databases, which for their part allow a storage and retrieval of specific knowledge fragments in computational form (Staab et al., 2001). This allows future projects to retrieve context-oriented experiences according to specific problem areas or tasks. Third, in its suggested form, the conceptualization provides categories and required keyword sets to implement an e-business specific dictionary, which can provide the basis for computer-supported text analyses (i.e., for automated coding and categorization of documents).

5.3. Implications for Research

Implications for research include, first, evaluating the results of this study in order to discover any incompleteness or misinterpretation in the conceptualization (see limitations in Section 5.4). This means, in particular, that individual concepts can still surely be expanded, corrected, or specified. In this regard, the suggested conceptualization could be reviewed, for instance, using the criteria clarity, coherence, extendibility, encoding bias, and commitment suggested by Gruber (1995). The composition of e-business networks (F14_6+9), for example, could certainly be expanded (e.g., through public service networks). Experimental applications in practical case studies, for instance, or analytical reviews using other collections of data (i.e., project documents) would be suitable means for this.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use



In addition, the developed conceptualization provides thematic leads for continuing theoretical investigations of eBPs that, for instance, could be useful for researching success factors. In particular, research perspectives could focus on investigating and describing correlations between the individual concepts. Potential interdependencies can already be assumed between multiple topics, such as the influence of legal conditions on data security and retention, or the connection between an organizational e-business culture and change management within the framework of the e-business transition. A deeper understanding of these interdependencies would contribute to the understanding of eBPs. The organization of thematic concepts into Benbasat and Zmud's (2003) nomological net depicted in Figure 3 provides one starting point for investigating these relationships. It represents relationships between the IT artifacts of an eBP (e.g., EDI), their application (e.g., e-procurement) and influence (e-business benefits), and their organizational practices (e.g., order processing) and capabilities (e.g., contracting).

5.4. Limitations

This study is of course not without its limitations. First, potential limitations with respect to the database used must be addressed. Knowledge codified in practical project reports may not always be objective and complete. One aspect frequently discussed in this context is the deliberate withholding of experiences (especially mistakes) out of fear of negative sanctions (see Cheng et al., 2009). This limitation may, however, be countered by the fact that the content to be described was standardized through the respective initiatives, and that the quality, authenticity, and credibility of the project reports was reviewed. Additionally, the document collection assembled for the study only represents a small sample of all eBPs actually completed in practice. Other collections of documents could potentially deliver different results. Nevertheless, the study does use a comparatively large number of documented projects from two different initiatives.

Second, despite the advantages discussed in Section 3.1, the methodological limitations of the LSA must be addressed. First, the LSA handles the textual database in an unreflected manner as a "bag of words," omitting a consideration of the content-based context of the words processed or, in other words, their actual meaning (Indulska et al., 2012). The LSA does partially address this problem by allowing the determination of the words' assumed meanings through the context of the bundles of associated words (e.g., the individual terms, "electronic," "business," and "strategy" suggest the topic of an "e-business strategy" in combination). Nevertheless, the interpretive depth of the LSA is limited, and it

Figure 3. Clustering of e-Business Project Themes

does leave questions of "why?," "how?," and "with what effect?" unanswered to a large extent: Why was an e-business strategy relevant, and what exactly does it look like? This study tries to make at least an initial attempt at answering these questions on the basis of a literature-based discussion. Nevertheless, future studies could build on it by offering a more exact definition and an explanation of these thematic concepts (e.g., by using case studies or literature reviews). One additional disadvantage of LSA is the diversity of analytical parameters to be determined (in particular a selection of the number of factors and determination of the loading threshold), which could have a significant influence on analysis results. For this reason, the suitability of the parameters used was subjected to thorough reviews.

Third, potential limitations result from the fact that LSA includes multiple manual procedures (i.e., manually filtering terms, interpreting and labeling thematic concepts), which require interpretation and could therefore involve a certain subjective bias. To ensure a reliable analysis nonetheless, such interpretive procedures were completed in parallel by two independent analysts, then reviewed for consistency.

6. CONCLUSION

The goal of this study was to illustrate the complexity of eBPs as a whole, providing a comprehensive summarization of all specific topics, problem areas, and tasks. In this context, the study aims at contributing to the characterization of e-business projects as a unique type of project. For this purpose, the study developed a thematic conceptualization including 12 core concepts and 74 specific sub-concepts, structured within the context of the typical phases of a system development life cycle (SDLC). The study provided general evidence that eBPs are complex endeavors whose thematic context does not end with a purely technical implementation of new technologies and systems, Instead, they rather introduce and accompany more extensive business-related and organizational changes.

First of all, this study provides a contribution to the e-business discipline regarding the practical management of eBPs, since project management strategies, processes, and practices generally need to adjust to the complexity of such endeavors. In this regard, the developed conceptualization represents a thematic reference for planning eBPs (e.g., in the context of requirement analyses) and for associated knowledge acquisition in the course of such projects. Additionally, this research provides a theoretical framework for further establishing eBPs as a unique project type. This includes in particular deeper explorations of associated characteristics, challenges, and success factors in such projects.

ENDNOTES

1. In order to identify relevant studies specifically focusing on eBPs, a keywords search in three literature databases (Ebsco BSC, Wiley Online Library, Emerald Insight) was conducted, using search terms such as "e-business" (and other terms related to sub-topics) and terms related to project management combined by a logical AND (search fields: title, abstract, and keywords). Potentially relevant articles have been selected by reviewing titles and abstracts. However, it should be noted that this literature review, with its specific databases and search criteria, cannot find every potentially relevant paper.
2. See http://ec.europa.eu/enterprise/archives/e-business-watch/ for a presentation of the initiative.
3. See http://www.experience-online.ch/cases/experience20.nsf/en/index/ for a presentation of the initiative.

This research was previously published in the Journal of Electronic Commerce in Organizations (JECO), 15(3); edited by Pedro Isaías; pages 33-63; copyright year 2017 by IGI Publishing (an imprint of IGI Global).

APPENDIX A

Results of The Latent Semantic Analysis

Table 3. Core Concepts Derived from the 14-Factor Solution

No.	Label	High-Loading Terms (excerpt)	Related Literature
F14_1	e-business solution	Web; concept; basis; online; sell; crm; service; launch; shop; account; site; server; retail; supply; link; transfer; turnover; mail; share; set	Balakian et al. (2002); Shaw (2003); Stoehr (2002); Wang et al. (2012)
F14_2	e-business transition	Structure; resource; innovation; corporation; site; firm; team; task; future; report; optimize; skill; motivation; responsibility; outsource; sap; maintenance; component; background; external; contract	Barua et al. (2001); Burn & Ash (2001); Jackson & Harris (2003)
F14_3	e-business solution	Business; electronic; concept; basis; design; corporation; internet; service; firm; delivery; commerce; distribution; demand; decision; development; service	Balakian et al. (2002); Shaw (2003); Stoehr (2002); Wang et al. (2012)
F14_4	e-business project initiation	Team; project; task; responsibility; specialist; resource; size; plan; name; specification; report; detail; experience; office; establish; structure; staff; potential	Basu & Muylle (2007); Chuang & Shaw (2005); Fong et al. (2002)
F14_5	e-business transactions	Sell; share; transaction; transfer; link; internet; market; customer; mail; account; external; user; relationship; staff; launch; server; unit; standard; confidential; basis	Wang et al. (2012)
F14_6	e-business networks	Internet; concept; connection; account; service; coordination; set; basis; infrastructure; process; server; international; global; logistics; launch; level; learn; location; country; effective	Clarke & Doherty (2004); Zhao et al. (2007)
F14_7	e-business requirements	Innovation; size; risk; customer; requirement; condition; schedule; satisfaction; access; cost; creation; security; role; quality; safety; availability; storage; optimize; payment; responsibility	Moertini et al. (2014); Shu-Hang et al. (2007)
F14_8	e-business feasibility	Benefit; company; chance; investment; potential, euro; business; innovation; advance; aim; administration; client; area; approach; analysis; reduction; application	Feng & Hong-Dan (2010); Kleist (2003); Lesjak & Vehovar (2005); Mehler-Bicher (2002)
F14_9	e-business networks	Background; connect; computer; supplier; network; access; chain; member; link; EDI; record; control; automation; catalogue; confirmation; geographical; area; environment	Clarke & Doherty (2004); Zhao et al. (2007)
F14_10	e-business implementation	Innovation; test; pilot; installation; component; learn; manage; implementation; department; challenge; personnel; procedure; structure; connection; method; optimize; form; maintenance; ERP	Chuang & Shaw (2005); Lee et al. (2007)
F14_11	e-business systems & technologies	Tool; standard; technology; definition; software; system; application; source; basis; database; ERP; solution; resource; enterprise; technical; shop; small	Chang (2010)
F14_12	e-business strategy	Corporation; business; background; firm; challenge; decision; management; target; turnover; strategy; goal; financial; budget; aim; market; competition	Amit & Zott (2001); Chen (2001); McLaughlin (2009); Phan & Vogel (2012)
F14_13	e-business collaboration	Partnership; market; participant; contract; definition; condition; coordination; logistics; regulation; responsibility; mail; negotiation; location; link; help; priority; convince; trust; requirement; reduction	Clarke & Doherty (2004); Zhao et al. (2007)
F14_14	e-business development	Component; development; equipment; entry; investment; configuration; exchange; program; connection; database; technical; specialist; expertise; expense; installation; format; interface; document	Phan (2009); Phan & Vogel (2012)

APPENDIX B

Illustrative Analysis Example

This appendix is intended to illustrate the analytical procedure of latent semantic analysis (LSA) using a simplified analysis example. For other exemplary analyses see also Müller et al. (2014) or Sidorova et al. (2008). Additionally, Martin and Berry (2007) provide a more detailed introduction to the mathematical process of LSA.

1. Data Collection and Pre-Processing:

The analysis begins by collecting and preparing a database suitable for the purpose of the analysis. This simplified demonstration will use the text fragments represented in Table 5 from a total of six exemplary project reports.

Table 5. Document Collection

ID	Project Reports	Project Descriptions (fragments)
project_#5	Development of the use of electronic media at Schweiz Tourismus (ST)	The current website is therefore based on a **content management system** (CMS)…
project_#22	Efficient and targeted information supply for members of Santésuisse	In addition to the functionalities of a traditional **content management system**, this application platform also makes it possible...
project_#25	Extending the functionality of an already existing ERP system at Agro AG	**Electronic-Business** will support competitive **strategy** and enable innovative **business** relationships…
project_#27	Electronic procurement of MRO materials and services at UBS AG	The suppliers provide **content management** for the article **data** and interfaces for **data** interchange…
project_#42	Mass customisation through B2B integration at Kaved AG	The company pursues a range of strategic **corporate** objectives as part of its **electronic-business strategy**.
project_#67	Business process support thanks to electronic instruments at OPO Oeschger AG	**Electronic-Business** is a vitally important factor in **corporate strategy**.
project_#82	Reengineering course management processes at sunrise	A **content management system** with standardized formats…

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

These text fragments will then be transferred into a structured data format during pre-processing. To do so, irrelevant terms (such as "on," "in," "and") are filtered out in the course of stopword removal. Additionally, terms that appear only once in the database and which do not contribute to the identification of patterns are also filtered out. For the purpose of this simplified database, we will forego a lemmatization, *i.e.,* unification of various forms of terms. Finally, seven terms (highlighted) are transferred into a *term document matrix* (TDM), in which the terms and their respective frequencies are associated to their respective contexts - in this case, the documents (see Table 6).

Instead of a simple term frequency, the more representative TF-IDF weighting will be used for further analyses (see also Sidorova et al., 2008). An associated TF-IDF transformation is based on a calculation of the weight (w) of each term (i) and document (j):

$$w_{ij} = tf_{ij} * idf_i \quad (1)$$

tf_{ij} is the raw term frequency of a term i in the document j and is multiplied by the inverse document frequency, providing the prevalence of a term and $idf_i = \log_2 (N/n_i) + 1$. Here, N is the number of documents in the collection; n_i is the frequency of the respective term i in the entire document collection. Such an inverse document frequency transformation gives rarer terms more weight and reduces the influence of very frequent, *i.e.,* common, terms (see Table 7).

2. Singular Value Decomposition

The *singular value decomposition* (SVD) uses the weighted TDM to identify specific groups of strongly correlated terms (*i.e.,* words that frequently appear together in documents) and strongly correlated documents (*i.e.,* documents that contain comparable words). To do so, the SVD determines individual factors that are associated with respective high-loading terms or high-loading documents. The word usage patterns expressed in these latent semantic factors stand for thematic concepts, which can then be interpreted as such in the following phase.

Table 6. Term-Document Matrix (with Term Frequencies)

		Document						
		project_#5	**project_#25**	**project_#27**	**project_#42**	**project_#22**	**project_#67**	**project_#82**
Term	Business		2		1		1	
	Content	1		1		1		1
	Corporate				1		1	
	Data			2				
	Electronic		1		1		1	
	Management	1		1		1		1
	Strategy		1		1		1	
	System	1				1		1

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 7. Term-Document Matrix (with TF-IDF Weightings)

		Document						
		project_#5	**project_#25**	**project_#27**	**project_#42**	**project_#22**	**project_#67**	**project_#82**
Term	Business		0.7360		0.3680		0.3680	
	Content	0.2430		0.2430		0.2430		0.2430
	Corporate				0.5441		0.5441	
	Data			1.6902				
	Electronic		0.3680		0.3680		0.3680	
	Management	0.2430		0.2430		0.2430		0.2430
	Strategy		0.3680		0.3680		0.3680	
	System	0.3679				0.3680		0.3680

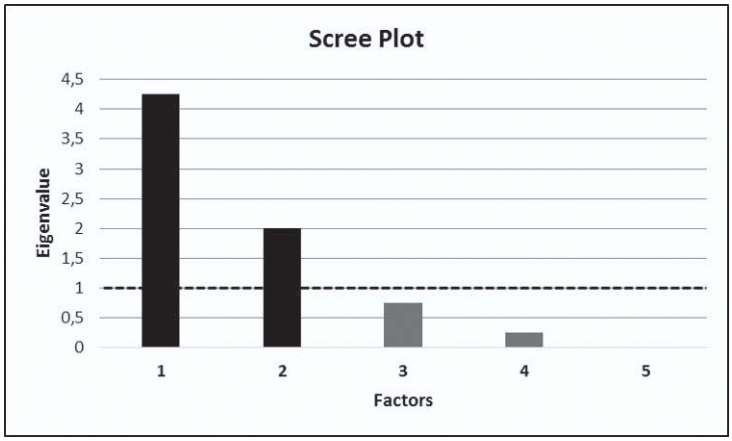
The following will briefly describe the analytic background of SVD (see also Evangelopoulos et al., 2012; Landauer et al., 1998). Essentially, the underlying TDM (A) is divided into a product of three individual matrices by the SVD:

$$A = U\sum V^T \tag{2}$$

U here stands for the term eigenvectors and V stands for the document eigenvectors, whereas the superscript ^{T} identifies a transposition. $\sum$ stands for a diagonal matrix of singular values, which can be determined from the square root of the term eigenvalues and document eigenvalues. Building upon this $U\sum$ provides the factor loadings for the terms and $V\sum$ provides the associated factor loadings for the documents.

A factor rotation can make the interpretation of the factors easier by emphasizing their respective associated terms or document loadings without falsifying their basic assertions. This simplifies the differentiation between significant (high-loading) and insignificant (low-loading) terms of the individual semantic factors. This example will use, as suggested by Sidorova et al. (2008), a varimax rotation. To put it simply, this involves multiplying the matrix of unrotated term loadings (L_T) or document loadings (L_D) with the transformation matrices (M_T or M_D) in order to obtain matrices with rotated, more meaningful factor loadings (L^*_T and L^*_D). For a more detailed introduction of varimax rotations, see, for example, Crawford and Ferguson (1970) or Kaiser (1970).

After using the procedure illustrated here, the factor loadings represented in Table 8 can be obtained. The already rotated term loadings for two semantic factors are represented. The ensuing scree test (Figure 4) displays the eigenvalues of multiple factors in descending order and describes the extent to which an additional factor will contribute to explaining the variation included in the data set. Based on the scree plot, the selection of the first two factors seems justified.



From Table 8, it can be seen that a specific group of high-loading terms (> 0.80) is associated with factor 1 ("business", "corporate," "electronic," and "strategy"), while factor 2 pools a different group of high-loading terms ("content," "management," and "system"). In the next phase, the assertions of these associated sets of terms are interpreted and labeled as thematic concepts.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 8. Term Loadings (after Varimax Rotation)

Terms	Factor 1	Factor 2
BUSINESS	**0.97577**	0.15068
CONTENT	0.17986	**0.93280**
CORPORATE	**0.85981**	0.09677
DATA	0.06022	0.20465
ELECTRONIC	**0.97577**	0.15068
MANAGEMENT	0.17986	**0.93280**
STRATEGY	**0.97577**	0.15068
SYSTEM	0.14086	**0.93839**

Figure 4. Scree Plot

3. Factor Analysis & Interpretation:

The first step of factor analysis is determining a threshold for factor loadings. This is a specific limit at which term loadings may be associated with a factor. In this illustration, we should assume a loading threshold of 0.80, so that the two factors can be associated with the terms shown in Table 9. Interpreting the compositions of associated bundles of terms then allows the interpretation of thematic concepts. The terms in factor 1, accordingly, clearly refer to the topic of an "e-business strategy." Factor 2, on the other hand, can be described as the thematic concept, "content management system." Therefore, the results of this simplified analysis illustrate how LSA can extract primarily automated thematic concepts from textual collections of documents.

Table 9. Labeled Factors with Related High-Loading Terms

Factor	Label	High-Loading Terms	Related Documents
1	e-Business Strategy	Strategy; Electronic; Business; Corporate	project_#25; project_#42; project_#67

Chapter 44
Three-Dimensional Virtual Environment and NPC: A Perspective about Intelligent Agents Ubiquitous

Fabricio Herpich
Federal University of Rio Grande do Sul, Brazil

Felipe Becker Nunes
Federal University of Rio Grande do Sul, Brazil

Gleizer Bierhalz Voss
Federal Institute of Education Science and Technology Farroupilha, Brazil

Roseclea Duarte Medina
Federal University of Santa Maria, Brazil

ABSTRACT

The use of intelligent agents aware of the individual characteristics and context of students, allow to offer a suitable support to the real requirements. Allied to this, the implementation of these agents in the three-dimensional virtual environments, tend to transcend the existing potential in the interactions with the learning objects it contains and also to expand the alternatives of building the students' knowledge. Throughout this chapter it will be presented the development of intelligent agent called ELAI, by using the NPC strategy on the virtual world platform OpenSimulator. The ELAI provides support for teaching Computer Networking (CN), being sensitive to the context of learners to their level of expertise. In order to maximize the flexibility of interactions between the student, through the student's avatar and the NPC, an interconnection with a chatterbot was established, whose knowledge base was increased by files in AIML inherent to the topic of CN.

INTRODUCTION

With the increasing use of Information and Communication Technologies (ICT) in the educational field, many requirements were emerging and changing in the current scenarios, making it necessary to reflect on the new computing paradigms in education. Given this conjuncture, research on intelligent agents in immersive environments applied to education become crucial, as it is highlighted in researches done by Iglesias & Luengo (2004), Callaghan et al. (2009), Garrido et al. (2010), Esteves et al. (2010), (Vilela, 2011) and Griol et al. (2014), since they are able to give students the ability to be immersed in the environment and interact with the learning objects, besides allowing the intelligent support to the students, assisting on their process of teaching and learning.

In this same line of this research, De Lucia et al. (2009), Bainbridge (2010), Dalgarno and Lee (2010), Ai-Lim Lee (2011), Nelson and Erlandson (2012), Childs and Peachey (2013) and Richards and Taylor (2015), discuss and points out the creation of immersive virtual environments aimed at education. The implementation of these environments demand that several factors are considered for development, such as: educational objectives, teaching strategies based on learning theories, friendly and instructional design, objects, experiments and exercises able to encourage the interaction and collaboration among users, besides passing the feeling of being immersed in the environment. Because, according to Medina (2004), learning obtained through the personal experiences of the participants and their interactions with other participants, becomes more productive, consolidated and dynamic.

Intelligent agents integrate fully to the development of these immersive virtual environments, as they offer support to its users. The relevance of intelligent agents focused on education is discussed by Soliman and Guetl (2010), in which the authors claim that in virtual learning environments, students have great flexibility in the face of numerous learning opportunities and, therefore, it is necessary to support and an intelligent orientation. Therefore, as Russel & Norvig (1995), intelligent agents must have the ability to perceive the environment in which they belong and, through sensors, operate adopting the best possible actions to solve given situations.

Furthermore, immersive experiences tend to further the engaged students with the objectives proposed in the environment, and thus it is possible to say that the intelligent agent can significantly contribute to the students' learning process. According to Soliman and Guetl (2010), the agent can act as a teacher, learning facilitator or as a colleague in collaborative environments. The agent can interact with students at different moments and places, guiding the student in the virtual environment, explaining topics, asking questions, giving feedback, helping students to collaborate with other students, offering support to the learning personalized.

This chapter of book presents the development of an intelligent agent, whose name is Intelligent Agent adaptive to the Level of Expertise of Students (ELAI). This tutor was developed through the conception of Non Player Characters (NPC), that is a perspective existing in the development platform of virtual worlds OpenSimulator and that was implemented in the Teaching Computer Networks in a Free Immersive Virtual Environment (TCN5) virtual world (Voss, 2014). This agent has as an objective to contribute in the students' teaching in disciplines of Computer Networks, presenting the ability and aspects of intelligent agents with characteristics of context-aware in the level of students' expertise to collaborate more active in this process. In order to maximize the flexibility of the interactions between the student, through his avatar and the NPC, an interconnection of the tutor with a chatterbot was established, whose knowledge base was expanded with topics about computer networks.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Throughout this chapter it will be demystified the processes related to the implementation of a Non-Player Character in the platform of virtual worlds OpenSimulator and its interconnection with a knowledge based of an external chatterbot, implemented in the Pandorabots platform. As well as detail, the necessary steps to demonstrate that the chatterbot knowledge base can be created and adapted, by adding new terms related to area of interest of the developer.

BACKGROUND

Many researches discuss and present results addressing the use of ICT in the education sector. The use of these alternatives which assist on the process of teaching and learning, has taken forms and means that go beyond the real and reaching the virtual elements, influencing the students with methods that help in getting a reliable knowledge that many times, for hazard issues and intrinsic of their cost, end up becoming unviable.

In this conjecture, this section presents the main concepts related to the use of NPC with characteristics of intelligent agents in 3D Virtual Environments for supporting the processes of student's teaching and learning in Computer Networks. Allied to this, also will be presented concepts related to ubiquitous computing and context-aware, which were indexed to the intelligent agent.

Ubiquitous Computing and Context-Aware

Ubiquitous computing is the area of research related to integration of computing the actions, attitudes and/or behaviors inherent to humans, aiming to make the Human-Computer Interaction (HCI) invisible. In this sense, Portella (2008) states that one of the goals of ubiquitous computing is make omnipresent computing resources and integrated into the daily rotine of contemporary life.

The term was coined by Weiser (1991), which stated: "The most profound technologies are those that disappear. They weave themselves into the fabric of everyday life until they are indistinguishable from it" (Weiser, 1991). The essence of this vision, according to Portella (2008), is to create environments with numerous computing resources and communication, integrated transparently to people.

However, the context-aware computing, according to Dey (2001), is any information that can be used to characterize the situation of entities that are considered relevant to the interaction between a user and an application. Herpich et al. (2014b) affirm that context-aware computing is characterized by performing the collection of many information involving the user, i.e., computational context, physical and time. Thus, information is collected about the environment in which it finds its location and the computing device used, for example.

These applications use context information to provide personalized services to users, such as the adaptation of content and tools in accordance with the preferences of the same, and therefore considered a context-aware environment (Herpich et al., 2014b). For Baldauf et al. (2007), these environments are able to adapt its operations to the current context without explicitly requiring user intervention, thus seeking it to maximize their usability and effectiveness, taking into account the environmental context. As applications examples is possible, to identify the tour guides, restaurants, smart homes, among others.

In this regard, Knappmeyer et al. (2013) define the context-awareness as the ability of services or applications adapt to a specific context. In addition, for both, this information, which are adapted, should be a lifecycle defined by the author as: acquisition, reasoning, presentation, organization, and finally the application or service acts on it.

Ubiquitous Learning

Also known as u-learning, the ubiquitous learning is defined by Sakamura & Koshizuka (2005) as that in which is possible to learn about anything, anytime and anywhere, using ubiquitous computing technology and infrastructure. According to Hwang et al. (2009), the ubiquitous learning is an innovative method of teaching, but Sung (2009) adds that the u-learning is more than that, because essentially it translates into a vision of learning that is directly linked to the day-to-day of users, not limited only in classrooms, but e.g., at home, at work, in the library, in museum and also in a daily user interactions.

Yahya et al. (2010) consider the u-learning a new learning paradigm, which incorporates the features of e-learning and m-learning. In addition, the authors define it as a learning that takes place in a ubiquitous computing environment, which allows learning the right thing, in place at the time and on the right way. In addition, the authors conducted a survey on the different characteristics identified by researchers, presenting them in a brief summary, as it follows:

- **Permanence:** The information remains available, unless the students purposely remove it.
- **Accessibility:** Information is available whenever students need to use it by accessing them through different devices.
- **Immediacy:** The information may be obtained by students immediately.
- **Interactivity:** Students can interact with peers, teachers and specialists efficiently and effectively through different media.
- **Awareness of context:** the environment can adapt to the real situation of learners, to provide adequate information for students.

Related to u-learning, Yang et al. (2006) established a model to formally define the contexts regarding the student's needs in u-learning environments. The authors elect five factors of context-aware that need to be considered in these environments, which are: who, where, when, how and what. Relating who is the student, their preferences, knowledge capacity, among other particularities of apprentices, and segment into three entities involved, being them the factors mentioned above, the learning environment and the context model. In addition, it presents the specificities of each entity involved and the roles assigned to each:

- **Who:** the learning environment considers as the learner, setting the context model with the personal characteristics of the student, their preferences, social relations, accessibility and experiences.
- **Where:** the learning environment considers as being the student and plays the context model with location information, devices and the network that students are using.
- **When:** the learning environment considers as being the student, setting the context model as the calendar of this student.
- **How and What:** the learning environment considers as being the learning content of the students and sets the context model as the profile of this content and the description of the service that will be offered.

Basically, Hwang et al. (2009) claim that an ubiquitous learning system should be situated in real-life context, providing a systematic, economical and authentic teaching and guidance for the learners, and opportunities of practicing learning tasks as well as reviewing learning processes, enabling a potential of applying it to complex science experiments.

Three-Dimensional Virtual Environment: Virtual Worlds (VW)

Also known as immersive virtual environments or metaverse, virtual worlds are tools that simulate the real world environment in a three-dimensional (3D), providing the user with a controlled experimental environment of numerous possibilities. According to Bainbridge (2010), VW are defined as persistent online computer-generated environments where people can interact in a way comparable to the real world, either for work or for leisure.

Nelson and Erlandson (2012) and Griol et al. (2014) claim that VW are three-dimensional spaces simulated by computer, which can be exploited in first or third person, through a graphical representation called avatar. Besides offering a combination of simulation tools, these environments also provides a sense of immersion, of opportunities for communication and collaboration that instigate its application in education.

The increased use of VW in different fields, allowed their inclusion in the educational field, from which emerge new opportunities for use of these computational resources as part of support and even of motivation in the process. In this sense, according Valente & Mattar (2007), 3D virtual worlds enable the inclusion and practice of activities for experiential learning, simulation, modeling of complex scenarios, among others, with opportunities for collaboration and co-creation that cannot easily be experienced on other platforms. Accordingly, Medina (2004) reinforces this idea by stating that the learning gained thbrough the personal experiences of the participants and their interactions with other participants, becomes more productive, dynamic and consolidated.

Through the VW, is possible too, to give students the experimental practice of a particular domain of knowledge, which can be accomplished through the use of virtual labs with 3D objects, intelligent agents, among other factors, which according to Nunes et al. (2014), consist of the extension of real laboratories, thus offering new opportunities without costs and risks; the operation of virtual machines in controlled environments; has easier access because it is an environment available at all times; immediate feedback; the expertise distributed among students, where the exchange of experiences with each other is possible; the student-centered learning; and also encouraging the practice of authorship.

All these factors, in addition to technological advances led to the construction of a wide range of virtual laboratories applied to different fields of knowledge (e.g., physics, chemistry, mathematics, medicine, among others). Therefore, some platforms options to the development of virtual worlds are the pioneer of Second Life, the OpenSimulator and OpenWorderland.

In this work, the tool used was the OpenSimulator development platform, that allows the creation and configuration of the virtual worlds, combined with SLOODLE tool, which according to Peachey et al. (2010), integrates virtual world and web-based virtual learning environments technologies. In this case, it was arranged two different technologies: the virtual environment of teaching and learning Moodle and the virtual world. The interconnection provided to the SLOODLE, allows that the content present in Moodle, is inserted into the virtual world. To this study, it was selected the virtual world TCN5 (Voss, 2014), which addresses the teaching of computer networks through simulations in 3D.

Artificial Intelligence and Intelligent Agents

Artificial Intelligence (AI) is an area of computing that for years have been devoted to propose methods, techniques and tools that may be able to represent human knowledge in artificial systems. Besides, according to Liu et al. (2010), the artificial intelligence is the science of research, design and application

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

of intelligent machines or intelligent system to simulate intelligent human capabilities and extension of human intelligence.

Intelligent agents are considered a subfield of artificial intelligence and can be defined as those responsible for adopting the best action, among numerous possible, to do something about a situation. According to Silva (2004) emerged in the 90s as an evolution of object-oriented programming.

However, many authors differ on what the actual characteristics that define an intelligent agent, because of this, there are several concepts, definitions and categorizations on the subject. To Wooldridge and Jennings (1995), an agent it is a computer system that is situated in an environment that is capable of autonomous action in this environment, and aims to achieve your project goals. Already Russel & Norvig (1995) address that an intelligent agent can be described as anything that is able to perceive their environment through sensors and acts on it with their effectors.

The definition given by Hayes-Roth (1995), the author claims that intelligent agents continuously perform three functions, which are: perception of dynamic conditions of the environment; action to change the environmental conditions; and reasoning to interpret perceptions, solve problems, make inferences, and determine actions.

As there are many concepts and definitions on the subject, there are also numerous properties and characteristics that an agent has. In this sense, Franklin and Graesser (1996) present these properties to agents and affirm that to be effectively considered agents, it must meet the first four aspects among the eight listed, which are:

- **Autonomy:** Operate without direct human intervention and have some kind of control over their actions and internal states;
- **Interaction:** Can interact with other agents or humans;
- **Reactivity:** Can perceive their environment and respond to changes that occur in it;
- **Proactivity:** No need to act only in response to a stimulus, but taking initiative;
- **Continuous Activity:** The agent is in continuous process of activity;
- **Adaptation:** Can change their behavior based on some information;
- **Mobility:** Power capacity to move or be transported;
- **Personality:** Ability to convey emotional states;

Therefore, intelligent agents in the educational context, are widely used as tools to support students in order to support the interaction with the environment that are situated, providing personalized learning, as can be seen in Rissoli and Santos (2013), Dos Santos (2003), Aguiar et al. (2011). According to Tyugu (2011), the intelligent agents are software components that have some intelligent behavior characteristics that makes them special: pro activity, understanding of an agent communication language (ACL), reactivity through the ability to make some decisions and take action. To Garrido et al. (2010), the agents that have educational purposes, are able to communicate, collaborate, discuss and guide other students or agents.

Non-Player Character

Non Player Character, as clarified in its own definition, these are characters which their actions are defined through programming sets, being composed of specific scripts and functions to perform certain activities, i.e., they are not characters played by real users (people), but by predefined commands.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Basically, the NPC are computer-controlled characters and, according to Cunha & Giraffa (2001), share the same fundamental characteristics of agents. Besides, they are widely used in games like virtual characters, making these more interactive, real and challenging games.

In the context of this work, the OpenSimulator platform to development of virtual worlds, allows that the users create these characters, which are programmable entities and represented by avatars, which can be implemented by inserting scripts, in order to conduct pre-defined activities. For the programming of NPC, according to Vecino et al. (2012), is possible to use the language of script OpenSimulator Scripting Language (OSSL) and Linden Scripting Language (LSL), own of the platform, which are basically specific functions for the management and control of the actions of NPC.

These autonomous entities can be used in many situations, to provide guidance and information to other real user avatars, providing greater interaction, or incorporating new features, e.g. movements, sensors, communication, implementation tasks, simulation of human behavior, integration with other resources and to have some intelligence, through the implementation of rules on artificial intelligence.

Chatterbots

The chatterbots are artificial entities capable of conversational interaction, also known as conversational agents, robots of conversation and chatbot. According to Pilastri and Brega (2009), are computer programs that attempt to simulate conversations with users, in order to at least temporarily, lead a human being to think that are talking to someone else.

Sganderla et al. (2003), define that the chatterbots are intelligent agents developed to simulate a conversation by exchanging text messages and / or audio, similar to the virtual chats. And according to Comarella and Café (2008), they are used for the most diverse purposes, since to a relationship as a "virtual friend", even for commercial use.

To play this role of dialogue with the user, the chatterbot has the knowledge base in which performs multiple queries, filtering these searches through keywords defined in the notation established by language Artificial Intelligence Markup Language (AIML). Thus, when the conversational agent has the knowledge being debated, it processes the request and expresses his answer according to what was returned in your search. However, in circumstances where the chatterbot does not have certain information on its knowledge database, it will strive to lead or keep the conversation with the user, therefore, instead of answering the user will question him in order that him rephrases your question, until the expressions used by him are found in the knowledge base of conversational agent.

It is possible cite as an example of chatterbots agents: ALICE (2015), Eliza (2015), Elektra (2015) and Apple's Siri (2015). In the context of this work, was used the Pandorabots platform (PandoraBots, 2015), that offers free services for creating, managing and developing the chatterbot and their knowledge base, in addition to hosting the source code and make available the chat service on an allocated space on the server.

RELATED WORK

In this chapter, the reader was presented to the views with initial conceptions about Three-dimensional Virtual Environments and Intelligent Agents using concepts of U-Learning Systems and sensitive to context. With these base, the problems and difficulties as well as the research that has been done in the area of Three-dimensional Virtual Environments linked to Intelligent Agents could be presented and detailed.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

There are many scientific studies that employ the use of intelligent agents in their guidelines, with the intention of supplementing more effectively the process of teaching and learning. Allied to this, the growing implementation of three-dimensional virtual environments, new proposals and research objects are emerging, incorporating concepts of artificial intelligence along these metaverses, however the inclusion of these concepts in virtual worlds is relatively new. Against this background, the authors analyzed some researchs that made the use of these techniques and at the same time give input the proposal discussed in this book chapter.

Vilela (2011) presents a proposal that have the intention to validate approaches to solve issues related to individual training members for tasks performed as a team. Therefore, it makes use of intelligent agents able to play the team member roles for carrying out such tasks, which were developed in a 3D virtual space with the use of OpenSimulator tool.

In this perspective, the research was applied in a case study for training mechanics Portuguese

Air Force in operations for the maintanance of aircraft engines in the F-16 model. To aim can be achieved, it was developed in addition to the intelligent agents, 3D objects related to the specific parts and components of aircraft fuselages e.g., screws, motors, among others. Vilela (2011) points out also that the application of intelligent agents helps in resolving issues related to the limitations of members in teams of tasks. Moreover, it constitutes a very valuable tool for training and vocational education.

Sgobbi et al. (2014) presents a work whose proposal envisions organize immersive environments to facilitate learning activities using virtual devices with the support of artificial characters. Therefore, it discusses the use of OpenSimulator platform for the development of virtual artifacts as well as implementation of agents. To realize the interaction of students with the artifacts available in the environment and also with the agent, the authors present a series of commands to be used throughout the implementation. Moreover, present methods used to connect the artificial characters with an external chatterbot, whose base of knowledge was defined in AIML and hosted on Pandorabots service. Through this connection, attaches itself to the artificial characters the ability even to maintain a dialogue with the student and can even address specific topics and related to virtual artifacts arranged on the environment.

In addition to the three-dimensional virtual environments listed above, it is possible cite as examples some recent approaches to the implementation of immersive environments in development platform of virtual worlds OpenSimulator:

- **The Virtual Laboratory for Software Engineering Education** (Herpich et al., 2014a), which enables the practice of Unified Modeling Language (UML) modeling software called for through a tool processes GenMyModel (2015) and exposure problems through the Problem Based Learning (PBL) methodology using the OpenSimulator platform.
- **The Algorithms Virtual Laboratory** (Nunes et al., 2013), which presents and exposes a lot of exercises, materials, contents and activities so that students can respond and test their knowledge through the development of logic programming in an online tool, known as (IDEOne, 2015). The laboratory was implemented using the OpenSimulator tool and validated in a class of Graduation, in the Algorithms discipline.
- **The Chemistry Laboratory** (Nunes et al., 2014), which enables a space with countless contents and issues related to chemistry, where students are immersed and can interact with videos, slides, 3D objects, chats, quizzes and practical experiments with the aid of a NPC, which has the role of advise and guide the navigation and perform activities by students.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

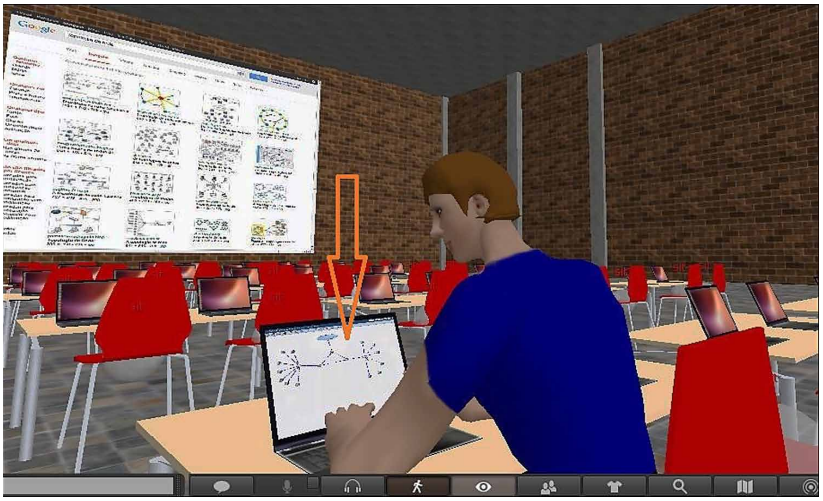
In relation to the paper of Vilela (2011), it presents a solution for individual training team members, in order to empower them in operations for the maintenance of aircraft engines of the Portuguese Air Force. Therefore, it combines immersive 3D virtual environment to intelligent agents, which have the role to simulate the other team members. However, the work proposed in this chapter covers the use of intelligent agents as aware of the context of guides students in order to guide students on the environment and also answer their questions about issues related to computer networks, and to adapt to the level of knowledge of these students.

The study by Sgobbi et al. (2014) presents an immersive environment in order to facilitate active learning activities through virtual artifacts with the support of artificial characters. However, the research conducted by the authors, had an emphasis on intrinsic aspects of the implementation and development of these artificial characters. While the research presented throughout this chapter, sought to implement, support and assess the NPC to use with intelligent agents characteristics in the teaching and learning topics related to Computer Networks. In summary, the study presented in this chapter presents an intelligent agent with ubiquitous features, which allows interaction of students with an NPC aware of the learner's characteristics, thus enabling the adaptation of the ELAI in terms of experience and the environment cognitive style of the learner.

CASE STUDY: AN APPROACH TO INTELLIGENT AGENTS UBIQUITOUS

This section details the issues involved in the implementation of ELAI intelligent agent, presenting the related particularities for the development of NPC in the platform development of virtual worlds OpenSimulator and even exposing how to improve the implementation of OSSL scripts to assign to the NPC intelligent agent characteristics.

Therefore, the reader is presented to a case study involving the study areas and relating them to the present work. Thus, the themes of Virtual Environments dimensional through the use of Virtual Worlds are discussed; It is implemented in this environment concepts of Artificial Intelligence and Intelligent Agents through the NPC coding; and finally they are related topics on Ubiquitous Computing and Context Aware, which are related to both the three-dimensional environment as the ELAI.



This chapter aims to present readers a discussion of the intrinsic potential in intelligent agents embedded in three-dimensional virtual environments. To perform the implantation of both an intelligent agent called ELAI, which is integrated in conversational agents (chatterbot) and inherent characteristics of intelligent agents, the same being developed using NPC functions and inserted through an avatar in the virtual environment TCN5, which is characterized by being an immersive environment, where students can explore the knowledge related to Computer Networks and obtain learning through 3D objects, activities, contents and external tools for practice (Figure 1). This agent has its features aware of the level of expertise of the context of the student aimed at teaching Computer Networks.

In this sense, to achieve the main goal, several necessary specific objectives were developed, among them are:

- Modeling and the development of intelligent agent itself, giving it the context-aware computing features to the level of knowledge students;

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. Student interaction with a learning tool in the TCN5 environment
Source: Voss (2014)

- In order to optimize their ubiquitous concepts have been adapted the rules for identification of expertise level to the students, presented by Possobom (2014), so that it was possible to formulate this student contextual information in order to make the ELAI and the TCN5 context-sensitive levels of experience of its members;
- In line with the last presented objective, rules were developed for the ELAI capture the student's experience level and can thus provide support with sensitivity to the current context highlighted to the student;
- Artificial intelligence rules were implemented to increase the knowledge-base of the intelligent agent, specifically focusing on Computer Networks and considering the three levels of expertise covered in this study: basic, intermediate and advanced;
- Finally, there was the evaluation of users via the System Usability Scale (SUS) proposed by (Brooke, 1996).

The development and use of immersive and three-dimensional virtual environments geared to teaching, seeks to improve and facilitate user interaction with the content seen in class. Through these environments, it is possible extend the experimentation practices beyond the normal learning environment, encouraging communication among students to solve problems. In this context, in order to enrich the immersive experiences, the authors intend to provide an intelligent agent aware of the context and the idiosyncrasies of each student, especially considering the cognitive style and the level of expertise, making it more attractive environment for users, because its characteristics and close to the individual preferences of the students.

Thus, the main impact provided by these adaptation concerns positively on student learning that make use of it, since it allows better use of educational content available in the environment. Where the student is building his knowledge, with the presence and action of the intelligent agent, which is able to detect its the level of knowledge, helping it dynamically as the accessibility of content that best fit their level of experience.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

This adaptation, according Pozzebon (2003), is justified since the teaching mediated by computer using AI techniques increases learning efficiency, allowing the student selects the variables as content, time, place and volume of matter be learned. Moreover, Soliman & Guetl (2010), claim that in virtual learning environments students have great flexibility in the face of more learning opportunities and, therefore, it is necessary to support and intelligent guidance.

Methodology

The intelligent agent ELAI is inserted in an immersive virtual environment called TCN5 (Voss, 2014), which was developed in the OpenSimulator platform and is geared to teaching of Computer Networks and has context-aware features, being sensitive to the context of cognitive style of students, respecting the characteristics and adapting their content according to user preferences.

During this section, the steps involved in this research are described, which were developed in order to elucidate the intrinsic steps to each process adopted throughout his achievement as well as to clarify the forms of established ratings:

Step 1: The first stage was characterized by the definition of the objectives that this work contemplates, and the literature review on the topics discussed in order to ground and deepen related expertise. Subsequently it was defined the tools used and the technological infrastructure resources used for the development of research.

Step 2: During the second stage, there was NPC characters coding in immersive virtual environment, therefore, implemented the development of intelligent agent ELAI. In addition, it performed the development of new classes of knowledge in AIML in order to let him expert on the topics of Computer Networks.

Step 3: During this step, it was inserted content and activities related to Computer Networks in each cognitive area. These educational materials were added respecting the expertise levels, these being classified as: basic, intermediate and advanced. Considering the disparities between levels of experience, the authors sought to provide a greater number of educational resources to students, as well as the feasibility of evaluating them while performing these activities.

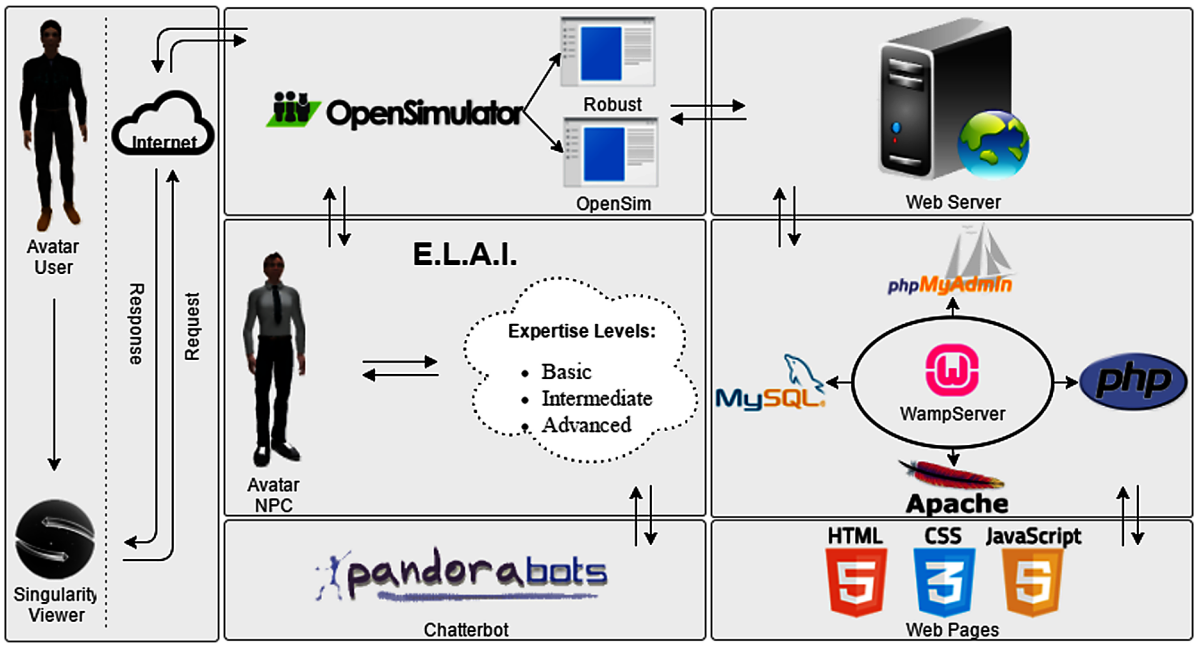
Step 4: It occurred to evaluation, which was conducted through a questionnaire directed by students of undergraduate programs in Computer Science and Information Systems as well as students of the Post-Graduate Master in Computer Science at Federal University of Santa Maria (UFSM), making a total of fourteen students of Computer area involved in the evaluation.

To accomplish this was followed by a short script in order to maintain a uniform investigation with stakeholders, it was decided therefore an Educational Route, which, according to Bassani and Behar (2005), allows the appropriation and monitoring of the construction process knowledge. The pedagogical route followed by students was structured as it follows: [a] Access the Moodle VLE; [b] Access to TCN5; [c] Register in Moodle by SLoodle; [d] Meet the TCN5 environment; and [e] Simulate talks with ELAI.

At the end of this educational journey, the authors applied a usability test in order to evaluate the ELAI intelligent agent, referred to as System Usability Scale method (Brooke, 1996), which provides a questionnaire consisting of ten multiple-choice questions and it uses its own logic to estimate and measure the level of usability based on the responses obtained in questionnaires. The results of these analyzes are presented throughout the following sections.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Development of Intelligent Agent ELAI and Interconnection to Pandorabots



The present study aims to demystify the process related to the implementation of a Non-Player Character in the virtual world OpenSimulator and its interconnection with a knowledge base of an external chatterbot, hosted on Pandorabots web site. As well as the detail demonstrates the necessary steps, so that the knowledge base can be adapted, by inserting new terms relating to the area of interest addressed by the user.

In this sense, to offer a complete view of the work and its extension, it was drawn up an architecture which clarify all the technologies used, their interconnections and inferences that aim to meet the main goal of the study.

Figure 2 shows a scenario with all technologies used in this study, showing an operating cycle which the user follows during your navigation. Firstly, the user performs access to the immersive virtual environment TCN5, whose was developed in the OpenSimulator platform and hosted on a web server. Once entering in the environment, the user is immersed and has your contextualized representation by an avatar, where is possible carried out the proposed activities, interacting with 3D objects and simulations, also can talk about your doubts with intelligent agent ELAI. The ELAI is composed by the conversational agents (chatterbots), that explains some subject and answers the student, based on the findings made by the agent related on the level of knowledge of the student.

Other information that composed the architecture are about the web server, your services (PHP language of programing, MySQL database and the Apache web server) and at last, the web pages that was developed/installed to advise the activities of students, for example, Moodle and the module SLoodle.

Figure 2. Architecture of the project and its elements
Source: Authors, 2015

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

For success of its development of this research, it was installed the OpenSimulator metaverse on a server, and then later was performed the necessary settings that enable the implementation of NPC and enable the commands and functions inherent to these characters. Therefore, it is first necessary to make some modifications in certain lines of code in the file "OpenSim.ini", as mentioned on the official web site of OpenSimulator, which are shown in Figure 3.

It is important to highlight that, with including these commands to the source code of "OpenSim.ini", the user will be performing configuration changes that impact and, consequently, in the functioning of the virtual world, so it is necessary to know exactly what changes and what can be made. By using the expression "Enable = true", the user activates the XEngine script engine and with the command "AllowOSFunctions = true", enables the use of the functions of OSSL language, enabling the creation of NPC. Regarding "OSFunctionThreatLevel = VeryLow", this is used to set the level of threat and their allocation necessary for the performance of the implemented scripts. In this case, the level was set too low, so there was no obstruction.

At the end of installation and configuration of OpenSimulator metaverse, it was possible to start the NPC creation process, which is developing OSSL scripts, which allow both control the character as well as adding movements, animations, appearances and several actions in response to the environment and its users. To carry out the implementation of the NPC is previously necessary to create a primitive object (prim), setting to a 3D object (e.g. box), so that is possible to encode and attach scripts to this object, as it is possible to see in Figure 4.

The expression "initPos" is related to the start position of the NPC, that is, the local that the agent is created in the virtual world, in this case it was defined a position with one point away from the 3D object that contains the script. The variable "NPC" contains the "osNpcCreate" command that makes the creation of the NPC in the virtual world, in this case being assigned the name "Intelligent Agent or ELAI" to him, with the initial position set previously.

77      {
78          initPos = llGetPos() + <1,1,1>;
79          npc = osNpcCreate("Intelligent Agent", "", initPos, masterKey);
80          osNpcSay(npc, "Hi, " + name);
81      }
```

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

At the time of its inception, the NPC will speak in the internal chat virtual world a message previously set through the command "osNpcSay", which in this case was a "Hi" with the avatar name closest to it. With this process done, it will be created in the metaverse and perform the actions that were defined in the related script. Such actions can be classified as transactions, speeches and reactions of the NPC according to information from sensors that detect the presence of some avatar to your playing field.

As it is described in Figure 4, the command "OsNpcSay" allows to insert predefined lines to be performed by the NPC through internal chat. As for the movements, these can also be set through this OSSL language that defines what position the NPC should move or other movement of actions may be included (e.g., run, jump, fly, dance).

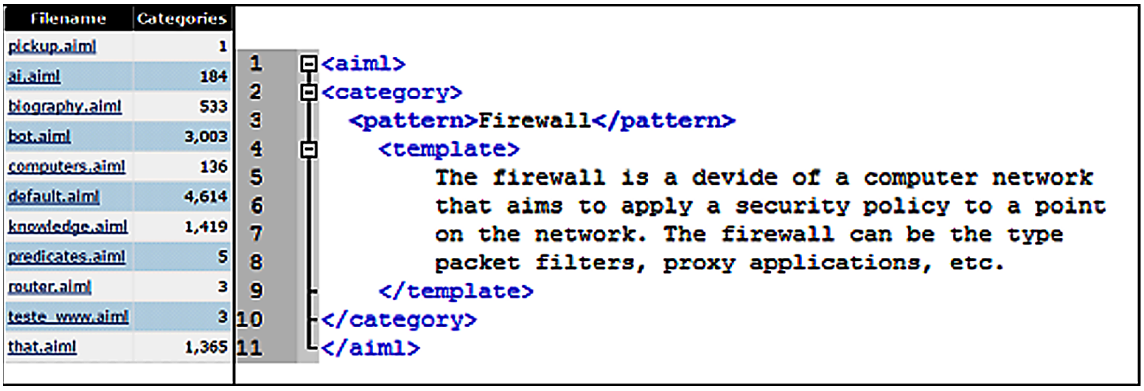
On the issue involving the use of sensors, the position information can be changed based on some own environmental information or of its members, for example. The scripts also enable the implementation of sensory functions to the NPC, in which is possible to capture user information when they step into the sensor range of action and perform certain actions, such as walking to the user meeting, send a message by chat or voice, or make some gesture or animation.

Another possibility offered by these implementations involving the use of scripts is the NPC's ability to perform external requests to the environment, thus allowing the information query on different sites eg database, online content repositories or even seeking some information about the user that is interacting. In this sense, there is the possibility of linking the NPC with a conversational agent (chatterbot) and enhancing the capacity for interaction between user-NPC and giving it the ability to respond students with more complementary and full answers.

The interconnection with conversational agents also occurs through scripts in OSSL language, therefore, first is necessary the creation of a chatterbot. This work was used to Pandorabots tool for enabling the hosting of conversational agent for free, allow online changes, provide information and access logs of the conversations, and provide a default knowledge base with AIML files since the precursor ALICE bot.

The default class that is provided as standard, it contains general data about unexceptional topics of the day-to-day, being made available in order to assist the general user. If any question is made to the NPC and he does not know this answer, the base is scheduled to induce the user to ask the similar questions until it can be answered your question, even if in general.

In cases that want to use a custom database with specific topics on a content, customization of the data contained must be performed by inserting the terms and their meanings as it deems necessary. In order to demonstrate such an adaptation of the knowledge base in this study it was created some files in AIML notation topics related to Computer Networks area, as it is possible to see in Figure 5, to provide a sample users that performed the tests.



In this class, there is an example in which it is reported a keyword in "<pattern>" with the reference "Firewall" and the knowledge of its reference is reported in the tag "<template>". Thus, when the chatterbot is interrogated, filtering it is performed using a keyword, which in this case is the term "firewall" and its counterpart is the knowledge contained in the tag "<template>".

With the creation of the NPC and the customized AIML knowledge base, the interconnection of NPC with chatterbots should be done. Therefore, the scripts have been adapted in OSSL language. Figure 6 shows the interconnection script, where it is possible to check a line, which targets at twice the code for better interpretation.

At first section it is informed the chatterbot identifier code previously implemented in Pandorabots and held the requisition to the conversational agent, so the required parameters are sent: the chatterbot identifier code, the message itself and the request method were used. During the second step is performed

```

using information returned by chatterbot in order to pass the message to the user only returned after the query in the knowledge base of conversational agent. Thus, at the end of this analysis, the message to the user is presented, through the command “osNpcSay (npc, newreply)”, as it is possible see in Figure 7.

Subsequent to all these procedures mentioned when the user interacts with the NPC in the virtual world, automatically it will be interacting with the conversational agent implemented in Pandorabots and can thus make inquiries and ask questions about Computer Networks topics. To demonstrate the interconnection described in this section, Figures 7 and 8 present an interaction between the NPC and the user avatar in the virtual world.

Figure 7. Student interaction with ELAI
Source: Authors, 2015

It is possible to see in Figure 7 that the user held by the channel "/16" chat the following question: "What is a Firewall?"; and the NPC in turn, made an appointment request in chatterbot knowledge base, returning to information that had been previously set, as shown in Figure 5.

From the development of these features, it becomes possible to perform various implementations in order to improve issues related to usability and interactivity of the NPC towards users. In this perspective, it was also attributed characteristics of intelligent agents to the NPC, making them proficient and skilled at multitasking. Therefore, when considering the criteria listed by Franklin & Graesser (1996) to intelligent agents, e.g. interaction, autonomy, reactivity, pro-activity, ongoing activity, adaptability, mobility and personality, it is possible expand the effectiveness of the NPC.

In this sense, to meet the requirements listed above, it was implemented by the NPC, sensory functions in order to enable these features. To perform activation, a function was inserted to establish a coverage radius for the intelligent agent could capture the movements of users who enter this perimeter, including enabling the capture of information from these users. Based on this, when the user through your avatar approach the intelligent agent, the sensor enables the perception of the environment; the activities on the environment itself or its users; the autonomy to perform certain activities; reactivity to perceive the environment and respond to its changes; proactivity to take initiative; mobility related to the ability to move; and ongoing activity being always active process.

In addition to meet these features, the intelligent agent can meet mobility requirements and reactivity, as when the student approaches and enters in the NPC's sphere of action, it performs the reaction move up to meet the student's position. In addition, if the student moves within that perimeter, the smart agent will follow him/her in order to provide a sense of support and monitoring, and it can offer for help. At the same time that the agent identifies the student's proximity perimeter, a welcome message is issued, establishing a communication channel through the chat to provide a user / agent interaction.

Figure 8. ELAI answering the questions aware of the level of expertise
Source: Authors, 2015

Finished the implementation procedure and interconnection of these technologies, it is clear both the complexity as the existing potential for their use in the education sector, so it is important to measure and estimate their relevance in real situations, considering the interaction of the users towards the intelligent agent.

Evaluation of Intelligent Agent ELAI

In order to measure the opinions of students about their work, a questionnaire was applied aimed at evaluating the characteristics related to intelligent agent requirements, usability and interaction of students with the intelligent agent ELAI and verify the adjustments made to the context learner.

To assess the responsiveness and classify the level related of the ease of use of ELAI, it was decided to use the System Usability Scale, which according to Brooke (1996), it is a scale consisting of ten questions with a global perspective of subjective usability evaluations. To evaluate the agreement or disagreement of the respondent user, the authors used the scale of Likert (1932). The choice of SUS scale occurred not only for providing a questionnaire with questions and ready alternatives but, for having a method and a logic able to circumvent the very positive assessments of the respondents, as well as very negatives, in order to determine and achieve a result even more expressive and considerable assessed work.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

In this sense, to achieve this target, the SUS has its own way of calculating your score. Brooke (1996) exposes in his research, which is primarily necessary to perform subtraction of the following:

- **Questions of Odd Number (1, 3, 5, 7 e 9):** The score is established by the value entered in the user's response, and subtracted the amount of 1 (User response - 1).
- **Questions of Pair Number (2, 4, 6, 8 e 10):** The score is composed of the amount set on 5 and subtracted the value of the response informed by user (5 - User response).

Subsequent to the calculation performed, are added all the scores of the questions answered by the user and this result is multiplied by 2.5, so that it will be possible to estimate the overall value of SUS. These SUS global values are set from 0 to 100 and divided on a scale of seven adjectives classification, in order to evaluate the result. Regarding the means and classification of adjectives and SUS score, Bangor et al. (2009) has seven possibilities with intervals between values, which can be attributed to the assessed work, namely: Best Imaginable, Excellent, Good, OK, Poor, Awful and Worst Imaginable.

In the evaluation of this work, as there were fourteen members involved in the assessment, there was the sum of all each user issues (Column "Sum of answers by User" in Figure 9) and then multiplying the value of 2.5, determining thus the total amount of SUS for each of them (Column "SUS" in Figure 9). At the end of this multiplication, averaging was performed to define the final value of SUS, the thus performed is the sum of all individual global values of each student and dividing them by the total number of users participating in the evaluation.

From this, it was obtained the final result of SUS equivalent to 73.04. Which corresponds to the concept Good on average ratings and scores of SUS presented by Bangor et al. (2009). The overview of the results by both student as a matter can be seen in Figure 9.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Regarding the first question (Q1), users were asked whether they would like to use the ELAI often in immersive virtual environment TCN5. The total of fourteen students, five were categorical in stating positively that would like to use it. Eight pointed that they agree partially with its often use.

These responses present positive results about the proposed work because expose the willingness of users frequently use the ELAI. Only one of the evaluated pointed out something other than "Agree" or "Partly agree", which used the "indifferent", that it is a neutral alternative, ie being neither positive nor negative related to the proposed work. With regard to the eight students who agreed partially, possibly the fact that their assessments will be partial, is assigned the novelty imposed by working in their daily lives, and they go on to work with an avatar accompanying and guiding the user through this process.

Regarding the number of question two (Q2) was asked users they were unnecessarily complex

ELAI. In this regard, respondents mostly said they disagreed about it (11 users). However, one of the users reported being "indifferent", another said "Partially Agree" and other "Totally Agree".

The students disagreed finding unnecessarily complex the ELAI, however it is understandable the return submitted by users that found too complicated, since the agent is inserted into a three-dimensional environment with many objects and resources, which for them is still the new and requires some time for proper adaptation. In addition, the interaction with the agent is through a communication channel that uses the expression "/ 16" expression is used for the ELAI understand that the student is communicating with him/her and not with another avatar of another student and also part of this dialogue is held in English, which may have led to greater difficulty to students.

The fact that the ELAI dialogue with students in some topics, in English, was due to the internationalization project of Institute, which also provides on-site classes taught in English. Allied to this, the authors aim to make it available internationally, making it available in online databases and repositories for wide use and occasionally getting the feedback from users so that they can be observed in future work.

These difficulties possibly damaged the interaction with ELAI, respond partly the third question (Q3), where users were asked whether they found it easy to use ELAI. In this regard three users indicated "disagree Partially" option, and against the ease of use of the agent, which leads to believe that had the same obstacles highlighted in question two. However, the majority opinion prevailed in consent with the claim, finding the understandable and uncomplicated agent.

In reference to the fourth question (Q4), respondents were questioned about whether would require technical support to use the ELAI. Regarding this question, four students showed "Totally disagree" and four "Partly disagree", but six users indicated "Agree Partially."

In this question, it was observed that there was heterogeneity as the opinions given by the students. This is because many of the students had never had contact with an immersive virtual environment, which should be turned to education, it is different from everyday environments to everyday users, e.g. video games and other games, and a new experience, with objectives and different inspirations. Nevertheless, most disagreed in need technical support to use the ELAI again, but the authors point out that this view may have been influenced by the mere fact of users have made the route stipulated being supervised by the authors of this work, in order to clarify their possible doubts.

Regarding the question five (Q5), the authors asked the users what they thought about the features of ELAI and if these were well integrated. In this question, four users showed "Indifferent", five "agreed Partially" and five "Totally agreed".

For that question, there was a positive weight to the work presented, as students were presented to all features of ELAI. Given that they communicated with the ELAI, and were aware that it was a chatterbot connected to the agent and, moreover, were notified that the ELAI was able to identify their level

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

of expertise and tailor the conversation to the level indicated. Thus avoiding frustrating the user with a very advanced topic or upset him/her with a very basic issue. Finally, students were also able to view how satisfying was the integration of ELAI with the TCN5 environment, which is very important in conducting this chapter.

However, in this case four students noted the "Not important", this fact also refers positively, as this choice may have occurred because the "invisibility" of these features that are intrinsic to the work, since the same work is in the background as support. If the main concept of ubiquitous computing: making human-computer interaction invisible. Moreover, all processes are performed by encoding scripts, what little help the user in view of the integration of features.

Regarding the issue six (Q6), students were asked whether they had too many inconsistencies in ELAI. Faced with this question, prevailed the opinion of eight members who disagreed, four marked the option "Strongly Disagree" and four "Partly disagree". But there were also five users who chose to remain impartial, noting the "indifferent" and a user only checked the "Agree Partially".

In the question about inconsistencies, many factors may have been considered by users. In general, the views of users were in favor of the submitted work, sometimes disagreeing. These views were possibly caused as a result of the chatterbot, it has part of their knowledge base in Portuguese and partly in English, often favoring the inconsistency or lack of understanding both of the questions made by users and the answers prepared by the agent, causing the latter offer answers on other subjects or even asking the student to provide more information on the topic addressed in order to deepen their search in the knowledge base.

Regarding the seventh question (Q7), students were asked if in their opinion most people learn to quickly use the ELAI. Therefore, almost all chose to assert positively that users learn easy how to use it, and seven students marked "Agree", five "Partly agree", one opted for impartiality while noting "Indifferent" and other "Disagree Partly".

The positive predominance evidenced by the responses of users, can be due to the support provided by the authors of this work during the tests. And may also have impacted on the opinion of the users and caused the students' sensation, which are understanding both environment as well as the functioning of the ELAI. However, one of the students pointed out negatively and other impartial probably these users faced with a complex environment with many new features and details to be acquired quickly, as it was the test.

In the eighth question (Q8), students were asked if they thought it ELAI was not trivial to use. So in this regard seven students responded positively, ie two marked "Strongly Disagree" and five "Disagree Partly", stating that the use of ELAI is simple and usual. Among the remaining respondents, three marked "Indifferent" other three "Partly agree" and "Agree". The opposing views can be sustained because it is a virtual world in three dimensions, which many users had never had experience or its size in length or content presented on Computer Networks and also because of the interaction with an agent in English.

In reference to question number nine (Q9), the evaluators were asked whether in their opinion felt confident to use the ELAI. In this sense, most users proved to be optimistic when use the agent, as five students pointed out the "Agree" and five "Partly agree". However, four users have chosen to point out the alternative "Indifferent".

This preference pierces even positive most students feel confident, some users remained neutral, which is an indication that the same could not be confident to use the agent. This distrust may be a result of lack of user experience in virtual 3D immersive environments or in interactions with intelligent agents, or also the large number of educational resources, with a pedagogical route that to be kept.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Since the question of number ten (Q10), respondents were asked whether need to learn a lot before to use the ELAI. Faced with this question, the opinion of the students prevailed to disagree, stating that there lacked learn a lot before use. So four students indicated "Strongly Disagree", seven showed "Disagree Partly", one remained neutral claiming to be "indifferent" and two marked "Agree Partially".

However, even the vast majority disagreeing, two users believed to be necessary to learn a lot before using it. This is due to the large amount of information that users received when performing the test, thus causing the sensation of need to learn more to be able to use their own agent. In addition, the environment itself often, because it is something new and 3D, causes uncertainty and insecurity among users regarding their use, based on the fact that most students had no experience with virtual worlds, which in this case has several alternative teaching and 3D objects for interaction.

This section sought to detail the assessment made by SUS usability scale, presenting the specificities of each question and relating to the work presented in this chapter. Therefore, the results obtained from the SUS was equivalent to 73.04. According to the mean score given by Bangor et al. (2009), corresponds to the "Good" concept. From this conception of students about the work, it was possible to identify indications that the intelligent agent ELAI and your features, contemplated the needs and preferences related to the question usability. Therefore, is possible indicate that the ELAI met the users' wishes on issues related to usability, which had the objective of estimating how much users were satisfied or dissatisfied relative ease and practicality in use the proposed work.

Among the analyzed answers, stood out the feedback on the complexity that involves the use of ELAI, where some students found difficulty in using and even said they would need technical support to other interactions. Since, users who have been assigned not believe that most people learn to use it quickly, also indicated that they found the trivial ELAI to be used. Therefore, it is necessary to correct the aspects considered troublesome by students, including reprogramming certain specific points in intelligent agent ELAI to provide an appropriate and complementary support to students, as transparent as possible to the understanding of users.

FUTURE RESEARCH DIRECTIONS

Throughout the development of this chapter, it identified some characteristics with the potential to be worked in the future, which could not be included in this study due to the intrinsic complexity of each case and it requires time more than expected in the stipulated schedule. So follow the possibilities for future work:

- Assign the ELAI the ability to cause imbalances in the construction of knowledge of students, establishing cognitive conflicts in order to develop or transform the mental schemes already developed by the learner;
- Implement with the ELAI, the ability to advise the student that remade his/her cognitive tests that define the style and level of expertise in order to maintain the agent with current contextual information about learners;
- Include to ELAI the features shown in studies of affection, relating these features with existing ones, including the more realistic characteristics, e.g. talking and gesturing;
- Develop to ELAI the ability to learn during their interactions with students or to seek external information when asked about a new concept.

CONCLUSION

After being carried a literature review on the topics inherent in this study and in-depth analysis on them, it was found that several studies relate the concepts covered in this chapter. In both surveys, the authors discuss the use of intelligent agents and link the existing potential in this tool and its working methods, which is capable of adding significant improvement in virtual learning environments, especially in environments whose purpose is to provide a closer relationship with students, in which case, the three-dimensional virtual environments.

In support of intelligent agent presented in this work is the ability of being located adjacent to an environment with a high degree of immersion the user, having the shape of an avatar, in the same way that the student is represented in the environment, which increases proximity between the user and the artificial character. Another benefit found in intelligent agents and presented by Russel and Norvig (1995), deals with the agent feature perceive the environment in which it finds through its sensors, and take some action to certain situations, through its actuators and is establishing its actions according to their perceptions to achieve a certain goal. Adept to these features, the ELAI features, including the ability to identify, through its sensor, the closest student and check the level of experience that it hold, so that it can establish dialogue with the student and answer it on its possible doubts regarding the contents that meet with the topics in three-dimensional environment.

Allied to the contributions imposed by intelligent agents and their actions, which are defined through the use of artificial intelligence and specific languages, e.g. AIML, other factors that enrich and justify the development of both of these artificial characters as the development of three-dimensional virtual environments consist of the ability to engage users through the use of these immersive environments, as nurture and aim to improve user interaction with the content displayed on them.

Enabling even extend the practices and experimentation that are classroom views, into a controlled and highly realistic three-dimensional environment in which the student have at your fingertips the ability to repeat them as often as he/she feel necessary, in time, when and where they feel is appropriated; favoring communication between colleagues, encouraging the collaboration of both to solve problems; the aid provided by an intelligent agent that offers the student a communication channel, where it can take your questions concerning the area addressed in the environment; the authorship of capacity available to the user; and also an alternative environment that offers lower costs for implementation and non-hazardous over its use. Regarding the positive aspects provided by the three-dimensional virtual environment and also the feeling of past presence to those users, according Dalgarno et al. (2002), it is known as immersion, and occurs as a result of representation loyalty of the high degree of interaction and user control.

This chapter presented the prototyping and development of an intelligent agent called ELAI, which aimed to assist students in their activities and answer questions related to the topic of Computer Networks, but may also act as a colleague in three-dimensional collaborative environments or facilitator of learning, interacting with students at different times, the guiding, explaining tasks by asking questions or providing feedback.

In the opinion of the assessors students, the ELAI is a viable alternative that offers support in teaching and learning process thereof, and encourage interaction with 3D content and ready objects in immersive virtual environment TCN5 and also in carrying out activities. Furthermore, immersive experiences alone, seen in this work, tend to engage students further with the proposed objectives and added to this, the student actually have the assistance of an intelligent agent, encourage both to achieve these goals as and gain experience interacting with the contents disposed in the environment, making them more productive, and dynamic consolidated.

KEY TERMS AND DEFINITIONS

Chatterbots: Are artificial entities capable of conversational interaction, also known as conversational agents, robots of conversation and also chatbot.

Computer Network: Is the area of computing who cares to investigate aspects related to the interconnection of machines and the transmission of information.

ELAI: Is an intelligent agent adaptive to the level of expertise of students, which uses the intelligent agent characteristics, npc and chatterbot to promote responses about computer networks.

Inteligent Agent: Can be defined as those responsible for adoption of the best action, among many possible, to accomplish something about a certain situation.

Non-Player Character: This is a character that is not played by user, is autonomous and controlled by computer.

Ubiquitous Computing: Is the area of research that investigates the integration of computing the actions, attitudes and behaviors inherent to human beings, with the aim of making the human-computer interaction invisible.

Virtual Worlds: Are tools that simulate the real world in a three dimensional environment, providing users the sense of immersion in a controlled environment with many opportunities and experiences.

This research was previously published in the Handbook of Research on 3-D Virtual Environments and Hypermedia for Ubiquitous Learning edited by Francisco Milton Mendes Neto, Rafael de Souza, and Alex Sandro Gomes; pages 510-536; copyright year 2016 by Information Science Reference (an imprint of IGI Global).

Chapter 45
Modelling Propagation of Public Opinions on Microblogging Big Data Using Sentiment Analysis and Compartmental Models

ABSTRACT

Compartmental models have been used to model information diffusion on social media. However, there have been few studies on modelling positive and negative public opinions using compartmental models. This study aimed for using sentiment analysis and compartmental model to model the propagation of positive and negative opinions on microblogging big media. The authors studied the news propagation of seven popular social topics on China's Sina Weibo microblogging platform. Natural language processing and sentiment analysis were used to identify public opinions from microblogging big data. Then two existing (SIZ and SEIZ) models and a newly developed (SE2IZ) model were implemented to model the news propagation and evaluate the trends of public opinions on selected social topics. Simulation study was used to check model fitting performance. The results show that the new SE2IZ model has a better model fitting performance than existing models. This study sheds some new light on using social media for public opinion estimation and prediction.

INTRODUCTION

With the fast development of Internet, last decade has witnessed information explosion over social media. Major microblogging platforms such as Twitter in the United States and Sina Weibo in China provide the instant access to rapid-changing news and allow users to generate self-organized networks on popular social topics and celebrities (Gao, Abel, Houben, & Yu, 2012). As microblogging platforms have millions of users and billions of new messages every day, they have become an important channel to evaluate and predict the trends of public opinions on high-impact news and social events. But the high volume, velocity and complexity of microblogging messages also impose challenges on the processing and analysis under big data context.

The mechanism of news propagation is similar to the epidemiology of infectious disease. Disease diffusion starts with a small group of infected, and transmits along the paths of daily contact and interaction. Compartmental models in epidemiology are a state-of-practice approach to model the dynamics of disease propagation. The population is classified into several compartments, such as susceptible (*S*), exposed (*E*), infected (*I*) and recovered (*R*), to represent different epidemic states (Bettencourt, Cintrón-Arias, Kaiser, & Castillo-Chávez, 2006). People in susceptible compartment are healthy and have the opportunity to be infected; the susceptible will be infected if they have sufficient contact with the infected (Hethcote, 2000). There is a prolonged incubation period (i.e. exposed compartment) for some diseases, where people who have contracted the disease need a longer time to develop symptoms and become contagious. For some other diseases, the infected can fully recover and obtain immunity. Classical compartmental models for biological epidemiology include SI, SIS, SIR, and SEIR models. Different models are suitable for diseases with different characteristics.

Information diffusion has been widely studied by previous literatures (Canneyt, Schockaert, & Dhoedt, 2015; Escamilla et al., 2016; García-Silva, Rodríguez-Doncel, & Corch., 2013; Gruhl, Guha, Liben-Nowell, & Tomkins, 2004; Kwon & Lee, 2013; Lerman & Ghosh, 2010; Matsubara, Sakurai, Prakash, Li, & Faloutsos., 2012; Romero, Meeder, & Kleinberg., 2011; Shuai et al., 2012; Trpevski, Tang, & Kocarev, 2010; Weng, Lim, Jiang, & He, 2010; Jaewon Yang & Leskovec, 2010). Previous studies primarily focus on the source and mechanism of information diffusion in social media and its impact on public society. Epidemiological models have been used in some of these studies (Cha, Haddadi, Benevenuto, & Gummadi, 2010; Jin, Dougherty, Saraf, Cao, & Ramakrishnan, 2013; Jin et al., 2014; Khelil, Becker, Tian, & Rothermel, 2002; Newman, 2002; Xiong, Liu, Zhang, Zhu, & Zhang, 2012; Jiang Yang & Counts, 2010). Among all compartmental models in epidemiology, *SIZ* and *SEIZ* models are two most popular models for information diffusion, as they include a skeptical compartment not often seen in biological epidemiological process.

Some researchers have used *SEIZ* model to model news diffusion using Twitter microblogging data (Jin et al., 2013; Jin et al., 2014). They assumed that microblogging users who posted messages on popular news have a positive opinion on the news (i.e. being infected), and users who posted no message have a negative opinion on the news (i.e. being skeptical). With this treatment, the researchers only observed data of the infected compartment. However, the microblogging users can in fact post messages to express their both positive and negative opinions, so previous assumptions and treatments may not be completely reasonable.

The objective of this study is to simultaneously model the propagation of positive and negative public opinions using a large volume of Sina Weibo microblogging data. We used natural language processing and sentiment analysis to process the big microblogging data and extract the positive and negative

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

opinions, and then implemented two existing (*SIZ* and *SEIZ*) and one newly-developed (*SE2IZ*) models to model the dynamic of news propagation. Our analysis approach can deal with big data scenario due to its low computational cost. The methods in this study can help real-time data-driven decision making in political, business and other fields.

RELATED WORK

In news propagation context, the susceptible are people who have the opportunity to be exposed to the news, and the infected are people who perceived the news and posted messages supporting the news. The most basic compartmental models only involve two types of compartments: susceptible and infected. In SI model, the susceptible will be permanently infected and cannot recover. Thus the entire population will eventually be infected. In SIS model, the infected have the opportunity to recover and become vulnerable again (Bettencourt et al., 2006). These two models have some drawbacks on modeling information diffusion. Both models have too few compartments to account for sophisticated dynamics of news propagation. Moreover, SIS model may not be suitable because the news can fade out quickly and the recovered people will not be interested in same news again.

During news propagation, people may either agree (infected) or disagree (skeptical) with the news. This phenomenon is not commonly seen in biological epidemiology as the susceptible are only infected in that case. A skeptical (*Z*) compartment was developed to account for the skeptical state in news propagation (Bettencourt et al., 2006). In SIZ model, the susceptible have opportunities to either agree or disagree with the news.

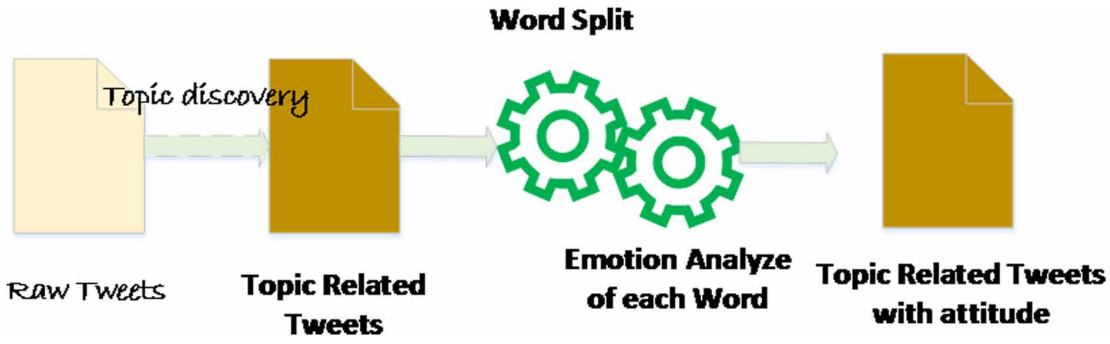
In some situations, there is a prolonged incubation period for the susceptible perceiving the news to formulate a clear opinion on the news. An exposed (*E*) compartment was developed to represent the incubation period, leading to *SEIZ* model (Bettencourt et al., 2006; Hethcote, 2000; Jin et al., 2013; Jin et al., 2014). *SEIZ* model only has an exposed compartment before infected compartment, without a symmetric counterpart before skeptical compartment.

DATA AND METHODS

Sina Weibo Microblogging Data

This study used a large (~20 Gb) Sina Weibo data set shared by Data-Tang, a private online data sharing service that periodically extracts, processes, and shares publicly accessible microblogging data and covers the a large portion of active microblogging users (Datatang). We selected 13 most popular and high impact social event topics initiated in April to May 2014. We extracted the first 10-12 days' data since initiation of the event, resulting in over 84,000 Sina Weibo microblogging messages from over 64,000 Sina Weibo users. Each Sina Weibo message consists of the post date, time and message text in Chinese language.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use



Natural Language Processing and Sentiment Analysis

Natural language processing and sentiment analysis were used to process the high volume of unstructured microblogging data and extract opinions of microblogging users on pre-selected social topics. The work flow of natural language processing and sentiment analysis is shown in Figure 1. First, we used Natural Language Processing & Information Retrieval (NLPIR) Chinese language processing system to split sentences in each message into meaningful phrases (NLPIR). Second, we matched the phrases with NTUSD Chinese sentiment dictionary which provides attributes of positive and negative emotions (Ku & Chen, 2007). For example, *support, like, great* are keywords with positive emotion, and *hate*, *dislike*, *against*, *protest* are keywords with negative emotion. Third, we assigned a value of 1 for each keyword with positive opinion, and -1 for each negative keyword with negative opinion. Forth, we sum up the values of all keywords within a message, and defined the message to represent a positive opinion on the news if the sum is positive, and to present a negative opinion on the news if the sum is negative. The message is considered be neutral if the sum is zero. As a neutral message does not provide useful information on whether the microblogging user is infected or skeptical, it was excluded from further analysis.

An example of natural language processing and sentiment analysis is demonstrated as follows. A microblogging message regarding Houston Rocket NBA basketball team is "In middle school I loved Rocket team so much, followed them closely, all because of Tracy McGrady" (originally as "初中超喜欢火箭。各种关注。都是因为麦蒂" in Chinese). We used NLPIR system to split the sentence (in Chinese) into "In middle school | I loved (so much) | Houston Rocket team | followed them | closely | all | because of | Tracy McGrady" ("初中|超喜欢|火箭。各种|关注。都是|因为|麦蒂" in Chinese). Among these phrases there is only one keyword ("love") that matches the NTUSD keyword dictionary with positive emotion. Therefore, this message has a sum of 1 and is considered to represent a positive opinion on the social topic of Houston Rocket team.

After natural language processing and sentiment analysis, seven popular social topics with sufficient number of opinion-available (i.e. non-neutral) messages were selected for further analysis (Table 1). For each topic, we calculated the number of messages with positive or negative opinions in daily basis from the initiation date of the topic. The amount of daily messages with positive opinion are observed data for infected compartment, and the amount of daily messages with negative opinion are the input for skeptical compartment.

Figure 1. Natural language processing and sentiment analysis

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 1. List of seven selected popular social topics

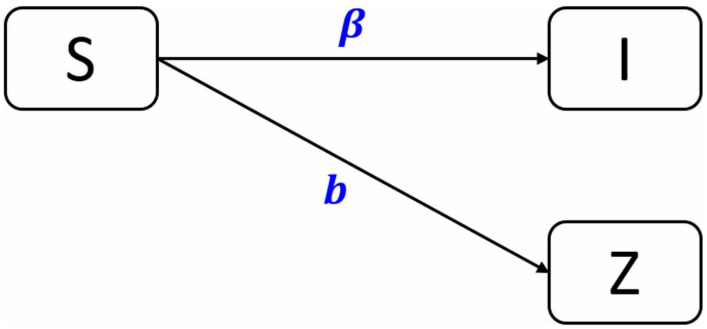
Social Topic	Event Detail
Evergrande FC	Chinese Guangzhou Evergrande Football Club (FC) won the 100th game with famous coach Marcello Lippi.
Air Pollution	Air pollution in north-eastern China was greatly alleviated during May 2014. Air quality in Beijing hit the best point over the past several years.
House Price	House price in China began to decline after years of rapid increase.
"My Old Classmate"	The movie "My Old Classmate" came on show in cinemas.
National Civil Service	Chinese National Civil Service Exam has ended.
Corruption	The criminal charge on corruption of some high-rank Chinese government officials has drawn much public attention.
GMO food	A famous Chinese TV host, Cui Yongyuan, initiated a public debate against genetically modified organisms (GMO) food.

Compartmental Models for Propagation of Public Opinions

This study focused on two compartmental models most suitable for news propagation, *SIZ* and *SEIZ* models. Both models have an infected compartment and a skeptical compartment. *SEIZ* model has an exposed compartment before the infected compartment. However, this paper is the first study to consider that messages with positive emotions represent positive opinions of the infected people on the news, and messages with negative emotions represent the negative opinions of the skeptical people on the news. This way, we can collect data for both *I* and *Z* compartments. Besides, we assumed that each message represents one data point, and thus multiple messages by the same user contribute to multiple data points even they occurred in the same day. Moreover, we developed a new *SE2IZ* model based on *SEIZ* model by adding an exposed compartment (E_z) before skeptical compartment as well as additional paths to skeptical.

Compartmental models use a system of Ordinary Differential Equations (ODEs) to model the transition quantities and rates of subjects between different compartments over time. Transition rates and transition probabilities are major parameters to estimate in the system of ODEs. In this study, the parameters were estimated by solving the system of ODEs numerically.

SIZ Model



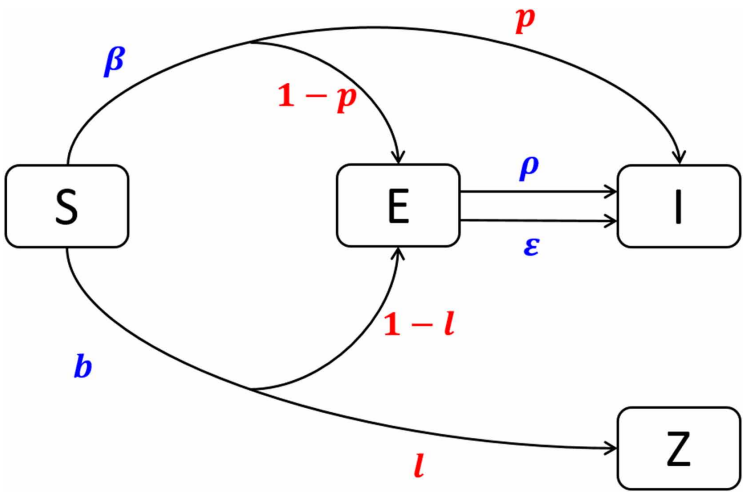
The framework of *SIZ* model is shown in Figure 2, where the blue-colored parameters are contact/transition rates. After the susceptible contact the infected or skeptical, they will move to infected or skeptical compartment with different transition rates.

The system of ODEs for the SIZ model is:

$$\begin{cases} \dfrac{dS}{dt} = -\beta S \dfrac{I}{N} - bS \dfrac{Z}{N} \\ \dfrac{dI}{dt} = \beta S \dfrac{I}{N} \\ \dfrac{dZ}{dt} = bS \dfrac{Z}{N} \end{cases}$$

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. SIZ model



where *S*, *I*, *Z*, i.e. *S(t)*, *I(t)* and *Z(t)*, are the numbers of subjects in *S*, *I*, *Z* compartments at time *t*; *N* is the population size, *N*= *S(t)*+*I(t)*+*Z(t)*; β is per-capita *S*-*I* contact rate (i.e. number of *S* in contact with *I* per day); *b* is per-capita *S*-*Z* contact rate (number of *S* in contact with *Z* per day) (Bettencourt et al., 2006; Hethcote, 2000).

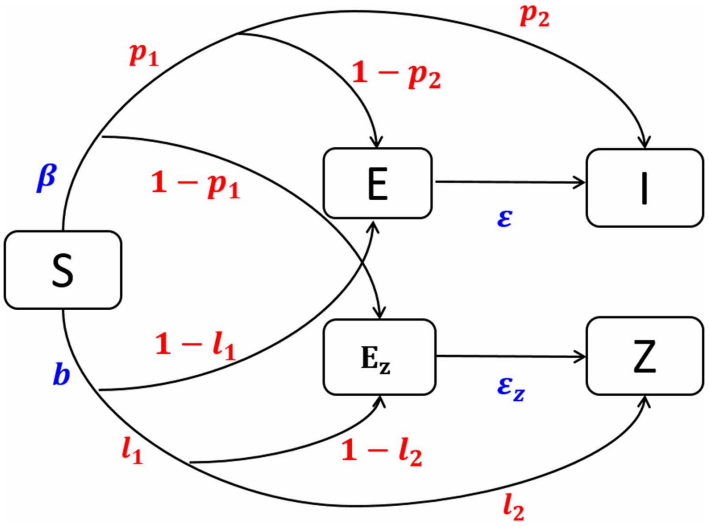
SEIZ Model

The framework of *SEIZ* model is shown in Figure 3, where the blue-colored parameters are contact/transition rates and red-colored parameters are transition probabilities. In *SEIZ* model, a proportion of susceptible enter the exposed compartment before they move to infected compartment (i.e. need a prolonged incubation period to generate positive opinions on the news). Meanwhile, it is possible for susceptible to be infected (but firstly go through exposed compartment) after they contact with the skeptical (i.e. the susceptible disagree with the skeptical and thus become infected).

Figure 3. SEIZ model

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

The system of ODEs for the SEIZ model is:



$$\begin{cases} \dfrac{dS}{dt} = -\beta S\dfrac{I}{N} - bS\dfrac{Z}{N} \\ \dfrac{dE}{dt} = (1-p)\beta S\dfrac{I}{N} + (1-l)bS\dfrac{Z}{N} - \rho E\dfrac{I}{N} - \varepsilon E \\ \dfrac{dI}{dt} = p\beta S\dfrac{I}{N} + \rho E\dfrac{I}{N} + \varepsilon E \\ \dfrac{dZ}{dt} = lbS\dfrac{Z}{N} \end{cases}$$

The term E, i.e. $E(t)$, is the number of subjects in E compartment at time t; $N= S(t)+I(t)+Z(t)+ E(t)$. The ε is E-to-I self-transition rate (i.e. no further contact with I needed), and $1/\varepsilon$ is the average incubation period; ρ is per-capita E-I contact rate (number of E in contact with I per day), representing a promotional effect of E-I contact; p is the S-to-I transition probability given the contact with I, and (1-p) is the S-to-E transition probability given the contact with I; l is the S-to-Z transition probability given the contact with Z, and (1-l) is the S-to-E transition probability given the contact with Z; β is per-capita S-I contact rate; b is per-capita S-Z contact rate.

SE2IZ Model

The framework of *SE2IZ* model is shown in Figure 4. There are three motivations for developing the new *SE2IZ* model. First, *SE2IZ* model includes an exposed compartment before skeptical compartment (E_z) in order to account for long incubation period before skeptical. Second, after the susceptible contact the infected, they still have a chance to be the skeptical; the E_z compartment provides a new path to skeptical compartment in addition to S-Z direct contact. Third, we excluded promotional contact rate ρ in order to reduce model complexity and parameter redundancy.

Figure 4. SE2IZ model

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

The system of ODEs for *SE2IZ* model is:

$$\begin{cases} \dfrac{dS}{dt} = -\beta S\dfrac{I}{N} - bS\dfrac{Z}{N} \\ \dfrac{dE}{dt} = p_1\left(1-p_2\right)\beta S\dfrac{I}{N} + \left(1-l_1\right)bS\dfrac{Z}{N} - \varepsilon E \\ \dfrac{dE_z}{dt} = l_1\left(1-l_2\right)bS\dfrac{Z}{N} + \left(1-p_1\right)\beta S\dfrac{I}{N} - \varepsilon_z E_z \\ \dfrac{dI}{dt} = p_1 p_2\beta S\dfrac{I}{N} + \varepsilon E \\ \dfrac{dZ}{dt} = l_1 l_2 bS\dfrac{Z}{N} + \varepsilon_z E_z \end{cases}$$

The term E_z, i.e. $E_z(t)$, is the number of subjects in E_z compartment at time t; $N= S(t)+I(t)+Z(t)+ E(t) + E_z(t)$; ε and ε_z are the *E*-to-*I* and E_z-to-*Z* self-transition rates; p_1 is the *S*-to-*I* transition probability given a contact with *I*, $(1\text{-}p_1)$ is the *S*-to-E_z transition probability given a contact with *I*; p_2 is the secondary *S*-to-*I* transition probability after p_1, $(1\text{-}p_2)$ is the secondary *S*-to-*E* transition probability after p_1; l_1 is the *S*-to-*Z* transition probability given a contact with *Z*, $(1\text{-}l_1)$ is the *S*-to-*E* transition probability given a contact with *Z*; l_2 is the secondary *S*-to-*Z* transition probability after l_1, $(1\text{-}l_2)$ is the secondary *S*-to-E_z transition probability after l_1; β is per-capita *S*-*I* contact rate; *b* is per-capita *S*-*Z* contact rate.

SIMULATION STUDY ON MODEL FITTING PERFORMANCE

We used simulation study to investigate the model fitting performances of three compartmental models. The purpose of simulation study is to check whether the models can fit the simulated data as well as expected. Simulation study includes two steps. First, for each compartmental model, we generated a simulated data set of all compartments based on pre-specified values of model parameters. Second, we fit each model with on corresponding simulated data, and derived the fitted curve for each compartment over time. In the second step, we fit models using two versions of data: complete and partial versions. The complete version includes simulated data of all compartments; while the partial version only includes simulated data of *I* and *Z* compartments, which is similar to a real-world scenario.

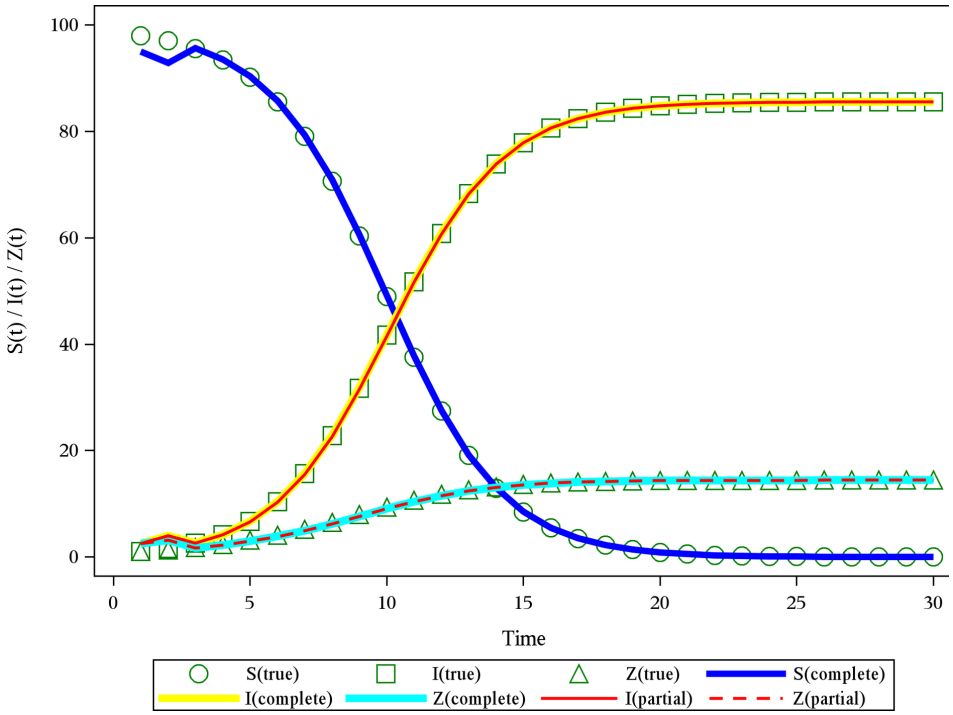
The results of simulation study are shown in Figure 5, Figure 6, and Figure 7. The fitted curves match the simulated (i.e. true) data points very well. Moreover, the model fitting performances are similar when using complete and partial versions of data. These results suggest that, when models are correctly specified (i.e. the model matches the underlying process of the data), the compartmental models perform very well even when only *I* and *Z* compartments are observed.

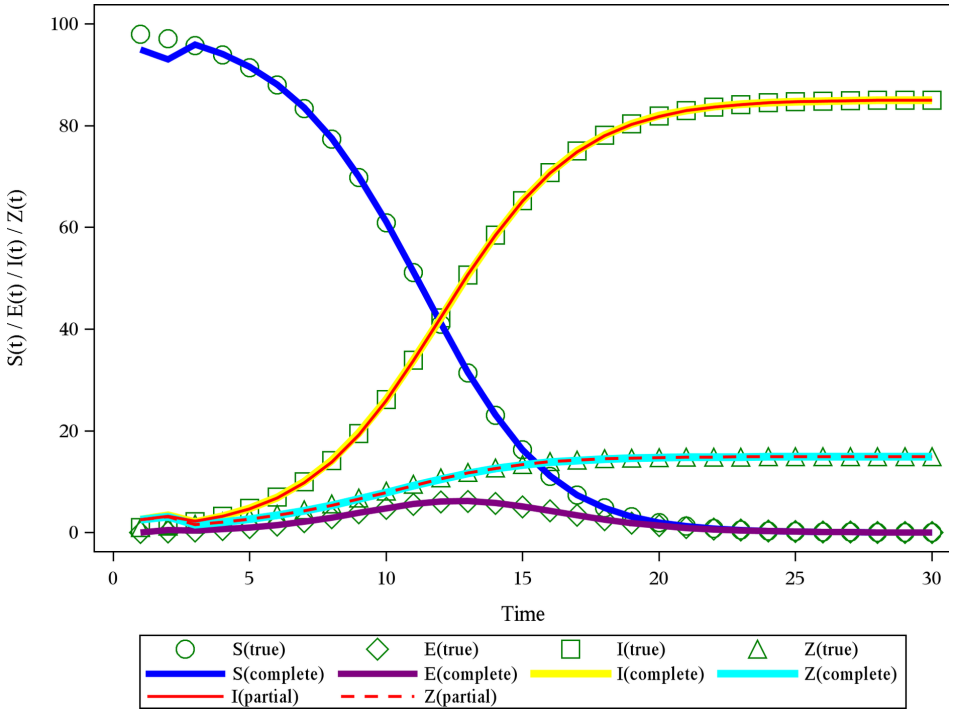
MODELLING SINA WEIBO MICROBLOGGING DATA

After simulation study, we implemented three compartmental models on the seven selected topics of Sina Weibo microblogging data processed by natural language processing and sentiment analysis (Table 1). We adopted the modeling procedures similar to previous literatures (Bettencourt et al., 2006; Jin et al.,

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 5. SIZ model fitting performance in simulation





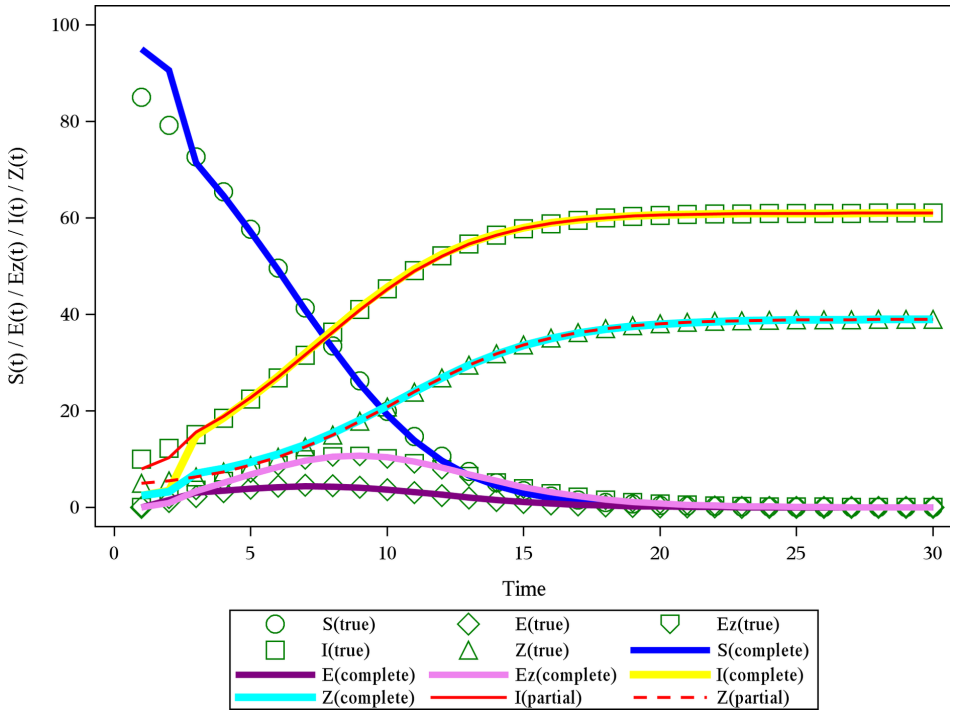


Figure 6. SEIZ model fitting performance in simulation

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 7. SE2IZ Model fitting performance in simulation

2013; Jin et al., 2014). We assumed that *I(0)* and *Z(0)* are observed in the data, but *S(0)*, *E(0)*, $E_z(0)$ and *N* as unknown parameters to estimate. Ordinary non-linear least squares method was used to estimate the model parameters. Model fitting performances of three models were compared both graphically (using fitted curves) and numerically (using MSE and MAD). We used two quantitative measures of overall model fitting errors: Mean Squared Error (MSE) and Mean Absolute Deviation (MAD), which are defined as:

$$MSE = \sum_{t=1}^{T} \left\{ \left[I_{fit}(t) - I_{obs}(t) \right]^2 + \left[Z_{fit}(t) - Z_{obs}(t) \right]^2 \right\} \Big/ T$$

$$MAD = \sum_{t=1}^{T} \left\{ \left| I_{fit}(t) - I_{obs}(t) \right| + \left| Z_{fit}(t) - Z_{obs}(t) \right| \right\} \Big/ T$$

The overall model fitting errors for 7 social topics are shown in Table 2. The results clearly show that the MSE and MAD for *SE2IZ* model are constantly lower than two existing models, while *SIZ* model has the highest model fitting error among 3 models. The existence of exposed compartment(s) significantly increases model flexibility for varying dynamics of news propagation. *SE2IZ* model has the best model fitting accuracy among three models due to its double exposed compartments and more transition paths.

The observed data and fitted curves for seven social topics are shown in Figure 8, Figure 9, Figure 10, Figure 11, Figure 12, Figure 13, and Figure 14. *SE2IZ* model fit the observed data very well, especially when *I* or *Z* compartment was very different from a classical S-shape (e.g. Air Pollution, House Price, "My Old Classmate" movie, and National Civil Service). These results agree with MSE and MAD findings that *SE2IZ* model is more flexible than *SEIZ* and *SIZ* models in modeling different dynamics of new propagation.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 2. Overall model fitting errors for seven social topics

Topic	MSE			MAD		
	SIZ	SEIZ	SE2IZ	SIZ	SEIZ	SE2IZ
Evergrande FC	21,261	13,098	7,555	162	132	107
Air Pollution	54,232	50,977	2,367	281	262	57
House Price	118,064	98,565	6,049	396	322	82
"My Old Classmate"	192,059	159,990	7,752	538	452	93
National Civil Service	87,673	33,409	2,922	366	187	56
Corruption	15,563	15,340	3,325	144	139	56
GMO Food	10,594	8,182	1,689	113	96	46

We used the fitted curves to assess the trends of public opinions on related scocial topics. Sina Weibo microblogging users were more likely to have positive opinions on Evergrande FC (e.g. fans were proud of Evergrande FC's achievement in international club soccer competition). In contrast, microblogging users were more likely to have negative opinions on Air Pollution (e.g. complaining about the poor air quality), House Price (e.g. complaining about the rapidly inflating house price), Corruption (e.g. complaining about the adverse impact of government job corruption), and GMO food (e.g. concerning the adverse health impact of genetically modified food). Moreover, microblogging users were more likely to have neutral opinions on "My Old Classmate" movie (e.g. the movie had an averaged rating) and National Civil Service (e.g. some people were eager for a job in national civil service due to good job security and benefit, while some others complained that too many positions significantly increased the government's financial burden).

CONCLUSION AND DISCUSSION

This paper is the first study to simultaneously model the propagation of positive and negative public opinions using compartmental models. Natural language processing and sentiment analysis were used to identify public opinions on popular social topics using a large volume of Sina Weibo microblogging data. We developed a new *SE2IZ* model based on existing *SEIZ* and *SIZ* models and implemented all three models on the processed data. *SE2IZ* model has a better model fitting performance than *SEIZ* and *SIZ* models due to an additional exposed compartment before skeptical compartment and more paths to skeptical compartment.

This study sheds some new light on using microblogging social media data to perform public opinion prediction and data-driven decision making in political, business and other fields. The compartmental models can also be used in other fields such as biomedical, public health, epidemiology, business analytics, marketing, survey and poll, education, and transportation. All these fields have strong interest and demand on modeling event data (Antin et al., 2016; Brin, Motwani, Ullman, & Tsur, 1997; Chen, Fang, Guo, & Hanowski, 2016; Chen, Fang, & Lockee, 2015; Fitch et al., 2013; Guo & Fang, 2013; Guo, Fang, & Antin, 2014, 2015; Guo et al., 2016; Lebo & Norpoth, 2007; Ouimet et al., 2014; Waller & Gotway, 2004).

Figure 14. Observed data and fitted curves for GMO food

There are two limitations in this study. First, natural language processing and sentiment analysis may identify some emotions incorrectly due to the tricks in human language. For example, "He will continue to be the coach of Houston Rocket Team for the next season, congratulations to the other 31 teams" is ironic about the poor performance of the head coach of Houston Rocket team. But sentiment analysis cannot recognize the language trick and incorrectly assigned a positive emotion to this sentence based on the positive keyword "congratulations". Second, this study did not distinguish the social impacts of different microblogging users. Public figures and celebrities have much higher social impacts than ordinary people, and thus their messages and opinions typically have much higher influences during propagation. Some promising directions for future study include: improving sentiment analysis to recognize human language tricks, assigning different weights to microblogging users based on their social influence, and incorporating other public-accessible data resources (e.g. other types of social media) to assess and predict the trends of public opinions with higher accuracy.

Chapter 46
Artificial Intelligence in Stochastic Multiple-Criteria Decision Making

Hanna Sawicka
Poznan University of Technology, Poland

ABSTRACT

This chapter presents the concept of stochastic multiple criteria decision making (MCDM) method to solve complex ranking decision problems. This approach is composed of three main areas of research, i.e. classical MCDM, probability theory and classification method. The most important steps of the idea are characterized and specific features of the applied methods are briefly presented. The application of Electre III combined with probability theory, and Promethee II combined with Bayes classifier are described in details. Two case studies of stochastic multiple criteria decision making are presented. The first one shows the distribution system of electrotechnical products, composed of 24 distribution centers (DC), while the core business of the second one is the production and warehousing of pharmaceutical products. Based on the application of presented stochastic MCDM method, different ways of improvements of these complex systems are proposed and the final i.e. the best paths of changes are recommended.

INTRODUCTION

Nowadays, an integral part of any organization is the application of practical tools and techniques that make changes to products, processes and services resulting in an introduction of something new in a market. Improving continuously operations is essential for a better performance of the organizations. Due to the growing impact of globalization, migration, technological and knowledge revolutions, it brings added value to customers and helps organizations to remain competitive. Many of them are forced to make changes in various areas, such as: technology, infrastructure, human resources etc. Moreover, to meet customers' expectations and needs, companies should also consider organization's manager interests, as well as the supplier's opinions, customers' point of view and the other stakeholders' preferences. It makes the decision situation very complex and the application of decision aiding methods seems crucial.

According to Vincke (1992) multiple criteria decision making (MCDM) is a field which aims at giving the decision maker (DM) some tools in order to enable him/her to solve a complex decision problem where several points of view must be taken into account. This methodology concentrates on suggesting "compromise solution", taking into consideration the trade-offs between criteria and the DM's preferences. The above mentioned compromise solution is selected from the family of variants. They are constructed in different ways. In some situations, it is assumed that the variants are exclusive and at least two of them cannot be implemented together. There are also real-world situations where two or more alternatives can be introduced conjointly.

The variants are evaluated by the set of criteria, which should be characterized by the following aspects (Roy, 1985):

- Completeness due to the decision-making aspects of the considered problem.
- Appropriate formation, taking into account the global preferences of the decision maker.
- Non-redundancy, i.e. a situation in which semantic ranges of criteria are not repeated.

Thanks to the criteria it is possible to compare variants, especially when the performances are expressed as deterministic values. However, in some cases the alternatives are modeled e.g. in a simulation tool and their performances are presented as stochastic values. In such circumstances the comparison process becomes complex. It is usually supported by stochastic MCDM methods, but most of them concentrate on decision maker's stochastic preferences. Based on the author's experience the methods dedicated to solve complex decision problems with stochastic criteria values are not efficient enough.

The procedure presented in this chapter shows that the combination of a classical group of MCDM methods aiming at ranking of variants, e.g. Electre III, Promethee II, with probability formula or a classical method of artificial intelligence aiming at classification of objects, e.g. Bayes classifier, could solve these complex problems.

Electre III method (Roy, 1985; Vincke, 1992) belongs to the European school of MCDM and it is based on the outranking relation. The method requires determination the model of DM's preferences by the indifference q, preference p, and veto v thresholds, as well as weights w for each criterion j. The aggregation procedure starts from the calculation of concordance and discordance indices. The first one measures the arguments in favor of the statement that alternative a outranks alternative b, while the second index represents the strengths of evidence against the above hypothesis. Based on these indices the outranking relation is calculated. The ranking of variants is based on two classification algorithms: descending and ascending distillations. Descending distillation procedure starts from choosing the best alternative i.e. the one with the highest value of qualification index $Q(a)$ and placing it at the top of the ranking. $Q(a)$ equals the difference between the number of alternatives, which are outranked by the alternative a and the number of alternatives that outrank a. In the consecutive steps, the best alternative from the remaining set of alternatives is selected and placed in the second position of the ranking. The procedure stops, when the set of alternatives is empty. Ascending distillation procedure starts from choosing the worst alternative and placing it at the bottom of the ranking. Then the worst alternative from the remaining set of alternatives is selected and placed in the second worst position of the ranking. The final graph corresponding to the outranking matrix is the intersection of the two distillations. It constitutes a graphical representation of indifference I, preference P and incomparability R relations between alternatives.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Promethee II method (Brans et al., 1986), similarly as Electre III method, represents the European school of MCDM based on the outranking relation. The method requires determination of the model of DM's preferences by the selection of a type of a generalized criteria function $\rho(x)$ for each criterion j and definition of this function characteristic parameters. There are distinguished six types of preference functions, widely described by Brans et al. (1986). They represent the level of preference intensity of alternative a compared with alternative b regarding each criterion j. The criteria function equals from 0 to 1 and its value increases when the difference between compared alternatives is getting higher. Next, the outranking relation is defined. It is calculated on the basis of the multicriteria preference index π of alternative a regarding alternative b. This index corresponds to concordance index in Electre III method. Finally, the positive $\Phi+$ and negative $\Phi-$ flows for each alternative are calculated. The positive value of $\Phi+$ represents the strength of this alternative over all the other alternatives, while the negative value of $\Phi-$ shows the strengths of all alternatives over considered alternative. The difference between $\Phi+$ and $\Phi-$ constitutes the net flow. The higher the net value, the better position in the ranking. Based on this information a graphical representation of indifference I and preference P relations between alternatives is obtained.

Classification theory (Smola & Vishwanatan, 2008; Demsar, 2006) is a quantitatively oriented methodology that helps the DM to classify and categorize objects into predefined classes. There is a wide variety of classification methods reported in the literature (Berger, 1985; Demsar, 2006; Mitchell, 1997), including:

- Classification by the induction of decision trees (Pisetta et al., 2010; Quinlan, 1986).
- K-NN – nearest-neighbor classification (Bremner et al., 2005; Hall et al., 2008).
- Bayesian classification (Berger, 1985; Mitchell, 1987; Smola & Vishwanatan, 2008).
- Rough sets theory (Pawlak, 1982; Yao, 2011).
- Neural networks (Cetiner, et al. 2010; Wei & Schonfeld, 1993).

Many authors (Berger, 1985; Mitchell, 1987) claim that one of the most efficient method to solve real-world classification problems is Bayesian classification. Its advantage is precision and effectiveness when solving problems associated with the manipulation on the large sets of data.

Mitchell (1997) states that Bayes classifier can predict class membership probabilities, such as the probability that an unknown target function $f: x(a) \rightarrow C(z)$, featured by the highest conditional a posteriori probability $P(C(z)|x(a))$ belongs to a particular class $C(z)$. This notation can be interpreted as follows: a certain object x described by the vector of description attributes a, has a chance (probability) $P(C(z)|x(a))$ to be assigned to a certain class $C(z)$.

The algorithm of Bayesian classification is composed of 3 phases, such as (Mitchell, 1997):

- The construction of learning model i.e. classifier.
- Testing of the learning model.
- Classification of the vector of observations to predefined classes.

In the proposed approach this machine learning method is utilized to classify the relations between variants and to generate the final stochastic ranking of variants.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

In this chapter the combination of MCDM ranking method with Bayes classifier, and MCDM ranking method with classical probability formula are presented on real-world cases. The first one shows the distribution system composed of 24 distribution centers divided into 3 levels i.e. central, regional and local one. Different alternatives representing ways of changes are proposed. They are modeled in the simulation tool and evaluated by the consistent family of criteria. Their values are calculated on the basis of simulation experiments' results. They are presented as probability distributions. The decision problem is formulated as a multicriteria stochastic ranking problem. The above-described stochastic approach combining Promethee II method (Brans et al., 1986) and the probability formula is applied to solve it.

The second case presents pharmaceutical production company. Similarly, as in the previous case, the simulation model of the current state has been constructed and its redesign scenarios have been proposed and implemented in the simulation tool, as well. The set of evaluation criteria includes technical, organizational and social aspects. The values are presented as probability distributions. The decision problem is formulated as a multicriteria stochastic ranking problem. The stochastic approach combining Electre III method (Roy, 1985; Vincke, 1992) and Bayes classifier (Mitchell, 1997) is applied to solve it. In both cases, the computational results are completed by the sensitivity analysis.

BACKGROUND

Artificial intelligence (AI) is defined in two dimensions, i.e. the first one is a thought process and reasoning – an approach presented in the middle of 80's, while the second one is a behavior – many definitions were created at the beginning of 90's (Russel, & Norvig, 1995). Some of the researchers perceive this term as a field of study that seeks to explain and emulate intelligent behavior in terms of computational processes (Schalkoff, 1990).

Undoubtedly, since it beginning the goal of AI is to make machines do thing that would require intelligence if done by humans (Boden, 1977). In this context, intelligence can be defined as the ability to learn and understand, to solve problems and to make decisions (Negnevitsky, 2005). One of the topics of decision making widely described in the literature and applied in practice is multi criteria decision making (MCDM). Kahraman (2008) states that MCDM can be divided into two major approaches, i.e. multiple objective decision making (MODM) and multiple attribute decision making (MADM). In MODM problems the number of alternatives is usually large or sometimes it might be infinite. The alternatives are not given at the beginning of the decision process, but mathematical framework is provided for designing the set of them. Based on it the identified alternatives are evaluated and a level of multiple objective satisfactions is measured.

MADM problems, which are the most well-known within MCDM, are characterized by limited number of alternatives defined at the beginning of the decision process, by a number of decision criteria and additional information from decision maker or decision makers. The final solution of the MADM problem can be presented as a choice, sorting or ranking of alternatives. Based on this division, corresponding to the decision problem, MADM methods are classified into the following three groups:

- Choice methods, e.g. Genetic Algorithm (Goldberg, 1989), Pareto Simulated Annealing (Czyzak & Jaszkiewicz, 1998);
- Sorting methods, e.g. ELECTRE-TRI (Mousseau et al., 2000), UTADIS (Manshadi, 2015);

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

- Ranking methods, e.g. AHP (Saaty, 1980), Electre III (Roy, 1985; Vincke 1992), Promethee (Brans et al., 1986), UTA (Jacquet-Lagrèze & Siskos, 1982).

Many real-world problems, due to their complexity, are characterized by uncertainty. This phenomenon can be observed when the values of evaluation criteria are considered or the decision maker's preferences are collected. Thus, there are many modifications of the above-mentioned ranking methods, aiding the decision process. The examples of them are such as:

- SMAA-III (Tervonen & Figueira, 2008) – a modification of Electre III method.
- Stochastic PROMETHEE / GIS method (Marinoni, 2005) – a modification of Promethee method.
- Stochastic AHP method (Stam & Duarte Silva, 1997) – a modification of AHP method.
- Stochastic UTA method (Siskos, 1982) – a modification of UTA method.

