Library of Congress Cataloging-in-Publication Data

Names: Information Resources Management Association, editor.
Title: Natural language processing : concepts, methodologies, tools, and applications / Information Resources Management Association.
Other titles: Natural language processing (Engineering Science Reference (Publisher))
Description: Hershey : Engineering Science Reference, 2019. | Includes bibliographical references and index. | Summary: “This book examines the latest concepts, processes, and techniques for communication between computers and humans”-- Provided by publisher.
Identifiers: LCCN 2019023675 (print) | LCCN 2019023676 (ebook) | ISBN 9781799809517 (hardcover) | ISBN 9781799809524 (ebook)
Subjects: LCSH: Natural language processing (Computer science) | Computational linguistics. | Human-computer interaction--Industrial applications.
Classification: LCC QA76.9.N38 N3835 2019 (print) | LCC QA76.9.N38 (ebook) | DDC 006.3/5--dc23
LC record available at https://lccn.loc.gov/2019023675
LC ebook record available at https://lccn.loc.gov/2019023676

British Cataloguing in Publication Data
A Cataloguing in Publication record for this book is available from the British Library.

The views expressed in this book are those of the authors, but not necessarily of the publisher.

Table of Contents

Preface xxi

Volume I

Section 1
Fundamental Concepts and Theories

Chapter 1
Background Review for Neural Trust and Multi-Agent System 1
Gehao Lu, University of Huddersfield, UK & Yunnan University, China
Joan Lu, University of Huddersfield, UK

Chapter 2
Applications of AI in Financial System 23
Santosh Kumar, IMS UNISON University, India
Roopali Sharma, Birla Institute of Technology, India

Chapter 3
Aspect-Based Sentiment Analysis of Online Product Reviews 31
Vinod Kumar Mishra, Bipin Tripathi Kumaon Institute of Technology, India
Himanshu Tiruwa, Bipin Tripathi Kumaon Institute of Technology, India

Section 2
Development and Design Methodologies

Chapter 4
Compliance with International Soft Law: Is the Adoption of Soft Law Predictable? 49
Michael D'Rosario, Deakin University, Australia
John Zeleznikow, Victoria University, Australia

Chapter 5
Predicting Credit Rating Migration Employing Neural Network Models 65
Michael D'Rosario, Deakin University, Australia
Calvin Hsieh, Deakin University, Australia

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Chapter 6
A Thorough Insight into Theoretical and Practical Developments in MultiAgent Systems 83
Dimple Juneja, Dronacharya Institute of Management and Technology, India
Aarti Singh, Maharishi Markandeshwar University, India
Rashmi Singh, Banasthali University, India
Saurabh Mukherjee, Banasthali University, India

Chapter 7
A Hybrid Intelligent Risk Identification Model for Configuration Management in Aerospace Systems 112
Jose Nava, Pinnacle Aerospace, Inc., Mexico
Alejandro Osorio, Pinnacle Aerospace, Inc., Mexico

Chapter 8
Smart Grid and Demand Side Management: Application of Metaheuristic and Artificial Intelligence Algorithms 139
Alper Ozpinar, Istanbul Commerce University, Turkey
Eralp Ozil, Zeta Information Technologies, Turkey

Chapter 9
Society of Agents: A Framework for Multi-Agent Collaborative Problem Solving 160
Steven Walczak, University of South Florida, USA

Chapter 10
Applying Optoelectronic Devices Fusion in Machine Vision: Spatial Coordinate Measurement 184
Wendy Flores-Fuentes, Autonomous University of Baja California, Mexico
Moises Rivas-Lopez, Autonomous University of Baja California, Mexico
Daniel Hernandez-Balbuena, Autonomous University of Baja California, Mexico
Oleg Sergiyenko, Autonomous University of Baja California, Mexico
Julio C. Rodríguez-Quiñonez, Autonomous University of Baja California, Mexico
Javier Rivera-Castillo, Autonomous University of Baja California, Mexico
Lars Lindner, Autonomous University of Baja California, Mexico
Luis C. Basaca-Preciado, Center of Excellence in Innovation & Design – CETYS University, Mexico

Chapter 11
Play in the Museum: Design and Development of a Game-Based Learning Exhibit for Informal Science Education 214
Jonathan P. Rowe, North Carolina State University, USA
Eleni V. Lobene, Aon Hewitt, USA
Bradford W. Mott, North Carolina State University, USA
James C. Lester, North Carolina State University, USA

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Chapter 12
Using Physics Inspired Wave Agents in a Virtual Environment: Longitudinal Distance Control in Robots Platoon 232
Baudouin Dafflon, Université de Lyon, France
Maxime Guériau, Univ Lyon, ENTPE, IFSTTA, LICIT UMR_T 9401, F-69675, France
Franck Gechter, LE2I, UTBM, University of Bourgogne Franche Comté, France

Chapter 13
A Geometric Dynamic Temporal Reasoning Method with Tags for Cognitive Systems 248
Rui Xu, Beijing Institute of Technology, China
Zhaoyu Li, Beijing Institute of Technology, China
Pingyuan Cui, Beijing Institute of Technology, China
Shengying Zhu, Beijing Institute of Technology, China
Ai Gao, Beijing Institute of Technology, China

Chapter 14
Artificial Intelligence for the Identification of Endometrial Malignancies: Application of the Learning Vector Quantizer 266
Abraham Pouliakis, National and Kapodistrian University of Athens, Greece
Niki Margari, National and Kapodistrian University of Athens, Greece
Effrosyni Karakitsou, University of Barcelona, Spain
Evangelia Alamanou, Tzaneio Hospital, Greece
Nikolaos Koureas, St. Savas Hospital, Greece
George Chrelias, National and Kapodistrian University of Athens, Greece
Vasileios Sioulas, National and Kapodistrian University of Athens, Greece
Asimakis Pappas, MHTERA Maternity Hospital, Greece
Charalambos Chrelias, National and Kapodistrian University of Athens, Greece
Emmanouil G Terzakis, St. Savas Hospital, Greece
Vasileia Damaskou, National and Kapodistrian University of Athens, Greece
Ioannis G Panayiotides, National and Kapodistrian University of Athens, Greece
Petros Karakitsos, National and Kapodistrian University of Athens, Greece

Chapter 15
Expanding Bloom's Two-Sigma Tutoring Theory Using Intelligent Agents: Application to Management Education 280
Owen P. Hall Jr., Pepperdine University, USA

Chapter 16
A User-Aware and Semantic Approach for Enterprise Search 302
Giacomo Cabri, University of Modena and Reggio Emilia, Italy
Riccardo Martoglia, University of Modena and Reggio Emilia, Italy

Chapter 17
Use of Chaotic Randomness Numbers: Metaheuristic and Artificial Intelligence Algorithms 322
Alper Ozpinar, Istanbul Commerce University, Turkey
Emel Seyma Kucukasci, Istanbul Commerce University, Turkey

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Chapter 18
The Media-Sphere as Dream Researching the Contextual Unconscious of Collectives 343
Stephen Brock Schafer, Digipen Institute of Technology, USA

Chapter 19
On the Use of Bayesian Network in Crime Suspect Modelling and Legal Decision Support 372
O. E. Isafiade, University of Cape Town, South Africa
A. B. Bagula, University of the Western Cape, South Africa
S. Berman, University of Cape Town, South Africa

Chapter 20
Information Extraction for Call for Paper 394
Laurent Issertial, Osaka Prefecture University, Japan
Hiroshi Tsuji, Osaka Prefecture University, Japan

Chapter 21
Word Sense Based Hindi-Tamil Statistical Machine Translation 410
Vimal Kumar K., Jaypee Institute of Information Technology, India
Divakar Yadav, Jaypee Institute of Information Technology, India

Chapter 22
Exploiting Chi Square Method for Sentiment Analysis of Product Reviews 422
Nilesh M Shelke, Priyadarshini Indira Gandhi College of Engineering, India
Shrinivas P Deshpande, DCPE, HVPM, India

Chapter 23
Business Applications of Deep Learning 440
Armando Vieira, Redoctopus, UK

Section 3
Tools and Technologies

Chapter 24
Agreement Technologies for Conflict Resolution 464
Vicente Julian, Universidad Politécnica de Valencia, Spain
Victor Sanchez-Anguix, Coventry University, UK
Stella Heras, Universidad Politécnica de Valencia, Spain
Carlos Carrascosa, Universidad Politécnica de Valencia, Spain

Chapter 25
Virtual Soar-Agent Implementations: Examples, Issues, and Speculations 485
Jeremy Owen Turner, Simon Fraser University, Canada

Chapter 26
Applications of PNC in Artificial Intelligence 509
Dariusz Jacek Jakóbczak, Technical University of Koszalin, Poland

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Chapter 27
Fair Use Defences During Copyright Litigation: Is the Success of a Fair Use Defence Strategy Predictable? 539
Michael D'Rosario, Deakin University, Australia

Volume II

Chapter 28
A Graphical Tool for the Creation of Behaviors in Virtual Worlds 561
Andrea Corradini, Design School Kolding, Denmark
Manish Mehta, Accenture Technology Lab, USA

Chapter 29
Contour Reconstruction: 2D Object Modeling 584
Dariusz Jacek Jakóbczak, Technical University of Koszalin, Poland

Chapter 30
Statistical Features for Extractive Automatic Text Summarization 619
Yogesh Kumar Meena, MNIT Jaipur, India
Dinesh Gopalani, MNIT Jaipur, India

Chapter 31
Improving Collaborative Filtering Algorithms: Sentiment-based Approach in Social Network 638
Firas Ben Kharrat, University of Carthage, Tunisia
Aymen Elkhleifi, Paris-Sorbonne University, France
Rim Faiz, University of Carthage, Tunisia

Chapter 32
Knowledge-Based Support to the Treatment of Exceptions in Computer Interpretable Clinical Guidelines 658
Alessio Bottrighi, University of Piemonte Orientale, Italy
Giorgio Leonardi, University of Piemonte Orientale, Italy
Luca Piovesan, Università degli Studi di Torino, Italy
Paolo Terenziani, University of Piemonte Orientale, Italy

Chapter 33
Statistical Relational Learning for Collaborative Filtering a State-of-the-Art Review 688
Lediona Nishani, University of New York Tirana, Albania
Marenglen Biba, University of New York in Tirana, Albania

Chapter 34
An Artificial Intelligence-Based Vehicular System Simulator 708
Marvin T. Chan, University of Regina, Canada
Jonathan T. Chan, University of Regina, Canada
Christine Chan, University of Regina, Canada
Craig Gelowitz, University of Regina, Canada

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Chapter 35
A Novel Architecture for Learner-Centric Curriculum Sequencing in Adaptive Intelligent Tutoring System 722
Ninni Singh, University of Petroleum and Energy Studies, India
Neelu Jyothi Ahuja, University of Petroleum and Energy Studies, India
Amit Kumar, University of Petroleum and Energy Studies, India

Chapter 36
Designing a Socially Open Narrative Generation System 743
Taisuke Akimoto, The University of Electro-Communications, Japan
Takashi Ogata, Iwate Prefectural University, Japan

Chapter 37
Conceptual Graphs Based Approach for Subjective Answers Evaluation 770
Goonjan Jain, Jawaharlal Nehru University, India
D.K. Lobiyal, Jawaharlal Nehru University, India

Chapter 38
Wild Architecture: Explaining Cognition via Self-Sustaining Systems 791
Vincent T. Cialdella, Illinois State University, USA
Emilio J. C. Lobato, Illinois State University, USA
J. Scott Jordan, Illinois State University, USA

Chapter 39
Predictive Analysis of Emotions for Improving Customer Services 808
Vinay Kumar Jain, Jaypee University of Engineering and Technology, India
Shishir Kumar, Jaypee University of Engineering and Technology, India

Chapter 40
A Fuzzy Logic Based Synonym Resolution Approach for Automated Information Retrieval 818
Mamta Kathuria, YMCA University of Science and Technology, India
Chander Kumar Nagpal, YMCA University of Science and Technology, India
Neelam Duhan, YMCA University of Science and Technology, India

Section 4
Utilization and Applications

Chapter 41
Finding the Semantic Relationship Between Wikipedia Articles Based on a Useful Entry Relationship 838
Lin-Chih Chen, National Dong Hwa University, Tawian

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Chapter 42
Co-Designing Participatory Tools for a New Age: A Proposal for Combining Collective and Artificial Intelligences 860
José Luis Fernández-Martínez, Institute of Advanced Social Studies (IESA-CSIC) & University of Granada, Spain
Maite López-Sánchez, Universitat de Barcelona, Spain
Juan Antonio Rodríguez Aguilar, Artificial Intelligence Research Institute (IIIA-CSIC), Spain
Dionisio Sánchez Rubio, Universitat Politècnica de València (UPV) & Escola d'Art i Superior de Disseny de València EASD, Spain
Berenice Zambrano Nemegyei, MediaLab Prado, Spain

Chapter 43
Exploring the Conceptual Nature of e-Business Projects 878
Benjamin Matthies, South Westphalia University of Applied Sciences, Germany
André Coners, South Westphalia University of Applied Sciences, Germany

Chapter 44
Three-Dimensional Virtual Environment and NPC: A Perspective about Intelligent Agents Ubiquitous 912
Fabricio Herpich, Federal University of Rio Grande do Sul, Brazil
Felipe Becker Nunes, Federal University of Rio Grande do Sul, Brazil
Gleizer Bierhalz Voss, Federal Institute of Education Science and Technology Farroupilha, Brazil
Roseclea Duarte Medina, Federal University of Santa Maria, Brazil

Chapter 45
Modelling Propagation of Public Opinions on Microblogging Big Data Using Sentiment Analysis and Compartmental Models 939
Youjia Fang, Virginia Tech, USA
Xin Chen, Virginia Tech, USA
Zheng Song, Virginia Tech, USA
Tianzi Wang, Virginia Tech, USA
Yang Cao, Virginia Tech, USA

Chapter 46
Artificial Intelligence in Stochastic Multiple-Criteria Decision Making 957
Hanna Sawicka, Poznan University of Technology, Poland

Chapter 47
Trends of Educational Informatics in Latin America 983
Adán A. Gómez, Universidad de Córdoba, Colombia
Manuel F. Caro, Universidad de Córdoba, Colombia
Angela M. Solano, Universidad de Córdoba, Colombia
Yina M. Vega, Universidad de Córdoba, Colombia

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Chapter 48
Patient Data De-Identification: A Conditional Random-Field-Based Supervised Approach 991
Shweta Yadav, Indian Institute of Technology Patna, India
Asif Ekbal, Indian Institute of Technology Patna, India
Sriparna Saha, Indian Institute of Technology Patna, India
Parth S Pathak, ezDI, LLC, India
Pushpak Bhattacharyya, Indian Institute of Technology Patna, India

Chapter 49
Neural Network Model for Semantic Analysis of Sanskrit Text 1011
Smita Selot, SSTC, India
Neeta Tripathi, SSTC, India
A. S. Zadgaonkar, CV Raman University, India

Chapter 50
Probabilistic Nodes Combination (PNC): Formulas and Examples 1026
Dariusz Jacek Jakóbczak, Technical University of Koszalin, Poland

Chapter 51
Can Computers Create Comics and Animations? 1058
Miki Ueno, Toyohashi University of Technology, Japan
Kiyohito Fukuda, Osaka Prefecture University, Japan
Naoki Mori, Osaka Prefecture University, Japan

Chapter 52
A Novel Approach to Managing the Dynamic Nature of Semantic Relatedness 1085
Youngseok Choi, Brunel University London, UK
Jungsuk Oh, Seoul National University, South Korea
Jinsoo Park, Seoul National University, South Korea

Volume III

Chapter 53
Emotion Mining Using Semantic Similarity 1115
Rafiya Jan, Central university Of Kashmir, India
Afaq Alam Khan, Central University of Kashmir, India

Chapter 54
Development of Part of Speech Tagger for Assamese Using HMM 1139
Surjya Kanta Daimary, Punjabi University, India
Vishal Goyal, Punjabi University, India
Madhumita Barbora, Tezpur University, India
Umrinderpal Singh, Punjabi University, India

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Chapter 55
A Survey on Supervised Convolutional Neural Network and Its Major Applications 1149
D. T. Mane, SGGS IE&T, India
U. V. Kulkarni, SGGS IE&T, India

Chapter 56
From Citizens to Decision-Makers: A Natural Language Processing Approach in Citizens' Participation 1162
Eya Boukchina, University of Carthage, Tunisia
Sehl Mellouli, Université Laval, Canada
Emna Menif, University of Carthage, Tunisia

Chapter 57
Logs Analysis of Adapted Pedagogical Scenarios Generated by a Simulation Serious Game Architecture 1178
Sophie Callies, University of Québec à Montréal, Canada
Mathieu Gravel, University of Québec à Montréal, Canada
Eric Beaudry, University of Québec à Montréal, Canada
Josianne Basque, TELUQ University, Canada

Chapter 58
A Study of the State of the Art in Synthetic Emotional Intelligence in Affective Computing 1199
Syeda Erfana Zohora, Taif University, Saudi Arabia
A. M. Khan, Mangalore University, India
Arvind K. Srivastava, Systron Donner Inertial, USA
Nhu Gia Nguyen, Duy Tan University, Vietnam
Nilanjan Dey, TechnoIndia College of Technology, India

Section 5
Organizational and Social Implications

Chapter 59
Eventuality of an Apartheid State of Things: An Ethical Perspective on the Internet of Things 1214
Sahil Sholla, National Institute of Technology, India
Roohie Naaz Mir, National Institute of Technology, India
Mohammad Ahsan Chishti, National Institute of Technology, India

Chapter 60
Security Solutions for Intelligent and Complex Systems 1232
Stuart Armstrong, Future of Humanity Institute, UK
Roman V. Yampolskiy, JB Speed School of Engineering, USA

Chapter 61
Homo-di-fict: Creations Turn Against Humanity in South Park Town 1272
Filiz Erdoğan Tuğran, Ondokuz Mayis University, Turkey
Aytaç Hakan Tuğran, Istanbul University, Turkey

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Chapter 62
The Internet of Things and Beyond: Rise of the Non-Human Actors 1286
Arthur Tatnall, Victoria University, Australia
Bill Davey, RMIT University, Australia

Chapter 63
The Rise of Artificial Intelligence: Its Impact on Labor Market and Beyond 1298
Robert Niewiadomski, NYCDOE, USA
Dennis Anderson, St. Francis College, USA

Chapter 64
Realistic Simulation of Cultural Heritage 1314
Chairi Kiourt, Hellenic Open University, Greece
George Pavlidis, University Campus at Kimmeria, Greece
Anestis Koutsoudis, University Campus at Kimmeria, Greece
Dimitris Kalles, Hellenic Open University, Greece

Chapter 65
Enhanced Virtual Reality Experience in Personalised Virtual Museums 1348
Chairi Kiourt, Athena Research Centre, Greece
Anestis Koutsoudis, Athena Research Centre, Greece
Dimitris Kalles, Hellenic Open University, Greece

Chapter 66
High Performance Computing of Possible Minds 1367
Soenke Ziesche, Maldives National University, Maldives
Roman V. Yampolskiy, University of Louisville, USA

Preface

Information in today's advancing world is rapidly expanding and becoming widely available. This eruption of data has made handling it a daunting and time-consuming task. Natural language processing (NLP) is a method that applies linguistics and algorithms to large amounts of this data to make it more valuable. Persistent research in the field of natural language processing enables an understanding of the world around us in addition to opportunities for manmade computing to mirror natural language processes that have existed for centuries.

Staying informed of the most up-to-date research trends and findings is of the utmost importance. That is why IGI Global is pleased to offer this three-volume reference collection that will shed light on critical issues on the methods and applications of linguistic information processing and its computational properties by providing both broad and detailed perspectives on cutting-edge theories and developments. This reference is designed to act as a single reference source on conceptual, methodological, technical, and managerial issues, as well as provide insight into emerging trends and future opportunities on the fundamental concepts and techniques of natural language processing.

Natural Language Processing: Concepts, Methodologies, Tools, and Applications is organized into seven distinct sections that provide comprehensive coverage of important topics. The sections are:

1. Fundamental Concepts and Theories;
2. Development and Design Methodologies;
3. Tools and Technologies;
4. Utilization and Applications;
5. Organizational and Social Implications;
6. Critical Issues and Challenges; and
7. Emerging Trends.

The following paragraphs provide a summary of what to expect from this invaluable reference tool.

Section 1, "Fundamental Concepts and Theories," serves as a foundation for this extensive reference tool by addressing crucial theories essential to the understanding of natural language processing. Introducing the book is "Background Review for Neural Trust and Multi-Agent System," by Prof. Gehao Lu of the University of Huddersfield, UK & Yunnan University, China and Prof. Joan Lu from the University of Huddersfield, UK: a great foundation laying the groundwork for the basic concepts and theories that will be discussed throughout the rest of the book. Section 1 concludes and leads into the following portion of the book with a nice segue chapter, "Aspect-Based Sentiment Analysis of Online Product Reviews," by Profs. Vinod Kumar Mishra and Himanshu Tiruwa from Bipin Tripathi Kumaon Institute of Technology, India.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Section 2, "Development and Design Methodologies," presents in-depth coverage of the conceptual design and architecture of natural language processing. Opening the section is "Compliance With International Soft Law: Is the Adoption of Soft Law Predictable?" by Prof. Michael D'Rosario from Deakin Business School, Deakin University, Sydney, Australia and Prof. John Zeleznikow from the College of Business, Victoria University, Melbourne, Australia. Through case studies, this section lays excellent groundwork for later sections that examine present and future applications for natural language processing. The section concludes with an excellent work by Prof. Armando Vieira of Redoctopus, UK, "Business Applications of Deep Learning."

Section 3, "Tools and Technologies," presents extensive coverage of the various tools and technologies used in the implementation of natural language processing. The first chapter, "Agreement Technologies for Conflict Resolution," by Prof. Vicente Julian from the Universidad Politécnica de Valencia, Spain; Prof. Victor Sanchez-Anguix from Coventry University, UK; and Profs. Stella Heras and Carlos Carrascosa from the Universidad Politécnica de Valencia, Spain, lays a framework for the types of works that can be found in this section. The section concludes with "A Fuzzy Logic Based Synonym Resolution Approach for Automated Information Retrieval," by Profs. Mamta Kathuria, Chander Kumar Nagpal, and Neelam Duhan of the YMCA University of Science and Technology, Faridabad, India. Where Section 3 described specific tools and technologies at the disposal of practitioners, Section 4 describes the use and applications of the tools and frameworks discussed in previous sections.

Section 4, "Utilization and Applications," describes how the broad range of natural language processing efforts has been utilized and offers insight on and important lessons for their applications and impact. The first chapter in the section is "Finding the Semantic Relationship Between Wikipedia Articles Based on a Useful Entry Relationship," written by Prof. Lin-Chih Chen from the Department of Information Management, National Dong Hwa University, Hualien, Taiwan. This section includes the widest range of topics because it describes case studies, research, methodologies, frameworks, architectures, theory, analysis, and guides for implementation. The breadth of topics covered in this section is also reflected in the diversity of its authors, from countries all over the globe. The section concludes with "A Study of the State of the Art in Synthetic Emotional Intelligence in Affective Computing," by Prof. Syeda Erfana Zohora from Taif University, Taif, Saudi Arabia; Prof. A. M. Khan from Mangalore University, Magalore, India; Prof. Arvind K. Srivastava of Systron Donner Inertial, Concord, CA, USA; Prof. Nhu Gia Nguyen from Duy Tan University, Da Nang, Vietnam; and Prof. Nilanjan Dey of TechnoIndia College of Technology, Kolkata, India, a great transition chapter into the next section.

Section 5, "Organizational and Social Implications," includes chapters discussing the organizational and social impact of natural language processing. The section opens with "Eventuality of an Apartheid State of Things: An Ethical Perspective on the Internet of Things," by Profs. Sahil Sholla, Roohie Naaz Mir, and Mohammad Ahsan Chishti from the Computer Science and Engineering Department, National Institute of Technology Srinagar, India. This section focuses exclusively on how these technologies affect human lives, either through the way they interact with each other or through how they affect behavioral/workplace situations. The section concludes with "How Games Improve Language in People With Language Dysfunctions," by Robert Wahlstedt, an Independent Researcher, USA.

Section 6, "Critical Issues and Challenges," presents coverage of academic and research perspectives on natural language processing tools and applications. The section begins with "Research on Human Cognition for Biologically Inspired Developments: Human-Robot Interaction by Biomimetic AI," by Profs. Marko Wehle, Alexandra Weidemann, and Ivo Wilhelm Boblan from the Technische Universität Berlin, Germany. Chapters in this section will investigate theoretical approaches and offer alternatives

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

to crucial questions on the subject of natural language processing. The section concludes with "Social Implications of Big Data and Fog Computing," by Prof. Jeremy Horne of Inventors Assistance League, Prescott, USA.

Section 7, "Emerging Trends," highlights areas for future research within the field of natural language processing, opening with "State of the Art Recommendation Approaches: Their Issues and Future Research Direction in E-Learning – A Survey," by Profs. Bhupesh Rawat and Sanjay K. Dwivedi from the Department of Computer Science, Babasaheb Bhimrao Ambedkar University (BBAU), Lucknow, India. This section contains chapters that look at what might happen in the coming years that can extend the already staggering amount of applications for natural language processing. The final chapter of the book looks at an emerging field within natural language processing, in the excellent contribution, "Events Automatic Extraction From Arabic Texts," by Profs. Emna Hkiri, Souheyl Mallat, and Mounir Zrigui from the Faculty of Sciences, University of Monastir, Monastir, Tunisia.

Although the primary organization of the contents in this multi-volume work is based on its seven sections, offering a progression of coverage of the important concepts, methodologies, technologies, applications, social issues, and emerging trends, the reader can also identify specific contents by utilizing the extensive indexing system listed at the end of each volume. As a comprehensive collection of research on the latest findings related to using technology to providing various services, *Natural Language Processing: Concepts, Methodologies, Tools, and Applications* provides researchers, administrators, and all audiences with a complete understanding of the development of applications and concepts in natural language processing. Given the vast number of issues concerning usage, failure, success, policies, strategies, and applications of natural language processing in countries around the world, *Natural Language Processing: Concepts, Methodologies, Tools, and Applications* addresses the demand for a resource that encompasses the most pertinent research in technologies being employed to globally bolster the knowledge and applications of natural language processing.

Chapter 1
Background Review for Neural Trust and Multi-Agent System

Gehao Lu
University of Huddersfield, UK & Yunnan University, China

Joan Lu
University of Huddersfield, UK

ABSTRACT

This chapter provides a systematic background study in the neural trust and multi-agent system. Theoretic models are discussed in details. The concepts are explained. The existing systems are analyzed. The limitations and strength of previous research are discussed. About 59 references are cited to support the study for the investigation. The study did address the research importance and significance and finally, proposed the future directions for the research undertaken.

1. INTRODUCTION

Multi-agent systems are initially introduced as a branch of distributed artificial intelligence. In 1986, Minsky and Murata proposed the concept of agents and he thought some problems could be solved through the negotiation among the social individuals (Minsky & Murata, 2004). These social individuals are agents. Agents should be highly interactive and intelligent. Hewitt thought that it is difficult to define agent as it is to define intelligence (Hewitt, 1985). Wooldridge and Jennings thought that agents should be autonomous, social interactive, proactive, and reactive (Wooldridge & Jennings, 2002). Eberhart & Shi thought that agents can react through sensing the outside environments (Eberhart & Shi, 2007).

With the increased size and complexity of the computer systems, it is nearly impossible to design a system from scratch and control every details of the system purely by human brain (Simon, 1996). It is difficult to control millions of transactions occurring in a large-scale E-market. It is also difficult to monitor an enterprise information system which encompasses huge amounts of heterogeneous devices which covers thousands of different geographical locations (Rothkopf, 2003; Coulouris, Dollimore & Kindberg, 2000a). Grid Computing, Autonomous Computing, Pervasive computing and Multi-agent systems, are

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

all committing themselves to challenging the design of large-scale distributed system (Coulouris et al., 2000b). Computational trust is to make an intelligent agent trust another agent and delegate part of their tasks to the target agent in a heterogeneous distributed multi-agent environment. Delegation of action is the result of trust and it also forms the foundation of future large-scale cooperative computer systems. Generally, trust toward specific agent is generated through recognition and experience under repeated transactions with that agent. Reputation is the socialized trust which can be propagated through a social network of agents. It helps agents trust the target agent without any direct interaction with the target agent. The benefits of introducing trust and reputation into multi-agent system include:

- As a lubricant, trust can eliminate much of unnecessary communications which are currently necessitates many interaction protocols thus greatly improve the performance of the multi-agent systems.
- An agent can make decision easier based upon the evaluation of the trustworthiness of another agent. Computational trust is also a very beneficial addition to the traditional decision theory.

Trust is a kind of soft security which complements the traditional hard security like encryption, authorization, and authentication. An agent that exists in complex heterogeneous environment must possess both securities in order to be safe and effective.

The mechanisms for coordinating interactions among agents are always pre-defined, that is, the designer specifies how one agent responses to another agent in a fixed protocol (Huynh, 2006). Such mechanisms are not flexible enough because of the intrinsic high openness and variability of the distributed systems (Ferber, 1999). For example, in open MAS (Multi-agent Systems), an agent cannot expect to always interact with the agents in the predefined application domain in a predetermined way (Subrahmanian, Bonatti, Dix, Eiter, Kraus, Ozcan & Ross, 2000). Agents will interact with different agents coming from heterogeneous applications and they may face challenges from lying, deceiving and accidental incidents (Ferber, 1999). Such complexity creates the following questions: can agents accept services from other unfamiliar agents? Can agents make use of the interaction history and transform them into experiences? Can agents avoid excessive negotiation with a familiar agent in an efficient way? Computational trust seems to be the answer and the next step of research for the multi-agent systems. Thus, a systematic review on the existing trust models is necessary.

Trust actually is a belief that someone or agents can delegate the host to finish some actions. There are two layers of meaning in the expression: first, agents should generate the belief of trustworthiness toward some other agents in some specific form; second, agents should make decision whether to delegate actions to the trusted agent. The first layer is actually to study how agents generate and update their belief which is part of research from computational intelligence. The second layer is an extension of the traditional decision theory which adds agent's belief and trustworthiness as one of the concerns during decision making.

There are a few computational trust models and reputation models that have been proposed from (Subrahmanian et al., 2000) to (Huynh, 2006). From a point of dimensional view, there are two types of models involved, i.e. local trust based and reputation based models. For local trust based model, the early model developed by Marsh, University of Stirling, 1994, only considers the local trust dimension which only derives trust from the agent's direct interaction without referencing to the recommendations from other witness agents (Marsh, 1994a). For reputation based models, like SPORA (Zacharia, 1999), they only consider the reputation (witness trust) dimension without looking at the local experience of

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

the agent itself. Recently RegreT, Referral Network and TRAVOS take both local trust and witness trust into account (Teacy et al., 2005; Sabater, 2003). They combine the value of the two dimensions with relative weights and finally get a sum. Some models, such as FIRE, even introduce additional dimension called as role-based trust and certified reputation (Huynh, 2006; Huynh et al., 2006).

From a point of algorithmic view, different ways of calculating trust and reputation are proposed. For example, Bayesian systems take binary ratings as input and are based on calculating reputation scores by statistical updating of beta probability density functions. Such models include TRAVOS (Teacy, 2006; Teacy et al., 2005). Models such as RegreT (Sabater & Sierra, 2001) are based on discrete trust model to represent trustworthiness and untrustworthiness as a discrete value. A detailed analysis about the composing elements of trust and reputation model will be given.

The objective of the study is finding out the current situation and future trends of computational trust for multi-agent systems. It also aims at looking for common necessary compositional elements that compose the models through extracting the essence of those representative models and summarizing their common weaknesses through comparison, discussion and analysis. Finally, a clear research path is proposed to help the community to promote the research of computational trust.

2. BACKGROUND STRUCTURE

2.1 Distributed Artificial Intelligence

Intelligence and distribution are the future direction of software design. The subject of Distributed Artificial Intelligence (DAI) is a combination of Artificial intelligence and distributed computing. The Distributed Artificial Intelligence attracts the interests from researchers. The other requirement is interoperability, that is, the capabilities to exchange information and cooperate in fast changing heterogeneous environment.

In DAI, the intelligence is not an independently existing concept as it only exists in a group of agents. The interaction and cooperation among agents are the major research areas in DAI. DAI can be divided into two parts: Distributed Problem Solving (DPS) and Multi-agent System (MAS). DPS mainly considers how to decompose a problem into tasks that can be allocated to cooperating and knowledge sharing modules or nodes. The multi-agent system mainly focuses on the coordination of behaviors among autonomous agents.

Both fields need to investigate the division of knowledge, resource and control. However there is big difference between DPS and MAS. In DPS, there is only one conceptual model, one global problem, and success criteria; while in MAS, there are multiple local conceptual models, problems and success criteria. The purpose of DPS research is to create a coarse grained cooperating module. The modules in DPS cooperate to solve a problem. The problem is usually decomposed into several tasks. Each task is executed by a specialized module. All the policies of interactions are integrated as a whole. DPS is a top down approach of designing systems. On the contrary, MAS is a bottom up approach of designing systems. There are no global controls or global criteria for agents. The dispersed agents are defined first and then the problem is decomposed into several tasks which can be assigned to different agents. The relationship among agents may be cooperative, competitive or even hostile.

2.2 Intelligent Agent

2.2.1 Concepts

Although the word "agent" is widely used in different areas, "agent" is still an ambiguous concept. It is difficult to find a definition accepted by all researchers. The most common viewpoint is that an agent is a computer system designed for some purpose and the system is autonomous and flexible. Wooldridge and Jennings summarize the work done in this field by pointing out that it is better to understand agent from the broad sense and the narrow sense (Wooldridge, 2002).

From the broad sense, nearly all agent based software or hardware have the following characteristics:

- **Autonomy:** Agents are not controlled by humans or other programs. They have control over the behaviors and the internal states.
- **Social Ability:** Agents can exchange information through agent communication languages. This is also called communicability.
- **Reactivity:** Agents can sense from the environment and also influence the environment. Whether the agents in real world or the agent in virtual society, they need to sense their environments and change their environments. A program which cannot influence the environment cannot be called as an agent.
- **Pro-Activeness:** The traditional application is passively run by the users and strictly follows the instructions from the users. Agents behave actively or spontaneously. Through sensing the changes in the environments, agents can perform some goal directed behaviors.

Some researchers believe that agents should have some human like characteristics such as knowledge, belief, intention, and desire. Some researchers even propose emotional agents (Bates, 1994; Bates et al., 1992). According to (Shoham, 1992, 1993), an agent is an entity with states composed of belief, capability, choice, commitment and mental component.

1.2.2 Theoretical Models

Mind elements in order to adapt to the environment and cooperate to solve problems, intelligent agents must use knowledge to change its internal status, that is, the mental state. The mental state drives the actions of the agents. It is possible to build an agent mental state from three aspects: emotion, feeling, and intention. The most famous model based on formal method is the BDI (Belief, Desire, and Intention) model. Belief represents the basic opinions owned by agents toward the environment; an agent also can use it to represent the future possible states. Desire is derived from belief. Desire includes the estimation of the future for agents. Intention confines the activities of agents; it is the subset of goals.

Logic is the most important tool to depict the mental state. Moore is one of the first researchers who used formal logic to model agents (Moore, 1990). His research focuses on the relationship between knowledge owned by agents and the realized activities. He introduces modal operator of knowledge into logic and use dynamic logic to represent actions. Such formalization allows agents to own beliefs about how to achieve goals. And agents can acquire information through executing actions. The disadvantage

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

is his modeling is too simple and incomplete. Cohen and Levesque designed a formal model which is based on linear sequential logic (1990). The model introduces concepts like time, event, behavior, goal, belief, and intention. The model also depicts the relationship among these concepts. However, the model does not reveal the relationship between intention and goal, and the model is also very abstract and difficult to implement. Kinny proposes the BDI model of rational agent based on nonlinear branch temporal logic (Kinny, George & Rao, (1996)). They use three modal operators, belief, desire and intention, to build a BDI model. Singh uses agent logic to describe intention, belief, knowledge and communication. Its logic is also based on branch temporal logic (Singh, 1994).

The behavior of rational agent cannot be driven directly from belief, desire or their combination. There should be an intention between the desire and the plan. The reason is that the behavior of agents is confined by limited resources. Once an agent decides to do some task, it needs to build a commitment with limited form. In a multi-agent environment, there must be a commitment to coordinate the behaviors of agents. Without commitment, there are no actions. Intention is just one type of commitments. In an open environment, a rational agent's behavior must be restricted by intention. If an agent changes its own intention, the changes must have some reasons. An agent cannot ignore the changes in environment and keep unimportant or not realistic activities.

1.2.3 Structures

An agent can be looked as a black box with sensors and effecters. Agents use sensors to sense the environment and use effecters to change environment. Except when interacting with environment, agents need process and explain information received from outside. The information is merged and processed into understandable data. There are three types of agent structures: deliberative agent, reactive agent, and mixed structure.

Deliberative agent is also called cognitive agent. It is an explicit symbol based model which has abilities of logical deductions (Wooldridge, 2002). It is a knowledge based system that keeps the essence of the traditional artificial intelligence. There is an environment model implemented as the major component of the knowledge library. Agents using this structure will face two basic problems (Castelfranchi, 1999): (1) transformation problem: how to translate the real world into an accurate, appropriate symbol description; (2) Representation/deduction problem: how to use the symbols to represent the entities and processes in the real world, and how to let agents make decision through deducing the information. The BDI model (Kinny et al., 1996) is a typical deliberative agent structure. The biggest disadvantage for deliberative agent is its fixed structure. In a complex, fast changing environment, it is too stationery to be reactive. The reactive agent is an agent without complex symbol deduction and symbol based world model (Cruces, 2000). It uses the condition-action rule to connect perception and action.

Neither the symbol base deliberative agent nor condition-action based reactive agent can be built into a perfect agent. Some researchers propose the mixed structure in order to combine the advantages of both types. The most direct method is to build two sub systems in an agent: one for deliberative structure, the other for reactive structure. Usually the reactive sub system has higher priority than the deliberative sub system because the agent needs to react to important event in real-time. Each agent contains a series of modules including sensory, action, reaction, modeling, planning, communication and decision making. The agent has an agent kernel which allows additional modules be attached to the kernel dynamically. The kernel is made up of internal database, mail box, and blackboard and execution engine.

1.2.4 Communications

The commonly used communication methods include the black board system and the message/dialog system. The black board system provides a public working area; agents can exchange information, data, and knowledge there. The black board is the medium between agents. Agents do not communicate with each other directly. Message based communication is the foundation of realizing complex coordination policies. Through the specified protocol, agents can exchange messages to build communication and coordination. It is different from the black board system in that the messages are directly exchanged between two agents without any caches. Message is sent to one specific agent or specific group. Only the agent or group with that address can read the message. The protocol must specify the process of communication, format of messages, and languages of communication. Of course, agents must understand the semantics of the language.

Knowledge Query Manipulation Language (KQML) is a uniform agent communication language (Labrou & Finin, 1997). KQML specifies the format of messages and the message transmitting system. It also provides a group of protocols for recognizing, establishing connection and exchanging messages. But the semantics of message content is not specified clearly in KQML. KQML can be analyzed from three layers: communication, message and content. The communication layer specifies the techniques, and the parameters of communications. The message layer specifies message related types of speech acts. The content layer specifies the content.

FIPA (Foundation for Intelligent Physical Agents) defines a language and designs supporting tools. The language is called Agent Communication Language (ACL) (Labrou et al., 1999). The thoughts of ACL are originated from interaction of human society. It does not specify any low level service like network protocol or transmitting services. It assumes the physical infrastructure exists. The characteristics of ACL including: defining goal driven behavior, defining autonomous decision making processes for agent actions, building interaction protocol through negotiation and delegation, creating models of mind states, and enhancing the adaptability to environments and requirements. In this research, ACL is followed as the communication language among agents.

2.3 Multi-Agent System

2.3.1 Coordination and Cooperation

Coordination and cooperation is the core research topics for multi-agent systems. It is also the major difference between multi-agent systems and the other types of computer systems. The purpose of build system in a multi-agent way is to coordinate the knowledge, desire, intention, planning, and actions so that the agents can cooperate to complete the tasks.

Coordination is to change the intention of the agents. Cooperation is a special case of coordination. In an open dynamic environment, agents with different goals need to coordinate its goals and resources. If there is a conflict in using resources, without a good coordination, there will be a dead lock. In another scenario, if a single agent cannot finish its goal, it may need helps form other agents, this requires coordination.

Cooperation can improve the performance of the multi-agent system and enhance its capability to solve problems. It also improves the flexibility of the system. While individual agents are independent from other agents and only care about its own needs and goals, when in a multi-agent system, agents must fol-

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

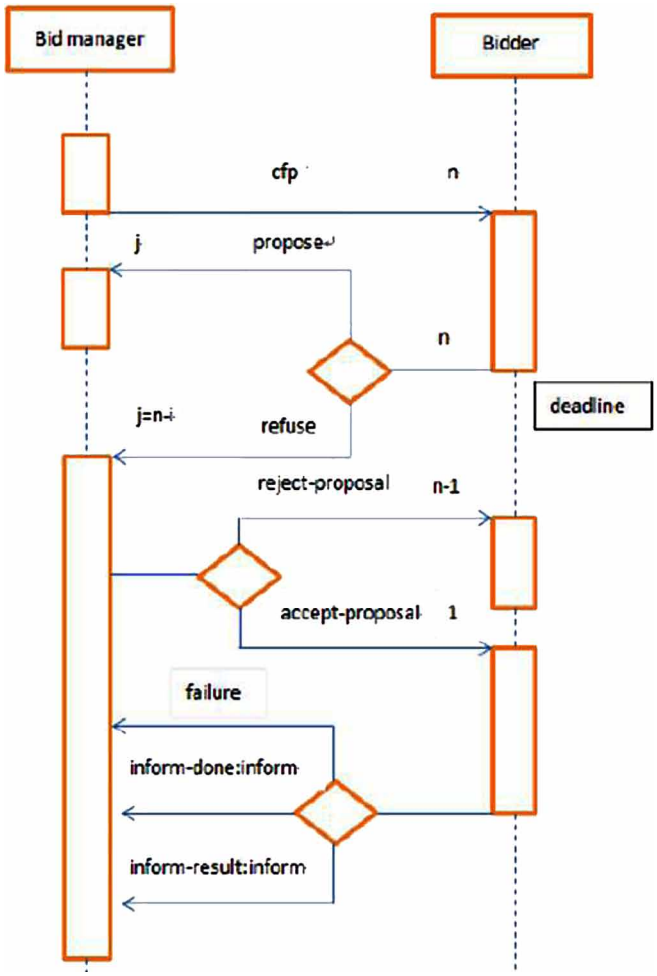
low the predefined social rules and its behaviors must meet the preset social norms. The interdependency among agents strictly restricts the interaction and cooperation of agents. Based on different mechanisms of interaction and cooperation, the implementation of agents in a multi-agent system is different.

Nowadays, the researches on agent cooperation mainly fall into two types. The first type is to migrate the theories into other domains (Game theory, classical dynamics) for agents (Kraus, 1997). The second type is to research the cooperation from the idea of mind attitude as goals, intension, planning like model named as FA/C (Kraus, 1997), joint intention framework (Levesque, 1990; Wooldridge & Jennings., 1994), and shared planning (Grosz & Kraus, 1996). The first type of mechanisms is not as widely used as the second because once the environment changes, the number of agents, types, and interaction relationships might be different from the situations that are suitable for the theories. The theory based interaction thus loses its advantages. The second type focuses on problem planning and solving.

2.3.2 Contract Net

Contract net (Smith, 1980) is widely used in coordination of multi-agent systems. The communications among agents are usually built on agreed message formats. Contract net is actually a contract or a protocol that is based on formats of contract net. The contract net specifies task assignments and roles of agents. It is made up by task processor, contract processor, communication processor and local database.

The local database contains the nodes related knowledge base, information about the current states, and problem solving processes. The other three components use the local database to execute their tasks. The communication processor is responsible for communicating with other nodes. All nodes connect to the network through this processor. The contract processor receives the tasks from bidding. It sends application and finish jobs. It also explains and analyzes the received information. The contract processor executes the coordination among nodes. The task processor is responsible for processing and solving the assigned tasks.



The working process of the contract net is as follows: the problem is decomposed into several sub problems. A node is chosen as the manager to manage the bidding processes. The manager encapsulates the sub problems as bids and publishes them to the nodes. The bids are open to all agents and can be processed through contract processor. The contract processor decides whether to accept the bid. If it accepts, it will inform the manager. The manager chooses the appropriate sub problem for the agent. The agent sends an acknowledge confirming it has accepted the contract. When the processing or solving is completed, the result is sent back to the manager. The essence of the contact net is task distribution. Figure 1 illustrates the process of the contract net with a sequence diagram.

2.3.3 Cooperation Planning

When an agent believes that cooperation bring benefits like improving efficiency or finishing unavailable tasks for single agent, it will have the desire of cooperating and looking for partner to do it. Or when multiple agents find that they can achieve bigger goals, they will form federations and take cooperative actions. The principle of cooperation is setting roles on demand and acquiring roles through competition. The roles are preset according to the goals and the needs of cooperation. The agents play specific roles only when they win in the competition attended by multiple agents.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. How a contract networks

The process of cooperation can be divided into six steps:

- Set goals and produce requirements;
- Cooperation planning and decide cooperation structure;
- Search for cooperating partners;
- Choose a cooperation solution;
- Realize goals;
- Evaluate results.

There are many formal methods to describe the cooperation process. Fox example, d'Inverno uses Z notation (Luck & d'Inverno, 1995), Fisher use sequential logic (Fisher & Wooldride, 1997), Kinny uses modal logic base on derived channel (Kinny et al, 1996). Although the logic based formal method can accurately describe the mind attitude and time series for agents, the action norms depicted by logics is still far away from implementation. The logic method is good at depicting the static properties and so-

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

cial norms, but it is not good at depicting communication and interaction structure among agents. Some researchers use process calculus in process algebra such as calculus to describe the dynamic behavior processes, concurrent interactions and cooperating structures. Some researcher combines the formal methods and process calculus into a uniform formal structure (Werger, 1999). Using sequential logic depicts goals of cooperation while using calculus depicts interaction processes and cooperation structures.

2.3.4 Ecology Based Coordination

The distributed computing system has similar social, organic characteristics as living beings. Such open system is different from the current computing system. It can do asynchronous computing against complex tasks; it can generate nodes in different types of machines. Each node may make local decision according incomplete knowledge and delayed information. There is no central control; instead, it uses interaction among nodes to cooperate to solve problems. These characteristics form a concurrent composition. Their interactions, policies and competitions for resources are similar to pure ecology.

Ecology computing looks the computing systems as an ecosystem. It introduces many biological mechanisms such as mutation and evolution. The mutation leads to genetic variation and create diversities of species with stronger adaptation. The policies of mutation can be a method to improve the ability of agents in artificial intelligence.

Lenat and Brown (Lenat & Brown, 1984) introduce mutation mechanism into their AM and Eurisoko system through grammar mutating in Lisp programs to discover mathematical concepts. They believe the future successful systems should be a series of social systems with abilities of evolution and self-organization. Miller and Drexler (Drexler, 1988) discuss models of evolution such as biological ecosystem, commodity market and points out the difference between ecosystems and computing systems. They also think that a direct computing market is the most ideal system model. Huberman and Hog propose and analyze the process of the dynamic game (Huberman & Hogg, 1995). When different processes interact to finish the computing tasks, if there are multiple optional strategies, the dynamic gradual process may turn into nonlinear oscillation and chaos. This means that there are no stable strategies of evolution for computing ecology systems. Rosenschein and Zlotkin (1994) propose to use static game theory to solve conflicts in multiple computing nodes with different goals (Parsons, 2002).

The most famous ecosystem model includes biological ecosystem model, species evolution model, economic model, and social model of scientific group. The intelligence for the ecosystem usually supersedes the individual intelligence.

2.4 Learning

The basic learning mechanism tries to transfer a successful behavior in one circumstance to another similar circumstance. Learning is a process to gain knowledge, accumulate knowledge, improve performance, discover order, and adapt to environments. There are four basic nodes in a learning system: learning node, execution node, knowledge base and environment. The environment provides outside information. The learning node (or learning algorithm) process the information provided by the environment (Panait, 2005). The knowledge base stores the information in some knowledge representation form. The execution node uses the knowledge from the knowledge base to accomplish some tasks and provides the feedback regarding the execution to the learning node. Learning improves the performance of the system.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

The quality and level of information that is provided by the environment directly influences the ways and effects of learning. The level of information refers to the degree of abstracting information. The low level information refers to detailed, concrete and raw information while high level information refers to processed abstract information. The quality of information decides the difficulty of learning. If the information is incorrect, incomplete or imprecise, it is impossible to gain the right knowledge.

The learning node is actually learning methods and algorithms; it is also called the learner. There are many methods and algorithms for machine learning such as inductive learning, learning by analogy, analytic learning, genetic learning and connectionist learning. The knowledge base is place for storing knowledge. It should select the appropriate ways of representing knowledge and it should allow modification and extension. The execution node use knowledge to guide actions and to change environments. The results of the execution are provided to the learning node so that the learning node can be improved. Only through the effect of the environments can the learning algorithm be evaluated.

In agent learning, there are two streams: one is to improve performance of the system through agent learning; the other one is to improve learning efficacy and quality of knowledge through agent learning (Alonso & Noble, 2001).

2.4.1 Active Learning

When an agent works in an environment, the method of gaining experiences of the autonomous agent is active learning. It is different from passive learning. In passive learning, the teachers or domain experts need to choose groups of training data. In active learning, agents learn the effects of actions or plans and amend their domain knowledge. There two types of learning methods for domain knowledge. The first type is theory amendment system such as EITHER (Ourston & Mooney, 1994), OCCAM (Pazzani & Kibler, 1991), CLIPS-R (Pazzani et al., 1994). These systems are representatives of the passive learning. They have preselected one group of training data which is unrelated to the status in training. The second type is reinforcement learning such as Q-learning, classifiers, back propagation. These types of systems do not explicitly focus on the correctness of the learned domain knowledge. They care about the results of executions. The reinforcement learning is widely used. Agents make a plan based on their current knowledge. The execution of the plan produces results which become a feedback to the learning algorithm.

2.4.2 Case Based Reasoning

In case based reasoning, the situations or problems that the agent face are called target case. The memorized situations or problems are called source case. CBR is a strategy that let agent search source cases according to target cases and uses the source cases to help solve the target cases.

Cases are the fundamentals of knowledge representations in CBR (de Mantaras, 2001). Acquiring cases is easier than acquiring rules. This can greatly simplify the process of knowledge acquisition and reuse the experiences of past processes. Agents do not need to start everything from scratch so that the efficiency of processing new problems is improved. Past successful or failure experiences can provide hints to solving current problems and to avoid future failures.

There are two types of CBR in multi-agent systems: process oriented multi-agent CBR and task oriented multi-agent CBR. The process oriented CBR focuses on the processes. Each process can be implemented as an agent. The process oriented CBR is made up of five agents. The case maintenance agent is responsible for maintaining the case library; The case searching agent is responsible for search-

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

ing and matching the new case; The case modification agent is responsible for the transformation of the case solutions; The case reuse agent is responsible for dealing with the target case according to the transformed solution; The case storing agent is responsible for putting the new case into the case library.

Task oriented CBR focuses on the tasks instead of processes. It provides a CBR agent with multiple strategies to deal with complex tasks. According to the requirements of the specific tasks, it constructs and organizes agents with different functionalities. Every agent is a small CBR system doing specified tasks. Such agent is called a CBR agent. The functionalities of the agents are relatively independent to each other and these agents have their own unique capabilities. Multiple CBR agents can cooperate to finish complex tasks through the form of contract net.

2.5 Research Areas

Design new theoretical model for intelligent agents is one of the interesting research areas. Nowadays, researchers are trying to build better theoretical agent models. The models should be based on the autonomous agents and should find the balance between social interactivity and individual intelligence. Some researchers propose to build rational agents and multi-agent system made up of the rational agents. For example, the logic rationality based BDI model (Kinny et al., 1996); the behavior rationality based Rational Agent (Wooldridge, 2000); The MAS sociality based semantics of open information systems and economic methodologies using game theory and decision making theory.

Negotiation mechanisms and organizations are also important topics that attract many researchers. Another important stream is to research the MAS frameworks and MAS related methodologies for the opening dynamic environments. Such research covers negotiations, cooperation, and task allocation mechanisms, social rules, filtering strategies, behavior normalization and federations. An agent organization is a structured agent group with clear goals. In agent organization researches, the hotspots include the models for agent organization, the formation and evolution of the organization, rules of organizations and patterns of organizations. Sociality is an important aspect to indicate the social abilities of agents in MAS. The modern organization theory based agent sociality can become the foundation of the agent theories. It also stands for the research direction of agent theories and technologies.

Implementation tools and applications are the research areas that focus on how the theoretical models can be applied into the real world. The implementing technologies for Agent and MAS are also hot research topics. The current technologies are based upon the existing social organization theory and modeling theories. Many tools have been developed to support MAS including experimental test beds, integrated systems, blackboard framework and object oriented concurrent programming OBCP (Briot & Gasser, 1998). The most representative work in this area is the Agent Oriented Program (AOP) program designing (Bresciani et al., 2004). There are lots of applications with logically distributed problems or physically distributed problems. Nowadays, the major application domains include: language processing, industry manufacturing, organizational information systems, air traffic controls, concurrent engineering design, distributed sensor systems, transportation planning, monitoring and robots. With the high speed development of the Internet, the integration technology based on mobile agents and multi-agent also become new hot research spots.

Intelligent agent should have the ability of learning from their environment. Trust and reputation are important mechanisms that support coordination and cooperation. 22 If agents can evaluate the trust or reputation of another agent, the performance and reliabilities of the coordination and cooperation can be greatly enhanced. If the agent can learn the trust and reputation through its past interaction experiences,

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

the agent can then dynamically adjust its belief about other agents in the fast changing environments. Thus the framework, mechanisms and algorithms that the research proposes contributes both to the agent coordination and agent learning. The trust learning algorithms give agents learning ability while the reputation mechanisms improve the quality of coordination and cooperation.

3. EXISTING SYSTEMS

3.1 Method Employed

The investigation is carried out through viewing and analyzing conference papers, journal papers and technical reports on computational trust from varieties of sources. The criteria of choosing analyzing target are based on whether the model is representative and whether the model reflects the latest trend of the research. To achieve a comparative result, the first thing is to figure out the common basic compositional elements of different models. Taking the elements as parameters then compares the above models in the form of table; it will also try to find out the significance of the result table.

The results will be organized in the form of spider graph to show the reader a clear relationship between the evaluation criteria. The study will also differentiate research paths of different models through quantitative analysis and statistics.

3.2 Investigation Results

Results are shown from two approaches, i.e. centralized approach and distributed approach. The centralized approach saves all the rating procedure, storage of reputation, query of reputation, searching of comments to the computer server, while the distributed approach finishes all these jobs by agents themselves.

3.2.1 Centralized Approach

There are two existing models that take the centralized approach. They are eBay (Ebay, 2012) and SPORAS (Zacharia, 1999). eBay has built a feedback reputation system for its customer-to-Customer web-sites. The goal of designing such a system is to transfer the trust and reputation mechanism in the real life human market to the internet-based e-Market. SPORAS is a reputation model was developed by Zacharia in MIT, 1999. It is an evolved version of the eBay's online reputation models. In this model, only the most recent rating between two users is considered. Another important characteristic is that users with very high reputation values experience much smaller rating changes after each update than users with a low reputation. SPORAS incorporates a measure of the reliability of the users' reputation based on the standard deviation of reputation values.

3.2.2 Distributed Approaches

The research lists five existing models that take the distributed approaches and analyze their characteristics respectively. They are Marsh's Model (Marsh, 1994a), RegreT (Sabater & Sierra, 2001), Referral Reputation (Yu & Singh, 2002, 2003), FIRE (Huynh, 2006; Huynh et al., 2006), and TRAVOS (Teacy, 2006; Teacy et al., 2005).

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

The pioneer work on computational trust model was done by Marsh (Marsh, 1994a) in 1994. Marsh thought that knowledge, utility, importance, risk, and perceived competence are important aspects related to trust. He defined three types of trust: dispositional trust, general trust and situational trust. The trust management provided by Marsh does not treat the collection of recommendations provided by other agents; he only models direct trust between two agents. The aspect of risk is dealt with explicitly based on costs and benefits of the considered engagement. The decision making is threshold based. Among other parameters, the cooperation threshold depends on the perceived risk and competence of the possible interaction partner. If the situational trust is above the value calculated for the cooperation threshold, cooperation will take place otherwise it will not. Furthermore, the decision making can be extended by the concept of reciprocity, i.e. it is expected to be compensated at some time, if one does another one a favor.

RegreT takes trust as a multi-facet concept and a combination of pieces of information (Sabater & Sierra, 2001). In RegreT, reputation is a combinatorial product of individual dimension, social dimension, and ontological dimension. The calculation of reputation is same as the calculation in individual dimension. The only difference is that all the reputation under each sub-ontological dimension should be summarized. The model deals with three dimensions of trust or reputation. The individual dimension is based on self-made experiences of an agent. The trust values are called direct trust or outcome reputation. The social dimension is based on third party information (witness reputation), the social relationships between agents (neighbor-hood reputation), and the social role of the agents (system reputation). The ontological dimension helps to transfer trust information between related contexts. For all trust values, a measurement of reliability is introduced, which depends on the number of past experience and expected experience (intimate level of interaction), and the variability of the ratings.

The underlying computational framework for Referral Reputation (Yu & Singh, 2002, 2003) is based on Dempster-Shafer theory (Dempster & Arthur, 1968). The model has a well-defined trust network to propagate the trust value from the witnesses, the proposed approach does not concern the uncertainty which surely occurs in the interaction and there is no risk management in this model.

The FIRE model (Huynh, 2006; Huynh et al., 2006) believes that most of the trust information source can be categorized into the four main sources: direct experience, witness information, role based rules and third party references. FIRE integrates all four sources of information and is able to provide trust metrics in a wide variety of situations. The reliability value bases on the rating reliability and deviation reliability to counteract the uncertainty due to instability of agents.

TRAVOS (Trust and Reputation model for Agent-based Virtual OrganizationS) is based on probability theory (Teacy, 2006; Teacy L, W. T., Patel, J., Jennings, N. R. & Luck, M, 2005) and Bayesian system (DeGroot & Schervish, 2002). The prominent feature of TRAVOS is that it takes confidence into account and the trustor makes decisions based upon the confidence level instead of the trust value. The reputation is not simply added to the direct trust value or confidence value, the introduction of reputation depends on the value of confidence level. If the agent can achieve the minimum confidence level through checking belief of its direct interaction, then it does not have to query other agents. But if the agent cannot find enough confidence, then the agent needs to seek more evidence from the witness.

The researcher needs to build a test-bed for implementing TROVOS model. Such test-bed is also useful for future evaluation of the researchers own model and other models. The test-bed can mimic a general market where agents carry on business by automatically standing in for humans. Each agent seizes some resources and cost specific amount of resources with time elapsing (charging energy). The lifetime of the agent ends when the agent owns nothing (starving to death). The goal of each agent is to

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

maximize their assets (resources) and keep itself alive as long as possible. Transaction is the only way to accumulate resources and avoid dying because the system is designed to make agents achieve more resources in transaction than the resources elapsing with time. There are two attitudes held by the agents: benevolence and malevolence. Under the attitude of benevolence, the agent tends to give full value to the other agent in a transaction; under the attitude of malevolence, the agent tends to give partial value to the other agent in a transaction.

Before any transaction, an agent should find out a target agent and evaluate the trustworthiness of that agent. To find out a target agent, the usual way is to use Contract Net Protocol, the agent broadcast its needs and the other capable agents who are willing to sell goods will response to the request listing their preferred price and quantities. However, in our design, to simplify the scenario and focus on the effect of trust model, the target agent is selected randomly by the simulation engine. The trustworthiness is calculated by the agent through combining the reputation from other agents and the experience accumulated in past transactions with the target agents. The evaluation engine is based on TRAVOS model. Agents must consult other agents through broadcasting request for reputation. If the agent has knowledge (experience) about the target agent then the agent should respond to the request and send their experience to originated agent. The originated agent then combine these experience with its own experience according to the TRAVOS model to decide whether to make transaction with the target agent.

- Dimension is to study what the sources of the trust values are.
- The semantics focus on the meaning behind the trust in case that the outcome from the trust is a composite product.
- The mathematical model employed in calculating trust or reputation is sometime called trust computation engine (Josang, Ismail & Boyd, 2007).Trust network is the study on the topology of organizing witness agents and the host agent.
- Uncertainty refers to the management of risk which monitors the accidental incident and environmental changing, and reliability which ensures that the trusted agent is reliable enough even though it is trustworthy that is based upon the result of mathematical calculation.

Table 1. Comparison: the difference among different computational trust models

Model Name	Dimension	Semantics	Architecture	Trust Network	Uncertainty	
					Reliability	Risk
eBay	Reputation	Single	Centralized	N/A	N/A	N/A
Marsh	Local trust	Single	Distributed	N/A	N/A	N/A
SPORAS	Reputation	Single	Centralized	N/A	Exogenous	N/A
Referal System	Local trust reputation	Single	Distributed	Directed graph With depth limit	N/A	N/A
Regret	Local trust Reputation	Ontology-based	Distributed	N/A	Endogenous	N/A
FIRE	Local trust Reputation Role-based trust Certified trust	Single	Distributed	Directed graph with depth limit	Exogenous	N/A
TRAVOS	Local trust reputation	Single	Distributed	N/A	Exogenous	N/A

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

3.2.3 Observations

Different models are compared in Table 1. Significant observations from the table can be listed as follows.

1. There are multiple facts (cardinality of dimensions) to forge the trust or reputation. 3 models are single dimension and 4 models are multiple dimensions.
2. 6 models presume the semantics behind trust is consistent to all agents except that RegreT adds an ontological dimension to deal with the semantic difference.
3. 5 models choose distributed architecture rather than centralized architecture.
4. 6 mathematical models are based on summation or product of different dimensions with selected weights representing their influences. TRAVOS is an exception which is based on Bayesian probability theory. (The evaluation criterion is the confidence level instead of the trust or reputation value).
5. 5 models, except Referal System and FIRE, don't take trust network and trust transitivity into account.

Their hypothesis is that trust propagates from the target witness to the host agent without any distortion or loss. The findings are: semantics, risks, trust network pose weak points for most models, whereas the dimension, architecture and mathematical models are intensively studied by researchers.

4. DISCUSSIONS

Most models have two basic dimensions: local trust and reputation. But they aren't the only dimensions that can be used to deduce trust. FIRE (Huynh, 2006; Huynh et al., 2006) introduces role-based reputation, which models the trust to the specific role in the society. This is similar to the situation that people always tend to trust some group of people with occupations like professor, doctor or police in real world society. FIRE (Huynh, 2006; Huynh et al., 2006) also has a design called "certified reputation" which is reputation collected by the trustee from its previous interactions. The truster then does not need to contact its acquaintances to know about the trustee thus the design improves the efficiency of communication. Some idea can be borrowed from social science study on trust; cultural trust and mechanism trust (Sztompka, 2000) are trust that may find their places in computational trust. Their potential hypothesis is that their trust is restricted to a predefined topic. For example, in eBay, trust (reputation) to the seller implicitly means the belief held by the buyer that the seller will send the correct product to the correct location within the right time frame (Ebay, 2012). However, this is an ambiguous semantic. Some sellers may believe that the correct product to the correct location with a little delay deserves the buyer's trust. Such gaps of semantics lead to disruption between buyers and sellers. In multi-agent systems, if two agents with different trust semantics meet, do they simply refuse to trust the other because of incompatible semantics or they need to build up a consensus through negotiation? If the semantics of trust can be adjusted, how often should such adjustment happen and to what extent? It is necessary to create an ontology built upon XML and RDF that allows systems to provide machine-readable semantic annotations for the trust of specific domain. Most models do not explain how the trust network work and what mechanism the trust transitivity is based. How the trust or reputation value is transferred? Does it simply keep the original value from the witnesses? Or does its value attenuate a long distance as same as what

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

happens in the transitivity of human reputation? The solutions to these questions are keys to implement a practical system. Theories about social network analysis in social science make sense to build algorithms for searching witnesses in the network of intelligent agents. The transitivity or propagation algorithm can also benefit from studying the social network analysis. Some researchers have already noticed the transitive trust and proposed their ideas (Josang & Pope, 2005).

None of the reviewed models introduce risk management to control the uncertainty due to the environmental influence or accidental incidents, although they do define reliability to counteract the uncertainty due to instability of individual agent. It is necessary to use risk evaluation to evaluate the risk associated with the prospective transaction under specific environmental facts. The risk here mainly means the risk derivate from the environmental influence or accidental incidents. For example, agent A trust a reliable agent B, but B's environment is instable (B's system often breaks down due to an accidental power off). Such type of risk can be called as environmental reliability. If agent A has assessed the risk of B's unstable environment additional to its reliability and trust, it will be more careful when making decision about whether to trust B or not.

An important part is not listed in the comparison table but deserves discussions. Most models stay as a theoretical model without performing a strict experiment in the real system. A few of them do have simple test but are not complete. A complete experiment to assess the trust model for MAS should at least pass the functionality test, the performance test and the security test. The functionality test focuses on whether the model supports heterogeneous agents to effectively cooperate with each other in different scenarios. The performance test focuses on measuring the efficiency of the model in the form of comparison with other models. The security test needs to measure whether the trust model enhances or does harm to the traditional security like authorization and authentication. The test environment should firstly be a simple but complete multi-agent system. Some tools of building multi-agent system can be applied to the experiment like JADE (Java Agent Development Environment), FIPA-OS, zeous, etc. The details about different tools can be seen in technical report from Gerstner Laboratory (Laboratory, 2005).

JADE (Bellifemine, Caire & Greenwood, 2007), FIPA-OS (coordinating team, 2012), and ZEUS (Nwana, Ndumu, Lee & Collis., 1999) are the most prominent and prevalent platforms that support MAS development. The similarities among the three platforms are: all of them are based on Java programming language, all of them are open-source project, and all of them claim to strictly follow the FIPA (Foundation for Intelligent Physical Agents) specification. Through comparing these tools, the following observations and conclusions can be made:

- JADE platform is a better choice for MAS development than FIPA-OS and ZEUS in FIPA compliancy, platform maturity, and non-technical concerns.
- Adopting XML as the specification message encoding, representation, and content language can be a good choice to alleviate interaction problems.
- It is necessary to extend the range of applicability of the agent mobility to low-end devices.
- Web Service enhanced agent can freely integrate with any system that supports Web Services; The combination of agent paradigm and the Web Service paradigm may form an intelligent service provision network to complement the traditional static service oriented architectures (SOA).
- It is necessary to introduce agent oriented software engineering process and agent based modeling tools such as AUML (Luke, 2006) into MAS platforms.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

The continuity of development efforts is important for the maturity of a successful agent platform. For the MAS research community, it is possible to develop better tools and platforms to support the agent development through three routes. The first route is to update the FIPA specification with continuously absorbing new findings and new mechanisms, to incorporate with the existing widely adopted specifications such as XML and UML; the second route is to build more powerful application platform through strengthening the administration, monitoring, debugging and logging functionality, to exploit the successful development tools like eclipse, to incorporate Web Service and agent oriented software engineering; the third route is to maintain and enlarge the open source communities and let more researchers take part in and contribute to the development of platforms. A framework is designed for the computational trust and reputation. In the mental space, agents carry out trust learning through observing the results of actions. Such learning leads to the generation, increasing or decreasing of trustworthiness. The learning process is discussed later in details. Next to the mental space is the decision space where agents use trustworthiness derived in the learning process to make delegation decisions. It is combinatory decision making process in that the risk and utility evaluation are also included. The outcomes of specific transaction are constantly observed by the other agents. The observation will become the input of next round trustworthiness learning. Apart from the agents own experience, the trust from the other agents, reputation, is also part of the input of trust learning. The reputation from an organized social network and its propagation mechanism is also a research topic in future work. Most aforementioned trust and reputation models are mathematically based upon simplistic algebraic summation or explicit statistical deduction through counting the success or failure of historical transactions toward the target agents. Surely these methods can produce reasonable numerical results and then translate them into thresholds which help agents make decisions. However, the assumption that the agents always repeat the same transactions with the same target opponents is impossible in an ever changing complex multi-agent environment.