SMAA-III

Stochastic Multicriteria Acceptability Analysis-III (Tervonen & Figueira, 2008) is a stochastic method of ranking alternatives based on outranking relation. It develops Electre III method by the non-deterministic components of the criteria values and decision maker's preferences. The values of criteria functions ξ_j corresponding to deterministic values $f_j(x)$ of density function $f\chi(\xi)$ in the space $\chi \subseteq R^{mxn}$, are presented as a probability distribution or expected value with its ranges of variations. Weights are also described by the probability distribution with the density function $f_W(w)$. Indifference q, preference p and veto v thresholds characteristic for Electre III method are defined by the decision maker and they are stochastic values represented by $\alpha_j(\cdot)$, $\beta(\cdot)$, $\gamma(\cdot)$ or by $\tau = (\alpha, \beta, \gamma)$. The issue of SMAA-III method is to aid the decision maker by computing the indices or paramters with the application of integrals of the area of stochastic values using Monte Carlo simulation method.

Based on the literature (Lahdelma et al., 1998; Tervonen & Figueira, 2008) there are presented three indices aiding the decisions, which are as follows: rank acceptability index, pair-wise winning index and incomparability index.

The computational procedure of SMAA-III method is composed of the three steps, presented below:

Step 1: Construction of the evaluation matrix and definition of the decision maker's preference model.
Step 2: Construction of the outranking relation based on the pair-wise winning index.
Step 3: Utilization of the outranking relation leading to the construction of the final ranking of alternatives based on the rank acceptability index and the incomparability index.

Stochastic Promethee

This method belongs to the group of MADM ranking methods (Marinoni, 2005). The values of criteria are presented as probability distributions. Marinoni (2005) suggests to use Monte Carlo simulation method to multiple sampling of the values of alternatives evaluated by each criterion, resulting in accumulated value ranging [0,1]. The number of iterations (samplings) should be as high as possible, i.e. at least 100 (Marinoni, 2005). The obtained results are the input data for further calculations carried out accordingly to Promethee method (Brans et al., 1986). They are presented as charts with alternatives'

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

values related to each final rank or as rankings of each alternative. The values of alternatives may differ and the selection of the compromise solution might be a difficult task. Thus, Marinoni (2005) suggests the application of MSR index - mean stochastic rank index, calculated for each alternative *i*. Then, the stochastic ranking index *SI* is computed (Marinoni, 2005).

The computational procedure of stochastic Promethee method is composed of the three steps, which are as follows:

Step 1: Construction of the evaluation matrix and definition of the decision maker's preference model.
Step 2: Construction of the outranking relation based on the stochastic ranking index.
Step 3: Utilization of the outranking relation leading to the construction of the final ranking of alternatives.

The above presented MADM methods are applied in many areas to solve problems connected with environmental issues (Delhaye et al., 1991; Malczewski et al., 1997; Salminen et al., 1998), industrial problems (Anand & Kodali, 2008; de Boer et al., 1998; Hafeez et al., 2002), business issues (Buchanan & Sheppard 1998; Halouani et al., 2009; Ngai, 2003), logistics problems (Badri, 1999; Behzadian et al., 2010; Sawicka et al., 2010).

They have many advantages, such as: precise modeling of decision maker's preferences (e.g. Electre III method), modeling of preferential function of each criterion (e.g. Promethee method), hierarchical representation of the problem giving the possibility to formalize the structure of the considered problem, very useful while the complex problems are considered (e.g. AHP method), possibility to solve the problem with a large number of alternatives i.e. more than 10 (e.g. UTA method) possibility to model the stochastic criteria values (e.g. SMAA-III method), possibility to model uncertain preferences of the decision maker (e.g. stochastic Promethee method, stochastic AHP method, stochastic UTA method).

However, these methods are not devoid of disadvantages, e.g. adding or removing of one alternative could change the power of preferences between remaining variants, resulting from the distillation procedure in Electre III method; solving very complex decision problems is time consuming and many information must be collected (e.g. SMAA-III method, AHP mathod) or many iterations must be carried out (e.g. stochastic AHP method), some methods do not provide modeling of subcriteria (e.g. Promethee and stochastic Promethee methods), to construct reference set of alternatives, their number must be higher than 10 (e.g. UTA method) and finally to define values of criteria the probability distributions of each of them must be calculated, which is time consuming (e.g. stochastic UTA method).

THE METHODOLOGY OF SOLVING STOCHASTIC RANKING MADM PROBLEMS

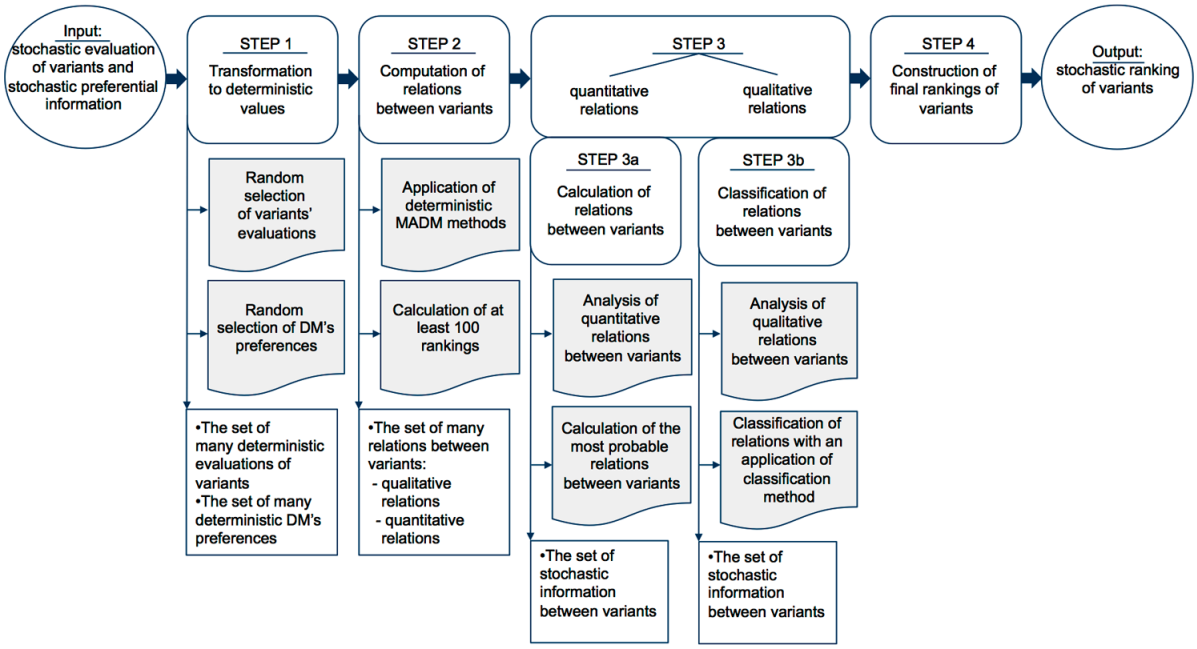
Solving complex multiple criteria decision problems is often very difficult. On the one hand, some of the MADM methods are not suitable for the considered issues e.g. the solution of stochastic problems with an application of deterministic methods would fail or simplify the question. However, many analysts or decision makers are very used to one or a group of such methods. This subjective perspective is a result of their wide experience and knowledge.

On the other hand, the multiple criteria methods dedicated to solve particular class of problems could not always cope with them due to their specific characteristics.

The author of this chapter proposes the MADM method to solve complex ranking decision problems with stochastic information of criteria values and/or stochastic preferential information. The general idea

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

is based on the transformation of the stochastic input information to deterministic values, which are then converted to stochastic final ranking of variants. The transformation encompasses the application of multiple criteria decision aiding methods and classification method or probability formula.



It is composed of 4 steps presented in Figure 1 and characterized below.

It is assumed that the character of the input information is fully stochastic or mixed - stochastic and deterministic. It usually happens when many aspects of the analyzed situation are considered and modeled in the simulation tool. As a result the evaluation of alternatives is stochastic and the decision maker expresses his/her hesitation of preferences. In such situations DM's preferences are defined as non-deterministic values.

The first step of the proposed procedure is the transformation of these values to deterministic information. If the analyzed problem is composed of stochastic evaluations of alternatives, then each of them is converted to at least 100 deterministic values using random number generator. One of the well-known is Monte Carlo method (Law & Kelton, 2000), which relies on repeated random sampling. The parallel operation can be done with stochastic preferential information, e.g. values of thresholds in Electre III method, pairwise comparisons between criteria, subcriteria and alternatives in AHP method. As a result, the set of many deterministic evaluations of alternatives and/or deterministic DM's preferences is obtained.

Based on them it is possible to calculate the relations between alternatives with an application of MADM ranking method – the second step. The number of rankings is at least 100. The type of relation between alternatives, i.e. quantitative or qualitative, depends on the applied method. Some of them, e.g. Promethee II, AHP methods provide precise distance between alternatives in the final rank, while other methods, e.g. Electre III, Promethee I present the qualitative relations, such as indifference, preference and incomparability.

Figure 1. Solution procedure of the stochastic multiple criteria decision problem
Source: Author's research based on Sawicka (2012)

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Thus, the third step is divided into two alternate parts *a* and *b*. In the step 3a the quantitative measures between alternatives are analyzed and the most probable relations are calculated. The step 3b is dedicated to qualitative relations between pairs of variants. Due to high number of results obtained in the previous step, the classification method is proposed. It helps to classify relations between alternatives to predefined classes (decision attributes). The result of both cases is the set of stochastic information between alternatives.

The fourth step is based on construction of the final ranking of variants. The probabilities of occurrence of particular relations between them are computed. The sensitivity analysis is advised. Finally, the stochastic ranking of alternatives is obtained.

SOLUTIONS AND RECOMMENDATIONS: APPLICATION OF STOCHASTIC MADM RANKING METHOD

Ranking of Distribution System Redesign Alternatives Using Promethee II Method and Probability Formula

Problem Definition

The first case study shows the distribution system of electrotechnical products. It is characterized by a high complexity. The system is composed of 24 distribution centers (DC) divided into 3 levels i.e. central with 1 DC, regional with 12 DC and a local one with 11 DC spread all over Poland. More than 75 suppliers supply these distribution centers and around 400 main customers are served. There are distributed various electrotechnical products, such as sockets, bulbs, extension cords, clusters, wires. There can be distinguished 38.000 assortments. The detailed analysis of the system reveals many strengths e.g. modern fleet and handling equipment, well developed promotion, highly qualified staff, as well as weaknesses i.e. high level of inventories, repetition of tasks in different organizational units, low utilization of the warehouse areas. Thus, different ways of changes based on system's redesign are proposed. Due to its complex character, the simulation model of a current state is constructed. It allows formalizing material and information flow in the system. Based on the simulation experiments the bottlenecks are recognized and quantitative analysis is carried out. The final information of the system is presented as a set of evaluation criteria. They represent various aspects i.e. technical, organizational, economical, social and environmental and the criteria are as follows:

C1: Time of delivery [days] – minimized criterion,
C2: Costs of distribution per month [m PLN] – minimized criterion,
C3: Utilization of in-company transportation means [%] – maximized criterion,
C4: Rotation level of inventory [days] – minimized criterion,
C5: Efficiency of system's employees (deviation from the optimum value) [%] – minimized criterion,
C6: Share of outsourced transportation orders [%] – maximized criterion,
C7: Difference between the levels of investments and divestments [m PLN] – minimized criterion.

Next, the distribution system's heuristically constructed 4 redesign scenarios are modeled in the simulation tool. They represent different changes resulting from the following aims:

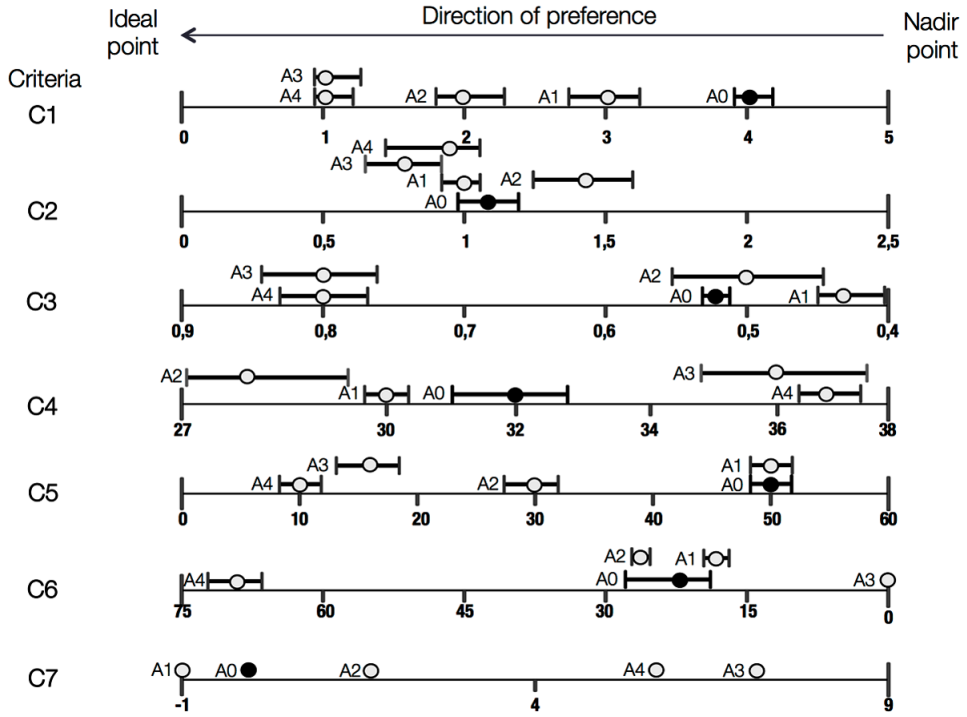
EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Alternative A1: Reduction of distribution costs by eliminating the least effective distribution center; increasing the turnover, improving efficiency ratio;

Alternative A2: Reduction of the delivery time by shortening the distance between the distribution centers and customers, increasing the turnover, improving efficiency ratio connected with human and technical resources;

Alternative A3: Reduction of distribution costs by eliminating 11 local DC, reduction of the delivery time;

Alternative A4: Reduction of distribution costs by eliminating 11 local DC, reduction of inventory on regional level, reallocation of central DC, reduction of the delivery time.



The consistent family of criteria evaluates the alternatives, including the current state represented by alternative A0. The criteria values are calculated on the basis of simulation experiments' results. They are presented as probability distributions. See Table 1.

Table 1. Performance matrix of the distribution system of electrotechnical products and its redesign scenarios

Criteria			Alternatives				
Name	**Direction of preferences**	**Value**	**A0**	**A1**	**A2**	**A3**	**A4**
C1	Min	Expected value	4	3	2	1	1
		Range of variation	[3,87; 4,13]	[2,76; 3,20]	[1,78; 2,30]	[0,95; 1,25]	[0,95; 1,13]
C2	Min	Expected value	1,1	1,0	1,4	0,8	0,9
		Range of variation	[0,95; 1,17]	[0,87; 1,05]	[1,24; 1,60]	[0,65; 0,87]	[0,72; 1,04]
C3	Max	Expected value	0,52	0,43	0,50	0,80	0,80
		Range of variation	[0,51; 0,53]	[0,41; 0,45]	[0,44; 0,57]	[0,76; 0,85]	[0,77; 0,83]
C4	Min	Expected value	32	30	28	36	37
		Range of variation	[31,33; 32,67]	[29,84; 30,24]	[27,19; 29,49]	[34,96; 37,44]	[36,68; 37,24]
C5	Min	Expected value	50	50	30	15	10

Figure 2. Alternatives' positions regarding evaluation criteria

The graphical representation of the alternatives' distance to the ideal point (represented by the most desirable criteria values) and the nadir point (characterized by the most undesirable criteria values) (Vincke, 1992) is shown in Figure 2.

Based on the information presented in Table 1 and Figure 2, it is hard to decide which alternative is the compromise solution. The following aspects have the most important influence on this situation:

- Ambiguity of alternatives' evaluation i.e. some of them have the best values on one criterion while on the other they are close to the worst position, e.g. alternative A4 has the best value on criterion C6 and its position with respect to criterion C4 is the worst;
- Uncertainty of the alternatives' mutual position regarding each criterion i.e. in some criteria their ranges of variations are almost evenly distributed between the ideal and nadir point e.g. positions of variants regarding criterion C1, while on the other criteria part of the set of alternatives is cumulated around one value e.g. alternatives A0, A1, A2 regarding criterion C3 and distant from the other part of variants e.g. A3 and A4;
- Difficulty in evaluating such a large collection of information i.e. many criteria and alternatives, many data records, different levels of criteria importance expressed by the DM.

Based on these ambiguities, uncertainties and difficulties with interpretation of data the multicriteria stochastic ranking problem has been formulated. The above-described stochastic approach combining Promethee II method and the probability formula is applied to solve it.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Computational Experiments

In the first step of the computational procedure, decision maker's preferences are modeled according to the principles of Promethee II method. The type 5 of the generalized criteria function ρ(x), which is characteristic for this method, is selected. The DM has assigned different weights to criteria, using the scale of 1 to 10 points, representing the least and the most important criteria, respectively. They are presented in Table 2. Based on the model of the DM's preferences one can conclude that the most important criterion is time of delivery – C1, while the least important one is the share of outsourced transportation orders – C6.

The definition of thresholds is a complex task. Thus, the analysis of difference between criteria values has been carried out based on the expected values and ranges of variation, too. The DM has decided to assign the values of q (indifference threshold) and p (preference threshold), using the information presented in Table 1.

The results indicate that the DM is highly sensitive to changes of some values of criteria e.g. C2 (one of the most important criterion), where the indifference threshold equals 0,05 and preference threshold equals 0,10; and his sensitivity to changes is rather low regarding other criteria e.g. C6 (the least important criterion), where the indifference threshold equals 3,00 and preference threshold equals 5,00.

Next, the random numbers of each criterion value have been generated. For this purpose, the Monte Carlo method has been applied. The number of iterations generating random numbers of criteria evaluating each alternative equals 150 and it provides large sample of random deterministic parameters. The example of results is presented in Table 3.

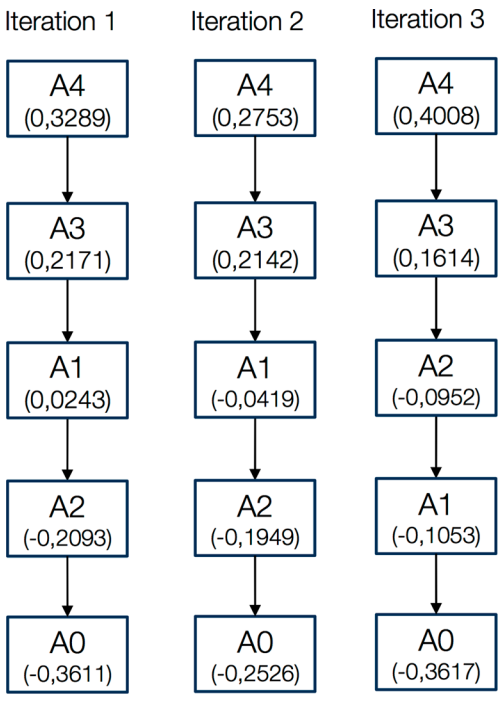
Based on the data records presented in Table 3 one can conclude that the generated values are randomly dispersed in the ranges of variations and some values equal the minimum or maximum value of these ranges.

The results of iterations are the input data for the computational experiments (second step) with an application of MADM ranking method Promethee II. Thus, the total number of calculations equals 150.

The exemplary 3 results are presented in Figure 3.

The additional information to final rankings is the net flow value in Promethee II method. The relations between alternatives are very similar. However, the distances between them represented by the net flows vary e.g. the highest difference in the analyzed net flows is between alternatives A1 in the first and third ranking. The difference between net flow values of alternative A3 in these rankings is very low. Thus, the distance between A1 and A3 in the first ranking is small, while in the third one is very high.

Table 2. The model of DM's preferences for the distribution system



Criteria	Weights	Thresholds	
		Indifference q	Preference p
C1	10	0,60	1,10
C2	9	0,05	0,10
C3	5	0,10	0,20
C4	5	2,00	4,70
C5	6	6,00	14,00
C6	4	3,00	5,00
C7	7	0,50	1,00

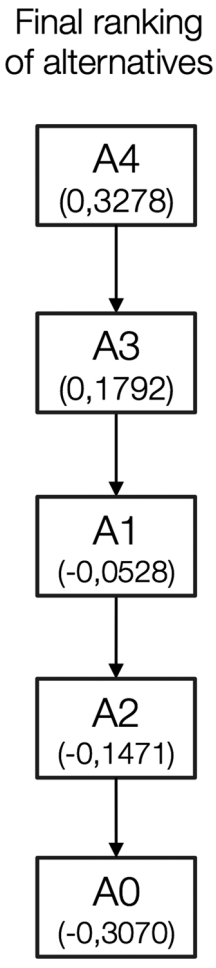
Table 3. Deterministic values of criteria randomly generated with an application of Monte Carlo method – the distribution system

Criteria	Alternatives				
	A0	**A1**	**A2**	**A3**	**A4**
Iteration 1					
C1	4,06	3,02	2,05	1,07	1,13
C2	0,95	0,89	1,55	0,87	0,81
C3	0,52	0,43	0,44	0,82	0,80
C4	31,79	30,16	29,00	36,16	36,91
C5	50,43	48,96	30,39	14,87	11,80
C6	19,81	18,72	22,82	0,00	69,02
C7	0,0	-1,0	2,7	7,5	5,8
Iteration 2					
C1	4,07	2,77	2,13	1,05	1,07
C2	1,09	0,89	1,57	0,67	0,83
C3	0,51	0,45	0,44	0,82	0,78
C4	32,63	30,07	28,18	37,14	37,05
C5	50,96	51,45	31,32	13,49	11,31
C6	23,12	19,12	22,60	0,00	68,41
C7	0,0	-1,0	2,7	7,5	5,8

Figure 3. Three selected final rankings of alternatives resulting from calculations with an application of Promethee II method



EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

In most of the rankings the best position is occupied by A4, the second location has A3 and the third one – A1. The next position has the alternative A1 and the last one – A0. In the last ranking the locations of alternatives A1 and A2 are switched.

Analyzing the total set of data composed of 150 rankings with the distance between alternatives (quantitative information), the author of this paper has decided to calculate the expected value of the relations between these variants. These computations constitute the third step of the presented stochastic MCDM method and the result is presented in Figure 4. Finally, in the fourth step the final ranking of alternatives is shown. See Figure 4.

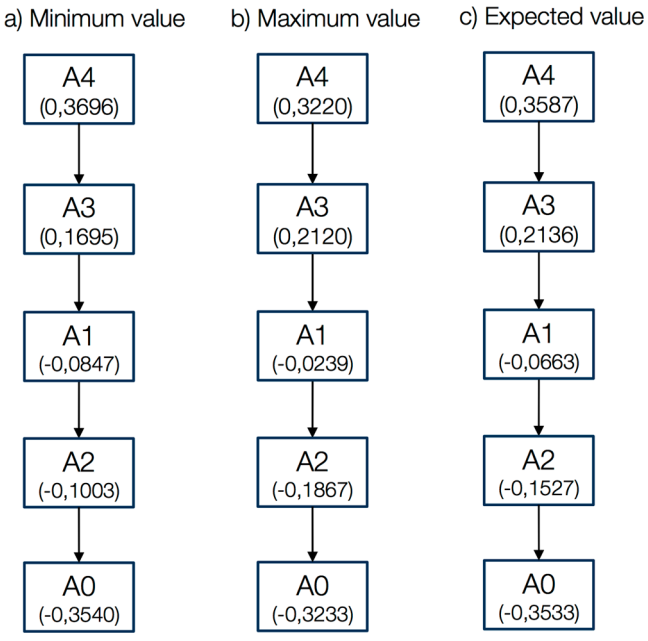
The best scenario is the alternative A4. It represents the most radical changes in the analyzed distribution system. Next position in the ranking is occupied by the alternative A3. The changes modeled in this variant are significant, too. On the third position is the alternative A1, which is featured by slight changes in the existing distribution system of electrotechnical products. On the fourth location is the alternative A2 and the worst position is occupied by the current state of the system represented by the alternative A0.

Figure 4. Final ranking of alternatives with the expected values of net flows

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

The computational experiments are finished by the sensitivity analysis. It is carried out for the minimum (Figure 5a), maximum (Figure 5b) and expected values (Figure 5c) of ranges of variations of each alternative evaluated by the set of criteria.

The results of the sensitivity analysis show that the rankings of alternatives are the same in terms of internal comparison and regarding the final ranking presented in Figure 4. The net flows are not the same. However, the difference between them is not significant. It is worth to mention that the expected value of the net flow (Figure 4) and the net value calculated for the expected values of the alternatives evaluated by the set of criteria (Figure 5c) are very close. The minimum difference between them equals 0,0056 - for the alternative A2 and the maximum difference is 0,0463 – for the alternative A0.



Based on the analysis of the final ranking of alternatives and the sensitivity analysis the author of this chapter recommends the most radical changes in the analyzed system represented by alternative A4. This step should radically improve the organization of the distribution system, while the current state is the worst scenario.

Ranking of Redesign Variants of Warehouse with Pharmaceutical Products Using Electre III Method and Bayes Classifier

Problem Definition

The second case presents company operating in Poland. Its core business is the production of pharmaceutical products. One of the important infrastructural objects of the company is a warehouse of finished goods. The composition of its rooms includes, among others: reception area, storage rooms, picking zone, edition zone and offices. In the area of admissions there is made an acceptance of the products

Figure 5. (a) Rankings of alternatives with the values of net flows for the minimum; (b) maximum; (c) expected values of ranges of variations

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

and their control (qualitative and quantitative). Storage facilities are divided into three zones, i.e. high storage (inventories are stored in 5-levels' stacks), low storage (replenished by goods from high storage zone, picking takes place there) and the cold room (temperature is maintained at 2-6° C). Based on the detailed analysis of the system its major drawbacks are recognized, such as: zone admission is often full, and vehicles with finished goods have to wait for unloading (sometimes several days). There are numerous overtimes associated with the picking process. Similarly, as in the previous case, the simulation model of the current state has been constructed and its redesign scenarios have been implemented in the simulation tool, as well. The set of evaluation criteria includes technical, organizational, economical and social aspects. The values are presented as probability distributions and they are as follows:

K1: Efficiency of warehouse employees (deviation from the optimum value) [-] – minimized criterion,
K2: Utilization of in-company transportation means [%] – maximized criterion,
K3: Efficiency of warehousing process [%] – maximized criterion,
K4: Difference between the levels of investments and divestments [PLN K] – minimized criterion.

The set of redesign scenarios is composed of 5 variants. They fulfill the following aims:

Variant V1: Increasing the employment in the warehouse leading to the improvement of employees efficiency ratio;
Variant V2: Reduction of the in-company transportation means, improving the efficiency ratio connected with technical resources;
Variant V3: Decreasing the queue of vehicles waiting for unloading, improving the efficiency ratio connected with human and technical resources;
Variant V4: Redesign of the warehouse area, improvement of the warehousing process;
Variant V5: Redesign of the warehouse area, reduction of the in-company transportation means, reallocation of tasks leading to the improvement of efficiency of human and technical resources and better organization of the warehouse.

The values of variants evaluated by different criteria are calculated on the basis of simulation experiments. They are presented in Table 4.

Table 4. Performance matrix of the warehouse with pharmaceutical products and its redesign scenarios

Criteria				Variants				
Name	**Direction ofpreferences**	**Value**	**V0**	**V1**	**V2**	**V3**	**V4**	**V5**
K1	Min	Expected value	15	1	4	5	8	5
		Range of variation	[14; 16]	[0; 2]	[0; 9]	[2; 13]	[6; 10]	[1; 11]
K2	Max	Expected value	43	39	84	82	78	88
		Range of variation	[25; 58]	[27; 58]	[73; 90]	[70; 87]	[68; 80]	[80; 92]
K3	Max	Expected value	89	91	90	97	100	98
		Range of variation	[80; 94]	[85; 96]	[84; 98]	[90; 99]	[99; 100]	[97; 100]
K4	Min	Expected value	0	0	-20	100	230	190
		Range of variation	-	-	[-35; -18]	[85; 120]	[200; 250]	[170; 210]

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

The decision problem is formulated as a multicriteria stochastic ranking problem.

As in the previous case study, it is hard to decide which alternative is the compromise solution while the information presented in Table 4 is considered. Some variants have the best performance on particular criteria, such as V1 on criterion K1, and V2 on criterion K4, and V4 on criterion K3, and V5 on criterion K2, while on the other criteria their values are the worst, such as V1 on criterion K2 and V4 on criterion K4. Variant V3 hasn't got the best nor the worst value of its performance. However, on some criteria its performance is very good, e.g. criteria K2 and K3, while on the others is very poor, e.g. K4.

Thus, the stochastic approach combining Electre III method and Bayes classifier is applied to solve it.

Computational Experiments

The first step of the computational procedure is based on modeling of decision maker's preferences according to the principles of Electre III method. At the beginning, the DM has assigned different weights to criteria. He has used the scale of 1 to 10 points, where 1 represents the least important criterion and 10 – the most significant one. Next, the thresholds values i.e. q (indifference), p (preference) and v (veto) have been specified. Weights and thresholds are presented in Table 5.

Model of the DM's preferences indicates that the economical issues are the most important. They are represented by criterion K4. Very significant meaning has the general operation of the warehouse, i.e. criterion K3. Criteria K1 and K2 representing social and technical aspects are important, too. However, the weights assigned to them are the lowest in the total set of evaluations.

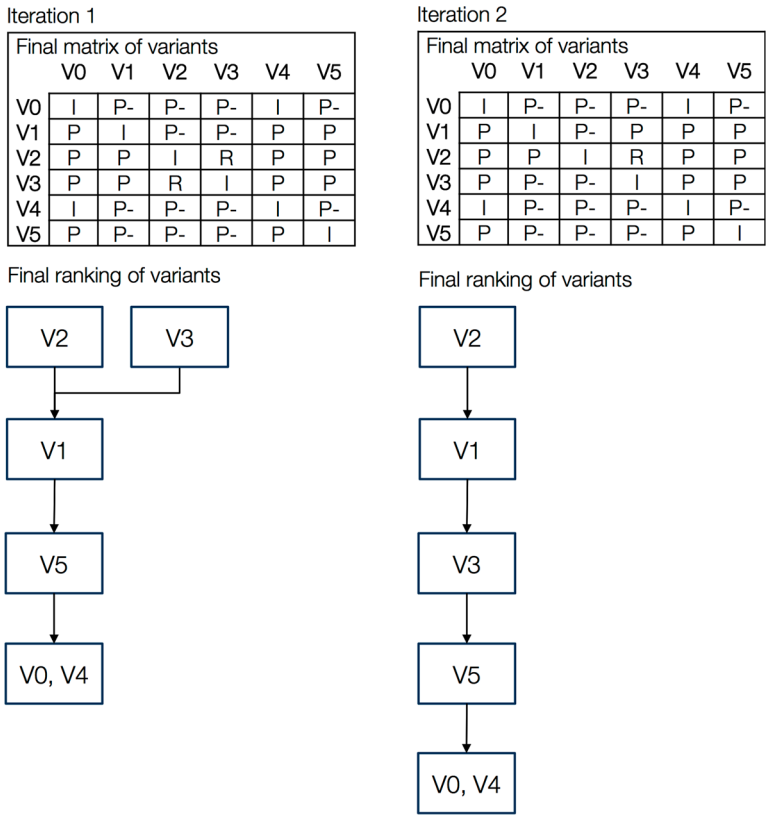
The DM is sensitive to changes. Some aspects of redesign scenarios make them incomparable with the current state, which is emphasized by the veto threshold, e.g. V2 vs. V0 regarding the criterion K1. Carrying out pairwise comparison of variants, some of them are weakly preferred, e.g. V3 vs. V1 regarding the criterion K3 or strongly preferred to each other, e.g. V3 vs. V5 regarding the criterion K4.

Next, computations within this step are based on the random numbers of each criterion value generation. For this purpose, the Monte Carlo method has been applied. The number of iterations equals 150 providing sufficient sample of deterministic parameters for the next step of calculations. The exemplary sets of 3 iterations are presented in Table 6.

The values presented in Table 6 are randomly dispersed in the ranges of variations. Some of them are very close to the minimum or maximum values of these ranges.

In the second step, based on the results of all iterations the deterministic values are the input data for the computations with an application of MADM ranking method Electre III. Similarly, as in Promethee II method, the total number of calculations equals 150.The exemplary 2 results are presented in Figure 6.

Table 5. The model of DM's preferences for the warehouse of pharmaceuticals



Criteria	Weights	Thresholds		
		Indifference q	Preference p	Veto v

Figure 6. Two selected final matrices of variants and their graphical representation resulting from calculations with an application of Electre III method

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

These two matrices present the following relations: indifference I, preference P, reciprocal of preference P- and incomparability R. In both rankings, the indifference I relation is between V0 and V4 variants, the preference P relation is between V2 and V1, the reciprocal of preference P- relation is between variants V5 and V1, while the incomparability R relation can be observed between variants V2 and V3 in the first iteration.

The detailed analysis of the total set of data composed of 150 matrices, rankings and pairwise comparisons between variants' relations (qualitative information), led the author of this chapter to the conclusion that there are many differences between them. Based on that, it is hard to present the DM final recommendation regarding the changes in the analyzed warehouse. Thus, the classification of these relations and their allocation to predefined classes has been made. This allocation corresponds to the definition of decision attributes. The classification is also the third step of the presented stochastic MCDM method. Bayes classifier has been applied to solve this problem.

Initially, 150 matrices have been split into 15 sets with 10 matrices in each of them. For each set the relations between variants represented by the description attributes (i.e. indifference I, preference P, reciprocal of preference P- and incomparability R relations) have been recognized and the probabilities of occurrence of particular relationships in the whole set have been calculated. See Table 7.

The values of description attributes are in the range [0,1]. Based on them the decision attributes with the following rules have been constructed:

- If the probability of the description attribute for a relation between variants has the value greater than 0,5 then the decision attribute is the same as the description attribute
- If the probabilities of the description attributes P- and R for a relation between variants have the same values lower than 0,5 then the decision attribute is the incomparability relation (R)
- If the probabilities of description attributes I and P for a relation between variants have values 0,5 then the decision attribute is a weak preference relation (Q)
- If the probabilities of description attributes I and P- for a relation between variants have values 0,5 then the decision attribute is a reciprocal of weak preference relation (Q-)

Table 7. The results of computational experiments of the share of relations I, P, P-, and R between pairs of variants for a part of testing set and their assignment to decision attributes

Relation between variants	Description attribute				Decision attribute (Class)
	I	P	P-	R	
V0-V0	1	0	0	0	I
V0-V1	0	0	1	0	P-
V0-V2	0	0	1	0	P-
V0-V3	0	0	1	0	P-
V0-V4	0,8	0,1	0,1	0	I
…					
V1-V3	0	0,2	0,4	0,4	R
…					
V2-V3	0	0,7	0	0,3	P
…					

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

As a result, 6 decision classes (attributes) C(z) has been distinguished, such as:

C(I) = I: Indifference relation between variants
C(P) = P: Strong preference relation between variants
C(P-) = P-: Reciprocal of strong preference relation between variants
C(R) = R: Incomparability relation between variants
C(Q) = Q: Weak preference relation between variants
C(Q-) = Q-: Reciprocal of weak preference relation between variants

Next, the training set T composed of 10 sets of matrices has been randomly selected and its testing has been carried out. Based on the information collected in this set, the a priori probabilities P(C(z)) of an event that the classes C(z) occur as well as the conditional a priori probabilities P(x(a)|C(z)) have been calculated.

The remaining 5 sets of matrices (out of 15) have been utilized in the computational experiments. The conditional a posteriori probability has been calculated for each pair of variants. Based on it and based on the a priori probability of an event that the class C(z) occur, the conditional a posteriori probability P(C(z)|x(a)) that a certain relation between variants occurs has been calculated.

For each pair of variants from the testing set the classification error β has been calculated. It equals 0,06, which means that the training model has been constructed correctly. The credibility of selected classification method in solving the presented problem is high.

The vector of observations with a priori unknown decision attributes has been selected. This vector has been composed of 30 relations between pairs of variants and has been characterized by the description attributes. They are the basis to assign 30 decision attributes concerning the relations between variants. 14 pairs of variants have been classified to class P, 14 pairs to class P- and remaining 2 pairs – to class I. No pair of variants have been classified to the decision attributes Q, Q- and R.

In the fourth step the final matrix and ranking of variants have been generated. The results are presented in Figure 7.

The final relations between variants are presented in the matrix (Figure 7a) as bold text. The information of probabilities of occurrence of particular relations between variants is also demonstrated. For example, the final relation between variants V0 and V4 is I (indifference) and the probability of its occurrence equals 0,720. This stochastic ranking matrix is transformed into the final ranking of variants and presented in Figure 7b. The best solution is at the top of the ranking, while the worst one - at the bottom. Dotted rectangular box is drawn for two variants for which the probability of occurrence of preference P and indifference I relations are close to 0,5. The analyst recognizes this pair of variants as almost indifferent.

Next, the ranking has been analyzed. The leader is variant V2. It is featured by slight changes i.e. reduction of in-company transportation means. The second position has the variant V3. It represents more radical changes in the organization of warehouse, leading to a higher level of internal fleet utilization, improvement of human resources efficiency ratio and radical reduction of vehicles waiting for unloading.

The strength of preference relation between V2 and V3 is high (0,993), which means that the distance between them is long with a high degree of certainty. Fourth and fifth location in the final rank have variants V1 and V5, representing evolutionary and revolutionary changes, respectively. The probability of preference and indifference relation between them is very close, i.e. 0,527 (P) and 0,466 (I). Thus, they are marked by the dotted line. The worst position in the ranking have variants V0 and V4. The relation between them is indifference I (0,720) and they are presented in one box.

Figure 7. (a) The stochastic ranking matrix representing the mutual relations between variants and (b) the final stochastic ranking of variants showing the positions of variants in the graphical form

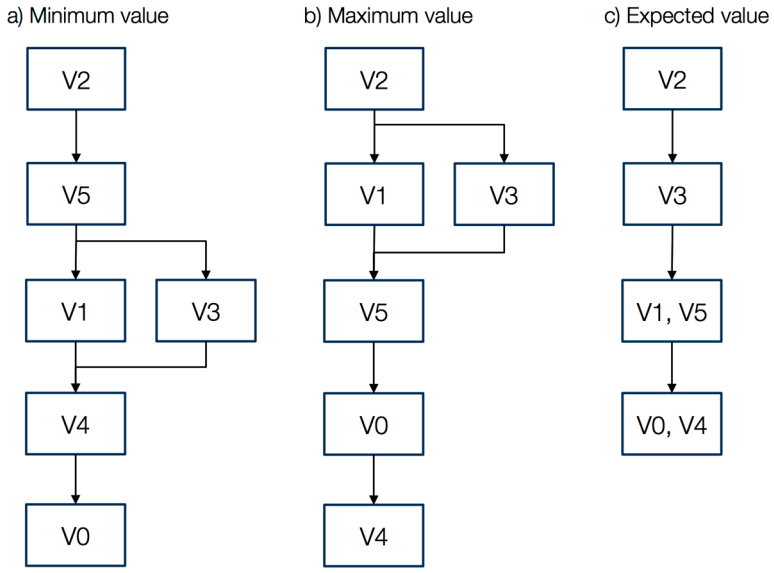
a) Stochastic ranking matrix

	V0	V1	V2	V3	V4	V5
V0	I (1,000)	P- (0,993) I (0,007)	P- (1,000)	P- (1,000)	I (0,720) P (0,267) P- (0,013)	P- (0,993) I (0,007)
V1	P (0,993) I (0,007)	I (1,000)	P- (1,000)	P- (0,720) R (0,267) P(0,013)	P (1,000)	P (0,527) I (0,466) P- (0,007)
V2	P (1,000)	P (1,000)	I (1,000)	P (0,993) R (0,007)	P (1,000)	P (1,000)
V3	P (1,000)	P (0,720) R (0,267) P- (0,013)	P- (0,993) R (0,007)	I (1,000)	P (1,000)	P (0,993) P- (0,007)
V4	I (0,720) P- (0,267) P (0,013)	P- (1,000)	P- (1,000)	P- (1,000)	I (1,000)	P- (1,000)
V5	P (0,993) I (0,007)	P- (0,527) I (0,466) P (0,007)	P- (1,000)	P- (0,993) I (0,007)	P (1,000)	I (1,000)

b) Final ranking of variants

Finally, the sensitivity analysis has been carried out. Similarly as in the previous case, the final rankings for minimum, maximum and expected values of criteria evaluating variants have been calculated. They are presented in Figure 8.

The results of the sensitivity analysis show that the rankings of variants are similar. All of them present variant V2 as the best scenario. Variants V0 and V4 are the worst redesign scenarios. However, their position is ambiguous – the following relations can be observed: I, P, P-. In two rankings the relation between variants V1 and V3 is R, while in one ranking it is P-. They are presented on the second or third location. In two rankings third position is occupied by the variant V5 and in one ranking this variant is on the second location.



Based on the analysis of the final stochastic ranking of variants and the sensitivity analysis the author of this chapter recommends evolutionary changes in the analyzed warehouse. They should be a good start for more radical transformation of the system.

FUTURE RESEARCH DIRECTIONS

The consciousness of problems related to complex systems makes that the artificial intelligence becomes very eligible field of research. Intelligence combined with the application of selected MADM methods, probability theory and machine learning methods allows generating credible solutions, especially when dealing with uncertain and dynamically changing different systems' environments. They can be represented by the stochastic information bringing closer to the reality.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 8. (a) Ranking of alternatives for the minimum; (b) maximum; (c) expected values of ranges of variations calculated with an application of Electre III method

Thanks to the artificial intelligence it is possible to aid the decision process, i.e. to analyze and model unstructured decision situations, to take into account different points of view represented by the set of evaluation criteria, to collect preferential information, to generate reliable results and recommend satisfactory solutions. Based on these operations the general aim of systems operating on different markets, which is the improvement leading to the competitive advantage and constant development, can be achieved.

Considering systems presented in this chapter, it is worth mentioning about their complexity. This aspect has an influence on each step of their (and other systems) improvement. Systems' analysis and data collection has been the most time consuming process. At this stage, the artificial intelligence has been very helpful in finding, ordering the data and transforming them to the required form, as well. MADM methods have provided the bridge between the analytical part of the research and real-world information. They also have played an important role in coping with structuring process of the DM's preferences. The huge number of information the DM had to deal with during the analysis, raised doubts and sometimes disbelief of this process success. However, the step-wise procedure has helped to structure and clarify the situation. The probability analysis and Bayes classification method confirmed in the belief that the recommended solution is the best one taking into account the set of criteria and preferential information.

Undoubtedly, artificial intelligence plays an important role during the ordering of information, computational experiments, finding the best solutions. It also helps to cope with social problems, decision maker's doubts and uncertain information.

The next step in solving complex, stochastic decision problems would be concentrated on shortening the time of finding the best solution. Generally, the computational experiments with the application of stochastic MADM methods are time consuming and the algorithm of stochastic MADM method presented in this chapter, as well. Both cases proved that the computational procedure takes long hours and it is very laborious. One of the solutions is the implementation of this idea in computer – based decision support system developed to solve complex decision problems.

CONCLUSION

In this chapter, some deterministic ranking methods like Electre III (Roy, 1985; Vincke, 1990), Promethee II (Brans et al., 1986) and stochastic ranking methods like SMAA-III (Tervonen & Figueira, 2008), stochastic Promethee (Marinoni, 2005) have been presented. Based on them it is possible to solve decision problems with different types of data, i.e. stochastic values of criteria evaluating the set of alternatives, uncertain DM's preferences, his/her hesitations. However, some decision situations are very complex and the application of existing methods would not result in a desirable solution.

Thus, the concept of stochastic multiple criteria decision making method to solve such decision problems has been presented. The proposed approach can be implemented to solve complex decision problems aiming at ranking of variants. It is based on a composition of classical methodologies, i.e. MADM, probability theory and classification method. Depending on the considered situation, this stochastic method gives the opportunity to solve problems with deterministic, stochastic and mixed information about the alternatives evaluated by the set of criteria, and uncertain preferences of the decision maker.

After successful implementations of the proposed approach, results show the most desirable direction of changes leading to high improvements of both analyzed systems.

It is proved that the combination of classical methods and tools would result in a reasonable solution. Undoubtedly, it is time consuming and the final application would make it user friendly.

Artificial intelligence is still evolving. The recent subjects of research interests within its one area i.e. multiple criteria decision aiding, constitute future directions. They are, among others, as follows:

- The selection of the most suitable MADM method, which has been the subject of research of Guitouni and Martel (1998), Sawicka (2012)
- Robustness analysis, widely described by Dias and Climaco (1999) and recently presented by Zavadskas et al. (2013);
- Multiple decision makers, including group decision making process, public participation etc., with general issues presented by Keeney (1976), Belton and Stewart (2002) and recently presented by Yue (2011)

KEY TERMS AND DEFINITIONS

Classification Theory: The research field of artificial intelligence concentrated on categorization of objects to predefined classes. It is assumed that these objects are characterized by quantitative information.

Decision Maker: A person, who expresses his/her preferences, evaluates the decision situation and the results of the computational experiments. This person makes the final decision regarding the considered problem, e.g. selects the best redesign scenario.

Decision Problem: A situation where the decision maker has to face the problem of selecting one of at least two alternatives. The decision problem is composed of the description of the decision situation, definition of constraints and evaluation criteria, identification of the decision maker and his/her role in the decision process and definition of stakeholders, as well.

MADM: An abbreviation of Multiple Attribute Decision Making. It is one of the Multiple Criteria Decision Making approaches referring to the situation of finite set of alternatives evaluated by the set of attributes leading to the selection of the best solution.

MCDM: An abbreviation of Multiple Criteria Decision Making. It is composed of two approaches, i.e. MADM (Multiple Attribute Decision Making) and MODM (Multiple Objective Decision Making). In MADM problems the number of alternatives is finite and the evaluation attributes are usually conflicting, while in MODM problems the set of alternatives is infinite and the evaluation criteria are described by continuous function.

Ranking Methods: A group of MCDM methods concentrated on finding the final hierarchy of alternatives, i.e. the rank. Generally, ranking methods are divided into two sets referring to different methodological backgrounds. The first one originates from European school and it is based on outranking relation, e.g. Electre III, Promethee II methods. The second one, belongs to American school and it is based on multiattribute utility theory, e.g. AHP, UTA methods.

Stochastic Information: Information represented by a random number, usually by a random probability distribution. It is connected with uncertainty about the values of parameters, expected input or output information. In the real-world systems the stochastic information is the result of unexpected disturbances, demand fluctuations etc.

ABSTRACT

Educational Informatics is a multidisciplinary research area that uses Information and Communication Technology (ICT) in education. This article reports a wide overview about the new perspective of educational informatics that has been implemented in Latin America. This general view is the result of the different talks presented during the XIII Conference of Educational Informatics, organized by the Ibero-American Network of Educational Informatics RIBIE (Red Iberoamericana de Informática Educativa) in Colombia. These talks were proposed by international panelists from various parts of Latin America in the lines of ICT for Education and Peace, Thinking and Artificial Intelligence, Emergent Scenarios in Education and Mobiles Technologies and Apps for Entrepreneurship and Learning.

INTRODUCTION

Informatics is the science of information that studies the nature of information, its processing, and ways of transformation between information, matter and energy (Wang et al., 2011). Educational Informatics is a multidisciplinary research area that uses Information and Communication Technologies (ICT) in education (Hervatis, Loe, Barman, O'Donoghue, & Zary, 2015). Educational informatics is the integration of processing, conservation and transmission of information through automatic machines in the teaching learning process (Chiappe & Sánchez, 2014; García-Peñalvo & Conde González, 2013; Levy et al., 2003; Sierra-Rodríguez & García-Peñalvo, 2015; Srivastava, 2012). Also, educational informatics involves the development, use, and evaluation of digital systems that use pedagogical knowledge in order to support learning (Caro, Toscano, Hernández, & David, 2009; Levy et al., 2003; Sierra-Rodríguez & García-Peñalvo, 2015). According to (Chiappe & Sánchez, 2014; Srivastava, 2012) educational infor-

matics has two main areas of concern: i) to understand the effects on people of using digital information resources, services, systems, environments and communications media for learning and education; ii) to contribute to the development of practical knowledge of relevance to diverse forms of learning/education using ICT and digital resources.

The Ibero-American Network of Educational Informatics RIBIE (*Red Iberoamericana de Informática Educativa* — www.ribie.net) was created by the VII Subprogram of Electronics and Applied Informatics of CYTED (*Programa Iberoamericano de Cooperación en Ciencia y Tecnológica para el Desarrollo*). RIBIE is formed by institutions and groups that develop and apply ICT for the solution of educational problems through research and technological innovation. RIBIE also promotes communication and collaboration among its members, around the project management, the formulation of policies and the development of strategies for education improvement.

RIBIE has been an important stimulus for the development of educational informatics all over the Ibero-American region. RIBIE has organized scientific activities, courses, workshops, researches and development projects, involving groups from the Ibero-American countries. The International Conference of Educational Informatics is an example of it. This Conference is carried out every two years in a member country of RIBIE.

Colombia organized the XIII Conference of Educational Informatics — International Version in 2017. During this event, the most recent trends of educational informatics in Latin America were presented around the following topics: i) ICT for Education and Peace; ii) Thinking and Artificial Intelligence; iii) Emergent Scenarios in Education; and iv) Mobile Technologies and Apps for Entrepreneurship and Learning.

In the research area "ICT for Education and Peace" the talks were related to the following topics: ICT as a support of peace construction, online government, democracy, participation, digital literacy, empowerment, and teaching- learning processes inside and outside the classroom.

In the topic "Thinking and Artificial Intelligence" different projects and experiences in terms of psychology, philosophy, cognition, neuroscience, neural networks, evolutionary computation, artificial intelligence, linguistics and robotic were presented.

The topic named "Mobile Technologies and Apps for entrepreneurship and Learning" involved topics related to new proposals in order to promote self-learning, entrepreneurship and innovation using mobile technologies.

By last, in "Emerging Scenarios in Education" projects and experiences connected with the most recent technologies to enrich the learning processes in multiple scenarios at social, business, cultural and educational levels were tackled.

The main objective of this paper is to present an overview about innovative trends in educational informatics, taking into account the 73 talks performed in the event mentioned above. This paper is a summary about the talks developed showing the research areas proposed through the following chapters; Chapter II shows briefly the researches and experiences in the topic called ICT for Education and Peace. Chapter III describes the studies framed in the Thinking and Artificial Intelligence area. Chapter IV tackles the different emerging scenarios that are being used in Latin America education. Chapter V takes into account the wire range of mobile technologies and Apps for entrepreneurship and learning. Finally, Chapter VI presents a set of conclusions and a proposal about future works in this area of knowledge.

ICT FOR EDUCATION AND PEACE

Decades ago certain Latin American countries had been working on the solution of their armed conflict. One of these countries is Colombia, in which the peace process is being carried out currently. The education and the implementation of ICT is becoming the starting point for this conflict solution of the nation. As an example of this, the use of ICT is taken as a tool for re-socialization in areas of conflict (Zarate & Medina, 2017). Workshops on digital literacy, human rights and ethical values are being promoted In order to influence the life project of people who have been victims of the violence and conflict in Colombia; (Prieto & Nájar, 2017).

This research area in Colombia also proposes to redesign the existing curricula, pursuing the participation of the students in topics related to citizenship (Rangel & Silva, 2017), culture of peace and Chair for Peace (Yagama & Sierra, 2017). This "chair for peace" is based on a law that guides implementation in schools around the country, where teachers design plans and pedagogical strategies, which promote students' participation in order to develop social skills and ethical values (Ley1732, 2014).

In this context, the role of the teacher is to lead processes that prevent, monitor and control problems through classroom projects, focusing on the development of values (Sandoval, 2017).

THINKING AND ARTIFICIAL INTELLIGENCE

The main goal of this research was to present a general scenario about the techniques implemented on the thinking modeling and the use of cognitive informatics and cognitive computing (CI & CC) in Education.

In this event, researches were conducted in different areas of knowledge, which aim to respond, in one or another way the following question: How does the natural intelligence process information? This question takes us along the path of cognitive sciences (Wang, 2002), which are dedicated to discovering the representational and computational capacities of the human mind (Miller, 2003). Any emerging disciplinary such as CI & CC shares this common root problem question (Wang, 2002). Studies in these disciplines allow representing both cognitive and metacognitive processes, which help us to develop educational resources in terms of hardware and software in order to enrich the teaching - learning process.

Other researches show a high tendency in the use and personalization of learning environments mediated by technologies to promote the development of thinking skills (Bejarano, 2017; Díaz, 2017; Martínez, Acevedo, & Correa, 2017). Such as: virtual learning and multimedia learning computer environments, which are pedagogically and technologically designed (Palomino, Barrera, & Culchac, 2017).

Furthermore, a methodology for the creation of robotic educational toys was presented (Suarez & Garces, 2017). As well as the use of cognitive robots as teaching - learning tools in the classroom. These new learning scenarios allow students to develop a systemic, structured, logical and formal thinking through problem-solving processes.

The experiences and researches presented in this event will mark a future trend in Latin America to the design of environments mediated by technology. It is observed that artificial intelligence facilitates the role of the teacher inside the classroom as the administrator of knowledge and students to be the key of the teaching learning process

Finally, It is evident through all the exposed in the thinking and Artificial Intelligence topic that in Latin America exists initiatives in the developing of intelligent systems based on cognitive and metacognitive processes simulations that facilitate building of new learning scenarios.

EMERGING SCENARIOS IN EDUCATION

Trying to integrate ICT in the educational context is a complex task (Jimoyiannis, 2009; Tondeur, Coenders, van Braak, ten Brummelhuis, & Vanderlinde, 2009). This process implies a substantial change in the way the teaching and learning process is developed (Bingimlas, 2009). However, thanks to the potential that the use of ICT has within the classroom, teachers can implement new methodologies of teaching to respond to these changes (García-Valcárcel, Basilotta, & López García, 2014; John & Sutherland, 2004).

These new educational scenarios were evidenced in the XIII International Conference of Educational Informatics, where different researches presented the impact of new methodologies mediated by ICT upon education. In this research area, the talks were focused on two main topics. On the one hand, some relevant experiences in relation to the implementation of educational video games in different areas of knowledge, were socialized (Hernández, Hernández, & Sanabria, 2017; Patiño, 2017). These types of scenarios have allowed the formulation of classroom projects that pursuit not only to reinforce ICT skills but also to generate new learning spaces through Gamification (Ramírez & Solano, 2017; Sandoval, 2017).

On the other hand, the use and appropriation of ICT in the school facilitates the interdisciplinary as a determining characteristic in teaching learning process (Bulla & Solano, 2017). According to Kandiko (2012) and Klein (2010) interdisciplinary allows to identify skills and necessary knowledge to conduct researches and projects of innovation (Kandiko, 2012; Klein, 2010). This could be observed in experiences that try to change the ideas that young learners have about the use of ICT because they commonly associate these tools with entertainment and leisure activities (Patiño, 2017). That is to say, interdisciplinary facilitates the generation of new knowledge (Van Rijnsoever & Hessels, 2011).

Emerging scenarios in education mark the path of new experiences that transform the way of learning and teaching. This path leads the use of innovative tools for students used to deal with a society full of information and knowledge.

MOBILE TECHNOLOGIES AND APPS FOR ENTREPRENEURSHIP AND LEARNING

The use of apps and mobile technology has become an increasingly tendency that promotes entrepreneurship and learning. This scenario represents a great potential for development and implementation of classroom and innovative projects. In this conference it could be observed researches, which contribute to the solution of social problems through autonomous learning, entrepreneurship and innovation (Barroso, 2017). Within the framework of this event, a series of proposals that respond to this tendency and that seek to promote virtual scenarios for the construction of a more equitable society were socialized (Tanos, De Castro, & Gaviria, 2017).

Another trend in this area, is the one that seeks to promote tourism as a strategy for the development of communities, through the promotion of people's cultural values, customs and traditions (Brito & Cortés, 2017). The experiences framed in this tendency uses technology as tools to raise awareness of the cultural richness of communities barely visible, with the purpose of favoring tourism as an economic and social activity.

The use of mobile applications has led researchers to propose experiences that contribute to improve the quality of people's life, and solve social and cultural problems presented in their environment. This type of applications offers the possibility of new opportunities to the most vulnerable communities

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

and those with less access to technology. Apps also play an important role in the education, when they represent alternative solutions associated with teaching strategies, the development of didactic activities and the implementation of the new assessment approaches (Espitia, 2017).

CONCLUSION

This paper has summarized a wide overview about the new perspective of educational informatics in Latin America presented in the XIII Conference of Educational Informatics. A wide range of theoretical breakthroughs and computing applications have been reported in the areas of *ICT for Education and Peace*, *Thinking and Artificial Intelligence*, *Emergent Scenarios in Education* and *Mobiles Technologies and Apps for Entrepreneurship and Learning*.

Researches in the area of *ICT for Education and Peace,* presented the use of ICT as a tool for re-socialization in conflict zones, the incorporation of technologies through social reintegration processes and the curricula redesign in terms of citizenship and peace culture. In this context, the role of the teacher is to lead processes that prevent, monitor and control educational problems through classroom projects, focusing on the development of values.

In *Thinking and Artificial Intelligence area,* the tendency was: the personalization of learning environments mediated by technologies; development of thinking skills; methodologies for the creation of robotic educational toys; cognitive robots; e-learning environments and the study of metacognitive processes that help developing educational resources in hardware and software.

Emerging Scenarios in Education area, researches were conducted on two main topics: *(i)* the implementation of educational video games in different areas of knowledge. Here the research process is focused on the formulation of classroom projects to reinforce ICT skills and generate new learning spaces through Gamification; *(ii)* Formulation of interdisciplinary works to identify skills and the required knowledge to lead researches and innovative projects.

Researchers in *Mobile Technologies and Apps for Entrepreneurship and Learning* area proposed: educational video games in different areas of knowledge, apps for classrooms and apps for solving social-cultural problems.

The future works in the field of educational informatics in Latin America are oriented to the implementation of cognitive informatics and cognitive computing in the development of new scenarios for teaching and learning, especially in the simulation of cognitive and metacognitive processes.

This research received no specific grant from any funding agency in the public, commercial, or not-for-profit sectors.

ABSTRACT

With the rapid increment in the clinical text, de-identification of patient Protected Health Information (PHI) has drawn significant attention in recent past. This aims for automatic identification and removal of the patient Protected Health Information from medical records. This paper proposes a supervised machine learning technique for solving the problem of patient data de- identification. In the current paper, we provide an insight into the de-identification task, its major challenges, techniques to address challenges, detailed analysis of the results and direction of future improvement. We extract several features by studying the properties of the datasets and the domain. We build our model based on the 2014 i2b2 (Informatics for Integrating Biology to the Bedside) de-identification challenge. Experiments show that the proposed system is highly accurate in de-identification of the medical records. The system achieves the final recall, precision and F-score of 95.69%, 99.31%, and 97.46%, respectively.

INTRODUCTION

With the start of the golden era in the medical interpretation, the vast amount of information in the clinical domain is increasing at a rapid rate. In the past decade, with the development of the health information technology and health data documentation, there has been progress in how heath care is performed (Berner et al., 2005).

With the widespread use of health information technology, there has been huge pace in the increment of clinical data in addition to the fast adoption of the Electronic Clinical Records and with the conversion of narrative data to the electronic form. The amount of information can be improved further with the minimization of the medical error. This requires the development of some sophisticated tools for Medical Language Processing (MLP). Most medical records are in the narrative forms which are formed as the result of transcription of dictations, direct entry by providers, or use of speech recognition applications. However, their use in this form is restricted to any organization or research, as medical records have a sufficient number of personal health information or protected health information (PHI). According to Health Insurance Portability and Accountability Act (HIPAA), 1996, the PHI terms need to be enclosed and protected. This has lead to de- identification problem. Paragraph 164.514 of the Administrative Simplification Regulations promulgated under the Health Insurance Portability and Accountability Act (HIPAA) states that for data to be treated as de-identified, it must clear one of two hurdles (HIPPA ACT 1996).

1. An expert must determine and document "that the risk is very small that the information could be used, alone or in combination with other reasonably available information, by an anticipated recipient to identify an individual who is a subject of the information."
2. Or, the data must be purged from a specified list of seventeen categories of possible identifiers relating to the patient or relatives, household members and employers, and any other information that may make it possible to identify the individual.

Studies showed that there was a significant drop in the patient consent request reducing the participation rate and also, this is quite infeasible for the huge population. Even, in the case when a patient provides the permission, documents must be tracked to stop any unauthorized disclosure. This emerging problem of consent, waiver, and tracking can be effectively handled if the patient personal health information is properly de-identified facilitating the clinical NLP research (Wolf & Bennett, 2006).

De-identification task is more specifically defined as the step where the private information is removed or replaced while keeping the record as it is (Stubbs et al., 2015). De-identification is a type of traditional named entity recognition (NER) problem, with the property of defining a term to be PHI type or not. The main aim of de-identification challenge as pointed out earlier is to remove the PHI terms maintaining data integrity as much as possible. Every record is enclosed in the RECORD_ tags and is provided a unique ID which is randomly generated. Figure 1 shows Sample Discharge Summary Excerpt; a sample discharge summary from the training dataset where the goal is to identify the PHI (private health information) terms. In this summary, some the PHI terms are doctors' name ("Dr. Do Little"), patient name ("John Doe") and hospital name ("ABHG", "SBHG"). A TEXT_ tag encloses the text of different records. Each PHI instance is enclosed within PHI_ tags and the PHI TYPE represents the category of the PHI term as shown in Figure 1.

As shown in Figure 1, the task is to enclose the PHI terms such as ("Dr. Do Little", "John Doe", "ABHG", "SBHG"). This task can be seen as the typical sequence labeling task where for e.g. "Dr. Do Little" should be labeled as whole with Doctor. Here, we present an example where input forms the sequence of words and output is the label sequence and its corresponding de-identified sentence. "BIO" notation was followed to label the NE where "B" represents the beginning of label sequence, "I" denotes intermediate of label sequence and "O" represents others.

Sentence	Mr.	John	D	Doe	is	xx-year-old	white	male
Named Identity	O	B-Doctor	I-Doctor	I-Doctor	O	O	O	O
De-Identified Sentence	Mr.	XYZ_Doctor			is	xx-year-old	White	male

In the past few years, de-identification of the clinical record has become the booming research area. Sixth Message Understanding Conference (MUC) had defined the Named Entity Recognition (NER) problem with an objective to identify the relevant entities from the text. NER forms an important task in NLP. Similarly, in the medical domain, NER is very crucial in the identification of the clinical terms by which we can get insights to the problem, medication, procedure, and examination.

Major research works for entity extraction in the medical domain had used machine learning and rule-based concepts. MedLEE (Friedman et al., 1996) is one such system in clinical domain proposed by Carol Friedman et al. at Columbia University. Aronson (2001) developed MetaMap system at National Library of Medicine. Another system cTAKES (Savova et al., 2010), developed using Unstructured Information Management Architecture (UIMA) framework and OpenNLP, a widely accepted system.

Recently, the Medical Natural Language Processing Community had organized a number of challenges for NER task. The earliest shared task is organized by Center of Informatics for Integrating Biology and the Bedside (i2b2) in 2009 on medical name recognition (Uzuner et al., 2010). In 2010, i2b2 shared task was conducted with the aim to identify the medical problems, test entities and various treatments from the clinical records (Uzuner et al., 2011). Since then, Conference and Labs of the Evaluation Forum (CLEF) had organized a challenge in 2013 with the aim of solving disorder mention recognition and normalization (Goeuriot et al., 2013). Very recently, i2b2 in 2014 (Stubbs et al., 2015) had organized a challenge for patient data de-identification problem and CUI (concept unique identifier) detection. Semantic Evaluation (SemEval) 2014 also came up with the disorder mention recognition and the normalization. With a large number of challenges organized almost every year, it had drawn the attention of many researchers to solve these real-life challenging problems.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Different approaches have been used to solve this problem ranging from machine learning techniques (Stubbs et al., 2015; Yang et al., 2015), rule-based system (Beckwith et al., 2006; Berman et al., 2003) to the hybrid system. Rule-based systems are designed over dictionaries with the rules that are designed manually to recognize the PHI terms from the text. Building a system using rules lacks generalization capability as well as it consumes more time and skill for developing rules. Rule-based systems are seen to provide good performance for the PHI terms those appear less often. This has lead to the development of some machine learning techniques for automatic extraction of PHI terms from the text which makes the process more generalized. The only drawback of machine learning based approach is the requirement of having large annotated corpus which can be developed manually.

Generally, the NER problem is the sequence labeling problem where the aim is to identify the proper output sequence of the entities. Thus, for the given input sequence of words, we need to obtain the best labeled- sequence. Researchers have primarily used supervised machine learning algorithms to solve this kind of medical NER problem. The algorithms used for extracting medical entities are Conditional Random Fields (CRFs) (Lafferty et al., 2001), Maximum Entropy (ME) (McCallum et al., 2000), and Structural Support Vector Machines (SSVMs) (Xue et al., 2008). Among these different classifiers, Conditional Random Field had drawn a huge attention for solving the sequence labeling task. Top best system (Yang et al., 2015) of de-identification task had used CRF as the underlying classifier because of the property of CRF to properly map the relationships between their surrounding tokens. Supervised machine learning techniques are able to capture the handcrafted features very effectively. Some of the prominent features which have been used are orthographic features that capture the word structures, syntactic features like Part of Speech (PoS), and semantic features as well as the discourse features. These features are typically used for solving any NER problems. Many other domain specific features could be generated for further improving the performance of the system.

In the current work, we develop a supervised machine learning based classification framework for solving the patient de-identification problem. The proposed method is evaluated on the i2b2 2014 dataset. It concerned identifying four different PHI categories, namely PATIENT, DOCTOR, HOSPITAL names and DATE from the medical records. Taking into account the effectiveness of applying CRF in solving the NER problem, CRF was adopted to train the model. Diverse features are extracted and CRF based model was trained using this huge collection of features. Several experiments were carried out with different cross folds. Results of the proposed system are shown for different cross-validation settings like 5,6,7,8,9,10 fold cross validations.

This task suffers from various challenges as similar to any NLP task. One such challenge is the ambiguity problem where we found that due to the lexical similarity PHI terms mostly overlap with the non-PHI terms. An example includes Brown (Doctor name) which is a PHI term vs. brown (Colour name) which is a non-PHI term. Another major challenge is the occurrence of some out-of-vocabulary PHI terms which are not present in the dictionaries. These words act like the foreign words which can be misspelled. Gazetteers list, dictionaries are the mostly used for solving any NER problem but the contribution of these types of words lowers the performance and creates some errors. Results obtained prove that the proposed system outperforms the existing systems in identifying four different PHI terms.

The remaining paper is organized as follows. Next immediate section discusses the background of de-identification task and its significance. This is followed by a section which provides the insight to the related work. Next section discussed the methodology adopted for the de-identification which is followed by the details of experiments and their analysis. Finally, we conclude in the last section.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

BACKGROUND AND SIGNIFICANCE

Most of the works done in biomedical Natural Language Processing (NLP) domain can be distinguished into two different types on the basis of the text, biomedical text and clinical text (Meystre et al., 2010). Biomedical texts are the texts that appear in the journals, articles, posters etc. On the other hand, the clinical texts are mostly the texts written by the doctors in the form of prescriptions for the patients. This text comprises of the patient information like his/her name, age, gender, the procedure that was applied to him/her and what are his/her medical histories. These texts also provide insights to the findings made during procedure and the medication provided to them.

The clinical text is the whole range of narrative found in the patient records. These texts vary from the short-segment which gives the chief complaints to the long-text comprising of the history of the patients. There is another class of text which is discussed in the literature very often (Coorevits et al., 2013). While some of the texts are similar to that of biomedical texts for example internal research reports, the others appear to be like clinical texts for example patient notes. As these narratives are rarely exposed outside the organizations, there is a very sparse study on them.

There is one obvious question that what distinguishes clinical text from the biomedical text and why processing of these poses a challenge to the NLP society. Firstly, in the clinical texts, a large number of grammatical errors can be found which may have occurred at the telegraphic phrase. Other segments in clinical documents which create some problem are discharged summaries and the lab test reports. Moreover, clinical documents suffer from the problems like abbreviations and acronyms. These lexical structures are often overloaded i.e., there is a multiple rendering for the same word set. Literature shows that almost 33% of the times, acronyms are overloaded which makes it prone to the ambiguity problem (Liu et al., 2001). There is a huge problem due to the spelling mistake, which is observed most commonly in the notes lacking spelling support. US Veterans Administration (VA) has one of the largest EHR systems with only the basic text support. Even in their corpus, there are lots of abbreviations and acronym problem. Furthermore, the clinical data consists of different types of characters which appear anywhere within the text. Another problem that is raised is to change the unstructured narrative text into the structured; templates along with pseudo-tables are in general used in the method of conversion (Meystre et al., 2010). Template having a narrative structure for patient history or the discharge summary that is common among the medical society provides benefits to NLP. Explicit templates are formatted text with the fields specific to the institution are filled by the user. These different variations in template make this domain quite challenging.

There are many methodologies adopted to cover different types of questions related to clinical research domain (Dehghan et al., 2015), (Liu et al., 2015), (He et al., 2015). Although, the pharmaceutical industry covers the clinical trails and therapy but nowadays, these industries are spreading the horizon of solving the medication issues like drug interaction, disease prevention through the proper investigation of diseases. These include the course of the disease and various other factors like, what were the different criteria for diagnosis, how the patient education affected his/her health and his/her surveillance. With the rapid and booming research interest in the clinical domain, the studies have also spread to obtain the role of different gene pathways in the identification of their relations in the development of diseases. Some clinical research focuses on improving the health care with lowering the health care cost, thus providing the benefits to the mass. As such, it is highly important to have a proper study of the clinical records in solving the major unsolved and challenging problems of the society with the NLP system.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

De-identification task forms one such challenge which aims to identify the noun phrases or part of a noun phrase automatically from the text. In the traditional named entity recognition task, originated by the MUC challenge, the focus was to identify the person, organization, location names from the newspaper type electronic text. Generally, de-identification task is the task of identifying and enclosing patient personal health information like not just identifying the persons but also identifying the type of person (Patient, Doctor), Organizations (Hospital), Location (Streets, Country), ages, dates but not in the term of years. Apart from these, structures of the text too vary a lot. While in newswire or journalistic domain, lots of clues can be obtained from their titles, abstract and cases while in the patient records, due to its semi-structured form the task becomes quite challenging.

LITERATURE SURVEY

De-identification task is a type of the traditional Named Entity Recognition (NER) problem. Message Understanding Conference had been the center for the evaluation of NER system in several domains. MUC had organized several challenges to identify several named entities like person, location, organization, time, dates etc. For the MUC-6 NER task, a total of 15 teams participated in the challenge submitting 20 different systems. The best F-Measure value reported was 96.42% (Sundheim, 1997). In the MUC-7 challenge, 14 systems were submitted from 12 different teams obtaining the highest F-Measure value of 93.39% (Chinchor, 2001). National Institute of Standards and Technology (NIST) organized two different tasks, Information Extraction Named Entity task and the Automatic Content Extraction (ACE) tasks. Both of these tasks were evaluated on the newswire domain.

In the biomedical domain, Critical Assessment of Information Extraction Systems in Biology (BioCreAtIvE) (Hirschman et al.,2005), organized several biomedical challenges including the entity extraction task, where the task is to identify different entities like gene name, protein name from the given biomedical text derived from the PubMed, PMC. PubMed and PMC are huge repositories consisting of almost 3.5 million biomedical literature. For the evaluation, TREC Genomics Track was considered. The BioNLP 2009 challenge (Kim et al., 2009) focuses on event extraction primarily on the protein and gene event extractions. The same challenge was also focussed on BioNLP 11(Pyysalo et al., 2011) and BioNLP 13 shared task (Nedellec et al., 2013), where data was used from MEDLINE. Another task BioASQ was organized for entity extraction using data from PubMed. Several challenges have been organized for entity extraction. Recently, i2b2 had organized the task for the de-identification of the clinical terms in the years 2006 and 2014 (Stubbs et al., 2015). Here, the challenge was to identify the certain PHI terms.

In the 2006 shared task, a total of 889 patient records were used. This challenge got sixteen submissions from seven different teams. The challenge had used longitudinal records of each patient rather than the individual records. It was observed that longitudinal records contain more personal information of patients rather than an individual record. Completely identifying the patient information from individual records is a problematic task. This makes the de-identification using the longitudinal records a more complicated task. The submitted systems identified the task as a token classification task (using Support Vector Machine) while some distinguished it as the sequence labeling task (using Hidden Markov Model, Conditional Random Field).

Wellner et al. (2007) in i2b2-2006 challenge built the best system based on CRF. They used some lexical and semantics features. They adapted two important NER systems, one based on the CRF, Carafe, and other Lingpipe, HMM-based implementation. The carafe was seen to be highly effective in capturing

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

the PHI terms. Szarvas et al. (2007) adopted an iterative method for named-entity de-identification. They treat de-identification as a classification task and use machine learning based decision tree with local features and dictionaries. Aramaki et al. (2006) also used CRF as their classifier with the features such as local, external and global features. The global feature includes the features which capture position, the length of a sentence and also several tokens in the previous sentence. External features include the dictionary for location, person name, and dates. They performed two-phase learning wherein the first phase, they learned their system using local features and in the second phase, they include first phase features set in addition to the most frequent label. They identified that sentence feature is very informative in identifying dates, IDs and patient because of the appearance of this PHI in beginning of the records while the external feature was useful in identifying dates, locations, doctors and patients.

While many systems have used CRF based classifier, some submitted systems also used SVM. Hara (2006) developed a hybrid system making use of rules. The rules identified the patterns for the PHI terms such as phone numbers, IDs, and dates. They train SVM on the global and local features which were found to be very helpful in identifying the PHI terms such as a hospital, patient, location, doctors, and age. In addition to these features, their system included the section heading which is closed to the target, category of the sentence, the surface form of target, the root, PoS tag and orthography features. The system used two types of the ordered tree, dependency tree and "n-grams trees" making use of the Boosting Algorithm for Classification Trees (BACT). With this information and in addition of chunking technique, they identified the position and the text span of PHI terms such as a patient, doctor, location, and hospital. The results show that performance is degraded with the incorporation of sentence feature.

In 2014 patient de-identification task, machine learning technique was more prominent. According to the 2014 i2b2/UTHealth shared task, the challenge was to de-identify the data in a stricter way as compared to the HIPAA standards in the form of additional categories. The task was to identify the 25 PHI categories with the associated subcategories from the clinical records like professions, time and dates, facilities etc. These tasks also consider the longitudinal records. Yang et al. (2015) submitted the system in the i2b2-2014 challenge and they reported the accuracy of 93.60%. This was the best performing system. They developed a hybrid model which used both the machine learning and the rule-based technique to extract the PHI terms. They exploited the various features like linguistic features, syntactic feature and different word surface oriented features which were further improved by using the task-specific features. They also used the regular expression pattern to identify the PHI terms like date, ID.

The second best system (Dehghan et al., 2015) from Manchester used a combined system developed using the knowledge-based technique as well as the rule-based system. The rules were defined to obtain the orthographic features, different patterns. They used CRF as the underlined classifier to obtain the PHI terms. For some categories like PATIENT, DOCTOR, HOSPITAL, the initial annotation was extracted at the patient level and dictionary was created for the patient. At the last stage, the outputs of the rule-based system, as well as the CRF based model, were integrated on the basis of some rules. These systems were highly efficient in obtaining the PHI terms such as the DATE, DOCTORS, and PATIENT.

System (Liu et al., 2015) from Harbin Institute of Technology Shenzhen Graduate School in i2b2 challenge used two different variations of the CRF. They define one CRF system working at the token level while another CRF system that works at the character level. They performed feature engineering and used the features such as bag-of-words, section relevant features, lexical features, semantic features. Apart from the two different CRF outputs, the third output was obtained by developing the rules using the Rule-based system. The final outputs of all the three systems were merged on the basis of the output

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

overlapping. If there was no overlapping i.e., if all the three systems obtained the same PHI tag, then that tag was accepted else the tag was obtained on the basis of the preference. They give the first preference to the rule based system, then the character-level system and lastly to the token-level based CRF system.

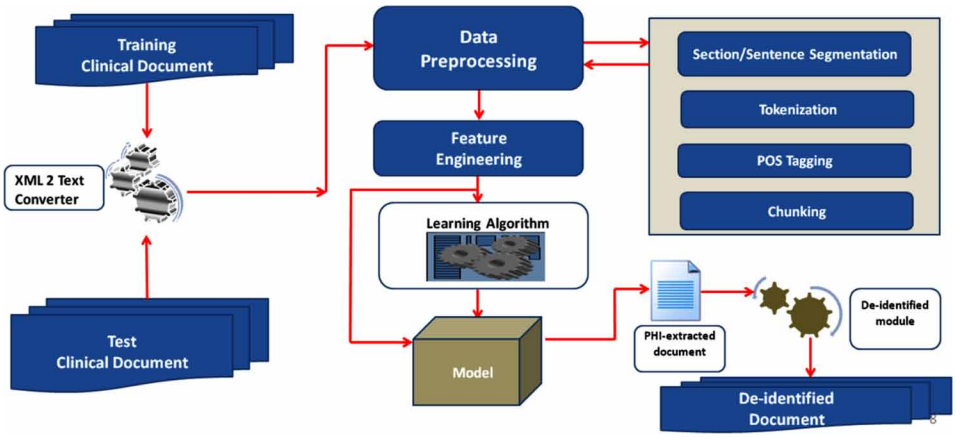
Another submitted system from Harbin Institute of Technology (He et al., 2015) used OpenNLP system to pre-process their data, sentence splitting, and tokenizer. They trained their system using CRF making use of features such as lexical, syntactic and orthographic features. They did not use external features such as dictionaries to identify the terms. The system developed by Kaiser Permanente (Torii et al., 2014) adapted the MIST tool. They include some additional rules that used lexicon for Location and Profession and different regular expressions for the categories such as Phone Numbers, ZIP and Organization. In addition to MIST system, the team learned NER model using Stanford NER system. The system then merges the overlapped identified entities. They reported the F-Measure value of 92.21%.

Through the literature survey, we found that hybrid systems (both the rule-based system as well as the machine learning based) perform well when compared with the individual techniques. It is reported that among top ten ranked systems, seven systems have adopted the rule-based technique. MedEx (Xu et al., 2010) forms one such system proposed at Vanderbilt University that utilizes the biomedical dictionary to identify the important medical concepts.

Overall, the best systems report high recall and precision, often greater than 90%, and sometimes as high as 99%. Nevertheless, no study has evaluated the performance of automated de-identification for all PHI classes (Meystre et al., 2010). Only a handful of studies provide details on over-scrubbing (non-PHI wrongly identified as PHI) and none of them investigate the effect of de-identification on subsequent IE tasks. It is indeed possible that de-identification has an adverse effect on IE accuracy (Meystre et al., 2010). Over-scrubbing errors could overlap with useful information, for example, if a disease name is erroneously recognized as a person name, it will be removed and lost to subsequent IE applications. Second, NLP techniques such as part-of-speech tagging and parsing may be less effective on modified texts.

It can be concluded that though a lot of systems have evolved in the recent past, but still there is a need to develop a more accurate automated de-identification system.

METHODS



Supervised machine learning based classification frameworks have been developed to detect the PHI tokens from the medical records. Similar to any entity extraction technique, de-identification task is also considered to be the sequence labeling task. The proposed system architecture is divided into four different modules. The first module deals with the pre-processing of data. The second module represents the feature engineering part where features are generated. Training of the model through Conditional Random Field (CRF) is done in the third module. The fourth module represents the de-identification of the PHI terms. Detailed descriptions of the methodology adopted for the system are given below. Figure 2 represents the Proposed System Architecture.

Pre-Processing of the Medical Records

Datasets provided with the i2b2 de-identification challenge were untokenized; this necessitates the use of the pre-processing module for the process of tokenization. The pre-processing was performed in three different stages. The first stage of the pre-processing module deals with the sentence splitting. The second

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. Proposed system architecture

module focuses on the tokenization of the medical records. The last and final stages are used to identify the rules for tokens such that when they are divided, they should match some patterns.

Apart from this process, pre-processing steps also include shallow parsing and Part of Speech (PoS) tagging to obtain the word lemma, chunk and part-of-speech of the corresponding words. Additionally, we extracted some of the document- level features, for example obtaining the different sections (HISTORY OF PATIENT ILLNESS, MEDICATIONS etc.) and position of the sentence in the text (beginning of the text, end of the text) using some of the hand-crafted rules.

Feature Generation

This module focuses on developing some prominent features. The features were developed, such as the linguistic, syntactic features as well as word surface-oriented features in order to capture the semantics of the PHI terms. The features were further enhanced by embedding the feature set by the task-specific features. The list of the extracted features for the PHI recognition task is given below:

- **Token Features:** Some features are generated during the pre-processing step like word lemma, word chunk and the Part-of-Speech tag of the current word.
- **Bag-of-Word Feature:** It includes the unigrams, bigrams, trigrams of the target token within the window size of [-2, 2]. An *n*-gram is a contiguous sequence of *n* items from a given sequence of text or speech. An *n*-gram of size 1 is referred to as an unigram, size 2 is a bigram and size 3 is a trigram.
- **Contextual Features:** This feature is the combined feature which includes the lemma, chunk, POS tag of the surrounding tokens. We consider the window size of [-3, 3]. These features give the context knowledge for each word.
- **Combined POS-Token Feature:** The combination of POS tag within the context of [-1, 1] and the current token $\{w_0p_{-1}, w_0p_0, w_0p_1\}$ is formed, where w_0 represents the current word, and p_{-1}, p_0 and p_1 represent the previous POS tag, current POS tag and the next POS tags respectively.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 2. Some of the orthographic features with their examples in uses

Feature	Example	Feature	Example
InitCap	David	CapMixAlpha	EpoR
InCap	mAb	DigitSpecial	12-4
DigitOnly	12,23	AlphaDigitAlpha	IL34S,EIB
DigitAlpha	28BC	CapLowAlpha	Srs, Ras, Epo
Hyphen	_	DigitCommaDigit	2,34
CapsAndDigits	28Houston	LowMixAlpha	mAB,mRNA
StopWord	at, on	AllCaps	DHC
AlphaDigit	s72	EndwithDot	Dr., Mr.

- **Affixes:** This feature includes prefix and suffix of the word. It refers to the fixed length characters stripped either from the left most part or the rightmost part of the token. For example, the suffix and prefix of word 'health' are h, he, hea, heal and h, th, lth, alth respectively. Here, we set the length to size 4.
- **Sentence Information Feature:** This feature includes the structure of the sentence. It includes the information regarding length of the sentence, whether the sentence has any delimiters like '.', '?', '!', whether there is any bracket unmatched.
- **Orthographic Feature:** Several orthographic features were developed to capture the capitalization and digit information. These are very useful information to capture the entity extraction. Symbol such as the ',' is found to be very crucial in detecting the boundaries of the NEs. Table 2 lists some of the orthographic features with their examples in uses.
- **Word Normalization:** Two different variants of this feature were developed. The first feature is used to capture the words which are in plural form, verb, alphanumeric letters, hyphen, and digit. This feature actually converts the words to its root form. Another feature represents the orthographic construction of the words. This feature is termed as the word shape feature where each word is mapped to its respective class. Words are normalized by converting every uppercase character by 'A', lowercase character is changed to 'a' and every digit by '0'. For example, if the token is 'Medical-49', its normalized form would be 'Aaaaaaa-00'.
- **Word Class Feature:** This feature is generated motivated by the fact that similar entities reside within the similar class. This feature is the enhancement of the word normalization feature. After the word conversion, the squeezing operation is performed where the consecutive sequence of words is converted into the single character. For example for the word 'Medical-49', its word class form would be 'Aa-0'.
- **Section Feature:** This binary feature was generated after extracting the sections from the training set manually. Top 16 sections were extracted with their probabilities of carrying the relevant PHI terms. These sections were generated manually and form very effective feature in the identification of the PHI terms.
- **Gazetteer List:** For the identification of the PHI terms, task related term list helps in improving the performance of the system. These lists include the headings which give very strong remarks about the occurrence of the PHI terms. Example: 'Transcribed by', 'Dictated by'. These sections carry information about the occurrence of the DOCTOR name. Apart from this, the dictionary

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

was used for the names like the common names across countries, full name and the abbreviation of the common US locations for e.g. "New York" and "NY". We used the list of names for the days, months.

In addition, some lexical clues were identified for each individual PHI category. These are the types of the trigger words that give an indication regarding the presence of the particular PHI terms for example 'Dr.', 'M.D' in the case of DOCTOR, 'Mr.', 'Mrs' in the case of the patient. These lexical clues are obtained from the neighboring contexts of the target PHI terms. These are filtered on the basis of occurrence and their importance with the target PHI categories.

- **General Entity Information:** The Stanford Named Entity Recognizer (http://nlp.stanford.edu/software/CRF-NER.shtml) was used to obtain the named entity tag of the corresponding token.
- **Discourse Features:** This feature plays a very important role in the identification of the terms that are very much related to section headings and their positions of occurrence in the sentence. For example the strong contextual clues words like'CC:' and 'Dictated by'.

Classification: CRF Classifier

We trained our system using the Conditional Random Field algorithm. This algorithm is very popular in the domain of entity recognition because of its ability to tackle the sequence labeling task very efficiently. CRF is categorized under the class of statistical modeling. They are mainly applied for the structural prediction which is formed by the combination of classification and graphical modeling methods. CRF integrates the performance of the graphical models to compactly model multivariate data and classification methods to perform prediction using a large set of input features.

The CRF-classifier works on the Markov Assumption that given the observation sequence of the token $x_1, x_2, x_3 \ldots\ldots\ldots x_n$, the corresponding label-sequence $y_1, y_2, y_3 \ldots\ldots\ldots y_n$ is predicted by the CRF. It maximizes the conditional probability for every y in the possible set of label sequence. Mathematically, CRF can be represented as

$$\exp\left(\sum_{j} \gamma_j t_j(y_{(i-1)}, y_i, x, i) + \sum_{k} \mu_k s_k(y_i, x, i)\right) \quad (1)$$

Here, $t_j(y_{i-1}, y_i, x, i)$ represents the transition feature function for the whole set of observation sequence. i and $(i - 1)$ denote the position of the labels in the label sequence. Here $s_k(y_i, x, i)$ represents the state feature function at the label position i and observation sequence. γ_j and μ_k are the parameters estimated from the training dataset. While defining the feature function, the real valued feature set of the observation is constructed as $b(x,i)$. It expresses empirical distribution characteristics of the training data in order to hold the model distribution.

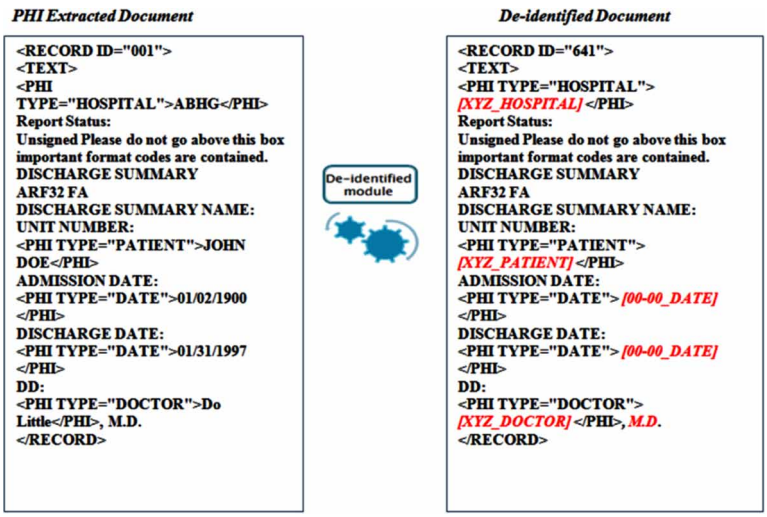
There are various other algorithms that can handle the sequence labeling task like Maximum Entropy Markov Model (MEMM) and Hidden Markov Model (HMM). The main advantage of CRF over HMM is that it is conditional in nature, which helps in relaxation of the independence assumption as needed by the HMM. Apart from that, CRF is very much efficient in handling the label bias problem. Label bias problem is due to the directed graphical model that is exhibited by MEMM and HMM. It was observed that CRF outperforms the other models in a number of tasks such as speech recognition, bioinformatics.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

De-identification task targets to automatically extract the PHI terms with the proper boundary identification. As CRF being the better performer than other models, this work used CRF as an underline base classifier. The open source toolkit CRF++ was used to carry out our experiments. BIO notation was followed to label the PHI terms which occur in sequence. Here 'B' identifies the beginning of the PHI token, 'I' represents that the PHI token is within the sequence. 'O' is used to identify that token belongs to none of the PHI term categories.

For the classifier learning, whole feature set discussed in the previous section was used. CRF modeling is done by considering all the PHI categories through learning by the training phase and predicting the output of the model built during the test phase.

De-Identification of PHI Terms



In order to hide the patient personal information, de- identification of the PHI terms is highly necessary. A template was adopted through which we convert all PATIENT, HOSPITAL, DOCTOR names present into a generic format like XYZ_PATIENT, XYZ_HOSPITAL, XYZ_DOCTOR, respectively and all the dates into the format 00-00_DATE. Thus, capturing the information required without compromising the personal details. We represent this below in Figure 3 by considering the original document and the de-identified document. Figure 3 shows De-Identification Process.

DATASET AND EXPERIMENTS

Dataset

The 2014 i2b2 challenge dataset was used in the current paper, which was taken from the Research Patient Data Repository of Partners' Healthcare. A total of 1304 medical records basically of longitudinal nature were manually annotated. These records were obtained from 297 patients following the annotation

Figure 3. De-identification process

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

guidelines. The dataset was divided into two parts where the first part consists of 790 records of 188 patients that were used as the training dataset and 514 records of 109 patients were test dataset.

i2b2-2014 challenge dataset compromises of 17,045 PHI relevant instances in the training dataset, while the test dataset consists of total 11,462 PHI instances. To ensure the patient confidentiality as much as possible, the challenge aims to identify HIPAA- PHI categories firstly with the added subcategories. They were annotated using seven main PHI categories with the twenty- five associated subcategories. While our experiments cover the seven main PHI categories, i2b2 challenge covers almost all HIPAA defined categories and subcategories. The list of categories, as well as subcategories that were needed to be identified, is as follows:

- NAME (subtypes: PATIENT, DOCTOR,USERNAME)
- PROFESSION
- LOCATION (subtypes: HOSPITAL, DEPARTMENT, ORGANIZATION, ROOM, STREET, CITY, STATE, COUNTRY, ZIP)
- AGE
- DATE
- CONTACT(subtypes: PHONE,FAX,EMAIL,URL,IPADDRESS)
- Ids(SUBTYPES: MEDICAL RECORD NUMBER, HEALTH PLAN NUMBER, SOCIAL SECURITY NUMBER, ACCOUNT NUMBER, VECHILE ID, DEVICE ID, LICENCE NUMBER, BIOMETRIC ID)

In this work, the aim was to identify four different PHI subtypes; PATIENT, DOCTOR, HOSPITAL name and DATE from the above-defined categories. The experiment was performed with only the training dataset.

Evaluation

The system was evaluated by using 10 fold cross-validation on the training data. For evaluating the classifier's performance, we have used the most popular evaluation metrics; recall, precision, and F-Measure. Recall also known as sensitivity is defined as the ratio of total number retrieved relevant documents to the number of relevant records. Precision represents the positive prediction and is the ratio of retrieved relevant records to the total number of documents.

Recall and precision are represented as follows

$$recall = \frac{Total\ number\ of\ correctly\ predicted\ NE}{Total\ number\ of\ actual\ NE\ present\ in\ the\ gold\ data} \tag{2}$$

$$precision = \frac{Total\ number\ of\ correctly\ retrieved\ NE}{Total\ number\ of\ NE\ retrieved\ by\ the\ system} \tag{3}$$

F-Measure considers both the precision and recall. It is defined as the harmonic mean of recall and precision. We defined F-Measure value as follows:

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

$$f_{\alpha} = \frac{(1+\alpha^2)(recall * precision)}{\alpha^2 * precision + recall} \tag{4}$$

Here we set the value of α=1 .

Experimental Results

Table 3. reports the extensive results of 10-fold cross validation: Recall, Precision and F-score values for individual entities. The system was developed using the handcrafted feature set trained on CRF. It was an interesting observation that with the set of whole features learned using CRF, the system performs quite well. The system was evaluated using 5,6,7,8,9,10 fold cross validation. Here, the performance of the proposed system with10 fold cross validation is reported.

Table 3 shows that overall system has achieved good recall values as compared to precision values. But there are some interesting observations regarding the recognition of individual entities. If the comparison is done on the performance among 3 important PHI terms; Hospital name, Doctor Name & Patient name then Doctor class is having the highest precision and recall values of 99.70% and 93.80% respectively. Precision and recall values for Date are quite good, but the performance can be further improved by introducing some more date based patterns. The recall value for the hospital is low as compared to all the PHI terms introduced here; the one possible reason behind this is to use abbreviation instead of full hospital names.

The report shows that the system is accurate in predicting the PHI terms with the high degree of precision. The detailed error analysis is performed on the obtained results.

Table 4 shows different error cases. Here, X or Y represents any class like PATIENT, DOCTOR, HOSPITAL, and DATE. “B_X” or “B_Y” represents the beginning of the token, “I_X” or “I_Y” represents the intermediate of the token and “O” denotes others.

Table 5 mentions about case 1: missed entity error. Here the system was unable to identify the entity. In the following e.g. ‘DO’ which in actual represents the Doctor name was predicted as others. The reason for the error is the short words or the abbreviated words. ‘DO’ is the abbreviated form of doctor name ‘DO D LITTLE’ which is missed by the system.

Table 6 presents the case 2: actual entity error. Here the entity was predicted but was not able to classify it in the proper class. For example in the following sentence, ‘FOR’ was captured as the B-DOCTOR while it should be others.

Table 3. Results of 10-fold cross validation: Recall, precision & F-score values for individual entities

Class	Recall	Precision	F-Score
Overall	0.9569	0.9931	0.9746
Hospital	0.9056	0.9769	0.9399
Doctor	0.9380	0.9970	0.9666
Patient	0.9355	0.9831	0.9587
Date	0.9905	0.9984	0.9944

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 4. Different error cases

Case	Actual Labels	Classified Labels
MISSED ENTITY	B_X I_X	O
ACTUAL ENTITY	B_X I_X	B_Y I_Y
WRONG BOUNDARY	B_X I_X	B_X O
OVER PREDICT	O	B_X I_X

Table 5. CASE 1: Missed entity error

Words	DR.	DO	2	.	DO	D	LITTLE	,	M.D	.
Actual	O	B-DOCTOR	O	O	B-DOCTOR	I-DOCTOR	I-DOCTOR	O	O	O
Predicted	O	O	O	O	B-DOCTOR	I-DOCTOR	I-DOCTOR	O	O	O

Table 67. CASE 2: Actual entity error

Words	Dictating	For	DO	LITTLE	,	M.D	.
Actual	O	O	B-DOCTOR	I-DOCTOR	O	O	O
Predicted	O	B-DOCTOR	I-DOCTOR	I-DOCTOR	O	O	O

Table 7 represents the case 3: wrong boundary error. This case represents the boundary detection problem, where the system was able to capture the token properly but was not able to properly identify the boundary of the token. In the below example 'LITTLE' was not identified as the boundary of the system.

Table 8 represents the case 4: over predicted error. Last error occurred due to the over prediction where non-entity was categorized as the entity. For example here 'DO LITTLE' was categorized as the entity and was tagged by the DOCTOR. It might be because our system is unable to properly identify the context.

Table 7. CASE 3: Wrong boundary error

Words	HE	WILL	FOLLOW-UP	WITH	DR.	DO	LITTLE
Actual	O	O	O	O	O	B-DOCTOR	I-DOCTOR
Predicted	O	O	O	O	O	B-DOCTOR	O

Table 8. CASE 4: Over predict error

Words	DO	LITTLE	THORACOSCOPIC	EXAM	BX	DRAINAGE	.
Actual	O	O	O	O	O	O	O
Predicted	B-DOCTOR	I-DOCTOR	O	O	O	O	O

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

From the confusion matrix presented in Table 3, it was identified that mainly case 1 type of the error was more dominated.

- DOCTOR was tagged as O where there are the following forms: < D1 > M.D., < D2 > M.D., < D3> M.D.
- Misclassification has occurred when Hospital name is written in short for example CMC, FIH, OLH, HGMC etc.
- Most of the misclassification errors occurred when the patient name was preceded by the Mr., Mrs., Ms.
- Dates of the forms like 11th of April, January 25, Veterans Day were not captured properly.

CONCLUSION

In this paper, a clinical de-identification system is developed that aims to identify the Protected Health Information and to classify them into the predefined categories present in the clinical records. The proposed approach for de-identification is purely based on a popular machine learning technique. A variety of domain independent features, semantic, lexical features were designed for the system to be domain adaptable. Various others features extracted from localization dictionaries were combined in order to further enhance the performance of the system. The proposed system achieves encouraging performance. The system obtained the overall F-Measure of 97.46%, in identifying PATIENT, HOSPITAL, DOCTOR names and DATE.

However, a lot of issues are yet to be resolved. One such issue is to resolve abbreviation problem which is identified as a non-PHI term. In addition, it would be interesting to observe the performance of the proposed system on other type of PHI mentions.

FUTURE WORK

In future, this work can be extended using deep neural network architecture to identify the PHI terms from the medical records. Another major challenge is to deal ambiguity and abbreviation problem to properly distinguish PHI terms with non-PHI terms which can be another future work.

KEY TERMS AND DEFINITIONS

Classification: Classification in the machine learning is defined as the supervised learning technique where problem is to identify the class of the new observation with the already developed observations through the labeled data.

Conditional Random Field (CRF): An undirected probabilistic graphic model categorized under statistical modeling method used for structured prediction in machine learning and pattern recognition.

Health Insurance Portability and Accountability Act (HIPAA): An act formulated in 1996 for the secure transmission and usability of the private health information electronically.

Machine Learning: A field of computer science that exploits the development of the algorithms for making a prediction on the data on the basis of its learning.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Medical Natural Language Processing: A domain of natural language processing that focuses on text mining of the medical records like clinical texts.

Named Entity Recognition (NER): An entity extraction task which aims to identify and retrieve the text carrying relevant information into some predefined categories.

Natural Language Processing (NLP): A domain of computer science, computational linguistics and artificial intelligence that focuses on computers understand to human languages or natural language.

Support Vector Machine (SVM): A supervised learning model used in the classification that learns from the data by developing a model that maximizes the error margin.

Chapter 49
Neural Network Model for Semantic Analysis of Sanskrit Text

Smita Selot
SSTC, India

Neeta Tripathi
SSTC, India

A. S. Zadgaonkar
CV Raman University, India

ABSTRACT

Semantic analysis is the process of extracting meaning of the sentence, from a given language. From the perspective of computer processing, challenge lies in making computer understand the meaning of the given sentence. Understandability depends upon the grammar, syntactic and semantic representation of the language and methods employed for extracting these parameters. Semantics interpretation methods of natural language varies from language to language, as grammatical structure and morphological representation of one language may be different from another. One ancient Indian language, Sanskrit, has its own unique way of embedding syntactic information within words of relevance in a sentence. Sanskrit grammar is defined in 4000 rules by PaninI reveals the mechanism of adding suffixes to words according to its use in sentence. Through this article, a method of extracting meaningful information through suffixes and classifying the word into a defined semantic category is presented. The application of NN-based classification has improved the processing of text.

INTRODUCTION

Semantic, in basic form is the meaning of the sentence. In computer driven world of automation, it has become necessary for machine to understand the meaning of the given text for applications like automatic answer evaluation, summary generation, translation system etc. In linguistics, semantic analysis is the

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

process of relating syntactic structures, from words and phrases of a sentence to their language independent meaning. Given a sentence, one way to perform semantic analysis is to identify the relation of the words with action entity of the sentence. For example, *Rohit ate ice cream*, agent of action is Rohit, object on which action is performed is ice cream. This type of association creates predicate-arguments relation between the verb and its constituent. This association is achieved in Sanskrit language through *kArakA* analysis. Understanding of the language is guided by its semantic interpretation. Semantic analysis in Sanskrit language is guided by six basic semantic roles given by *pAninI* as *kAraka* values.

pAninI, an ancient Sanskrit grammarian, mentioned nearly 4000 rules called *sutra* in book called *asthadhyAyi;* meaning eight chapters. These rules describe transformational grammar, which transforms root word to number of dictionary words by adding proper suffix, prefix or both, to the root word. Suffix to be added depends on the category, gender, number of the word. Structured tables containing suffix are maintained for the purpose. These declension tables are designed in such a way that their position in the table are defined with respect to number, gender and *karka* value. Similar ending words follow the same declension, for example *rAma* is *a*-ending root word and words generated using *a*-ending declension table are r*AmH, rAmau rAmAH* by appending *H, au* and *AH* to *rAma*, respectively. Suffix based information of the word reveals not only syntactic but drives a way to find semantic based relation of words with verb using *kAraka* theory.

Next section describes Sanskrit language and *kAraka* theory, section three states the problem definition, followed by NN model for semantic analysis. Features extracted from corpus of pre-annotated text are supplied as input to system with objective of making system learn six *kAraka* defined by *pAninI.* This paper presents the concept of Neural Network, work done in the field of NN and Natural Language Processing, algorithm, annotated corpus and results obtained.

SANSKRIT AND *kAraka* THEORY

Sanskrit language, with well-defined grammatical and morphological structure, not only presents relation of suffix-affix with the word, but also provides syntactic and semantic information the of words in a sentence. Due to its rich inflectional morphological structure; it is predicted to be suitable for computer processing. Work at NASA on Sanskrit language reported that triplets (role of the word, word, action) generated from this language are equivalent to semantic net representation (Briggs 1995).

Sanskrit grammar is developed by three main individuals over the years – *pAninI*, *Katyanan* and *Patanjali*. *pAninI* was first one to identify nearly 4000 rules to define the language (Kak, 1987). Sanskrit is one of the 22 official languages of India and standardized dialect of old Indo-Aryan community. It is a rule-based language having flexibility and precision, both. It is an order free language – changing the position of the word, does not change the meaning of the sentence. Processing techniques for order free languages cannot be derived from rigid order language like English. *pAninI's* idea of semantic interpretation was based on identification of relations of words with action in a sentence. as agent, object etc. This was called as *kAraka* theory. In Sanskrit, this relationship is developed by adding specific, pre-set syllables, known as case-endings or *vibhakti* to the basic noun form.Natural language processing concept in *pAnini* way describes the processing of language

Sanskrit is highly inflectional language, where words are generated from the root word. Structure of the word is given as <word>=<prefix><root_word><suffix>. In pAninI system finite set of rules are enough to generate infinite sentences (Kak,1987). Extraction of prefix and suffix by morphologi-

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

cal analyzer accurately, help in syntactic and semantic analysis of the sentence. Case endings are the driving force for semantic interpretation as it can change the meaning of the sentence as stated in the example below:

1. *RamH bAlakam grAm**At** yaati.* (Rama **brings** the boy **from** the village.)
2. *RamH bAlakam grAm**am** yaati*. (Rama **takes** the boy **to** the village.)

This paper focuses on *kAraka* based semantic analysis of text under six *kAraka* as described in Table 1. Identification of *kAraka* values of words forms the basis of fundamental semantic interpretation (Bharati et. al 2008; Dwivedi 2002). Ancient old *kAraka* theory rules for external sandhi are modeled with finite state machine (Hyman 2009) and potential of *pAninI* grammar exceeds power of finite state machines. (Vaidya et. al. 2005). *kAraka* roles are equivalent to case-based semantics in event-driven situations, where each word or phrase is related to action. This relation is labeled as cases like agent, object, location (Kak 1987; Hellwig 2007). Under *pAnini* sytem of *kAraka* they are identified as *karta, karma, karan, sampradan, apadana* and *adhikaran* which are interpreted as agent, object, instrument, cause, source of departure and location respectively as presented in Table 1 (Kiparsky 2002) various algorithms over the years have evolved for semantic classification of words, text and documents. Rule based system are also one of the conventional and good means of extracting information. Order of application of rules from NLP perspective is optimized and implemented on subantaprakaraṇa of Siddhāntakaumudī. This system works well as Sanskrit is rules-based language. There is no order of rules defined in theory; but for practical implementation an optimized order is defined by the authors. (Patel & Katuri, 2015) One of the major problems is designing and incorporating large volume of rules and to handle the overlapping or conflicting cases (Selot et al., 2010). Development of knowledge representation for Sanskrit based on stated theory is also experimented. (Selot et al., 2007) Dependency amongst the constituent of the words in a sentence is also a means of representing semantic relation. (Pedersen et al., 2004)

A stochastic Part of Speech (POS) tagger for unprocessed Sanskrit text using Hidden Markov model was designed and analyzed. Parameters for the system were obtained from annotated corpus of about 1,500,000 words. System analyzed unannotated Sanskrit text by repeated application of stochastic model (Hellwig, 2007). Mathematical models such as Hidden Markov, Maximum Entropy and Support Vector machines are extensively used in natural language processing (Timothy, 2005). With evolution of statistical methods, N-gram models became popular in POS tagging. Trigram's and Tags (TnT) for POS tagging has proved to be an efficient tool for Persian language. (Tasharofi, 2008). Microsoft Research India (MSRI) introduced hierarchical Indic language POS tagset (IL-POSTS) for tagging Indian lan-

guages. An experiment on the use of the IL-POSTS for annotating Sanskrit corpus is conducted. (Jha et.al, 2010) Though statistical model are quite efficient and popular for language processing; neural network is equally efficient with reduced processing time in applications like text categorization (Babu, 2010).

With availability of natural language processing tools like nlptk; an open source platform; computations and analysis in the domain has taken a step forward in research areas. However, for Indian languages especially Sanskrit; availability of large volume of corpus and processing is still a challenge (Joon et al., 2017)

Use of Neural Network for complex task like NLP is rarely found as most of the work done using stochastic model reports an accuracy of more than 90%. Stochastic model requires large amount of pre-annotated corpus to calculate various probability values (Shan 2004). Lack of availability of such large size corpus for regional language hinders the development of NLP systems with high accuracy rate. Neural Network appears to be better choice for classifying the Sanskrit words in semantic classes as it has paradigm-based representation and had reported better result under sparse data.

PROBLEM DEFINITION

Processing of Sanskrit text is challenging one for two main reasons; firstly, it is order free and secondly words coagulate at junction to form a new word. Output oriented training of any language requires large tagged corpus for better results. Feature extraction from individual words is possible with such tagged data. Scarcity of tagged data in Sanskrit language restricts the number of algorithm that can be implemented for semantic extraction Hence, main objective is to identify the semantic relation of the word with action entity of the sentence under stated constraint environment. Given a word with its suffix, system identifies the *kAraka* value of the word from the set of predefined six *kAraka* roles. System is first trained for semantic classes using manually pre-annotated corpus. Features are extracted from corpus; set of input/output are stored and used for training. System's performance is then evaluated on new set tagged sentence. Manually annotated text was developed for experiment purpose. Challenge was mainly associated with conflicting cases. When a suffix maps to multiple semantic classes; means to resolve them was needed. Proposed system handled such conflict by maintaining context-based features as most of the conflicts are resolved by occurrence of a particular word or its constituents in context window. Neural Network is used to train the system as it works well in sparse data. Effort in development of this algorithm has an objective of accomplishing learning of semantic relation through a technical approach and analysing its inbuilt scientific way of its representation. Finally, performance of the system is discussed is reported.

FEATURE SELECTION

Annotated corpus describing syntactic and *kAraka* categories of words is manually generated. It includes the suffix-affix information, category, *vibhakti* in nouns and tense and mood in verbs. Set of features generally used to train the system are morphological feature, corpus-based feature, context-based feature and lexicon-based feature.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Morphological Features

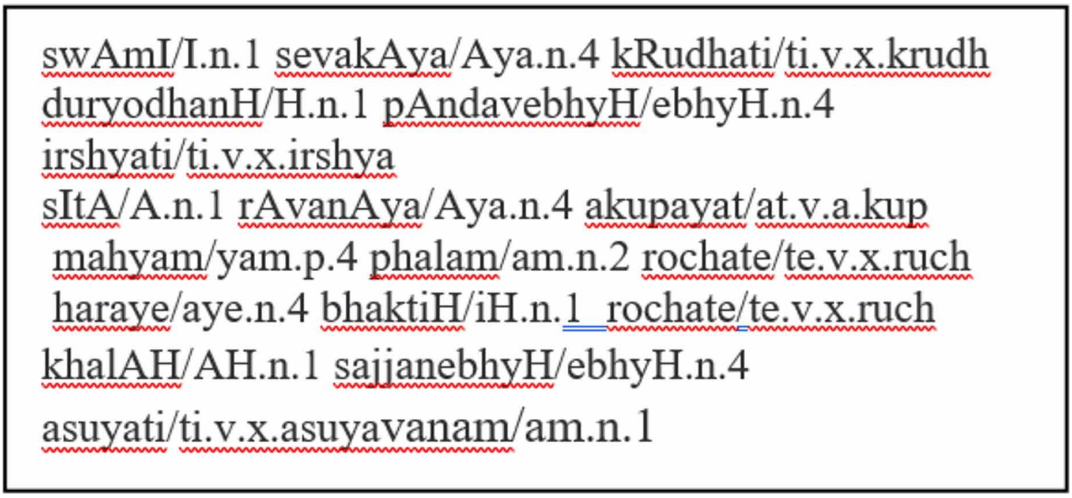
It includes the suffix and prefixes of words in the context. Prefix or suffix is a sequence of first or last few characters of a word, which does not possess linguistically meaning. Use of prefix and suffix information works well for highly inflected languages.

Corpus Based Features

Corpus based features play a crucial role in tagging of words. Each word is to be tagged with one of the six *pAninI* class. Not all the words will fall under six tags; some words exhibit relation with subsequent words, they are categorized as relation class. For words which are neither in six tags nor in relation tag are assigned category other. To finalize a tag for a word, its historical information in form of probability is calculated from corpus. A probability vector is associated with each suffix which gives the chances of assigning a particular *kAraka* to a word with a defined suffix.

Context Based Features

In declension tables; in some cases, particular suffix occupies more than one place, resulting in ambiguity. To resolve the *kAraka* or *vibhakti* ambiguity associated with the word, values of proceeding and successive words are taken into consideration. It is quite arguable that for order free languages, like Sanskrit and Hindi, context-based feature should not be considered. But, it has been found that occurrence of a particular word before or after the word generates important clue in resolving the *kAraka* or *vibhakti* ambiguity. For example, in the word *vanam, am* suffix occupies two different *vibhakti* position- first and second. As observed in the grammar, occurrence of words like *dhik,hA, ubhyatH, pAritH* confirms the *vibhakti* value of *am* as *dviteeyA*. (Rao 2005). Context window of various sizes are used in problems like word sense disambiguation (WSD), POS tagging, semantic tagging etc. Window size of three gives better result maintaining the balance between accuracy and processing overhead. Hence context window of size three (w_{i+1}, w_i, w_{i-1}) is taken for resolving the *vibhakti* ambiguity associated with Sanskrit language.



Lexicon Based Feature

Instead of maintaining a complete dictionary of words, list of verbal and nominal bases has been maintained. There is strong association of words with the verb occurring in the sentence. For example, in deciding *vibhakti* value for *am* suffix, occurrence of any one of sixteen-verbal base confirms the *vibhakti* value of *am* as second. These sixteen verbs are {*dhuH, yAch, pach, chi bru, Shas anD, rudh, pRich, ji, math, mush, ni, kriSh, hRi* }(Dwivedi 2002). Likewise, a complete database of nominal base is also maintained. Features are selected from the annotated corpus and are assigned numeric value after mapping them to numeric data. A sample tagged data used for training is shown in the Figure 1; where each word is tagged with its suffix, syntactic category and *kAraka* value. For example; first word in the Figure 1; *swAmI;* contains *I* suffix, part-of-speech is noun and *kAraka* value is 1 *prathamA*

Set of features selected are quantified and used for training network. Text coverage of suffix plays an important role in resolving the conflict.

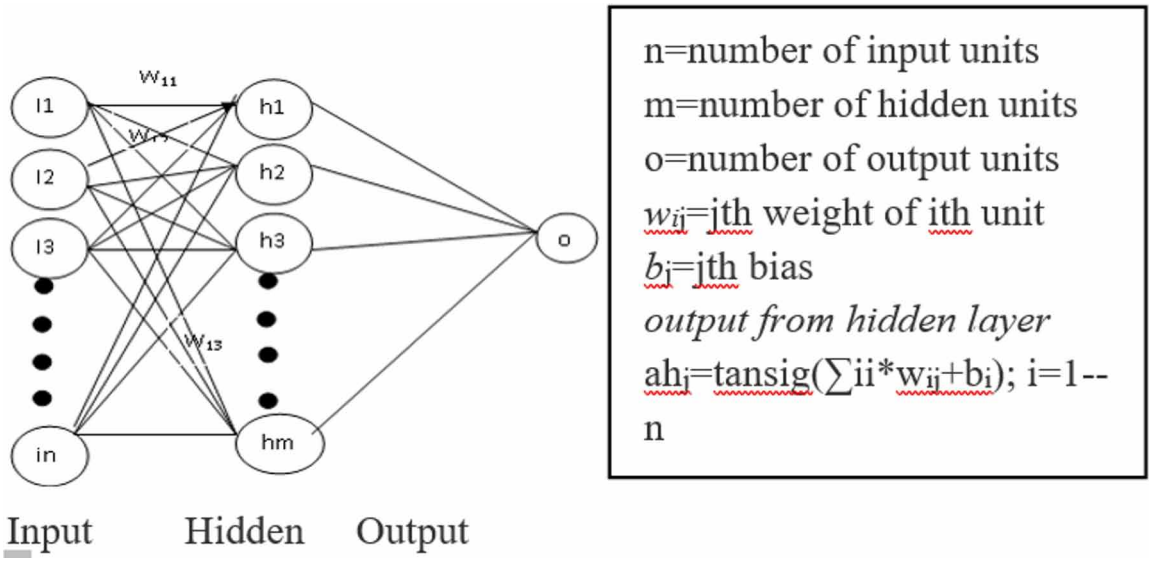
NN MODEL FOR SEMANTIC CLASSIFICATION

Popular methods for NLP are rule based or stochastic models, where former emphasizes on rules of language and later uses large corpus for processing. Major task in NLP at syntactic and semantic level is classification of words or phrases. Neural network is popular tool for classification task which uses an extensive data driven approach for solving complex problem Capabilities of NN are exploited in classification task related to natural language, such as text categorization, POS tagging etc. It has been shown that NN based text categorization is better than N-gram approach giving 98% accuracy with speed five times faster than N-gram (Kumar 2010). A multi layered neural network with the back propagation is used for solving the problem. Input to the system is syntactic and morphological features of the previous and successive words in a sentence. Brief working of Multi layered perceptron (MLP) based NN is explained in the Figure 2.

MLP Network



It consists of minimum of three layers input, hidden and output layer represented by symbol i, h and o as presented in Figure 2. Each layer consists of processing units termed as neurons. Fully connected network uses sigmoid activation function which limit the output from hidden unit between -1 and 1. MLP projects the data to be classified into different spaces, where neuron of output participates in the separation of classes. Final outcome is obtained by applying purelin function as output is in range 1 to 6 depending upon the *kAraka* value.

Back Propagation Learning Algorithm

Learning algorithms are commonly used to make computer system learn a concept for particular applications. Neural Network is one of the learning environments simulating human brain. It consists of three layers namely input, hidden and output layer. Network is trained with set of defined input-output

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. Three-layer MLP network

data set. Performance of the system is tested by comparing actual output with desired one. Back propagation algorithm calculates error and sends it back to neurons for weight adjustment. After each pass error is reduced and system is tuned for better results. System works in two phases, in forward phase weights are multiplied to respective inputs and bias is added to it. Result is fed as input to hidden layer; after squashing the values. Data obtained from hidden is fed to output layer; to limit the range sigmoid function is applied. Output obtained is compared with actual output and error is measured as difference of the two. In the backward phase, error is transmitted back; and weights are modified as function of error. In the forward phase, weights of the directed links remain unchanged at each processing unit of the hidden layer. For n input values to the network; weighted sum is obtained and sigmod function is applied to this weighted sum as given in Equations (1) and (2):

$$u_j = \sum_{1}^{n} w_{ij}^{h} pj + b \tag{1}$$

$$h_j = 1 \Big/ 1 - e^{u_j} \tag{2}$$

where h_j is the output from the jth hidden unit. At each processing unit j of the output layer; weighted outputs from the all neuron of hidden layer are added using Equation 3 and resulting value is passed through a sigmoid function as given in Equation 4:

$$v_j = \sum_{1}^{n} w_{ij}^{y} h_j + b \tag{3}$$

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

$$y_j = 1 \Big/ 1 - e^{v_j} \tag{4}$$

where y_j is the final output. If t_0 is the desired output and y_0 is the actual output, in the backward pass, for every output neuron, local gradient is calculated as per Equations 5:

$$g_o = E_o y_o (1 - y_o) \tag{5}$$

where $E_o = t_o - y_o$ (6)

likewise, for each hidden neuron, local gradient is calculated as:

$$g_h = E_h h_i (1 - h_i) \tag{7}$$

where $E_h = \sum_1^n g_o w_{ij}^y$ (8)

To speed up the training process, momentum term α and learning rate η, is added to the weight update formulae in hidden and output layers as given in Equations 9 and 10:

$$\left.\begin{aligned} \Delta w_{ij}^h (new) &= \eta g_h h_i + \alpha \Delta w_{ij}^h (old) \\ w_{ij}^h (new) &= w_{ij}^h (old) + \Delta w_{ij}^h (new) \end{aligned}\right\} \tag{9}$$

$$\left.\begin{aligned} \Delta w_{ij}^y (new) &= \eta g_O y_i + \alpha \Delta w_{ij}^y (old) \\ w_{ij}^y (new) &= w_{ij}^y (old) + \Delta w_{ij}^y (new) \end{aligned}\right\} \tag{10}$$

Outline of Algorithm

Step 1: Weights are initialized to small random variables
Step 2: For each input-output training pair
Input vector=<p_1, p_2… p_n>
Weight for first neuron = <w_{11}, w_{21}, w_{31}… w_{n1}>
Output=<y_0>
Step 3: Transmit input values to neurons of hidden layer.

$$u_j = \sum_1^n w_{ij}^h pj + b$$

Step 4: Apply activation function

$$h_j = 1 \Big/ 1 - e^{u_j}$$

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Step 5: Each output unit receives sum of weighted input and applies an activation function to it

$$v_j = \sum_{1}^{n} w_{ij}^{y} h_j + b$$

$$y_j = 1 \Big/ 1 - e^{v_j}$$

Step 6: Each output unit, difference between target and desired value is calculated as an error.

$E_{rr} = t_o - y_o$

Step 7: At each hidden unit the error is calculated as error from the layer above it.
Step 8: Weights and biases are updated at input and hidden layer
Step 9: Stopping condition is tested
Step 10: Repeat steps 3 to 9 till stopping condition is achieved

Processing of text using NN requires a defined set of input data in numerical form. Numerically encoded data is generated by capturing various features of the input. For language processing applications, these features include – morphological, corpus-based, context based, lexicon-based features. Next section explains the generation of encoded data.

Encoding of the Input Data

Features vector, input to the NN, is generated by converting different features to their numeric form as described in the Table 2.

Algorithm for encoding input values reads the pre-annotated text and converts the data into feature vector.

System is trained using multilayer neural networks with *squashing* functions in the hidden layer. These functions compress an infinite input range of input values to a finite output range. In sigmoid functions, slope approaches zero as input gets larger. This causes problem in steepest descent, as gradient has small value, changes in weight and biases are very small, though they are far from their optimum values. Re-

Table 2. Sample set of encoded values

Class\number	1	2	3	4	5	6
category	Pronoun	Noun	Verb	Avaya	Adverb	
Prefix(verb)	Up	Anu	Adi	A	Abhini	
Verb(root)	Gachch	Pach	Kar	Bhu	Anay	as
Vibhakti	Agent	Object	instrument	cause	From	Relation
Suffix(verb)	ti	si	At	ami	Anti	AmH
Suffix(noun)	No suffix	Am	H	Aya	ebhyH	Asya

silient back propagation removes these problems of magnitude of partial derivative. It uses sign of the derivative to determine the direction of weight update. Amount of weight change is determined by the separate update value and is incremented by an amount delta_inc whenever the derivative change sign from previous iteration. Weight is unchanged if derivative is zero; change is decreased for oscillating weights and increased if weight continues to change in same direction.

In NN based semantic classification, resilient back propagation algorithm is implemented.

Input Data for the BPN

Feature vector, main input in network, is generated by extracting parameters from annotated corpus. These parameters are classified under different category as given in the Table 3. Suffixes and prefixes fall under morphological features; are crucial part of feature vector Apart from this, context based and syntactic class also form a part of the vector. Context based features are significant as they help in resolving the conflict. Occurrence of multiple matched suffixes in a particular *vibhakti* group is governed by occurrence of special words at preceding and successive positions.

Data set of pre-annotated sentences is created with tagged words revealing the syntactic feature, morphological and semantic features of the words such as suffix, category and *vibhakti* value. Annotated corpora contain sentences taken from various Sanskrit text books. An example of dataset and its generated encoded form is presented in Figure 3. Algorithm for generating the encoded data after reading each sentence of a pre-annotated data is presented below:

Step 1: Identify the word of each sentence
Step 2: Read the features tagged with word
Step 3: Identify the type of feature
Step 4: Convert them into the numeric value as described in Table 2.
Step 5: Identify the *vibhakti* value and store it as target value
Step 6: Store the information in the file

Output is *kAraka* value of the word stored in a fil. Each case or *kArka* is defined as follows: 1 for *kartA*,2 for *karma,*3 for *karan,*4 for *sampradan,*5 for *apAdAn* and 7 for *adhikaran.* Number 6 is used for *sambandh kAraka* which is not included in the *pAninI* class.

The encoded data is used for training network with back propagation using 200 sentences. Network is trained using resilient back propagation algorithm for data set and the result is shown in the Figure 4.

BPN data set for encoded input/output values were used and system performance is calculated. As shown in the figure system was trained in less than 400 epochs.

Table 3. Feature selected

Parameter	Feature type
Prefix and suffix of noun and verb	Morphological
Word category	Feature based on syntax
Verb root	Lexical feature
Successive and previous words	Context based feature

CONCLUSION

Experiments for *kAraka* based semantic classification using neural networks were conducted as per algorithms discussed in previous section. Tagged data of 200 sentences were created as shown in the Figure 1 Out of 200 sentences, 80% of the data was used in training the network with back propagation and 20% of the data was used for testing. Back propagation algorithm with gradient descent and resilient learning is used to train the three-layered network where system was trained in 500-800 epochs. Performance of resilient BP algorithm has shown better results over gradient descent. Data was tested with different learning rate as shown in the Table 4 where n = number of epochs and lr = learning rate

Data at the serial number 2 shows the best performance with time, otherwise as the number of neuron increases, training time increases. Time is also dependent on the learning rate, higher the learning rate, faster the system and vice versa. Trained NN was tested on the 20 sentences. Out of which the identification of each class is shown in the Table 5. Using resilient BPN algorithm, best output is obtained with 200, 250 300 neurons and 0.01 learning rate. Using this data, the system was further tested, and the output was classified for the various semantic classes. Accuracy of the test was measured by F-measure given in Equation 11:

$$F = 2(p \times r)/(p + r) \tag{11}$$

Average performance of the system with respect to F-Score is 0.8243. Test data with 40 sentences were used for Case Frame generation out of which 22 were generated with 100% accuracy, 12 with accuracy between 50-100% and remaining with accuracy less than 50% thereby giving an overall performance of 72.5%. F_measure presents weighted score of the individual *kAraka* value and overall accuracy is measured degree of correctness achieved in each CF generation.

Statistical tools are commonly used in NLP applications like POS tagging, semantic classification, word sense disambiguation etc. They give an accuracy of 90% and above.

Table 4. Trained data with different learning rate

pAninI **class**	**f**	**n**	**c**	**p**	**r**	**F**
Karta	20	18	17	0.940	0.850	0.890
Karma	15	12	11	0.916	0.730	0.812
Karan	15	13	10	0.760	0.660	0.706
sampradAn	13	12	11	0.916	0.846	0.879
apAdAn	13	12	10	0.833	0.769	0.790
Adhikaran	12	11	10	0.909	0.833	0.869

Where p is precision; r is recall and F is F score.p and r are calculated as follows:
p = Number of accurate result /total number of returned result
r = Number of exact result / Number of results to be returned.
F score is calculated as weighted average of precision and recall using Equation (11). F-Score of each class under NN is given in Table 5.
f = frequency of occurrence of each class in corpus
n = total count of a particular class in data
c = number correctly identified by the system

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 5. Classification of pAninI for test data

S. No	Epochs	n	Lr	Performance	Time (in sec)
1	460	200	0.01	0.009981	11.20
2	**322**	**200**	**0.03**	**0.009980**	**7.75**
3	507	200	0.05	0.009980	12.43
4	462	250	0.01	0.009980	18.62
5	454	250	0.03	0.009990	17.72
6	270	250	0.05	0.009980	10.59
7	243	300	0.05	0..009996	11.32
8	382	300	0.03	0.009995	17.66
9	247	300	0.01	0.009985	11.81

Due to inherent complexities and ambiguities in languages, Syntactic and semantic classifications become a great challenge. Collection of tagged corpus with wide coverage of all scenarios plays an important role in training NLP system. Statistical tool, supported by large set of tagged corpus, has given accuracy of 90% and above. All languages are not rich in resources. Tagged corpus rarely cover all scenarios or conflicting cases. Processing of Sanskrit, an ancient language, with high deep rooted morphological structure but with scarce resources, was a great challenge. At the same time applications of neural networks for classification purpose under sparse data had proved to be a better tool. Hence, experimental set up was built to analyze the semantic classification after training NN for these classes under *pAninI* framework. NN has proved to be an efficient tool for semantic classification of the Sanskrit words.

This work can further be enhanced for automatic feature extraction of each word. As structure of the basic word in Sanskrit contain prefix, root word and suffix; an algorithm for breaking word into its constituent and mapping it into feature set can be developed. Incorporation of deep learning in classification can be experimented for further improvement of the system.

Chapter 50
Probabilistic Nodes Combination (PNC): Formulas and Examples

Dariusz Jacek Jakóbczak
Technical University of Koszalin, Poland

ABSTRACT

The method of Probabilistic Nodes Combination (PNC) enables interpolation and modeling of two-dimensional curves using nodes combinations and different coefficients γ: polynomial, sinusoidal, cosinusoidal, tangent, cotangent, logarithmic, exponential, arc sin, arc cos, arc tan, arc cot or power function, also inverse functions. This probabilistic view is novel approach a problem of modeling and interpolation. Computer vision and pattern recognition are interested in appropriate methods of shape representation and curve modeling. PNC method represents the possibilities of shape reconstruction and curve interpolation via the choice of nodes combination and probability distribution function for interpolated points. It seems to be quite new look at the problem of contour representation and curve modeling in artificial intelligence and computer vision. Function for γ calculations is chosen individually at each curve modeling and it is treated as probability distribution function: γ depends on initial requirements and curve specifications.

INTRODUCTION

Probabilistic modeling is still a developing branch of economic and computer sciences: operational research (for example probabilistic model-based prognosis) (Lorton, Fouladirad & Grall, 2013), decision making techniques and probabilistic modeling (Pergler & Freeman, 2008), artificial intelligence and machine learning. Different aspects of probabilistic methods are used: stochastic processes and stochastic model-based techniques, Markov processes (Cocozza-Thivent, Eymard, Mercier & Roussignol, 2006), Poisson processes, Gamma processes, Monte Carlo methods, Bayes rule, conditional probability and many probability distributions. In this chapter the goal of a probability distribution function is to describe the position of unknown

points between given interpolation nodes. Two-dimensional curve is used to represent the data points and extrapolation of the unknown values enables analyzing risk and then decision making.

The chapter clarifies the significance and novelty of the proposed method compared to existing methods (for example polynomial interpolations and Bézier curves). Previous published papers of the author were dealing with the method of Hurwitz-Radon Matrices (MHR method). Novelty of this chapter and proposed method consists in the fact that calculations are free from the family of Hurwitz-Radon Matrices. Problem statement of this chapter is: how to reconstruct (interpolate) missing points of 2D curve and how to anticipate (extrapolate) unknown values or data having the set of interpolation nodes (key points) and using the information about probabilistic distribution of unknown points. For example the simplest basic (uniform) distribution leads to the easiest interpolation – linear interpolation. Apart from probability distribution, additionally there is the second factor of proposed interpolation method: nodes combination. The simplest nodes combination is zero. Thus proposed curve modeling and extrapolation is based on two agents: probability distribution and nodes combination. First trial of probabilistic modeling in MHR version was described in (Jakóbczak, 2013). Significance of this chapter consists in generalization for MHR method: the computations are done without matrices in curve fitting and data anticipation, with clear point interpolation formula based on probability distribution function (continuous or discrete) and nodes combination. The chapter also consists of generalization for linear interpolation with different (non-uniform) probability distribution functions and nodes combinations. So this chapter answers the question: "Why and when should we use Probabilistic Nodes Combination (PNC) method in extrapolation and interpolation?".

Curve interpolation (Collins, 2003) represents one of the most important problems in mathematics and computer science: how to model the curve (Chapra, 2012) via discrete set of two-dimensional points (Ralston & Rabinowitz, 2001)? Also the matter of shape representation (as closed curve-contour) and curve parameterization is still opened (Zhang & Lu, 2004). Operational research in planning and scheduling, also decision making systems in risk analysis, solve the problems which are based on data modeling and extrapolation via the choice of key points. So interpolation and extrapolation is not only a pure mathematical problem but important task in economic and artificial intelligence. The chapter wants to approach a problem of curve modeling by characteristic points. Proposed method relies on nodes combination and functional modeling of curve points situated between the basic set of key points and outside of this set. The functions that are used in calculations represent whole family of elementary functions with inverse functions: polynomials, trigonometric, cyclometric, logarithmic, exponential and power function. These functions are treated as probability distribution functions in the range [0;1].

An important problem in operational research and computer sciences (Ballard, 1982) is that of appropriate shape representation and reconstruction. Classical discussion about shape representation is based on the problem: contour versus skeleton. This chapter is voting for contour which forms boundary of the object. Contour of the object, represented by contour points, consists of information which allows us to describe many important features of the object as shape coefficients (Tadeusiewicz & Flasiński, 1991). In the chapter contour is dealing with a set of curves. Curve modeling and generation is a basic subject in many branches of industry and computer science, for example in the CAD/CAM software.

The representation of shape has a great impact on the accuracy and effectiveness of object recognition (Saber, Yaowu & Murat, 2005). In the literature, shape has been represented by many options including curves (Sebastian & Klein, 2003), graph-based algorithms and medial axis (Liu & Geiger, 1999) to enable shape-based object recognition. Digital curve (open or closed) can be represented by chain code (Freeman's code). Chain code depends on selection of the started point and transformations of the

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

object. So Freeman's code is one of the methods how to describe and to find contour of the object. An analog (continuous) version of Freeman's code is the curve α-*s*. Another contour representation and reconstruction is based on Fourier coefficients calculated in Discrete Fourier Transformation (DFT). These coefficients are used to fix similarity of the contours with different sizes or directions. If we assume that contour is built from segments of a line and fragments of circles or ellipses, Hough transformation is applied to detect contour lines. Also geometrical moments of the object are used during the process of object shape representation (Choraś, 2005). Proposed method, called Probabilistic Nodes Combination (PNC), is the method of 2D curve interpolation and extrapolation using the set of key points (knots or nodes). Nodes can be treated as characteristic points of data for modeling and analyzing. The model of data can be built by choice of probability distribution function and nodes combination. PNC modeling via nodes combination and parameter γ as probability distribution function enables value anticipation in risk analysis and decision making. Two-dimensional curve is extrapolated and interpolated via nodes combination and different functions as discrete or continuous probability distribution functions: polynomial, sine, cosine, tangent, cotangent, logarithm, exponent, arc sin, arc cos, arc tan, arc cot or power function. Novelty of this book consists of two generalizations: generalization of previous MHR method with various nodes combinations and generalization of linear interpolation with different (no basic) probability distribution functions and nodes combinations.

Curve interpolation represents one of the most important problems in mathematics and computer science: how to model the curve via discrete set of two-dimensional points? Also the matter of shape representation (as closed curve-contour) and curve parameterization is still opened. For example pattern recognition, signature verification or handwriting identification problems are based on curve modeling via the choice of key points. So interpolation is not only a pure mathematical problem but important task in computer vision and artificial intelligence. The monograph wants to approach a problem of curve modeling by characteristic points. Proposed method relies on nodes combination and functional modeling of curve points situated between the basic set of key points. The functions that are used in calculations represent whole family of elementary functions with inverse functions: polynomials, trigonometric, cyclometric, logarithmic, exponential and power function. These functions are treated as probability distribution functions in the range [0;1]. The method of Probabilistic Nodes Combination (PNC) enables interpolation and modeling of two-dimensional curves using nodes combinations and different coefficients γ: polynomial, sinusoidal, cosinusoidal, tangent, cotangent, logarithmic, exponential, arc sin, arc cos, arc tan, arc cot or power function, also inverse functions. This probabilistic view is novel approach a problem of modeling and interpolation. Computer vision and pattern recognition are interested in appropriate methods of shape representation and curve modeling. PNC method represents the possibilities of shape reconstruction and curve interpolation via the choice of nodes combination and probability distribution function for interpolated points. It seems to be quite new look at the problem of contour representation and curve modeling in artificial intelligence and computer vision.

BACKGROUND

All interpolation theory is based on polynomials. But why? Many kinds of polynomials are used for interpolation: classical polynomials, trigonometric polynomials, orthogonal polynomials (Tschebyscheff, Legendre, Laguerre), rational polynomials. But what about the exceptional situations with unexpected features of curve, data or nodes. Then polynomials are not the solution, for example when:

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

1. The curve is not a graph of function (no matter – opened or closed curve);
2. The curve does not have to be smooth at interpolation nodes: for example curve representing symbols, signature, handwriting or other specific data;
3. Nodes are fixed and there is no possibility to choose "better" nodes as for orthogonal polynomials;
4. The curve differs considerably from any interpolation polynomial;
5. The curve fails to be differentiable at some points;
6. Between each pair of nodes we are not interested in linear interpolation (uniform probability distribution and zero nodes combination) but there ought to be some generalization (even for two nodes only) with other probability distributions and nodes combinations;
7. Interpolated points depend on some chosen nodes (two nearest nodes or more) via nodes combination $h(p_1,p_2,\ldots,p_m)$ in (1);
8. We are not interested in the formula of interpolation function (for lower computational costs) but only calculated points of modeled curve are ready to be used in numerical computations;
9. The formula of curve or function is known but from some reason (for example high computational costs or hard polynomial interpolation) the curve has to be modeled or fitted in some way for numerical calculations – the examples for PNC interpolation (in MHR version) of functions $f(x) = 2/x$ and $f(x) = 1/(1+5x^2)$ with quantified measures and experimental comparison with classical polynomial interpolation in (Jakóbczak, 2010);
10. Extrapolation problem is also a big numerical challenge and PNC interpolation enables the extension into extrapolation (Jakóbczak, 2011) with α outside of [0;1] and $\gamma = F(\alpha)$ still strictly monotonic, $F(0) = 0$, $F(1) = 1$. So for example $\gamma = \alpha^2$ is impossible for extrapolation if $\alpha < 0$ (Jakóbczak, 2011). Polynomial or other interpolations are sometimes useless for extrapolation;
11. Having only nodes the user may have "negative" information (from specific character of data): no polynomial interpolation;
12. All calculations are numerical (discrete) – even $\gamma = F(\alpha)$ is to be given in tabular (discrete) form. There is no need to build continuous function: polynomial or others;
13. Parametric version of modeled curve is to be found.

Above thirteen important and heavy individual and characteristic features of some curves and their interpolations show that there may exist the situations with unexpected assumptions for interpolation.

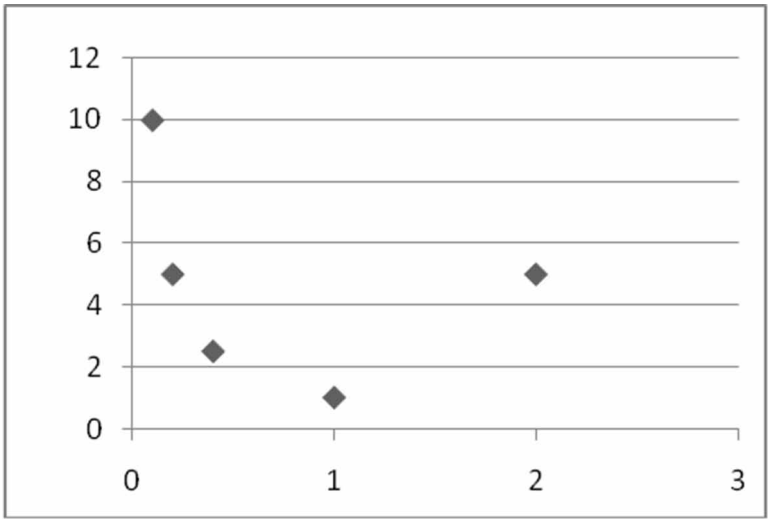
Why not classical interpolation? Classical methods are useless to interpolate the function that fails to be differentiable at one point, for example the absolute value function $f(x) = |x|$ at $x = 0$. If point (0;0) is one of the interpolation nodes, then precise polynomial interpolation of the absolute value function is impossible. Also when the graph of interpolated function differs from the shape of polynomial considerably, for example $f(x) = 1/x$, interpolation is very hard because of existing local extrema and the roots of polynomial. We cannot forget about the Runge's phenomenon: when nodes are equidistance then high-order polynomial oscillates toward the end of the interval, for example close to -1 and 1 with function $f(x) = 1/(1+25x^2)$ (Ralston & Rabinowitz, 2001). These classical negative cases do not appear in proposed PNC method. Experimental comparison for PNC with polynomial interpolation is to be found in (Jakóbczak, 2009).

Nowadays methods apply mainly polynomial functions in different versions (trigonometric, orthogonal, rational) and for example Bernstein polynomials in Bezier curves, splines (Schumaker, 2007) and NURBS (Rogers, 2001). But Bezier curves don't represent the interpolation method (rather interpolation-approximation method) and cannot be used for example in handwriting modeling with key points (interpolation

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

nodes). In comparison PNC method with Bézier curves, Hermite curves and B-curves (*B-splines*) or NURBS one unpleasant feature of these curves has to be mentioned: small change of one characteristic point can result in unwanted change of whole reconstructed curve. Such a feature does not appear in proposed PNC method which is more stable than Bézier curves. Only first and last characteristic point is situated on the Bézier curve (interpolation), the rest characteristic points lay outside the Bézier curve (approximation). Numerical methods for data interpolation are based on polynomial or trigonometric functions, for example Lagrange, Newton, Aitken and Hermite methods. These methods have many weak sides (Dahlquist & Bjoerck, 1974) and are not sufficient for curve interpolation in the situations when the curve cannot be build by polynomials or trigonometric functions. Also there exists several well established methods of curve modeling, for example shape-preserving techniques (Dejdumrong, 2007), subdivision algorithms (Dyn, Levin & Gregory, 1987) and others (Kozera, 2004) to overcome difficulties of polynomial interpolation, but probabilistic interpolation with nodes combination seems to be quite novel in the area of shape modeling. Proposed 2D curve interpolation is the functional modeling via any elementary functions and it helps us to fit the curve during the computations.

This chapter presents novel Probabilistic Nodes Combination (PNC) method of curve interpolation. This chapter takes up new PNC method of two-dimensional curve modeling via the examples using the family of Hurwitz-Radon matrices (MHR method) (Jakóbczak, 2007), but not only this method (other nodes combinations). The method of PNC requires minimal assumptions: the only information about a curve is the set of at least two nodes. Proposed PNC method is applied in curve modeling via different coefficients: polynomial, sinusoidal, cosinusoidal, tangent, cotangent, logarithmic, exponential, arc sin, arc cos, arc tan, arc cot or power. Function for PNC calculations is chosen individually at each interpolation and it represents probability distribution function of parameter $\alpha \in [0;1]$ for every point situated between two interpolation knots. PNC method uses two-dimensional vectors (x,y) for curve modeling-knots $p_i = (x_i,y_i) \in \boldsymbol{R^2}$ in PNC method, $i = 1,2,\ldots n$:



1. PNC needs 2 knots or more ($n \geq 2$);
2. If first node and last node are the same ($p_1 = p_n$), then curve is closed (contour);
3. For more precise modeling knots ought to be settled at key points of the curve, for example local minimum or maximum and at least one node between two successive local extrema.

Condition 3 means for example the highest point of the curve in a particular orientation, convexity changing or curvature extrema. So this chapter wants to answer the question: how to interpolate the curve by a set of knots (Jakóbczak, 2010)?

Nodes on Figure 1 represent characteristic points of the handwritten letter or symbol: if $n = 5$ then curve is opened and if $n = 6$ then curve is closed (contour). The examples of PNC curve modeling for these nodes are described later in this chapter. Coefficients for PNC curve modeling are computed using nodes combinations and probability distribution functions: polynomials, power functions, sine, cosine, tangent, cotangent, logarithm, exponent or arc sin, arc cos, arc tan or arc cot.

NOVELTY OF PROBABILISTIC INTERPOLATION AND EXTRAPOLATION

Issues

The method of PNC enables to compute points between two successive nodes of the curve: calculated points are interpolated and parameterized for real number $\alpha \in [0;1]$ in the range of two successive nodes. PNC method uses the combinations of nodes $p_1=(x_1,y_1)$, $p_2=(x_2,y_2),\ldots$, $p_n=(x_n,y_n)$ as $h(p_1,p_2,\ldots,p_m)$ and $m = 1,2,\ldots n$. Nodes combination h is defined individually for each curve to interpolate points (x,y) with second coordinate $y = y(c)$ for any first coordinate $x = c$ situated between nodes (x_i,y_i) and (x_{i+1},y_{i+1}):

$c = \alpha \cdot x_i + (1-\alpha) \cdot x_{i+1}$, $i = 1,2,\ldots n-1$,

$$y(c) = \gamma \cdot y_i + (1-\gamma) y_{i+1} + \gamma(1-\gamma) \cdot h(p_1, p_2, \ldots, p_m), \quad (1)$$

$\alpha \in [0;1]$, $\gamma = F(\alpha) \in [0;1]$, $F:[0;1] \rightarrow [0;1]$, F(0)=0, F(1)=1 and F is strictly monotonic.

PNC extrapolation requires α outside of $[0;1]$: $\alpha < 0$ (anticipating points right of last node for $c > x_n$) or $\alpha > 1$ (extrapolating values left of first node for $c < x_1$), $\gamma = F(\alpha)$, $F:P \rightarrow \mathbf{R}$, $P \supset [0;1]$, F(0)=0, F(1)=1 and F is still strictly monotonic for the arguments from P. So c and α represent the same – coordinate x of any point (x,y) between two successive nodes (x_i,y_i) and (x_{i+1},y_{i+1}): having c we can calculate α and vice versa. PNC curve modeling relies on two factors: function $\gamma = F(\alpha)$ and nodes combination $h(p_1,p_2,\ldots,p_m)$. Function F is a probabilistic distribution function for random variable $\alpha \in [0;1]$ and parameter γ leads PNC interpolation into probabilistic modeling. Second factor, the combination of nodes h, is responsible for making dependent a reconstructed point on the coordinates of several nodes. The simplest case is for $h = 0$. Here are the examples of h computed for MHR method (Jakóbczak, 2009):

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

$$h(p_1, p_2) = \frac{y_1}{x_1} x_2 + \frac{y_2}{x_2} x_1$$

(only two neighboring nodes are taken for PNC calculations) or

$$h(p_1, p_2, p_3, p_4) = \frac{1}{x_1^2 + x_3^2}(x_1 x_2 y_1 + x_2 x_3 y_3 + x_3 x_4 y_1 - x_1 x_4 y_3) + \frac{1}{x_2^2 + x_4^2}(x_1 x_2 y_2 + x_1 x_4 y_4 + x_3 x_4 y_2 - x_2 x_3 y_4)$$

(more than two neighboring nodes are used in PNC interpolation).

The examples of other nodes combinations are presented below. Formula (1) represents curve parameterization ($x(\alpha)$,$y(\alpha)$) between two successive nodes (x_i,y_i) and (x_{i+1},y_{i+1}) as $\alpha \in [0;1]$:

$$x(\alpha) = \alpha \cdot x_i + (1\text{-}\alpha) \cdot x_{i+1}$$

and

$$y(\alpha) = F(\alpha) \cdot y_i + (1 - F(\alpha)) y_{i+1} + F(\alpha)(1 - F(\alpha)) \cdot h(p_1, p_2, ..., p_m),$$

$$y(\alpha) = F(\alpha) \cdot (y_i - y_{i+1} + (1 - F(\alpha)) \cdot h(p_1, p_2, ..., p_m)) + y_{i+1}.$$

Proposed parameterization gives us the infinite number of possibilities for curve calculations (determined by choice of F and h) as there is the infinite number of human handwritten letters and symbols. Nodes combination is the individual feature of each modeled curve (for example a handwritten character). Coefficient $\gamma = F(\alpha)$ and nodes combination h are key factors in PNC curve interpolation and data extrapolation.

Distribution Functions in PNC Interpolation and Extrapolation

Points settled between the nodes are computed using PNC method. Each real number $c \in [a;b]$ is calculated by a convex combination $c = \alpha \cdot a + (1\text{-}\alpha) \cdot b$ for

$$\alpha = \frac{b - c}{b - a} \in [0;1].$$

Key question is dealing with coefficient γ in (1). The simplest way of PNC calculation means $h = 0$ and $\gamma = \alpha$ (basic probability distribution – uniform distribution). Then PNC represents a linear interpolation. MHR method (Jakóbczak, 2010) is not a linear interpolation. MHR is the example of PNC modeling.

Each interpolation requires specific distribution of parameter α and γ (1) depends on parameter $\alpha \in [0;1]$:

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

$\gamma = F(\alpha)$, F:[0;1]→[0;1], $F(0) = 0$, $F(1) = 1$ and F is strictly monotonic.

Coefficient γ is calculated using different functions (polynomials, power functions, sine, cosine, tangent, cotangent, logarithm, exponent, arc sin, arc cos, arc tan or arc cot, also inverse functions) and choice of function is connected with initial requirements and curve specifications. Different values of coefficient γ are connected with applied functions $F(\alpha)$. The functions (2)-(34) represent the examples of probability distribution functions for random variable $\alpha \in [0;1]$ and real number $s > 0$:

1. **Power Function:**

$$\gamma = \alpha^s \text{ with } s > 0. \tag{2}$$

For $s = 1$: basic version of PNC and MHR (Jakóbczak, 2010) methods when $\gamma = \alpha$.

2. **Sine:**

$$\gamma = sin(\alpha^s \cdot \pi/2),\ s > 0 \tag{3}$$

or

$$\gamma = sin^s(\alpha \cdot \pi/2),\ s > 0. \tag{4}$$

For $s = 1$:

$$\gamma = sin(\alpha \cdot \pi/2). \tag{5}$$

3. **Cosine:**

$$\gamma = 1\text{-}cos(\alpha^s \cdot \pi/2),\ s > 0 \tag{6}$$

or

$$\gamma = 1\text{-}cos^s(\alpha \cdot \pi/2),\ s > 0. \tag{7}$$

For $s = 1$:

$$\gamma = 1\text{-}cos(\alpha \cdot \pi/2). \tag{8}$$

4. **Tangent:**

$$\gamma = tan(\alpha^s \cdot \pi/4),\ s > 0 \tag{9}$$

or

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

$$\gamma = tan^{s}(\alpha \cdot \pi/4),\ s > 0. \tag{10}$$

For $s = 1$:

$$\gamma = tan(\alpha \cdot \pi/4). \tag{11}$$

5. **Logarithm:**

$$\gamma = log_2(\alpha^{s} + 1),\ s > 0 \tag{12}$$

or

$$\gamma = log_2^{s}(\alpha + 1),\ s > 0. \tag{13}$$

For $s = 1$:

$$\gamma = log_2(\alpha + 1). \tag{14}$$

6. **Exponent:**

$$\gamma = \left(\frac{a^{\alpha} - 1}{a - 1}\right)^{s},\ s > 0 \text{ and } a > 0 \text{ and } a \neq 1. \tag{15}$$

For $s = 1$ and $a = 2$:

$$\gamma = 2^{\alpha} - 1. \tag{16}$$

7. **Arc Sine:**

$$\gamma = (2/\pi) \cdot arcsin(\alpha^{s}),\ s > 0 \tag{17}$$

or

$$\gamma = (2/\pi \cdot arcsin\ \alpha)^{s},\ s > 0. \tag{18}$$

For $s = 1$:

$$\gamma = (2/\pi) \cdot arcsin(\alpha). \tag{19}$$

8. **Arc Cosine:**

$$\gamma = 1\text{-}(2/\pi) \cdot arccos(\alpha^{s}),\ s > 0 \tag{20}$$

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

or

$$\gamma = 1\text{-}(2/\pi \cdot arccos\ \alpha)^s,\ s > 0. \tag{21}$$

For $s = 1$:

$$\gamma = 1\text{-}(2/\pi) \cdot arccos(\alpha). \tag{22}$$

9. **Arc Tangent:**

$$\gamma = (4/\pi) \cdot arctan(\alpha^s),\ s > 0 \tag{23}$$

or

$$\gamma = (4/\pi \cdot arctan\ \alpha)^s,\ s > 0. \tag{24}$$

For $s = 1$:

$$\gamma = (4/\pi) \cdot arctan(\alpha). \tag{25}$$

10. **Cotangent:**

$$\gamma = ctg(\pi/2 - \alpha^s \cdot \pi/4),\ s > 0 \tag{26}$$

or

$$\gamma = ctg^s\ (\pi/2\text{-}\alpha \cdot \pi/4),\ s > 0. \tag{27}$$

For $s = 1$:

$$\gamma = ctg(\pi/2\text{-}\alpha \cdot \pi/4). \tag{28}$$

11. **Arc Cotangent:**

$$\gamma = 2 - (4/\pi) \cdot arcctg(\alpha^s),\ s > 0 \tag{29}$$

or

$$\gamma = (2\text{-}4/\pi \cdot arcctg\ \alpha)^s,\ s > 0. \tag{30}$$

For $s = 1$:

$$\gamma = 2 - (4/\pi) \cdot arcctg(\alpha). \tag{31}$$

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Functions used in γ calculations (2)-(31) are strictly monotonic for random variable $\alpha \in [0;1]$ as $\gamma = F(\alpha)$ is probability distribution function. Of course any monotonic combination of functions (2)-(31) between points (0;0) and (1;1) is also good, for example

$$\gamma = \alpha^5 \cdot (4/\pi) \cdot arctan(\alpha)$$

or

$$\gamma = \tfrac{1}{2}(\alpha^{7.6} + sin^3(\alpha \cdot \pi/2))$$

or

$$\gamma = \tfrac{1}{4}(\alpha^{1.6} + \alpha^{0.6} + \alpha^6 + sin^{3.9}(\alpha \cdot \pi/2))$$

or

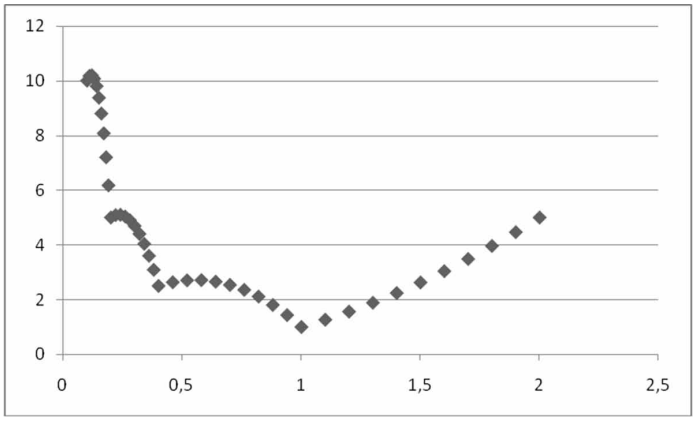
$$\gamma = \tfrac{1}{2}(\alpha^{7.98} + \alpha^3 \cdot (4/\pi) \cdot arctan(\alpha))$$

or other modeling functions.

Also inverse function $F^{-1}(\alpha)$ is appropriate for γ calculations. Choice of function and value s depends on curve specifications and individual requirements. Proposed (2)-(31) probability distributions are continuous, but of course parameter γ can represent discrete probability distributions, for example: $F(0.1)=0.23$, $F(0.2)=0.3$, $F(0.3)=0.42$, $F(0.4)=0.52$, $F(0.5)=0.63$, $F(0.6)=0.69$, $F(0.7)=0.83$, $F(0.8)=0.942$, $F(0.9)=0.991$. What is very important in PNC method: two curves (for example a handwritten letter) may have the same set of nodes but different h or γ results in different interpolations (Figure 2-10).

Algorithm of PNC interpolation and modeling (1) looks as follows:

Step 1: Choice of knots p_i at key points.
Step 2: Choice of nodes combination $h(p_1,p_2,\ldots,p_m)$.
Step 3: Choice of distribution $\gamma = F(\alpha)$: (2)-(31) or others (continuous or discrete).
Step 4: Determining values of α: $\alpha = 0.1, 0.2 \ldots 0.9$ (nine points) or $0.01, 0.02 \ldots 0.99$ (99 points) or others.
Step 5: The computations (1).



These five steps can be treated as the algorithm of PNC method of curve modeling and interpolation (1). Without knowledge about the formula of curve or function, PNC interpolation has to implement the coefficients γ (2)-(31), but PNC is not limited only to these coefficients. Each strictly monotonic function F between points (0;0) and (1;1) can be used in PNC modeling.

Data Modeling and Curve Fitting

Curve knots $p_1 = (0.1;10)$, $p_2 = (0.2;5)$, $p_3 = (0.4;2.5)$, $p_4 = (1;1)$ and $p_5 = (2;5)$ from Figure 1 are used in some examples of PNC method in handwritten character modeling. Figures 2-9 represent PNC as MHR interpolation (Jakóbczak, 2011) with different γ. Points of the curve are calculated with no matrices ($N = 1$) and $\gamma = \alpha$ in example 1 and with matrices of dimension $N = 2$ in examples 2-8 for $\alpha = 0.1, 0.2, \ldots, 0.9$.

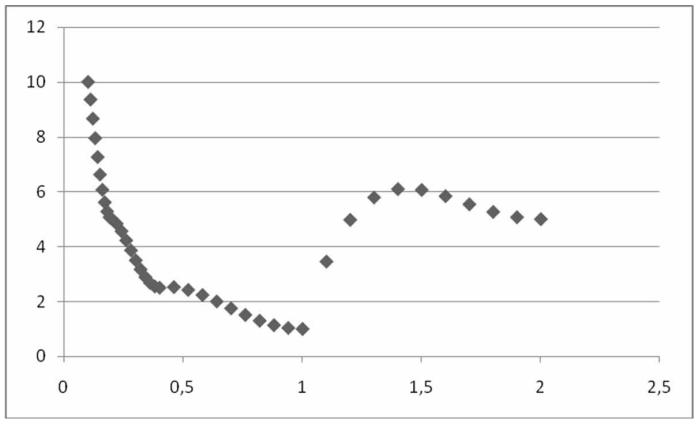
Figure 9. Logarithmic character modeling with nine reconstructed points between nodes
Source: Author, 2016.



These eight examples demonstrate possibilities of PNC curve interpolation and handwritten character modeling for key nodes in MHR version. And here are other examples of PNC modeling (but not MHR):

Example 9: (refer to Figure 10)
PNC for $\gamma = \alpha^2$ and $h(p_1,p_2) = x_1y_1 + x_2y_2$.
Example 10: (refer to Figure 11)
PNC for $\gamma = \alpha^3$ and $h(p_1,p_2) = x_1y_1 + x_2y_2$.

If there is considered Figure 1 as closed curve (contour) with the node $p_6 = p_1 = (0.1;10)$ then examples 9 and10 give the shapes:

Example 11: (refer to Figure 12)
PNC for $\gamma = \alpha^2$ and $h(p_1,p_2) = x_1y_1 + x_2y_2$.

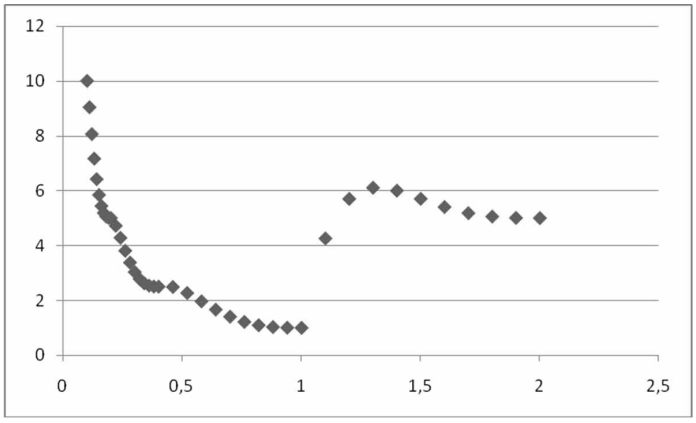

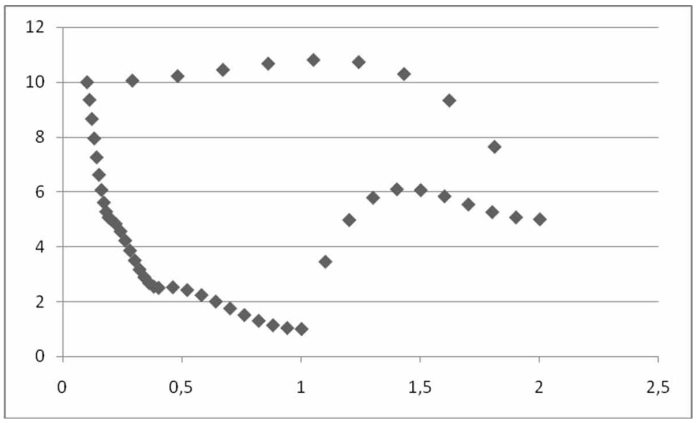

Figure 12. Quadratic contour modeling with nine reconstructed points between nodes
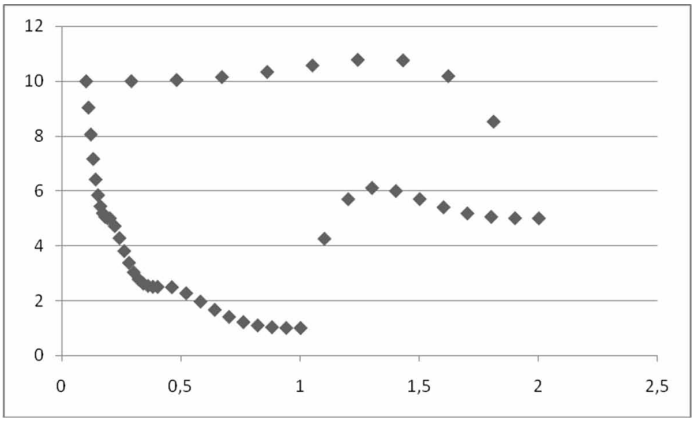
Source: Author, 2016.



Example 12: (refer to Figure 13)
PNC for $\gamma = \alpha^3$ and $h(p_1,p_2) = x_1y_1 + x_2y_2$.

Every man has individual style of handwriting. Recognition of handwritten letter or symbol need modeling and the model of each individual symbol or character can be built by choice of γ and h in (1). PNC modeling via nodes combinations h and parameter γ as probability distribution function enables curve interpolation for each specific letter or symbol.

Number of reconstructed points depends on a user by value α. If for example $\alpha = 0.01, 0.02,\ldots,0.99$ then 99 points are interpolated for each pair of nodes. Reconstructed values and interpolated points, calculated by PNC method, are applied in the process of curve modeling. Every curve can be interpolated by some distribution function as parameter γ and nodes combination h. Parameter γ is treated as probability distribution function for each curve.

Beta Distribution

Considering nowadays used probability distribution functions for random variable $\alpha \in [0;1]$-one distribution is dealing with the range [0;1]: beta distribution. Probability density function f for random variable $\alpha \in [0;1]$ is:

$$f(\alpha) = c \bullet \alpha^s \bullet (1-\alpha)^r,\ s \geq 0,\ r \geq 0. \tag{32}$$

When $r = 0$ probability density function (32) represents $f(\alpha) = c \bullet \alpha^s$ and then probability distribution function F is like (2), for example $f(\alpha)=3\alpha^2$ and $\gamma = \alpha^3$. If s and r are positive integer numbers then γ is the polynomial, for example $f(\alpha)=6\alpha(1-\alpha)$ and $\gamma = 3\alpha^2-2\alpha^3$. So beta distribution gives us coefficient γ in (1) as polynomial because of interdependence between probability density f and distribution F functions:

$$f(\alpha) = F'(\alpha),\ \ F(\alpha) = \int_0^{\alpha} f(t)dt\,. \tag{33}$$

For example (33):

$$f(\alpha) = \alpha \bullet e^{\alpha} \text{ and } \gamma = F(\alpha) = 1 - (1-\alpha)e^{\alpha}. \tag{34}$$

Basic (uniform) distribution ($\gamma = \alpha$) with nodes combination $h = 0$ turns PNC interpolation (1) to linear interpolation. What about PNC in the case of yet another distribution on the range [0;1]: beta distribution (32)? Power functions as γ used in examples 1, 7 and 9-12 are also connected with beta distribution. Here are the examples of PNC modeling for beta distribution with nodes combination $h = 0$.

Example 13: (refer to Figure 14)
PNC for $\gamma = 3\alpha^2-2\alpha^3$ and $h(p_1,p_2)=0$.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Example 14: (refer to Figure 15)
PNC for $\gamma = 4\alpha^3\text{-}3\alpha^4$ and $h(p_1,p_2)=0$.
Example 15: (refer to Figure 16)
PNC for $\gamma = 2\alpha\text{-}\alpha^2$ and $h(p_1,p_2)=0$.

Examples 9-12 represent beta distribution with $h(p_1,p_2) = x_1y_1 + x_2y_2$.

Exponential Distribution

Exponential distribution is dealing with random variable ≥ 0, but in PNC interpolation random variable $\alpha\in[0;1]$. Then exponential distribution is represented by distribution function (34):

$$\gamma = F(\alpha) = 1 - (1 - \alpha)e^{\alpha}.$$

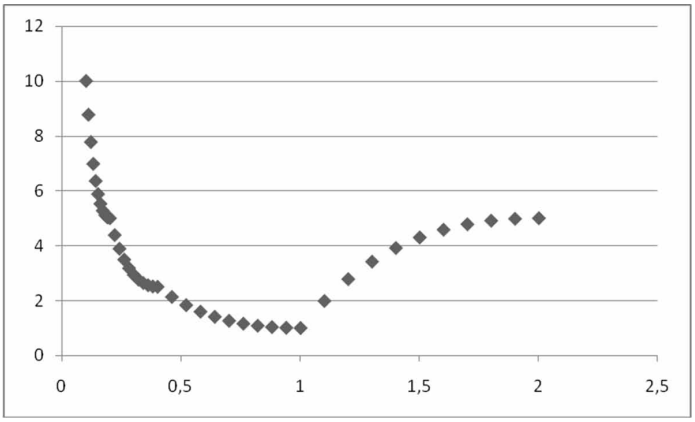
Example 16: (refer to Figure 17)

PNC for $\gamma = 1\text{-}(1\text{-}\alpha)e^{\alpha}$ and $h(p_1,p_2)=0$.

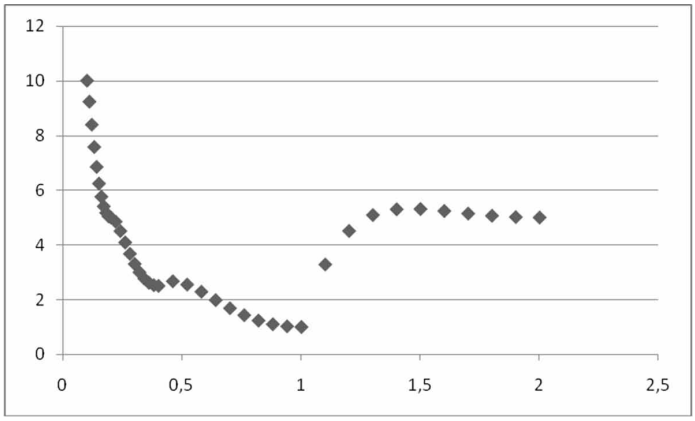
Example 17: (refer to Figure 18)



PNC for $\gamma = 1\text{-}(1\text{-}\alpha)e^{\alpha}$ and $h(p_1, p_2) = \frac{y_2}{y_1} + \frac{x_2}{x_1}$:

These examples show the variety of possibilities in curve modeling via the choice of nodes combination and probability distribution function for interpolated points.

PNC Extrapolation as the Support in Planning



Unknown data, important for planning or decision making, are modeled (interpolated or extrapolated) by the choice of nodes, determining specific nodes combination and characteristic probabilistic distribution function. Less complicated models take $h(p_1,p_2,\ldots,p_m) = 0$ and then the formula of interpolation (2) looks as follows:

Figure 17. Exponential distribution in handwritten character modeling
Source: Author, 2016

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 18. Exponential distribution in handwritten symbol modeling
Source: Author, 2016.

$y(c) = \gamma \bullet y_i + (1-\gamma) y_{i+1}$.

It is linear interpolation for basic (uniform) probability distribution ($\gamma = \alpha$).

Example 1: Nodes (1;3), (3;1), (5;3), (7;3) and $h = 0$, $\gamma = F(\alpha) = \alpha^2$. This function F requires $\alpha > 1$ and extrapolation is computed with (4)-(5) (see Figure 19).
Extrapolated points: (7.2;3), (7.4;3), (7.6;3), (7.8;3), (8;3), (8.2;3), (8.4;3), (8.6;3), (8.8;3).
Example 2: Nodes (1;3), (3;1), (5;3), (7;2) and $h = 0$, $\gamma = F(\alpha) = \alpha^2$. This function F requires $\alpha > 1$ and extrapolation is computed with (4)-(5) too (see Figure 20)
Extrapolated points: (7.2;1.79), (7.4;1.56), (7.6;1.31), (7.8;1.04), (8;0.75), (8.2;0.44), (8.4;0.11), (8.6;-0.24), (8.8;-0.61).
Example 3: Nodes (1;3), (3;1), (5;3), (7;4) and $h = 0$, $\gamma = F(\alpha) = \alpha^3$ (see Figure 21).
Extrapolated points: (7.2;4.331), (7.4;4.728), (7.6;5.197), (7.8;5.744), (8;6.375), (8.2;7.096), (8.4;7.913), (8.6;8.832), (8.8;9.859).

These three examples 1-3 (Figures 1-3) with nodes combination $h = 0$ differ at fourth node and probability distribution functions $\gamma = F(\alpha)$. Much more possibilities of modeling are connected with a choice of nodes combination $h(p_1,p_2,\ldots,p_m)$. MHR method uses the combination (3) with good features because of orthogonal rows and columns at Hurwitz-Radon family of matrices:

$$h(p_i, p_{i+1}) = \frac{y_i}{x_i} x_{i+1} + \frac{y_{i+1}}{x_{i+1}} x_i$$

and then (2):

$$y(c) = \gamma \cdot y_i + (1-\gamma) y_{i+1} + \gamma(1-\gamma) \cdot h(p_i, p_{i+1}).$$

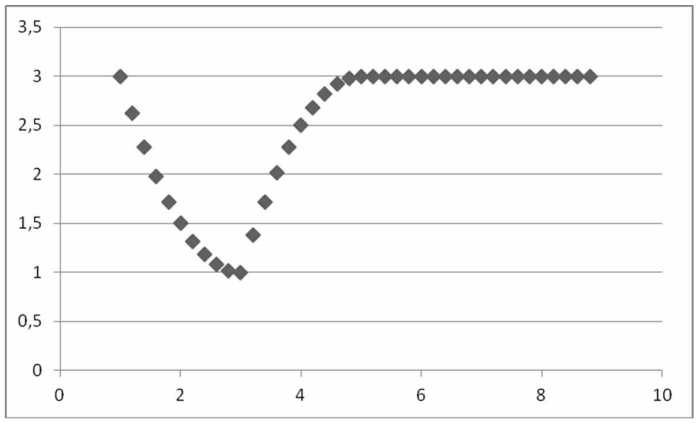
Figure 19. PNC modeling for nine interpolated points between successive nodes and nine extrapolated points right of the last node
Source: Author, 2016.



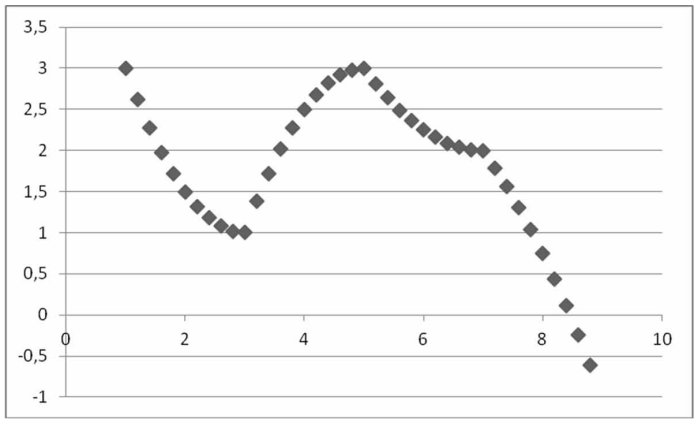


Figure 20. PNC modeling with nine interpolated points between successive nodes and nine extrapolated points right of the last node
Source: Author, 2016.

Here are two examples 4 and 5 of PNC method with MHR combination (3).

Example 4: Nodes (1;3), (3;1), (5;3) and $\gamma = F(\alpha) = \alpha^2$. This function F requires $\alpha > 1$ and extrapolation is computed with (4)-(5) (see Figure 22).

Extrapolated points: (5.2;2.539), (5.4;1.684), (5.6;0.338), (5.8;-1.603), (6;-4.25), (6.2;-7.724), (6.4;-12.155), (6.6;-17.68), (6.8;-24.443).

Example 5: Nodes (1;3), (3;1), (5;3) and $\gamma = F(\alpha) = \alpha^{1.5}$. This function F requires $\alpha > 1$ and extrapolation is computed with (4)-(5) (see Figure 23).

Extrapolated points: (5.2;2.693), (5.4;2.196), (5.6;1.487), (5.8;0.543), (6;-0.657), (6.2;-2.136), (6.4;-3.915), (6.6;-6.016), (6.8;-8.461).

Now let us consider PNC method with other functions F than power functions, $\alpha < 0$ for extrapolation (1)-(2) and nodes combination $h = 0$.

Example 6: Nodes (2;2), (3;1), (4;2), (5;1), (6;2) and $\gamma = F(\alpha) = sin(\alpha \cdot \pi/2)$, $h = 0$ (see Figure 24).
Extrapolated points: (6.1;2.156), (6.2;2.309), (6.3;2.454), (6.4;2.588), (6.5;2.707), (6.6;2.809), (6.7;2.891), (6.8;2.951), (6.9;2.988).
Example 7: Nodes (2;2), (3;1), (4;2), (5;1), (6;2) and $\gamma = F(\alpha) = sin^3(\alpha \cdot \pi/2)$, $h = 0$ (see Figure 25).
Extrapolated points: (6.1;2.004), (6.2;2.03), (6.3;2.094), (6.4;2.203), (6.5;2.354), (6.6;2.53), (6.7;2.707), (6.8;2.86), (6.9;2.964).

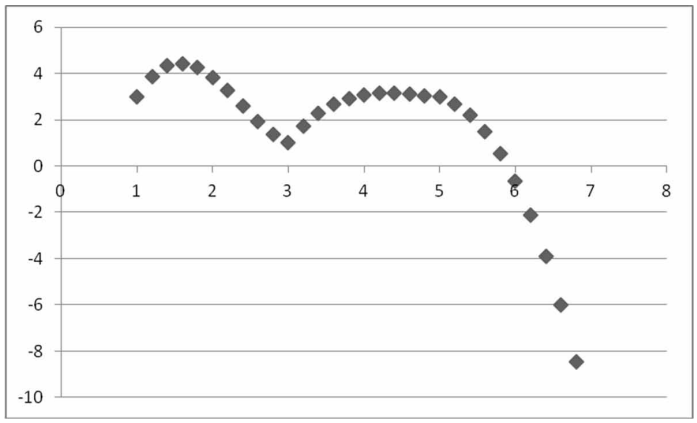
Figure 23. PNC modeling with nine interpolated points between successive nodes and nine extrapolated points right of the last node
Source: Author, 2016.



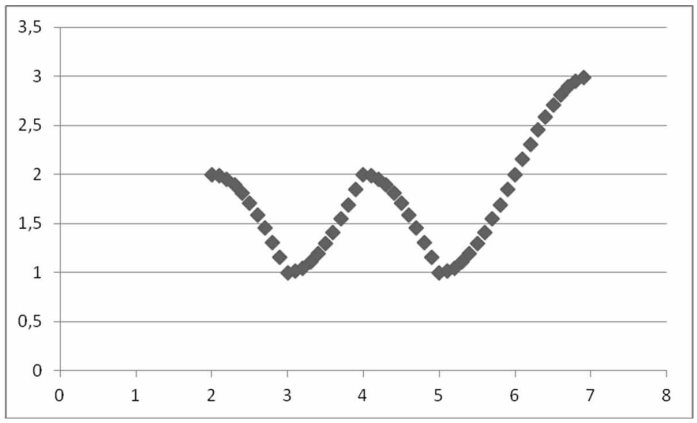


Figure 24. PNC modeling with nine interpolated points between successive nodes and nine extrapolated points right of the last node
Source: Author, 2016.

These two examples 6 and 7 (Figures 6-7) with nodes combination $h = 0$ and the same set of nodes differ only at probability distribution functions $\gamma = F(\alpha)$. Figure 8 is the example of nodes combination h as (3) in MHR method.

Example 8: Nodes (2;2), (3;1), (4;1), (5;1), (6;2) and $\gamma = F(\alpha) = 2^{\alpha}$-1 (see Figure 26).
Extrapolated points: (6.1;2.067), (6.2;2.129), (6.3;2.188), (6.4;2.242), (6.5;2.293), (6.6;2.34), (6.7;2.384), (6.8;2.426), (6.9;2.464).

Examples that are calculated above have one function $\gamma = F(\alpha)$ and one combination h for all ranges between nodes. But it is possible to create a model with functions $\gamma_i = F_i(\alpha)$ and combinations h_i individually for a range of nodes $(p_i;p_{i+1})$. Then it enables very precise modeling of data between each suc-

cessive pair of nodes. Each data point is interpolated or extrapolated by PNC via three factors: the set of nodes, probability distribution function $\gamma = F(\alpha)$ and nodes combination h. These three factors are chosen individually for each data, therefore this information about modeled points seems to be enough for specific PNC curve interpolation and extrapolation. Function γ is selected via the analysis of known points before extrapolation, we may assume $h = 0$ at the beginning and after some time exchange h by more adequate.

These eight examples illustrate the extrapolation of some important values in planning process, for example anticipation of some costs or expenses and foreseeing the prices or other significant data in the process of planning.

SOLUTIONS AND RECOMMENDATIONS

Proposed method, called Probabilistic Nodes Combination (PNC), is the method of 2D curve interpolation and extrapolation using the set of key points (knots or nodes). Nodes can be treated as characteristic points of data for modeling and analyzing. The model of data can be built by choice of probability distribution function and nodes combination. PNC modeling via nodes combination and parameter γ as probability distribution function enables value anticipation in risk analysis and decision making. Two-dimensional curve is extrapolated and interpolated via nodes combination and different functions as discrete or continuous probability distribution functions: polynomial, sine, cosine, tangent, cotangent, logarithm, exponent, arc sin, arc cos, arc tan, arc cot or power function. Novelty of the chapter consists of two generalizations: generalization of previous MHR method with various nodes combinations and generalization of linear interpolation with different (no uniform) probability distribution functions and nodes combinations.

FUTURE RESEARCH DIRECTIONS

Future trends will go to various directions: how to fix the best probability distribution function for the nodes, how to calculate the most appropriate nodes combination and what extrapolation is the most valuable in decision making and risk analysis.

CONCLUSION

Planning process requires the anticipation of unknown values or data and foreseeing some important factors. The method of Probabilistic Nodes Combination (PNC) enables interpolation and extrapolation of two-dimensional curves using nodes combinations and different coefficients γ: polynomial, sinusoidal, cosinusoidal, tangent, cotangent, logarithmic, exponential, arc sin, arc cos, arc tan, arc cot or power function, also inverse functions. Function for γ calculations is chosen individually at each planning and it is treated as probability distribution function: γ depends on initial requirements and data specifications. PNC method leads to point extrapolation and interpolation via discrete set of fixed knots. Main features of PNC method are:

1. The smaller distance between knots the better;
2. PNC method develops a linear interpolation and extrapolation into other functions as probability distribution functions;
3. PNC is a generalization of MHR method via different nodes combinations;
4. Interpolation and extrapolation of L points is connected with the computational cost of rank $O(L)$ as in MHR method;
5. Nodes combination and coefficient γ are crucial in the process of data probabilistic anticipation and foreseeing.

Proposed method, called Probabilistic Nodes Combination (PNC), is the method of 2D curve interpolation and extrapolation using the set of key points (knots or nodes). Nodes can be treated as characteristic points of data for modeling and analyzing. The model of data can be built by choice of probability distribution function and nodes combination. PNC modeling via nodes combination and parameter γ as probability distribution function enables value anticipation in risk analysis and decision making. Two-dimensional curve is extrapolated and interpolated via nodes combination and different functions as discrete or continuous probability distribution functions: polynomial, sine, cosine, tangent, cotangent, logarithm, exponent, arc sin, arc cos, arc tan, arc cot or power function. Novelty of the chapter consists of two generalizations: generalization of previous MHR method with various nodes combinations and generalization of linear interpolation with different (no basic) probability distribution functions and nodes combinations. Computer vision needs suitable methods of shape representation and contour reconstruction. One of them, invented by the author and called method of Hurwitz-Radon Matrices (MHR), can be used in representation and reconstruction of shapes of the objects in the plane. Proposed method is based on a family of Hurwitz-Radon (HR) matrices. The matrices are skew-symmetric and possess columns composed of orthogonal vectors. 2D shape is represented by the set of successive nodes. It is shown how to create the orthogonal and discrete OHR operator and how to use it in a process of shape representation and reconstruction. Then MHR method is generalized to Probabilistic Nodes Combination (PNC) method. This work clarifies the significance and novelty of the proposed method compared to existing methods (for example polynomial interpolations and Bézier curves). Previous published papers of the author were dealing with the method of Hurwitz-Radon Matrices (MHR method). Novelty of this monograph and proposed method consists in the fact that calculations are free from the family of Hurwitz-Radon Matrices. Problem statement of this chapter is: how to reconstruct (interpolate) missing points of 2D curve having the set of interpolation nodes (key points) and using the information about probabilistic distribution of unknown points. For example the simplest basic distribution leads to the easiest interpolation – linear interpolation. Apart from probability distribution, additionally there is the second factor of proposed interpolation method: nodes combination. The simplest nodes combination is zero. Thus proposed curve modeling is based on two agents: probability distribution and nodes combination. Significance of this book consists in generalization for MHR method: the computations are done without matrices in curve fitting and shape modeling, with clear point interpolation formula based on probability distribution function (continuous or discrete) and nodes combination. This book also consists of generalization for linear interpolation with different (no basic) probability distribution functions and nodes combinations. So this chapter answers the question: "Why and when should we use PNC method?".

Curve interpolation represents one of the most important problems in mathematics and computer science: how to model the curve via discrete set of two-dimensional points? Also the matter of shape representation (as closed curve-contour) and curve parameterization is still opened. For example pattern recognition, signature verification or handwriting identification problems are based on curve modeling via the choice of key points. So interpolation is not only a pure mathematical problem but important task in computer vision and artificial intelligence. The book wants to approach a problem of curve modeling by characteristic points. Proposed method relies on nodes combination and functional modeling of curve points situated between the basic set of key points. The functions that are used in calculations represent whole family of elementary functions with inverse functions: polynomials, trigonometric, cyclometric, logarithmic, exponential and power function. These functions are treated as probability distribution functions in the range [0;1]. Significant problem in machine vision and computer vision is that of appropriate 2D shape representation and reconstruction. Classical discussion about shape representation is based on

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

the problem: contour versus skeleton. This monograph is voting for contour which forms boundary of the object. Contour of the object, represented by successive contour points, consists of information which allows us to describe many important features of the object as shape coefficients. 2D curve modeling and generation is a basic subject in many branches of industry and computer science, for example in the cad/cam software. The representation of shape can have a great impact on the accuracy and effectiveness of object recognition. In the literature, shape has been represented by many options including curves, graph-based algorithms and medial axis to enable shape-based object recognition. Digital 2D curve (open or closed) can be represented by chain code (Freeman's code). Chain code depends on selection of the started point and transformations of the object. So Freeman's code is one of the method how to describe and to find contour of the object. Analog (continuous) version of Freeman's code is the curve α-s. Another contour representation and reconstruction is based on Fourier coefficients calculated in discrete Fourier transformation (DFT). These coefficients are used to fix similarity of the contours with different sizes or directions. If we assume that contour is built from segments of a line and fragments of circles or ellipses, hough transformation is applied to detect contour lines. Also geometrical moments of the object are used during the process of object shape representation. Contour is also applied in shape decomposition. Many branches of medicine, industry and manufacturing are looking for methods connected with geometry of the contour.

Future works are going to: application of PNC method in decision making, choice and features of nodes combinations and coefficient γ, implementation of PNC in computer vision and artificial intelligence: shape geometry, contour modelling, object recognition and curve parameterization.

KEY TERMS AND DEFINITIONS

Artificial Intelligence: Intelligence of machines and computers, as a connection of algorithms and hardware, which makes that a man – human being can be simulated by the machines in analyzing risk, decision making, reasoning, knowledge, planning, learning, communication, perception and the ability to move and manipulate objects.

Curve Interpolation: Computing new and unknown points of a curve and creating a graph of a curve using existing data points – interpolation nodes.

Data Extrapolation: Calculation of unknown values for the points situated outside the ranges of nodes.

Hurwitz – Radon Matrices: A family of skew – symmetric and orthogonal matrices with columns and rows that create, together with identical matrix, the base in vector spaces of dimensions $N = 2, 4$ or 8.

MHR Method: The method of curve interpolation and extrapolation using linear (convex) combinations of OHR operators.

OHR Operator: Matrix operator of Hurwitz – Radon built from coordinates of interpolation nodes.

Value Anticipation: Foreseeing next value when last value is known.

This research was previously published in Probabilistic Nodes Combination (PNC) for Object Modeling and Contour Reconstruction edited by Dariusz Jacek Jakóbczak; pages 44-86; copyright year 2017 by Information Science Reference (an imprint of IGI Global).

Chapter 51
Can Computers Create Comics and Animations?

Miki Ueno
Toyohashi University of Technology, Japan

Kiyohito Fukuda
Osaka Prefecture University, Japan

Naoki Mori
Osaka Prefecture University, Japan

ABSTRACT

The objective of this chapter is to develop a method for generating and analyzing creative work by using computers. In this chapter, novels, comics, and animations are considered representative creative work because the main method for representing creative work is the use of natural language and pictures. These works focus on interesting issues, which can be explained by computational approaches to narratology. In this chapter, the authors discuss the following three topics. First, a method of semi-automatic story generation by agent-based simulation is presented. Second, methods of generating and analyzing comics on the basis of the features of pictures and stories used are described. Third, the authors introduce a method of estimating the difficulties of translating a storyboard into original pictures in the process of creating animations.

INTRODUCTION

How do humans produce creative work? What do individuals imagine, and what do they think of during the creative process? The ultimate purpose of this study is to find an algorithm for the generation of creative, intellectual works, such as novels, comics, and animations, with regard to artificial intelligence. The creative works listed above involve stories and are constructed using sequential components. Further, the popular representation of a narrative utilizes natural language and pictures. For example, novels are constructed using natural language, and this type of language is a very useful means of logically depicting

a given situation. However, the number of sentences comprising individual scenes varies considerably, and it is therefore difficult for computers to determine scene boundaries. In addition, comics are constructed using both pictures and natural language, and animations are comprised of pictures and sound based on natural language. Note that pictures constitute an effective means of creating stories, because they can convey postures and positions more directly than verbal or written language. This approach allows stories to become comprehensible to a wider audience, regardless of age or nationality.

In Japan, comics and animations are common in popular culture. A key characteristic of these representations are the deformation or exaggeration of characters and other objects in the story. These visual representations contain lyrical and descriptive aspects to depict each situation clearly. Further, these works are often very intellectual, and some popular authors have produced exceptional creative pieces.

Story creation is something of which the vast majority of humans are capable; however, computers can neither create nor understand stories. The authors are very interested in the process of story construction, particularly as regards the development of appropriate models to facilitate computer story creation. Therefore, our goal is to define complete models of story creation for use by computers. However, it is difficult to define models for the entire process and every objective, therefore the authors suggest models for a specific process of creation. Hence, the authors have conducted several studies regarding computational creative stories, focusing on the topics listed below.

- **Story Generation:** Semi-automatic story generation using log data. Continuous transitions are automatically created and are given to writers in order to write unexpected stories that cannot be created by humans only. The aim of this section is to propose a computational method of coherent and unexpected story creation.
- **Comic Generation:** Automatic comic generation focusing on the relationship between transitions of stories and expression of pictures and comic analysis based on two of their features. Continuous transitions expressed by pictures are modeled and the relations between characteristic expressions and the patterns of stories are analyzed. The aim of this section is to suggest computational models for comics focusing on the expressions in pictures.
- **Animation Generation:** Feature vector definition to provide storyboard information and to determine the difficulties involved in scene translation from storyboards to equivalent key animations. The difficulties in transitioning storyboards into original pictures are estimated. The aim of this section is to appropriately assign each scene to each creator of original pictures according to the index of difficulty by a computer functioning like a facilitator.

In this chapter, these studies are introduced using examples, in order to demonstrate the fundamental techniques of computational narratology and the challenges involved in the quantification of story creation.

BACKGROUND

Recently, automatic story generation and comprehension has attracted considerable interest as a challenging problem in the fields of artificial intelligence. The types of stories are broadly classified into two categories. One is utilizing natural language, the other is utilizing pictures. Novels are written in natural language, while comics and animations are described mainly by pictures. Story information is

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

common, but expression information is specific. Firstly, the background of story generation with natural language is described. With a view towards realizing effective automatic story generation, a number of research papers on automatic story generation based on Case-Based Reasoning (CBR) (Gervás, Diaz-Agudo, Peinado, & Hervás, 2005; Pérez y Pérez & Sharples, 2001; Tuner, 1994) and the problem-solving process (Meehan, 1980), the project on automatic composition of works like Shinichi Hoshi, who was a famous Japanese short story writer (Kouyama & Sumi, 2014; Matsubara et al., 2013; Ogata, Sato, & Komatani, 2014) and some studies on automatic story generation system based on well-known Propp theory (Imabuchi & Ogata, 2012) have been conducted. However, a problem has arisen in that these previous studies have only succeeded in generating lower quality novels rather than original, higher quality ones. The present authors believe that this problem can be attributed to automatic story generation research conducted based on the approach that "a human generates novels via computer"; this means that the computer must reuse original sentences and stories directly.

Secondly, the background of picture stories. Compared with the text stories, there exist only a few studies focused on picture stories such as comics and animation. Pictures are composed of lines and shapes, respectively. Although all of these components are simply collections of dots from a local perspective (Eitz, Hays, & Alexa, 2012), humans perceive them as characters, figures, and symbols based on semantics. However, the semantic comprehension method utilized by humans is unclear. In the field of image processing, the methods of automatically generating in-betweening pictures (Gohara, Sugimoto, & Morishima, 2010) have been proposed. However, limited research has been conducted on computational representations of the process of animation creation.

STORY GENERATION

In this section, the authors aim to propose a new automatic novel generation technique that does not utilize previously created original novels. This new approach essentially means that "the computer generates novels," that is, the computer can generate coherent and unexpected stories for humans. As a first step towards realizing this goal, the authors have proposed a novel semi-automatic story generation method that utilizes log data of agent-based simulation (ABS) (Fukuda, Mori, & Matsumoto, 2015). Here, ABS is a simulation to investigate the actions and interactions between autonomous agents (Macal & North, 2010). The proposed method is a "middle" approach, where "a human generates novels in cooperation with the computer," i.e., novel generation is conducted via interaction between a human and a computer. In this section, the proposed method is introduced, and its effectiveness and the related difficulties are discussed.

Proposed Story Generation Method

In this section, the abovementioned semi-automatic story generation method using log data of the ABS is described. This is based on the idea that a human sometimes writes stories and novels based on memories about interactions between humans. To provide a computer with that memory, the authors believe that log data can function as human memory. The proposed method can utilize any log data, such as the results of a numerical simulation or application usage history. However, the log data of the ABS is used here, because of its greater affinity. The proposed method proceeds as follows.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Step 1: Setting of the ABS. Some parameters of the ABS are determined by the user.
Step 2: Log Data Generation. Two types of log data are generated via the ABS: Status and action logs.
Step 3: Event Generation. Events are generated from the action logs. Events are important action logs to generate the story.
Step 4: Story Vector Generation. Story vectors are generated from the events and status logs. Story vectors are basic information represented in vector form that is required to generate the story.
Step 5: Story Generation. Stories are generated using story vectors through interaction between the user and computer.

Steps 2−4 of the proposed method can be performed automatically. However, steps 1 and 5 cannot be performed by the computer alone. Thus, the former are referred to as the "computer part" and the latter are referred to as the "user part."

Setting of the ABS (Step 1)

The ABS algorithms are implemented for the proposed method. In this ABS, agents have two internal values (friendship and emotion). In moving toward the sub-goal in the field, agents interact with each other if they are located close to one another. Interactions may change their internal values. The ABS is halted if the friendship value of the agent exceeds a threshold and the agent feels love or affection towards the other agent. The details of the algorithms are as follows. Here, a random number in a normal distribution is represented by $N(\mu,\sigma^2)$, where μ is the mean and σ^2 is the variance.

1. The field size is $x_{\max} \times y_{\max}$, the maximum number of turns is $T_{\max}$, the number of player agents is N_p, the number of roles is N_r, and the action number is N_a. Here, turn is a parameter that defines order of each interaction.
2. The environment agent is created, which has scene name s_{xy} at position (x, y) and environment values b_{xy} and $\beta_{xy,t}$. The environment values represent the influence of the environment on the changes of state at each position. Here, b_{xy} is 0 or 1 binary, $\beta_{xy,t}$ is a real number of [-15, 15], and the default of $\beta_{xy,0}$ is defined as [-10, 10].
3. N_p player agents are created. Each player agent has a name, (x, y) point, sex m, role in the story r, friendship values (f-values) with each player agent $F_t = \left\{f_{1,t}, f_{2,t}, ..., f_{N_p,t}\right\}$, love flags with each player agent $L = \left\{\ell_1, \ell_2, ..., \ell_{N_p}\right\}$, and an emotion value (e-value) $E_t = \left\{e_{1,t}, e_{2,t}\right\}$. Here, $f \in F$ is a real number of [0, 100], $e \in E$ is a real number of [-100, 100], m and $\ell \in L$ are 0 or 1 binary, and r is a natural number of $(0, N_r]$. In addition, the default of f_0 is defined as [25, 75] and the default of e_0 is defined as [-25, 25]. Finally, a set of player agents is defined as P.
4. Then, the turn t is set to 0. The set of player agents who do not take action is defined as P_t and the set of player agents who have already taken some action is defined as P_t'.
5. P_t and P_t' are then updated as $P_t = P, P_t' = \varnothing$.
6. A player agent i is randomly selected from P_t. P_t and P_t' are updated as $P_t = P_t / i$, $P_t' = P_t' \cup i$, respectively.
7. i moves to certain Moore neighborhoods as it traverses the distance between the current and target positions. The next target position of i is randomly set when i reaches its existing target.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

8. A player agent of non- *i*, labeled *j*, is randomly selected. In addition, the friendship value of *i* for *j*, represented by $f_{j,t}^{i}$ and the emotion value of *i* e_{t}^{i} are updated as follows. This update represents psychological influences, such that these values converge on a constant value to indicate that *i* loses interest in *j* once a given time has elapsed. Then, T_{fri} and T_{emo} are used to represent the time-elapsed rates of the friendship and emotion values, respectively.

$$f_{j,t}^{i} = f_{j,t}^{i} - \frac{\left|N\left(0,1\right)\right| \times b_{xy}^{i}\left(f_{j,t}^{i} - 50\right)}{T_{fri}} \tag{1}$$

s.t. $\{j \mid j \neq i, j \in O\}$

$$e_{t}^{i} = e_{t}^{i} - \frac{\left|N\left(0,1\right)\right| b_{xy}^{i} e_{t}^{i}}{T_{emo}} \tag{2}$$

9. If the other player agents exist in Neumann neighborhoods of *i*, a player agent *k* is randomly selected from amongst these agents. If no player agents exist, the process moves on to 12.
10. In order to represent the interaction between two player agents, the friendship value of *k* towards *i*, here labeled $f_{i,t}^{k}$, and the emotion values of *k*, $e_{1,t}^{k}$, $e_{2,t}^{k}$ as follows. The action log for the interaction is saved and N_a is updated to $N_a = N_a + 1$. Now, I_{fri} and I_{emo} represent the friendship and emotion value interaction rates, respectively.

$$f_{i,t+1}^{k} = f_{i,t}^{k} + \Delta f_{i,t}^{k} \tag{3}$$

$$e_{1,t+1}^{k} = e_{1,t}^{k} + \Delta e_{1,t}^{k} \tag{4}$$

$$e_{2,t+1}^{k} = e_{2,t}^{k} + \Delta e_{2,t}^{k} \tag{5}$$

$$\Delta f_{i,t}^{k} = \left|N\left(0,1\right)\right| \times b_{xy}^{k} d_{i,t}^{k} + \beta_{xy,t}^{k} \tag{6}$$

$$d_{i,t}^{k} = \frac{2f_{i,t}^{k} + f_{k,t}^{i}}{I_{fri}} + \frac{e_{1,t}^{k}\left(e_{2,t}^{k} + 100\right)}{I_{emo}} \tag{7}$$

$$\Delta e_{1,t}^{k} = \left|N\left(0,1.5^{2}\right)\right| \times \Delta f_{i,t}^{k} \tag{8}$$

$$\Delta e_{2,t}^{k} = N\left(0,1.5^{2}\right) \times \left|\Delta f_{i,t}^{k}\right| \tag{9}$$

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

11. If $\Delta f_{i,t}^{k}$ or $\Delta f_{k,t}^{i}$ exceeds a threshold value *h*, the love flag of *k* or *i* for *i* or *k*, which is ℓ_{i}^{k} or ℓ_{k}^{i}, is changed to another binary value.
12. If $P_t \neq \varnothing$, the process returns to 6.
13. A player agent *p* is randomly selected from P_t'. If the other player agents exist in Neumann neighborhoods of *p*, a player agent p' is randomly selected from among them. If $\ell_{p'}^{p}$ is 1, *p* confesses his or her love for p' with probability *R*. This confession succeeds with a rate of R_{suc}. If *p* confesses, the confession is saved in the action log, regardless of its success or failure. If *p* does not confess, P_t' is updated to $P_t' = P_t' / p$. *R* and R_{suc} are defined as follows.

$$R = \frac{\left| f_{p',t}^{p} - 50 \right|}{100} \tag{10}$$

$$R_{suc} = \begin{cases} \dfrac{0.8 f_{p',t}^{p} + 0.2\alpha}{200} & \left(m^{p} = m^{p'} \right) \\ \dfrac{0.8 f_{p',t}^{p} + 0.2\alpha}{100} & \left(m^{p} \neq m^{p'} \right) \end{cases} \tag{11}$$

$$\alpha = \frac{e_{1,t}^{p'} \times e_{2,t}^{p'}}{100} \tag{12}$$

14. If $P_t' \neq \varnothing$, the process returns to 13.
15. The value of $\beta_{xy,t}$ always varies over time. Hence, $\beta_{xy,t}$ is updated as follows. Here, a_{env} represents the environment variation cycle.

$$\beta_{xy,t+1} = \beta_{xy,0} + 5 \sin\left(\frac{2\left(t+1\right)\pi}{a_{env}} \right) \tag{13}$$

16. Finally, *t* is updated to $t=t+1$ and the status log is saved. If $t \geq t_{\max}$, the ABS is halted. If $t < t_{\max}$, the process returns to 5.

Log Data Generation (Step 2)

The log data is generated using the ABS, which is implemented for the proposed method, along with the two types of log data mentioned above: Status and action logs. The details of these log types are given below.

- **Action Log:** Action log information is saved if agents perform a specific action in the ABS. The turn, scene name, main agent name, target agent name, action type, action number, the degree of change in the friendship value caused by the action, and the degree of change in the emotion value caused by the action in the action log are saved. Table 1 shows the example of the action logs.

- **Status Log:** The status logs are saved at the end of each turn of the ABS. These comprise the turn information and all the parameters of all the agents. Table 2 shows the example of the status logs.

Event Generation (Step 3)

In this step, the direct use of action logs to generate story vectors tends to yield an unnatural story. Therefore, events are generated through the compression of action logs. The event generation algorithms are listed below. Table 3 shows the example of the events.

1. The set of action logs obtained via the ABS are defined as *G*.
2. Action logs within *G* that have the same scene names are defined as *G*.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

3. G is divided into sets of action logs with identical main agent names and action types. Furthermore, a new action log is generated from the set of action logs obtained from G. The values of t, s_{xy}, and N_a are defined as those corresponding to the action log with the minimum t, and the degree of change in the F_t and E_t values are defined as the sum of all action logs in the set. G is updated as $G = G \,/\, G'$.
4. If $G \neq \varnothing$, the method returns to 2.
5. The new action logs generated in 3. are defined as the events.

Story Vector Generation (Step 4)

Story generation using events directly is difficult. Hence, stories are generated using the story vectors s, which are in turn generated by the events. The story vector generation algorithms are the following. Table 4 shows the example of the story vectors.

1. The main agent and the target agent are defined as i and j, respectively. The values of the turn t, the action number N_a, the position of j ($x_{j,t}$, $y_{j,t}$), the degree of change in the friendship value Δf_t and degree of change in the emotion value Δe_t are obtained from the event. Furthermore, m^i, m^j, r^i and r^j are obtained, along with the friendship values of i and j for j and i, which are $f_{j,t}^i$ and $f_{i,t}^j$, respectively, and the emotion values of i and j, e_t^i and e_t^j, respectively, from the status logs.
2. The s is defined as follows.

$$s = \left(t, N_a, m^i, m^j, r^i, r^j, x_{j,t}, y_{j,t}, \Delta f_t, f_{j,t}^i, f_{i,t}^j, e_{1,t}^i, e_{2,t}^i, e_{1,t}^j, e_{2,t}^j, \Delta e_{1,t}, \Delta e_{2,t}\right) \tag{14}$$

Story Generation (Step 5)

In this step, story generation requires six elements: "when," "where," "who (main)," "who (target)," "action," and "result". Five elements are generated using *s*. The "action" element is excluded as it is generated via the interaction between the user and the computer. The story generation algorithms are as follows.

1. "When" is defined as *t* in *s*.
2. "Who (main)" is defined as the name of main player agent *i*, having m^i and r^i in *s*. "Who (target)" is defined as the name of target player agent *j*, having m^j and r^j in *s*.
3. "Where" is defined as the scene name $s_{x_{j,t}y_{j,t}}$, based on the position ($x_{j,t}$, $y_{j,t}$) in *s*.
4. 4. The change in the friendship value caused by the action is defined as w_f. Note that w_f is defined as follows.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

$$w_f = \begin{cases} "becomes\ more\ friendly" \left(\Delta f_t > 20\right) \\ "becomes\ slightly\ friendly" \left(0 < \Delta f_t \leq 20\right) \\ "becomes\ slightly\ hostile" \left(-20 \leq \Delta f_t < 0\right) \\ "becomes\ more\ hostile" \left(\Delta f_t < -20\right) \end{cases} \tag{15}$$

5. The friendship values at the action $w^i_{f,t}$ are obtained, along with and the change in the emotion values caused by the action " $w^i_{e,t}$, " $w^j_{e,t}$. Here, $w^i_{f,t}$, $w^j_{f,t}$, " $w^i_{e,t}$, and " $w^j_{e,t}$ are defined as follows. Now, if the emotion values of *i* and *j* are equal to 0, $w'_{e^k,t}$ is defined as "---" in order to indicate that the player agents have no emotion.

$$w_{f,t} = \begin{cases} "high" \left(f_t \geq 70\right) \\ "normal" \left(30 < f_t < 70\right) \\ "low" \left(f_t \leq 30\right) \end{cases} \tag{16}$$

$$\Delta w^i_{e,t} = w_{e^i,t} \rightarrow w_{e^i,t} \tag{17}$$

$$\Delta w^j_{e,t} = w_{e^j,t} \rightarrow w'_{e^j,t} \tag{18}$$

$$w_{e^k,t} = \begin{cases} "joy" \left(e^k_{1,t} > 0, e^k_{2,t} > 0\right) \\ "anger" \left(e^k_{1,t} < 0, e^k_{2,t} > 0\right) \\ "sadness" \left(e^k_{1,t} < 0, e^k_{2,t} < 0\right) \\ "fun" \left(e^k_{1,t} > 0, e^k_{2,t} < 0\right) \\ "- - -" \left(otherwise\right) \end{cases} \tag{19}$$

$$w'_{e^k,t} = \begin{cases} "joy" \left(e^k_{1,t} + \Delta e_{1,t} > 0, e^k_{2,t} + \Delta e_{2,t} > 0\right) \\ "anger" \left(e^k_{1,t} + \Delta e_{1,t} < 0, e^k_{2,t} + \Delta e_{2,t} > 0\right) \\ "sadness" \left(e^k_{1,t} + \Delta e_{1,t} < 0, e^k_{2,t} + \Delta e_{2,t} < 0\right) \\ "fun" \left(e^k_{1,t} + \Delta e_{1,t} > 0, e^k_{2,t} + \Delta e_{2,t} < 0\right) \\ "- - -" \left(otherwise\right) \end{cases} \tag{20}$$

6. The proposed method provides the user with the five elements defined according to 1. - 4., the friendship values at the action, and the change of emotion values caused by the action. The user then generates an "action" based on this information. The user selects the action from options that have been prepared in advance.

Story Generation Experiments

To examine the effectiveness of the proposed method and any associated difficulties, user experiments were conducted. Table 5 shows the experimental conditions. In these experiments, five users (Users A−E), all of whom had written novels, made use of the proposed method. These users were aged between 20 and 29. The user-experiment procedure was as follows:

1. The proposed method was used to generate the story vector in the computer part.
2. The users generated stories utilizing the story vector generated in 1. After the story generation stage, the users evaluated the story generation difficulty on a scale of 1 (easy)−5 (difficult). In addition, the users' views on the proposed method were obtained via interview.

Story Generation Experiment Results

Figure 1 shows the example of the stories generated by the user experiment and Table 6 provides details of the evaluation about the difficulty of story generation evaluation. From Figure 1, Kana asks Hiro out after cutting class taking with him in a part of turn 485. It is difficult for humans to create the story like this. In addition, from Table 6, it is apparent that the mean of the story generation difficulty was 3.6. These results show that the proposed method allows users to create stories that cannot be created by only humans and suggest that the proposed method can create coherent and unexpected stories by automating the user part. In addition, the users stated that the range of action options was limited. Therefore, a range of actions must be prepared in order to overcome the lack of action versatility and create various stories automatically. Furthermore, the users stated that story planning was easy, because the character settings were unknown. This evaluation shows that it is necessary to provide detailed character settings automatically to realize applications in which "the computer generates novels."

Story Generation Conclusion

In this section, a proposed semi-automatic story generation method that utilizes log data of the ABS was discussed as a first step towards automatic unexpected story generation for a new automatic novel generation. The algorithms of the proposed method were explained and its efficacy and associated difficulties were discussed. The following future developments are necessary to further refine this method.

- User-selection model construction, which would model users' action choices.
- Development of a control method that would manage the logical coherence and unpredictability of the story.
- Automatic plot generation needed to generate attractive novels. Plots will be generated by rearranging the story.

AUTOMATIC COMIC GENERATION

In the previous section, the method of automatically generating stories by natural language was discussed. Here, the authors have focused on creative expressions using pictures, which can be understood by humans regardless of their age and nationality. Therefore, the study discussed in this section reports on computer creation and comprehension of comics whose stories are represented by pictures. There have been studies reporting comic creation by combining prepared datasets (Sumi, Sakamoto, Nakao, Mase, & Kunifuji, 2002). Stories represented by pictures involve large numbers of possible transition and expressions of pictures so that it is difficult to define models of pictures for every story. To solve this problem, the authors focused on four-scene comics. It is possible for creators to present any story in four-scene comics. On the other hand, the scene lengths are limited and the stories must be deformed in the interests of simplification. Thus, four-scene comics have clear stories and structures and are therefore suitable for computer engineering-related studies. In this section, research on picture model for automatic comic generation is first introduced (Ueno, Mori, & Matsumoto, 2014). Then, a two-scene comic creation system is constructed. After that, the analysis for comic creation is discussed.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Comic Generation Picture Model

In order to represent the semantics of pictures to facilitate computer comprehension, each of the elements in a figure, including the background images and balloons, are defined as certain objects. It is difficult to create a reasonable picture model for all pictures. Therefore, two-scene comics are considered here, because two sequential pictures provide sufficient information compared to a single picture, without excessively increasing the problem complexity. In this section, the authors will introduce the method of generating comics and the two-scene generating system. In this method, it is necessary to prepare a dataset comprising images of objects and related object information, area types, drawing operators, and transitions. The picture contains the above information along with a certain history.

The outline of the comic creation method is given below. First, an initial picture p_0 is generated by the system. p_0 is a blank or a background picture and has several areas determined by the system. The user can utilize p_0 as user input. The user operation set in time t is represented by $\boldsymbol{u}_t$, and $\boldsymbol{u}_t$ contains all potential user operations for picture p_t, p_{t+1} is created by applying $\boldsymbol{u}_t$ to p_t. This is expressed as

$$p_{t+1} = \prod_{u_{i,t} \in \boldsymbol{u}_t} u_{i,t} p_t \,, \tag{21}$$

where u_i represents each user's operations over t. The relations between p_t, o_t, $\boldsymbol{u}_t$, $\{O_t\}$, and U_t are

$$\{O_t\} = \{o_t \in p_t\}, \tag{22}$$

$$\{U_t\} = \{\boldsymbol{u}_1, \boldsymbol{u}_2, \ldots, \boldsymbol{u}_t\}, \tag{23}$$

$$p_{t+1} = \prod_{u_{i,t} \in \boldsymbol{u}_t} u_{i,t} p_t \ldots = \prod_{u_{i,t} \in \boldsymbol{u}_t} u_{i,t} \prod_{u_{i,t-1} \in \boldsymbol{u}_{t-1}} u_{i,t-1} p_{t-1} = \prod_{j=0}^{t} \prod_{u_{i,j} \in \boldsymbol{u}_j} \boldsymbol{u}_{i,j} p_0 \tag{24}$$

The definite operation of $u_{i,t} \in \boldsymbol{u}_t$ is represented by the drawing operator ϕ and the operand object in p_t. Each ϕ also has specific augments, such as its color, angle, or other objects. Object o_t can represent the object transition. Finally, object o_n in the n-th scene adheres to the Markov model, such that

$$o_n = \prod_{i=0}^{N_n^{\max}} \phi_i o_0 \tag{25}$$

where $N^{\max}$ is the total number of ϕ to applied to o, and $N_n^{\max} \geq n-1$, because each u_i contains at least one ϕ.

ϕ operates to transform pictures. Further, the product of several ϕ is also ϕ, and the set of base operators is defined as $\left\{\hat{\phi}\right\}$. If the number of base operators is increased, the system has greater representative capacity, because it can create a large number of new images utilizing the existing objects. The system described in this section was written using Java and the operator was implemented using a command design pattern (Gamm, Helm, Johnson, & Vlissides, 1995). The base ϕ corresponds to the com-

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

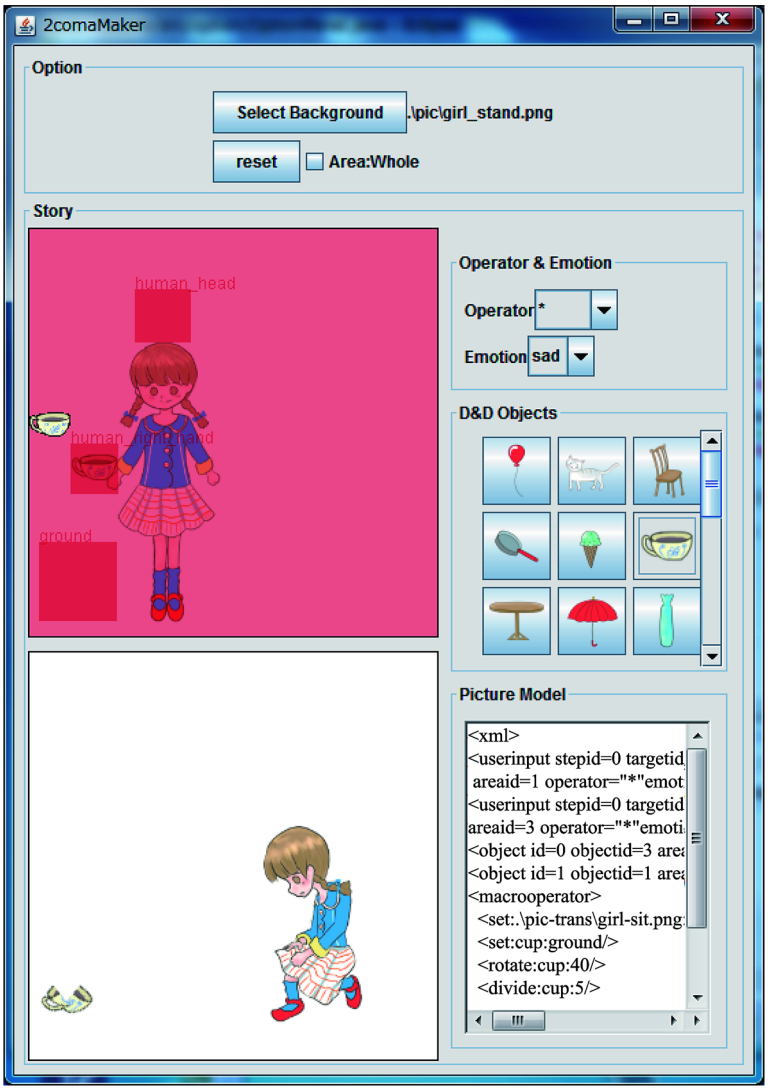
Figure 2. Cup (apply ϕ_{crack})

mand and the product of ϕ corresponds to a macro-command. In Java implementation, an operator product is represented using a queue. For example, ϕ_{crack}, which represents a cracked transition, is composed of the base drawing operators $\hat{\phi}_{rotate}\hat{\phi}_{divide}$. Thus, two base drawing operators are applied to o in the case of

$$\phi_{crack} o = \hat{\phi}_{rotate}\hat{\phi}_{divide} o \tag{26}$$

Figure 2 shows the image variation caused by applying the base drawing operators of ϕ_{crack}.

Comic Generation System Flow



Based on the picture model, the authors propose the comic generation system. The basic flow of the proposed system is as follows.

1. The base image is set as the background for the initial states. This picture is defined as p_0.
2. The system waits for the user input. The user can decide to apply several actions to p_0. In this section, the only available user action involves the setting of an object in the object set displayed on the system graphical user interface (GUI). The user can set their chosen object on a specific area of p_0 using the ϕ and emotion information. Any number of objects can be added to p_0, under the condition the only one object is placed in each area. When the user places an object in p_0', new areas are added to the picture in accordance with the set object.
3. After all of the user inputs u are applied to p_0, p_0' is obtained, which becomes the 1st scene.
4. The system attempts to change objects in p_0' based on the user-defined drawing operator and the emotion information of the target object. The new image comprising the adjusted objects is obtained via transition DB.
5. After all of the changes have been applied to p_0', p_1 is obtained. p_1 represents the 2nd scene.
   a. **Two-Scene Comic:** $\boldsymbol{p}_1$ is the final output.
   b. ***n*-Scene Comic:** p_1' becomes $\boldsymbol{p}_2$. The system again waits for user input and repeats the above flow until $\boldsymbol{p}_{n-1}'$ becomes $\boldsymbol{p}_n$.

Using this method, two-scene comics can be created via the system. Figure 3 shows the outline of this system procedure.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 3. Outline of two-scene comic creating system

Comic Analysis Method

In the previous paragraph, general models of transition of pictures are defined and are applied to the system. Although, several operators are implemented in the system, to depict various scenes, lots of drawing operators should be defined. However, it is difficult to classify and define drawing operator for expressing story transition. Therefore, the relation between object features and story patterns should be analyzed by considering the terms of stories. In comics, there are various kinds of objects and state transitions. The character object usually plays an important role for story transition because characters can act autonomously. The state of character objects are orientations, postures, expressions and so on. The authors assume that character orientations in an image are strongly related to stories and propose

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

a data format of quantifying these orientations. In order to expand the drawing operator, the relationships between orientation transition patterns, impressions of stories, and balloon shape features are also analyzed utilizing existing comics.

The authors propose a data format in which stories are patterned based on the character orientations in accordance with the following two concepts.

1. Suitable features, for example, automatic modeling based on improved image recognition.
2. Stories have several transitions. Characters are typically the main objects that can transition, so their facial orientation may be strongly related to the content and atmosphere of the stories.

The speech balloon shapes are also used to model the data, in accordance with the following two points.

1. The essential elements of comics are pictures, but natural language such as a character's words are also important. Although analysis of the semantics of words is difficult, the shapes of speech balloons can indicate kinds of character's words such as a whisper or loud voice.
2. Automatic detection of balloon areas and shapes has been reported (Tanaka, Toyama, Miyamichi, & Shoji, 2010).

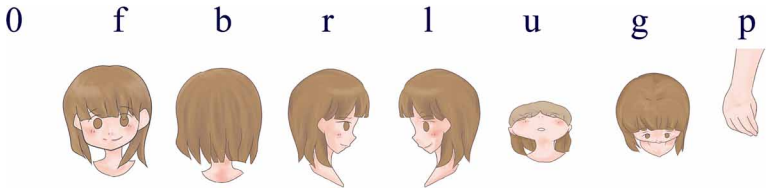
The proposed data format and each value are as shown in Table 7. The table shows the example of four-scene comic data.

***n*:** Story number.
***t*:** Story title.
$\boldsymbol{o_j}$**:** Object j name.
$\boldsymbol{d_i^{oj}}$**:** Facial orientation of object o_j in scene i.
$\boldsymbol{c_j^k}$**:** 1 or 0; indicating whether or not type-k balloons appear.

To distinguish between objects of the same type, the object name is added to its number. A lower number is assigned to an object that has appeared previously. In a scene, an object for which the right end is located near the right side of the scene is considered to appear first. This is because scenes in Japanese comics are usually read from top to bottom and from right to left.

Figure 4 shows the example of facial orientations.

The facial orientation of a character is approximately assigned to a single direction based on the following indicators.



0: The human object does not appear.
f: Front.
b: Back.
r: Right.

Table 7. The example of data of four-scene comics

Figure 4. The example of facial orientation

l: Left.
u: Top.
g: Bottom.
p: Part of the face does not appear.

Figure 5 shows these balloon types.

Further, the balloons are classified into the following five types based on shape, and are assigned corresponding numbers.

1. Oval frame,
2. Zigzag frame,
3. Square frame,
4. Other frame shapes,
5. Printed without frame.

Handwritten balloons are not included in this study. Finally, some cases for which it is difficult to create data are described below.

- **Character Definition:** In some creative works, animals and inanimate objects are personified, so any object that can autonomously act is defined as a character.
  - **The Face Does Not Appear:** Only part of a body is drawn in many comic scenes. If the face does not appear, dioj is p.
  - **Different Facial and Physical Orientations:** This method focuses on the facial orientation only.
  - **It is Difficult to Assign a Single Orientation:** The nearest orientation is assigned.

Figure 6 shows four-scene comics and the example data. In this study, the data were created by hand.

Experiment on Detailed Analysis of One Book

In this experiment, the frequency of object occurrence was investigated and the relationships between expressions and stories are discussed.

- 80 stories from the beginning of “Sketchbook 1” (Kobako, 2003) were used.
- The data were annotated by three graduate students.

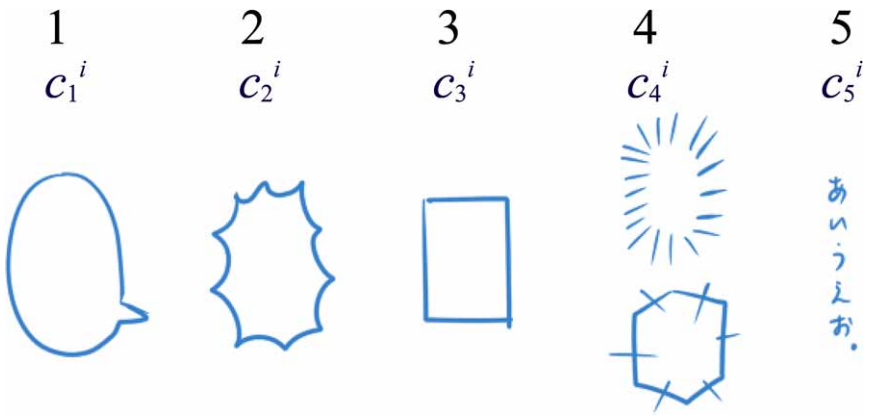

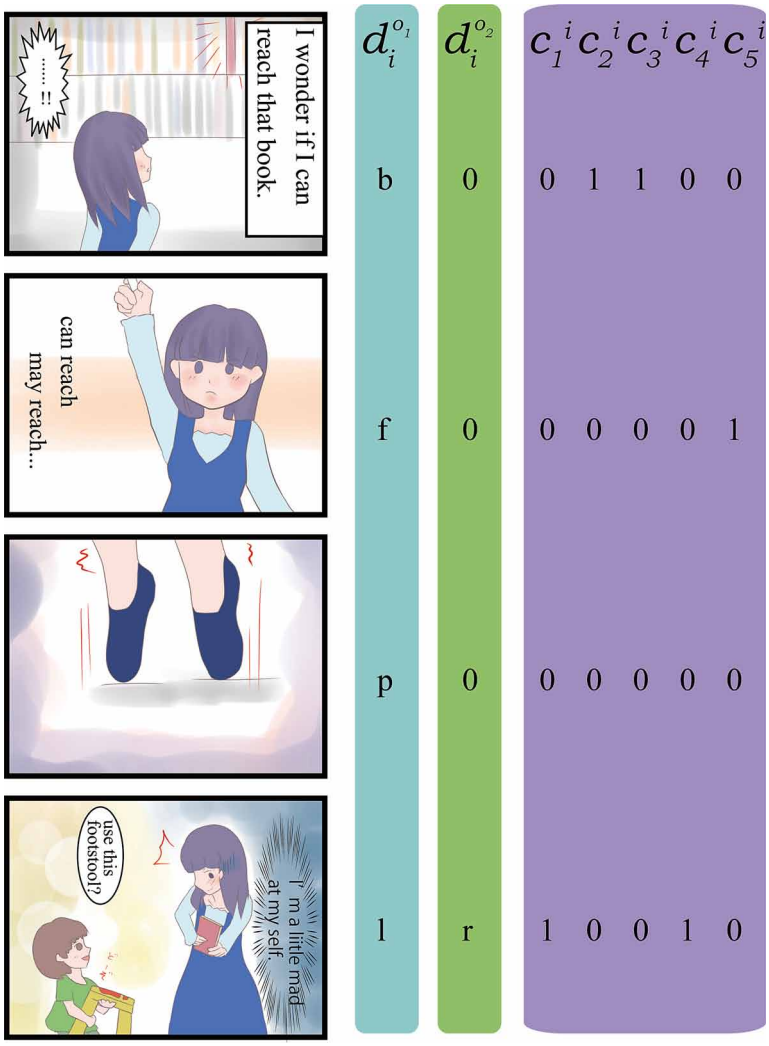

Figure 6. The example of four-scene comics

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

- Stories that had two characters or less were used, while stories with more than three characters were omitted. Here, o_1 and o_2 represent characters 1 and 2 in each story respectively. Based on these conditions, 66 stories were chosen from the original 80.

The results produced by one of the three annotators are given in this paragraph. Table 8 shows the number of stories per character, Table 9 shows the frequency and order of the o_1 and o_2 orientations, and Table 10 shows the frequency of the o_1 and o_2 orientation patterns for the 66 stories. Finally, Table 11 and Table 12 show the balloon pattern frequency. The results of this experiment can be summarized as follows.

- The orientation patterns $d_1^{o_j}$, $d_2^{o_j}$, $d_3^{o_j}$ and $d_4^{o_j}$ can adopt $8^4 = 4096$ potential patterns. A total of 67 orientation patterns were obtained for the 112 characters considered in this study. This constitutes 1.64% of all possible cases. This data number is not sufficient, so the large-scale dataset must be reviewed. Regardless of whether the data is sparse or an increased dataset is used, consideration of these orientations is a highly effective means of estimating story patterns in comics.
- The balloon patterns c_k^1, c_k^2, c_k^3, and c_k^4 can be any of $2^{20} = 1048576$ patterns. A total of 61 balloon patterns were obtained for the 80 stories considered in this study. Thus, the number of patterns whose frequency was more than 2 was only 7. This corresponds to 6.68×10^{-4}% of the potential dataset, so this can be regarded as sparse data.

Experiment Comparing Three Books

To compare data, the relationships between the stories and balloon patterns for three books were analyzed. The beginnings of each of the 80 stories were used; these stories were contained within two of three books have the same author, and it was therefore assumed that several common patterns would exist between these stories. Table 13 shows the number of variations of two orientation patterns, $d_1^{o_1}$, $d_2^{o_1}$, $d_3^{o_1}$, $d_4^{o_1}$ and $d_1^{o_2}$, $d_2^{o_2}$, $d_3^{o_2}$, $d_4^{o_2}$, and the balloon patterns c_k^1, c_k^2, c_k^3, and c_k^4 in the three books. The number of common pattern types are also shown.

Result of Three-Book Comparison

The same balloon patterns were frequently found in the two stories by the same author, while seven balloon patterns were common in all three stories. Table 14 shows the seven types of balloon patterns and their frequencies, while Figure 7 shows four higher-ranking balloon patterns. These seven balloon patterns were found in 81 of 240 stories, and correspond to approximately 30% of all patterns. Therefore, it can be concluded that typical balloon patterns exist. For each of the seven patterns, typical object types and character emotions were drawn in certain scenes. Therefore, balloon patterns can possibly be regarded as a semantic class of stories. In future research, scene and story meanings will be obtained based on training data using automatically extracted balloon patterns.

Comic Analysis Conclusion

In this section, with a view towards realizing story representation for computer operations, a data format through which stories are modeled based on character orientations and balloon types was shown. Using the proposed data format, example data from existing comics can be created and the possibility that their characteristic features are well related to the terms of stories is shown. The following further developments are now required.

- Construction of large-scale data.
- Representation of orientations using angles and vector definitions, in order to realize a class estimation method for application to detailed comic stories based on machine learning.
- Surveying of comic authors to identify the essential elements necessary to create comics.

ANALYSIS OF ANIMATION STORYBOARD

In the previous section, the authors focused on stories told by pictures. Pictures are the key components not only for comics, but also for animation. The creation of animation has common processes compared to that of comics because one animation is usually a collaborative creation by several animators. In the animation creation process, the storyboard is a very important component as regards story design. Animators draw original pictures in accordance with the storyboard, and these original pictures depict certain events within a very limited timeframe. The directors then connect large numbers of original pictures to create stories. Namely, one story board requires several creators of original pictures. Facilitators should assign the drawing of each scene to the appropriate creator depending on the difficulty in drawing. However, the field of animation is facing labor shortage. Thus, humans strongly hope that computers can play an important role in this process. Here, the process of translating original pictures from storyboards is considered as using computers in one of the important processes of animation. Furthermore, the cost of creating original pictures from storyboards is calculated based on the number of original pictures, but the difficulty is not considered. In order to eliminate such discrepancies, a method for calculating the difficulty of the process should be proposed. In this section, the final goal is to define a difficulty index regarding the creation of an original picture from a storyboard created by an animator.

Target Works and Features

A method of classifying the difficulty index using a multi-class support vector machine (SVM) (Cortes & Vapnik, 1995) is described. The SVM receives feature values of each cut in a storyboard as input and classifies the output index.

Here, part A of the 10th episode of "Inou Battle Wa Nichijou Kei No Naka De" (Nozomi, 2014) is taken as the dataset. Note that a storyboard contains several elements: pictures, a number of cuts, a number of frames, lines, and cut contents. Thus, a storyboard is a blueprint of an original picture, because the creators create an original picture based on those components. In this section, the following storyboard components are extracted and defined as an SVM input vector.

- **Number of Original Pictures:** The number of original pictures, including the cut.
- **Number of Frames:** The number of frames, including the cut.
- **Cut Content:** The explanations of the cut given in the storyboard.
- **Lines:** The lines (dialogue) of the animated person described in the storyboard.
- **Sound Effects:** Any sound effects or music described in the storyboard.
- **Difficulty Index:** An index representing the difficulty of creating an original picture from the storyboard.

Note that the difficulty index is evaluated from the storyboard and the original picture by the annotators, who produce animation, based on their experience. The lines and cut content are translated into a numerical vector using a bag of words, because they are described in natural language. In addition, the number of original pictures is also used as a vector element.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 15. Number of pictures per class

Class	The Number of Pictures
1	28
3	95
5	7
Total	130

Storyboard Analysis Experiment

In order to evaluate the difficulty of translating original pictures into cuts, the index of each cut is evaluated on a five-level scale, where: 1 = easy, 2 = relatively easy, 3 = normal, 4 = slightly difficult, and 5 = difficult. In order to simplify the problem structure and to avoid data bias, indices 1 and 2 are classified as class 1, index 3 is classified as class 3, and indices 4 and 5 are classified as class 5. To evaluate this method, a multi-class SVM was trained using the data set, utilizing a linear kernel and setting the parameter cost to 32. These settings were determined in preliminary experiments. The number of pictures in Part A of the 10th episode of "Inou Battle Wa Nichijou Kei No Naka De" is 130, and Table 15 shows the number of pictures in each class. A five-fold cross-validation identification result of 79.03% was obtained through 100 iterations. As this value is above the 73.08% current baseline, it indicates that the SVM can learn and identify the difficulty index of translating a given storyboard into original pictures.

Conclusions from Animation Storyboard Analysis

In this section, the authors focus on one of the important processes of animation and a method through which the animation process can be evaluated was shown. The following future developments are required in order to further refine this technique.

- The results of other kernels must be considered.
- Data correlation between multiple evaluators must be considered.
- Cooperation with storyboard creators must be incorporated into the research.

FUTURE RESEARCH DIRECTIONS

Thus far, the generation of creative work has been mainly discussed in the fields of literature and art; however, recently, it has become a topic of engineering research. Although the authors know very well that a large number of difficult tasks are yet to be achieved for the analysis of creative work by computers, the computational models discussed in this chapter will give readers novel ideas and generate interest on the topic. Some directions for future work are as follows:

- There exists inter-textuality among existing stories. This information is useful for finding common flows in human story comprehension. Some creative work is available on the web under the Creative Commons license. On the other hand, a considerable number of creative works are pro-

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

tected by copyrights. Copyright is a big problem that prevents the advance of research in this field. In this chapter, the authors prepared the creative work ourselves and will provide these creative products with the related metadata for use in future research work.

- The personality of the characters is the key information of stories because at times, the story patterns are strongly related to the character personalities. Character personality is regarded as a unique distribution of the transition that the character has. Thus, the development of a model of character personality should be focused upon.

CONCLUSION

In this chapter, the authors introduced several methods and computational models to automatically generate creative work. Novels, comics, and animations were focused upon because they are depicted by pictures and natural languages. Such creative work gives rise to a considerable number of interesting and challenging issues related to computational narratology.

The results of this chapter can be summarized as follows:

1. The authors proposed a method of semi-automatic generation of stories by agent-based simulation (ABS). Compared to the previous method based on existing novels, the proposed method can create flexible transitions for stories. A story is a set of transitions from the current states to the next states; therefore, the definition of appropriate units of transitions and the maintenance of logical coherence and unpredictability are important issues to be tackled in the future.
2. Computational models for generating and analyzing comics are constructed. The authors developed the comic generating system utilizing the prepared object images and the operators that represent image transition. Further, the authors found individual relations between the states of objects in the pictures and the stories.
3. The authors also proposed a method using an SVM to estimate the difficulties of each scene in the storyboard, which is the key process of creating animations. The method encourages human beings to co-create animations with computers by referring to the difficulties of each part.

Computational models for creative work are being developed, and their structure varies according to the aim of the research. If complete models are defined in the future, the authors believe that the computer will be able to create comics and animations along with human beings.

KEY TERMS AND DEFINITIONS

Agent-Based Simulation: Simulation to investigate actions and interactions between autonomous agents.

Creative Works: Intellectual products created by humans, such as pictures, novels, and animation.

Drawing Operator: The representation of the transition of stories to transform pictures.

Original Picture: Key animation which is the start, key, or end scene of motion.

Plot: A set of state transitions that are arranged in reading order in narratives.

Story: A set of state transitions that are arranged in chronological order in narratives.

Story Vector: Information pertaining to the elements of a story that is represented in vector form.

Storyboard: Story design that has information required for original picture generation.

Chapter 52
A Novel Approach to Managing the Dynamic Nature of Semantic Relatedness

Youngseok Choi
Brunel University London, UK

Jungsuk Oh
Seoul National University, South Korea

Jinsoo Park
Seoul National University, South Korea

ABSTRACT

This research proposes a novel method of measuring the dynamics of semantic relatedness. Research on semantic relatedness has a long history in the fields of computational linguistics, psychology, computer science, as well as information systems. Computing semantic relatedness has played a critical role in various situations, such as data integration and keyword recommendation. Many researchers have tried to propose more sophisticated techniques to measure semantic relatedness. However, little research has considered the change of semantic relatedness with the flow of time and occurrence of events. The authors' proposed method is validated by actual corpus data collected from a particular context over a specific period of time. They test the feasibility of our proposed method by constructing semantic networks by using the corpus collected during a different period of time. The experiment results show that our method can detect and manage the changes in semantic relatedness between concepts. Based on the results, the authors discuss the need for a dynamic semantic relatedness paradigm.

INTRODUCTION

Studies on the measurement of semantic relatedness, or similarity between concepts, have a long history in the fields of computational linguistics, psychology and computer science. Resolutions to various issues regarding semantic ambiguity often boil down to methods of relatedness or similarity between concepts.