- First, the semantics are various among objects and it does not make sense to hold some invariable elements as formula to calculate the trustworthy or not trustworthy.
- Second, the count of success or failure of transaction is non-sense when the target of discussion is different. It is impossible to draw an equivalence between a successful coke transaction and a successful airplane transaction.
- Third, there is no sure clear border between trustworthiness and distrust-worthiness, that is, trustworthiness or its opposite should be a pattern generated from the repeated transactions instead of a simplistic value.

The above analysis leads the modeling of trust and reputation to the area of computational intelligence. Actually, trustworthiness is one kind of belief. The research on generation of trustworthiness is to model a specialized kind of belief for the computer agent. In the study of computational intelligence, several streams are popular and focused in recent years: neural networks, evolutionary computation, swarm intelligence and fuzzy systems. Since 1970s, neural network becomes one of the main research streams of computational intelligence. It is widely applied in machine learning, pattern recognition, and biological science. The reasons of choosing neural network as the basic calculating mechanism are listed as below:

- Instances are represented by many attribute-value pairs. The target function to be learned is defined over instances that can be described by a vector of predefined features.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

- The target function output of the computational trust can be discrete-valued, real-valued or a vector of several real or discrete-valued attributes.
- Neural network learning is good choice for fast evaluation of the learned target function. Usually, the recognition of trustworthiness should be finished several times per second by the agents.
- The ability of humans to understand the learned target function is not important. The weighted learned by neural networks are often difficult for humans to interpret.

The input layer is composed by dynamically organized element. The elements are extracted from the semantic library according to the target object. For example, if the target object is digital camera, then the elements extracted maybe price, quality, guarantee and delivery. The neural network will gradually adjust its weights in a way of unsupervised learning.

5. SUMMARY

Here the background knowledge of intelligent agent and multi-agent systems has been reviewed. The difference between DPS and DAI has been explained with a detailed description. Then the intelligent agent is reviewed from its concept, structure and communication. The explanations cover the concepts and meanings of agent in both broad and narrow sense. The popular theoretical models are listed. The differences of these models are compared. The discussions are focused on rational agent and Belief, Desire, Intention model. The intelligent agents are the fundamentals of multi agents. The investigation also includes the coordination and cooperation mechanisms. The advantages and disadvantages of different mechanisms are analyzed. The agent learning topics is also covered. The rational of learning is explained and the common algorithms such as active learning and CBR are mentioned. Finally, some interest topics in the field are listed and stated how the related results are located in the background.

Plenty of interests have been attracted to the construction of computational trust from various research communities. Through analyzing and comprising these models, the research proposes that a complete computational trust model should at least have seven fundamental elements. Some conclusions are drawn as follows:

- The current trust dimensions are not enough to represent trust in multi-agent systems and new dimension can be modeled through introducing concepts in sociology.
- Agents from different domains must fill their semantic gaps through constructing ontology with XML and RDF.
- The searching algorithm for trust network and the propagation mechanism for trust network can be progressed through introducing techniques in social network analysis.
- Except for the reliability of target agents, agents also need to manage the risk (or environmental reliability) due to environmental changes or accidental incidents.
- A complete experimental platform which used to test the functionality, performance and security of computational trust model is a necessity.
- The future work of the research domain can also be naturally derived from the above conclusions.
- The dimension of trust can be extended based on the study of trust in sociology and psychology. It is necessary to categorize the scenarios where the dimension is appropriately used.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

- The results in the research of semantic web can be used in the computational trust model. It is necessary to create an ontology built upon XML and RDF that allows systems to provide machine-readable semantic annotations for trust of specific domains.
- Theories about social analysis in social science can be used to build algorithms for searching witnesses in the network of intelligent agents. It is necessary to develop a trust transitivity or propagation mechanism which fulfills the requirement of different situations.
- There is still a need for a simplified, effective mathematical model which can be evaluated through appropriately constructing experiments.

Chapter 2
Applications of AI in Financial System

Santosh Kumar
IMS UNISON University, India

Roopali Sharma
Birla Institute of Technology, India

ABSTRACT

Role of computers are widely accepted and well known in the domain of Finance. Artificial Intelligence(AI) methods are extensively used in field of computer science for providing solution of unpredictable event in a frequent changing environment with utilization of neural network. Professionals are using AI framework into every field for reducing human interference to get better result from few decades. The main objective of the chapter is to point out the techniques of AI utilized in field of finance in broader perspective. The purpose of this chapter is to analyze the background of AI in finance and its role in Finance Market mainly as investment decision analysis tool.

OBJECTIVES

Role of computers are widely accepted and well known in the domain of Finance. Artificial Intelligence(AI) methods are extensively used in field of computer science for providing solution of unpredicted event in a frequent changing environment with utilization of neural network. Professionals are using AI framework into every field for reducing human interference to get better result from few decades. The main objective of the chapter is to point out the techniques of AI utilized in field of finance in broader perspective. The purpose of this chapter is to analyze the background of AI in finance and its role in Finance Market, mainly in process of investment decision making from evolution and use of AI techniques in this respect.

INTRODUCTION OF ARTIFICIAL INTELLIGENCE

Few decades before, a computer program was only used for a numerical computation and computing the path of a bullet. Now a days, a computer programs are used in decision making in important decisions area, supported by a big database across global. As the tasks that computers perform are getting complex and intertwined with the daily life decisions, such behavior of decision making from the computer programs associate with intelligence. So these programs labeled as intelligence incorporated without human neural system, named Artificial Intelligence (AI). However experts are using AI and its concepts in every area of decision making still this branch is unexplored and not known to masses. AI as an academic discipline started from Dartmouth conference organized by John McCarthy from Stanford University and Marvin Minsky from MIT in the 1955 as "the science and engineering of making intelligent machines". Many researchers define AI, as branch of computer science concerned with making computers behave like humans. While some define AI as extension of human intelligence through use of computers.

Alan Turing undertook a test of a machine's ability to demonstrate intelligence, Turing Test, by judgment to distinguish between human and AI machine on natural language conversation .The AI approach can further divided into two major areas -Conventional AI and Computational AI .Conventional AI is based out on logic and rules to make decisions. Computational AI takes biological mechanisms. Computational AI are more advanced form and broadly used in decision making in economy and social sciences. Artificial Neural network (ANN), Expert system (ES), Fuzzy systems (FS), Genetic algorithms (GA) are examples of Computational AI used in field of Financial and Investment decision making.

We use AI every day, without knowing the facts, a simple conversational navigator's application like Google Voice for Android. Our smart phones are getting better day by day; remind us on simple things like birthday of friends, time to go to work, hands free searching and messaging and even telling us if we forget attachment in an email. Such automations are based on concept and application of AI. Currently IBM along with Google is working on AI research for creating a Super computer, WATSON that could change our future significantly. WATSON is learning everything related to human behavior, nature and other complexities in order to forecast and recommend on our future actions.

Concepts of AI has been used in every industry, from computers to pharmaceutical .After gain of trust in these field, professional are start using AI in financial services decision making as well.

HISTORY OF AI IN FIELD OF FINANCE

History of AI in Financial services domain can be traced back from Pacific National Bank of USA in 1987, set-up a Fraud Prevention Security Task force to check the unauthorized use of cards at ATM machines and vendor counters. The bank build a prototype on a regular office computer to perform as warning system for fraud prevention, modeled around the weather warning systems that warned before possible natural disasters like cyclones and earthquakes. This prototype was successful and paved the way for AI-based technology into consumer interactive products and services. Thus,AI has found a new home in financial industries and used as a valuable tool to many business applications for decision making.

In 2001, Wednesday, 8 August, BBC has flashed a new "Robots beat humans in trading battle". Technology giant IBM pitted robotic commodity trading agents, known as "bots", in opposition to humans in trading Commodities, pork bellies and gold. The bots made 7% more return than the human traders, reported in New Scientist magazine.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

A book titled "Foundation of Investment Systems Using Artificial Intelligence and the Web" authored by Robert R. Trippi (2002), identify AI as Wall Street's most promising technologies. AI enabled systems can handle more information and react more quickly for consistent decisions than a group of human. Authors methodically explain how AI systems can help in higher investment returns, with real-life examples.

Sycara, Decker, Pannu, Williamson, & Zeng,(1996), researchers at Carnegie Mellon University, designed an integrated multi agent system that considers data of asset valuation, and risk management, named WARREN, which refers to the first name of the famous investor Warren Buffet .

The recent literature by Tsakonas, Dounias, Doumpos, & Zopounidis(2006) highlighted the role of neural network in investment by combination of knowledge based techniques, neural network and techniques of genetic algorithm .Bhattacharyya, Pictet, & Zumbach,(2002) have used knowledge-rich operators for investing in foreign exchange markets.

Many literatures supporting benefits of AI in investment and financial market has been published in last 2 decades. Thus different concept and use AI in different segments of finance market has been evolved. Kun Chang Lee, Namho Chung & Inwon Kang (2008), M. Uther & H. Haley (2008), Shun-Yao Tseng (2012), Rustam Vahidov and Gregory E. Kersten etc are the major contributors in the research of this field.

APPLICATION OF AI IN FINANCIAL MARKET

Accurate and effective decisions are required in constantly changing financial market condition. There is a massive increase in use of information technologies for accurate decisions making in finance field. Conventional statistical methods are regularly complemented by application of machine learning in recent times. The area of applied machine learning also helps in discovering hidden facts in huge amounts of data. The major techniques of AI utilized in finance Markets are as follows.

Expert (Knowledge) Systems (ES)

An expert system (ES) is a AI enabled computer-based system that emulates the logic process of an expert within a particular domain of knowledge. ES are designed on explicitly formulated specific knowledge gathered from experts for decision making as explained by Feigenbaum et al.(1988). The aim of an ES is not to copy the mental processes of experts during a decision making process but attainment of high quality decision. ES have capacity to give recommendation even the sufficient required data is un- available by using database of alternative inferences.

The research by Armstrong and Collopy (1992), developed a role model for making an annual extrapolation forecasts for demographic and economic time series on data.

This rule based ES produced more accurate forecasts than the traditional random walk and statistical tools combined. They performed better, especially in long periods for series with major trends, high uncertainty and low stability.

The comparative study by Korczak and Lipinsky (2004) between two real time trading systems by use of Stochastic oscillators based on relative Strength index & Ease of Movement. The first trading system was based on 350 trading rules and other on 150 trading rules created in linear combination on data of Paris Stock Exchange . They concluded that reduction in trading rules decreased the computation time without change on expertise quality. This highlights the main advantages of ES as they combined knowledge from different sources for decision making process.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Artificial Neural Networks (ANNs)

Artificial neural networks (ANNs) are combination of simple neural elements in parallel arrangement and mesh like a human nervous system likened data source with explicit knowledge about target values . The functioning of ANNs is largely depend on values in the network, widely used to solve problems of prediction, classification, and control by adjusting the weights between connected elements

The major advantage of ANNs is their capabilities to capture nonlinearity without predefine information about relationships between variables. ANNs operate as "universal approximation systems" with the skill to imitate almost any function related to variables. In comparison to traditionally used econometric models ANNs provide results in very short period. The drawback in ANNs based applications is the non existences of a standard pattern to design the network .ANNs have been successfully applied to solve problems of generalization in prediction of corporate bond rating. ANNs are used by central banks across globe to forecast the interest rates and the monetary policy.

The result of an empirical research shown in Table 1, depicts the association between forecasting accuracy of ANN and ARIMA model using Mean Square Error(MSE) on data of the USA GDP deflator, 1st quarter 1960 to 3rdquarter 2003. The performance of ANN better than AIRMA models in the first two quarters on test set, while the advantage disappeared for longer horizon due to early stopping approach .

There has been abundance of studies attempting to forecast the price levels in exchange by using indicators of technical analysis as input variables in ANNs framework (Egeli et al., 2003); (Gençay, r.; Stengos, t., 1998); (Safer, 2003). (Chen et al., 2008); (Mizuno et al., 1998); (Nagarajan et al., 2005); (Yao et al., 2000). The results show that indicators as inputs into ANN framework improve the forecasting accuracy of stock prices. Figure 1 shows the data transformation process in ANN framework applied on Japanese stock exchange.

Table 1. Ratio of ANN and AIRMA

	Forecast Horizon (quarters)					Forecast Horizon (quarters)			
	1	2	3	4		1	2	3	4
Ar1	0.84	0.77	0.98	1.20		0.85	0.77	0.77	0.72
Ar2	0.89	0.84	1.04	1.18		0.86	0.81	0.81	0.73

Figure 1. System composed of ANNs and indicators of technical analysis as inputs into network

Source: Mizuno et al., 1998.

Fuzzy Systems

Fuzzy systems are a knowledge based expert system designed on Fuzzy logic concept. Fuzzy Logic calculates uncertainty from membership values in between the range of 0.0 to 1.0 with 0.0 indicates absolute failure and 1.0 represents absolute Success.

The fuzzy system is made up of three steps - Fuzzification, fuzzy inference and defuzzification . Fuzzification is the conversion of real to fuzzy data, and defuzzification is transformation of fuzzy data to real data after inference by fuzzy system, usually based on IF…THEN rules.

A fuzzy rule based neural networks have been used to predict stock market returns many times in various research. A stock trading system proposed by Ang and Quek (2006) on moving average rules achieved higher return than a traditional random trading system. Fuzzy neural network (FNN) based on general stock trading rules developed by Wong et.al achieved better return single ANNs and other traditional trading system in Taiwan stock Exchange.

Agent-Based Computational Economics (ACE)

Agent based Computational Economics (ACE) is an example of AI enable agent (variables) based model, suitable for economy modeled based forecasting . Economics can be study as a complex adaptive system to adapt changes in the external agents (environment). Bruun (2006), ACE is a bottom up system forming models of agents and interaction rules which lead to setting up the whole system using simulations within this modeling approach the structure evolves without forcing any presumptions upon it. The resulting ACE models must be dynamically create a economic system solely on the basis of agents' interactions without further intervention from the other modeler.

Early researches of artificial agents are based on zero intelligent agents. Le Baron (2000) investigated the efficiency of zero intelligence traders on artificial foreign exchange markets and he found that budget allocation of these agents was similar to human agents.

In other studies simulations with more sophisticated agents have evolved. Raberto et al. (2003) set up a model where trading strategies of agents were based on technical trading rules and fundamental values. Kendall and Su (2003) utilized agent based approach on five selected stocks from London Stock Exchange, trading behavior of artificial agents was based on indicators of technical analysis. This research

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

demonstrated stable and satisfactory learning abilities of artificial traders, different learning behavior related to the different stock price patterns was discovered, an important finding for further research in portfolio selection. Kumar and Bhattacharya (2009) used multi agent approach for portfolio selection and they achieved higher average returns across one month, two months and three months out-of-sample period than the FTSE 100 index.

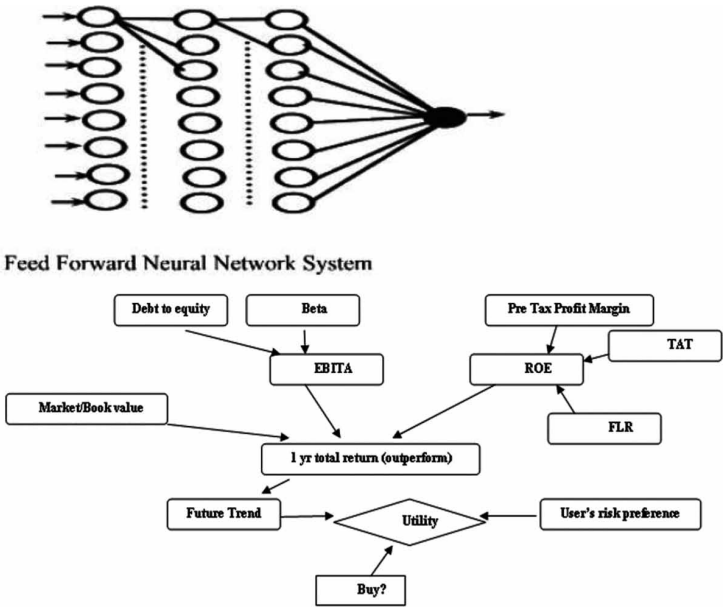
The relative disadvantage of ACE modeling is that it requires detailed specification for agent data and methods determining structural attributes, behavioral dispositions and institutional arrangements. If the agent interactions induce sufficiently strong positive feedbacks, small changes in initial specifications could radically affect the types of outcomes that result.

COMPARATIVE STUDY IN PORTFOLIO PERFORMANCE

The investment and portfolio domain is changing in stochastic and random environment. Take the stock exchange as an example; there are more than five thousand securities available for selection by portfolio manager or individual investors. This creates a problem of filtering all those stocks to find the ones that are good for investment. There is also availability of enormous information that may affect the performance in market to some extent, as stock market is efficient. All above is making tremendously difficult for a portfolio manager to create the portfolio without relying on any tools.

An experiment has been conducted by department of commerce, Texas A&M University. In the experiments, commonly used AI systems - Bayesian network system, and a feed forward neural network system as shown in figure 2. The data of eight financial ratio mentioned below of the S&P 500 companies as the input variables these systems, from the period of 1987 to 1996.

- Debt to equity
- Market /book value
- EBIT
- Return on Equity (ROE)
- Pre-tax profit
- Total asset turn over (TAT)
- Financial leverage ratio (FLR) and
- Beta (β)



To test the performance, all these systems made the decision proposal on which of the S&P 500 stocks to be included in the portfolio. Compare the return output from selected portfolio by these AI system with return obtained from mutual funds, human portfolio selection, in same period.

Return from both AI systems outperforms the leading mutual fund by a large margin in 1997. They also ran these AI systems with the data from a negative return year (2000); the S&P 500 and the primary mutual fund houses produced negative return for the year while both AI systems produced a positive return.

By above experiment on real time data, we could conclude that the use of AI system for security selection in portfolio outperformed over the human portfolio manager.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. Artificial Intelligence systems for portfolio selection

SUMMARY

The chapter offers supportive evidence for suitability of use AI enabled systems in various financial applications according to their capacity to process non-linear variable relationships, ability to learn and evolve in time and also ability to make decisions at expert level.

AI algorithms are used for optimization problems - optimization of stock market timing and portfolio creation. These tools can be used for creation of quantitative tools for short-time prediction of exchange, inflation and interest rates. Expert systems try to make decisions on the expert level and they are applied in analysis of securities as well as in company assessment. If we have an uncertain notion of the methods for a decision (what is typical for human decision makers), fuzzy systems could be the appropriate solution. In last decades the Agent-based Computational Economics has emerged. Current ACE concentrates on financial market modeling. The approach of artificial neural networks is put into effect due to their ability to study the nonlinear relation between variables and their ability to work with uncertainty. They are frequently used for solving prediction problems, forecasting macroeconomic indicators and time series prediction on financial markets.

Chapter 3
Aspect-Based Sentiment Analysis of Online Product Reviews

Vinod Kumar Mishra
Bipin Tripathi Kumaon Institute of Technology, India

Himanshu Tiruwa
Bipin Tripathi Kumaon Institute of Technology, India

ABSTRACT

Sentiment analysis is a part of computational linguistics concerned with extracting sentiment and emotion from text. It is also considered as a task of natural language processing and data mining. Sentiment analysis mainly concentrate on identifying whether a given text is subjective or objective and if it is subjective, then whether it is negative, positive or neutral. This chapter provide an overview of aspect based sentiment analysis with current and future trend of research on aspect based sentiment analysis. This chapter also provide a aspect based sentiment analysis of online customer reviews of Nokia 6600. To perform aspect based classification we are using lexical approach on eclipse platform which classify the review as a positive, negative or neutral on the basis of features of product. The Sentiwordnet is used as a lexical resource to calculate the overall sentiment score of each sentence, pos tagger is used for part of speech tagging, frequency based method is used for extraction of the aspects/features and used negation handling for improving the accuracy of the system.

INTRODUCTION

Sentiment analysis is an area of text classification that starts in early of the last decade and has recently been receiving a lot of attention from the researchers and academicians. Sentiment analysis includes an analysis of data sets, such as online review, social media, blogs, and discussion groups, which contain opinions and opinion can be classify as positive, negative, or neutral. Opinion plays an important role in our information-collection behavior before taking a decision with applications in many fields, including recommender, customer intelligence, advertising systems and information retrieval.

Sentiment analysis can be also considered as the computational study of human opinions and sentiments, likes/dislikes, good\bad toward an entity such as products, services, organization, individual, issues, event, topics and their attributes. It is basically combination of natural language and data mining process that aims to extract user opinion and sentiment, expressed in positive, negative and neutral comments, by analyzing a large amount of unstructured user generated data. It is a task of automatically extracting the user opinion and sentiment from a plain text over the web. Sentiment analysis or opinion mining refers to the application of natural language processing, computational linguistics and text analysis to identify and extract subjective information from large amount of data.

Sentiment analysis also refers to identification and extraction of subjective information from text sources. It aims to determine the opinion of a person with respect to something in particular or the overall contextual polarity of a document. Sentiment analysis and its application in various disciplines; in information extraction, it is used to discard subjective information, in question-answering, it identifies opinion-oriented questions. Sentiment analysis is also used in the business intelligent and politics. Application areas of sentiment analysis are very vast and challenging. Sentiment analysis has focused on a great deal of attention as its very wide application in opinions detection, customer review summary, and other systems which is required to extract public opinions and sentiments. Some application areas of sentiment analysis are given in the next sub section.

APPLICATIONS OF SENTIMENT ANALYSIS

Sentiment occurs in almost all human activity because they describe the human behaviors. Whenever the human want to take a decision they want to know about others opinion. In real words, all business organization and all politicians want another opinion about their product and political condition even individual consumer also wants to know the opinion of the other user before purchasing any new product. In the past, whenever we want to take any decision we discuss it with our family member and friends for personel decisions and for taking any decision for an organizing we conducted the surveys. These traditional method are very time consuming and always does not give a good result.Application as a sub-component technology:Sentiment analysis plays an important role for enabling one technology for other system e.g. it cannot recommend those systems to be acquired with other if the systems contain more negative review. Detection of flame in the email and other type of communication is another use of sentiment classification. An online system, it helpful to take only the positive material in their system avoids all negative ads and content to be added to the online system and also helpful to the improve the online system and also helpful in the citation analysis, resulted increases the human computer interaction.

Application in Business and Government

Sentiment analysis is well suited in various intelligence applications. Business intelligence is one of the main application of sentiment analysis e.g. for any organization it is important to know what is the current position of their organization and for a businessman it is important to know the current position of their product and material in the market and due to the rapidly increase of web uses it is easy to analyze it with the help of user generated review and sentiment analysis is the best tool for it. Government intel-

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

ligence is the another application in which we can analyze the user opinion on the new policy started by the government allowing the automatic analysis of the opinions that people submit about pending policy or government-regulation proposals.

In this chapter we provide an overview of aspect based sentiment analysis with current and future trend of research. We gave a prototype algorithm for aspect based sentiment analysis and for better understanding of the topic we provide an experimentation for the aspect based sentiment analysis in which we use sentiwordnet as a lexical resource to calculate the overall sentiment score of each sentence, pos tagger is used for part of speech tagging and frequency based method is used for extraction of the aspects/ features. We also use negation handling for improving the accuracy of our system.

BACKGROUND

Now days the internet and web is used in every field of life. Due to the rise of internet and web its popularity among the peoples as a communication medium and business platform is increasing. People can very easily express their views on internet which generates very much amount of user data. Exponential growth of social networking has increased the amount of information generated over the internet on daily basis. The use of online shopping is also increasing as the vast amount of users is using internet to do shopping. The generated data of the views of customers is in unstructured form over the internet. The user generated content is the important source of extracting sentiment and opinions about the products. To extract the user opinion and sentiment from a large amount of data is very typical task. Many researchers have worked in this field of sentiment analysis in the last decade and still it's a very active research area. In last few years due to the rapid increase in the use of internet, plenty of work has been done in the field of sentiment analysis with special focus on aspect based sentiment analysis. Some important contributions are as follows:

- **Ghosh and Kar (2013)** has proposed a technique for sentence level sentiment classification of the online product review using the sentiwordnet a lexical resource. They semantically classify sentiment using rule based method and check the subjectivity and objectivity of an individual sentence and decided the semantic orientation using lexical resource.
- **Bhadane, et al. (2015)** gaves an overview of various type of method used for sentiment classification and techniques for measuring the opinions.
- **Varghese and Jayasree (2013)** has classified the unstructured user opinion text. They used sentiwordnet for classification, pos tagger for feature extraction, SVM classifier for quantitative classification and co reference resolution to resolve all the anaphora that appears in the opinion sentences. For the evaluation they checked the precision, recall and accuracy of a sentence and they achieved the 77.98% accuracy.
- **Chinsha and Shibily (2014)** have developed an aspect based opinion mining system for restaurant reviews, which automatically finds important aspects and opinions of a restaurant by analyzing the reviews. They used linguistic rule, sentiwordnet and two word phrases for sentiment detection with automatically extracted the aspect.
- **Singh, et al. (2013)** performed sentiment analysis using machine learning approach, unsupervised approach and two naive bayes approach and analytically showed that naive bayes approach gives better result in comparison to other two approaches. They also showed that semantic orientation

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

approach achieved good result but it need to calculate lots of PMI values which is very time consuming while sentiwordnet approach achieved lowest accuracy but are easy to use and does not require any training data set.

- **Nithya and Maheswari (2014)** performed a sentiment analysis of unstructured reviews for polarity and subjectivity detection. They used naive bayes classifier for identifying the feature and check their polarity. For feature extraction they used the pos tagger and for finding the polarity of a sentence they used a SentiStrength a lexical based classifier.
- **Taylor, et al. (2014)** extended the work of Bing Liu's aspect-based opinion mining approach. Bing Liu's approach is mainly focused on the physical product. They purposed a new NLP based rule for aspect level sentiment analysis which helps users to digest the vast availability of opinions in an easy manner.
- **Suchdev, et al. (2014)** classified the sentiment of the tweets using machine learning techniques and to increase the accuracy they used the symbolic technique with machine learning. They also used knowledge based approach and using backtracking method to measured the slag word frequency count.
- **Abulaish, et al. (2009)** presented an opinion mining system to classify the opinion and product feature from reviews. They used the semantic and linguistic approach for classifying the feature and used the sentiwordnet for classifying the polarity. They refine the rule based method to achieve the good accuracy and generate the feature based summary.
- **Gautam and Yadav (2014)** proposed a set of machine learning techniques with semantic analysis for classifying product reviews based on twitter data. They classified a large amount of reviews by using twitter dataset which are already labeled. They used naïve byes technique to improve the accuracy over maximum entropy and SVM technique and shows that the accuracy has improved from 88.2% to 89.9%.
- **Jo and Oh (2011)** proposed two models to discover aspects and sentiment in reviews. There models assume that one sentence contains exactly one aspect, they split sentences not only by punctuations but also by conjunctions. They use a part of-speech tagger for more accurate negation detection to make each aspect clear, filter out words that are common across many senti-aspects by adding a background language model. They show that the senti-aspects found by aspect based sentiment unification model (ASUM) can be used to illustrate direct sentiments toward the same aspect, in the evaluation of sentiment classification.

MAIN FOCUS

Sentiment Analysis is basically process of identifying whether a given text is subjective or objective and if it is subjective, then classify whether it is negative, positive or neutral. Sentiment analysis is basically study in three levels: document level, sentence level and entity\aspect level. In document level we identify the whole document as a positive, negative or neutral, in sentence level we analyze a particular sentence as a positive, negative and neutral and in entity\aspect level, which is also known as feature level, we analyze the feature of a particular product or item. Aspects\features can be understood with an example of restaurant review in which we can extract the aspects like its food, service, location, charges etc which described whole restaurant easily. Aspect based opinion mining deals with the extraction of opinion aspects by applying various techniques. Aspects are either in hidden form in the text or itself

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

appears in the text accordingly known as implicit and explicit aspects. Aspect level is very useful for taking fast decisions. In document and sentence level classification, each document/ sentence is classified as a single entity, a negative opinion document/sentence about an entity does not mean that the customer has negative opinions about all aspects of the entity. Likewise, a positive opinion document does not mean that the author is positive about everything. For effective and correct opinion about an entity, we need to classify the sentiment on the basis of different aspect of an entity.

Types of Opinions

The opinions can be categorizes as regular opinion and comparative opinion. A regular opinion is a simple opinion expressed in any document and it is mainly divided in two sub task namely direct opinion and indirect opinion. Direct opinion is expressed directly on an entity or entity aspect e.g. "the sound quality is great" describe directly the sound quality and give positive opinion. Indirect opinion is an opinion that is expressed indirectly on any product or document or aspect of product or document and based on its effects on some other entities e.g." after seeing the environment of restaurant my mood going worse" describe the bad environment of a restaurant which indirectly give the negative opinion. Most of the study focuses on direct opinion. Indirect opinion needs more analysis and complex task. Comparative opinion expresses a relation of similarities or differences between two or more entities and a preference of the opinion holder based on some shared aspects of the entities like nokia is better than micromax. Nokia is better shows two comparative opinions.

The opinions can be also classified on the basis of how they express in the text as explicit and implicit opinion. An explicit opinion is an opinionated statement that gives a regular or comparative opinion e.g. "nokia perform great" and "nokia is better than micromax". An implicit opinion is an objective statement that implies a regular or comparative opinion. Objective statement is the statements which cannot directly contain any opinion it only contain facts e.g. "The battery life of Nokia phones is longer than micromax phones".

Opinion and Target Relations

The opinions expressed in sentence have certain targets and they are clearly related to each other. Their relationships can be abused to find aspects, which are opinion targets, because opinion words are generally known for us e.g. "The battery is good". In this sentence the good is the opinion word and with the help of this it is easy to find an aspect of battery. This type of relation is also useful for finding the infrequent aspect. Several methods are used for better understanding of the relation between the opinion word and target e.g. dependency parsing and rule based method. The same opinion word can be used to classify or customize the different aspects. If a sentence does not have a frequent aspect but has some opinion words, the nearest noun/noun phrase to each opinion word is extracted. This method turns out to be very useful in practice even when it is applied alone. This is very useful relation in sentiment analysis because an aspect is rare to be important if nobody expresses any opinion or sentiment about it.

Aspect Level Classification

We can classify the sentiment at the aspect level, which we called aspect based sentiment analysis, it is also called feature based sentiment analysis. It covers both the entity and aspect to achieve the goal in aspect level; it discovers every quintuple in a given document. Aspect can be categories as an explicit

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

aspect or implicit aspect. Explicit aspects are directly present in the document e.g. “the size of the phone is not good” it directly shows the feature of a particular domain. Explicit aspects are only noun and noun phrase. Implicit aspect are hidden aspect in the document e.g. “the phone is not fit in my pocket” this show the indirect aspect size and it indirectly shows the feature of a particular domain.

- **Aspect Extraction:** Aspect is basically the noun and noun phrase so first we use the pos tagger to extract all nouns and noun phrase then we apply different approach to extract the aspect. Some of these approaches are:
- **Frequency Based Approach:** In this approach to extract the aspect first we used a pos tagger to extract the noun and noun phrases and check their occurrence frequencies and only the frequent ones are kept. Frequent one can be decided on the basis of a threshold value of the frequency and frequency threshold can be decided experimentally. This method work well in the medium size corpus while in large size corpus they extract a large number of frequent noun and noun phrases as a product aspect which may be not a genuine aspect.
- **Propagation Approach:** In this method the opinion lexicon expansion and target extraction tasks iteratively based on propagation using the dependency relations between the opinion word and target (aspect/feature). In this process initially we require only seed opinion lexicon and using the seed opinion lexicon we extracted new opinion words and targets for further target and opinion word extraction. This method adopts a rule based strategy, it follow a dependency rules to extract the opinion words and targets (aspect/feature) The propagation ends until no more new opinion words or targets can be identified.
- **Aspect Ranking Based Approach:** In aspect rankling approach, we arrange all aspects in the decreasing order of their frequency of occurrence and take only highest frequent aspect. The basic idea for aspect ranking is that, those aspects which most frequently talked and consider in the review has higher importance in the analysis and subsequently considered as high ranking aspect. We can also maintain a list of opinion words which are generally used to modify a particular feature to compute feature relevance. Relevant features are generally modified by various opinion words.
- **Other Approaches:** In 2007 a language model for aspect extraction came into existence and in this model it is assumed that the important aspect are used more often in the review in the same year and it is used as a syntactic pattern learned via pattern mining to extract the aspect. In 2008 author used a supervised technique to extract the aspect they treated target extraction as a topic co reference resolution problem. The key of their approach is use of cluster opinions, sharing the same target together. Another approach to extract aspect is the use of topic modeling. Topic modeling is to model the generations of a document set and mine the implied topics in the documents.

Opinion Aspect Pruning

During the extraction some incorrect opinion target and word are extracted so opinion aspect pruning is remove the noise beside the genuine target and opinion word, this is not essential only desirable. Currently no effective method for pruning is available. There are two types of noise occuring during the aspect extraction, one is the ordinary nouns that are not targets but are extracted as targets due to parsing errors and second is names of other competing products on which the reviewers also expressed opinions. The problem of extraction of incorrect opinion target can be avoided by doing pruning based

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

on clauses and pruning of other products and dealers. In pruning based on clauses method the sentence contains only one target unless there are any conjunction like “and” and “or”. If the sentence does not contain any conjunction and contain two aspects then we remove one of them. Filter non-aspect based on frequency and which is less frequent are removed and in pruning of other products and dealers method is used when comparing one aspect of a review product with the other.

Popular Techniques/Approaches for Sentiment Analysis

Machine learning approach, lexical based approach and hybrid approach are most popular approach/ techniques for sentiment analysis.

Machine Learning Approach

This approach basically works on machine learning algorithm to classify the sentiment analysis and uses the syntactic and linguistic feature (Medhat et al., 2014). In this approach there is a set of training records and each record is defined by a class and the classification model is exhibit one of the class label. This approach can be further classified as supervised learning approach and unsupervised learning approach. Supervised learning approach depends on the existing training data set and in supervised learning we need a labeled training and test data set for classification. Test and training data are usually product review. The major disadvantages of supervised machine learning approach is use of large labeled data for training which is very time consuming as well as this is also very difficult to create this large amount of labeled data. Unsupervised learning approach does not use the labeled data set and obviously the collection of unlabelled data is easier in comparison to the labeled data.

Lexicon-Based Approach

Lexicon based approach used a lexical resource for the classification process. In this approach we use the opinion lexicons and they are the collection of positive and negative opinion word express in the document. These are also called opinion phrase and idioms and together are called opinion lexicon. This approach is further classified as manual approach or automatic approaches. Dictionary based and corpus based approach are widely used automatic approaches. In dictionary based approach first we manually select the small set of opinion words and then these word are search for its synonyms and antonyms from WordNet or other corpa and repeat the process until no new opinion word are found and last manually check the error. Disadvantage of this approach is the inability to find opinion words with domain and context specific orientations. Corpus-based approach depends on syntactic pattern in which one set of opinion word is used to find the other opinion word in the large corpus. It also overcomes with the problem of finding opinion words with context specific orientations.

Features for Sentiment Analysis

Feature selection is the very essential task for the sentiment analysis in data driven approach. To convert a sentence in a feature vector is very important step for sentiment analysis.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Term Presence and Term Frequency

Term frequency is very essential part in the text classification and information retrieval task. Term presence is more important than term frequency for a sentiment analysis task. For indicating the occurrence of word we used a binary-valued feature vector, 1 for occurring and value 0 for not occurring, but for numerous sentences it countered as we seen many more frequent occurring sentence contain less information than the rare occurring sentence or word.

Term Position

Word appearing elsewhere contain less sentiment and weightage than the word contain in certain position. This is similar than information retrieval. In the review, the word contains negative sentiment throughout but the presence of positive word at the starting of the review play a very important role for determines the sentiment. Thus the sentence appearing in the first and last in sentence has more weightage than it appear elsewhere.

N-Gram Features

N-grams are able to capture the context up to some degree and are mostly applied to natural language processing task. Generally N-gram are of three types 1-unigram 2-bigram 3-trigram. In the movie review unigram perform better than bigram but doing some changes bigram and trigram give better performance.

Part of Speech

In most of the NLP task, part of speech information is most commonly used. They provide a raw form of word sense disambiguation; this is the most important reason of using part of speech. Pos tagger will be used for part of speech and with the help of part of speech we can extract all noun, adjective and adverb from a text document. Adjective and adverb are basically the opinion word and noun and noun phrases are feature and aspect of given product review. There is a strong correlation between the adjective and subjective. It achieved an accuracy of around 82.8% in movie review domains using only adjectives in movie review domains.

Topic-Oriented Features

Phrases and bag-of-words are broadly used as features. But in different domain a specific phrase value carry a small relation with whole text sentiment. Analyze the text which feat those aspects and which represent whole text is a challenging task in the sentiment analysis. With the use of phrases and bag-of–word will cannot differentiate the locally and globally meant of text in review and all of which are used in affluence in many converse domain.

Prototype Algorithm for Aspect Based Sentiment Analysis

Input: Labeled Data Set
Output: Positive and negative polarity of a particular feature in the data set

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Step 1: Pre-processing the review
- a. Remove unwanted text
- b. Remove stop words
- c. Stemming

Step 2: Find the feature \Aspects and opinion words
- a. Find noun, adjective, adverb and verb using pos tagger
- b. Noun\Noun phrases = Aspect\Feature
- c. Adjectives = opinion words

Step 3: Apply frequency based method for finding feature\aspect
- a. Check the frequency of noun in the review data set
- b. Take the most frequent noun as feature\aspect
- c. Ignore unfrequented nouns

Step 4: Check the polarity of the opinion word with respect to feature using sentiwordnet

Step 5: Match the words with review dataset
- a. If (positive polarity score > negative polarity score)
- b. Print ("the feature is positive")
- c. If (positive polarity score < negative polarity score)
- d. Print ("the feature is negative")

Step 6: Apply negation handling.
- a. Input – Negation word file which contain all negative words
- b. If (opinion word found in the sentence)
- c. If (opinion word is positive)
  - i. If (negation word found in the sentence)
  - ii. Print (polarity of a sentence should be negative)
  - iii. Else
  - iv. Print (polarity of a sentence should be positive)

End
- a. If (opinion word found in the sentence)
  - i. If (opinion word is negative)
  - ii. If (negation word found in the sentence)
  - iii. Print (polarity of a sentence should be positive)
  - iv. Else
  - v. Print (polarity of a sentence should be negative)

Detail Description of Terminology used in Algorithms

Review Sentence Tagging

A POS tagger parses a string of words and tags each word with its part of speech. The use of Stanford pos tagger for POS tagging is beneficial because of its good performance. It helps to tag the texts of the reviews without any need for training data. This tagger used by splitting text into sentences and to produce the part-of-speech tag for each word (whether the word is a noun, verb, adjective, etc) e.g. of pos tag sentence of the sentence ….this is really big step with quality of camera…. is….. this/DT is/VBZ really/RB big/JJ step/NN with/IN quality/NN of/DT camera/NN.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Aspect Extraction

The process of aspect extraction is described in following steps:

Step 1: From all tag sentences by pos tagger we collect all nouns and find the unique noun among the nouns.

Step 2: Retrieved the entire frequent nouns and ignore the unfrequented nouns. Then set the threshold value for frequent nouns and extract all nouns as an aspect/feature which is above the threshold value.

Sentiment Classification using Sentiwordnet

As we know sentiwordnet is an open lexical resource for sentiment classification in which all the score of the opinion word are store in the positive and negative way in the synset term. Each score are from 0.0 to 1.0 and there sum is 1.0 for each synset. To calculate the score of each sentence with the help of these score we calculate the score of all sentences which consist an aspect term and finally combine the score and if the positive score is grater then negative score then we consider the polarity of a feature is positive otherwise negative.

Negation Handling

Negation handling is an important task in the sentiment analysis. Without the explicit use of any negative word, negation can be expressed in different ways. In the sentence "i do not like this move" the negation handling can be done by reverse the polarity of all words appearing after negative word which is 'do not' in this sentence but it cannot work in the sentences like "I do not like the movie but I like the action". Therefore for negation handling we need to consider also the scope of negation as well. So in this case the thing that can be done is to change polarity of all words appearing after a negation word till another negation word appears. But still there can be problems, for example, in the sentence "Not only did I like the acting, but also the direction", the polarity is not reversed after "not" due to the presence of "only". So this type of combinations of "not" with other words e.g. "only" has to be kept in mind while designing the algorithm.

Performance Measuring Parameters

The performance of aspect based sentiment analysis (Figure 1) can be measured as the precision, recall and accuracy which are defined as follows:

$$\text{Precision} = \frac{TP}{TP + FP} \tag{1}$$

$$\text{Recall} = \frac{TP}{TP + FN} \tag{2}$$

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

$$\text{Accuracy} = \frac{TP + TN}{TP + FN + FP + FN} \tag{3}$$

Where:

- TP is true positive. True positive means predict the sentence positive and it also really positive
- TN is true negative. True negative means predict the sentence negative and it also really negative
- FP is false positive. False positive means predict the sentence positive but it is not actually positive it is either negative or neutral
- FN is false negative. False negative means predict the sentence negative but it is not negative actually it is either positive or neutral.

Experimentation

We collected the reviews for the product (Mobile Nokia 6600) from the internet domain and we generated the data set from those reviews. Table 1 shows the data set for the product reviews of Nokia 6600. It contains number of total sentences from reviews and number of positive and negative sentences in the reviews. This is obtained after the process of finding the subjectivity of the sentences and splitting the sentence into positive and negative sentences.

Figure 1. Graphical representation of aspect based sentiment analysis

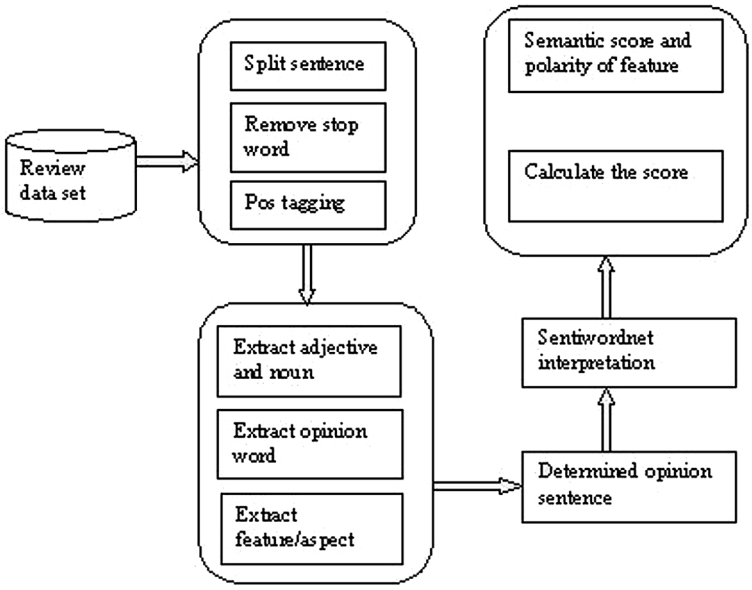

Table 1. Data set for Nokia 6600

	Total Sentence	Positive Sentence	Negative Sentence
Nokia 6600	546	250	118

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 2. Scores and polarity of aspects/features

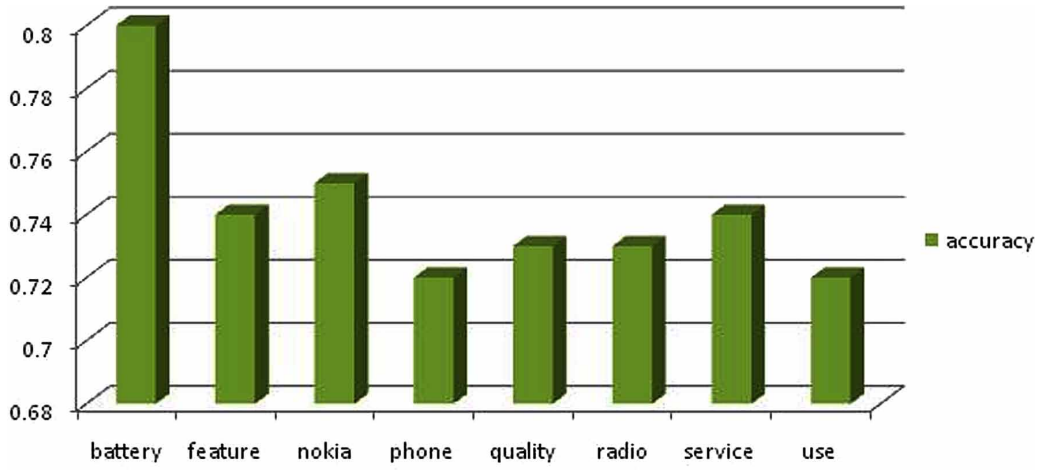
Aspect/Feature	Positive Score	Negative Score	Polarity
Battery	0.08	0.02	Positive
Feature	0.11	0.28	Negative
Nokia	0.12	0.18	Negative
Phone	0.02	0.05	Negative
Quality	0.00	0.00	Neutral
Radio	0.00	0.00	Neutral
Service	0.00	0.00	Neutral
Use	0.00	0.00	Neutral

We calculated the positive score, negative score and polarity of each aspect of products using sentiwordnet. The Table 2 shows the positive score, negative score and the polarity of the features.

From the Table 2 it is clear that the polarity of the product is negative on the basis of average scores of the aspects. To check the accuracy we calculate the precision and recall. For this task we firstly categorised the true positive, true negative, false positive and false negative from the review sentences then calculated the precision, recall and accuracy from the Equations 1, 2 and 3.

Table 3 shows the scores of the precision, recall and accuracy of the aspects.

Basic Requirement for Experimentation



This experimentation has done on eclipse or Netbean platform which have a development interface for java programs. We use a Stanford parsing tool for finding adjective and noun/noun phrase and an open lexical resource sentiwordnet for obtaining the positive or negative scores of all opinion words in the form of synset terms. We also use the list of all positive and negative words which is very useful for splitting the review data in the positive and negative reviews.

Table 3. Precision, recall and accuracy of the aspects

Aspect/Feature	Precision	Recall	Accuracy
Battery	1.0000000	0.80000000	0.8000000
Feature	0.9736842	0.75510204	0.7400000
Nokia	0.9846154	0.76190480	0.7529412
Phone	0.9891892	0.72332020	0.7176471
Quality	0.9900498	0.73431736	0.7289377
Radio	0.9907407	0.74564460	0.7343174
Service	0.9911111	0.74581940	0.7408638
Use	0.9919028	0.72700300	0.7227139

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. Accuracy of aspects

After calculating the accuracies of each aspect (Figure 2), we calculate the average accuracy for the product by applying the following formula:

$$\text{Average accuracy} = \frac{\sum_{n=1}^{n} score\,of\,Aspects}{total\,no\,of\,aspects} \tag{4}$$

The final accuracy of the aspects of the product Nokia 6600 is calculated as 74%.

FUTURE AND CURRENT TRENDS

Sentiment analysis is basically a classification task in three different levels: aspect level, document level, and sentence level. Sentiment analysis mainly concentrate on identifying whether a given text is subjective or objective and if it is subjective, then whether it is negative positive or neutral. Sentiment analysis is also considered as a subfield of computational linguistics concerned with extracting sentiment and emotion from text. The data set is the main issue in sentiment analysis and the main source of the data set is product review. Sentiment analysis is not important for only product, review it is also used in many other fields like the stock market, politics etc. The major challenges and scope for the researcher in the sentiment analysis are as follows.

Comparative Sentence Identification

Comparative sentence means where the comparison between two object is done e.g. “product a is better than product b” it completely change the polarity of a sentence. To clearly understand these comparative sentence, a well effective sequential information, modelling and structure are needed. Product review are mainly contain subjective information but comparative sentence contain both subjective and objective items. Thus to identify the comparative sentence is very difficult task because only few indicator will help to identify such sentence and those indicator also present in the sentence which are not comparative.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Leveraging Domain-Dependency

Almost all sentiment analysis and opinion mining research the domain dependency is an important issue. All approaches perform differently in different domain e.g. any approach can perform well in the product domain but may be not suitable for the politics feedback analysis. The one major and obvious reason is the difference in vocabularies across different domains. So designing the domain dependent model is also a very challenging task. Lots of work can be done in this field. In 2006 a reasearcher build a domain dependent classifier using a machine learning technique. In 2009 they build a query-specific subjective lexicon to improve the result but it also exploit some domain independent feature. Yang et al. (2006) propose a set of domain in dependent features and performed in the movie and product domain. There are several avenues open for the research in this field using the machine learning techniques that achieves good accuracy.

Association of Different Opinion

A document contains much opinionated information about many different topics in a single document. In this situation separation of opinionated information from factual information and look for opinion–topic associations in the documents need a very effective approach. To finding the association between the topic and corresponding opinion, various techniques can be used. Some of these techniques are: Natural language processing (NLP) techniques (like POSTagging and Syntactic Parsing) are used to identify opinion words and syntactic relation between the sentiment expression and subjective terms. Pos tagger is helpful to identify the opinion word as they identify all noun, adjective, verbs in the given piece of a document and the adjective is considered as a opinion word, Proximity-based techniques used to find the topic-association in textual document for example it say the proximity of the query terms to the opinionated sentences in the document helps to find that level of opinion–topic association necessary for opinion finding task. They just check the occurrence opinionated word around the query word.

Challenges in Natural Language Processing (NLP)

It is not forget that sentiment analysis is a NLP problem. It touches every aspect of NLP, e.g., negation handling, coreference resolution and word sense disambiguation, which combines more difficulties, since these are not solved problems in NLP. However, it is also useful to understand that sentiment analysis is a highly restricted NLP problem because the system does not need to fully understand the semantics of each sentence or document but only needs to understand some aspects of it, i.e., positive or negative sentiments and their target entities or topics. In this sense, sentiment analysis offers a great platform for NLP researchers to make tangible progresses on all fronts of NLP with the potential of making a huge practical impact.

Contextual Polarity of Words

An accurate polarity identification of a opinion word is still need a deep analysis. We cannot assign a polarity with respect to the prior polarity of a word. A polarity of a word is also affected by its surrounded word for example if the word “good” show the positive polarity the word “not good” it show the negative polarity because it contains a negation word. The new polarity define by its context is called contextual

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

polarity the context can be defined by the negation or by other ways. In 2003, Yi et al. used a lexicon and manually developed high-quality patterns to classify contextual polarity. Popescu and Etzioni (2005) use a relaxation labelling of an unsupervised classification technique to recognize the contextual polarity of words. They use the bootstrapping approach to classify the polarity of tuples. Negations (only not) has also taken into account when identifying contextual polarities

CONCLUSION

In this chapter first we provide an overview of sentiment analysis with special emphasis on aspect based sentiment analysis. A prototype algorithm has introduced for aspect based sentiment analysis and a case study has carried out for better understanding of aspect based sentiment analysis. For the aspect based sentiment analysis we have used the sentiwordnet 3.0 and for implementation of proposed system we used java programming language on eclipse platform. For the simulation and analysis of the system we used mobile (Nokia-6600) review data. The pos tagger, which does not need of trained data, has been used to tag the sentences. To remove the stop word and unwanted data, we pre-process the data and not using stemming because it put the distortion in review data. We checked the subjectivity of the sentence using the list of positive and negative word and used frequency based method for aspect extraction in which we checked the frequency of noun which is considered as aspect and take most frequent noun as a product aspect. We used sentiwordnet for semantic analysis of data and calculate the final score for classifying the polarity of each aspect/feature in terms of positive and negative. By using these techniques we obtain a good result in terms of precision, recall and accuracy. These techniques are very easy to use with respect to supervised machine learning techniques because it cannot need any training and testing data. This technique is also taking less time for computation in large data set because it cannot need to train a data. This system extract only the explicit features therefore in order to upgrade the system in future, we plan to develop some extraction technique which also extract the implicit feature of a product. The other possible extension of this system is hybrid approach i.e. by combining the sentiwordnet lexical resource method with the supervised machine learning method to improve the accuracy of this system.

KEY TERMS AND DEFINITIONS

Bayesian Network (BN): Bayesian network iis the directed acyclic graph in which the nodes represent the random variable and the edge represent the conditional dependencies. it specified the joint probability distribution over all the variable.

Decision Tree Classifiers: In decision tree classifiers we provides the training data in the hierarchical form and for dividing the data we used the conditions on attributes and to perform the spilt we use the similarity based multi-attribute split.

Maximum Entropy Classifier: This classifier determine the most likely class for a document set it convert the labelled document set into a vector using encoding and with the help of encoded vector we calculate the weight of a document and combine to get the result.

Naive Bayes Classifier: It is a simple probability based classifier based on bayes theorem with strong independence assumption it compute the posterior probability of a class based on the distribution of the word in the document it ignore the position of the word in the document.

Neural Network (NN): Neural network is combination of neuron. Neural network is used for both classification and prediction. Neural network contain three layers for computation first is input layer second is hidden layer and last is output layer.

Rule-Based Classifiers: Rule based classifier is a sets of rule for classification and uses term absence and presence for the classification. In this classifier we define some criteria to generate the rule and theses rule are generates at the training time.

Support Vector Machine (SVM): It determine the linear separator by constructing hyperlanes that separates the cases that belong to different categories. Hyperlanes provide best separation between the class and it takes the maximum margin for separation because the normal distance between any data point is largest.

Chapter 4
Compliance with International Soft Law:
Is the Adoption of Soft Law Predictable?

Michael D'Rosario
Deakin University, Australia

John Zeleznikow
Victoria University, Australia

ABSTRACT

The present article considers the importance of legal system origin in compliance with 'international soft law,' or normative provisions contained in non-binding texts. The study considers key economic and governance metrics on national acceptance an implementation of the first Basle accord. Employing a data set of 70 countries, the present study considers the role of market forces and bilateral and multi-lateral pressures on implementation of soft law. There is little known about the role of legal system structure-related variables as factors moderating the implementation of multi-lateral agreements and international soft law, such as the 1988 accord. The present study extends upon research within the extant literature by employing a novel estimation method, a neural network modelling technique, with multi-layer perceptron artificial neural network (MPANN). Consistent with earlier studies, the article identifies a significant and positive effect associated with democratic systems and the implementation of the Basle accord. However, extending upon traditional estimation techniques, the study identifies the significance of savings rates and government effectiveness in determining implementation. Notably, the method is able to achieve a superior goodness of fit and predictive accuracy in determining implementation.

INTRODUCTION

The decision to implement international soft law maybe motivated by a number of different factors as noted by Ho (2002) the implementation of economic soft law, specifically in the case of the Basle Accord of 1998, appears to be driven by the strength of the underlying democratic system of governance in place within a particular jurisdiction affording credence to the democratic legalists theories of international

law. While the extant research does appear to support this proposition, there appears to be little, if any, credence afforded to the interaction between democracy and government effectiveness and their impact on the implementation of international soft law. Artificial intelligence methods have been largely absent from discussions of international soft law implementation. This appears problematic and potentially inapt given the plausible interaction effects that exist between government effectiveness democracy and other macro-economic variables in determining the likelihood of soft law implementation.

The concept of soft law, pertains to quasi-legal instruments which have no formal legally binding capability, or where the enforcement capability is assumed to be weaker relatively speaking than the force that underlines traditional law, sometimes in this context referred to as hard law. While the term soft law is largely synonymous with discussions with international law, it may also be referred to when commenting on domestic legal and doctrinal matters. Herein, our focus remains on international law. An apt example of what may be described as soft law would include resolutions and declarations of the United Nations general assembly components of bilateral and multi-lateral treaties, such as codes of practice and other non-treaty obligations. It is nonetheless problematic identifying a consistent definition of soft law given the fervent debate that exists between those denying that such a legal paradigm exists and those that deem it an additional sphere of international law. Shelton (2000), offers the following guiding definition that soft law is in essence the normative provisions contained in non-binding texts. Arguably, the works of Baxter (1980), and Weil (1983), are seminal within the sphere of research. Baxter (1980), contends that soft law is representative of the different intensity of agreement that exists within the expression of international law. Weil (1983), responds to this assertion and argues for caution when seeking to derive concepts of relative normativity in international law. Shelton (2000), and Abbott & Snidal (2000), offer a unifying set of theses that serve as the conceptual framework for the present study. Specifically, Shelton (2000), outlines compliance with soft law through the analysis of a wide variety of non-binding legal instruments within a variety of domains. Abbott & Snidal (2000), contend that soft law exists by virtue of the weakening of a legal arrangement with respect to the obligations delegation and precision of said arrangement. Having accepted the existence of soft law, it is pertinent to understand what factors motivate the enactment of international soft law.

Guzman & Meyer (2010), offer a worthwhile summation of why soft law is employed by states. The authors advance for complementary explanations for why states employ soft law that seek to describe a much broader range of state behaviour than has been previously explained.

First, and least significantly, states may use soft law to solve straightforward coordination games in which the existence of a focal point is enough to generate compliance.

Second, under what we term the loss avoidance theory, moving from soft law to hard law generates higher sanctions that both deter more violations and, because sanctions in the international system are negative sum, increase the net loss to the parties. States will choose soft law when the marginal costs in terms of the expected loss from violations exceed the marginal benefits in terms of deterred violations.

Third, under the delegation theory, states choose soft law when they are uncertain about whether the rules they adopt today will be desirable tomorrow and when it is advantageous to allow a particular state or group of states to adjust expectations in the event of changed circumstances. Moving from hard law to soft law makes it easier for such states to renounce existing rules or interpretations of rules and drive the evolution of soft law rules in a way that may be more efficient than formal renegotiation.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Fourth, we introduce the concept of international common law (ICL), which we define as a nonbinding gloss that international institutions, such as international tribunals, put on binding legal rules. The theory of ICL is based on the observation that, except occasionally with respect to the facts and parties to the dispute before it, the decisions of international tribunals are nonbinding interpretations of binding legal rules. States grant institutions the authority to make ICL as a way around the requirement that states must consent in order to be bound by legal rules. ICL affects all states subject to the underlying rule, regardless of whether they have consented to the creation of the ICL. As such, ICL provides cooperation minded states with the opportunity to deepen cooperation in exchange for surrendering some measure of control over legal rules.

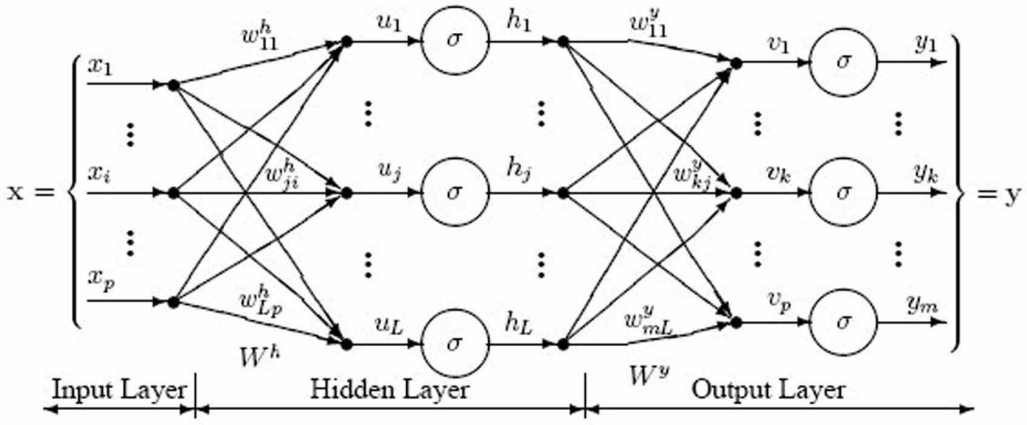
Ho (2002), offers a worthwhile account of the economic and institutional determinants of the implementation of the first Basle accord employing traditional empirical method. The study of 107 countries explored the importance of factors such as banking sector concentration, democracy, macro-economic conditions and savings rates on the likelihood of implementation of the accord. As noted, the study identified both a positive and significant effect associated with the nature of the jurisdictions degree of democracy, as measured by the author using an ordinal sale variable.

The noted study employs logistic regression modelling techniques. This is consistent with much of the extant research when exploring relationships involving dichotomous dependent variables. The most commonly method employed in empirical legal research is logistic regression, largely because it is well suited to the dichotomous dependent variables that serve as the subject of many studies within the legal sciences. While the contributions to empirical legal research have been apt, many complex non-linear problems have not been considered empirically. The present article proffers an alternative method asserted to be parsimonious for research in the legal domain, representing a viable alternative to the commonly employed logit model.

An Introduction to the Multilayer Perceptron

While there remains the need for further acknowledgement of the benefits associated with parametric estimation methodology within the law and economics, the so called second wave of law and economics (Richardson, 1989), it is apparent that novel non-parametric methodologies made possible by modern computing technologies represent an equally important sphere of inquiry. In particular, the advantages of multi-layer perceptron models in comparison to logit models when modelling complex nonlinear processes are pertinent to consider a number of recent studies have sought to advance the role of artificial intelligence methods within legal research and legal practice. Hanke (2017), considers the role of artificial methods intelligence in response to dispute resolution. The author contends that artificial intelligence applications will augment the capabilities of lawyers and as a consequence should make them more productive and reduce the cost associated with legal advice provision. Nissan (2017), offers a precis on recent advancements within law and A.I. as it relates to the legal profession. The author explains how machine learning technologies and non-machine learning based applications are supplementing and augmenting legal service provision and legal practice. Artificial intelligence methods and the role of such technologies in advancing justice outcomes has been the focus of much recent research (see inter alia Bench-Capon & Modgil, 2017; Branting, 2017; Verheij, 2017; D'Rosario, 2017a, 2017b). This notable interest extends upon the substantial interest in the law and A.I. field of research, deriving from recent advancements in autonomous vehicle technologies and their associated law and artificial

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use



intelligence ethics questions. There remains however, only a small number of studies employing artificial intelligence methods when addressing empirical legal questions pertaining to economic soft law. The multilayer perceptron model is simply a form of artificial neural network model (herewith MP-ANN), a non-parametric predictive model that seeks to replicate the structure of a biological neuron as it occurs in nature. More plainly it is a series of weighted, aggregative, non-linear values. Neural network models emerged out of the Artificial Intelligence body of research that should to attempt to model the human process of learning through the development of a modelling framework resembling the structure of the human brain (Patterson, 1996). The MP-ANN model has the potential to provide more accurate predictive outcomes than traditional parametric estimation techniques, it is therefore well suited to the present research questions (D'Rosario, 2017). Rosenblatt (1958) posited the perceptron model, framing the concept of the retina layer, distributing input values. The work of Minsky & Papert (1969) asserted a number of the limitations of the perceptron model, the work brought about a diminution of interest in perceptron modelling. The key challenge evidenced in the perceptron model as posited by Rosenblatt was the step function that made problematic to train (D'Rosario, 2017). A revival of sorts occurred as a result of the work of Rumelhart, Hinton and Williams whose seminal paper "Learning Internal Representations by Error Propagation", offered resolution. Their work enabled the effective training or a multilayer neural network. The backpropagation training method and viable algorithm was first asserted in Rumelhart and McClelland (1986); it was the first practical method for training neural networks (D'Rosario, 2017).

Figure 1 illustrates conceptually the study's posited three-layer perceptron network.

This visual depiction is of a three-layer perceptron model, though more layers are possible, notwithstanding the significant increase in resources required for multiple hidden layers being employed. The three-layer perceptron is constituted by an input layer, hidden layer and an output layer. The first layer is the input layer. The input layer processes and standardises a vector of the predictor variables ($x_1 ... x_p$). These variables then take the range of -1 to 1. These standardised values are then passed through to the hidden layer. This process loosely resembles the process of "saltatory conduction" with a biological neuron.

The standardised vector values of the predictor variables, for example standardised vectors of amici curie and/or attitudinal variables, reach the hidden layer. At the hidden layer, the standardised values are multiplied by a weight (w_{ji}), with the weighted values aggregated (u_j) and passed forward to the transfer function. The values from the transfer function are passed to the output layer (h_j).

Figure 1. Three-layer perception network

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

The output layer accepts the values from the hidden layer, multiplying the values by weights (w_{kj}), with the weighted values then aggregated resulting in a composite value v_j . The v_j value is then passed forward to the transfer function. The values from the transfer function are the model outputs y_k. Should the target variable be dichotomous, then there will be *2* neurons in the output layer producing *2* values, one for each of the categories of the target variable. Where the output value takes greater than to values (y_k = n), then the output layer will be constituted by n values.

Neural Models as an Alternative to Logistic Regression in Legal Science Research

The use of such methods is not uncommon in the social sciences but remains relatively underemployed within interdisciplinary legal research. Buchanan & Headrick (1970), offers an early speculative account in regard to the role of artificial intelligence methods within the legal profession asserting the role of artificial intelligence in modelling legal reasoning and argumentation. Rissland (1989), provided an account of the potential role of artificial intelligence methods in modelling legal process. The author provided practical insight into how reasoning could be captured and implemented within an artificial intelligence framework. This study extended upon the earlier work of McCarthy & Haze (1981), who addressed many of the issues associated with subsuming complex logic into an artificial intelligence framework. Bench-Capon (1997), provided a formal explication on the manner with which results-based frameworks and rule based legal information could be incorporated into artificial intelligence models of legal argumentation. The study outlined four areas where legal argument has been applied. Specifically, legal reasoning based on cases, explaining results based on rules of law and rule based legal information in resolution of normative conflict and problems on non-monotonicity and the basis of dialogue games to support the modelling of legal argument. Walton (2005), offer some refinement to these methods in the authors text, Walton (2005) outlines methods of argumentation and their application in artificial intelligence methods research relating to law incorporating practical and legal profession relevant guidance. However, it is noteworthy to acknowledge that artificial intelligence methods remain underutilised within legal research in comparison with other disciplines.

Importantly, there remains a dearth of research considering key empirical questions, such as the impact of legal experience of lawyers and the role of amicus curie on legal outcomes; and an even greater dearth of literature positing practically framed deterministic models of legal outcomes utilising the posited non-parametric models. Notable parametric studies within this area of research include those of Matthew Sag, Tonya Jacobi and Barton Beebe. There is little if any non-parametric research within this field. The use of neural networks is not however absent within the broader body of legal research. Warner (1990, 1992, 1993), was amongst the first to posit the benefits of logic based legal expert systems and one of the first legal realists to employ neural networks within legal expert systems. Warner (1990, 1992, 1993), contends that neural networks have the unique capacity to replicate deontic logic. However, the use of neural networks has not been limited to legal realists alone. Lothar Philipps (1991), emphasis the benefit of neural networks within the legal domain. Hobson & Slee (1994), emphasis the benefits of neural networks in their application to case analysis and case based reasoning. Rose & Belew (1989, 1991), claim that neural networks can retrieve appropriate data while employing a legal realistic perception of the law.

The first significant practical use of artificial neural networks in law was first developed by Stranieri et al (1999). They used a combination of rules and artificial neural networks and rules to determine what percentage of the common pool of assets a husband would receive following divorce in Australia. The

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

argument structure of Toulmin (1958) was used to justify conclusions made by their Split-Up system. In Stranieri and Zeleznikow (2005) the authors provided a detailed discussion on how knowledge discovery from legal databases could be gainfully used to assist legal decision making.

While some of these assertions may possibly overstate the benefits of neural networks within the legal domain to an extent, it is undeniable that neural networks possess greater pattern identification and are more consistent with logic and rule base systems of case classification than logistic regression techniques. The current study responds to both the noted dearth of deterministic research and the dearth of empirical work considering these matters.

The Multi-layer perceptron model is asserted to be a viable alternative to the logit model because it offers a more accurate framework for prediction. Consider some of the challenges associated with alternative parametric techniques. Firstly, there are obvious issues associated with predictive analysis where the process is non-linear. Logit and Probit models are relatively less capable of modelling non-linear decision processes. MP-ANN overcomes this challenge through the application of weighted, aggregative non-linear values based estimation. Neural networks have been advocated as an alternative modelling technique to logistic regression within the applied sciences, however there is a dearth of research considering the viability of such methods within law and economics research.

Within law and economics research, logistic regression is by far the most commonly employed method, given its suitability to dichotomous dependent variables. Within the applied sciences many more complex alternatives are being adopted. These methods present as viable alternatives to logit and probit modelling.

As asserted by Tu (1996) neural networks offer a number of advantages over logistic regression, including the ability to implicitly detect complex nonlinear relationships between dependent and independent variables, ability to detect all possible interactions between predictor variables, and the availability of multiple training algorithms. Driesietl and Ohno-Machado (2002) offer a formal methodological review of each modelling technique, noting the formal association between the techniques. The multi-layer perceptron model can be seen as an abstraction of the logistic model, employing a sigmoid function. A more apt description however would be that the logistic model is a simple single layer perceptron model, that does not employ a second (layer) weighted aggregate input set. [1] Indeed, there are a number of benefits associated with neural networks that render the approaches advantageous in comparison to traditional logistic estimation. Firstly, the methods appear to evidence greater consistency with legal decision making. If it is assumed that all decision making is linear or sigmoidal, and therein all decisions can be estimated with a linear or stigmoidal function then neural networks and logistic regression offer similar estimates.

Neural models appear more consistent with legal decision making (see Kannai et al 2007, D'Rosario, 2017). Members of the legal system carefully weigh alternative criteria, balancing competing criteria and implicitly employ these weighted considerations in their decision making. While the process may not be explicit it is nonetheless essential to legal decision making.

Moreover, the perceptron may be more accommodating of non-linear decision processes. The perceptron model and back propagation method were developed to respond to complex non-linear processes and problems (n.b. Rumelhart, Hinton and Williams). This is because of the existence of the hidden layer that accepts input values from vectors of the predictors. This allows for the combination of vector inputs, rather than the direct pass through of the predictor weights directly to the output/dependent variable. The logistic regression method involves the direct pass through of the predictor weights. This is largely because the logistic regression method can be seen as a simple form of single layer feed forward neural network. It is this assertion that may result in greater consideration being afforded to non-parametric models of estimation.

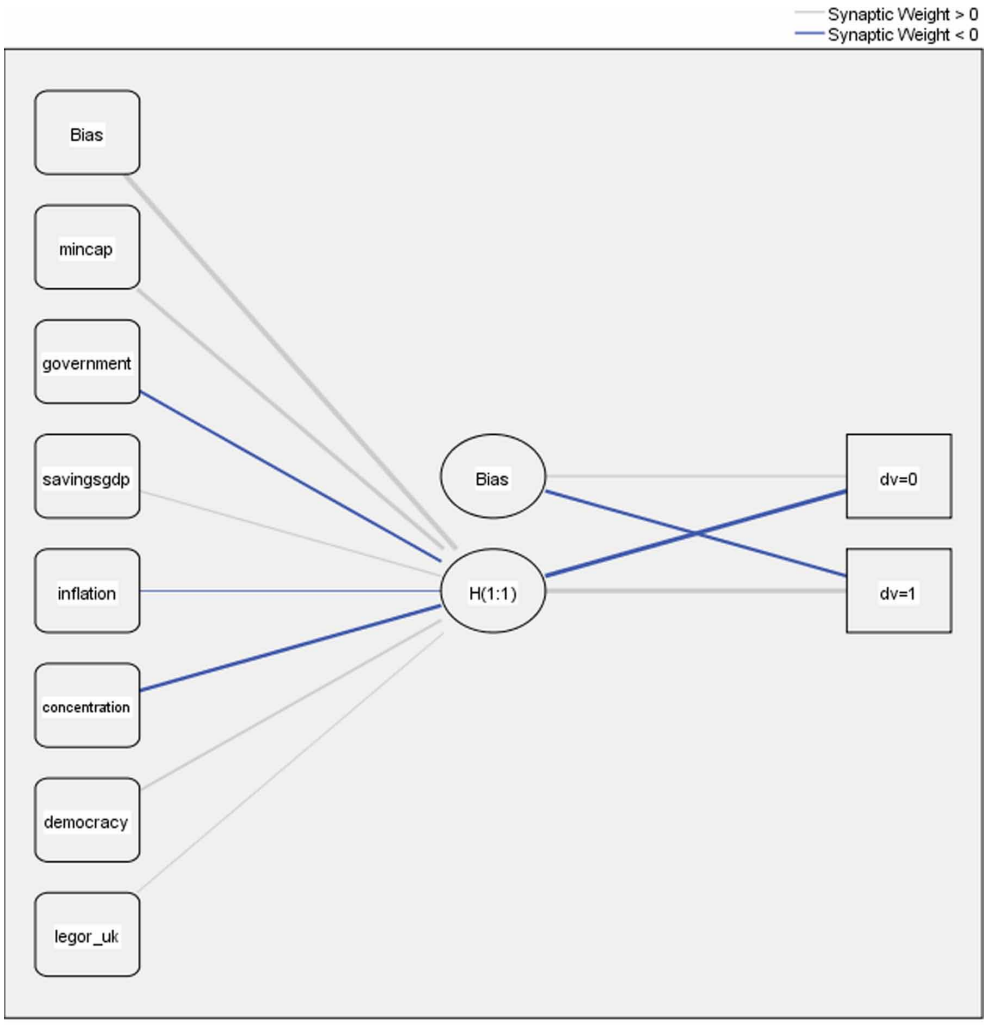
EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Neural models have been shown to provide more accurate prediction rates in legal studies such as those of Stranieri et al. (1999), Kannai et al (2007), D'Rosario (2017) and D'Rosario (2017). As such where outcome prediction is assigned the highest priority it is a superior estimation methodology. Where there is complex interaction between predictor variables the neural model is likely to provide a better rate of prediction. Many legal decision processes involve complex interactions between predictor variables. As such these legal decision processes are not well suited to conventional regression based estimation, and in particular linear regression. Perceptron models appear to be well suited to modelling legal decision process because of the formal consistency of the modelling technique with the process of legal decision making.

The method is not without its challenges. The most obvious challenge associated with the use of neural network models are the computing resources required for the employment of such modelling techniques. Multilayer perceptron models are more resource intensive than traditional parametric techniques, though this is of little consequence given the ubiquity of modern computing technology.

The most significant challenge of neural network-based modelling and machine learning generally is the perception of such methods as black boxes that are difficult to understand. This is a misnomer as there are now many techniques available to understand the relative importance of model variables and model parameter impacts. Given the techniques developed by Garson (1991) and Goh (1995), as well as more contemporary methods, this is certainly no longer an accurate representation of the methodology. Normalised importance analysis allows for the interpretation of neural network connection weights. Thus, providing a set of compelling metrics for the interpretation and analysis of predictor variables, and determinations about the relative importance of predictor variables.

The Logit model is the obvious choice when a dependent variable is non- continuous. It is also useful when addressing non- liner associations. However, the technique fails to properly measure threshold events and specification effects. This results in model specifications incapable of analysing and measuring complex interactions between regressors. A number of non-parametric techniques are more capable of accommodating complex relationships with threshold and interaction effects.



MODEL STRUCTURE AND PARAMETERS

The model seeks to determine the likelihood of soft law (Basle Accord) implementation given a series of macroeconomic, legal and demographic variables. Specifically, the specification models the implementation of the Basel accord based on a number of viable estimators. Figure 2 conceptually illustrates the study's posited three-layer perceptron network. The model is a three-layer network where Basle Accord implementation, the dependant variable is a binary variable taking the values of implement or no implementation. (This model denotes the layer and node structure of the model. It does not define weights and connections, which are purely illustrative):

The ANN model employed — the MP-ANN model — is a three-layer model with an input layer deriving from the variables provided by Ho (2002). Accord implementation is the variable denoting the implementation of the first Basle accord denoted as a binary dummy variable. Government is a scale variable denoting the effectiveness of government. SavingsGDP is a continuous variable denoting the level of savings relative gross domestic product measured in U.S. dollars (U.S. constant dollars base year 2000). Inflation denotes the rate of inflation within each jurisdiction in average terms during the preceding year. Concentration is a measure of the level of banking sector concentration. Democracy is

Figure 2. Conceptual model diagram

a proxy variable quantifying strength of democratic practices within the jurisdiction. Corruption (denoted in the model as corrupti80-89, as per Ho (2002)) is a measure of corruption deriving from World Bank corruption statistics. RL is a measure of the rule of law within each jurisdiction. Lngdpcap is the log value of GDP per capita. Signatory id a variable denoting whether the nation is a signatory to the Basle accord. Oppositionul is a variable denoting division within government. Debtwldperc is a variable denoting the current level of debt. Lndebt is the log value of the current level of debt. Lninswld is a measure of international insurance and financial exposure. Supervise is a measure of banking sector supervision (see Table 1).

Note: This table summarises the data employed within the study. All data was sourced from Ho, (2001).

THE LAYERS OF A NEURAL NETWORK

The first layer is the input layer. The input layer processes and standardises a vector of the predictor variables, herein the macroeconomic, governance and stability variables. These variables then take the range of -1 to 1. These standardised values are then passed through to the hidden layer. This process loosely resembles the process of "saltatory conduction" with a biological neuron.

The standardised vector values of the predictor variables, government, savingsgdp, inflation, concentration, democracy, corruption, rl, lngdpcap, signatory, oppositionul, debtwldperc, lndebt, lninswld, Supervise, reach the hidden layer. At the hidden layer, their standardised values are multiplied by a weight, with the weighted values aggregated and passed forward to the transfer function. The values from the transfer function are passed to the output layer.

The output layer accepts the values from the hidden layer, multiplying the values by weights, with the weighted values aggregated and passed forward to the transfer function. The values from the transfer function are the model outputs. As the target variable is the outcome for the petitioner, there are *2* neurons in the output layer producing *2* values, one for each of the categories of the target variable.

The hidden layer size was determined based on Heaton's work, noting optimality generally exists between the number of input layers and output layers (Heaton, 2011). Moreover, two hidden layers may be employed when modelling data that evidences discontinuities, such as a saw-tooth wave pattern. Given the nature of the underlying dataset, this is not the case. The use of an additional hidden layer reduces estimation efficiency and offers no improvement to the model. Herein, a single hidden layer model is employed to avoid a greater risk of converging to an incorrect local minima. One potential shortcoming

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

of the selected methodology relates to the efficiency of ANN models in accommodating non-numeric variables, commonly referred to as dummy variables in economics. This is, however, only the case where non-numeric variables can take a large number of values, which is not the case in the present study. The total number of units employed in the model was 16, and determined through optimisation, again indicating interaction effects.

Data pruning techniques were not employed to improve model resolution, and the model performed efficiently and robustly absent of any node reduction. As such, the input values remain the same as those employed in Ho (2002). This is pertinent as it ensures that each predictive modelling framework can be compared on equal terms employing the same parameter set (see Table 2).

MODEL FINDINGS

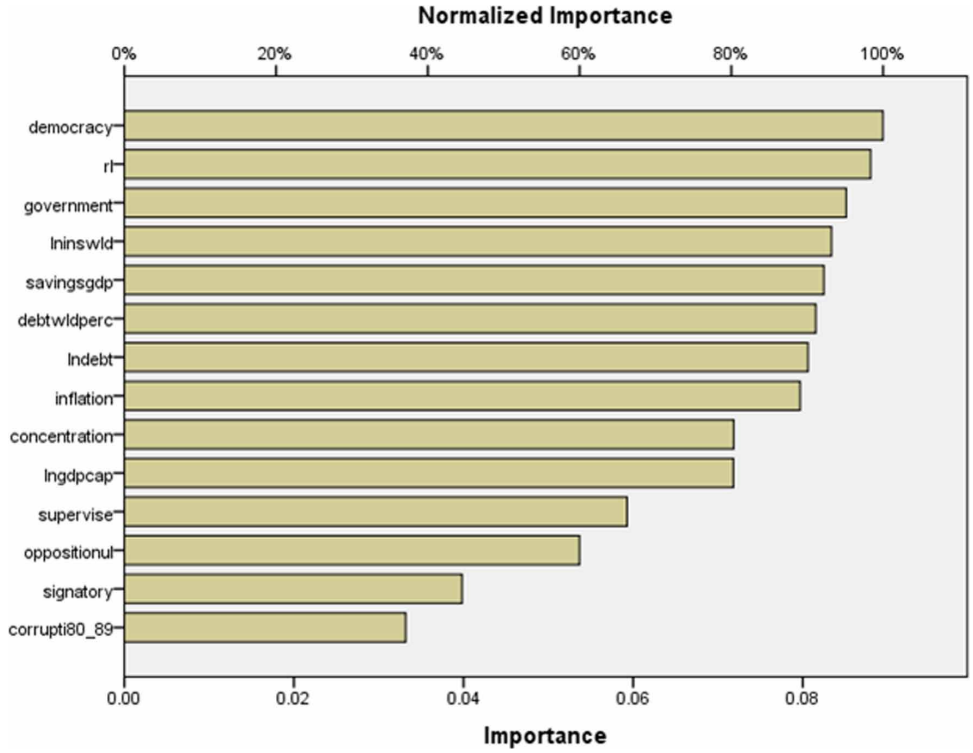
The MP-ANN is able to robustly predict the decision to implement the Basel Accord 100 per cent of the time (with no converging minima) with accuracy in prediction and goodness of fit far greater than the traditional logistic regression. This suggests that the underlying variables are useful in the determination of the outcome of a soft law implementation process. The model is capable of robustly predicting outcomes more consistently than any of the models in the extant literature. The size of the relative weights employed in the model is detailed in Table 3.

The goodness-of-fit measures suggest that the MP-ANN is superior to the logistic model in the Ho study (Ho, 2002). While the Ho model remains conceptually and empirically sound, it does not achieve the same level of predictive accuracy. The findings suggest that this model is more predictively capable, with an improvement in predictive accuracy of a minimum of14 per cent. This is amongst the most pertinent contributions of the present study. The study conveys the benefits associated with non-parametric methods of prediction in economic soft law research and the benefit of MP-ANN modelling in the development of predictive models in the economics law.

Employing the methods of Garson (1991) and Goh (1995), the normalised importance analysis suggests that the democracy (the proxy of the strength of democratic practices) ranks as the most important determinant of litigant success, followed by the government effectiveness measure and the strength of the rule of law measure. The data is presented graphically in Figure 3. The variation in the hidden layer structure yields comparable results and robustly achieves a 100 percent predictive accuracy. Thought that it is notable that the relative ranked importance of government effectiveness and democracy was reversed in some model specifications, lending credence to the assertion that government effectiveness may be of equal importance to the strength of democratic practices when determining the likelihood of soft law implementation. These findings are broadly consistent with the findings of the Ho study, with a few notable points of difference (Ho, 2002).

Firstly, unlike the Ho study, the current study indicates that government effectiveness and the rule of law may rank as equally important to the strength of democracy in determining the likelihood of soft law implementation. Additionally, the network results suggest that threshold and interaction effects may exist between key independent variables democracy rule of law government effectiveness and savings GDP. Again, noting that substantial improvement in pseudo R-Squared values ranging between 0.65 – 0.81 in contrast of the present study of 0.99 to 1.0.

CONCLUSION



The study has evidenced the benefits associated with non-parametric predictive modelling and specifically the benefits of artificial neural networks in legal research. Unlike a number of recent studies employing time series and panel data in non-parametric modelling in legal research, specifically employing artificial neural networks, the present study makes evident the efficacy and efficiency of neural networks in legal research employing cross sectional data. The findings indicate the employed predictive methods may be of greater utility than logistic models when emphasis is placed on outcome prediction rather than casual association, which is particularly important when seeking to determine the likelihood of economic soft-law adoption. The study indicates that while logit and probit models are worthwhile exploratory tools when engaging in empirical work in law and economics and can accommodate non-linear problems;

they are less capable of accommodating non-linear problems with complex interactions as efficiently as multilayer perceptron models, at least when the desire is to engage in a predictive exercise. Logit and probit models cannot capture threshold and interaction effects unless such effects are known and understood and can be specified in model prior to estimation. Additional research is nonetheless necessary to determine the potential generalizability of this claim but the claim appears to be highly plausible in light of recent studies. The notion that perceptron modelling may be beneficial and potentially superior in soft law and social sciences research represents the first contribution of the study. A further contribution of the study is its response to the dearth of studies employing empirical methods to legal research pertaining to economic soft-law, and in particular methods beyond logistic regression.

Importantly the current research displays the potential benefits associated with legal system and legal structure data collection efforts when employed with modern parametric estimation techniques. The MP-ANN models may be useful tools in determining the relative importance of independent variables and the model of estimation to employ when engaging in casual analysis. The modelling methodology employed herein evidences the benefit of the presented empirical technique in predicting soft law outcomes. Critically, the role of MP-ANN models in empirical legal research is advanced based on the notion that such models require heuristic knowledge pertaining to data preparation and cataloguing, and sufficient technical knowledge to employ the appropriate ANN for the estimation. It is hoped that the present study shall inform future legal researchers engaging in empirical legal research employing non-parametric estimation technique such as those employed herein. The ANN models are more conceptually simple than linear modelling techniques (albeit more mathematically complex); not to mention more appropriate for modelling complex decision models, thus supportive of greater potential adoption by the legal fraternity. It would be apt for future research to consider the potential application of probabilistic neural networks to such empirical legal analysis of soft law variables.

ACKNOWLEDGMENT

The authors would like to thank the anonymous reviewers and the editor for their insightful comments and suggestions.

Chapter 5
Predicting Credit Rating Migration Employing Neural Network Models

Michael D'Rosario
Deakin University, Australia

Calvin Hsieh
Deakin University, Australia

ABSTRACT

Credit rating migration ranks amongst the most pertinent issues concerning institutional lenders and investors alike. There are a number of studies that have employed both parametric and non-parametric methodologies to forecast credit rating migration, employing machine learning methods; and notably, artificial intelligence methods becoming increasingly popular. The present study extends upon research within the extant literature employing a novel estimation method, a neural network modelling technique, herewith the MPANN (multi-layer neural network). Consistent with the extant literature, the present article identifies that the legal framework and system of taxation enacted within a polity are pertinent to predicting rating migration. However, extending upon traditional estimation techniques the study identifies that a number of different model calibrations achieve greater predictive accuracy than traditional parametric regression. Notably, the method is able to achieve superior goodness of fit and predictive accuracy in determining credit rating migration than models employed within the extant literature.

INTRODUCTION

Credit rating migration is one of the most significant concerns for institutional lenders and investors alike. Credit rating migration is a risk that individuals or financial institutions are both exposed to. In essence, rating migration is the worsening or upgrading in credit rankings, assigned by an independent ratings agency. There are a number of studies that have employed both parametric and non-parametric methodologies to forecast financial outcomes, employing machine learning methods; and notably,

artificial intelligence methods becoming increasingly popular, (see inter alia, Martinez et al., 2016). There are only a handful of studies on employing artificial intelligence methodologies to determine their ability to predict changes in credit status. Bhattacharya (2006), found that artificial neural network models had outperformed linear discriminant models; the study gave rise to further studies employing neural network models (see inter alia D'Rosario, 2017). Given the advancements achieved in artificial intelligence methods, such methods can now be employed more efficiently and robustly in application to financial research. The present study seeks to predict credit migration of sovereign ratings in Latin America, employing a multi-layer perceptron, artificial neural network model.

The present study is timely in light of changes to the Basel Accord. The Basel accord has generated interest in credit ratings methodology and prediction since banks and financial institutions employ the prescribed risk weights to determine the probability of default and estimate capital adequacy requirements (Behr and Guttler, 2008). There is an increasing number of users interested to predicting credit migration and the probability of credit rating changes of the borrowers (Jarrow et al., 1997). A few studies have tried employing credit transition matrices (Jarrow et al., 1997). However due to variations in the credit quality of borrowers, various credit rating agencies quote variations in the rating of the same borrower, mainly due to the timing of the changes of credit rating, the current rating grade and various other factors (Hill, Brooks & Faff, 2010). It is noteworthy that the afore stated studies employ traditional parametric methods, rather than the contemporary artificial intelligence methods employed herein.

The critical aspect of credit rating of sovereign bonds is that they act as a signal in the market, which helps government issuers and corporations issuing securities alike to attract both domestic and foreign investment. As noted, there have been a number of studies predicting credit rating migration using credit transition matrices, while others employing financial time series data and associated time series estimation techniques, such as GARCH and related statistical tools in credit rating migration analysis. There is a genuine dearth of studies employing artificial neural network models to predict credit migration of sovereign bonds. Moreover, the majority of credit migration studies focus on individual credit ratings prediction and ratings migration. The present study addresses the dearth of research employing artificial intelligence methods and specifically multi-layer perceptron artificial neural network models to predict the migration of sovereign ratings.

LITERATURE REVIEW

Over the past few years Latin America has seen a change in how foreign capital is acquired. In the 1960's the alliance program provided assistance, the 1970's was when the commercial banks had an influx of funding due to the petroleum boom, which led foreign countries to lend aggressively to developing countries. In recent times these nations have become reliant on the IMF and other international agencies and other private sources (Sinclair, 2003). Apart from private funding, sovereign bonds and debt securities issued by government agencies are increasing in popularity in Latin America. Due to the rise in popularity, investors usually look at the credit ratings of major credit rating agencies, such as Moody's Investor Services, Standard & Poor's Rating service to assess the likelihood of default. As credit rating agencies have grown in importance and become a key intermediary between investors and borrowers and are nothing less than guardians of capital assigned to emerging markets (Sinclair, 2005).

In recent times due to the increasing complexity of financial markets, it becomes increasingly difficult to assess or predict the credit rating of governments/ sovereign bonds. The more effectively credit migra-

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

tion is estimated, the more efficiently capital can be allocated. The complexity of securities in facilitating credit risk transfers, securities such as credit derivatives and collateralized debt obligations (CDO), has led to increased complexity in how credit risk is shared with market participants (Ferguson, 2001). As such, recent sovereign defaults on foreign denominated debt have increased, the 1994 Mexican Peso Crisis, the 1997 Asian financial crisis, the 2001 credit failure in Argentina and the recent European debt crisis (Greece) have raised concerns within financial institution about their risk exposures in emerging markets. Financial institution & regulators use VaR models or the expected shortfall to price risky loans (J.P Morgan's Credit Metrics, 2018). Additionally, with recent acceptance of the Basel Accords, capital adequacy requirements have been set in place for financial institutions by regulators.

The amount (in terms of currency) of debt written off in a sovereign crisis has exceed any corporate default. In this respect, it is necessary that credit migration warrants particular attention when assessing risk. Sovereign credit migration is difficult, mainly due to lack of data, with samples being small in both time series and cross-sectional terms. To estimate credit migration with high accuracy becomes challenging when it comes to emerging markets since it requires sovereign bonds to transition from one category to another. It becomes difficult since the data on emerging markets goes back only a few years. One plausible solution to this issue is to look at corporate bonds within a given country (Jackson & Perraudin, 2000), but this approach inherently assumes that sovereign bonds credit migration process follows corporate bonds, while empirical evidence suggests otherwise. Fundamentally, sovereign bonds have much smaller spreads when compared with corporate bonds. Additionally, sovereign bonds have evidenced greater variation in ratings among credit rating agencies as compared to corporate bonds.

The use of neural network models to predict credit migration has only been a source of focus and enquiry in recent times. Linear discriminant models (herewith LDA) and the Artificial neural network models (ANN) were used to predict credit migration, where the ANN employed back propagation with 3 layers in Bhattacharya et al, (2006). In Bhattacharya et al, (2006) where the ANN was set against the linear model, the ANN outperformed the linear model comprehensively (see inter alia. Bhattacharya et al., (2006), Zhang et al. (2004)). In the context of credit migration, when governments default on their obligations, this has serious ramifications within the financial market. Beyond LDA, there are several studies that employ neural networks to classify corporations based on nine popular financial ratios (see inter alia, Odom & Sharda 1990, Alam et al. 2005, Kim & Kang 2010), and have evidenced prediction accuracies of up to 73%. Other studies in financial services research beyond credit migration also employ ANN models in financial data mining (n.b. Zhiang et al (2004) and Chen et al, 2003). The noted studies which employed Probabilistic Neural Network, identified Neural networks achieved higher returns when compared to traditional parametric investment selection methodologies.

It is notable that, the usual methodologies used to predict credit rating migrations use a discrete homogeneous Markov Process. This approach disregards, the timing of the ratings changes and the duration of each rating. Typically, discrete multinomial estimators were employed by the credit rating agencies (Carty & Forns, 1993) and produces zero probability for unobserved transitions (e.g. Aa to a default). Basel II supports having a 0.03% for such rare events (events of Aa to default). Additionally, Basel has a positive weight on sovereign bonds which moves from Aa to Baa, but this implies that the migration risk is constant over time which clearly simplifies their model (Carty & Forns, 1993). The duration of credit ratings affects the probability of the transition (credit migration). Lando & Skodeberg (2002) and Kavvathas (2001) both confirm earlier findings of Carty & Fons (1993) which states that the duration of the credit rating effects the Corporate ratings but evidence on the sign of the ratings are mixed.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

There are two notable studies which look at sovereign bonds credit migration risk, namely Wei (2003) proposes Markov Model which accommodates time heterogeneity, but the sample size of the study was relatively small. Hu et al. employ a substantially larger data set and employ a probit analysis offering a more robust set of findings. Both studies achieved modest predictive accuracies, but are pertinent and serve to inform the present study. In this regard, much of the extant of the studies use linear statistical model to estimate sovereign credit migration. Other proximate studies that use Artificial neural nets study corporate bankruptcy, personal insolvency among other areas of study, while omitting credit rating migration. Our research seeks to employ artificial neural networks to estimate sovereign credit rating migration risk with the intention of providing robust and accurate predictive models.

An Introduction to the Multilayer Perceptron

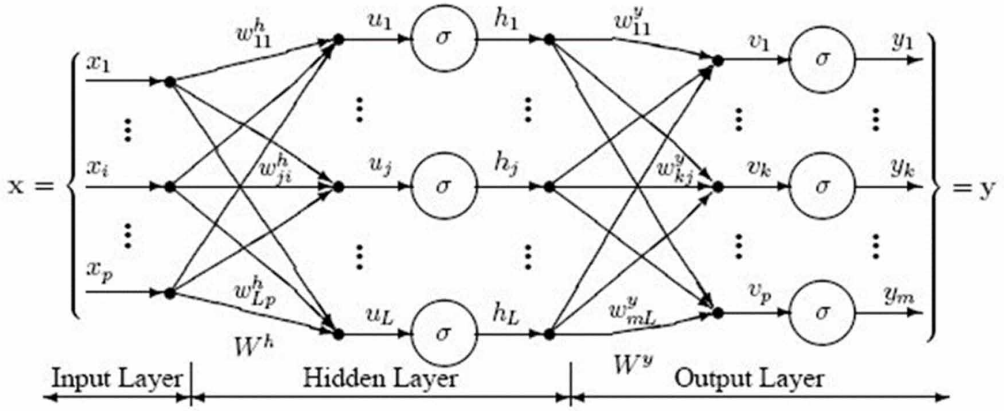
While traditional statistical methods have some restrictive assumptions such as linearity, normality and independence among variables, there remains the need for further acknowledgement of the benefits associated with parametric estimation methodology within the law and economics, the so called second wave of law and economics (Richardson, 1989). Considering these assumptions of the statistical methods, financial data constantly violate these assumptions. Hence the methods can have limitations in validity and accuracy (Elliot & Kennedy, 1998). It is apparent that novel non- parametric methodologies are made possible by modern computing technologies which represent an important sphere of inquiry. In particular, the advantages of multi-layer perceptron models & artificial neural networks, in comparison to logit models when modelling complex nonlinear processes, a number of recent pertinent studies have sought to advance the role of artificial intelligence methods within finance & financial research studies. There remains however, only a small number of studies employing artificial intelligence methods when addressing credit migration of sovereign bonds. With the advancement of computing power and artificial intelligence, soft computing methods specifically when applied to predicting credit migration, include backward propagation and probabilistic model's neural networks, these models unlike traditional statistical methods offer qualitative tools which statistical methods can't estimate (Bhattacharya et al., 2006). The biological structure of a neuron is complex to model, but a non-parametric predictive model, i.e., the multilayer perceptron model is a form of artificial neural network model (herewith MP-ANN), that seeks to replicate it, essentially it is a series of weighted, aggregative, non-linear values.

Artificial Intelligence being the main body of research led to the emergence of neural network models. Given that neural network models is a form of AI, it therefore attempts to model the process of learning which in part resemble the human brain (Patterson 1996). Since the MP-ANN model (Figure 1) has the potential to estimate more accurate outcomes than traditional statistical models, it is well suited to shed light onto the present research study (D'Rosario, 2016). The work of Minsky & Papert (1969) asserted a number of the limitations of the perceptron model which led to a fall in interest in perceptron modelling. Although the perceptron model has its advantages over the traditional parametric estimation models, the key area of challenge in the perceptron model as posited by Rosenblatt was the step function that made it problematic to train the neural network (D'Rosario 2016). Rumelhart, Hinton and Williams research work on "Learning Internal Representations by Error Propagation", offered resolution to the problem of training the neural network. Their work enabled the effective training or a multilayer neural network through backpropagation training method and viable algorithm which was first asserted in Rumelhart and McClelland (1986); it was the first practical method for training neural networks (D'Rosario, 2016).

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

The ANN gets more efficient with each training iteration by adjusting positive weights when it predicts the right outcome. Although the work of Rumelhart, Hinton & Williams citation needed had posited a practical solution for training neural networks, which makes the ANN useful when a model is unknown since it can learn from the data set.

ANN are good at grouping data for classification, which has made such methods more efficient than other traditional parametric models in predicting outcomes. This discover has made neural networks become of significant interest in the financial industry, since vast amounts of historical financial data are available to train ANN models. Increasingly, the use of such methods has not only made it easier to accurately predict financial outcomes, but it also outperformed traditional statistical approaches (n.b. Schoneburg (1990) & Francis et al. (1994)).



The image below is a visual depiction of a Multi-layer perceptron model:

This visual depiction is of a multi-layer perceptron model, a popular ANN structure (though more layers are possible, nonetheless there stands a significant increase in resources required for multiple hidden layers being employed). The multi-layer perceptron is constituted by an input layer, hidden layer and an output layer. The first layer being the input layer. The input layer processes and standardises a vector of the predictor variables ($x_1...x_p$). These variables then take the range of -1 to 1. These standardised values are then passed through to the hidden layer. This process loosely resembles the process of "saltatory conduction" with a biological neuron.

The standardised vector values of the predictor variables, for example standardised vectors of macroeconomic parameters such as inflation or GDP, reach the hidden layer. At the hidden layer, the standardised values are multiplied by a weight (w_{ji}), with the weighted values aggregated (u_j) and passed forward to the transfer function. The values from the transfer function are passed to the output layer (h_j) (D'Rosario, 2017b).

The output layer accepts the values from the hidden layer, multiplying the values by weights (w_{kj}), with the weighted values then aggregated resulting in a composite value v_j. The v_j value is then passed forward to the transfer function. The values from the transfer function are the model outputs y_k. Should the target variable be dichotomous, then there will be *2* neurons in the output layer producing *2* values,

Figure 1. Conceptual diagram of MPANN

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

one for each of the categories of the target variable. Where the output value takes greater than to values ($y_k = n$), then the output layer will be constituted by n values. The present MP-ANN outputs are denoted by the ordinal scales of the ratings agency ratings for the selected countries.

Beyond Parametric Regression, Can Neural Models Predict Credit Migration with Improved Accuracy

The use of such methods is not uncommon in financial studies but remains relatively underemployed within sovereign bonds ratings migration. There are several studies which employ OLS estimators to determine credit migration. Cantor & Packer (1996), Horrigon (1966) & Vaaler & McNamara (2004) are a few papers which have used OLS estimators to estimate credit migration. Given the simplicity of this approach, the model in some aspects is easy to interpret, but the main drawback of the model, if any, in setting a panel due to panel heteroskedasticity of the errors, which leads to inconsistent standard errors for the panel data. Due to such errors, panel corrected standard errors were used to accommodate for such variation. Beck & Katz (1995) had employed this approach to solve for the issue, but this method assumes that heteroskedastic errors/ disturbances are correlated across the panel. This is an issue since it fundamentally assumes correlation across the panel, which in part may not be true, i.e., for instance, tax reform, recession, GDP per capita a correlated and have similar effect across the panel, but may not be true when it comes to other variables in a model. The studies show that while quantitative data can be accounted for in the estimations, qualitative data such as, tax reform & liberalisation of trade can't be accurately accounted for in the model.

A related area of study by Elena et al. (2007) which uses transition matrices & hazard rate estimators to determine the risk of sovereign credit migration. However, the study tested the model for a Markov-Process, with spectral analysis and logit models for the transition matrix, both of which implied that it followed a non-Markovian process. But the Markovian process assumes that transition probability remains constant over time, which inherently means that the model can't accommodate for momentum and duration effects.

The use of Artificial Neural Nets in recent studies has increased partly due to the advancement of technology and deeper understanding of neural nets and lastly, not to ignore the fact that neural networks are more accurate than traditional statistical models. Zhang et al. (2007) which used neural networks in financial data mining, showed that it could effectively forecast financial time series data, although the accuracy was about 56.3%, nonetheless it still resulted in the neural network could achieve a 3-fold gain in profit as compared to buy and hold investors. It can also be noted that the model did better in bear market conditions than bull market, which suggests that the data mining system was better at managing risk.

Furthermore, studies carried out by Francisco Venegas-Martinez et al. (2013) which studied the effectiveness of ANN models with respect to financial time series data. In the paper, the authors posited that, the Multi-layer perceptron was the best ANN model when it came to forecasting financial time series data, which is the main reason it is widely used in the financial industry. Mainly due to the MLP being a feedforward model and the model inherently, unlike traditional statistical models, have no underlying assumptions.

Bhattacharya et al. (2006) had looked into the effectiveness of linear discriminant analysis (LDA) models versus ANN, which indicated that the ANN had outperformed the LDA by 79% to 33.33% when it came to a blind set test, although there were large unexplained variations in the models, it was mainly due to the fact that the data used were financial ratios and it suggests that CRA's don't just use financial

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

ratios when it comes to corporate credit rating. This is not to say that the model has no technical variation, but it shows the effectiveness of ANN over LDA models. Nonetheless the study concluded by suggesting that the ANN can deal with more complex models and doesn't require inherent assumptions such as normality & linearity. Given that most of these studies that use ANN models, study financial time series forecasting & corporate credit migration, not many have used it to predict sovereign credit rating migration and this study in particular would shed light on that area of finance.

Model Structure and Parameters

The model seeks to predict credit migration on sovereign bonds, given a series of macroeconomic, legal and demographic variables. Specifically, the specification models the movement of sovereign bonds, either them being upgraded or downgraded. The model is a single layer network where Risk of credit migration, the dependant variable is a multinomial variable taking the values of the ratings scale converted into numeric form.

The ANN model employed — the MP-ANN model — is a multi-layer model with an input layer deriving from the variables provided by. The dependent carriable credit rating is the variable denoting the credit rating assigned by each of Moody's and S&P respectively. The rating agency is a variable used to denote which credit rating agency appraises the bond. Rating (lagged) is the latest or the most recent credit rating given to the bond. Inflation denotes the rate of inflation within each jurisdiction in average terms during the preceding year. A number of other macroeconomic variables are included in the specification, listed in the table summary below. All variables derive from the noteworthy study of Biglaiser & DeRouen (2007).

The first layer is the input layer. The input layer processes and standardises a vector of the predictor variables, herein the macroeconomic, governance and stability variables. These variables then take the range of -1 to 1. These standardised values are then passed through to the hidden layer. This process loosely resembles the process of "saltatory conduction" with a biological neuron.

The research data is of 16 Latin American countries for 1992-2003, these years were used since market reform had impacted nearly all the Latin American countries during this period. The table below (Table 1) illustrates summary statistics of the data set.

The Dependent Variables in the Model

The sovereign bond ratings are sourced from S&P & Moody's, was used since these rating agencies are the most commonly employed and utilised ratings service providers in the world and were used extensively during this period. Additionally, Bloomberg international (2005) was used to collect data on ratings migration changes of ratings of the above stated bonds by the credit rating agencies. Since the credit agencies followed a lettered system of rating bonds, it was normalized to a 17-point scale, with 0 being the lowest credit ("C") score and 16 being the highest ("AAA").

The Independent Variables in the Model

While a number of specifications were employed as part of the initial study estimations, The standardised vector values of the predictor variables, Lagged rating, tax rates, Rating Agency, COM (commercial index), FRI (financial reform index), PRI (privatisation index), CPI (unlagged), Current account balance

External debt/GDP	117	0.3945228	0.1451298	0.18904221	0.129269

(% of GDP) (lagged), External Debt (lagged), GDP (Current), Budget Balance, GDP (constant 1995 US$, lagged), GDP growth (lagged) were found to be sound parameters for inclusion in the representative specification. These variables are consistent with the extant literature and the comparative study of

The hidden layer size was determined based on Heaton's work, noting optimality generally exists between the number of input layers and output layers (Heaton, 2011). Moreover, two hidden layers may be employed when modelling data that evidences discontinuities, such as a saw-tooth wave pattern. Given the nature of the underlying dataset, this is not the case. The use of an additional hidden layer reduces estimation efficiency and offers no improvement to the model. Herein, a single hidden layer model is employed to avoid a greater risk of converging to an incorrect local minima. One potential shortcoming of the selected methodology relates to the efficiency of ANN models in accommodating non-numeric variables, commonly referred to as dummy variables in economics. This is, however, only the case where non-numeric variables can take a large number of values, which is not the case in the present study. The total number of units employed in the model was 16, and determined through optimisation, again indicating interaction effects.

Data pruning techniques were not employed to improve model resolution, and the model performed efficiently and robustly absent of any node reduction. As such, the input values remain the same as those employed in Biglaiser & DeRouen, (2007). This is pertinent as it ensures that each predictive modelling framework can be compared on equal terms employing the same parameter set.

Table 2. Variable descriptions

Variable Name	Abbreviation	Definition
Moody's Bond rating/ S&P Bond rating	Rating	These variables denote the score given to a (default risk) sovereign nation/government.
Financial reform	FRI	Financial reform being the policies/laws that influence investments and other capital flows into a nations' financial system, where liberal policy positively impacts the bond rating and protectionist policy have a negative impact on it.
Privatization	PRI	Denotes privatisation status of key utilities. Privatisation is the purchase of all outstanding shares of a publicly traded firm/ the sale of a state-owned firm into the private sector.
Tax reform	TAX	Changes in tax laws in a country.
Capital Account Liberalisation	CALI	A measure of international financial liberalisation.
Honeymoon	Honeymoon	Honeymoon referring to the newly elected officials have more freedom implement reform.
Polity (Democracy)	Polity	The political environment which consists of Political position of a nation (democratic/ Authoritarian), the president's ideology, IMF agreement & election cycles
Election year	Election	Elected year is election cycle of a nation, which represents the change of leadership.
President's ideology	Ideology	A scale measure of Presidential ideology. President's ideology also influences economic reform since leftist presidents oppose such reform which lead to job losses/price hikes.
IMF agreement	IMF	Variable denoting whether IMF agreement is in place. IMF agreements positively influence bond ratings since it signifies economic reform
Inflation	CPI	A sustained increase in general price levels measured by a basket of goods and services over several months or a fiscal year.
Current account balance	Current Account Balance	Consisting of the balance of payments, net transfers and net income.
GDP growth	GDP	Rate of change in economic production. Economic growth is an increase in the capacity of an economy to produce goods and services compared from one period to another.
GDP per Capita	GDP Per Capita	This measure compares the GDP on a purchasing power parity basis, which is divided by a country's population.
Bond default	Bond Default	Bond default measure whether a nation has previously defaulted or the percentage of bonds which have been written off as a loss.
External debt/GDP	External Debt	External debt/ GDP is the amount of outstanding debt that a nation borrows from the public/foreign investors and divided by the GDP of the nation.
Commercial Index	COM	This variable indexes measures trade liberalisation based on tariff policy.
Budget Balance	Budget Balance	This variable captures the government budgetary balance capturing whether it is in deficit or surplus.

MODEL FINDINGS

The MP-ANN is able to robustly predict the risk of credit migrating risk at 98.5% accuracy, while the model was trained, which showed that the increased accuracy and far greater goodness of fir than traditional Regression models. This finding suggests that the variables in the model are useful in determining the outcome/risk of credit migration. The model is capable of robustly and more consistently determining the outcome of credit migration than traditional regression model previously used in this area of study. Though it needs to be noted that when the model came to testing phase, its accuracy dropped slightly to 75.5%, which suggests that it still is better at predicting credit migration risk than traditional regression models. Table 2 shows the prediction accuracy of the model during training and testing phases.

Dependent Variable: Rating													

In terms of training the model, 70% of the data set was used to train the neural net and 30% was used to test the model. In essence, a neural network is ideal when it can be used to predict outcomes which it have not seen before. This makes the neural net a lot more accurate when it comes to estimating non-parametric models than traditional regression models.

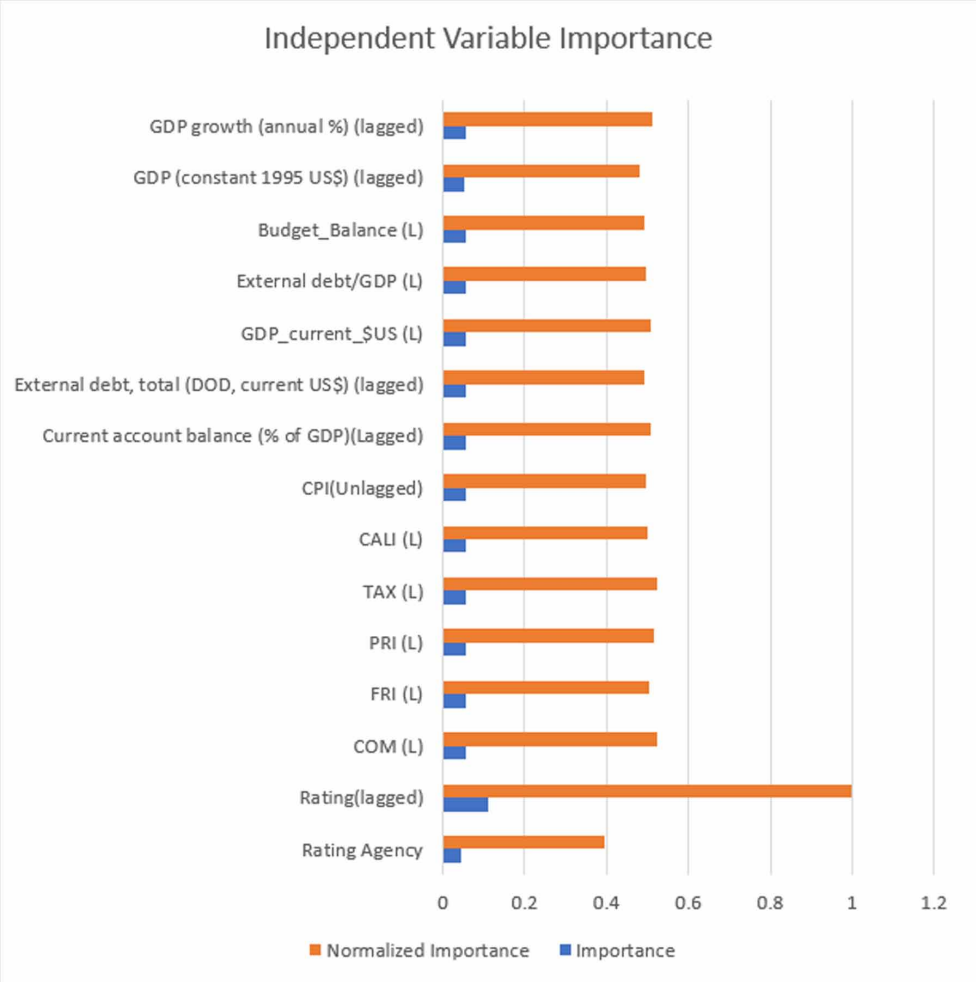
As seen in Table 3 the correlation or r-squared for the estimated model is at 0.956, which suggests that the MP-ANN explain 95% of the variation in the estimates. Generally, when this is compared to a traditional regression model, the r-squared values of multi nominal logit models employed in comparable specifications within the earlier citation study achieve only modest goodness of fit relatively speaking

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

suggesting that the neural network is capturing significant threshold and interaction effects not captured within the comparable multinomial logit specifications. this suggests that the MP-ANN model is better when it comes to a measure of goodness-of-fit.

The goodness-of-fit measures suggest that the MP-ANN is superior to the logistic model in the Biglaiser & DeRouen study (Biglaiser & DeRouen, 2007). While the former study model remains empirically sound, it does not achieve the same level of predictive accuracy. The findings suggest that this model is more predictively capable, with an improvement in predictive accuracy of a minimum of 14 per cent. This is amongst the most notable contributions of the present study. The study makes clear the benefits associated with non-parametric methods of prediction in credit migration research and the benefit of MP-ANN modelling in the development of predictive models in the judicial sciences.

Employing the methods of Garson (1991) and Goh (1995), the normalised importance analysis (Figure 2) suggests that the lagged rating variable ranks as the most important determinant of credit ratings, followed by the TAX measure and the GDP variable. The data is presented graphically below. The variation in the hidden layer structure yields comparable results and robustly achieves a 100 percent predictive accuracy. Thought that it is notable that the relative ranked importance of GDP and PRI was reversed in some model specifications, lending credence to the assertion that government effectiveness may be of equal importance to the importance to the privatisation program of an economy when determining the credit rating predication. These findings are broadly consistent with the findings of the Biglaiser & DeRouen, (2007) study, with a few notable points of difference (n.b. Biglaiser & DeRouen, 2007).



Firstly, unlike the Biglaiser & DeRouen study, the current study indicates that GDP, TAX, COM and as anticipated lagged rating and the ratings source (i.e. Standard & Poors, or Moody's, denoted by the variable ratings agency) rank as important to the ratings prediction. Additionally, the network results

Table 4. Normalized variable importance

	Importance	Normalized Importance
Rating Agency	.044	39.3%
Rating(lagged)	.112	100.0%
COM (L)	.058	52.2%
FRI (L)	.056	50.4%
PRI (L)	.058	51.5%
TAX (L)	.058	52.2%
CALI (L)	.056	49.9%
CPI(Unlagged)	.056	49.7%
Current account balance (% of GDP) (Lagged)	.056	50.6%
External debt, total (DOD, current US$) (lagged)	.055	49.4%
GDP_current_$US (L)	.057	50.7%
External debt/GDP (L)	.055	49.7%
Budget_Balance (L)	.055	49.4%
GDP (constant 1995 US$) (lagged)	.054	48.0%
GDP growth (annual %) (lagged)	.057	51.2%

Figure 2. Independent variable importance analysis

suggest that threshold and interaction effects may exist between key independent variables GDP, COM and TAX. Again, noting that substantial improvement in pseudo R-Squared values ranging between 0.65 – 0.81 in contrast of the present study of 0.95 to 0.97.

CONCLUSION

The study has made clear the predictive gains associated with MPANN modelling and specifically non-parametric modelling in financial research. The findings indicate the predictive techniques utilised herein may be more beneficial than logistic models when emphasis is placed on outcome prediction rather than casual association which is pertinent to ratings migration. The study suggests that while logit and probit models are useful exploratory tools when engaging in empirical work and can accommodate non-linear problems; they appear to be less able to accommodate non-linear problems with complex interactions as efficiently as multilayer perceptron models. Moreover, they are incapable of accounting for thresh-

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

old or interaction effects unless explicitly specified within the estimation particularly important when the desire is to engage in a predictive exercise. Further research is necessary to determine the potential generalizability of this claim. The notion that perceptron modelling may be beneficial and potentially superior in financial services and social sciences research when focused on predictive accuracy represents the first contribution of the study. A further contribution of the study is its response to the dearth of studies employing empirical methods to credit rating migration research, and in particular methods beyond logistic regression and linear discriminant analysis.

Importantly the current research displays the potential benefits associated with big data capture efforts when employed with modern parametric estimation techniques. The MP-ANN models may be highly effective tools in determining the relative importance of independent variables and the model of estimation to employ when engaging in casual analysis pertaining to rating migration. Moreover, the modelling methodology employed herein evidences the benefit of the presented empirical technique in predicting migration at high levels of accuracy with minimal variation in predictive outcomes relative to reality. Critically, the role of MP-ANN models in empirical financial research is advanced based on the notion that such models require heuristic knowledge pertaining to data preparation and cataloguing, and sufficient technical knowledge to employ the appropriate ANN for the estimation. The ANN models are more conceptually simple than linear modelling techniques (albeit more mathematically complex); not to mention seemingly more appropriate for modelling complex processes that replicate decision models, thus supportive of greater potential adoption by the financial services fraternity. It would be apt for future research to consider the potential application of probabilistic neural networks to such financial analysis of credit migration to discern its potential efficacy.

ABSTRACT

Multiagent systems have been a fascination for research community and are often seen as an intelligent solution to many complex real world problems. Researchers have been active in the domain since last three decades and many developments pertaining to theoretical design and practical developments of multiagent systems are worth appreciating. The growth in MAS is multidirectional ranging from conceptual ideas to practical implementations and from the wide range of applications; it appears that multiagent systems are proving to be universal. The paper presents a concise survey of developments in MAS highlighting the important contributions in the field and also questions the universal applicability of agents.

INTRODUCTION

With the transformation from individual computing technologies to self-motivated distributed systems, a lot many research opportunities and threats have evolved. Dynamic and open environments (Shakshuki, Ghenniwa & Kamel, 2003) extent across business boundaries where in heterogeneous systems (Sycara, 1998) not only cooperates but also operate reactively and proactively. Such systems are capable of adapting to rapidly changing environments and are also able to respond to complex queries in real time. However, such systems demand high degree of autonomy (Barber & Martin, 1999; Lange & Oshima, 1999; Suzanne

DOI: 10.4018/978-1-7998-0951-7.ch006

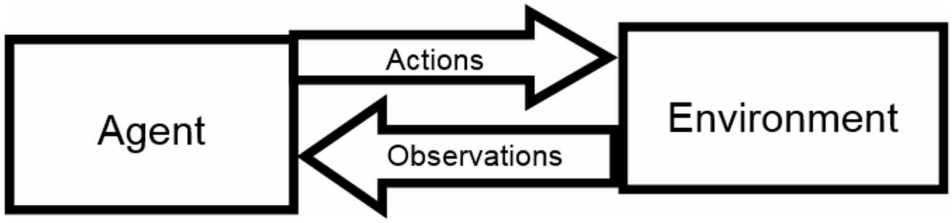
Barber, Goel & Martin, 2000) which actually becomes a threat. For instance, web services (Alberti, Chesani, Daolio, Gavanelli, Lamma, Mello & Torroni, 2007) are the most sought after way of carrying out business activities as it offers service oriented architecture where in divergent and self-governing software components interact to offer automated solutions. Such automated systems are employing software entities more commonly known as software agents (Mařík & Lažanský, 2007; Pěchouček & Mařík, 2008) that offer powerful solutions to the emerging issues and are also able to manage the complexity of entire system. Since 1990, agent-based computing (Graesser, Jeon & Dufty, 2008; Nwana & Wooldridge, 1996; Nwana, 1996) is attracting community of researchers and lot many developments and changes can be seen in the technology. Simply speaking, a software agent is a software component capable of carrying out rational and self-directed actions in a typical multi-agent system (Panait & Luke, 2005; Hoek, Wiebe & Wooldridge, 2008). Agentsare finding applicability in a miscellaneous array of domains including intelligent manufacturing (Shen, Hao, Yoon & Norrie, 2006), traffic and transportation systems (Chen &Cheng2010), communications (Manvi & Venkataram, 2004), industrial process control (Mařík & Lažanský, 2007, Metzger & Polakow, 2011), Military applications (Cioppa, Lucas & Sanchez, 2004), geographical systems (Heppenstall, Crooks, See & Batty, 2011), optimization problems (Barbati, Giuseppe& Andrea, 2012), disaster management (Fiedrich & Burghardt, 2007)and many more.

AGENT BASED COMPUTING: IS IT SUPREME THAN ITS COUNTERPARTS?

The concept of software agents have evolved from Distributed Artificial Intelligence (DAI) (Ferber, 1999) research which was conducted about 3 decades ago.Carl Hewitt proposed an Actor system (Hewitt, Bishop & Steiger, 1973)and defined actors with clear internal definitions with the potential to communicate with peers in the system. The succeeding developments focused on making intelligent actors now known as software agents where the word agent has evolved from Greek word '*agein*', which implies to guide (Milojicic, 2000). The term is being explored by research fraternity continuously and many reports pertaining to the developments in agent oriented techniques that enable a more active role of the computers in knowledge acquisition have been contributed. In the domain of computer science, a software agent is a special software entity dedicated to perform an assigned task on behalf of a human or an object (Nwana, 1996).

Following definition has been adopted from (Smith, Cypher & Spohrer, 1994) and the agent is known as KidSim Agent, in particular.



…an agent is a persistent software entity dedicated to a specific purpose. 'Persistent' distinguishes agents from subroutines; agents have their own ideas about how to accomplish tasks, their own agendas. Special purpose' distinguishes them from entire multifunction applications; agents are typically much smaller. (Smith, Cypher & Spohrer, 1994)

Franklin and co-authors define an agent as

… special software entities carry out some set of operations on behalf of a user or another program with some degree of independence or autonomy, and in so doing, employ some knowledge or representation of the user's goals or desires… (Franklin & Graesser, 1996)

Figure 1. Agent Interaction Environment

Defining it more precisely, A Software Agent is

… an object of the environment that can be viewed as perceiving its environment through sensors and acting upon that environment through actuators… (Russell, Norvig & Intelligence, 1995)

Figure 1 represents the agent interaction environment.

Study in this domain reveals that the agent paradigm is an extension rather than a replacement of conventional systems that are either object-oriented or component-based. The software group at MIT[1] compared and contrasted software agents to conventional software and concluded that software agents have longer life, partially autonomous and these can be designed to behave proactive as well as adaptive.

Another popular definition of agent states that

… Autonomous agents are computational systems that inhabit some complex dynamic environment, sense and act autonomously in this environment and by doing so realize a set of goals or tasks for which they are designed… (Maes, 1995)

According to the definitions, software agents are good to be employed as subordinates, memorize important tasks, wisely recapitulate intricate data, acquire knowledge from user's actions and hence recommend on the topics of user's interest (Maes, 1994). Realm of software agents has fascinated the researchers to a great extent because of its significant properties (Bauer, Jörg & Odell, 2001) (see Table 1) as compared to object oriented and expert systems, which make it stand ahead of its counterparts.

Though the concept of software agent looks much like the conventional objects of OOP, it differs from later in terms of being autonomous or the self-initiating-property. However, an agent may or may not possess all the above-mentioned characteristics for acting in an agency. They can in fact, function efficiently even by possessing some of the features. The taxonomy of agents, depending upon the properties they possess is given in the next section. Since the origin of agent-based computing, researchers have shown non-consensus over defining agents and different research community has been defining them according to the situation in which these have been employed. In general, an agent situated in an environment should be autonomous and flexible (Franklin & Graesser, 1996).

Here, situated in an environment implies agent is proficient of accepting input from the environment and hence carry out the actions which may change the state of environment. The actions may be carried out autonomously without direct intervention of human user (Russell, Norvig & Intelligence, 1995). Most popular and common examples of such intelligent systems are simple thermostats (Jennings, Sycara &

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 1. Comparison of agents, objects and expert systems

Entities / Properties	Agent	Object	Expert system
Social	Include social ability	Have social ability	Lack social ability
Autonomous	Can work independently	Need command to invoke	Can work on their own
Reactive	React to changes in their environment	React to change in input values	Work on input provided, only when commanded
Adaptable	Change as per preferences of the user	Work as per the input values	Work as per the input values
Intelligent	Can handle uncertain or new situations	Can work only for specified situations	Can handle uncertainty to some extent
Goal Oriented	Plan actions to achieve a goal	Works to solve a problem	Works towards specified problem
Mobile	Can move with its data and instructions	Can't port	Can migrate
Learning Ability	Can learn from user behavior	Don't have provision to learn or change on its own	Can learn from user behavior so can update itself
Pro-Activity	Can initiate actions to change the environment	Works only on command	Can initiate actions

Wooldridge,1998). However, these systems offer no flexibility so these are not pure agent based systems. A flexible system must be either reactive or proactive and should respond to change in state of the system well within time. In order to respond actively and accurately, the agent should be social and when required should interact with its environment including humans to resolve a problem. Some other desired facets of being agents are mobility, adaptability, learning and responsive. It is these properties that make agent-based computing more supreme than its counterparts such as object-oriented systems, distributed systems, and expert systems (Jennings, Sycara, & Wooldridge, 1998).

It is obvious from the above discussion that an agent based system comprises of many agents making it to be a multi-agent system (Vigna, 2004; Weiss, 1999; Wooldridge, 1998) (see Figure 2) where many agents cooperate, coordinate, negotiate and communicate to solve problems. Numerous heterogeneous agents offer variety of problem solving methods with different viewpoints. In fact, these flexible interactions make MAS more powerful than conventional software systems.

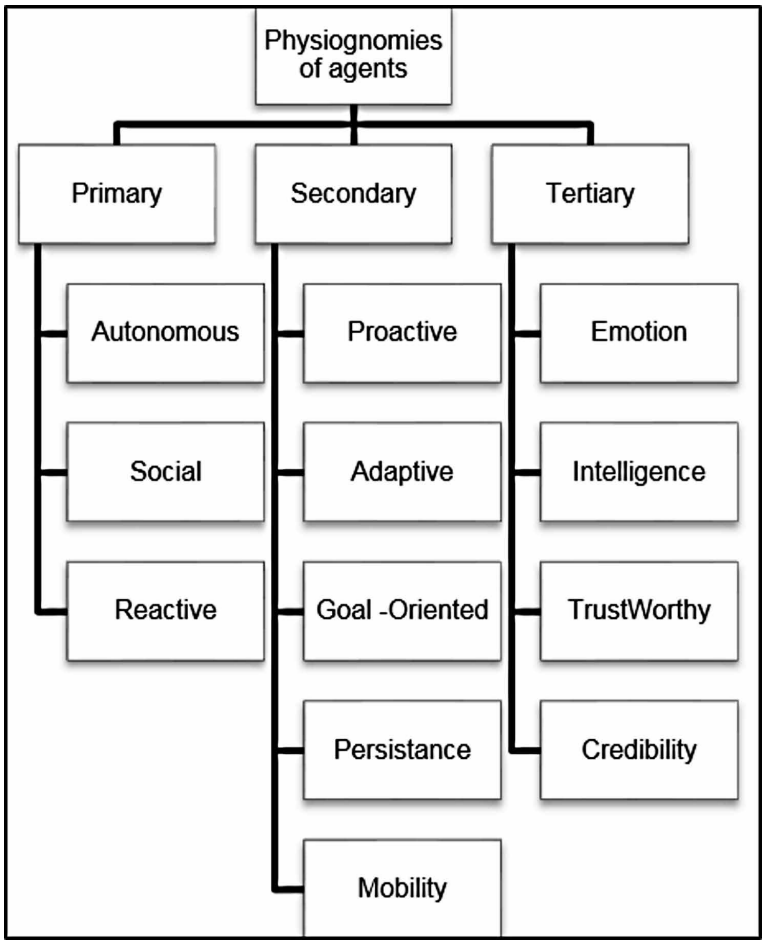
MULTIAGENT SYSTEMS: THE THEORETICAL DEVELOPMENTS

The emergence of software agents has offered a different perspective of understanding and hence developing the complicated software systems. In fact, the technique offers new tools and methods to design the software applications ranging from simple to complex real time control systems. A multi-agent system encapsulates the complexity of the complex software systems and hence presents an abstract and a simple view to its users. Researchers (Laghari & Niazi, 2016; Sim, 2012) are finding the field interesting and available literature (Barbati, 2012; Barbati, Giuseppe & Andrea, 2012; Dam, Governatori, Ito & Xu, 2016) indicates that lot many efforts are being put to improve the computing. On contrary, few works (Brooks,1991a; Brooks, 1991b; Chapman, 1987; Jennings, Sycara & Wooldridge, 1998; Vigna, 2004) also reflect that with the level of activity going on, the computing may become frenzy and disjoint. The section talks about the developments in MAS restricting to physiognomies, categorization, agent communication and the concept of ontology.

Physiognomies of Agents



The penetrating agent based approaches demanded for a concrete definition and the classification of agents. The developments projected many independent and application specific definitions (Genesereth & Ketchpel, 1994). At present, several definitions exist however, each definition reflects that all agents are expected to possess some basic characteristics that define the behavior of every agent. For instance, BDI agents (Rao & Georgeff, 1995; Sharma & Juneja, 2006) must show explicit beliefs, desires and intentions (Jennings, 2000), while Woodridge and Jennings (Wooldridge & Jennings, 1995) desire agents to be independent, responsive and societal. In addition, Franklin & Graesser (1996) lists agents as self-directed, responsive, communicative, learning, portable, rational, goal-oriented, and unremitting and should also have human like emotions. Using such definitions from the literature, it has been possible to create a set of primary, secondary and tertiary agent characteristics. Primary characteristics are inherent to most of the popular agent definitions while secondary characteristics are the set of extended characteristics usually associated with agents. The third set of characteristics contains more abstract, desirable, human-like features. Figure 2 illustrates the physiognomies of agents thus summarized from literature and further discussion regarding the same is being overlapped in the next section.

Categorization of Software Agents

Scientists have suggested numeral contemporary categories and criterion required for an entity to be termed as software agent. For instance, (Nwana, 1996) identifies three key attributes namely autonomy, learning and cooperation. The author further classifies these agents as collaborative agents, reactive agents, interface agents, information agents, hybrid agents, mobile agents and ants. Wooldridge and Jennings (Wooldridge & Jennings, 1995) distinguish agents to be weak agents and strong agents. While a weak agent is self-directed, societal, and responsive and takes the initiative, the strong agent follows Belief-Desire-Intention (BDI) model. Further, (Jennings, 2000) define an agent as "a computer system in an environment that can take autonomous actions to meet the objectives." Magedanz, Rothermel & Krause (1996) divides agents as local agents, networked agents and mobile agents, DAI-based agents and MultiAgent Systems (MAS) respectively. In addition, there also exist advisory agents acting as personal assistants (Nangle, Cunningham & Evans, 1998) supporting web browsing, searching etc. Number of

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

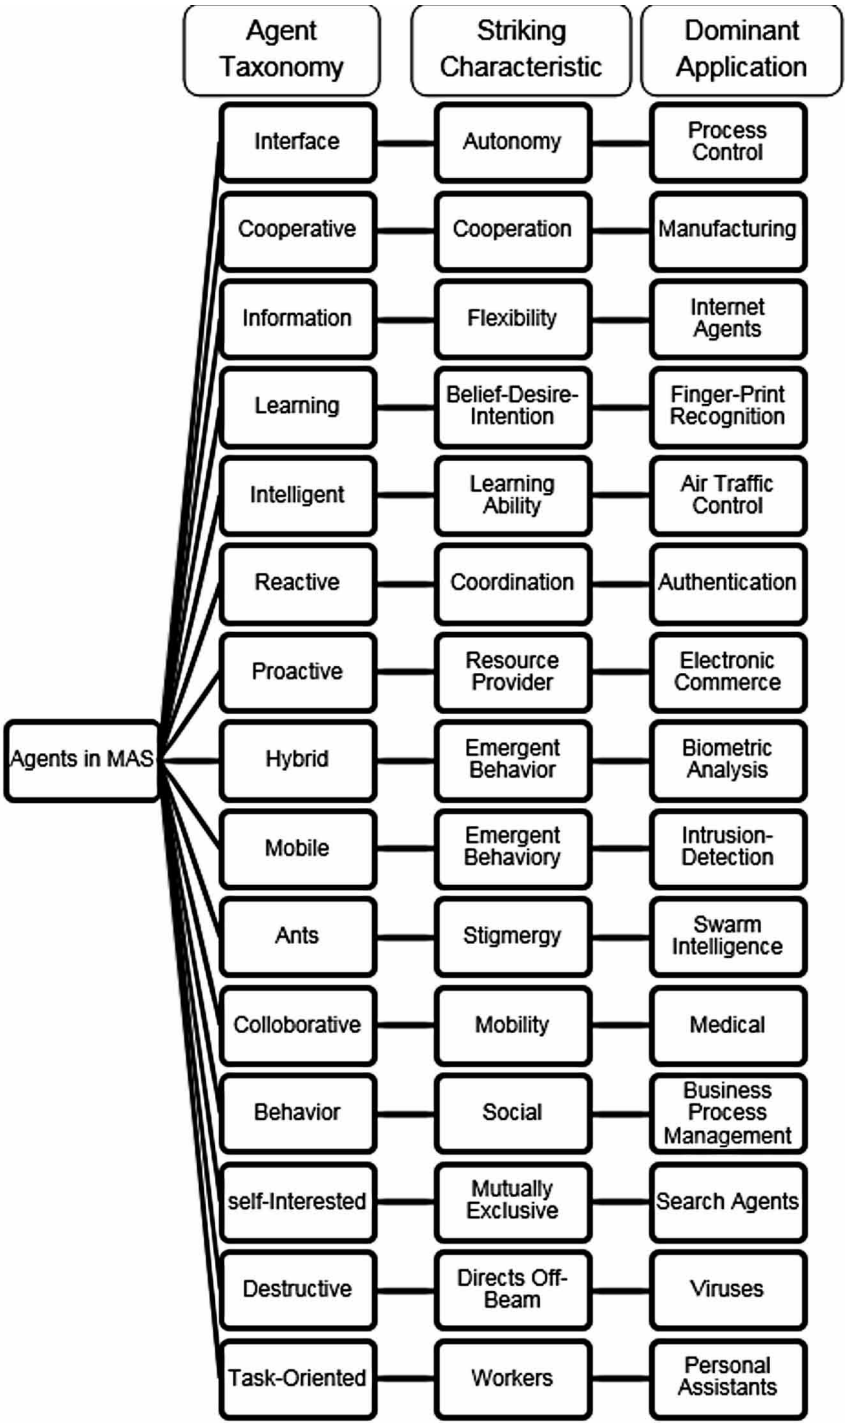
Figure 2. Physiognomies of Agents

researchers has classified agents as task-specific and performative agents (Etzioni & Weld, 1994), (Heger & Koen, 1991), (Sycara, Pannu, Williamson, Zeng & Decker, 1996) such as search agents, navigation agents, information agents, softbots, knowbots, infobots, autobots, webbots and so on. Depending upon the responsibilities to be carried out and aims to be achieved, agents with different attributes is designed.