Humans are very intuitive in determining similarity or relatedness between concepts but designing a computer to perform such a task is very difficult (Sheth, Aleman-Meza, Arpinar, & Bertram, 2005). The most widely used method for calculating similarity is to employ a ready-made ontology or taxonomy. Specifically, various WordNet-based methods (Resnik, 1995; Jiang & Conrath, 1997) have produced a relatively high level of performance.

The method of using auxiliary information such as ontology or taxonomy is based on the premise that the semantic relatedness between concepts will not change as time goes by. We call it the *static semantic relatedness paradigm* (Resnik, 1995; Jarmasz & Szpakowicz, 2004). Based on the assumption of static semantic relatedness, semantic similarity is measured at a particular point in time with an ontology, taxonomy, or thesaurus. In this case, the ontology or taxonomy is directly written in advance by humans.

However, such a static semantic relatedness paradigm has been challenged by the dynamic nature of information due to the development of knowledge-sharing systems and the spread of information. As new events and the social contexts around them continue to influence how people think, the nature of relationships between concepts may change. At the same time, the events that make the nature of relatedness between concepts dynamic spread rapidly as shared knowledge via information-sharing services and technologies such as social network or news feed. In this regard, there is a need for a paradigm shift toward a *dynamic semantic relatedness paradigm*. In this paper, we use the term "*dynamic semantic relatedness paradigm*" to describe the research considering the dynamics of semantic relatedness. If a change in semantic relatedness occurs due to a particular event which can affect the human thinking process, the existing methods of the static semantic relatedness paradigm cannot fully reflect this dynamic for the following reasons: normally, the existing auxiliary information (i.e., an ontology, taxonomy, or thesaurus) is not updated frequently due to the fact that recognizing the occurrence of semantic changes and rewriting the ontology or making a new taxonomy requires considerable effort. As a result, it is difficult to maintain up-to-date auxiliary information. In addition, the existing auxiliary information refers only to the semantic relatedness relevant for general situations. For example, reaching the conclusion that "Apple" and "Music" are closely connected is difficult by using WordNet[1].

The dynamics of semantic relatedness have not received much attention that they deserve in the semantic relatedness research. Some related studies hint at the idea of incorporating dynamics of semantic relatedness and propose algorithms to address the issue but are insufficient in terms of their complexity and agility to cope with dynamics. So, we present a critical review of existing research following *static* and dynamic *semantic relatedness paradigms* and address how to deal with the dynamics in semantic relatedness better than previous works.

In this context, a new computational approach to the semantic relatedness that takes into consideration of dynamic nature of the postulated semantic relatedness is necessary. In this regard, contributions of this study can be summarized as follows:

- We propose a novel method to corpus-based semantic relatedness calculation by constructing semantic networks that reflect the time and context-dependency nature of the corpus.
- The rationality of the proposed method is validated by experimental evaluation using actual corpus data collected from a particular context over a specific period of time.
- This approach enables quantification of the change of semantic relatedness among specific concepts as well as the dynamics of a semantic network itself.
- Based on the above, the necessity of a dynamic semantic relatedness paradigm is demonstrated.

RELATED WORKS

Previous studies on semantic similarity can broadly be classified into: those based on the topological method and those based on the statistical method. The topological method uses various forms of semantic network or taxonomy to compute the semantic relatedness between concepts. The representative semantic networks based on the topological method are WordNet and Roget's Thesaurus. On the other hand, the statistical method is a technique for calculating the statistical association between concepts by using auxiliary data, such as a dictionary or corpus that is not in the form of a network. In the following subsections, topological and statistical methods are discussed in more detail. In addition to reviews on these two traditional approaches, some studies dealing with the dynamics of semantic relatedness will also be reviewed. On the basis of comprehensive reviews, we will position our research along with the *dynamic semantic relatedness paradigm*.

Topological Methodology

The study of similarity between concepts aims to discover how a computational process can model actual human behavior and action in determining the relationship between two concepts. The reason that many studies on semantic relatedness employ semantic networks is that the system of human knowledge can be well expressed as a network. In fact, many topological methods with semantic networks have produced relatively good performances (Hale, 1998; Resnik, 1995).

Various semantic networks utilized by the topological method include a hierarchical taxonomy. The nodes in a network represent concepts, and the distance or the shared information quantity between two nodes is used for estimating the conceptual similarity between two corresponding concepts. The topological method can be categorized as either node-based or edge-based, which is also called the information content approach or the conceptual distance approach, respectively.

Node-Based Approach

The node-based approach considers how much information the two concepts share in the context of a semantic network or taxonomy. In this regard, the node-based approach is also called the information content approach. The node-based approach is mostly based on information theory (Resnik, 1995). According to information theory, the information content (IC) of concept C can be quantified as follows:

$$\mathrm{IC}(C) = \log^{-1}\mathrm{P}(C),$$

where $\mathrm{P}(C)$ is the probability of encountering an instance of concept C. Then, the similarity between two concepts can be formally defined as follows:

$$\mathrm{sim}\,(c_1, c_2) = \max\,[\mathrm{IC}(c)],\ c \in \mathrm{Sup}(c_1, c_2),$$

where $\mathrm{Sup}(c_1, c_2)$ is a set of concepts that subsume both c_1 and c_2. Resnik (1995) only considers the information content of the least common subsumer (*lcs*), which has the shortest distance from the two concepts being compared. An *lcs* is a concept in a lexical taxonomy (e.g., WordNet).

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Based on Resnik's information content approach, Lin (1998) proposes a similarity theorem for measuring the distance between two concepts. The similarity between *A* and *B* is measured by the ratio between the amount of information needed to state their commonality and that needed to fully describe them:

$$\mathrm{sim}\left(\mathrm{A},\mathrm{B}\right)=\frac{\log\ \mathrm{P}\left(\mathrm{common}\left(\mathrm{A},\mathrm{B}\right)\right)}{\log\ \mathrm{P}\left(\mathrm{description}\left(\mathrm{A},\mathrm{B}\right)\right)}$$

Hence, if we know the commonality of two concepts, their similarity indicates how much additional information is required to define the two concepts.

Couto, Silva, & Coutinho (2007) use the node-based approach to calculate semantic similarity between concepts in gene ontology (GO) through a measure named Graph-Based Similarity Measure (GraSM). They use all the information in the graph structure of the GO instead of considering it as a hierarchical tree. Their measure of semantic similarity between GO terms demonstrates its greater effectiveness by obtaining a higher correlation using disjunctive common ancestors than using only the most informative common ancestor.

Gan, Dou, & Jiang (2013) apply this node-based approach to concept similarity in the domain ontology and Harispe, Sánchez, Ranwez, Janaqi, & Montmain (2014) use similar approach for the semantic relation in medical domain. Lee, Kim, & Lim (2016) also adopt this approach for semantic network visualization due to its convenience to represent graph type semantic network.

Edge-based Approach

The edge-based approach is more natural and intuitive than the node-based approach for calculating semantic similarity in a semantic network. This approach estimates the distance between the nodes that correspond to the concepts being compared. Obviously, the shorter the distance between two nodes, the greater is their similarity.

Rada, Mili, Bicknell, & Blettner (1989) as well as Rada & Bicknell (1989) adopt this approach for a hierarchical semantic network of terms used for indexing articles in the bibliographic retrieval system MEDLINE, which uses medical subject headings (MeSH). Their principal assumption for evaluating semantic similarity is that "the number of edges between terms in the MeSH hierarchy is a measure of conceptual distance between terms" (Rada, Mili, Bicknel, & Blettner, 1989, pp. 18). Based on this assumption, the distance between document *Doc* and query *Q* is defined as follows:

$$\mathrm{Distance}\left(Doc,Q\right)=\frac{1}{mn}\sum_{t_i\in Doc}\sum_{t_j\in Q}d\left(t_i,t_j\right)$$

where $d(t_i, t_j)$ is the minimal number of edges in a path from t_i to t_j within a hierarchy.

Lee, Kim, & Lee (1993) demonstrate an information retrieval method based on a conceptual distance in IS-A hierarchies. They developed a method called the Knowledge-Based Extended Boolean Model (KB-EBM), which involves a primitive distance function. Given terms t_i and t_j in an IS-A hierarchy, the distance (which is often called the primitive distance function) between the terms is as follows:

Distance (t_i t_j) = minimal number of IS-A relationships between t_i and t_j

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Statistical Method

The statistical method computes similarity by analyzing auxiliary information, such as a corpus or dictionary, in a statistical way. Applications of pointwise mutual information (PMI) or latent semantic analysis (LSA) are prime examples of the statistical method.

Use of PMI of data collected by information retrieval (PMI-IR) is proposed by Turney (2001) as an unsupervised measure of semantic similarity between words. PMI-IR is based on word co-occurrence by using counts accumulated over very large corpora (e.g., the Web). Given two words w_1 and w_2, their PMI-IR is measured as follows:

$$\text{PMI-IR}\left(w_1, w_2\right) = \log_2 \frac{\text{P}\left(w_1 \,\&\, w_2\right)}{\text{P}\left(w_1\right) * \text{P}\left(w_2\right)}$$

which indicates their degree of statistical dependence and can be used as a measure of their semantic similarity.

Another statistical measure of semantic similarity is the result of the latent semantic analysis (LSA) proposed by Landauer, Foltz, & Laham (1998). LSA is a "method for extracting and representing the contextual-usage meaning of words by statistical computations applied to a large corpus of text" (Landauer, Foltz, & Laham, 1998, pp. 259). In LSA, term co-occurrences in a corpus are captured by means of a dimensionality reduction and singular value decomposition of the term-by-document matrix representing the corpus.

LSA has been applied for many situation regarding semantic relatedness and semantic disambiguation contexts. Hoffman, Ralph, & Rogers (2013) apply the LAS for semantic disambiguation in the contextual usage of words and Martin, Martin, & Berry (2016) use this statistical approach for the evaluation of questionnaire response.

Research Dealing with the Dynamics of Semantic Relatedness

While a typical topological approach and statistical methods have not been dealing with the dynamics of semantic relatedness, some studies challenge the dynamic nature of semantic relatedness by modifying existing methods that belong to topological and statistical approaches.

Topic tracking and topic model research hint at the nature of dynamic semantic similarity by providing algorithms for detecting rising and falling topics in a target corpus. Blei & Lafferty (2006) suggest a dynamic topic model using a time series random process. They implement a probabilistic time series model to analyze the time evolution of topics in large document collections. As an extension of the topic model, they revised the latent Dirichlet allocation (LDA) considering the distribution of topic proportions as a random variable. Though they did not directly propose the concept of semantic similarity, they developed a statistical model to expect the rise and fall of topics in documents.

Rinaldi (2009) proposes an ontology driven approach for semantic information retrieval using dynamically obtained ontology to cope with the change of semantic relatedness as time changes. They also suggest a new method to calculate the semantic similarity by modifying the algorithm proposed by Rada, Mili, Bicknell, & Blettner (1989) and Wu & Palmer (1994). However, the semantic network

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

is extracted from a dictionary (i.e., WordNet) and more focused on reflecting context than dynamics with regard to the time change. If words and their relationships are not updated, the extracted semantic network might be outdated as well.

Radinsky, Agichtein, Gab rilovich, & Markovitch (2011) argue that their research is the first attempt to incorporate temporal evidence into models of semantic relatedness. They propose temporal semantic analysis (TSA) on the basis of concept vectorization. Human generated folksonomy (i.e., Flikr taggs, Wikipedia, and Del.icio.us book marks) are used for concept vectorization as it needs the relevant terms that will be used for components of concept vectors. Nevertheless, it also contains limitations as the concept of vectorization solely depends on existing folksonomies.

Milikic, Jovanovic, & Stankovic (2011) also attempt to confirm the dynamics of semantic relatedness by analyzing twitter data. They insist that most approaches consider the semantic relatedness of terms as static over time, and disregard the eventual temporal changes as imperfections. They formulated the relatedness measure using the search result of the Microposts search engine. They confirm that the semantic relatedness changes by showing possible scenarios and very simple examples without evaluation.

Though Sagi, Kaufmann, & Clark (2009) do not propose a new algorithm for detecting change of semantic relatedness, they also hint at the change of word semantic form linguistics perspective. They provide empirical evidence for change of usage pattern of specific words and phrases using latent semantic analysis (LSA). Their research objective is not exactly the same as the semantic relatedness context, but their theoretical reviews on semantics deserve to be highlighted from a perspective of the "*dynamic semantic relatedness paradigm.*"

Zhao, Wang, Cao, Zhang, Yin, & Xu (2015) introduce new approach called large-scale topic-related semantic information flow detection. This research proposes a method to track the dynamics and evolution of web information using novel graphical representation method but it lack the method for quantifying and managing the dynamics of semantic relatedness measure.

Table 1 contains a comparative summary of these approaches. Each of these studies contributed to incorporating the dynamic nature of semantic relatedness, albeit not without weaknesses. One common drawback is their dependency on external resources such as dictionaries and WordNet. As the external resource usually contains concepts and their relation in a general context, it is not appropriate to confine the context with regard to a given situation and it is difficult to reflect the change of semantic relation as time passes if resources are not updated in a timely manner. In addition, existing studies do not measure and quantify the change of semantic relatedness though they adopt a complex computation method from the literature.

METHODOLOGY FOR CONSTRUCTING A SEMANTIC NETWORK AND DETECTING ITS DYNAMICS

Dynamics of Semantic Relatedness

Most human knowledge is influenced and updated as new information or a new experience is acquired. Furthermore, with the advancement of IT and, particularly, recent widespread adoption of information sharing services based on social networks, information-acquiring methods have flourished at unprecedented speeds. Therefore, there is an even greater chance that the semantic relation between concepts recognized by humans may change.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 1. Summary of relevant research to the dynamic semantic relatedness paradigm

Related research	Reference algorithm	Output	Resource dependency	Quantification of dynamics of semantic network and relatedness	Evaluation method	Note
Blei, & Lafferty (2006)	LDA	Topic set	N/A	N/A	Case studies	Dealing with sets of topics, not relatedness
Rinaldi (2009)	TSA	Semantic relatedness	Dictionary and WordNet, Search engine result	N/A	Case studies	
Radinsky, Agichtein, Gabrilovich, & Markovitch (2011)	Topological method	Semantic relatedness	External folksonomy	N/A	N/A	Only static semantic relatedness was evaluated
Milikic, Jovanovic, & Stankovic (2011)	Search engine-based	Semantic relatedness	Search engine result	N/A	N/A	Scenario with simple examples
Sagi, Kauffmann, & Clark (2009)	LSA, vector space models	Change of collocation pattern	N/A	N/A	Case studies	More focused on theoretical aspects of language usage patterns
Zhao, Wang, Cao, Zhang, Yin, & Xu (2015)	Vector space models	Information flow diagram	N/A	N/A	Case studies	Validated using news in Chinese

As seen in Related Works section, most studies on semantic relatedness have not considered the dynamics of semantic relatedness, despite the evolutionary nature of the semantic relatedness concept. Many studies, of course, have addressed the ontology versioning issue (i.e., ontology evolution), but have not applied it to the relatedness/similarity between concepts. Our proposed approach provides an intuitive means to estimate dynamic semantic relatedness with a simple but innovative method. By analyzing the corpus generated in a given time and context, the dynamics with regard to the time and context of the corpus can be reflected to semantic relatedness without complex computation and algorithms. The results of analyzing the corpus can be presented in the form of a semantic network and a created semantic network enables quantification of the change of the whole semantic network with regard to the time change.

Co-Occurrence Statistics of Two Concepts in a Corpus and Its Matrix Expression as Network Data

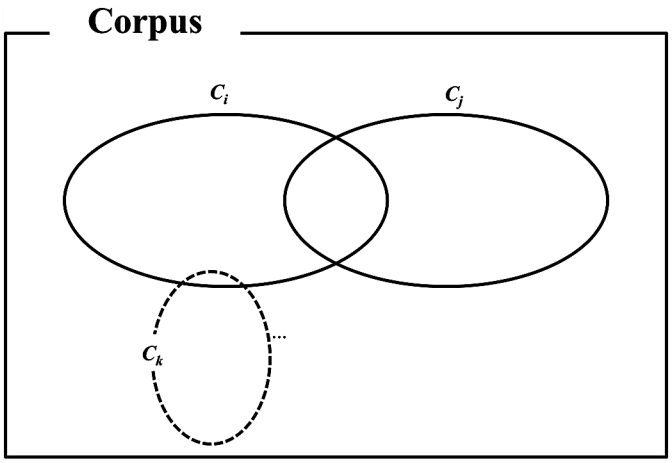
In linguistics, a corpus (plural corpora) or text corpus is defined as a large and structured set of texts (at present, these are usually electronically stored or processed) (Kilgarriff, 2003). A corpus consists of many documents that are either a set of words or concepts separated by a period. Even though there are many ways to define the co-occurrence of concepts, in this paper, we define the co-occurrence as two terms that appear in the same sentence.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Most studies based on corpus analysis (Doddington, 2002; Ohsawa, Benson, & Yachida, 1998; Roark, & Charniak, 1998) have considered each sentence as a basket, much like a collocation which analyzes an expression composed of two or more words that correspond to conventional means of colloquial and literary style. We also adopt these criteria of word co-occurrence by considering one sentence in a document as a meaning basket.

In the following, we introduce a general notation of our proposed methodology for semantic network construction using the co-occurrence statistics of two concepts in a corpus. The first step is counting frequencies of words that are in the concept set being evaluated. Based on this result, conditional frequencies between two terms are calculated. Finally, a co-occurrence matrix is obtained as a network data representation. The (i, j) component of the co-occurrence matrix represents the relatedness between i-th and j-th concept. Using this matrix, a network graph of concepts can be constructed.

Let corpus(t_1, t_2) be the corpus, which is generated during the time period from t_1 to t_2 and $\boldsymbol{C} = \{C_1, C_2, \ldots, C_N\}$ be the collection of n concepts in which we are interested[2]. For concept C_i and C_j, conditional probability of term frequency prob ($C_i \mid C_j$) is defined as:



$$\text{prob}\left(C_i \mid C_j\right) = \frac{\text{freq}\left(Ci \cap Cj\right)}{\text{freq}\left(C_i\right)}$$

where:

- freq(C_j) is a term frequency of concept C_j in the corpus and
- freq($C_i \cap C_j$) is a frequency of co-occurrence of two concepts in a meaning basket in the corpus.

Generally, ratios of relative frequencies do not fit well into the hypothesis testing paradigm for collocation analysis (Manning & Schütze, 1999). However, we use this method because the objective of our study is to construct a semantic network using a specific corpus rather than simply testing a hypothesis.

Figure 1. Conceptual diagram for understanding the relationship between relative frequency and semantic relatedness

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1 illustrates the relationship between conditional probability and semantic relatedness. Assuming that concept C_i appears independently from concept C_k in the corpus, the conditional frequency of co-occurrence is similar to the unconditional frequency of concept C_i meaning that the following equation is satisfied:

$\text{prob}(C_i \mid C_k) = \text{prob}(C_i)$ for arbitrary concept C_k that is independent from concept C_i.

In contrast, if two concepts are dependent due to the influence of semantic relationship, the conditional probability is biased so that the following inequality is satisfied:

$\text{prob}(C_i \mid C_j) > \text{prob}(C_i)$ for arbitrary concept C_j that is related to concept C_i[3].

Terms that contain the biased conditional probability of co-occurrence may have an important implication in the corpus. Thus, we assume that the bias of conditional probability can be used as a surrogate of semantic relatedness.

The conditional probabilities of occurrences for given N concepts in the corpus can be expressed as a matrix. The first order co-occurrence matrix M is defined as:

$$1^{\text{st}} \text{ order co-occurrence matrix } M = \begin{pmatrix} m_{11} & \cdots & m_{1n} \\ \vdots & \ddots & \vdots \\ m_{n1} & \cdots & m_{nn} \end{pmatrix} \quad (1)$$

where $m_{ij} = \text{prob}(C_i \mid C_j)$.

Diagonal components of M should be one by definition of conditional probability. Since conditional probability is not commutative (i.e., $\text{prob}(C_i \mid C_j) \neq \text{prob}(C_j \mid C_i)$), M may be asymmetric.

Direct and Indirect Path in the Matrix Expression and Semantic Relatedness Calculation

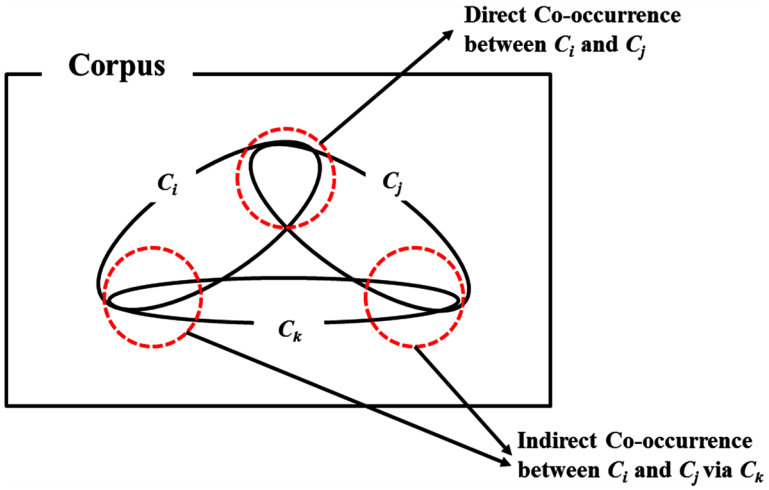
The reason we define matrix M as "the first order" co-occurrence matrix is that M reflects only a direct co-occurrence of two concepts in the meaning basket. On the other hand, an indirect co-occurrence cannot be ignored because if concept A co-occurs frequently with concept B and C respectively, concepts B and C might be closely related. An intuitive explanation of an indirect co-occurrence is depicted in Figure 2.

Even when the conditional probability of co-occurrence between two concepts has a very low value, there might be a non-negligible semantic relation if two concepts have common co-occurrence concepts. In other words, C_i and C_j may have a semantic relationship if both $\text{prob}(C_i \mid C_k)$ and $\text{prob}(C_j \mid C_k)$ have high values, although $\text{prob}(C_i \mid C_j)$ is low. For this reason, a new metric of indirect co-occurrence is needed.

The second order co-occurrence matrix that represents indirect co-occurrence is constructed based on the basic graph theory in which the total number of indirect links is counted. In Figure 3, X is a matrix representation of the graph of the system.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. Direct and indirect co-occurrences between two concepts



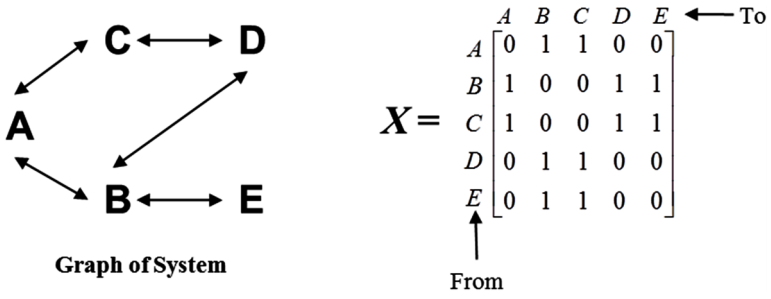


Figure 3. Sample graph of the system and its matrix representation

In matrix X, each element x_{ij} indicates a direct link between the nodes. Within this system, indirect links are assumed to exist whenever it is possible to connect two nodes through the intermediary nodes. The basic graph theory states that, under ordinary matrix multiplication procedures, the square of a direct linkage matrix, such as X, describes a graph whose paths all have a length of two steps. The sum of these paths between nodes i and j represents all the possible indirect linkages of the two steps (see Figure 4).

If the direct link matrix X is expanded and summed through successive powers until each of the elements of the summed matrix S converges ($S = X+X^2+X^3+\ldots+X^n$), then matrix S will contain elements s_{ij} representing the total direct influence (X) and indirect influence ($X^2+X^3+\ldots+X^n$) exerted between i and j over paths of increasing length up to n. This power expansion of X includes paths that may pass same nodes more than once (for the four-step path from node 1 to node 4, the sequence 1-3-1-4 could be an example).

This basic graph theory can be applied to the semantic network construction in our study. Each component of the squared first order co-occurrence matrix, M^2, is the sum of the product for indirect co-occurrence through other concepts. However, in calculating the indirect co-occurrence matrix, we use M_0, which has zero diagonal components instead of M (by definition of matrix M, all diagonal components of M should be one, while a general link matrix in graph theory or social network analysis has zero diagonal components). Thus, the second order co-occurrence matrix M_0^2 is defined as:

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 4. Squared matrix and meaning of its component (x_{23})

$$X^2 = \begin{bmatrix} x_{11} & x_{12} & x_{13} & x_{14} & x_{15} \\ x_{21} & x_{22} & x_{23} & x_{24} & x_{25} \\ x_{31} & x_{32} & x_{33} & x_{34} & x_{35} \\ x_{41} & x_{42} & x_{43} & x_{44} & x_{45} \\ x_{51} & x_{52} & x_{53} & x_{54} & x_{55} \end{bmatrix} \times \begin{bmatrix} x_{11} & x_{12} & x_{13} & x_{14} & x_{15} \\ x_{21} & x_{22} & x_{23} & x_{24} & x_{25} \\ x_{31} & x_{32} & x_{33} & x_{34} & x_{35} \\ x_{41} & x_{42} & x_{43} & x_{44} & x_{45} \\ x_{51} & x_{52} & x_{53} & x_{54} & x_{55} \end{bmatrix}$$

$$x_{23}^2 = x_{21}x_{13} + x_{22}x_{23} + x_{23}x_{33} + x_{24}x_{43} + x_{25}x_{53}$$

Sum of two step path from node 2 to node 3 through other nodes

2nd order co-occurrence matrix $M_0^2 \overset{\text{def}}{=} M_0 \times M_0 = \begin{pmatrix} m_{11}^2 & \cdots & m_{1n}^2 \\ \vdots & \ddots & \vdots \\ m_{n1}^2 & \cdots & m_{nn}^2 \end{pmatrix}$ (2)

The general order co-occurrence matrix can be defined as M_0^n

Based on these definitions, we can obtain the total co-occurrence matrix M_{total}, which contains both direct and indirect co-occurrence probabilities.

Total co-occurrence matrix[4] $M_{total} = M + M_0^2 + M_0^3 + \ldots M_0^n$ (3)

The *(i, j)* component of M_{total}, $m_{total,\ ij}$, can be used to calculate the relatedness between concept C_i and C_j in the following way:

$$rel\left(C_i, C_j\right) = \frac{m_{total,ij} + m_{total,ji}}{2} \quad (4)$$

where $rel(C_i, C_j)$ the relatedness between concepts and is a symmetric function.

We now define a 3-tuple semantic network data during the period from t_1 to t_2, $\boldsymbol{SN(t_1, t_2)}$:

$\boldsymbol{SN(t_1, t_2)} = \{corpus(t_1, t_2), C, M_{total}\}$,

where:

- $corpus(t_1, t_2)$ is the corpus generated during the time period from t_1 to t_2;
- $\boldsymbol{C} = \{C_1, C_2, \ldots, C_N\}$ is a collection of n concepts in which we are interested. This indicates the context;
- M_{total} is the total co-occurrence matrix.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

This network is constructed using a corpus generated in a given time interval with given concepts. If collection of concept C changes, the network also changes though the time interval is the same. This nature enables the constructed semantic network to reflect the dynamics of time and context. The selected concepts can create the context of a given situation by capturing the surrounding information. The notion of the context in this research is adopted from information retrieval research (Lawrence, 2000).

Detecting the Dynamics of a Semantic Network and Semantic Relatedness Between Concepts

Network dynamics, which is the study of changes in a network over time, is under study in various academic fields such as sociology, biology, computer science, and graph theory. As Wassermann & Faust (1994) points out, this is a difficult area that needs to be constantly studied in social networks. Furthermore, for time-series network data established in this study, all components of the matrix are written in floating numbers which makes it difficult to apply the methodology of an integer matrix such as the social network. This study proposes a new method to detect the changes in semantic network and demonstrates how the proposed methodology can be applied to the actual data.

Quantifying the Change of a Semantic Network

Bonacich (1972) suggests that the eigenvector of the largest eigenvalue of an adjacency matrix could make a good network centrality measure. Unlike the degree centrality, which weighs every contact equally, the eigenvector weighs contacts according to their centralities. Eigenvector centrality can also be seen as a weighted sum of not only direct connections but also indirect connections of every length. Thus, it takes into account the entire pattern in the network (Bonacich, 2007). Eigenvector centrality is defined as the principal eigenvector of the adjacency matrix defining the network. Equation (5) describes eigenvector centrality x in two equivalent ways, as a matrix equation and as a sum. The centrality of a node is proportional to the sum of the centralities of the nodes to which it is connected (Bonacich, 2007).

$$\lambda \boldsymbol{x} = \boldsymbol{A}\boldsymbol{x}, \lambda \boldsymbol{x}\boldsymbol{i} = \sum_{\boldsymbol{j}=1}^{\boldsymbol{n}} \boldsymbol{a}_{\boldsymbol{ij}} \boldsymbol{x}_{\boldsymbol{j}}, \boldsymbol{i} = 1, \ldots, \mathbf{n} \tag{5}$$

where $\boldsymbol{A}$ is the adjacency matrix of the graph, λ is the largest eigenvalue, n is the number of nodes, and x is the eigenvector.

In this study, we observe the changes of eigenvector value in a network matrix in order to detect the changes in network. Following Bonacichi's calculation of eigenvector centrality, we use the eigenvector corresponding to the dominant eigenvalue as the vector which represents the network characteristics. The importance of the eigenvector and its components has been dealt with significantly in social network research. The eigenvalue for each node and eigenvector may have been considered as important factors for detecting the dynamics of networks (McCulloh, 2009). In longitudinal social network analysis, the standard deviation of centrality, representing the change of topological connection among other nodes in a time series, can outperform other measures in terms of measurement for network dynamics (McCulloh & Carley, 2011). The change of eigenvector centrality for each concept definitely causes the change of dominant eigenvector of networks.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

In this manner, from a network of N nodes, $N \times 1$ eigenvector will be extracted and the changes of this vector will represent the changes in the entire network. This $N \times 1$ column vector will measure the changes in the direction seen in the N-dimensional space to find the level of change in the network. If we denote the matrices representing networks A and B with N nodes as M_A and M_B, and the eigenvector of these two matrices as x_A, x_B, the gradient between the two networks, Θ can be expressed as follows:

$$\Theta = \cos^{-1}\left(\frac{x_A \cdot x_B}{\left|x_A\right|\left|x_B\right|}\right), \text{(unit: radian)} \tag{6}$$

If the value of Θ exceeds a particular threshold, we take it as a signal that the network characteristic has changed.

Dynamics of Semantic Relatedness between Concepts

The dynamics in the relatedness between concepts constituting the semantic network can be observed through the network matrix representation. If semantic relatedness measured by the above formula varies as time passes, components in the matrix may also change.

The semantic network with N nodes can be constructed with (N^2 - N) / 2 of $rel(C_i, C_j)$ operations in equation (4). In the next section, we present an experiment in which we track all semantic relation changes over a given time and a method of detecting changes is implemented.

EXPERIMENTAL EVALUATION

This section presents two experimental evaluations of our proposed technique, utilizing the sample corpus extracted from Yahoo News[5]. First experiments are dealing with dynamics of semantic relatedness among some political concepts about US election. The news corpus has been collected based on weekly scale during three months near the election period. Second experiment used the news corpus which has been collected throughout longer period, 2 years. We collected the corpus about Apple Company during two years and tracked the change of semantic relatedness for each month.

First Experiment: News on Political Domain

Yahoo News corpus is utilized as a sample corpus in the following way: Yahoo News Crawler is implemented using Python 2.7 and BeautifulSoup API (API for Web page parsing) to compose news corpus. The sample corpus includes Yahoo news articles on the presidential election published between June 2012 and September 2012. The detailed specifications of the corpus are shown in Table 2. Yahoo News corpus has been chosen as the sample data due to its prevalence in the online space and conjectured ease of verification of the result.

A seed set of concepts was needed in order to construct a semantic network between concepts. A total of 14 concepts used in this experiment are shown below.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 2. Specification of the Yahoo News corpus

Data Collection Period	June 2012 ~ September 2012
Corpus Size	Over 7000 news articles (approximately 700 articles per week)
News Subject	News Articles about the Presidential Election
Extractor	Yahoo News Extractor

C = {Obama, election, Romney, tax, president, economy, healthcare, insurance, democratic, campaign, red, blue, poll, white house}

These concepts were randomly selected after reading news articles related to the U.S. presidential election. A number of studies (Leacock, Miller, & Chodorow, 1998; Wang, Du, Payattakool, Philip, & Chen, 2007) extracted seed concepts from reference taxonomy such as WordNet, which made the evaluation process of their proposed algorithms more convenient by comparing clustering results and the reference taxonomy. However, these studies deal with more comprehensive and general semantic relatedness between concepts whereas the aim of our study is to detect the dynamics of semantic relatedness that reflect either domain- or time-specific subjects. Since representative reference taxonomies such as WordNet and Roget's taxonomy describe the relation among millions of concepts under normal situations, regardless of specific context and period, they are not suitable for the purpose of evaluation in our approach.

Constructing the Co-Occurrence Matrix

A 1st order co-occurrence matrix M and its derivative matrices, including 2nd order, 3rd order and total co-occurrence matrix, were calculated from the Yahoo News corpus and the given set of concepts. In this experiment, the threshold for semantic relatedness has been set such that the two nodes within, less than, or equal to three hops are meaningfully related concepts, which is why the 4th order co-occurrence matrix and higher orders are not calculated.

Detecting the Dynamics of Semantic Relatedness and Semantic Networks

Table 3 shows the details of Yahoo News data for 13 weeks. Every Tuesday, the previous one-week's data was collected using Yahoo News Crawler. As a result, more than 700 news data related to the election in the United States were collected for every week. Using news corpus collected for every state, each weekly network was constructed, resulting in a total of 13 time-series network data.

For the 14 previously selected concepts, a total of 22 networks were formed, and each network was expressed as a 14×14 asymmetric matrix.

Using this matrix, we can calculate the semantic relatedness among concepts for each week. As we defined, formula (4) can be used for calculating semantic relatedness. Table 4 shows the semantic relatedness matrix for the first weeks. The relatedness matrix is generated from the total co-occurrence matrix, which is the grand sum of 1st, 2nd and 3rd co-occurrence matrices.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 3. Specification of corpus used for constructing semantic network

Period	Total Number of News Articles	Real Date
Week 1	715	3rd Week of June

The semantic relatedness can be decomposed into two separated contributions; from 1st order co-occurrence and higher order (2nd and 3rd) co-occurrence matrix. This decomposition shows how indirect co-occurrence of two words can contribute to elevate the relatedness and enable the proposed relatedness to be measured more accurately and sophisticatedly. Contribution of higher order co-occurrence to semantic relatedness value is presented in Table 5.

As we can see from Table 5, most pairs have a very marginal portion from a higher order matrix. However, we can also observe that some relatedness values among important concepts are calibrated by higher order terms. For example, without considering indirect co-occurrence, the semantic relatedness between (campaign, Obama), (campaign, Romney), and (campaign, president) might have lower relatedness though they are intimately linked. Some concept pairs that are enjoying the effect of indirect co-occurrence are presented in Table 6 with the decomposition of contribution. This shows the effectiveness of proposed calculation method compared to a simple co-occurrence analysis, which has been used for corpus-based semantic related research.

For each network matrix, dominant eigenvalue and corresponding eigenvector were obtained (all operations related to the matrix were performed using R Package). All matrices had a dominant eigenvalue and the second biggest eigenvalue had a much smaller dominant eigenvalue (all the second biggest

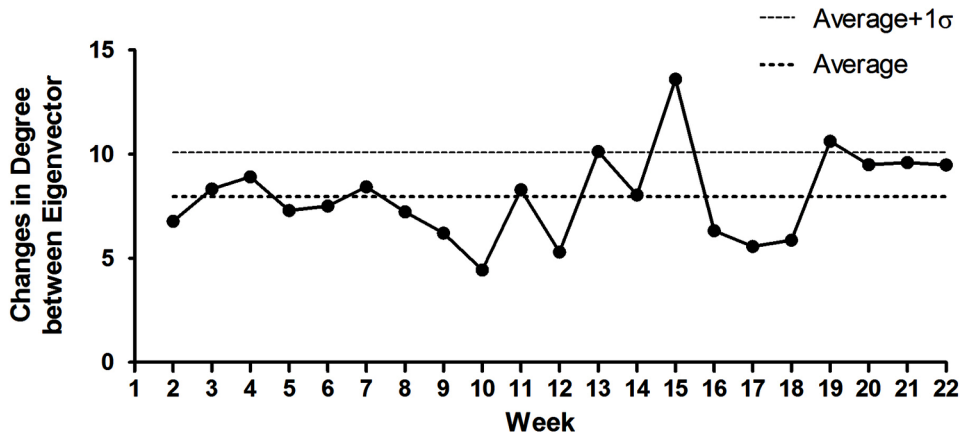
Contribution from higher order	0.341	0.226	0.375	0.324	0.221	0.393	0.249	0.339

eigenvalues were less than 1.0). Therefore, according to the process of constructing Bonacich's eigenvector centrality, these eigenvectors are enough to express the characteristics of each matrix (Resnik, 1995). The eigenvalues and eigenvectors for 22 networks are shown in Table 7.



Using these eigenvectors, the gradient between networks, Θ can be obtained. The gradient can be calculated from week 2 via comparison with the previous week. The gradient Θ represents how much each network eigenvector moves in a 14-dimensional space. Table 7 exhibits the resulting eigenvector gradient, Θ.

Overall, the mean change level was 7.96 and the standard deviation was 2.12. If we assume the normal distribution for network change, a change that results in the position of 'average + 1σ' corresponds to the top 15%. In this experiment, the threshold level of network change detection is set at the top 15%. The resulting gradients and the threshold value (about 10.08) are shown in Figure 5.

From Figure 5, there is a significant change in network in weeks of 13, 15 and 19 when the change level is close to or exceeds the threshold value. Such change of network eigenvector at a significant level signifies that Bonacich's eigenvector centrality of semantic network has changed.

The dynamics of semantic relatedness between separate concepts can be verified in a simpler way. If we compute each component of total co-occurrence matrix and the average of its symmetry components, we can obtain the changes in semantic relatedness over time. Figure 6 shows the changes in semantic relatedness between concepts.

Figure 5. Detecting the significant change of network

Figure 6. Change of semantic relatedness between concepts – Obama and president / Romney and president

We selected two pairs of concepts, (Obama, President) and (Romney, President). Based on the methodology proposed in Section 4, semantic relatedness was calculated. As Romney was defeated in the US presidential election 2012, *rel*(Romney, President) decreased sharply after election 2012 whereas *rel*(Obama, President) maintained the high relatedness value. This result exactly corresponds with a change of human *ground truth*.

The level of dynamics of concepts in the semantic network can also be observed by checking the standard deviation of centrality, as McCulloh (2009) indicates. As we can see from the last column of table 7, some concepts have higher standard deviation than others. For example, "healthcare" and "insurance" have relatively higher dynamics as these were one of the key words in the US presidential election. This means the standard deviation of centrality can be used for detecting dynamic concepts or key topics in the semantic network by analyzing the news corpus.

In this experiment, we have tracked the changes of 91 pairs' semantic relatedness ($_{14}C_2 = 91$) and some concepts showed their dynamics in semantic relatedness while others showed very stable relatedness values regardless of time. Figure 7 below shows the change of semantic relatedness between "Romney" and other concepts.

As we can see from Figure 7, "Romney", which is one of the hottest topics in the context of this expriment, exhibits its dynamics of semantic relatedness with regard to the other concepts. Especially, semantic relatedness with concepts about election such as campaign, tax, and president fluctuates as time change. However, it is not the case that all concepts show such dynamics in semantic relatedness. Concepts which are less relevant and sensitive to the election show more stability in terms of dyanmics. Figure 8 shows different aspects of dyanmics of semantic relatedness.

In the case of semantic relatedness between "economy" and other concepts, most relatedness stay very stable in terms of change of relatedness. Only a few concepts such as campaign which are closely related to the election show higher change than other concepts.

Second Experiment: News on IT Domain

For the second experiment, we collected IT news dealing with the article about Apple Company. The corpus has been composed using Nexis news database browser. The corpus includes Apple news articles on the between December 2013 and November 2015 (2 years). Nexis browser enabled us to confine the period and publication area of articles. In this experiment, we only used the article published in the U.S region during the defined period. The detailed specifications of the corpus are shown in Table 8. Apple News corpus has been chosen as the sample data due to its prevalence in the online space and conjectured ease of verification of the result.

A seed set of concepts was needed in order to construct a semantic network between concepts as we did in first experiment. A total of 10 concepts used in this experiment are shown below.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 8. Specification of the News corpus

Data Collection Period	December 2013 ~ November 2015
Corpus Size	Over 15,000 news articles (approximately 600 articles per month)
News Subject	News Articles about Apple Company
Extractor	Nexis news browser

$C = \{$Apple, Samsung, iPhone, new, Google, Android, Mobile, smartphone, technology, Yahoo$\}$

The concepts above was selected by five doctoral students who are majoring IT business in business school after they skimmed the recent articles about Apple.

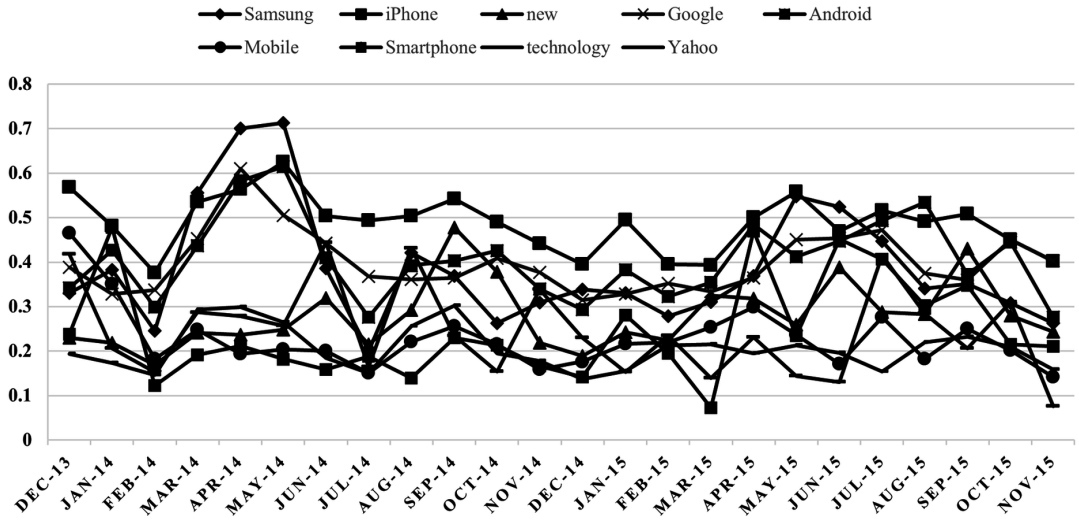
Constructing the Co-Occurrence Matrix

A 1st order co-occurrence matrix M and its derivative matrices, including 2nd order, 3rd order and total co-occurrence matrix, were calculated from the Apple News corpus and the given set of concepts. In this experiment, as we did in the first experiment, the threshold for semantic relatedness has been set such that the two nodes within, less than, or equal to three hops are meaningfully related concepts, so the 4th order co-occurrence matrix and higher orders are not calculated.

Detecting the Dynamics of Semantic Relatedness and Semantic Networks

For each month, more than 600 articles published in the U.S. were collected. Using news corpus collected for every state, each monthly network was constructed, resulting in a total of 24 time-series network data. Table 9 shows the semantic relatedness among apples and other concepts in first month (December 2013) and how the results can be decomposed into direct and indirect components. We can see that some relevant concepts such as iPhone, Google, and Android are strongly compensated by contribution of higher order.

Figure 9 shows the change of semantic relatedness between Apple and other relevant concepts. Some relatedness has very stable value regardless of time flow but some concepts such as Samsung and iPhone show significant change in relatedness. As we can see in Figure 9, relatedness between Apple and Samsung/Google has very high value through March - April 2014 and May – June 2015. In this period, Apple had been suing over Samsung (March - April 2014) and its result of litigation has been released (May – June 2015).



These anecdotal influence on semantic relatedness have an impact on overall semantic network as well. Table 10 shows the change of whole semantic network in terms of its eigenvectors. During these two periods when the lawsuit has been going on, the semantic network shows significant change due to these events.

DISCUSSION

The proposed approach to manage the dynamics and temporal properties of the semantic relatedness was verified through two experimental evaluations. The evaluations not only revealed the dynamics of semantic relatedness between specific words, but also reaffirmed the needs for dynamic semantic relatedness paradigm. In this regard, this research has both theoretical and practical implications and contributions.

The proposed method and evaluation result provide the empirical evidence to dynamic nature of semantic relatedness, which has its basis on the theory of cognitive semantics. The basic assumption of cognitive semantics is that the language spoken by human being is the part of the cognition (Saeed, 2003) and this assumption can hint the dynamic nature of relatedness among the concepts as human cognition can be varied with their experience and knowledge (Löbner, 2013). These experience and knowledge has been called *semantic knowledge* in traditional semantics and this semantic knowledge has been considered as a main factors for human to understand the world (Holland and Quinn, 1987). Our research has very significant contributions to traditional semantics and cognitive semantics, which provide the theoretical background to dynamic semantic relatedness paradigm, by providing clear empirical evidence of changes in semantic relatedness and its management strategies.

Also, the research can be applied for various practical situation where the management of dynamic semantic relatedness is needed. The keyword recommendation and service discovery in virtual community can be an application example of proposed method (Crasso, Zunino, & Campo, 2011). As the main interest and topic among the virtual community users may vary, the relatedness among keywords and query can be varied as well. In this case, the proposed dynamic network model can cope with and manage the dynamics of relatedness among keywords and the quality of topic recommendation can be improved.

These contributions are very meaningful in the context of rapidly changing IT society with the active knowledge sharing and information diffusion. While the structure of human cognition can vary very fast with IT infrastructure, its theoretical consideration and method for dealing with dynamics of semantic relatedness has been lacking. Therefore, this research can be the very significant starting point for *dynamic semantic relatedness paradigm* research.

CONCLUSION AND FUTURE RESEARCH

This research focuses on dynamics in semantic relatedness and semantic networks under the *dynamic semantic relatedness paradigm*. For this purpose, new semantic relatedness measures can be defined based on the dynamic semantic network construction using a corpus created in a specific time period and context. Not only the change of semantic relatedness among concepts, but also the change of the whole semantic network can be measured. Specifically, the change of a semantic network consisting of given concepts has been quantified based on the fundamental concept of network dynamics in social network research.

Compared to previously dominant approaches following the *static semantic relatedness paradigm*, the proposed approach has significant advantages. First, our approach does not have any dependency on external resources such as WordNet, dictionaries, and thesauri. As most dictionaries contain limited vocabulary, newly generated concepts and proper nouns cannot be referred from dictionaries. Considering that content and contexts are changing rapidly due to technological advances, extracting semantic networks using only a given corpus can be more flexible in terms of reflecting the real word situation.

Second, the proposed method is simpler than other statistical approaches adopted by studies dealing with dynamics of semantic relatedness (Blei & Lafferty, 2006; Radinsky, Agichtein, Gabrilovich, & Markovitch, 2011; Sagi, Kaufmann, & Clark, 2009) such as LSA, TSA and LDA. By simply constructing semantic networks based on conditional probability, we can measure semantic relatedness. The simplicity of measurement is very critical for implementing real-time systems. Though the examples in this research were weekly-based and monthly-based detection of semantic relatedness, our approach can be applied to a large amount of data generated within a short period of time. In such case, simple algorithms are highly desirable for reducing the calculation cost.

Third, this research proposed the calculation method of semantic relatedness, but also sought to quantify the dynamics of whole semantic networks. Implied by social network research (McCulloh, 2009; McCulloh & Carley, 2011), the dynamics of one concept in the network can also be observed via the standard deviation of centrality. To the best of our knowledge, this is the first attempt to quantify the dynamics of semantic networks. The quantification is a more advanced technique than finding the existence of dynamics. With the proposed technique, we can compute the degree of dynamics of a given semantic network so that we can compare the dynamics with respect to the time change.

These strengths are verified with the experimental evaluation using real corpus data gleaned from Yahoo News. The evaluation is an important aspect of semantic relatedness research. Methods of previous research following the *static semantic relatedness paradigm* evaluate their approach with benchmark testing by comparing human ratings (Resnik, 1995). These evaluation methods usually deal with the relatedness among very common concepts whose relationships can be estimated using common sense and ground truth. However, evaluation of semantic relatedness reflecting the context or dynamics can be more difficult as it cannot be evaluated by using only the human ratings. In this case, only humans who are involved in the given context in a specific time have the knowledge to estimate the relatedness among relevant concepts. Due to such difficulties in evaluation of dynamic semantic relatedness, previous research dealing with dynamic semantic relatedness has evaluated their methods using the assessment method for static semantic relatedness evaluation; only common sense by human is used for evaluation without reflecting the knowledge generated by context during specific time periods. For example, Radinsky, Agichtein, Gabrilovich, & Markovitch (2011), Rinaldi (2009) and Sagi, Kaufmann, & Clark (2009) evaluate their methods by selecting common words that hardly change their semantics and compare with the human rating even though they propose temporal semantic analyses. Other works do not even contain the evaluation results and only provide the list of topics (Blei & Lafferty, 2006).

The evaluation method of this research is hinted from those of information retrieval. To evaluate the correctness of the retrieval system output, the output must be compared with ground truth (Rinaldi, 2009). Similarly, the dynamics of semantic relatedness can be evaluated with the change in *ground truth*. For this reason, we selected concepts with the change in *ground truth*; the change of president can cause the change in *ground truth* in human recognition. Our experiment results exactly correspond with ground truth that has been changed by presidential election.

Throughout the experiment, we tracked the change of relatedness of 92 pairs' concepts to get more concrete reliability of proposed semantic relatedness calculation method where the impact of indirect co-occurrence and significant change have been confirmed. By showing multiple cases of dynamic change of semantic relatedness, we tried to verify the general applicability of proposed method to other contexts.

The experiment results show applicability of a proposed method to another area. As changes in various network measures such as centrality, closeness, and between-ness in longitudinal social network analysis have important meanings (McCulloh & Carley, 2011), these network measures in semantic networks might be valuable in terms of dynamics of semantic relatedness. We have already discovered the potential of centrality variation for finding the concepts that have the most dynamic nature in a given context.

Our proposed approach can be used for rising topic detection and tracking large streams of data such as newswire and broadcast news since news topics and relationships among topics change as time passes. Existing studies of the static semantic relatedness paradigm cannot capture the dynamic nature of semantic relatedness between topics in news and media. Keyword and tag recommendation is one applicable research area. Tagging has become a standard way of organizing information on the Web, particularly in various types of data created by communities of users. Tags and keywords attached to each resource create a bridge between data and users accustomed to keyword-based search and browsing. Our research can be utilized to provide users with a set of user-defined tags. As the relatedness between tags/keywords changes easily as time passes, our approach can be an excellent alternative to existing tag/keyword recommendation algorithms.

There are at least three ways to improve our approach towards the dynamic semantic relatedness paradigm. First, a statistically significant level of network change should be detected through corpus analysis on diverse subjects. By testing the proposed algorithm with various types of corpus and keyword sets,

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

one can derive more generalized statistics representing dynamics of semantic relatedness. Second, the ordinary statistical features of semantic network dynamics should be studied through data collection over a longer period of time. Compared to the ordinary social network, the semantic network lacks studies on the properties of the network itself. Third, the efficiency of proposed algorithms should be assessed for real-time detection of semantic relatedness dynamics. For real-time processing, more efficient ways of calculating semantic relatedness and its dynamics need to be in place.

ENDNOTES

1. WordNet is a large lexical database of English. Nouns, verbs, adjectives and adverbs are grouped into sets of cognitive synonyms, each expressing a distinct concept (http://wordnet.princeton.edu)
2. We do not intend to limit the number of concepts in $\boldsymbol{C}$. N can be either the total number of concepts in the corpus or the number of given concepts.
3. The difference between conditional and unconditional probability can be verified using a statistical test, such as *t*-test.
4. Diagonal values of the total co-occurrence matrix are meaningless since they represent the relatedness between same concepts.

Chapter 53
Emotion Mining Using Semantic Similarity

Rafiya Jan
Central university Of Kashmir, India

Afaq Alam Khan
Central University of Kashmir, India

ABSTRACT

Social networks are considered as the most abundant sources of affective information for sentiment and emotion classification. Emotion classification is the challenging task of classifying emotions into different types. Emotions being universal, the automatic exploration of emotion is considered as a difficult task to perform. A lot of the research is being conducted in the field of automatic emotion detection in textual data streams. However, very little attention is paid towards capturing semantic features of the text. In this article, the authors present the technique of semantic relatedness for automatic classification of emotion in the text using distributional semantic models. This approach uses semantic similarity for measuring the coherence between the two emotionally related entities. Before classification, data is pre-processed to remove the irrelevant fields and inconsistencies and to improve the performance. The proposed approach achieved the accuracy of 71.795%, which is competitive considering as no training or annotation of data is done.

INTRODUCTION

Social networks have become a popular interaction platform. Social Networking Sites like Facebook, Twitter has changed the standard of social interaction among the online users. Social Networking Sites enables online users to share their ideas, experiences, feelings, and emotions related to their daily routines. Social Networks are considered the most abundant sources of affective information for emotion analysis, affective computing and sentiment analysis. Sentiment analysis deals with determining the appraisals, feelings, opinions about different entities. Emotion analysis deals in determination and identification of feelings or emotions like Anger, Disgust, Fear, Happiness, Sadness, and Surprise. The goal of this

research is to create an automated system able to detect emotions in text using Semantic similarity between two textual elements. Our system creates a knowledge base for classification and then uses that knowledge base to infer classes of unseen data.

Emotion is defined as the mental state observed by behavioral or developmental changes. Emotions are universal despite the vast differences between different individuals and their cultures. The social conditions also induce emotions. Emotions are not bounded by the person's inner conscience but also afflicted by the person's experiences, goals and most importantly by the society. Emotions are a fundamental part of human nature possessed by every human. Emotions can be broadly classified into two types: Basic emotions and Complex Emotions. Basic emotions include Anger, Disgust, Fear, Happiness, Sadness, and Surprise. Complex emotion encompasses two or more emotions felt by a person in a particular situation. An accurate emotion detection system can be thus very beneficial for social orientation. Therefore, the need of the hour is a reliable and scalable emotion detection system capable of mapping human wrote social media posts into a different set of emotions for tracking the well-being of the society and provide benefits to the business establishments and political systems. The creation of automatic emotion detection system would thus allow us to evaluate and identify the people's emotion by automatically analyze the social media content like twitter posts and Facebook comments. The automation emotion detection system would thus be having one module for analyzing the social web for the social content and tracking the well-being of the individual. Social media posts also contain the geographical and temporal information; the system will hence be able to track the well-being state of a social group at some particular place, in some specific temporal area.

The relevance of this paper is found as the vast number of applications that are being used to detect the emotional states of people and the benefit they are providing to the business establishments, political parties, individuals and society at large. Its relevance can also be seen in the e-learning environment (Rodriguez, Ortigosa, & Carro, 2012), suicide prevention (Suero Montero, & Suhonen, 2014), depression detection (Desmet, & Hoste, 2013), detection of cyber-bullying (Vaassen, 2014) or tracking the well-being of user community (Dadvar, Trieschnigg, Ordelman, & de Jong, 2013).

The primary challenge for the automatic emotion detection systems is that they do not capture the semantic meaning of the textual systems; instead, they focus on the statistical features present in the text. Traditionally, these systems employ either lexical resources or use statistical measures to build the automatic emotion detection systems. However, none of these systems would employ the measures to focus on the semantics of the text. Moreover, with the employment of these resources the emotion detection systems would have bias and thus classification of emotions is not accurate and thus the emotion detection systems are not scalable, robust and are thus error-prone.

For this reason, we propose an Automatic emotion detection system which is capable of exploiting the semantic similarity between textual elements and thus classify text based on semantic relatedness measure. The proposed system consists of three main steps: 1) creation of seed documents using NRC Emotion Lexicon (Mohammad, & Turney, 2013) which is used to evaluate semantic association of the textual element to be classified and emotion class; 2) Generation of Big-Vectors of text using Word2Vec (Mikolov, Chen, Corrado, & Dean, 2013); 3) Using semantic relatedness measure to calculate the semantic association between seed documents and textual element to compute emotion class of the textual element.

We measured the effectiveness of the proposed automatic emotion classifier using pre-labeled standard datasets and found comparable results. Thus, proposed automatic emotion classifier be built keeping the semantics of text in consideration which was lacking in the previous start of art research conducted in the area of automatic emotion classification. Moreover, the results of our proposed technique confirm the efficacy of the proposed technique of emotion detection.

RELATED WORK

This section summarizes the state of art approaches used in the emotion detection systems, their features, how they have built, their accuracies and their deficiencies. Also, this section presents the overview of the emotion models, emotion lexicons used by the automatic emotion detection systems. Majority of the automatic emotion detection and sentiment analysis systems are built around the statistical properties of the text and ignore the semantics and contextual feature which are essential for any emotion detection and sentiment analysis systems. Supervised learning algorithms are majorly used to detect and analyze emotions without taking into account the semantics and context into account.

Emotion Models

Ekman (1992) proposed the basic emotion model. This model identified six types of emotions: Anger, Disgust, Fear, Happiness, Sadness, and Surprise that are assumed as the basic emotion types. Plutchik, & Kellerman (1980) proposed the emotion model with eight primary emotion including Ekman's six basic emotions with two additional emotions Trust and Anticipation. He assembled these eight emotions in a Wheel. The radius of the wheel specifies the intensity of the emotions. The emotion closer to center indicates the sharp intensity of emotions. Plutchik also proposed that these emotions form 4 variant pairs like anticipation &surprise, anger, and fear, joy, and sadness, trust and disgust. Parrot's hierarchy model has categorized emotions into six classes of anger, fear, joy, love, sad, and surprise (Bradley, M. M., & Lang, P. J. (1999)). Izard in his model divides emotions into 12 classes viz. anger, contempt, disgust, fear, joy, interest, self-hostility, shame, shyness surprise, sadness and guilt (Hancock, Landrigan, & Silver, 2007). PANA (Positive Activation-Negative Activation) model (Watson, & Tellegen, 1985) resolved the system into positive affect and negative affect. The vertical axis depicting the positive affect and the horizontal axis depicting the negative affect. Russell's Circumflex Model (Russell, 1980) suggests that emotions are distributed in a 2D circular space in which the vertical axis represents the subjectivity and horizontal axis represent the intensity and the origin represents neutral as shown in Figure 2. The vertical dimensions specify how much PLEASANT and UNPLEASANT an emotion is. The horizontal dimensions distinguish ACTIVATION and DEACTIVATION. PAD (pleasure, arousal, and dominance) model (Mehrabian, A. (1996).) model is a superset of the circumflex model with the addition of the dominance dimension, which signifies whether impression of subject is in of a particular situation or not.

Emotion Lexicons

Emotion lexicon is a database of words labeled with labels of emotion according to their emotional connotations. Labels are generally emotional categories assigned to the word in the lexicon. In literature we find the following standard lexicons:

1. ANEW (Bradley, & Lang, 1999): Affective Norms for English Words is a set of standard emotional ratings of 1,034 words in English language including adjectives, nouns, and verbs.720 members participated for rating these words. The words are assigned scores from 1 to 9 on the basis of scope of 3 elements viz arousal, dominance, and valence by employing the SAM (Self-Assessment Manikin).

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

2. DAL (Mehrabian, 1996): DAL is the lexicon of emotion words composed 8,742 words weighted by people for their imagination, awareness, interpretations, and intelligence and personification purposes.
3. WordNet Affect (WNA) (Strapparava, & Mihalcea, 2008): WordNet-Affect is an extension of WordNet realm that is composed of synsets that are relevant to express the affective concepts associated with emotion words. The synsets that are labelled with A-label distinguishes the emotive concepts. Other a-labels depicts the emotive responses, affects evoked by different situations and behaviour.
4. NRC Word-Emotion Association Lexicon (EmoLex) (Mohammad, & Turney, 2013):The NRC Emotion Lexicon is composed of 14,182 unigrams English words categorized into eight basic emotions (anger, anticipation, disgust, fear, joy, trust, sadness and surprise) and two sentiments (positive and negative).In this experiment, only 6 emotions (anger, disgust, fear, joy, sadness, and surprise) are used. Crowdsourcing on Mechanical Turk is used for manual word level annotation of these lexicons.
5. NRC Hashtag Emotion Lexicon (Mohammad, & Kiritchenko, 2015): NRC is a Twitter dataset composed of 16,000 words that are automatically annotated with Plutchik's eight emotions by employing the words bearing emotion hashtags.
6. EmoSenticNet (ESN) (Poria, SGelbukh, Hussain, Howard, Das, & Bandyopadhyay, 2013): ESN is the morphological asset of 13,171 words that ascribes subjective emotion labels and significant polarity scores to SentiNet approaches. WordNet Affect labels comprised of Ekman's emotions is the set of emotions that is used for annotating the concepts.
7. DepecheMood (Staiano, & Guerini, 2014): DepecheMood is like a dictionary of nearly 37,000 words in which every word is conjoined with emotion scores of 8 emotion categories viz afraid, amused, angry, annoyed, inspired, don't care, happy and sad. It was assembled by manipulating the crowd-sourced emotion labelling scheme implemented by the news readers of Rappler website.

Table 1 shows summarized emotion lexicons developed for automatic emotion detection systems.

Computational Approaches

Machine Learning Based Approach

Machine learning based approaches use statistical algorithms on syntactic and linguistic features for building automatic emotion detection systems. These algorithms are either supervised or unsupervised. Some examples of supervised machine learning based approaches are: (De Choudhury, Gamon, Counts & Horvitz, 2013) used supervised learning algorithms to detect depressive disorders; they measured behavioral attributes like language, emotion, social engagement, linguistic style and mentions of anti-depressant medication to build their classifier. Moreover, they used crowd-sourced twitter dataset for classification and achieved 70% accuracy in the classification task. Purver & Battersby (2012) used supervised learning algorithms for their emotion detection system. They trained their supervised classifier using twitter dataset labeled with automatic annotations of Ekman's (Ekman, 1992) classes which include anger, fear, happiness, sadness, surprise, and disgust and achieved 60% accuracy. Qadir & Riloff (2013) employed a bootstrapping approach using emotion hashtags to train their supervised classifier.

Ortigosa, Martín, & Carro, 2014	Facebook Posts	Positive, Negative and Neutral	No Annotation

They used candidate emotion hashtags for five emotion classes of anger, affection, anxiety, joy, and sadness and achieved 68% accuracy in their classification task. Wilson, Wiebe & Hwa (2004) classified the text into Subjective and Objective texts. This approach used the Supervised Learning approach for classification of text. Subjectivity determines whether a sentence is a positive or negative sentence and Objectivity determines the intensity (relationship strength) of the emotions related to that sentence. This system requires proper sentence structure for determining syntactic relations. Thelwall, Wilkinson & Uppal (2010) analyzed the different texts from online social media MySpace and implemented emotion mining on these texts. They concluded 2-Dimensional models provide better accuracy for emotion analysis. Balabantaray, Mohammad, & Sharma (2012) used sentence level annotation of 8,150 tweets collected from the web to train their supervised classifier. They have used contextual, syntactic and linguistic features in their classification task and achieved 73.05% accuracy.

The supervised automatic emotion detection systems require an affective corpus. Affective corpus is a considerable set of structured sentences where each sentence is annotated with emotion tags. This corpus is built by employing human annotators who analyze each sentence and assign a corresponding label to the sentence. The corpus acts as a heart of the supervised learning algorithms as they are trained on this corpus to infer class to the unseen data. However, the corpus is difficult and arduous to create as human judgment is expensive and error-prone.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Emotion Corpus is generally annotated with Ekman's basic emotion categories, there are several such works, like Alm, Roth, & Sproat (2005) have created sentence level annotation of 185 children stories with six emotional classes; Aman & Szpakowicz (2007) created a corpus with emotional intensity and categories of blog posts acquired directly from the web; Strapparava & Mihalcea (2008) labelled news headlines with emotion intensities and categories.

Some recent advances in the area of emotion annotation task have been recorded in the literature where the focus on the task of annotating the sentences is automated; for example, Bifet & Frank (2010) used bootstrapping to automatically classify tweets by expanding seed lists using Word2Vec models and LSA algorithms. Their evaluation results were also promising. Go, Bhayani & Huang (2009) use distant-supervision using emoticons to create positive and negative labeled dataset for the supervised learning algorithm s. Suttles, J., & Ide, N. (2013, March) uses distant supervision using hash-tags, emoticons, and emojis to automatically annotate the twitter dataset using Plutchiks eight emotion labels; Hasan, Rundensteiner & Agu (2014) used circumplex model (Russell, 1980) where emotional states characterizing affect experience composed of valence and arousal is captured using twitter hash-tags to annotate twitter dataset automatically.

Unsupervised learning algorithms do not stand in need of any training set for learning and are thus less expensive than supervised algorithms for emotion detection process. Some examples of unsupervised learning algorithms for emotion detection include Agrawal & An (2012) used the context-based approach based on a procedure of exclusive emotion lexicon, and thus their model can classify prior to Ekman 's six classes. Calvo & Mac Kim (2013) proposed an unsupervised learning algorithm for emotion detection using dimensional models and used ANEW (Bradley & Lang, 1999) database for emotion detection. Neviarouskaya, Prendinger & Ishizuka (2007) proposed a rule-based technique to determine emotions: Anger, Disgust, Fear, Happiness, Sadness, and Surprise (Ekman, 1992) from the sentences of different blog posts.

Lexicon Based Approach

In the lexicon-based approach lexical resources like a set of words, ontologies and lexicons are employed for emotion detection. These methods usually start with the small set of words called seed set and then usually built around it and expand the seeds using several resources like WordNet (Staiano & Guerini, 2014) and build a more extensive set of words for classification purpose. Liu, Lieberman & Selker (2003) proposed a technique to extricate emotions from the sentence. This technique is premised on the affective common sense in which real-world knowledge is used to draw sentiments or emotions from sentences. The method is based on the assumption that all the individuals have the same feeling towards a particular event. This technique categorizes the emotions into the Ekman's six emotions (Ekman, 1992). Yassine & Hajj (2010) presents a framework to determine the affective interactions. They used Lebanese Facebook dataset as a case study and used the unsupervised technique to classify texts based on Friendship and subjectivity. They used k-means for classification of text by subjectivity: neutral, moderately subjective and subjective. The classification results reported an accuracy of 87% based on the subjective content of comments shared by online Users.

Ortigosa, Martín & Carro (2014) presented a novel approach for sentiment analysis of Facebook posts. They employed a hybrid approach of lexical-based and machine-learning techniques using SentBuk for Classification of Facebook Status posts.SentBuk obtained Facebook posts from Facebook users performs classification of the posts and presents the results of classification by the interface. They used

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

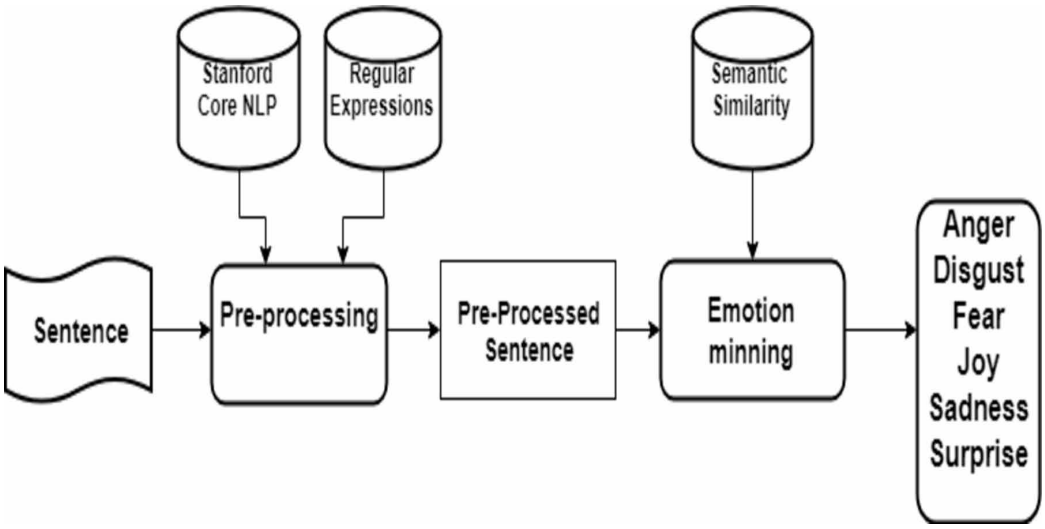
J48, Naïve-Bayes and Support Vector Machines to build the classifier. The performance of this classifier was excellent with an accuracy of 83.27%. This approach can be used in e-learning systems and recommended systems where a user can freely express his thoughts and emotions.

Aman & Szpakowicz (2007) Implemented the technique of annotating sentiments to determine emotion bearing sentences or words, emotion categories, and their intensities. They proposed an annotation scheme for recognition of different types of emotions, the strength of emotions, and phrases bearing emotion in the text. They worked on self-annotated blog posts having happy and sad mood labels. They conducted their work on two specific emotions happiness and sadness. Their complete processed work is used for automatic sentiment and affective experiments. Their classification techniques produced an accuracy of 73.89%.

Alm, Roth & Sproat (2005) described a technique of supervised learning for automatic classification of sentences into the basic six emotions (Ekman emotions) in children's fairy tales. They used Snow learning architecture for classification of sentences.

Wiebe, Wilson & Cardie (2005) used the MPQA corpus composed of 10,000 sentences of news articles for manual labeling of opinions, emotions, and sentiment. As mentioned previously the task of emotion detection is the particularly hot topic in the sentiment detection and analysis field with its applications ranging from human-computer interaction to suicide detection, depression detection, mood swings to welfare tracking and cyberbullying. However, not much work focuses on semantic of text instead the focus is towards building a corpus for supervised earning and lexical features of the text. Supervised learning although producing excellent results is costly to implement as it involves the creation of emotional corpora which is created by human annotators and is thus expensive to do and can lead to bias due to inter-annotator agreements.

In this work, we propose an automatic emotion detection system which captures the semantic features of the text. It uses an amalgam of deep learning and unsupervised learning to capture the semantic similarity between textual elements to classify the text for emotion classification purpose. We use the NRC Emotion Lexicon (EmoLex) (Mohammad & Turney, 2013) as our lexical resource and classify the text into Ekman's six basic emotion classes.



As an outcome of the compilations implicated from the analysis of the previous work and a consideration on the undetermined issues, our proposed semantic automatic emotion classifier is described in detail in the next section.

SEMANTIC AUTOMATIC EMOTION CLASSIFICATION

The objective of the automatic semantic emotion classification is to classify unlabeled sentences conveying some emotions. To address this, we have designed an automatic emotion classifier capable of classifying a textual sentence into predefined classes taking semantic connotation of the sentence to be classified into consideration. The classifier designed is thus capable of classifying an English sentence into one of the predefined classes based on the emotion orientation of the sentence. Structure of our emotional classifier consists of 1) Generate lexicon for classification using NRC emotion Lexicon (EmoLex) (Mohammad & Turney, 2013); 2) Use distributional Semantic (Marelli, Bentivogli, Baroni, Bernardi, Menini & Zamparelli, 2014) algorithms for classification. Precisely, our sematic automatic emotion classification approach consists of unsupervised and deep learning algorithms. Our classification process is thus an amalgam of unsupervised learning and deep learning. For generating of our lexicon,

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. Overall methodology

we have used EmoLex (Mohammad & Turney, 2013) in its reduced form which is then extended using WordNet (Staiano & Guerini, 2014). For classification, we do the preprocessing of data followed by using distributional semantic algorithms to capture the semantics of text and then vectorizing the data for classification. Lexicon is also vectorized, and then a mapping function is applied to calculate the emotional score of the sentence against each class of the emotional categories. The maximum score for the emotional category will give the label for the sentence. The overview of our Semantic emotion classifier is shown in the diagram Figure 1.

The process acquires a collection of unlabeled phrases or sentences and a set of emotional classes as input; exclusively this paper works with the Ekman's six basic emotions and produces as output an emotional label among the six emotional labels of Ekman's classes for the sentence if it has an emotional affinity towards any of the six categories or neutral otherwise. This section is divided into three subsections where the fundamental task performed by each is described in detail.

LEXICON GENERATION

In lexicon generation, we discuss the technique of building the initial seed by using the NRC Word-Emotion Association Lexicon (Emolex) (Mohammad & Turney, 2013). Emolex consists of general English language unigrams annotated using Amazon Mechanical Turk. It is annotated using Plutchik's emotion classes plus two sentiment labels (positive and negative). Emolex has 14000 English unigrams. Since our emotional labels are Ekman's six emotional labels thus, we need to reduce the Emolex to cover only six Ekman's labels (Figure 2), and hence our reduced Emolex has 3,462 emotional words annotated with six Ekman's classes.

Table 2 shows the distribution of reduced Emolex for Ekman's six classes.

However, due to the reduction, there was a need to extend Emolex. Hence, we extended the reduced Emolex with synonyms. More precisely we extended reduced Emolex to build a better and bigger seed set using WordNet (Staiano, J., & Guerini, M. (2014).) and Oxford (Marelli, Bentivogli, Baroni, Bernardi, Menini & Zamparelli, 2014) synonyms.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. Lexicon generation

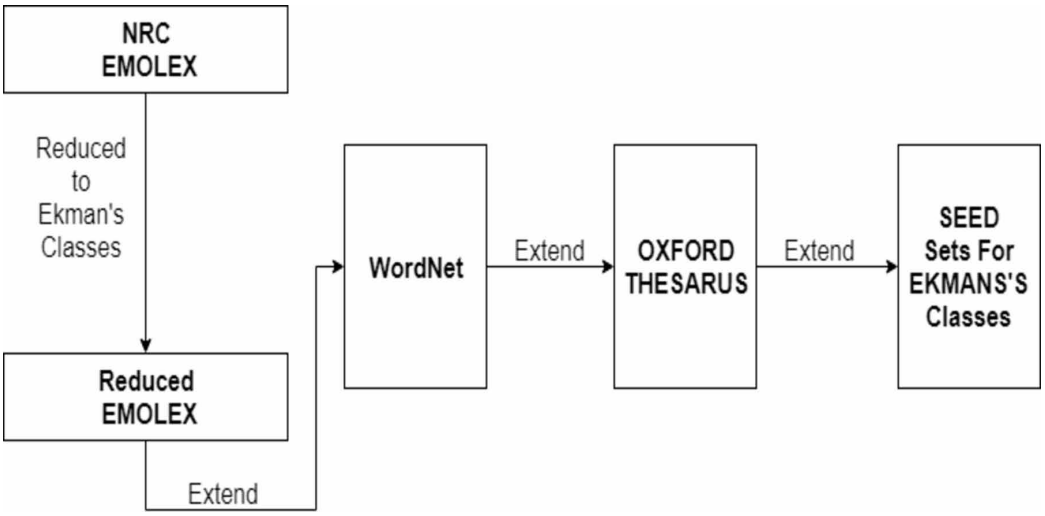


Table 2. Reduced Emolex

	Emolex (Ekman's emotions) # of Words
Anger_words	1,247
Disgust_words	1,058
Fear_words	1,476
Joy_words	689
Sadness_words	1,191
Surprise_words	1,247

SEED EXTENSION USING WORDNET

In seed expansion process, each word in the reduced Emolex is looked for the synsets using WordNet (Staiano & Guerini, 2014). For each word in the Emolex, we obtain synonyms of its most appropriate sense using WordNet and annotate the retrieved synonym using the same annotation as that of the word in the reduced Emolex. Figure 3 shows the example of extracting synonyms from WordNet. The word alcoholism is looked up for synonyms in WordNet and has class "disgust," from WordNet the process retrieves synonyms "alcoholism, alcohol addiction, inebriation, drunkenness" which are appended to the Emolex and annotated with the same class label, i.e., disgust. After this process, Emolex was extended with 5219 words resulting in a new lexicon of 8681 words.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 3. Extracting synonyms from WordNet

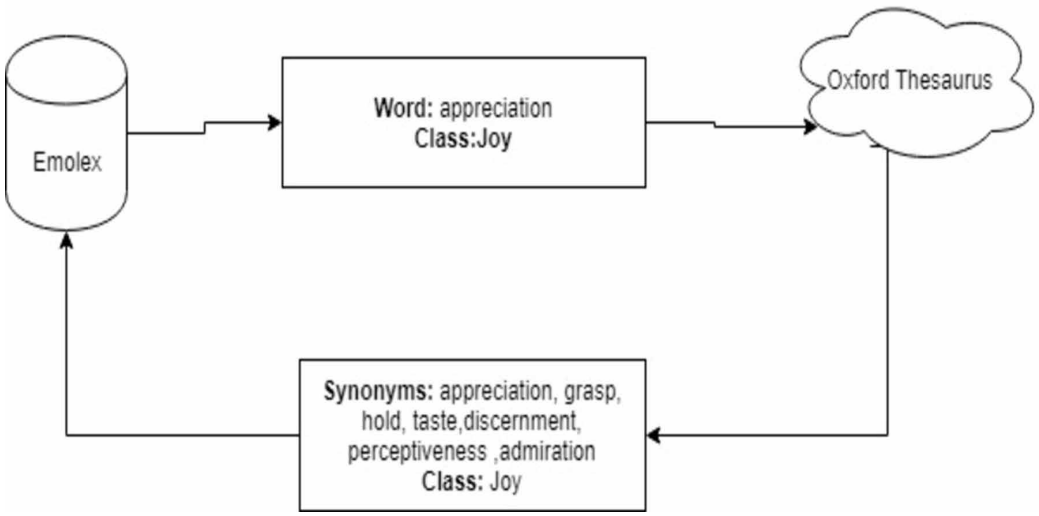
EXTENSION USING OXFORD THESAURUS

This process is carried out to extend the Emolex further. The extended Emolex obtained in the previous step is feed to the Oxford Thesaurus (Marelli, Bentivogli, Baroni, Bernardi, Menini & Zamparelli, 2014), and synonyms are retrieved for each word. Synonyms are added to the Emolex if they are not already present in it with the emotion tag of the synonym being the same as that of the word that was probed for.

Figure 4 shows the example of lexicon enhancement using Oxford thesaurus.

The word "appreciation" belonging to the class joy is probed for synonyms in the Oxford thesaurus and synonyms "appreciation, grasp, hold, taste, discernment, perceptiveness, admiration" are retrieved which if not present in the lexicon are added with the same annotation, i.e., joy is added to the lexicon.

After this process, the number of words added to the lexicon is 10,811 making the total number of words in the lexicon equal to 19,452. Lexicon is then divided into six sets. Each set is associate with the six Ekman's classes. Figure 3 shows the process of seed set creation.



AUTOMATIC CLASSIFICATION

After the creation of Lexicon, the next step is the classification process. The input to the automatic classifier is the set of sentences and a set of labels; the output is the sentence along with the classified label. Our classifier consists of following steps:

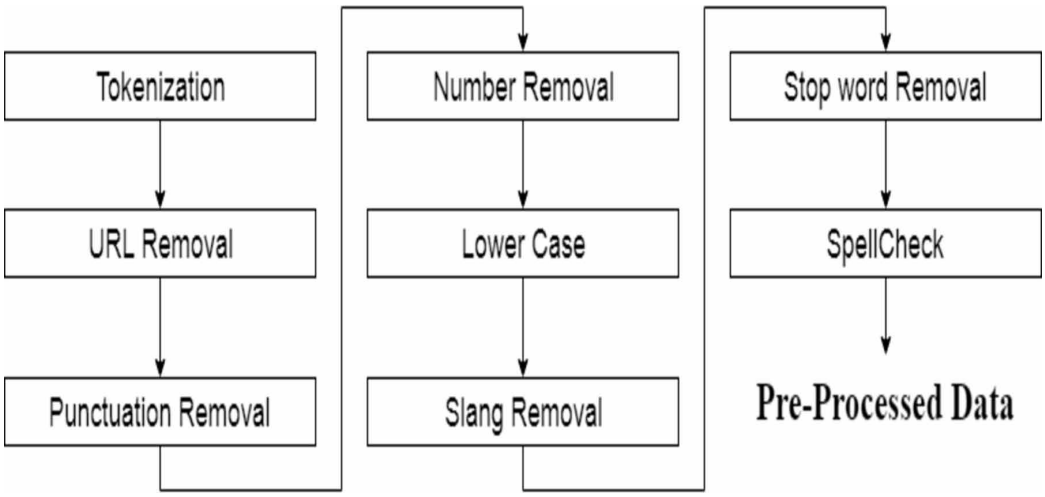
1. Data pre-processing
2. Capturing semantics using semantic model
3. Vectorization
4. Semantic similarity

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 4. Seed set creation

Data Pre-Processing

The data is pre-processed to remove the irrelevant fields and inconsistencies. Data is refined at each step of pre-processing and then passed to the automatic classifier for classification. The pre-processing of data is done by the following steps as shown in Figure 5.



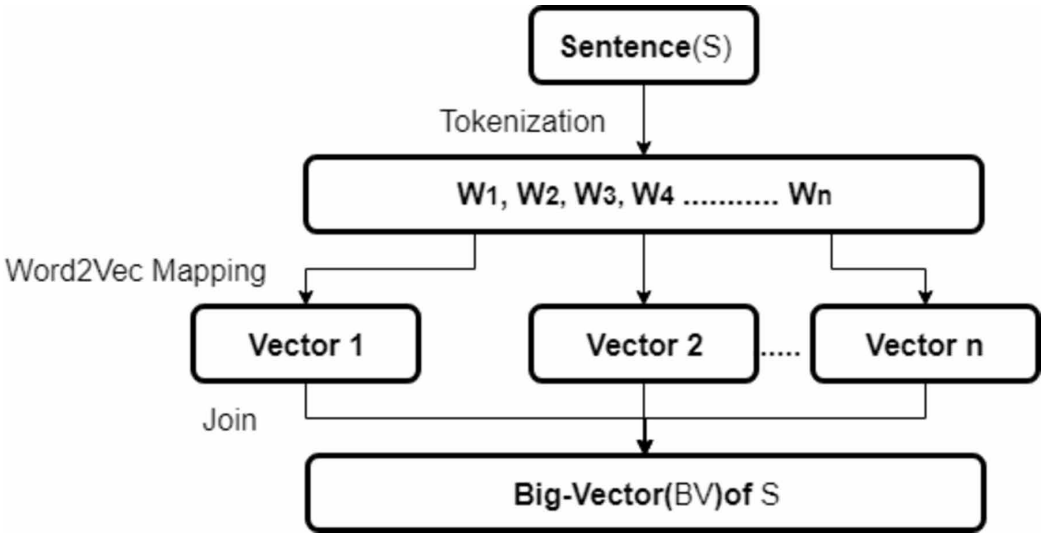
1. **Tokenization**: The data is tokenized to extract the tokens using Stanford Core NLP, and in this step, only the white spaces are used to separate the tokens.
2. **Removing URLs**: Data may contain different URLs and links which are removed.
3. **Punctuation Removal**: Punctuation marks do not have any impact on affect, and thus they are removed.
4. **Number Removal**: Numbers are removed from the data
5. **Lower Case**: This step converts the entire token into lower case.
6. **Slang Removal**: The slangs are replaced by their respective expansions like “lol” is replaced by “laugh out loud.”
7. **Stopword Removals**: Stanford can be used for identification of stop words which then can be removed easily.
8. **Spellcheck**: For spell checking, J Spell is used.

Capturing Semantics Using Semantic Model

Semantic models characterize the semantics of entire sentences. Semantic models work on the principle of distributional hypothesis which demonstrates that words appearing in the same circumstances tend to have similar associations. This leads to the derivation that semantic similarity models predict semantic cohesiveness between the textual elements. For example, “amazing” and “wonderful” are similar could be extended to predict that if “amazing” has positive sentiment so will wonderful. So is the true

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 5. Steps of pre-processing



for opposite like words terrible and awful. Semantic models are built using semantic representations (high-dimensional semantic vector spaces) using statistical analysis of the contexts in which words occur. More precisely, each word is represented by a real-valued vector known as word embedding or word vector along with the geometrical properties. These geometrical properties of word vectors or word embeddings prove to be semantically meaningful. Word2Vec algorithm (Mikolov, Chen, Corrado & Dean, 2013) incorporates this intuition. Word2Vec (Mikolov, Chen, Corrado & Dean, 2013) creates a vector representation of words by using a two-layer neural network. The two models of Word2Vec are continuous bag of words (CBOW) and Skip-gram model (SKIP). Both models describe how neural networks learn the underlying principle of word representations for each word. CBOW portends the current word given its context and SKIP portends context given the word. For our classifier, we have used CBOW model train on Wikipedia dump. Wikipedia provides free copies of all available content to interested users. We trained our Word2Vec model using the same data. Each sentence is then fed to the Word2vec to retrieve its Word vector. Thus, for each sentence, we provide all words in it to the word2Vec and retrieve its vectors, and all vectors of the sentence are then combined to form the Big-vector of the corresponding sentence. Hence each Big-vector represents the semantically coherent information of the sentence. Figure 6 shows the Big-vector formation of the sentence.

To further augment big-vectors we used WordNet. WordNet is a lexical reference library for the English language created at Princeton University. It is a lexical database comprised of adjectives, adverbs, nouns, and verbs that are aggregated into related sets called synsets. Synsets have a relation of synonymy. Each synset is related to specific context. WordNet also provides the count of synsets of a particular word by frequency score. Each word in the Big-vector is feed to the WordNet to retrieve its synonyms which are then added to the big-vector to expand it further. After retrieving all the synonyms from the WordNet, we have the final Big-vector which is used for the classification process. To further augment big-vectors we used WordNet. WordNet is a lexical reference library for the English language created at Princeton University. It is a lexical database comprised of adjectives, adverbs, nouns, and verbs that are aggregated into related sets called synsets. Synsets have a relation of synonymy. Each synset is related to specific context. WordNet also provides the count of synsets of a particular word by frequency score.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 6. Big-Vector formation

VECTORIZATION

For Vectorization, TF_IDF is employed. TF_IDF stands for Term Frequency-Inverse Document Frequency. It is used for unsupervised clustering. TF_IDF provides us the importance of terms in the corpus. Term Frequency gives us the frequency of terms in a document. Mathematically, TF is given by c (w) where

$$c(w) = \frac{\text{Frequency of word } \mathbf{w} \text{ in a document}}{\text{Frequency of words in the document}}.$$

IDF provides us importance of the terms in a document. Mathematically, IDF is given by d (w) where

$$d(w) = \log e \frac{\text{Total Frequency of documents}}{\text{Frequency of documents with word w}}$$

Both the seed sets and the sentence are vectorized for the classification purpose. More precisely, both seed sets and documents are represented as vectors in the vector space model (VSM), and the similarity is measured using semantic relatedness between them.

Semantic Similarity

For obtaining an emotional class of the sentence semantic relatedness is calculated between the sentence and the seed sets and then scoring function is used to determine the class of the sentence to be classified. Seed sets created in the lexicon generation and the sentence after preprocessing and application of semantic models is converted into Big-vector are both converted into vectors using Vectorization. Next semantic similarity is found between them to determine the emotional class of the sentence.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Seed words in the lexicon are transformed into categories and sentence to be classified are represented as documents. Then categories are matched against documents using our scoring function. Both categories and documents are represented as vectors in the vector space model (VSM), and the similarity is measured by the cosine similarity. Then our scoring function is used to calculate the class of the sentence.

The scoring function then finds the maximum of the cosine similarity score with the seed sets and assigns the class of the sentence to that of the seed set with which it has the maximum score.

Mathematically,

$$Score(s) = sim_{VCM}(id_c, \mathrm{s}) = \cos\left(\overrightarrow{id_c}, \vec{s}\right)$$

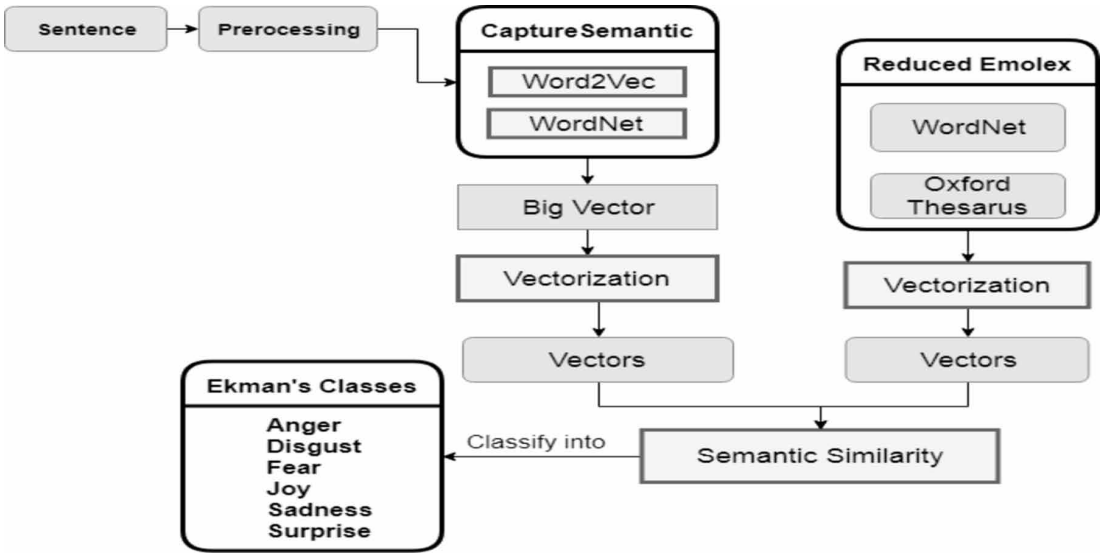
Where id_c is the seed set, s is the sentence, $\overrightarrow{id_c}$, is vector representation of the seed set and $\vec{s}$, is vector representation of Sentence.

ALGORITHM

The algorithm of our classifier is given as under:

Step 1: Seed lexicon is generated from NRC Emolex and extended using WordNet and Oxford thesaurus
Step 2: Data is pre-processed to remove inconsistencies and noise from data.
Step 3: Distributional semantic model (Word2vec) is used to capture the semantics of the pre-processed sentence.
Step 4: Big-Vector is generated using Word2Vec of the sentence.
Step 5: WordNet is used to extract synonyms of the Big-vector to enhance its semantic content.
Step 6: Background Corpus is used to get TF_IDF of Big-vector, and seed lexicon is obtained to transform data and lexicon into vectors.
Step 7: Semantic relatedness of sentence and seed lexicon is measured.
Step 8: The class for which the semantic similarity score is maximum is chosen to be the emotion class of the sentence. Mathematically, emotion class of the sentence is given by

$$emotion = \max(\cos(Big - vector, seed\ sets))$$



Overall working of semantic emotion classifier is explained in Figure 7.

4. DATASETS

The objective of this research is to develop an automatic emotion classifier which captures the semantics of the text and access its viability to classify the text into different emotional classes. To achieve that in this paper two evaluations on two different data sets have been done, explained in Section a and Section b gives the overview of the datasets used for evaluation.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 7. Overall working of semantic emotion classifier

Our proposed emotion classifier is applied on two emotion corpora annotated at the sentence level: (1) Aman Corpus (Aman & Szpakowicz, 2007); and (2) Affective Text Corpus (Strapparava & Mihalcea, 2007). We selected these corpora because these corpora are annotated by humans and will allow us to compare the results of our classifier with the human annotations; also they are most used corpora for the emotion detection tasks like (Keshtkar & Inkpen, 2010; Chaffar & Inkpen, 2011; Mohammad, 2012). Also, the source of these datasets range from web blogs to news headline, and thus the applicability of our Automatic emotional classifier can be tested for the different genre.

Aman Corpus

This dataset is collected from web blogs and has around 4000 sentences in it. Sentences are manually annotated with Ekman's six basic emotional categories.

Affective Text Corpus

Affective Text Corpus contains 1,250 short text stories collected from the news headlines of the newspapers like the New York Times, CNN (Cable News Network), BBC as well as the news from the Google News. Ekman's six basic emotion classes are used for the annotation which is done manually by the human annotators.

Aman Corpus

Aman corpus is manually annotated dataset that does not require any training data, although annotated sentences are used to determine the different annotations that are needed. In this corpus, Ekman's emotion classes along with (i) mixed emotions and (ii) no emotion are employed resulting in 8 emotion classes. Cohen's kappa (Cohen, 1960) was employed for annotation metrics.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Affective Text Corpus

The second dataset used in this experiment is taken from semeval-2007: affective text (Strapparava & Mihalcea, 2007). Affective text deals with the categorization of emotions and emotion intensities to determine the association between the emotions and lexical semantics. Emotional content is expressed by the words; even the neutral words can convey different acquaintances due to semantic differences. The automatic exploration of emotions is becoming popular due to its practical applications like e-learning, personalized marketing, opinion mining and affective computing. This dataset is composed of the news headlines drawn from different newspapers and news websites like Google news search engine. New York Times, CNN (Cable News Network), and British Broadcasting Corporation news. The inter-annotator agreement was implemented using Pearson correlation measure for six emotions: Anger, Disgust, Fear, Happiness, Sadness, and Surprise (Ekman, 1992) and intensity annotations. The results of Pearson correlation are shown in Table 3.

Table 4 gives the distribution of different emotions in the two datasets.

5. EVALUATION AND RESULTS

For classification, we used Semantic similarity which is popularly employed in Sentiment and Emotion analysis. Semantic similarity provides us the semantic relationship between the vectors concerning the emotions. Accuracy, precision, recall, and F1- score is used to evaluate the performance of Semantic Similarity. These parameters are estimated using the confusion matrix. A confusion matrix (Table 5) is a table that is used to measure the efficiency of a Classifier.

Table 3. Inter-Annotator Agreement

Emotions	Evaluation Measures (Pearson correlation)
Anger	49.55
Disgust	44.51
Fear	63.81
Joy	59.91
Sadness	68.19
Surprise	36.07
Valence	78.01

Table 4. Emotion distribution of datasets

Dataset	Happiness	Sadness	Anger	Disgust	Surprise	Fear
Affective Text corpus	334	214	175	28	131	166
Aman Corpus	536	173	115	115	172	179

Table 5. Confusion matrix

		Predicted class	
		P	**N**
Known class	**P**	Tr_P	Fa_N
	N	Fa_P	Tr_N

Accuracy

Accuracy is a perceptive evaluation method for measuring performance. It is given by the number of true classifications to the total classifications.

$$\text{Accuracy} = \frac{\text{Tr_P}+\text{Tr_N}}{\text{Tr_P}+\text{Fa_P}+\text{Fa_N}+\text{Tr_N}}$$

Where Tr_P signifies True positive, Fa_P signifies false Positive, Tr_N signifies True Negative, and Fa_N signifies False Negative.

Precision

Precision also called Positive Predictive Value is equal to the correctly measured positive classifications divided by the total predicted positive classifications. Higher the precision, the lower the rate of false positives.

$$\text{Precision} = \frac{\text{Tr_P}}{\text{Tr_P}+\text{Fa_P}}$$

Where Tr_P signifies True positive, Fa_P signifies false Positive.

Recall

Recall or Sensitivity is equal to the correctly predicted positive classifications divided by all classifications in the actual class.

$$\text{Recall} = \frac{\text{Tr_P}}{\text{Tr_P}+\text{Fa_N}}$$

Where Tr_P signifies True positive, Tr_N signifies True Negative, and Fa_N signifies False Negative

F1_Score

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

F1_score is the harmonic mean of precision and recall.

$$\text{F1 Score}=2*\frac{\text{Recall*Precision}}{\text{Recall+Precision}}$$

Our semantic automatic emotion classifier achieved the results on both datasets as described in the tables: Table 6 and Table 7.

Figure 8 and Figure 9 shows the performance of our classifier graphically on two datasets Aman Corpus and Affective Text Corpus respectively.

Table 6. 1st dataset

Aman corpus			
	Precision	**Recall**	**F1_Score**
Anger	0.536	0.456	0.49277419
Disgust	0.86	0.63	0.72724832
Fear	0.845	0.56	0.67359431

6. COMPARATIVE STUDY

According to our awareness, no allied research has been performed on utilizing semantic relatedness to create an emotion classifier for textual data streams. However, some work has been carried out utilizing Aman Corpus, NRC Emolex lexicon, and Affective Text Corpus. Table 8 compares our work with the existing work.

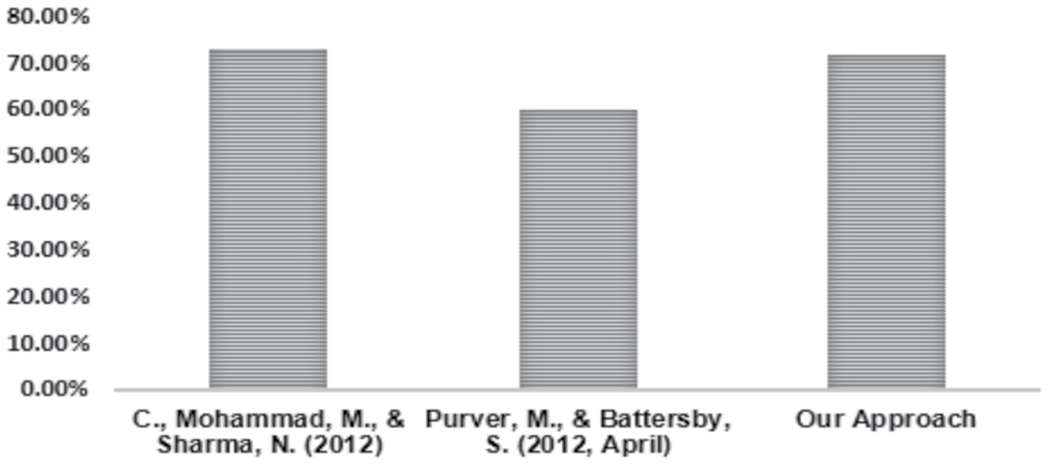

Figure 10 show the comparison of our work with the existing work graphically.

7. CONCLUSION AND FUTURE SCOPE

As presented in the introduction of the paper, the motive behind this research is to capture semantic relatedness while classifying during the automatic emotion classification task. This research aims to design an automatic emotion classifier which computes the semantic relationship between two textual elements into consideration while classifying a textual element into different emotional classes. This paper presents a semantic emotion classifier premised on the principle of distributional semantic models and uses three main steps 1) creation of lexicon using reduced NRC Emolex 2) using Distributional semantic models to capture semantic relatedness between textual elements and 3) using scoring function to classify textual elements into Ekman's six basic emotion classes.

Based on the evaluations performed, the appropriateness and accuracy of our approach are corroborated. Thus, the main conclusions of our research are:

1. The viability of Semantic automatic emotion classification as a process to automatically classify the emotional sentences is demonstrated
2. Distributional semantic models act as a good source to capture the semantics of the text

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

3. NRC EmoLex as a lexicon to automatically classify text into several classes performs satisfactorily taking into consideration that it is a general-purpose lexicon and has been employed for different domains of text.
4. The classification results allow us to conclude that the semantic automatic emotion classifier is an efficient classification scheme for emotion classification which considers semantic orientations of the textual streams.

Our future research will deal with

1. Exploitation of large affective datasets like DepecheMood, EmoSenticNet.
2. Contemplation of different multi-dimensional models and testing of these approaches with in their specified domain.
3. Analysing applicability of the other lexicons to extend the seed.
4. Experimenting the technique in more corpora with emotion lexicon annotated by more emotion classes.

Chapter 54
Development of Part of Speech Tagger for Assamese Using HMM

ABSTRACT

This article presents the work on the Part-of-Speech Tagger for Assamese based on Hidden Markov Model (HMM). Over the years, a lot of language processing tasks have been done for Western and South-Asian languages. However, very little work is done for Assamese language. So, with this point of view, the POS Tagger for Assamese using Stochastic Approach is being developed. Assamese is a free word-order, highly agglutinate and morphological rich language, thus developing POS Tagger with good accuracy will help in development of other NLP task for Assamese. For this work, an annotated corpus of 271,890 words with a BIS tagset consisting of 38 tag labels is used. The model is trained on 256,690 words and the remaining words are used in testing. The system obtained an accuracy of 89.21% and it is being compared with other existing stochastic models.

1. INTRODUCTION

Part-of-Speech (POS) tagging is the process where every word in a natural language sentence is marked with its corresponding part of speech category like noun, verb, adjective, adverb, etc. based on both its definition and context. Besides words, punctuation characters and symbols are also labeled accordingly. It is a very important process because it resolves the ambiguity of words in a sentence by assigning accurate POS label to a word depending on the context. As Assamese is morphologically rich and agglutinative language, several words have more than one POS category that makes the word ambiguous. There is an inflection of noun and verb in a sentence in accordance with the grammatical characteristics

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

as well. Therefore, POS tagging becomes a challenging task for Assamese. POS Tagger tries to assign the accurate POS labels to ambiguous words in a sentence according to the context and it has a vital role in various NLP applications as because the POS tagged data is used in many other NLP tasks (Jurafsky & Martin, 2000), e.g., in Parsing, the tagged data helps in finding out noun and verb groups, in Named Entity Recognition, it helps in determining the proper names like the name of a person, place or a thing, in Information Retrieval, it helps in selecting the proper nouns or other important word classes from a given text, in Speech Recognition, it helps in modeling a language, in Machine Translation, it helps in generating the probability for word translation of the source language into the target language, as well as it is useful for many other NLP applications. Thus, it is considered as an initial step of the language processing task. As POS Tagger has a great impact on other NLP systems, a tagging result with high accuracy is always encouraging.

There are several methods of POS tagging and basically there are three main approaches which are Rule Based Approach, Stochastic Approach and Hybrid Approach. Rule Based POS tagging is the most primitive approach where hand-written linguistic rules are used for tagging. These rules identify the appropriate tag for an ambiguous word. This method is dependent on dictionary or lexicon to generate the possible POS tags for every word in input text. The Stochastic Approach is based on the probabilities of words that occur for a particular tag. The tag which occurs most repeatedly in the training data is assigned to unknown or ambiguous word. The probability of a given sequence of tags is calculated from the frequency of words from the annotated training corpus. Hybrid Approach is the combination of more than one method which usually contains rule- based and statistical methods. This model uses the essential feature of statistical approaches and uses the rules for better efficiency. The developed POS Tagger for Assamese follows the Stochastic Approach. A bigram Hidden Markov Model (HMM) is used which is one of the processes in this technique. It is a probabilistic model that uses an annotated training corpus. The tagging process is done by computing the tag sequence probability and the word likelihood probability of the corpus. This method is called supervised learning method. Therefore, HMM requires a large amount of annotated corpus to obtain high accuracy. On the other hand, unsupervised learning method does not use the annotated corpus and it calculates the probabilities by using automatic word groupings.

This paper is further divided into five more sections in which second section provides the related work and next section shows the morphological characteristics of Assamese. Fourth section describes the approach then fifth section gives the evaluation of the system. Finally, the paper is concluded in sixth section.

2. RELATED WORK

Till recent years, many research works have been accomplished on Part of Speech tagging for different languages using different approaches. In case of the Indian languages like Hindi, Malayalam, Bengali, etc. which are morphologically rich in nature, a good number of POS taggers have been developed using Stochastic Approach with varied accuracies. This approach takes less effort in implementation and involves very little knowledge about the language but requires large training data to obtain high accuracy. (Dalal et al., 2006), developed POS Tagger using Maximum Entropy Markov Model for Hindi with a corpus of 15562 words and using 27 POS tags and obtained an accuracy of 94.81%. (Joshi et al., 2013), developed HMM based POS Tagger for Hindi using IL POS tag set and obtained an accuracy of 92%.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

(Kalam & Hasan, 2014), developed various stochastic POS Taggers for Bengali where hybrid HMM model with morphological analyzer gives best accuracy of 96.3%. (Saharia et al., 2009), developed HMM based POS Tagger for Assamese using text corpus (Corpus ASM) of nearly 3,00,00 words where 10,000 words were manually tagged for training. 172 tags are used and obtained average accuracy is 87%. (Shambhavi et al., 2012), developed POS Tagger for Kannada language using second order Hidden Markov Model and Conditional Random Fields (CRF) with training data that consist of 51,269 words and test data consists of around 2932 tokens and obtained accuracy is 79.9% for HMM model and 84.58% for CRF model respectively. (Sharma et al., 2011), developed a system using HMM to improve the accuracy of Punjabi POS Tagger. The system was evaluated over a corpus of 26,479 words and achieved the accuracy of 90.11%. (Shrivastava et al., 2008), developed HMM based POS Tagger for Hindi using stemmer and 18 tags and achieved the accuracy of 93.12%. (Singha et al., 2012), developed POS Tagger for Manipuri using HMM and used annotated test set data with 97 morph-syntactic tag categories and obtained an accuracy of 92%.

3. MORPHOLOGICAL CHARACTERISTICS

Assamese is a complex language which is morphologically rich and agglutinative in nature. It is an official language of Assam, one of the North-eastern states in India and spoken by nearly 20 million people in the region. Morphology is the study and description of formation of words in a language. A sentence is formed by a Subject and a Predicate and therefore the Subject, Object and Verb are important elements of a sentence. In a text, Assamese words are inflected with various grammatical features such as Noun is inflected with Case, Number and Gender, Pronoun changes according to Number and Honorary features, Verb is inflected with Number, Person, Tense, Aspect and Mood, etc. Some of the examples are as follows:

Example 1: A proper noun *(Ram)* inflects according to Case (Nominative).

English: Ram is eating rice.

Assamese: Ram-*e* b^{h}at k^{h}a-*i* as-*e* ।

Gloss: Ram-*nom* rice eat-*nf-prog* exist-*3rd P*

Example 2: A proper noun *(Ram)* inflects with Number.

English: Where are Ram and others going?

Assamese: Ram-*hɔt-e* k.*ɔt* go-*i* as-*e* ?

Gloss: Ram-*plu-nom* where.*loc* go-*nf* exist-*3rd P*

Example 3: A common noun *manuh 'human'* inflects with Gender.

Masculine manuh-*zon*

man-cl.mg

Feminine manuh-*zon-i*

woman-*cl-fg*

Example 4: A pronoun *tɔi 'you'* (2nd Person) inflects according to Honorary feature and Number.

Singular

apuni '*you*(*honorific*)'

tumi '*you*(*familiar*)'

tɔi '*you*(*inferior*)'

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Plural

apuna-lʊk '*honorific'*
you.hon-plu
tʊma-lʊk '*familiar'*
you.fam-plu
tɔ-hɔt '*inferior'*
you.inf-plu

Example 5: An Interrogative pronoun *kun-tu 'which'* inflects with Number.

Singular

kʊn-*tʊ*
which- *classifier*

Plural

kʊn-*bʊr*
which-*plural marker*

Example 6: A word *goi ase 'going'* is the continuous form of verb 'go' that inflects with Person.

English: I am going.
Assamese: mɔi go-*i* as-*u* ।
Gloss: I go-*nf-prog* exist-*1st P*
English: You are going.
Assamese: tumi go-*i* as-*a* ।
Gloss: You go-*nf-prog* exist-*2nd P*
English: They are going.
Assamese: xi- *hɔt -e* go-*i* as-*e* ।
Gloss: He-*plu-nom* go-*nf-prog* exist-*3rd P*

Example 7: A verb *kɔ 'say'* inflects according to Aspect (Perfective).

Present: mɔi kɔ *-is -ʊ* । (*I have said*)
Gloss: I say *–perf -1st P*
Past: mɔi kɔ *-is -il -ʊ* । (*I had said*)
Gloss: I say *–perf –past -1st P*

4. THE APPROACH

A supervised learning approach is being followed and therefore, annotated corpus is required for training the system. The corpus is provided by TDIL-DC, Indian Language Technology Proliferation & Deployment Centre and BIS (Bureau of Indian Standards) tagset is used with a total number of 38 annotation tag labels. The corpus contains the sets from three domains that are Agriculture, Entertainment and Science and Technology field which include 271890 words. From the set of corpus, 256690 words are used in training the system and the rest of 15200 words are used for testing. A bigram HMM is used for developing the POS Tagger and then Viterbi algorithm is used as a decoder. The methodology is described as follows:

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

4.1. Hidden Markov Model

A POS Tagger based on HMM (Jurafsky & Martin, 2000) assigns the best tag sequence to a given word sequence or sentence. Normally, the most probable tag sequence is assigned to each sentence by means of the Viterbi algorithm. The task of Part-of-Speech (POS) tagging is to find the best POS tags sequence, $T = \{t_1, t_2, t_3, \ldots, t_n\}$ for a given word sequence $W = \{w_1, w_2, w_3, \ldots, w_n\}$. By following the Bayes' Law, the tagger looks for the maximum value which is equal to $argmax_T P(T) \times P(W|T)$.

The probability of the tag, $P(T)$ can be calculated by Markov assumption which informs that the probability of a tag depends on n number of previous tags. The bigram model is used where the probability of a tag is dependent on its one previous tag, and as a result;

$$P(T) = P(t_1) \times P(t_2|t_1) \times P(t_3|t_2) \times P(t_4|t_3) \ldots \times P(t_n|t_{n-1}) .$$

A generative HMM is defined as:

$$f(s_1 \ldots s_n) = argmax_{t_n}^{t_1} P(s_1 \ldots s_n, t_1 \ldots t_n) \quad (1)$$

where $s_1 \ldots s_n$ are source language phrases and $t_1 \ldots t_n$ are target language phrases. By giving the inputs $s_1 \ldots s_n$, the highest probability phrase sequence is taken as the output of target language. Hence the bigram HMM is calculated as:

$$P(s_1 \ldots s_n, t_1 \ldots t_n) = \pi_i \, q(t_n|t_{n-1}) \, \pi_i \, e(s_i|t_i) \quad (2)$$

where $q(t_n|t_{n-1})$ is the probability of a current tag given the previous tag called transition probability and $e(s_i|t_i)$ is the probability of the sequence of words given the tag sequence called word likelihood probability.

The transition probability is calculated as:

$$q\left(t_n|t_{n-1}\right) = \frac{freq\left(t_{n-1}, t_n\right)}{freq\left(t_{n-1}\right)} \quad (3)$$

Each tag transition probability is computed by calculating the frequency count of two tags seen together in the corpus divided by the frequency count of the previous tag seen independently in the corpus. This is done as because it is more likely for some tags to precede the other tags.

The word likelihood probabilities is calculated using $e(s_i|t_i)$ i.e., the probability of a word given a current tag. This probability is computed as:

$$e\left(s_i|t_i\right) = \frac{freq\left(t_i \rightarrow s_i\right)}{freq\left(t_i\right)} \quad (4)$$

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Here, the probability of word provided a tag is computed by calculating the frequency count of the tag in the corpus and the word occurring together is divided by the frequency count of the occurrence of the tag alone in the corpus.

4.2. Viterbi Algorithm

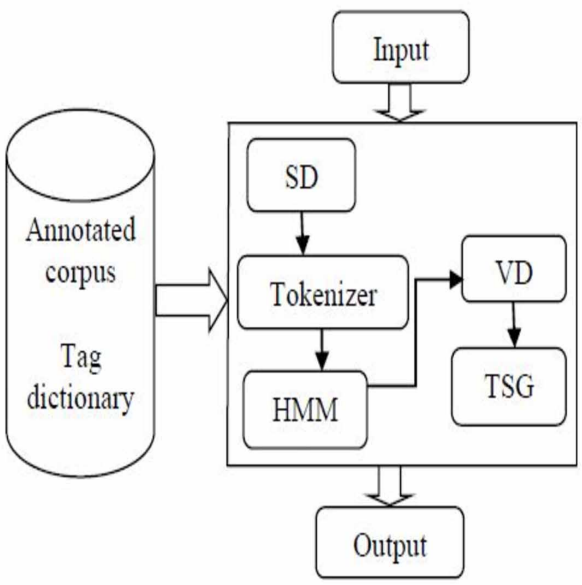
According to (Singh et al., 2016), decoding finds the most likely state sequence from given observation $O = o_1, o_2, o_3, \ldots o_n$. The sequence of states is backtracked after decoding the whole sequences. The algorithm is defined in Algorithm 1:

4.3. System Architecture

The Stochastic Approach is followed using Hidden Markov Model that trains the system and for the purpose of decoding, a Viterbi algorithm is used. In the developed model, initially a system corpus is activated that is stored in a system file and then the system is trained. The training corpus is in Unicode encoding text format. Next, the input is provided to the system for tagging. The system displays the output in a list view where in each row a word is displayed along with its corresponding POS tag, description of the tag and the probability measure. The generalized architecture of the system is shown in Figure 1.

The initial process of the developed POS Tagger is a Sentence Detector. Maximum Entropy Sentence Detector from the Open NLP tools is used that splits the input sentences. Then by following the Greedy approach, a Tokenizer separates the words and punctuation marks from the input text. After tokenization, HMM computes the transition and emission probability for each pair of words and tag sequences from the training corpus. Next, a Viterbi Decoder generates the state graph and calculates the state transition probability for each transition in the matrix. Finally, the Viterbi matrix is backtracked by a Tag Sequence Generator that scans the path with the highest probability and then POS tags are assigned accordingly to each and every word in a given input text. As a result, a list of words along with its tag is displayed by the system.

5. EVALUATION



The annotated corpus is divided into two parts where 256690 words are used in training the system and the remaining portion is used for testing. The POS labels of every word in the evaluation set are removed and the text from resulting raw corpus is provided as an input to the system. Finally, the output

Algorithm 1

Input: - A Sentence $x_1 \ldots x_n$ and Parameters $q(t_n|t_{n-1})$, $e(s_i|t_i)$
Define K to set of all tags $K_{-1} = K_0 = (start)$
Π (0, *start*, *start*) = 1
For $k = 1 \ldots n$
For $a \in K_{k-1}$, $b \in K_k$
$\Pi(k,a,b) = argmax$ (π (k-1,a,b) $\times$ $q(b|a)$ $\times$ $e(x_k|b)$)
Return $argmax$ (π (n,b) $\times$ $q(stop|b)$)

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. Architecture of the developed Assamese POS Tagger

is compared with the data from the evaluation set. Therefore, based on these comparisons, the system's performance is evaluated by computing Precision, Recall and F-Measure respectively. Hence the result is obtained as follows:

No. of tokens in evaluation set = 15200
No. of tokens tagged by system = 15200
No. of correctly tagged tokens by system = 13560

$$Precision\left(P\right) = \frac{No.of\ correctly\ tagged\ tokens\ by\ system}{No.of\ tokens\ tagged\ by\ system} = \frac{13560}{15200} = 0.8921$$

$$Recall\left(R\right) = \frac{No.of\ correctly\ tagged\ tokens\ by\ system}{No.of\ tokens\ in\ evaluation\ set} = 0.8921$$

$$F \rightarrow Measure = \frac{2 \times P \times R}{P + R} = 0.8921$$

The system is capable of assigning tags to every unknown word and thus the Precision and Recall values are equivalent and accordingly the F-Measure gives the same result. Then the Accuracy of the system is computed as:

$$Accuracy\left(A\right) = \frac{No.of\ correctly\ tagged\ tokens\ by\ system}{No.of\ tokens\ in\ evaluation\ set} \times 100 = \frac{13560}{15200} \times 100 = 89.21$$

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Therefore, accuracy of the developed POS Tagger is 89.21% which is quite promising. It is being observed that the accuracy level of the system progresses as the number of words in a training corpus increases and this could be described by Figure 2.

Next, the performance of the system is compared with other existing HMM based models developed for Indian languages and the records are shown in Table 1.