A critical look at the literature highlights that agents are classified (Brenner, Zarnekow & Wittig, 2012; Franklin & Graesser, 1996; Nwana, 1996 & Wooldridge; Nwana, 1996; Singh, Gulati & Niranjan, 2012) according to the behavior they present within and outside a multi-agent system. For instance, a collaborative agent cooperates with its peers to perform an assigned task. They possess social and communicative abilities. Every agent has some knowledge and experience of a particular domain and can also seek services of other agents having specialization in other domains. An interface agent provides an interface to users without explicit instructions from the user. These are possessed with autonomy, responsiveness, skill and user-friendly characteristics. The interface agent accepts input from the user and may delegate the same to other agents changing the state of environment. The interface agent might be designed to have learning abilities and hence can directly take decisions by observing user input over

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

long durations. Information agents gather information from various resources including the environment in which these are situated and support the smooth conduct of task. To an extent such agents can be treated as intelligent and hence are designed to be proactive, societal and autonomous. Reactive Agents upholds the continuing communication with the environment and peer agents as well. These are required to reactwell within time. An agent does not reflect the long-term effects of its actions, and does not consider the coordination of activity with other agents. A mobile agent is a special agent which in addition to the basic properties of agents also has the special ability to migrate in a distributed network of nodes. It carries code and data with itself. On completing the task in the destination node, such agents are required to return to the originating node. Ants are another type of agents which are alike mobile agents i.e. are possessed with ability to travel from hop to hop but the former ones can stay at the destination node even after task completion and during the next event, the last node visited becomes the originating node. A new form of software agents is known as SMART (System for Managing Agents in Real Time) agents. Such agents are self-organizing and agree to be the part of an entire multiagent system. The intelligent agents are agents with learning capabilities and exhibit adaptive behavior. They may or may not have social abilities. In addition to intelligent agents, developers are now designing agents having cognitive behavior and have named such agents as cognitive agent. The cognitive agents are being designed with the aim to work with minimum user intervention and should be self-capable similar to human beings.



Considering the above significant types of agents, it is evident that over the years the big community of information has been restructured into smaller elements called agents that are now possessed to have many abilities well suited to handle complex applications. In other words, groups of software agents can be treated as a dynamic collection of simple agents with self-describing interfaces who while progressing through their life span continue to collect the information in a "knowledge soup," and same is presented to the user according to the application in which these agents operate. In such an environment, individual agents do not manage the entire system to achieve the target where as they would interact and collaborate actively forming a multi-agent system (MAS) (Sycara,1998). In such a system agents integrate to provide the needed information and such a system in which a community of software agents works in collaboration and coordination with each other to realize a shared objective is called an agent-based system. It has evolved as a result of sociological relationships among agents. In MAS, at least one agent has an ascribed set of goals and other agents in the system may adopt the goal. On the basis of above study, Figure 3 concludes following types of prominent agents and their most striking characteristics.

Agent Communication and Interaction

In order to maximally utilize the potential of agents, agents form a multi-agent system and moreover, agents in a multi-agent system and an entire system in turn must communicate and interact to realize shared targets. Further, in order to establish the communication, various agents in MAS need to interact and hence these need a language to communicate, a commonly agreed upon ontology and also are required to follow certain rules known as Interaction Protocols. Upcoming sections briefly extract the literature to discuss the three prime components listed above (see Figure 4).

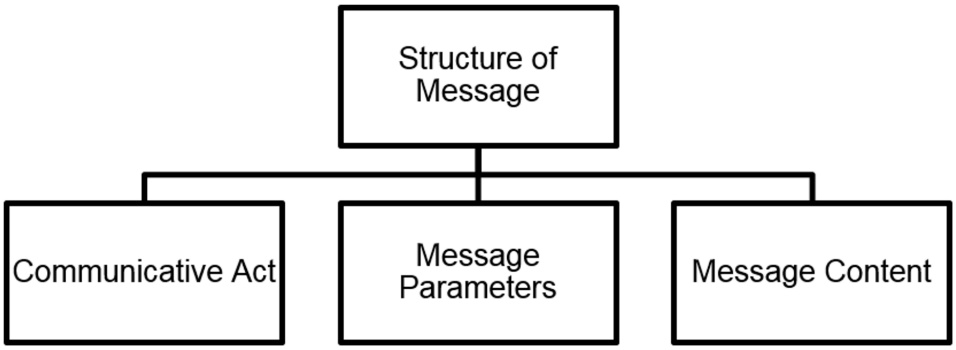
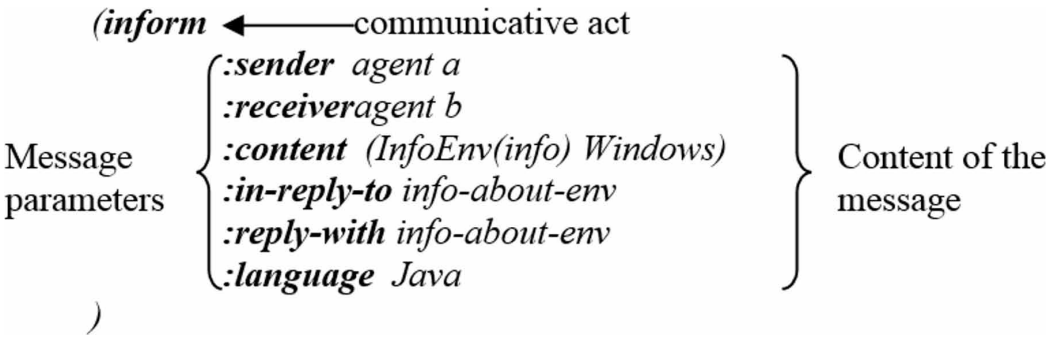
Figure 4. Components of Agent Communication



The Communication Languages

The communication languages for agent, more popularly known as Agent Communication Languages (ACL) (Kone, Shimazu & Nakajima, 2000) are utilized to exchange facts and figures among agents in multi-agent environment. ACL provides an interface that allows diverse agents to communicate with semantically true statement that deliver information about their environments. Although literature reflects many developments (Chaib & Dignum, 2002), (Labrou, Finin & Peng, 1999) in the domain of ACL but the most popular languages are FIPA-ACL, KQML, KIF.

A) FIPA-Agent Communication Language

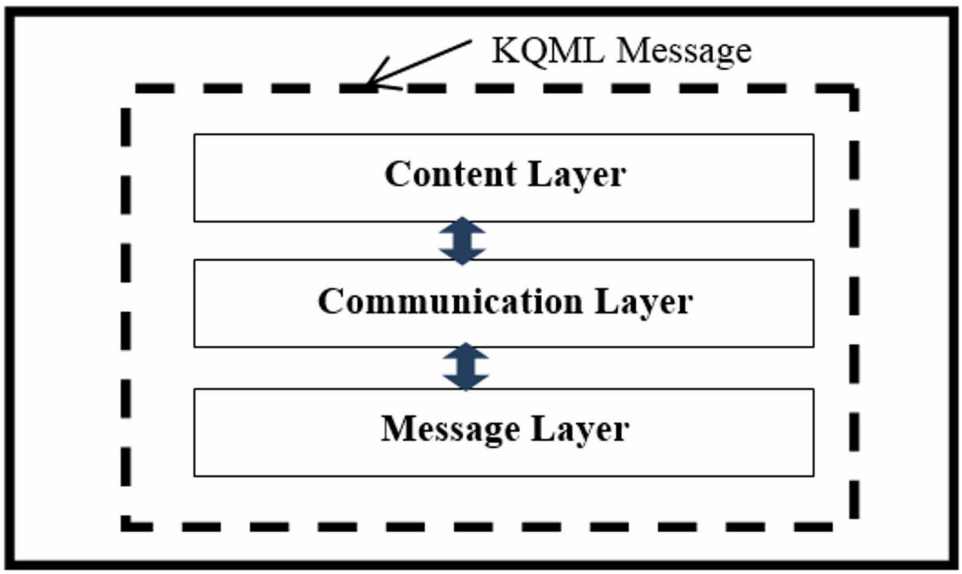


Specification for FIPA-ACL was proposed by Foundation for Intelligent Physical Agents (FIPA). The language enables interoperability between different agents and is adopted as the standard language for agent communication (Juneja, Jagga & Singh, 2015). Speech act theory forms the underlying backbone for FIPA-ACL and alike speech act theory, makes use of communicative acts for exchanging messages. A FIPA-ACL message comprises three components shown in Figure 5 and same is being illustrated through the example shown in Figure 6.

Figure 5. Structure of FIPA-ACL Message

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 6. Example of FIPA-ACL message



Here, inform is the communicative act,:sender,:receiver,:content, etc., are the message parameters and agent a, agent b etc. represents the content of message. It shall be noted that every FIPA-ACL message begins and ends with a round bracket. The complete list of reserved message parameters along with their description permitted by FIPA-ACL is given in Table 2 and Table 3 lists the communicative acts defined in FIPA-ACL. For more details, readers are deferred to technical document by FIPA[2].

B) Knowledge Query and Manipulation Language

KQML (Finin, Fritzson, McKay &McEntire, 1994; Labrou & Finin, 1997) is the result of further efforts by research community to support agent communication. KQML is not only a language but also a protocol that supports sending and receiving general purpose messages among distributed agents. It supports exchange of messages which are syntax and ontology independent. Primarily a KQML message comprises of three layers i.e. content, communication and message as shown in Figure 7.

Figure 7. Layers of a KQML Message

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

The content layer bears the actual content of the message in the program's own representation language. KQML can carry any representation language, including languages expressed as ASCII strings and those expressed using binary notation.

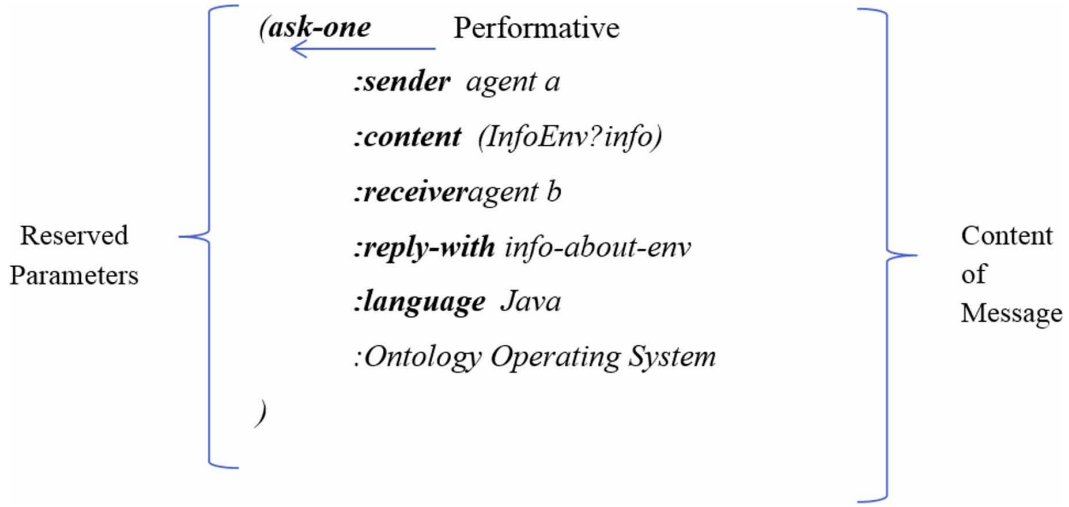
Every KQML implementation ignores the content portion of the message, except to determine where it ends. The communication layer encodes a set of features of the message that describe the lower-level communication parameters, such as the identity of the sender and receiver, and a unique identifier associated with the communication. This layer is the core of KQML and determines the kind of interactions one can have with a KQML-speaking agent. Function of this layer is to identify the speech act or performatives that the sender attaches with the content. This speech act indicates whether the message is an assertion, a query, a command, or any other from a set of known performatives, where a performative stands for primitive message type. Additionally, as the content is hidden from KQML, the message layer also includes optional features that describe the content language, the ontology it assumes, and some type of description of the content, such as a descriptor naming atopic within the ontology. These features make it possible for KQML implementations to analyze and properly deliver messages with hidden contents. Alike FIPA-ACL, the structure of a KQML message is being illustrated with the example given in Figure 8.

Alike FIPA-ACL, a KQML message also begins and ends with a round bracket. It also has some reserved parameters (see Table 4) mentioned within a predefined performative. In this message, the KQML performative is *ask-one*, the content is *(InfoEnv?info)*, the ontology assumed by the query is identified by the token *Operating System,* the receiver of the message is agent 2 and the query is written in a Java. The detailed list of KQML performatives is given in Table 5.

C) Knowledge Interchange Format (KIF)

KIF (Genesereth& Fikes, 1992) is based on first order predicate logic and provides a high-level intermediate language for communication between agents. It is capable of expressing facts and rules. It provides constructs for describing procedures, i.e. programs to be executed by an agent. KIF specifies its syntax and semantics similar to Lisp and is more or less alike FIPA-Semantic language (FIPASL) (McArthur, Davidson, Catterson, Dimeas, Hatziargyriou, Ponci & Funabashi,2007).

Table 2. Description of Message Parameters



Parameter	Description
:sender	Represents the name of the agent sending the message
:receiver	Represents name(s) of the recipient(s) of the message.
:content	The content of the message is expressed in this section
:in-reply-to	Represents that this message is a reply referring to an earlier action
:language	Language of representing the content of the message.
:reply-with	Reply desired with an expression or a conversation thread identifying the original message.
:ontology	Ontology gives meaning to the symbols in the contents
:reply-by	Represents the deadline by which reply must be received
:protocol	Protocol being used by communicating agents.
:conversation id	Represents the identification for ongoing sequence of communicative acts.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 3. Description of Communicative Acts

Act	Description
accept-proposal	The action of accepting a previously submitted proposal to perform an action.
agree	The action of agreeing to perform some action, possibly in the future.
cancel	The action of cancelling some previously requested action.
cfp	The action of calling for proposals to perform a given action.
confirm	The sender informs the receiver that a given proposition is true, where the receiver is known to be uncertain about the proposition.
disconfirm	The sender informs the receiver that a given proposition is false, where the receiver is known to believe, or believe it likely that, the proposition is true.
failure	The action of telling another agent that an action was attempted but the attempt failed.
inform	The sender informs the receiver that a given proposition is true.
Inform-if (macro act)	A macro action for the agent of the action to inform the recipient whether or not a proposition is true.
Inform-ref (macro act)	A macro action for sender to inform the receiver the object which corresponds to a definite descriptor (e.g. a name).
Not-understood	The sender of the act informs the receiver that it has not understood the latest action performed by receiver.
propose	The action of submitting a proposal to perform a certain action, given certain preconditions.
Query-if	The action of asking another agent whether or not a given proposition is true.
Query-ref	The action of asking another agent for the object referred to by an expression.
Refuse	The action of refusing to perform a given action, and explaining the reason for the refusal.
Reject-proposal	The action of rejecting a proposal to perform some action during a negotiation.
request	The sender requests the receiver to perform some action.
Request-when	The sender wants the receiver to perform some action when some given proposition becomes true.
Request-whenever	The sender wants the receiver to perform some action as soon as some proposition becomes true and thereafter each time the proposition becomes true again.
subscribe	The act of requesting a persistent intention to notify the sender of the value of a reference, and to notify again whenever the object identified by the reference changes.

Figure 8. Structure of a KQML Message

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 4. Reserved Parameters in KQML

Parameter	Description
:sender	the actual sender of the performative
:receiver	the actual receiver of the performative
:from	the origin of the performative in:content when forward is used
:to	the final destination of the performative in:content when forward is used.
:in-reply-to	the expected label in a response to a previous message (same as the:reply-with value of the previous message)
:reply-with	the expected label in a response to the current message
:language	the name of the representation language of the:content
:ontology	the name of the ontology (e.g., set of term definitions) assumed in the:content parameter.
:content	The information about which the performatives expresses attitude

Ontology

The agent community has borrowed ontologies (Gruber, 1995) because they offer a global worldview which allows all agents to ground their beliefs and actions. Ontologies provide agents with a powerful domain of discourse. Before conversing, agents can agree to use a particular ontology, which defines some aspect of the world. Using such a shared ontology, agents can then discuss a topic with complete confidence that other agents have the same understanding of the items discussed. For instance, mutually exchanged 'airplane' ontology allows one agent to talk about a particular airplane e.g. Boeing 747 or Airbus320, and for the other agents to understand that Boeing 747 is a type of airplane object, which has several properties. Ontologies are playing significant role in semantic web since it aims at automation of searching and extraction of useful information spread across the web through multi-agent systems, which exploit ontologies for understanding their domain. Agents are required to have knowledge about its environment, application for which it is working and should also be aware of its neighbor agents. Communicating agents can communicate only if they share the ontology and the information is expressible using shared ontology. Figure 9 given below illustrates this concept through Use case diagram. Different agents may have similar concepts defined differently as per concerned applications. Thus, while communicating agents need to make use of concerned ontology so as to communicate properly. In Figure 9, agent1 and agent2 are using animal domain ontology which provides them knowledge about white mouse whereas agent1 and agent3 are using computer domain ontology where mouse is defined as a physical input device for computer systems.

It is actually the matter of regret that ontologies are usually expressed ambiguously and are generally embedded into agents and moreover, there is no external repository available that describes the ontology specifically i.e. semantics defining ontology are lacking. Research related to such definitions and structure of ontological databases is lagging behind. Such deficiencies further double when the communicating agents are heterogeneous and hybrid and belong to different multi-agent systems. Each MAS is possessed with its local ontology and hence the external agents do not have the idea of ontologies belonging to other MASs. In order to establish the communication link between heterogeneous MAS, ontology shall be linked using some specified standards that supports interface between different ontologies.

Table 5. Performatives in KQML

Sr. No.	Performative	Associated Meaning
37.	ask-if	S wants to know if the:content is in R's VKB
38.	ask-all	S wants all of R's instantiations of the:content that are true of R
39.	ask-one	S wants one of R's instantiations of the:content that is true of R
40.	stream-all	multiple-response version of ask-all
41.	eos	the end-of-stream marker to a multiple-response (stream-all)
42.	tell	the sentence is in S's VKB
43.	untell	the sentence is not in S's VKB
44.	deny	the negation of the sentence is in S's VKB
45.	insert S	asks R to add the:content to its VKB
46.	uninsert	S wants R to reverse the act of a previous insert
47.	delete-one	S wants R to remove one matching sentence from its VKB
48.	delete-all	S wants R to remove all matching sentences from its VKB
49.	undelete	S wants R to reverse the act of a previous delete
50.	achieve	S wants R to do make something true of its physical environment
51.	unachieve	S wants R to reverse the act of a previous achieve
52.	advertise	S wants R to know that S can and will process a message like the one in a:content
53.	unadvertise	S wants R to know that S cancels a previous advertise and will not process anymore messages like the one in the:content
54.	subscribe	S wants updates to R's response to a performative
55.	error	S considers R's earlier message to be malformed
56.	sorry	S understands R's message but cannot provide a more informative response
57.	standby	S wants R to announce its readiness to provide a response to the message in:content
58.	ready	S is ready to respond to a message previously received from R
59.	next	S wants R's next response to a message previously sent by S
60.	rest	S wants R's remaining responses to a messapreviously sent by S
61.	discard	S does not want R's remaining responses to a previous(multi-response) message.
62.	register	S announces to R its presence and symbolic name
63.	unregister	S wants R to reverse the act of a previous register
64.	forward	S wants R to forward the message to the:to agent (R might beThat agent)
65.	broadcast	S wants R to send a message to all agents that R knows of
66.	transport-address	S associates its symbolic name with a new transport address
67.	broker-one	S wants R to find one response to a <performative>(some agent
68.	broker-all	S wants R to find all responses to a <performative>(some agentother than R is going to provide that response)
69.	recommend-one	S wants to learn of an agent who may respond to a <performative>
70.	recommend-all	S wants to learn of all agents who may respond to a <performative>
71.	recruit-one	S wants R to get one suitable agent to respond to a <performative>
72.	recruit-all	S wants R to get all suitable agents to respond to a <performative>

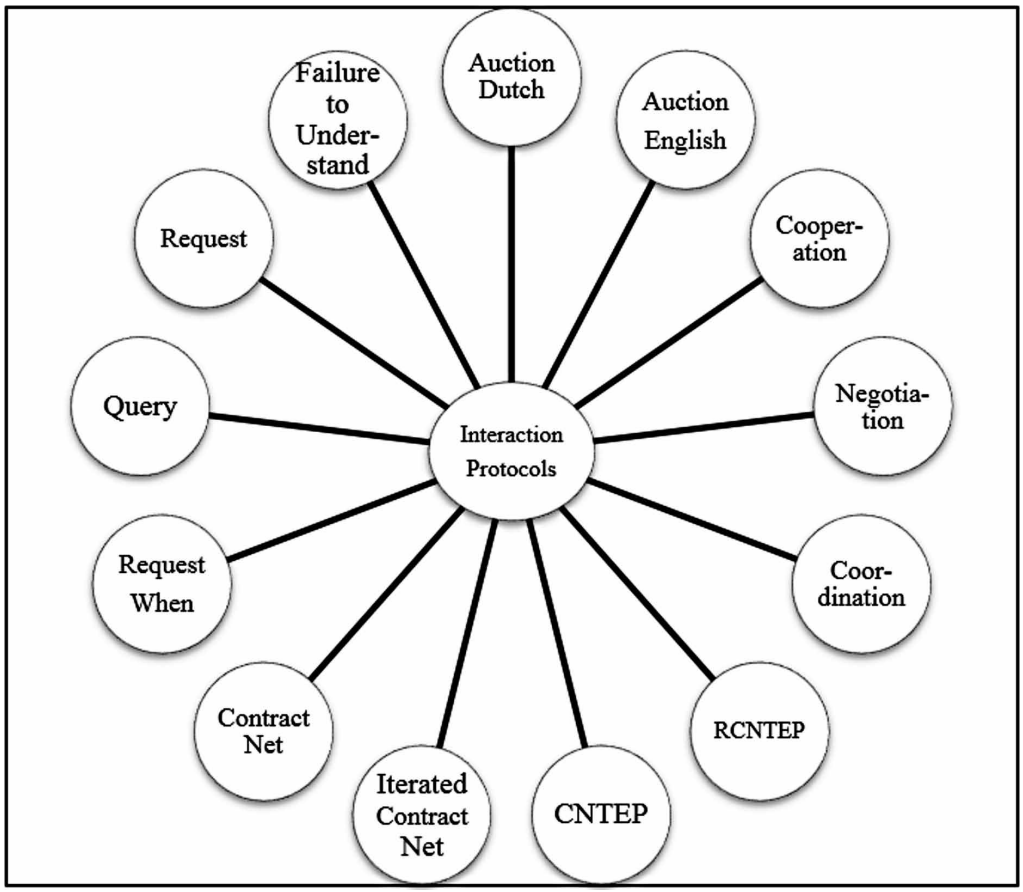
Figure 9. Use Case Diagram Describing Ontology



Interaction Protocols

As is already mentioned that an interaction protocol enables agents to exchange messages and establish conversation with other competing agents. Agents communicate with their peers to achieve better goals and enhance the efficiency of the system. During this communication, agents coordinate, cooperate, compete, plan and negotiate on various aspects turning into a social entity. FIPA has put in many efforts to facilitate agent interaction and thus has continually been updating interaction protocols. Few important protocols are shown in Figure 10.

Amongst the various protocols, failure to understand protocol is the simplest protocol and it assumes that all communicating agents are following the same protocol. It offers flexibility in terms of offering "not-understood" communicative act to the agent not able to either understand the message or is unable to fulfil the desired goal. The request protocol is request-response pair protocol as to every request, listening agents are required to respond positively be it that they do not understand the message. An extension of this protocol is request-when protocol which restrains the response only if the set of preconditions are found to be true i.e. if the preconditions are not satisfied, the agents may not respond to the message thus saving the network traffic. The query protocol allows sending query to the receiver and receiver is required to respond to the sender with the results. Above protocols are suitable for homogenous communicating agents but cannot be applied to heterogeneous communicating agent. Contract Net Protocol is a FIPA standardized protocol that is suitable for the latter category of agents operating in distributed MAS. An agent desiring to establish the communication initiates the communication with many agents and selects only few agents for establishing final communication link. The listening agents either complete the task and inform to initiator agent or even if they fail, failure message is communicated. It allows only onetime connection in contrast to iterated contract net protocol which permits iterative call for proposals and thus continues to execute until initiator stop issuing further calls. Both the above protocols do not evaluate the trustworthiness of agents and thus lacked on the issue. Contract Net Trust Establishment Protocol more commonly known as CNTEP overcomes the limitation of CNP by introducing trust in CNP and another extension Reliable Contract Net Trust Establishment Protocol extension (RCNTEP) is

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 10. Agent Interaction Protocols

also available which considers reliability of agents as an important factor before granting bids to listening agents. The underlying principle behind all above protocols is coordination, cooperation and negotiation and thus are based on the general coordination, cooperation and negotiation protocols. The protocols are executed when no single agent is capable of completing the task alone and need support from peers. In coordination protocol agents coordinate to achieve a common goal while cooperation protocol follows divide and conquer approach and divides a complex problem into sub-problems and solve each one of them cooperatively. Negotiation protocol allows agent to negotiate to reach to a common solution. In such situations agents either reach to a consensus or may raise further conflicts.

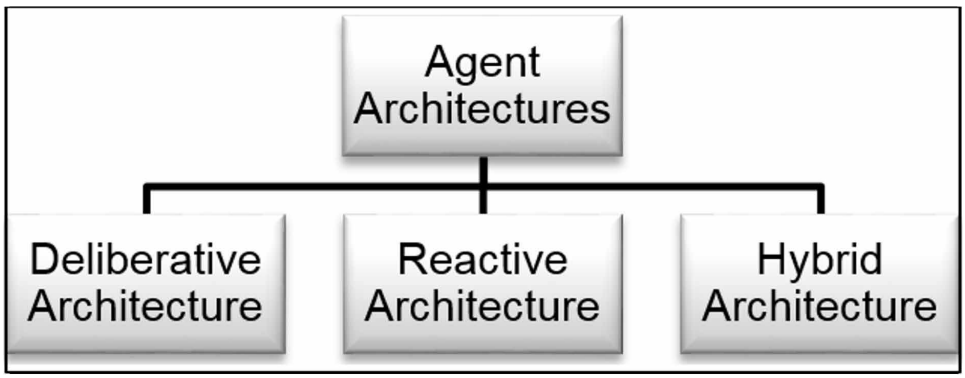
Both auction-English and auction-Dutch protocol are two variations of auction protocol and are based on auction procedure i.e. call for bids and select the most suitable bid. However, auction-English protocols begins by selecting the lowest bid while auction-Dutch protocol selects a quite higher bid and then reduces the value of bid gradually to settle to an optimum bid. For further details, readers are defered to (Alberti, Chesani, Daolio, Gavanelli, Lamma, Mello, & Torroni, 2007; Juneja, Jagga & Singh, 2015; Singh, Singh & Mukherjee, 2014).

Multiagent interaction is in existence since the inception of technology wherein the number of agents interact through various communication links. Although various agents have their own globe of authority, However, these may depend on each other in various ways. For instance, two interacting agents do

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

not depend at all on each other while in another case, one agent depends on another but vice-verca is not true. The interacting agents might get mutually dependent for achieving a goal. The next section sheds light on the type of agent interaction, in particular.

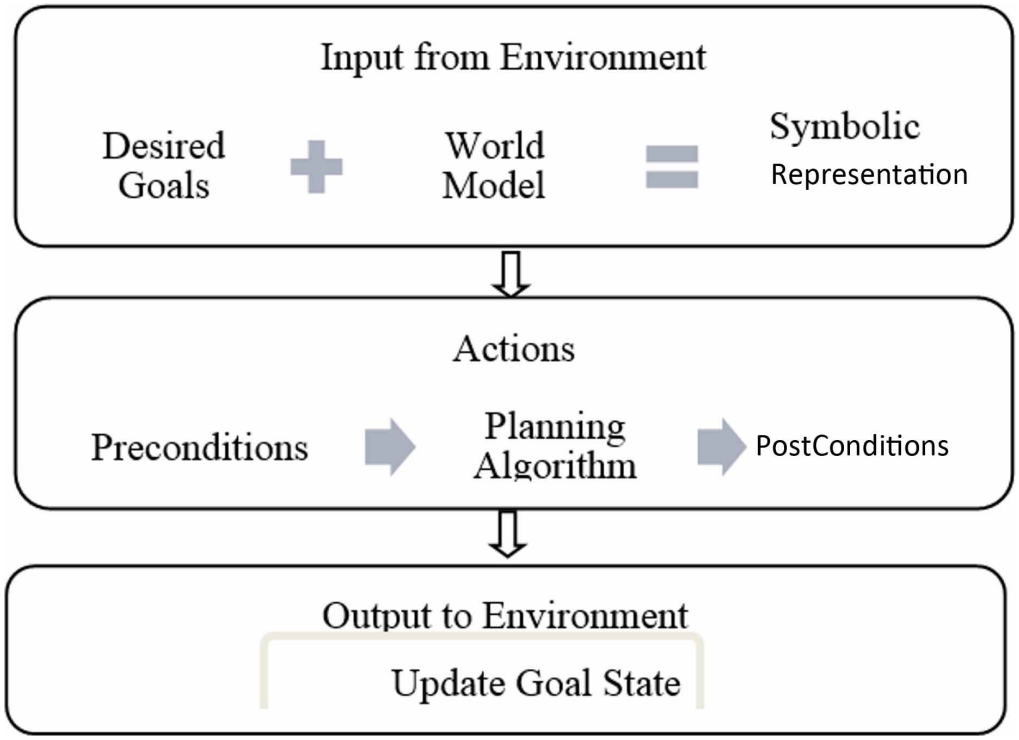
MULTIAGENT SYSTEMS: THE PRACTICAL DEVELOPMENTS



This section aims to highlight the importance of agents in practice and hence various architectures supporting the construction of agents since the inception of agent paradigm are being presented in this section. In general, architecture is known as a precise procedure for constructing autonomous agents. It usually considers decomposition of a problem into sub-problems and thereby the construction of agent is also considered as construction of a few components which are intelligent enough to pursue a goal. The ultimate aim of a practically important architecture is that agents thus developed are able to respond to a query either by input data or by changing its internal states and taking the action. According to the literature, many agent architectures supporting the design and developments of artefacts are available. However, owing to the limited scope and space available, the important architectures (see Figure 11) are being illustrated below.

Deliberative Architectures

Newel and Semon formulated the very first AI paradigm and named it as physical symbol system hypothesis (Newell & Simon, 1976; Newell, 1980). Here physical symbol system represents a physically attainable set of symbols that together form a structure and are capable of running processes as directed. The authors further called such a system as a general intelligent system. On this foundation, Geneserth (Michael & Nils, 1988) introduced deliberative agent architectures in which a deliberative agent takes the decision using logical reasoning, pattern matching and represent symbolic model of the world. In fact, it employs sense-plan-act problem solving paradigm for solving AI problems (see Figure 12).



In deliberative architectures, planning agents play the important role and has been in picture since 1970. STRIPS (Fikes & Nilsson, 1971) is one of the earliest systems that has employed planning agents. In such a system, both real world and desired goals are represented symbolically and sub sequentially for

Figure 11. Agent Architectures

Figure 12. Deliberative Architecture

actions, preconditions pertaining to planning agent execution are imposed to ensure that desired goals are achievable. Planning algorithm involves steps to be executed to achieve the goal and later applies postconditions to guarantee the legitimacy of outcomes. Although, the planning algorithm is simple but the same is inefficient when applied to solve real world complex problems. Hence the demand to have better planning algorithms continues to evolve and lot of time in research has already been devoted, such as developments of systems that support automated planning exists, such as Integrated Planning Execution and Monitoring (IPEM) (Ingerson, Jose & Steel,1988), AutoDrive system, just to list a few.

The developments of such agents are assisted with various design challenges. For instance, representing exact and accurate symbolic description of real world is unrealistic. Moreover, limit on the amount of symbols required to represent physical world is indefinite. In any case, agents designed for an application can neither be granted nor expected to acquire through experience based learning, intelligence equivalent to human developers. Owing to the above challenges, developments in the theories pertaining to learning, knowledge representation, intelligence are still open research gates. Further, research in the direction classified planning as hierarchical planning and non-linear planning (Sacerdoti, 1974; Sacerdoti, 1975). However, (Chapman, 1987) contradicted to above classification also and proved them a failure again in case of real time systems. Results by Chapman had a strong impact on the planning AI and enforced researchers to think about alternative solutions such as reactive agent architectures.

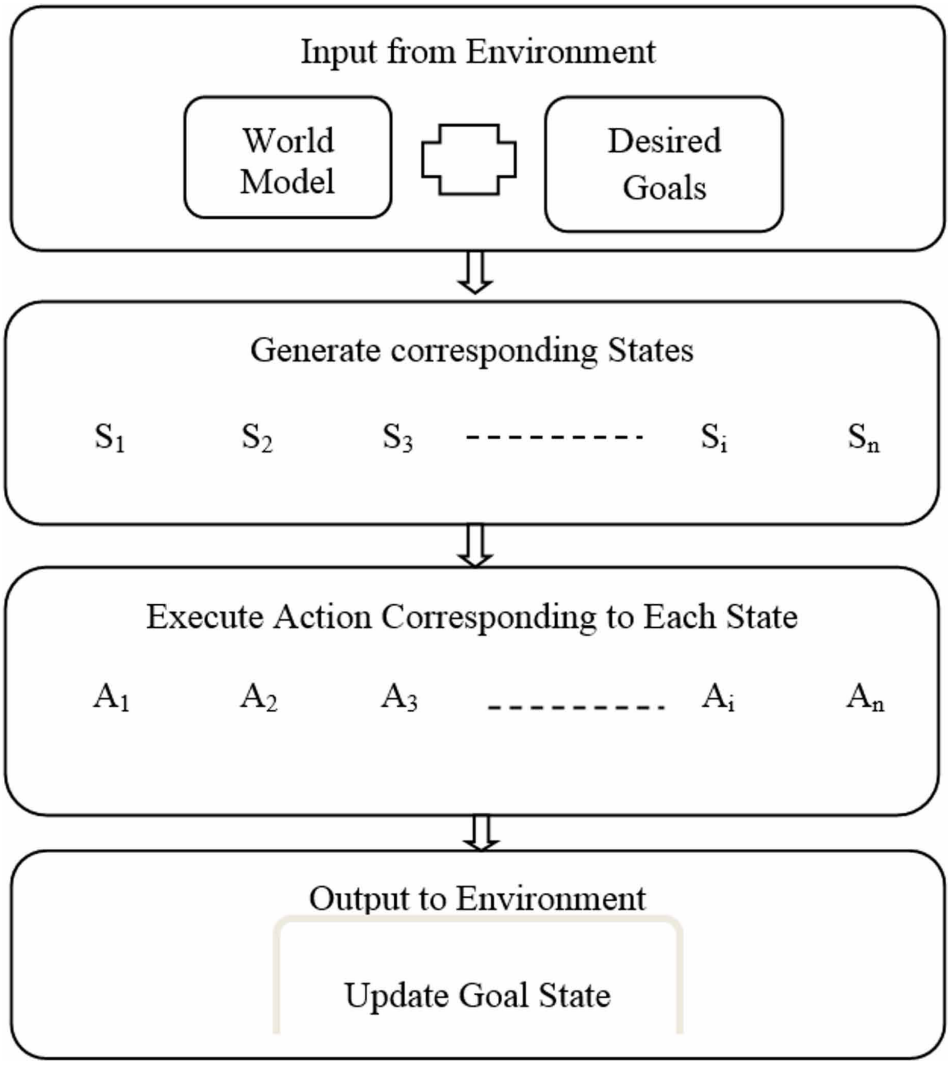
Reactive Architectures

Looking into the unfolded challenges in founding planning architectures, many researchers raised questions on the practicality of agent based computing leading to the origin of reactive architecture (Bonasso, Firby, Gat, Kortenkamp, Miller, & Slack, 1997). In contrast to deliberative architecture, reactive architecture does not focus on symbolic representation and hence symbolic reasoning.

Significant contribution to the development of these architectures is credited to Brooks. Brooks (Brooks,1991a; Brooks,1991b) emphasized that intelligence among agents neither depend on symbolic representation nor on symbolic reasoning. He further mentioned that intelligence among agents is due to the environment in which these are situated and also its emergence is the temporal result of agent interaction with its peers in respective multiagent systems. Reactive architectures represents the world model in very simple form. However, it runs strong bonding between input and respective action. These exhibit behaviour-based paradigms where behaviour persistently matches perceptual input to action output without any reasoning. Such architectures respond as directed. The reactive behaviour is depicted as *output action*: *State→primitive action* where *State* represents the states of the environment, and *primitive action*is the set of basic actions (see Figure 13). Thermostats are the most common example of reactive architecture and actions executed are depicted through equation (1) below:

$$action\left(s\right)=\begin{Bmatrix} Heater\,off\,if\,temperature\,OK \\ Heater\,On\,Otherwise \end{Bmatrix} \tag{1}$$



Hybrid Architectures

The research and practical solutions presented by both deliberative and reactive architectures proved that both the architectures are not the best solutions for constructing agents. On-going research efforts further suggested amalgamating both the above architectures and termed the new one as hybrid architecture (Wooldridge & Jennings, 1994). General hybrid architecture is shown in Figure 14. An agent in such architecture comprises of several multiagent systems where each system has its own plans and makes use of deliberative architecture (symbolic reasoning) for taking decisions. Few agents are designed so as to react to an event as directed making reactive architecture a reality. A hybrid architecture usually employs layered approach.

A popular category of agents known as Belief-Desire-Intention (BDI) agents (Haddadi & Sundermeyer, 1996) are also developed under the umbrella of hybrid architectures only. The BDI agents not only uphold a schema of their world but also maintain an explicit standpoint which can be altered using symbolic reasoning. The agents have their set of facts or known inputs known as agent beliefs, desires are the inputs from users or system representations while intentions are the actions that are executed to achieve the stated desires. A BDI agent encapsulates a collection a beliefs or behavior known as goals and the methods for selecting them. Each intention triggers itself when it matches the input in the form of desires either being sensed from the environment or generated due to an event. Depending upon the learning and sensing abilities of agents, new behavioral actions may be added periodically. The agent thread constantly checks the environment to ensure if the current desire is applicable. If it finds the desire to be a false application, it stops its intention by calling the respective methods. The agent on its own is accountable for initiating and dismissing itself.

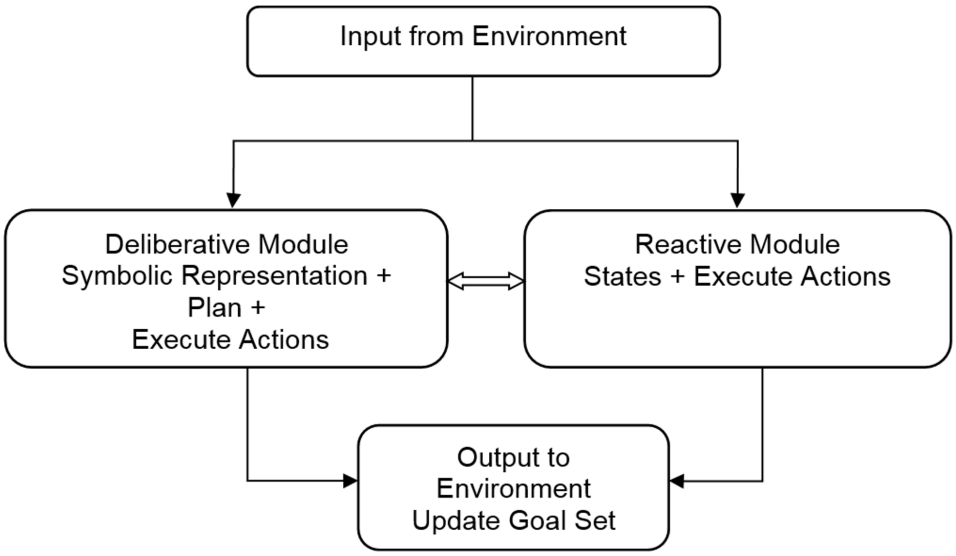

Figure 13. Reactive Architecture

The BDI-based architecture of intelligent agent primarily comprises of five components namely an Agent, an Environment, a Belief Component, Desire Component and Intention Component. The flow diagram as well as class diagram of design of intelligent agent architecture (Sharma & Juneja, 2006) is shown in Figure 15 and Figure 16. Jam-packed agent-based software requires message communication mechanism, information gathering and dissemination services, event notification and lot of signaling information. These are usually provided by agent-friendly platform such as JADE, IBM-Aglet or Aglet Software Development Kit (ASDK), Voyager, Anchor and Zeus and so on. According to the available literature (Macal & North, 2014; Nguyen, Dang, Hluchy, Balogh, Laclavik & Budinska, 2002; Singh, Juneja & Sharma, 2011) more than 100 products are available. However, at fundamental level, each framework provisions three modules for agent development namely creation, communication and discovery. Creation provides the capability to quickly build and execute agents within a supported atmosphere and communication employs speech acts to mitigate inter-agent communication. Discovery lets agents

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

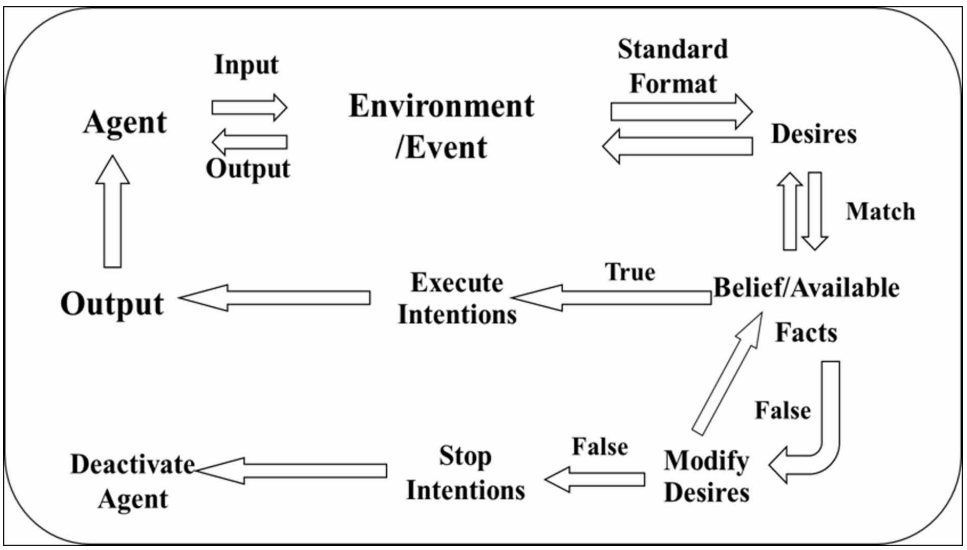

Figure 14. Hybrid Architecture

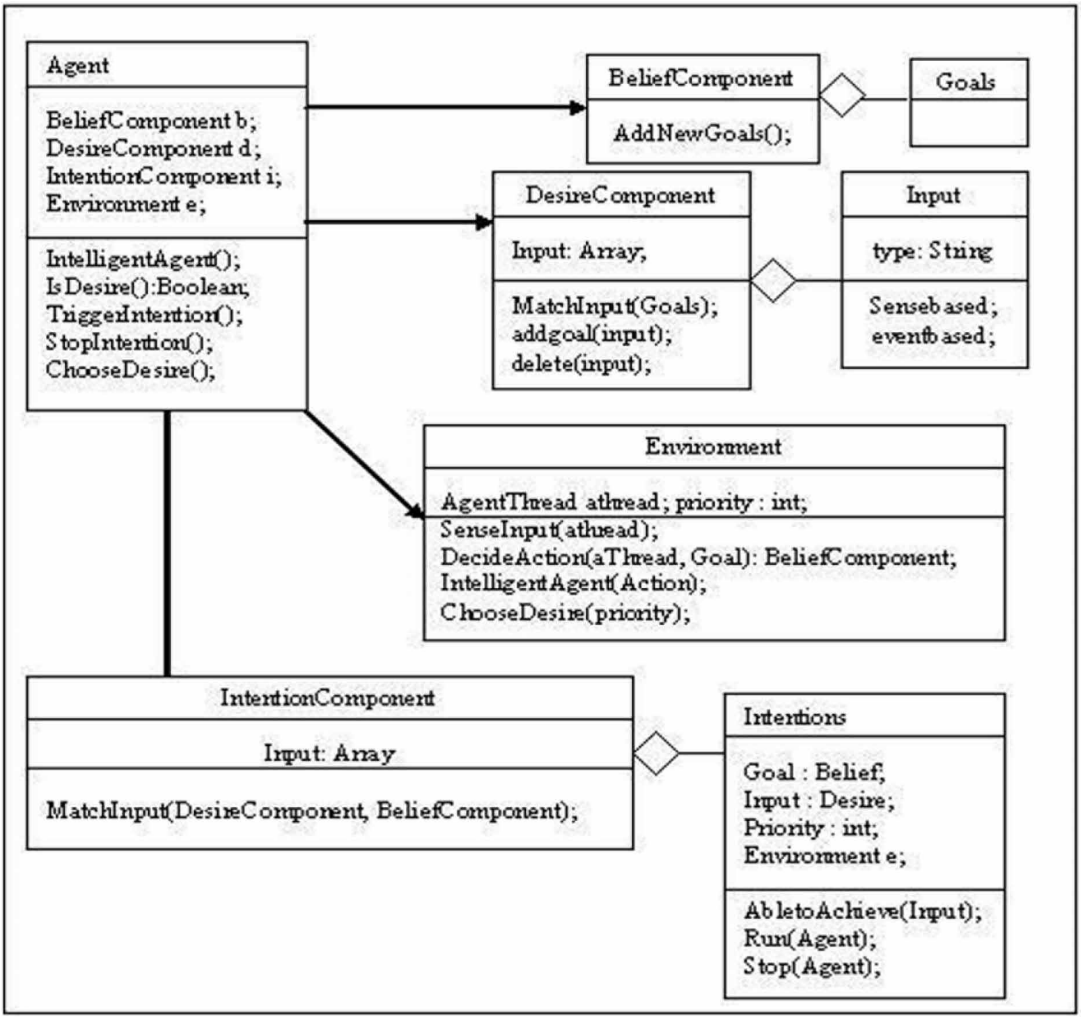
to explore undiscovered agents using a service-based discovery mechanism. Each framework though offering the above mentioned common services, also offers a unique set of additional features such as standards compliance, mobility, interoperability, knowledge-based ontologies, graphical interfaces etc. Table 6 delineates a comparison of few popular agent development frameworks.



From Table 6 it is clear that most of agent development tools are open source and freely available thereby attracting developers and making intelligent agents appealing solutions for many web based applications.

Figure 16. The Class Diagram of BDI Based Agent (Sharma & Juneja, 2006)

AGENT-BASED SYSTEMS: ARE THESE REALLY UNIVERSAL?

It is evident from the study presented above that agent based systems are proving to be promising solutions to the development of latest applications such as process control, telecommunication, business processing, air-traffic control, medical domain and many more. The basic attributes of agents being autonomous, communal entities make them responsive enough to reflect to alterations in the environment. Owing to the strong behavioral aspects of agents, developers are able to design dependable, strong, extensible and accessible systems. The major advantages of the agent paradigm is that it can overcome delay in communication, reduce user load, execute at different times and independently, adapt with dynamism, can operate in varied environments, and usually have strong and fault-tolerant behavior. Since the design approach is modular, the agent architecture also reveals software reusability. Secure communication mechanisms exist to alleviate inter-agent, agent-to-platform and vice-versa. Once designed, agents can interchange their roles in order to fulfil the user's demand. Agents are atomic and

isolated i.e. they don't get distracted easily during processing of any task. Agents can be programmed to avoid flaws of reasoning that usually humans have. The agent concept provides a scalable, modular, flexible and a robust architecture. Also, if the goal is safe, agents are more reliable than object-oriented or component-based solutions. Agents are useful in reducing manual load and can serve as knowledge resources. Agents never get tired. Although an agent-based system can have any number of agents but security tools presents performance limitations that command design decisions and may adversely affect the advantages of agent-based systems.

Despite of the many benefits, agents cannot be applied in all situations. A multi-agent system implicitly is possessed with complicated inter-agent communication which in turn makes the behavior of agent unpredictable. Such complex systems can adversely affect real time applications which demand output in real time. However, with the technologies evolving at a fast pace making the information technology networked as well as distributed, agents have emerged as most fascinating paradigm for system and application development. It appears that more trust than required is being shown in the technology as many applications where agents are being deployed could have been developed and executed without agents as well. In fact, developers are applying agents to almost all distributed domains even if the proposed agent-based solution may not be the most optimal solution. The choice of weather an agent based solution is feasible and shall be applied or not, depends on many factors. Although, agent based solutions are offering many pros but it also has some inherent cons. For instance, MASs are usually application specific and thus are not good for all domains having different constraints especially the real-time systems. Further, in most of the applications where agents are deployed, the response depends on its native state and it is impossible that within MAS, all agents will possess the complete information about the entire system. Hence, the outcome of sub-problems may not be accurate and will finally affect the performance of the entire system. The lack of global knowledge and its adverse effect on the entire system is one of the primary issues and has always been attracting research attention. Moreover, in order to get the job done from agents, users delegate the tasks to agents which demand that these agents are trustworthy and their users have confidence in them. For agents to gain trust and confidence of users these must work

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

efficiently and further, the decision pertaining to the limit on autonomy of agents is also challenging. One can say, that an agent based systems although seems to be fascinating and promising but we must know the limitations these offer and hence cannot be trusted to be applied in every distributed system.

CONCLUDING REMARKS

The domain of multi-agent is highly effervescent and escalating at an exponential rate. The basic concepts offer powerful solutions for designing variety of agent-based solutions. Since last three decades, the advances in the domain are significant specifically pertaining to agent interaction and communication in complex distributed systems. The technology is now finding space in commercial applications and complex and mission critical applications as well. Efforts to improve the computing are still going on and many issues such as defining the limit on trust, intelligence and their applicability are yet open. Full potential of agents is yet to be realized.

Chapter 7
A Hybrid Intelligent Risk Identification Model for Configuration Management in Aerospace Systems

Jose Nava
Pinnacle Aerospace, Inc., Mexico

Alejandro Osorio
Pinnacle Aerospace, Inc., Mexico

ABSTRACT

This chapter proposes a multi-dimensional patterns recognition model for Configuration Management's Risk Identification in Aerospace Safety Critical Systems. This work has been designed for Aerospace software systems where companies require full compliance with the Aerospace Standard DO-178b. The solution focuses on Risk Identification for the Configuration Management Process Area. An Anomaly Detection Solution has been designed through the modeling of statistics and artificial intelligence algorithms, following CRISP-DM model standard for data mining solutions. A dimensional architecture was designed to model the problem through three dependent and interconnected dimensions. The first dimension, Behavioral Biometrics, which this model has extended to Human Behavioral Patterns. The second dimension is Infrastructure, which represents all physical specialized equipment, environments, networking, and its configurations. The third dimension is space-time, which in this model represents a time dimension against all geographical information project related (code, files, among others).

INTRODUCTION

Software products are deployed across a wide range of global industries, but when it comes to Aerospace safety critical systems; security and criticality are strictly rigorous. In these kinds of systems, a software failure or malfunction could result in loss of life and significant property damage.

Aviation systems development has been evolving for almost a hundred years now. One of the more notorious development evolving areas is the instruments and displays that were electro-mechanical in the past and now are composed by electronic parts, which make them more reliable, secure and lighter. The biggest priority of this evolution has always been to avoid aircraft accidents and providing security in the air. The rapid increase in the use of software in airborne systems and equipment used on aircraft and engines in the early 1980s resulted in a need for industry-accepted guidance for satisfying airworthiness requirements. DO-178, "Software Considerations in Airborne Systems and Equipment Certification", was written to satisfy this need.

Developing reliable software products becomes more and more challenging for Safety Critical Industries due to specific regulations, short production cycles or high complexity design.

One of the more challenging aspects when working with Aerospace Software is maintaining a good Configuration Management control. A well planned strategy for this area can result in the fault tolerant system we have designed since the beginning.

Configuration Management has always been a complex, dynamic and constantly changing area, which not only interacts with the project team members and the IT department of the service provider, but also with those entities from the client side. This configuration makes it more complex because each company has its own Configuration Management practices, tools, and processes. Other important risk factor is that no matter the technical level of the involved teams, each employee works differently when it comes to practices like code design, SVN activities like commits, check in/out, updates, merges, syncs, cleanups, or other activities like estimation, activities tracking culture, among others.

The Federal Aviation Administration and the Joint Aviation Authorities have defined a list of Failures Condition Categories within DO-178b, as well as a list of Software Level Definitions based upon the contribution of software to potential failure conditions.

The Software level implies that the level of effort required showing compliance with certification requirements varies with the failure condition category (Radio Technical Commission for Aeronautics, 1992). These software level definitions are described below:

- **Level A (Catastrophic):** Software whose anomalous behavior would cause or contribute to a failure of system function resulting in a catastrophic failure condition for the aircraft, and multiple deaths. An example of this anomalous behavior can be the Turbine Engine Monitoring Software, which malfunction can cause a fatal accident.
- **Level B (Hazardous/Severe-Major):** Software whose anomalous behavior would cause or contribute to a failure of system function resulting in a hazardous/severe-major failure condition for the aircraft, and some deaths or severe injuries. An example of this anomalous behavior can be the Landing Gear Control Software, which malfunction can cause a big accident.
- **Level C (Major):** Software whose anomalous behavior would cause or contribute to a failure of system function resulting in a major failure condition for the aircraft, and severe injuries. An example of this anomalous behavior can be the FMS/NAV/COM System, which malfunction can cause damages and accidents.
- **Level D (Minor):** Software whose anomalous behavior would cause or contribute to a failure of system function resulting in a minor failure condition for the aircraft, and minor injuries. An example of this anomalous behavior can be the A/C monitoring system software, which malfunction can cause a failure condition.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

- **Level E (No Effect):** Software whose anomalous behavior would cause or contribute to a failure of system function with no effect on aircraft operational capability or pilot workload. An example of this anomalous behavior can be the Entertainment audio system software, which malfunction can cause just a minimal failure condition.

We will describe the software level definitions that we are covering in this work, and the reasons to cover these levels.

The general objective of designing this model is to avoid Configuration Management issues during Aerospace software development and verification projects through artificial intelligence and statistical techniques like anomaly detection and pattern recognition in exploratory data analysis.

The specific objectives of this model are:

- Based on the most threatening issues in Configuration Management, to identify user behaviors through the project life cycle.
- To have a real-time intelligent pattern recognition algorithms tool based on these behaviors to detect anomalies.
- To have a real-time risks notification and diagnosis tool.
- Based on the previous intelligent pattern recognition algorithms, to have valuable statistical information, which cannot be detected or accessed through traditional mathematical methods.
- To use this statistical information to improve real-time decision making, and have informational tools to build performance improvement plans in real-time without having an impact in the project.

BACKGROUND

Over time, Aerospace companies have always put special attention at the moment of creating the Configuration Management strategy for each project at the initial phases. In this sense, special controls, monitoring strategies, resources and processes are put in place to overcome the big risks that the development and testing teams are phasing in a daily basis. These controls are not enough because there are several factors that can trigger a failure in a system; some examples are listed below:

- A failure in a build
- Bad version control
- Poor requirements traceability, bad hooks strategy
- Design complexity
- Disaster recovery issues
- Change control confusions
- Confusing environments' configuration
- Bad release management or deployment management
- High estimations' deviations
- Poor activities tracking
- High overtime rates

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

The Software Configuration Management Process, in cooperation with other processes during the software life cycle process assists in satisfying general objectives to:

1. Provide a defined and controlled configuration of the software throughout the software life cycle.
2. Provide the ability to consistently replicate the executable Object Code for Software Manufacture or to regenerate it in case of a need for investigation or modification.
3. Provide control of process inputs and outputs during the software life cycle that ensure consistency and repeatability of process activities.
4. Provide a known point of review, assessing status, and change control by control of configuration items and the establishment of baselines.
5. Provide controls that ensure problems receive attention and changes recorded, approved, and implemented.
6. Provide evidence of approval of the software by control of the outputs of the software life cycle processes.
7. Aid the assessment of the software product compliance with requirements.
8. Ensure that secure physical archiving, recovery and control are maintained for the configuration items.

The daily execution of each of the hundreds of configuration management processes and good practices each engineer has to perform for these complex systems can lead to a minimal to moderate deviation in the execution's exactness. For this reason, we can say that the avionics process could be perfect, and the way a team of several engineers execute within a project could not be exactly the same in detail. In aerospace systems, a minimal deviation is a risk and a possible failure. For creating this model, we did an extensive research in Artificial Intelligence techniques to find a way to use patterns recognition to derive with behavioral biometrics mathematical solutions which can perform as a live system focused in each micro-technical movement of the engineers within a project, to detect these deviations and avoid issues within the configuration management process.

Below we provide detailed background information in Safety Critical Systems, Configuration Management in DO-178, Artificial Intelligence, Data Mining and Anomaly Detection techniques.

AEROSPACE SAFETY CRITICAL SYSTEMS

Safety Critical Systems have been evolving exponentially during the last 50 years. Technology advances are helping to have better processes and better controls over these kinds of Systems.

The ultimate objective of any system is the performance of any function. This function is frequently called the mission. The term often used to describe the overall capability of a system to accomplish its mission is system effectiveness. For consumer products, system effectiveness is related to customer satisfaction, which is related to the overall concept of quality. Quality of products and services is defined and evaluated by the customers and users of the product. System effectiveness is defined as the probability that the system can successfully meet an operational demand within a given time when operating under specified conditions. (Salvendy, 2001).

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Safety-critical systems are introduced into a system to prevent, or stop the development of an accident. Safety-critical functions carried out by these systems may range from simple physical barriers to very complex systems including a lot of software. The safety-critical functions can be of technical nature, but the interaction with administrative controls and human actions may need to be included to fully understand how the performance is affected. Several international standards have been introduced related to design and evaluation of safety-critical functions. Among these standards are the IEC61508 standard, and its application specific versions/related standards, such as IEC 61511 for the process industry, IEC 62061 for machinery (ISO 13849), ISO 26262 for automotives, EN 50126/EN 50129/ IEC 50128 for railway (IEC versions are IEC 62278, IEC 62425, and IEC 62269), and IEC 61513 for nuclear.

Some of the more important concepts we should understand to have an accurate idea of what Safety Critical Systems mean for us are: Safety is freedom from accidents or losses. Safety is not reliability.

Reliability is one of the major attributes determining system effectiveness. It is generally defined as the probability that a system will perform its intended function satisfactorily, for its intended life, under specified operative conditions (Salvendy, 2001).

Safety is not security, is protection or defense against attacks, interference, or espionage. Accident is a loss of some kind, such as injury, death, or equipment damage. Risk is a combination of the likelihood of an accident and its severity:

$$risk = p(a) * s(a)$$

Hazard is a set of conditions and/or events that leads to an accident. A failure is the nonperformance or inability of a system or component to perform its intended function for a specified time under specified environmental conditions. Failures are events. e.g.. a component failure. An error is a systematic fault, which is a design error.

Errors are states or conditions, e.g. a software bug. A fault is either a failure or an error.

Safety must be considered in the context of the system, not the component or the software. It is less expensive and far more effective to build in safety early than try to tack it on later. The Hazard Analysis ties together hazards, faults, and safety measures.

Some of the most common types of Hazards are described below:

- **Actions**
  - inappropriate system actions taken
  - appropriate system actions not taken
- **Timing**
  - too soon
  - too late
- **Sequence**
  - skipping actions
  - actions out of order
- **Amount**
  - too much
  - too little

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

System safety is a planned, disciplined and systematic approach to preventing or reducing accidents throughout the life cycle of a system.

As an example of a Safety Critical System we can mention a common instrument system which is a configurable color display that provides backup information for attitude, altitude, airspeed, heading, and navigation all plains have installed in the cockpit. This instrumentation can have the capability of interfacing with several types of sensors and protocols that can be installed in different airplane models.

CONFIGURATION MANAGEMENT IN DO-178

Having a good Configuration Management control is critical in any Industry; a company's quality level can be measured by its configuration management process and control. This is a very complex area because it involves different departments as Development, Testing, IT, and Quality. Maintaining a perfect log database of a picture of every second of the life of the project in terms of configurations it is always very complex and challenging.

The objectives for Software Configuration Management are independent of software level. However, two categories of software life cycle data may exist based on the Software Configuration Management controls applied to the data.

The Software Configuration Management process includes the activities of configuration identification, change control, baseline establishment, and archiving of the software product, including the related software life cycle data. The following guidelines define the objectives for each Software Configuration Management process activity. The Software Configuration Management process does not stop when the software product is accepted by the certification authority, but continues throughout the service life of the airborne system or equipment.

The objective of the Configuration Identification activity is to label unambiguously each configuration item (and its successive versions) so that a basis is established for the control and reference of configuration items. Guidance includes:

1. Configuration identification should be established for the software life cycle data.
2. Configuration identification should be established for each configuration item, for each separately controlled component of a configuration item, and for combinations of configuration items that comprise a software product.
3. Configuration items should be configuration-identified prior to the implementation of change control and traceability data recording.
4. A configuration item should be configuration-identified before being used by other software life cycle processes, referenced by other software life cycle data, or used for software manufacture or software loading.

Baselines and Traceability

It is important to state that at the beginning of a project, we need to establish baselines when planning. The objective of baseline establishment is to define a basis for further software life cycle process activity and allow reference to. Control of configurations and traceability in a project is complex. Guidance includes:

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

1. Baselines should be established for configuration items used for certification credit. (Intermediate baselines may be established to aid in controlling software life cycle process activities).
2. A software product baseline should be established for software product and define in the software configuration index.
3. Baselines should be established in controlled software libraries (physical, electronic, or other) to ensure integrity. Once a baseline is established, it should be protected from change.
4. Change control activities should be followed to develop a derivative baseline from an established baseline.
5. A baseline should be traceable to the baseline from which was derived, if certifications credit is sought for software life cycle process activities or data associated with the development of the previous baseline.
6. A configuration item should be traceable to the configuration item from which it was derived, if certification credit is sought for software life cycle process activities or data associated with the development of the previous configuration item.
7. A baseline of configuration item should be traceable either to the output it identifies or to the process with which it is associated.

Problem Reporting, Tracking and Corrective Action

The objective of problem reporting, tracking and corrective action is to record process non-compliance with software plans and standards, to record deficiencies of outputs of software life cycle processes, to record anomalous behavior of software products, and to ensure resolution of these problems.

Guidance includes:

1. A problem report should be prepared that describes the process non-compliance with plans, output deficiency, or software anomalous behavior, and the corrective action taken.
2. Problem detection should provide for configuration identification of affected configuration items or definition of affected process activities, status reporting of problem reports, and approval and closure of problem reports.
3. Problem reports that require corrective action of the software product or outputs of software life cycle process should invoke the change control activity.

Change Control

The objective of the change control activity is to provide control for recording, evaluation, resolution and approval of changes throughout the software life cycle.

Guidance includes:

1. Change control should preserve the integrity of the configuration items and baselines by providing protection against their change.
2. Change control should ensure that any change to a configuration item requires a change to its configuration identification.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

3. Changes to baselines and to configuration items under change control should be recorded, approved, and tracked. Problem reporting is related to change control, since resolution of a reported problem may result in changes to configuration items or baselines.
4. Software changes should be traced to their origin and the software life cycle processes repeated from the point at which the change affects their inputs. For example, an error discovered at hardware/software integration, that is shown to result from an incorrect design, should result in design correction and repetition of the associated integral process activities.
5. Throughout the change activity, software life cycle data affected by the change should be updated and records should be maintained for the change control activity.

ARTIFICIAL INTELLIGENCE

The term Artificial Intelligence was conceived in 1956 used by researches in universities within different scientific areas. Artificial Intelligence has acquired several definitions along the years. One of the most known is "A field of study that seeks to explain and emulate intelligent behavior in terms of computational processes" (Schalkoff R., 1990). We defined Artificial Intelligence as the science that tries to emulate evolution, and within evolution, natural selection and cognitive modeling.

Artificial Intelligence has several branches, the most known are shown below:

- **Logical AI:** What a program knows about the world in general the facts of the specific situation in which it must act, and its goals are all represented by sentences of some mathematical logical language. The program decides what to do by inferring that certain actions are appropriate for achieving its goals (McCarthy, 2007).
- **Search:** AI programs often examine large numbers of possibilities, e.g. moves in a chess game or inferences by a theorem proving program. Discoveries are continually made about how to do this more efficiently in various domains.
- **Pattern Recognition:** When a program makes observations of some kind, it is often programmed to compare what it sees with a pattern. For example, a vision program may try to match a pattern of eyes and a nose in a scene in order to recognize a face. More complex patterns, e.g. in a natural language text, in a chess position, or in the history of some event are also studied. These more complex patterns require quite different methods than do the simple patterns that have been studied the most.
- **Representation:** Facts about the world have to be represented in some way. Usually languages of mathematical logic are used.
- **Inference:** From some facts, others can be inferred. Mathematical logical deduction is adequate for some purposes, but new methods of non-monotonic inference have been added to logic since the 1970s. The simplest kind of non-monotonic reasoning is default reasoning in which a conclusion is to be inferred by default, but the conclusion can be withdrawn if there is evidence to the contrary. For example, when we hear of a bird, we can infer that it can fly, but this conclusion can be reversed when we hear that it is a penguin. It is the possibility that a conclusion may have to be withdrawn that constitutes the non-monotonic character of the reasoning. Ordinary logical reasoning is monotonic in that the set of conclusions that can be drawn from a set of premises is a monotonic increasing function of the premises. Circumscription is another form of non-monotonic reasoning.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

- **Common Sense Knowledge and Reasoning:** This is the area in which AI is farthest from human-level, in spite of the fact that it has been an active research area since the 1950s. While there has been considerable progress, e.g. in developing systems of non-monotonic reasoning and theories of action, yet more new ideas are needed.
- **Learning from Experience:** Programs do that. The approaches to AI based on connectionism and neural nets specialize in that. There is also learning of laws expressed in logic. The field of Machine Learning is concerned with the question of how to construct computer programs that automatically improve with experience (Mitchell, 1997). Programs can only learn what facts or behaviors their formalisms can represent, and unfortunately learning systems are almost all based on very limited abilities to represent information.
- **Planning:** Planning programs start with general facts about the world (especially facts about the effects of actions), facts about the particular situation and a statement of a goal. From these, they generate a strategy for achieving the goal. In the most common cases, the strategy is just a sequence of actions.
- **Epistemology:** This is a study of the kinds of knowledge that are required for solving problems in the world.
- **Ontology:** Ontology is the study of the kinds of things that exist. In AI, the programs and sentences deal with various kinds of objects, and we study what these kinds are and what their basic properties are. Emphasis on ontology begins in the 1990s.
- **Heuristics:** A heuristic is a way of trying to discover something or an idea embedded in a program. The term is used variously in AI. Heuristic functions are used in some approaches to search to measure how far a node in a search tree seems to be from a goal. Heuristic predicates that compare two nodes in a search tree to see if one is better than the other, i.e. constitutes an advance toward the goal, may be more useful.
- **Genetic Programming:** Genetic programming is a technique for getting programs to solve a task by mating random Lisp programs and selecting fittest in millions of generations.

We will explain which Artificial Intelligence techniques we have chosen to design this model and help solving this problem, from the most mentioned nowadays like Anomaly Detection, to using a clustering-based technique called K-means for Pattern Recognition and descriptive statistics techniques.

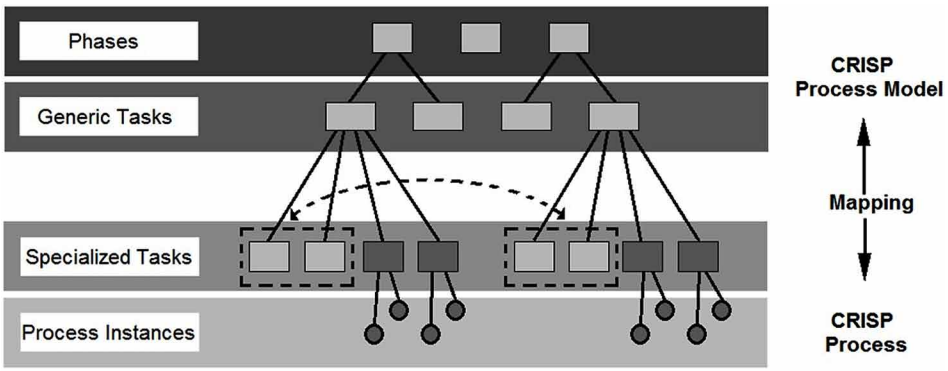
Data Mining

Data mining is a complex process that involves the interaction of the application of human knowledge and skills, and technology. This must be supported by clearly defined processes and procedures.

The main purpose of data mining is the extraction of hidden and useful knowledge from large volumes of raw data. However data mining is not simply about technology, it brings together different disciplines like software engineering, computer science, business intelligence, human-computer interaction and analysis techniques. Phases of these disciplines must be combined for data mining project outcomes. CRISP-DM methodology defines its processes hierarchically at four levels of abstraction, from general to specific, allowing a project to be structured modularly, being more maintainable, scalable and the most important, to reduce complexity. At the first level we have the phases, the second level consists of generic tasks, the third level is the specialized task level, and the fourth level is the process instance.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

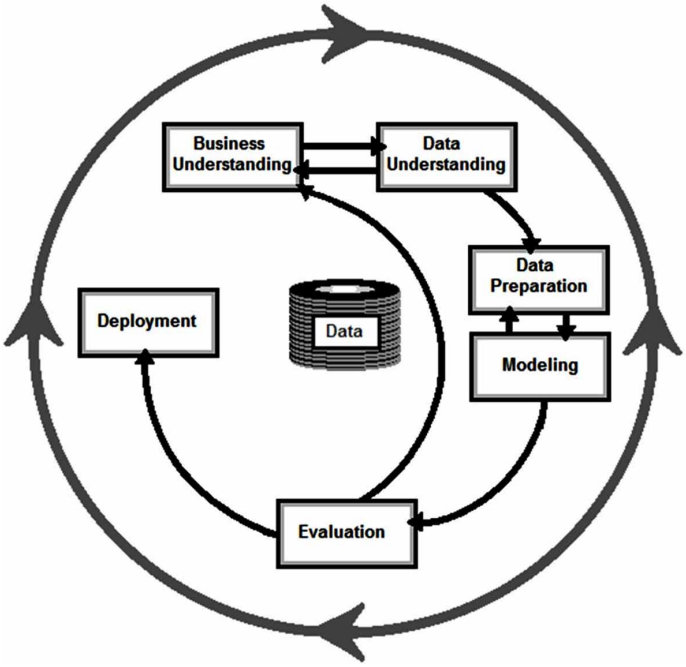
CRISP-DM describes the life cycle of a data mining project consisting of six phases: business understanding, data understanding, data preparation, modeling, evaluation and deployment. The sequence of the phases is not rigid, moving back and forth between phases is always required and allowing a data mining project to have a flexible development during its life cycle.



The most important and core in CRISP-DM methodology is that defines its processes hierarchically, consisting of a set of tasks at four levels of abstraction, from general to specific, explained below:

- Using levels of abstraction, at the top level we have the phases, the data mining process is organized into a number of phases, where each phase consists of several second-level generic tasks.
- At the second level we have the generic tasks, which must be general enough to cover all possible data mining situations and must be as complete and stable as possible. Complete means covering all possible applications and the whole process of data mining. Stable means this model and process must be valid for any kind of problems, and for old and new modeling techniques.
- The third level is the specialized task level, which describe how actions in the generic tasks should be carried out in specific situations. Ideally, the phases and tasks must be described as discrete steps and must be performed in a specific order. In practice, many of the tasks can be performed in a different order and it will often be necessary to repeatedly backtrack to previous tasks and repeat certain actions.
- The fourth level is the process instance, a record of the actions, decisions and results of an actual data mining engagement. A process instance is organized according to the tasks defined at the higher levels, but represents what actually happened in a particular engagement, rather than what happens in general.

According to CRISP-DM, the life cycle of a data mining project contains the phases of the project and the respective tasks and relationships between these tasks. At this description level, it is not possible to identify all relationships (see figure 1).



Essentially, relationships could exist between any data mining tasks depending on the goals, the background and interest of the user and most importantly on the data.

Figure 1. Four level breakdown of the CRISP-DM methodology

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. Phases of the CRISP-DM reference model

A data mining project involves more than modeling. The modeling phase is just one phase in the implementation process of a data mining project. Steps of critical importance proceed and follow model building and have a significant effect on the success of the project (Chorianopoulos & Tsiptsis, 2009).

The CRISP-DM process model contributes to data mining as a process, which is reflected in its origins (McCue, 2007).

The life cycle of a data mining project consists of six phases. Figure 2 shows the phases of a data mining process. The sequence of the phases is not rigid. Moving back and forth between different phases is always required. It depends on the outcome of each phase which phase or which particular task of a phase, has to be performed next. The arrows indicate the most important and frequent dependencies between phases.

The outer circle in Figure 2 symbolizes the cyclical nature of data mining itself. Data mining is not over once a solution is deployed. The lessons learned during the process and from the deployed solution can trigger new, often more focused business questions. Subsequent data mining processes will benefit from the experiences of previous ones.

The Data Mining Phases

- **Business Understanding:** This initial phase focuses on understanding the project objectives and requirements from a business perspective, then transforming this knowledge into a data mining problem definition and a preliminary plan designed to achieve the objectives. This phase also includes assessing the current situation, establishing data mining goals, and developing a project plan (Delen & Olson, 2008).

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

- **Data Understanding:** The data understanding phase starts with an initial data collection and proceeds with activities in order to get familiar with the data, to identify data quality problems, to discover first insights into the data or to detect interesting subsets to form hypotheses for hidden information.
- **Data Preparation:** The data preparation phase covers all activities to construct the final dataset (data that will be fed into the modeling tool(s)) from the initial raw data. Data preparation tasks are likely to be performed multiple times and not in any prescribed order. Tasks include table, record and attribute selection as well as transformation and cleaning of data for modeling tools.
- **Modeling:** In this phase, various modeling techniques are selected and applied and their parameters are calibrated to optimal values. Typically, there are several techniques for the same data mining problem type. Some techniques have specific requirements on the form of data. Therefore, stepping back to the data preparation phase is often necessary.
- **Evaluation:** Model results should be evaluated in the context of business objectives established in the first phase (Delen & Olson, 2008). At this stage in the project you have built a model (or models) that appears to have high quality from a data analysis perspective. Before proceeding to final deployment of the model, it is important to more thoroughly evaluate the model and review the steps executed to construct the model to be certain it properly achieves the business objectives. A key objective is to determine if there is some important business issue that has not been sufficiently considered. At the end of this phase, a decision on the use of the data mining results should be reached.
- **Deployment:** Creation of the model is generally not the end of the project. Even if the purpose of the model is to increase knowledge of the data, the knowledge gained will need to be organized and presented in a way that the customer can use it. It often involves applying "live" models within an organization's decision making processes, for example in real-time personalization of Web pages or repeated scoring of marketing databases. However, depending on the requirements, the deployment phase can be as simple as generating a report or as complex as implementing a repeatable data mining process across the enterprise. In many cases it is the customer, not the data analyst, who carries out the deployment steps. However, even if the analyst will not carry out the deployment effort it is important for the customer to understand up front what actions need to be carried out in order to actually make use of the created models.

Anomaly Detection

Anomaly Detection is an artificial intelligence area which focuses in detecting patterns in data that are not complying with the expected behavior. These anomalies are also known as outliers in the data. These kinds of solutions are widely used in critical industry applications like intrusion detection in security, fraud detection, stock market, insurance, fault detection in critical electronic systems, among others.

Anomaly detection is about finding what we don't know to look for. We are searching for anomalies, but we don't know what their characteristics or properties will be present in the information. When we know the data in detail, we can use machine learning techniques, like classification, we can just write specific rules to find the anomalies. Classification is a form of supervised learning where in the data; we have examples of each kind of thing we are looking for. We can use a learning algorithm for these examples to build a model that can use features of new data to classify them into categories that represent each kind of data of interest. When we have examples of normal and some number of abnormal situations, classifiers can help

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

us to mark new situations as normal or abnormal. Even when we know about some kinds of anomalies characteristics, it is good to keep an eye to monitor new kinds that we don't know about. That is where anomaly detection is applied, so we use the unsupervised-learning approach of anomaly detection when you don't know exactly what you are looking for. Outliers (anomalies) are those events that don't match what you already know. Together, anomaly detection and classification make for a useful pair when it comes to finding a solution to real-world problems. We will use the anomaly-detection model to spot outliers.

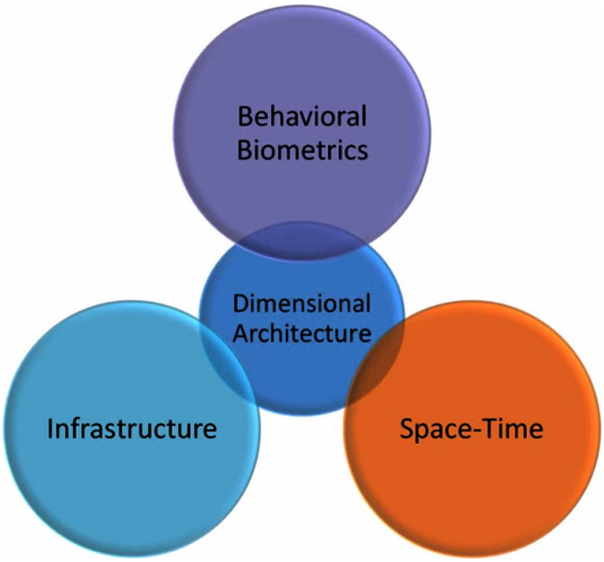
So the first step in anomaly detection would be using our model to discover what is normal. This also requires human insight both to structure the model mathematically as well as to interpret what aspect of a pattern is of interest and whether or not it represents a reasonable view of a normal situation.

We then must experiment to determine at what sensitivity you want your model to flag data as anomalous. In one of the algorithms used for this problem, this is possible by calibrating a variable. If it is set too sensitive, random noise will get flagged, and with huge amounts of data, it will be essentially impossible to find anything useful beyond all the noise. Even if you've adjusted the sensitivity to a coarser resolution such that your model is automatically flagging actual outliers, you still have a choice to make about the level of detection that is useful to you.

For an anomaly detection solution, we need to identify the cost of false-positives and false-negatives, in order to know how we will be calibrating our solution. To exemplify a case, we can say that if a false-positive is too expensive, we will try to calibrate the algorithms to get a low quantity of anomalies.

For this problem, we will need to define a strategy to calculate these costs, and design the architecture based on this. There could be a need of a very high performance infrastructure in case the cost of false-positives is low for the solution, this means that the algorithms will end up with a results of a high volume of anomalies.

SOLUTION ARCHITECTURE



An Anomaly Detection Solution (within the solutions spectrum of Data Mining) has been designed through the modeling of statistics and artificial intelligence techniques, following CRISP-DM model standard for data mining solutions.

We describe how we have implemented CRISP-DM model and its activities below, for each phase of the methodology.

- **Business Understanding:** For this initial phase, we have analyzed and understood the project objectives, which are described in the introduction of the chapter.
- **Data Understanding:** For data understanding and preparation we used the same approach, looking at the initial data collection and analyzing the data. Also we have built a dimensional architecture.
- **Data Preparation:** During this phase, the modeling of a properties vector took place, looking for properties adding value to help to have rich data in the vector.
- **Modeling:** During the Modeling Phase, the selection of algorithms and creation of the model design were done. Iterations for the algorithms selected were run and it was necessary to iterate the design of the model. In this phase, various modeling techniques are selected and applied and their parameters are calibrated to optimal values. Typically, there are several techniques for the same data mining problem type. Some techniques have specific requirements on the form of data. Therefore, stepping back to the data preparation phase is often necessary.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 3. Dimensional Architecture

- **Evaluation:** In this Phase, we were stressing the algorithms with real data, to iterate over results, and to see how real the data was behaving, and how efficient the algorithms were.
- **Deployment:** As we mentioned before, the creation of the model is generally not the end of the project, so we modeled this system for the results of data to be organized in a way that the information is easily understandable and valuable.

A dimensional architecture was designed to model the problem through three dependent and interconnected dimensions. The first dimension, Behavioral Biometrics, is a scientific area defined by the Human-Computer-Interaction (HCI), which this model has extended to Human Behavioral Patterns. The second dimension is Infrastructure, which represents all physical specialized equipment, environments, networking. The third dimension is space-time, which in this model represents a time dimension against all geographical information project related (code, file, systems and environments and its physical and logical locations).

This dimensional architecture will allow us to identify, separate and relate the different problem components, to understand and abstract each entity separately and be able to design and develop the problem in an organized way (see figure 3).

The dimensional entities are explained below:

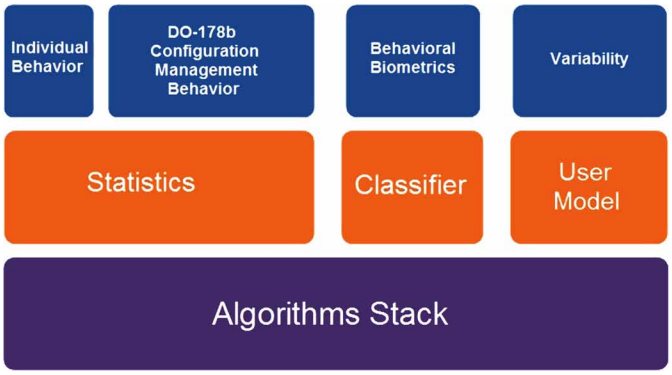
- Behavioral Biometrics will represent Human Behavioral Patterns, where we will identify the individuals activities as team members of each project:
  a. Configurations
  b. Development Activities
  c. Testing Activities
  d. Technical Activities
  e. Others...

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

- Infrastructure is representing the physical entity of the problem:
  a. Equipment
  b. Environments
  c. Network Architecture
  d. Others...
- Space-Time is representing the dimension with which we will be able to contrast the other dimensions:
  a. Geographical information
  b. Time

It is very important to emphasize that the problem would not have a possible solution if one the dimensions was not existing, we exemplify this below with two possible scenarios:

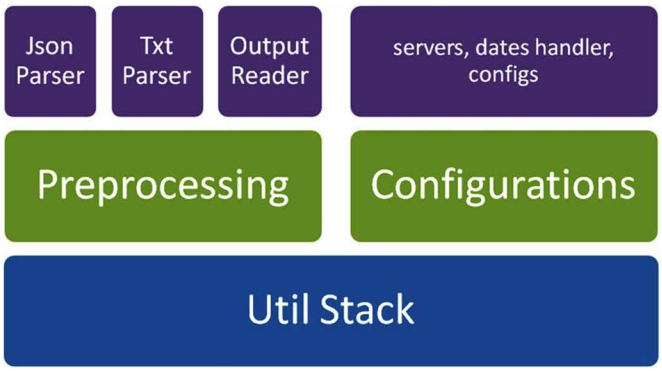
1. Having only Infrastructure and Space-Time dimensions; in this scenario we will not be able to identify who is performing activities, neither to know what this individual is doing (behavior).
2. Having only the Behavioral Biometrics and Infrastructure dimensions; in this scenario we will not be able to contrast these dimensions with time, so we will not have the "when", and the information will not be complete.



Now we can see that each dimension is critical for the problem, and that all possible data we can enter to each dimension will be important for the model.

For the Model Design and Architecture, a General Solution Framework was designed with two architectural stacks. The first stack is the Algorithms Stack, which will contain the Business Logic of the model containing a Statistics module, a Classifier module and a User Profiling module (see figure 4).

The second stack is the Utilities Stack, which will perform as an ETL standard process, containing a Preprocessing module in charge of the readers and parsers of the information and a Configurations module (see figure 5).



To explain the algorithms we have used in our architectural design, we will develop the methods in detail. In the first step of the model, a filter has been designed implementing a partitioning-based clustering algorithm, ***k-means*****,** which will attempt to find k non-overlapping clusters to recognize patterns

Figure 4. Algorithms Stack, The Business Logic

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 5. Utilities Stack

and identify types of behaviors of each individual. Each cluster is represented by a mean point in the data, called centroid. This algorithm will iterate and group the data based on behavioral patterns until its convergence, this means that the algorithm has grouped the information.

In order to mathematically model the information to be processed, a properties vector has been designed containing Configuration Management behavioral data for each active team member of the project.

Attributes for the Properties Vector:

A1. Commit Size.
A2. Failed Changes Frequency.
A3. Unauthorized configurations Frequency.
A4. Incidents caused by releases.
A5. Number of Bugs.
A6. Code integration issues.
A7. Unit testing´s code coverage.
A8. Release document correctness.
A9. Overtime factor.
A10. Standards Compliance.
A11. Code design accuracy.
A12. Requirements traceability process execution.
A13. Tracking accuracy.
A14. Trunk destabilization.
A15. SVN File-Sharing problems.
A16. Big average file size.
A17. Unexecuted code.

A properties vector with this design would be formed as follows:

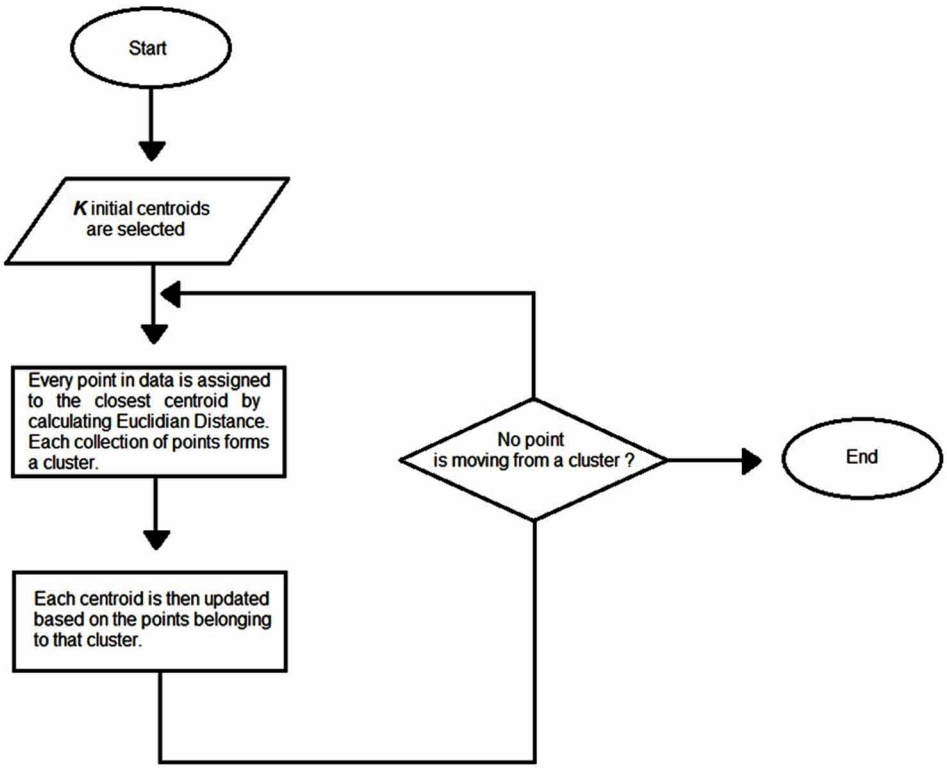
$v = \{3, 4, 2, 5, 0, 2, 5, 3, 1, 0, 1, 1, 2, 3, 3, 2, 0\}$

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 1. Data matrix example

	A1	A2	A3	A4	A5	A6	A7	A8	A9	A10	A11	A12	A13	A14	A15	A16	A17
Data 1	4	2	1	...	...	...	…	…	…	…	…	…	…	…	…	…	…
Data 2	...	…	...	…	…	…	…	…	…	…	...	…	…	…	…	…	…

Then data matrix of this problem will be represented by Table 1:



Based on DO-178b Configuration Management guidelines and best practices, specific data from the properties vector are labeled (Table 1).

The information is analyzed separately for Aerospace Software Development teams, and Aerospace Verification or Testing teams; this is because the Configuration Management activities within both groups can vary significantly and cause noise in the system. The objective of this separation is to avoid false-positives in the system results.

The clustering process of the algorithm is as follows (see figure 6):

Our K-means implementation for this problem is detailed in the procedure shown below:

Figure 6. K-means Algorithm Process

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

1. The Data Matrix

To explain the methodology we have designed with a visual example for representation purposes, we have chosen three of the seventeen properties of the vector model, shown in the following list (this way, a three dimensional figure can visually represent the individuals in our system):

1. Commit Size.
2. Failed Changes.
3. Number of unauthorized configurations.

The data Matrix of ten individuals or team members will be represented by the following table (see table 2):

2. Centroids Selection for Iteration 0:

For the centroids quantity selection, we will determine this number based on what we are looking for at this moment, which is patterns or types of behavior to determine anomalous data for each tester. We defined 4 centroids as the first set of centroids (the first four testers). We will denote the coordinates of the centroids by:

$C_1(4,2,1)$
$C_2(3,0,3)$
$C_3(2,1,2)$
$C_4(4,1,2)$

3. Objects-Centroids Distance for Iteration 0:

For this step of the algorithm, Euclidean Distance formula is used:

$$dij = \sqrt{\sum_{k=1}^{n} (x_{ki} - x_{kj})^2}$$

Table 2. Data matrix

	Tester 1	**Tester 2**	**Tester 3**	**Tester 4**	**Tester 5**	**Tester 6**	**Tester 7**	**Tester 8**	**Tester 9**	**Tester 10**
A1	4	3	2	4	4	3	2	4	2	4
A2	2	0	1	1	2	0	1	1	5	2
A3	1	3	2	2	1	3	2	2	0	1

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

In this case, we have *x,y,z* coordinates to be used in the formula to obtain the Distance Matrix for iteration 0, calculating the distance between each centroid to each object (testers data):

$$D^0 \begin{bmatrix} 0 & 3 & 2.45 & 1.41 & 0 \\ 3 & 0 & 1.73 & 1.73 & 3 \\ 2.45 & 1.73 & 0 & 2 & 2.45 \\ 1.41 & 1.73 & 2 & 0 & 1.41 \end{bmatrix} \begin{matrix} C1(4,2,1) group1 \\ C2(3,0,3) group2 \\ C3(2,1,1) group3 \\ C4(4,1,2) group4 \end{matrix}$$

$$\begin{matrix} t1 & t2 & t3 & t4 & t5 \end{matrix}$$
$$\begin{bmatrix} 4 & 3 & 2 & 4 & 4 \\ 2 & 0 & 1 & 1 & 2 \\ 1 & 3 & 2 & 2 & 1 \end{bmatrix} \begin{matrix} x \\ y \\ z \end{matrix}$$

4. Objects Clustering for Iteration 0.

Now we have to assign each object to a group based on the minimum distance. The elements of the Group matrix below has a value of 1 if and only if the object has been assigned to that group or cluster.

$$G^0 \begin{bmatrix} 1 & 0 & 0 & 0 & 1 \\ 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \end{bmatrix} \begin{matrix} group1 \\ group2 \\ group3 \\ group4 \end{matrix}$$
$$\begin{matrix} t1 & t2 & t3 & t4 & t5 \end{matrix}$$

5. Iteration 1, Determine centroids.

Now we know the members of each group or cluster, we calculate the new centroid of each cluster based on the new memberships, where the centroid of each group is the average coordinate among the members. In groups with one member, the centroid is the only object.

$$C1 = \frac{4+4}{2}, \frac{2+2}{2}, \frac{1+1}{2} = \frac{8}{2}, \frac{4}{2}, \frac{2}{2} = (4,2,1)$$

$$C2 = (3,0,3)$$
$$C3 = (2,1,2)$$
$$C4 = (4,1,2)$$

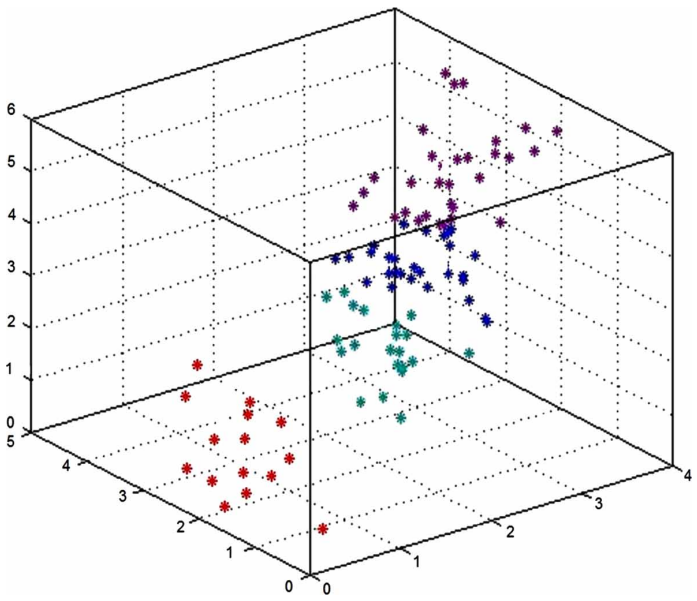
EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

6. Objects-Centroids Distance for Iteration 1:

We will repeat step 3 with the new centroids coordinates we just obtained.

7. Objects Clustering for Iteration 1.

We will repeat step 4 with the new centroids coordinates we just obtained.



8. When the group *Gn*=*Gn* - 1, the algorithm has converged, and we have a result, no objects are moving, and we have our clusters defined.

$$G^0 \begin{bmatrix} 1 & 0 & 0 & 0 & 1 \\ 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \end{bmatrix} \begin{matrix} group1 \\ group2 \\ group3 \\ group4 \end{matrix}$$
$$t1 \quad t2 \quad t3 \quad t4 \quad t5$$

The following figure (figure 7) illustrates visually a converged k-means for this problem, but with 91 objects we have added, in order to have an understandable representation of our 4 clusters.

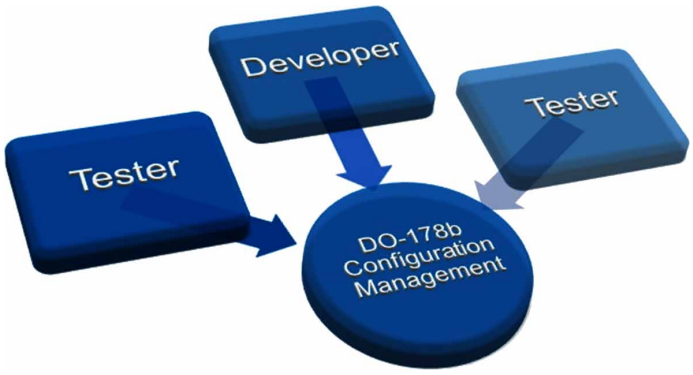
The following step is the cluster selection performing an exploratory analysis, in order to discriminate the rest of the data.

Figure 7. K-means Results Represented in a 3 Dimensional Plot

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

An analysis to try to identify a threshold and categorize a good behavior and a bad behavior with all seventeen attributes of data together will be performed to the different components of the properties vector, this is, k-means clusters results will be analyzed to find which cluster is maximizing or minimizing behavioral values, this is, which cluster represents a good or a bad behavior. This part of the design can be categorized within the Non-Supervised Learning techniques. The cluster with more anomalous characteristics will be selected and will be entering to the next statistical filter which will utilize the exploratory data represented in the figure below (see figure 8).

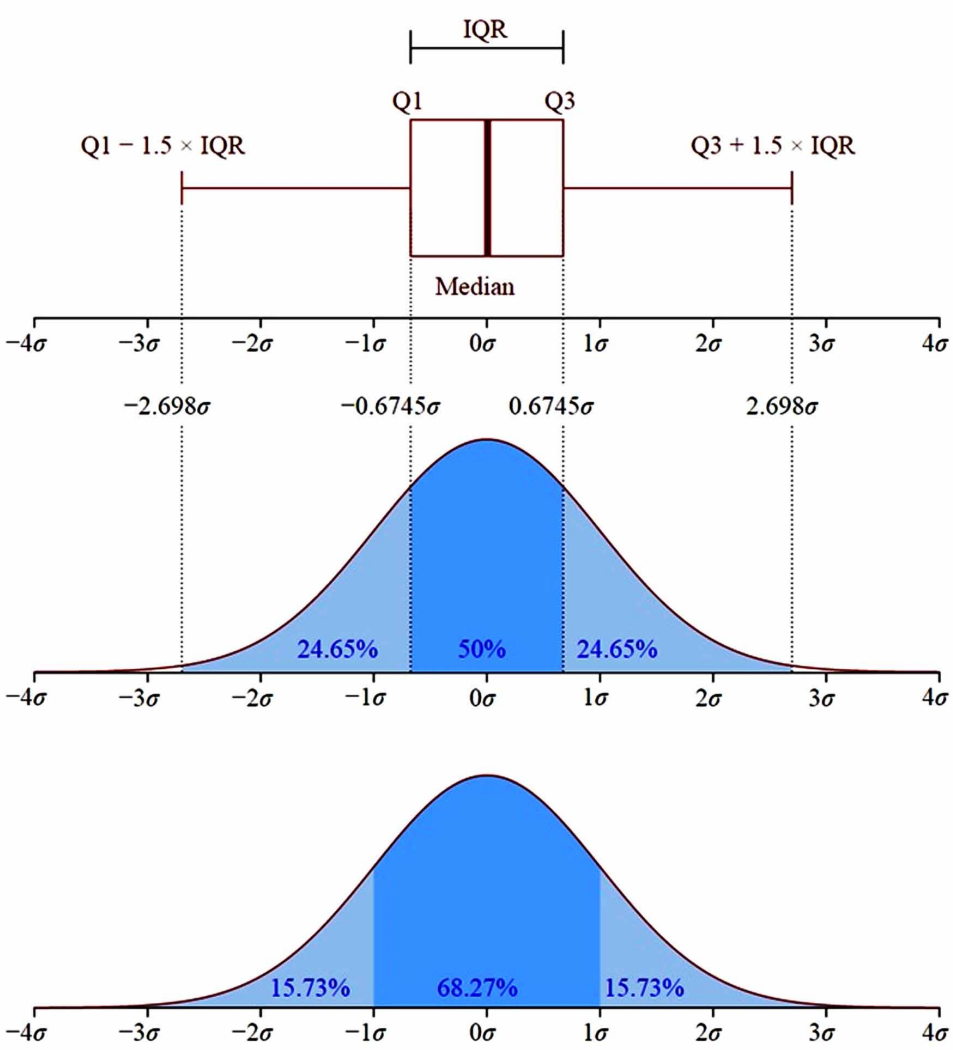
As we can see in the above image, exploratory data will come from different entities or individuals; testers and developers working with DO-178 standard in its b revision.



For the next step of this solution, the anomaly detection, an exploratory analysis is performed by using an anomaly detection technique of the descriptive statistics area. In this area, a box plot or boxplot is a convenient way of graphically depicting groups of numerical data through their quartiles. Box plots display variation in samples of a statistical population without making any assumptions of the underlying statistical distribution. The spacings between the different parts of the box indicate the degree of dispersion (spread) and skewness in the data, and show outliers. In addition to the points themselves, they allow one to visually estimate various L-estimators, notably the interquartile range, range, midrange, and trimean. Boxplots can be drawn either horizontally or vertically (McGill, et al., 1978). John W. Tukey, an American mathematician, introduced this type of visual data display in 1969.

A graphical representation of a boxplot and a probability density function, emphasizing the quartiles, is shown in the figure below (see figure 9).

The outliers' detection will be performed by an exploratory data analysis through Tukey Criteria, a statistical method constructing a lower and a higher thresholds to flag data as anomalous, where the lower and upper Tukey limits (lower and higher thresholds) correspond to a distance of 4.5 σ (standard deviations) from the sample mean. Any observations falling beyond these limits are considered as anomalous.



To explain how the probability distribution is formed by the problem data, we have modeled the information with vectors identified by two dimensions: *i* and *j*, where *i* represents the individual ID (i.e. 1714), and *j* represents the day ID (i.e. 01.25.2015).

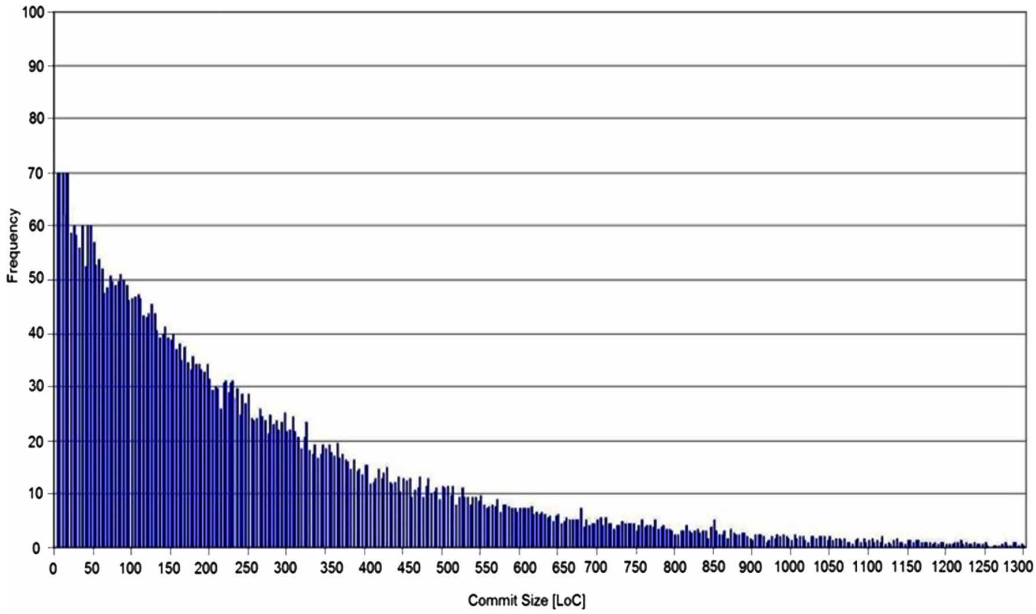
Figure 9. Boxplot and a probability density function of a Normal N(0,1σ2) Population



Vectors of different users and dates with the form $V_{ij}\{x,x1,x2\ldots\}$, would be represented as follows:

$$V_{1714,05.19.2015} = \{3,4,2,5,0,2,1,4,2,5,4,2,0,2,1,4,2\}$$
$$V_{2302,05.19.2015} = \{1,4,2,5,4,2,0,4,1,1,0,2,3,5,4,2,0\}$$
$$V_{1995,05.20.2015} = \{0,2,1,4,2,5,4,2,2,5,1,4,1,4,2,5,4\}$$
$$V_{0988,05.20.2015} = \{3,3,2,0,3,2,5,4,2,2,5,1,4,3,2,0,3\}$$
$$V_{1554,05.21.2015} = \{1,4,2,2,5,0,2,1,4,2,5,4,2,4,2,2,5\}$$
$$V_{1645,05.21.2015} = \{3,0,2,4,5,2,2,5,0,2,1,4,2,2,4,5,2\}$$

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 10. Frequency Distribution of Attribute 1 in our Data Matrix (2 weeks)

This data will be arranged in an ascending order from the smallest to the largest observation. The ordered data is broken into four quarters, the boundary of each quarter defined by Q_1, Q_2, and Q_3, called the 1st quartile, 2nd quartile, and 3rd quartile respectively. The difference $|Q_3 - Q_1|$ is called the inter-quartile range. The Tukey upper and lower thresholds for anomalies respectively are: $ltl=Q_1 - 3|Q_3 - Q_1|$ and $Q_3+ 3|Q_3 - Q_1|$· Observations falling beyond these limits are called serious anomalies and any observation, X_i, $i= 1,2,\ldots,n$ such that $Q_3+ 1.5|Q_3 - Q_1| \leq X_i \leq Q_3+ 3.0|Q_3 - Q_1|$ will be called a possible anomaly (Wang Ch. et al. 2011).

To illustrate one of the 17 distributions types we have worked with, the following distribution is representing the Commit Size Attribute Frequency from our data matrix in a DO-178 Project, in a period of time of 2 weeks (see figure 10).

With this frequency distribution we can see that we are working with an Exponential Distribution (see figure 11). The Tukey criteria formula for this the type of distribution ideal for this project (exponential probability distribution) would be defined as follows:

$$Q3 + 1.5IQR = \ln(4)/\lambda + 1.5\ln(3)/\lambda$$

The results for the Tukey Criteria Analysis will be thrown for each Vector´s Attribute Frequency Distribution which we will refer to as "Rules". After a Tukey Analysis has been performed, we can observe the results in a bar chart represented in the image below to identify anomalies per rule (see figure 12):

Tukey method allows the user flexibility in setting the threshold limits (see table 3). This way we can calibrate the strictness level of the algorithms. This will depend on the problem, the model efficiency, and the needs of the user. The upper and lower limits for Tukey can be set to $Q_3+ k|Q_3 - Q_1|$ and $Q_1 - k|Q_3 - Q_1|$.

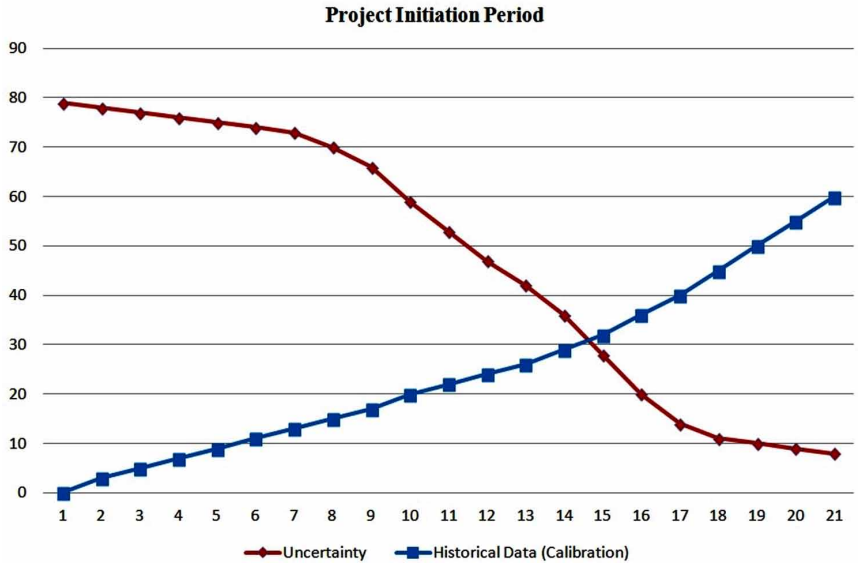
Table 3. Tukey Threshold Calibration

Tukey Criteria	Threshold	Anomalous Population
$Tk_1 = 1.5$	X = 3.034213 / λ	4.81125%
$Tk_2 = 0.834044$	X = 2.302585 / λ	10.0%
$Tk_3 = 0.464974$	X = 1.897120 / λ	15.0%
$Tk_4 = 0.203114$	X = 1.609438 / λ	20.0%

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

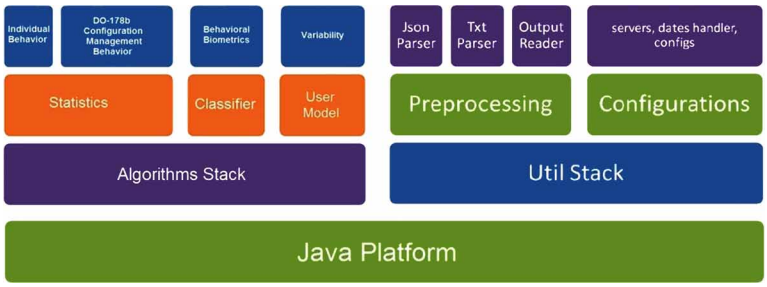
It is important to mention that at the beginning of each project, there is a phenomenon we call calibration period for the algorithms that take place during the first two weeks (initiation period). During this period, the system's uncertainty is high because there is not enough data to have a good level of efficiency in the algorithms results. This will be decreasing in parallel with increasing historical data after this period (see figure 13).



A Remediation Process for noise reduction purposes has been designed; this process is a quarantine that takes place after each algorithm's cycle has delivered results of anomalous data. This Remediation process takes the outliers individuals and start a pre-defined period of time quarantine of deep detailed supervision, where the system compares the behavioral biometrics in deeper detail, and the results for each individual are compared against a longer period of time. This process allows the system to look for false-positives or noise in the system, this way the system is able to eliminate possible noise.

The pre-defined period of time for the remediation process will depend on the combination of two constants of the system, the false-positives cost and the true-negatives cost for the needs of the project.

The results of this Remediation Process can represent two scenarios: The first one is when the outlier(s) was detected as noise in the system, then this individual is extracted of the remediation process. The second scenario is when the remediation process result is a true-positive, then the individual is a real outlier, and specific actions are to be taken.



A real-time notifications system has been designed, which will notify when an individual enters or exits Remediation, this will trigger an alert to the manager, so a deep analysis of the case can be performed with the information provided by the system. The outliers' notification will report a graphical behavioral diagnosis to demonstrate the results (see figure 14).

Figure 13. Calibration Period Representation

Figure 14. Solution Framework

FUTURE RESEARCH DIRECTIONS

The design of solutions for risk identification within the spectrum of complex systems will be always involving different areas of the science and different approaches.

After working with this project, we were identifying possible future work for scope augmentation on this problem. We can add some other techniques like Principal Component Analysis if we increase the number of factors and variables to identify risks company wise, instead of identifying risks at a project level. We also identify the needs of a prediction model in the future, to be able to exploit a big quantity of projects historical information with forecasting techniques like Time Series, Linear Regression, Support Vector Machines or Neural Networks. A prediction model would let a company to be prepared in advanced, and create strategies to improve its projects efficiency.

CONCLUSION

Configuration Management provides all the important control elements to the process: configuration items (CIs), environments' configurations, project libraries, version control, records and other configurations to identify parts and software that should be perfectly working in compliance with the approved versions, but this does not have an impact in the real-time detection of process and human errors, or requirements' specifications during the execution.

Configuration Management risks and issues have not been decreasing over time or with technology improvements, on the contrary, its complexity is growing with time. This model represents a significant help in risks identification for software development and testing projects in the aerospace industry. The behavioral diagnosis when reporting outliers are a valuable visual tool not only to avoid impacts in projects, but also to help to create real-time performance improvement plans for engineers, and to optimize and continuously improve the Configuration Management strategy, with valuable statistical data obtained by this model.

KEY TERMS AND DEFINITIONS

Anomaly Detection: A Data Mining technique in charge of the identification of events, items and observations not expected as a pattern.

Biometrics: In Computer Science, this term refers to the metrics related to human characteristics.

Clustering: An Unsupervised Learning technique of Data Mining used for identification and grouping of objects with similar characteristics.

Configuration Management: An area of the Software Industry related to configuration control activities.

Data Mining: An area of Artificial Intelligence related to the Knowledge Discovery through exploiting big quantities of data.

Pattern Recognition: A science that focuses in finding regularities in data.

Safety Critical Systems: Systems where a failure can result in big damages like loss of life, environment or property damage.

Chapter 8
Smart Grid and Demand Side Management:
Application of Metaheuristic and Artificial Intelligence Algorithms

Alper Ozpinar
Istanbul Commerce University, Turkey

Eralp Ozil
Zeta Information Technologies, Turkey

ABSTRACT

Energy becoming more and more crucial and critical in the civilized populations and locates itself as one of the major requirements of living standards. Obtaining the energy from fossil fuels still is one of the common sources of energy production; however, there is a common understanding of increasing the potential use of renewables, carbon capture and storage, energy efficiency and intelligence and smart applications for collecting, distributing and transmission of the energy between the supply and demand locations. Those applications and generating the new policies, roadmaps in order to make an energy revolution and increase the usage of low-carbon energy technologies targeting the decrease of energy related emissions. In this chapter, the authors explains the common issues about smart grid and demand side management and possible use artificial intelligence and metaheuristic algorithms for smart grid and demand side management optimization and scheduling.

INTRODUCTION

From the beginning of life in our universe, the mankind has needed and depended on energy in one form or another, from food to the operation of the most sophisticated machine we know today, for its existence, survival and progress. As the key commodity in the world, most physical laws, axioms and rules that are valid today either directly or indirectly related to energy. Especially with the start of industrial revolution it has become clear that the man needs to control the energy and the energy controls

the man. This dual relationship finds its true meanings from the laws of thermodynamics. The first law of thermodynamics is actually nothing but the accounting process of the energy, which eventually leads to the somewhat philosophic statement of the concept of conservation of energy which means that the energy can be transformed from one form to another, but cannot be created or destroyed. In other words, as we engineers say, the total energy of an isolated system is constant. The second law identifies which processes naturally occur in the environment and which do not. Because these two laws and many others related ones tell us that it is impossible to create new energy in our universe, we have over all these years taken the only plausible route and have chosen to transform otherwise non useful forms of energy, however abundant they may be, such as fossil fuels and brought it in one useful form or another to our homes, to industry and put them into use wherever and whenever we need it. Transforming processes include exploration, extraction, enrichment, cleaning, transporting, conducting, transmitting, distributing of energy among others.

Among the forms of energy known to all of us, electricity has become the leading form of energy starting from the second half of the twentieth century. With the recent improvements on the global education, increased awareness on the environment, and the goal of all the countries on increasing the welfare and prosperity of their people, the demand for electricity is increasing at a faster rate than any other form of energy. It is a known fact that new technological advancements and related end products most likely require electricity. In addition, environmental concerns has inevitably increased the demand for electricity consuming equipment at end use levels. Especially ever increasing demand for use electricity both for short and long range transportation in the sector which is in dire need for pollution control, will skyrocket the demand for electrical power. Finally, the diurnal variation for electricity demand in the industry, buildings and the commercial sector necessitates larger production facilities with high peak loads. This unstoppable increase in demand for electricity puts the existing power grids in a tremendous stress in all the countries.

Power grid is defined as interconnected network of power stations, substations, transmission/distribution lines, transformers that produce electricity from the power plants and deliver to the consumers. Power stations are operated by fossil fuels such as natural gas, coal, oil, nuclear fuel or by renewable resources. For the majority of last century electricity was mostly generated in large centralized power plants (Chan et al., 2012). And no care was paid whether or not they were placed and operated near heavily populated area. Some of the major characters of this type of a power grid is that the power is produced centrally. Secondly, in these classical power grids, electricity flows only in one direction, from the production point to the consumption site. Finally, the longer the transmission and distribution network, lower is the efficiency, reliability, and security. we may also add to these drawbacks, the issue of sustainability.

However when the first signs of climate change and increasing pollution appeared during the second half of the last century, it became apparent that there was a need for implementing new policies on the choice and quality of the fuel types, production processes, and setting new stringent pollution targets. In other words, the whole system of electricity production, transmission, distribution and consumption on the supply side and the energy consuming systems on the demand side needed new thinking, research, design, production and operation methods to be redefined and realized.

The reduction of greenhouse gases and emissions by using carbon free and clean production technologies like renewables is fast becoming one of the major alternatives to energy harnessing. But the renewables have issues of their own. First of all, if not most of renewables such as solar, wind, and hydraulic energy to certain extend all are intermittently available and their intensities are low. Just like fossil fuels

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

their availability widely varies on the earth. Some locations has a great wind power potential, some has solar, some has a small hydro potential as well as the biomass and other possible renewables. But none of them will be available at certain capacity at all times everywhere. We should never the less note that the number of renewable power stations are increasing at a promising pace all over the world. However, still theoretical and practical research on capturing and converting methods for most of the renewable systems, short and long term storage options as well as durability, maintenance and related fields.

We should emphasize that insisting on the continued use of fossil fuels for producing electricity as it was rightfully put in front of the humanity first by United Nations Framework Convention on Climate Change (UNFCC) in 1992, later by KYOTO Protocol and Copenhagen Convention, will increasingly produce wide range of pollutants and irreversibly harm the atmosphere and the ecosystem globally. In addition, more centralized energy production based on fossil fuels will result adverse effects on human health as proven statistically by many countries in Europe.

Nuclear power seems to be an alternative for fossil fuel based energy production for many years and it is the second-largest source of low-carbon electricity generation worldwide, after hydropower. According to IEA nearly all new nuclear construction in recent years has taken place in price-regulated markets or in markets where government-owned entities build, own and operate the plants (IEA, 2015b). However long term nuclear waste storage problems, huge risk potential of catastrophic accidents such as 1986 nuclear meltdown in Chernobyl and 2011 earthquake and the resulting tsunami's destruction of various Japanese nuclear plants, decommissioning problems and security issues needs to policy makers reconsider their nuclear investments.

The idea of decentralized power production and smart grids has evolved from the fact that, switching completely to new renewables energies, that is replacing all the fossil fuel using power plants, is not going to be possible in a very short time or it may be never be possible. Smart grid approach basically considers both sides of the operation, one side being the supply side where more clean electricity production will be achieved and the demand side will truly have decentralized production or even micro-generation at homes, buildings, large housing complexes as well as renewable energy based generation and cogeneration plants. All these will be planned and regulated by the newer set of regulations and rules. Inevitably, decentralized generation means transmission and distribution has to evolve into a new form and options like onside storage, short term switching and the most crucial idea of "two way operating" which makes each and every nodal point both a consumer and a producer in the grid. So the overall progress has to be optimized and scheduled as the constraints of the grid needs to become more intelligent.

The main objectives of the chapter is to provide a common understanding of the use of new and improving algorithms for optimization and scheduling for smart grids and demand side management applications in order to meet the future requirements of energy markets and usage. There are already a number of classical optimization and planning applications and algorithms available without the use of artificial intelligence and metaheuristics. However due to the success and widely adaptability and the increase the computational power of the computers these methods are becoming more popular applicable.

BACKGROUND

This part of the chapter starts with a short review of the related topics in order to provide the understanding of the topics and relationship between them. There are some great recommendations in the references and further readings part who wants to get involved in to these algorithms more detail. The authors do

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

not provide any language specific codes whereas algorithms and general parameter selection recommendations has been made. There are abundance of commercial and open source software packages in the market for the general use of artificial intelligence and metaheuristic methods.

Future Projections and Scenarios

IEA International Energy Agency, which is aiming to promote energy security to physical disruptions in oil supply, looking for ensure reliable, affordable and clean energy for the world publishes several reports on energy policies and perspectives and future projections each year. Their reports are key sources that provides the user with a common understanding to the needs of the energy issues. According to IEA reports, since the first Conference of the Parties (COP) held in Berlin Germany, in 1995, greenhouse-gas (GHG) emissions have risen by more than % 25 and the atmospheric concentration of these gases has increased steadily to 435 parts per million carbon-dioxide equivalent (ppm CO2-eq) in 2012. According to the International Panel on Climate Change (IPCC), humanity and all the countries have to take fully committed and urgent action. Otherwise climate change will have severe and irreversible impacts across the world. The international commitment to keep the increase in long-term average temperatures to below two degrees Celsius (2 °C), relative to pre-industrial levels, will require substantial and sustained reductions in global emissions

In order to obtain this level and reach the goals energy sector needs to be transformed since two-thirds of all anthropogenic greenhouse-gas emissions produced by energy sector. There are some good news in recent years about the application of these policies and precautions. Global energy production oriented CO2 emissions stayed flat in 2014 even there is an increase of around 3% in the global economy. (IEA, 2015a; IEA, 2006; IEA, 2015b) It is assumed to be the energy sector can achieve a peak in GHG emissions by the year 2020, with almost the same level of economic growth and development.

There are three main scenarios widely accepted in order to control the global warming and climate change. Kyoto Protocol and Copenhagen Climate Change Conference studies and outcomes becoming outdated and replaced with new policies and scenarios. Those scenarios have a common goal but they differ according to their assumptions about the evolution and application of government policies. These scenarios are the “Intended Nationally Determined Contributions (INDC) Scenario”, the “Bridge Scenario” and the “450 Scenario”.

In the Intended Nationally Determined Contribution (INDC), countries and unions like Switzerland, European Union, Norway, Mexico, United States, Gabon, Russia, Liechtenstein and Andorra which collectively represent more than one third of the global energy-related CO2 emissions submit their contributions in order to obtain the goals. All of the contributors have their own targets mostly based on reducing their GHG emissions by at least x % compared with 1990 levels by the year “y”. The numbers for x and y changes from country to country.

The “Bridge Scenario” is an improvement to the INDC and creating a bridge between INDC and 2°C target by focusing on research and development activities for the key energy technologies and making these technological steps and improvements to build up the bridge. Some examples of these technological improvements will be based on increasing energy efficiency, limiting least-efficient coal power, raising renewable investments, reforming fossil fuel subsidies and reducing upstream methane.

450 Scenario on the other hand have a different perspective but same target of global increase in temperature to 2°C can be obtained by limiting concentration of GHG in the atmosphere to around 450 parts per million of CO2.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

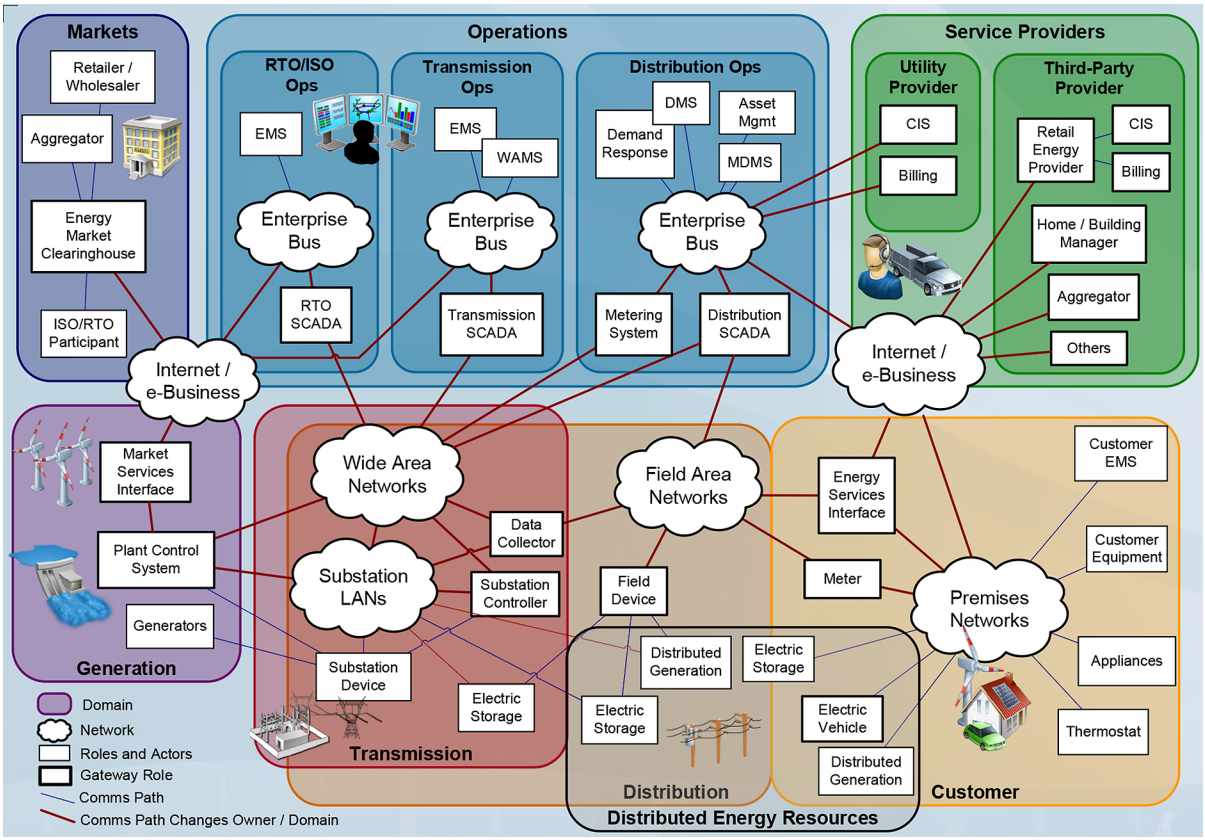
Smart grid, microgeneration and demand side management are key factors in all of the above policies and targets.

Smart Grid, Microgeneration, and Onside Storage

Power grid was defined above, as an interconnected network of power stations, substations, transmission/distribution lines, transformers that produce electricity from the power plants and deliver to the consumers. The classical grids have a history over one hundred years starting from the invention of electricity. However making a grid smarter requires new technologies in order to collaborate the market, producers, operators and various consumers and end point devices. According the definition of NIST, "Smart Grid" refers to a modernization of the current electricity delivery system so that the system able to monitor, protect and automatically optimizes the way of operation between the interconnected elements in the system. Energy transferred from centralized or decentralized distributed energy generator through the high-voltage transmission network and the distribution system, to industrial users, factories, commercial buildings and building automation systems, as well as energy storage installations and also to end-use consumers and their thermostats, electric vehicles, appliances and other household devices.

The Smart Grid mainly differs from one way flow operation of classical girds with a two-way flow of electricity and information to create an automated, widely distributed energy delivery network based on real time information and optimization. (Von Dollen, 2009)

There are major benefits that can be obtained from smart grids. First of all by the use of information technology, cloud computing, high speed communication between the devices in the smart grid system in order to automate and control the grid, the system behaves like an autonomous structure so power reliability and power quality can be obtained within the grid. This autonomous grid has a self-monitoring property to detect unsafe, insecure and risky situations which may result in malfunction or unreliable working conditions. Encryption, secure communication, cyber security included in to the all components of the smart grid when required and available. These standards and applications makes grid more safe and secure comparing with the classical grid. One major benefit of the smart grid which is mostly related with our chapter is the energy efficiency benefits. Smart grid can adapt itself to operate in different conditions providing higher efficiency, reducing the peak demand, minimizing the energy losses and interact with the end user. As mentioned on the previous paragraphs, there is a need for smarter technologies in order to reach the goals of different scenarios. Smart grid helps to reduce the GHG and other pollutants by reducing or swapping the energy production from inefficient energy sources, least-efficient coal power, supports the use of renewable energies even in the household level and moreover to replacement in the transportation from fossil fuel operated vehicles to electric vehicles. And finally smart grid has direct financial benefits for all contributors and actors. Operational costs reduced, avoided or balanced with different policies and operational models between customers and the market. The customers have a direct feedback option via display devices and indirect feedback within the bills. This will enhances the demand control and provide energy savings from reducing the peak demands. Controlling the demand will be explained more in detail in demand side management. (Gellings, 2009)



Smart grid also improves operational efficiency. In order to obtain and maximize these benefits grid has to be more smarter with the implementation and use of communications, electronics, and other related technologies like automatic sensors, data loggers, PLC's and control cards and units such as phase measurement units (PMUs) which measures and tracks voltages and currents at transmission lines and distribution stations. All these devices, units stations makes the grid smarter for reliable detection,

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

isolation, and recovery of faults and greatly simplifies distributed state estimations in power systems for better monitoring for grid system operating stability, planning, scheduling, optimization, and recovery. Since there are lots of computational requirements for the monitoring and calculation of frequency, amplitudes, and transients of power signals different mathematical models and algorithms implemented in to smart grids. (Chan et al., 2012)

Two way operation system gives the potential to the customers being energy generators to their neighbors and the grid. Especially use of small wind turbines, smart buildings with PV's, solar water heating, air source heap pumps, micro CHP allows on-site energy efficiency production and storage. In order to support and encourage microgeneration and on-site storage systems governments offers various tax discounts, financial plans and credits with a guarantee for buying the excess energy produced via smart grid. Considering the future use of electricity driven transportation vehicles, and networks, microgeneration is becoming more important by removing most if not all the emission from vehicles and thus minimizing the carbon footprint. Figure 1 shows the NIST conceptual reference diagram for the smart grid and microgeneration. (Locke & Gallagher, 2012).

Figure 1. NIST conceptual reference diagram for the smart grid information networks

Demand Side Management and Planning

As mentioned on the previous paragraphs smart grid includes the generation, transmission, distribution and finally consumption in two directions. Although the improvements and the innovations in the field of generation, transmission and distribution provides better results and efficiency in order to reach the goals in the scenarios effective controlling and management of the demand is also essential. A good demand side management policy, when implemented, helps to plan and optimize the generation capacity, plant utilization and efficiency by adapting the flexible demand hours on the time domain. Controlling the peak demand, reducing the duration of the peak hour operations, directly eliminates the inefficient, high carbon cost power stations from total generation capacity. They may still be used in the grid as backup and emergency generators. Controlling the peak and fluctuations also improves the operation and the efficiencies of the transmission and distribution networks. The smart grid network expected to be operate even loss of a single circuit due to a fault, malfunction or overload due to peak requirements the rest of the circuits in the grid takes over the operating load of the faulty line. So as a good operating practice requirement during peak-load conditions, grid circuits in the interconnected transmission network are generally loaded below 50% capacity. (Strbac, 2008).

There are various demand side management programs based on the energy efficiency on the demand side by replacing the devices with better, efficient and green technologies which is not directly related with the smart grid and optimization. A dynamic demand planning as a part of demand side management, monitors the smart grid's power factor which is defined by the ratio of the real power flowing to the load to the apparent power in the grid, and aims to increase the diversity factor of the grid by smart opening and closing or shifting the operating cycles which can be controlled and programmed automatically. A management on the demand response is the most widely and easily adaptable part of demand side management programs. The aim of the program is to stabilize the demand in to some limits regarding from the time and season and avoid peaks, fluctuations in the grid. This type of program can be achieved mostly by changing the demand characteristics of the consumers. In order to convince and control consumers' consumption habits educational means, social responsibility and awareness schemes can be employed. However, use of dynamic pricing based on the time of the day and the season is the most effective ways of achieving the goals. For example critical-peak pricing (CPP) in which prices during the top 40–150 hours of the year rise to previously specified levels designed to recover the full capacity and energy cost of power plants that run primarily during those hours. During all other 210 hours of the year, prices are lower than existing rates by an amount sufficient to leave the bill unchanged for a customer whose load shape mirrors that of the rate class. (Sioshansi, 2011) Practical use of CPP can be operating the washing machine, dishwasher and electrical heaters for taking a shower in the other than the peak hours mostly late in the evening or early in the morning where the general demand by the industry is low.

Methods for Decision Taking, Optimization, and Scheduling

Smart grid and demand side management applications and problems can be solved by various mathematical methods and algorithms. The overall solution progress includes both deterministic and probabilistic approaches. Energy production based on fossil fuel can be modelled and controlled by deterministic models, however in case of renewables and customer behavior that generates the demand and as well as the possible microgeneration within the grid cannot be modelled by using simple deterministic models. It is possible to calculate and simulate the model by using assumptions and sophisticated deterministic

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

models operated with calculated and defined parameters and rules. Even these models can calculate the demand and supply, the deterministic part of the model mostly static not dynamic. Making them dynamic requires lots of computational power, based on iterations and long calculations. Another point on the deterministic models they does not include randomness. Since the smart grid has the tools for information and gathering statistical historical data and real time operating data includes a bias and some uncertainty due to human and nature behaviors hybrid models includes both deterministic and probabilistic parts can be used.

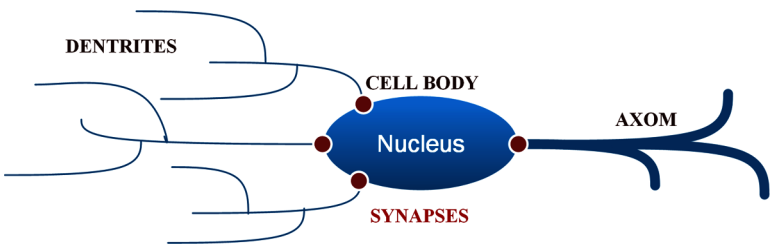
Artificial intelligence can be considered as the art of perceiving the situation and taking decisions by the machines in which the rules are not clearly defined and there are some uncertainties within the situation so it is not an automation performed by a machine. Artificial intelligence has been misinterpreted with the keyword machine automation. An air conditioning system that operates according to the indoors and outdoors temperature levels looks like an intelligent system for most of the users. However, a programmable logic control based on the simple rules operated by the temperature information coming from the sensors gives the indoor, outdoor and comfort temperature values based on the readings and assumptions. Operating the air conditioner in cooling mode based on a simple proportional feedback controller solves all the problem. There is no decision nor an intelligence required in this progress after it has been programmed. Programming this controller involves a decision and intelligence progress by humans, but operating is totally different process. An improved version of automation can be considered as machine learning and expert systems. Where the lack of information and necessary acts can be taken by both rules and statistical learning progress. Table 1 shows a conceptual definition of automation and intelligence. As explained a plc automation is a pure rule based system without and decision. A bank ATM can be considered as a rule based automation machine, if the customer have a positive bank account then depending on the daily limits and amounts cash withdrawal can be automated. During this progress the ATM machine does not make any decision, all the progress clearly defined by the bank standard operating procedures. However when the customer asks for a loan or a credit the system transforms in to an intelligent machine acting like an expert system operating if-then rules and knowledge databases, moreover a much more intelligent system learning from previous customer experiences and evaluation of financial indicators also with standard operating rules of the bank, the ATM machine makes a decision of giving a credit or not. Moreover to this decision, the machine follows the payback period and progress, compares with the previous credits decisions segmenting them false positive, false negative, true positive and true negative and learns to make better decisions for the next customer.

Table 1. Automation versus intelligence by means of information, tools and operation data

PLC and Machine Control	Expert Systems	Metaheuristics	Machine Learning	Self-Aware AI
Automation with rules and SOP	if-then rules Knowledge database Decision tree	Optimization search Imperfect info Incomplete info Limited computation Resource allocation Stochastic process	Statistics Knowledge Optimization Learning Pattern Recognition Decision trees Artificial Intelligence	Decision without rules and SOP
100% automation 0% AI	0% < AI, Automation <100%			0% automation 100% AI

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Demand side management and smart grid operations are similar decision making processes. There are some rules based on operational procedures but cannot be classified as pure automation. There is no simple weather model accurately forecasting the weather for the short, mid and long term. The operators and the market need both supervised and unsupervised learning and which will improve the system outcomes for the policy and scenario targets. For example a load forecasting in the smart grid that uses weather forecasting by artificial intelligence and price optimization by metaheuristic model can be applicable. Main advantages of these methodologies are that, they are mostly dynamic, self-learning and self-improving algorithms so they can provide sustainable solutions for the future based on the current and historical data. So if the growth rate of the county will change in the future due to economic conditions and global competition, algorithms can improve the working parameters, set the new critical peak hour pricing values. Also increase and decrease in the pricing is based on common optimization rules.