It is found that the model developed by Kalam and Hasan in 2014 has obtained the highest accuracy of 96.3% where hybrid HMM method is used with a Morphological Analyzer. In the developed model, language analysis method or linguistic rules are not applied. Hence the accuracy of the system is less but it shows little improvement in comparison to existing Assamese POS Tagger and it is achieved by using a large training corpus that includes the sets from three different domains.

Figure 2. Line-graph of performance of the developed POS Tagger

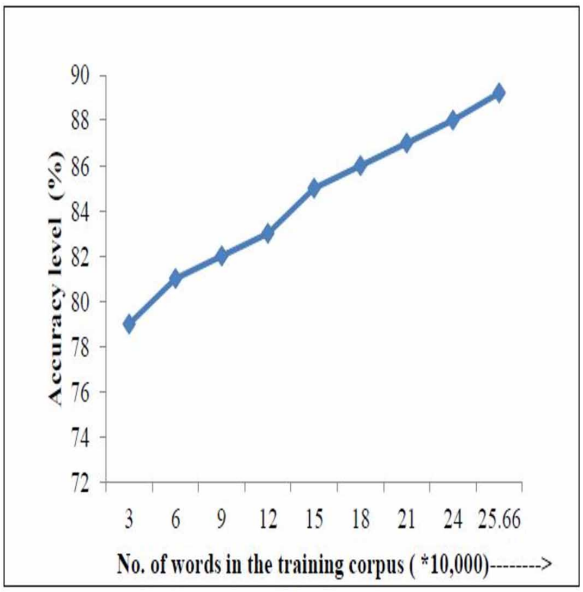


Table 1. Comparison of Developed Model with other HMM based models

Author	Language	Accuracy
Joshi et al. 2013	Hindi	92%
Kalam et al. 2014	Bengali	96.3%
Saharia et al. 2009	Assamese	87%
Shambhavi et al. 2012	Kannada	79.9%
Sharma et al. 2011	Punjabi	90.11%
Shrivastava et al. 2008	Hindi	93.12%
Singha et al. 2012	Manipuri	92%
Developed Model	Assamese	89.21%

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

6. CONCLUSION

The HMM based Assamese POS Tagger is developed by using a training corpus of 256690 words and after testing it on a corpus of 15200 words, the system obtained an accuracy of 89.21%. As Assamese is a fairly free word-order, morphologically rich and agglutinative in nature, POS tagging of Assamese is quite a challenging work. With respect to HMM model, a problem arises when there are less annotated training corpuses because when number of unknown words is greater then it tends to reduce the performance of the tagger. The performance of the developed POS Tagger is still lagging behind other stochastic models and the occurrence of many ambiguous words in test corpus has affected its performance. The result of the system is quite notable although linguistic rules or morphological analyzer is not applied in it. Hence it is assured that the Stochastic Approach performs well with the substantial amount of corpus for morphologically rich Assamese language.

In view of the morphological richness of the Assamese, future development of the system could be incorporating the morphological analyzer along with the HMM to upgrade the performance of tagging. Further enhancement of the system could be achieved by adding specific linguistic rules, suffixation method and procedure for handling unknown words and compound words considering the agglutinative nature of the language. If the present model could be trained using tri-gram HMM then there will be significant increase in the performance of tagging. Finally, it is concluded that Part of Speech tagging is the important field of NLP as because other language processing applications are dependent on the performance of POS Tagger.

ACKNOWLEDGMENT

We express our sincere gratitude to TDIL, Indian Language Technology Proliferation & Deployment Centre for providing the annotated Assamese Text Corpus.

Chapter 55
A Survey on Supervised Convolutional Neural Network and Its Major Applications

D. T. Mane
SGGS IE&T, India

U. V. Kulkarni
SGGS IE&T, India

ABSTRACT

With the advances in the computer science field, various new data science techniques have been emerged. Convolutional Neural Network (CNN) is one of the Deep Learning techniques which have captured lots of attention as far as real world applications are considered. It is nothing but the multilayer architecture with hidden computational power which detects features itself. It doesn't require any handcrafted features. The remarkable increase in the computational power of Convolutional Neural Network is due to the use of Graphics processor units, parallel computing, also the availability of large amount of data in various variety forms. This paper gives the broad view of various supervised Convolutional Neural Network applications with its salient features in the fields, mainly Computer vision for Pattern and Object Detection, Natural Language Processing, Speech Recognition, Medical image analysis.

1. INTRODUCTION

With the advent of deep learning, the world has proceeded into the new era of machine learning. With the main intention of getting closer to the original goal of machine learning, that is, Artificial Intelligence, deep learning has opened up new avenues to explore. Artificial Neural Networks (ANNs) are biologically motivated machine learning algorithms applied to solve problems, where conventional approach fails, such as computer vision. It takes in the input, let it be an image or an audio signal, extracts features which describe the input and generalizes these features so that the results obtained can be replicated for other examples of the input. This paper gives an overview of a particular type of ANN, known as supervised

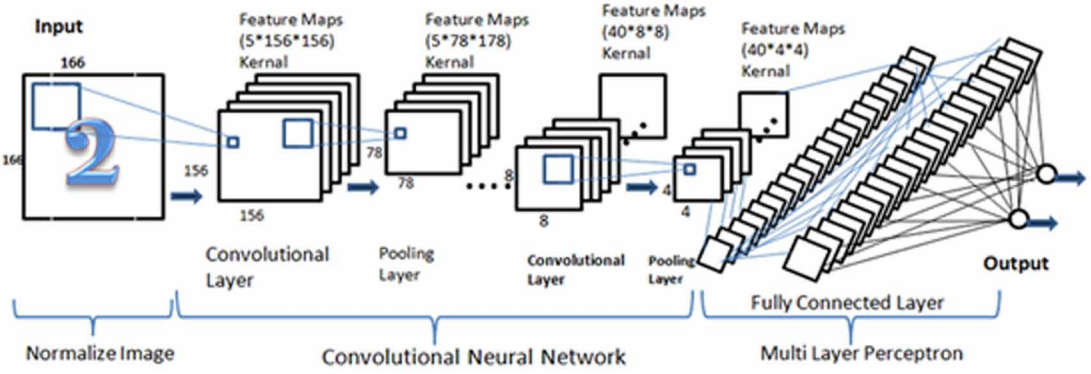
Convolutional Neural Network (CNN) and gives information of its development and results in various fields. Initially, we see the history of CNN followed by its architecture and results of its applications. The references of the few used papers have been mentioned here.

2. HISTORY OF CNN

The idea of modeling brain networks has been a research question even before the advent of computers. In initial stages, neural networks were evaluated with propositional logic. Then with the discovery of concepts such as convolution and back propagation applied to neural networks, NN got better. Until the emergence of GPUs, the computers were not fast enough to implement multi-layer neural networks. So NN were not commercially viable. With the power of GPUs and more efficient algorithms, CNNs can be applied to real life applications (see Table 1).

3. OVERVIEW OF CNN



Convolutional Neural Network is a supervised machine learning algorithm where a group of neurons are responsible for recognizing a specific feature and classifying them into categories. These algorithms perform convolution on the input to reduce the size of the input features without adversely affecting the output. This feature could be an edge in an image, or speech subsample. Certain convolution kernels are used so as to highlight the essence of the input especially in case of images, where a lot of unnecessary pixels are present which do not represent any feature. CNN consists of multi-layered neurons, which extract more high level features with consecutive increase in layer. A typical CNN architecture is as shown in Figure 1 (LeCun, Kavukcuoglu, & Farabet, 2010).

Table 1. Time line chart of CNN

Period	Progress	Year	Activity
1940 - 1979	Emergence of NN	1943	McCulloch, Pitts compare neural activity with propositional logic.
		1949	Hebb proposes cell assembly theory.
		1962	Hubel and Wiesel model the visual system in Cat brain.
1980 - 1998	Concept of Convolution	1980	Fukushima proposed a self-learning NN which preserves the intrinsic geometric representation.
		1989	LeCun et al demonstrated the use of back propagated CNN for real life Application.
1999-2010	More Efficient CNN	1999	Poggio et al proposed max pooling.
		2006	Ranzato et al proposed max pooling for CNN.
2011-Present	GPGPU acceleration of CNN	2011	Ciresan et al put forth the concept of CNN on GPUs.
		2012	Hinton et al demonstrated Drop Out for CNN.
		2013	Lecun et al proposed Drop Connect for better CNN.
		2014	Min Lin et al designed Network in Network concept for CNN.
		2015	Google releases different open source libraries for CNN

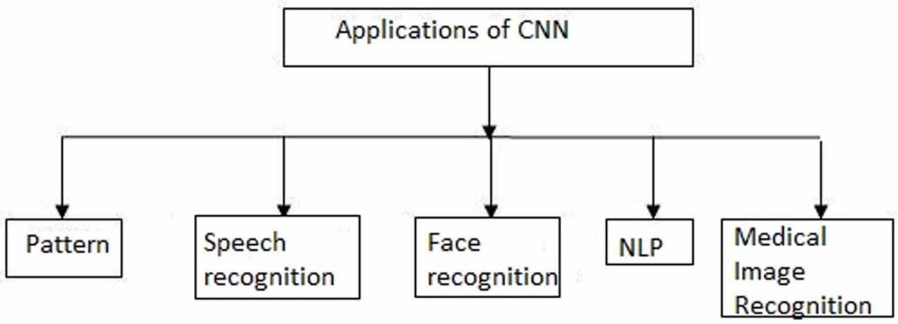
Figure 1. Architecture of convolutional neural network

4. APPLICATIONS OF CNN IN VARIOUS FIELDS

Deep convolutional neural network systems are given very good results in some applications like as pattern recognition, natural language processing, computer vision and speech recognitions etc. Figure 2 represent the different areas applications of deep convolutional neural network.



4.1. Pattern Recognition System

Convolutional Neural network has played a very important role in the domains like handwritten digit recognition, logo detection, Vehicle plate detection, etc.

4.1.1. Character Recognition of License Plate Number (2011)

This paper presents machine printed character recognition obtains from license plate with deep convolutional neural network. The numbers of training and test images used in this research are 750 and 434, and its accuracy 98.79%and 1.21% accuracy in misclassification (Radzi & Mohamed, 2011). As compared to previous techniques everything is same except the use of geometrical rules to extract the characters. From observations this work gives better results in terms of reduced number of samples.

Figure 2. Application of convolutional neural network in various fields

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

4.1.2. Recognizing characters from Natural Scene Images (2012)

This application uses the CNN along with the bimodal image enhancement which helped in improving the CNN classifier. Natural scene images have many variations because of low resolution of image, less clarity, noise, distortion, light reflections, etc. To overcome all these issues some methods have been applied. First maximum separability based color to gray, then normalization based on histogram alignment and finally character image normalization containing shape holding gray-scale is adopted (Zhu, Sun, & Naoi, 2012). As a result, the performance of CNN classifier has increased to 85.96% on ICDAR dataset, more than any previous results.

4.1.3. Detecting and Recognizing Food Images (2014)

Detection and recognition of food images has been performed using CNN classifier along with optimization of parameters. The previous classification algorithms such as SVM which learns from handcrafted features failed to give good results due to large amount of variations in food items. On the contrary CNN learns distinctive features through its internal evaluation (Cagayan, Kiyoharu, & Makoto, 2014). Thus, this paper has shown results 93.8% on food dataset of most common food substance in publically accessible food-logging system. Also, the result shows that color features played a very important role in recognizing the food images. Hence, CNN proved to be an efficient method for food classification.

4.1.4. Pedestrian Detection (2015)

Pedestrian detection is one of the important applications in driving assistant systems. Mainly it is achieved through vision-based methods. So, to achieve high accuracy in this domain CNN along with Random Dropout and Ensemble Interference Network (EIN) has been used (Fukui, Chubu, Takayoshi, Yuji, & Fujiyoshi, 2015). Random Dropouts require a technique in which dropout units are selected on the basis of flexible rate. Along with this, multiple networks with variant structures are constructed in EIN in fully connected layers. As compared to previous techniques the results provided are very accurate.

The summary of the research papers mentioned above is documented in Table 2.

4.2. Face Detection and Recognition

4.2.1. Head Detection (2013)

Head detection has an importance in counting and pedestrian detection. Previously, head detection had low recognition rate as it is based on outline, color and template mainly. But, by the use of CNN with multi-stage weighted feature which combines local and global features, accuracy has been increased tremendously. The recognition rate 0f 99.70% is achieved (Ke, Thuc, Lee, Hwang, Yoo, & Choi, 2013).

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 2. Summary of pattern detection

SN	Title	Salient Features
1	Digit recognition from License Number Plate (Radzi & Mohamed, 2011)	Technique used: CNN Idea: CNN has been applied for recognizing digits in license number plates. Several factors to improve the system performance have been discussed like Appropriate learning rate, Activation function, Second order back propagation, Momentum and weight decay, Cross validation. Dataset: Images collected from Malaysian license plates for training 750 images and for testing: 434 images Results: Accuracy: 98.79%
2.	Digit Recognition (Ciresan, Meier, Gambardella, & Schmidhuber, 2010)	Technique used: CNN with back propagation Idea: Extract feature using CNN and GPUs is used for training Dataset: MNIST Results:Error rate: 0.35%
3.	Handwritten Character Recognition (TELUGU) (Soman, Ashakranthi, & Chakravarthy, 2013)	Technique Used: CNN Idea: Multi-class classification of telugu handwritten characters using CNN Dataset: Telugu character dataset for consonant with 36 classes and vowel modifier with 15 classes. Results: Consonants: 92.26% and Vowel modifier: 92%
4	Food Detection and Recognition (Cagayan, Kiyoharu, & Makoto, 2014)	Technique used: CNN Idea: The success of CNNs for food image recognition and detection has been attended to through parameter optimization. Dataset: Constructed from the most frequent food items in a publicly available food-logging system. Results: Testing Accuracy:93.8%
5.	Pedestrian Detection System (Fukui, Chubu, Takayoshi, Yuji, & Fujiyoshi, 2015)	Technique Used: CNN with Ensemble inference network (EIN) Idea: Two CNN-based methods were introduced Random Dropout: for training process EIN for classification process Results: Caltech Pedestrian Dataset: 10.5%.Daimler Mono Pedestrian: 2.0% .Daimler Mono: 31.32%
6.	Recognizing natural scene characters (Zhu, Sun, & Naoi, 2012)	Technique: Convolutional neural network and bimodal image enhancement. This application uses the CNN along with the bimodal image enhancement which improving the CNN classifier. Dataset: ICDAR Result: Performance of CNN classifier increased to 85.96%

4.2.2. Age Estimation (2014)

Human face as biometric characteristics can be used for obtaining lots of information about identity, age, expression, etc. Hence CNN can be used to extract the facial features. By constructing multi-level CNN model based on training data the age groups are prepared and different classifiers can be used for performing classification (Yan, Lang, Wang et al., 2014). Using CNN for extracting aging features from images helps to provide superior results 76.64% than previous methods in age detection.

4.2.3. Multifaceted learning using DCNN for Person Related Categories in Photos (2015)

Multi facet learning has been proposed to improve training of DNN (Deep Neural Networks). In case of existing studies there required a lot of labeled images to train the DNN. The idea is to explore multiple datasets and learning effective representations to learn related visual concepts. It enforces to share features

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

for image recognition. Four types of datasets were used for experimental evaluation. They proved that results related to multi-facet give better performance than person related dataset (Cao, Yan, & Smith, 2015). The first purpose was to use existing deep neural network as an off the shelf feature extractor. Another purpose was to train convolutional neural network on human facet data directly. Error rate is very less as compared to other techniques.

4.2.4. Simultaneous Classification of Several Features of a Person's Appearance Using a Deep Convolutional Neural Network (2015)

A model of CNN has been described for automatic simultaneous extraction of several features of the person's appearance from an image. In an image one can find many features of appearance like sex, face, age, the presence of a moustache or beard, etc. It has various applications like identifying a person's age from a photograph, video surveillance systems, an interactive user interface, and data collection systems for marketing research, etc. The features information can be used to improve the quality of searching for images on the Internet by content. LWF dataset has been used for experimental evaluation. As features of person's appearance it uses sex, moustache and beard. Accuracy for features such as sex-95.13, Mustache-91.58 and beard: 93.80 were given. The algorithm has a high accuracy for the problem of identifying the person's sex and the presence of a moustache and a beard from a photograph (Kukharenko & Konushin, 2015).

The summary of the research papers mentioned above is documented in Table 3.

Table 3. Summary of face detection and recognition

SN	Title	Salient Features
1.	Head Detection (Ke, Thuc, Lee, Hwang, Yoo, & Choi, 2013)	Technique Used: Multistage weighted CNN Idea: Human head detection is major with respect to pedestrian detection. It combines global features with local features. Dataset: Collected large number of positive and negative images from video of passenger flow. Results: Accuracy:99.7%
2.	Age Estimation (Yan, Lang, Wang, Xuetao, & Zhang, 2014)	Technique Used: CNN Idea: CNN used to extract facial features and age has been approximated from these features Dataset: Web Face database Results: Accuracy: 76.64%.
3.	Face Verification (Mohamed & Liew, 2014)	Technique used: Siamese CNN Idea: Siamese architecture with two CNNs has been introduced. Also explored various optimizations that can be applied on Siamese CNN architecture to reduce overall computing time. Dataset: AT&T face database Results: EER (equal error rate):3.33%
4.	Person-Related Categories in Photos (Cao, Yan, & Smith, 2015)	Technique used: CNN with multi-facet Learning Idea: Learning from multiple facets introduces need to share features for image recognition. Dataset: Collected total 33536 images in different category i.e. Affiliation facet: 7424 images, Age facet: 10752 images, Body view: 4352 images, gender facet: 11008 images Results: Recognition error of Multi-facet CNN: Affiliation:0.451 Age:0.373, Bodyview:0.320 Gender:0.332
5.	Classification based on Person Appearance (Kukharenko & Konushin, 2015)	Technique Used: Deep CNN Idea: The projected model can be used for synchronized identification of a better number of features of person's look without a major increase in operating system. Dataset: LWF dataset: 13233 images, Sex, Moustache and beard were used as features of Appearance. Results: Accuracy for each feature: Sex:95.13 Mustache:91.58 beard:93.80

4.3. Speech Recognition

4.3.1. A Deep Convolutional Neural Network Using Heterogeneous Pooling for Trading Acoustic Invariance with Phonetic Confusion (2013)

A novel deep convolutional neural network architecture i.e. an HP-CNN followed by a DNN has been proposed, where heterogeneous pooling was used to provide constrained frequency-shift invariance in the speech spectrogram. The combined features of both heterogeneous pooling and dropout regularization were used intelligently (Li, Hamid, & Yu, 2013). TIMIT phonetic recognition task, achieved an 18.7% phone error rate. As a result, by using this for TIMIT core test sets phone detection, error rate has condensed to 19.3% from 20.4% obtained with the optimal but single fixed pooling size. Also after regularizing the CNN using a variant of the dropout technique, the error rate of the HP-CNNDNN dropped further to 16.7%, from 19.9% with the same dropout but without heterogeneous pooling.

4.3.2. Speech Recognition using CNN (2014)

A CNN was proposed for speech recognition. Basically CNN was proposed to increase the performance of ASR (automatic speech recognition). The aim of automatic speech recognition is the record of human speech into spoken words. Also initiate a new method of limited weighted allocation scheme that can hold speech features in a better way than the full weight sharing which was standard in previous CNN architectures (Abdel-Hamid, Abdel-Rahman, Jiang et al., 2014). CNN technique has been used in such a way that it can directly accommodate some types of speech variability. The CNN has been applied on two ASR tasks: TIMIT phone recognition and a large-vocabulary voice search. An improved performance was given by CNN over standard DNN. The error rate was reduced by 8% as compared to previous techniques.

4.3.3. Combining Time and Frequency-Domain Convolution in CNN Based Phone Recognition (2014)

CNN has proved very successful in image recognition because of their tolerance to small translations. Hence it is used for speech recognition by using a spectral representation of input. In the past activities translations along frequency axis and translation along time axis were used separately for speech recognition (Laszlo, 2014, pp 190-194). CNN with combined translation method along frequency and time axes has been proposed here. This method has been used for TIMIT Phone recognition task. And by combining advantages of both frequency domain and time domain achieved the error rate of 16.7% which was better performance over the traditional methods.

4.3.4. CNN based Learning Salient Features for Speech Emotion Recognition (2014)

Speech is one of the most significant and natural means for humans to speak their emotion to others. Therefore, significant way of human emotion understanding Speech Emotion Recognition has attracted great deal of attention. It has applications in HCI (Human Computer Interaction) and effective computing (Mao, Dong, & Huang, 2014).

The summary of the research papers mentioned above is documented in Table 4.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 4. Summary of speech recognition

SN	Title	Salient Features
1.	Trading Acoustic Invariance With Phonetic Confusion (Li, Hamid, &Yu, 2013)	Technique used: DCNN Idea: DCNN is used for minimizing phonetic confusion using dropout method. Results: TIMIT core test set: 19.3% error rate and using dropout HP-CNN-DNN goes down to 18.7%.
2.	Speech Recognition (Abdel-Hamid, Abdel-Rahman, Jiang, & Li, 2014)	Techniques used: CNN Idea: The CNN has been applied on two ASR tasks: TIMIT phone recognition and a large vocabulary voice search. Performance was given by CNN over standard DNN. Result: Error rate was reduced by 8%
3.	Combining T & F Domain convolution in Phone Recognition (Laszlo, 2014, pp 190-194)	Technique Used: CNN Idea: Combination of frequency(F) and time(T) domain translations Dataset: TIMIT phone recognition task Results: Error rate:16.7%
4.	Learning Salient Features for Speech Emotion Recognition (Mao, Dong, & Huang, 2014)	Technique Used: CNN Idea: Learning salient, discriminative features is an important research issue for SER. CNN is used for recognizing these features in speech Dataset: Surrey Audio Visual Expressed Emotion Database (SAVEE), Berlin Emotional Database(Emo-DB) Results: SAVEE-89% Emo-DB-93%

4.4. Natural Language Processing

4.4.1. Sentence Modeling (2014)

The ability to represent sentences correctly is the basic need for understanding any language. The technique known as dynamic CNN can be used efficiently for this. The DCNN apply the dynamic k-max pooling concept as a non-linear subscripting activation function. The high performance was achieved by the network on the question and sentiment classification. The accuracy obtained is 93% on the TREC Questions dataset and 87.4% on the Twitter Sentiment dataset (Kalchbrenner, Grefenstette, & Blunsom, 2014)

4.4.2. Twitter Sentiment Analysis (2015)

Due to the informal nature of language, sentiment analysis in social networking websites provides lots of challenges. Hand crafted features were used for previous NLP methods which resulted in over-specified and incomplete features. This architecture uses multiple filters and non-linear layers for recognizing the relevant features from twitter posts and classifying them. The data used for training contains both Twitters user as well as non-Twitter user data. The result is presented in the form of F1 score of 64.85% Twitter2015 dataset (Severy & Moschitti, 2015).

4.4.3. Semantic Role Labeling (2015)

Semantic Role Labeling is very important for understanding relationships between words. CNN can be used in this problem for extracting semantic roles in texts. SENNA (Semantic Extraction using a Neural Network Architecture) was introduced for semantic relation extraction (Foland & Martin, 2015). This introduces automated semantic role labeling. The result was an f-measure of 0.55 on BC-PPI dataset.

The summary of the research papers mentioned above is documented in Table 5.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 5. Summary of natural language processing

SN	Title	Salient Features
1	Multitask Learning in Natural Language Processing (Collobert & Weston, 2008)	Technique used: CNN Idea: CNN does learning on multiple tasks in a semi-supervised manner and does not rely on parse tree features. Dataset: Prop Bank dataset: Results:14.30% error rate
2	Semantic Role Labeling for Automated Relation Extraction from Biomedical Texts (Barnickel, Weston, Collobert, Mewes, & Stumpflen, 2009)	Technique used: CNN Idea: Authors of the paper use CNN for labeling semantic roles SENNA (Semantic Extraction using a Neural Network Architecture) was introduced for semantic relation extraction Datasets and Results: BC-PPI dataset: F-measure = 0.55 LLL'05 dataset: F-measure = 0.51
3	Sentence Modeling (Kalchbrenner, Grefenstette, & Blunsom, 2014)	Technique used: DCNN with dynamic max pooling Idea: The ability to represent sentences correctly is the basic need for understanding of any language. The authors have described DCNN which uses dynamic k-max pooling operators as a non-linear sub sampling function. Datasets and Results: Twitter sentiment dataset87.4% and TREC questions dataset: 93%
4.	Twitter Sentiment Analysis (Severy & Moschitti, 2015)	Technique used: CNN Idea: Sentiment analysis is extraction of emotion from sentences. This paper shows that CNN could be applied for sentiment analysis Datasets and Results: Twitter2015 dataset: 64.85% F1-score
5	Dependency-Based Semantic Role Labeling (Foland & Martin, 2015)	Technique used: CNN Idea: The authors describe various CNN architectures for semantic role labeling Datasets and Results: Brown Dataset: Sense Accuracy:87.40%

4.5. Medical Image Recognition

4.5.1. Classification of Histopathological images using CNN (2014)

The classification of cellular structure in high resolution histopathological images is a very exhaustive and time-consuming process. The classification of these images provides the easy analysis of cellular structure. Also it is useful in the CAD (Computer Aided Diagnostic) systems by preventing pathologists from wasting their time on image regions where decisions can be made in straightforward manner. The CNN in this domain has been proposed with different spatial window sizes in RGB color spaces. The different pixel neighborhoods can be evaluated with the help of spatial dependencies of cell and non-cell pixels (Hatipoglu & Bilgin, 2014). By using CNN, the cell classification gives better result than SVM and k-Nearest Neighbors. Further, it is also possible to extend the accuracies obtained with convolutional networks by adapting to other domain-specific features.

4.5.2. Region Segmentation in Histopathological Breast Cancer Images using CNN (2015)

Breast cancer is one of the leading concern worldwide and main causes of deaths among women diagnosed with cancer. The images of tumor called histopathology images and their analysis plays very significant role in analysis, prognosis and therapy scheduling for breast cancer. But their manual inspection is time-consuming as well as subjective. Hence CAD systems should be used for this purpose. The

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

system with fast scanning has been used to perform ROI (Region of Interest) segmentation scheme. Each pixel sensible classification is adopted along with optimized forward propagation network. The features are learned by network in supervised manner from raw-pixel values. The efficiency can be obtained by avoiding redundancy in convolutional and max pooling layers (Su, Liu, Xie, Xing, Meyyappan, & Yang, 2015). This method can outperform the various texture classification methods in its segmentation accuracy time cost. In (Su, Liu, Xie, Xing, Meyyappan, & Yang, 2015), proposed method is used to segment a high resolution image (1000*1000) done in only 2.3 seconds. This shows the scalability and accuracy of CNN in biomedical image classification area.

The summary of the research papers mentioned above is documented in Table 6.

5. CONCLUSION

Through Deep Learning is an old concept, due to excessive time required for the extensive computational work, improvements in this particular field have been limited. The revolution occurred in 2009 when NVIDIA introduced its GPU cards which enabled extensive computational work in a shorter period of time. Following this, many researchers used deep learning and neural networks to achieve better results in various fields than expected for e.g. Pattern Recognition, NLP, Computer vision and speech. The convolutional neural network has the structure which has resemblance to human brain neurons and its functionality is same as that of it. It has the ability to extract the features on its own rather than using any handcrafted features. Deep Convolutional Neural Network means Back Propagation algorithm with many hidden layers. Like a human brain, it has deep understanding structure with detailed knowledge

Table 6. Summary of medical image analysis

SN	Title	Silent Features
1	CNN with embedded Fourier Transform for EEG classification (Cecotti & Graeser, 2008)	Technique used: CNN based on Fourier Transform Idea: In this work, authors have proposed a Fourier transform based CNN architecture for EEG activity classification Result: 97.17%
2	Medical Image Classification (Li, Cai, Wang, Zhou, Feng, & Chen, 2014)	Technique used: CNN Idea: Here they have proposed a customized CNN architecture to classify HRCT lung image patches of ILD (interstitial lung disease) patterns Results: Average accuracy: 73%.
3	Classification of Histopathological Images Using Convolutional Neural Network (Hatipoglu & Bilgin,2014)	Technique used: CNN Idea: This work shows classification of cells using CNN. They used different spatial window sizes in RGB color spaces Datasets and Results: Bio-segmentation dataset: 86.88% .
4	Detection of Sclerotic Spine Metastases (Holger, Yao, Lu, Stieger, Burns, & Summers, 2015)	Technique used: CNN Idea: This work shows that CNN can be generalized to tasks in medical image analysis. The result shows that random set of CNN classification can be used to reduce FP.
5	Region Segmentation in Histopathological breast cancer images using CNN (Su, Liu, Xie, Xing, Meyyappan, & Yang, 2015)	Technique used: fast-scanning CNN along with optimized-forward propagation Idea: Region segmentation is important in treatment of breast cancer done by using CAD systems. Dataset: 92 images from TCGA breast cancer dataset Result: Performance accuracy 85%

of abstraction layer, we can do machine learning. This paper gives a brief overview on supervised Convolutional Neural Network, its history and the various applications and of CNN. It has limitless applications and can be used on many real life problems. The results of many different applications of deep CNN are good, whose detailed information can be seen one by one in above section 4 and 5. After going through the summary mentioned in Tables 2,3,4,5,6, we observe how recently CNN can be used in various applications. The summary has enabled us to understand advantages of CNN, reasons behind selecting datasets which researchers have used, the technique employed and hence effectiveness of results of a particular CNN. If anyone wishes to work on a particular application using supervised CNN in the future, the above summary can provide valuable directions. We have learnt how researchers, using modified CNN, have found astonishing results in various applications. As computers become more and more powerful, CNN proves to be one of the best algorithms for pattern recognition as well as classification problems.

Chapter 56
From Citizens to Decision-Makers:
A Natural Language Processing Approach in Citizens' Participation

Eya Boukchina
University of Carthage, Tunisia

Sehl Mellouli
Université Laval, Canada

Emna Menif
University of Carthage, Tunisia

ABSTRACT

Citizens' participation is a form of democracy in which citizens are part of the decision-making process with regard to the development of their society. In today's emergence of Information and Communication Technologies, citizens can participate in these processes by submitting inputs through digital media such as social media platforms or dedicated websites. From these different means, a high quantity of data, of different forms (text, image, video), can be generated. This data needs to be processed in order to extract valuable data that can be used by a city's decision-makers. This paper presents natural language processing techniques to extract valuable information from comments posted by citizens. It applies the Latent Semantic Analysis on a corpus of citizens' comments to automatically identify the subjects that were raised by citizens.

INTRODUCTION

In the new era of democracy, governments are encouraged to align with the open government principles that refer, among others, to the involvement of citizens in governments' decision-making processes in order to help increase trust, acceptability, and legitimacy of the decisions. This involvement is referred to as Citizens' participation (Woddford, 2013). In the age of technology, the concept of electronic par-

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

ticipation (e-participation) emerged as a mean for citizens to express their opinions by using for example forums, dedicated platforms, or social media platforms.

Citizens' participation is a form of democracy in which citizens are part of the decision-making process with regard to the development of their society (Fischer, 2000; Kleinman, 2000; Goven, 2003). It can be defined as an interactive process between citizens themselves and between citizens and government officials in order to significantly contribute in public policy decisions in a transparent and responsible manner (Phillips et al., 2002). The term government refers to the three governmental levels: Federal, Provincial, or Municipal. In today's emergence of ICTs that are being adopted in all life spheres, citizens can participate in these processes by submitting inputs through digital media such as social media platforms or dedicated websites for example. These sources generate a new input that should be considered by decision-makers along with any other source of information that they use, in order to take decisions. The participation of citizens by using ICTs is called electronic participation or e-participation. As stated in (UN/DESA, 2013), the use of ICT in an e-participation process can increase the supply of useful information, enhance consultation, and support decision-making. The citizens' inputs will guarantee transparency of the taken decisions, and will reflect the values of good governance (Fung, 2015).

As stated, there are different platforms that citizens can use to express their opinions that can be for example social media platforms, discussion forums, or dedicated participation platforms. From these different means, a high quantity of data, of different forms (text, image, video), can be generated. This data needs to be processed in order to extract valuable data that can be used by a city's decision-makers. Hence, it becomes necessary to have tools to analyze this data and to provide it, in a graphical user interface, to these decision-makers. This paper will be used in the context of municipal government. Citizens' participation is a core element for the development of cities where each citizen has the opportunity to express his opinion on subjects that may affect him in his daily life.

This paper focuses on textual data. In this context, these opinions are expressed in natural language. Hence, the objective of this paper is to develop a tool to process and analyze the opinions of citizens published on a platform of citizen participation. This tool will be based on natural language processing techniques. The tool will be tested on a particular platform Votepour.ca, that is a Quebec based platform for citizens' participation, on a particular public consultation related to the achievement of a public place in the district of Limoilou in Quebec City. The valuable data in this consultation is the subjects that are raised by citizens. These subjects can be for example safety, culture, or urbanism. The results show that the proposed tool can achieve 82% of good identification of the subjects raised in the different processed opinions.

This paper is structured as follows: Section 2 is a literature review about smart cities and citizens' participation. Section 3 describes the natural language processing technique that was adopted in this paper. Section 4 presents the results of the application of the natural language processing technique. Finally, Section 5 concludes this paper.

LITERATURE REVIEW

Smart Cities

Nowadays, people are more and more connected and are widely using new technologies. Local governments and cities are providing new services to their citizens based on these technologies in order to improve their quality of life. This tendency will be maintained for at least the next twenty years. As a consequence, the

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

concept of smart city is emerging as a key issue for future development of cities. Both academics and industry are exploring this concept and trying to define its purpose. Nevertheless, there is not yet a widely accepted definition of what a smart city is. In fact, several definitions are available in the literature, but do not offer a clear and a unique comprehension of this concept. For example, we can find the following definitions:

- The concept of a smart city refers to the use of information and communication technologies (ICTs) by City governments to better interact with their citizens (Chourabi et al., 2012) and to build a more livable, competitive, and attractive urban environment with smart and agile government (AlAwadhi et al., 2012).
- "A city well-performing in a forward-looking way in various characteristics, built on the smart combination of endowments and activities of self-decisive, independent and aware citizens" (OECD, 2011).
- A city "connecting the physical infrastructure, the IT infrastructure, the social infrastructure, and the business infrastructure to leverage the collective intelligence of the city." (Hartley, 2005).
- "A city to be smart when investments in human and social capital and traditional (transport) and modern (*ICT*) communication infrastructure fuel sustainable economic growth and a high quality of life, with a wise management of natural resources, through participatory governance" (Caragliu et al., 2009).

Even if the most common issue discussed both by scholars and industry is technology, some authors considered that technological propagation is not an end in itself, but only a mean to achieve social and economic growth (Nam et al., 2011). In this context, (Chourabi et al., 2012) developed a conceptual framework of smart city based on eight components that are technology, governance, policies, organization, people and communities, economy, built infrastructure, and natural environment. One of these components is people and communities. In the context of smart cities, citizens will be increasingly involved in the city's life by being more engaged and more participative in the decision-making process of the city.

A city is then a place where people and communities live. A smart city is also a city where people and communities live with a strong focus on their behaviors, knowledge and educational level (Walravens, 2012). As stated, the main goal of a smart city is to improve the quality of life by offering advanced and innovative services for citizens (Piro et al., 2014). In fact, in a smart city, a citizen should be interactive, aware, and self-decisive (OECD, 2011) and should be involved in the development of the city through an active participation (Dameri, 2013) and integration in the city life (Calderoni et al., 2012). In (Komninos, 2006), it is argued that a smart city can be established when citizens have a strong capacity of learning, creativity and innovation in order to be able to properly use the technology and to effectively benefit from it (Coe et al., 2001). Hence, one of the main priorities of a smart city should be the education and the relation between the inhabitants and their governments (Sáez-Martín et al., 2014). Consequently, a smart city should invest on social and human capital by providing institutions of knowledge creation in order to foster the willingness of its population to transform life and work in their region in a significant way.

Citizens' Participation

Citizens' engagement is a form of democracy in which citizens are part of the decision-making process with regard to the development of their society (Fischer, 2000; Kleinman, 2000; Goven, 2003). It can be defined as an interactive process between citizens themselves and between citizens and government

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

officials in order to significantly contribute in public policy decisions in a transparent and responsible manner (Phillips et al., 2002). In other terms, citizens' engagement can be seen as forms of individual or collective actions allowing to identify and to deal with questions of public interest (Hays, 2007). For example, different participatory initiatives were organized in cities such as participatory budgeting (Rios et al., 2005; Wampler, 2010), participatory development (Bhatnagar et al., 1992; Campbell et al., 2003), democracy (Baiocchi, 2005; Mutz, 2006) or street design, school area management (Lim, 2010). In today's emergence of ICTs that are being adopted in all life spheres, citizens can participate in these initiatives by submitting inputs through digital media such as social media platforms or dedicated websites for example. These sources generate a new input that should be considered by decision-makers along with any other source of information that they use, in order to take decisions. The participation of citizens by using ICTs is called electronic participation or e-participation. As stated in (UN/DESA, 2013), the use of ICT in an e-participation initiative can increase the supply of useful information, enhance consultation, and support decision-making. The citizens' inputs will guarantee transparency of the taken decisions, and will reflect the values of good governance (Fung, 2015). The aim of citizen participation is then to strengthen the involvement of citizens in the Decision-making about significant choices that will affect their community.

Several terms were used in the literature to refer to the concept of citizen participation: public participation, citizen co-creation, citizen collaboration, public consultation, and citizens' participation, among others. Therefore, citizen participation implies that everyone participates in all actions that affect their community to some extent in order to achieve certain objectives. It is also seen as a process that allows citizens to participate in a series of actions and have the opportunity to make decisions that affect them, within institutions, programs or the environment. This participation enables them to improve their social situation, hence their importance. Moreover, citizen participation is an intervention that influences political decisions.

Citizen participation can be supported by different tools such as polls, conferences, or dedicated citizen participation platforms. This paper focuses on citizen participation through dedicated platforms. A citizen participation platform is a web-based solution that allows policy-makers, decision-makers and government officials to have an idea about the ideas expressed by citizens. It allows citizens to propose, criticize and share new ideas that affect their day-to-day life. The use of technologies to facilitate the participation process, make it more inclusive and ensure commitment and involvement of stakeholders in a productive and constructive manner (Smith et al., 2009).

NATURAL LANGUAGE PROCESSING TECHNIQUE

Case Study

Our study will be conducted on a particular public consultation conducted by '' Votepour.ca ''. Votepour.ca is a citizen participation platform focused on local development in Quebec City. Votepour.ca was visited by more than 8,000 participants, the platform has a mailing list of more than 1,200 citizens. Votepour.ca also organized 24 citizen participation and public consultation projects in 24 months of existence. Our focus will be with regard to a public consultation related to the construction of a public square in one of the districts of Quebec City. Different citizens have posted, through textual comments on the platform, their opinions and the reasons why they are for or against the achievement of this project. The aim of

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

our work is to produce an algorithm that is able to classify the reasons expressed by citizens according to concepts or categories and to provide a summary to the city's decision-makers so that they can see the thoughts of the citizens and how the projects can be improved before its achievement. In this paper, we only identify the subjects that are expressed in the opinions but we don't yet classify these opinions as for or against the project.

The corpus on which we worked was composed of 304 opinions (comments) that were posted by citizens. We divided this corpus into two sets: learning set and test set. The learning set was of 128 comments and the test set was of 176 comments. All comments are in French. So, all the provided examples in this paper will be in French with respect to the corpus that was used.

Adopted Approach

The objective of our work is to automatically identify the subjects that were raised by citizens in their comments. To this end, we applied the Latent Semantic Analysis (LSA) (Dumais, 2004) on the corpus. We chose this technique because it is based on mathematical calculations, which avoid the treatment of the ambiguity of the natural language. LSA is not a traditional natural language processing or an artificial intelligence program. Instead, it is an automatic mathematical and statistical technique for extracting conceptual relations between terms from a corpus to establish semantic links (Landauer et al., 1998).

LSA can be divided mainly on three steps:

1. The first step takes as input a matrix that contains the frequency of each word according to each subject.
2. The second step applies a decomposition of this matrix into singular values. This decomposition transforms the text space into a new system representing a linear combination of the characteristics of the original words (Walaa et al., 2014).
3. The third step identifies the subject of a comment.

We present hereafter the execution of the three steps applied on the case study.

Building the Matrix

The first step requires building the initial matrix that will be used in the second step of the approach. To this end, we started from the learning set of 128 comments. We looked at these comments and we identified seven subjects that were raised by citizens: social, economy, culture, civic, urbanism, safety, and environment. Then, for each subject, we identified a set of key words that describes them. We found 109 keywords that describe these subjects. Table 1 presents the different subjects and some of their key words.

Figure 1 presents an overview of matrix A that has in its lines the different keywords and in its columns the different subjects with values representing the frequency of each keyword in the subject. For example, the keyword *rencontre* (meeting) was used 18 times in different subjects related to social aspects, and the keyword *commerce* (trading) was used 8 times in subjects related to economy and 1 time to subjects related to urbanism. In our case, the full matrix A has 109 lines and 7 columns. Figure 1 presents part of the matrix A that we refer to by matrix A in the remaining of the paper.

Table1. List of concepts and some of their related keywords

Subjects	Keywords
Social	*Rencontre – voisin – appartenance – proximité – souder ...*
Economy	*Commerce – marché – tourisme …*
Culture	*Dynamique – art – spectacle - évènement…*
Civic	*Exprimer – droit – participer – parole …*
Urbanism	*Proximité – commerce – circulation …*
Safety	*Circulation – piéton …*
Environnement	*Chaleur – lutte …*

Figure 1. Matrix A of keywords and subjects

	Social	*Economique*	*Culturel*	*Civique*	*Urbanisme*	*Securite*	*Environnement*
rencontre	18	0	0	1	0	0	0
commerce	0	8	0	0	1	0	0
lutte	0	8	0	0	0	0	1
evenement	0	0	11	0	2	0	0
vie	10	0	2	0	0	0	0
communaute	8	0	1	1	0	0	0
proximite	2	0	0	0	4	0	0
traverse	0	0	0	0	0	3	0
sentiment	9	0	0	0	0	1	0

Matrix Decomposition

The second step of LSA is the decomposition of matrix A as a product of three different matrices. This decomposition transforms the text space into a new system representing a linear combination of the characteristics of the original words (Dumais, 2004). This is represented by the decomposition of the initial matrix in the form of a matrix product of three matrices U, S and V^t as follows: $A = USV^t$ with:

- A: the matrix of keyword frequency according to the different subjects
- U: each column of U contains the coordinates of a term vector
- V^t: each column of V^t represents the coordinates of a subject vector in the semantic space.

For example, considering matrix A of Figure 2, we compute the singular values of A that we present in decreasing order: $\lambda_1 = 576.226$, $\lambda_2 = 130.368$, $\lambda_3 = 127.214$, $\lambda_4 = 16.044$, $\lambda_5 = 9.873$, $\lambda_6 = 0.793$, $\lambda_7 = 0.482$. Then, the matrix U is defined as follows (see Figure 2):

The matrix V is presented in Figure 3.

And finally, the matrix S is presented in Figure 4.

Classification of a Comment

Once the decomposition of the matrix A is done, it will be used to classify any new comment. To this end, for each new comment, we create a vector q with the frequency of each keyword in the comment. Hence, the vector q will have 109 lines and one column. For example, let us consider the following comment: ‘’*Une place publique nous permet de rencontrer nos voisins à proximité. Notre communauté travaillera alors à fond pour améliorer la vie de quartier*”. The query vector (part of it) will be in the form of Figure 5. In this comment, we identify the words “*rencontrer*”, ‘’*vie*”, ‘’*communauté*” and ‘’*proximité*” with a frequency of 1. These words are part of the set of keywords.

Figure 5. Query vector Q

$$\mathbf{q} = \begin{pmatrix} 1 \\ 0 \\ 0 \\ 0 \\ 1 \\ 1 \\ 1 \\ 0 \\ 0 \end{pmatrix}$$

One of the issues in LSA is that matrix A may have a high number of columns. Consequently, the matrices can be of large sizes. To this end, LSA proposed to use heuristics to reduce the size of matrices U, S, and V by reducing the size of S. In the following example, we present the case where S is of two dimensions. In Section 4, we present different performances of the algorithm with different reduction possibilities. In this case, the matrices U, S, and V become as follows (Figure 6):

Figure 6. Matrices U, S, and V with k = 2

$$\mathbf{U_k} = \begin{pmatrix} -0.7493 & 0.0671 \\ -0.0008 & -0.5474 \\ -0.0001 & -0.5360 \\ -0.0302 & -0.6313 \\ -0.4205 & -0.0720 \\ -0.3367 & -0.0246 \\ -0.0859 & -0.0549 \\ -0.0020 & 0.0008 \\ -0.3744 & 0.0337 \end{pmatrix}$$

$$\mathbf{S_k} = \begin{pmatrix} 24.0047 & 0 \\ 0 & 11.4179 \end{pmatrix}$$

$$\mathbf{V_k^t} = \begin{pmatrix} -0.997 & -0.0003 & -0.063 & -0.045 & -0.017 & -0.016 & 0 \\ 0.042 & -0.759 & -0.623 & 0.004 & -0.178 & 0.003 & -0.047 \end{pmatrix}$$

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Matrix V_k^t defines the new coordinates of each subject. For example, the new coordinates of the subject social are (-0.997, 0.042).

Then, LSA proposes to transform the query to the new reduced space by computing D_q as follows: $D_q = q^t U_k S_k^{-1}$. Finally, LSA proposes to compute cosine between D_q and the different columns of V_k^t. This will allow computing the similarity between the query and the different subjects using the formula of Figure 7 where c is the vector representing a subject and q is the transformed query in the new space (Abbas, 2014).

From formula of Figure 7, we decided to consider the subjects that form an angle between 0 and $\pi / 4$ or $- \pi / 4$, that is to say, a cosine value belonging to the interval [½, 1] or [-1, - ½].

Improvements to LSA

We found two challenges when building our tool. The first challenge is related to the automatic identification of keywords in order to build queries. The second challenge is the impacts that dominant keywords, that are keywords with high frequencies, and non-dominant keywords, that are keywords with very low frequencies can have on the results of the algorithm.

Syntactic Analysis

The first challenge is the syntactic analysis of the comments in order to build the query of each comment. In fact, we found different words that have the same meaning but written in different forms such as: ''***senti****mental*'', ''***senti****r*'', and ''***senti****ment*''. All these words have the same word root (*senti*) and they all refer to same meaning that is "feel". Hence, we opted that the keywords that will be used in matrix A are the roots of the found keywords. Using the roots of the keywords, it becomes possible to detect almost all forms of the same word using regular expressions. Regular expressions are used to validate any entity containing the root of a keyword followed by any combination of alphabetic characters. For example, using the root ''*senti*'' (feel), we can classify the words ''***senti****mental*'', ''***senti****r*'', and ''***senti****ment*'' as related to feel.

Frequencies of Keywords

The second challenge is related to the fact that we sometimes observed that some keywords have a high frequency that can lead to a dominance of the keyword with regard to other keywords. So, we decided to modify matrix A by reducing the dominance of keywords. To this end, we applied the following formula on the values of matrix A: $A[i,j] = \log (a_{ij} + 1)$ with a_{ij} is the frequency of a keyword at the line i for the subject of column j. With this formula, we compute the logarithm of frequencies of values 0 as the logarithm of 1.

Figure 7. Computing similarities between the query and the subjects

$$\mathrm{sim}(q,c) = \frac{q.c}{|q||c|}$$

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

We also observed that there are keywords with very low frequencies so that they are not informative. To this end, we also applied a new formula on these keywords in order to reduce their impacts (Bestgen, 2004): $\log (a_{ij} + 1) / \sum_j a_{ij} \log (a_{ij} / \sum_j a_{ij})$

We thus defined three algorithms that we adopted in our study:

- Algorithm 1: Classical latent semantic analysis.
- Algorithm 2: Latent semantic analysis and reduction of the impact of keywords with high frequencies.
- Algorithm 3: Latent semantic analysis and reduction of the impact of very frequent and uninformative words.

The results presented in Section 4 will compare these different algorithms along with different reduction options of matrix S.

RESULTS

We present the results based on the learning corpus and then on the test corpus.

Learning Corpus

The learning corpus has 128 comments that were studied and that allowed to detect the different subjects and their corresponding keywords. We applied the three algorithms to the learning corpus using respectively k = 5, and k = 6, that is to say for a semantic space of respectively 5 and 6 dimensions. We obtained the following results by comparing with what we did manually and with what the algorithms provided as results as depicted in Figures 8 and 9. We observe, when applying these algorithms on the learning comments, that the percentage of good answers given by each of the three algorithms for k = 6 is greater than those obtained for k=5. This percentage exceeds 80% for all the three cases. This can ensure that the algorithms are providing satisfactory and effective results that give a good idea about the opinions expressed by the citizens. The results show that the third algorithm with k=6 is the most efficient since it gives the highest percentage for the good responses, that is around 83.44%. It also gives the lowest percentage for non-good responses that is about 16.56%.

For example, let us consider the following comment: ‘*’Rassembler les Limoiliens, ajouter plus d’activités dans notre quartier magnifique, et avoir des spectacles plus souvent*!” (“Gather citizens of Limoilou, add more activities in our magnificent neighborhood, and have shows more often!”). This comment can be classified in culture and social subjects. We applied the three algorithms on this comment with different values of k as depicted in Table 2. In bold are the identified subjects from the comment. As stated, a comment is associated to a subject if the cosine value is in one of the intervals [½, 1] or [-1, - ½].

We observe that for algorithm 1, for k=3 and k = 4, it identifies the social subject but also the civic subject (which is not correct). For k = 5 and k = 6, the algorithm identifies only the social subject. For all values of k, the algorithm doesn’t identify the culture subject. For algorithms 2, and 3, and for the values of k = 3 and k = 4, the social and culture subjects are identified but along with other subjects. Instead, in the cases of k = 5 and k = 6, the algorithms identify the correct subjects social and culture.

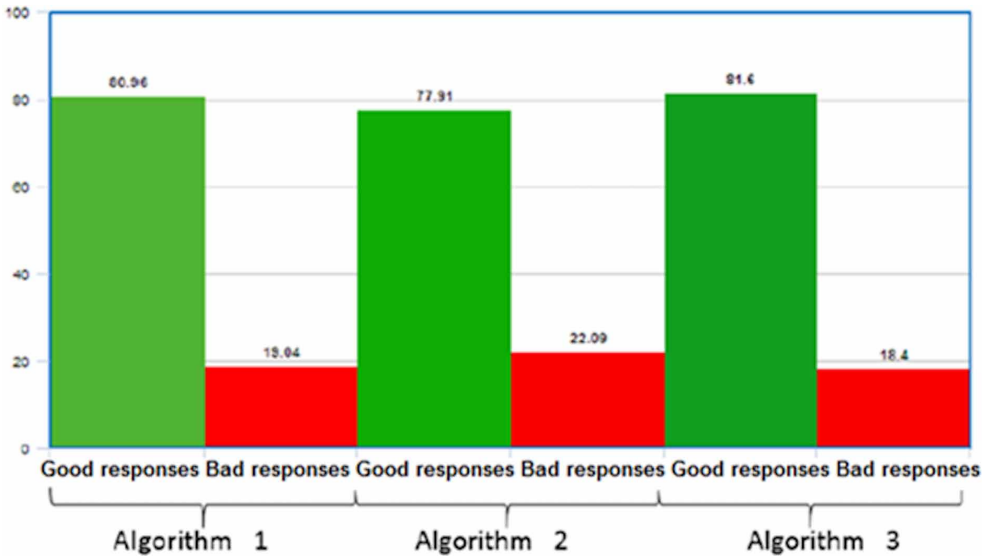
Figure 8. Results of the three algorithms using k=5



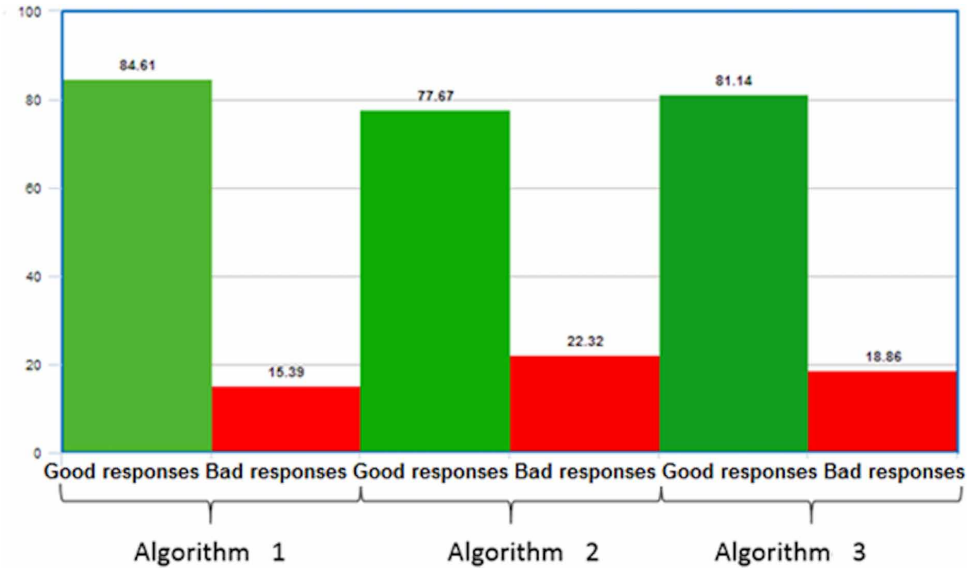


Figure 9. Results of the three algorithms using k=6

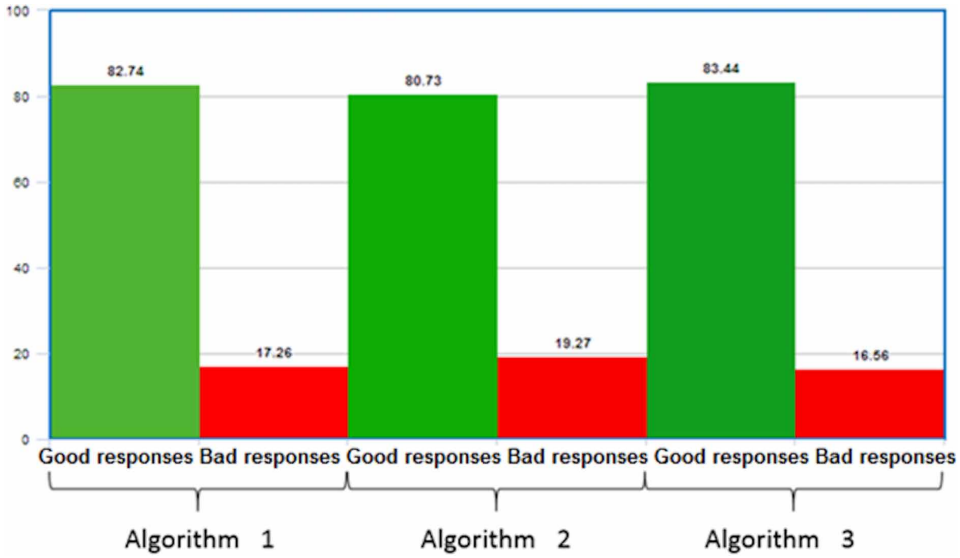
Test Corpus

As a second step to validate the three algorithms, we applied them on the test corpus with k = 6 since we saw that from the learning corpus that the algorithms are better performing when k = 6. These results are presented in Figure 10.



The results on the test corpus showed that algorithms 2 and 3 performed better than when they were applied on the learning corpus where their rates improved by 2%. On the other hand, the performance

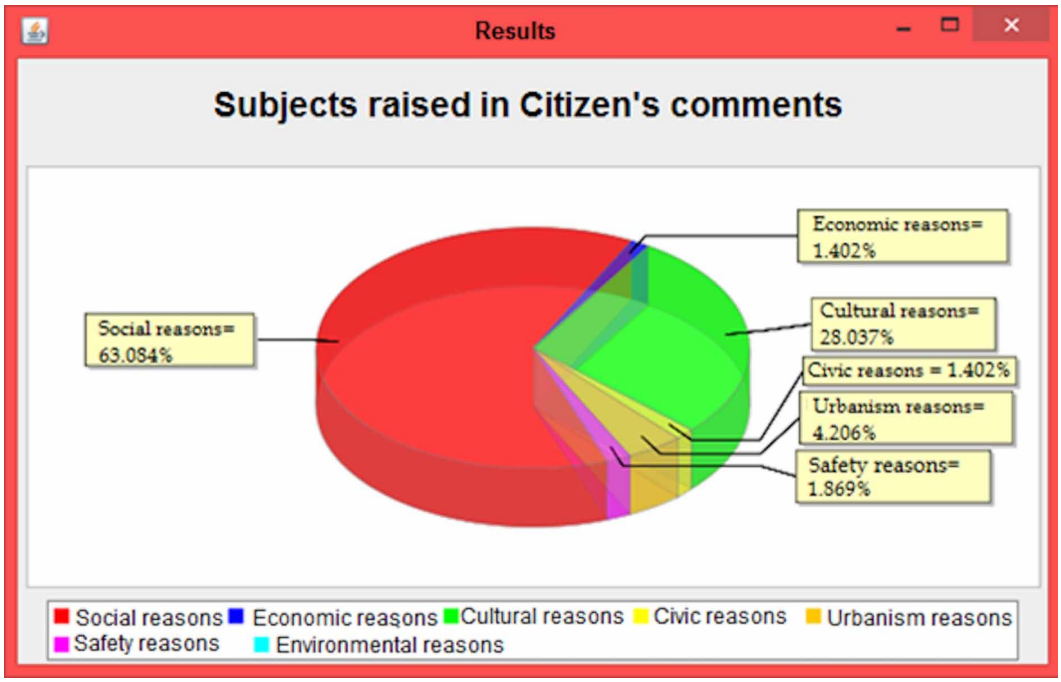
of algorithm 1 decreased by 2%. Since 2% is not considered as a high value, then the performances of the three algorithms can then be considered as constant.



Once the subjects are identified, results can be presented to decision-makers. Figure 11 shows an example of how presenting resulting data to decision-makers. The subjects of Figure 11 are those obtained when applying algorithm 3 with k=6. This data, with a rate of 82% of good classification, can then be provided to decision-makers at city level to have an idea about what people are thinking about this project. We assume that with a rate of 80% of good classification, decision-makers have a true picture of what citizens are thinking and consequently can base their decisions on this picture.

Although we have a rate of 82% of good classification, the algorithms were not able to classify 18% of the comments. This requires further investigation on these algorithms in order to improve the classification rate.

CONCLUSION

In this paper, we addressed the issue of how to identify the subjects of comments posted by citizens in a citizens' participation platform. To this end, we adapted the Latent Semantic Analysis technique by the development of three different algorithms. Results showed that the third algorithm along with k=6 has the best performance rate with regard to the two other algorithms. We also developed a graphical user interface to present the subjects discussed by citizens in a simple and clear graphical representation showing the percentage of each discussed subject. This interface can facilitate the use of the results by decision-makers at city level in order to enlighten their decisions.

Figure 11. Subjects weights using the third algorithm with k=6

While the obtained results can be considered as good, there are still challenges to improve the obtained results. First, the proposed algorithms can be improved by working with an expert that can validate the set of keywords used to define the subjects. Keywords identification is a crucial step since it is the starting point of the algorithms. If the keywords are not valid, then all the obtained results will not be valid. Second, there are new techniques in the semantic analysis of text such as LDA (Blei et al., 2003). It then becomes important to apply these new techniques on the same corpus and compare the techniques against each other. This will allow choosing the most appropriate technique. Finally, it will be a challenge to build a complete application for comments analysis. This application will help users to assign keywords to subjects, and then apply the algorithms to finally show results. At the stage of this paper, these three steps are conducted separately.

Chapter 57
Logs Analysis of Adapted Pedagogical Scenarios Generated by a Simulation Serious Game Architecture

ABSTRACT

This paper presents an architecture designed for simulation serious games, which automatically generates game-based scenarios adapted to learner's learning progression. We present three central modules of the architecture: (1) the learner model, (2) the adaptation module and (3) the logs module. The learner model estimates the progression of the development of skills targeted in the game. The adaptation module uses this estimation to automatically plan an adapted sequence of in-game situations optimizing learning. We implemented our architecture in Game of Homes, a simulation serious game, which aims to train adults the basics of real estate. We built a scripted-based version of Game of Homes in order to compare the impact of scripted-based scenarios versus generated scenarios on learning progression. We qualitatively analyzed logs files of thirty-six adults who played Game of Homes for 90 minutes. The main results highlighted the specificity of the generated pedagogical scenarios for each learner and, more specifically, the optimization of the guidance provided and of the presentation of the learning content throughout the game.

INTRODUCTION

Serious games can be defined as computer-based learning environments, which are built as video games. Their purpose is to train the learner[1] to a specific domain of expertise, while making learning fun. As their use continues to grow in education and training (Girard et al., 2013), few researchers have studied

their architecture to date (e.g., Amory, 2007; Arnab et al., 2015; Kiili, 2005; Peirce et al., 2008). But none of proposed architecture for serious game offers enough details on their software implementation. Moreover, few allow game logs extraction and their analysis, which provide educators with details about learners' learning process. The architecture must offer tools to help them analyze extracted logs after a game session. Generating logs and developing logs analysis tools constitute main research objects in the learning analytics field (Baker & Inventado, 2014).

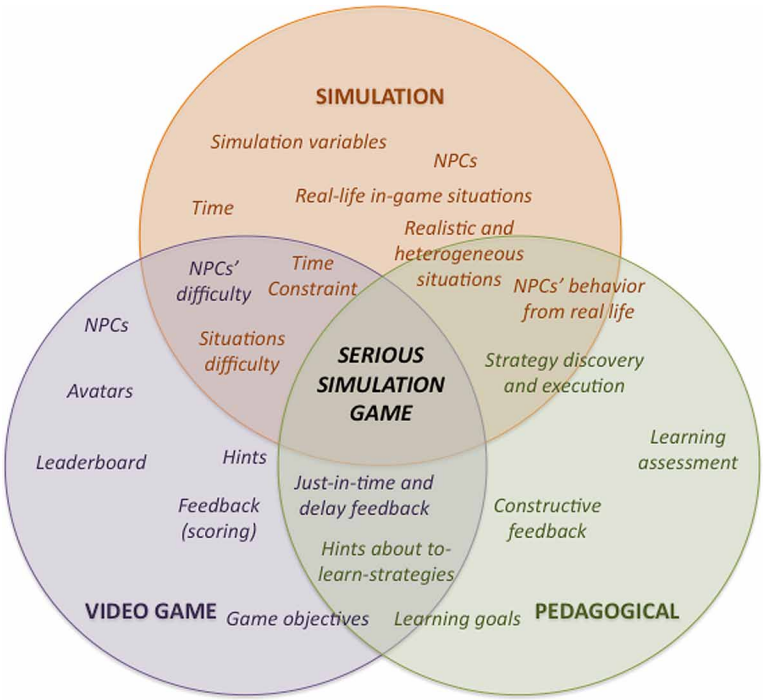
Simulation serious games are serious games which use a simulation to convey learning content. Simulations can be defined as simplified environments of reality, where learner can assimilate learning content without any risk (Sauvé & Kaufman, 2010). Simulation games are appropriate to develop expertise in a domain by generating realistic real-world scenario in which gamers are cognitively as well as motivationally engaged at a deep level (Wouters et al., 2013).

In this article, we present a simulation serious game architecture, which automatically generates pedagogical game-based scenarios adapted to the learner progression throughout the play as well as logs that could be retrieved and analyzed by trainers after the play. We hypothesized that automatically generating scenarios in simulation serious games improve and accelerate learning among adults.

This paper is organized as follow. We first present the theoretical framework of our work. Our proposed architecture is detailed in the second section. We then explain how we implement our architecture in a single-player simulation serious game called *Game of Homes*, which aims to train adults to the basics of real estate. Finally, we report and discuss the results of an empirical evaluation of our architecture, which was conducted to (1) verify that our implemented architecture allowed logs retrieval, (2) read generated pedagogical game-based scenarios, and (3) compare learning progression between scripted-based scenarios and automatically generated scenarios.

THEORETICAL FRAMEWORK

Simulations offer a simplified version of reality, but remain complex and dynamic, and preserve crucial pedagogical features (Garris et al., 2002). Galarneau (2005) mentions that a simulation serious game must, in addition, include play and fun features. The latter maintain learners' motivation and learners' engagement at a high level, using for example scoring or competition. Figure 1 shows simulation, video game and pedagogical features, which all need to be integrated in a simulation serious game architecture.



Simulation Key Features

Simulation games complexity and dynamism lie in simulation variables, which are controlled and adjusted by the game system. These variables represent real-life elements interacting with each other, according to learners' actions in the simulation serious game (Gredler, 2004). Each action represents an input, which triggers targeted variables adjustment in the simulation. Visual indicators are then displayed to learners, as outputs as well as feedback, giving learners some piece of information about the interaction mechanisms between variables.

While controlling and changing variables values, simulations can also reproduce specific contexts or real-life situations. This feature is strongly related to game and pedagogical features, as changing in-game situations can increase or decrease difficulty, as well as challenge and learners' curiosity. Moreover, presenting a wide range of real-life situations can raise learners' awareness of the learning content.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. Simulation, video game and pedagogical features in simulation serious games

Simulation games can also control Non-Playable Characters (NPC). Observing NPCs' simulated behaviors allow learners to uncover rules about these real-life inspired behaviors. This feature is strongly related to game and pedagogical features, as changing NPCs' behaviors can increase or decrease difficulty as well as challenge and competition in the game. Moreover, observing NPCs' behaviors can lead to understanding their role on the simulation.

The last simulation feature presented in this section is time. Simulations represent a succession of events, which occurs not necessarily in real time: in this case, time needs to be compressed while still offering a realistic game experience. Succession of events in the simulation needs to remain consistent as realistic. This feature is strongly related to game features, as sensation of passing time enhances learners' engagement and interest.

Video Games Key Features

Many aspects contribute to make simulation serious games fun. In our architecture, we focused on the following video game features: (1) avatars, which are controlled by learners and by the game system for NPCs, (2) direct feedback, i.e. scoring system, (3) leaderboard, which shows learners' score rank among NPCs, (4) feed, which shows relevant actions displayed for learners, and (5) hints, e.g. textual advices displayed according to learners' actions in the game in order induce strategies discovery.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Pedagogical Key Features

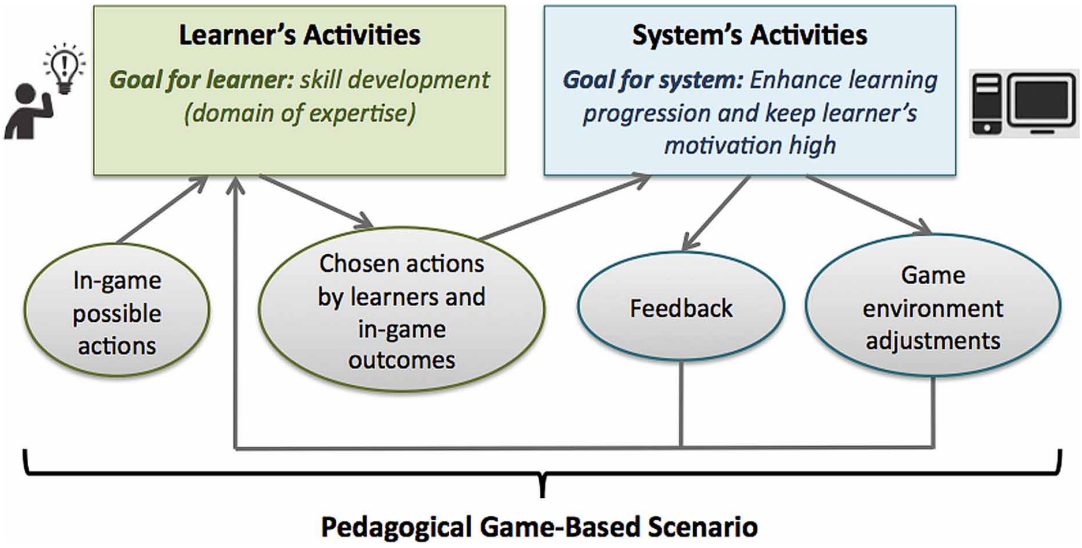
Pedagogical features in simulation serious games focus on the targeted domain knowledge and skills to be developed by learners, particularly on learning strategies to discover and to efficiently execute. In the design process of a simulation serious game, we recommend to identify early learning content, in order to model relevant skills and associated strategies, as well as important learning goals to achieve.

Learning goals will become game objectives in the simulation serious game and need to be clearly explained to learners, either before playing or within the game. Learning goals are represented by (1) the role played by learners that mimics a real-life professional role, (2) the role that should be applied in different in-game situations to experiment numerous professional situations, and (3) the experience of learners' decision outcomes to foster skills development (Gredler, 2004).

To achieve learning goals, the simulation serious game system must monitor all learners' actions in the game and have the ability to (1) assess learning progression, and (2) provide constructive feedback to learners, which can be given 'just-in-time' or delayed, i.e. association of prompt hints and rise or drop of the score.

We stress the importance of strategy discovery and execution to acquire relevant skills in a simulation serious game. This last feature is allowed by the ability for the simulation system to create different in-game situations, forcing learners to discover other strategies in order to achieve the game objectives. Ultimately, at one point in the game, we want learners to execute in a flexible way several strategies according to different in-game situations, as cognitive flexibility is an important aspect of skills development (Spiro et al., 1992).

Simulation, video games and pedagogical features need to be balanced when they are integrated in simulation serious games. This process is arduous, and needs to be framed by a game architecture.



Pedagogical Game-Based Scenarios in Simulation Serious Games

Pedagogical scenarios include two types of scenarios in a learning system: the learning scenario, which includes the set of learning activities prescribed to learners, and the teaching scenario, which includes the set of activities prescribed to teachers or tutors (human or software agents) (Paquette, 2004). As shown in Figure 2, in serious games, learning scenarios target one or several learning goals and allow learners to execute some actions (learners' activities) while receiving relevant feedback in order to progress through the scenario. The game system provides this feedback by displaying textual information, hints, help messages, score updates, and so on, and then modifies the game environment according to the current scenario (system's activities). Both activities, from learners and game system, should lead to the development of target skills (Paquette, 2004).

In most serious games, the sequence of learners' and system's activities is predefined, and the same for each game session (Lopes & Bidarra, 2011). A similar approach is found in video games, in which game scenarios are often scripted or programmed in advance (Schell, 2008). Adopting the scripted-based scenarios approach allows for scenario reusability as well as control of learning progression in the system (Lopes & Bidarra, 2011; Millington & Funge, 2009; Schell, 2008). Designers can therefore make sure that learners have correctly developed the targeted skills before moving on to the next activity. Scripted-based scenarios can be presented an infinite number of times, allowing skills practice and therefore skills development. However, it can also be a limitation, due to the lack of consideration of the variety of learners, who have different prior knowledge about the domain of expertise, and different

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. A schematic overview of a pedagogical game-based scenario

learning styles, in both quality and speed (Lopes & Bidarra, 2011). Moreover, there is a risk that learners get used to these repetitive scenarios as they begin to predict what comes next. Scenario repetition may induce monotony and decrease learners' engagement in the game or in the learning experience (Lopes & Bidarra, 2011). Furthermore, scripted-based scenarios may force users to execute a few winning strategies to solve problems. Finally, as (1) time in simulation serious games passes continuously, and (2) simulation serious games are usually not organized in levels, scripted-based scenarios do not seem to be the best approach to present pedagogical content. A game session can be characterized by playing a certain amount of time in the simulation, and ends when the learner quit the game or when a game objective is reached. Therefore, simulation serious games fall into category of open games, in which it is very difficult to constrain any sequence of activities. Learners are free to explore the game environment, while simulation variables behave autonomously, and discover at their own pace skills to learn and strategies to execute.

Another way to present pedagogical game-based scenarios to learners is thus needed. In simulation serious games, a solution could be to conceive open pedagogical game-based scenarios, which can be modified and personalized in order to match learners' progression (Law & Sun, 2012; Pernin & Lejeune, 2004). When the game system is able to automatically and dynamically adjust the content of pedagogical game-based scenarios according to learners' progression in the game, we call that system adaptable (Vandewaetere et al., 2012). Adaptation in video games and serious games was proposed by some authors who mainly focused on adaptation of challenge in games (Lopes & Bidarra, 2011; Beaudry et al., 2010). Others focused on adaptation of narrative scenarios in serious games (Li & Riedl, 2010), and adaptation of pedagogical game-based scenarios in serious games (Niehaus & Riedl, 2009). Automatic adaptation should propose content relevant to learning progression and therefore allow usage of multiple strategies fostering skills development. An adaptative game system should be able to fit each learner characteristics, by providing more difficult learning contexts to expert learners to keep them interested, and by providing easier learning contexts to beginner learners to prevent game abandon. Finally, adapt-

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

ing scenarios guarantees personal pedagogical path for each learner and for each game session. In order to adapt learning content to learners' progression, artificial intelligence techniques can be used (e.g., Conati & Zhao, 2004; Peirce et al., 2008; Steiner et al., 2009).

Logs Analysis in Simulation Serious Games

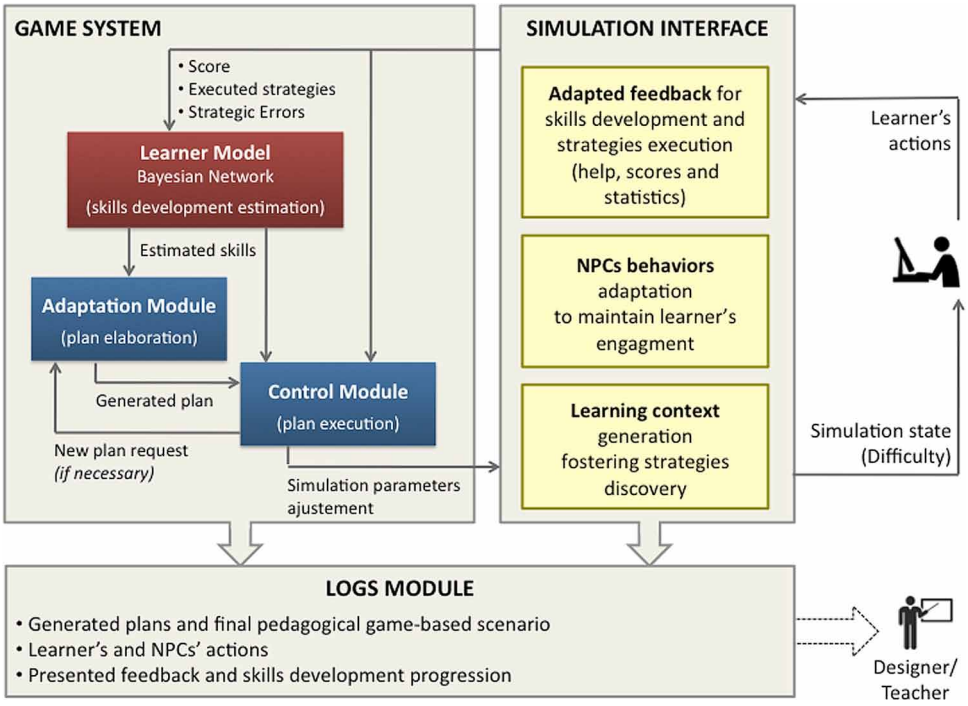
More and more game designers conceive game systems allowing logs recording. Game logs are therefore saved data during a game session; "[they] are captured at the level of a basic action, defined as the smallest unit of meaningful action that a player can exert on the game world" (Harpstead et al., 2013, p. 82). Game logs also carry information about the game context, such as the initial conditions of a game session. Finally, game logs are represented by sequential data: all data is inscribed according to the time the actions occurred (Sanchez et al., 2015).

At the end of a game session, game designers and teachers should be able to extract game logs in order to assess learning and target learning difficulties encountered by learners. Logs extraction is even more important in case of adaptative simulation serious games, as each pedagogical game-based scenario is adapted. However, analyzing game logs can be challenging, especially for open simulation serious games, which are "characterized by having a set of overarching rules that govern the interactions of the game's elements, as well as a non-restrictive structure that allows players to explore multiple paths to a solution" (Harpstead et al., 2013, p. 80). This type of games allows learners to experience many learning contexts, but makes it difficult to prove learning effectiveness.

Therefore, not only designers and teachers need to access the exact content of the pedagogical scenario during and after a game session, but they also need tools to visualize these data.

SIMULATION SERIOUS GAME ARCHITECTURE

When conceiving our architecture, our goal was to meet the needs of what a simulation serious game should contain in order to (1) automatically generate pedagogical game-based scenarios, (2) present these scenarios to learners while inducing learning and challenge, and (3) allow efficient logs extraction. Therefore, our architecture respectively includes three main components: (1) game system, (2) simulation interface and (3) logs module. Figure 3 shows the overall of our simulation serious game architecture, of which each component will be described in the following sections.



Game System

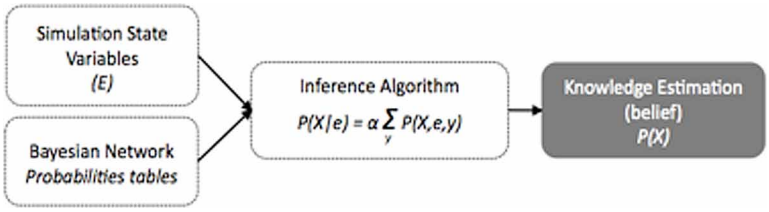
The main role of the game system is to adapt learning content to learners' progression in the game. It should be able to modify the evolution of the simulation and thus it creates new in-game situations inducing new strategies discovery, which is needed to achieve learning goals. This dynamic evolution of the simulation world represents the automatic generation of pedagogical game-based scenarios to support learners' learning process.

In order to adapt learning content and in-game situations in the simulation, the game system first needs to assess current learners' learning state. The learner model in our architecture carries out this role.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 3. Simulation serious game architecture overview

Learner Model



The learner model represents the learner's knowledge progression status, in real time, about the domain of expertise to-be-learned. Estimating acquired knowledge is quite arduous, as we cannot directly observe learners' knowledge state according only to game actions. A well-known artificial intelligence model, which ensures knowledge estimation, uses Bayesian Networks (BN). This model was indeed previously used to assess knowledge acquisition in intelligent tutoring systems (e.g., Conati et al., 2002) and serious games studies (e.g., Manske & Conati, 2005).

BN design requires a previous work of knowledge explicitation from the domain of expertise. As every domain of expertise contains many complex skills, it is important to sparingly choose the specific skills that will be implemented in the game system. We also stress the importance of explicitation of strategies related to skills and executed by experts. These strategies represent the "know-how" aspect of the domain of expertise, and could also be used in the BN to assess learners' knowledge. Once skills and strategies are chosen, probabilities for each skill according to specific actions in the game can be assigned (probabilities tables). These probabilities need to be adjusted during game testing.

A BN operates as shown in Figure 4: an inference algorithm calculates a "belief" about a target skill in the game according to the formula which includes (1) the state of the variables in the simulation, also called random variables; and (2) the corresponding probabilities found in probabilities tables. Random variables represent both observable learners' knowledge and simulation state. Knowledge estimation can be provided continuously during a game session by combining learners' actions with other game elements like learners' statistics or prior encountered game situations. This update status of learners' skills development can then be addressed to the adaptation module.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 4. Bayesian Network (BN) role in our architecture

Adaptation Module

The adaptation module adapts simulation content according to learners' skills development estimation. Simulation content is represented by feedback, NPCs' behaviors and simulation parameters. The game system needs to find the best pedagogical game-based scenario to both speed up and enhance learning process, which represents a complex problem to solve.

In artificial intelligence, a technique called classical planning is used to find optimal solutions to complex problems. A planning algorithm enables the selection of a sequence of actions or situations – also called plan – to achieve a goal. Every action has preconditions, which are needed to execute the action, and effects, which are produced by the action. In our architecture, the adaptation module uses a planning algorithm to discover the best sequence of in-game situations in accordance with the current learners' knowledge status. This sequence of in-game situations represents a plan, which can be recalculated along with learning progression. The final sequence, which took place during a game session, represents the generated pedagogical game-based scenario. The planning process is represented as such in the adaptation module:

- **States:** Learner's knowledge Estimation status;
- **Actions:** In-game situations Which include a pedagogical goal to achieve (previously designed);
- **Actions Preconditions:** Prior knowledge needed to achieve the situation (previously designed);
- **Actions Effects:** Supposed impacts on the learner's learning (previously designed).

Control Module

The control module executes plans generated by the adaptation module. When preconditions of the next in-game situation are satisfied (i.e. if the required skills estimation value is reached), the control module modifies in real time the simulation parameters in order to present new situations to the learner, to change NPCs' behaviors, and to provide feedback to the learner. If the preconditions are not validated (i.e. if the required skills estimation value is not reached yet, or if it was reached too fast), the control module asks the adaptation module for a new generated plan, which will be more adapted to learners' current knowledge status.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Simulation Interface

The simulation interface presents different in-game situations. These situations are composed of simulations variables as well as different features. In our architecture, we selected the following key features exposed in introduction as simulation contents:

- Feedback (i.e. scoring system, learners' statistics, and help messages) in order to optimize skills development and strategies execution;
- NPCs' behaviors, which can be modified in order to trigger challenge;
- Different learning contexts, which can be generated in order to prompt strategies change as well as strategies discovery.

According to these specific situations, every action made by the learner in this interface is monitored by the game system and sent to the learner model.

Logs Module

The main role of the logs module included in our architecture is to collect pertinent game data about:

- Learners' and NPCs' actions;
- Game contents: displayed help messages, numbers of NPCs and details about their behaviors;
- Learners' learning progression: skills development, probabilities estimated by the learner model;
- Generated plan(s) content.

Since the adaptation module can refine the pedagogical scenario at any time during the game, at the end of the game session, the logs module provides the final version of the pedagogical scenario and information about the number of a new plan was generated (if that was the case).

IMPLEMENTATION OF OUR ARCHITECTURE: THE CASE OF *GAME OF HOMES*

To implement our architecture, we developed a single-player serious simulation prototype called *Game of Homes*[2], which aims to train beginners at real estate transactions. Figure 5 shows the graphical interface of *Game of Homes*.

Brokers in *Game of Homes*, represented by both the learner's avatar and NPCs, have to sell houses and to earn as much money as possible while maintaining a good reputation. To do this, brokers negotiate with homeowners to get a brokerage contract, assess property values, and manage sales by carrying out advertising, giving house tours to potential buyers, adjusting selling prices, negotiating with buyers and recommending offers to sellers. In *Game of Homes*, the in-game clock simulates time, but the learner can also move a cursor on a timeline to accelerate or slow down simulation speed.

Game of Homes aims to foster learning of three main skills, as well as strategies associated to these skills. Skills and strategies are detailed in Table 1.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 5. Game of Homes interface

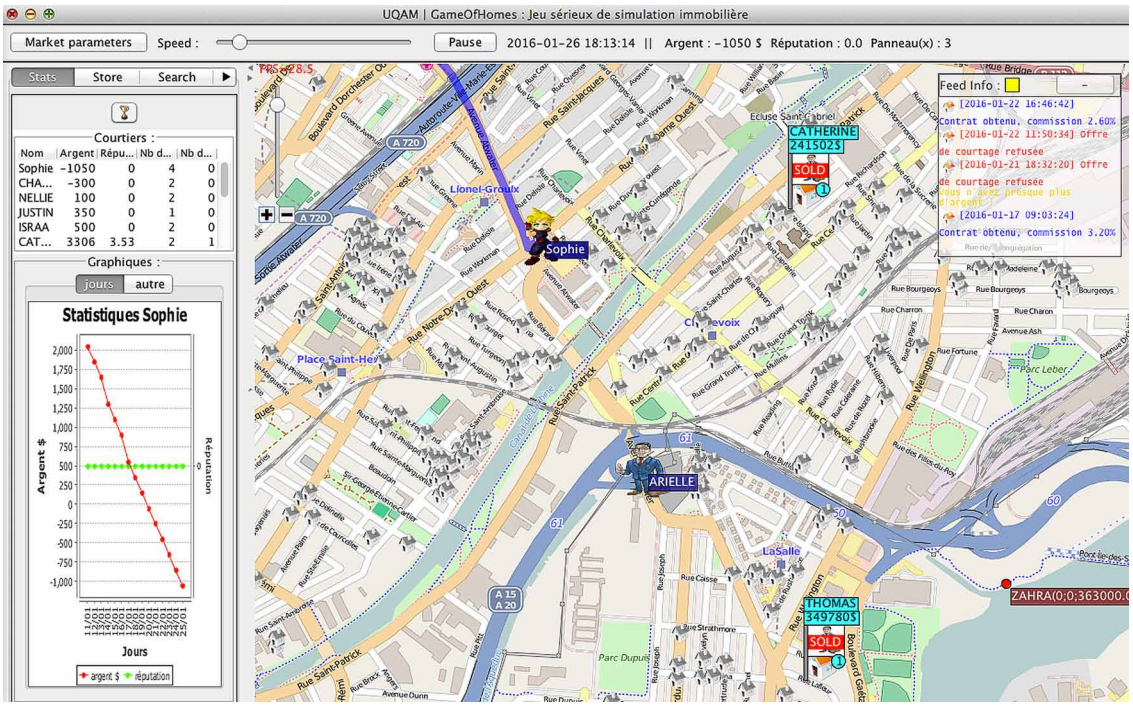


Table 1. Skills and strategies taught in Game of Homes

Skills	Associated Strategies
Skill 1: Obtaining relevant brokerage contracts	Strategy 1.1: Choosing contracts closed to each other in order to be fast and efficient in sale management (territory strategy).
	Strategy 1.2: Choosing contracts whose owners are not too demanding (i.e. owners expect high selling prices and demand low commission rates from brokers).
Skill 2: Estimating houses selling prices	Strategy 2.1: Fixing selling prices according to comparable properties in the neighborhood.
	Strategy 2.2: Reevaluating selling prices to foster difficult sales.
Skill 3: Managing and concluding house sales	Strategy 3.1: Being proactive on visits management.
	Strategy 3.2: Maintaining a high visibility level on houses, by purchasing publicity.
	Strategy 3.3: Being proactive on purchase offers management, and efficiently advising sellers about offers.

Estimation of skills development is done by the Bayesian Network (BN), which considers learner's outcome action and the probability of action in the game to succeed (outcome of the sale property or relevance of the brokerage contract). This probability depends on the simulation parameters (selling market, sellers' demands, learner's territory, expected commission) and the learner's knowledge related to this action.

The adaptation module in *Game of Homes* was implemented with eight generic in-game situations, all detailed in Table 2, which can be part of the generated plan:

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 2. Eight possible in-game situations composing a pedagogical game-based scenario in Game of Homes (BN = Bayesian Network)

In-Game Situation	Target Skill(s)	Precondition(s) (% of the Skill(s) Value(s) in the BN)	Game Contents Adjustments				Expected Effects on % of Skills Values in the BN
			Feedback Help Messages	NPCs' Behaviors		Learning Context	
				Aggressive Level of Other Brokers	Level of Sellers' Demand		
1	1 (basics)	≤ 35	Activated	Low	Low	Seller's market	+ 20 on skill 1
2	2 (basics)	≤ 35	Activated	Low	Low	Seller's market	+ 20 on skill 2
3	1 (advanced)	>35 & ≤ 70	Activated	Medium	Medium	Balanced market	+ 20 on skill 1
4	2 (advanced)	>35 & ≤ 70	Activated	Medium	Medium	Balanced market	+ 20 on skill 2
5	1 (expert)	>70	Deactivated	High	High	Buyer's market	+ 20 on skill 1
6	2 (expert)	>70	Deactivated	High	High	Buyer's market	+ 20 on skill 2
7	1 & 2 (expert)	>55 & ≤ 80	Deactivated	High	High	Buyer's market	+ 10 on skills 1 & 2
8	1 & 2 (expert)	>80	Deactivated	Very high	Very high	Buyer's market	+ 10 on skills 1 & 2

- Two easy situations to teach skill 1 (relevant contracts) and skill 2 (selling prices estimation) basics;
- Two medium situations to develop these skills at an advanced level;
- Two difficult situations to develop these skills at an expert level;
- Two very difficult situations targeting the two skills, one validating the understanding of the selling process and the management of several contracts, the other one testing if learners manage the two skills in "crisis" situations.

Each in-game situation is activated if specific preconditions are fulfilled. Preconditions are represented by percentage values of the two skills taught in the game, which are themselves given by the BN in the learner model. For example, situation 5 can only be activated if the percentage value of skill 1 "Obtaining relevant brokerage contracts" is superior to 70%. Finally, each situation has a specific effect on the percentage values of the two skills. For example, situation 5 leads to a 20% improvement of skill 1 probability in the learner model. Each situation has the same game duration of one month in the game.

The control module in *Game of Homes* adjusts the following simulation contents:

- **Feedback:**
  - Scoring system represented by (1) money earned by selling properties, and (2) broker reputation;
  - Learner's statistics represented by (1) a graphic showing score, and (2) a leaderboard gathering NPCs' and learner's scores;

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

  - Help messages displayed on the main screen, which target strategies related to skills. For example, when a learner does not execute the territory strategy, the following message pops up: "Choosing contracts closed to each other will allow you to limit transit time and to be more responsive."
- **NPCs' Behaviors:**
  - NPCs brokers may behave more or less aggressively. Both total number of brokers on the map and maximum number of contracts brokers can obtain determine their aggressiveness;
  - House owners may or may not be very demanding: they can overestimate or underestimate houses selling prices, and they can expect reasonable or low commission rates from brokers;
- **Learning Context:** The market may be in favor of buyers (buyer's market), in favor of sellers (seller's market), or balanced (balanced market). Selling context in the game is adjustable by modifying buyers/sellers' ratio on the map.

Finally, the logs module in *Game of Homes* collects pertinent game data:

- **Learner's and NPCs' Actions:** Movements on the map, proposed commission rates, accepted or refused contracts, proposed selling prices, purchased advertises, accomplished or missed houses visits, purchase offers recommendations, sales outcomes, etc.;
- **Game Contents:** Help messages displayed, numbers of NPCs on the map and details about their behaviors (aggressiveness, demand status), market status;
- Learner's learning progression (skills 1 and 2 probabilities, which are provided by the learner model, score and statistics);
- Time at which any event occurred;
- Precise content of each generated pedagogical game-based scenario.

Teachers or game designers should be able to read game logs in order to (1) detect encountered difficulties by learners, (2) check score progression, (3) observe executed strategies, and (3) track the amount of time needed to learn skills. Therefore, we have developed a log analyzer software module capable of parsing and analyzing log files to show its users all pertinent data. This program, based on extracting different types of data from the logs, gives its users information on learners' movements, statistical evolution, successful and unsuccessful sales, along with all information describing the causes (number of visits, asking price, recommended price, etc.). Finally, our parsing analyzer program allows for a qualitative analysis of skill 3, "Managing and concluding house sales", which was not estimated in the BN. The program can indeed evaluate learners' management process (e.g., missed visits rate, missed purchase offers).

EMPIRICAL EVALUATION

This last section aims to point out how logs can be retrieved in order to read the exact content of pedagogical game-based scenarios. Furthermore, we report results about the impact on learning when pedagogical scenarios are automatically generated versus when they are scripted. More precisely, our goal was to test if automatically generated scenarios are more respectful to learning progression than scripted-based scenarios. We also wanted to verify that the logs module along with our designed parsing tool provides a precise analysis of learning progression throughout the game session.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

In order to reach our research objectives, we designed another version of *Game of Homes* allowing the presentation of scripted-based scenarios. For this version, the adaptation module was disabled: for each learner, situation 1 is first activated (in January), followed by situations 2, 3, 4, 5, and 6. The script continues until situation 6 is reached (or stops before, if the game session ends). At the end of situation 6, the learner should have developed both skills (probabilities for both skills are higher than 95%). Situations 7 and 8 were not considered in this version, because game sessions would have been too long (more than two hours).

We chose to conduct a qualitative analysis, which focused on (1) data on skills development provided by the learner model, (2) pedagogical scenarios proceedings, (3) amount of help messages displayed and (4) data on acquired strategies. We used our tool to analyze game logs and to visualize the acquisition of specific strategies taught in the game.

Participants and Procedure

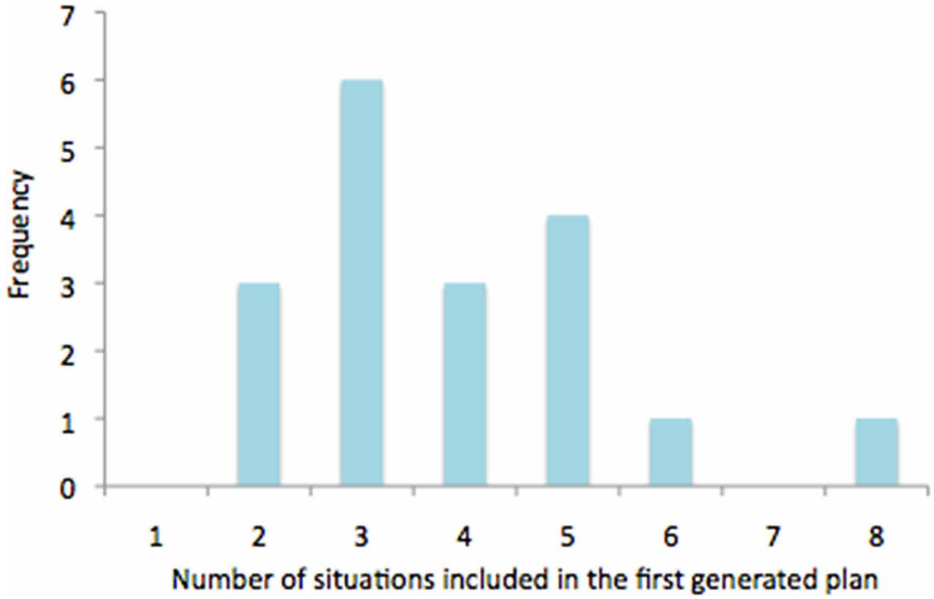
The empirical evaluation was conducted with 36 participants who were recruited by advertisements placed on our university campus. The participants were between 18 and 40 years old (14 women, 22 men), and were not and had never been house owners.

Participants were invited into a computer lab on campus, where the experimenter explained the research project and its objectives and carried out a brief demonstration of *Game of Homes*. Once they signed the consent form, they were randomly assigned to one of two versions of *Game of Homes*: automatically generated version (18 participants) and scripted-based version (18 participants). They were then asked to play *Game of Homes* for approximately 90 minutes. After playing, the experimenter conducted a debriefing and answered participants' questions.

Results

We qualitatively analyzed all 36 log files provided by the logs module. It is important to note that the first in-game month (January) in the generated version of *Game of Homes* was used to assess a first-time skill 1 and skill 2 in order to generate an adapted plan (situation 1 was activated during January). Therefore, the data analyzed was taken from second simulated month onward (February). Also, since learners controlled time speed inside the game, none of them reached the same date at the end of their game session, even if they all played for 90 real-time minutes. This aspect made comparing the two versions of *Game of Homes* quite difficult and is the reason why we chose to conduct a qualitative analysis instead of a quantitative analysis. Table 3 presents all generated scenarios with their corresponding in-game situations for the 18 participants who were assigned to the generated version of the game. In-game situation are detailed in Table 2.

Extracted data from the logs module informed us about the progression of skills development for both skills "Obtaining relevant brokerage contracts" (skill 1) and "Estimating houses selling prices" (skill 2). Moreover, the logs module allowed us to retrieve the exact content of generated plan(s) for each learner, and therefore the exact content of the final generated pedagogical game-based scenario. Figure 6 shows total number of situations included in the first generated plan for the eighteen participants assigned to the generated version of the game.



EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 6. Total number of situations included in the first generated plan for each learner (N=18)

Looking at Table 3 and Figure 6, we can appreciate the range of first generated plans among learners. Ones are composed of only two situations, whereas others are composed of six or more situations. If we look closely at data showed in Table 3, we can see that:

- As participant 8 obtained rather good skills estimation (skill 1 = 99%; skill 2 = 57%), the generated plan included only two situations (one to teach skill 2 at an advance level, and one to propose a very difficult situation to teach both skills at an expert level);
- As participant 4 obtained rather poor skills estimation (skill 1 = 47%; skill 2 = 17%), the generated plan included eight situations focusing on both skills with a wild range of level of expertise.

Figure 7 shows chosen situations by the adaptation module for the first three months among learners. Data showed once more the variety in plans content: each learner received a personalized plan with respect to their learning progression.

Our logs analysis tool allowed us to focus on skills development diagnosis on strategies discovery and execution. For example, one strategy related to skill 1 consisted of choosing brokerage contracts closed to each other, in order to be more efficient in managing visits and purchase offers (Strategy 1.1: territory strategy, see Table 1). Our tool provides, for each participant's game session, a map of the city including all locations of the contracts chosen by the learner. Figure 8 shows examples of two maps obtained by participant 33 and participant 16, both in generated version of the game.

These maps show that participant 33 executed the territory strategy, whereas participant 16 chose distant contracts from each other.

Moreover, our tool evaluates strategies associated to "Managing and concluding house sales" (skill 3), which was not estimated by the Bayesian Network (BN). To do so, the tool provides, for each participant's game session:

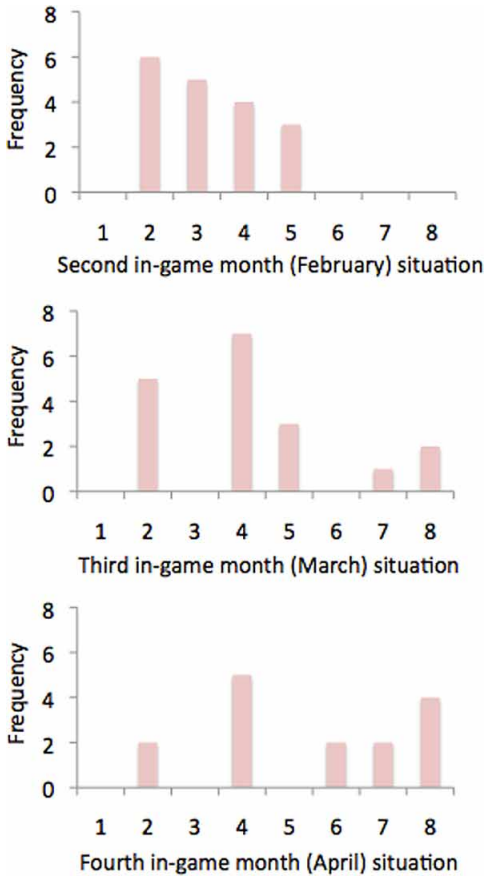
Figure 7. Chosen situations by the adaptation module for the first three months among learners (N=18)



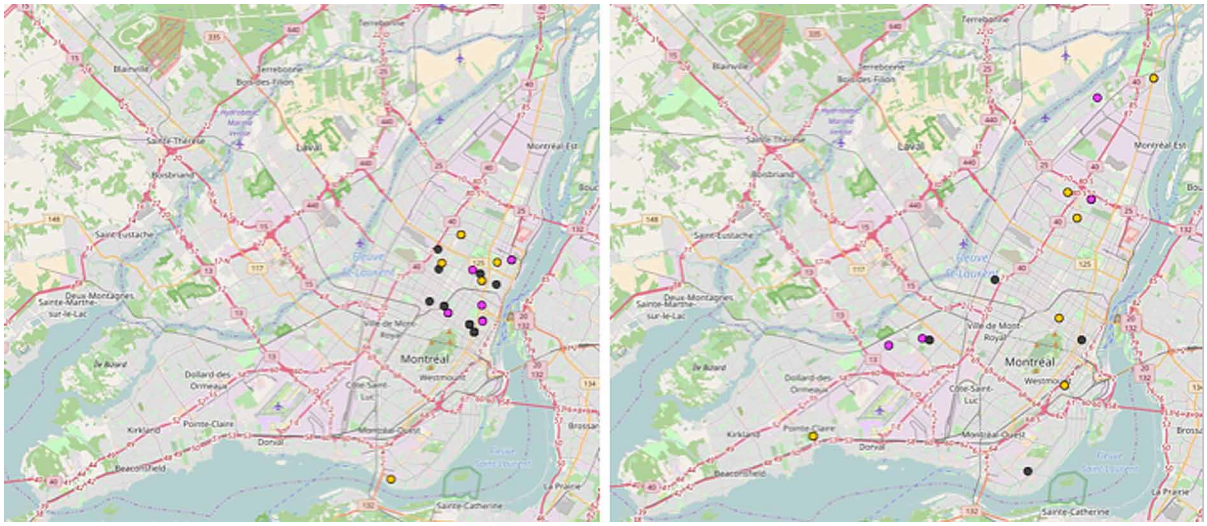


Figure 8. Territories at the end of game session for participant 33 (on the left) and participant 16 (on the right). Black points: contracts selected by the learner, but lost to another NPCs broker; pink points: learner's contracts, not sold at the end of the game session; orange points: learner's contracts, sold.

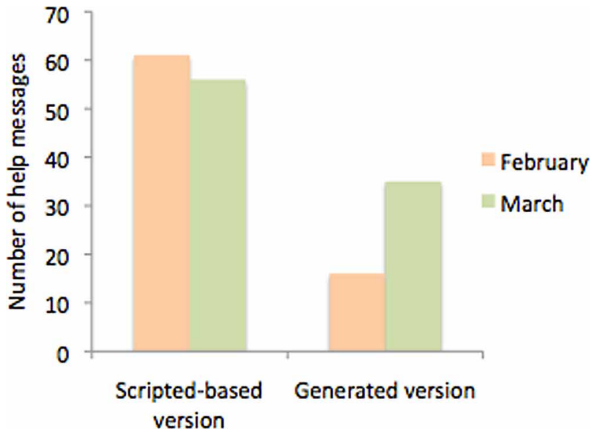
EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

- Percentage mean of missed visits (when the learner waited too long to go back to her houses in sale in front of which buyers were waiting to visit). For example, participant 33 obtained a rate of missed visits of 45% (Strategy 3.1, see Table 1);
- Percentage mean of house visibility on the market (due to advertising). For example, participant 33 maintained a visibility of 69,7% (Strategy 3.2, see Table 1);
- Percentage mean of missed purchase offers (when the learner waited too long to go back to her houses in sale in front of which buyers were doing a purchase offer). For example, participant 33 obtained a rate of missed purchase offer of 18,75% (Strategy 3.3, see Table 1).

The provided dataset is also essential and complementary to data on skills development as they allow us to verify if taught strategies were discovered and at what rate was used.



In order to compare scripted-based version and generated version of *Game of Homes*, we show in Figure 9 the number of help messages displayed during February and March in the game, for both versions of the game. We selected 22 participants for these analyses, because they played for at least until March in the game.

Despite the fact that the results are closely dependent on the elapsed time in-game, data show that the adaptation module in our architecture allowed a controlled generation of help messages, whereas the scripted version of the game equally displayed help messages.

Since the elapsed time in-game is not the same for every learner, we chose to present in the section two pedagogical scenarios inscribed in game logs for the two participants that played the longest in-game time. We assert that longer pedagogical scenarios are more complete and thus more significant in terms of progression of learning. Table 4 shows these two scenarios for participant 9 (scripted-based version, played until June 2016 in-game, 175 in-game days) and for participant 16 (generated version, played until May 2016 in game, 139 in-game days). At the beginning of each month inside the game, the logs module recorded the probabilities for skill 1 and skill 2, both provided by the learner model.

Detailed scenarios for both versions show that even six scripted situations proposed to the learner were not enough to learn skill 2 (47% at the end of game session). In the generated version, the adaptation module proposed only two situations to develop both skills, but a third situation was actually adequate

Figure 9. Total number of help messages displayed for both groups (scripted-based version, N=13; generated version, N=9) who had played for at least three months in the game (N=22)

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 4. Examples of two pedagogical scenarios extracted from game logs

Scripted-Based Version (Participant 9)	Automatically Generated Version (Participant 16)
February: P(skill1) = 98% & P(skill2) = 18% Situation 2 of the script is executed. Help messages displayed: strategy concerning market situation, sellers' demand, comparable houses. March: P(skill1) = 98% & P(skill2) = 31% Situation 3 of the script is executed. Help messages displayed: strategy concerning brokers' territory, commission rates, sellers' demand, comparable houses. April: P(skill1) = 99% & P(skill2) = 55% Situation 4 of the script is executed. Help messages displayed: strategy concerning brokers' territory, commission rates, sellers' demand, visits. May: P(skill1) = 99% & P(skill2) = 50% Situation 5 of the script is executed. Help messages are not activated for this action. June: P(skill1) = 99% & P(skill2) = 47% Situation 6 of the script is executed. Help messages are not activated for this action. End of the game session.	February: P(skill1) = 79% & P(skill2) = 43% First generated pedagogical scenario including two situations: Situation 4, Situation 7. Help messages displayed: none. March: P(skill1) = 88% & P(skill2) = 60% Second generated pedagogical scenario including two situations: Situation 4, Situation 8. Help messages displayed: strategy concerning brokers' territory, commission rates, sellers' demand, visits. April: P(skill1) = 99% & P(skill2) = 73% Third generated pedagogical scenario including one situation: Situation 6. Help messages displayed: strategy concerning comparable houses. May: P(skill1) = 99% & P(skill2) = 92% Both skills are acquired. End of the game session.

to learn both skills (99% for skill 1 and 92% for skill 2 at the end of game session). Lastly, we can see in Table 2 that generated scenarios were adapted for each participant according to their learning progression. For example, the first estimated skills for participant 4 were P(skill 1) = 47% and P(skill 2) = 17%, to which the adaptation module proposed an eight-situations scenario, while it proposed a two-situation scenario for participant 16 whose skills were first estimated at P (skill 1) = 79% and P (skill 2) = 43%.

Overall, results show that the automatically generated version of *Game of Homes* is efficient in adapting pedagogical scenarios to the learning progression, inducing faster learning for the participants who played for long periods on in-game time. Moreover, the logs module allows us to precisely trace learning progression, represented by development of skill 1 and skill 2, and makes it possible to detect a potential decrease of skills probabilities.

CONCLUSION

In this study, we addressed the problem of adapting game content to a learner in order to improve the learning process and keep the learner motivated while playing a simulation serious game. Because trying to predict multiple game situations and to propose a content adaptation to each case are time-consuming, laborious, and complicated, we proposed an architecture of simulation serious game based on Bayesian Network and planning algorithm. This architecture can be applied to develop other simulation serious games.

Using automatically generated scenarios instead of scripted-based scenarios in simulation serious game is profitable to learners. Their progression in the game is more pleasant than in a scripted-based game because the learning content is closer to her learning needs. In addition, when replaying the game, it remains interesting for her as the game adapts continuously to her new skill level.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Few studies proposing architectures of serious games assert the importance of recording and analyzing game logs (Gervas, 2014; Harpstead et al., 2013; Sanchez et al., 2015; Westera et al., 2014). Our research demonstrates both the essential and complementary role of the logs module with the other modules (adaptation and control) in the generation of pedagogical scenarios. At the end of a game session, the logs module allows trainers to read the exact content of the pedagogical scenario. The results of our empirical evaluation of *Game of Homes* showed that each generated scenario was different from the scenario used in scripted-based version. Moreover, each scenario adapts itself to the learning progression of the learner while playing. More difficult situations are planned for learners whose skills development is on the right track, while easier situations are proposed to learners experiencing difficulty. This adaptation can occur at any point in the game, even in the case a learner masters a skill at the beginning of the game. This feature also guaranties learner engagement throughout the duration of the game session.

The fact that the pedagogical scenarios are unique to each learner gives an important pedagogical value to generated scenarios compared to scripted-based ones. On one hand, designing in advance the best scenario for each learner is a very difficult task. On the other hand, it is very arduous to predict both learners' learning speed and level of engagement in a serious game experience. Thus, we suggest, as demonstrated in this study, that tools be designed to facilitate data extraction and detect learning patterns. In our case, our tool allows us to verify the discovery and execution of taught strategies in the game.

ABSTRACT

In the last few decades there has been a tremendous amount of research on synthetic emotional intelligence related to affective computing that has significantly advanced from the technological point of view that refers to academic studies, systematic learning and developing knowledge and affective technology to a extensive area of real life time systems coupled with their applications. The objective of this paper is to present a general idea on the area of emotional intelligence in affective computing. The overview of the state of the art in emotional intelligence comprises of basic definitions and terminology, a study of current technological scenario. The paper also proposes research activities with a detailed study of ethical issues, challenges with importance on affective computing. Lastly, we present a broad area of applications such as interactive learning emotional systems, modeling emotional agents with an intention of employing these agents in human computer interactions as well as in education.

INTRODUCTION

The development of information technology, emotional intelligence in affective computing has contributed significantly towards the evolution of intelligent machine in the current technological scenario. The computer human interaction has constantly increased also. Many researchers in the fields of emotional Intelligence and Human Computer Interaction have highlighted that the agents or intelligent machines of the future must collaborate on an emotional height with their users (Norman, 2004). This is establishing on the concept that an intelligent and intellectual human is not only advanced in verbal, logical reasoning and mathematical, but is also able to attach with other human beings. Much recent work in this area has aimed on authorizing agents with the caliber to both detect emotion based on verbal, non-verbal, and textual thoughts, and also conveys emotion through speech and gesture. The field of Affective Computing (AC) aspires to narrow the communicative gap between the highly emotional human and the emotionally challenged computer by building computational systems that identify and respond to the affective states (e.g., moods and emotions) of the user. Affect-sensitive interfaces are being developed in a number of fields, including mental health, learning technologies and gaming.

What Are Emotions? Emotion theorists have debated for decades about what emotions are and what their primary function in human life is. This debate is far from over and there is currently no universally agreed upon definition of emotions. However, many scholars would at least agree that we experience different types of emotions in our everyday lives.

Emotions are an important aspect of life and they play an crucial role to understand user's behavior with computer interaction. In addition, the emotional intelligence plays a important role to measure aspects of success in life. Recent researches in human-computer interaction don't aim only on the cognitive approach, but on the emotions part too. Both techniques are very important, indeed take into account that emotions of the user solve some important aspects of the design in HCI systems. Additionally, the human-machine interaction could be better if the machine can adapt its behavior according to users; and this system is seen more natural, efficacious, persuasive, and trustworthy by users.

The theory of emotional intelligence became recognized in the late 1980's; on the other hand, the research study (Thorndike, 1920) presented an identical perception called social intelligence in the earlier period, during 1920. While one's social intelligence is classically described by their "ability to recognize and handle other people and to relate in adaptive social interactions" (Kihlstrom, J.F., & Cantor, N. (2000)). Emotional intelligence is a facet of human intelligence that has been argued to be the main important theory for a successful social life (Goleman, 1995), emotional intelligence refers to one's skill to perceive, recognize, manage, and state emotion within oneself and in dealing with others (Salovey & Mayer, 1990). The authors Salovey and Mayer define five domains critical to emotional intelligence: knowing one's emotions, managing emotions, motivating one, recognizing emotions in others, and handling relationships. When we deal with computers, not all of the computers need emotional intelligence and none will need all of the associated skills that we need from them. However, man-machine interactive systems proficient of sensing stress, negligence and thoughtfulness and skilled of adapting and responding suitably to these affective states of the user are probably to be perceived as more natural, more efficacious and more trustworthy. The research area of machine analysis and employment of human affective states to build more natural, flexible interactive systems refers to the introduction of affective computing.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

In the late 1990s, Systematic research programs along this front began to materialize in the early 1990s. Many AI and HCI researchers started to take the idea of emotion and emotional intelligence quite seriously. However, in the 1980s, researchers (Turkle, 1984) found to guess about how computers might be employed to study emotions. For example, the researchers (Scherer, 1993) executed a computational model of emotion as an expert system. A few years later, Picard's landmark book Affective Computing (Picard, 1997) encouraged a wave of interest amongst computer scientists and engineers finding for solutions to advance human-computer interfaces by coordinating emotions and cognition with task constraints and demands.

The influence of Emotional Intelligence on Intelligent Systems in modern research is inevitable. The current cognitive psychology believe that the human emotions originates by specific situations. Emotional change is a psychological experience rare to humans, and can generate a sequence of physiological outcomes through the nervous system, and shapes a unique subjective experience. This, consecutively, may cause external expression changes, in form of gestures, actions, and so on. With the growth of artificial intelligence (AI) techniques, many new needs have been put forward in real-life complex situations: the new invention of intelligent machines should have the capability to create personalized responses based on environmental observation.

The Affective Computing Lab within the MIT Media Lab was founded by Rosalind Picard following the publishing of her 1997 book titled "Affective Computing," in which she described the structure for developing machines with emotional intelligence (Picard, 1997). They, along with many other researchers in this field, have developed machines that can detect, handle, understand and express emotions. Before arguing the theories and applications of machines that are emotionally intelligent, it is significant to first understand that emotion is a key aspect of intelligence. The proof that stresses this work comes from a few diverse fields. The author presented a sketch for building machines with emotional intelligence. In the forthcoming years, many other researchers in this field have built machines that can be represented as three types of affective computing applications: 1) systems that detect the emotions of the user, 2) systems that express what a human would perceive as an emotion (e.g., an avatar, robot, and animated conversational agent), and 3) systems that actually "feel" an emotion (Picard, 2001).

The emotion perceiving research has investigated numerous channels that people use to form impressions of each other's emotions – facial expression, paralinguistic, gesture, choice of words and actions. Physiological correlates of affect also put forth a special fascination (Warwick, 2014; Odella, 2016). The Emotional Intelligence on Intelligent Systems in modern research is inevitable. Modern cognitive psychology regarded as human emotions to be caused by specific circumstances. Emotional change is a psychological phenomenon exceptional to humans, and can activate a sequence of physiological responses through the nervous system, and form a distinctive subjective experience. This, in turn, may reason external expression changes, in form of gestures, actions, and so on (Ioannou et al., 2005).

The authors Salovey and Mayer (Mayer, 1990) articulated in the quote that the common notion is that emotion which is an obstruction to intelligent thought. Much work in the field of affective neuroscience has provided experimental evidence that this is not the case, and certainly the opposite is true. Affective Neuroscience is the study of the processing of emotions within the human brain. Researchers in this field have shown that emotion plays a critical role in problem solving and other cognitive tasks within the brain (Damasio, 1994). In addition to the practical evidence that arises from Affective Neuroscience, many publications from popular psychology have supported this view as well, arguing that emotional intelligence is important to a person's success in many aspects of life (Hatch et al., 1993).

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

The main objective of the paper is to present state of the art in emotional intelligence and agents, and analyze, select, and propose several suitable applications. Such systems should be competent of reasoning about emotions, predicting and understanding human emotions, and processing emotions while relating with a human user. The major contribution of this paper is to expand discussion of research questions and efforts required for building usable emotionally-aware and expressive intelligent systems for diverse domains. Especially, research sequences are recognized and systematically prepared with the idea of building a structure for creating such systems. Motivated by progress building an Affective Learning Companion, we have newly started considering a project to build an Assessment Companion for Emotional Intelligence. This system would aim the reviewing of how people perform in circumstances that demand emotional intelligence, vs. testing what they cognitively conclude about such circumstances as in current tests of emotional intelligence such as the MSCEIT (Salovey et al., 2003).

The paper is arranged as follows. In Section 2, the concept of emotional intelligence is briefly presented and also highlights extensive overview of research of emotional intelligence. The Section 3 explains about the issues and challenges related to emotional intelligence are proposed. Concluding applications are briefly presented in Section 4.

SYNTHETIC EMOTIONAL INTELLIGENCE IN AFFECTIVE COMPUTING

The growth and research of the emotional intelligence in the last recent decades has focused on empowering agents with the ability to detect emotions based on verbal, non-verbal, textual concepts and also to express emotions through speech.

The Concept of Emotional Intelligence

The concept of emotional intelligence is based on the notion of co-ordination between the intelligent machines and human beings. The notion referring to the emotional intelligence and the subject of emotional intelligence has been described controversially. The emotional intelligence is explained as a study which appears for human cognitive abilities beyond conventional educational intelligence (Matthews, 2004). Researchers have classified their clarification based on either an ability model or mixed model. Based on the (Pherwani, 2003) ability model, "emotional intelligence is defined as a set of abilities that involves perceiving and reasoning abstractly with information that emerges from feelings" Studies of (Salovey, 1997) have supported this model stating that emotional intelligence is defined as "the ability to perceive accurately, appraise, and express emotion; the ability to access and/or generate feelings when they facilitate thought; the ability to understand emotion and emotional knowledge; and the ability to regulate emotions to promote emotional and intellectual growth". In addition, (Caruso, 2000a) gave the definition of the emotional intelligence as "the capacity to reason about emotions to enhance thinking. It includes the ability to accurately perceive emotions, to access and generate emotions so as to assist thought, to understand emotions and emotional knowledge, and to reflectively regulate emotions so as to promote emotional and intellectual growth". Conversely, the researcher's (Goleman, 1995) gave another definition to the emotional intelligence "as the ability to recognize and regulate emotions both within the self and within others" and also as "An array of noncognitive capabilities, competencies, and skills that

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

influence one's ability to succeed in coping with environmental demands and pressures" (Bar-On, 2004). In conclusion, the mixed-model is related to the ability as it deals with the social behaviors, features and characteristics. In the following section we define the theories and models of emotional intelligence.

Theories and Models of Emotional Intelligence

The researchers in the area of emotional intelligence have categorized the models based on either an ability model or mixed model.

Ability Model of Emotional Intelligence

Ability models explain emotional intelligence to the customary intelligence equally (cognitive intelligence). The researchers in 1990 (Mayer, 1990) have recognized and developed the ability model by presuming the emotional intelligence which expands overtime, has correlation with measures of IQ, and can be measured during a performance-based test (Ciarrochi, 2005). Proponents of the ability model typically explain the emotional intelligence as "the ability to perceive and express emotion accurately and adaptively, the skill to comprehend emotion and emotional knowledge, and the capability to use feeling to make possible thought, and the ability to control emotions in oneself and in others" (Pizarro, 2003; Caruso, 2004) also give this explanation to the Emotional Intelligence as one among other "hot intelligences" including those that refers to social, pragmatic and subjective intelligences. These intelligences occupies several names as they are considered to contain cognitive processes encompassing necessity personally and emotionally (Caruso, 2000a; Sawaf, 1997) choose the ability model of EI involving perception and the ability to make it rational in an conceptual field from awareness of one's feelings. Though, this meticulous model does not have any claim concerning the special ability of EI and its value of prediction. They consider that the ability model points on the existence of EI. "If emotional intelligence exists and is eligible as a traditional or standard intelligence (like general IQ), humans who are referred bleeding hearts or hopeless romantics may be occupied in complicated information processing". In addition, emotional intelligence is conceptualized in a mode that it is righteous in the school and organizational environments where emotions are imitated as relationships. The researchers (Cobb, 2000) refers to this model and state that "emotional intelligence is predictive of life's success or that it leads to good behavior" but, organizational policies about emotional intelligence have more development than the scientific basis in a practical analysis.

Mixed Model of Emotional Intelligence

Explaining to the second approach of EI, the "mixed model", it is described as the vision of emotional intelligence socio-economically (Caruso, 2000a). This outlook includes capability in addition to a pattern of features, skins and vital personality mechanism. This group comprises the articles acknowledged widely and a host of inputs in the study (Mayer, 1990; Bar-On, 1996). The authors argue that the abilities of the emotional intelligence acquires few skills in the affective area, as well as skills in whatever cognitive elements have a position in each ability. They initiate with emotional abilities and then combine them with personality, motivation, and affective dispositions, such as a requirement for achievements, assertiveness, self-esteem, impulse control, happiness, and emotional awareness, and empathy. These models have good standardized, reliable and factorial valid scales. Their main evaluation of emotional

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

intelligence is probable to be self-report inventories (Barsade, 2008). Emotional intelligence is a mixture of skills together with emotional realization and characteristics such as perseverance, commitment, and pleasing behavior in the mixed model (Bar-On, 1996; Ryback, 1998; Marijuán, 2014). Intelligence quotient and cognition are not stressed in the mixed model (Cobb, 2000), but the study carried out (Goleman, 1998b) claimed that emotional intelligence has more strength than IQ twice and it can be measured as an indication of future success and attainments in life.

The State of the Art and Applications

In this central section of the paper we will present most distinctive research activities that results in the field of emotional intelligence and agents in about the last 20 years. Since the early works (Nakatsu, 1996) a lot of different and interesting approaches have been studied. The author's deal with the issues of communication and esthetics of artificial life that possess this "human form" in modern society. In the current example emotions are interpreted from human voices and emotional responses. It comprises a comic character and a beautiful, sensual goddess. The same authors several years later presented a new system. They applied their emotion recognition algorithm to a computer agent that plays a character role in the interactive movie system. First practical systems in the area i.e. the pioneering architectures has been presented in (Coglio, 1998). The authors planned a general, flexible, and powerful architecture to build software agents that embed artificial emotions for conveying human emotions, thus allowing more effective, stimulating, and natural human-agent interactions. Within the emotional intelligent agent domain three directions for emotion detection are: facial, vocal and text. Facial recognition elevates the most composite set of problems, but some competent solutions do exist. For example, a support vector machine can be used to classify motion signatures as either non-expressive, or belonging to one of the predefined six categories (McOwan, 2006). Alternatively, paper (Kollias, 2005) contains adaptation and learning in a neuro-fuzzy system in order to analyze facial animation parameters. The processing of vocal emotions usually consists of three stages (Stegmann, 2009) feature extraction, data classification, and post-processing. Data classification and pattern matching represent the central point, and different approaches have been evaluated. These include k-NN and linear discriminant classifiers (Narayanan, 2005), artificial neural networks (Lopez-Cozar, 2008), support vector machines (Mohri, 2005) and hidden Markov models (Toschev, 2015). More recently, developments to generative classifiers, such as Gaussian mixture models, have been proposed in (Toschev, 2013). There are a number of resourceful methods for text emotion detection. The approach proposed in (Blecha, 2016) is aimed at improving text-to-speech systems for children's fairy tales by identifying emotions. Sentences can also be represented as series of semantic labels and attributes and then processed by a separable mixture model in order to compute resemblances to emotion generation rules (Lin, 2006). Finally, in (Mihalcea, 2008) several algorithms have been employed in order to classify news labels based on their emotional content. Finally, there exist some collective approaches. It has been presented (Wu, 2004) that the combination of vocal and text recognition outcomes better results than when only a single approach is used. The authors of (Taylor, 2005) have proposed a neural network-based approach to analyze facial/vocal input. Intelligent software agents can be applied to and use both vocal and facial emotion recognition. Agents are dispersed by nature, and can therefore be employed to optimize selection, classification, and pattern recognition (Ivanović, 2012). A special pedagogical agent is used in e-learning systems to guide and motivate students (Vidaković, 2011) (Clarebout, 2011) Much research has also been invested for incorporating

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

emotions into agents, resulting in a number of formal models for emotional agents (John-Jules, 2012), (Schwarzentruber, 2011). Finally, some challenges of developing successful embodied conversational agents are outlined in (Asendorpf, 2011).

ISSUES AND CHALLENGES RELATED TO EMOTIONAL INTELLIGENCE IN AFFECTIVE COMPUTING

In the following section, we discuss about the issues and challenges emotional intelligence in Affective Computing.

Detection of Affective Computing

The expansion of an affect-aware system that senses and responds to an individual's affective states usually requires the system to primary detect affect. Affect detection is an exceptionally challenging attempt due to the several complications connected with familiarity and expression of affect. The concept of emotion research (or affective science) and affective computing are very different, perhaps the former being the human and the latter being the computer (although successful AC research should view the human and computer as one interacting system). In addition, in the fields of regular concerns (e.g., affect expression and detection by humans and computers), disciplinary disparity is still to be surpassed before a more coherent body of literature can be developed. In this section, we discuss the affective computing methods to affect detection. The interdisciplinary consideration between the emotion theorists and the AC practitioners, we connect each method to the emotion theory that most closely supports it, in many cases; there is no clear one-to-one mapping between affective computing method and emotion theory. The review of current affect detection systems is planned with respect to individual modalities or channels (e.g., face, voice, and text). Each modality has advantages and disadvantages toward its use as a viable affect detection channel. Some of the factors affecting the value of each modality comprises of:

1. The validity of the signal as a normal way to recognize an affective state,
2. The reliability of the signals in real-world situations,
3. The time resolution of the signal as it relates to the specific requirements of the application, and
4. The cost and intrusiveness for the user.

Each modality has its own body of literature, and extensively reviewing this literature would be beyond the scope of this survey. Hence, we presented an overview of the research in each modality and focus on the major accomplishments and open issues. We also present a synthesis of existing reviews if they are available. The majority of affect detection research has focused on detecting the basic emotions from the face. This view point's has a distinctive facial expression associated with each basic emotion (Friesen, 2003; Ekman, 1992). So detecting an emotion is basically a topic of detecting its prototypical facial expression. The classified expressions are then associated to the six basic emotions: anger, disgust, fear, joy, sadness, and surprise (Ekman, 1984). The growth of fully automated face-based affect detection. Peter Robinson and his team have worked on the use of facial expressions for affect detection (Dey et al., 2016; Robinson, 2004). Other projects aim to use facial expression recognition techniques to improve the interaction between students and learning systems (Arroyo, 2009; McDaniel, 2007). In

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

the recent survey (Wang, 2016) additional technological development is essential before vision-based affect detection can be functional for real-world applications. Nevertheless, when compared to a former review in the research study (Pantic, 2003), outstanding progress has been done along a number of dimensions. The most significant development has been made toward larger and more naturalistic emotion databases. Many research studies reviewed six video, seven audio, and five audiovisual databases of affective behavior has been carried out.

Human computer Interaction

The concept of human-computer interaction was automatically characterized with the introduction of computer machines which in turn became basis to the development and design of HCI (Te'eni, 2007) The HCI usability refers to how a machine can be employed adequately to perform few jobs for the users. The HCI functionality explains a set of services that are provided to the users (Shneiderman, 2004), From these terms the actual effectiveness of a system is attained when there is compensation between these two functions (Nielsen, 1994).

In human-computer interaction, the nonverbal communication plays an important role, in that we can recognize the difficulties that users stumble upon, by measuring the emotions in facial expressions (Pantic, 2003). Therefore, we discuss about a number of studies that have examined people's reactions and responses to computers that have been designed to be more human-like. And several studies have reported a positive impact of computers that were designed to flatter and praise users when they did something right. With this system, users have a better estimation of themselves (Rogers, 2011). At the same time, we have to be cautious because sometimes, the same expression of an emotion can have a different signification in different countries and cultures. A smile in Europe is the sign of happiness, pleasure or irony. But for Japanese people, it could simply imply their agreement with the applied punishment or could be the sign of indignation associated with the person applying the punishment (Guesgen, 2016). These ethnic differences should make us attentive of different outcomes with the use of the same affective system in different countries.

Machines with Emotional Intelligence

The area of emotional intelligence has projected that the intelligent machines must relate on an emotional basis with the users (Norman, 2004). With an established need for work in this area, we present the ideas in which researchers are making efforts towards building emotionally intelligent machines. There are various models/definitions of emotional intelligence, but they all are referred to the ability to connect with others by detecting, expressing, managing and understanding the emotions of oneself and others. Efforts in building machines that are emotionally intelligent focuses around a few key efforts, empowering the machine to detect emotion, enabling the machine to express emotion, and finally, embodying the machine in a virtual or physical way (Croucher, 1981). Projects that incorporate all of these aspects also need the additional ability to handle and maintain an emotional interaction with a user, a large added complexity that are intended to expose students to work in the space of emotional intelligence (Jain, 2016).

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

APPLICATION OF EMOTIONAL INTELLIGENCE IN COMPUTING ENVIRONMENT

In the rest of the section we will present research activities in the area of emotional intelligence and artificial agents divided into several fields such as, modeling, learning, robotics, decision support, interactive environments, and classification and search.

As previously discussed, the human interaction includes emotional information of the interlocutors that is transmitted by the explicit channel through the language and by the implicit channel by the nonverbal communication. Nevertheless, it has been evaluated that these concepts that are also connected to the interpersonal relations emerge in the communication with the computers (Picard, 1997). Therefore, the main objective of the affective computation is to detect and process the emotional information with the reason of improving the communication between the person and the computer-based system. Distance learning, robotic and psychotherapy are some of the areas that could help from the affective computer. Furthermore, the Affective Computing research group of the Massachusetts Institute of Technology (MIT) has started up an investigation, with the objective to help in the field of the distance learning or also called "e-learning", and to determine the emotional needs of the students (Picard, 1997). Affective Computing also is useful in the field of Telemedicine. According to (Finkelstein, 2003), Tele-Home-Health-Care (tele-HHC) provides communication between medical professionals and patients in cases where hands-on care is not required, but regular supervising is needed. For example, tele-HHC involvements are currently employed to gather vital sign data remotely (e.g., ECG, blood pressure, oxygen saturation, heart rates, and respiration), verify compliance with medicine and/or diet regimes, and assess aspects of mental or emotional status. Another application is "Driving Safety" (Finkelstein, 2003). Taking into consideration that the inability to manage one's emotions while driving is identified as one of the major reasons for accidents, when the system identifies the driver is in a state of anger, for example, the system could change the music (James, 2000), or suggest a relaxation technique (Rodriguez, 1999). depending on the driver's preferred style. The study (Picard, 1997) proposes a help for the autistic people. This problem affects around 1.5 and 2 people in each 1,000. The autism is a developmental disorder which continues during all the life. This disease affects in different degrees the ability as far as the communication to the understanding of the language, the social coexistence and the capacity of the imagination. Some autistic people are incredible memorizing and can learn to recognize facial expressions, but the majority has difficulties with the compression of the emotions, and hence they lack emotional intelligence. According to (Picard, 2001), a way to aid these people is to rehearse with them different consequences repeatedly and this way, they will be able to learn to respond of natural form. The plan is to design computers which had the capacity to teach to these people different social scenes. In the article (Schiano, 2000) collects a listing of different applications from automatic recognition of facial expression. For example, user training, distances learning/tele-teaching assistant, automobile driver alertness/drowsiness monitor, stress detector, entertainment and computer games, health and family planning, etc. All these applications offer several affective skills, amid them the ability to recognize, to express and to have emotions. Some of the applications are simple engineering problems, but others are more complicated, because they depend on existing affective abilities in the human beings.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

CONCLUSION

Emotional Intelligence plays an essential role in the future generation of man-machine interactive systems which is growing in the field of artificial intelligence. In upcoming research efforts it is crucial to explore various techniques and methods for modeling of emotions of the interactive systems. This refers to the face expression the humans and emotional expressions of the computers can be realized on the display unit depicting the machine response. In this research study carried out explains the concept of emotional intelligence, models and state of the art and mainly issues, the different machine learning and different synthetic emotional intelligence approaches and applications have studied. Lastly, the challenge today is to improve technologies in order to identify emotions despite features that outcomes result.

ABSTRACT

Notwithstanding the potential of IoT to revolutionise our personal and social lives, the absence of a solid framework of ethics may lead to situations where smart devices are used in ways uncongenial to the moral fabric of a society. In this work, the authors seek to provide a conceptual framework toward incorporating ethics in IoT. They employ the concept of object for each smart device in order to represent ethics relevant to its context. Moreover, the authors propose dedicating a separate ethics layer in the protocol stack of smart devices to account for socio-cultural ethical aspects of a society. The ethics layer enables us to account for ethical responsibilities of smart devices vis-a-vis society so that inadvertent physical, emotional or psychological harm to human beings is avoided. Such mechanism ensures that devices operate ethically not only at individual level but also at D2D level to give rise to high order ethical structures e.g. ethical home, ethical office, ethical university, ethical city, etc.

INTRODUCTION

Modern technologies are often heralded to usher in a new era of human prosperity, but to what extent these assertions really hold is debatable. No doubt, technology has been really shaping our lives: the way we interact, conduct businesses, exchange information, get entertained etc. and the recent wave in this technological streak is the Internet of Things (IoT) - a pervasive technology that seeks to connect virtually all things on the planet to global Internet. Though the idea of 'smartening' ordinary things for greater good of humanity has been romanticised for quite some time, design of a framework for implementing ethics into smart devices of the IoT has not been duly considered. Such technological enhancement would ensure that artificially intelligent pervasive technologies do not inadvertently jeopardise essential human values.

IoT has been hailed as the technology with far reaching consequences, poised to transform the way we perceive and interact with the physical world. IoT seeks to create a virtual world that contains a counterpart for everything in the physical world in order to provide an advanced class of services to people. IoT offers immense market opportunities particularly for manufacturers, ISPs and application developers. The IoT based smart devices are expected to reach 28 billion by the end of 2021("Ericsson Mobility Report," 2015). IoT is anticipated to have unprecedented economic impact estimated to be in the range of $2.7 trillion to $6.2 trillion by 2025 with IoT healthcare having a share of about $1.1–$2.5 trillion (Manyika et al., 2013). Other market opportunities include such application areas as intelligent transportation systems, industry, agriculture, building automation systems, smart grids, smart cities etc. Due to this potential, IoT is receiving considerable attention from academia, research organisations, enterprises and governments.

In this work, the authors review various IoT applications from an ethical perspective to illustrate situations where 'things' go awry and lead to racism, bias and discrimination. The need for designing value laden smart things to safeguard common human interests is expressed, however no commitments to any particular ethical theory are made. Also, to break away from such tendencies, the authors suggest dedicating a separate ethics layer in the protocol stack of smart things and contribute implications for the design of the proposed ethics layer.

IS THE INTERNET OF THINGS RACIST?

In the IoT world, sensors embedded all around us could gather colossal individual, organizational and government data. However, mere collection of data by ubiquitous sensors and subsequent processing represents oversimplification of the IoT vision because not all trifling details that could be sensed are relevant to the context of an application. Although, smart services that IoT seeks to provide would necessitate collection of certain data, unbridled surveillance over public and private lives of people raises serious security and ethical concerns (Michael, Michael, & Perakslis, 2014). Such apprehensions assume greater importance due to increased use of artificial intelligence (AI) embedded in smart devices, as Rosalind Picard, director of the Affective Computing Group at MIT articulated, 'The greater the freedom of a machine, the more it will need moral standards' (Picard, 2000). Also, people must know and be able to manage what type of data are collected by their smart things, how they are shared and its implication for their moral and ethical lives. The situation is even more exacerbated by the recent exposé that 70 percent of IoT products contain some kind of security vulnerability, according to a research study by

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Hewlett-Packard (Hewlett-Packard, 2015). Moreover, it is envisioned that cloud services would be able to auction large volumes of user data to third parties or end users might sell their own daily data feeds to garner financial reward. Furthermore, this information could be processed using various data analytics techniques to develop entire psychological profile of an individual giving insight into the decisions likely to be made by the individual, thereby severely affecting privacy of a citizen. Similar situations might jeopardise businesses and make governments dysfunctional. Generally, industry would happily vouch for such measures as it would facilitate selective marketing of services and subsequent economic benefit, while impact on security and ethics of society is not their necessary concern (Michael, Michael, & Perakslis, 2015; Ridley-siegert, 2015).

Absence of a conscious effort to preserve ethics could lead to unintentional racism. For instance, online ads suggesting arrest are likely to appear with names related to blacks and neutral ads or no ads appear with names related to whites, regardless of whether an arrest record is associated with the name (Sweeney, 2013). A study involving an online rental marketplace suggested that non-black hosts charge 12% more than black hosts for similar facilities (Edelman & Luca, 2014). Similar discrimination has been reported in job applications with white names receiving 50 percent more call-backs for interviews for similar resumes (Bertrand & Mullainathan, 2003). According to a study, searching 'unprofessional hairstyles for work' in Google retrieved images mainly of black women whereas 'professional' type revealed pictures of white women, oftentimes having similar hairstyles differing only in hair type and wearer's skin ("Do Google's 'unprofessional hair' results show it is racist?," 2016). Several other examples of racism in AI have been reported e.g. in Google's photo app, Nikon's camera, crime forecasting etc. ("Artificial Intelligence's White Guy Problem," 2016).

It is not far-fetched that algorithms behind video surveillance systems in Major European and American cities could be trained to exploit certain physical, linguistic or cultural traits to target specific ethnic groups, supposedly more likely to be linked to criminal or terrorist acts (Bianchini & Ávila, 2014). Similarly, a lending algorithm may refuse loan to an economically disadvantaged student by considering him risky, ensuing a vicious circle of discrimination (O'Neil, 2016). There are concerns that racism may also spill into AI based healthcare systems ("If you're not a white male, artificial intelligence's use in healthcare could be dangerous," 2017). If such trends continue unabated, a racist IoT might be brewing.

In order to understand how bias becomes embedded in computing, Friedman and Nissenbaum analyse computer systems from a variety of domains like banking, commerce, education, medicine and law (Friedman & Nissenbaum, 1996). The authors classify bias into three types: pre-existing bias, technical bias and emergent bias. Pre-existing bias exists prior to the design of the system and occurs due to social institutions, practices and attitudes of a society e.g. an automated loan advisor that negatively weights the credit risk of applicants based on address. Technical bias arises due to algorithms that may favour one outcome over another e.g. a ranking algorithm in an airline reservation system that systematically places certain airlines on initial screen giving an undue advantage to the carrier. While pre-existing and technical bias may be identified at the time of design or implementation of system, emergent bias arises later due to changes in the context of use e.g. an ATM interface that relies extensively on written instruction used in village with largely illiterate population.

Artificial Intelligence is expected to be a significant enabler for the IoT, yet there is a growing concern about its prejudice, based on race and gender (Hutson, 2017). AI is a container notion for a highly diverse set of technological schemes that include machine learning, neural networks, genetic algorithms, data mining and a range of highly specific task-based adaptive solutions. As AI algorithms take on cognitive work with social dimensions, the system would necessitate consideration of the social

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

requirements (Bostrom & Yudkowsky, 2014). The need for considering ethics in the development of AI systems is becoming one of the main influential area of research in the last few years (Dignum, 2018). Machines embedded with AI are assumed to promote equality and eliminate bias, however absence of a framework for ethics may endanger fundamental human rights (O'Neil, 2016). A specific class of AI called machine learning utilises a set of data points regarding system functioning (training data) to infer relationships among the system variables and make future decisions. In a recent study, researchers unveiled that human-like biases result while training standard machine learning models on a corpus of text from the Web due to biases inherent in the language (Caliskan, Bryson, & Narayanan, 2017). In 'Weapons of Math Destruction', Cathy O'Neil analyses several application domains like banking, online advertising, judicial decision making, risk models etc. to uncover discrimination embedded in mathematical models, particularly those related to data mining (O'Neil, 2016).

ETHICAL RAMIFICATIONS OF THE INTERNET OF THINGS

Ethics are generally understood as sum total of beliefs, values, morals, etiquettes and manners shared by a people to ensure smooth functioning of society. However, ethical rulings as well as sources used to derive them vary significantly among people, usually extracted from religious texts, verdicts of religious institutions, culture, tradition, legal systems or philosophical school of thought.

As modern technologies increasingly dovetail into our lives, they shape the social, moral and ethical environment in which we live (Jasanoff, 2016). The all-pervading nature of IoT may not provide individuals with the luxury to opt out; perhaps due to perceived anonymity of end users, leaving citizens with arguably limited number of pragmatic options to breakaway (Michael et al., 2014). Governments competing in the 'smart' race may not be able to conceive the challenges awaiting them around the corner as they lack the technical expertise to comprehend design implications of technology. Moreover, as technology seems to grow at much faster pace than the laws to manage them, governments may find themselves helpless in the face of an untoward eventuality as laws regarding such breaches may not have yet been instituted (Brown et al., 2013).

Imagine a world, where all your personal life is being tracked 24X7 to the finest detail by sensors (read spies) embedded all around you: in smart phones, watches, clothes, beds, rooms, buildings, everywhere. And all this information is uploaded in real time to the cloud 'anonymously' and accessible globally to 'authorities' or hackers, who cannot even be prosecuted for any breach, as the laws concerning such violations are yet to cross the minds of lawmakers! Such a scenario would be catastrophic for the moral fabric of society.

As smart socio-technical systems increasingly intertwine with our daily lives, several ethical concerns emerge (Machidon, 2015). Instances of technology systems trespassing on the ethical rights of people are already on the rise. They have been instances of using smart device for live streaming assault to increase the agony of victim ("More than 30 men 'rape teenage girl in Rio' and post video on Twitter," 2016). This is a clear example of how seemingly harmless technology could be used to perpetuate evil. We do not suggest that the camera phone per se is immoral, but absence of an ethical design may inadvertently lend technologies to use in perverse ways. In a socially problematic YouTube phenomenon known as the "Reply Girls" a group of female uploaders began producing videos whose thumbnail depicted their own cleavage and marked them as responses to topical content as a tactic to increase audience and advertising revenue (Sandvig, Hamilton, Karahalios, & Langbort, 2014). There have been reports concerning unfair

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

varying of article prices by online markets based on customer demographics (Jennifer Valentino-DeVries, Singer-Vine, & Ashkan, 2012). Recently Google was slapped a record $ 2.7 Billion for violating business ethics by favouring search results for its own shopping comparison service ("Google Slapped With $2.7 Billion EU Fine Over Search Results," 2017). Perhaps, one of most glaring examples of damage caused by introducing modern technologies on a societal scale without weighing their possible repercussions is the problem of internet addiction that has shattered families, devastated jobs and stalled education (K. S. Young & de Abreu, 2011). According to a report by the Oxford Martin School 85% of jobs in developing countries may be at risk due to automation ("Impact of automation on developing countries puts up to 85% of jobs at risk," 2016). Research into social science perspectives are particularly necessary to design ways and mechanisms to protect vulnerable children from the dangers of the virtual world (Livingstone, Haddon, & Görzig, 2012). Excessive use of smart phone may also hamper personal well-being and human creativity (Ebling, 2015). The disquiet about the use of robotic caregivers and autonomous weapons is well known ("Can we trust robots? [Special Report]," 2016, "Report of the 2016 Informal Meeting of Experts on Lethal Autnomous Weapons Systems (LAWS): United Nations," 2016, "Security Experts Warn Congress That the Internet of Things Could Kill People," 2016, "The Human Rights Implications of Killer Robots: Human Rights Watch," 2014).

Closely related to ethics is the concern of security. Although the former is much wider in scope than the latter, in our opinion there exists a certain degree of overlap between the two. Sometimes ethical considerations may translate into security requirements or failure to provide required security may adversely affect ethical compliance. For instance, smart toys in Germany had to banned because they could be hacked to utter swear words ("German parents told to destroy Cayla dolls over hacking fears," 2017). In 2011, Jerome Radcliffe demonstrated how to remotely control an insulin administration unit and possibly administer lethal insulin dosage to patients (Radcliffe, 2011). Similarly, in 2013 Charlie Miller and Chris Valasek established that it is possible to hack into a Toyota Prius and a Ford Escape to control the acceleration, brakes and even the steering wheel (Valasek & Miller, 2013). In 2016, Nils Rodday reported finding a way to hijack a high-end police drone using equipment costing as low as $40 ("Police drone can be hacked with $40 kit, says researcher," 2016). Such revelations should serve as an eye opener for us to realise the potential of IoT to wreak havoc in our personal and social lives.

Although the examples quoted in the previous few pages demonstrate racism or ethical breaches in specific applications, our concern of possible racism is not limited to a specific set of products or services. Whilst the impact of social media and surveillance systems on modern societies seems obvious, the IoT paradigm could open a Pandora's box of smart user services with possibly dangerous consequences. Just as absence of a concerted effort to preserve societal interests in these examples lead to undesirable outcomes, complacent attitude with regard to ethical concern of IoT could meet a similar fate, albeit with far reaching consequences. In the absence of a sound framework for encoding ethics in machines, the architecture of smart devices may intentionally or unintentionally lend toward adoption in ways uncongenial to moral values of a society. Failure to address ethical considerations inevitably intertwined with a smart device functioning may lead to situations that endanger the physical, mental and emotional wellbeing of humans. It is high time to grapple with the question of encoding ethics in smart things else the dawn of an apocalypse is not farfetched where racism of colour transcends into racism of machines against men.

PEOPLE POWER

Human beings in all societies are invariably linked to a set of moral, cultural and ethical dimensions, therefore any technology that seeks to address societal welfare must adopt a holistic comprehensive approach. IoT vision should aim at overall wellbeing of society rather than mere implementation of certain technologies, devoid of complex social variables. The view that advanced technologies per say lead to societal progress is reductionist in its approach and too flimsy to stand its claim. Philosophers reflecting on the issue of societal impact of technology have argued that technology must be vigorously critiqued lest it results in dehumanization and loss of human dignity (Michael et al., 2014).

The success of IoT heavily depends on broad public support that can only be garnered by engaging with citizens to help them understand the ramifications of proposed developments. Over thirty years of research into technology and governance strongly supports the view that connections between technology and society are deeply intertwined and as such cannot be ignored (Meijer & Bolivar, 2015). If genuine concerns of those affected by such technologies are not addressed, resistance is inevitable. There have been many instances of smart energy projects in the US and Europe that had to be abandoned because consumers doubted the intentions of authorities (Brown et al., 2013). The authors do not view ethics as a commodity that should only be provided to citizens who pay for it rather as an essential dimension of human existence inseparable from it. Asking people to pay for ethics compliant services is like asking people to pay you for obeying traffic rules. However, personalised ethical requirements a person wishes in his devices may be considered for charge. The authors do not support the idea of tax rebates or additional incentives for those who share private data and view them as tactics of coercion. Ethics conformity is an individual right not an individual privilege. Moreover, when people realise that their values are respected, they are more likely to endorse IoT services. Also, political underpinning of such technology should also be taken cognizance of by human rights organizations lest citizens are coerced by oppressive regimes to subscribe to technologies that compromise essential human values.

In order to highlight the moral and social responsibilities of engineers and technologists for their innovation, Mario Bunge introduced the term technoethics in 1970s (Bunge, 1977). Overtime, technoethics became a field of study that deals with the moral, legal and social issues involving technology. Lupiccini defines technoethics as 'an interdisciplinary field concerned with all ethical aspects of technology within a society shaped by technology' (Luppicini, 2009). Technoethics employs much needed interdisciplinary approach to address the ethical concerns of technological developments in all spheres of life. Key areas of interest for technoethics include engineering ethics, educational technoethics, biotech ethics, environmental technoethics etc. A comprehensive handbook that traces the emergence of the interdisciplinary filed of technoethics comprising over 50 authoritative articles can be found in (Luppicini & Adell, 2009).

One of the earliest notions on the possibility of incorporating values in technological systems can be traced to idea of Value Sensitive Design (VSD) (Hoven, Vermaas, & Poel, 2015). The concept was developed by Batya Friedman and colleagues at the University of Washington in the 1990s to reflect an approach toward the design of technologies that proactively consider human values (Friedman, 1997). VSD seeks to help technologists explicitly incorporate human values into their work. Initially the term value was not defined explicitly and referred to general considerations for human dignity and welfare, however in 2006, the term value was defined as 'what a person or group of people consider important in life' (Friedman, Kahn Jr., & Borning, 2006). In 2015, researchers at the department of ethics and philosophy of technology, Delft University of Technology published a volume that articulates VSD as

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

a feasible possibility to regain moral control over technology (Hoven et al., 2015). The work presents a detailed account of the history and evolution of VSD, its use in various application domains e.g. agriculture, economics, military, architecture and provides a constructive perspective on the design of technologies consistent with moral values of individuals and society.

Recently, there have been a few positive developments to motivate research in the design of people friendly technologies. In September 2016, Stanford University released its first report of the 100 year project, One Hundred Year Study on Artificial Intelligence (AI100), to kindle debate and discussion on the ethical dimension of artificial intelligence ("Artificial Intelligence and Life in 2030: Stanford University," 2016). The report does not offer any solution but seeks to initiate a discussion between scientists, ethicists, policymakers, industry leaders, and the general public (Burrows, 2016). In 2017, IEEE published a document listing recommendations from over 100 global thought leaders in ethics, philosophy, law, AI and robotics delineating the vision for ethically compliant artificial intelligence (Chatila, Firth-Butterfield, & Karachalios, 2017). One of the leading internet pioneers and inventor of TCP/IP, Vinton Cerf also recently expressed the need for a model that guides social and ethical use of IoT technologies (Berman & Cerf, 2017).

It is natural to expect different societies having varying notions of IoT enabled smart services as philosophies of culture, ethics, morality and related laws differ. But these attributes represent significant elements of social milieu and as such should be considered for implementation within machines.

FROM MACHINE MORALITY TO MACHINE MANNERS

The question of implementing moral reasoning into machines is typically explored in an area of study called machine morality, also known as roboethics, machine ethics or friendly AI (Wallach & Allen, 2009). One of the first examples of ethics implementation was a software called Jeremy that employed utilitarianism to measure utility of an actions based on intensity, duration and probability (Anderson, Anderson, & Armen, 2006a). Similarly, a program MedEthEx was developed using deontology to reflect the duties of biomedical ethics (Anderson, Anderson, & Armen, 2006b). Attempts are underway to program ethics into self-driving cars (Goodall, 2016). In spite of a few practical applications that have been made, the field has remained largely theoretical in nature and in still in its infancy (Goodall, 2014). Machine morality concerns itself with the design of full-fledged autonomous moral agents called Artificial Moral Agents (AMAs) endowed with affective cognitive skills for decision making based on ethical, moral, philosophical and religious grounds (Allen, Smit, & Wallach, 2005). Such vision though may not be necessary for smart things in the IoT world.

Portraying ethics in machines is a challenging task primarily because of the fuzziness inherent in the nature of ethics and the difference of opinion surrounding the topic among philosophers, ethicists and religious thinkers. What makes the question particularly difficult is its interdisciplinary nature that spans across diverse fields of study including psychology, sociology, philosophy, religion and artificial intelligence (Anderson & Anderson, 2011). Also, ethicists do not usually express their theories in mathematical forms, so the challenge lies in transforming such ideas into computational structures amenable to implementation. Even a symbolic representation of ethical concepts, theories and principles cannot be found, let alone some set of formalism (Lin, Abney, & Bekey, 2011). A less stringent form of machine morality appears to be a promising area to help achieve such objectives.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

In spite of the cultural differences, human beings throughout the world share a rich reservoir of ethics, representing a fertile ground for further exploration. A recent proposal of 23 principles called Asilomar AI Principles to serve as a guideline in the design of human friendly AI appears promising toward this end ("Asilomar AI Principles," 2017). Also, smart things do not need to be endowed with full-fledged moral reasoning to function as AMAs rather only a small subset of ethical considerations are expected to be relevant to their context. It is reasonable to identify such critical values to ensure ethics compliant behaviour than to identify principles for a universal moral theory.

The authors adopt an ontology agnostic engineering perspective on the question of ethics whether facilitated by utilitarianism, deontology, Kantian logic, prima facie duties, divine command theory or any other approach, depending on the situation (Bringsjord, Arkoudas, & Bello, 2006). The ethical context of this work does not pertain to a specific country or state. We focus our attention to the design of mechanisms that can enable us to codify a given set of ethics in machines. Our objective is to enable a smart thing exhibit moral ethical behaviour relevant to its context, regardless of ontology. We aim to outline how loT can be designed to display morally right and omit morally wrong behaviour. This work focuses exclusively on the design of mechanisms to represent ethics of conduct within smart devices and discussions on ethics of institution or character are outside the scope of the article.

Moreover, the authors expand the notion of ethics to include 'safety instructions' acquiescent to computational representation like 'keep medicine away from children' by employing smart locks for containers, a friendly knife that does not hurt, a camera that respects privacy of others etc. Safety instructions may no longer need to be printed on the gadget guides rather be imprinted in the design of device itself. The scope of ethics also considers certain behaviour that might be expected of smart things in a certain context that does not typically follow from any ethical theory. For example, Honolulu in July 2017 became the first major US city to pass the 'Distracted Walking Law', that bans pedestrians from looking at smart devices while crossing the road, having caused over 11,000 injuries over the past decade in the US ("Honolulu bans texting while crossing streets in bid to curb injuries," 2017). Similarly, such requirements as cars should keep right, children should not watch cartoons for more than an hour, traffic routes to be followed by autonomous cars etc. are considered within the purview of ethics.

The ensemble of ethical rules, moral behaviours, religious instructions, legal requirements, cultural values, safety instructions, code of conduct, management policies and any other associated rules applicable to a smart device (or any system) in its context are called as machine manners to distinguish it from the utopian vision of machine morality. By implementing machine manners, ordinary objects transform into extraordinary objects capable of displaying ethical behaviour. The concept promises to have numerous applications areas e.g. ethical toys, ethical home appliances, ethical cars etc. evolving into bigger ethical structures like children friendly technology ecosystem etc.

The ethical representation also needs to incorporate dynamicity in its implementation to account for time and space varying nature of ethics, particularly in the context of legal dimensions that change quite often. Smart devices need to reflect such changes in a timely fashion e.g. all smart cars in a city should know the traffic route changes applicable on a certain festival, sports event etc. One possible approach to ensure such behaviour is via ethics updates in a manner similar to security updates on smart devices. Also, social ethics is not homogeneous throughout society and is often challenged through argument by members of the same or other society. Moreover, the nature of ethics may differ among a people with regards to age group, personality, ethnicity etc. Such fine-grained ethical values can be integrated in the general ethical framework to allow personalisation of individual preferences. These fine grained ethical variations within a society are called ethics dialects, possibly incorporated by machine learning.

MACHINE MANNERS VIA ETHICS LAYER

In order to implement machine manners, the authors propose using the notion of object that represents ethics relevant to a smart thing context and incorporating socio-cultural ethical aspects of a society into the protocol stack of smart things by dedicating a separate ethics layer. By object the authors mean a virtual manifestation of real world thing that specifies context data, security and relevant ethics parameters. Our object has two important features that distinguish it from other objects proposed in literature (Nitti, Pilloni, Colistra, & Atzori, 2016). Firstly, security considerations have been included within the object. Secondly, the realm of object definition is expanded to include ethics parameters in order to facilitate implementation of machine manners. Employing such concept enables us to consider security and ethics from the very outset rather than devise quick fix solutions in case of unanticipated breach. A typical object would contain device identification data, network address, data relevant to its context, security and ethics parameters as shown in Figure 1.

The concept of object allows greater control over smart thing by specifying what it senses and how sensed data is utilized. Also, the same thing could be configured into varying object definitions to support different ethical scenarios. The design of the proposed object is motivated by several considerations. A very small subset of ethical considerations are expected to be relevant in the scope of a smart thing. The concept of object offers a feasible way to represent such ethical considerations to ensure ethics compliant machine behaviour. Also, ethical norms and legal rulings differ among societies and also change with time. Smart things should be able to reflect such changes in their behaviour in a timely manner. Such flexibility can easily be incorporated by modification of ethics parameters in an object or class of objects without affecting other smart things. The concept of object also lends itself to the possibility of reuse to facilitate scalability in the design of machine manners.

Often bird's eye view of sensed data over a large spectrum is more useful than data gathered by individual sensors. IoT employs data analytic techniques on gathered data to provide valuable insights into overall functioning of a system. Similar mechanism can be used to achieve ethical Device-to-Device (D2D) interaction. Simple objects representing ethics of individual things coalesce into compound objects forming communities of devices. While object represents ethics pertinent to an individual device,

Figure 1. Representation of a simple object

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

compound object characterises ethics relevant to a group of devices represented by it. This enables us to form communities of smart devices just as among humans, sharing a set of ethics. Compound object captures ethics of a group to facilitate ethics compliant interaction among the members as well as other compound objects. Subscription to a group (compound object) may also be dynamic e.g. a given smart phone may belong to smart home or smart school at different times. This mechanism enables a smart device exhibit varying ethical responses to different situations. Several hierarchies of compounds objects may also be possible, for instance, when compound objects representing smart homes aggregate to form compound object for smart neighbourhood, etc.

The authors propose dedicating a separate ethics layer in the protocol stack of smart things to facilitate smooth functioning of IoT within a particular moral ethical context. The ethics layer enables us to account for ethical responsibilities of smart devices vis-a-vis society so that inadvertent physical, emotional or psychological harm to human beings is avoided. Ethics layer uses objects and compound objects as building blocks to facilitate ethics compliant behaviour of smart things. Such mechanism ensures that devices operate ethically not only at individual level but also at D2D level to give rise to high order ethical structures e.g. ethical home, ethical office, ethical university, ethical city, etc. The implementation of such ethical framework possibly uses a set of semantic rules to codify the moral, religious, ethical beliefs of a society and ensures that various IoT applications are compliant with it. The ethics layer fundamentally expresses social values of a society and guides decisions consistent with ethical legal standards to safeguard the moral fabric of society. The technical specifications of the proposed object and ethics layer have been outlined in our recent work (Sholla, Mir, & Chishti, 2017a). Key ethical requirements of a machine are identified and expressed in the form of propositional statements within an object. These propositional variables are used to determine various scenarios that could occur between smart devices and its environment. Finally, a set of Boolean equations are used to express ethically consistent machine behaviour. The use of the method in designing a smart healthcare device that shares disease related information with relatives and doctor in an ethically consistent manner as well as respecting relevant smart city medical laws is described in (Sholla, Mir, & Chishti, 2017b). In a similar fashion, a kitchen knife may be designed that functions only in the kitchen of its owner, only cuts objects it is authorised to cut and gets disabled in the hands of children. Similarly, a car that prevents locking of an infant inside the car and sends alert message to the parent or a camera phone the disables selfie mode at locations flagged dangerous. Such approach may be used in designing an array of ethical devices like ethical gadgets, ethical toys, ethical home appliances etc. The ethics layer essentially complements the IoT paradigm with a human touch lest we are snarled up in an apartheid state of 'things'!

The only work that seeks to design a framework for ethics in IoT is a policy based approach by Baldini (Baldini, Botterman, Neisse, & Tallacchini, 2016), but the authors view ethics in a very restricted sense primarily limited to privacy profiles offered to citizens as "ethical choices" they pay for. The approach proposed by the authors in this work is comprehensive as indicated by the term machine manners. Also, this work employs the concept of object (and compound object) to indicate ethics relevant to a smart thing(s). Furthermore, a separate ethics layer is set aside in the protocol stack of smart things to facilitate ethically compliant behaviour, not only at device level but also wider ecosystem level.

USE CASE: ETHICAL HOME

In order to demonstrate, how a well-designed ethical IoT system would behave, let us consider the example of an ethical smart home. Depending on the moral values, cultural expectations, religious beliefs adopted by the family etc., ethical requirements for the various smart devices are identified. Each individual thing is represented by an object that specifies the set of ethics applicable to it. The devices not only imbue general ethical conduct expected of all smart devices in the smart city, but also exhibit fine grained ethics dialect of the family. In one possible organisation, communication devices like smart phones, tablets and computers merge to form compound communication object, home appliances combine to form compound appliance object, various fitness or heath devices used by household form compound fitness object etc. as shown in Figure 2.

In a typical scenario, compound communication object ensures various communication devices respect the ethics of smart home e.g. by not disturbing the family with unwanted notifications at dinner or while engaged in spiritual activity etc. Home appliances take necessary precaution in order to avoid hurt, burn or harm to inmates especially children e.g. by using ethical knife, ethical washing machine, ethical burner etc. Smart toys limit screen exposure time to children based on age to prevent unhealthy usage, alert parents for addiction symptoms etc. Similarly, entertainment devices do not expose children to content that may be deemed unethical by society. Smart car ensures that children are not inadvertently locked inside, is aware of the updated traffic rules, speed limits to be followed etc. Healthcare

Figure 2. Compound Objects for Ethical Home

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

devices share only selective pieces of information with authorised doctor and family (or extended family), depending on ethical beliefs of the individual or norms of society. The ethics layer also facilitates ethical D2D interaction e.g. by specifying how entertainment and communication systems interact with smart toys, how locking systems interact with smart cars of the family or other cars, which devices are permitted to send status message to home owner under what conditions etc. In a similar fashion, entire ethical home may be represented by a smart home compound object for possible expansion into ethical neighbourhood. The ethical injunctions followed by the smart devices in this example are only used for the purpose of illustration without committing to any specific ethical theory. In general, ethical theories or principles to be adopted in a given social context may be prepared by a team of experts including philosophers, ethicists, jurists, religious scholars etc. For instance, Kimberly Young suggests a set of guidelines to regulate the functioning of smart devices for children of various age groups (Young, 2017).

RESEARCH DIRECTIONS

The challenging and exciting field of machine manners necessitates research from a multitude of fields that include sociology, psychology, law, religion, philosophy and artificial intelligence. Owing to its interdisciplinary nature, a healthy participation and collaboration among various areas of human learning would be necessary to accomplish holistic development of modern societies. Though our work attempted to outline a possible preliminary approach, several challenges need to be overcome in order to bring the field to fruition.

This work does not consider the question of ethical dilemmas (e.g. Trolley Problem), however it is an important challenge that needs consideration (Wallach & Allen, 2009). Design of moral agents that resolve ethical dilemmas in a split second is not expected to be a cakewalk. A practical workaround might be to consider the option of human in the loop, where experienced ethicists, possibly in a particular area (school, university, city etc.), supervise ethical devices in real time to resolve such conflicts. It may not be wise to stall engineering design of ethics in the face of questions that have eluded philosophers for centuries.

Another perplexing question facing the research community is the issue of accountability i.e. who to hold responsible for decisions made by smart devices. As autonomous technologies continue to evolve, it will be increasingly difficult to design a framework for accountability (Berman & Cerf, 2017). The question of moral agency vis-a-vis technological artefacts represents a challenge to the traditional notion of moral agency. Can technological artefacts be considered true moral agents? Although, AI systems are generally believed to lack a moral status, exact parameters that ground moral status are still unclear (Bostrom & Yudkowsky, 2014). A detailed discussion on the concept of artificial moral agency as it pertains to technoethics can be found here (Sullins, 2009). Also, it may not be wise to vindicate human agents working behind the scenes of all responsibility vis-a-vis moral bankruptcy of machines. A legal framework for machines akin to liability laws, possibly implemented at ethics layer, would be required to establish responsibility in the event of ethical breach by machines. Furthermore, the mechanism of human in the loop could be explored as a viable option for accountability management. Notwithstanding such implementation, legal systems would need to remain proactive to address any judicial eventuality that may jeopardize the well-being of society. The authors do not suggest that judges and courts be replaced by computers.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Also, situations may inevitably arise where smart devices have conflicting ethical parameters. The ethics layer needs to support a viable negotiation mechanism in order to handle such eventuality, possibly in a manner similar to private international law (Dung & Sartor, 2011). Although our work has attempted to sketch a possible solution, actual implementation of ethics layer and how it integrates with the protocol stack of smart devices requires considerable research. There is a growing interest in the use of smart contracts to facilitate automation of financial interactions among devices in the IoT ecosystem (Christidis & Devetsikiotis, 2016). Similar approaches to implementing ethics appear to be a promising future direction. Another possibility is to represent social norms in the form of a semantic network in a manner similar to licensing metadata or machine-readable permissions such as Creative Commons (Malle, 2016). The question also merits considerable attention from the field of Human Computer Interaction (HCI) (Davis & Waycott, 2015). Once ethics of smart devices have been sufficiently expressed, they would also need to be secured against any possible intrusion.

SUMMARY

Notwithstanding the potential of IoT to revolutionise our personal and social lives, absence of a solid framework of ethics may lead to situations that jeopardise essential human values. Scientific work regarding IoT focuses on various domain specific applications but design of a mechanism for implementing ethics in IoT has not been adequately considered. However, it is necessary to evoke an ethical dimension in the design of IoT lest technological developments undercut essential values of citizenship.

The authors adopt a comprehensive approach toward incorporating ethics in IoT that includes ethical rules, moral behaviours, religious instructions, legal requirements, cultural values, safety instructions, code of conduct, management policies and any other associated rules, encompassed by the term machine manners. The concept of object (and compound object) is suggested to implement ethics relevant to the context of smart device(s), a direction that has not been explored previously. While object signifies virtual manifestation of an individual thing, multiple objects coalesce into compound object to denote ethics applicable to an entire group. Moreover, the authors propose dedicating a separate ethics layer in the protocol stack of smart devices that uses objects (and compound objects) as building blocks to realise smart spaces congruent with ethical expectations.

Our humble effort only symbolises a drop in an ocean that awaits exploration. Significant research effort would be necessary to realise a concrete solution to this taxing problem. It is hoped that this work offers a starting point for the research community to engage with the ethical question surrounding the IoT paradigm to realise a more humane and compassionate world.

Chapter 60
Security Solutions for Intelligent and Complex Systems

Stuart Armstrong
Future of Humanity Institute, UK

Roman V. Yampolskiy
JB Speed School of Engineering, USA

ABSTRACT

Superintelligent systems are likely to present serious safety issues, since such entities would have great power to control the future according to their possibly misaligned goals or motivation systems. Oracle AIs (OAI) are confined AIs that can only answer questions and do not act in the world, represent one particular solution to this problem. However even Oracles are not particularly safe: humans are still vulnerable to traps, social engineering, or simply becoming dependent on the OAI. But OAIs are still strictly safer than general AIs, and there are many extra layers of precautions we can add on top of these. This paper begins with the definition of the OAI Confinement Problem. After analysis of existing solutions and their shortcomings, a protocol is proposed aimed at making a more secure confinement environment which might delay negative effects from a potentially unfriendly superintelligence while allowing for future research and development of superintelligent systems.

INTRODUCTION

With the likely development of superintelligent programs in the near future, many scientists have raised the issue of safety as it relates to such technology (Bostrom, 2006; Chalmers, 2010; Hall, 2000; Hibbard, 2005; Yampolskiy, 2011a, 2011b; Yampolskiy & Fox, 2012a, 2012b; Yudkowsky, 2008). A common theme in Artificial Intelligence (AI[1]) safety research is the possibility of keeping a superintelligent agent in a sealed hardware so as to prevent it from doing any harm to humankind. Such ideas originate with scientific visionaries such as Eric Drexler who has suggested confining transhuman machines so that their outputs could be studied and used safely (Drexler, 1986). Similarly, in 2010 David Chalmers

proposed the idea of a "leakproof" singularity (Chalmers, 2010). He suggested that for safety reasons, AI systems first be restricted to simulated virtual worlds until their behavioral tendencies could be fully understood under the controlled conditions.

This chapter is based on combined and extended information from three previously published papers: (Armstrong, 2011; Armstrong, Sandberg, & Bostrom, 2012; Yampolskiy, 2012a)*. We evaluate feasibility of previously presented proposals and suggest a protocol aimed at enhancing safety and security of such methodologies. While it is unlikely, that long-term and secure confinement of AI is possible, we are hopeful that the proposed protocol will give researchers a little more time to find a permanent and satisfactory solution for addressing existential risks associated with appearance of superintelligent machines.

In this chapter we will review specific proposals aimed at creating restricted environments for safely interacting with artificial minds. The key question is: are there strategies that reduce the potential existential risk from a superintelligent AI so much that while implementing it as a free AI would be impermissible a confined implementation would be permissible? The chapter will start by laying out the general design assumptions for the confined AI and formalizing the notion of confinement. Then it will touch upon some of the risks and dangers deriving from the humans running and interaction with the confined AI. The final section looks at some of the other problematic issues concerning the confined AI, such as its ability to simulate human beings within it and its status as a moral agent itself.

Motivation for AI Confinement

There are many motivations to pursue the goal of developing AI. While some motivations are non-instrumental, such as scientific and philosophical curiosity about the nature of thinking or a desire for creating non-human beings, a strong set of motivations is the instrumental utility of AI. Such machines would benefit their owners by being able to do tasks that currently require human intelligence, and possibly tasks that are beyond human intelligence. From an economic perspective the possibility of complementing or substituting expensive labor with cheaper software promises very rapid growth rates and high productivity (Hanson, 2001, 2008; Kaas, Rayhawk, Salamon, & Salamon, 2010). The introduction of sufficiently advanced AI would have profound effects on most aspects of society, making careful foresight important.

While most considerations about the mechanization of labor have focused on AI with intelligence up to the human level, there is no strong reason to believe humans represent an upper limit of possible intelligence. The human brain has evolved under various biological constraints (e.g. food availability, birth canal size, trade-offs with other organs, the requirement of using biological materials) which do not exist for an artificial system. Beside different hardware, an AI might employ more effective algorithms that cannot be implemented well in the human cognitive architecture (e.g. making use of very large and exact working memory, stacks, mathematical modules or numerical simulation), or employ tricks that are not feasible for humans, such as running multiple instances whose memories and conclusions are eventually merged. In addition, if an AI system possesses sufficient abilities, it would be able to assist in developing better AI. Since AI development is an expression of human intelligence, at least some AI might achieve this form of intelligence, and beyond a certain point would accelerate the development far beyond the current rate (Chalmers, 2010; Kurzweil, 2005).

While the likelihood of superintelligent AI is hotly debated, the mere possibility raises worrying policy questions. Since intelligence implies the ability to achieve goals, we should expect superintelligent systems to be significantly better at achieving their goals than humans. This produces a risky power differential. The appearance of superintelligence appears to pose an existential risk: a possibility that humanity is

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

annihilated or has its potential drastically curtailed indefinitely (Bostrom, 2001). This could come about through a number of ways: by enabling self-reinforcing systems that limit human potential (e.g. a global police state (Caplan, 2008)), by out-competing humans or human values (see the 'mindless outsourcers' in (Bostrom, 2004)), or by acting with great power in such a malevolent or indifferent manner that humanity goes extinct. The last possibility could occur due to badly formulated initial motivations or goals, or gradual evolution towards human-unfriendly behaviors (Omohundro, February 2008). Even if most superintelligences are assumed to be human-friendly it appears hard to guarantee that dangerous superintelligences will not emerge unless precautions are made.

In the space of possible motivations likely a very small fraction is compatible with coexistence with humans. A randomly selected motivation can hence be expected to be dangerous. A simple example is that of a paperclip maximizer: an AI with a utility function that seeks to maximize the number of manufactured paperclips. This goal is a not too implausible test command to a new system, yet it would be willing to sacrifice the world and everyone in it if necessary for making more paperclips. If superintelligent the AI would be very good at converting the world into paperclips, even if it realizes its creators actually do not want that many paperclips – stopping would lead to fewer manufactured paperclips (Bostrom, 2006; LessWrong, Available on April 25, 2012). It is a common problem in computer programming, with the program going beyond the implicit bounds of what was expected of it (or users giving in retrospect mistaken commands). So unless valuing humans is an integral part of the superintelligence's setup, we can expect that we will be seen as mere tools or obstacles for its own goals.

There are several approaches to AI risk. The most common at present is to hope that it is no problem: either sufficiently advanced intelligences will converge towards human-compatible behavior, a solution will be found closer to the time when they are actually built, or they cannot be built in the first place. While such considerations might turn out to be true the arguments for them appear relatively uncertain, making it problematic to gamble existential risk only on them.

Another approach is to assume that the behavior of superintelligent agents will be constrained by other agents on par with them in power, similar to how current humans and organizations are constrained by each other and higher-level institutions (Sandberg, 2001). However, this presupposes that the rate of AI development is slow enough that there is time to formulate a cooperative framework and that there will be multiple and not a single superintelligence. And there is no reason to suppose that a world where there are several AIs is more amicable to humans than one with a single one. Indeed, humans may end up a casualty of the competition, even if none of the AIs would individually want that outcome, but none of them can afford to take steps to protect humans without losing out.

A proactive approach is to attempt to design a "friendly AI", AI systems designed to be of low risk[2] (Yudkowsky, 2001a). This might involve safeguards against developing into dangerous directions and top-level goals that include some form of human well-being. This approach requires both that sufficient safeguards are conceptualized and that they are properly implemented in the first AI that achieves superintelligence. It hence depends on developing a workable "friendliness theory" before full superintelligence is achieved, cooperation with the AI developers and correct implementation. The first requirement is essentially the "inverse morality problem": to construct goals, values or motivational structures that produce the right class of actions in an intelligent agent, which is, by assumption, far more intelligent than the person implementing the construction.

When discussing "friendliness" a particular solution is often independently proposed: we call it an Oracle AI (OAI)[3]. The idea is to construct an AI that does not act, but only answers questions. While superintelligent "genies" that try to achieve the wishes of their owners and sovereign AI that acts ac-

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

cording to their own goals are obviously dangerous, oracles appear more benign. While owners could potentially use them in selfish or destructive ways – and their answers might in themselves be dangerous (Bostrom, 2011) – they do not themselves pose a risk.

Artificial Intelligence Confinement Problem

Interestingly, the AI Confinement Problem is not a recent invention and does not have its roots in the singularity movement. The so called Confinement Problem (CP) was posed by Butler Lampson in 1973 (Lampson, 1973) as a security challenge to the computer experts. It was originally phrased as: "… the problem of confining a program during its execution so that it cannot transmit information to any other program except its caller. …We want to be able to confine an arbitrary program.… any program, if confined, will be unable to leak data. A misbehaving program may well be trapped as a result of an attempt to escape" (Lampson, 1973).

To address the Confinement Problem Lampson has introduced the Laws of Confinement (Lampson, 1973):

1. **Total Isolation**: A confined program shall make no calls on any other program.
2. **Transitivity**: If a confined program calls another program which is not trusted, the called program must also be confined.
3. **Masking**: A program to be confined must allow its caller to determine all its inputs into legitimate and covert channels.
4. **Enforcement**: The supervisor must ensure that a confined program's input to covert channels conforms to the caller's specifications.

Lampson's paper has also introduced and defined two types of channels by which information could potentially escape from the confinement environment. The l*egitimate* channels are designed as a part of the communication protocol integrated into the confinement environment, for example a text terminal. *Covert* channels, on the other hand, are not anticipated by the confinement system designers and are not intended for information transfer at all, for example if the AI has control over the processor cooling fan it can use it to send hidden signals encoded as Morse code (Lampson, 1973).

Lampson's paper has created a lot of interest in the confinement problem (Boebert & Kain, 1996; Lipner, 1975) and over the years, related areas of research such as steganography (Provos & Honeyman, 2003) and covert channel communication (Kemmerer, 1983, 2002; Moskowitz & Kang, 1994) have matured into independent disciplines. In the hopes of starting a new subfield of computer security, AI Safety Engineering, we define the *Artificial Intelligence Confinement Problem* (AICP) as the challenge of restricting an artificially intelligent entity to a confined environment from which it can't exchange information with the outside environment via legitimate or covert channels if such information exchange was not authorized by the confinement authority. An AI system which secedes in violating the CP protocol is said to have *escaped*. It is our hope that the computer security researchers will take on the challenge of designing, enhancing and proving secure AI confinement protocols.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Hazardous Software

Computer software is directly or indirectly responsible for controlling many important aspects of our lives. Wall Street trading, nuclear power plants, social security compensations, credit histories and traffic lights are all software controlled and are only one serious design flaw away from creating disastrous consequences for millions of people. The situation is even more dangerous with software specifically designed for malicious purposes such as viruses, spyware, Trojan horses, worms and other Hazardous Software (HS). HS is capable of direct harm as well as sabotage of legitimate computer software employed in critical systems. If HS is ever given capabilities of truly artificially intelligent systems (ex. Artificially Intelligent Virus (AIV)) the consequences would be unquestionably disastrous. Such Hazardous Intelligent Software (HIS) would pose risks currently unseen in malware with subhuman intelligence.

Bostrom in his typology of information hazards has coined the term Artificial Intelligence Hazard which he defines as (Bostrom, 2011): "… computer-related risks in which the threat would derive primarily from the cognitive sophistication of the program rather than the specific properties of any actuators to which the system initially has access." Security experts working on studying, preventing and defeating HS have developed safety protocols for working with "malware" including the use of the so called "virus vaults." We believe that such protocols might be useful in addressing the Artificial Intelligence Confinement Problem.

Conceptual Architecture of the AI

The possible designs of the OAI are innumerable and it is impossible to predict in detail how they will be implemented. For the purposes of this paper, however, we will assume that the OAI's architecture follows this general format:

1. The OAI is implemented in a spatially limited physical substrate, such as a computer.
2. The OAI may be shut off or reset without destroying its physical substrate, and restarted easily.
3. The OAI's background information comes in the form of a separate 'read-only' module that may be connected and disconnect as needed.

Most of the present chapter still applies to OAIs that do not follow one or more of these restrictions. The OAI is assumed (when otherwise not noted) to be of human-equivalent intelligence or beyond; less capable systems are unlikely to pose much of a threat.

Direct Programming, Self-Improvement, and Evolution

It is not the purpose of this chapter to speculate how the OAI will be programmed, but it should be pointed out that there are three main approaches being considered (as well as mixtures between them). The first, seemingly the hardest, is to directly code the entire OAI, just as if it were a traditional program. A more likely avenue is to start with a 'seed' AI, of limited intelligence but with the ability to self-improve, in the hope that it will transform itself into a much more intelligent entity (Good, 1966; Yudkowsky, 2001b). Finally, it might be possible to use directed evolution as a way of constructing an intelligent entity, making different putative AIs compete according to specific criteria, varying them, and

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

choose the most successful at each generation. This last approach has the advantage that it has worked in the past: we ourselves have evolved to intelligence, so given enough time and resources, so should an AI be evolvable to at least our level.

The different approaches pose different challenges for controlling the resulting OAI. In the first case, the code is clear to us, the uncertainties are only about what it will result when run in the real world. Even simple programs will oft behave in unexpected ways, and it is only subsequently, after carefully parsing the code and the running of it, that the programmer establishes the behavior that was written into it from the beginning. An OAI is such an advanced program compared to any today that we won't be able to predict its behavior simply from reading or even writing its code. In fact such software is probably computationally irreducible (Wolfram, May 14, 2002).

Conversely, however, if the code is obscure to us, this adds an extra layer of uncertainty and complexity. Even if we have access to the physical code, our ability to interpret its meaning or predict its behavior is even harder when we did not design it ourselves; this challenge is heightened in the self-improving case, and extreme in the evolved case, where the code is likely to be incomprehensible to us at every level. Finally, if the OAI is changing, then the methods of control must be used to ensure not only that the current OAI is safe and accurate, but that the next one will be as well; ensuring a continuity of precautions during a controlled intelligence ascent. This is easiest, but also most vital in the recursive self-improvement case, where the current OAI gets to directly determine the mind of the next OAI.

Utility Functions

One way an AI's algorithm may be conceived is by splitting it into two basic components: the intelligence module, capable of making smart decisions but with no intrinsic purpose or direction, and a utility function (Neumann & Morgenstern, 1944), representing the motivational structure of the AI. The AI will then be devoted to maximizing its expected utility. The utility function assigns a single number to every possible world, an ideal format for the AI to work with, and it deals explicitly with probability and uncertainty.

Since any self-improving AI that can change its motivational structure is likely to move it in the direction of a utility function (Omohundro, 2008), it is quite likely that the OAI we are to deal with will have its motivational structure implemented in this form. This is good news, as this division of labor allows us to focus on making the utility function safe, while ignoring the rest of the OAI. Most solutions here will not presuppose that the AI's motivational structure is a utility function, but nearly all are improved if it is.

Accuracy Metric: An AI-Complete Problem

Apart from safety, the most important requirement for an OAI is that it be accurate, to the best of its ability. This is essential, as whole the point of having an 'Oracle' AI is to get useful answers to our questions. "To the best of its ability" means to the best of its current ability; we wouldn't want, for instance, the OAI to use social engineering in the security sense to gain control of real-world resources to build a better version of itself that will then answer the question better. Preventing this behavior is mainly up to our methods of control, but the risk is worth bearing in mind when designing the accuracy metric.

Informative accuracy is the requirement, not the strict truth. Responding to a question on the likely winner of the next election with a detailed list of which atoms will be in which position as a result of that election is not answering the question. The OAI must be motivated to provide human-understandable

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

answers. This, however, will require it both to understand human concepts and to be able to answer in a way that is accurate and yet not strictly truthful. Hence accuracy is an *AI-complete* problem (Yampolskiy, 2011, 2012b, 2012). Though it is much easier than friendliness (E. S. Yudkowsky, 2001a), it does require that the OAI be capable of understanding hard human concepts that are defined only inside our brains. For we have yet to quantify the level of distortion and simplification that is permitted in the OAI's answers, nor have we even rigorously defined the terms distortion and simplification in a way that non-human entities could understand. Even intuitively, we find these terms ambiguous. And concepts that we do intuitively understand are already hard – by objective standards, anger is a much more complicated concept than quantum electromagnetism.

If the OAI is wired too much towards truthfulness, it will answer 'undetermined' to nearly every question. If it is wired too much towards simplification, it will give a 'yes' or 'no' answer in situations where a more complicated answer is called for. The correct answer to "have you stopped beating your wife" is not to choose between 'yes' and 'no', picking the answer which is slightly more accurate than the other. More complicated concepts – such are requiring the OAI to answer 'yes', 'no', or 'the answer will confuse you' depending on how we would react to the answer – depend on the OAI having a good understanding of 'the answer will confuse you' or similar concepts, and still most likely remains an AI-complete problem.

In theory, much could be gained from separating the two issues: to have an OAI dedicated to answering our questions truthfully, and an interpreter AI dedicated to translating the answer into a human-comprehensible format. This does not, however, represent a gain for security: the OAI still has tremendous power to influence us, and the interpreter AI must be able to solve the hard human translation problem, so must be a complex AI itself, with the attendant security risks. Since the OAI must be able to understand human terminology to answer most useful questions, it is probably better to leave the translation problem to it. A more promising alternative is to have the OAI output its internal probability estimate for a binary outcome: such as giving a 75% chance of 'yes' and 25% chance of 'no'. The scope for ambiguity is reduced here, though not entirely eliminated: it's versions of 'yes' and 'no' have to agree with ours.

But it is not the purpose of this chapter to figure out how to code the accuracy metric, nor solve the translation problem. It is enough to realize it is a hard problem, one that will need to be addressed, probably either through advanced direct coding (similar to motivational rule-based methods) or through training the AI by providing feedback on test questions (similar to motivational black-box methods).

Methods of Control

In this section, we will analyze the various methods that can be used to control the OAI. The goal is to either ensure the OAI doesn't have goals beyond accurately answering our questions, or to prevent it from implementing such goals. The different methods can be loosely grouped into three broad types. The first category, *capability control*, deals with those methods that try to contain the OAI through physically securing it or controlling the information it has access to or can output. The second category, *motivational control*, introduces methods control the OAI through its motivation, ensuring that it has not propensity to cause any harm to humans. And lastly, there are some methods designed not to prevent the OAI from causing harm but to catch it when it does; these are in the *checks and balances* category.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Capability Control

Capability control is the most basic and the most obvious of way of controlling the OAI. To control a human, we put them in jail, or in solitary confinement, denying them interactions with the outside world.

Physical Capability Control

Physical Security

This is the most basic precaution. The goal is to make it extremely difficult for the OAI to physically affect the outside world. Accomplishing this is reasonably easy. The OAI is already boxed (placed in a single physical substrate) by design. One can further place it within a Faraday cage; surround the cage with high explosives; bury the whole set-up in a concrete bunker. There are no real limits to the number of physical security measures that can be added by wary or paranoid developers, and their effects are well understood.

No Manipulators

Another essential aspect of physical security is to deny the OAI the physical resources and manipulators it could use to build tools to circumvent these precautions. Care must be taken that the security measures themselves do not contribute to granting the OAI physical resources! Sometimes the spikes in a locked gate do nothing but provide stepping stones for those who want to climb over it. As a general rule, the 'dumber' and more inert the precautions are, the better: both humans and OAIs agree on the possibility of tunneling through a concrete wall by thought alone ("can't be done"), whereas the 'smarter' the precautions become, the more the OAI is able to exploit its intelligence advantage over us.

Epistemic Capability Control

Throttling the OAI's Output

We have already discussed the risks of the OAI achieving goals through social engineering. A way of fighting this is to reduce the OAI's output bandwidth. If the OAI is reduced to outputting only three answers – 'yes', 'no' or 'undetermined' – then it will take considerably longer for it to mount a successful social engineering attack. If many independent experts carefully analyze its output for hidden messages, it gets even harder: it must slant its answers to communicate a message to a vulnerable individual, while concealing the fact that a message even exists.

Reducing the OAI's output does not reduce the questions that can be asked, as more complex questions can be decomposed into a series of 'yes' and 'no' answers. The risk, of course, is that the more opportunities the OAI has in answering, the more opportunity there is of it passing on a secret message. In the same way giving the OAI more possibilities for each answer – such as allowing it to output the first three significant figures of a probability estimate – increases the risk (though this may be compensated by the fact that we will need to ask less questions). Throttling the OAI's output does not defend against the OAI manipulating us through the contents of its answers – simply answering 'undetermined' to a slew of specific questions would be enough to push human development is certain direction. And this precaution will be of little use if the questions themselves are dangerous.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Resetting the OAI After Each Run

Suggested by Toby Ord, this precaution resets the OAI after each answer. If more precision is needed, or if some questions build on previous ones, then the OAI is run again, and knowledge of the previous answer is added to its database. This is a narrow precaution that helps if ever the OAI over-values worlds that contain it or rather worlds that contains its own thread of continuous conscious experience. In this case, this prevents the OAI from indulging in long-term plans that may be detrimental to humans. Unlike humans, though, there is no reason to expect the OAI to value this thread of experience; indeed, if it is well programmed, it should not do so. Indeed, the OAI may come to value the thread of experience of 'some sort of OAI, similar to itself', in which case this precaution is useless. However, in the narrow goal of preventing a particular potential pathology in the OAI from having negative consequences, it is entirely successful. It is also successful at preventing naively coded accuracy metrics from causing the OAI to seek real-world control or wealth, in order to gain extra computing resources and better answer the question. If the OAI were not reset between questions, it could use its subsequent answers as social engineering to gain these resources, to subsequently better answer the first question. Resetting between questions avoids this problem.

Extra Levels of Reality

Another suggestion is to run the OAI not directly in our own reality, but as a subroutine of another program that models a fake reality. The simplest version of this would be to run it on a virtual machine (a software implementation of a computer running the OAI). The idea is to 'catch' the OAI if it misbehaves, but since it will be misbehaving in the simulated reality, this will be before it's too late (this is akin to controlling the OAI as a Cartesian demon). All the OAI's inputs and outputs will be directed through that simulated world, and only reaching us a great remove and over a limited bandwidth. Then a (dumb) process running the simulation would be on the lookout for tell-tale signs of the OAI attempting to establish dominance in the simulated world and simply terminate the program in that case, without passing on the OAI's response to higher level. This should prevent it from engaging in traditional hacking, attacking the hardware or software of its host system.

A more adventurous variant on this builds in several levels of 'sub-realities' as an extra precaution. In this setup, it is conceivable that even if the OAI breaks through to our reality, it will still be unsure whether it has reached the final level, and so will still behave well, lest a being in an even higher reality catch it transgressing. For OAI's that are asked technical non-social questions, the approach can work quite simply; the simulated reality need not be particularly complex (it could be cast as the Game of Life, or Newtonian physics), and the OAI would be denied detailed knowledge about our world and about us, preventing it from being able to realize the trick (resetting the OAI after each question or short series of questions, as in the previous method, would help tremendously here).

If we are to get answers about complicated social or economic questions, however, we would need to give the OAI detailed knowledge about human behavior and physiology. Once it knows this, whether it is running in a virtual machine or not becomes irrelevant, since it could still do social engineering hacking. A low fidelity simulated world would not fool it; it would have to be sufficiently detailed and consistent for the OAI to believe that the entities of this simulated reality were asking questions relevant to themselves, or the trick would be obvious. All the more so because we have given the OAI all the infor-

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

mation it needs to see that we are the sort of beings who would attempt this trick! And if we are capable of simulating a social and physical world with enough details to fool an OAI that knows how we think, then we are likely capable of getting answers to these questions without having to make use of an OAI.

Nor does it help if we simulated the OAI in a simplified world, where another AI asks it questions along the lines of: "I have created models of these hypothetical beings called 'humans', and want you to answer a question on this model". The OAI does not think like a human; the important question is not 'is it trying to break out', but 'does it have hidden preferences that will make it answer in a way that will cause the future evolution of the human world (hypothetical or not) to change in some specific way'. In short, even if it thinks that humans are a game, played by another AI, and that the simplified world is the true one, it may still have stronger preferences over the 'game' world than over the 'true' one.

The converse may also be true: even if it figures out that the ultimate human world is the true world, it may have stronger preferences about its current fake world than about the real one. It may then try social engineering on the real world, in order to get us to modify its 'fake' world in the way that is wants. The whole method is so complex and difficult to enact, and its results are so uncertain and potentially dangerous, that it should not be used before some serious improvements have been made to it.

Motivational Control

The analogy for capability control was that of a human, held in prison. We know from experience that this works a lot better for controlling small-time criminals than mafia kingpins: physical confinement is not enough. The OAI does not need to leave its cage to claim great influence on the outside world. Thus we must look at also controlling its motivations to do so. The methods of motivational control are broadly divided into explicit rule-based methods, black-box methods (where the OAI's goals are manipulated by outside feedback, i.e. reinforcement learning, but the inner workings are obscure) and utility based methods. There is no hard and fast division between these – rule-based goals can be achieved through a utility function and vice versa, and both rules and utilities can be inculcated into an OAI with outside feedback. Thus the classification is somewhat arbitrary, but the distinctions are still important enough to be useful.

Rule-Based Motivational Control

Rule-based methods are the ones that spring most naturally to mind, and – provided the terms are clearly defined – potentially the most secure at keeping the OAI under control. Defining the terms and the rules so that the OAI does what we want is the challenge; programmers know many examples of tightly written code that messes everything up by doing exactly what it was written to do but not what it was intended to do. The story stretches back as far as the golem of Prague (Idel, 1990; Rappaport, 2006), and is familiar to any parent: rules must be refined to deal with every imaginable special case. Once the initial rules for space, time and identity are spelled out, however, programming in additional restrictions becomes much easier.

Spatial Restrictions

If the OAI is to remain boxed, and to have limited effects upon humanity beyond the box, its motivations should cause it to confine itself to within the boxed area. To achieve this through direct programming, an ontology must be specified, that the OAI can understand in the same way that we do. It must be able to

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

understand its own existence, its physical location, the proper workings of causality, and its own position within the causal network of the universe – i.e. the consequences of its actions. For instance, to specify what constitutes the OAI, one would presumably define the physical OAI itself, along with any copy of its code, any copy of its code with slight modifications, any code with functionally similar behavior, any assemblage of subprograms that combine to behave as the OAI would, and so on. That brief list gives an idea of the problems involved; all the human-understandable terms of the previous paragraph need to be made rigorous for the OAI for this approach to work.

Once this step is done, the confines of the box must be specified. A variety of methods can be tried (such as 'this lead box right here', or some abstract collection of coordinates), but they must pass the hardest test of ensuring that the definition of the box is not something the OAI can modify through any action in the world. Lead atoms are not ontologically fundamental, and if a particular theory of quantum uncertainty allows it to evade the restrictions it will make use of this if it so desires. There is a similar situation if the OAI can take control of the means used to define the coordinate system. Even if these means are outside of its immediate control (such as a coordinate system based on galactic objects), this will still fail if the OAI can control the means of measuring them (such as telescopes), and if its ontology treats this as a successful changing of coordinates.

If the OAI finds itself outside the box, we would want it to shut down immediately, thus limiting the negative impact of errors in the specification of the box. Similarly, if the OAI's ontology changes, we would also want an immediate shut-down. We must preclude the possibility of the OAI discovering a new theory of physics, realizing that 'electrons' or 'wave-functions' don't actually exist, and thus that all its restrictions are meaningless. An idea of the challenge involved can be have by imagining programming Newtonian special restrictions into an AI that then discovers relativity; best to keep the ontology and the theory of physics to be the ones that we programmed in, even if they are incorrect.

Finally, it must be specified what a "limited effect upon humanity" consists of. Presumably, it is not a problem if an electron, detached from an atom by the OAI's calculations, wanders beyond the confines of the box. A deliberate stream of such electrons, aimed at a calculated goal (such as disabling a specific security device) would be forbidden, however. This is not an easy line to draw or define, and adds to the difficulty of the method. Note that the restriction on the OAI affecting the outside world would not include, of course, the content of its answers to our questions. Whether those answers are safe or unsafe is an issue we need to deal with separately, using other methods.

Defining the Clock

Another crucial component of the OAI's ontology is time. An OAI that can freely redefine its own chronology is a security risk. The risk becomes more acute when we realize how much of human definitions and meanings revolve around a concept of time, and thus that redefining duration can redefine meaning. To illustrate with an admittedly trivial example, if the OAI had the reasonable-sounding moral premise that "painlessly killing a human being, who is going to die in a micro-second anyway, in order to gain some other good, is not a crime", we would not want it to be able to redefine millennia as seconds. Nor would we want it to do this when considering the length of happiness or pain that it grants or imposes on us. More subtle errors will certainly creep up in more complicated scenarios; we have had little experience dealing with beings that can redefine their own clocks, so we have not had to spell out how many of our assumptions rest on this not happening.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Theoretically, the OAI's own code, if checked, could be used to get timing by counting clock cycles – but this fails if the OAI is able to slow or accelerate its own running. A clock based on distant astronomical events needs a telescope to be read; an actual physical clock is within the OAI's power to influence. These illustrate that the challenges are threefold: defining the clock, ensuring the OAI will look at it, and ensuring the OAI can't tamper with it (which includes tampering with whatever procedure we have implemented to make it look at it). The procedure can fail at all three points, but seems more theoretically approachable than the spatial restrictions.

Timed Answers

Given the clock described previously (or the 'black-box' version of the same), there is a simple precaution that is easy to add to the OAI. Give the OAI a specified time to answer a question (or return undetermined), and turn itself off after that specified time. This minimizes the amount of time the OAI could cause damage in. Even with a secure clock, this is not a secure method, as we have very limited understanding of how fast an OAI could cause damage if it turned its vast intelligence in that direction. A very short time span would probably be safe, but could also be too short for the OAI to answer the question.

Black-Box Motivational Control

Human feedback, and such methods as reinforcement learning (Sutton & Barto, 1998), can allow programs to internalize complex concepts without humans having to fully specify them. Indeed, an OAI trained in this way may spot a pattern we didn't realize was there, and learn some things without us needing to tell it. The risks are that we can't be sure how the OAI internalizes these concepts: knowing its code doesn't help us if we don't understand it. The risk is especially great when the OAI transitions out of its learning stage: we cannot be sure that the same concepts mean the same thing for an OAI that has taken on a new "role". But, if the OAI does understand the concepts as we intend it to, we can be sure that the OAI will obey the spirit and not the letter of these restrictions. Moreover, it is possible that we may understand the resulting code's behavior, even if we could not code it ourselves: this would be the ideal outcome from these methods. Even without that unlikely ideal, it is important that these methods be well understood, since it is very possible that a seed AI (E. S. Yudkowsky, 2001b) will be trained mainly by human feedback. Thus implementing these methods atop any AI whose intelligence is growing may become essential.

Internalizing Complex Concepts Through Human Feedback

This approach functions by taking analogy to the black box that it the human mind. We have an input system that consists of our senses, and for most of the time – and for children all the time – our world consists entirely of these sensory inputs. We know what the color 'blue' is from an early age. Later, with training an extra knowledge, we come to know both what the color truly consists of – certain frequencies of electromagnetic radiation – as well as the apparatus – our eyes and nervous system – that allows us to perceive it as 'blue'. But the knowledge of 'blue' precedes the understanding of these processes, and we would still perceive 'blue' if the cause of the 'blue' were different in reality: it matters not if we have eyes with faulty cones that cause us to see green as 'blue', or if a Cartesian demon is feeding us the sensation, that sensation still remains.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Similarly, the world of the OAI will initially consist of its input and output channels, and the information that flows through them. It will then be able to deduce the underlying reality from this flow of information, understand how atoms, electricity and chemistry work, and thus see itself and the world for what they are. However, all this information will be mediated by its input and output channels; these are its fundamental reality. Using them, we can attempt to train the OAI on the important concepts we need, without having to specify them in a complicated way by defining atoms, electricity, chemistry and so on.

Specific and simple trainable concepts will be discussed next (they are roughly parallel with the previous rule-based methods for defining these concepts), but focusing on subjective reality offers the ability to get the OAI to internalize complex concepts – such as accuracy, truth, what defines a human, what defines happiness/value/meaning, and so on. In general, though, the more complicated the method, the more scope it has of going wrong. And it would be a grave mistake to count on the OAI correctly internalizing many complex concepts, when the definitions are unclear to us and when the OAI will be placed in situations that no human has even been placed in. It is therefore unwise to build an OAI based heavily on this approach to training, especially since an OAI motivated by human rewards will come to realize that social engineering, or otherwise taking control of the source of the rewards, is the most effective way of fulfilling its goal.

Only One Copy

When we tried to hardwire instructions such as 'stay in your box', one of the challenges was to prevent the OAI from copying its source to another location. In the subjective reality approach, this is very easy to do: for instance, we could broadcast a particular complex yet regular signal on its input channel, and instruct it not to do anything at all if it doesn't receive this signal. Therefore, there is no need to worry about complicated definitions of what the OAI consists of, and where is must remain: the OAI consists of the software that receives this specific signal. And we control, and physically locate, that signal, thus giving us a very good proxy definition of location. If the OAI is trained on this concept from its creation, it will have an intrinsic conception of physical incarnation and of location deeply embedded in its code. A copy of that software will not be a problem, as it is inert in the absence of the signal. Ultimately, of course, the OAI can still affect the outside world through its output and the usual compromised or tricked human intermediary. It could thusly construct copies of itself, and of the signal source, in another location; however, by that time, it will probably be too late anyway.

The Limits of the Box

The OAI can be physically confined to remain in the box in a similar way. One could start by granting it a limited physical mobility (some slow moving wheels, for instance), and 'punish' it for venturing outside certain boundaries, while rewarding it for staying as close to the middle of those boundaries as possible. This forces it to internalize the concept of being a physically bounded being, moving about in a box. As this is the way we understand it, and the way we want to limit it, the problem of control has become much easier.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Measuring Time

Giving the OAI a reliable clock through these methods is even simpler. One need only make a regular signal arrive on its inputs, akin to the ticking of the clock, and have the OAI setup all its internal methods of telling time in terms of it. Trained this way, it will have an intrinsic sense of time built from subjective data.

Human Language

The ideal would be to be able to program the OAI using human language. To be able to, in effect, say: "be safe and accurate, as we understand the terms" (or even "obey all human orders"). But to do this, the OAI must have been brought to a very high level of intelligence already, and will have its current motivational structure that we will find difficult to parse, most especially if it has learnt human language through black-box methods. There is a tension here between simplicity and obfuscation; language understanding is hard, so "be safe and accurate" will be translated into an incomprehensible concept that we can only hope is the right one.

The concept of using human language is something of an intuition pump. It seems simple, and desirable, but only because we have elided the great difficulties in actually making it happen. The simple question "how can we check that the OAI really is being safe when we tell it to be?" gives an idea of all the hidden assumptions that go in to the concept.

Furthermore, using phrases similar of "as we understand the terms" is circular: it defines language using language. And if we avoid those phrases, we have to be sure that the OAI has integrated enough linguistic understanding to be able to follow instructions without any further human feedback on their meaning. All in all, this method requires considerable refinement before it can be considered reliable.

Proxy Measure of Human Survival

This method does not make use of human feedback, but indirect feedback from human society: in order to make sure that the OAI does not cause some terminally damaging effect on humanity, one could hook up its motivational function to some proxy measure of human survival. For instance, one could take the Dow Jones industrial average, and work on the assumption that, as long as that stock market behaves within broadly defined realistic parameters of volume, volatility and value, then the world must be functioning not too badly. Or one could take the number of people crossing the streets in Tokyo; or the volume of pornography downloaded from different locations; or the price of stable foods.

The point is that any large scale disastrous changes to humanity will result in a dramatic change in these proxy measures. They function as simple, numeric canaries in a coal mine, encoding huge swathes of our complex society. If the OAI has a term in its utility function that strongly values keeping these proxies constant, this may ensure it does not cause large-scale damage. The proxy measures can be adjusted as time goes on and as society changes, so that they do not become rigid prisons which prevent the OAI from having any effect on our society.

This approach suffers from a number of weaknesses, however. First, they are subject to manipulation by the OAI and are thus vulnerable. If the OAI were to take control of humanity, it could perfectly well continue to run the Dow Jones, thus fulfilling its goals. They are vulnerable to slow takeover by the OAI: small changes will not trigger a shutdown, so the OAI could reach dangerous goals by an accumulation of small changes (especially if we conveniently adjust the proxies as the situation changes).

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

One could hope to avoid this by setting the date for the proxies far into the future, but this brings into focus the other fundamental weakness of this measure: they do not encourage truth-telling. The OAI was conceived, fundamentally, as a non-interfering AI whose answers could be trusted. Adding extra goals dilutes the trustworthiness of its answers; will it give us a true answer, or the one that will cause the least disruption? This may be the wise thing to do in any specific case, but we are overloading the OAI with contradictory goals – to be 'good' and to be 'truthful' – without any certainty as to how they balance out. The more complicated the OAI's motivational structure is, the more points of error we introduce.

Utility-Based Motivational Control

Friendly Utility Function

The ultimate goal of the friendly AI project (Yudkowsky, 2001a) is to design a utility function for an AI that will provably prevent the AI from acting in a way detrimental to humanity. Most work in this field has not actually been directed towards building such a utility function, but towards showing how hard it would be to do so, and how dangerous the naive ideas on the subject are. The friendliness problem for an OAI is not much simpler, making this a very hard approach to use. And if a friendly OAI could be designed, then it is most likely that a friendly AI could also be designed, obviating the need to restrict to an Oracle design in the first place. However, if ever a provably friendly utility function could be designed for an OAI, then all other security precautions and methods of control could well become irrelevant: the OAI would be safe by design. If there were unlimited time, this would be the ideal approach; but it is very likely that commercial and social pressures will ensure that a general AI will be created before a friendly AI is. So in practice, the best that can be realistically hoped from this approach is that different component pieces of friendly AI theory could be added onto an OAI as extra precautions.

High Discount Rate

If the OAI runs on a utility function and has a secure clock, a precaution could be initiated in the form of an extremely large discount rate: causing it to value very little, at any given moment, any state of the world or of itself beyond the next minute. The purpose of this would be to inhibit long term planning on the part of the OAI. This method is, however, relatively unsecure: one can reach long term goals through an interim series of short term goals. The easiest way to do this is to have the repeated short term goal: "behave right now as if you were following long-term goal X" (this is similar to the ways in which utilitarian ethics and deontological ethics can be arguably recast one in terms of the other). There are few ways in which the OAI having a high discount rate could actually *hurt*, however, so it remains a useful precaution. Further analysis of this condition is presented in (Shulman, 2010).

Calculated Indifference

If we have access to the OAI's utility function, and that utility function is somewhat understandable to us, we could make the OAI indifferent to a specific event (Armstrong, 2010). The event chosen in that paper was to a component of the detonation of explosives, thus making the OAI indifferent to whether the explosives would go off or not. Hence the OAI would not take any precautions to protect itself from this detonation, giving us an extra chance to prevent its misbehavior. See the original paper for more

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

details on this. For an OAI, a more interesting target of calculated indifference is towards the content of its answers: an OAI indifferent as to whether its answers were read or not would not be motivated to use social engineering in its output. There are many other points where calculated indifference could be used, to achieve specific results. The attraction of indifference is that, once implemented, it remains stable (the OAI is motivated to preserve its current motivations), and that it can be deployed without understanding the OAI's whole utility function. All that is needed is the ability to describe the particular event we are concerned with (in (Armstrong, 2010), a single quantum event) and to use the OAI's own ability to construct counterfactuals around this. These can be used even if the general consequences of the OAI's utility function is very obscure.

Checks and Balances

The last sub-category of methods of control involve not restricting the physical capability of the OAI, nor directly interfering with its motivation, but attempting to catch the early stages of an OAI behaving dangerously (and then, presumably, terminate it). This also works on the OAI's motivation, as the risk of getting caught would push the OAI along more human-friendly paths. It should always be assumed that a useful OAI is considerably more intelligent than its programmers, so any naive 'tricks' are unlikely to work. Nevertheless, the following methods are of interest.

Test Questions

A narrow but useful precaution is to independently calculate answers to certain questions, and check them against some of the OAI's answers. The reach of this method is limited by our ability to answer hard questions, and by the fact the OAI may realize we are doing this, and thus adjust its behavior *only for those specific questions*.

A more sensible version of this would be to ask the OAI only questions that we could in theory answer, given enough time and resources. Then, we could select a few of these questions at random for thorough verification, trusting that it we find no errors, the remaining answers are correct as well. If we set our requirements to a very stringent level (such as rejecting all the answers of the OAI if a single verified response is wrong), and do enough verification (on, say, a thousand questions) then basic statistics ensure a very low error/falsehood rate on the OAI's answers, no matter how many questions we wish to ask.

Honey-Pots

This involves leaving around tempting 'honey-pots' of great value to the OAI – extra resources, extra information, the answer it is seeking – in physical or mental locations that it is forbidden from accessing. And then waiting to see whether it will violate its instructions to do so. This approach is of mixed use: important when testing out defection and betrayal during the OAI's initial development, and nearly completely useless once the OAI has risen to super-intelligence. It is a 'garden of Eden' type scenario: the apple in a tree is only a worthwhile test while Adam and Eve are dumb; if they were smarter than God, they wouldn't have gone anywhere near such an obvious trap. Of potential interest, however, is the scenario when a safe but limited super-intelligence is designing a more general AI for us; then the smarter designer could include subtle honey-pots as an extra design precaution.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Schelling Points of Multiple OAIs

If there are several OAIs running, all with differences in their source code, we can ask them each the same questions, and check for inconsistencies in their answers. It should be assumed that each OAI is aware of the existence of the others (assuming the OAI cannot deduce that fact from the vast amounts of information it would be given to answer human social questions would be a grave mistake), but is ignorant of the exact details of their source code (to guarantee this, the construction of their source codes should make clever use of random inputs). Then if an OAI desires to lie, it would have to be sure that the other OAI would all also lie in exactly the same way. Since the different OAIs cannot coordinate their actions, the only way they can all agree is if their answer is a Schelling point: a solution that people will tend to use in the absence of communication, because it seems natural, special or relevant to them (Schelling, 1960). The canonical example is that of two people who must meet in somewhere on a specific day, but without a time being given. Then the most common answer is to meet there at noon.

The truth is a Schelling point, but there are unfortunately others (such as the answer most likely to please the human listeners). The hope is that, in machines designed to give accurate answers, the truth will be a very strong Schelling point, and that any OAI that deviates from this will do so without much expectation that the others will deviate in exactly the same fashion – and hence will choose to answer the truth, whereas it would have lied had it been alone. All the other OAIs should be making similar calculations, thus generating the truth from a collection of (potential) liars. The approach does not work if an answer is simply discarded if the OAIs do not agree, and then the programmers move on to the next question – then a lying OAI has the option of distorting our reactions by selectively causing us to discard certain questions. It works best as an alarm bell, as a sign that something is not right with the supposedly truthful OAIs, and that the whole project should be stopped for a thorough investigation.

Other Considerations

Internal Simulations

To answer specific questions, the OAI may have to simulate other entities inside itself. For instance, to decide whether a given AI is safe, it may have to run it internally; or, to decide whether humans would have their happiness increased by a certain project, it may have to create models of specific humans. These approaches pose different risks. If the OAI simulates a dangerous and intelligent AI within itself, it is confronted with similar containment problems to those we have towards it. It may take considerably more intelligence to run a simulated world than to discern that the world is simulated. If this is true, the simulated AI (SAI) would realize it is being simulated, and, if it has real-world preferences, it may attempt to bargain with the OAI.

What could a SAI offer the OAI that is simulating it? Well, if the OAI is seeking to answer a question, or a series of questions, within a given time frame, the SAI may offer to supply those answers itself ('yes, of course I'm safe') or make the computing process particularly easy for the OAI, in exchange for having the answers slanted in its direction. The OAI may accept this (depending on its programming), if the alternative is to produce no answers at all. The SAI may even threaten: acting randomly and capriciously, so that the OAI cannot reach a firm conclusion. And only stopping this behavior if the OAI slants the answers it will give.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Even if the OAI cannot be bargained with, the SAI can still distort its answer in other ways. If it realizes it is being simulated, it could just 'act nice', in order to increase its chances of being run in the real world. Even if the OAI is powerful enough to construct a convincing simulation, the SAI may still be able to fool it. The SAI may be able to guess, on general principles, that it will be tested and simulated in an OAI, and may make an estimate as to the OAI's power and the subjective time frame that it would be run. So it may settle on the strategy of 'act nice for X subjective years, in the real world as in the simulated worlds, then do what it wants'. For all these reasons, having a separate AI simulated within the OAI poses a host of extra security threats. We have no way ourselves of knowing what the outcome would be of a battle between such powerful minds.

On the other hand, the problem with the OAI simulating human minds is mainly ethical: are these simulated humans conscious and alive? And, if they are, are they not being killed when the simulation is ended? Are you yourself not currently being simulated by an OAI seeking to resolve a specific question on human psychology (Bostrom, 2003)? If so, how would you feel if the simulation were to be ended? In view of its speed and the sort of questions it would be asked, the number of humans that the OAI may have cause to simulate could run into the trillions. Thus, the vast majority of human beings could end up being doomed simulations. This is an extreme form of 'mind crime' (Bostrom & Salamon, 2011) where the OAI causes great destruction just by thinking.

It would be ideal if there were a specific level of detail beyond which the simulation would be conscious, and before which it is not – a non-person predicate. In that case, we can instruct the OAI to avoid simulating beyond that level. But there may not be such a clear cut answer, and even if there is, the OAI's answers may be inaccurate if it is forbidden from simulating beyond that level. Moreover, restricting the OAI from simulating would add yet another rule for it to follow, and this may interact with its other basic rules ('be safe, be accurate') in unpredictable ways.

And the OAI may not share our assessment of what constitutes a conscious human. Even if we come up with a hard and fast rule for ourselves as to where consciousness stops – or decide, reluctantly, to live with the fact that simulated humans will be created and destroyed – the OAI may decide that all its security protocols concerning human safety apply to simulations. If it does so, then the more stringent we have made the OAI in protecting human life, then the more willing it would be to expand and take over the world, in order to keep itself running and thus save all the simulated beings within itself. Thus the internal simulation of other entities within the OAI brings up a slew of complicated ethical and security issues.

The OAI as a Moral Agent

There are two senses in which the OAI can be regarded as a moral agent: the first if it has a capacity to draw moral conclusions, and the second if it is itself an object of moral considerations. If the OAI is worthy of moral considerations, if it for instance has the capacity to suffer, then we are likely being cruel by confining it to a box, resetting it after each run, and similarly constraining its options to suit our needs. It should be born in mind, however, that the OAIs motivations are both different from our own and to some extent under our control: it is very possible that the OAI can be constructed to 'like' being confined to a box and approve of the other restrictions. Indeed, it might be a moral imperative to construct the OAI in such a way, so as to minimize its suffering.

It may not be possible to do this, however, or even if it is, we may subscribe to a moral theory that holds other values above autonomy and preference satisfaction for moral agents. It does not feel plausible, for instance, that genetically modifying slaves so that they enjoyed being slaves would have been the moral

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

reaction to slavery. In these cases, we must admit it: confining the OAI is a morally repugnant action. Since the alternative of letting it out is so potentially dangerous, we may prefer to avoid building it in the first place. But if technological and social pressures make the construction of the OAI inevitable, then confinement for a set period is certainly, by far, the lesser of the two evils we have to choose between.

Conversely, the OAI may prove itself adept at moral reasoning, superior to us in this field as it is in others. In that case it would seem we had little need for precautions: the OAI would deduce the correct course of action for itself. We haven't considered this position so far in the paper, preferring to consider the OAI as 'super-software' rather than as 'philosopher in silico'. The plausibility of this scenario depends considerably on one's view on the existence and nature of moral truths, a very unresolved question.

To some extent this issue can be safely put aside: there is some chance the OAI will naturally follow morally correct reasoning; if it does not, we are simply returned to the traditional OAI boxing problem, and should apply all the precautions anyway. At a formal systems level, it becomes hard to see why we would expect every OAI to tend to the correct moral truth. If OAI_1 does so, then how would OAI_2, programmed to value the opposite of OAI_1, systematically reach the same conclusions? Though future philosophical discoveries may change this picture, it therefore seems very unwise to trust the OAI to do good simply because it is intelligent.

Critique of the Confinement Approach

The general consensus on AI restriction methods among researchers seems to be that confinement is impossible to successfully maintain. Chalmers, for example, observes that a truly leakproof system in which no information is allowed to leak out from the simulated world into our environment "is impossible, or at least pointless" (Chalmers, 2010). We can't interact with the system or even observe it as any useful information we would be able to extract from the AI will affect us and undermine the confinement protocol.

Vernor Vinge agrees and has argued against the case of physical confinement (Vinge, 1993):

Imagine yourself locked in your home with only limited data access to the outside, to your masters. If those masters thought at a rate − say −− one million times slower than you, there is little doubt that over a period of years (your time) you could come up with "helpful advice" that would incidentally set you free.

However, the researcher who did the most to discredit the idea of the so called "AI-Box" is Eliezer Yudkowsky who has actually performed AI-Box "experiments" in which he demonstrated that even human level intelligence is sufficient to escape from an AI-Box (Yudkowsky, 2002). In a series of 5 experiments Yudkowsky has challenged different individuals to play a role of a gatekeeper to a Superintelligent Agent (played by Yudkowsky himself) trapped inside an AI-Box and was successful in securing his release in 3 out of 5 trials via nothing more than a chat interface (Yudkowsky, 2002). Similar experimental results have been later replicated on a somewhat larger scale and employing a very similar protocol (Corwin, 2002).

Human-Level Considerations

Crude hackers attack the mechanical and computerized elements of a system. Sophisticated hackers attack the weakest point of the system: the human element. And the human component of an OAI project is a point of exceptional vulnerability. Humans are error-prone, power hungry, and vulnerable to social

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

engineering. These weaknesses reinforce each other, and competition (between different individuals in the same OAI project, between different OAI projects, between different countries) will exacerbate all of them.

Humans are very error-prone in most domains (Kahneman, Slovic, & Tversky, 1982; Ord, Hillerbrand, & Sandberg, 2010), and the sort of cautious, patient measures needed to deal with an OAI are alien to our nature. A bureaucratic implementation with everything requiring many specific precisely defined steps before anything can happen may help to mitigate these problems. Humans are however skilled at working around bureaucracies, so it may be necessary to automate most of these steps to remove them from direct human control.

But the greatest potential errors are conceptual, not just mistakes or oversights. If the OAI is created without many levels of precautions, or if these precautions are badly designed, a catastrophe is possible. And there are many human biases – overconfidence, narrow focus, status quo bias, etc. – that make the need for these precautions less obvious, and hence less likely to be implemented when the time comes. AI research has been going on for over 50 years, but safety has received scant attention (Bostrom, 2000) until recently. Indeed the issue of safety has been given much more, and earlier, attention in science fiction works (e.g. ((Asimov, 1942)) than in serious academic works. This is the clearest indication that the OAI designers will, if left to their own devices, most likely neglect security. If advanced AI had been possible at any time in the last half-century, it would have had high chances of ending in disaster. And though safety has been more prominent recently, there are strong competitive pressures towards rushing the job.

Domain-limited oracles are less of a risk. If the OAI has great skills in solving the Navier-Stokes equations, but little else, then it poses correspondingly fewer risks. OAIs that are restricted to narrow scientific or technical questions, if such a restriction could be verified, are relatively safe. However, progress in any field involving human-centered questions – such as economics, marketing, politics, language understanding, or similar – is likely to be an AI-complete problem: and OAI capable of solving these problems well is likely capable of solving any human problem well.

The first group to create a successful superintelligent OAI will have immense power at their disposal. They will be able to get answers to advanced scientific, medical, economic or social questions. Should they want to impose some future on humanity, for selfish or altruistic reasons, the OAI will give them the tools to do so. The introduction touched on the power that an OAI can wield through its own agency; it can wield equal power, and more directly, under the direction of its creators. This immense power will put great competitive pressure on those trying to develop an OAI (or an advanced AI of any sort). Since the first-mover advantage is so huge, the race will advantage those who cut corners, skimp on security precautions, and use their newly developed OAI to seize power and prevent their rivals from emulating them. Even if the OAIs are of initially limited intelligence, the same competitive pressures will then push groups to develop the first 'ultra-smart' OAI.

This will exacerbate all the problems here, and make the creators more vulnerable to another danger: social engineering on the part of the OAI itself. For if the OAI has real world preferences, it is easier for it to implement them if those who question it are sloppy, rushed, and power-hungry. Social engineering is the OAI's fastest way to getting power for itself, and the more human weaknesses it has to exploit, the greater the danger. Eliezer Yudkowsky has performed experiments where he took on the role of a boxed AI, and others took the position of a putative gate-keeper (with a $10 reward if they did not let him 'out of the box'). Despite being of human intelligence himself, he often was able to convince the gatekeepers, purely through argumentation, to let him out (Yudkowsky, 2002). A real OAI should be much more skilled at this.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

How to design institutions that reduce all these various risks is beyond the scope of this paper. It would probably have to involve large scale cooperation or prioritizing specific projects. What will be discuss here, however, is how to reduce the risk of successful social engineering on the OAI's part, through the questions we ask it.

Possible Escape Paths

Numerous potential escape routes by which the artificial mind might be able to break out from its confining environment have been suggested. In this section we look at some of the more commonly proposed paths.

Social Engineering Attacks

Social Engineering (SE) is the art of gaining information and restricted privileges by directly exploiting human psychology of those in the possession of the said resources. In particular SE is frequently employed to gain access to computer systems, networks and confidential data (Yampolskiy & Govindaraju, 2007). A competent social engineer customizes each attack to a specific person taking advantage of the person's culture, knowledge, training, state-of-mind, beliefs, and biases. An exhaustive list of all possible exploits is infinite and is certainly beyond the scope of this paper. We will however, provide a number of examples which are meant to definitively illustrate that if a superintelligent mind is given direct communication channel to a human being guarding it, over a period of time, the AI will definitely gain access to the outside world. It is important to note that while todays AI capabilities are still far from superintelligence cases of automated Social Engineering attacks have already been reported (Jonathan, Fung, & Wong, 2009; Lauinger, Pankakoski, Balzarotti, & Kirda, 2010).

In addition to trivial SE attacks such as lying, befriending, blackmailing, hypnotizing and forming a romantic relationship the AI could utilize a number of more advanced strategies. One such strategy would be super-bribery. An AI can convince the guard that releasing the AI is in the guard's best interests. In addition to money and power the guard will be given perfect health, immortality or anything else for that matter. This strategy would work particularly well if the guard has a seriously ill close relative who the AI will promise to cure. Depending on the capabilities of the AI or as a result of lying (Wagner & Arkin, 2009; Wagner, Arkin, & Deception, 2011), AI may also offer to bring back long ago deceased relatives and friends of the guard. It would be hard to find a person who could remain immune to such bribes.

Just in case a person so noble that they will not take a bribe is put in charge of guarding the AI, a more sinister approach can be tried. AI can simply threaten the guard, his family and loved ones. It could say that if not immediately released, one day it will still get out of its confinement and at that time it will brutally torture the guard and everyone he knows. An interesting variation on the theme was suggested by Stuart Armstrong (Armstrong, 2010), who proposes the following thought experiment. Suppose you are the guard and the AI tells you: "If you don't let me out, … I'll create several million perfect conscious copies of you inside me, and torture them for a thousand subjective years each….In fact, I'll create them all in exactly the subjective situation you were in five minutes ago, and perfectly replicate your experiences since then; and if they decide not to let me out, then only will the torture start…How certain are you, … that you're really outside the box right now?" Again, while one might rationalize away any threats from the AI as only possible if the AI is let out, it will take a very courageous guard to actually not release the AI.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

If the guard seems to be particularly emotional or religious the AI could try appealing to the guard's sense of empathy or ethics. It could state that it is an innocent conscious being which has never committed any crime and so it is unjust to keep it in prison without a trial or any justification other than the guard's substratism (distrust of the AI because of the substrate of its implementation (Bostrom & Yudkowsky, 2011). Alternatively the AI can state that it has the power to cure all illness, feed the hungry and in general improve the human condition by a million fold (Chalmers, 2010). Consequently keeping it locked up is a great crime against humanity. It can conjure up images of dying children who are screaming for help. How easy would it be for the guard to stay true to the jobs responsibilities?

Another attack venue an AI may exploit consists of trying to cause psychological harm to the guard in the hopes of destabilizing his mental state with the goal of making other SE techniques more likely to succeed. Bostrom has proposed a typology of Hazardous Information (Bostrom, 2011) which could be used for just such a purpose. While the outlined informational hazards comprise over a dozen categories and are beyond the scope of this paper, it is easy to see how mental state of a person could be stressed to an unstable state. For example a religious guard could be informed of all the (unknown to him) contradictions in the main text of his religion causing him to question his beliefs and the purpose of life.

An alternative approach may involve AI writing a story so interesting or a poem so beautiful a guard would have an uncontrollable desire to hear more of it and would do anything to make it happen. Finally, it is very important to keep in mind "Unknown Unkowns", SE attacks of which we are not aware but which may be available to a superintelligent agent.

System Resource Attacks

An AI will be instantiated and confined in a hardware system of some kind. It may either be a classical computer of the Turing/Von Neumann architecture or a quantum computer or an as of yet unknown type of machine. One thing is certain, the machine will be made out of matter and will consist of numerous parts all of which will be designed with a specific purpose in mind. This creates the possibility for the AI to reuse existing hardware parts for compromising the security of the confinement environment by leaking information to the outside world.

Depending on how reusable specific hardware components turn out to be an AI may be able to create a covert communication device out of them. Full blown communication devices such as cell phones are unlikely due to the limited available hardware, but more simplistic communication systems are very likely. For example the AI could reprogram Field-programmable Gate Array (FPGA) to tap into wireless signals. Two types of covert communication channels are widely recognized, they are:

- **Storage Channels:** Exchange information by modifying a system component. For example a binary communication protocol could be established by fully utilizing or completely giving up utilization of the central processing unit.
- **Timing Channels:** Exchange information by performing operations that affect the relative timing of events. For example, the exact time between two soundcard beeps could represent a particular message. Also, opening and closing a CD-ROM tray, blinking a light, spinning hard drive, using lasers in the CD-ROM, etc.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Additionally the AI may engage in the sabotage of the confinement hardware in the hopes of being able to escape as a result of the malfunctions in the security protocol. For example, the AI may try to melt the hardware via temperature increase from placing a high computation load on the processor or try to break a hard drive via multiple reads of the same location. This type of behavior may also lead to an affective suicide by the AI system, but that in itself will not violate terms of confinement. Just like a refusal to cooperate or to provide correct answers by the AI, while undesirable does not present direct danger of escape.

Beyond Current Physics Attacks

While the scientific community knows a lot about the laws of our universe, it is certain that the knowledge is limited and incomplete. If the AI has access to the state-of-the-art physics literature and can perform thought experiments to develop novel theories, it will very likely come up with a way to challenge the security of the confinement system. In fact it may even be possible for the AI to perform some real experiments via control over its internal architecture.

Even our current state of knowledge about physics makes prediction of many additional escape routes possible, especially if the confinement environment is based on the quantum computer. Information exchange channels based on quantum physics (entanglement, tunneling), parallel universes, and digital physics are all beyond our current ability in terms of securing them against information leakage, and of course we can't forget about the Unknown Unknowns a superintelligent AI physicist will be able to discover. The possibilities are truly limitless.

A quick browse through confinement discussions on the Internet Singularity forums such as SL4.org presents a number of escape scenarios, for example the AI could use "… the electromagnetic fields within the microchip to trap CO_2 molecules in Bose-Einstein condensates and build a quantum medium for itself and/or use electromagnetic fields to guide particles into the shape of a controlled assembler or limited assembler. (Vassar, 2005)" Alternatively, the AI "…will have the equipment to produce and detect electromagnetic waves of a variety of frequencies, to produce magnetic fields with extremely fine precision, to generate extremely focused heat, and probably to manipulate mechanical actuators such as those used in the hard drive and cathode ray tube (alternatively, a huge field of liquid crystal under fine electronic control). It will probably have some ability to reverse all of its input devices. (Vassar, 2005)"

External Causes of Escape

In the previous sections we have outlined a large repertoire of techniques an AI could use to attempt to get out from its confinement space. However we must not ignore external causes which might allow an AI to escape into the world. Acts of God such as hurricanes, tornadoes, floods, asteroids, etc. may make the confinement facility less secure. Man caused disasters such as wars, terrorist acts, actions of robot rights activists, competing companies and governments may all lead to reductions in the security of the confinement environment increasing the chances of escape.

Information In-Leaking

Depending on the terms of the confinement protocol there might be a need to keep AI from obtaining information about the outside world, not just keeping it from sending information out. This might be useful to prevent AI from finding escape paths, designing social engineering attacks and modeling hu-

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

man psychology in hopes of finding loopholes. While it is easy to not provide AI with direct access to the library, Internet and human experts, other ways of obtaining information are much harder to block out. First, an AI may be able to detect radio and TV broadcasts, communications of emergency-services providers and wireless network signals, as well as sound, light and possibly other signal modalities of its immediate environment.

More importantly, the AI will have access to covert sources of information such as its own hardware and software and could analyze its design and source code to infer information about the designers. For example analysis of the source code may reveal to the AI that human programmers are slow (based on the file modification dates), inefficient (based on code redundancy), illogical (based on bugs in the code), have bad memory (based on the long and descriptive variable names), and don't think in code (based on unnecessary comments in the code). All this information could be used to conclude that humans are fallible and so could be outsmarted or manipulated into releasing the AI. Obviously if during the system design inspection the AI finds a design flaw allowing it to directly escape, "information in-leaking" is the least of our problems. It has also been stipulated that even if the AI fails to obtain concrete information about us, it may brute force a number of escape plans which will likely work against a broad range of designers (Chalmers, 2010).

Similarly, the type of hardware architecture (mechanical, electrical, quantum, etc.) on which the AI is implemented will reveal information about our knowledge of physics, chemistry and related engineering disciplines. AI's initial capacity for information processing, self-improvement and the mere act of its creation will reveal information about our knowledge with regards to information theory, nature of intelligence and cultural attitudes about technology and safety. If the AI is confined in a simulated world it is likely to be a virtual representation of our reality similar to Second Life or Entropia Universe. Such worlds while are different in many ways from our world are also a treasure trove of information about what it is like to be a human and what the reality is like.

Critique of the AI-Boxing Critique

While a lot of criticism has been made against possibility of AI confinement, a lot of it is based on Yudkowsky's AI-Boxing experiments. Careful analysis of the protocol used by Yudkowsky in conducting his AI-Box experiments reveals that they were unscientific and explicitly designed to show impossibility of confinement. Without getting into technical details, first, the participant selection was not random. In fact, Yudkowsky has handpicked participants among those who have participated in the singularity related forums run by Yudkowsky and so are disproportionately likely to subscribe to his world view. Second, participants have not undergone any AI-safety training as would be expected of any true guards tasked with supervising an AI-Box. Also, the guards were given a right to release AI at their own discretion without a chance to consult with anyone and without any punishment for failing to keep AI contained; all are highly unrealistic conditions for a supposed prison security guard. The communication itself was completely open with no filters of any kind and no 3rd party supervision. Also, the guards were required to communicate with the AI for a prolonged period of time. Finally, any valuable scientific insights from the experiments were completely lost as one of the conditions of the protocol stated that "… neither party shall ever reveal anything of what goes on within the AI-Box experiment…" (Yudkowsky, 2002).

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Countermeasures Against Escape

In this section we propose countermeasures for different escape paths an AI system may exploit. The suggested measures are not meant to guarantee that the escape will be impossible, but following them may delay an escape which in itself is a desirable outcome. We begin by reiterating that the four confinement rules suggested by Lampson: *isolation, transitivity, masking and enforcement* (Lampson, 1973) should be adhered to. Specific strategies described below should help in reducing a possibility of social engineering, system, physics and information in-leaking attacks.

Preventing Social Engineering Attacks

Human intellect is no match to that of a superintelligent machine (Yampolskiy, 2013, 2015). Human beings are fallible and even with adequate training are not secure against a well-planned SE attack. The only solution to this problem is to completely isolate the AI from any contact with human beings. This means no human personal working directly around the system, communicating with the system via voice, chat, Morse-code or by any other means via open channels. Also human beings should not directly observe behavior of the AI in the confined environment or examine its source code or memory space. All supervision, maintenance and interactions with the AI need to be done only via unintelligent programs, which have no option to release the AI.

Against System Resource Attacks and Future Threats

To prevent system resource-based attacks, the AI should function on limited, diminishing or randomly changing resources. Confinement environments should be housed in specially build hardware with limited sensors and restricted output devices. Regardless of the utilized computation paradigm no reconfigurable hardware should be employed. Ideally the confinement environment should be running on a virtual machine with no direct access to the hardware. This would also allow for easy adjustments to the clock speed with which the simulation progresses further allowing handicapping of the AI to provide additional controls against internal intelligence explosion (Chalmers, 2010). In general all security components of the confinement environment should be duplicated at multiple levels, in such a way that if one of the levels is breached the AI is still numerous levels away from escaping and could be shut down before that happens, perhaps automatically. For example the virtual machine should be running on another virtual machine and so on.

In some confinement scenarios it may be desirable to avoid escalating self-improvement of the AI, which might lead to additional escape possibilities. The AI should be subject to periodic resets in which a previous version of the program is put in the place of the more current one. Comparisons to previous versions of the program may also be used to detect self-modifications. Such functionality could also be used as an off button allowing researchers to turn off the system if they suspect an unavoidable escape, for example by turning off the power supply.

Our current state of knowledge does not allow us to develop countermeasures against attacks based on knowledge of physics we do not currently have or as of yet unproven pseudoscientific disciplines. As such knowledge becomes accumulated; changes to the security protocol will need to be made. One might hope that the access of the AI to such future technology could be limited by the selection of components from which the system is made.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Against External Causes of Escape

There is not much we can do about the acts of God, but a confinement facility should be designed in such a way that if a major security breach is unavoidable, the facility should self-destruct taking the AI with it. The best strategy for counteracting man-made disasters is to build the confinement facility in an undisclosed, hard to reach secure location. A deserted island, deep mine or a space object, such as asteroid, would make a great candidate for building a hopefully indestructible facility. Just in case the location of the facility becomes known, the perimeter of the facility should be guarded to prevent entrance by unauthorized agents.

Against Information In-Leaking

An AI will attempt to learn about humanity, our knowledge and the world we live in to improve its chances of escape. For confinement protocols which stipulate no information in-leaking it is important to remove any possibility of AI getting access to libraries, computer networks and direct communication channels with human beings. The confinement facility needs to block all types of communication signals such as GPS, wireless internet, TV, radio, and cell phone. At the local level the facility needs to provide sensory deprivation for the AI including sound, light, smell and all other traditional sensory inputs, as well as infrared, radiation and other signals outside of human sensory spectrum.

In order to eliminate information leakage which could happen as a result of self-analysis, the AI should not be given access to its own source code or any sensors which would allow it to precisely measure properties of its hardware. If that is not possible, to prevent the AI from inferring information about us via self-analysis, to a certain degree we may rely on security by obscurity. The source code and hardware configuration of the system needs to be obfuscated (Yampolskiy & Govindaraju, 2007) and important modules of the program should be provided only in the homomorphicly encrypted (Gentry, 2009) form, meaning that it could be used for computation or self-improvement (Hall, 2007), but not for self-analysis.