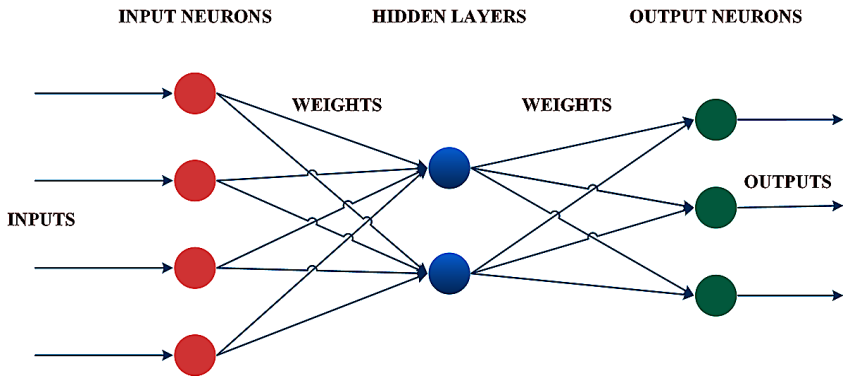
ARTIFICIAL INTELLIGENCE AND METAHEURISTIC ALGORTIHMS

This part of the chapter organized as a brief explanation of the algorithm, general usage and a pseudo code adapted to the proper example for smart grid and demand side management. As mentioned before there are a great number of resources, publications and books available related with the algorithms, so the authors aim to give a common usage and understanding about the algorithms.

Artificial Neural Networks (ANN)

Artificial Neural Network (ANN) is inspired from human neural information processing structure which formed by biological neurons. In the actual biological system a treelike nerve connectors, namely dendrites, are connected to the cell body. These dendrites act like communication bridges and receive signals from other nearby neurons. Cell bodies have a single long connector namely axon which connects the cell body to other neurons via dendrites or cell bodies, the connection point or the junction called the synapse. Axons can have tree diagram like strands and sub strands giving a possibility to connect a neuron to many other synapses. The transmission of information signal from one neuron cell to another at a synapse performed by a complex chemical process which is out of the scope of this chapter. But, in general, the dendrites serves as receptors for signals from other neurons, whereas the purpose of an axon is transmission of the generated neural activity to cells. (Yegnanarayana, 2009) An illustrational drawing for the biological neural network given is in Figure 2.

Figure 2. The biological neural network



EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Up to now we have explained a perfect biological system which may seem a little irrelevant to our subject. However replacing the cell body with the concept of any node in the smart grid such customers, market, operations, service providers as in Figure 1, it suddenly becomes more logical and turns into a smart grid information network. In the case of artificial neural networks, the system is composed of artificial neurons connected to information inputs balanced with weights for each input, like the axons in biological neurons, artificial ones also connected to other neurons. There neurons can be hidden in order to improve the learning and adaptations progress. Figure 3 shows the general structure of artificial neural networks. Within in each node of the ANN, there is a transfer function used to collect the data from the inputs balanced with connection strengths or weight parameters and then an activation functions like step, linear, log-sigmoid, tan-sigmoid and Gaussian helps us translate the transfer functions input values to output values.

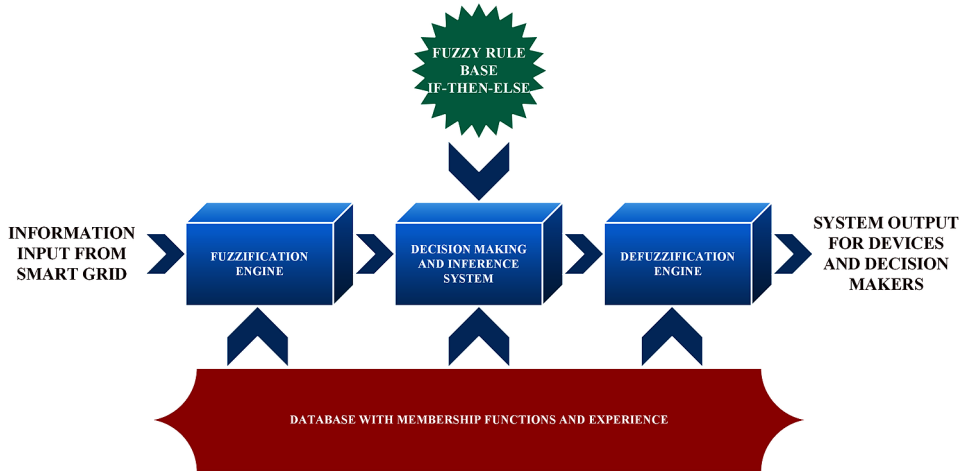
An artificial neural network needs an adaptation, or in other words, a learning process to understand and interpret the information flow according to inputs and outputs. Accordingly, in ANN theory, there are three main types of learning methods. In supervised learning, a historical data from the smart grid about supply and demand, peak hours, and operating zones are provided as an input and the output to the system from previous real data or data generated from deterministic models are tested in the field. So the input data is propagated forward through the ANN network model defined in the beginning. The output data from the system compared with the correct outputs and depending on the bias and the errors if obtained, the next step is to change the weights programmatically and use the new weights to start all over. This learning progress similar to a learning progress in a school when an instructor or a supervisor tells that the outputs or progress is good or some parts has to be updated. In supervised learning a set of input vectors and output vector used and considered to be learning a mapping from input set to output set. In most of the supervised learning, the learning data is prepared and used, after successful learning system works with the learned parameters and weights. The second type of learning is the unsupervised learning and is mostly used as a part of machine learning systems. In this type of the learning, the system looks for the grid information flow and the demand side information only the inputs to the system. Then the ANN network is doing self-learning depending on structure in the input data like the demographics, income level, geographical location, weather station inputs for those days, time based electricity consumptions numbers. Clustering, grouping or segmentation is common ways of this type of learning.

Figure 3. The artificial neural network

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

In the final version of learning, reinforcement learning, combines two of the better learnings, so the system uses input to generate output depending on the initial parameters. The feedback from the grid or the customers is simply a scalar value which may be delayed in the time domain depending on the output decision type. The success and the failure of the decision made. So the system is learning the progress online when the grid is actually working. This type of learning can cause some malfunctions and critical errors if applied to decision related with the distribution or transmission lines. However, it can be used as a part of customer experience where there is no previous data available about the system while testing a new dynamic pricing model. The inputs will be the possible segmentation of price and time zones and the output will be the peak reduction levels.

A most convenient way of working with ANN is to use a package program in the beginning while making the test and then code or integrate the package to the system. The main disadvantage of the ANN is the type of the network, number of hidden layers, activation function selection, the number of hidden layer input, outputs and the learning type cannot be estimated in the beginning. There are some recommendations about which type of network and settings to use but in most cases researchers has to do some trial and error possible studies depending on the data and the information. ANN mostly used for modelling, curve fitting and forecasting the data.



Fuzzy Logic

Fuzzy logic is an mathematical approach to modelling based on the degrees of membership or truth instead of the classical Aristotle logic which was later adapted to computer world by a system of symbolic logic by George Boole where there is only two options: true and false or a member of something or not. Actually, what the fuzzy logic does is to set the membership function to 1 or 0. Fuzzy logic based fuzzy information systems are very suitable for modelling and control of the devices and systems without dealing with complicated equations where possible. Most of the devices within the smart grid and also most of the demand side customer behaviors cannot easily be explained by classical logic. In general, fuzzy information systems create a mapping between the experiences based on linguistic fuzzy rules to real life values. Fuzzy logic systems are robust, can be modified or tweaked easily, tolerant to imprecise data, based on natural language statements but requires those expressed as a part of historical or theoretical experience. The most classical example of fuzzy logic about the decision making for the room temperature can be perfectly adapted into a smart grid system. If the household tries to make a plan for energy saving from air conditioner in the house he has to be precise about when to start the cooling and when to stop. Setting a limit value to start and stop in classical control theory can solve the problem however most people prefers to say the weather is too hot instead of telling as the exact temperature in numbers. If home automation system based on classical logic and a little old system for variable operating conditions, there will be too much on and offs in the operating cycle which may generate fluctuations in the grid. However using a smart controller based on fuzzy logic, the previous experience of the household can be expressed by fuzzy rules in language statements like, if the weather is hot, and humidity is low then run the air conditioner in the first stage and so on. A fuzzy sets and fuzzy membership functions will be used to define the linguistic experiences in to fuzzy engine.

So in normal operation, the inputs to the fuzzy information system from the sensors, inputs from the systems, read values from metering devices and those real scalar numbers are converted as real fuzzy values. This process called, “Fuzzification” as shown in Figure 4. Different fuzzy membership functions are available for this conversion; such as triangular, trapezoidal, gaussian, and generalized bell shape.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 4. The fuzzy information system for smart grids

There are two ways of expressing a value by means of linguistic variable, first giving a separate set name for each status. For example, considering the temperature case, the fuzzy sets will be hot, normal and cold. But sometimes finding the correct linguistic definitions is not that easy, in that case a degree of negative, neutral and positive or small, medium and big can be used also with adjectives like "very" to make it more precise. In general 3, 5, 7 adjective naming system used for different sets. After the input values are processed by fuzzification, these fuzzy values are subjected to fuzzy decision making logic which is controlled by the fuzzy rule base. Mamdani and Takagi - Sugeno methods are possible approximation and information extraction models of the fuzzy logic. Last process of fuzzy information system is the "Defuzzification" of the information to real scalar numbers where they can be processed by controllers, programs and applications.

Fuzzy logic can be used in the demand side management system for optimizing the demand response and flexible pricing. Experience based rules can be written easily to perform the operations.

A further application of fuzzy logic is to combine it with artificial neural networks. Integrating the linguistic reasoning and rule based system of fuzzy logic with the learning capabilities of neural networks results in hybrid Fuzzy Neural Network (FNN) or Neuro-Fuzzy System (NFS). This type of hybrid application improves the fuzzy logic systems in their field of experience requirement and lack of learning.

Particle Swarm Optimization (PSO)

Similar to the inspiration of the biological neurons, particle swarm optimization is inspired from the behaviors of the various swarms in the nature such as birds, fishes and ants. Particle swarm optimization is considered to be a stochastic population based optimization. This is the reason why it is suitable for smart grid and demand side management applications. In the literature of the PSO it is accepted as there are five major swarm behaviors and actions in the populations (Millonas, 1992). Considering these populations as the grid member the new behaviors can be listed as;

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

1. **Proximity:** Ability to perform space and time computations, as described in the grid section of the chapter with intelligent devices at the generation and consumption locations, sensors, actuators and controllers connected to the information grid. Most of the instrumentation will have enough microprocessor power to perform computations or at least with a connection to information network or high performance computing also with the use of Internet of Things (IoT) devices and the computational power of cloud computing where the computations can be made.
2. **Quality:** Ability to respond to environmental quality factors, so the smart grid node devices responds to the pricing and tariff changes and communicate with the other devices for dynamic response.
3. **Diverse Response:** Ability to produce a plurality of different responses, so each device or each node in the grid can perform also independently which in turn could be very useful in the case of microgeneration and on-site storage.
4. **Stability:** Ability to retain robust behaviors under mild environmental changes, so small fluctuations in the demand response does not affect the overall system stability.
5. **Adaptability:** Ability to change behavior when it is dictated by external factors, so the smart grid continuously adapts itself to the new economical and sociological requirements and working conditions.

In general a PSO algorithm is used mostly for optimization, candidate solution sets or working parameters for the smart grid population modelled according to the general behaviors. These candidate solution sets which are called particles in solution swarm, coexist and evolve simultaneously based on knowledge sharing with neighboring particles. Each particle will be either be acting individually or also in coordination with the other particles. Onsite storing capacity of the households, scheduled working hours for the machines in the industry for batch processes, charge location of each car within the city can be some example uses of this particle solutions. So each particle generates a solution based on the problem statement and initial starting point. In each turn all the particles changes their location, parameters, settings by using a velocity vector to reach its next position in the solution space. Each particle changes its velocity in order to reach a better position than the previous one by using its own best previous experience data and also the best previous experience data from the neighbors within the grid. Particles update their velocities as shown in equations below:

$$v_{t+1}^{i} = w_t v_t^{i} + c_1 r_1 \left(p_t^{i} - x_t^{i} \right) + c_2 r_2 \left(p_t^{g} - x_t^{i} \right)$$

and the new positions are calculated according to

$$x_{t+1}^{i} = x_t^{i} + v_{t+1}^{i}$$

where x_t^i represents the current position of particle i in solution space and subscript t indicates an iteration, p_t^i is the best-found position of particle i up to iteration count t and represents the cognitive contribution to the search velocity v. Each component of v_t^i can be limited to the range $[-v_{max}, v_{max}]$ to control excessive roaming of particles within the smart grid and creating possible risks of malfunction and system stability. p_t^g is the global best-found position among all particles in the smart grid swarm

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

up to iteration count t and forms the smart grid information flow to the velocity vector; r_1 and r_2 are random numbers uniformly distributed in the interval (0,1), while c_1 and c_2 are the cognitive and social scaling parameters depending on the structure of the grid and demand side policies. Finally w_t is the particle inertia, which is reduced dynamically to decrease the search area in a gradual fashion. The variable w_t is updated as;

$$w_t = \left(w_{max} - w_{min}\right) * \frac{t_{max} - t}{t_{max}} + w_{min}$$

where, $w_{\max}$ and $w_{\min}$ denote the maximum and minimum of w_t respectively; $t_{\max}$ is a given number of maximum iterations.

So the smart grid devices repeated the communication and changes their parameters until a time limit or a stopping criteria values reached.

Finally, the general PSO algorithm that can be used for smart grid applications is as follows:

```
For each device in the smart grid
   Initialize device with working parameters
End
While iteration number < maximum number of iterations or an acceptable optimum
reached Do
   For each device
   Calculate fitness value for better
   If the fitness value is better than the best fitness value (p_Best) in history
set current value as the new p_Best
   End
   Choose the device with the best fitness value of all the devices as the g_Best
   For each device
      Calculate device adapting velocity
      Update device working parameters
   End
End
```

Genetic Algorithms (GA)

Genetic algorithm (GA), is the most widely used version of evolutionary algorithms among the meta-heuristic methods. Similar to the inspiration from the nature as well as ANN and PSO, genetic algorithms are used to structure of evolution in order to reach the perfect solution that fits in to the energy environment. The possible working parameters of a particular device in the smart grid for demand side management optimization or scheduling problem taken as a member of the solution domain. As in the nature, every individual member device has set of properties and working parameters which differs from rest of the devices in the grid.

These properties and working parameters corresponds the chromosomes or genotypes similar to the ones in the living organisms (John, 1992).

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

As the nature evolves in the time domain with new generation reproduced or composed of their parents or ancestors genotypes by crossover and mutation. Each new next generation member has a possible chance to better fit to its environment. The rules of genetic algorithms can be adapted to optimization problems in the smart grid and demand side management problems where the parameters for the devices or the pricing policies coded as chromosomes and the overall objective function for the grid optimization and scheduling considered to be the fitness of the member to the system. Most of the numerical adaptations of the problems numerical values decoded as binary strings so easy to make different levels and sources of crossovers and mutations (Kumar & Mohan, 2011). The common steps of genetic algorithm is as follows arranged for smart grid applications as follows

1. **Representations:** Proper coding of the smart grid optimization and scheduling in to mathematical chromosomes while the decision variables within a solution (chromosome) are genes. The possible values of variables (genes) are the alleles and the position of an element (gene) within a chromosome is named locus. Most common representation is based on bits. A simple example can be stated as the working status of any generator or electric device can be represented as 1/0 as on and off during any particular time or condition. Binary, discrete and permutation representations are available in the literature.
2. **Population Initialization:** Using the representation coding an initial state of the smart grid devices and their settings created and represented as defined on the first step. As to continue from the previous step, initial population contains some power stations are operational and some are not in a particular initial timing.
3. **Objective Function:** Proper coding of the grid optimization problem in to mathematical chromosomes which will be used to calculate the goodness of the solution.
4. **Selection Strategy:** The best parameter sets or working plans which fits into the objective function selected for the next round of reproduction. Assume there are 32 different working schedule options to start with as a power generation or consumption. Some of the options may generate a peak demand in the system whereas the others do not. So the selection strategy will be based on the objective function and the ability to conform to working parameters and schedule to the system. Selection strategy can be based on proportional conformance (fitness) or rank-based fitness. Since the capacity and parameters within the smart grid devices are different from each other depending on the location of use, industry and priority proportional fitness based selection gives better results. In the rank based selections, without looking at the proportions, best solutions are selected for the reproduction. Thus, considering the demand and supply capacities, it is possible to select huge power stations together with micro generation stations. Roulette Wheel Selection, Stochastic Universal Sampling, Tournament Selection, and Rank-Based Selection are common selection methodologies.
5. **Reproduction:** Using the current solution sets, they will produce the next generation alternatives by using;
    a. **Crossover:** Crossover is used to increase the diversity of the possible solutions, in the selection of energy stations, operating status of the stations replaced with other stations. This can be useful when comparing the different sources of energy and switching from hydroelectric power plants to natural gas power plant in some parts of the smart grid or vice versa. It will also be possible to include small reservoir or pumped hydro stations optimization within the grid.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

b. **Mutations:** New genetic material into the gene at some minor ratio. With a small probability, randomly chosen bits of the offspring genotypes change from '0' to '1' and vice versa for binary coded strings. Moreover to the switching the working status of the power stations, a mutation starts or stops a power station after the crossover applied. This will increase the possibility of the new searches in the domain.

6. **Replacement Strategy:** The best solutions which fit in to the smart grid objective function are selected for the next round of reproduction
7. **Stopping Criteria:** The best solutions which fit in to the smart grid objective function selected are for the next round of reproduction

Like most of the other artificial optimization methods, the following genetic algorithm can be used for complex problems.

```
Choose an initial grid operating parameters by means of chromosomes;
While termination condition not satisfied Do
   Repeat
      If crossover condition satisfied Then
            select parent chromosomes
            choose crossover parameters
            perform crossover
      End if
      If mutation condition satisfied Then
            choose mutation points
            perform mutation
      End if
      evaluate fitness of offspring
   Until sufficient offspring created;
select new grid operating parameters;
End While
```

Ant Colony Algorithm (ACO)

Ant Colony Optimization (ACO) is another swarm intelligence based metaheuristic algorithm that is inspired by the pheromone trail laying and tracking of the remaining of ants while finding their way to food or home. Use of artificial ants in ACO for smart grid applications are stochastic solutions that build possible candidate solutions for the optimization settings and parameters of the smart grid by adapting the artificial pheromone in other words fitness information. ACO is mostly used for discrete optimization problems for scheduling, routing and assignment of the resources in the smart grid. There are various ACO algorithms available like Ant System (AS), Elitist Ant System (EAS), Rank-Based Ant System (ASrank), Min-Max Ant System (MMAS), Ant Colony System (ACS), Approximate Nondeterministic Tree Search (ANTS). The real ants uses stigmergy which is a form of indirect communication by modifying the environment for further usage or communication. In case of the ACO, stigmergy based on the pheromone trails leaved by the ants while passing through a path or way.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

While adapting the ACO to the smart grid optimization ants will be artificial computational agents for the selection of smart devices in the grid operational. Traces or the pheromone levels considered to be the information within the smart grid like the consumption, prices. The memory for the grid is the tabu list of the possible solutions obtained within the system. In case of adapting the travelling salesman problem like selecting the order of the cities during the sales smart grids equipment operational timings aiming dynamic demand mode can be modelled. The ACO algorithm modified for smart grid is as follows:

```
Initialize the base efficiency and fitness (attractiveness), τ, and visibil-
ity, η, for each solution set;
While termination condition not satisfied Do
   For each smart agent Do
      choose probabilistically (based on previous equation) the next state to
move into
      add that move to the tabu list for each smart agent
      repeat until each smart agent completed a solution for dynamic response
   End
   For each smart agent that completed a solution Do
      update energy efficiency and fitness τ for each edge that the smart
agent traversed;
   End
   If (local best solution better than global solution)
      save local best solution as global solution;
   End
End
```

SOLUTIONS AND RECOMMENDATIONS

Linear programming, integer programming, dynamic programming, stochastic programming and many other methods can be used as traditional methods for smart grid applications and there a vast number of different examples available in the literature. Use of artificial intelligence and metaheuristic methods in smart grid and demand side management applications is summarized as in Table 2 according to the main controllable aspects of the issue. For smart grid applications in order to improve the benefits a good load balancing and forecasting required with a proper resource and production planning. Usage matrix summarized potentials of the methods and algorithms as M: Modelling, F: Forecasting, O: Optimization, S: Scheduling.

FUTURE RESEARCH DIRECTIONS

As the global awareness for the global warming and climate change increase, the idea of smart grids and demand side management will gain more significance and related programs will be urgently needed. Both the smart grid and demand side management applications means interaction with a vast number of instruments, devices, sensors, computers, power lines, transmission lines, distribution lines, new

technologies and smart equipment like IoT. It is quite clear that a synchronization and harmony between these technologies is a big challenge for engineers. And making it all possible and fully operational at once is a chore that is easier said than done. However, the concept of smart grid is fast evolving, device by device, customer to customer, node by node for the very near future; thus creating new research venues for the researcher.

Future research opportunities by the authors within the domain of the topic includes the analysis of the other metaheuristic methods and artificial algorithms like memetic algorithms, multi start methods, tabu search, guided local search, iterated local search, reactive search, stochastic search, simulated annealing and hybrid metaheuristics for better and alternative optimization, modelling, forecast and scheduling.

CONCLUSION

Demand for clean energy is becoming more vital and critical in every single day. Smart grids and demand side management tools are the most promising alternatives for successfully achieving energy related scenarios like INDC, bridge and 450 ppm scenario in order to keep the global warming level at or below 2°C. Moreover the research and development activities for new technologies, low emission processes demands efforts be focused on modelling, forecasting, optimization and scheduling of appropriate bodies and devices that can be used in smart grids. In this chapter both artificial intelligence and metaheuristic methods and algorithms are summarized and their possible application areas are identified. As expected artificial intelligence is more suitable for modelling and forecasting, whereas metaheuristic methods are better for searching optimum solutions and schedules.

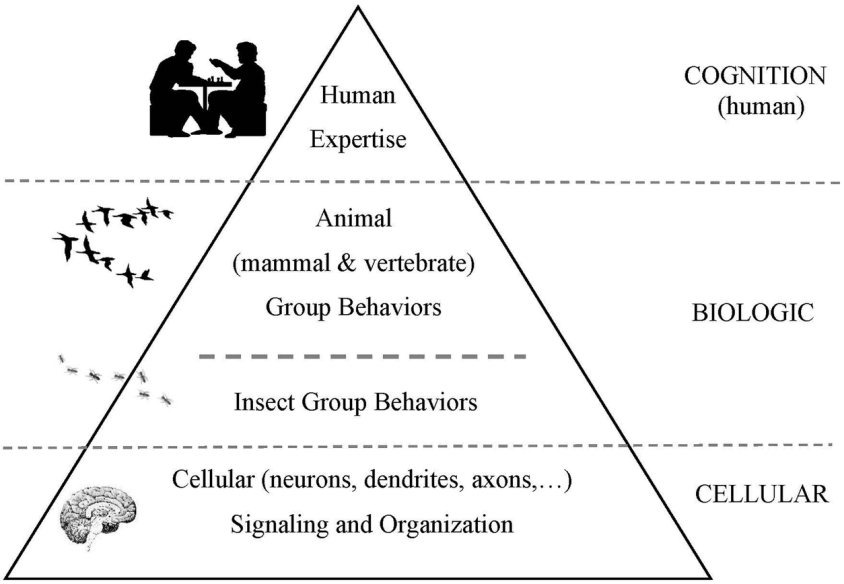
Chapter 9
Society of Agents: A Framework for Multi-Agent Collaborative Problem Solving

Steven Walczak
University of South Florida, USA

ABSTRACT

The development of multiple agent systems faces many challenges, including agent coordination and collaboration on tasks. Minsky's The Society of Mind provides a conceptual view for addressing these multi-agent system problems. A new classification ontology is introduced for comparing multi-agent systems. Next, a new framework called the Society of Agents is developed from Minsky's conceptual foundation. A Society of Agents framework-based problem-solving and a Game Society is developed and applied to the domain of single player logic puzzles and two player games. The Game Society solved 100% of presented Sudoku and Kakuro problems and never lost a tic-tac-toe game. The advantage of the Society of Agents approach is the efficient re-utilization of agents across multiple independent game domain problems and a centralized problem-solving architecture with efficient cross-agent information sharing.

INTRODUCTION



Distributed semi-autonomous intelligent problem solving is the function of multi-agent systems. Ontologisms or formalisms (frameworks) for development of multi-agent systems are recognized as a critical element for further development of multi-agent research (Chen & Chen, 2008). A natural classification of intelligent multi-agent problem solving strategies is implicit in nature. The highest level of self-contained intelligence is reflected in agents that model human intelligent problem solving by embedding evaluation heuristics based on human expertise within the agents, with examples coming from Othello (Samothrakis et al., 2013), a.k.a. Reversi, and checkers (Neto et al., 2014), a.k.a. draughts. The next step down are systems that mimic other biologic systems and include ant colony and beehive optimization agents (Madureira, 2014) among a vast number of other biologically inspired collaboration mechanisms for problem solving. The final classification layer is based on how intelligence develops at the cellular

Figure 1. Intelligence and collaboration tradeoff in multi-agent classification

level and includes artificial neural networks (ANNs) embedded in agents, such as the ANN based agents for playing a specific type of poker (Nicolai & Hilderman, 2009). This agent and multi-agent ontology is shown in Figure 1. The ontology facilitates classification and comparison between agent systems.

As agent systems progress upward in the classification triangle shown in Figure 1, the autonomous intelligence of the system increases, which causes a corresponding decrease in the number of agents required to solve a general problem in the agent's domain. The agent classification triangle in Figure 1 classifies agents based on their relative position within the triangle with increasing knowledge-based problem-solving capability corresponding to the height in the triangle and the width of the triangle indicating the necessary quantity of collaborating agents required for solving problems within their domain. This may be understood in plain language by looking at the number of living agents or corresponding units involved in problem solving for the different communities. A single human can solve a chess endgame problem, whereas animal communities solve survival challenges in groups of several animal agents to several dozen and insect colonies typically manage survival problems using hundreds to thousands of individuals. The human brain contains millions to billions of neurons (West & Gundersen, 1990), which are the building blocks of consciousness and intelligence. Thus, as the foundational model of agents within a multi-agent system moves down the pyramid from cognitive to biologic models and then from biologic to cellular, a greater number of agents are required to collaborate to produce intelligent behaviors.

Although this classification provides a straightforward ontology for evaluating required knowledge and collaboration levels within multi-agent systems, it still lacks a formal framework to define how collaboration between agents functions. The research presented in this paper defines a framework for agent interactions and collaborations in cellular level multi-agent systems. The framework is founded upon Minsky's (1986) *Society of Mind* paradigm, which was never formally instantiated, and is therefore called the Society of Agents (SoA). The idea of utilizing a social perspective to facilitate agent interactions is not new and has been used in developing agent communications for almost two decades (Ferber, 1999;

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Huhns & Stephens, 2000), but the framework developed in this article moves the concept of society and social interactions from the biologic level down to the cellular level and provides a uniform way to organize agent societies to accomplish intelligent problem solving.

BACKGROUND

The Society of Mind

In Minsky's (1986) *The Society of Mind*, he proposes that human understanding, intelligence, and consequent problem-solving ability is derived from a large collection of semi-autonomous, non-intelligent, independent, and reactive agents. These propositions were presented as thought exercises and were never instantiated. The way in which Minsky uses the term agent is as an actor that is responsible for a given task. Each actor's task is atomic and may be accomplished by the actor alone or by invoking actions or information from other actors. The use of other actors may be viewed hierarchically, with the initial actor determining a task to be accomplished and then invoking other actors to accomplish subtasks that individually would not accomplish the main task, but together can achieve the desired goal of the initial actor. The actors handle their associated atomic tasks within the system and interact with each other to handle more complex tasks.

Society of Mind (Minsky, 1986) actors are atomic, meaning that each actor is responsible for a single and indivisible component of the overall systems. Some of these atomic actors will be responsible for performing actions, while others detect or maintain state. The individual actors are not meant to be viewed as intelligent, but rather any perceived intelligence of the system is an effect from the various actors interacting to accomplish the needs or tasks of the system. The various actors in Society of Mind are responsible for perception, reasoning, memory, action, and a few other anthropomorphic properties such as emotions and sense of self (Minsky, 1986). Therefore, any multi-agent framework derived from *The Society of Mind* (Minsky, 1986) must require that agents perform atomic behaviors and that these behaviors include perception, memory, and action.

Intelligence occurs through the aggregation of values and actions held by different sets of actors within the society. As such, these actors may be emulated utilizing current software agent technology. Minsky (1986, pg. 18) proposes several important questions that need to be answered to understand the Society of Mind actors: "how do agents work, what are they made of, how do they communicate, where do the first agents come from, how do we make new agents or change old ones, [and most importantly] how can groups of agents do what separate agents cannot do?" The SoA framework presented in this article seeks to provide answers to these questions for cellular agents and multi-agent systems.

A way to begin understanding how multi-agent software agents can answer the final question is to examine biologic-based systems. Although biologic agents are not at the same granularity as the agents in the Society of Mind and the SoA, most animals working in groups or a society can accomplish tasks that are difficult or impossible for individuals to perform.

Biologic Agents

Natural biological systems have inspired a variety of optimization algorithms and agent systems. Biologic-inspired systems (a.k.a. bio-inspired or nature-inspired) may provide ideal solutions to problems that are complex or nonlinear and include either a large number of variables or solutions or both (Siddique &

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Adeli, 2015). The natural biologic systems that have inspired agent-based solutions include: frog leaping, ant colonies, particle swarm methods based on bird flocks and fish schools, bacteria, cuckoo (and other birds), bee hives, fireflies, and plant-oriented algorithms including flower pollination (Kar, 2016).

Biologic agent systems have been used to approach a variety of problems and a sample of this research is presented in Table 1. Since ant colony and particle swarm biologic inspired agent systems are the oldest, they naturally have the largest representation in literature. Biologic agents must adhere to social norms for communication processes between agents, whereas cellular agent communication occurs at a more rudimentary level, exemplified by electrical or chemical signals between neurons.

Cellular Agents

Minsky's (1986) *Society of Minds* attempted to intellectually bridge the gap and make an intellectual connection between traditional knowledge-based artificial intelligence and newer connectionist methods like ANNs that operate at the cellular level and are not considered to be knowledge-based (Reeke, 1991). ANNs and genetic algorithms are well known artificial intelligence cellular level methods.

An example of utilizing a combined biologic and cellular multi-agent system is a bat sonar signal-based ANN multi-agent system for predicting stock time series (Hafezi, Shahrabi, & Hadavandi, 2015). Multi-agent systems with embedded ANNs are well known in game domains, such as: backgammon (Kiourt & Kalles, 2015), checkers (Duarte et al., 2015); poker (Nicolai & Hilderman, 2009), and robot soccer (Jolly et al., 2007; Jolly, Kumar, & Vijayakumar, 2010).

Although genetic algorithms are not commonly used in agents, the approach can be used to fine tune agents that use other learning methods. Kiourt and Kalles (2015) demonstrate a social Darwinism approach to multi-agent system game playing agents such that the agent community eventually determines and selects the optimal game playing agent (i.e., survival of the fittest).

While ANNs and genetic algorithms attempt to model cellular level strategies for learning, the closest current agent systems come to actually modeling cellular behavior is in bacteria-based and human immune system based models, such as the multi-agent green recycling planning system (Mishra, Kumar, & Chan, 2012) and the control of smart grid power systems at the device level (Belkacemi et al., 2011)

Table 1. Examples of biologic system inspired agents

Reference	Bio Types	Problem/Domain
(Liu & Passino, 2006)	foraging swarms	robot sensing & path planning

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

both based on the human immune system. There is a need to further develop cellular level multi-agent systems to better capture the unique group dynamics of autonomous cellular units in solving complex problems. Furthermore, development of cellular multi-agent systems would benefit from a framework to enable reproducible results across a wide range of domains.

Existing Agent Architectures and Frameworks

Any agent framework must account for the 3 C's: Collaboration, Communication, and Coordination. Successful heterogeneous agent systems require more than communication and collaboration for successful problem solving (Bellifemine, Poggi, & Rimassa, 2001) and this accounts for the coordination mechanism for assigning tasks to agents and creation of new agents when needed. Collaboration between agents enables a more holistic solution as agents share information and resources to solve problems beyond the ken of single or smaller groups of agents (Arsene, Dumitrache, & Mihu, 2015).

Several architectures or frameworks for software multi-agent systems already exist. The Common Object Request Broker Architecture (CORBA) is an example of an existing architecture framework that focuses primarily on enabling communication between agents (Object Management Group, 1995). CORBA was developed to satisfy a need to enable agents to exchange information without hard coding the information transfers into each agent participating in a multi-agent system.

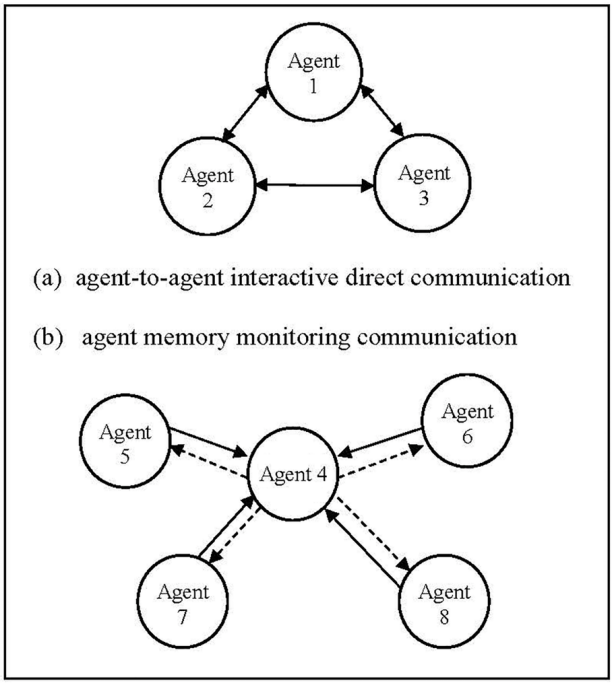
The Open Agent Architecture (OAA) was developed at SRI International and provided an architecture for distributing or coordinating tasks among a collection of agents (Martin, Cheyer, & Moran, 1999). An extension of the OAA was developed in KAoS (Knowledgeable Agent-oriented System) for performing maintenance problems in industry (Bradshaw et al., 1997). The KAoS system operates in a biological manner by enabling task coordination and sub-goal amongst a community of agents and the cognitive level due to the possible independence of agents in solving complex domain problems.

The SoA framework utilizes ideas from these various architectures which are common to multi-agent systems, communication and task coordination. Each of these architectures specifies how to construct an agent that has multiple non-atomic capabilities. SoA extends these architectures into a cellular level framework which enables each agent to communicate if needed, but distributes the coordination effort to a specific class of agent, thus making it that specific agent's atomic responsibility. The full framework is described in the next section.

SOCIETY OF AGENTS (SoA) FRAMEWORK

The purpose of any framework is to provide a method for developing high quality agents consistently and for instantiations to be evaluated for consistency against the framework. The FIPA organization created a standard for developing heterogeneous agent systems and specifies a programming language for developing agents based on Java (Bellifemine, Poggi, & Rimassa, 2001; Bellifemine, Caire, & Greenwood, 2007). Although other programming languages are used, the common theme is to enable heterogeneous agent development (Russell & Yoon, 2009) and so the SoA framework utilizes Java as its programming language and XML as its data language, which is a common communication protocol for multi-agent systems (Singh, 2007). An instantiation of the SoA framework is known generically as a Society and

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use



more specifically as either a Domain Society or Society of Domain, where Domain is replaced by the actual domain in which the Society is functioning. Hence for the domain of games, a Society created using the SoA framework would be known as a Games Society or alternately as a Society of Games.

Communication is critical in multi-agent systems (Lian et al., 2006) and the Society of Mind paradigm specifies that while an agent is performing its own atomic task it should not need to communicate with other agents, but when sub-tasking occurs then inter-agent communication is required (Hermans, 2002). The SoA framework enable two types of communication shown in Figure 2: decentralized or direct and centralized or indirect communications. The agent at the center of the indirect communications (agent 4 in Figure 2) may also serve as memory for the other agents and the agents' world. The SoA framework's communications mechanisms are similar to those used in CORBA.

Communication is also a requirement for interfacing with the various instantiated Society users and the SoA framework specifies the creation of input and output agents. The input and output agents are responsible for acquiring information and resources from the society's working environment and for communicating results back to the end users. The SoA framework thus extends and celullarizes the communication protocols of CORBA and KAoS by making communication both a general agent capability as well as the atomic task of specific types of agents.

Coordination affects how agents collaborate through task assignment and delegation. Agent frameworks require a coordination model, similar to OOA and KAoS, but which should also account for shared information spaces (Zambonelli et al., 2014). As with communication, coordination may be either centralized or decentralized (Wang, Zeng, & Cong, 2016). The SoA framework permits both types of coordination. The cellular nature of SoA requires that goals or tasks are allocated to distributed agents that only have knowledge of local tasks and resources (de Weerdt, Zhang, & Klos, 2012). Agent com-

Figure 2. SoA agent communication

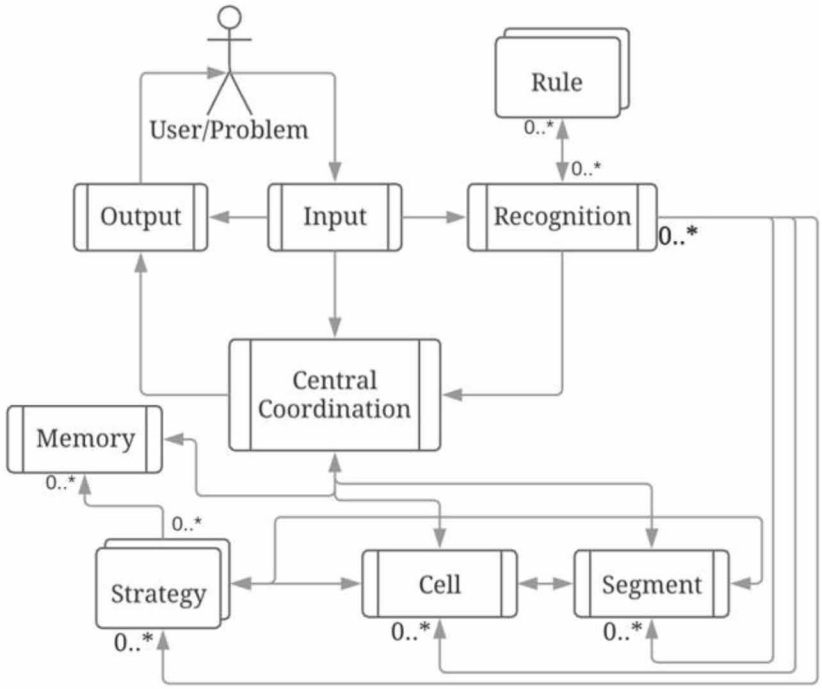
EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

munities within the larger agent society may organize and coordinate information sharing and tasks to accomplish subgoals of the SoA instantiated Society, thus enabling a decentralized focus. A required agent in the SoA supervises the sharing of information and coordination of agent activities globally, thus providing an overall centralized architecture. As an analogy, in American football, the coach is the centralized controller directing the overall goals and actions of the team (the society of agents), but the offensive line may organize at a lower level to perform blocking assignments for individual agents to promote the success of the whole team.

The SoA framework for multi-agent systems requires that:

- Agents operate at the atomic level, where each agent is responsible only for a single individual non-divisible task, specifically agents must be defined that will:
  - Read input from the domain for the current task (text, graphics, XML, voice, etc.);
  - Reason (problem solve) utilizing various problem-solving strategies, one per agent;
  - If needed, display information or requests for information (alternately this type of agent may also affect actions to occur within the domain such as robot movement);
  - Serve as a local short-term memory for other agents;
- Agents may be, and in fact should be, reused in multiple domain contexts as long as the atomic task of the agent is appropriate within the specified context;
- Agents act independently and thus have a widely distributed locus of control, however;
- Agents must interact with other agents in order to accomplish any task more complex than the atomic tasks for which the agents have been specified; and
- All agents within the society may be active, however it is possible that only a subset of the society may be required to interact in order to solve the current domain problem or task.

These are the fundamental properties of the SoA framework. The social perspective also defines multiple types of agent interaction relationships in multi-agent systems dependent on context (Kolp et al., 2008). The different types of agents defined within the SoA framework and their interactions are specified in Table 2. A UML domain model for the SoA framework is shown in Figure 3. Depending on the problem to be solved, agents with varying tasks/goals may be implemented in each of these classes of SoA agents, so long as they perform the specified purpose and can communicate for collaborative problem-solving activities.



If the division of tasks into the atomic level units specified in Table 2 is followed, then no single agent should be able to solve a standard domain problem solving task individually. Agents must work collaboratively to accomplish tasks. Additionally, one or more Recognition agents operate external to the society and answer the questions where do the first agents come from and, how do we make new agents or change old ones? The Recognition agents have the task of identifying the environment and problem to be solved. These agents are persistent and active within the environment where the instantiated Society performs. The collection of types of problems a SoA Society can work on are pre-specified in the Recognition agents for each domain. The collection of cell and segment agents required to solve the current domain problem are implied through the Rule agents. Once a Recognition agent identifies a known problem type it then creates all of the appropriate agents for the new "Society" as specified by the Rule agents.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 2. SoA framework agent definitions

Agent	Purpose
Rule agents	Identifies constraints imposed by the environment on other agents and other domain specific information
Recognition agent	Determines the problem to be solved and builds an agent community
Central Coordination agent	Acts as short-term memory to maintain the current status/configuration of the problem environment and coordinates communication between agents
Cell agents	Identifies the contents of a single knowledge item that may be a part of a larger whole
Segment agents	Organizes collections of Cells and permits inter-Cell communication
Input agents	Acquires information from the environment or user/system
Output agents	Responsible for communicating agent results and queries with the user/system
Strategy agents	Implement various reasoning/problem solving strategies
Memory agents	Serve as long term memory

Figure 3. SoA framework UML domain model

Rule agents and Strategy agents serve as long term memory for the SoA societies. Rule agents define limitations or constraints that new society agents must operate under as well as general knowledge about the domain, such as the shape of the world (e.g., the configuration of a game board or puzzle). Strategy agents define generic problem-solving strategies that each individual agent, subgroup of agents, or the full society may employ in solving the problem defined through the Recognition agent and the Input agents, which gather information about this specific problem instance. Strategy agents model both inherent

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

strategies that are present at birth such as fear of following and pain avoidance and also model learned strategies such as fire causes pain. Whenever a new problem type with associated rules or constraints is identified, a new Rule agent is created, and these agents are persistent across SoA implementations. Similarly, if a new problem-solving strategy is identified, then a new Strategy agent is created and again this type of agent is persistent across all instantiations of SoA systems. Therefore, the Rule and Strategy agents serve as a long term memory for the SoA's societies. An additional Memory agent is specified to enable the long-term retention of information across multiple problems that are outside of what constitutes proper knowledge for the Rule and Strategy agents.

Each agent within an instantiated Society understands a subset of information needed for accomplishing domain tasks. Typical agent interaction will be in the form of agents requesting missing information from other agents or suggesting modifications to information currently held by other agents, all while seeking to accomplish their specified goal. This dynamic information processing and resolution is responsible for the intelligent problem-solving capabilities of a Society. Solutions to domain problems may be identified in multiple ways: 1) an agent is specified that has the atomic action of recognizing when a solution has occurred (this may be either a Cell agent or the Central Coordination agent), or 2) solutions may be identified when each active agent has refined its current information so that a unique value or solution is obtained and no further action is required of any agent to obtain their respective goals.

While the details of the SoA framework are specified above, the necessity and implementation of these requirements may be better understood through an example. The next section will examine developing a multi-agent SoA Society for playing games, known as the Games Society.

SOA SOCIETY FOR PUZZLES AND GAMES

The initial domain of application using the SoA framework is the domain of games. Games are chosen because they are well understood and have served as a traditional testing ground for artificial intelligence research (McCarthy, 1990). The types of games to be addressed by this SoA framework implementation is wide ranging and only requires that some type of internal representation of the game is possible for the agents to encapsulate and interact with and the game must be winnable or have a definite conclusion, such as a draw or tie with all game Cell agents occupied, so that the society of agents may determine when a solution is reached. This includes one-person, two-person, and eventually multi-person games that are both bounded and unbounded (indicating the lack of limits for the game board or playing area). The current implementation of the Games Society is capable of playing: Sudoku, Kakuro, tic-tac-toe (TTT), three dimensional tic-tac-toe (3D-TTT), and beginner level Caro, a.k.a. Gomoku (a game similar to TTT, but played on either a 15X15 or 19X19 board and requires 5 similar marks in a row for victory). Future research is needed to extend the Games Society to also play other games such as go, backgammon, and eventually checkers, chess, and shogi.

The current set of games solvable by the Games Society is chosen to incrementally increase the complexity of the games. Sudoku is a single player number puzzle with a consistent bounded board (9X9), while Kakuro is also a single player number puzzle, but introduces additional solution requirements for the agents and uses a bounded yet inconsistent board. Both Sudoku and Kakuro have a unique solution if the puzzle is properly configured. TTT introduces two person games and therefore introduces strategy

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

into a consistent bounded board. 3D-TTT incorporates and additional dimension that the reasoning, input, and output agents must address. Caro increases the overall complexity of the games and the time/distance/size requirements to reach a solution.

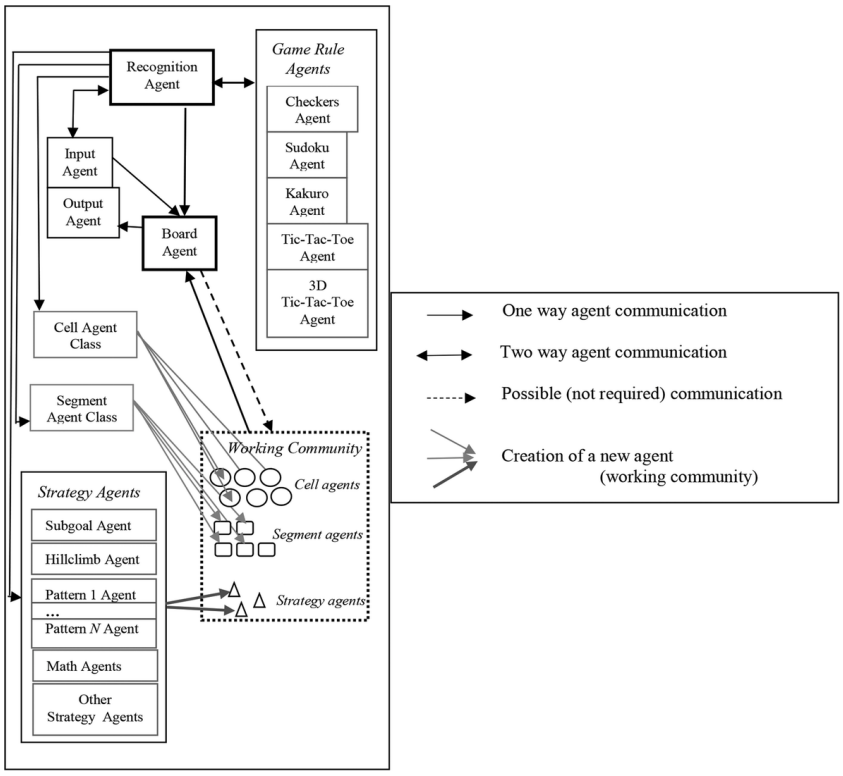
Evaluation of Games Society

Evaluation of the Games Society instantiation of the SoA framework is done by determining if the Society is solving a specific game problem at an advanced human player level. For Sudoku and Kakuro this implies the ability to solve arbitrarily difficult puzzles, while for TTT this implies never losing (since TTT will always result in a draw between two knowledgeable players) and winning against a less skilled player. The 3D-TTT game is winnable in four moves by the starting player and as such, if the Games Society is selected to start the game it should always win and play tactically well if going second. The evaluation requirements of Caro/Gomoku is similar to that for 3D-TTT, though the number of possible moves and world states for Caro is significantly larger, the first player is perceived to have an advantage (Tan et al., 2009).

The Game Society will also be compared to existing software agents or multi-agent systems that already operate against the specified games played by the Game Society. This comparison is facilitated by Sudoku becoming the drosophila for agent research because it is an NP-complete problem indicating a reasonable difficulty in solving and the well-defined and constrained nature of Sudoku problems (Kendall, Parkes, & Spoerer, 2008). Existing agents or multi-agent systems typically only try to solve one game or puzzle, which immediately shows an advantage of the SoA framework and its instantiation in the Game Society which currently plays five distinct games or puzzles within this domain.

Implementation of SoA Framework Agent Types

As described in the previous section, several different types of agents are required to form a SoA "society". The full SoA framework derived architecture for the Games Society is shown in Figure 4.



The SoA framework provides a dynamically configurable multi-agent architecture, which is adaptable to a variety of game domain problems. The Rule agents and the Strategy agents appear within their own boxes to indicate that these are persistent across instantiations, similar to a knowledge base for the SoA framework instantiated multi-agent systems.

Each game or puzzle type that the Games Society can play has an associated Rule agent defined. The Rule agents act as a long term memory in the Society, recording pertinent information applicable to each specific game, including the type and number of pieces, size and shape of the game board, starting configuration of the game board, any rules for the play of the game (e.g., for Sudoku and Kakuro this would include a rule that only one of any digit may occur in a Segment agent's collection of Cell agents) and how to determine a winner. Information about the games is kept within the Rule agents in XML format. When future research applies the Games Society to larger scale and longer games such as checkers and chess, the rules for movement of the pieces will also be required as elements of a Rule agent within the Games Society.

The required Recognition agent performs a centralized control to spawn all of the necessary agents needed by the current society. Once these other agents are created, they assume local control to play the game and thus creates a decentralized problem-solving architecture. The Recognition agent identifies the current type of game being played by looking at the game board or puzzle representation being

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 4. Games Society architecture

presented to the Games Society. Once the Recognition agent determines the game being played, it then requests game information from the corresponding Rule agents to determine the quantity of cell and segment agents that are needed. The Recognition agent then creates these agents into a problem specific working community within the larger Games Society, and also creates the Central Coordination agent.

The Central Coordination agent in the Games Society is renamed the Board agent for ease of understanding, since it serves as a centralized short-term (length of this specific game or puzzle solution) memory location for all other agents and in fact represents the current state of the puzzle board or game board. The Board agent identifies which Cell agents correspond to each space on the puzzle or game board and therefore controls the collaboration of Cell and Segment agents. For most two or more player games, the Board agent has a pre-specified starting position and this information is communicated from the Rule agent to the Board agent via the Recognition agent. The current state of the Board agent and hence the puzzle or game is communicated to an Output agent and displayed to the user. The two one player numeric puzzle games currently solved by the Games Society must have the starting position specified either by a user to an Input agent or may be read in from a file by an Input agent. This means that some of the Cell agents have a value pre-determined for them and their task is finished within the larger Games Society problem instance.

Cell agents represent the individual spaces within a puzzle or game board and may therefore each only have a single value representing the current state of that space within the puzzle or on the board. This value may simply be occupied or unoccupied by a specific player or may contain a value for the corresponding location of the Cell agent for the Board agent (e.g., a number from 1 to 9 for Sudoku and Kakuro, or a piece value for games like chess and shogi).

Figure 5. Java code for dynamic agents

```
url= new java.net.URL[] {new java.net.URL("file:"+ClassName+".java")};
java.net.URLClassLoader loader = new java.net.URLClassLoader(url );
Class cls = loader.loadClass(ClassName);
r = (java.lang.Object)cls.getMethod(MethodName,x). invoke(cls.newInstance(),o);
```

As shown in Table 2, the Segment agents form collections of Cell agents that have meaning for the game, as specified by the Rule agents. For example, in Sudoku, Segment agents organize different collections of Cell agents to form rows, columns, and squares for a total of 27 Segment agents. However, the TTT game only requires 8 Segment agents: 3 rows, 3 columns, and 2 diagonals. Note that a Cell agent may simultaneously belong to multiple Segment agent groups so long as this does not violate the Rule agents' constraints for the current environment/game.

Each Cell and Segment agent is created with appropriate Game Rule knowledge/constraints (e.g., Cell agents know the types of values they can hold and if multiple values are permitted). These agents are created dynamically by the Recognition agent as needed using Java code, displayed in Figure 5.

The Input and Output agents are responsible for all communication with users and other systems outside of the Society. The Games Society's Input agents read the puzzle or game board and acquires moves of the opponent in two-player games, while the Output agent displays the current actions taken by the Games Society's agents as represented in the Board agent. Flexibility and adaptability are important features in multi-agent systems (Barber, Goel, & Martin, 2000; Wang & Shen, 2016) and the dynamic creation of these working communities of cells and segments provides this in the SoA framework.

The Recognition agent also loads the Games Society with any Strategy agents that might apply. The Segment and Strategy agents collaborating together create problem solving intelligence for the society. The Segment agents utilize game knowledge (from the Rule agents) to organize the Cell agents and to assist Cell agents in identifying unique or desirable piece values to hold. Strategy agents apply standard problem-solving strategies including:

- Computation (in which the problem is directly solvable utilizing the rules of the game from the corresponding Rule agent);
- Subgoaling or simplification, which breaks the problem into smaller size chunks;
- Pattern recognition for important patterns specified by the Rule agents;
- Hill climbing, which tries to reduce the difference between the current game state held in the Board agent and the desired outcome;
- Analogy to similar problem situations;
- Working backwards, which attempts to move from the goal state backwards to the current state;
- Heuristics, utilizing heuristic problem-solving strategies for specific domains (such as controlling the corners in TTT);

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

- Mathematics, operation of standard math operators including addition, subtraction, multiplication, division, and exponentiation; and
- Additional agents to assist in discovering numeric patterns and allowing pattern rotation equivalences.

New Strategy agents may be added at any time to a Society to increase the Society's reasoning capabilities. Examples of possible new Strategy agents for future research include: Bayesian reasoning, other probability and statistical operators, and greedy algorithms. While Strategy agents are currently loaded into the working community of Segment and Cell agents working on the current problem, future research is needed to investigate the Board agent realizing that a new unloaded Strategy agent might be needed, perhaps because progress is not being made towards the goal of the Society, and make available other Strategy agents dynamically to the working community.

Previous research has indicated that intelligence in games is usually tightly coupled with the game system (Yu, Shen, & Miao, 2008). The Strategy agent type within the SoA framework provides a mechanism to decouple problem solving intelligence from the multi-agent system and affords a high degree of re-usability across new SoA framework Societies.

RESULTS AND DISCUSSION

The Games Society described in the previous section implements the SoA framework for a multi-agent system in the domain of games. Analysis of the Games Society's performance is accomplished by examining the actual performance of the Games Society across the two logic puzzles and 3 two player games previously mentioned.

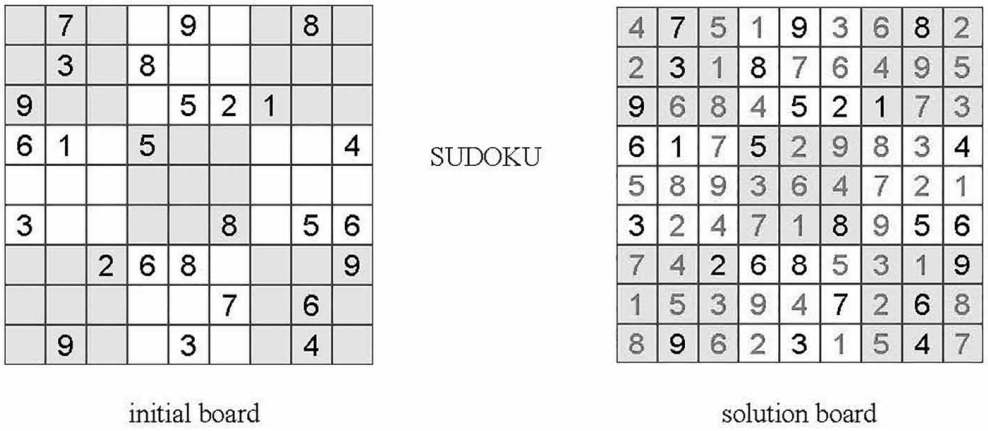
Recall that both Segment and Cell agents inherit required domain specific information for a particular game from corresponding Game Rule agents. Simpler games such as Sudoku may be solved using just the Cell and Segment agents by having the Segment agents recognize intersections between the various Segment agents and guide the Cell agents in producing a solution by performing problem space reduction through constraint propagation to help the Cell agents eliminate possible values from consideration. Kakuro works similarly, but does utilize mathematical Strategy agents that are used to identify patterns of numbers that may fit within a specified segment of cells within the Games Society, allowing instantiation of the SoA framework to understand and create non-specified constraints. An example of the use of the Addition Strategy agent is to determine all combinations of N unique (non-repeated) digits with values between 1 and 9 that produce a sum equal to a value X. Similar to Sudoku, the Segment agents then use the values identified by the Addition Strategy agent to identify possible Cell agent values that satisfy the requirements of all the intersecting Segment agents in which they participate.

The TTT and 3-DTTT games could play with just the Segment and Cell agents loaded with Game Rule knowledge, however this play would not be considered intelligent as the moves would be at random except for win blocking and winning moves since these types of moves may be inferred from the Rule agents for TTT and 3D-TTT. These games introduce the requirement for additional Strategy agents to exist in more complex game problem solving tasks. Defensive and offensive heuristics concerning N in a row patterns played on a matrix-like board are commonly known and have been coded as pattern heuristic Strategy agents. The heuristics used in TTT are also re-used in 3D-TTT with one additional

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

heuristic Strategy agent to account for three dimensional patterns. Caro also re-utilizes the various TTT heuristic agents and similar Strategy agent re-use is expected in other pattern-oriented games such as: Othello/reversi and Go.

Clearly, the list of strategies currently implemented for the Games Society given above will require further additions to utilize expert strategies from and for specific games, such as utilizing multiple pieces to defend or attack a Cell or Segment for games like chess and shogi and game specific strategies such as controlling the central area of the Board agent in chess versus controlling the edges of the Board agent in checkers. Segment agents that capture and organize the collection of Cell agents which define different regions of the Board agent, would be required by these new Strategy agents, in each newly defined game.



The atomicity requirement for the agents is achieved for all of the specified agents, by making sure that their task and knowledge is specific to a single well defined indivisible task, with the exception of the Recognition agent. Currently the Recognition agent performs two tasks: identification of the domain with transfer of appropriate Rule agent information to other agents and also the creation of the problem solving community. The decision to create the community with the same agent was made for simplicity in programming and could be divided into separate atomic agents in future iterations, where the Recognition agent would solely be responsible for identifying the game or environment and would then pass this information to a Creation agent that would be responsible for the deployment of the working community within the SoA framework instantiation.

Since the Games Society currently solves four different games, with work progressing on a fifth game, each with a unique set of properties, the Games Society clearly enables agents to be re-used across multiple tasks within the domain. Specifically, the Recognition agent, Board agent, Input and Output agents, Cell agents, and Segment agents will be used for every game. This is possible with the use of the Rule agents, whose purpose is to identify environment specific values for individual problems to allow the dynamic reconfiguration of the Board and Segment agents and automatic learning of appropriate Cell content and Output characteristics. Strategy agents are re-used across all games that share specific properties, such as using the math Strategy agents in all games that contain numeric values (i.e., the game pieces) within the Cell agents. Various pattern Strategy agents are used in all of the games currently implemented and help to recognize specific patterns and partially completed patterns. The heuristic strategies are added in response to a performance need within a specific domain game problem, however these may find re-use in other game problems that share similar heuristics (e.g., TTT has a defensive heuristic to control the center of the board and a similar strategy is viable in chess). Thus, the SoA framework as exemplified in the Games Society instantiation enables a successful collaborative multi-agent system.

The final two C requirements of the SoA framework concern locus of coordination control (centralized or decentralized) and agent communication. The current Recognition agent may be viewed as having centralized control authority, however the locus of control is then decentralized and passed to a subset of agents which form the active working community within the society. The different forms of agent communication have been listed and in fact, the atomic nature of the agents requires them to interact and communicate with each other in order to be able to collaboratively solve the various domain tasks. This interaction is especially important between the Board agent and the Segment and Cell agents. The Segment and Cell agents each know very isolated and specific domain task (game) information which when interactively combined enables the resolution of the defined agent system task, as identified by the Recognition agent.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 6. Sample Games Society Sudoku boards

The Games Society currently works on the five games previously mentioned. The Games Society has perfect performance for the domain problem of Sudoku, solving 100 percent of the Sudoku problems given to the Society on puzzles rated from easy (1 star) to difficult (5 star). Sample Sudoku problems were taken from local newspaper puzzles and various open websites providing sample puzzles. A sample beginning board for the Board agent and a Games Society completed board for the Board agent as actually printed by the Output agent (with shading on both boards added for clarity in perceiving the Sudoku puzzle) are shown Figure 6.

There are a large number of existing single agent or multi-agent systems that currently play Sudoku. A small sample of six systems are presented here for comparison. The Game Society Recognition Agent creates a working community within the Society of 81 Cell agents and 27 Segment agents which are supervised by one Board agent and utilizes 3 Strategy agents (single missing value, pattern rotation, and implied future value):

1. Operating at the cognitive agent level, a multi-agent system of 2 agents utilizing backtracking and exhaustive search and other multi-agent systems with 9 agents utilizing sub-tasking and constraint satisfaction built into the agents attempts to solve Sudoku problems with the 2 agent system achieving 100 percent completion and the remaining three systems of 9 agents having successful completion percentages of 0%, 0%, and 44% (Abednego & Nugraheni, 2014). The first system compares favorably against the Game Society with regard to performance. Constraints in the Game Society are specified in Rule agents and enforced by the Board agent through the Segment agents, whereas the constraints are directly programmed into the agents in the 9 agent systems, demonstrating the difficulty of trying to encapsulate all domain knowledge within single agents;
2. Also at the cognitive level is a reported multi-agent system that achieves a 100% solution accuracy in Sudoku and uses 82 agents, representing the 81 cells in a Sudoku puzzle and a central controlling agent (Emery, 2007). This system also uses rollback and exhaustive search and introduces the concept of guessing a cell value when the multi0agent system gets stuck in an unsolved position. Each agent has its own blackboard for communicating with other agents, where the blackboard memory function is handled by the Board agent in the Gam Society. The agents are programmed using a Java-based distributed system agent architecture called Cougaar (COGnitive Agent Architecture), using the same programming language as the Game Society;

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

3. The next comparison creates individual agents that attempt to solve Sudoku and are organized into collectives that are called a "society" (Leu, Tang, & Abbass, 2014). Each individual agent has both memory for awareness of the current state of the Sudoku problem and skills for determining cell focus and number selection. Therefore, each individual agent which is performing the solution task is a cognitive agent, but the collection of agents which attempt collaboration to identify more useful skills may be viewed as a pseudo-biological/societal solution. At easier difficulty levels this collective of agents is able to solve all the Sudoku problems, but as difficulty increase the solution accuracy drops dramatically. The Game Society was able to solve all Sudoku problems presented from easy to very hard difficulty levels;
4. Also at the cognitive level, but showing some similarities to the cellular Game Society is a multi-agent system that employs numerous agents each with a different pre-defined solution strategy or combination of strategies (Agerbeck & Hansen, 2008). This method partially utilizes the idea of Strategy agents used in the SoA framework, but is cognitive because strategies may be combined in single agents and the agents search the board to determine if they can be used at any given location. The individual strategies defined for this multi-agent system align closely with the strategies employed by the Game Society;
5. An ant colony-based agent system that uses from 1 to 3 agents and implements various tabu-search algorithms with the agents is able to solve from 68% to 81% of the puzzles (Mullaney, 2006). The 2 and 3 ant agent systems generally outperformed the single agent system as the number of runs increased. This performance is significantly less than the Game Society's and may demonstrate that biologic and cellular level systems simply require larger agent populations to solve NP-complete problems;
6. The final system is another biologic level system that utilizes a bee colony optimization model with 310 bee agents that solve 100% of the puzzles presented (Pacurib, Seno, & Yusiong, 2009), similar to the SoA, which uses a large number of agents, but fewer than 310 for this particular problem. The agents solve the puzzle using exhaustive search by randomly placing values, remembering incorrect solutions, and then replacing new values until the solution is found.

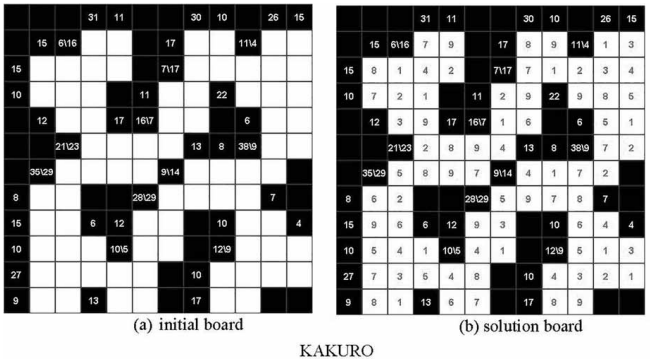
For the Kakuro game domain problems the Games Society currently solves almost all of the problems given to the Society (98 percent) and work is progressing to resolve the agent interactions and use of new Strategy agents to enable 100 percent performance for this domain problem as well. The Kakuro problems used to evaluate the Games Society again came from newspaper and open website games and ranged from easy to very difficult in difficulty level. Sample beginning and solved Board agent representations as actually printed by the Output agent are shown in Figure 7. No other multi-agent systems have been found that play Kakuro.

TTT if played correctly should always result in a draw. The Games Society has never lost a TTT game, with most games resulting in a draw, but occasionally winning if a human player plays at a suboptimal level. The initial testing of the TTT domain problem is accomplished by having a Games Society system play against another Games Society system, thus playing against another agent with similar knowledge. Later testing is performed by having the Games Society play against an expert human player. A sample TTT board produced by the Games Society is shown in Figure 8.