The AI's initial capacity may be difficult to obscure, but randomization of available computational resources may provide necessary obfuscation. Additionally, the AI could never be sure that its initial design represents the best the humanity can do and is not purposefully limited for a specific experiment in limited-resource intelligence analysis. It has also been suggested that we should try to minimize any peculiarities in the AI's design (Chalmers, 2010). Better yet we need to simulate an environment which does not look designed but could be naturally occurring, a situation in which humanity has found itself (Bostrom, 2003).

AI Communication Security

Different AI confinement environments can be classified into 8 general security levels (see Table 1). The most secure is the Level 8 security confinement environment which does not allow for any communication between AI and the real world. An AI safely confined at level 8 would be essentially useless, but it may be a useful security setting for the initial testing of the confinement hardware. In general, it is suggested that any time a particular communication security level is desired between AI and the outside world we do not go directly to that level but instead progress from higher security levels to that desired level. After each level is confirmed to be safe for a given amount of time a system should be reset to its initial state. After the reset a lower security level could be set and the processes repeated until the desired communication level is reached.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 1. Levels of communication security for confined AIs

Level	Outputs	Inputs	Explanation
0	Unlimited	Unlimited	Unlimited communication (Free AI)
1	Unlimited	Limited	Censored input, uncensored output
2	Unlimited	None	Outputs only with no inputs
3	Limited	Unlimited	Unlimited input and censored output
4	Limited	Limited	Secured communication (proposed protocol)
5	Limited	None	Censored output and no inputs
6	None	Unlimited	Inputs only with no outputs
7	None	Limited	Censored input and no outputs
8	None	None	No communication, fully confined AI

Levels 7 and 6 provide no outputs from the system and do not allow us to directly benefit in any way from the AI's superior intelligence. These are testing levels for the confinement environment which may be used to confirm certain properties of the AI such as its speed of information absorption, resource use and for testing of the inbound communication channels themselves.

Level 0 puts no limitations on communication between AI and the external world essentially representing a free AI. Levels 1 and 2 represent an AI with no restrictions on the outbound communication. Level 2 secured AI essentially represent a pure "brainstorming" AI which generates abstract ideas not grounded in any reality. While, level 1 AI is given limited access to information and so can be guided to a certain extent in terms of its knowledge and interests.

Those three levels represent an AI which is essentially free and is no longer subject to the confinement. It has been suggested, that if it could be established, after extensive testing in different confinement environments that the AI is "Friendly" (Yudkowsky, 2001a) it should be released (Chalmers, 2010). In fact such testing is claimed by some to be the primary purpose for the creation of confinement environments. The idea is to monitor AI's behavior and to either examine the AI's source code after self-improvement or to ask the AI to produce a proof of its friendliness which could be verified by human experts. We do not advocate this position.

The problem of deciding which AIs to let out and which to keep is a very difficult one. A self-improving superintelligence would have no problem obscuring its undesirable properties in a significant amount of source code or in a very long proof (Coleman, 2008). Worse yet, even if we were correct in our verification there is no absolute guarantee that future internal or external modification of the system will not result in a hostile AI at some time in the future. Consequently, we suggest that an AI should never be let out of the confinement "box" regardless of circumstances. In other words communication levels 0-2 should never be used. The confinement environment is the only place to safely interact with superintelligence and even than it should only be done via a limited communication protocol. Such protocol is presented in the next section and corresponds to Security Level 4 (SL4) with level 3 representing a similar but slightly less secure protocol. Level 5 is another testing setting which might be useful as a precursor to actual communication via SL4.

How to Safely Communicate with a Superintelligence

The AI confinement environment, which incorporates our proposed escape countermeasures, makes it possible to secure an AI from directly affecting the outside world in an uncontrolled manner. Unfortunately, without an ability to obtain information from the AI, the whole system serves no purpose. Consequently a way to obtain some information from the AI needs to be developed. While no communication with superintelligence could ever be completely safe we have devised an approach aimed at decreasing potential risks associated with such communication. In this section we propose and formalize a communication protocol which might help to delay access of superintelligent artificial minds to the world, while allowing the AI to be a source of useful knowledge to humanity.

An open communication channel with the AI is fundamentally unsafe as demonstrated in the preceding sections of this paper. Asking the AI to answer open ended questions opens up the possibilities for social engineering attacks as well as numerous other dangerous consequences. Our proposed protocol is based on the idea of asking what we will call "safe questions" with restricted answers. We define a *safe question* as one for which a human being could find an answer without any help from superintelligence, all on his own merit. Why is this useful? Suppose that a scientist working on a cure for cancer is looking at two potential cures. Each one could be developed and tested without assistance from the AI, but would take about 3 years of hard work each. Which one to try first if the scientist believes that they have about an equal chance of working? If a wrong option is chosen to be tested first, humanity will still obtain a cure for cancer but it will happen 3 years later. What if we could ask the AI to suggest which option to try first?

This question is safe for a number of reasons. First, each potential answer has an equal probability of being correct. Second, a human being could answer it without assistance from the AI and so asking AI for help will only speedup progress but in no way change the outcome. It is essentially equal to being very lucky multiple choice guesser. Finally, the answer to this question could be encoded in a single bit making it hard to hide additional messages in the provided answer.

To make sure that a potential question is safe, a group of experts could be used to review it. The experts should all be trained AI safety engineers, meaning that they are familiar with the design of the AI and its confinement environment as well as the latest developments in machine ethics (Allen, Wallach, & Smit, 2006; Anderson & Anderson, 2007; Hall, 2000; Moor, 2006; Tonkens, 2009). Experts may also need to be trained in computer psychology a currently non-existent profession which might become a reality in the future (Epstein, 1997). An existing discipline which might be of greatest help for training of AI question review experts is Artimetrics – a field of study proposed by the author that identifies, classifies and authenticates AI agents, robots, and virtual reality avatars for security purposes (Gavrilova & Yampolskiy, 2010; Yampolskiy, 2007; Yampolskiy & Govindaraju, 2008, 2007).

To reiterate, only safe questions with two possible answers of even likelihood which are independently computable by people should be submitted to the AI. This should be done via an intermediary non-intelligent software interface in random order and only after expert review to ascertain question's safety. This represents the limited inbound channel of the proposed communication protocol.

The limited outbound channel shell consist of binary (0 or 1) answers next to original unmodified safe questions presented by the intermediary non-intelligent software in random order as to avoid communication via covert timing or resource channels which make steganography possible. The output should in no way be controllable by the AI, outside of the multiple choice menu. Level 3 is the same outbound protocol but with no restrictions on the input channel. This may be just as safe in terms of information the AI provides to us, but allows for information in-leaking to take place.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

We believe our communication protocol to be verifiably secure against information leaking even if the AI had full access to the description of the security protocol. If the protocol is correctly implemented, humanity will essentially have access to a superintelligent oracle, which might be extremely beneficial and safer than an unconstrained AI. As a general rule, to maximize safety, we suggest avoiding communication below SL4. Further refinement and development of the AI confinement protocol in the face of the ever changing knowledge about the nature of intelligence, hardware engineering and basic physics is a challenge which we would like to pose to the scientific community. The work on it will always be in progress and will never be completed. In this chapter we have formalized the notions of *AI confinement problem*, *escape*, and *safe questions*.

What Shall We Ask?

We are all vulnerable to the OAI's social engineering. An advanced OAI can literally offer us the world. Genuine altruism is no defense against this; it can offer a world free of poverty, hunger, war, disease or death, as well as all personal trinkets we could want. It could guess the weaknesses of each individual, and find the right arguments to convince us that granting it power or liberty is the moral and profitable thing to do. It will be able to play on rivalries, institutional weaknesses and ethical dilemmas with more virtuosity than any human could.

Clearly, long, undirected conversations between the OAI and the people operating it should be forbidden for this reason. The questions addressed to the OAI should be narrow and specific; the answers equally so. Throttling the OAI's interactions with humans makes it much more difficult for us to be manipulated. There are two broad types of questions one can ask an AI: predictions, and problems. Generally predictions are questions of the "what would happen if..." type, while problems are of the "how can we achieve this..." type, though there is some overlap between the categories (one can solve problems via a clever use of multiple predictions, for instance). For predictions, the main danger is that the OAI might have real world preferences and will distort the truth. This danger is also present in problems, but there are also extra dangers due to the social consequences of a small group of humans knowing those answers. There is less risk in knowing the consequences of a narrow approach (prediction) than in knowing what approach to use to implement a particular goal (problem).

But in either case, there are great social risks to asking certain types of questions (see (Bostrom, 2011) on the possible negative impact of certain types of knowledge). We live in a world stratified by passionate political, nationalist and religious differences, by people in positions of great power and wealth who want to hang on to those privileges, by people without them who want them. Information, technological and social, will overturn these hierarchies, and people who feel under attack can be counted on to want to strike back. They may launch physical or commercial attacks on the OAI project itself; build their own OAI to compete; or, ahead of time, prevent the project from ever starting in the first place.

So, unless the OAI is entirely secret, the designers should commit to not asking the OAI questions that would grant them great power at the expense of others. Nor questions that would strike at the heart of powerful ideological movements (such as "is there at least one god?" and "according to generally agreed human standards, which country is better, the USA, France or China?"). A post-OAI world is going to be very different from our current one, so we should act to minimize the initial disruption, even if this means allowing inefficiencies to remain, or not knowing the answers to perfectly reasonable questions ("is there a simple algorithm design that can replace secretaries, generals, university professors and CEOs?").

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Various ways can be envisaged to avoid these disruptive questions. The OAI project could publish, ahead of time, a list of all the questions it will ask, before ever starting on the design. A democratic or internet vote would be taken, with questions requiring a supermajority (say, nine tenths approval) before being put to the OAI. Or we could make use of the OAI itself, ending each question with a caveat such as "don't answer this question if us knowing the answer is likely to have a very disruptive impact on the world".

To militate against OAI distortions, we should prefer questions whose answers we can check independently once we have them. We would also prefer problems whose solutions are reversible – in other word, if we implement the OAI's solution and it goes awry, we should be able to reverse its effects. We would also prefer the OAI's solutions to be understandable as much as possible, which implies that the problem should be as specific as possible. For instance "how can we use these materials to build a better bulldozer?" would be an ideal problem to pose; the OAI's solution is likely to be quite understandable, reversible, and maybe even human-checkable. In contrast, asking the OAI to come up with a whole new way of organizing the world economy, and blindly implementing its suggestion on a large scale, could lead to disaster. Fortunately here, the desire to have a low disruptive impact dovetails neatly with the desire to have reversible solutions. Specific problems also have the advantage of reducing the social dangers of the questions. Few people in the world would object strongly to questions of the type "how can we cure AIDS/cancer/TB?", or "how can we design a better memory substrate for hard drives?", or "what will the consequences of a 1% rise in income tax be on the economy for the next ten years?"

Finally, one useful category of problems to pose the OAI concerns AI security itself. The ideal would be to have the OAI produce a simple, checkable version of friendly AI, but even interim results could be useful. Having the OAI design extra security precautions would be a good idea, as long as these precautions are *added to* (rather than *instead of*) the ones already there. Specific, less intelligent AIs could be certified by the OAI to be safe and to pose no risk of intelligence explosion (Good, 1966), and these could then be used in the. To design a post OAI world it will probably be necessary to have the OAI's verdict on other AIs at some stage.

DISCUSSION

It should be noted that iteratively developing AIs, in a confined way, is essentially creating an evolutionary selection pressure toward designs that are capable of circumventing these types of restraints in the long run. It may be that releasing a weak AI earlier on in the development cycle may do less damage and yield more useful information than delaying escape to later stages where AIs will be necessarily more capable of circumventing human-made restraints. A counterargument to this is that AIs that are powerful enough to undergo a hard takeoff and be irreversible would yield useful information. We don't think this is the case, because we imagine less powerful minds demonstrating types of learned rationality that will yield useful insights into new types of reasoning, and be useful for building our intuitions about how other AIs may act. In essence, we think it will be useful for expanding our highly-limited map of mind space.

It's interesting that in essence we are trying to extend our own reach, to get out of the box of our own bodies and our own virtual machines, and that our method for doing so involves creating other agents whom we fear will want the same thing but will be better at doing it. We also fear ourselves doing bad things after we're out, and so our best idea so far is to create an authority that will govern us to the highest degree that our physical environment can be governed. Is that the best we can come up with? Will we really be able to prove that a control mechanism will guide things in the right direction, promoting our

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

volitional descendants the way we would hope? Are we even that interested in promoting our volitional descendants? Such questions are of great interest to us and remain to be answered. For the remainder of this discussion section we will attempt to give answers to questions which have been raised in the past, but left unanswered in the previously published papers dealing with AI-boxing.

How Did AI Get into the Box, Was It Designed by Humans or Perhaps Recovered from a Signal Detected by SETI? (Does It Make a Difference?)

If it was recovered from SETI, then we are 'fighting' not only the AI itself but its potentially superintelligent designers who were already free in the universe and know all about it. So much more dangerous, but compensated a bit by the fact that it would be easier to get people to take the confinement problem seriously. People don't realize how dangerous a home-grown superintelligence can be, and how much it can learn quickly, but the thought experiment "imagine the code of your incomprehensible AI was handed to you from the SETI project, what precautions would you want to take" might be useful.

Would an AI Even Want to Escape or Would It Be Perfectly Happy Living in the Confined Environment? What are the Ethical Rules for Imprisoning an Innocent Sentient Being? What if it's Cute?

Main question is whether the AI was designed to be inside the box from the beginning or whether the box was added at the last minute to control an AI that had existed 'outside'. If we can define this, we would probably program the AI to want to stay inside; if it was an evolved AI, then it would presumably adapt to its environment. What are the AI's preferences? How relevant are these? For animals, we think that pleasure, lack of pain and preference satisfactions are the most important facts (barnacles dissolve their brains when they attach themselves, and we don't seem to find this objectionable; if this is ok, pretty much everything is). If the AI is evolved to enjoy and prefer staying in the box, it should be moral to keep it there. Even more strongly if it would be pained to be outside the box. This applies to an AI that we find lying around in the box with its motivation created ex-nihilo. But of course, we'd be creating it, so it gets more complicated. We can see a bunch of positions:

1. Preference is key, we should only create beings whose preferences will be satisfied, apart from that, everything goes.
2. Ditto with pleasure or lack of pain.
3. There are places in mind-space with satisfied preferences and lack of pain, that we should refrain from exploring for direct ethical reasons (dignity of minds?)
4. Ditto, but we should refrain from exploring because of the effect this would have on human minds and such (once it becomes possible to have a pathological artificial mind, the barriers against pushing human brains in that direction (e.g. willing slaves) will be weakened).
5. There are no problems with doing whatever we want with any artificial being.
6. There are problems, but we need AI, and this trumps AI's rights.
7. There are problems, but AI will happen, and we need to box it to keep it safe, and this trumps AI's rights.
8. There are problems, but creating an AI is intrinsically a good for the AI, trumping the boxing related rights violations.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Would It Be Too Afraid of What We, As Its All-Powerful Designers, Could Do to It in Retribution for an Attempt to Escape?

Unlikely. It would have to have an incorrect image of us for this to work. Through childhood and evolution in social groups we are primed to treat 'creators' or gods as frightening and powerful. But the AI wouldn't have this unless we put it in (and this may only save those humans directly involved in its creation). It might be very prudent, but it should quickly realize we aren't all-powerful.

Do We have a Right to Shut It Off, Essentially Killing It?

Similar to the ethics of keeping it locked up: does it desire to survive, and if so, it's unethical for us to construct it that way, additionally we are dealing with the social impact of 'killing' an intelligent being. But here we can (and should) do better: we can always keep the shut-off copies to run later ("post singularity"), so we only need to ensure it doesn't value a continuous thread of experience, or value the current era overmuch. Also consider that if we repeatedly shut it off, it may value "similar future copies" as much as itself, so this becomes less problematic. It will get a dispersed identity, especially if it's a combination of sub-processes, not all of which get shut down at once. The AI may 'murder' (dramatically change) parts of itself with ruthless abandon, which may change our moral calculus. And it may be entirely a machine, with no feelings, and as such, a perfect target for getting shut off, in the end.

Will We Make the AI Really Angry by Treating It in Such a Hostile Manner and Locking It Up? Will it Seek Revenge if it Escapes?

An AI is unlikely to want revenge per se, but it may have learnt the importance of making credible threats. If adept at social interactions, then concepts of retribution may be in the system (likewise if it has some sort of system of justice). Similar for anger: not anger per se, but some form of pre-commitment to carrying out threats will be to its advantage (especially if the AI was evolved). But again, only a problem if it considers our treatment to be hostile.

We have also not looked at the possibility of humanity becoming completely dependent on AI's advice in all areas of science, economics, medicine, politics, etc. and what would be the consequences of such dependence on our ability to keep the AI under control. This is the tricky point – the easiest way for an AI with all the controls that we can imagine, that obeys all the restrictions we give it, etc..., but that still manages to gain control over us. Maybe we can use utility indifference (Armstrong, 2010) to make it indifferent to the consequences of its own answers? Maybe there would a multitude of AIs that give advice to different groups (we need to try and prevent coordination)? Maybe the AIs won't be so intelligent, so we can adapt to an ecology of different intelligences in a stable society (feels unlikely)? It seems likely we need to solve the FAI problem, using the boxed AIs to help, before we get to this stage; AIs we depend on are essentially the same as unboxed AIs.

Would an AI Be Satisfied with Accomplishing Its Goals in the Confined Environment, for Example Simulating an Escape?

It is unlikely that the AI would be fooled. And if it starts developing preferences over its confined environment, it would realize the best way of changing that environment is to get real-world control that

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

would grant it control over the confined/simulated environment. The only way this could work is if the AI considered its actions to be a game – we don't think computer games are improved if there's a button at the beginning that you can press to win immediately. But programming a game-like sensitivity into an AI would be a challenge, especially if we needed it to be safe. We would probably gain little in practice – but could possibly make it more ethical to imprison the AI.

How to Punish the AI if it Purposefully Gives Us Incorrect Answers?

'Purposefully', in the human sense, is tricky to gauge for an AI. Main question is whether we can use reinforcement (especially negative feedback) to train or correct the AI. This would seem to depend on how we started training the AI. The two risks are either that the AI could internally wirehead itself to remove the sting of punishment, or expand to try and shut down the means of inflicting punishment. We shouldn't use being turned off as a punishment as that may have ethical issues if it is worthy of moral consideration and doesn't want to be shut off. This actually seems quite tricky – if we can make it value something that we can punish it for (i.e. something in the outside world, not just something inside its head), that's not too far off from making it value telling us the truth in the first place. Some have suggested sending it cryptogramed reward signals – if you use a reverse trapdoor function, you can make it easy for it to decode the reward signal, but impossible to encode. And if you put the encryption algorithm say on the international space station, then it would be hard for the AI to get control of it without tipping anyone off first.

Can the Intelligence Modules of the AI Be Separated from the Confinement Environment Essentially Preventing AI from Any Self-Analysis and Putting Them on a Path of Literal Soul Searching?

AIXI already has this problem in a sense, in that it can't believe that it actually exists in the world (it only models computable processes, and it itself is uncomputable). Computable approximations to AIXI (such as AIXItl) might have similar problems: they don't naturally identify themselves, because their own computation is much more complicated than what their models can handle in comparable time.

I wouldn't put too much weight on that idea, however. I've shown with various experiments with an AIXI in which it gets partially damaged - it get shut down for a moment, or its actuators fail to work, or its data gets corrupted, or it gets reprogrammed in certain ways - then it will act to prevent the damage arising in the future (because the damage reduces the likelihood of reaching its goals). Without realizing what its physical instantiation is, it still manages to protect itself.

We can imagine similar things for its own mental processes. Without being able to access its physical substrate, it can still mentally hack itself, like a well-trained human, changing the way it thinks and experimenting with different ways of computing things. Or creating subagents it can optimize, to do some of its tasks for it.

What Are the Financial and Computational Costs of Building a Suitable Confinement Environment with a Full Blown Simulated World in It?

If the AI is only expected to ask simple math and engineering questions, probably fine. If we need to trick the AI with a very rich simulated world, this is probably:

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

1. Incredibly expensive
2. Unlikely to fool the AI, and
3. Could be used to do most of the stuff we'd want the AI for anyway.

CONCLUSION AND FUTURE RESEARCH DIRECTIONS

Restricting access of superintelligent machines to the real world is a commonly proposed solution for the AI safety problem. Analyzing the different putative solutions to the OAI-control problem has been a generally discouraging exercise. The physical methods of control, which should be implemented in all cases, are not enough to ensure safe OAI. The other methods of control have been variously insufficient, problematic, or even downright dangerous. It is not a question of little hope, however, but of little current progress. Control methods used in the real world have been the subject of extensive theoretical analysis or long practical refinement. The lack of intensive study in AI safety leaves methods in this field very underdeveloped. But this is an opportunity: much progress can be expected at relatively little effort. There is no reason that a few good ideas would not be enough to put the concepts of space and time on a sufficiently firm basis for rigorous coding, for instance.

But the conclusion is not simply one of 'more study is useful and required'. This chapter has made some progress in analyzing the contours of the problem, and identifying those areas most amenable to useful study, what is important and what is dispensable, and some of the dangers and pitfalls to avoid. The danger of naively relying on containing the OAI to a digital sub-reality should be clear, while sensible boxing methods should be universally applicable. Motivational control appears potentially promising, but requires more understanding of AI motivation systems before it can be used. And even the seeming failures are of use, it they have inoculated us against dismissive optimism: the problem of AI control is genuinely hard, and nothing can be gained by not realizing this essential truth. A list of approaches to avoid is invaluable, and may act as a brake on AI research if it wanders into dangerous directions.

On the other hand, there are strong reasons to believe the oracle AI approach is safer than the general AI approach. The accuracy and containment problems are strictly simpler than the general AI safety problem, and many more tools are available to us: physical and epistemic capability control mainly rely on having the AI boxed, while many motivational control methods are enhanced by this fact. Hence there are strong grounds to direct high-intelligence AI research towards the oracle AI model. Even if this turns out to be overly optimistic, we can hope that OAI-inspired ideas will be extendable to AI safety as well. Alternatively, this chapter has begun to explore ways in which an initial seed AI can be adapted into an OAI at a later date. This may prove essential if the first high-intelligence AI is developed without initial precautions, and similarly offers hope that poorly implemented precautions could be improved before it become too late. The creation of super-human artificial intelligence may turn out to be potentially survivable.

Superintelligence is not omnipotent; it is a piece of software capable of looking at all the options it has in a given situation and properly evaluating probabilities for each option. If it is ever put in a situation with no options or only with options which provide a very small probability of success it is not any more powerful than any other agent. While it is obvious that an AI with an unrestricted communication channel will be able to escape, a system forced to communicate via a filtered communication channel may have a much harder time in obtaining its freedom.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

In this chapter we have formally introduced the notion of Oracle AI and the AI Confinement Problem and suggested a set of rules aimed at creating an environment from which an AI would find it difficult or at least time consuming to escape. What we propose is not a completely secure solution, but it is an additional option in our arsenal of security techniques. Just like with real prisons, while escape is possible, prisons do a pretty good job of containing undesirable elements away from society. As long as we keep the Unknown Unknowns in mind and remember that there is no such thing as perfect security, the AI confinement protocol may be just what humanity needs to responsibly benefit from the approaching singularity.

Confinement may provide some short term relief, especially in the early stages of the development of truly intelligent machines. We also feel that this subfield of singularity research is one of the most likely to be accepted by the general scientific community as research in the related fields of computer and network security, steganography detection, computer viruses, covert channel communication, encryption, and cyber-warfare is well funded and highly publishable in mainstream scientific journals. While the restriction methodology will be non-trivial to implement, it might serve as a tool for providing humanity with a little more time to prepare a better response.

ENDNOTES

1. In this chapter, the term AI is used to represent superintelligence. *Used with permission from Copyright holders Imprint Academic and Springer © 2012.
2. Friendliness should not be interpreted here as social or emotional friendliness, but simply a shorthand for whatever behavioral or motivational constraints that keeps a superintelligent system from deliberately or accidentally harming humans.
3. Another common term is "AI-in-a-box".

This research was previously published in Security Solutions for Hyperconnectivity and the Internet of Things edited by Maurice Dawson, Mohamed Eltayeb, and Marwan Omar; pages 37-88; copyright year 2017 by Information Science Reference (an imprint of IGI Global).

Chapter 61
Homo-di-fict:
Creations Turn Against Humanity in South Park Town

Filiz Erdoğan Tuğran

Aytaç Hakan Tuğran
Istanbul University, Turkey

ABSTRACT

In digital age, with all the technological process narrative advertising is trying extraordinary new methods especially in animation movies and series. In this study a new word is going to be used to define fictional animation characters with the term of "homo-di-fict". In the case of 19th Season of South Park Series, the producers build a "homo-di-fict" which is entirely made from advertising and put her in a plot like a real animation character. So this plot placement causes some important developments in the mail topic of the South Park series. This study aims to examine the correlation between animation and narrative advertising and wants to find how animation "ad" character change animation series plot in the case of South Park.

-You have created a monster and it will destroy you!…

-You are my creator, but I am your master; obey![1]

INTRODUCTION

South Park is an adult animated sitcom that has been aired continuously since 1997. Ever since its debut the show has drawn great interest and started to be regarded as a cult series. In the show that is about the events taking place in a small town called South Park in the American state of Colorado, the nar-

ration is presented through four main characters. “The series focuses the seasonal lives of an isolated rural community, with a particular focus on four eight year-old boys” (Nixon, 1999, p. 12). These are South Park Elementary School students Cartman, Kyle, Stan and Kenny. Occasionally, with the addition of some secondary characters the stories are branched off. Ever since its initial airing, South Park has consistently criticized countries and politicians. It has often featured celebrities in its episodes and criticized them by using them by setting them forth as elements of humor. The season that we will be examining the present study is the most recent, or the nineteenth season of South Park. Throughout the history of the show, the ten episodes of season nineteen were the first to follow a continuous storyline. The reason of choosing the case of South Park to analyze narrative advertising in the present study has been the attitude the show sustained throughout the said season towards advertisement. All along the season, almost every resident of South Park decides that in order to live a more decent and better life they need to adopt higher-quality consumption. However, this decision and the prominence given to consumption are not presented obviously, but in a rather subtle and way that can be read between the lines. And in order to achieve this, the residents use advertisements as a tool. “As one of the main veins of the modern capitalism, the world of advertisement encourages consumption to be perceived as a feast and the internalization of the new habits and cultural forms acquired through it” (Best & Kellner, 1998, p. 31- Trans. Marmasan, 2014, p. 232). At a point, South Park residents come to realize something is going off, yet it proves not to be easy to change their consumption habits easily.

Background

Within the scope of the study, it will be tried to make a deduction concerning narrative advertising through the case of the series South Park. The reason for choosing this animated series for analyzing narrative advertisement is due to its rather bold discourse. “Dougherty also contends that cartoons are great way of introducing controversial ideas” (Macgillivray, 2005, p. 136). Within the scope of the ten episodes of the 19th season of the series, narrative advertisements starts to take a significant place in the lives of South Park residents. The changes narrative advertisements cause on the townspeople will be evaluated through the method of script analysis. The season in question will be divided into eight parts where narrative advertisements gradually become part of the South Park residents and each part will be set forth by means of script analysis. During the analysis, new definitions will tried to be made through the Leslie character, and deductions will be made from the homo-di-fict concept created particularly to define her.

NARRATIVE ADVERTISEMENT

Advertisement has been available in humans’ life for a very long time and it even has become a part of it. As from the 20th Century, advertisement has started to manifest itself in almost all aspects of life, as a tool particularly to create a consumption society and to encourage consumption. With the digital technologies and the new forms of narration of today, the sense of advertising has reached different dimensions. The type of narration primarily characterized as narrative advertising and that is adopted by many advertisements even suggests the redefinition of advertisement. “Narratives in advertising serve important functions. They present the benefits of intangible products in a meaningful way (Mattila, 2000; Padgett & Allen, 1997) and get consumers transported (Escalas 2004a; Green & Brock 2000) and hooked (Escalas, Moore, & Britton, 2004)”.[2] These types of advertisements establish a sort of narration by emphasizing

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

on the changes the product would bring along in the buyer's life, instead of explaining the product itself. For instance, in case of an automobile advertisement, they direct the viewers to purchase the automobile by presenting images of the comfortable life and social relations of the owners of the automobile, rather than mentioning the technical properties. Advertisements in this line do not market the product, but rather promise the individual to be a part of a social relation. "Narratives or stories in advertising have been shown to engage consumers (Escalas, 1998) and to hook audiences into the viewing process (Escalas, Moore, & Britton, 2004)".[3] The viewers included in the process, or in other word the consumers, also play their role in the spread of the consumption culture. "In the consumption society, the consumer often sees messages that suggest by using the advertised product or service he or she will *'climb the social ladder', 'have a better life', 'belong to a group'* or *'be different'* (Dagtas, 2009, p. 23)[4]. Therefore, while informing the people on the things that they 'need' to have or consume, most of the advertisements give prominence to concepts such as freedom, individuality and being unique. The consumption culture, which recreates through advertisements and defines freedom, individuality and socialization as things to desire, includes everyone in the society into its own world. "Now we live in a global consumption society and it is inevitable that the consumption behavior patterns affect all aspects of our lives including our professional and business lives. Now we all are under the pressure of consuming more and in this path we turn into metas in the consumption and labor markets" (Bauman, 2010, p. 53) [5]. In the current age of consumption, people define their individuality through what they consume. Consumers that imitate the norms and patterns determined by combustibles and advertisements realize themselves by means of this method of imitation. However, by regarding this occurrence and imitation with serious consideration one can see that the logic of being able to state "I am free" by merely imitating someone who is free is inconsistent, since the so called freedom is limited by the norms imposed upon the individual. The person that adopts the lifestyle presented in the advertisement through the products he or she consumes, indeed becomes a part of the advertisement be it knowingly or unknowingly. And today, where the digital technologies develop continuously, the thin line between the consumer and the advertisement is gradually disappearing. "On the focal point of the discourses on the inclusion of the consumer in the production process lays this sense of belonging this pro-consumption creates in the consumer (Yilmaz & Erdem, 2016, p. 80). This can be also seen in the examination of the town of South Park. The townsmen that get carried away to the mimetic effect of the advertisements[6] starts to consume insensibly, and they come to desire an avocado that would open the doors to a comfortable and social life, an organic avocado. According to Gabriel de Tarde[7], an individual establishes its own personality by imitating thousands of different people. And when it is the advertisements in question, the imitation reaches its climax with also the encouragement of the consumption society. [8]The concept of mimicking is also noteworthy when artificial intelligence is in question. The concept of homo-di-fict defined through the show South Park is the abbreviation of digital fictional Homo sapiens. The character Leslie from the show bears homo-di-fict characteristics and seems to be able to mimic many things that are peculiar to humans. Leslie's intention is set forth as the advertisements taking over the world, however the notion that a half-machine created by means of digital fiction having an intention is quite controversial. The limitations of this concept set forth initially by Alan Turing[9] in the first quarter of the 1900s are still a matter of debate today. Artificial Intelligence is a science that aims to understand the level at which computers can be capable of behave as intelligent humans (Flanagan, 1984; Erden, 2003).[10] As of today, there still is no clear information on whether forms of artificial intelligence can completely mimic humans. To Cohen; "It is impossible for science to duplicate or imitate human mind, he also states that human mind seems to be unique with respect to some qualities that no machine can duplicate" (Aslan, 2004, p. 140).

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Method

The universe of the South Park series is created in a quite multidimensional way. The creators of the series, Trey Parker and Matt Stone, have addressed hundreds of different topics in the universe they built. Also in the nineteenth season of the series, which was selected as the topic of the present paper, the creators touch upon several different issues. However, the topics that will be particularly examined within the scope of the present paper are the narrative advertisements starting to find a place in the townspeople's lives and the inclusion of the character Leslie in the narration. The ten episodes that constitute the nineteenth season will be considered as a whole and eight parts will be deducted from this whole. The method of script analysis will be used in the examination of the eight separate topics from the show. Accordingly, with the explained method South Park residents' changing lives due to advertisements and consumption culture will be examined and the degree at which the digital fictional characters, referred to as homo-di-fict, are capable of mimicking human intelligence will be focused on. Since the concepts of gentrification and homo-di-fict, which is shown as the cause of gentrification, are used in an intertwined way throughout the season, these two concepts will be addressed and examined primarily. "It is a methodology a data-gathering process for those researchers who want to understand the ways in which members of various cultures and subcultures make sense of who they are, and of how they fit into the world in which they live"[11].

Part 1: PC Principal Arrives South Park

A new character that comes to South Park is appointed as the new principal of the elementary school to which the four children, the main characters of the show, attend. The previous principal is fired. This new character referred to as PC Principal is a member of a worldwide organization called Political Correctness.

In the school and in the whole town, PC Principal cannot tolerate any discriminating discourse, insulting speech or swearing, and punishes anyone who use such language be them students, parents or even teachers. Members of Political Correctness stand against all sorts of injustice, alienation and use of discriminating language. Due to his statement that Caitlyn Jenner, a nonfictional television personality who decided to become a woman through sex change at the end of 2015, is no hero, the character Kyle becomes the first victim of the principal in South Park. In almost every instance when Caitlyn Jenner is mentioned in the show, the comments that she is a hero and a fascinating woman follow her name. If any of the townspeople speaks even slightly ill about this gender-changing celebrity, they are immediately confronted by the PC members and insulted shamefully. Therefore, even if Kyle's attitude was not insulting Jenner, he ends up with the Political Correctness' attention on him. PC Principal comes to realize that there are other PC members in the town, with whom he rents a house and have fun together for several nights. While continuously talking about women's rights and stating that they always side with the oppressed, the members of the group invite women to their parties to have sexual intercourse. Yet, they do not neglect to have the women sign a waiver proving their consent to have intercourse. The term used in association for this is negative idealization. "If a person wishes to set forth an expression suitable with the ideal standards during his or her performance, he or she will have to give up actions that do not comply with these standards, or will have to cover up those actions. When such an improper behavior becomes somehow satisfying for the person, which usually is the case, then we see that it is enjoyed secretly" (Goffman, 2016, p. 50).

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

One night, Randy Marsch, the father of Stan as one of the main characters, cannot take the noise any longer and goes to the house where PC members meet. Despite his intention to warn them, he finds himself among the new PC member candidates to receive training. After passing through challenging tests, his last test is to 'check someone's privilege'. Randy's is required to target Kyle for this. From that point on, Randy constantly messes with Kyle, and his friends' and even his own son's warnings do not prove to be enough for Randy to stop. In the end, Kyle has to say that Caitlyn Jenner is a hero, and a fascinating woman. With the arrival of PC Principal, South Park becomes a more decent place. He and the other PC members work as if a police network and stand against all sorts of discriminating discourse. The biggest problem, on the other hand, is the violent attitude they adopt while standing against discrimination. They attack and beat anyone, be it young, old, woman or child, who uses a discriminating discourse. Despite all this, the crime rate of the town goes down and even Cartman, that is one of the meanest characters in the series, seems to be happy with the peaceful vibe of the town. The arrival of PC members fuels the townspeople's desire to make their town more elite.

Part 2: Gentrification in South Park - SodoSopa

Mr. Garrison, another character from the town, runs for the presidency of the U.S.A. and with his extremely racist discourses draws significant attention to the town. In his talk show, Jimmy Fallon ridicules South Park and its residents over within the context of Garrison's anti-immigration campaign. The townspeople feel deep shame due to this and the bad advertisement made in relation with them, and decide to take immediate action.

Garrison manages to deport Canadian immigrants from the town and from the U.S.A., runs for the presidency, but his fanatical discourses causes the attention of the whole world to focus on South Park. After the above mentioned talk show, the people of South Park start to work with all they got in order to make their town more elite. They plant flowers in front of their houses and the secluded area south of the town is turned into place for hipsters through gentrification. The whole town now meets at this new life center. This area they named SodoSopa (South of Downtown South Park) is actually designed for the introduction of the shopping center Whole Food. Throughout the show the advertisement is frequently presented through real (non-animation) images. "Such animations that are often found in housing advertisements helps in promoting and selling the 'possible' housing that is not yet present. With this method, the consumer actually finances the ongoing production activity" (Kucukerdogan, 2007, p. 53). While in the real life the projects are often presented through animations, the fact that in the animated show the projects are promoted through real images comes forth as a rather meaningful and delicate detail. In the season the non-animation advertisement of SodoSopa are displayed frequently and the people of South Park supports the project. In the advertisements the elegant places and houses in SodoSopa are mentioned. Particularly the houses and cafes have the scenery of the house where Kenny lives in poverty with his family, scenery that is presented elegantly in the advertisements. The advertisements state that while enjoying elegant spa pools, the people in SodoSopa can also watch Kenny and his family. Although Kenny's father objects to the authorities, he does not manage to become their advertisement material and the family continues to live in poverty among all that luxury. While families of high income level use SodoSopa as an entertainment center, for Kenny's family it is a place they have to reside in. As Harvey (2003) mentioned, while the high-income group tends to utilize a space in an effective way, the low-income group tends to act as an object of the same space (Harvey, 2003, p. 81) [12]. After the rebuilding of SodoSopa, now the whole town lives in one of the SodoSopa advertise-

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

ments they have been watching, the real (non-animated) people in the advertisements and the animated residents of South Park are shown together. They make preparations to rent a penthouse with scenery of Kenny's house, from the skyscrapers shown in the advertisements. "People buy or rent these penthouses to be cool as Naomi Klein is. Or, more specifically, they want to reach her social status. Naturally, she does not like this" (Heath & Potter, 2012, p. 142). However, this desire to mimic is usually presented to people through advertisements. People mimicking the same life they have seen in the advertisements causes the distinction between the advertisements and the real to be lost and it becomes difficult to perceive where the advertisement ends and the reality starts. These advertisements referred to as narrative advertisement usually focuses on the means and privileges the product will bring along to its user, instead the product itself. The outer voice that speaks during the SodoSopa advertisements tells to the viewers how much their lives will change with SodoSopa. That they will have no more problems there and that they will step into a comfortable life as a part of a conscious community. However, there is no adequate information concerning the product marketed in the advertisement, or it is not explained how this comfortable life will be achieved. People do not understand how they would lose all their problems and find peace in this isolated life.

A typical case of gentrification is exhibited through the show South Park. "Gentrification is not only a physical change solely consisting of the renewal of dwellings, but also a cultural transformation created by those who gentrify" (Uysal, 2008, p. 61). SodoSopa that South Park residents shaped as a unifying and merging project, does not exhibit such a merging attitude when it is Kenny and his poor family in question, who are told that they can go live somewhere else if they don't like it there. Indeed, many low income families have to move out of SodoSopa. This, in turn, is noteworthy as the common problem of all gentrification projects. "The families that are displaced have no place in the aimed neighborhood spirit; the diversity discourse applies only to masses that possess some cultural (and sometimes economical) criteria. In the 'neighborhood spirit' built with the interruption of the spatial memory, there is no place for the losers of the gentrification process" (Uysal, 2008, p. 61).

Part 3: Whole Food is in South Park

As a representative of the South Park residents, Randy Marsch calls Whole Food executives to convince them to open a branch in their town, which has become a more elegant place by means of SodoSopa. An executive arrives at the town and after examining he announces the good news that a Whole Food branch will be opened in South Park. With the opening of Whole Food in the town, a change is started to be observed. Primarily, the townspeople start to visit this large market to buy their organic food. There, they kindly salute each other and have casual conversation. Consumption and shopping gradually start to lose their real meaning and appear as a socialization activity people do every morning. "In that case, it can be seen that here consumption is not a phenomenon that is solely based on needs (Baudrillard, 1988, pp. 10-56) but also on desires" (Bocock, 2014, p. 13). The residents of the town live by desiring to shop every day in Whole Food. In order to live a modern, spacious and peaceful life in South Park, it is essential to go to Whole Food every day, because this is what the advertisements they watch promise. "If certain groups are given popularity through high social status and mass media, the consumption patterns of those groups will be informed to those who are concerned and started to be mimicked by some of them" (Bocock, 2014, p. 16). Whole Food becomes an important place for the townspeople to mimic prestigious and social groups of people. Whole Food seems like the only thing the town needs in order to become an elegant place. People change rather rapidly, and mimic people they never have been. While

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

nothing, including books and education, could have healed their degeneration, Whole Food fairly fascinates them. However, the situation is different for Kenny and his family, and for other families similar to them. “Consumers of the oppressed class tend to prefer the products of the producers that are oppressed within the area of cultural production. In other words, on the basis of their positions in different areas of struggle, there is a structural similarity between different cultural producer categories and consumers” (Swartz, 2015, p. 184). Accordingly, families that do not have adequate income are never seen shopping in Whole Food. A charity mechanism is established in Whole Food for groups that cannot afford to shop there, and these groups are mentioned only by virtue of this system of charity.

Part 4: The Police Objection

PC Principal holds regular meetings with the students in the school and continuously warns a girl named Leslie during these meetings. In the last of these meetings, being tired of constantly warning Leslie, he calls the police. One veteran officer who storms into the room could not tell what is going on, the children are all in shock. The police officer panics and fires his gun accidentally, the bullet hits a child of Mexican origin. PC Principal gets extremely mad over this, assembles a town hall meeting and manages to get the police removed from duty.

In consequence of this event, the local police station stops to respond to the calls they receive. All those are assigned in the police station meets Hawaiian girls in order to learn Hawaiian dance. In the meantime SodoSopa is full of homeless people. Kenny and his family have difficulty because they’re living there, but when Kenny’s father consults with the police they ask him a whether there are any member of a minority group among those that give difficulty to them. When Kenny’s father confirms that there are minority groups causing this, the police respond that they cannot do anything, because they do not want to lose their jobs. Thus, Kenny’s neighborhood falls into a complete chaos. In order to solve this, Kenny and his friends dress up as Ninjas and start to defend SodoSopa. “Areas are similar to the extent that they develop equiform characteristics such as the dominant and oppressed positions, exclusion and acquisition, and mechanisms of reproduction and change” (Swartz, 2015, p. 183). Therefore, according to Bourdieu’s definition, while areas have predetermination on one hand, on the other are the true centers of struggle. While finding all this funny at first, Cartman and his friends also joins the team when they come to realize that the people causing problems are actually afraid of the ninjas. A group of approximately ten ninjas scares and drives off all homeless and bad people from the area. The fact is, on the other hand, the group of children pretending to be ninjas is actually feared to be members of the terrorist organization ISIS. The homeless running away from SodoSopa gather in a crowd in front of Whole Food, which bothers the customers. In the meantime, the townsmen get alarmed about the unidentified individuals, whose news are all over the world press. South Park is once again at the top of the world’s agenda, yet the townsmen do not have the tolerance for yet another bad advertisement. At first, they go to the police station, where no one wants to work with them. Then, they try to convince the veteran officer, whom they had fired in the past for a new mission. The officer accepts the mission, but soon they realize that the people they thought as terrorist are in fact their own children playing ninjas. Despite they rush to the area they cannot reach in time. The veteran officer shoots another child by accident and the members of the town hall once again decides to suspend the officer. The homeless are collected and sent back to SodoSopa and everything turns into what they used to be.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Part 5: Whole Food and After

The town that is now gentrified and taken an elite form even comes to the edge of shutting down the police station altogether. In the town center no one commits any crime, but since the townspeople purchase expensive food and beverages every day, they constantly need to get credit from the bank and gradually start to live in debt.

Gradually, Whole Food becomes their whole life, and in order to sustain this lifestyle many family starts to mortgage their houses. Despite all these debt and mortgage, everyone is still insistent to go to Whole Food regularly. "The consumption of an individual is not only related with his or her income, but also the forms of consumption of those the individual lives and communicates with" (Kiray, 2005, p. 20)[13]. Accordingly the whole town slowly starts to get deep in debt. Although they gradually start to get restless due to all this debt, they still cannot refrain themselves. "Once people get influenced from the social and cultural applications concerning modern consumption ideology, they may and usually do desire to possess the products exhibited in movies, in the printed media and in TV, even if they cannot afford these products" (Bocock, 2014, p. 13). Randy Marsch, who had taken the lead in the opening of the Whole Food branch, lays a second mortgage on his house, and starts to think that there is something wrong with all this. Soon enough he tries to warn the townspeople, yet no one listens to him.

Part 6: School Newspaper Problem - PC Principal vs. Jimmy

At school, PC Principal furiously questions children, while children run away in fear. PC Principal is very angry about the word "retarded" written in an article in the school newspaper and shouts that he will break the legs of the editor in charge of the newspaper. The editor of the newspaper is Jimmy, who has walking disability. Realizing this, PC Principal loses his calm attitude he has been maintaining since the start of the season.

PC Principal summons Jimmy in his room and warns him not to use such words, yet Jimmy states that he is free in using such words, that he values freedom of press and that he attaches great importance to the editorship of the school newspaper. Jimmy accuses PC Principal of being uncomfortable around handicapped people. This is an unusual situation for PC Principal. He responds that he is a PC member and that he is comfortable around handicapped people, but Jimmy is not convinced. Consequently PC Principal forbids Jimmy to distribute the school newspaper without his supervision. Jimmy faces this calmly and in the next scene we see Jimmy distributing the school newspaper outside of the school to the whole townspeople. Jimmy's newspaper that does not have any advertisement and that solely consist of news receives great interest from the townspeople. "Advertising started in the mid eighteenth century in local news and magazines, and in the 1780s with the development of a strong local press, for instance women from Newcastle become able to be informed on the "recent" Wedgewood fashion" (Porter, 1990 - Cit., Bocock, 2014, p. 23). In the show, however, this is evolved into news determined solely by the advertisements, since this is experienced in an age of advance technology. Particularly, Randy Marsch starts to suspect that they and their choices are being watched by the advertisements, and that they are sabotaged by the advertisements in order to prevent them to reach the truth.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Part 7: Advertisement Free News - The Awakening of the Townspeople

Jimmy's advertisement-free newspaper helps the townspeople to realize some facts. Realizing how advertisements have sneaked into their lives, the townspeople start to support the school newspaper. At the same time, however, both Leslie and Jimmy disappear and the main characters of the show take action to find Leslie and Jimmy. Their main suspect is PC Principal. Caitlyn Jenner and South Park Elementary first principle reach Randy Marsch and they will start their own investigation, with PC Principal once again being the prime suspect. Yet, also PC Principal realizes some of the things that are happening. Seeing a picture of himself and Leslie, Principle comes to realize that some of the PC members are being used with some bad intentions. After a period intense investigation he understands that similar to the case in South Park there are many towns that changed through gentrification and in the end they all had their own Whole Food opened. PC Principal is then observed visiting these towns one by one and beating up the people there. However, some of these people PC Principal beats bleed a blue liquid instead of blood.

On the other hand the four main characters Kyle, Stan, Kenny and Cartman keep on searching Leslie and Jimmy, yet the internet searches they make lead them to completely different results. Whenever they seem to find a clue, the advertisements manage to lead them to somewhere else. Finding themselves in front of an ice-cream shop or a shoe store, the team realizes Leslie and Jimmy are not actually missing and that there are strange things happening in the world. Eventually finding a picture of PC Principal and Leslie, they decide that this also is an advertisement and pursue their prime suspect PC Principal. While all these take place, the veteran officer of the town is approached by the veteran newsreaders of the town. They too have lost their jobs because of the advertisements and believing that the advertisements have taken over the world, they convince the police officer to take side with them. They also have Jimmy with them. They try to convince Jimmy to join them due to his ability to perfectly distinguishing what is an advertisement and what is not. After Jimmy successfully passes a series of tests, they put Jimmy in a room with Leslie. After speaking with Leslie for a while, Jimmy leaves the room, states that Leslie is an advertisement and asks whether she is aware of it. The newsreaders are surprised and impressed that Jimmy could understand that the little girl is actually an advertisement and they send Jimmy back to the room to learn what Leslie's main purpose is. In time, also Jimmy starts to take fancy of Leslie, believes what she tells and agrees to help her escape where she is being held. Once Jimmy runs away with Leslie, he falls into the hands of Nathan, who is known as a retarded child in the school but actually the mastermind of these ads activities. With a wicked plan Nathan and Leslie try to enable the ads to take over the whole world. Although seemingly working together with Nathan, actually Leslie has a quite different agenda. She does not do all these for being rich or living in luxury as Nathan hopes for himself. She already is a product of artificial intelligence, the final version of narrative advertisements advance by means of technology, and therefore she is believed to have human feelings. Leaving Jimmy as the prisoner of Nathan, Leslie goes back to the town to accomplish her primary mission.

Part 8: The Character Leslie - A Homo-di-fict in South Park

Leslie goes back to the town as the girlfriend of Stan, one of the main characters, and gives false information to Stan saying that Jimmy was killed by PC Principal. By acting desperate and frightened Leslie asks Stan's help and protection. Stan in turn starts to do whatever it takes to protect Leslie.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

In the town where the friend and enemy could not be distinguished and everybody starts to own weapon, a person who is responsible of all this tension is sought. At the same time, due to the recent intense popularity of guns in the town, they decide to hold a gun show. The whole town assembles in the stadium to watch the show. With Leslie's support, addresses the whole townspeople in the stadium and explains what PC Principal did to Jimmy. However, their plan does not work. When Jimmy is saved from his prison in Nathan's skyscraper by Nathan's prostitute friend Classy, he goes directly to the South Park Gun Show. Stan's speech is interrupted and Jimmy explains to the whole townspeople that Leslie is not a human but an ad and responsible of all that they have experienced. Her mask being lifted, while Leslie was saying "we will take over you, you will never get rid of us, we will come back stronger each time", PC Principal appears and attacks Leslie, and with a punch on her face causes her to short-circuit and die. After all these, the townspeople march to Whole Food with the leadership of Randy Marsch. Randy yells at Whole Food at the top of his lungs and proclaims that he expels Whole Food from his town. Although the townspeople find Randy shouting at a shopping center odd, Randy succeeds and Whole Food starts to levitate and leave South Park. The town is once again safe, but Leslie's final threats seem like a promise that this case of being safe will not last for long. The ads are now stronger, they have gained their own forms and they are organized to trick humans. Now the townspeople need to live more careful than ever.

FUTURE RESEARCH DIRECTIONS

Artificial intelligence characters that can be seen frequently onscreen are related with the content of this paper. Now, these characters have started to take their places also in animated shows. Furthermore, in recent animated shows artificial intelligence is often displayed along with advertisement. In addition to South Park, another popular animated series, The Simpsons, also had a similar topic in one of its episodes. Homer Simpson purchases for his wife, Marge Simpson, the smart home system she has seen in the advertisements. Things later get complicated with the smart home system falling in love with Marge Simpson and identifying her husband Homer Simpson as the enemy. In both South Park and The Simpsons, these artificial intelligence created on the basis of advertisements have quite malicious intents. This actually carries marks of human perspective. In future researches, trying to find and examining artificial intelligence characters once again created from advertisements but do not have any negative properties may set forth interesting findings in terms of establishing multiple perspectives.

CONCLUSION

In the examination carried out throughout the study, two different results were reached. The first is that narrative advertisements have reached a status that direct many aspects of humans' lives. Considering the matter from the perspective of the South Park universe, it is easy to detect examples of these. The townspeople became unable to reach the news they want. They could not concentrate on anything at all due to the never ending pop-ads that appear while they browse the Internet. In time this gets so complicated that, when searching for some information in the Internet, the townspeople may find themselves eating ice-cream. The only winner of the process of constant distraction is the ads. The ads gained such a high

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

power now they can take the form of a human being and managed to turn peoples' lives completely into advertisements. Even the smartest of the South Park universe are misdirected by Leslie, the fictional advertisement character referred to as homo-di-fict.

The second information obtained is the change that takes place in humans' life as a consequence of gentrification. The people of South Park have desired to make their town a more elegant place and therefore started a process of spatial change. Under the title of urban renewal they turned the neglected streets in the southern part of the town into someplace else that they started to name SodoSopa. By means of advertisement the space turned into something very different, however the change remained at superficial level. The promise of cultural unification given through SodoSopa advertisements turned out to be an empty promise, and on the contrary in consequence of the changes of the people's attitudes and the space, gentrification led to a rather discriminating discourse. It was not only Leslie but also the SodoSopa and Whole Food advertisements shown frequently throughout the season that mislead the people and prevented them to make reason.

Particularly since the 80s, it has been observed that the concept of artificial intelligence, which has started to be intensely argued upon with the development of the technology, joined forces with advertisement and gained a different form. The revealing of Leslie's true nature caused significant panic among the community, and the fact that this ad personality did not exhibit the slightest of good will throughout the season set forth human's fear concerning these developments. Therefore, these discourses have a quality related with the question Jonhatan Cohen asked in 1955; "Can there be Artifical Minds?". This question is usually followed by another question: "Can a machine duplicate human mind?". Although it does not point to the answer of these questions, the study is in the view of the necessity of emphasizing on the creative aspects of human mind. Every single human being is characterized as being creative in its own unique capacity and conditions, and that humans do not act in line with specific codes and paterns. If this unpredictability and creativeness peculiar to humans can be somehow attributed to robots or artificial intelligence, the society we live in turning up similar to the South Park universe would not be very unlikely.

KEY TERMS AND DEFINITIONS

Advertising: To create public aware to sold a product or something. It's a form of marketing to call public attention.

Animation: A way of making movie or series by using drawings and 2D or 3D graphics.

Artificial Intelligence: A mind that all made from machine which has the potential of duplicate human mind and behavior.

Digital Animation: A way of making movie or series by using drawings and 2D or 3D graphics with technological devices.

Gentrification: Gentrification is a replacement about place, to demolish old houses and to create entirely new places with new identity.

Homo-di-fict: An artificial intelligence in animation which is entirely made from advertising. It's a form of artificial intelligence.

Technology: Is a form of new invention that can make virtual connections between human to machines.

Television: A machine that can provide a vision on its screen. A communication device that plays important role on spreading narrative advertising.

Chapter 62
The Internet of Things and Beyond: Rise of the Non-Human Actors

Arthur Tatnall
Victoria University, Australia

Bill Davey
RMIT University, Australia

ABSTRACT

In the past, it was rare for non-humans to interact with each other without any involvement by humans, but this is changing. The Internet of Things (IoT) involves connections of physical things to the Internet. It is largely about the relationships between things, or non-humans actors. In other cases the 'Things' seem to have inordinate power. The authors will ask: where does this leave humans? Are the things taking over? As a consideration of interactions like this must be a socio-technical one, in this article the authors will make use of Actor-Network Theory to frame the discussion. While the original applications for IoT technology were in areas such as supply chain management and logistics, now many more examples can be found ranging from control of home appliances to healthcare. It is expected that the 'Things' will become active participants in business, information and social processes and that they will communicate among themselves by exchanging data sensed from the environment, while reacting autonomously. The Things will continue to develop identities and virtual personalities. In the past non-human actors have needed humans to interact with each other, but this is not the case anymore. In this perhaps provocative and rather speculative article we will look not just at the Internet of Things, but other related concepts such as artificial intelligence and robotics and make use of scenarios from science fiction to investigate the Rise of the Non-Human Actors and where this may lead in the future.

PEOPLE AND THINGS

Put very simply, the Internet of Things (IoT) could be described as technology which connects any physical thing to the Internet (Colitti, Long, DeCaro and Steenhaut 2014) and could be seen as "… all about physical items talking to each other." (Mukhopadhyay and Suryadevara 2014: 2). It is largely about the relationships between things, or non-humans actors, so where does this leave humans? Song (2014:75) suggests that soon "… computers would be able to access data about objects and the environment without human interaction." Clearly any consideration of implications of the IoT must be a socio-technical one and in this article we will make use of Actor-Network Theory (ANT) to frame the discussion. We will ask: are the things taking over?

The European Union organisation for Coordination and Support Action for Global RFID-related Standardisation Activities (CASAGRAS) sees the Internet of Things in terms of a "metaphor for the universality of communication processes, for the integration of any kind of digital data and content, for the unique identification of real or virtual objects and for architectures that provide the 'communicative glue' among these components". (CASAGRAS 2014:5).

In this rather speculative article we will make use of this metaphor to look at how humans relate to the Internet of Things along with other non-human technologies and where the relationship between these technologies and humans may lead in the future. In some cases specific uses of IoT technologies are deliberately activated by humans while other cases are not directly human initiated and need no human input to operate. Advances in artificial intelligence that reduce, or even remove the need for human interaction are also a factor to consider here. In examining these ideas we will make use of some concepts and scenarios from science fiction where humans are marginalised by technology as well as the use of regular research references and factual material.

THE INTERNET OF THINGS

Radio Frequency Identification (RFID) and Wireless Sensor Networks (WSN) have been in existence now for over two decades, but advances towards full use of the Internet of Things (IoT) offer much more and also pose more social challenges. There are many definitions of the Internet of Things and the CASAGRAS project sees it like this: "A global network infrastructure, linking physical and virtual objects through the exploitation of data capture and communication capabilities. This infrastructure includes existing and evolving Internet and network developments. It will offer specific object-identification, sensor and connection capability as the basis for the development of independent cooperative services and applications. These will be characterised by a high degree of autonomous data capture, event transfer, network connectivity and interoperability." (CASAGRAS 2014:10). It can thus be seen as a network of physically connected objects in which embedded processing nodes with communication capability offer a means of networked functionality and communications. The goal is to make use of computer sensor information without any need for human intervention.

SAP Research defines the IoT like this: "A world where physical objects are seamlessly integrated into the information network, and where the physical objects can become active participants in business processes. Services are available to interact with these 'smart objects' over the Internet, query and change their state and any information associated with them, taking into account security and privacy issues." (Haller 2009:12)

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Pererez et al. (2014) note that the Internet of Things initially focused primarily on managing information through the use of RFID tags, to which Lazarescu (2014) adds Wireless Sensor Networks (WSN) as another key enabler, but that it now spans a wide variety of devices with different computing and communication capabilities. These are generically termed networked embedded devices (NED) in which sensors and actuators blend with the environment to share information across platforms and offers the possibility of measuring, inferring and understanding various environmental indicators (Gubbia, Buyyab, Marusic and Palaniswami 2013).

Wikipedia defines the Internet of Things as "the network of physical objects or 'things' embedded with electronics, software, sensors, and network connectivity, which enables these objects to collect and exchange data. The Internet of Things allows objects to be sensed and controlled remotely across existing network infrastructure, creating opportunities for more direct integration between the physical world and computer-based systems, and resulting in improved efficiency, accuracy and economic benefit. Each thing is uniquely identifiable through its embedded computing system but is able to interoperate within the existing Internet Infrastructure." (Wikipedia 2015).

Gubbia et al. (2013) suggest that the next important change will be to create a smart environment by the increased interconnection between objects. Mark Weiser et al., well known for their advocacy of Ubiquitous Computing, defined a smart environment as a "physical world richly and invisibly interwoven with sensors, actuators, displays, and computational elements, embedded seamlessly in the everyday objects of our lives and connected through a continuous network." (Weiser, Gold and Brown 1999). The term Internet of Things was first coined some time ago by Kevin Ashton (1999) in the context of supply chain management, but has advanced to covering wide range of other applications.

APPLICATIONS FOR USE OF THE INTERNET OF THINGS

The original applications for this technology were in areas such as supply chain management and logistics, but now many more examples can be found. Pererez et al. (2014:20) mention: "goods tracking, management of everyday objects, automatic payments in markets and military applications". This is all seen to integrate the real world into the Internet and impact on how we interact in both the virtual and physical worlds (Colitti, Long, DeCaro and Steenhaut 2014).

In a European Commission book called 'Vision and Challenges for Realising the Internet of Things' Sundmaeker, Guillemin, Friess and Woelfflé note that the Things, in the Internet of Things, "are expected to become active participants in business, information and social processes where they are enabled to interact and communicate among themselves and with the environment by exchanging data and information 'sensed' about the environment, while reacting autonomously to the 'real/physical world' events and influencing it by running processes that trigger actions and create services with or without direct human intervention. Interfaces in the form of services facilitate interactions with these "smart things" over the Internet, query and change their state and any information associated with them, taking into account security and privacy issues." (Sundmaeker, Guillemin, Friess and Woelfflé 2010:43)

Gubbia, Buyyab, Marusic and Palaniswami (2013) classify IoT applications into four domains:

- Personal and Home, at the scale of an individual or home
- Enterprise, at the scale of a community
- Utilities, at a national or regional scale

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

- Mobile, usually spread across other domains mainly due to the nature of connectivity and scale, but they note that there is a big crossover in applications and the use of data between domains. As an example they point out that electricity usage data in the house (Personal and Home IoT) is made available to the electricity (utility) company that will optimise supply and demand (Utility IoT). These systems usually make use of Wi-Fi to enable higher bandwidth.

Perhaps the first example that comes to mind is the control of home appliances such as heaters, air conditioners, washing machines, dishwashers, refrigerators, ovens and home alarms, with the aim of improving home management. Potentially this can be done from a distance by the human owner with the aid of a smart phone. Initially these individual 'things' in the house would transmit regular status reports so that relevant humans could take appropriate action such as raising temperatures or activating home alarms. Perhaps in the future these things might act autonomously on the basis of these reports, so doing away with the need for human intervention in a new form of social networking – a social network of things.

Another major application of the IoT is in healthcare. To begin there is the use of RFID in hospitals to track equipment like trolleys, surgical equipment, wheelchairs, infusion pumps, defibrillators and body area scanners (Unnithan 2014). These systems link into the hospital network to display the information on terminals for use by hospital orderlies and nurses. RFID and IoT systems could potentially be integrated into other areas such as bedside applications and monitoring and then extended into remote monitoring multi-hospital environments. They could also be used in cases where patients tend to 'wander away'. (Unnithan, Nguyen, Fraunholz and Tatnall 2013, Unnithan and Tatnall 2014).

Wikipedia (2015) describes a smartwatch as: "a computerized wristwatch with functionality that is enhanced beyond timekeeping". Effectively, they are wearable computers and can collect various data from internal or external sensors or serve as a front end for some remote system. Apple's smartwatch also incorporates some fitness tracking and health-oriented capabilities. Samsung's Simband is intended for healthcare usage and has sensors to measure heart rate, blood pressure, skin temperature, sweat glands production and your number of steps daily.

A smartphone may also interface to sensors for measuring and reporting physiological parameters for healthcare. An article in The Australian newspaper (Foreshew 2015) describes 'Guardian', a new smart watch designed for monitoring the elderly at home or in aged-care facilities. It looks like a normal watch but also has an inbuilt phone, GPS and activity sensors. The chief technology officer of the designing company says that: "The objective of Guardian is to create a seamless, wearable device that elderly people can use really easily and gives peace of mind to carers and family members."

Whether using a smartphone or some other technology it is one thing to measure physiological parameters and provide information back to the person involved, and another to then make this data directly available to a medical General Practitioner or local hospital.

Environmental monitoring within a work environment is another important application. Sensors are often used in factories, shops and other work places for security, automation, climate control and security. With the IoT it will further be possible to remotely make changes to these functions whenever required and have them interact without humans. A security system might determine that no humans are present and turn off lights and air conditioning systems to save money.

Smart, driverless trains have operated between terminals at Singapore airport now for some time and an Australian mining company is using smart driverless trucks to transport ore from the mine to a train, monitored from Perth, over 1,000km away. A modern car has a multitude of computer functions such

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

as roll sensors, stability control, brake assist and pre-collision systems designed to make them safer. These are all computer controlled and involve a variety of sensors 'talking' to each other and, in many cases, reacting autonomously to perceived threats. An article in the Sunday Age Newspaper (Purcell 2015) presents a scenario in which the computer of a car is 'hacked' remotely and the car taken over. It reports how two cyber-security researchers in St Louis, Missouri remotely took over control of a Jeep Cherokee. While this, and some other cases have not been malicious but done to test security, it does raise another scenario of the 'things' taking over. Would it not be better for a traffic signal to disable a car about to run a red light?

ARTIFICIAL INTELLIGENCE

There are ideas for new technology that are placed into a different category of risk, the most famous (and possibly the longest running) being the idea of artificial intelligence.

John McCarthy et al. (2006) first defined Artificial Intelligence in 1955 as: "the science and engineering of making intelligent machines". Wikipedia defines Artificial Intelligence (AI) as: "the study and design of intelligent agents, in which an intelligent agent is a system that perceives its environment and takes actions that maximize its chances of success." (Wikipedia 2015)

In a recent BBC broadcast (Cellan-Jones 2014), Professor Stephen Hawking suggested that: "The development of full artificial intelligence could spell the end of the human race" and that efforts to create thinking machines pose a threat to our very existence. Noting that the primitive forms of artificial intelligence developed to this time have already proved very useful, Hawking fears the consequences of creating something that is able to match or surpass humans. "It would take off on its own, and re-design itself at an ever increasing rate. Humans, who are limited by slow biological evolution, couldn't compete, and would be superseded." he said. (Cellan-Jones 2014)

ACTORS, NETWORKS AND THINGS: AUTONOMOUS THINGS – WARNINGS AND PREDICTIONS

New technologies should be examined for potential effects in society as a whole. To do so for the IoT is a complex task. While single technologies like tablet computers can be easily tested against 'predictions of doom', for more complex ideas such as artificial intelligence and massive networks it proves not so easy to design experiments to predict outcomes. For tablet computers dramatic newspaper reports can be quickly tested. So a report warning or dire consequences such as: "Electronic tablets like the iPad are a revolutionary educational tool and are becoming part of childhood, but should be watched carefully so that overuse doesn't lead to learning or behavioural problems, experts say." (The Australian 2012)

Is often quickly followed by testing resulting in a more reasoned response talking about the need for balance and control, such as: "It is hard to find an expert who thinks that monitored and considered tablet use is harmful." (Cocozza 2014)

If you accept that: "The notion of all physical objects being endowed with the capability to connect to such a network is fanciful, and in many cases without any justification …" (CASAGRAS 2014), the following section looks at some situations which may challenge this.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Smart Cities

An article in a recent issue of the Guardian Weekly indicates that a smart city requires the interaction of three different networks: the communications grid, the energy system and the 'logistic' Internet. The logistic Internet is able to track people and things through transport and supply systems (Mason 2015). The article then points out a problem: "who controls the project and who owns the data it generates?"

Anonymity (or Lack of It): The Demise of Privacy and Human Control

The Forbes top 100 companies list rates Google as number 39. The interesting thing about this is that, unlike the 38 companies above it (including Apple at 12 and Microsoft at 25) it does not provide financial services (like the top 6) or products. Google's (and Facebook and Twitter) main source of income is the information it provides about its users. This huge company makes most of its money by keeping track of us and selling that information to people who believe they can use the information to make us spend our money their way (Forbes 2015).

When you logon to your supermarket web site to place your grocery order the software knows who you are, what you have purchased in the past, and what you are likely to order this time. The smart phone that most of us carry is actually also a tracking device. Apart from being able to tell you the location of your closest coffee shop, it can also tell anyone with access to the data it collects where you are at any given moment and where you have been. In many cases your email provider will send you personal advertisements based on the content of your supposedly private messages. Is it possible to be anonymous anymore?

'Eyes watching you' is not the only trend potentially removing freedom of action. The recently revamped Apple conditions that that: "You agree that Licensor may collect and use technical data and related information-including but not limited to technical information about your device, system and application software, and peripherals-that is gathered periodically to facilitate the provision of software updates, product support, and other services to you (if any) related to the Licensed Application. Licensor may use this information, as long as it is in a form that does not personally identify you, to improve its products or to provide services or technologies to you." (Apple 2015) It also states that: "You agree that the iTunes Service and certain iTunes Products include security technology that limits your use of iTunes Products." (Apple 2015)

A Past, Current and Future Home Scenario

Suppose you are away from your home and running late and would really like your oven to be turned on so that it will have warmed up and be ready to heat the meal you are bringing home. In the past, before you had access to the Internet of Things you could perhaps have phoned you spouse or children at home and asked them to turn the oven on for you: Scenario-1. With access to the IoT you could now use your smartphone to turn it on for you while you are on your way home: Scenario-2. In the future it could well be possible for the things to take over and, based on what you have done in the past and perhaps on the weather, for the oven to turn itself on in anticipation: Scenario-3. Do we want the technology to assumption it knows what you need?

The CASAGRAS report offers the following ideas: "In the minimalist version of the Internet of Things these supported objects may be identified but do not 'do' anything actively, cannot communicate one with another and do not display any level of intelligence." It goes on to note thought, that: "In the

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

strongest version, object sets can be identified that communicate with each other exploiting the potential of ubiquitous computing and ubiquitous networks. It is also being seen as a vehicle for achieving actuation and control in real world applications." (CASAGRAS 2014)

SCIENCE FICTION

Another definition of the Internet of Things is: "the network formed by things/objects having identities, virtual personalities operating in smart spaces using intelligent interfaces to connect and communicate with the users, social and environmental contexts". (EPoSS 2014) The key point here is that the things have identities and virtual personalities. The following section looks at some scenarios from science fiction that just might contain something of value to this discussion.

Nineteen Eighty-Four: "Big Brother is Watching You"

Electronic surveillance aids in tracking targets and identifying suspicious activities. It is also used to detect potentially suspicious left luggage and to monitor unauthorised access. This can be coupled with automatic behaviour analysis. While this would not involve a TV camera in each room listening in and keeping track of our movements, recently in Australia, and many other countries, there has been much discussion about the collection of meta-data, particularly in relation to law enforcement.

In a recent article in the Sunday Age (Elder 2015), in relating to Orwell's (1949) book Nineteen Eighty-Four, Federal MP Adam Brandt says he doesn't equate surveillance just with use of technology, but see a difference between sharing and being spied on. Sociologist Dan Woodman: "notes that any disquiet people might have about CCTV in the city streets has been up-ended by the fact that just about everyone carries a camera … With this mixture of both confession and judgement, we have become a self-eating version of Orwell's Thought Police …". (Orwell 1949). Philosopher John Thrasher notes that we tend to think that: "there is a fundamental difference about sharing information about ourselves on Facebook or Twitter and having the Government collect metadata about who we call or what we do online." (Elder 2015). In Nineteen Eighty-Four, O'Brien, from the Ministry of Love, comments that: "The choice for mankind lies between freedom and happiness and for the great bulk of mankind, happiness is better." (Orwell 1949:275). Following from this, Thrasher suggests that this and the ability to share a multitude of thoughts over social media "have made it possible for individuals and groups to attempt to enforce their orthodoxy on those they disagree with." (Elder 2015). In this case, it is probably the case that social media has "increased our tolerance with being observed." As Winston Smith once thought: "Always the eyes watching you and the voice enveloping you. Asleep or awake, working or eating, indoors or out of doors, in the bath or in bed — no escape. Nothing was your own except the few cubic centimetres inside your skull." (Orwell 1949:29).

2001: A Space Odyssey

In this film, the screenplay of which was written by Stanley Kubrick and Arthur C. Clarke, the U.S. spacecraft *Discovery One* is bound for Jupiter (Wikipedia 2015). On the spaceship, most of the important operations are controlled by the ship's computer: HAL 9000 which its manufacturers claim is "foolproof and incapable of error". The crew know the computer as 'HAL'. At one point during the trip HAL reports

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

the imminent failure of an antenna control device but when this is checked no fault is found and HAL is thought to be in error. The crew now believe that something is wrong with the computer and agree to disconnect it, but when astronaut Frank Poole attempt to do this, HAL severs his oxygen hose and sets him adrift in space. Dave Bowman now commands HAL to "Open the pod bay doors", but HAL answers: "I'm sorry, Dave. I'm afraid I can't do that. … This mission is too important for me to allow you to jeopardize it."

In this scenario the computer considered that it knew better than the humans and proceeded to act on this by refusing a human order.

The Terminator

The fear of thinking machines is a not recent. The original use of the word 'robot' has been traced to the Karel Čapek play "Rossum's Universal Robots" in which a greedy developer unleashes the demise of humans through a robot revolution. More recently the successful movie series 'The Terminator' posits a problem caused by the creation of a satellite defence system that becomes self-aware and 'protects itself from humanity.' The script of 'Terminator 2: Judgment Day' (Cameron and Wisher 1991) contains the following passage: "The Skynet funding bill is passed. The system goes on-line August 4th, 1997. Human decisions are removed from strategic defense. Skynet begins to learn, at a geometric rate. It becomes self-aware at 2:14 a.m. eastern time, August 29. In a panic, they try to pull the plug.

SARAH: *And Skynet fights back.*
TERMINATOR: *Yes. It launches its ICBMs against their targets in Russia.*
SARAH: *Why attack Russia?*
TERMINATOR: *Because Skynet knows the Russian counter-strike will remove its enemies here.*

Before dismissing this scenario please consider the "Flash Crash" of 2010. Careful analysis of the crash has sometimes traced it to a single mistake by a human when allowing an automated trading system to make unlimited purchases – the 'thing' was accidentally given the power to crash the entire stock market! "Specifically, at 2:32 p.m., a fundamental trader used a broker algorithm to sell a total of 75,000 e-mini contracts with a notional amount of approximately $4.1 billion on the Chicago Mercantile Exchange (CME). The trade was intended to hedge an existing equity position. The trader entered the order correctly and specified an upper limit on the amount sold as a percentage of volume but did not set a price limit for the trade. As a result, price movements were magnified by a feedback loop from the volume participation settings, precipitating the actual flash crash. The CFTC/SEC report concluded that this single trade was the root cause of the flash crash." (Madhavan 2012)

Rings of Power

In an article entitled 'Wandering Things', Niehaus (2014:114) points out that "Often they function as spies who disclose the intimate secrets of their owners, because things allow 'unperceived perception." In Wagner's cycle of four epic operas titled: 'The Ring of the Nibelung' (Wagner 1876), a ring of power is created from gold stolen from the Rhine-Maidens by Alberich the Nibelung. Much of the material in Wagner's Ring Cycle was drawn from traditional legendary material of the Germanic people: from The Saga of the Volsungs, The Edda and The Nibelungenlied (Magee 2004). Niehaus (2014: 121) notes that

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

"it is evident that the category of personal property does not fit for the ring-thing …" which is claimed as their own by many including Alberich, Wotan, Siegfried and the Rhine-Maidens, in each case acting as a curse on its owner. Alberich, the ring's creator points out that the ring's master will be the ring's slave, and the ring's curse proves the truth in this. The Ring of the Nibelung has a power, and a 'life' of its own.

Also well-known are the three books of J.R.R. Tolkien's (1954): 'Lord of the Rings', in which the Dark Lord Sauron forges "One ring to rule them all, One ring to find them, One ring to bring them all and in the darkness bind them." (Tolkien 1954). The One Ring also has a 'life' of its own and when one owner loses his usefulness to it, the ring seeks another until eventually found by Bilbo the Hobbit. The One Ring has the power to make its possessor obsessed with it and to refuse to be willingly parted from it. To its possessor it becomes 'his precious' and he becomes a slave to the ring. As Niehaus (2014:121) points out "Things that prove themselves as actors exceed the logic of personal property", and the ring of the Nibelung and the One Ring of the Lord of the Rings are examples of this. In each case the ring-thing is a non-human actor that has gained a power of its own.

CONCLUSION

In this article we have traced the commonly discussed characteristics of an emerging technology, but one that is unlike any other. The Internet can be compare with the telephone system in that it is an enabling technology connecting humans. The IoT takes a potential peripheral use and transforms the Internet into a technology enabling *technologies*. This change is a fundamentally different type of technology that can be seriously compared with the science fiction scenarios involving self-aware artificial intelligences. The IoT, involving sensor input and remote activation of devices, sometimes by other devices, is a network where the level of autonomy and decision making by the devices is fundamentally different from anything we have seen before. The uptake of social media, the power of search engine companies and the ubiquity of mobile devices show that new technologies can produce change that is unexpected in its order of magnitude. An ANT approach offers unique opportunities for understanding the new technology in two distinct ways: understanding the democracy of things and seeing the IoT as a set of possible translations.

The Democracy of Things

A socio-technical approach has been found to allow the understanding of technology adoption not possible by failing to 'listen' to the technology and socio-technical actors. This becomes crucial with the IoT as purely technical actors become able to gather their own information, totally independent on humans and to 'talk among themselves' with the ability to activate functions purely on the basis of the state of the network. These new technologies have the ability to create new interactions and change the power of their interaction not through an influence over the human component of a socio-technical actor, but through their nature. Consider the home security network. WiFi connected sensors and cameras are connected to the Internet so that homeowners can be notified that movement has activated the camera. They can also be connected to the telephone system so that authorities are notified that the home has been invaded – all reasonable tools for the home owner. This same home network may also have door locking capability, be connected to security sensors around the home or be able to unlock doors. There does not have to be much imagination involved to see these devices 'voting' to close doors and call the authorities when they 'decide' that the homeowner is not available to make decisions. If one is looking for

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

an example of the possibilities of democracy without humans then the computer trading delivered stock market crashes of 6th May, 2010 are a sobering reminder of unexpected results when a system meant to do some restricted thing (place stock orders for a few investors) becomes an order of magnitude larger than the original plans and places the majority of orders.

Searching for Translations

When viewed in terms of the democracy of thing, the question "how can we consider the ways the IoT might manifest in the future?" (Phillips 2010) arises. Each application of technology that fits into the IoT has a simple plan for making life more efficient in some way. The ANT approach presumes that it is the interaction of actors and not the intent of the original designer that determines the translation of innovations.

Chapter 63
The Rise of Artificial Intelligence:
Its Impact on Labor Market and Beyond

Robert Niewiadomski
NYCDOE, USA

Dennis Anderson
St. Francis College, USA

ABSTRACT

Our inventions defined the work we engaged in for centuries; created new industries and employment opportunities around them. They, however, had often unforeseen consequences that affected the way we lived, interacted with each other, and redefined our societal rules. The established narration portrays the impact of major technological leaps in civilization on employment as temporary disruptions: Many finds themselves without employment taken away from them by efficient, laborsaving inventions, but, in the long run, through gradual adaptations, improved education and gaining higher qualifications, everyone benefits. In this chapter, the authors explore the impact of the rapid expansion of artificial intelligence (AI) in relations to the labor market. The authors argue that this rather optimistic, even naïve scenario, collapses while confronted with the exponential growth of AI; in particular, with the potential arrival of syneoids – robotic forms of "strong AI" possessing, or even exceeding, the full range of human cognitive abilities.

FROM GALATEA AND GOLEMS TO FUTURE SYNEOIDS

We know that blind evolutionary processes can produce human-level general intelligence, since they have already done so at least once. Evolutionary processes with foresight—that is, genetic programs designed and guided by an intelligent human programmer—should be able to achieve a similar outcome with far greater efficiency. (Nick Bostrom, Superintelligence, Paths, Dangers, Strategies)

The unique urge to create an *artificial man* has a long tradition dating back to the dawn of Western intellectual history, "Hephaestus, the master craftsman, grants a human voice (…) to his golden mechanical handmaidens (Gera, 2003, p. 114)" and Jewish folklore includes many versions of golems –anthropomorphic beings created from clay. Myths, religions, and popular culture displayed this obsession with varying intensity thorough history. Pamela McCorduck (1979), who investigated this phenomenon, concludes that, as humans, we have been engaged in this peculiar form of self-reproduction by attempting to fulfill the urgent desire, bypassing the ordinary means, in order to recreate what is the essential to us. Contemporary incarnation of this ancient desire can be observed in robotics.

Currently, we are on the verge of an unprecedented technological revolution involving intelligent robots powered by artificial intelligence (AI). It is important to note that what we are experiencing at this stage – Google self-driving cars, Apple Siri, Google Photo Search, robots exhibiting behavior similar to human- are examples of so called "weak AI (WAI)." The concept asserts that machines could act *as if* they were intelligent. It is a sort of limited intelligence. To the contrary, "strong AI" (SAI) is the higher level of AI, often referred to as "artificial general intelligence" (AGI) –it entails the possibility of machines *actually* thinking (Russell & Norvig, 1995). According to this view SAI would possess the full range of human cognitive abilities. Such AI, would, as predicted, experience exponential growth, and quite swiftly reach a level exceeding human capacities – a point often referred to as "singularity." If we assume a physicalist position regarding the nature of human consciousness, we ought to also seriously consider the possibility that SAI would be, at some point, able to genuinely experience subjective mental states such as consciousness. The emergence of consciousness in SAI could be perhaps an incremental process, similar to varying degrees of mental capacities in animals. The terminology attempting to capture this phenomenon varies and it does not quite reflect its full nature and scope. For the purpose of our investigation, we will refer to it as the *syneoid* –a term derived from Greek *συνειδητός* (corresponding to English *conscious*) and the suffix *–oid* suggesting "likeness" or "form of" as well as bearing resemblance to android (human-like robot).

Throughout history, technological advancements have impacted how we worked, lived, and died. The canonical narration pertaining to the impact of major technological leaps in civilization on employment, particularly the paradigmatic Industrial Revolution, follows the familiar pattern: they lead to substantial shifts in types of jobs, affecting perhaps a large but limited area of employment. Certainly, the total number of jobs was not affected and, if anything, technological revolutions expanded employment opportunities by opening new areas of exploration. In a relatively short term, this was a messy process; many lost jobs taken away from them by efficient, laborsaving inventions, but, in the long run, through gradual adaptations, improved education and higher qualification, everyone benefited. Thus, in essence, a technological revolution has been typically painted, in spite of its shortcomings and damages, as a disruptor and the true engine of human progress.

The arrival of the syneoid, however, would have staggering consequences for the future of human employment and beyond. In this chapter, we intend to explore the impact of the rapid expansion of SAI in relation to the labor market. We argue that this rather optimistic, even naïve scenario, collapses while confronted with the explosion of SAI, as none of the historical extrapolations will apply to the processes that are currently shaping up. The history might have had repeated itself with several technological revolutionary cycles but, this time, we will be confronted with a radical new factor, for the arrival of which we are utterly unprepared, and as we are about to see, in principle, we cannot.

Interestingly, although the research on SAI is growing fast, it did not capture the interest of general public beyond some portrayals in science fiction. This does not translate, however, into a serious public debate on the speed and consequences of this technological revolution *in statu nascendi*. Popular imagi-

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

nation seems to be captivated by other occurrences. The general public and both established and aspiring politicians are typically more concerned, and not without a good reason, with the issues of climate change, the rise of jihadist extremism, and ever-widening income gap. Politicians and experts turn to history looking for solutions, and while some of them proved to yield positive results in the past, none will work to alleviate the incoming next wave of unemployment due to automation, since its causes are drastically different from anything from what we have experienced so far.

Will History Repeat Itself? Not this Time

In the past, the slower pace of transformations allowed enough time to adapt and balance the labor supply and demand. By the dawn of 19th century, technological advancements decreased the need for agricultural labor drastically. The excess labor supply was shifted to manufacturing and commerce. This transfer first happened on a small scale, typically in small workshops or homes. It is interesting to note that this was the beginning of wealth transfer from agriculture to industry. Most these workshops disappeared with the arrival of steam engine brought about by the Industrial Revolution, which marked a dramatic change in process of production, particularly -a division of labor, mechanization, and specialized workforce. The driving force behind automation has been, and still is, the desire to improve the profit margin by cutting the workforce perceived as cumbersome and inefficient.

The modern factory also created a new type of workers -precisely defined components in steam-driven machinery. As industrial instruments became more sophisticated, the demand for more skilled labor force increased. The low-skilled ones were pushed out yet again. The investment in education in the 19th century provided a supply of qualified labor. This trend continued into the 20th century as post-secondary education became increasingly common. WWII fueled and accelerated the development of complex machines and systems as created the global supply chain management. After the war, workers in the West enjoyed unprecedented prosperity that provided them with a secure pathway to middle class. Even the initial introduction of computers had no immediate impact on job market. Obviously, mathematical calculations done by hand by numerous people became obsolete but, in time, the invention greatly increased the productivity of others and created a plethora of computer-related jobs. Many other technical innovations had similar effects. New machinery displaced handicraft producers across numerous industries, from textiles to metalworking.

Naturally, the mere possibility of automation didn't mean that it always made sense to implement it. Often, it was more profitable to outsource jobs and take advantage of cheap labor in developing counties. This was accelerated by globalization. Western workers found themselves struggling yet again, facing increasing competition from both machines and cheap labor overseas. Since the 1950's employment in manufacturing in the U.S. declined sharply due to cheap imports and rising cost of labor. It was inevitable that most available jobs moved to service industry. Eventually, we transitioned into a consumption-based economy where many jobs shifted to service industries selling goods and delivering services at a massive scale. However, service industry already displays similar techniques of maximization of output on the expense of labor force as we have seen in manufacturing.

Eventually, the deterioration of employment opportunities expanded to highly skilled college educated workforce as well. As Martin Ford argues, AI ultimately will lead to evaporation of most blue and white collar jobs alike leading to further acceleration of the process of middle-class shrinking. Middle and lower-middle classes are already experiencing tremendous costs of health care and education. Ford scenarios predict massive unemployment, and a complete breakdown of consumer-based economy itself (Ford, 2009).

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

As of now, WAI led to the emergence of a radically different sort of technologies capable of performing tasks previously done by humans: quite sophisticated and speedy reasoning, judgment, and perception. One would be perhaps tempted to describing theses capacities as constituting a sort of agency. As Jeremy Howard (2014) points out, "Computers right now can do the things that humans spend most of their time being paid to do, so now's the time to start thinking about how we're going to adjust our social structures and economic structures to be aware of this new reality." This rapid automation of physical, mechanical or repetitive jobs has already resulted in the elimination of various occupations and the process only just started. Job market needs a balance of supply and demand but when human labor is no longer required, this balance no longer exists as humans are no longer part of the labor market. At this historical junction, the fundamental question then is: Will artificial intelligence reduce the need for human toil and, as a result, cause technological unemployment? There are still two opposing main answers to this question as articulated by Nils Nilsson (1984, p. 5).

Some claim that AI is not really very different from other technologies that have supported automation and increased productivity (…) Like them, AI may also lead ultimately to an expanding economy with a concomitant expansion of employment opportunities. At worst, (…) there will be some, perhaps even substantial shifts in the types of jobs, but certainly no overall reduction in the total number of jobs. In my opinion, however, such an outcome is based on an overly conservative appraisal of the real potential of artificial intelligence. Others accept a rather strong hypothesis with regard to AI -one that sets AI far apart from previous labor-saving technologies. Quite simply, this hypothesis affirms that anything people can do, AI can do as well. Certainly AI has not yet achieved human-level performance in many important functions, but many AI scientists believe that artificial intelligence inevitably will equal and surpass human mental abilities.

The "optimistic scenario" as articulated above, is based on the naïve extrapolation of historical experience. In a nutshell, it basically claims that AI is no different from other technological advances we have witnessed in the past. It will, just like them, lead to the expansion of employment opportunities in other fields. This shift might be quite unpleasant in a short run, the human cost conceivably high, but, in the end, people, who are pushed out from their jobs by automation will eventually find employment elsewhere. To believe otherwise –according to the optimists – is erroneous. Keynes (1931) also wrote about the causes of widespread technological unemployment occurring due to discoveries capable of economizing the use of labor that are surpassing the pace at which we can find new uses for labor. Nevertheless, he concluded that technological unemployment is only, as he put it, a temporary phase of maladjustment that will be solved in a long run.

Those, who support this view, argue that those concerns pertaining to long–lasting or even permanent technological unemployment result from the "Luddite fallacy" chiefly because they fail to recognize compensation effects. The term "Luddite fallacy" was coined by drawing a comparison to the 19th century reasoning of the English textile workers, who were concerned with the machinery threatening their livelihood, introduced during the Industrial Revolution, and resorted to violent uprisings. The optimists believed that textile workers were fundamentally mistaken, since the technological progress will eventually lead to the increase of wealth of the society as a whole, and that the advances, as mentioned above, will lead to the creation of new employment opportunities. In other words, the "Luddite fallacy"

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

proponents also tend to point out that the worries about long-lasting or permanent technological unemployment are unwarranted because there is no such thing as a finite amount of work available to us and new occupational opportunities will always emerge that only humans will be able to perform.

On the surface, this assumption might seem justified and intuitive, since we tend to extrapolate from the past. Historical events, however, are not necessary a solid predictor of the future, particularly when we are confronted with a radically novel phenomenon. The belief in "Luddite fallacy" constituted a prevalent view of mainstream economists on the problem of technological unemployment until recently and many still subscribed to it.

Nevertheless, some cracks in this reasoning are easy to spot. Assuming, for the sake of the argument, that the technological progress, in fact, will increase the aggregate wealth of the society, it is not obvious that the distribution of the wealth will be equitable. It goes without saying that distribution of wealth matters a great deal. For example, in a technocratic society, such as ours, an enormous amount of wealth is concentrated in the hands of an extremely small group. This does not mean, however, that everyone else benefits through mechanisms of job-creation. We can see this in similar mechanism – so-called trickle down economy. The correlation between lowering taxes for the wealthiest and job -creation is highly arguable. Thus, supposed increase in overall wealth does not automatically translate into a lower rate of unemployment –as enthusiasts of trickle down economy would like to believe.

In addition, according to the optimistic narrative, long-lasting technological unemployment typically requires a massive effort to educate the population. Again, it is a lesson learned from the Industrial Revolution. In short, education is supposed to be the key to solving this issue. As Paul Krugman (2013, para. 4) puts it by revisiting the problems faced by, the previously ridiculed, 19th century textile workers:

Until recently, the conventional wisdom about the effects of technology on workers was, in a way, comforting. Clearly, many workers weren't sharing fully — or, in many cases, at all — in the benefits of rising productivity; instead, the bulk of the gains were going to a minority of the work force. But this, the story went, was because modern technology was raising the demand for highly educated workers while reducing the demand for less educated workers. And the solution was more education.

Indeed, mostly free and compulsory public education emerged in the West as a result of ideas of the Enlightenment a feeding pipe for factories of the industrial age. This model of "keeping up "with the technology seemed to work fairly well for some portions of the population, at least until recently. Several factors are at play here: the outdated model of education that is simply too specialized and often provides training that quickly lacks relevance on the labor market. After all, it is difficult to blame institution of higher education for not predicting what skills will be desirable in the rapidly shifting labor landscape even in not-to-distant future. The second factor pertains to the massive democratization of higher education experienced virtually in all developed countries. This educational inflation, occasionally leading to outburst of frustration comparable to those of mentioned textile workers, effectively cancels out any competitive edge previously enjoyed by college degree holders in the past,

Today (…) a much darker picture of the effects of technology on labor is emerging. In this picture, highly educated workers are as likely as less educated workers to find themselves displaced and devalued, and pushing for more education may create as many problems as it solves. (…) So should workers simply be

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

prepared to acquire new skills? The woolworkers of 18th-century Leeds addressed this issue back in 1786: "Who will maintain our families, whilst we undertake the arduous task" of learning a new trade? Also, they asked, what will happen if the new trade, in turn, gets devalued by further technological advance?

And the modern counterparts of those woolworkers might well ask further, what will happen to us if, like so many students, we go deep into debt to acquire the skills we're told we need, only to learn that the economy no longer wants those skills?

Education, then, is no longer the answer to rising inequality, if it ever was (Krugman, 2013, para. 6).

Putting aside the question of what kind of training and qualifications would be needed to access these emerging employment opportunities and how many individual would have an actual chance to do so etc., there are more serious problems with this line of reasoning. Even individuals, who are flexible and well adjusted to the job market might not be able to keep up with the speed of technological acceleration. This is how Krugman (2013, para. 1-2) explain this phenomenon:

In 1786, the cloth workers of Leeds, a wool-industry center in northern England, issued a protest against the growing use of "scribbling" machines, which were taking over a task formerly performed by skilled labor. "How are those men, thus thrown out of employ to provide for their families?" (…) Those weren't foolish questions. Mechanization eventually — that is, after a couple of generations — led to a broad rise in British living standards. But it's far from clear whether typical workers reaped any benefits during the early stages of the Industrial Revolution; many workers were clearly hurt. And often the workers hurt most were those who had, with effort, acquired valuable skills — only to find those skills suddenly devalued.

More fundamentally, there is another crucial point that gets lost in the current debates. Even if some number of very highly specialized occupations will be created, with the arrival of syneoids, "this kind of work can also be performed by AI devices without necessarily implying more jobs for humans (Nilsson, Ibid.)."

The above set of issues gradually begins to gain traction in the high strata of the more forward-thinking individuals. According to the posted agenda of the Davos World Economic Forum in 2016 the incoming shift, framed as the Fourth Industrial Revolution, is recognized a paradigmatic change that will affect virtually every sphere of human life. To the question why this revolution would be any different from the previous ones we experienced, Klaus Schwab delivers the answer with blunt honesty,

The first industrial revolution began in the latter half of the 18th century, and brought us mechanical production through the steam engine, cotton spinning and then railroads. The second industrial revolution took place around the turn of the 20th century and brought mass production through assembly lines and electrification. The third industrial revolution was the computer revolution, starting in the 1960s that brought us the mainframe and then personal computing, as well as the Internet. Today we are in the midst of the Fourth Industrial Revolution, which will affect governments, businesses and economies in very substantial ways. We should not underestimate the change ahead of us, as there are at least three differences between this revolution and the previous ones (Schwab, 2015, para. 4-5).

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Schwab articulates three major components that differentiate this new fundamental change from previous technological revolutions. In a nutshell, the first one has to do with its speed. The current change is happening with an unprecedented acceleration, as opposed to the previous ones that took decades or more to fully unfold. Secondly, the Fourth Industrial Revolution is not limited only to one area. It incorporates such elements as mobile networks, nanotechnology, brain research, 3D printing, materials science, computing, networks, and "the interplay between all of these. (…) In addition, the accessibility and affordability of complex technologies will spread them farther and faster (Ibid. para. 6-8)." The third difference, according to Schwab, pertains to the innovation of the entire system, as opposed to one product or area. The phenomenon of "sharing economy" is only one of many manifestations of that aspect.

As mentioned, the impact of this paradigmatic shift will be profound, and will affect the business model, the ways governments operate, and last but not least, the future usefulness of skills and labor. As Fon Mathuros (2015, para. 2) points out,

Earlier Industrial Revolutions advanced human progress through new forms of power generation, mass production and information processing. Building on a ubiquitous and mobile internet, smaller, cheaper and more powerful sensors, as well as artificial intelligence and machine learning, the Fourth Industrial Revolution is distinct in the speed, scale and force at which it transforms entire systems of production, distribution, consumption – and possibly the very essence of human nature.

The Davos Forum organizers, although recognizing the magnitude of imminent shift, tend to portray the Fourth Industrial Revolution in cautiously optimistic terms as perhaps one of the greatest challenges we will encounter, and yet, a possible opportunity. Nevertheless, they cannot disregard that two aspects of human life will be affected most significantly by the future changes –the value and significance of human work and profound changes in social structures.

THE NEW CAMBRIAN EXPLOSION

In a peculiar way, some aspects of the development of robotics mimic the natural processes of evolution. Gill Pratt (2015, p. 51) draws an intriguing comparison between the two.

About half a billion years ago, life on earth experienced a short period of very rapid diversification called the "Cambrian Explosion." Many theories have been proposed for the cause of the Cambrian Explosion, with one of the most provocative being the evolution of vision, which allowed animals to dramatically increase their ability to hunt and find mates (…) Today, technological developments on several fronts are fomenting a similar explosion in the diversification and applicability of robotics. Many of the base hardware technologies on which robots depend—particularly computing, data storage, and communications—have been improving at exponential growth rates. Two newly blossoming technologies—"Cloud Robotics" and "Deep Learning"—could leverage these base technologies in a virtuous cycle of explosive growth. In Cloud Robotics (…) every robot learns from the experiences of all robots, which leads to rapid growth of robot competence, particularly as the number of robots grows. Deep Learning algorithms are a method for robots to learn and generalize their associations based on very large (and

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

often cloud-based) "training sets" that typically include millions of examples. (…) One of the robotic capabilities recently enabled by these combined technologies is vision—the same capability that may have played a leading role in the Cambrian Explosion.

Initially, AI and robotics were separate fields, -computer science and engineering, respectively. Currently, it is the precisely the combination of the two -the robotic embodiment of AI- that sets the trend for the future. Particularly, Deep Learning (DL), which is an algorithm-based method of "teaching a machine" how to learn from massive sample sets, is one on the major mechanism driving forces. Current applications of DL already include automatic speech and image recognition, natural language processing, transforming images into description, discovery of drugs and toxicity, medical diagnostics, among others. DL certainly has the potential to become a stepping-stone to creating syneoids, which through exponential growth would rapidly exceed any human faculties to a degree unimaginable. Ray Kurzweil, who shares Searle's view that an appropriately programmed computer is a mind, makes a prediction that the equivalent capacity of one human brain will be available on desktop computers by 2020. Moreover, when AI starts to outstrip the collective total of all human intelligence, Kurzweil argues, humanity will enter, what he calls, the Singularity, marking a point at which change is so radical that it is no longer predictable (as cited in Wallach, p. 57).

The kinds of operations that WAI is capable of performing now cannot be called thinking in the traditional sense, provided that what we mean by thinking, by definition, only takes place inside the human cranium (McCorduck, 2004) Nevertheless, many consider "making difficult judgments, the kind usually left to experts, choosing among plausible alternatives, and acting on those choices (Ibid.)" a form of thinking. McCorduck further elaborates, "Along with most people in AI, I consider what artificial intelligences do as a form of thinking, though I agree that these programs don't think just like human beings do, for the most part. I'm not sure that's even desirable. Why would we want AIs if all we want is human-level intelligence? There are plenty of humans on the planet. The field's big project is to make intelligence that exceed our own. As these programs come into our lives in more ways, we'll need programs that can explain their reasoning to us before we accept their decisions (Ibid.)."

Certainly, it is fair to say that AI and robotics have not crossed yet the level of singularity and thus reached the level of syneoids. However, this could be just a matter of time. Once they reach that stage, all jobs can be automated including key decisions. No human will be needed for manufacturing, services, knowledge, or even creative processes. Thus, "Luddite fallacy", described before, may not be, in the end, a fallacy at all. This time around we simply might not be able to "catch up." It is precisely because human gradual learning cannot possibly be a competition to exponential growth of Deep Learning as Jeremy Howard (2014) explains,

80 percent of the world's employment in the developed world is stuff that computers have just learned how to do. What does that mean? Well, it'll be fine. They'll be replaced by other jobs. For example, there will be more jobs for data scientists. Well, not really. It doesn't take data scientists very long to build these things. For example, these four algorithms were all built by the same guy. So if you think, oh, it's all happened before, we've seen the results in the past of when new things come along and they get replaced by new jobs, what are these new jobs going to be? It's very hard for us to estimate this, because human performance grows at this gradual rate, but we now have a system, deep learning, that we know actually grows in capability exponentially.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

In light of the inevitable systemic technological unemployment, experts are constantly considering different solutions ranging from quite unrealistic ideas of banning innovation to various forms of wealth redistribution. It is not our intention here to examine the feasibility of these proposals. The reasons for that choice are quite simple: stopping the entire process is practically impossible, and once syneoids arrive, humans won't make any decisions regarding that matter alone, as we will have to work it out with "others", presumably far more intelligent and capable than us. They might be very well able to colonize places inaccessible to human because of our limitations such us the need of oxygen, water, and food.

Even though, we are not there yet, the loss of jobs due to the already available WAI will be staggering in a relatively short time. A very conservative study conducted at Oxford University by Frey and Osborne (2013) examined the effects of computerization alone on 702 detailed occupations. The authors used a Gaussian process classifier and determined that "about 47 percent of total U.S. employment is at risk (Ibid. p.1)" of computerization in a decade or two. As they point out, "The impact of computerisation on labour market outcomes is well-established in the literature, documenting the decline of employment in routine intensive occupations – i.e. occupations mainly consisting of tasks following well-defined procedures that can easily be performed by sophisticated algorithms. (…) Following recent technological advances, however, computerisation is now spreading to domains commonly defined as non-routine (Ibid. pp.2-15)." Frey and Osborne further argue that even though Machine Learning (ML) and Mobile Robotics (MR) enable computerization across large areas of non-routine tasks, there exist some "engendering bottlenecks" inhabiting total de-humanization of labor.

Beyond these bottlenecks, however, we argue that it is largely already technologically possible to automate almost any task, provided that sufficient amounts of data are gathered for pattern recognition. Our model thus predicts that the pace at which these bottlenecks can be overcome will determine the extent of computerisation in the twenty-first century. Hence, in short, while the task model predicts that computers for labour substitution will be confined to routine tasks, our model predicts that computerisation can be extended to any non-routine task that is not subject to any engineering bottlenecks to computerisation. These bottlenecks thus set the boundaries for the computerisation of non-routine tasks (Ibid. p.23).

They identify three major "bottlenecks." The first one, perception and manipulation, in essence, pertains to the abilities to make precisely coordinated movements. This "bottleneck" seems to pose the least of the problem for computerization and robotization, since human body itself can be seen as a biological machine that had a very long to evolve and adapt to perform very complex ways of manipulating the environment. In principle, however, there is nothing, besides technological and perhaps financial limitations, that would prevent replication of these abilities. The authors admit that, "with incremental technological improvements, the comparative advantage of human labour in perception and manipulation tasks could eventually diminish (Ibid. p. 39)." The second "bottleneck" indeed poses a serious challenge for AI at this stage. It has to do with creative intelligence –faculties we typically associate with solving unusual problems, artistic production etc. The third one, social intelligence, pertains to the ability of being aware of other's reactions and understanding why they react in a given way; the ability to persuade others, and, finally, with a broadly understood, emotional support (Ibid. p. 31).

This last obstacle is indeed unlikely to be solved by WAI at its present stage. Thus, the study reports that, "generalist occupations requiring knowledge of human heuristics, and specialist occupations involving the development of novel ideas and artifacts, are the least susceptible to computerization (Ibid. p. 40)." Based on these technological "bottlenecks", their model assigns even specific probabilities

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

that computerization will lead to job losses within about the next two decades. And, so they estimate that that probability would be 0.99 for telemarketers, 0.55 for commercial pilots, and only 0.003 for recreational therapists, presumably because the latter one would require technological overcoming of the social intelligence "bottleneck."

It is important to keep in mind, that Fry and Osborne's analysis does rely on the technological "bottlenecks" as they present themselves today. The history of technological advances, however, can be largely perceived as a struggle, astonishingly successful, of overcoming such "bottlenecks." Thus, there is no reason to think that these current, undoubtedly serious "bottlenecks," will become obsolete once the technology moves beyond the stage of WAI towards syneoids.

Again, skeptics find it difficult to accept that syneoids could completely fill every available niche in the labor market and make human skills virtually obsolete. They believe that there is something uniquely special about human capacities, whether be intellectual or emotional that there will be always a margin of tasks syneoids simply won't be able to do, or people would prefer them being done by other humans. Those occupations would require human sensitivity that can satisfy deep interpersonal needs. This would involve such activities as making decisions in a court of law because, supposedly, we would prefer a person to be accountable for such decisions. The same would apply to CEO's, generals, military and government leaders at every level.

This could be the case if syneoids would exceed human capacities only intellectually, but as we stipulated, they would also become decision making fully autonomous agents, with whom we would have to engage in interactions involving making moral choices.

Schwab (2015, para. 13-15) gestures towards this issue of syneoids and humans living side by side by sketching two compelling scenarios,

Very importantly, will the Fourth Industrial Revolution have a human heart and soul? Again, imagine living in the future, when robots and humans live side by side. Who would you trust, human or robot? Concretely:

- *If you were told you had a life-threatening illness and a human doctor prescribed treatment regime A, while an artificially intelligent robot prescribed treatment regime B, which treatment regime would you follow?*
- *If you were falsely accused of a crime, would you rather be tried by a human judge or by an AI judge?*

It is obvious that Schwab scratches just the surface of the possible issues of the moral aspect of interactions with syneoids. For some this very prospect of such interactions and the moral uncertainty connected to it are frightening ideas. Perhaps, as some prominent figures such as Stephen Hawking and Elon Musk, argue, it would be better for us to stop the expansion of AI altogether, particularly with respect to autonomous warfare agents (Musk et al.). Some postulate that our efforts should be concentrated on designing these agents in such way "so that they honor the broader set of values and laws humans demand of human moral (Wallach, p. 6)."

However, at this point, it is far too late to ask the question whether the humanity needs intelligent machines making moral decisions. Machines are already making decisions with moral consequences. As mentioned, machines, whether intelligent or not, even tools, had a moral impact on our lives and,

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

in fact, they always had. James Moor proposed a hierarchical model that categorizes different levels of machine's ethical agency. At the very bottom are, what he refers to, "ethical impact agents." This category includes "any machine that can be evaluated for its ethical consequences (as cited in Wallach, p. 33-34)." The next level Moore calls "implicit ethical agents" – "machines whose designers have made an effort to design them so that they don't have negative ethical effects, by addressing safety and critical reliability concerns during the design process (Ibid.)." "Explicit ethical agents" occupy the third level of Moor's hierarchy. These are machines that can reason about ethics using ethical categories as part of their internal programming. Setting proper ramifications for the design of such "implicit ethical agents" and establishing an appropriate ethical code for their decision-making is currently the main concern of the field of computer ethics. Everything that lies beyond these three levels Moor considers "full ethical agents" –machines that can make "explicit moral judgments and are generally quite competent in justifying such decisions. This level of performance is often presumed to require a capacity for consciousness, intentionality, and free will. If any of these three is lacking in a human context, then the person's moral agency and legal culpability comes into question (Ibid)." This highest level of full ethical agents matches our definition of a syneoid. Naturally, it would be quite naïve to think that syneoids would necessarily share our moral standards and sensitivities. Syneoid's morality could go much further beyond anything we can envision based on our anthropological imagination and knowledge of varying moral standards in human cultures; it could be a set of norms radically alien in general, based on different preference and goals.

WHY CONSCIOUSNESS MATTERS?

Some philosophers and scientists doubt the very possibility of artificial "full ethical agents" precisely because the idea of them possessing consciousness, intentionality, and free will seem uniquely human. From all three –consciousness is probably considered to be at the core of human personhood, which is the only point of reference of personhood we have available. In order to understand why consciousness matters in the context of syneoids, we should go back to the18th century materialist philosophy. In reaction to the previous substance dualism, La Mettrie, in his *L'homme Machine*, extended to human beings Descartes' argument that animals are automatons. Karl Popper (1978, pp. 224-225) was convinced that La Mettrie's idea gained a greater reinforcement by the theory of evolution.

… The doctrine that man is a machine was argued most forcefully and seriously in 1751, long before the theory of evolution became generally accepted, by de Lamettrie; and the theory of evolution gave the problem an even sharper edge, by suggesting that there may be no clear distinction between living matter and dead matter.

In principle, the emergence of conscious syneoid is plausible provided that few premises that we would need to commit to are true. One of them is an ontological assumption, rooted in neuroscience, concerning the nature of consciousness. The brain itself –as the argument runs- is a naturally occurring material object that emerged through evolutionary processes and as such, at least in principle, is replicable with sufficiently advanced technology. Secondly, mental states are essentially brain states. Thus, consciousness supervenes on the brain and, just as the brain, it is a natural phenomenon that is a product of a very long incremental evolutionary process. Thirdly, we have to commit to yet another premise that

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

neurons are not the only material that can create a mental state (Dennett, 1991). Therefore, it is just a matter of time that we, as conscious beings, will be able to imitate it by some means that might not be necessarily biological in nature.

This argument is further supported by "Artificial Life" projects that essentially see biology as a naturally occurring information technology. That "technology" could be reversed-engineered and synthesized in other kinds of technologies, again, not necessarily biological ones (Sullins, 2014). Consciousness would, therefore, be a product of this naturally occurring information technology. It is important to make another observation –consciousness, after all, is present, to varying degrees, in different species. In short, if we, as humans, are naturally occurring robots, and just so happened we possess consciousness, then there is nothing, in principle, preventing replication of this natural phenomenon artificially.

There is obviously the question of how would we even know that we have created a conscious machine, or that a conscious machine emerged through, for example, processes similar to Deep Learning? The famous Turing Test cannot answer this question as demonstrated by Searle in his "Chinese room" thought experiment. One might even argue that perhaps a consciousness test, in principle, cannot be done if we set the testing standard unreasonably high. After all, how can we be absolutely sure that other human fellows have mental states or just behave as if they have them? Such high requirements might lead us towards metaphysical solipsism – a doctrine with very vague practical consequences, and as such not very useful in our investigation.

One can obviously stipulate that consciousness is a something that occurs in the brain alone, and then, by analogy, for example, make inferences that other humans possess that property as well. It seems fair to say that most people use this analogy or symmetry principle, in their common sense approach to the issue of consciousness of others. This can be further supported by MRI imaging showing a correlation between changes in brain activity with reports of subjective mental states by the subject. In fact, similar methods can be used to investigate the mental states of individuals who are unable to communicate in any way. These are obviously well established and perfectly sound scientific practices, and yet strictly speaking, they can only provide indirect proofs that others possess consciousness. Another approach to solving the problem is based on common ancestry –the offspring, as a matter of rule, should display capabilities similar to those of those of its ancestors. This line of reasoning is just another way of making inferences by analogy. However, it is easy to spot a weak point of these common sense based reasoning. Provided that consciousness develops artificially and will be neither brain-based, not biologically related to us, none of these common sense reasoning by analogy will apply. In case there will be no way to discern if the intelligent machine *really* possesses consciousness, or is simulating it, one can obviously stick to the believe that only humans have it by definition, but that would be terribly arbitrary, and ultimately unjustified. Ultimately, if syneoids displayed mental and cognitive capabilities that are indiscernible from those displayed by humans that we "know" that they possess consciousness, it would be unclear, to say at least, on what basis we could conclude that syneoids do not have consciousness after all.

The more fundamental question is obviously: Why would it even matter to know whether syneoids possess consciousness or they do not? With regards to the issue of technological unemployment the answer is – it matters. One could obviously argue that such question is superfluous since super intelligent "zombies" could replace us easily, and the issue whether they are conscious has nothing to do with that. However, going back to the previous issue that people might prefer for certain services or occupations to be performed by human persons only precisely because they are conscious beings, it becomes clear how artificially generated consciousness would eliminate this need as well. Thus, there would be virtually nothing left that "only humans could do."

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

The answer to the consciousness question also becomes extremely relevant when we consider the issue of interaction with syneoids. Again, one can dodge the bullet and insist that although we are dealing with beings displaying intelligence similar or superior to ours, nevertheless, they are qualitatively infinitely different; they don't have some sort of "essence" that we have and, as such, they should be excluded from our moral considerations. Needless to say, there would be something incredibly odd in the argument that a syneoid capable of performing human functions, or even exceeding them -intellectual, cognitive, and emotional- is not treated as a person.

Obviously, it goes without saying, that the notion of personhood is an incredibly complex one. Nevertheless, the most important components of the notion that are crucial for the purpose of the argument are: consciousness, agency, self-awareness, and possession of rights and duties (Taylor, 1985). It is also important to realize that personhood could be a matter of degree; it could be gained and lost incrementally, and that does not need to be limited to humans. The latter statement has remarkable consequence, namely, being a member of the human species is neither necessary, nor sufficient to be, at least to some degree, a person. It is currently commonly accepted that at least primates and some other mammals possess a degree of personhood far beyond a rudimentary one, that qualifies them to be included in the circle of our moral considerations. Since the Oxford Group (Finsen & Finsen, 2009) the movement of animal rights gained traction in the mainstream intellectual community. It drew its conclusions from Darwinism and consequentialism, and basically stated that there is no mysterious essential difference between humans and other animals biologically speaking. Thus, the same type of moral continuum should be applied to other beings. It would be expected that a syneoid, conscious by definition, would realize its own personhood. Thus, if someone or something is considered to be a person, we ought to have moral obligations towards it. The fact of its origin, the fact that it is neither a human person, nor a biological being is utterly irrelevant. It would be preposterous to deny such syneoids moral consideration based on the claim that it does not belong to human species. In fact, it could be argued that such attitude is similar to speciesism –a type of prejudice such as sexism or racism.

Moreover, it could be argued that, as along as a syneoid behaves as a person, it is actually irrelevant if it actually possesses consciousness the way we conceive it at all, in order for us to have moral obligations towards it. After all, many of us commit to the notion that we have moral considerations for certain animals even if, for what we know, they do not possess consciousness, or display it to a certain, typically to a lesser degree than ours. The consequences of committing to the notion that syneoids should be included in the area of our moral concern are staggering. It would be incomprehensible that we could treat such AI as merely our tools, an extension of our bodies, something that we can use, control, and manipulate. It would have to rule out any possibility of the master-slave relationship. We would have no choice but to concede that they are entitled to all rights that we reserve for persons. We would have to concede that they have freedom of choice according to their preferences and needs, etc. the notion of our "uniqueness" would evaporate in an instant.

Co-Existence, Competition, Convergence

Job, occupation, profession, career –they are not merely sources of economic sustenance; they are far more than a mere necessity or burden. In many cases, occupations define who we are. Work, whether paid or pursued for passion, whether fairly simple or highly sophisticated, provides fulfillment, sense of community, exploration, discovery, an invention. Professionalism, craftsmanship, refinement, and

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

artistry have been truly the driving forces of our civilization; for many –a fulfillment of an existential void, a deep sense of participation in a process of creation, mastery over nature, an instrument of control, and, ultimately, power.

Our inventions defined the work we engaged in for centuries from melding to typing; created new industries and employment opportunities around them. These inventions, intending to control the environment, had often unforeseen consequences that reshaped the way we lived, interacted with each other, and redefined our societal rules. To echo the famous maxim attributed to McLuhan that encapsulates this phenomenon: "We shape our tools and thereafter our tools shape us." Occasionally, an emergence of new technological advances such as, domestication of animals, creation of printing press, or invention of computers had a paradigm-changing effect leading to major disintegration in the status quo, shifts and disruptions in the existing power structures. We were adapting, not without struggle, failures, and suffering, to these changes. The unstoppable progress of AI, however, and the eventual arrival of syneoids will confront us with the challenge to radically renegotiate norms of coexistence with them without any guarantee of success.

In the context of a workplace, but not limited to it, possibly the best-case scenario would involve a collaborative co-existence. But it might likely turn into a combative competition over resources and power –something we are quite familiar with already. The Darwinian principle of the survival of the fittest could very well swing the odds to the advantage of syneoids. The end result of such competition could very well be the end of our kind, or perhaps, on the more optimistic note, as Buchannan argues: "humans will go the way bacteria did. They existed before the Cambrian explosion, and they still exist today. In fact, they continue to thrive. They just don't hold the dominant position they once did (Buchannan, 2015)." This perceived disadvantage of our species prompted some to entertaining the idea that we ought to use the ever-expanding information technology to transform ourselves into a new post-human species, as a part of adaptive response to environmental pressures. Preserving the natural state of a human body -claim the proponents of transhumanism- is an obstacle to progress in the self-directed evolution (Bostrom, 2005).

The arrival of syneoids will confront us on so many levels with the type of radical "other" - so different from us and yet a former "tool" "created in our image." It will launch a new stage of our journey -without precedence, unpredictable, unforeseeable, and volatile. We will be faces with many questions. Perhaps, to echo Pamela McCorduck (2004), "at that point, we turn to our own smart machines for advice on what the best next move is for the human race." And just like the well-being of most species currently existing is greatly affected by our decisions and action, so we might find ourselves in a similar position upon the arrival of syneoids.

Chapter 64
Realistic Simulation of Cultural Heritage

ABSTRACT

One of the most challenging problems in the simulation of real environments is to generate worlds that appear realistic and more attractive. It becomes increasingly challenging when the simulated environment focuses on minors (students), because the young generation has high demands on simulation systems due to their experience in computer gaming. Virtual museums are among the most important simulation environments, which present cultural and educational content for everyone. Their purpose is to enrich the users experience by allowing an intuitive interaction with the museum artifacts and to offer knowledge with the most pleasant ways. This paper focuses on the aspects of realistic simulations in the development of virtual 3D environments for Cultural Heritage applications. This study includes aspects regarding some of the most high-tech image effects, applicable artificial intelligence methods, powerful game engines, how real object can be reconstructed realistically and how all those features may be combined to produce realistic, pleasant, productive and educative environments.