A previous single agent system at the cognitive level, but which incorporates a cellular ANN as its board evaluation function, that plays TTT claims that it can be trained to never lose against an opponent that uses a consistent strategy (Sardinha et al., 2003). This result is expected in any intelligent agent

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 7. Sample Games Society Kakuro boards



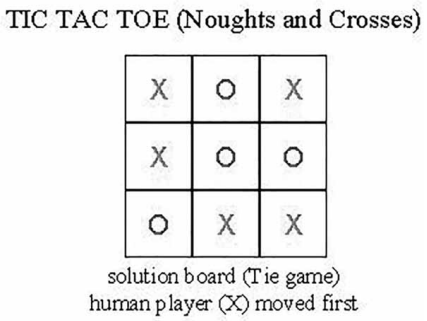


Figure 8. Sample Games Society completed Tic-Tac-Toe board

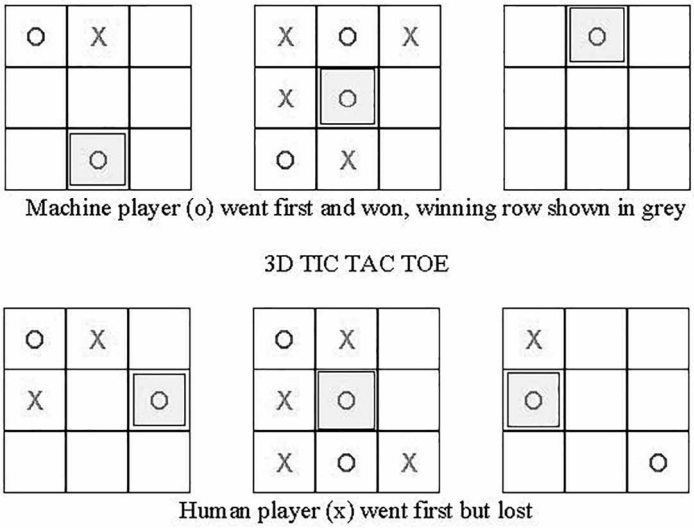

system and the Game Society does not lose regardless of opponent strategies. This agent system uses a training strategy similar to the Game Society by having individual agents play each other to improve their performance. Another cognitive level agent system utilizes 2 player agents, each of which incorporates different reinforcement learning strategies, and one board agent to teach itself to play TTT, but this system continues to lose (as the first player agent) after significant training (Batalov & Oommen, 2001).

The 3D-TTT game is winnable and the Games Society wins approximately 60 percent of its games, which depends on two factors: if it is the starting player (the Games Society wins 100 percent of the games in which it starts) and the level of play of the opponent. Again, initial testing is accomplished by letting the society play against a copy of itself and then later against an experienced human player, who intentionally played at various skill levels. Sample Output agent output for two completed 3D-TTT games are shown in Figure 9 (with shaded squares to highlight the Games Society's winning moves added), where the bottom board is shown on the left and the top board is shown on the right. The output from the Board agent in the first game example indicates that the Games Society is not playing a perfect game, since it should have only taken four moves to win versus the six moves indicated, thus the Games Society for 3D-TTT still has learning to accomplish or requires a new Strategy agent heuristic strategies to improve its performance. Also seen in the second 3D-TTT game in Figure 9 is that the Games Society for TTT and 3D-TTT always represents the opponent as the X player. A new Rule agent is needed for both TTT and 3D-TTT to let the Games Society know that the player who moves first should be represented with an X mark.

Figure 9. Sample Games Society 3-D Tic-Tac-Toe boards

The Caro board is unbounded and initially looks like a large TTT board. Because of the unbounded board, the game may not have a limit, but does have a winning condition (exactly 5 marks of the same player in a row, either horizontal, vertical, or diagonal). The Games Society was trained against a strong intermediate or mid-level player who intentionally played at both a beginner level and an intermediate level. The Games Society operated continuously for a pre-specified number of games prior to playing 5 evaluation games at each level. Due to the large board, no image is provided. The Games Society is able to progress in ability as the agents recognize different moves. The progression of the Games Society in learning to play Caro against a beginning player is shown in Table 3, which demonstrates the SoA capability for agents to adapt and learn from their environment during continuous play.

Because the Games Society is having difficulty winning Caro against a more advanced player, this implies the need for additional Strategy agent strategies that are not currently encoded. The Games Society does not currently implement any Memory agents. Addition of Memory agents, which would be initially created by the Recognition agent and then populated with information from Cell and Segment agents through the Board agent, would benefit games like Caro and also checkers and chess where knowledge

Table 3. Caro/Gomoku performance of the Games Society over multiple training examples

Games Trained	Opponent's Level	Games Society Performance		
		Win	Tie	Loss
0	Low	2	1	2
	Mid	0	0	5
10	Low	4	0	1
	Mid	0	0	5
25	Low	5	0	0
	Mid	0	0	5

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

of previous opponent move patterns could be exploited by the agents in the working community. The purpose of the Memory agent is to recall well known or solved positions, such as opening and closing books currently employed in checkers and chess programs. Future research is needed to investigate the implementation and effect of Memory agents and their utilization by Strategy agents, and other working community type agents.

Although the Games Society has demonstrated that it can learn, the intricacies of stronger play require more advanced heuristic Strategy agents. The response times of this Games Society distributed agent community approach to playing games are very fast, with no perceived (real-time) delay due to computation and interaction amongst the agents for each of the five solved games.

As indicated above and demonstrated in the Games Society instantiation, the SoA framework enables both centralized and decentralized agent coordination and multiple communication mechanisms to achieve collaborative problem solving, thus providing for the 3 necessary C's of multi-agent architectures. Furthermore, the definition and consequent instantiation of agents from the SoA framework limits agents to atomic well-defined tasks, including sensing the environment (perception), reasoning, memory (short term in the current games Society), and action. The SoA framework requires agents to work together to solve more complex (non-atomic) tasks. These cellular features of the SoA framework follow directly from the *Society of Mind* (Minsky, 1986) paradigm that inspired the SoA framework for multi-agent systems.

CONCLUSION AND FUTURE RESEARCH

The research reported in this article makes several advancements for multi-agent systems. First a new ontology for classifying and comparing agent and multi-agent systems is presented. Next, a new framework for development of multi-agent systems at the cellular level called the Society of Agents has been presented. This SoA framework is then utilized to develop a Games Society instantiation of the framework to demonstrate a collaborative multi-agent system for solving a wide variety of one and two person games with very high reliability and performance.

Additional research will progress in two distinct areas. The first will be to increment the quantity and type of games playable by the Games Society and to examine SoA Societies for other problem domains such as vehicle routing. As indicated work is currently progressing on solving the game Caro and future work is needed to examine checkers, chess, shogi, and Go. Additional games that rely on chance, such as backgammon, monopoly, and others, but which have recognized strategies and heuristics will also be developed. These additional games will increase the type and quantity of Strategy agents and Rule agents within the society. The application of the SoA framework to non-game domains will require defining new Rule agents for how to interpret the SoA Society's environment and possibly how the domain is represented in the Central Coordination agent. Tasks that are highly similar to games and have definable Central Coordination representations include network traffic analysis, power grid maintenance, supply chain management, and vehicle routing.

The second area for the research to progress in is the development of a learning capability within the SoA. Biologic-based agent systems have shown that the incorporation of cognitive capability does not improve agent performance over a traditional ant colony model (Sekara et al., 2015), but Stone (2007) states that multi-agent systems need to incorporate learning if they are truly to be qualified as intelligent. Currently the Games Society does not learn from past games and relies on its own inherent knowledge

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

from the Segment agents and various Strategy agents. The issue of short-term memory has been identified as a necessity for the SoA framework. If the SoA framework is to be used for development of "intelligent" multi-agent systems then the Memory agents defined within the SoA framework will need to be instantiated and added to the Games Society as well as new Strategy or Segment agents defined that will be able to utilize this long-term memory to analyze the efficacy of various Strategy agents within specific domain games and perhaps assist in the development of new Strategy agents dynamically. This instantiation of Memory agents into the Games Society would enable well-known strategies in games like chess, where opening and some ending moves in the domain are well known. A longer-term memory will also greatly enhance the analogy Strategy agent's applicability.

Cellular-level agents in multi-agent systems are shown to be adaptive problem solvers able to communicate and work collaboratively and cooperatively with other cellular-level agents to solve a diverse set of problems through reapplication of specific agent types across multiple domain problems. The SoA framework, operating at a cellular level, permits both centralized and decentralized communication amongst its atomic agents to support collaborative and cooperative problem solving. Based on the evidence produced in this research, new cellular-level agent research is needed to explore the capabilities of cellular-level multi-agent systems across a variety of problem types and domains.

ACKNOWLEDGMENT

The author would like to thank his colleague Dr. Reijer Grimbergen who first raised the idea of using the *Society of Mind* paradigm for creating intelligent systems and as a possibility for multi-agent systems. I would also like to thank my former doctoral student Dr. Toan Ong, who helped realize the Game Society instantiation of the proposed SoA framework by doing much of the Java programming and XML encoding.

ABSTRACT

Machine vision is supported and enhanced by optoelectronic devices, the output from a machine vision system is information about the content of the optoelectronic signal, it is the process whereby a machine, usually a digital computer and/or electronic hardware automatically processes an optoelectronic signal and reports what it means. Machine vision methods to provide spatial coordinates measurement has developed in a wide range of technologies for multiples fields of applications such as robot navigation, medical scanning, and structural monitoring. Each technology with specified properties that could be categorized as advantage and disadvantage according its utility to the application purpose. This chapter presents the application of optoelectronic devices fusion as the base for those systems with non-lineal behavior supported by artificial intelligence techniques, which require the use of information from various sensors for pattern recognition to produce an enhanced output.

INTRODUCTION

The present chapter surged in the research continuity of a 3D Vision System for mobile robot navigation application, a 3D medical laser scanner, and a structural health monitoring system. With the objective of increasing the accuracy of the systems, digital and analog processing signals methodologies have been developed in order to find the energetic center of the optoelectronic signal handled by these systems. Into the task of systems overall robustness, its measurement data has been submitted to statistical analysis, finding a non-linear behavior of the systems, leading to the need of artificial intelligence applications such as neuronal network (NN) and support vector machine regression (SVMR), in a modern approach to the prediction of the non-linear measurement error of the systems to compensate it. In the process of obtaining enough information from a measurement system to extract from it a model to predict its measurement error. It has been done a search of attributes to build the training dataset and test dataset. Ha been found that the pattern recognition can be enhanced by the sensor fusion and redundancy theory. This theory refers to the synergistic use of information from various sensors to achieve the task required by the system. Input data (attributes) are combined, fused and grouped for proper quality and integrity of the decisions to be taken by the intelligent algorithm. Besides, the benefits can be extracted from the redundant data, the reduction of uncertainty and the increasing of precision reliability. By these reasons, the photodiodes and charge coupled devices (CCD) are fusion in the task of robust systems building for machine vision by Spatial Coordinates Measurement (Weckenmann, 2009; Elfes, 1992; Zhang, 2008; Shih, 2015). The specific properties of both, their advantages and limitations have been considered, since, the photodiode is the sensor who gives place to the laser-scanning and the CCD is the sensors who gives place to the close-range photogrammetry. The energetic center of the laser optoelectronic signals from the photodiode and the energetic center of the image signal from the CCD sensor are detected to combine these sensors outputs, and to exploit their natural synergy new experimental results are presented to demonstrate the increase of systems accuracy.

BACKGROUND

Optoelectronics is the study of any devices that produce an electrically-induced optical output or an optically-induced electrical output and the techniques for controlling such devices (Marston, 1999), it includes generation, transmission, routing, and detection of optoelectronic signals in a widespread of applications (Dagenais, 1995). Wherever light is used to transmit information, tiny semiconductor devices are needed to transfer electrical current into optical signals and vice versa. Examples include light-emitting diodes, photodetectors and laser diodes (Piprek, 2003).

Most optoelectronics devices applications have focused on single sensors and relatively simple processes to extract specific information from the sensor, however the use of multiple sensors by an optoelectronic device fusion technology deliver more advanced information and enable to develop intelligent and sophisticated optoelectronic systems, in special for machine vision applications (Yallup, 2014). More than one optoelectronic sensor may be needed to fully monitor the observation space at all times. Methods of combining multiple sensor data are in developing due to the availability and computational power of communications devices that support algorithms needed to reduce the raw sensor data from multiple sensors to convert it to the information needed by the system user (Klein, 2003).

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Optoelectronic systems with only one sensor are not recommended for those optoelectronics signals with non-lineal behavior, the observations made by one sensor could be uncertain and occasionally incorrect, a single sensor could not detect all the critical characteristics of the optoelectronic signal as could be done with multiple sensors, which could provide different information each one, in special if they are from different technologies, they can provide different information regarding the target under observation. Besides, if a unique sensor is used, and it fails, the optoelectronic system is shutdown, while this sensor it is not working. Several sensors deliver redundant information to increase reliability in case of errors or failure of a sensor. The redundant information can reduce uncertainty and increases the accuracy with which the characteristics are perceived by the optoelectronic system. Further information from various sensors is obtained to characterize the environment, perceived in a way that would be impossible using only the information for each sensor separately (Castanedo, 2013).

Machine vision is supported and enhanced by optoelectronic devices, the output from a machine vision system is information about the content of the optoelectronic signal, it is the process whereby a machine, usually a digital computer and/or electronic hardware automatically processes an optoelectronic signal and reports what it means. That is, it recognizes the content, it not only locates the content, but to inspect it as well. Machine vision includes two components, measurement of features and pattern classification based on those features. Defining the pattern classification as the process of making decision about a measurement, with a set of measurements knowledge about the possible classes could be obtained, leading to make a decision (Snyder, 2010).

The machine vision technology has a widespread of applications, as is the automatic target recognition, 3D vision, vehicle vision and the industrial inspection, that make use of it for replace or complement manual inspections and measurements, to automate the production, in order to increase production speed and yield, as well as to improve product quality.

In special, machine vision methods to provide spatial coordinates measurement has developed in a wide range of technologies for multiples fields of applications such as robot navigation, medical scanning, and structural health monitoring. Each technology has specific properties that could be categorized as advantage and disadvantage according its utility to the application purpose.

The computer vision has guide the machine vision to the tendency of duplicate the abilities of human vision by electronically perceiving and understanding an image with a high a dimensional data, increasing the data storage requirement, and the time processing due to the complexity of algorithms to extract important patterns and trends and understand what data says (learning data). For some applications it is not necessary to acquire the whole vision of a scene as makes the human vision to extract the features of interest, it is possible to only extract the significant characteristics from the scene by the use of a positioning laser (PL) (Rodriguez-Quiñonez, 2014), a rotatory mirror scanner and dynamic triangulation and/or by the extraction of important features from images captured through the use of camera with CCD (Charge Coupled Device) (Hou, 2011).

Researches previously published has found that the 3D modelling of objects and complex scenes constitutes a field of multi-disciplinary challenges and difficulties, in the going-over accuracy, reliability, quality, portability, low cost and automatization of the whole procedure. By these reasons although there are a wide variety of sensors, the optical scanning and the digital cameras play the main role in this application, because even though these two types of sensors can work in a separate fashion, it is when are fusion together when the best results are attained. The sensor fusion, in particular concerning these both technologies appears as a promising possibility to improve the data acquisition and the geometric and radiometric processing of these data (Gonzalez-Aguilera, 2010).

Optoelectronic Device Fusion in Machine Vision is expected to play an increasingly important role in the near future, by its desired characteristics, such as: optimization, deduction, robustness, flexibility, inference, accuracy, reliability, speed and cost-effectiveness.

By this motivation it is presented a review of modern optoelectronic devices, including light-emitting diodes, edge-emitting lasers, vertical-cavity lasers, electro absorption modulators, a novel combination of amplifier and photodetector (Piprek, 2003), and CCD, to know the diverse optoelectronic devices, and which are the most suitable according to the needs in numerous machine vision applications.

The available sensor fusion techniques are classified into three nonexclusive categories:

1. Data association,
2. State estimation, and
3. Decision fusion.

Also architectures and algorithms are introduced.

Machine vision operation are described, an introduction to the methods for imaging, processing, analysis, communication and actions are developed.

The current optoelectronic scanning technology and image processing for 3D reconstruction techniques are fusion, and a briefly introduction to the optimal hardware architecture is reviewed.

OPTOELECTRONIC SENSORS FUSION IN MACHINE VISION

Spatial Coordinate Measurement

Machine vision methods to provide spatial coordinates measurement has developed in a wide range of technologies, the computer vision has guide the machine vision to the tendency of duplicate the abilities of human vision by electronically perceiving and understanding an image with a high a dimensional data, increasing the data storage requirement, and the time processing due to the complexity of algorithms to extract important patterns and trends and understand what data says (learning data). For some applications it is not necessary to acquire the whole vision of a scene as makes the human vision to extract the features of interest (Sonka, 2014), it is possible to only extract the significant characteristics from the scene by the use of a positioning laser (PL), a rotatory mirror scanner and dynamic triangulation, for detailed system overall see (Basaca-Preciado, 2014; Rodriguez-Quiñonez, Sergiyenko, Preciado, et al, 2014; Flores-Fuentes, 2014a; Flores-Fuentes, 2014b).

Optoelectronic Devices

Optoelectronic devices take advantage of sophisticated interactions between electrons and light, it combines electronics and photonics. Photons are the smallest energy packets of light waves and their interaction with electrons, energy exchange between them is the key physical mechanism in optoelectronic devices. Optoelectronics brings together optics and electronics within a single device, a single material, semiconductors designed to allow for the transformation of light into current and vice versa.

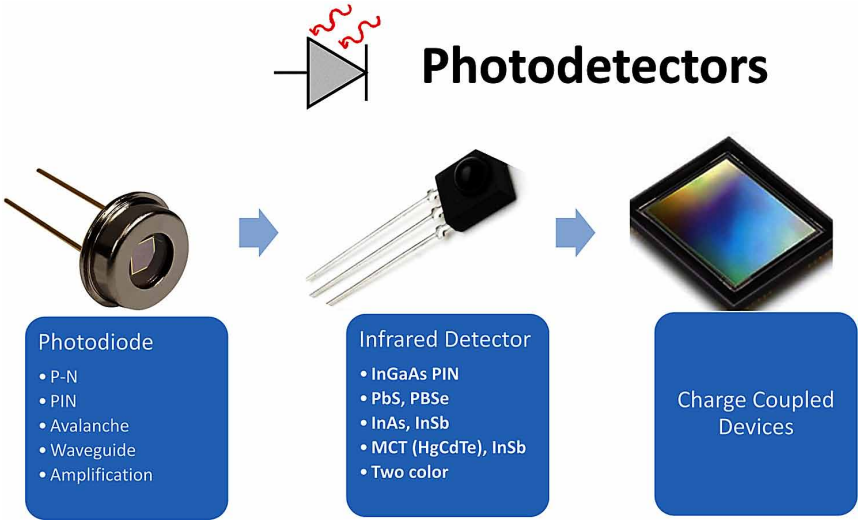
EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

1. **Photodetector Devices:** The purpose of any photodetector is to convert light (photons) into electric current (electrons). Photodetectors are among the most common optoelectronic devices; they are used to automatic open doors, detect the signal from infrared remote controls, and record pictures in modern cameras. Photodetectors are fabricated from various semiconductor materials, since the band gap needs to be smaller than the energy of the photons detected. Photon absorption generates electron–hole pairs which are subsequently separated by the applied electrical field. Depending on the desired use, photodetectors are designed in many different ways, and can be classified in photodiodes, infrared-detectors and charge coupled devices (CCD), as shown in Figure 1. Modern photodetectors include an amplifier; the amplification photodetector simultaneously amplifies and absorbs the incoming light.
    a. **Photodiode:** Photodiodes are light detecting devices fabricated in semiconductor materials, when a photon of sufficient energy strikes a diode, it creates an electron-hole pair. This mechanism is also known as the inner photoelectric effect. If the absorption occurs in the junction's depletion region, or one diffusion length away from it, these carriers are swept from the junction by the built-in electric field of the depletion region. Thus holes move toward the anode, and electrons toward the cathode, and a photocurrent is produced. The total current through the photodiode is the sum of the dark current (current that is generated in the absence of light) and the photocurrent, so the dark current must be minimized to maximize the sensitivity of the device. Photodiodes are similar to regular semiconductor diodes except that they may be either exposed or packaged with a window or optical fiber connection to allow light to reach the sensitive part of the device (Tavernier, 2011). The most common photodiodes are the P-N photodiode, PIN photodiode, avalanche photodiode, waveguide photodiode and amplification photodiode (Syms, 1992; Piprek, 2003).
    b. **Infrared-Detectors:** This detector is sensible to infrared radiation (IR). Thermal and photonic photodetectors are the main types of infrared-detectors. The effects of the incident IR radiation can be followed through many temperature dependent phenomena; a thermal detector type has no wavelength dependence. Major characteristics indicating infrared detector performance are photo sensitivity, the photodetector is wavelength dependent. In comparison with visible and ultraviolet rays, infrared radiation has small energy. To increase infrared detection efficiency, the detector should be cooled. The signal output from a detector is generally quite small and needs to be amplified. When designing a preamplifier, it is considered the impedance match between the detector and the amplifier, if the incident light is modulated by a chopper, the use of a tuned amplifier is necessary to reduce noise. If the detector is cooled, it is also practical to cool the amplifier. IR photodetectors are classified in intrinsic type and extrinsic type (Ge:Au, Ge:Hg, Ge:Cu, Ge:Zn, Si:Ga, Si:As), the intrinsic type is classified on Photoconductive type (PbS, PbSe, InSb, HgCdTe) and Photovoltaic type (Ge, InGaAs, Ex. InGaAs, InAs, InSb, HgCdTe) (Rogalski, 2002). The most common infrared detectors are InGaAs PIN photodiode and linear image sensor, PbS and PbSe photoconductive detector, InAs and InSb photovoltaic detector, MCT (HgCdTe) and InSb photoconductive detector, and two color detector (McClure, 2003; Tribolet, 2008).
    c. **Charge Coupled Devices (CCD):** CCD is the abbreviation for charge-coupled device, also known as CCD image sensor. CCD sensors are typically built with silicon technology. Silicon based integrated circuits (ICs), consisting of a dense matrix of photodiodes or photogates that

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

operate by converting light energy, in the form of photons, into electronic charges. When a photon strikes a silicon atom in or near a CCD photosite, the photon usually produces a free electron and a hole via the photoelectric effect.

The primary function of the CCD is to collect the photogenerated electrons in its potential wells (or pixels) during the CCD's exposure to radiation, and the hole is then forced away from the potential well and is eventually displaced into the Si substrate. While more light that is incident on a particular pixel, the higher the number of electrons that accumulate on that pixel. The output signal is then transferred to the computer for image regeneration or image processing (Li, 2006).



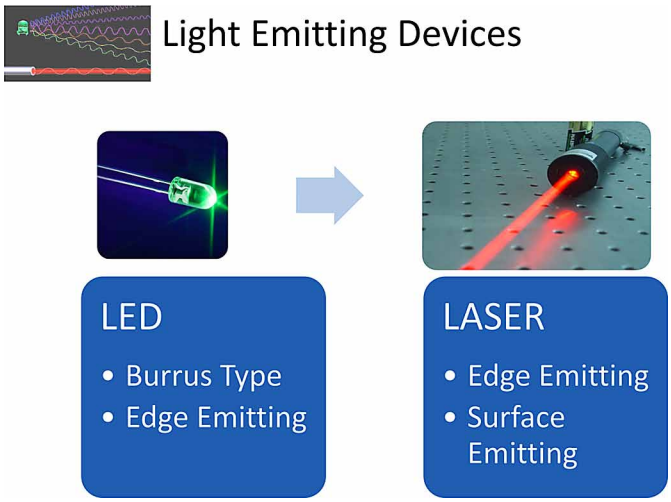
The pixels in a CCD sensor can be arranged in various configurations, the linear and area array are the classical architectures. A linear or linescan CCD sensor consists of a single line of pixels, adjacent to a CCD shift register that is required for the read-out of the charge packets. The isolation between the pixels and the CCD register is achieved by a transfer gate. Typically, the pixels of a linear CCD are formed by the photodiodes. Two-dimensional imagining is possible with area array CCD sensors; the entire image is captured with one exposure, eliminating the need for any movement by the sensor or the scene. As charge coupled device (CCD) technology matures it dominates the digital imaging, for commercial and industrial manufacturing applications (Janesick, 2001).

Conventional CCDs are designed for the front illuminated mode of operation. Front illuminated CCDs are quite economical to manufacture by using standard wafer fabrication procedures, and are popular in consumer imagining applications, as well as industrial-grade applications. However, front-illuminated CCDs are inefficient at short wavelengths (e.g., blue and UV) due to the absorption of photons by the polysilicon layers if photogates are used as the pixel element. Typically, conventional front-illuminated CCDs are adequate for low-end applications and for consumer electronics. But, for large, professional observatories and high-end industrial inspection systems that demand that require extremely sensitive detectors, conventional thick frontside-illuminated chips are rarely used. Thinned back-illuminated CCDs offer a more compatible solution for these applications. Backside-thinned back-illuminated chips are rarely used. Thinned back-illuminated CCDs offer a more compatible solution for these applications. Backside-thinned back-illuminated CCDs exhibit a superior responsively, remarkably in the shorter wavelength region (Li, 2003).

2. **Light Emitting Devices:** Other application of the p-n junction is as a light source, known as a light emitting diode (LED). It is based in the electroluminescence optical-electrical phenomenon, electrical generation of light through spontaneous emission. It is when a material emits light in response to the passage of an electric current, a radiative recombination of electrons and holes are done in the material, usually a semiconductor. In a semiconductor electrons and holes are separated by doping the material to form a p-n junction, then a recombination of electrons and holes are done, and it is when the excited electrons release their energy as photons (light). As an isolated lump of material will not emit significant quantities of light, in thermal equilibrium (room temperature) the number of downward electron transitions is extremely small. To improve the optical output, the material should be moved far from equilibrium, so that the rate of spontaneous emission is considerably increased. This might be done by taking (for example) a p-type material, which already contains a large holes density, and pouring electrons into it by a forward-biased p-n junction. Spontaneous emission generates photons that travel in random directions, so the emission is isotropic, the emission is also un-polarized, and the output is incoherent, with a spectrum consisting of a broad range

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. Photodetectors classification



of wavelengths, consequently, the LED cannot be used as a source for high-speed, long-distance optical communications; the dispersion caused by such an extended spectrum would be far too large. LED transmitters are therefore restricted to short-haul applications.

A single photon is able to generate an identical second photon by stimulating the recombination of an electron-hole pair. This photon multiplication is the key physical mechanism of lasing. The second photon exhibits the same wavelength and the same phase as the first photon, doubling the amplitude of their monochromatic wave. Subsequent repetition of this process leads to strong light amplification. However, the competing process is the absorption of photons by the generation of new electron-hole pairs. Stimulated emission prevails when more electrons are present at the conduction band level than at the valence band level. This carrier inversion is the first requirement of lasing and it is achieved at pn-junctions by providing conduction band electrons from the n-doped side and valence band holes from the p-doped side. The photon energy is given by the band gap, which depends on the semiconductor material. Continuous current injection into the device leads to continuous stimulated emission of photons, but only if enough photons are constantly present in the device to trigger this process. Therefore, optical feedback and the confinement of photons in an optical resonator is the second basic requirement of lasing.

The absorption and simulated emission process produced in a LED is the principle of a light amplification by stimulated emission of radiation (LASER), the exponentially growing wave produce an amplification ought to offer a method of light generation. To achieve this, the electron density is raised far above the equilibrium level by the injection of electrons across a forward-biased diode. The laser is a device based on the stimulated emission of electromagnetic radiation. It emits light through a process of optical amplification; it emits spatial coherently light as a tight spot, achieving a very high irradiance, or they can have very low divergence in order to concentrate their power at a great distance. The laser enables applications such as cutting, welding and lithography for optical disk drives, laser printers, barcode scanners, fiber-optic, optical communication, surgery, skin treatments, device enforcement for marking targets and measuring range and speed, and lighting display.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. Light emitting devices classification

The first semiconductor lasers consisted of heavily doped p-n junctions with cleaved facets. This construction is inefficient, as there is no defined region in which recombination can take place. Carriers can be lost to diffusion before recombination occurs. As a result, these early devices required a lot of current to reach threshold. Threshold currents were reduced with the developments of the double-heterostructure laser, which has a thin region of semiconductor with a smaller energy gap sandwiched between two oppositely doped semiconductors with a wide bandgap energy. When forward biased, carriers flow into the active region and recombine more efficiently because of the potential barriers of the heterostructure confine the carriers to the active region. There is an added advantage of guided the laser light, because the refractive index of the cladding layers is less than the active region. See Figure 2.

a. **Burrus-Type LED:** In place of the simple p-n junction, a more complicated structure is used for the Burrus-type LED. Typically, this might be a P-n-N double heterostructure, containing three layers: a p-type layer with a wide energy gap, a narrow-gap n-type layer, and a wide-gap n-type layer. A single heterojunction provides potential barriers of different heights for electrons and holes; the double heterostructure provide a high barrier at different positions for electrons and holes. In this way, the recombination region may be limited to a defined region of space, resulting in an increase in the radiative recombination efficiency. This is a high-efficiency device, suitable for use with multimode fiber. To fabricate the device, a double heterostructure is first grown on a substrate, and a SiO_2 isolation layer is then deposited on the lower layer of the heterojunction. This layer is etched, to expose the hetero- junction over a small window. Metallization layers are then added to the upper and lower surfaces; clearly, the lower of these makes contact with the heterojunction only in the region of the window. A deep well, aligned with this window, is then etched right through the substrate to the upper layer of the heterojunction, and a multimode optical fiber is epoxied into the well in contact with the LED surface. When a forward current is passed through the LED, it flows mainly through the region immediately below the fiber. The recombination region (or active region) is therefore confined vertically by the double heterojunction and laterally by the distribution of current flow.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

b. **Edge Emitting LED:** This Edge Emmiting LED also called superluminescent LED presents an alternative geometry to the Burrus-type LED (Fukuda, 1999). This is also based on a double heterostructure, but now the emission is taken from the edge of the junction rather than its surface. Generally, the current is forced to flow through a narrow strip down the device center line by the introduction of a current-blocking silica layer. As a result, the active volume is constrained vertically by the double heterostructure and laterally by the current flow. Most importantly, light generated by spontaneous emission is also confined vertically to a certain extent; the refractive index difference at the top and bottom of the active layer results in total internal reflection. This tends to channel a large fraction of the light towards the emission windows at relatively shallow angles.
c. **Edge Emitting Laser:** In this Laser the light propagates in a direction along the wafer surface of the semiconductor chip and is reflected or coupled out at a cleaved edge. These are the original and still very widely used form of semiconductor lasers. Within the edge-emitting laser structure, the laser beam is guided in a waveguide structure. Typically, one uses a double heterostructure, which restricts the generated carriers to a narrow region and at the same time serves as a waveguide for the optical field. This arrangement leads to a low threshold pump power and a high efficiency. Depending on the waveguide properties, particularly its transverse dimensions, it is possible either to obtain an output with high beam quality but limited output power, or an output with high output power but with poor beam quality.
d. **Surface Emitting Laser:** In the surface-emitting laser, the light propagates in the direction perpendicular to the semiconductor wafer surface. These are further subdivided into monolithic and external-cavity devices: Monolithic means that the laser resonator is realized in the form of two semiconductor Bragg mirrors with the quantum well section in between. Such a device is called VCSEL (vertical cavity surface-emitting laser) and is electrically pumped in most cases (Lorenser, 2003).

Sensors and Data Fusion

Data fusion refers to the synergistic use of information from different sensors for proper quality and integrity of the decision making to accomplish a task required by a system. All tasks that demand any type of parameter estimation from multiple sources can benefit from the use of data/information fusion methods. The terms information fusion and data fusion are typically employed as synonyms; but in some scenarios, the term data fusion is used for raw data (obtained directly from the sensors) and the term information fusion is employed to define already processed data. In this sense, the term information fusion implies a higher semantic level than data fusion. Other terms associated with sensor fusion that typically appear in the literature include decision fusion, data combination, data aggregation, multi-sensor data fusion, and data fusion (Castanedo, 2013).

Systems with only one sensors are not recommended for those with non-lineal behavior, the observations made by one sensor could be uncertain and occasionally incorrect, a single sensor could not detect all the critical characteristics of the system as could be done with multiple sensors, which could provide different information each one, in special if they are from different technologies and can provide different information regarding the system. Besides if a unique sensor is used, and it fails the system is shutdown while this sensor it is not working. The redundant information can reduce uncertainty and increases the accuracy with which the characteristics are perceived by the system. Several sensors delivering redundant

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

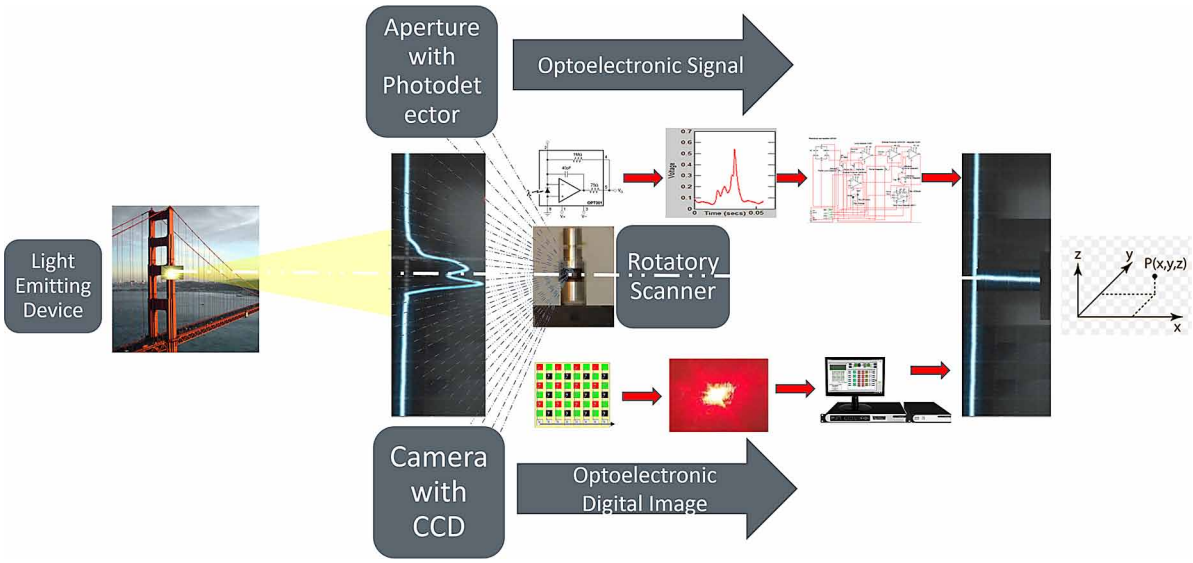
information increase reliability in case of errors or failure of a sensor. Further information from various sensors to characterize the environment perceived in a way that would be impossible using only receive the information for each sensor separately.

The goal of using sensor fusion in multi-sensor environments is to obtain a lower detection error probability and a higher reliability by using data and information from multiple distributed sources, as shown in Figure 3.

1. **Sensors and Data Fusion Classification:** Fusion techniques and methods are difficult to classify due to they involve a big variety of application fields. A general classification is based on data criteria, as described at Figure 4.
    a. **Relation between the Input Data Sources (Sensors):** Complementary: Each sensor provides complementary information that can be combined together, the information provided by the sensors represents different parts of the scene and could thus be used to obtain more complete global information (Vauhkonen, 2014).
        i. **Redundant:** Various sensors providing information about the same target or scene (Abidi, 1992).
        ii. **Cooperative:** Two or more sensors are independently used to perform detection, providing information that is combined into new information that is typically more complex than the original information (Labayrade, 2005).
    b. **Input/Output Data Sensors Types and Their Nature:** Low Level Data in-Data out (DAI-DAO): The raw data are directly provided as an input to the data fusion process. This type of data fusion process inputs and outputs raw data; the results are typically more reliable or accurate. Data fusion at this low level is conducted immediately after the data are gathered from the sensors. The algorithms employed at this level are based on signal and image processing algorithms.
        i. **Low Level Data In-Feature Out (DAI-FEO):** At this low level, the data fusion process employs raw data from the sources to extract features or characteristics that describe an entity in the environment;
        ii. **Medium Level Feature In-Feature Out (FEI-FEO):** At this medium level, both the input and output of the data fusion process are features or characteristics (shape, texture, and position), the data fusion process addresses a set of features with to improve, refine or obtain new features. This process is also known as feature fusion, symbolic fusion, information fusion or intermediate-level fusion.
        iii. **High Level Feature In-Decision Out (FEI-DEO):** Takes symbolic representations as sources and combines them to obtain a more accurate decision, this high level obtains a set of features as input and provides a set of decisions as output. Most of the classification systems that perform a decision based on a sensor's inputs fall into this category of classification.
        iv. **High Level Decision in-Decision out (DEI-DEO):** This type of classification is also known as decision fusion. It fuses input decisions to obtain better or new decisions (Dasarathy, 1997).
        v. **Multiple Level:** It is a combination of data provided from different levels of abstraction.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 3. Sensors and data fusion applied to systems with non-lineal behavior



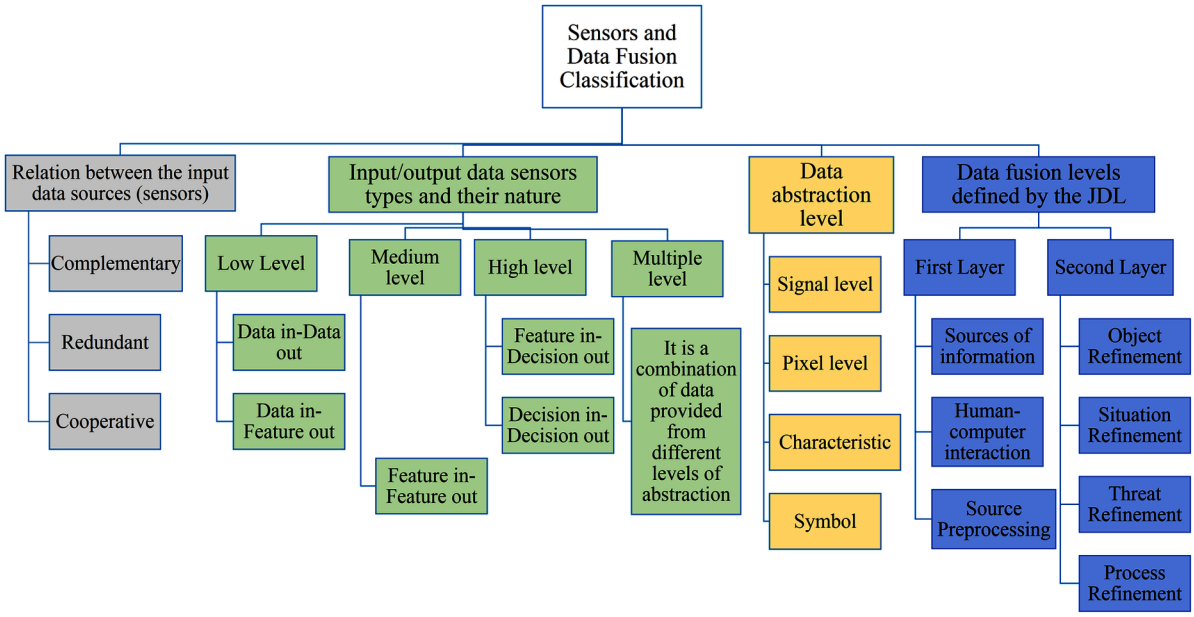


Figure 4. Sensors and data fusion classification

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

c. **Data Abstraction Level:** It is typically classified in three levels of abstraction: measurements, characteristics, and decisions. Other possible classifications of data fusion based on the abstraction levels are as follows:
   i. **Signal Level:** Directly addresses the signals that are acquired from the sensors.
   ii. **Pixel Level:** Operates at the image level and could be used to improve image processing tasks.
   iii. **Characteristic:** Employs features that are extracted from the images or signals (i.e., shape or velocity),
   iv. **Symbol:** At this level, information is represented as symbols; this level is also known as the decision level (Luo, 2002).

d. Data fusion levels defined by the JDL (Joint Directors of Laboratories).
   i. **First Layer Sources of Information:** Local and distributed sensors linked to a data fusion system, and or a priori information, as databases.
   ii. **First Layer Human-Computer Interaction (HCI):** It is an interface that allows inputs to the system from the operators and produces outputs to the operators. HCI includes queries, commands, and information on the obtained results and alarms. It incorporates not only multimedia methods for human interaction (graphics, sound, tactile interface, etc.), but also methods to assist humans in direction of attention, and overcoming human cognitive limitations.
   iii. **First Layer Source Preprocessing:** An initial process allocates data to appropriate processes and performs data pre-screening. Source preprocessing reduces the data fusion system load by allocating data to appropriate processes. The database management system stores the provided information and the fused results. This system is a critical component because of the large amount of highly diverse information that is stored.
   iv. **Second Layer Level 1 Processing (Object Refinement):** Transforms sensor data into a consistent set of units and coordinates, refines and extends in time estimates of an object's position, kinematics, or attributes, assigns data to objects to allow the application of statistical estimation techniques, and refines the estimation of an object's identity or classification.
   v. **Second Layer Level 2 Processing (Situation Refinement):** Formal and heuristic techniques are used to examine, in a conditional sense, the meaning of Level 1 processing results.
   vi. **Second Layer Level 3 Processing (Threat Refinement):** It is an impact assessment, at this level the impact of techniques used in level 2 are evaluated to obtain a proper perspective. And a future projection is performed to identify possible risks, vulnerabilities, and operational opportunities. This level includes an evaluation of the risk or threat and a prediction of the logical outcome.
   vii. **Second Layer Level 4 Processing (Process Refinement):** It is a process concerned about other processes, monitors the data fusion process performance to provide information about real-time control and long-term performance, identifies what information is needed to improve the multilevel fusion product (inferences, positions, identities, etc.), determines the source specific requirements to collect relevant information (i.e., which sensor type, which specific sensor, which database), and allocates and directs the sources to achieve mission goals (Luo, 2002).

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

2. **Sensors and Data Fusion Methods:** Most current sensors data fusion methods algorithms can be broadly classified as illustrate at Figure 5.
    a. **Estimation Methods:** These methods take the weighted average of redundant information coming from a group of sensors and use it as the value of the fusion sensors. These methods determine the state of the target under movement (typically the position) given the observation or measurements. State estimation techniques are also known as tracking techniques with a final goal of obtain a global target state from the observations. The estimation problem involves finding the values of the vector state (e.g., position, velocity, and size) that fits as much as possible with the observed data. From a mathematical perspective, we have a set of redundant observations, and the goal is to find the set of parameters that provides the best fit to the observed data. In general, these observations are corrupted by errors and the propagation of noise in the measurement process. State estimation methods fall under level 1 of the JDL classification and could be divided into two broader groups:
        i. **Linear Dynamics and Measurements:** Here, the estimation problem has a standard solution. Specifically, when the equations of the object state and the measurements are linear, the noise follows the Gaussian distribution, do not refer to it as a clutter environment; in this case, the optimal theoretical solution is based on the Kalman filter;
        ii. **Nonlinear Dynamics:** The state estimation problem becomes difficult, and there is not an analytical solution to solve the problem in a general manner. In principle, there are no practical algorithms available to solve this problem satisfactorily. This method allows real-time processing of data. Some of them are: Maximum Likelihood and Maximum Posterior, Particle Filter, The Kalman Filter, The Distributed Kalman Filter, Distributed Particle Filter, and Covariance Consistency Methods: Covariance Intersection/Union. Being The Kalman filter the most popular.
    b. **Classification Methods:** A data association is performed to determine the set of measurements that correspond to each target. The multidimensional feature space can be partitioned into distinct regions, each representing an identification or identity class. The location of a feature vector is compared to pre-specified locations in feature space. A similarity measure must be computed, and each observation is compared to a priori classes. A feature space may be partitioned by geometrical or statistical boundaries. Therefore, the templating approach may declare a unique identity or an identity with an associated uncertainty. The implementation of parametric templates is computationally efficient for multisensor fusion systems. The most common methods are Nearest Neighbors and K-Means.
    c. **Inference Methods:** Bayesian inference allows multisensor information to be combined according to the rules of probability theory. Bayes' formula provides a relationship between the a priori probability of a hypothesis, the conditional probability of an observation given a hypothesis, and a posteriori probability of the hypothesis. Bayesian inference updates the probabilities of alternative hypotheses, based on observational evidence. New information is used to update the a priori probability of the hypothesis.
    d. **Artificial Intelligence Methods:** In these methods decisions are typically taken based on the knowledge of the perceived situation, a high-level inference is required, as the human reasoning, for pattern recognition, planning, induction, deduction, and learning.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

The artificial intelligence methods are based on an initial data set and the rule-based knowledge base comprising rules, frames and scripts. The inference process uses the a priori data set, and searches the complete set of rules to identify applicable rule. The rule selection strategies from among multiple applicable rules include refraction, actuation, rule ordering, specificity, and random choice. Examples of these methods are Neuronal Network, Fuzzy Logic, Support Vector Machines, etc.

Artificial intelligence methods can be seen as the advanced versions of the estimation, the classification, and the inference methods. Artificial intelligence methods can be model-free, rather than model-specific, and have sufficient degree of freedom to fit complex nonlinear relationships, with the necessary precautions to properly generalize. As a result, artificial intelligence methods can effectively conduct sensor fusion at different levels (Hall, 1997).

3. **Sensors and Data Fusion Architectures:** This describes where the sensors and data fusion process will be performed, as shown in Figure 6.
    a. **Centralized Architecture:** All of the fusion processes are executed in a central processor that uses the provided raw measurements from the sources.
    b. **Decentralized Architecture:** It is composed of a network of nodes in which each node has its own processing capabilities and there is no single point of data fusion. Therefore, each node fuses its local information with the information that is received from its peers. Data fusion is performed autonomously, with each node accounting for its local information and the information received from its peers.
    c. **Distributed Architecture:** Measurements from each source node are processed independently before the information is sent to the fusion node; the fusion node accounts for the information that is received from the other nodes. Therefore, each node provides an estimation of the object state based on only their local views, and this information is the input to the fusion process, which provides a fused global view.
    d. **Hierarchical Architecture:** Other architectures comprise a combination of decentralized and distributed nodes, generating hierarchical schemes in which the data fusion process is performed at different levels in the hierarchy.

MACHINE VISION FOR SPATIAL COORDINATE MEASUREMENT

Machine vision methods to provide spatial coordinates measurement has developed in a wide range of technologies, the computer vision has guide the machine vision to the tendency of duplicate the abilities of human vision by electronically perceiving and understanding an image with a high a dimensional data, increasing the data storage requirement, and the time processing due to the complexity of algorithms to extract important patterns and trends and understand what data says (learning data). For some applications it is not necessary to acquire the whole vision of a scene as makes the human vision to extract the features of interest (Luo, 2002), it is possible to only extract the significant characteristics from the scene by the use of a positioning laser (PL), a rotatory mirror scanner and dynamic triangulation as shown at Figure 7, for detailed system overall see (Basaca-Preciado, 2014; Rodriguez-Quiñonez, Sergiyenko, Preciado, et al, 2014; Flores-Fuentes, 2014a).

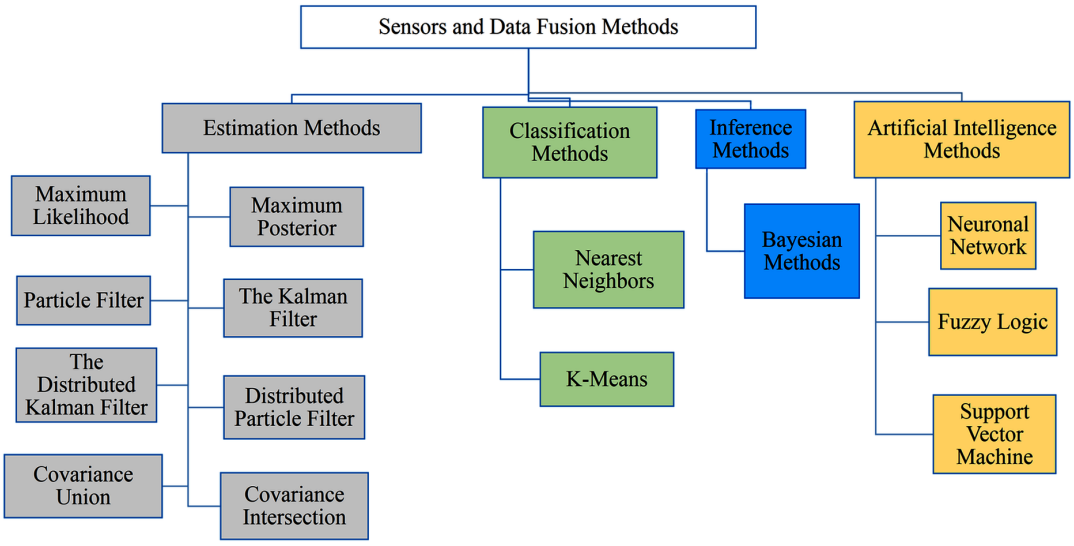
Figure 5. Sensors and data fusion methods



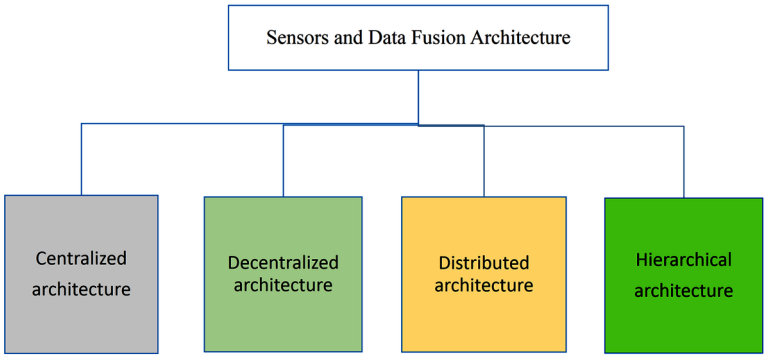


Figure 6. Sensors and data fusion architectures

Machine Vision System Overall

The main sensor is a light scanning system, it can be a coherent light emitter source such as a laser or an incoherent light source such as a bulb like the ones used in motor vehicles. We assume that for any light emitter source there is only one energy centre that represents its point position.

A rotating optical aperture, designed as a 45° slanted mirror surface attached to a cylindrical rod that deflects the light beam into a double convex lens provided with an interference filter and a photodiode. The cylindrical rod is mounted onto the shaft of a dc electrical motor, and as it rotates, an electronic signal is generated. Figure 8 shows the main elements of the optical scanning aperture. When the mirror starts spinning, the sensor "s" is synchronized when the origin generates a pulse indicating the 0° position and the starting of a cycle of 360° that finishes immediately before the "s" sensor generates the next beginning pulse. These pulses are used to calculate the scanning frequency and the zero reference, which is used to measure the angle where the light emitter source is positioned.

The signal timing diagram in Figure 9 shows the starting pulse and the optoelectronic signal relation used to calculate the light emitter energy signal centre position as described in the equations below. The interval $T_{2\pi}$ is the time for one motor revolution, defined as the time between m_1 and m_1 as in (1), which are expressed by the code $I_{2\pi}$ as defined in (2). As for m_1, it is the reference of the starting of one motor revolution (0°).

$$T_{2\pi} = \frac{2\pi}{\omega} = \frac{2\pi}{2\pi f} = \frac{1}{f} \tag{1}$$

$$I_{2\pi} = T_{2\pi} f \tag{2}$$

The time t_α is the time between the reference of the starting of one motor revolution and the energy signal centre, that is, the interval between m_1 and m_2. This can be expressed by the code I_α as defined in (3). As for m_2, it is the energy signal centre. The angle under measurement is then calculated by (4).

$$I_\alpha = t_\alpha f \tag{3}$$

$$\alpha = \frac{2\pi I_\alpha}{I_{2\pi}} = \frac{2\pi t_\alpha f}{T_{2\pi} f} = \frac{2\pi t_\alpha f}{\frac{2\pi}{\omega} f} = t_\alpha \omega = t_\alpha 2\pi f \tag{4}$$

where:

m_1 is the reference of the starting of one motor revolution.
m_2 is the energy signal centre.
$T_{2\pi}$ is the time interval of one cycle, from m_1 to m_1.
ω is the angular speed
f is the scanning frequency (cycles per second).
$I_{2\pi}$ is the interval code of one cycle, from m_1 to m_1.
I_α is the range code from the starting of one cycle to the energy signal centre.
t_α is the interval from the starting of the signal to the energy signal centre, from m_1 to m_2.

Applications of Machine Vision for Spatial Coordinate Measurement.

The present chapter surged in the research continuity of a 3D Vision System for mobile robot navigation application, a 3D medical laser scanner, and a structural health monitoring system, shown at Figure 10.

1. **Mobile Robot Navigation:** Mobile Robot Navigation, also known as Navigation System (NS) utilizes Technical Vision System (TVS) to obtain the characteristics of obstacles appearing in the field of view (FOV) of a mobile robot; with that information the NS calculates a new trajectory to reach its programmed goal. The mobile robot needs to have a goal programmed to begin operation, then an initial trajectory is calculated by calculating the shortest path between current position and goal. The mobile robot will follow the initial trajectory until an obstacle is detected by an array of

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

infrared (IR) sensors. The IR sensors signal will trigger the TVS to perform a scan and obtain the characteristics (3D coordinates) of the detected obstacles. If no obstacles are detected, the mobile robot will reach its goal and stop advancing.

This NS is based in the Pioneer 3-AT (Figure 11) which is a small, four-wheel, four-motor skid-steer intelligent robotics platform, with all the characteristics to be a very suitable research development platform to implement the navigation and 3D vision system for autonomous mobile robots (Basaca-Preciado, 2014).

2. **3D Medical Laser Scanning:** For Medical Scanning System, the 3D measurements of the human body surface or anatomical areas have gained importance in many medical applications. Medical professionals widely use size and shape to assess nutritional status and developmental normality and to calculate the requirements of drug, radiotherapy, and chemotherapy dosages, as well as the production of prostheses. This system has the capability to realize precise measurements by 3D point clouds sampled from the surface of human body, used to obtain the 3D coordinates of the body that are in the FOV in front of the system as shown in Figure 12. This system is based in medical professional traditionally manual measurement of the body size and shape to assess health status and guide treatment (Rodriguez-Quiñonez, Sergiyenko, Preciado, et al, 2014).
3. **Structural Health Monitoring System:** Important engineering constructions as shown at Figure 13, require geometrical monitoring to predict their structural health during their lifetime. Structure experiences deterioration and damage due to environmental conditions and excessive load conditions. Optical Scanning Systems (OSS) provides position measurements for structural health monitoring (SHM) task by a spatial coordinates measurements. This system is based on an initial prototype consisting of an incoherent light source emitter (non-rotating) mounted on the structure under monitoring, a passive rotating optical aperture sensor designed with a 45°-sloping mirror, and embedded into a cylindrical micro rod. A photodiode to capture the beam of light while the cylindrical micro rod mounted on a dc electrical motor shaft is rotating, and a signal energetic centre detector by digital and analog processing (Flores-Fuentes, 2014a), (Flores-Fuentes, 2014b).

Optoelectronic Scanning and Digital Image Processing through the Energetic Center of Laser Spot

Optoelectronic scanning systems generate different shapes of signals, depending on the light source and the sensor of the scanner. A typical position measuring process includes an emitter source of light, as a laser diode or an incoherent light lamp and the position sensitive detector like photodiode and CCD as a receiving device, which collects a portion of the back-reflected light from the target.

When a photodiode is used as a sensor on a scanner with rotating mirror it can also originate a similar Gaussian-like shape with some noise and deformation, the spatial distribution function of light has an Airy-function-like shape, by the other side the CCD produces output currents related to the “centre of mass” of light incident on the surface of the device, CCD use the light quantity distribution of the entire beam spot entering the light receiving element to determine the beam spot centre or centroid and identifies this as the target position.

Concluding that, the photodiode signal originates a similar function to a CCD, consequently, it is possible to enhance the accuracy measurements in optoelectronic scanners with a rotating mirror, using a method for improving centroid accuracy by taking measurement in the energy centre of the signal (Sonka, 2014), (Li, 2014).

1. **Energetic Center of Laser Optoelectronic Signal Detected by Photodiode:** The photodiode is the sensor, which is used for laser-scanning (Beiser, 1995). As SHM is an upcoming tendency of determining the integrity of structures and development of strategies to prevent undesirable damage, the OSS was designed, it has the necessity off detect a light emitter mounted on the structure under monitoring and calculate its energy centre localization. The OSS generates the targeted signals to be analyzed by the proposed methods previously assessed (Rivas-Lopez, 2014).

These six Energy Centre Localization Methods (ECLM), (Geometric Centroid, Power Spectrum Centroid, Analog Processing by Electronic Circuit, Saturation and Integration, Rising Edge, and Peak Detection), Figure 14 shows MATLAB code for Power Spectrum Centroid y graphical results of six ECLM. ECLM were assessed based on the assumption that the OSS signal from light emitter scanning is a Gaussian-like shape signal, the light emitter is an incoherent light, considered a punctual light source and due to the fact that with distance the light source expands its radius a cone-like or an even more complex shape is formed depending on the properties of the medium through which the light is travelling. And to reduce errors in position measurements, the best solution is taking the measurement in the energy centre of the signal generated by the OSS.

According with the results from previous assessment made with incoherent light source the most accurately ECLM are the Geometric Centroid and the Power spectrum centroid, by this reason the Geometric Centroid ECLM was selected to perform the energetic centre localization of a laser spot to measure laser beam deviation.

Figure 14. ECLM graphic representation

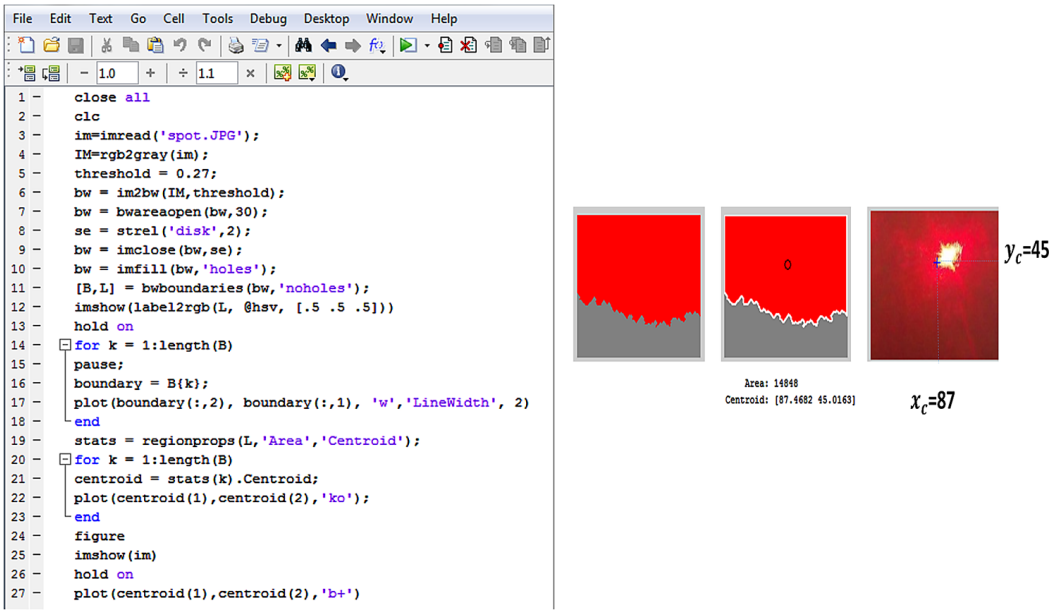
EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

2. **Energetic Center of Laser Image Signal Detected by CCD:** The CCD is the sensor who gives place to the close-range photogrammetry (Franca). Photogrammetry gives information about the geometry of an object or surface through the use of photographs, provides less dense surface information but with high quality, especially along object space discontinuities, edges and borders, it can be defined as the automation of information extraction from digital images, based on image analysis methods.

A camera is located parallel to the OSS photodiode to obtain a second source of information regarding angle β_1, by using a CCD sensor to acquire an image of the FOV at the same time as the OSS photodiode. The use of two methods has been proposed, one focused in the determination of edges and the shape centroid and other focused in the density of points measured on the surface of laser reflection. Both of them calculate the energetic center (image matrix centroid) applying morphological operations. Mathematical morphology is a tool for extracting image components that are useful in representation and description of region shape, it works directly on spatial domain, is a non-linear approach for detection of edges, by image transformations based on simple expanding and shrinking operations. Edge detection identifies and locates discontinuities in an image. An edge may be regarded as boundary between two dissimilar regions in an image, classical methods of edge detection involve the convolution of an image with an operator (like Canny and Prewitt), which is developed to be sensitive to gradients in the image and returning values of zero in uniform areas.

In the method focused in the determination of edge and the shape centroid, a laser light beam is projected in a desired coordinate to create an edge, then the laser light scattered reflection is used to generate a minimum illumination difference (MID), to isolate only the laser light reflection from the image and to detect the edges between the two images (with/without laser light beam), a continuity the edge location is performed by an operator like Canny or Prewitt. Second, the laser light reflection energetic center is localized by the application of several morphological operations as dilation, erosion, boundaries location, fill image regions and remove open area (Li, 2013). MATLAB code and results in Figure 15.

In the method focused in the density of points of laser reflection, the first step the image is captured, and the red color spectrum is obtained, a Gaussian blur filter (5x5 averaging matrix) is applied to smooth the captured image. By calculating the convolution of the original image and a 5x5 averaging matrix, is obtained the desired smoother image which allows to find the center of the laser spot more precisely. Straightforward formal implementation of the two-dimensional convolution equation in spatial form is used, calculated for finite intervals, defined by image frame limits.



After the image has been blurred the maximum values of red color are calculated for each row (x) and column (y) of the 2D matrix representing the image; the brighter the red color in the image, the higher the red value.

The final results are the x and y coordinates of the center of the laser spot inside the captured image (i.e. these coordinates instantly represented in pixels and further, converted to X and Y) (Damelin, 2012; Zhang, 2012). MATLAB code and graphical results are shown in Figure 16.

These two Energy Centre Localization Methods (ECLM) for CCD Images have not been formerly evaluated to compare them, due to the measurement quality depends on surface reflection properties and lighting conditions, the surface reflection properties are dictated by a number of factors, as a) angle of the laser ray hitting, b) surface material, and c) roughness. Although for this fusion sensor purpose, the method focused in the density of points of laser reflection has been selected to be used during the experimentation.

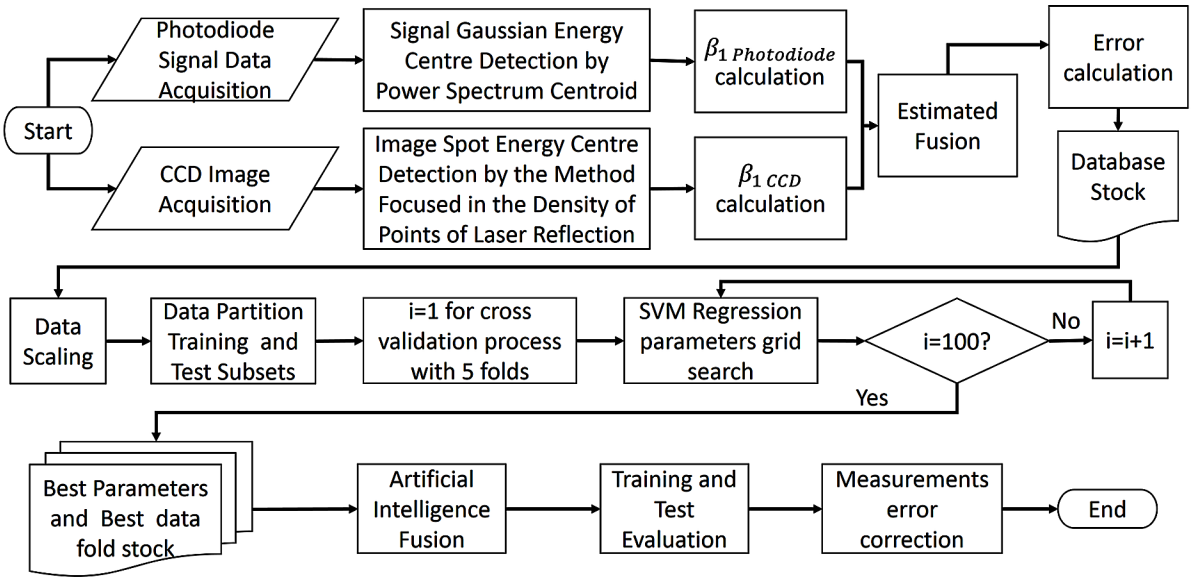
Photodiode and CCD Fusion for Machine Vision

The photodiode and CCD sensors fusion is the base for those systems with non-lineal behavior that require the use of information from various sensors for pattern recognition to produce an enhanced output. The goal of using data fusion in multisensor environments is to obtain a lower detection error probability and a higher reliability by using data from multiple distributed sources. Artificial intelligence methods for sensor and data fusion require human reasoning such as pattern recognition, planning, deduction and learning. The processes of inference used by expert systems begin with a group of initial data (data prior) and some basic rules. Machine Learning algorithms are investigated to fuse the sensors data, such as Support Vector Machine (SVM). The best model generated by each algorithm is called estimator. It is shown that the employment of estimators based on artificial intelligence can improve significantly the performance achieved by each sensor alone (Faceli, 2004; Banerjee, 2012; Waske, 2007).

In previous OSS experimentation angle β_1 measurements with photodiode has been done through an optical table, to observe the measurement error through the FOV, a total of 6020 measurements built the dataset that was used to train and to test an SVM algorithm in the error prediction, to measurement corrections of angle β_1, obtaining a satisfactory improvement, increasing from 53.39% to 97.60% the percentage of measurements with error lower than 2.9°. Corrected angles β_1 were used to calculate the spatial coordinates by dynamic triangulation. At the same time Navigation and Medical Scanning Systems experimentations were applying the Feed Forward back propagation neural networks (NN) Levenberg−Marquardt algorithm with Widrow-Hoff Height/bias learning function to predict the error of spatial coordinates previously calculated with measurement of angle β_1, NN provided an acceptable approximation of the measurement error up to 99.97%, however, the validation of the method shows only a 96% of performance.

For sensors and data fusion experimentation the designed process explained at Figure 17 was followed. A total of 80 measurements built the new experimentation database of 80 instances (*n* rows) and 6 variables (*p* columns), the database values corresponding for column *p*=1 are the real objective angle under measurement (β_{1R}), for *p*=2 are the real objective distance under measurement, for *p*=3 are the system scanning motor frequency, for *p*=4 are the angle calculation from photodiode output ($\beta_{1photodiode}$), for *p*=5 are the angle calculation from CCD output (β_{1CCD}), and for *p*=6 are the error measurement (*E*) calculated by (5).

$$E = \beta_{1R} - \beta_{1M} \tag{5}$$



where:

E is the measurement error, representing how far the measurement from the real value is.
β_{1R} is the angle real value.
β_{1M} is the angle measured by the system (estimated fusion of photodiode and CCD by weighted average).

A scaling step on each column took place (from -1 to 1). The scaled database was partitioned in two sets, 80% training dataset and 20% test dataset, obtaining a training dataset of 64 rows with 6 columns and a test dataset of 16 rows with 6 columns. The 5 first columns are indicated as attributes and the last column as target.

Figure 17. Sensors and data fusion experimentation flowchart

In order to fusion data by artificial intelligence, a properly validate the SVM regression performance was executed, the well-known k-fold cross-validation method was executed, repeating 100 times a 5-fold and in each run performing grid search parameters, as illustrated at Figure 18.

The following kernel parameters were analyzed:

- **Kernel Type:** [Polynomial, RBF],
- **Gamma:** [2^{-5}, 2^{-4}, 2^{-3}, 2^{-2}, 2^{-1}, 2^{0}, 2^{1}, 2^{2}, 2^{3}, 2^{4}, 2^{5}],
- **C:** [2^{-5}, 2^{-4}, 2^{-3}, 2^{-2}, 2^{-1}, 2^{0}, 2^{1}, 2^{2}, 2^{3}, 2^{4}, 2^{5}],
- **NU:** [0.015, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9],
- **Polynomial Degree in Polynomial Kernel:** [1, 2, 3].