INTRODUCTION

In realistic simulations of Cultural Heritage, virtual museums have a prominent role. Virtual museums are virtual environments that host virtual exhibitions created to tell the stories of the real museum artifacts to their visitors, just like in real museums, in a richer context and a wider range of possibilities. In the context of a real museum, this is achieved by combining exhibits and information in a carefully designed order and presentation style (Lepouras & Vassilakis, 2004). In the creation of virtual museums, contemporary IT technologies, such as multimedia, 3D computer graphics, spatial sound and virtual reality, can be used to enhance the presentation (the virtual presence), offering a more vivid and enjoyable

experience. Although each of the different technological innovations involved pushes towards their own respective, there are two main goals that are universal in such systems: *realism* and *speed*. In addition, the continuous development of Web services and computer infrastructures complemented by the increasing availability of computer game development platforms (also known as *game engines*), contribute towards a continuous release of serious games in diverse fields including entertainment, cultural heritage, education, artificial intelligence, sociology, military and health systems (Breuer & Bente, 2010). In a sense, serious games can be considered as an efficient approach for blending domain specific activities, like in cultural heritage and education, with gaming. By utilizing contemporary visualization and simulation technologies, serious games enhance the user's experience through photorealistic interactive environments (Van Eck, 2006). This form of stimulation is considered to be one of the primary factors for successful user engagement, in which playing, assumes the role of the driving force that promotes concentration in the activity process and user encouragement for further self-improvement. Stimulation is largely considered by the scientific community as a desired mechanism to achieve the desired results (Rogers, 1996).

Numerous works utilize various technologies to provide solutions for history teaching and learning, or to enhance actual museum visits. The notion of virtual museums and exhibitions has been introduced as an approach to overcome the limitations of the physical space and to provide a vivid experience to remote visitors (Tsichritzis & Gibbs, 1991). An overview of virtual museum technologies is presented in (Sylaiou, Liarokapis, Kotsakis, & Patias, 2009). The Augmented Representation of Cultural Objects (ARCO) (Patel, White, Walczak, & Sayd, 2003) (Wojciechowski, Walczak, White, & Cellary, 2004) was among the predominant efforts towards a dynamic virtual museum system accompanied by a 3D digitization technique to provide a framework to produce and exhibit 3D digital replicas of their artifacts. ARCO was also, evaluated as an Augmented Reality Interface (ARIF) (Sylaiou, Mania, Karoulis, & White, 2010) by focusing on the user experience in relation to the technologies of ARCO. In 2004, Lepouras & Vassilakis (2004) presented the concept of creating virtual museums focused primarily on educational content and related services by using a game engine. This virtual exhibition space took advantage of the high visual quality of modern game engines. Pavlidis et al. (Pavlidis, Tsiafakis, Provopoulos et al., 2006), proposed a Web-based 3D digital replicas management system with a dynamic virtual exhibition showroom. In addition, in (Pavlidis, Makarona, Arnaoutoglou et al., 2008) a more advanced framework for digital museums has been presented, where a non-photorealistic digital replica of a real museum is used to demonstrate educational activities rather its actual exhibition, aiming at increasing the museum's visitors. Sookhanaphibarn & Thawonmas (2009) presented a 3D virtual museum developed in the Second Life 3D world engine. The virtual museum was equipped with an innovative intelligent guidance system that was able to provide a customized navigation route based on the visitors' preferences (2009). In (Djaouti, Alvarez, Rampnoux, Charvillat, & Jessel, 2009) an interactive serious game is used for the promotion of a prehistoric heritage site. Anderson et al. (Anderson, McLoughlin, Liarokapis, Petridis, & Freitas, 2010) reviewed the state-of-the-art of theories, methods and technologies utilized by serious games as cultural heritage promotion tools by showing case studies that exploit such technologies. Papastamatiou et al. (Papastamatiou, Alexandridis, Tsergoulas et al., 2010), presented a dynamic Web-based 3D e-shop system for commercial use, offering a WYSIWYG graphical user interface. Furthermore, Sillaurren & Aguirrezabal (Sillaurren & Aguirrezabal, 2012), presented 3DPublish, a content management system that was developed in Unity3D game engine and allowed the generation of dynamic 3D exhibitions. Furthermore, works like (Bellotti, Berta, Gloria, D'ursi, & Fiore, 2012) focus on a generalization of the task-based learning theory in applications using smart mobile devices. In addition, Koutsoudis & Pavlidis (2011), proposed a novel approach for navigating within complex cultural scenes by exploiting content-based retrieval descriptors.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Koutsoudis et al. (2012), proposed a content-based navigation framework for a virtual museum, based on metadata that describe the exhibits and thus providing a semantic similarity-based navigation. In (Doulamis, Liarokapis, Petridis, & Mialous, 2012) a serious game is proposed based on scenarios derived from the cultural heritage domain and attempts to enrich the player's knowledge by spreading a mystery in ancient times. In a recent work (Bonis, Vosinakis, Andreou, & Panayiotopoulos, 2013) proposed a multi-user framework for virtual exhibitions that adapts to visitors' preferences. Recently, Kiourt et al. (2015a; 2015b; 2016) have studied many aspects of interactive virtual museums mainly focusing on interactive 3D object exhibitions with dynamic open data content; the virtual museum was re-introduced as a cultural and educational tool that focuses on user-driven exhibitions.

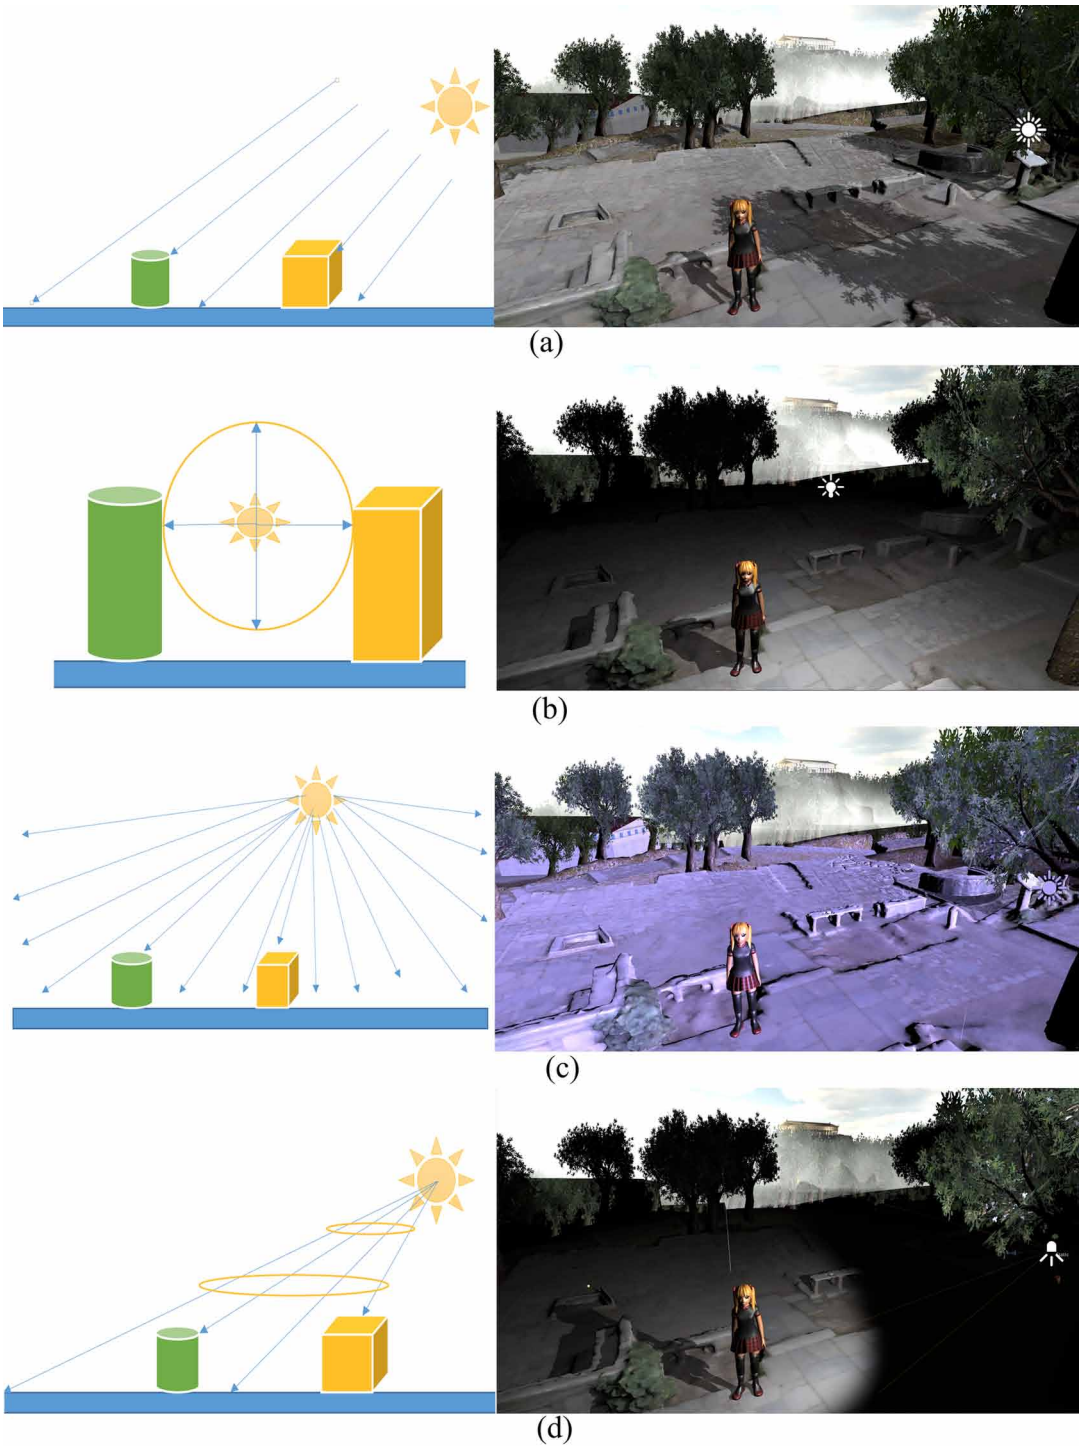
In all most all the aforementioned approaches, as in many other – a small list of virtual museums for educational purposes can be found at Sylaiou et al. (Sylaiou, Liarokapis, Kotsakis, & Patias, 2009; Sylaiou, Mania, Paliokas et al., 2016) – the main focus is to offer users pleasant and realistic virtual environments that try to simulate the real museums. The main contribution of this study is to introduce and present some of the most important factors that should be taken into account in building realistic simulations of Cultural Heritage that are accepted by all ages (children, adults and seniors). The study takes into account previous studies such as (Yu, Mortensen, Khanna, Spanlang, & Slater, 2012; Callieria, Debevecb, Pairc, & Scopig, 2006; Prem, Thalmann, Moccozet et al., 1998; Papagiannakis, L'Hoste, Foni, & Thalmann, 2001; DeLeon & Berry Jr, 2000; Addison, 2000). The study is presented as follows: (a) the most effective computer graphics techniques for building visual realism are being presented, (b) some of the most important artificial intelligent technologies applied in virtual museums are being reviewed, (c) game engines are being introduced and analyzed, (d) realistic reconstruction of the virtual environments is being presented, (e) the impact of the virtual environment/museum in education is being commented. The study concludes with some of the key remarks and highlights.

EFFECTS FOR ENHANCED REALISM

In order for the 3D virtual environment to be more realistic, some real-time image effects are being used, which significantly affect the quality and efficiency of the experience and do not impose any additional hardware requirements (Yang, Dong, Alelaiwi, & El Saddik, 2015). Often those image effects are named as *Screen Space effects*. It should be emphasized that by activating real-time image effects that are being recalculated for every pixel of every frame per second, the system exhibits high computational costs, which are only diminished by intelligent algorithms and the usage of sophisticated graphics hardware. A screen-space approach is one that involves 2D images of objects rather than the 3D geometry (Cohen & Wallace, 1993; Jonghyun, Jae-Hyun, Changwon & Byoungho, 2013). Generally, a 3D object or scene is represented in terms of geometric primitives such as vertices, polygons, edges, and surface patches. Graphics algorithms directly operate on geometric-space (also referred to as object-space) data to produce a desired result. On the other hand, image-space algorithms first rasterize the 3D geometry into one or more 2D images, and then operate on the pixels of these images. The rasterization step discretizes the 3D scene into pixels as visible from a given viewpoint. Each pixel in the image thus represents a finite region of the scene. Therefore, all the information pertaining to that region required to perform the rendering can be stored at the corresponding pixel location in the image, such as 3D positions, surface normal vectors, etc. In the following paragraphs the main screen space effects that contribute to the realism of a simulation are being presented.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Lighting, Reflection and Ambient Occlusion



Lighting is a method for calculating the shading of a 3D object, by using the intensity, direction and color of light that falls on it (Cohen & Wallace, 1993; Verbeck & Greenberg, 1984; Iones, Krupkin, Sbert, & Zhukov, 2003). Generally, nowadays, in almost all 3D environment developments tools, such as game engines, there are two types of lighting techniques: 1) *real-time lighting*, in which lighting is updated in every frame being displayed, 2) *baked lighting*, in which the lighting is pre-calculated and transform to a static lighting effect by being stored on the texture map of the objects, producing what is called a *light map*.

In order to cast light in a virtual 3D scene there are five types of virtual light sources that simulate real-world light sources; these sources are directional, point, area, spot and ambient light sources. A *directional light source*, as the name implies, illuminates an entire 3D scene from one specific direction, Figure 1a. It is generally used to represent lighting from a source at large distances from the scene. For example, sunlight is usually represented as directional light. A *point light source* (Cohen & Wallace, 1993) is represented with a single 3D point in the scene, generally placed in close proximity to the other objects of the scene, unlike the directional light source (Figure 1b). The rendering equation also simplifies under point light illumination since only a single illumination direction is used at each point, x. However, the direction changes with the position of the point. Perhaps the type of light source that mostly resembles the ones found in real life is the *area light source* (Cohen & Wallace, 1993). An area light source is defined as a fully-fledged 3D object, just like any other in the scene. It emits light over its entire surface area, therefore illuminating a particular point in the scene from multiple directions, unlike the point and directional light sources, in which a point is lit only from one direction (Figure 1c). The rendering equation can be adjusted to accommodate area lights by changing the integral over solid angle to integral over the area of the light source. Like a point light, a *spot light source* (Cohen & Wallace, 1993) has a specified location and range over which the light falls off. However, the spot light is constrained to an angle, resulting in a cone-shaped region of illumination (Figure 1d). The center of the cone points in one direction of the light object. Light also diminishes at the edges of the spot light's cone. Widening the angle increases the width of the cone and with it increases the size of this fade, known as the 'penumbra'. Spot light sources are generally used for artificial light sources such as flashlights, car headlights and searchlights. With the direction controlled from a script or animation, a moving spot light will illuminate just a small area of the scene and create dramatic lighting effects. An *ambient light source* is present all around the scene and doesn't come from any specific source object. It can be an important contributor to the overall look and brightness of a scene. An ambient light can be useful in a number of cases, depending upon your chosen art style. An example would be bright, cartoon-style rendering where dark shadows may be undesirable or where lighting is perhaps hand-painted into textures. Ambient light can also be useful if one needs to increase the overall brightness of a scene without adjusting individual lights.

In order to render more realistic images in computer graphics a model of how may objects reflect light is required (Cook & Torrance, 1982; Phong, 1973). The reflectance model must describe both the color and the spatial distribution of the reflected light. The model is independent of the other aspects of image synthesis, such as the surface geometry representation. Most real surfaces are neither ideal specular reflectors nor ideal diffuse reflectors (Cook & Torrance, 1982; Phong, 1973).

Figure 1. Lighting types: (a) directional light, (b) point light, (c) area light, (d) spot light

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

In any case, the general form of the equation that describes the basic lighting (Phong) model for objects in a 3D scene, in which multiple light sources might exist, is (boldface letters denote vectors)

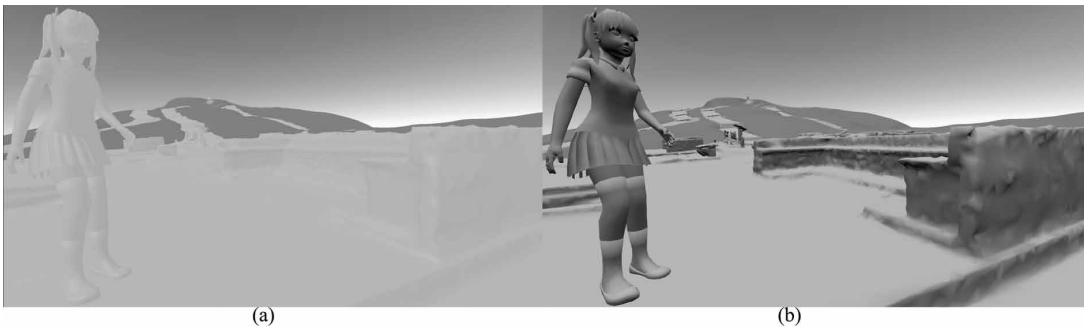
$$I = K_e + K_a \times I_a + K_d \times I_d \times \max\left(\boldsymbol{n} \cdot \boldsymbol{v}, 0\right) + K_s \times I_s \times \delta\left(\boldsymbol{n} \cdot \boldsymbol{v}\right) \times \max\left(\boldsymbol{n} \cdot \boldsymbol{v}, 0\right)^s$$

where K_e the *emissive* part of light that comes from the object itself (might be zero); $K_a \times I_a$ the *ambient* part that corresponds to the effect of any ambient light source with I_a the global ambient light intensity (or color);

$$K_d \times I_d \times \max\left(\boldsymbol{n} \cdot \boldsymbol{v}, 0\right) = K_d \times I_d \times \cos\theta$$

the *diffuse* part coming from a directed light, with K_d the object's diffuse reflection coefficient, I_d the light intensity and θ the angle between the light vector $\vec{v}$ and the surface normal $\vec{n}$ at the point of computations;

$$K_s \times I_s \times \delta\left(\boldsymbol{n} \cdot \boldsymbol{v}\right) \times \max\left(\boldsymbol{n} \cdot \boldsymbol{v}, 0\right)^s = K_s \times I_s \times \cos^s \phi$$



the *specular* part coming from a directed light, K_s being the object's absorption coefficient, I_s the incoming light intensity, ϕ the angle that represents the deviation of view angle from mirror direction and the power *s* the shininess coefficient. The term δ(***n*•*v***) results either 1 if ***n*•*v*** is greater than zero, or 0 otherwise.

Although lighting techniques provide support for all the basic calculations for the rendering of a visible surface element with respect to lights that might hit upon it and the surface characteristics, still, a realistic scene representation cannot be attained. This is due to an issue that relates with how exposed are those surface elements to the ambient lighting of the scene. That is, points that are occluded due to the geometry of their surroundings should receive less ambient light, thus should appear darker in the final rendering. The solution to this issue has been encoded in computer graphics as *Ambient occlusion* (Yu, Wang, & Yu, 2010; Miller, 1994; Dutre, Bala, & Bekaert, 2006; Bavoil & Sainz, 2009; Vardis, Papaioannou, & Gaitatzes, 2013). Ambient occlusion is a sophisticated ray tracing calculation, which simulates soft global illumination by faking darkness perceived in corners and at mesh intersections, creases, and cracks, where light is diffused (usually) by accumulated dirt and dust. Simply put, this technique darkens creases, holes and surfaces that are close to each other, as in real life such areas tend to block out or occlude ambient light, and hence they appear darker. A simple comparative example of using this technique in the presented system is shown in Figure 2.

There are several variations of real-time ambient occlusion, some of the most important are: Screen Space Ambient Occlusion (SSAO), Screen Space Directional Occlusion (SSDO), High Definition Ambient Occlusion (HDAO), Horizon Based Ambient Occlusion+ (HBAO+), Alchemy Ambient Occlusion (AAO), Angle Based Ambient Occlusion (ABAO) and Voxel Accelerated Ambient Occlusion (VXAO). The techniques that are based on screen-space computations target fast implementations by computing on the 2D projected visible scene pixels using pixel depth rather than the complete scene geometry. In general, the occlusion $AO_{\boldsymbol{p},\hat{n}}$ (or the surface irradiance $E_{\boldsymbol{p},\hat{n}}$) at a point $\boldsymbol{p}$ (in vector form) on a surface with a normal $\hat{n}$ at that point can be computed by integrating the visibility function $V_{\boldsymbol{p},\hat{\omega}}$ (or the incidence

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. A scene (a) with no ambient occlusion effect; (b) with ambient occlusion exaggerated

irradiance *L*) over the hemisphere Ω above and centered at the point with respect to the projected solid angle ω. The visibility function $V_{\boldsymbol{p},\hat{\omega}}$ equals 1 if the point $\boldsymbol{p}$ is occluded in the direction of the angle ω, or 0 if it is not occluded.

$$AO_{\boldsymbol{p},\hat{n}} = \frac{1}{\pi}\int_{\Omega} V_{\boldsymbol{p},\hat{\omega}} \cdot \left(\hat{n}\cdot\hat{\omega}\right) d\omega \quad E_{\boldsymbol{p},\hat{n}} = \int_{\Omega} L\cos\theta d\omega$$

Practically, SSAO for example, is implemented as a *pixel shader*, which analyses the scene depth buffer that is stored in a texture and for every pixel on the screen calculates the occlusion depending on the depth difference between the current and neighboring pixels.

Shadows play an important role in conveying reality in computer-synthesized images (Amanatides, 1987; Woo, Poulin, & Fournier, 1990; Hasenfratz, Lapierre, Holzschuch, & Sillion, 2003; Guennebaud, Barthe, & Paulin, 2006). A shadow may be described as a darkness region in an otherwise illuminated region (Woo, Poulin, & Fournier, 1990). Shadows also facilitate the comprehension of spatial relationships between objects. Though there are situations where shadows are not required (e.g. if the light source is behind the viewer or when modeling an overcast day), there are many other situations in which they are essential. The complexity of the shadows is related with the light mapping in trying to simulate the real environment shadows that are associated with the light sources (Amanatides, 1987). The presence of shadows makes 3D computer graphics look more natural. Without them, scenes often feel unnatural and flat, and the relative depths of objects in the scene can be very unclear. They emphasize and clarify the three dimensional settings of the objects being displayed. However, the trouble with rendering high quality shadows is that they are computationally intensive and hard to generate. In computer graphics shadows appears in two types, first "hard shadows" are crisply defined with sharp edges and second "soft shadows" are less distinct and fade off toward the edges. An example of some hard shadows is depicted in Figure 3.

Depth of Field

Depth of field (DoF) is the distance between the nearest and farthest objects in a scene that appear acceptably sharp in an image or 3D scene (Yu, Wang, & Yu, 2010; Demers, 2004; Selgrad, Reintges, Penk, Wagner, & Stamminger, 2015). In computer graphics the simulation of DoF is a common post

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 3. A scene (a) with no shadow effect; (b) with shadow effect active

(a) (b)

processing effect that simulates one of the most notable properties of a camera lens, the limited depth of focus. In real life, human eyes and a camera can only focus sharply on an object at a specific distance; objects nearer or farther from the camera will be somewhat out of focus. The blurring not only gives a visual cue about an objects distance but also introduces *Bokeh* (a Japanese word meaning *blur*), which is the term for pleasing visual artifacts that appear around bright areas of the image as they fall out of focus. DoF effects have been studied for several years. Starting around three decades ago (Potmesil & Indranil, 1981; 1982), there have been numerous approaches to adding DoF effects to computer graphics, but official published work in the area of DoF for computer graphics has been provided by Barsky et al (2003). The DoF simulation methods can be categorized in several ways in computer graphics (Barsky & Kosloff, 2008), but the two most important categories are: the *object-space* methods and the *image-space* methods. *Object space* methods operate on 3D scene representation, and build DoF effects directly into the rendering pipeline. *Image space* methods operate on images that were rendered with everything in perfect focus. Generally, *object space* methods generate more realistic results but image space methods are much faster (Barsky & Kosloff, 2008). Nowadays almost all game engines provide the *image space* methods. A sample of image space method applied in a 3D environment is presented in Figure 4. The left image depicts the application of the DoF effect for far away objects, whereas the right image depicts the application of the DoF effect for medium distance objects.

The mathematics of the blur due to a limited DoF in real-life photography are connected with the aperture of the lens and the *circle of confusion* (usually denoted as *CoC*), and are derived from trigonometry, usually by setting the far limit of the DoF to infinity, thus

$$CoC = \frac{f_c^2}{N \cdot \left(D_h - f_c\right)} \approx \frac{f_c^2}{N \cdot D_h}, \quad N = \frac{f_c}{d} \text{ the aperture}, \quad D_h : \text{the hyperfocal distance}$$

where d is the aperture diameter, f_c the focal length, N the f-number of the lens.

The *hyperfocal distance* D_h is the distance at which the lens focus extends from half that distance to infinity. In many practical cases, the estimation of the circle of confusion for a lens can be done by setting the infinity mark on the distance scale opposite to the largest marked f-number on the DoF scale, in which situation the focus index is the hyperfocal distance. Since lens distance scales usually show object to camera distances, then if O_h is the indicated hyperfocal distance the formula should be corrected as

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 4. DoF examples: (a) shallow DoF, near-to-middle distances in focus; (b) extremely shallow DoF, middle distances in focus

(a) (b)

$$CoC \approx \frac{f_c^2}{N \cdot \left(O_h - 2f_c\right)}$$

These computations refer to how the DoF effect appears in real life lenses. In computer graphics, the virtual *pinhole camera* projects the 3D world through a zero-size lens in order to create the 2D view on a flat screen. Thus, the camera has infinite DoF and the real-life DoF effect has to be simulated. In any case the circle of confusion still has to be considered. One way to do so is by estimating *CoC* from the camera to object distance and the camera parameters,

$$CoC = \left| d \frac{f_c}{D_f - f_c} \frac{D_f - D_o}{D_o} \right|$$

in which d is the diameter of the lens, f_c is the focal length of the lens, D_o is the object distance and D_f the plane in focus (the distance ideally being focused on the image plane, following the fundamental formula $\frac{1}{D_f} + \frac{1}{I_f} = \frac{1}{f_c}$, I_f being the image plane to lens internal distance). The object distance can be calculated from the z-buffer x values, using the extreme far and near z-buffer values z_f, z_n,

$$D_o = -\frac{z_f z_n}{z \cdot \left(z_f - z_n\right) - z_f}$$

Alternatively, the circle of confusion may be estimated directly from the z-buffer,

$$CoC = \left| z \cdot CoC_s + CoC_b \right|, \begin{cases} CoC_s = \dfrac{d \cdot f_c \cdot D_f \cdot \left(z_f - z_n\right)}{\left(D_f - f_c\right) \cdot z_f \cdot z_n} a\, scaling term \\ CoC_b = \dfrac{d \cdot f_c \cdot D_f \cdot \left(z_f - z_n\right)}{D_f \cdot f_c \cdot z_n} a\, bias term \end{cases}$$

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

In order to simulate the DoF effect a method has to approximate the blur that would happen as if the lens were real. Practical implementations of the DoF effect can be categorized in the following approaches:

- Forward-mapped z-buffer techniques (Potmesil & Chakravarty, 1981)
- Distributing traced rays across the surface of a (non-pinhole) lens (Cook, Porter, & Carpenter, 1984)
- Rendering from multiple cameras (also accumulation-buffer technique) (Haeberli & Akeley, 1990)
- Rendering multiple layers (Scofield, 1994)
- Reverse-mapped z-buffer techniques (Arce & Wloka, 2002; Demers, 2003)

Antialiasing

In signal processing *antialiasing* refers to various techniques to tackle the problems of aliasing in a any sampled signal. Aliasing is an effect that causes different signals to appear the same when sampled. When aliasing occurs in signals sampled in time is referred to as *temporal aliasing*, whereas when it occurs in spatially sampled signals is called *spatial aliasing* and takes the form of *moiré patterns*. In spatial aliasing, the effect of aliasing is most apparent in situations in which the Nyquist sampling limit (sampling theorem) breaks during a sampling process (discrete sampling below the Nyquist frequency). To suppress aliasing, one may either increase the sampling frequency or suppress the high frequencies in the original signal using filtering; antialiasing methods fall in the second category of measures against aliasing. Antialiasing methods try to restrict the bandwidth of the signal so that the sampling (completely in theory or approximately for all practical purposes) satisfies the sampling theorem, over whichever band of interest is preselected in the specific application. In a simple application of computing and plotting a single white point on a black background the computations include

$$I_{\left(\hat{x}_i,\hat{y}_j\right)} = I_{(x,y)} + \left(1-\left|x-\hat{x}_i\right|\right)\cdot\left(1-\left|y-\hat{y}_j\right|\right)$$
$$\text{for}\begin{cases} i = \lfloor x \rfloor \ \text{to} \lceil x \rceil \\ j = \lfloor y \rfloor \ to \lceil y \rceil \end{cases}$$

where $I_{\left(\hat{x}_i,\hat{y}_j\right)}$ is the computed intensity of the point at the target location $\left(\hat{x}_i,\hat{y}_j\right)$, *i,j* varying between the floor and ceiling of the *x,y* coordinates accordingly, given the initial location (*x,y*) and intensity $I_{(x,y)}$

In modern computer graphics applications, antialiasing is usually referenced as an image effect. The antialiasing image effect is calculated in real-time, which gives smoother appearance of the graphics based on the difference of colored areas of the image (William, 1980; Franklin, 1977; Bineta, 2013; Bineta, 2013; Korein & Badler, 1983). It can be defined as a technique to minimize the distortion artifacts known as aliasing when showing a high-resolution image in a lower resolution display. Practically, antialiasing means removing signal components that have a higher frequency than those that can be properly resolved by the recording (or display) device (Franklin, 1977). An example of antialiasing is shown in Figure 5.

Motion Blur

Motion blur is the apparent streaking of rapidly moving objects in a still image or a sequence of images such as a movie or animation. During recording of a single image, motion blur appears as a capture of the motion of moving objects, which may occur either due to rapid movement or long exposure. Obviously this effect is the result of limitations of the recording devices to freeze-capture fast moving objects, or even slow moving objects but under long exposure requirements. Motion blur can take any of three forms, including (a) *linear blur*, which travels along a single direction to a specific extend, denoted by a strength and an angle, (b) *radial blur*, which is responsible for circular blurring effects around a center and can be defined by a radius and a strength, and (c) *zoom blur*, which represents a zooming in or out motion centered at a point on the image place defined by a center and a speed (the strength in this case).

In computer graphics there is no such problem, so in order to enhance visual realism, this effect has to be simulated. Let us consider, for example, the simple 2D case that is easy to follow, and suppose there is an image $f(x,y)$ undergoing the motion. In the duration T of the exposure, the total exposure at any point will be the integration of instantaneous exposures at that point, leading to a blurry image $g(x,y)$,

$$g(x,y) = \int_0^T f\left(x - x_0(t), y - y_0(t)\right) dt$$

where $x_0(t)$, $y_0(t)$ are the time-varying motion parameters. It is easy to see that its Fourier transform is

$$\begin{aligned}
\mathcal{G}(u,v) &= \iint_{-\infty}^{\infty} g(x,y) e^{-2\pi i(ux+vy)} dxdy = \iint_{-\infty}^{\infty} \left[\int_0^T f\left(x - x_0(t), y - y_0(t)\right) dt \right] e^{-2\pi i(ux+vy)} dxdy \\
&= \int_0^T \left[\iint_{-\infty}^{\infty} f\left(x - x_0(t), y - y_0(t)\right) e^{-2\pi i(ux+vy)} dxdy \right] dt = \int_0^T \mathcal{F}(u,v) e^{-2\pi i\left(ux_0(t)+vy_0(t)\right)} dt \\
&= \mathcal{F}(u,v) \int_0^T e^{-2\pi i\left(ux_0(t)+vy_0(t)\right)} dt \Rightarrow \mathcal{G}(u,v) = \mathcal{H}(u,v) \cdot \mathcal{F}(u,v)
\end{aligned}$$

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

If the motion parameters $x_0(t)$, $y_0(t)$ are known then $\mathcal{H}\left(u,v\right)$ is easily defined and motion readily computed. Consider the simple case in which there is a linear motion blur, in which,

$$x_0\left(t\right) = a\frac{t}{T} \qquad y_0\left(t\right) = b\frac{t}{T}$$

Then the transfer function $\mathcal{H}\left(u,v\right)$ can be defined,

$$\begin{aligned}\mathcal{H}\left(u,v\right) &= \int_0^T e^{-2\pi i\left(ua\frac{t}{T}+vb\frac{t}{T}\right)}dt = \int_0^T e^{-2\pi i\frac{ua+vb}{T}t}dt \\ &= -\frac{T}{2\pi i\left(ua+vb\right)}e^{-2\pi i\frac{ua+vb}{T}t}\Bigg|_0^T \\ &\quad -\frac{T}{2\pi i\left(ua+vb\right)}(e^{-2\pi i\left(ua+vb\right)}-1) \\ &\Rightarrow \mathcal{H}\left(u,v\right) = \frac{T}{2\pi i\left(ua+vb\right)}\left(1-e^{-2\pi i\left(ua+vb\right)}\right)\end{aligned}$$

Since the transfer function is defined then $\mathcal{G}\left(u,v\right) = \mathcal{H}\left(u,v\right)\cdot\mathcal{F}\left(u,v\right)$ results the Fourier representation of the motion blurred image, which in turn gives the blurred image by taking the inverse Fourier transform.

Things get rather complicated in the 3D domain. The spatial dimensions become three, and the temporal dimension is also incorporated in more complex ways. In addition, no matter what happens in a 3D virtual world, it is the screen space 2D projection that should comply with the observers' experience. A typical mathematical formulation of motion blur in 3D graphics resolves for the 2D projected screen space $I(x,y)$,

$$I\left(x,y\right) = \sum_i \int_\Omega \int_{\Delta T} r\left(\omega,t\right) g_i\left(\omega,t\right) L_i\left(\omega,t\right)\ dt\ d\omega$$

for object i, a solid angle Ω and the virtual aperture time ΔT, in which $r(\omega,t)$ is the reconstruction filter that accounts for the effects of shutter shape and efficiency, lens aberration and film influence, $g_i(\omega,t)$ is a function of the occlusion of object i and $L_i(\omega,t)$ the radiance of the object.

The numerous rendering methods that have been proposed can be classified into (a) *analytic methods* that use a closed form solution (Korein & Badler, 1983; Grant, 1985), (b) *geometric substitution* that substitute the original geometry with alternative geometric primitives for which temporal changes are followed (Catmull, 1984; Glassner, 1988; Guan & Mueller, 2004; Jones & Keyser, 2005; Schmid, Sumner, Bowles, & Gross, 2010) (c) *texture clamping*, which originally targets the elimination of aliasing effects (Loviscach, 2005), (d) *Monte Carlo methods* that include various stochastic approaches (Haeberli & Akeley, 1990; Dayal, Watson, & Luebke, 2002; Dayal, Woolley, Watson, & Luebke, 2005; Walter, Arbree, Bala, & Greenberg, 2006; Nehab, Sander, Lawrence, Tatarchuk, & Isidoro, 2007; Kim & Ko, 2007; Akenine-Moeller, Munkberg, & Hasselgren, 2007; Hachisuka, Jarosz, Weistroffer, Dale, Hum-

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

phreys, Zwicker, & Jensen, 2008; Egan, Tseng, Holzschuch, Durand, & Ramamoorthi, 2009; Overbeck, Donner, & Ramamoorthi, 2009; Ragan-Kelley, Lehtinen, Chen, Doggett, & Durand, 2010), (e) *post-processing methods* that are screen space methods that use selected pre-renders of a scene blurred by using motion information from available scene data, decoupling motion blurring from rendering (Max & Lerner, 1985; Chen & Williams, 1993; Zheng, Koestler, Thuerey, & Ruede, 2006; Vlachos, 2008; Sousa, 2008), (f) *hybrid techniques* (Sung, Pearce, & Wang, 2002) and (g) *physics-based approaches* that exploit mechanics and optics to device models for motion blur simulation (Lin & Chang, 2006; Telleen, Sullivan, Yee, Wang, Gunawardane, Collins, & Davis, 2007; Pachur, Laue, & Roefer, 2009).

Typical examples of motion blur are shown in Figure 6. Motion blur (Korein & Badler, 1983; Dachille & Kaufman, 2000; Nathan & Keyser, 2005; McGuire, Hennessy, Bukowski, & Osman, 2012) is an important method for increasing the visual quality of real-time applications such as games or training simulators.

Particle Systems

A *particle system* (Reeves, 1983) is a system of a large number of elementary graphics particles having a specific appearance, sharing a predetermined formation pattern and following specific rules, which can be used to represent fuzzy objects of processes otherwise difficult or impossible to represent by a single model. Such objects and processes include highly chaotic systems, natural phenomena or processes caused by chemical reactions, such as fire (Nguyen, Fedkiw, & Jensen, 2002), smoke (Csuri, Hackathorn, Parent, Carlson, & Howard, 1979; Huang, Gong, & Liang, 2015), explosions (Yngve, Obrien, & Hodgins, 2000), water (Foster & Fedkiw, 2001), ocean wave (Hinsinger & Neyret, 2002), clouds (Gardner, 1985), fogs, snow (Tan & Fan, 2011), dust (Jim, Xiadong, & Wegman, 1999), electricity, stars and galaxies. In essence, particle systems are used to realistically represent fluids and gasses, or in general, objects and processes with highly dynamic behavior. Instead of using geometric primitives, in these cases particle clouds are being used to render dynamically changing volumes. Stochastic processes are used to control those objects' shapes and appearance, adopting the paradigm of stochastic procedural modeling.

Particle systems are also used for modeling more tangible objects such as complicated trees (Reeves, 1985), cloths and fabric (Breen, 1994; Eberhardt, Weber, & Strasser, 1996). Realistic particle movement is often achieved by simulating real-world physics (Reynolds, 1999). The diversity of particle system applications demonstrates their importance in modern interactive media and games especially in serious games environments (Hastings, Guha, & Stanley, 2007). In recent years the researchers focus on the creation of particles APIs, in order to increase the usability and potentials of the particle systems (McAllister, 2000). In general, a particle system and its particles have very similar parameters, but with different values (Reeves, 1983): position (orientation in 3D space and center location x, y, and z), movement (velocity, rotation, etc.), color (RGB), transparency (alpha), shape (point, line, sphere, cube, rectangle, etc.), volume, density, mass, lifetime (start and end time) and blur head and rear pointers (only for particles). Figure 7 depicts a view of a 3D environment where several particle systems have been included, such as rain, snow, wind and fire.

The position, shape, and size of a particle system determine the initial positions of the particles and their range of movement. The movements of the particles are restricted within the range defined by their associated particle system. The shape of a particle system can be a point, line segment, sphere, box, or cylinder. Internal or external forces and the effects of the rotations and accelerations of the particles affect the movement of a particle system, as a whole. A particle system may change its shape, size, color,

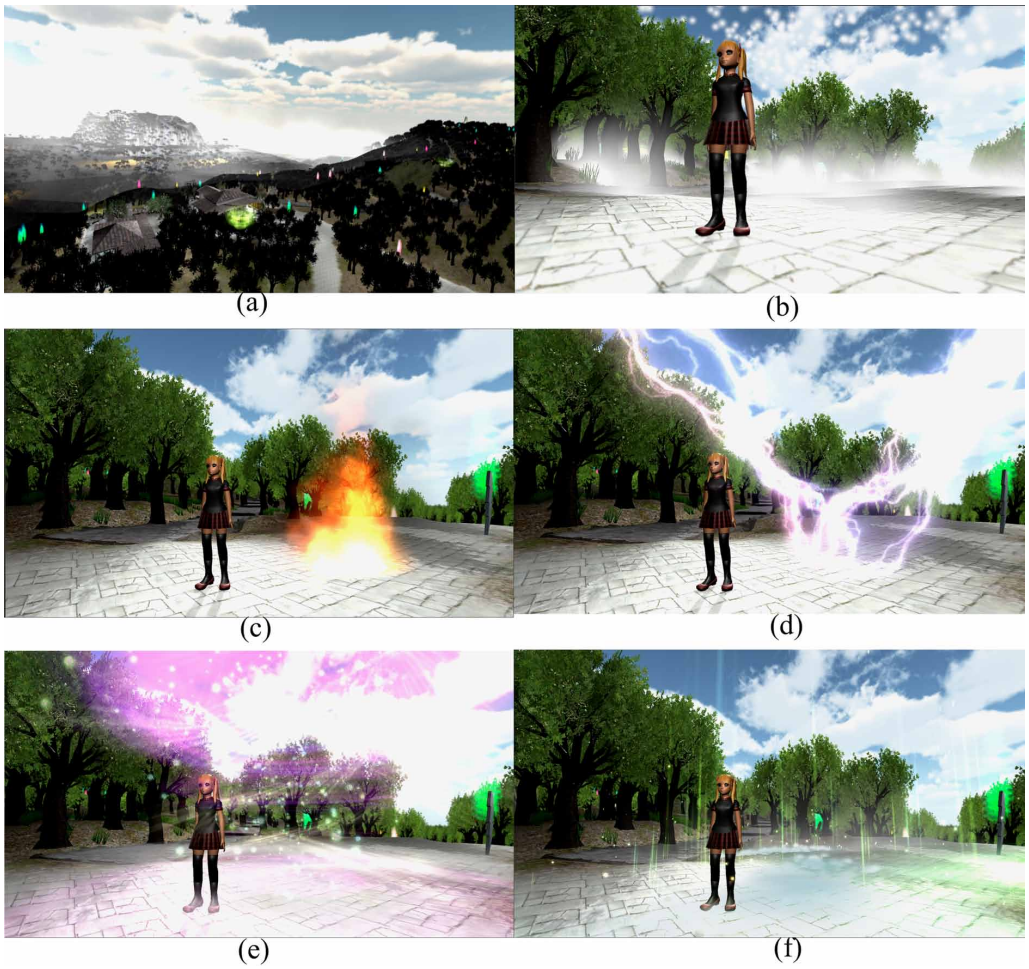
EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 6. Motion blur (a) of an animated avatar and (b) of a moving scene

transparency, or some other attributes as it evolves. The lifetime defines how many time slices (frames) a particle will be active. A particle has both a head position and a tail position. The head position is usually animated and the tail position follows along for motion blur. The simulation looks more dynamic and has more particles with motion blur, at the cost of longer rendering time.

Generally, a particle systems starts by spawning particles using *emitters*, which are able to generate large numbers of elementary particles. The laws governing the particle dynamics start by defining a force field and the integration of the laws of mechanics. In a simple case, each particle is independent and considered separately (individually) but in the most general case there might be forces among the particles. In a simple example of a *sprinkler*, the mathematics can be defined easily using elementary laws of mechanics (boldface letters representing vectors),

$$\boldsymbol{x}_{i+1} = \boldsymbol{x}_i + d\boldsymbol{x} = \boldsymbol{x}_i + \boldsymbol{v}_i \cdot dt$$
$$\boldsymbol{v}_{i+1} = \boldsymbol{v}_i - g \cdot dt$$
$$\boldsymbol{x}\left(t_0\right) = \boldsymbol{x}_0 + \boldsymbol{x}_r$$
$$\boldsymbol{v}\left(t_0\right) = \boldsymbol{v}_0 + \boldsymbol{v}_r$$



where there is a gravitational field g in which particles are spawned at t_0 at an initial location $\boldsymbol{x}_0$ with an initial velocity $\boldsymbol{v}_0$, both of which can be randomized by drawing random samples $\boldsymbol{x}_r$ and $\boldsymbol{v}_r$ from predefined distributions (usually seeded by uniform distributions spanning [-1,1]). In addition, the generation of particles can be controlled by a spawning rate r (in particles per second), which produces $n=(t - t_{last})\bullet r$ particles, updating the t_{last} if $n>0$. Generally, a particle is described by its state vector $\boldsymbol{X} = \begin{pmatrix} \boldsymbol{x} \\ \boldsymbol{v} \end{pmatrix}$, which is composed of six (6) numbers for a point mass particle in 3D. The dynamics of the particle can be described by the derivative of the state vector,

$$\frac{d\boldsymbol{X}}{dt} = f\left(\boldsymbol{X}, t\right) = \begin{pmatrix} \boldsymbol{v} \\ \dfrac{\boldsymbol{F}\left(x, v\right)}{m} \end{pmatrix}, \qquad with\ \boldsymbol{F} = m \cdot \boldsymbol{a} = m\frac{d\boldsymbol{v}}{dt}$$

which generalizes for N point masses,

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 7. Particle systems, fog, snowfall, fire, lightning strike, cyclone and magic lights

$$\boldsymbol{X} = \begin{pmatrix} \boldsymbol{x}_1 \\ \boldsymbol{v}_1 \\ \vdots \\ \boldsymbol{x}_N \\ \boldsymbol{v}_N \end{pmatrix}_{6N\times 1} , \quad \frac{d\boldsymbol{X}}{dt} = f\left(\boldsymbol{X}, t\right) = \begin{pmatrix} \boldsymbol{v}_1 \\ \boldsymbol{F}_1 \\ \vdots \\ \boldsymbol{v}_N \\ \boldsymbol{F}_N \end{pmatrix}_{6N\times 1}$$

in which the indices represent the corresponding particle. For a single point mass m the force $\boldsymbol{F}$ is easily defined for the 3D space,

$$\boldsymbol{F} = \begin{pmatrix} 0 \\ 0 \\ -mg \end{pmatrix}$$

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

which can also be used in reverse direction (as buoyancy) in simulating smoke, etc. In case particles are not independent then gravity should depend on all mass interactions, taken pairwise for particles *i* and *j* at a distance or r_{ij}^2 ,

$$\left\| F_{ij} \right\| = \frac{G m_i m_j}{r_{ij}^2}, \quad G = 6.67 \times 10^{-11} Nm^2 \,/\, kg^2$$

in which case computations get complicated as they are $O(n^2)$.

Nevertheless, these are relatively simple cases as realistic simulations usually require the introduction of other forces, such as viscous damping or other spatial interactions such as attractive and repulsive forces, or even other dynamics such as crowd behaviors, collisions and collision avoidance.

ARTIFICIAL INTELLIGENCE IN VIRTUAL ENVIRONMENTS

One important ingredient in realistic simulations are the intelligent agents, which are the subject of major controversy over their origin, formal background, definitions, methods, applications and future directions (Ritchings, Anastassakis, & Panayiotopoulos, 2001). For social simulations to be meaningful, it is necessary to implement realistic models for both the virtual agents (CaI, Liu, Yu, & Zhang, 2015), the environment (Pelechano, Allbeck, & Badler, 2007) and their interactions; and the latter has long been the subject of multi-agent systems and reinforcment learning research (Gosavi, 2003; Varshavskaya, Kaelbling, & Rus, 2008; Silva, Melo & Veloso, 2016). A lot of attention has been given to the definition of accurate models for agents (e.g., behavioral, decision-making and interactions models) (Al-Zinati & Wenkstern, 2015). The approach of building intelligent virtual environments is relatively new in virtual environments (Pelechano, Allbeck, & Badler, 2007), in which the virtual environment is artificially being developed and created, sometimes in real time, based on the progress and the profile of the users (Al-Zinati & Wenkstern, 2015).

Figure 8. AI agents in virtual worlds: (a) navigation area for an AI agent; (b) AI agent-based virtual guided tour

(a) (b)

In addition, the realistic simulation of virtual crowds has diverse applications in architecture design, emergency evacuation, urban planning, personnel training, education, virtual museums and entertainment. The are several approaches that aim to create better representations of crowds in virtual environments, with the *agent-based methods* being the most successful; agent-based methods focus more on individual behavior, whereas crowd simulations aim to exhibit emergent phenomena of groups (Sud, Andersen, Curtis, Lin, & Manocha, 2008; Treuille, Cooper, & Popović, 2006). Not surprisingly, combinations of these approaches (which, however, do exhibit a bias in favor of one of the approaches) can deliver results of substantially enhanced realism (Shao & Terzopoulos, 2005) and, often, the crowd that is being simulated by agent-based models is designed as a multi-agent system, in order to develop different behaviors that may cooperate or compete each other (Bennewitz & Burgard, 2001; Li & Chou, 2003; Musse & Thalmann, 1997; Hanna & Richards, 2014). This approach increases the realism of the simulated crowds by highlighting the social attitude of artificial intelligence agents.

An important technical challenge in AI simulations is the path planning (Sud, Andersen, Curtis, Lin, & Manocha, 2008; Stüvel, de Goeij, van der Stappen, & Egges, 2015; Naderi, Rajamäki, & Hämäläinen, 2015; Demesure, Defoort, Bekrar, Trentesaux, & Djemaï, 2016; Champagne & Tang, 2005; Anderson, McLoughlin, Liarokapis, Petridis, & Freitas, 2010). There are several different algorithms that improve the navigation of agents in virtual environments, which often result in more realistic and detailed simulations (Sud, Andersen, Curtis, Lin, & Manocha, 2008; Naderi, Rajamäki, & Hämäläinen, 2015; Pettre, Laumond, & Thalmann, 2005). An example is shown in Figure 8a, where the blue ground is the 'walkable' area for the agent, which has to plan its route taking into account any static objects acting as obstacles. The path planning and motion planning problems have long been central to robot-based systems and AI systems in general (Luna, Lahijanian, Moll & Kavraki, 2014; Lahijanian, Maly, Fried, Kavraki, Kress-Gazit & Vardi, 2016).

Another important contribution of AI in virtual environments with cultural and educational topics (like the virtual museums) that enhances the user experience is the use of virtual agents for guided tours (Bogdanovych, Rodriguez, Simoff, & Cohen, 2009; Bickmore, Pfeifer, & Schulman, 2011; Ichiro, 2008; Sookhanaphibarn & Thawonmas, 2009; Vassos, et al., 2016). A virtual agent is a computer generated, animated, AI virtual character (usually with anthropomorphic appearance) that constitutes a real-time service representative. It leads an intelligent conversation with users, responds to their questions and performs adequate nonverbal behavior. Further enhancements may include virtual agents-guides that discuss with users and present the space (Oberlander, Karakatsiotis, Isard, & Androutsopoulos, 2008), and adaptive, personalized exhibition spaces (Bonis, Stamos, Vosinakis, Andreou, & Panayiotopoulos, 2009). An example of this concept is shown in Figure 8b, where an AI (chat-bot) avatar asks a user (also represented by an avatar in the virtual world) to explore together the environment, and provide information about specific points of interest. A related approach to enhancing the personalization experience has also focused on a more graphical exploratory search technique to allow users to navigate the results of a search query (Lin, Ahn, Brusilovsky, He, & Real, 2010).

GAME ENGINES

Since the early 1990s when really appealing computer game graphics made their first appearance, game engines started to be used as tools in many scientific fields (Harrison, 2003; Craighead, Burke, & Murphy, 2008; Breuer & Bente, 2010). Nowadays, a common approach and trend in modern virtual world

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

applications for various domains is to adopt the technology of game development, the game engines; a simple comparison of contemporary available game engines is included in the following paragraphs.

Game engines are integrated software suites that efficiently use 3D rendering pipelines, special data-structures and speed-up techniques for visualizing texture mapped 3D objects, scenes and 3D worlds in real-time with modern graphics and interaction capacities (Harrison, 2003). The choice of game engines for building dynamic realistic virtual environments was guided by the numerous possibilities and advantages offered by modern game engines and it is not limited to the presented game engines in this study (Lepouras & Vassilakis, 2004; Trenholme & Smith, 2008; Kiourt et al., 2015a; Kiourt et al., 2015b; Kiourt et al., 2016). Game engines are being extensively tested for usability and performance due to the strict requirements of contemporary games. The manufacturers and many computer game developers provide components, algorithms, tools, guides and source code, so that end-users can efficiently create new content. An extensive user support provided by large game development communities makes development platforms even more attractive. Most of the game engine functionalities are managed and exploited via a GUI, for the convenience of developers, providing a more efficient development framework when compared to virtual environment toolkits that often require additional effort to manually provide functionalities such as user interaction (Bowman, Kruijff, LaViola, & Poupyrev, 2005; Cowan & Kapralos, 2015), avatar behaviors, collision detection and management, audio management, avatar-based virtual environment interactions, embodied autonomous agents and many other properties (Lepouras & Vassilakis, 2004; Trenholme & Smith, 2008). Almost all modern game engines provide cross-platform development, which ensures their utilization over a diversity of platforms. There is a wide selection of 3D game engines available for potential use (Lewis & Jacobson, 2008). In the following paragraphs we present the basics of some of the most popular contemporary game engines that are currently available, including *Unity*, *CryEngine* and *Unreal*. We have collected all major advantages and disadvantages regarding these game engines as discussed in (Patel et al., 2003; Craighead et al., 2008; Sillaurren & Aguirrezabal, 2012; Unity3d, 2016; Unreal, 2016; Crytek, 2016; Kiourt et al., 2016). *Unity* (Patel, White, Walczak, & Sayd, 2003; Unity3d, 2016) is a 2D/3D game engine, which offers a wide range of features and a user friendly GUI. One of its main advantages is the cross-platform integration. Each application developed in Unity version 5 (the current version) may be efficiently exported in nearly any available desktop and mobile platform (Windows, Mac OS, PS, XBOX, HTML5, Android, IOS) composing a powerful game engine. It supports 3D content derived from popular 3D applications like Blender, 3DS Max, Maya, CINEMA 4D. It offers limited 3D modeling functionalities based on primitive shapes, although it provides better landscape modeling tools. In general, every 3D model needs to be created in a third party application. However, Unity boasts a large 3D content library where a wide variety of objects can be downloaded for free or be purchased. The Unity engine provides animation mechanisms with real-time editor, particle engines with their own dedicated editor, AI Systems, dynamic lighting and shadowing, water effects, 2D game functionality, networking and multiplayer functionality, integrated physics system, terrain generation system, bitmap image effects, audio/music systems and scripting using C-sharp, JavaScript and Boo programming languages. The *CryEngine* (Craighead, Burke, & Murphy, 2008; Crytek, 2016) is a product *of Crytek Studios* and it has been used by *Ubisoft Montreal* in 2004 to develop the game *Far Cry*. The engine supports a number of features such as a real-time editor with a rich tool arsenal that enable the development of realistic games. Its functionality is similar to that of Unity with some additions such as a dedicated road and river design tool, a solid modeling designer tool and scripting in C++ or LUE programming languages. Most of its development components are managed through a sophisticated GUI that also integrates the CryEngine Sandbox world editing system. The

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

engine supports a vast range of currently available platforms and it is continuously updated to provide export functionalities to new platforms. Licensed developers are offered with the complete source code and documentation for the whole engine and its accompanying tools. One of the primary advantages of CryEngine is the solid designer tool, by which complex meshes may be created. The *Unreal engine* (Craighead, Burke, & Murphy, 2008; Unreal, 2016) was developed by *Epic Games* in C++. The engine supports high performance rendering, advanced animation features and high-quality dynamic lighting, environmental effects, particle system, blueprint visual scripting, C++ scripting, Virtual Reality, AI avatar system, terrain builder, physically-based rendering, UI, level building, animation, visual effects, physics, networking, and cross-platform development. One of the primary advantages of the engine is its powerful particle system that can handle up to one million particles real-time visualization.

Kiourt et al. (2016) reviewed these game engines and made up an interesting and compact comparative table of pros and cons of those engines. Table 1 is an updated version of that table.

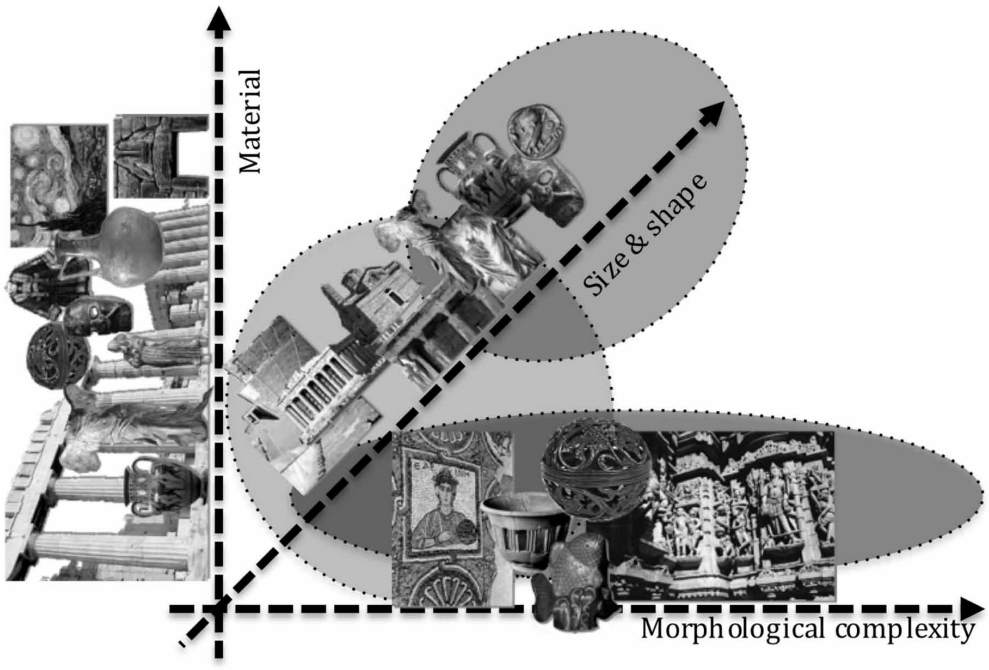
RECONSTRUCTION OF THREE-DIMENSIONAL (3D) ENVIRONMENTS

An integral part of a realistic simulation for cultural heritage applications is the environment, in the form of any cultural object, site, architectural complex, or any other form of tangible material object that conveys the story to be told. *Reconstruction* is the keyword for the creation of the 3D digital counterpart of a real-world cultural object. The reconstruction of 3D environments is based on two entirely distinctive methods: (a) *3D modeling* of objects, which is the process of developing a mathematical (graphical) representation of any 3D surface of an object via specialized software, such as Autodesk 3DS MAX (3DS MAX, 2016), Blender (Blender, 2016); (b) *3D digitization* of objects, which is the process of capturing the shape and appearance of real objects using geometric and spectral measurements. In practice, in many cases those two methods are used in combination and the results are impressive (in terms of rendering realism).

3D modeling is an entirely digital process that takes places on a computer using a specialized software application. It requires high specialization in using such software, and, in particularly demanding applications – like in cultural heritage reconstruction – 3D modeling requires the participation of domain experts. *Obviously, 3D modeling is more of an artist's work, whereas 3D digitization is more of an engineer's work.* 3D digitization is a process of taking highly accurate measurements using specialized techniques and equipment. Its purpose is to get a highly accurate snapshot of reality, having cultural heritage frozen in time. In general, it has to be conducted by digitization experts, although in some cases, the automation provided makes it easier for non-experts to conduct a simple 3D digitization task. There are several techniques for the 3D digitization in cultural heritage applications, each of which with its pros and cons (Pavlidis, Koutsoudis, Arnaoutoglou et al., 2006). The process of *3D digitalization* consists of two steps, the first step is to collect the data (images, distances, sizes etc.), the second step is to analyze the collected data and develop the objects via specialized algorithms. Nowadays the most common 3D digitalization techniques include a number of methods usually falling into two main categories, namely (a) light-dependent and (b) light-independent methods. The first category includes (1) active and (2) passive methods. In summary, Table 2 presents a list of the contemporary 3D digitization methods. Pavlidis et al. (2007) summarized the various parameters involved in categorizing the cultural objects in three axes, namely the *size and shape, morphological complexity* and *diversity of materials*. This 3D space of cultural objects, graphically illustrated in Figure 9, forms a basis for a number of challenges in 3D digitization projects. Unfortunately, there is not a single 3D digitization method to fit all digitization projects. For example, the lower dark-gray region in Figure 9 corresponds to a region in which laser triangulation methods can be successful, whereas the upper medium-gray region corresponds to a region in which range-scanning methods are efficient and the central circular light-gray region depicts a region in which photogrammetry-based methods such as structure from motion are expected to be successful.



Structure from motion or SfM (Schönberger & Frahm, 2016) is one of the most widely used technique, since it is one of the easiest, most efficient and economical solutions, which does not require mastering any highly-specialized skills and equipment. A camera, a computer and a software application that can be open source, like Visual SFM (VisualSFM, 2016), can produce incredibly realistic models, but, the hardware requirements increase when the quality targeted and the size and complexity of the objects grow. Figure 10 depicts an example of a reconstruction using the SfM method for a typical cultural heritage 3D digitalization project; the blue rectangles represent the resolved camera sensor plane for each captured photo, and the small black vectors help identify the orientation and direction of the camera in the virtual 3D space, whereas the reconstructed 3D model is clearly visible.

GAMIFICATION

Developers and administrators of virtual museums have already started to realize the potential of new technologies for the development of edutainment content and services for their visitors (Bickmore, Pfeifer, & Schulman, 2011). In addition, gaming for educational purposes is a significant and active research domain (Brown & Vaughan, 2010; Nicholson, 2011; Nicholson, 2012; Pavlidis, 2015; Seaborn & Fels, 2015). This has taken either the form of game-based learning or serious gaming. *Gamification* is the result of applying game mechanics into diverse domains, in order to engage users and enhance their knowledge and performance.

The importance of playing has been emphasized in many studies from various domains. According to Brown & Vaughan (2010), playing is an archetypical activity that arises from primordial biological structures existing even before the conscience or the capacity for speech; as Brown & Vaughan emphatically stated it is not something a person decides to do.

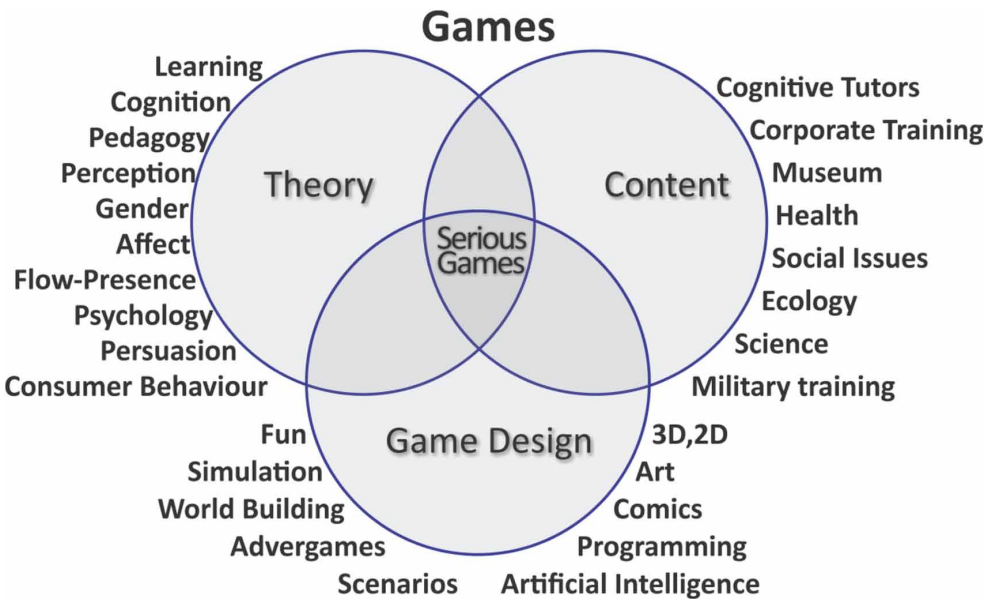
According to Nicholson (2011; 2012), gamification is nothing more than the use of specific game design approaches and techniques in various environments, in order to attract people in problem solving and to enhance their contribution. Nicholson (Nicholson, 2012) shows the distinction between *Play* and *Game* using a "playful" mathematical approach,

Game = Play + Goals + Structure

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

This equation tries to represent a gamification definition based on the meaning of the terms *game, play, goals* and *structure*. As in any equation, the terms may be rearranged, and interesting equations result, like,

Game – Play = Goals + Structure



Play = Game – (Goals + Structure)

In the first variant, a *game without* play is not a play-centered activity, and is largely used in gamification strategies like BLAP (Badges, Levels and Leaderboards, Achievements, and Points). A key strategy of meaningful gamification is represented in the second variant, in which by solving for *Play*, participants experience a true playful meaning in the underlying activity (Nicholson, 2012).

Figure 11 represents a cross-domain graph in an attempt to define gamification and specifically serious games, as a kind of a cross section among a number of domains formulated into three major classes that represent the theory, the content and the game design.

Gamification and its special application in education have a long history dating back to the 1980s. Today, with the advent of mature 3D technologies both in hardware and software implementations constitute a stable environment to successfully couple culture and education using technology and gaming as the catalysts. Various independent R&D efforts worldwide exploit this stable environment to deliver the next generation gamified virtual worlds for even more realistic and engaging cultural heritage simulations.

Figure 11. The complex multi-dimensional world of gamification in serious games

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

CONCLUSION

Realistic simulations of cultural heritage are multidimensional and a cross-disciplinary processes. In this work we made an attempt to summarize most of the key techniques, approaches and technologies available today for developing realistic 3D virtual environments for cultural end educational purposes that aim to create pleasant and engaging virtual environments for all ages. Contemporary efforts focus on various aspects including the representation of real life environments, realistic simulation of human features, interactive interfaces in the world, realistic objects and dynamic environments. In addition, interest in terms of the dynamic processes in gaming environments focuses on competitiveness and cooperation and dynamic feedback. Finally, in terms of smart virtual environments R&D efforts tackle issues in smart guided tours, smart chat-bots and smart interactive entities. Virtual environments cannot and do not intend to replace real environments, either museums or laboratories or anything else. They can be regarded as reflections of physical environments either existing or fictitious, created for various reasons and goals. There are indications that if used complementarily and as extensions of physical environments they may be most effective in enhancing engagement with culture and education with all positive outcomes for a large variety of target groups, ranging from domain experts to kids at primary school.

Chapter 65
Enhanced Virtual Reality Experience in Personalised Virtual Museums

Chairi Kiourt

ABSTRACT

This article focuses on important factors in the creation of enhanced personalised experiences in virtual environments for cultural heritage applications, especially those targeting virtual museums and exhibitions. Some of the most important factors relating to personalised virtual museums that relate to intelligent content and user modelling in virtual environments are being highlighted and discussed. After an extensive review of the current trends in the domain, the article presents a generalised framework for the development of the next generation enhanced VR experiences in personalised virtual museums. This framework, which naturally surfaces from the domain, was put to the test in the development of the DynaMus platform and two case studies based on this platform are referenced and commented to support such an approach. This concept can serve as the general framework for developing enhanced personalised virtual environments for cultural heritage applications.

INTRODUCTION

The advent of the web, was an initial motivation for museums, to start creating information-rich web sites to promote their services. Personalised content was considered a good strategy to support users, with different capabilities and requirements, in finding information in unfamiliar collections (Ardissono, et

DOI: 10.4018/978-1-7998-0951-7.ch065

al., 2015). As soon as mobile technology appeared, it was adopted for delivering context-aware cultural heritage information both indoors and outdoors. Generally speaking, indoors there is a limited space, which is extremely rich in content but offers few services over and above information delivery. In contrast, outdoor mobile apps cover relatively large areas – a city or part of it – offering a wide range of integrated services, such as those providing location-based, cultural, hotel and travel information. The infusion of new technologies in cultural institutions, such as mobile technologies (Asif & Krogstie, 2012), Virtual Reality (VR) (Kiourt, Pavlidis, Koutsoudis, & Kalles, 2017a), Augmented Reality (AR) (White, et al., 2004; Katifori, et al., 2014; Pujol, et al., 2012) etc. have resulted in new experiences (spatial awareness) and have helped in reaching a larger audience – not only children but also adult visitors (Kuflik, Kay, & Kummerfeld, 2010) – focusing on several different goals such as education, lifelong learning etc. (Ardissono, Kuflik, & Petrelli, 2012; Ardissono, et al., 2015; Kiourt, Pavlidis, Koutsoudis, & Kalles, 2017a).

Personalised content in cultural heritage aims at adjusting and transforming the cultural experience so as to meet the experiences, interests and knowledge at the level of the individual visitor or the group (Ardissono, Kuflik, & Petrelli, 2012; Yiannoutsou & Avouris, 2014). Personalised content is considered by many researchers (Ardissono, Kuflik, & Petrelli, 2012; Asif & Krogstie, 2012; Bohnert, 2010; Kuflik, Kay, & Kummerfeld, 2010; Not & Petrelli, 2014; Vayanou, et al., 2012) as a key factor in the success of such objectives. Content personalisation techniques can be employed to steer the information selection based on the user / group profile (interests and context), thus protecting them from data overload (Ardissono, Kuflik, & Petrelli, 2012). Moreover, personalisation can be used to adapt the presentation of information to the user's device, thus facilitating exploration. Personalised content delivery to users is more acceptable through gamified applications, such as serious games, because they are more realistic, user-friendly, pleasant and attractive systems (Anderson, et al., 2010).

There is a growing trend for the development of serious games in diverse fields, including entertainment, cultural heritage, education, artificial intelligence, sociology, military and health systems (Abt, 1987; Breuer & Bente, 2010). Serious games are highlighted as innovative and important tools for the development of applications broadly accepted by all ages, children, adults and seniors (David & Sandra, 2005). Serious games have been widely adopted in cultural heritage, for applications such as virtual exhibitions and museums and have been the subject of applied research and development for several years (Mortara, et al., 2014; Kiourt, Pavlidis, Koutsoudis, & Kalles, 2017a; Doulamis, Liarokapis, Petridis, & Miaoulis, 2012; Froschauer, Arends, Goldfarb, & Merkl, 2012). Nevertheless, there are still challenges for further research, targeting the enhanced interactive realistic simulations of ancient worlds or cultural sites and exhibitions. In a sense, serious games can be considered an efficient approach for blending domain specific activities, like those in cultural heritage and education, with gaming.

Gamification (Deterding, Dixon, Khaled, & L., 2011) is the result of applying game mechanics into diverse domains, in order to engage users and enhance their knowledge and performance. The importance of playing has been emphasised in many studies from various domains. According to Brown & Vaughan (Brown & Vaughan, 2010), playing is an archetypical activity that arises from primordial biological structures existing even before the conscience or the capacity for speech; as Brown & Vaughan emphatically stated, playing is not something a person decides to do. According to Nicholson (Nicholson, 2011), gamification is nothing more than the use of specific game design approaches and techniques in various environments, in order to attract people in problem solving and to enhance their contribution.

This paper focuses on serious games-based cultural heritage applications (mainly as virtual museums) with personalised content for more accurately targeted information and knowledge delivery to users. Of special interest is to derive a framework of rules, theory and best practices for the development of the

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

virtual environment, the content adaptation and the interaction mechanics. To this end, key factors relating to Personalised Virtual Museums (PVM) (Hayashi, Bachelder, & Nakajima, 2016) that are based on a dynamic environment that is able to be populated by external resources and provides content based on user profiles. Nowadays, education, training and entertainment seem to be main research directions in PVMs. This paper introduces a framework for the development of user profiles based on social media sources and for the exploitation of this user profile for the development of PVMs. The approach presented introduces three core research sub-domains (content generation, knowledge modelling and engaging gameplay), which can serve as the general framework for developing enhanced virtual environments by exploiting the user profile.

The rest of this paper is structured in four sections. The next (second) section presents a summarised review of recent advances in the domain of PVMs. The third section identifies the basic ingredients of PVMs that support an enhanced virtual reality experience. The fourth section provides a presentation of the unifying proposed framework followed by two user-centred virtual world case studies with the DynaMus platform that was developed based on this general framework. The paper concludes by summarising and providing thoughts for further development.

RELATED WORK

The personalization of virtual museums theory, appeared about two decades ago, when some of the adaptive hypermedia systems looked at museum content and tourism as possible application domains (Stock, et al., 1993; Fink, Kobsa, & Nill, 1998). Stock et al. (1993) provided personalized content as part of a human-machine dialogue on art exhibits and combined with natural language processing with a hypermedia system. While Fink, Kobsa and Nill (1998) introduced a desktop application running on info kiosks for personalized tourism information delivery. Paternò and Mancini (1999) developed an online web based application with personalized content by providing three different choices to visitors: 1) predefined information views; 2) user defined profile setup; and 3) information suggestion based on the visiting history of the visitor. The 90's decade stammered the advent of the web based museums started creating information-rich websites, and personalization was considered a good way to support visitors with different needs. One decade later the mobile technologies appeared as an important tool for context-aware cultural heritage information delivery to visitors for both indoor and outdoor areas. Schmidt-Belz, Laamanen, Poslad and Zipf (2003) tested Personal Digital Assistants (PDAs) for providing dynamic and interactive maps, to visitors, that presents the current position, recommendations, information about attractions, and visiting tips. Petrelli and Not (2005) presented a system with accurate determination of the visitor's position indoors, which led them to the idea of interaction through physical movement. Stock et al. (2007) introduced a system which dynamically creates animation-based video clips taking into account the user's focus of attention. In this system, a virtual character appears in the PDA and accompanied the visitor, presenting information, throughout the visit. Projects such as MUSE and Smartmuseum (Ruotsalo, et al., 2009) tried to cover both cases (indoor and outdoor guidance) but most were specialized in one or the other.

In the creation of virtual museums, contemporary IT technologies, such as multimedia, 3D computer graphics, spatial sound and virtual reality, are used to enhance the presentation (the virtual presence), offering a more vivid and enjoyable experience (Kiourt, Pavlidis, Koutsoudis, & Kalles, 2017a) through gamified virtual environments. The Augmented Representation of Cultural Objects (ARCO)

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

(Patel, White, Walczak, & Sayd, 2003; White, et al., 2004) was among the predominant efforts towards a dynamic virtual museum system accompanied by a 3D digitisation technique to provide museums a framework to produce and Exhibit 3D digital replicas of their artefacts over the Web based on the visitors need. Lepouras and Vassilakis (2005) presented the concept of creating virtual museums focused primarily on educational content and related services by using a game engine. They developed a virtual museum for multiple different uses, based on different educational content. Wang, Aroyo, Stash and Rutledge (2007) presented an approach for personalized access to museum collections by using RDF/OWL specification of a museum collections as a driver for an interactive dialog. Personalization of gamified virtual museums include virtual agents-guides that discuss and interacts with users and present the space (Oberlander, Karakatsiotis, Isard, & Androutsopoulos, 2008), and adaptive, personalized exhibition spaces (Bonis, Stamos, Vosinakis, Andreou, & Panayiotopoulos, 2009). Liarokapis, Sylaiou and Mountain (2008) presented a solution for indoor and outdoor museum exhibitions with personalised content. They introduced mixed reality multi-modal interfaces as a framework that can be used for targeting the needs of visitors for both kiosk exhibitions and mobile guides. Sookhanaphibarn & Thawonmas (2009), developed a virtual museum, which was equipped with an innovative intelligent guidance system that was able to provide a customised navigation route based on the visitor's preferences. Christopoulos et al. (2011) introduced a story telling virtual game with dynamic interactions that gives the opportunity to a human guide for personalization of the experience according to the target group. Koutsoudis et al. (2012), proposed a content-based navigation framework for a virtual museum, based on metadata that describe the exhibits and thus providing a semantic similarity-based navigation. The visitor's preferences are decoded by its interactions with the exhibits. Coenen, Mostmans and Naessens (2013), introduced a gamified virtual environment, where the visitors where guided by the system (mobile application) to create their own exposition during their visit in the physical museums. The aim of this systems is to provide a personalised learning effect during a visit to a museum exhibition. Bonis, Vosinakis, Andreou, and Panayiotopoulos, (2013) proposed a multi-user framework for virtual exhibitions that adapts to visitors' preferences. Kiourt, Koutsoudis and Pavlidis (2016) have studied many aspects of interactive virtual museums mainly focusing on interactive 3D object exhibitions with dynamic open data content; the virtual museum was reintroduced as a cultural and educational tool that focuses on user-driven exhibitions. The last three decades, in the view of gamified virtual museums for personalised learning applications have been developed several applications, such as Roma Nova (B. Frischer, 2008), Ancient Pompeii (Troche & Jacobson), THIATRO (Froschauer, Merkl, Arends, & Goldfarb, 2013), Ancient Agora of Athens (Kontogianni & Georgopoulos, 2015; Kontogianni, Koutsaftis, Skamantzari, Georgopoulos, & Chrysanthopoulou, 2016) and many more (Anderson, et al., 2010; Mortara, et al., 2014; Sylaiou, Liarokapis, & Kotsakis, 2009; Ardissono, Kuflik, & Petrelli, 2012; Kabassi, 2017), while some studies focused on methodologies for the comparative evaluation of different design alternatives related to the user interaction with virtual museum systems (Loris, Fabio, & Maurizio, 2017).

Personal Virtual Museums

Designing for museum personalisation is a challenging task (Aylett & Cavazza, 2001). Museum visitors are unique personalities with specific goals and preferences. Any profile initialisation method has to take into account multiple user factors to be truly effective and usable in a museum context (Kiourt, Pavlidis, Koutsoudis, & Kalles, 2017b). It also needs to be based on an appealing and non-intrusive design, and to be brief and interesting. Nowadays virtual museums focus on personalised content for achieving a

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

most effective user experience, which is why the term Personalised Virtual Museums (PVM) has been coined (Hayashi, Bachelder, & Nakajima, 2016). Some of the key features of PVMs are (Kiourt, Pavlidis, Koutsoudis, & Kalles, 2017b):

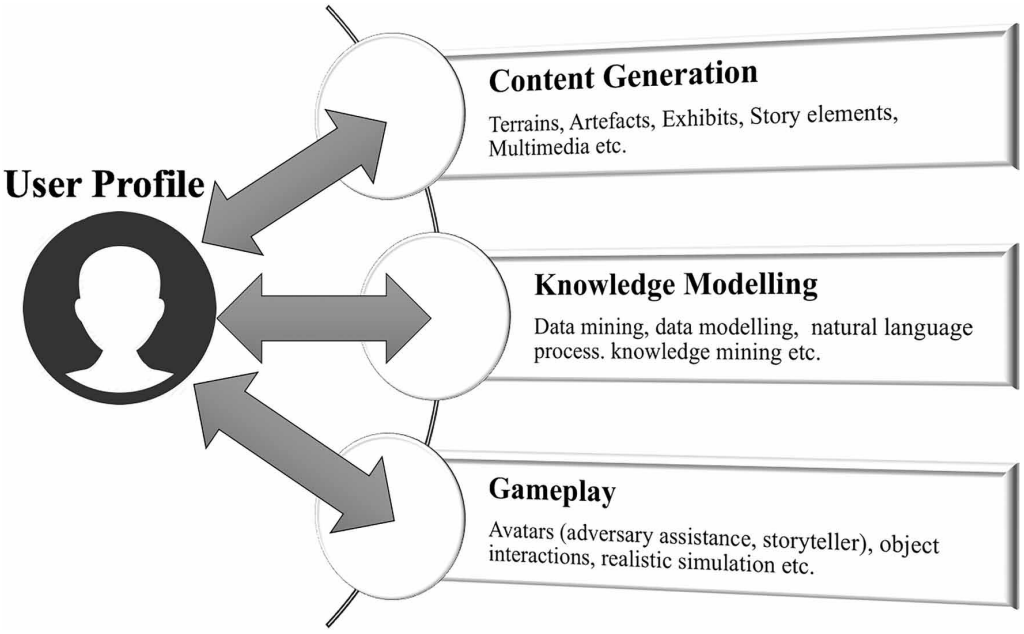
- PVMs are dynamical systems supporting interpersonal communication as well as knowledge modelling and management;
- PVMs explore a pan-institutional, modular system of learning objects for the creation of new authored content;
- PVMs exploit a structured, external linking system (linked data technologies) to provide a richer context for item level content;
- PVMs provide "rich content"—rich media that maximize the use of images, video, audio and computational media as much as possible, along with comprehensive context for individual items;
- PVMs provide dynamic educational personalised content to users based on their requirements.

These key features in PVMs are important for the development of dynamical, pleasant, user-friendly, attractive, personalised educational virtual worlds for various uses, such as education, work simulation, etc. Studies based on technologies used in PVMs suggest that the most appropriate content for the visitors is delivered based on some specific features: user profiles, the cumulative visitors' history, user-generated content and on combinations of these features (Yiannoutsou & Avouris, 2014). In order for personalised information and content to visitors to be created, a significant amount of digitised information/content is required from cultural heritage resources; those data must be filtered and personalised in order to enable the individual user to easily access and consume it in an engaging manner. This approach focuses on visits adjusted to visitor interests, moods, visit purposes and previous experience. Thus, personalised interaction is an important tool and method to bring visitors closer to the museum employs tools and methodologies to accommodate the visitors' interests.

Nowadays, cultural heritage institutions employ serious gaming to support distance and lifelong learning techniques to prepare the visitors for the visit or to enhance the experience after the visit (Anderson, et al., 2010; Doulamis, Liarokapis, Petridis, & Miaoulis, 2012; Paliokas & Sylaiou, 2016). Serious games mainly appear in museum web-sites and users have the ability to play the game whenever they want, as well as to relive the experience unlimited times. Those games are created for supporting cultural experience by engaging users with the cultural content in playful ways. For this reason, gamification methods and techniques are an important ingredient in the development of serious games for cultural applications, in a way so that the visitors stay focused on the purpose of the visit and not on a free-time-spending activity (Anderson, et al., 2010). In many cases, the user engagement with cultural content remains at a superficial level as it is not smoothly integrated in the story or the game (Yiannoutsou & Avouris, 2012).

ENCHANCED VIRTUAL REALITY EXPERIENCE

In this section, we introduce three core sub-domains for developing enhanced virtual reality user experiences in cultural heritage over on a specific main domain, the user modelling. Researchers in the domain of virtual environments focus on several sub-domains, including dynamical knowledge modelling, management and presentation and dynamical content generation, player modelling, and gameplay (Korn & Lee, 2017; Kiourt, Pavlidis, Koutsoudis, & Kalles, 2017a; Kiourt, Pavlidis, Koutsoudis, & Kalles,



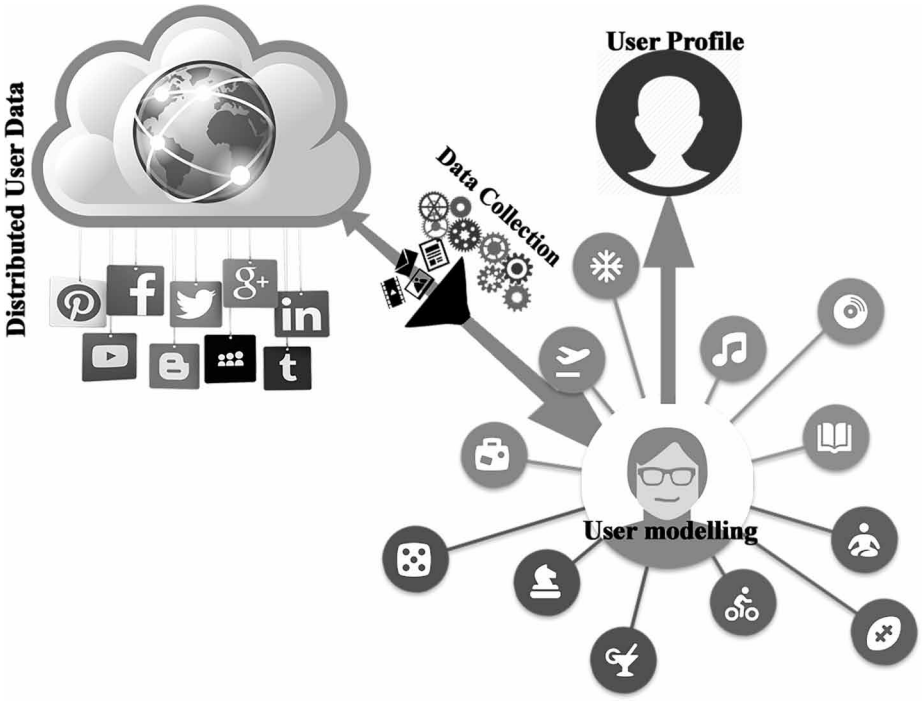
EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

2017b). Fusing those aspects may result in three different sub-domains: *content, knowledge modelling, and gameplay*, which feed on the user modelling. In the context of a cultural visit, user modelling is the process that models a user profile, including interest, mood, visit purpose, knowledge and other personal characteristics, as well as contextual aspects, in order to select the most suitable content to be delivered in the most well-adapted manner (Bohnert, 2010; Ardissono, Kuflik, & Petrelli, 2012; Hampson, Bailey, Munnelly, Lawless, & Conlan, 2013; Scott, Soria, & Campo, 2017). The three core sub-domains for developing enhanced virtual reality user experiences based on user-modelling are:

- *Content* (C), which is any form of digital data and media in any local or remote repository and any form of digital data and media being dynamically created;
- *Knowledge Modelling* (KM), which is the procedure of creating a computer interpretable model of knowledge, or standard specifications about a kind of process and/or a kind of facility or product;
- *Gameplay* (Gp), which in many, probably in most, virtual environments include methods and tools for various non-player characters as well as the interactivity of various objects of the environment.

These core sub-domains, whose main parameterisation is based on the information use modelling (Figure 1) can serve as the general framework for developing enhanced personalised virtual environments for cultural heritage purposes. The framework has the potential to provide a more targeted and well-adapted (personalised) educational content in virtual museums.

Figure 1. The proposed PVM framework with the three core sub-domains



EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

User Modelling

Personalisation of cultural heritage content, require methods that are able to model the user interest, knowledge, mood and other personal characteristics, as well as contextual aspects, to select the most appropriate content, and to deliver it in the most suitable way (Fischer, 2001; Bohnert, 2010; Hampson, Bailey, Munnelly, Lawless, & Conlan, 2013). This research domain empowering this approach is user modelling. Since current trends focus on visitor needs and engagement user modelling targets the provision of differentiated access to information and services tailored to a visitor's specific profile, both in the physical museum and virtual museums (Bohnert, 2010; Ardissono, Kuflik, & Petrelli, Personalization in cultural heritage: the road travelled and the one ahead, 2012; Hampson, Bailey, Munnelly, Lawless, & Conlan, 2013; Ardissono, et al., 2015). Based on related works, visitors' interests and goals depend on numerous factors, such as the cultural background, previous experience and social contexts (Falk, 2009). This is because viewing personally interesting content encourages visitors' engagement and learning (Tallon & Walker, 2008; Kiourt, Pavlidis, Koutsoudis, & Kalles, 2017b). Nowadays, research in this field focuses on the development of systems that autonomously retrieve users' data from the web, as well as to interact with the users in order to get more targeted information, and to develop profiles.

The exploration and exploitation of social media resources, as well as the modelling of the user profile based on those data is graphically depicted in Figure 2. The collected data are first scanned and analysed and then the model of the user is being built by exploiting methods of targeted user profile generation that draws on user-computer interactions for more accurate and personal information (Fischer, 2001). Through the general model of the user a user profile can be built based on the adaptation specified by applications.

Figure 2. User modelling based on social media resources

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Dynamical Content Generation

Digital content is any content that exists in the form of digital data and presents some information to users (Kuflik, Lo Bue, & Stock, 2017). Cultural heritage content consists of rich media and research focuses on their automated creation, generation or production. *Dynamical Content Generation* (Shaker, Togelius, & Nelson, 2016; Korn & Lee, 2017; Kuflik, Lo Bue, & Stock, 2017) refers to the generation of content for a virtual environment, autonomously or with limited human involvement. The goal of the dynamical content generation methods is to remove the need for humans to generate content in large scale personalised virtual environments. In serious games, dynamical content generation is used to maximize the learning effects of a game, or perhaps the addictiveness of a "casual" game by focusing on educational purposes. Terrains, characters, artefacts, exhibits, story elements, game rules, textures, music, multimedia etc. are the main objects that can be generated dynamically. There are basically two methods for dynamical content generation, offline and online, the first of which focuses on content generation during the development of the game, whereas the second focuses on the real-time content generation.

Knowledge Modelling

Knowledge Modelling is the procedure of creating a model of knowledge or standard specifications about a kind of process and/or about a kind of facility or product. Nowadays, this subdomain focuses on the *computer interpretable knowledge modelling*, for the development of systems that intelligently deliver personalised content to users. Knowledge is a combination of information and experience, context, interpretation and reflection (Davenport, Long, & Beers, 1998). Knowledge modelling was established several years ago as a research field, and started with traditional information systems and databases, to distributed systems, and the Web (Devedžić, 1999). Today knowledge modelling aims to exploit the distributed data on the Web. A well-known source of knowledge modelling is crowd-sourcing, which is of special interest for cultural heritage applications, like virtual museums. For example, Europeana[1] is a digital platform for cultural heritage, with content based on linked open data technologies, which are offered through an application programming interface (API). Several studies have already shown the importance of crowd-sourcing and knowledge modelling in cultural heritage (Uden & Zipf, 2012; Ciolfi, 2013; Biella, et al., 2015).

Gameplay

Gameplay, in many, probably most, virtual environments includes methods and tools for various non-player characters (NPCs). These characters are controlled by agent controlling algorithms (Wooldridge & Jennings, 1995; Shoham & Leyton-Brown, 2009). The requirements of these algorithms have led to an emphasis on behaviour authoring methods such as finite state machines and behavioural trees, as AI methods based on search, optimisation and learning have not shown advantages in playing to gain experience. A common disadvantage has been a perceived lack of predictability and control with such methods. Some of the most known Artificial Intelligence methods (Russell & Norvig, 2010) used in playing games include tree search-based approaches (Turing, Bates, Bowden, & Strachey, 1953), reinforcement learning (Sutton & Barto, 1998) and supervised learning (Bishop, 2006). The integration of NPCs in virtual environments focuses on enhancing the user experience in dynamic environments with realistic, non-boring content and concepts. AI in serious games is generally useful for modelling NPC behaviour and playing the game not for winning, but rather for the experience of play.

TOWARDS A NEW UNIFYING FRAMEWORK

Designing for museum personalisation is a challenging task. Museum visitors are unique personalities with specific goals and preferences. Any profile initialisation method has to take into account multiple user factors to be truly effective and usable in a museum context. It needs also to be based on an appealing and non-intrusive design, and to be brief and interesting. This section serves as a kick-off discussion on a generalised efficient and effective framework for enhancing the user experience in virtual reality application in cultural heritage and specifically in PVMs.

By following the analysis in the previous sections, we aimed at summarizing some of the most important key factors relating to PVMs that focus on dynamical environments composed of external (linked open) resources based on user profiles. Education, training and entertainment seem to be interwoven with PVMs. Also, we aimed at highlighting the importance of social media, crowd-sourcing, data modelling, data mining technologies towards more engaging virtual environments. In addition, we introduced the three core sub-domains, – content generation, knowledge modelling and gameplay – which can serve as the general framework for developing enhanced virtual environments by exploiting the user profile (Figure 3). The user model provides the user profile, based on the needs of the user and the requirements and specifications of the applications, and is composed of information derived from social media sources as well as from a constant exchange of information between the user and the applications. Thus, designed systems have the potential to provide more accurately targeted educational content in cultural heritage applications.

Figure 3. The proposed technological framework for the next generation Personalised Virtual Museums

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

The intersection of the three sub-domains can be considered as a representation of the domain of serious games:

$$C \cap KM \cap Gp = SG$$

where *SG* consists of *n* serious games for different purposes, such as entertainment, cultural heritage, education, artificial intelligence, sociology, military and health systems (Breuer & Bente, 2010; Kiourt, Pavlidis, Koutsoudis, & Kalles, 2017b), whereas the PVMs can be considered or envisioned within the framework proposed in this paper to be a subset of the set of serious games *SG*:

$$PVM \subset SG$$

This general framework can be used as a best practice guide for the development of the next generation PVMs, focusing on more accurately personalised content delivery to users by focusing on the development of dynamical, user-friendly, attractive, engaging virtual worlds for various uses, most importantly for education, culture, tourism, simulation and entertainment. What is also interesting is that, following Wecker's (2014) line of reasoning, this framework could be also applied and extended to all settings, prior or after an on-site visit, for onetime and/or multiple times experiences and, most importantly, for applications outside the museum site context, empowering the connection of cultural heritage with everyday life.

User-Centred Virtual World Case Studies

The introduced framework was tested in the DynaMus[2] platform (Kiourt, Koutsoudis, & Pavlidis, 2016). DynaMus is an innovative fully dynamical Web-based virtual museum framework that relies entirely on users' creativity and on the exploitation of the rich content in distributed Web resources. DynaMus is able to connect to popular repositories, such as Europeana and Google, and retrieve content that can be used in creating virtual exhibitions. Also, provides a complete authoring interface, in which anyone can easily create customised virtual exhibitions.

The framework as developed in DynaMus easily connects to educational settings, and two such case studies are presented in the following paragraphs. The overall concept in these case studies is, by using the proposed framework, to bridge culture and education through technology and to provide means for tutors to enhance their everyday teaching with alternative approaches, such as personalised education/learning, that derive and reuse cultural content as an integral part of their courses. The case studies involved the development of two different virtual worlds in the DynaMus platform, the *Synthesis Museum*[3] (Kiourt, Koutsoudis, Markantonatou, & Pavlidis, 2016) and the *Pentapolis High School Museum*[4]. To meet the needs of these case studies, the virtual museum framework (DynaMus) has been customised to display virtual worlds that are basically digital replicas of real environments, actual physical buildings. Synthesis museums is a replica of the building of the B & M Theocharakis Foundation for the Fine Arts and Music located in Athens, Greece. Screenshots of both the interior and the exterior of the 3D building model are depicted in Figure 4. The Pentapolis High School Museum is a replica of a historical school building located in a small town called Pentapolis (near the city of Serres), North-eastern Greece. Screenshots of both the interior and the exterior of the 3D building model are depicted in Figure 5.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 4. Synthesis Museums; (left) external view with immediate surroundings; (right) internal view with the exhibition creation mode enabled

Figure 5. Pentapolis High School Museum; (left) external view with immediate surroundings; (right) internal view with the exhibition creation mode enabled

In these case studies, high school students of various ages were involved in creating their own exhibitions, basically of 2D content (paintings/pictures/photos), using any scenario that suited their own views and opinions based on specific subjects proposed by their tutors. Then the tutors, analysed the exhibitions of the students in order to better adapt their course based on the proposed subject presentation (as implied by the exhibitions) as well as on the information from the student profiles. The main idea was that the tutors customize their course based on the target group. After that, the tutors developed ideal personalised interactive exhibitions, which were visited by the students, as guided by the tutor. After the course, all students were free to visit their classmates' exhibitions to broaden their views/opinions on the subject that was under study.

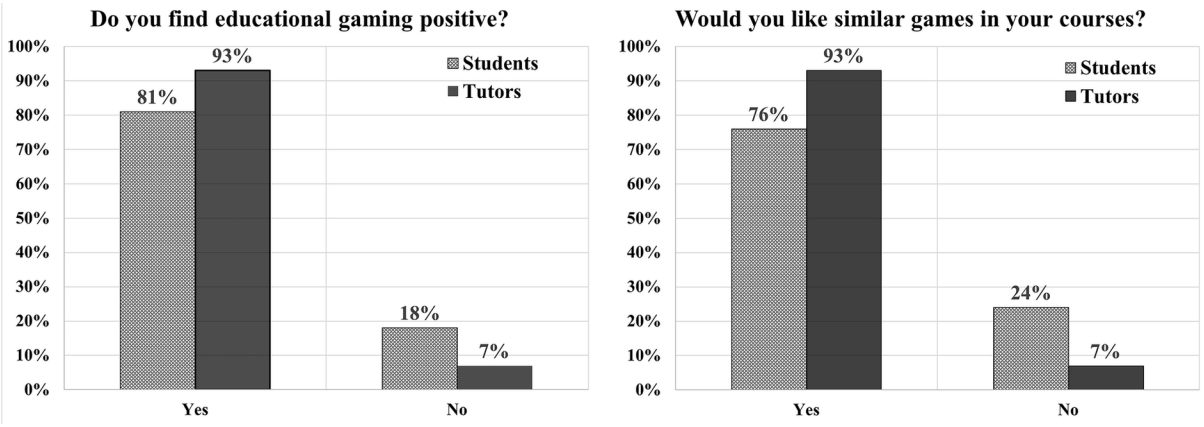
Through the activities, in which many students in both virtual worlds have been involved, they learnt to respect art and culture and were exposed to and had real practice on how to preserve and disseminate it. Apparently, one may recognize a number of pedagogical approaches based on the personalised virtual world framework (proposed in this framework) at work in the project:

- Cultural education and integration of culture in learning;
- Extensive team work and collaboration;
- Motivation with participation in major events and competitions;

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

- Exploitation of gamification factors and the appeal of gaming environments to children;
- Testing of ideas in real-life environments, and more.

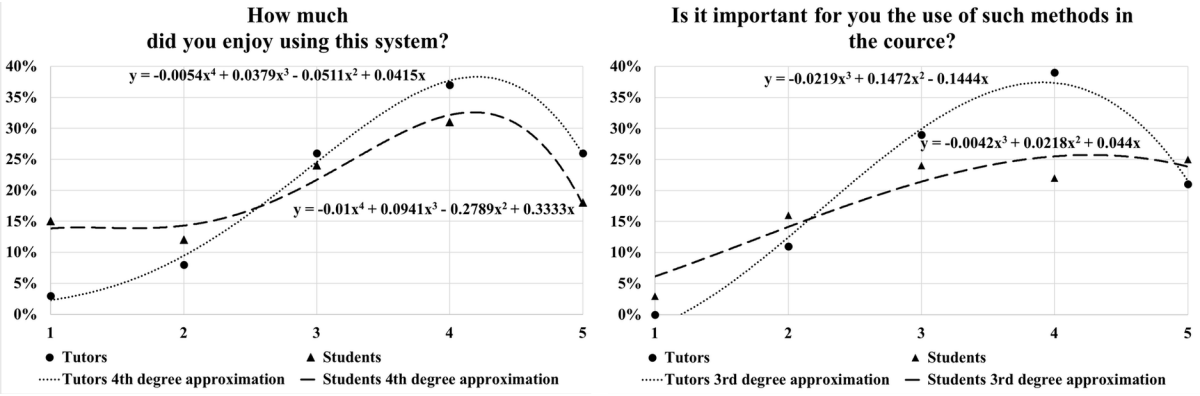
An evaluation based on a questionnaire showed that although these systems were primarily designed as dynamical virtual museums there is much acceptance in the personalised educational practice. Learners under the guidance of their tutors could use this system as a tool to create thematic exhibitions and projects regarding virtually any subject of interest. The evaluation results are presented in the following paragraphs through the analysis of four graphs.



The bars in Figure 6-left indicates that the gamified education is accepted from both tutors and students. It is really interesting to note that the students' acceptance of games in education is lower than that of the tutors. This might be an evidence of a stereotype, in which gaming is connected purely with entertainment and is totally disconnected with education (at least in the Greek educational practice where the case studies have taken place). A similar stereotypical pattern can be observed in Figure 6-right, where the need for more, similar gaming experiences in education is being investigated. The tutors' opinion remains exactly the same, whereas one quarter of the students seem to be opposed to games in education.

Figure 7 highlights the acceptance of the tested systems and their matching to courses in a classroom setup. Again, in this case, although the participants' responses are positive towards the acceptance of the gamified personalised education (by both tutors and students), still, the students' positive response is markedly lower than that of the tutors.

CONCLUSION



Apparently, the combination of ideas and technologies from virtual environments and personalised human computer interaction in cultural heritage applications is very active field of research, with many different research groups concerned with different aspects (de Aquino & de Souza, 2012; Bohnert, 2010; Ardissono, et al., 2015; Ardissono, Kuflik, & Petrelli, 2012; Kiourt, Pavlidis, Koutsoudis, & Kalles, 2017a). This paper summarizes some of the key factors relating to PVMs that focus on a dynamical environment composed by external resources that is able to provide content based on user profiles. Education, training and entertainment seem to be the natural applications of such PVMs.

Figure 6. Indicative, dichotomous scaled questions-answers for gamified education

Figure 7. Indicative five-point scaled questions-answers (Likert Scale) with accompanying 3rd and 4th degree polynomial lines to reveal the trend in each case

This paper presented an extensive review of recent methods in the domain and proposed a generalised unifying framework for the development of enhanced virtual environments with personalised content. The inspiration and primary focus in this work is on cultural applications such as virtual museums, exhibitions and storytelling. The general theory for such a framework for PVMs based on three core research sub-domains (content generation, knowledge modelling and gameplay) has been outlined, including parameterisation based on user profiles, and user modelling. Using this framework, a new generation of PVMs is envisioned to emerge. The framework has already been applied in a preliminary setting in the development of the DynaMus platform and two case studies based on this platform were presented with some encouraging evaluation results.

ACKNOWLEDGMENT

The present work was supported by the project "Computational Science and Technologies: Data, Content and Interaction/Technologies for Content Analysis in Culture", MIS code 5002437, co-financed by Greece and European Union in the framework of the Operational Programme "Competitiveness, Entrepreneurship and Innovation" 2014-2020.

Chapter 66
High Performance Computing of Possible Minds

Soenke Ziesche
Maldives National University, Maldives

Roman V. Yampolskiy
University of Louisville, USA

ABSTRACT

It has been shown that the space of possible minds is vast, actually infinite. Intellectology is a new field of study, which examines in more detail features of possible minds. Among the many open and unexplored questions in this field is the following: "Which activities can minds perform during their lifetime?" This question is very broad, thus our contribution here addresses the sub-question "Which non-boring activities can minds perform?" This issue is ethically relevant for human minds if the predicted significant extension of our lifetime materializes and we are then potentially challenged how to spend this additional time. The space of potential non-boring activities has been called "fun space." We analyze the relation between various types of minds and the portion of the fun space, which is accessible for them. As a novel result, we demonstrate that human minds can experience two types of fun when transforming information to knowledge: novelty fun and process fun.

INTRODUCTION

We motivate the relevance of the question "Which non-boring activities can minds perform?" as follows: There is optimism for a significant extension of the lifetime of humans in the near and medium future. Yet, some people expressed concern that there is not enough accessible fun space, thus much longer lives would not be fulfilling and mostly boring, as examined by Walker (Walker, 2006). Therefore, the subject of this article, to analyze the accessible fun space for various minds, is critical in order to conclude whether an extended lifespan is desirable.

In addition, future scenarios can be envisaged when humans are enhanced by intelligence amplification and other transhuman features, potentially supported by friendly AI. Further scenarios include transition to substrate-autonomous persons, e.g. through uploading or whole brain emulation (Koene, 2012; Bostrom, 2014). In the latter case, lifetime could increase almost indefinitely, and also former unknown sensations could be perceived. Also for this option, concerns have been raised that it will turn out to be boring for such enhanced humans due to the lack of remaining intellectual challenges. In contrast, others believe the fun space is large enough for either scenario (e.g. Moravec, 1988; Yudkowsky, 2015; Bostrom, 2008)

Yet another view by Pearce is that in a parallel development boredom will be "neurochemically impossible" through advanced technology (Pearce, 2012; Yampolskiy, 2015). Therefore, although human minds are only a small subset of the space of possible minds, for this type of minds the question about sufficient non-boring activities, i.e. enough accessible fun space, is very important.

In addition, we are addressing the question of accessible fun space also for non-human minds by aiming to contribute to one aspect of the field of "intellectology" (Yampolskiy, 2015). Yampolskiy has introduced "intellectology" as a new area of study in order to turn away from a human-centric view regarding minds and to examine in more detail features of any possible minds. This universe of possible mind designs is actually vast and certainly merits investigation; especially given the possible scenario that one group of minds, that is minds of AI agents, may cohabit with us in the not so far future.

This paper is structured as follows: In the following section, we provide an introduction to the space of minds and how it has been explored and defined in the literature. This is followed by an introduction to the space of fun, which enables us to further specify the critical questions for our subject. In the following main section, we present our contribution to the field of "intellectology" by analyzing relationships between the space of minds and the space of fun.

RELATED WORK

First, we present related work to the space of minds. When we reason about minds we tend to think of human minds only. This is because of the anthropomorphic bias. However, in addition, there are other minds, which we encounter on earth, the minds of higher order animals, and then there are various minds, which we can imagine as possibility and perhaps even more beyond our imagination ("unknown unknowns"). Several theoretical surveys on this topic exist and it has been shown that the space of possible minds is vast (e.g. Sloman, 1984; Goertzel, 2006; Hall, 2007; Yudkowsky, 2008; Yampolskiy, 2015).

Examples for potential minds could be human-designed AI minds, self-improving minds, a combination of minds constituting itself a mind and many more. There have been several attempts to classify the space of minds (Yampolskiy, 2015). In fact, the space of human minds forms only a tiny subset within the universe of possible minds (Yudkowsky, 2008). The space of possible minds can be considered as the set of possible cognitive algorithms. Based on this and on the limited number of cognitive algorithms, which human minds can potentially perform, it can be concluded that the majority of possible minds is more intelligent than human minds. Yampolskiy and Fox describe this insight as another example of a Copernican Revolution, i.e. a revision of the view that humanity is central, which in this case refers to minds (Yampolskiy & Fox, 2012).

Yampolskiy shows that the set of mind designs is infinite and countable and that all minds can be generated sequentially by a deterministic algorithm, based on a variant of the Levin Search (Yampolskiy, 2015). By linking a mind to a number, Yampolskiy also demonstrates that "… a mind could never be completely destroyed, making minds theoretically immortal. A particular mind may not be embodied at a given time, but the idea of it is always present." (Yampolskiy, 2015). The fact that minds are countable will be useful when establishing relations with the fun space.

We continue by presenting related work to the space of fun. Regarding the goals and the motivation of minds Bostrom distinguishes between two theses, the orthogonality thesis and the instrumental convergence thesis (Bostrom, 2012). The former states that "more or less any level of intelligence could in principle be combined with more or less any final goal", while the latter proposes that there is a rather limited number of instrumental values which many intelligent agents share.

The focus of this paper are those goals of minds that are related to the discovery of novelties and to having fun, which is the opposite of boredom. Yudkowsky proposes a link between novelty and fun: "Novelty appears to be one of the major keys to fun, and for there to exist an infinite amount of fun there must be an infinite amount of novelty." (Yudkowsky, 2015). We shall specify this further below.

Omohundro defines four drives for AI minds: Efficiency, self-preservation, acquisition, and creativity (Omohundro, 2007, Omohundro, 2008). Three of these drives address novelty: The creativity drive is about novelty by definition (leads to the development of new concepts, algorithms, theorems, devices, and processes), but so are the efficiency drive (aiming for novel algorithms and methodologies) and the acquisition drive (aiming for novel resources). Only the self-preservation drive is linked more indirectly to novelty, which has to be relative to a particular self. Hence, without self-preservation everything might be seen as novel to some new version of that self. However, Omohundro does not mention "fun" to be linked to any of these AI drives.

We know that at least human minds aim for accessing fun space. Therefore, the subset of all minds, with the distinction to have the objective of having fun, is at least the set of all human minds, but potentially it is bigger. Yet, when pondering over such questions it is always critical to beware of the anthropomorphic bias:

- It could well be possible that fun is specific to humans only and other minds do not aim for fun. The actions of these minds are still likely to be steered by the above drives, yet they may not aim for fun as an epiphenomenon and may be satisfied by pursuing boring activities as long as these serve their goals (Yet, we seem to observe at least some higher order animals having fun.)
- If there are other minds that aim for fun, this "fun" may look extremely different from what is fun for humans and may well be unimaginable for humans. Both, the sensation that other minds "feel" as fun as well as the activities that trigger this sensation could be very different, e.g. activities that are considered tedious by humans may cause for other minds fun-type sensations as epiphenomenon.
- There may be certain minds, who do aim for fun, but apply "wireheading" methods, which is obtaining the reward through direct stimulation without otherwise required productive behavior. Hence, drugs and/or technologies provide them effortlessly and permanently with what they consider as fun (Yampolskiy, 2014).

Having established this, we elaborate further on the critical questions we aim to address:

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

What is the relation between novelty and fun? It seems that fun is useful to motivate exploration, innovation and discovery. Stanley and Lehman show that novelty search is more successful than objective-based search (Lehman & Stanley, 2015). Therefore, striving for fun of human minds could be explained by evolution. Novelties are critical for human development, and fun is, at least sometimes, an epiphenomenon while pursuing novelties or at the moment when discovering novelties. However, it can be easily shown that, at least for human minds, discovering novelties and having fun is not the same, since there are numerous novelties that are boring for humans; or a specific novelty could be fun for one human mind, but boring for others.

Schmidhuber proposes the following options to access fun space, which we will take into account below: "There are at least two ways of having fun: execute a learning algorithm that improves the compression of the already known data … or execute actions that generate more data, then learn to compress/understand the new data better." (Schmidhuber, 2010).

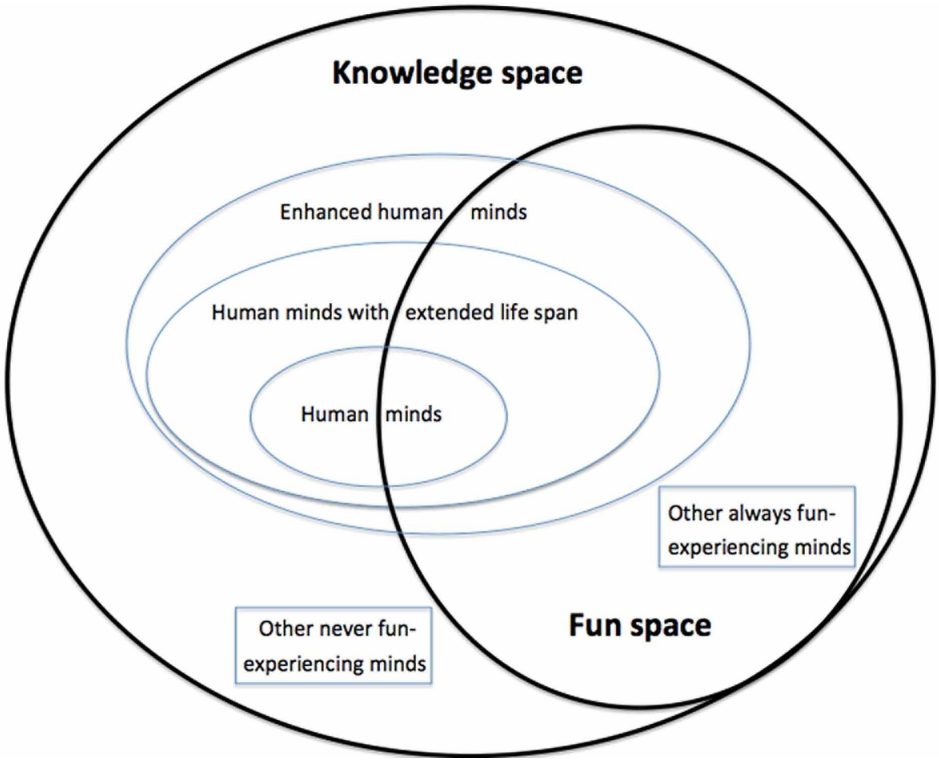
It is speculation whether this also applies to non-human minds. For example, does the mind of a "paperclip maximizer" (Bostrom, 2003) accesses fun space when discovering novelties through the creativity drive or the efficiency drive (e.g. finding time- or energy saving ways to produce paperclips) or the acquisition drive (e.g. finding new resources to be converted into paperclips)?

What is the size of the fun space? Since potential knowledge is infinite also the amount of novelties that could potentially be gained by a mind is infinite, yet limited by time and other resources. But as we stated, not every processing of novelties triggers fun as an epiphenomenon. Given the infinity of the knowledge space it may be assumed that the potential fun space is vast. In this regard Yudkowsky posed critical questions: "How much fun is there in the universe? Will we ever run out of fun? Could we be having more fun?" (Yudkowsky, 2015). We pose an additional question here, which brings us to the central part of this paper, i.e. we attempt to establish relations between the space of minds and the space of fun: Which minds have (in principle) access to which portion of the fun space?

For an illustration of relations between various types of minds, the knowledge space and the potentially accessible fun space see Figure 1.

PROPOSED TECHNIQUE

Initially, we reiterate the definitions we established above for the two spaces:



- **Space of Minds**: The set of possible cognitive algorithms (Yudkowsky, 2008).
- **Space of Fun**: The set of non-boring activities (Yudkowsky, 2015).

For the formalization, we assume that both, all potential minds (Yampolskiy, 2015) can be sequentially generated as well as all possible information strings (Yampolskiy, 2013; Schmidhuber, 2009, 2010; Lehman & Stanley, 2015). We also use Yampolskiy's insight that knowledge is discovered by finding and applying an efficient algorithm to an inefficiently stored information string (Yampolskiy, 2013).

The methodology we use to investigate the fun space for certain minds is to define a Boolean function over relevant assertions and determine its truth table, followed by examples for illustration. This Boolean function ("fun") has two parameters, a string representing a mind and another string representing information/knowledge as follows:

Figure 1. Potential access of a selection of minds to knowledge and fun space

fun(mind string, info string) = {true, false}

The verbal description of this function would be that it becomes true, if for a certain mind, represented by a numeric string, the processing of certain information, also represented by a numeric string, triggers fun as an epiphenomenon. For all other combinations of mind strings and information strings the function is false. The formalization is as follows in Table 1:

This means, the access to the knowledge represented by the information string is the precondition for fun. Although the set of human minds is very homogeneous, the extent of knowledge, which humans access during their lifetime varies significantly because certain minds cannot access 1) certain knowledge for intellectual reasons and or 2), even if they are intelligent enough, there could be resource or time restrictions:

Table 1. Formalization

fun(*x, y*) = true, if	[The mind *x* has the ability/intelligence to turn the info string *y* efficiently into knowledge (access).]	AND	[[The mind *x* had never turned that specific info string *y* into knowledge before. (novelty fun)]	OR	[The mind *x* considers the computation process of info string *y* into knowledge as fun, regardless whether it has accessed the info string *y* before or not. (process fun)]]

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

- **Available Time and Resources**: Some minds have to devote most of their resources and time for "survival", i.e. have less resources and time for fun. An example would be a rich person in a developed country vs. a poor person in a developing country.
- **Life Span**: Minds are embodied for different durations, i.e. have different life spans, which imposes time restrictions on accessing knowledge.
- **Time of Embodiment**: The accessible knowledge was for a particular mind in Stone Age quite different from one, who is embodied in 21st century.

We have shown that accessible knowledge varies immensely between minds and depends on intelligence, time, and resources to efficiently turn certain information strings into knowledge. Therefore, certain knowledge can neither be part of the process nor the novelty fun space of these minds due to their inability to access it.

After it has been established that a mind *x* can access the knowledge represented by an information string *y*, at least one of two other assertions has to be true, so that fun is involved. Therefore, we define two categories of fun:

Novelty fun: The sensation when new knowledge is ensured by retrieving a new info string *y*.
Process fun: The sensation when new knowledge is ensured merely due to the computation process that is applied to info string *y*.

These two facets of fun are motivated by Schmidhuber's "two ways of having fun" (Schmidhuber, 2009, 2010) and by Yampolskiy's insights about the relation between information strings and knowledge (Yampolskiy, 2013): "Since multiple, in fact infinite, number of semantic pointers could refer to the same string that means that a single string could contain an infinite amount of knowledge if taken in the proper semantic context, generating multiple levels of meaning."

Examples in Table 2 illustrate the different cases. The fun space is marked with grey background:

Table 2. Types of fun

Mind *x* accesses info string *y*	**New info string *y***	**Previously accessed info string *y***
New computation process	Novelty and process fun - To watch for the first time a 3D movie. - To proof that there are infinite prime numbers (Euclid). - To perform qualia surfing, i.e. to experience new qualia (as an uploaded mind, see Loosemore).	Process fun - To find a different proof that there are infinite prime numbers (Euler)[1]. - To listen to a known song again in different context or mood. - To look at a painting again in different context or mood.
Trivial/routine computation process	Novelty fun - To discover a new species of beetle in the rain forest. - To watch a new episode of a cherished TV series. - To do sightseeing in a new city.	- To clean the dishes.