EXPERIMENTAL RESULTS

By implementing the method of finding the energetic center of the laser spot by CCD, a second value of the β_1 angle was obtained, the average of that value and the previously corrected angle by artificial intelligence algorithm generated a new value for the β_1 angle, being the first fusion sensor experimentation.

Since the first experimentations for β_1 angle error correction included the known values of frequency (scanner rotation), angle and distance of the scanning aperture (SA) and the angle of incidence β_1 of the laser light on the phototransistor as input data (attributes) for the intelligence algorithm, this new experimentation, utilizes the intelligence algorithm SVMR as a fusion sensor technique, to include as attributes for the training process the β_1 angle measured for both sensors, photodiode and CCD in order to obtain the best sensors characteristics fusion. Showing results illustrated on Table 1.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 18. Flowchart critical steps illustration

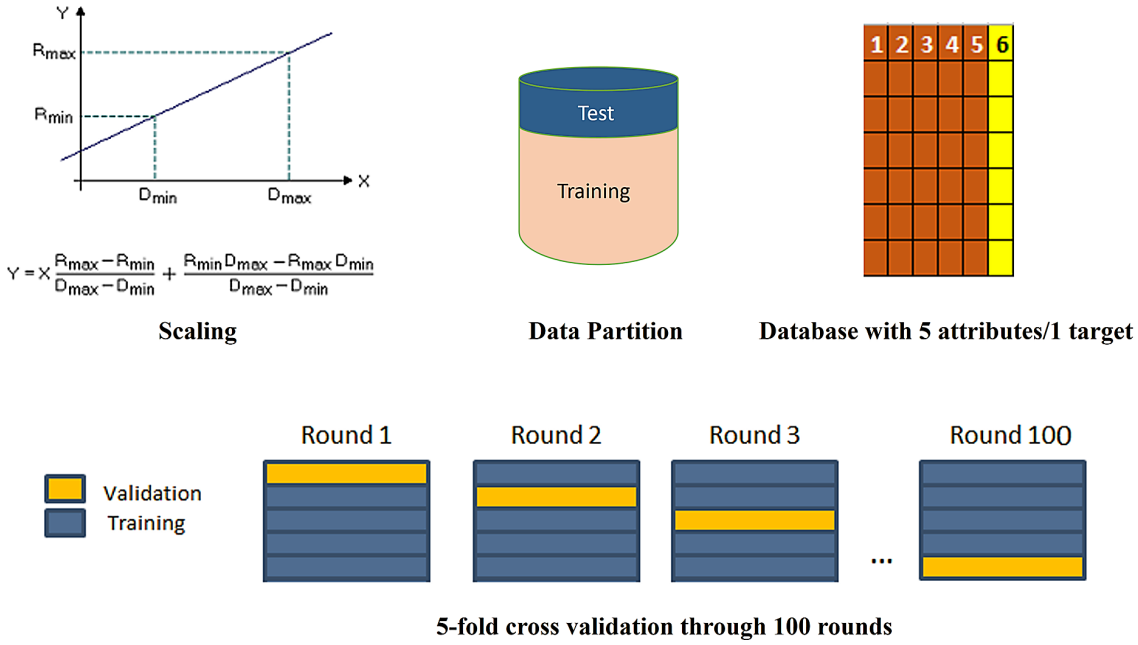

Table 1. Photodiode and CCD fusion sensor

Target	Photodiode Result	CCD Result	SVM Prediction	Fusion Result Error
90°	89.4°	91.1°	90.35°	0.35°
95°	98.1°	99.9	95.60°	0.60°
100°	99.4°	101.0°	100.08°	0.08°
⋮	⋮	⋮	⋮	⋮
105°	103.2°	104.0°	104.60°	0.40°
110°	108.0°	108.0°	109.80°	0.20°

The SVMR algorithm has demostrated been an efficient intelligent tool for prediction, the change of attributes for the target prediction to include the CCD sensor, has improved the β_1 angle measurement accuracy (with error lower than 1°), for the spatial coordinate dynamic triangulation calculation.

CONCLUSION

The goal of using sensor fusion in Machine Vision for Spatial Coordinates Measurement is to obtain a lower measurement error probability and a higher reliability by using data from multiple distributed sources (signal energetic center of sensors, previously corrected by artificial intelligence). This method implements the use of a second value of a measured variable to be used as an atributte in SVMR prediction, which directly affects the overall system accuracy and consequently the monitoring, navigation and scanning systems performance.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Due to the measurement quality depends on surface reflection properties and lighting conditions, the surface reflection properties are dictated by angle of the laser ray hitting, and surface roughness material, further experimentation will be realized scanning over different surface materials like wood, skin, paper, paperboard, egg carton, etc, to build a database to train the system to be able to operate in almost any environment, installed in an optimal hardware architecture in order to further increase the system accuracy and expand the optical scanning applications.

The author's project consists of three main research stages (Laboratory, Outdoor, and Field). The design of experiment and measurements in this chapter describes the results of the Laboratory research stage, and takes them as background for Outdoor research stage, where the fusion of 2D/3D Image and Range Scanner Datasets will be done with data from real environment measurements, while the Field research stage summarize future challenges for accomplish the project scope of SHM for heritage buildings in Autonomous University of Baja California at Mexicali city. In the Laboratory Research Stage, we started with the build of the one OSS for 3D measurements, the use of one OSS provides of polar coordinates in a plane, the use of two OSS separated at known distances, provide of a spatial coordinate in a plane by dynamic triangulation calculations, while the use of three OSS provides the full scope of 3D spatial coordinates measurement. In this stage one OSS was built and characterized at laboratory environment. During tests has been observed that it presents a non-linear behavior throughout all scanning scene, and in order to obtain an accuracy increase the requirement of computational intelligence techniques support surged, for pattern recognition to produce an enhanced output in a modern approach to the prediction of the non-linear measurement error of the OSS to compensate it. The outcome of our project has been a prototypal system for supporting an expert user in conducting structural analyses on building by extracting spatial coordinate information from light emitters mounted over a structure as indicator, in order to evaluate any structural displacement. Users may thus monitor the state of previous interventions, reason about the stability and integrity of the structure, identify potential risks, and plan reinforcement activities accordingly. Besides the specific scenario considered here, such a system may find application in several areas, as for instance in a museum scenario, bridge, damp, industrial structures or any other historical building monitoring projects. Concluding that this chapter outlines the proposed strategy by Artificial Intelligent Algorithms, and the capability to understand images and range scanner data through their fusion.

Future challenges for accomplish the project scope of SHM for buildings are:

- Incorporate a third aperture to the OSS, the use of three apertures in the OSS provides the full scope of 3D spatial coordinates measurement.
- Perform real time measurements by the integration of the signal processing stages (acquisition, energy signal centre calculations, error compensations, fusion and triangulation).
- Integrate the OSS signal processing by hardware, such as Field Programmed Gate Array (FPGA) to satisfy the monitoring system requirements to continue their tasks with safety and high accuracy on temporary occlusion condition.
- Include adaptive elements to the signal processing task in order to enhance the system to be capable of performance at an unknown environment.
- Implement a communication system for measurements record by wireless.
- Evaluate the requirement of time processing reduction.
- Reduce the energy consumption of the OSS.
- Perform measurement analysis to identify structures natural patterns from damages.

Chapter 11
Play in the Museum:
Design and Development of a Game-Based Learning Exhibit for Informal Science Education

ABSTRACT

Digital games have been found to yield effective and engaging learning experiences across a broad range of subjects. Much of this research has been conducted in laboratory and K-12 classrooms. Recent advances in game technologies are expanding the range of educational contexts where game-based learning environments can be deployed, including informal settings such as museums and science centers. In this article, the authors describe the design, development, and formative evaluation of Future Worlds, a prototype game-based exhibit for collaborative explorations of sustainability in science museums. They report findings from a museum pilot study that investigated the influence of visitors' individual differences on learning and engagement. Results indicate that visitors showed significant gains in sustainability knowledge as well as high levels of engagement in a free-choice learning environment with Future Worlds. These findings point toward the importance of designing game-based learning exhibits that address the distinctive design challenges presented by museum settings.

INTRODUCTION

Over the past decade, growing evidence has emerged that games are effective learning tools for a broad range of subjects and student populations (Connolly, Boyle, MacArthur, Hainey, & Boyle, 2012; Clark, Tanner-Smith, & Killingsworth, 2016; Wouters, van Nimwegen, van Oostendorp, van der Spek, 2013). Much of the work has focused on two categories of game-based learning: 1) games for formal educa-

tion settings such as schools (Habgood & Ainsworth, 2011; Wouters et al., 2013), and 2) serious games, which typically investigate game technologies for training (Johnson, 2010) or increasing awareness of social, geopolitical, or economic issues (Mitgutsch & Alvarado, 2012). While important, these research directions do not address a notable class of educational contexts that stands to benefit as much, or perhaps even more, from the introduction of well-designed educational games: informal education settings, such as science museums.

Formal education settings, and particularly schools, differ from science museums in several important respects (National Research Council, 2009). Schools and museums serve different populations: Schools are responsible for educating school-age children, whereas museums are visited by learners of all ages. Museums have a particular emphasis on affective outcomes, such as sparking interest and excitement, and they rarely use tests or grades. In schools, learners typically sit at designated desks for prescribed class periods. Museums are free-choice learning environments; visitors come and go as they please, and there is no teacher to provide instruction. Museum learning, quite literally, *looks different* from classroom learning. These distinctions have significant implications for the design of educational games—including pedagogical and gameplay designs—and they merit careful consideration to ensure effective and engaging learning experiences.

In this article, we explore the design of game-based learning environments for museums by presenting a case study of Future Worlds, a game-based learning environment for collaborative explorations of environmental sustainability. Future Worlds is an interactive exhibit designed to enrich museum visitors' understanding of sustainability, promote collaboration and scientific reasoning, and foster engagement in environmental science. We outline the design principles that drove the iterative development of Future Worlds, and we illustrate the methods utilized to investigate Future Worlds' effectiveness for fostering learning and engagement.

BACKGROUND AND RELATED WORK

The affordances of digital games align naturally with the goals of museum education, such as fostering engagement in science, and enabling learners to manipulate, test, and explore hypotheses about the natural world (National Research Council, 2009). However, designing game-based learning environments presents several challenges. Game design is multidisciplinary, requiring close collaboration between software developers, educators, artists, testers, and other specialists. Games are complex, requiring myriad design decisions with uncertain impacts on learners' experiences. Most notably, there is a dearth of evidence-based research on the design principles and methods necessary for creating effective game-based learning environments.

Reviews of the game-based learning literature have broadly concluded that games can yield positive learning outcomes across a range of educational subjects (Connolly et al., 2012). In recent years, a pair of prominent meta-analyses independently concluded that, in general, digital game technologies are often more effective than traditional instructional methods in fostering learning and retention (Clark et al., 2016; Wouters et al., 2013). Expanding on this conclusion, Wouters et al. (2013) advise, "the next step is more value-added research on specific game features that determine ... effectiveness" (p. 262). Clark et al. (2016) echo this argument, concluding, "[Research on game-based learning] should thus shift emphasis … to cognitive-consequences and value-added studies exploring how theoretically driven design decisions influence situated learning outcomes" (p. 116).

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

With the aim of identifying evidence-based design principles for game-based learning, Isbister, Flanagan, and Hash (2010) conducted interviews with experienced game developers to identify key design practices used within the professional game industry. The interviewees described themes such as emphasizing fun as a central design value, requiring high levels of polish and well-tuned end-user experiences, emphasizing deep learning content rather than "bolted on" learning materials, supporting collaboration and specialization, designing for role-playing and emotional engagement, and including affordances for exploring complex systems. While the identified themes are high-level and abstract, they do describe characteristics often lacking in game-based learning environments. Isbister et al. (2010) account for this by pointing to problems in the communication pathways between practitioners and theorists, describing situations where design choices are not well articulated or discussed critically.

In other work, Linehan, Kirman, Lawson, and Chan (2011) describe methods for educational game design rooted in applied behavior analysis. Their framework emphasizes personalized instruction and mastery learning, describing a four-step design pattern that involves 1) defining and measuring learners' behavior, 2) recording and analyzing changes in learners' behavior, 3) providing immediate corrective feedback, and 4) tailoring game events based on learners' performance. It is notable that the guidelines from Linehan et al. are theoretically grounded, but unfortunately they are not examined in the context of an actual educational game.

A handful of empirical studies have been conducted to investigate the learning impacts of specific game design decisions. Habgood and Ainsworth (2011) found that tight integration of subject matter and game mechanics in a game for elementary mathematics yielded enhanced learning outcomes compared to versions that separated content and gameplay. Other work has investigated the impacts of narratives in games (Adams, Mayer, MacNamara, Koenig, & Wainess, 2012; Rowe, McQuiggan, Robison, & Lester, 2009). Results suggest that narratives may be effective in fostering student motivation, but narrative designs should be crafted sparingly in order to avoid distracting learners or imposing extraneous cognitive load.

Much of this research has taken place in the context of formal education settings, such as K-12 classrooms. However, the design requirements for game-based learning in museums differ from games in schools because of the distinct characteristics of museum-based learning. As outlined in a report from the National Research Council (2009), the informal science education community has identified six interrelated strands of informal science learning: sparking interest and excitement in science; enabling learners to understand, remember, generate, and use science concepts; encouraging learners to test, explore, question, and observe the natural and physical world; fostering reflection on the scientific process; creating opportunities for learners to participate in scientific activities; and encouraging learners to think of themselves as scientists.

Museums and schools share many of these objectives, but they prioritize the objectives differently. Schools are responsible for preparing students to meet academic standards focused on student knowledge, skills, and abilities. Attendance is often compulsory, and instructional practices are aligned with school objectives. In contrast, the voluntary nature of many museum visits leads toward an increased emphasis on non-cognitive outcomes, such as visitor interest and engagement. Museum visitors typically spend brief amounts of time at each exhibit—a few minutes or shorter—which limit expectations for deep knowledge gains. Museums also have different educational resources (e.g., panoramic theaters, fossil collections) and physical layouts (e.g., open floor plans) than schools, which shape the learning experiences that are available to visitors. Discerning the extent to which a game-based learning environment embodies the six strands of informal science learning, as well as the extent to which it accounts for the distinct capabilities and constraints of museum settings, provides a framework for evaluating a game-based learning exhibit's design.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Recent years have witnessed growing interest in the application of digital game technologies in informal settings, including animated pedagogical agents (Lane et al. 2013; Schulman, Sharma, & Bickmore, 2008), interactive tabletop-based games (Horn et al., 2012), and mobile games (Greenspan & Whitson, 2013). For example, advanced learning technologies in museums now utilize the high-end rendering capabilities of game engines so that virtual humans serve as simulated docents. These docents offer personalized guidance and feedback to visitors through natural language and affective expression (Lane et al., 2013). Game-based learning exhibits have also been developed for a range of subjects, including evolution (Horn et al., 2012), sustainability (Antle, Bevans, Tanenbaum, Seaborn, & Wang, 2011), and history (Greenspan & Whitson, 2013). These exhibits have shown promise for promoting engagement and visitor enthusiasm by leveraging game designs centered on brief visitor interactions, multi-touch interfaces, and multi-user hardware technologies (Antle et al., 2011; Horn et al., 2012;). However, there has been relatively little empirical research on visitor learning and individual differences with game-based exhibits in science museums. Further, few projects have explicitly examined the design factors that distinguish game-based learning in museums from game-based learning in schools. In the next section, we outline these design factors, which shaped the development of the Future Worlds exhibit.

DESIGN FACTORS FOR GAME-BASED LEARNING IN MUSEUMS

During the early stages of the project, we held a series of discussions with partners at the North Carolina Museum of Natural Sciences about interactive science exhibits and the dynamics of visitor learning. Further, we reviewed several interactive exhibits in prominent science museums across the eastern United States to inform our efforts to gather software requirements for the game's design. From this analysis, we identified five overarching design principles for Future Worlds to address the objectives, affordances, and constraints of game-based learning in museums (Table 1).

1. **Low barrier to entry**. Because interactions with museum exhibits can be either short or long in duration, embedding game mechanics that are accessible and quick-to-learn is critical. For this reason, we adopted natural user interfaces—in our case multi-touch interaction—and highly

Table 1. Alignment between museum-based learning attributes and game design principles

Museum-Based Learning Attributes	Design Principles for Game-Based Exhibits
Emphasize interest and excitement	• Foster exploration and curiosity • Present melodramatic feedback • Leverage novel hardware
Feature short dwell times	• Prioritize low barriers to entry
Appeal to diverse learners (i.e., age, gender)	• Prioritize low barriers to entry • Utilize inviting aesthetics with broad appeal
Support solo and collaborative interactions	• Leverage novel hardware • Provide flexible user experiences
Support active and passive engagement	• Leverage novel hardware • Provide flexible user experiences
Account for free-choice movement between exhibits	• Foster exploration and curiosity • Present melodramatic feedback

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

streamlined heads-up displays (HUD) to guide learner interactions. Similarly, we sought to leverage learners' prior knowledge whenever possible, adopting multi-touch controls that are widely adopted in modern computing (e.g., tap, swipe, pinch-to-zoom, two-finger rotation), as well as game paradigms that are widely recognized by the public (e.g., SimCity-style visual appearance).

2. **Exploration and curiosity**. Effective interactive exhibits typically avoid didactic instructional methods, such as lengthy text presentations and non-interactive animations. Our design, therefore, emphasizes learners' direct manipulation of the virtual environment, as well as explorations of cause-and-effect and interrelations between disparate environmental elements. We sought to minimize the amount of text in the game and avoid direct instruction about environmental science concepts.
3. **Immediate and dramatic feedback**. Immediate feedback is important for any educational setting, but discussions with museum partners yielded recommendations for incorporating melodramatic feedback (in their words, "use fireworks") to convey the effects of learners' decisions. This advice was specifically targeted at young learners, with the implication that subtle effects are often missed or ignored in museum-based learning. Museum spaces often house many competing exhibits, and learner attention is easily diverted. Therefore, we sought to integrate rich combinations of animation, color, and sound to make the effects of young learners' actions clear.
4. **Inviting visual aesthetics with broad appeal**. Although the project targeted young learners, parents and guardians often accompany these visitors. Given the broad range of potential participants found in science museums, we sought to devise a visual style that was inviting and had broad family appeal; we chose not to adopt a visual style that was edgy or dystopian in conveying the impacts of environmental decisions. While labor-intensive, we also sought to emphasize visual "polish," consistent with recommendations from the educational game design literature (Isbister et al., 2010). The importance of visual polish was particularly salient in our review of exhibits in prominent science museums. High-quality visual presentations are the standard, not the exception, in museum-based learning. This emphasis on visual quality is a notable differentiator from many game-based learning environments for classroom learning.
5. **Novel hardware platforms**. Given the leisure-based nature of many museum visits, and relatively high bar for learners' attention[1], we determined that using a novel hardware platform was an important opportunity for fostering learner interest and engagement. We decided to utilize surface computing hardware to create interactive learning experiences that were not feasible in most school or home settings. This criterion is contrasted with formal education settings, where even rudimentary games are often viewed as being more engaging than conventional instructional methods, such as lectures. Surface computing tables simultaneously integrate multi-touch interfaces, which are immediately familiar to many learners, with novel multi-user collaboration possibilities. We then extended the platform by integrating the surface computing table with a second, vertically mounted high-definition digital display, doubling the available screen real estate for the exhibit (Figure 1). One collaborator described the platform as akin to a "giant Nintendo DS."

In addition to these principles, we came to recognize several interaction patterns that distinguish museum-based learning from other settings, particularly classroom learning. These point to the need for a sixth design principle: providing flexible user experiences that accommodate the broad range of visitor interactions typified by museum-based learning.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. Early artist rendering of Future Worlds multi-display exhibit

1. **Solo vs. collaborative interactions**. Learners approach museum exhibits in many different types of configurations. Learners may explore museums individually, engaging in solo learning experiences involving limited conversation and social interaction. Young learners may explore exhibits while accompanied by siblings, parents or guardians. Adults, who may or may not directly interact with the exhibit themselves, will often scaffold young learner's interactions by asking questions or giving advice. In another interaction pattern, learners may approach exhibits that are already partially occupied, engaging in collaborative or cooperative learning with "strangers" with whom they share no prior relationship. Alternatively, learners may approach exhibits as part of large field trip groups, exploring exhibits collaboratively with large groups of peers with whom they have strong social bonds. Given these distinct types of configurations, game-based learning designs for museums should be compatible with a broad range of solo and multi-player interaction paradigms.
2. **Short vs. long durations**. Learner interactions may be shallow and brief—5 second interactions that are quickly abandoned—or they may be deep and extensive—30 minute explorations involving detailed conversations and reflection. Paradoxically, learner interactions may also be long in duration but shallow in terms of learning. In these cases, learners play with surface features of the exhibit but fail to deeply engage with the subject matter. Gameplay and content in a museum-centric game-based learning environment should be devised to accommodate these different extremes of engagement, providing positive educational value in as many scenarios as possible.
3. **Active vs. passive engagement**. Active prolonged engagement is an oft-cited goal in museum exhibit design (Horn et al., 2012). However, in practice, learners may engage with an exhibit in many different ways. Some learners confidently approach an exhibit and begin physically interacting immediately. Others initially hold back, passively watching or deliberating whether to explore the exhibit more actively. Learners may also passingly engage with an exhibit while walking en route to another destination, judging whether to explore the exhibit at a later point in time. A salient indicator of these differences in engagement is physical proximity; active engagers are often

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

physically close to the exhibit, while passive engagers are often farther away. Another important indicator is dwell time, which denotes the amount of time that a visitor spends at an exhibit. In our work, we attend to both factors together, investigating how long visitors spend at several different tiers of proximity to the exhibit. Given individual differences in engagement, game-based learning exhibits should be designed to support learning across different physical distances and durations, gradually easing learners toward higher levels of active engagement as they are comfortable.

Having identified these design principles and museum-centric interaction patterns, we embarked on the design and development of a game-based learning environment for sustainability education in museums, Future Worlds.

DESIGN AND DEVELOPMENT OF FUTURE WORLDS

To create Future Worlds, we adopted an iterative design process that involved close interdisciplinary collaboration between developers (game designers, software engineers, digital artists), educators (informal science educators, elementary science educators), and subject matter experts (environmental engineers, environmental scientists). The game design model involved several iterations of designing, developing, evaluating, and refining prototypes of Future Worlds, including both paper and software-based prototypes.

Future Worlds

Future Worlds is a prototype game-based learning exhibit about environmental sustainability for children ages 9–12. The exhibit integrates turn-based strategy game mechanics, pedagogical agents, and surface computing tables to support collaborative explorations of environmental sustainability. In Future Worlds, learners solve sustainability-centered problems by investigating the impacts of alternate environmental decisions in a 3D simulated environment. Learners explore environmental decisions—such as modifying a region's electricity portfolio or a farm's waste management practices—through collaborative, multi-touch interactions on the exhibit's interactive tabletop display. The effects of learners' environmental decisions are realized in real-time through rich 3D virtual environments, and they are accompanied by narrated explanations from a virtual docent who observes the learners' actions.

The design of Future Worlds is intentionally aligned with several strands of informal science learning (National Research Council, 2009). Specifically, Future Worlds offers opportunities for enriching visitors' understanding of environmental sustainability; it fosters high levels of visitor engagement; it enables visitors to test, manipulate, and observe changes in the simulated environment; and it fosters collaboration and conversation about environmental science. Future Worlds also accounts for the distinctive capabilities and constraints of science museums. The game accommodates different levels of visitor engagement, ranging from brief passive encounters to extended hands-on experiences. Future Worlds' multi-touch gameplay is designed to be easily accessible, particularly for learners with minimal game-playing experience. Further, the game's 3D graphics are designed to appeal to a broad range of visitors.

The prototype exhibit's physical design is comprised of two adjacent digital displays: a horizontally oriented Samsung SUR40 interactive tabletop, and a vertically oriented non-interactive 50" high-definition television (Figure 1). The configuration provides an integrated two-screen setup; visitors congregate

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

around the horizontal display to explore the science simulation through multi-touch interactions, and the vertical display provides additional screen real estate for explanations of sustainability concepts, which are also accessible to learners standing farther away from the exhibit.

Future Worlds focuses on three integrated themes of sustainability: water, food, and energy. Visitors' objective during learning interactions with Future Worlds is to use the interactive tabletop display to collaboratively (or individually) reconfigure an unsustainable virtual environment into a sustainable environment. Learners can engage in deep, extended interactions with Future Worlds —solving sustainability problem scenarios and identifying complex relationships between alternate environmental decisions—or they can engage in shallow interactions with Future Worlds, tapping on the virtual environment and briefly listening to a narrated explanation before moving on.

As an illustration of a typical learning interaction with Future Worlds, consider the following scenario. A small group of learners approaches the exhibit. Tapping on the start screen causes a 3D model of Earth to rotate into view. From the globe, a small environmental region from the United States' eastern coast emerges. The virtual environment represents the first problem-solving scenario: a portion of a simulated watershed that is in an unsustainable state.

The virtual environment is divided into several discrete, hexagon-shaped locations (Figure 2). Each hexagon encompasses an atomic geographic region that can be acted upon by learners as part of solving the environmental sustainability problem scenario. The virtual environment's three-dimensional appearance is stylized, and at first it appears to be brown and lifeless. The environment's appearance is a melodramatic visualization illustrating that the virtual environment is "unhealthy," that is, the environment is in an unsustainable state. Shortly afterward, a short description of the scenario's sustainability-centric objective is presented. The scenario focuses on issues related to farming, particularly waste management and electricity sources. Learners are instructed to explore alternate choices for improving the sustainability of the farms. At this stage, learners are free to begin manipulating the virtual environment to explore the effects of alternate environmental decisions.

Learners can manipulate the virtual environment using multi-touch gestures, such as pinch-to-zoom and rotations. Additionally, learners can tap on various hexagon-shaped locations in the virtual environment, request information about the different factors that bear on the environment's sustainability, and change the behavior of the farms. For example, one of the farms appears to be contaminating a nearby river through fertilizer runoff from a crop field. A learner taps on the farm, and a menu appears offering several options for changing the farm's fertilizer runoff management practices. In order to learn more about the farm's current management practices, the learner taps an "Info" button on the menu. In response, a virtual docent appears on the second vertical display providing a short narration about fertilizer runoff and waste management.

Another example of the use of Future Worlds is that a learner encounters the option to add a riparian buffer to the hog farm. The docent explains that a riparian buffer consists of plants and tree roots that can absorb hazardous nitrogen levels, which leach from synthetic fertilizers used by many farms into nearby water bodies. The learner decides that installing a riparian buffer is worth exploring, and she taps on the menu to enact it. In response, the virtual environment begins to change in appearance: the farm's 3D models transform as the brown-colored fertilizer runoff disappears and a stretch of small bushes, shrubs, and tall grass appears between the farm and adjacent riverbank (Figure 2). Nearby terrain grows greener, and portions of the environment begin to animate. The 3D virtual environment—replete with aesthetic lighting, detailed 3D models, high-resolution textures, and believable animations—provides

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. Successive stages of a virtual environment in Future Worlds

a dynamic visualization of the learners' environmental actions through immediate feedback, in effect making learners' sustainability choices "come to life." Using this feedback, learners explore the sustainability simulation and solve the problem scenario (Figure 2).

Paper Prototyping

After identifying design requirements to guide the development of Future Worlds, we undertook an iterative paper prototyping process that involved developing, testing, and refining several paper-based versions of the system (Figure 3). Paper prototypes emulate the visual appearance and interaction design of the final game environment while providing a low-cost method for rapidly creating, deploying, and refining alternate interaction designs. Paper prototypes resemble a "board game" version of the final system—they are typically made using paper and cardboard cutouts—and they source difficult-to-model aspects of the system's functionality to a human "game master." Pilot testing paper prototypes with young learners shares similarities with Wizard of Oz studies (Kelly, 1983). In both cases a human emulates functionality that will eventually be provided by software, such as simulation systems or artificial intelligence functionalities.

During the project's first phase, the team conducted two studies to test early paper prototypes of Future Worlds. The first study was held during a teen-focused event at the North Carolina Museum of Art, and it focused on Future Worlds' interaction design and visual style. The second study was held at the North Carolina Museum of Natural Sciences, and it focused on a refined version of the Future Worlds paper prototype, investigating the complexity of the environmental problem-solving tasks.

During the first study, 11 learners ranging in age from 13-17 interacted with the paper prototype. The prototype focused almost entirely on tradeoffs between energy generation and pollution. Its main purpose was to support investigations of Future Worlds' core gameplay dynamics. In addition to testing basic interaction design, the study provided an opportunity to investigate methods for presenting scientific information, and compare alternate visual styles for the virtual agents. Learners worked individually and collaboratively to solve two problem scenarios with assistance from a project team member. All learners solved the scenarios, and several learners identified alternative solutions to the scenarios. However, the research team observed that learners did not appear to engage deeply with the descriptions of alternate energy sources or consider a broad range of environmental factors in their decision making. The project team reviewed the paper prototype following this first focus group in order to generate feedback about the science content and presentation. The paper prototype was modified in order to enhance the science content, refine the task descriptions, introduce an additional problem scenario, and modify the input mechanics.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 3. Future Worlds paper prototype

The second study was held in coordination with a science summer camp program hosted by the North Carolina Museum of Natural Sciences. The study was designed to examine the revised implementation of the Future Worlds paper prototype. The focus group involved 17 learners in total. The learners were divided into groups so that learners could work on the paper prototypes in pairs while a designated researcher oversaw each paper prototype. Each group interacted with the paper prototypes for approximately 15–20 minutes.

During the focus group's pre- and post-assessments, learners completed a drawing task that involved creating a picture of what is an environment based on their understanding. Participants were asked to label parts of the drawing and write an explanation of what makes their drawing a representation of an environment. Learners produced images of forests, towns, water bodies, animals, and the sky. As part of the post-assessment that was administered after the Future Worlds experience, learners were given the opportunity revise their original drawings. Of those learners, 16 elected to make changes and improve their representation of the environment. All of these learners chose to make additions and not remove aspects of their original drawings. The most common new inclusions were representations of energy sources such as wind (windmills), solar (the sun), petroleum (oil power plants), hydroelectric power (water sources) and human beings, providing preliminary evidence of positive gains in sustainability understanding.

Iterative Development

Although agile-based software development processes are common practice in the game industry, only in recent years have iterative development processes begun to gain attention in the research literature on educational game design (Chamberlin, Trespalacios, & Gallagher, 2012). Our process further contributes to this growth: Upon establishing a benchmark design through several iterations of paper prototyping and pilot tests, we began software production on the Future Worlds game-based learning environment. Future Worlds was built with the Unity game engine. An agile-based development process was employed, which involved identifying, prioritizing, and developing targeted sets of features for 2-4 week development "sprints." During each sprint, software development and art production activities focused only on the features identified for that sprint. At the conclusion of each sprint, an incremental build of the system was demoed internally to the project team, as well as outside collaborators, for constructive feedback. Software production proceeded in this manner for approximately six months.

MUSEUM PILOT TEST

A study was conducted at the North Carolina Museum of Natural Sciences to investigate visitors' learning and engagement with the Future Worlds prototype game-based learning exhibit. Participants were summer campers enrolled in existing summer camp programs at the museum and visited the exhibit in small groups. The study was designed to investigate the prototype exhibit's impacts in a free-choice learning environment that approximated real-world use—this included several competing co-located exhibits—as well as the influence of learners' individual characteristics on sustainability learning and dwell time.

Participants

A total of 43 participants interacted with Future Worlds during the study. The campers were grouped into separate cohorts divided across three sessions ($N = 14, 16, 13$). Of the sample of 43 campers, a majority was male (57.4%). Participants ranged from ages 8-14 with a mean age of 10.7 years. The majority of participants identified as Caucasian (75.9%), followed by Asian/Pacific Islander (7.4%), Black (3.7%), and American Indian/Alaskan Native, Hispanic, and Other (1.9%).

Materials and Apparatus

Learners completed three complementary measures of sustainability concept understanding: a personal meaning map, a sustainability identification task, and a sustainability image-sorting task. These measures were devised to assess visitors' ability to understand and remember sustainability concepts, while remaining consistent with a spirit of voluntary participation and leisure-based learning in museums. To investigate learner engagement, video recordings of participant behavior were recorded and analyzed to determine dwell times.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Personal Meaning Maps

In order to investigate learners' conceptual understanding of sustainability, participants completed personal meaning maps (PMMs). Each PMM consisted of a blank piece of paper with a brief set of instructions and a prompt phrase: sustainability. Participants used a blue ink pen to write or draw words, phrases, and pictures about what they thought and knew about the prompt word on the blank paper. After leaving the exhibit space, participants were given the opportunity to revise their PMM using a red ink pen. After the study, two raters scored each PMM based on the relevance and accuracy of each element included on the page. Typical features that were considered *sustainability-relevant* included drawings of windmills, trees, and solar panels, as well as descriptive words such as "renewable energy" and "ecosystem." Irrelevant features included drawings of pizza and other foods—some learners appeared to confuse "sustenance" with "sustainability"—as well as words that indicated misconceptions or guessing, such as "strong." The raters summed the total number of relevant and correct items listed and subtracted the total number of irrelevant and incorrect items included. The inter-rater reliability for the pre-test ($r = .84$) and post-test ($r = .88$) grades achieved acceptable levels.

Identification Task

Learners were instructed to inspect an illustrated picture of an environment—which depicted both sustainable and unsustainable environmental practices—and annotate the picture by circling "good" environmental practices and crossing out "bad" practices. Learners' pictures were returned during the post-test, and participants revised their annotations. Two independent raters scored learners' annotations using a rubric vetted by subject matter experts. The raters obtained high scoring agreement on both the pre-test ($r = .97$) and post-test ($r = .95$) versions.

Image Sorting Task

Learners were given paper copies of ten images depicting various environmental practices (e.g., recycling, solar panels, heavy traffic congestion, off-shore drilling). Participants were asked to organize the images into two categories of their choosing and were instructed to select the two categories such that they contained as similar a number of images as possible. An expert-based categorization of the images into "sustainable" and "unsustainable" categories was considered the most disciplinarily sophisticated response, and this benchmark was used to grade students' responses. This activity was completed as part of both the pre- and post-test.

Dwell Times

Sessions were video recorded by two cameras strategically placed in the study room to collect data on visitor dwell behavior. Through post-study analyses of the video data, dwell times were determined for each participant in order to assess durations of learner engagement. For each learner, two coders determined total dwell time (time spent interacting with the exhibit to any extent) as well as time spent in each of three possible "tiers of proximity" relative to the Future Worlds exhibit. The first tier is defined as touching the table or standing directly against the interactive tabletop. The second tier is defined as

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

standing immediately behind the first tier participants. The third tier is one layer behind the second tier, within an approximately 5-foot radius of the exhibit. Inter-rater reliability was established with a subset of the study data and then the remainder was coded independently ($k = .70$).

Study Design and Procedure

Pre-test measures were administered on the first day of each cohort's week-long summer camp. The pre-test included the PMM, identification task, sorting task, and demographic questionnaire. Later in the week, learners spent time exploring various parts of the museum, including a room with a thematic focus of "citizen science." This area served as the study room. The Future Worlds exhibit (Figure 4) was kept on-site and made available for use by the summer campers when exploring the citizen science area. During each study session, a human docent stood next to Future Worlds to resolve technical issues and answer questions. Conversation between the docent and participants was kept to a minimum. As part of their summer camp experience, learners were allowed to spend up to 40 minutes in the study room. For each cohort, all participants entered the room at the same time. Learners were told that they could leave the space at any time, and were free to explore the space as they saw fit. Once they left the room, they were not permitted to return.

Including Future Worlds, there were 13 exhibits in the study room. No other museum visitors had access to the citizen science area during the study. Eleven of the exhibits in the study room were permanent exhibits at the museum. In addition to Future Worlds, one temporary exhibit was added to serve as a control. This temporary exhibit was the only other exhibit with a human docent, and it consisted of

Figure 4. Visitors exploring the prototype Future Worlds game-based learning exhibit

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

a white board with a sign asking learners to write down the most interesting thing they learned in the citizen science area. Of the 12 distractor exhibits within the space, half of them ($N = 6$) were interactive and more than half were digital ($N = 7$). It should be noted that none of the content in the distractor exhibits overlapped with the content included in Future Worlds.

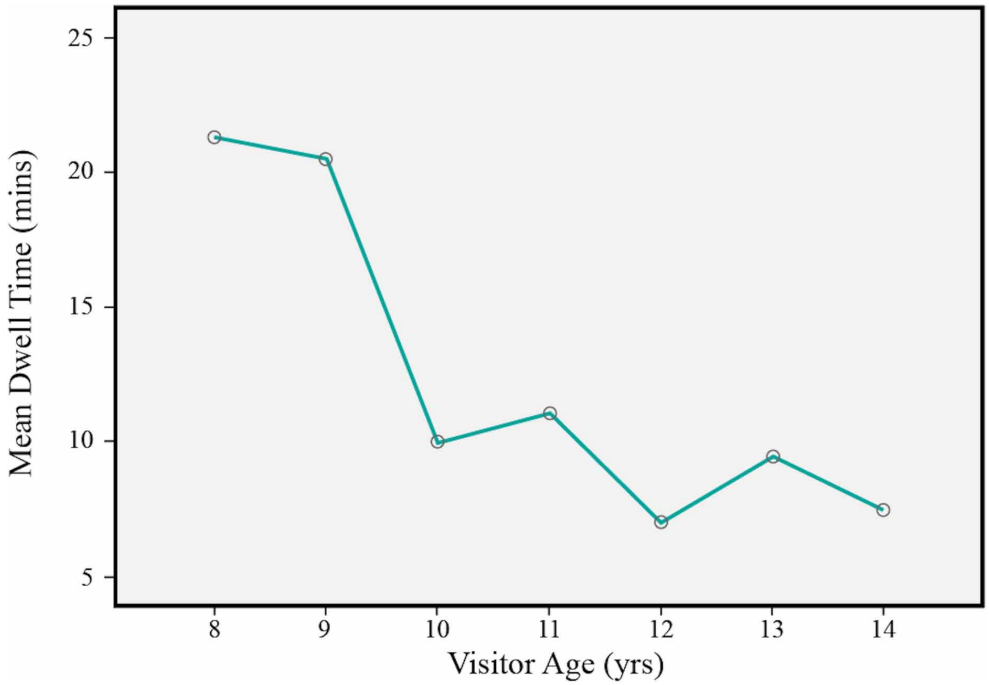
A post-test was conducted immediately following each participant's exit of the citizen science area. It included the same sustainability learning assessments as the pre-test.

FINDINGS

To investigate the learning impact of the Future Worlds exhibit, statistical analyses of the pre- and post-test measures, as well as coded video recordings, were conducted. Paired t-tests indicated that learners showed significant gains in PMM score from pre-test ($M = 0.8$, $SD = 1.8$) to post-test ($M = 1.2$, $SD = 2.3$), $t(37) = 2.5$, $p<.05$. There were also significant increases on the identification task from pre-test ($M = 6.0$, $SD = 2.5$) to post-test ($M = 6.4$, $SD = 2.6$), $t(37) = 3.3$, $p<.05$, as well as significant gains on the image sorting task from pre-test ($M = 7.1$, $SD = 3.8$) to post-test ($M = 8.7$, $SD = 2.7$), $t(37) = 2.6$, $p<.05$. Correlation analyses were conducted to investigate whether learners' individual characteristics—including age and gender—showed significant relationships with learning outcomes, but none were observed.

For each learner, total dwell time, as well as time spent in each of three proximity tiers, was determined using video recording data. Across all participants, the average dwell time at Future Worlds was 12.5 minutes. This is promising, given dwell times typically reported in other informal contexts, such as 5.0 minutes (Horn, Solovey, Crouser, & Jacob, 2009) and 4.9 minutes (Lane et al., 2013). However, it should be noted that Future Worlds dwell times were recorded in a semi-controlled study setting, whereas the above cited dwell times were recorded from observations of the general public in non-controlled settings.

We next investigated the effects of individual differences—specifically gender and age—on dwell time. A two-tailed independent samples t-test revealed a significant effect of gender on dwell time, where girls (M = 8m:46s, SD = 5m:21s) spent roughly half the time as boys (M = 16m:23s, SD = 10m:33s) engaging with Future Worlds, $t(35) = 2.9$, $p<.05$. To follow up on this analysis, tier-specific dwell time was examined by gender. Results indicated that males (M = 14m:12s, SD = 7m:34s) spent significantly more time in the first tier than females (M = 8m:56s, SD = 3m:56s), which is the tier of closest proximity to the exhibit, $t(29) = 2.3$, $p<.05$.



Additional findings about the influence of learners' individual characteristics emerged from analyses of engagement based on learner age. Results indicated that younger children spent more time at the Future Worlds exhibit than older children, $t(44) = 3.5$, $p<.01$. In fact, children under age 10 spent twice as much time (M = 20m:50s, SD = 12m:33s) as children age 10 and older (M = 9m:56s, SD = 6m:45s). Observations of mean dwell time by age are shown in Figure 5.

DISCUSSION

Our results suggest that learners' sustainability understanding improves from interactions with Future Worlds. Furthermore, evidence of extended dwell time, compared to the existing literature, suggests that learners are highly engaged with the exhibit. In combination, these two sets of findings suggest that learner

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 5. Mean dwell time (in minutes) with Future Worlds by visitor age (in years)

engagement with Future Worlds is not superficial; learners are actively engaged for prolonged periods at sufficient depth to yield significant learning gains across three distinct measures of sustainability knowledge.

Our observation that gender and age have significant effects on dwell time point toward engagement-centric design implications for future iterations of Future Worlds. Regarding gender, several possible mediating factors could explain why girls spent less time with Future Worlds than boys, such as video game interest or affinity for the game's visual aesthetic style. Gender is widely recognized for its importance in shaping the design and use of entertainment-focused games (Jenson & de Castell, 2010). Our findings support that gender is likely to be similarly important in the design and use of game-based learning exhibits in museums. Additional studies are necessary to isolate what design factors are responsible for the observed gender differences in visitor experiences with Future Worlds and to determine how Future Worlds' design should be augmented to appeal to females to an extent that is comparable to males.

Regarding age, results suggest that future iterations of Future Worlds should incorporate problem-solving scenarios that span a broader range of content and complexity. It is possible that the implemented problem scenarios in the Future Worlds prototype were sufficiently challenging for young children but were not difficult enough for older children, and thus did not sustain their engagement for extended periods. Older visitors may have solved all of the game's embedded sustainability challenges—in other words, they may have *finished* the game—more quickly than younger learners, leading to shorter dwell times. Incorporating intelligent tutoring system capabilities to dynamically adapt the difficulty of problem scenarios to individual learners, or groups of learners, is a promising way to match scenarios' content complexity to the capabilities of diverse visitors. Adaptive pedagogical planning will require models for automatically detecting learners' individual characteristics as they approach and use exhibits, since administering lengthy pre-tests is not a viable design choice for most informal settings.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Notably, we did not find a relationship between dwell time and learning. We expect that adding curricular material beyond the prototype's current proof-of-concept scope—creating opportunities for more variance in content exposure—could reveal relationships between dwell time and learning that have not thus far been observed.

CONCLUSION AND FUTURE WORK

Game-based learning environments show considerable promise for informal settings such as museums and science centers. Creating game-based learning environments for science museums raises challenges that are distinct from those raised by games for classrooms. Museums and classrooms emphasize different aspects of learning, serve different learner populations, and afford different levels of learner autonomy. To address these challenges, we have identified several design factors for creating game-based learning exhibits in science museums: (1) providing a low barrier to entry, (2) fostering exploration and curiosity, (3) delivering immediate and dramatic feedback, (4) prioritizing visual aesthetics with broad appeal, (5) leveraging novel hardware platforms, and (6) providing flexible user experiences. To investigate these design factors, we pilot tested a game-based learning exhibit called Future Worlds, which was created using these design criteria as a guide. The pilot study found that visitors achieve significant gains in sustainability knowledge, as well as high levels of engagement, while learning with the game. Boys were observed to actively engage with Future Worlds for significantly longer durations than girls, and young children engaged with the exhibit for longer periods than did older children. These individual differences underscore the importance of future work investigating adaptive pedagogical functionalities, as can be provided by intelligent tutoring system techniques, as well as automated detectors for diagnosing learners' individual and group characteristics.

ACKNOWLEDGMENT

Chapter 12
Using Physics Inspired Wave Agents in a Virtual Environment:
Longitudinal Distance Control in Robots Platoon

ABSTRACT

The monitoring and the surveillance of industrial and agricultural sites have become first order tasks mainly for security or the safety reasons. The main issues of this activity is tied to the size of the sites and to their accessibility. Thus, it seems nowadays relevant to tackle with this problem with robots, which can detect potential issues with a low operational cost. To that purpose, in addition to individual patrolling behavior, robots need coordination schemes. The goal of this paper is to explore the possibility of using interference fringes and waves properties in a virtual environment to tackle with the longitudinal distance regulation in the platoon control issue. The proposed model, based on a multi-agent paradigm, is considering each vehicle as an agent wave generator in the virtual environment.

1. INTRODUCTION

The monitoring and the surveillance of industrial and agricultural sites have become first order tasks for several reasons such as the security or the safety. For agricultural sites, the monitoring can also be used to adapt the feeding in fertilizer and the prevention of the expansion of diseases. The main issues of this activity is tied to the size of the sites and to their accessibility. Thus, it seems nowadays relevant to tackle with this problem with robots (wheeled or aerial) which can detect potential issues with a low operational cost.

To that purpose, in addition to individual patrolling behavior, robots need coordination schemes and strategies for surrounding a target or for moving collectively as a platoon to one specific location. Among these coordination schemes, platoon control algorithms are mostly used especially when one want to coordinate vehicles. Platoon control has become a wide spread research area for collective robot control but also for autonomous vehicles. A platoon system can be defined as a set of vehicles that move together without any material coupling while maintaining a specific geometric configuration that can be a column, a line, a diagonal or any combination of these. A lot of research projects have been dealing with platoon control for robots moves synchronization or vehicles on highways (Path (\cite{shladover2007path}), SARTRE European project[1]), in urban areas (SafePlatoon[2]) or for freight transportation (FurBot[3]). The column configuration (robots one behind another) is the most spread in literature even if other spatial configurations can also be useful such as in military or agricultural contexts for harvesting for instance.

Basically, there are two main trends for performing platoon control depending on whether the localization reference frame is local (tied to the robot we want to control) or global (common to all the robots of the platoon). In the global approaches, the reference frame can be a shared predefined trajectory, or the trajectory of the leader of the formation sent directly to all its mates. This approach relies on specific methods and sensors aimed at precisely determining each robots position relatively to the global reference frame. Besides, in the case of a transmission of the trajectory of one specific robot in run time, each of them must have efficient and reliable wireless communication devices. The global point is the most spread in literature (Guillet, Lenain, Thuilot, & Martinet, 2014), (Bom, Thuilot, Marmoiton, & Martinet, 2005), (Avanzini, Thuilot, & Martinet, Manual convoying of automated urban vehicles relying on monocular vision, 2012), (Avanzini, Royer, Thuilot, & Derutin, 2013).

On the other side, the local approaches are based on a reference frame local to each robot of the platoon. Thus, each of them is only capable of following one of the robots perceived in its neighborhood, which is thus considered as its local leader. For instance, in a column configuration (i.e. vehicle forming a row), the local leader is generally taken as the preceding robot in the row. Among the papers found in literature based on this approach, one can cite: (El-Zaher, Gechter, Gruer, & Hajjar, 2011), (Scheuer, Simonin, & Charpillet, 2009), (Bouchaala, Marouf, Abualhoul, Pollard, Shagdar, & Nashashibi, 2013), (Abualhoul, Marouf, Shagdar, & Nashashibi, 2013), (Dafflon, Gechter, Gruer, & Koukam, 2013), and (Yazbeck, Scheuer, & Charpillet, 2014).

Each of these solutions is linked to interesting properties. The local approaches are tied to a "individual" standpoint of the platoon function. Generally, they are more simple to put into practice but provide less precise results especially for lateral distance. However, some solutions (El zaher, Gechter, Hajjar, & Gruer, 2016), based on a virtual link with dynamic properties, can compensate this problem. By contrast, due to their "system" point of view, global approaches have better results but requires to design algorithms according to the specific required devices aimed at feeding them in data such as precise differential GPS, communication protocols...

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Among the solutions that rely on the local point of view some of them are based on multi agent paradigm, (Dafflon, Vilca, Gechter, & Adouane, 2015). Multi-Agent Systems (MAS) have become a widespread solution to tackle different kinds of issues in various application fields such as pedestrian simulation (Teknomo, 2006), robot control (Posadas, Poza, Simó, Benet, & Blanes, 2008), complex system description (Bonabeau, 2002), battery management systems... Among the two main trends in multi-agent approaches (cognitive *vs.* reactive), the reactive one is particularly interesting for applications that require both fast response time, adaptability and robustness (Nolfi, 2002). Reactive Multi-Agent Systems (RMAS) rely on simple interaction schemes between entities that can be inspired whether by Biology or Physics. Even if the biological approaches are the most represented in the literature (Leitão, Barbosa, & Trentesaux, 2012), (Biswas, Mishra, Tiwari, & Misra, 2013) the physical ones also allow to obtain good properties especially when they are applied to Cyber-Physical Systems (CPS) control and/or modeling (Sanislav & Miclea, 2012). Most of the models used are inspired by particles which interact through forces (conservative or not) and/or potential fields (Hagelbäck & Johansson, 2008). Few of them are dealing with waves propagation and their associated interaction pattern, known as interference fringes. The goal of this paper is to explore the possibility of using interference fringes and waves properties within a multi-agent standpoint so as to tackle with the issue of platoon longitudinal distance control. This issue has been already explored by different strategies including particle agents approaches or standard PID controller (Hallé, Chaib-draa, & Laumonier, 2003) but has never been studied using waves interaction. This paper is an extension of the paper published in the international conference on tools with artificial intelligence in 2016 (Dafflon et al. (2016)).

The paper is structured as follows: Section 2 presents a review of existing multi-agent approaches. Section 3 exposes the core of our contribution by describing the wave agent framework. Finally, simulations results, in the case study of platoon control, (Section 4) highlight the ability of the approach to cope with such complex problems. Then, in the conclusion, we provide some future development of the proposed framework.

2. RELATIVE WORK

2.1. From Distributed Artificial Intelligence to Multi-Agent Systems

The distributed artificial intelligence can have several forms. Basically, two main trends can be encountered. First, one can see distributed artificial intelligence as a collective behavior that stem from interaction between intelligent entities. These models, which comprise cognitive agents' models, are based on symbolic and explicit knowledge representation. These are then able to exhibit high-level capabilities such as deliberation, consensus or elections (Castelfranchi, Dignum, Jonker, & Treur, 1999). The second trends is relying on the fact that the intelligence is a collective property that emerges from numerous interactions between entities that are not necessary having intelligent individual behaviors. This last kind of models is based on stimulus/reaction behaviors tied to environment representation (Hagelbäck & Johansson, 2008).

In this paper, only the second type of models is considered since the environment is at the center of the problem. In this context, platoon system could be modeled as a classical attraction/repulsion problem between agents each representing a robot as in (El-Zaher, Dafflon, & Gechter, 2015).

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

MAS emergent properties are one of the main expected features by multi-agent designers. In (Drogoul, Vanbergue, & Meurisse, 2002), the authors provide a definition of emergence focused on the requirements needed to generate an emerging phenomenon in a dynamic system. In this type of system, emergence refers to the apparition of a phenomenon (the process, steady state or invariant) perceived by global entities, and monitored by an observer or by entities themselves. The aim of Multi-Agent System design is to achieve global objectives through local agent's behavior specifications. Then, its evolution directly depends on the environment modeling choices. Emergent behaviors can be exploited in the same way as convergence properties of classical systems. The study of emergent properties has to cope with some classical issues such as: stability, convergence, and robustness. Moreover, due the generally huge number of agents, the computational cost can be important especially when one need to deal with a high number of high-level agent perceptions. One of the possible solutions to overcome this issue is to use the environment as an active entity, thus not limiting its definition to a place where agents are living, and then giving the environment an active role for the global system behavior (Simonin & Gechter, 2005). For this reason, using waves to propagate information through the environment can be an interesting way to reduce the perception computational cost issues.

Others critical points are linked to the control of the system entities and to the characterization of emergent phenomena (Serugendo Di Marzo, Gleizes, & Karageorgos, 2005). Generally, emergent properties are observed or measured by an external entity. This observation can then be used to design control laws or can be interpreted as a solution to the targeted problem. The main challenge is to characterize the emergent property as a stable global feature of the system, whereas it stems from numerous dynamical interactions. In this context, we argue that waves can overcome this apparent contradiction by providing emergent global properties (interference fringes) arising from waves dynamical propagation. Thus, in opposition to classical MAS approaches based on a bottom-up modeling (*i.e.* from agents' behavior to system properties) we propose to minimize the non-deterministic aspects of multi-agent systems by transferring a part of the interactions in the environment model and dynamics using waves.

2.2. Biological and Physics Inspired Interaction Models

In literature, we can find two main trends for interaction models. The most commonly used is the biological inspiration which tends to reproduce behaviors and interaction that are existing in nature and for which we already know the expected global results. The inspiration sources are numerous for algorithms inspired by social insects (ants, termites, bees, spiders... (Hoolimath, Kiran, & Reddy, 2012), (Zhai, Xu, & Yang, 2015), (Chandran, Reddy, & Janet, 2016) to the use of bigger animals' behaviors inspired by wolfs or birds for instance. The second type of inspiration source is based on Physics. In this case, agents are generally considered as particles that can generate forces on other particles or are moving according to force fields. This kind of interaction can be expressed through forces and can be modeled by gravitation laws (\cite{Sampaio10}), spring and damper forces or Coulomb's laws (Gechter, Beresford, & Rice, Reconstruction of Battery Level Curves Based on User Data Collected from a Smartphone, 2016).

This "particles" point of view is nearly the only one used especially due to the situated properties of agents. This point of view has been used widely in many application fields such as robots foraging or patrolling strategies (Sampaio, Ramalho, & Tedesco, 2010), vehicle driving assistance (Gechter, Contet, Gruer, & Koukam, 2010), platoon control (El-Zaher, Dafflon, & Gechter, 2015) or optimization algorithms such as Particle Swarm Optimization (PSO).

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

From a computer execution standpoint, particle agent simulations are made through a scheduler. At each loop, this scheduler computes for each particle agent, the forces that are applied to it. These are collected depending on the perception properties of the considered agent. Once the forces are collected, they are applied to the agent using the second law of motion. Then, through two discrete integrations, the speed and the position of the agent can be determined.

In some ways, the particle inspired agent systems are similar to other particle based methods. The main difference is tied to the fact that each particle agent decides which force has got an influence on it. In classical particle systems, each force is applied to each particle without any estimation of the perception capabilities. This can be seen as a disruption of the interaction symmetry which allows the system to be generally more stable (Fass & Gechter, 2015).

3. WAVE AGENTS IN A VIRTUAL ENVIRONMENT

In this paper is introduced a first model of a multi-agent system where interaction relies on the superposition of waves. This model, called WAVE (Wave Agents in a Virtual Environment) can be considered as a generic approach developed to tackle non-linear decision-making problems. The originality of the approach relies on the use of concepts from wave mechanics to generate emergent stable behaviors. The role of the environment is the cornerstone of the model since it supports agents' interactions that are modelled through waves propagation. WAVE agents are mobile virtual entities, situated in this waves-built environment. They are able to generate and to perceive waves which dynamically modify the environment.

3.1. Objectives and Overview

The main goal of the presented work is to ensure a system high-level stability using low-level interactions based on the reactive multi-agent system paradigm. As described in Section 2, emergent properties of the multi-agent system are somehow difficult to predict or control. However, they offer the ability to model or to generate complex behaviors at the system scale. To enhance the stability of the system, the wave agent model proposes to use an a priori unstable phenomenon (waves propagation) and to exploit emergent stable patterns (interference fringes). To deal with these new kind of interactions, the agents evolve on an adapted environment model. According to these high-level needs, the proposed general framework can be described as the representation given in Figure 1. So as to apply the proposed framework, the first step is to extract the key features of the problem. This step can be done using knowledge on the system's targeted goal. Then the problem can be modeled using WAVE as a physics-inspired MAS environment using waves, distortions and classical Newtons laws. Two types of agents are then defined: The Surfers and the Emitters.

Surfer agents, that can be considered as elementary particles, evolve freely following the waves produced by the Emitter agents, the characteristics of which are tied to the problem. The final decision-making process relies on a dynamic and statistical evaluation of the agent's population.

Figure 2 shows the waves generated by two vehicles (preceding vehicle represented by a vehicle shape and follower vehicle represented by a big dot) and the surfer agents (light color small dots).

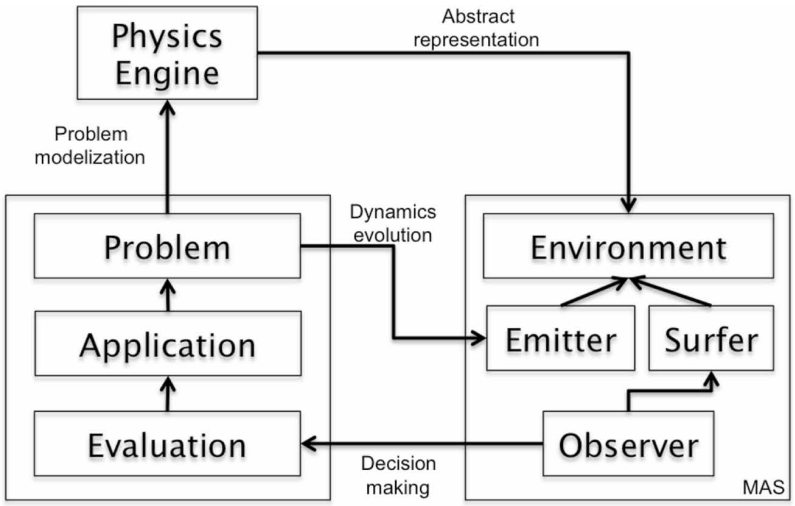
Figure 1. Global overview



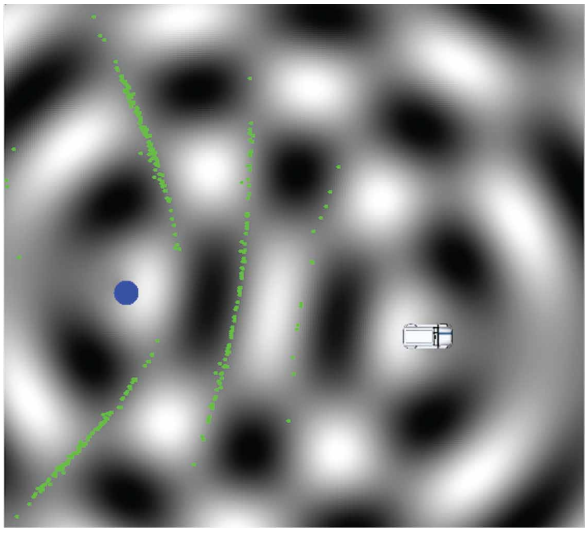


Figure 2. Car waves generated by two vehicles (big dot and vehicle shape) and Surfer agents (light dots)

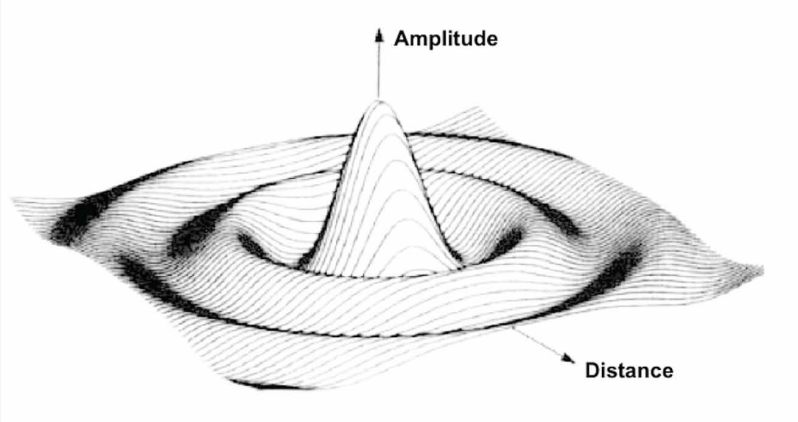


3.2. The Virtual WAVE Environment

The Wave agent framework relies on virtual environment in which situated mobile agents are evolving. The environment is modelled as a continuous 2-dimensional surface described in a 3-D space (Figure 3), the third dimension corresponding to the amplitude of the wave.

The purpose of the WAVE environment is to support, model and propagate waves emitted by agents and related to the problem one want to tackle with. In this work, we consider that the environment is homogeneous and isotropic (i.e. its properties are the same independently from the source position and from the direction of the wave propagation). This implies that waves velocity is fixed and constant, thus allowing the use of a traditional propagation model such as:

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

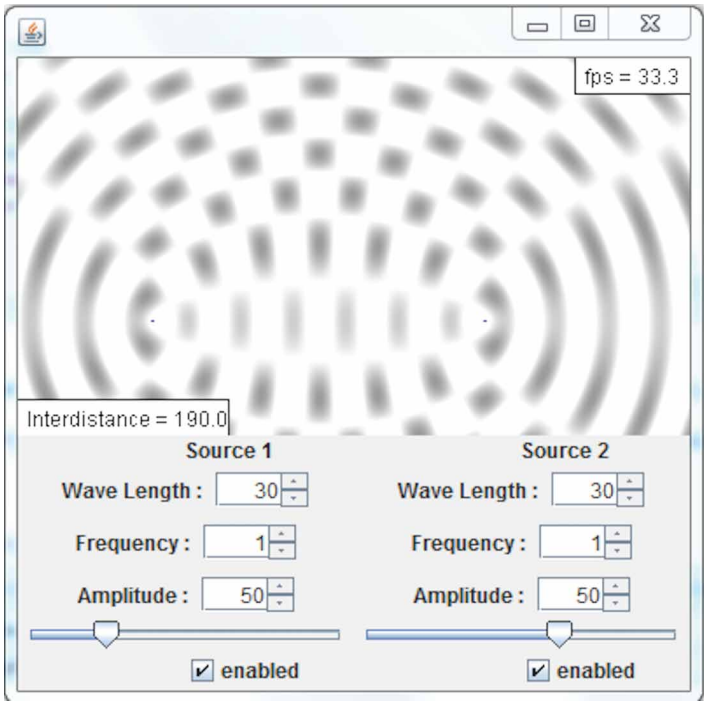
Figure 3. The WAVE environment

$$s(t) = A\cos(\omega t + \varphi)$$

where $s(t)$ denotes the amplitude at time t for given position; the maximum amplitude of the emitting source is denoted as A; ω is the source frequency and φ corresponds to the phase difference (set to zero since the synchronization is ensured by the modeled environment). The instantaneous wave amplitudes is computed by the environment for the local neighborhood of all agents, using the wave propagation model. The model basically computes the sum of the amplitudes at a given position when several wave sources are emitting at the same time. This requires a low computational cost and is able to dynamically combine a high number of influences from several source agents. Hence, the final goal is to seek, identify and exploit perceived global stable patterns.

3.3. Agent Roles

Through the observation of the resulting amplitude of the WAVE environment in their frustum, the agents are identifying and are following the stable patterns generated by their neighbors. We define two agent roles that are combined to generate a collective emergent stable behavior, observable at the system global level. Due to the generic framework of WAVE, the system can be adapted to different problems during the implementation. Thus, the agent roles introduced in this section can be extended, according to the considered problem. The proposed behaviors, called “emitter” and “surfer”, respectively describe the process of a wave source and of a simple entity reacting to perceived waves.



3.3.1. Emitters

Emitter agents are basically wave sources. They generate waves, according to their intrinsic parameters, that are propagated through the WAVE environment. The purpose of the environment is to combine several waves, which can lead to the apparition of an interference fringe pattern, as plotted in Figure 4.

The goal of each emitter agent is to model one of the several goals of the system, depending on the problem addressed. Choosing identical parameters for distinct emitter agents is not mandatory but it contributes to the generation of stable patterns. Otherwise, the fringes generated in the environment

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 4. Screen-shot of the experimental prototype of WAVE featuring the wave propagation model and using two emitter agents (black dots). The selected wave sources parameters generate distinct patterns called interference fringes.

could not remain static (the pattern still occurs but it can move into the environment). We do not consider such a case in this work, although this setting could be exploited to tackle problems where a system has to choose between several goals that are not equivalent. In section 4, we present simulations where two emitter agents are used with the same emission parameters to model a leader and a follower vehicle in a column platoon configuration.

3.3.2. Surfers

A population of moving entities called surfer agents is generated by the WAVE model. The goal of each individual is to reach a stable position in the interference fringes pattern. The key underlying idea is to use a combination of simple reactive agents to observe, as an evaluation, the collective behavior/pattern at the system global scale. The resulting behavior of a surfer agent is a composition of three basic behaviors:

- **Surf:** Surfer agents are attracted by low wave amplitudes (near to 0);
- **Separate:** Surfer agents tend to flee each other, enabling an increase of spatial spreading;
- **Source Attraction:** Agents are trying to stay as close as possible of a given source.

Each behavior is modeled using simple attraction-repulsion equations, based on gravitational laws in $1/(\text{distance}^2)$, involving a mass (set at the same value for all surfer agents). The combination of interactions is performed in the decision process of each surfer agent by applying proportional coefficients to each

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

behavior output. These coefficients are aimed at managing the importance of each behavior relatively to the others. Some behavioral control can also be done by modifying the mass affected to the agents (for both surfers and emitters).

3.4. Decision Making

The decision-making system in WAVE relies on the resulting position of the population of surfer agents. Emitter agents represent the goal of the system while the surfers are using the patterns generated by the emitted waves combination. The decision making relies on an evaluation at the system scale of the positions of the surfer agents relatively to the system goal. Hence, we chose to use the vector which starts from the emitter position and reaches the barycenter (i.e. the weighted average position of agents) of the surfers' positions. This vector can be directly used as an influence vector for the system or can be aggregated (for instance taking into account the distance or the direction only). Thus, the computation of the decision is expected to be robust since it relies on the individual behavior of all the WAVE agents. Next section is dealing with simulation results.

4. SIMULATION RESULTS

In the following simulation experiment, we use the decision-making process of WAVE to provide a longitudinal regulation command to an unmanned vehicle following a leader trajectory. This command must ensure the string stability in a column platoon configuration.

4.1. MAS Platform

Instantiating a multi-agent model requires a platform that aggregates agents, computes interactions and applies influences. To achieve this goal, a tinyMas plug-in was developed using distributed objects and implemented in Java language. tinyMas is a multi-agent platform specifically designed to deal with the implementation and the deployment of continuous environment, reactive agents and holonic multi-agent systems (Fischer, Schillo, & Siekmann, 2003).

It is based on an organizational approach and provides key features such as the support of the concepts of role and organization as first-class entities. This consideration has a significant impact on the agents implementation since it allows them to easily and dynamically change or adapt their behavior and thus contributes to fill the gap between conception and implementation phases in this domain.

4.2. Implementation

As previously said, the first stage of the implementation of the WAVE environment is to extract the main characteristics of the problem. In the case study of platoon control, the goal is to provide a stable longitudinal command to a vehicle which follows a leading vehicle. The leader vehicle is freely controlled by a human driver and the follower is driven by an embedded automated system. The goal of the decision making using WAVE is to compute a command vector for the follower vehicle. Thus, we model the positions of both vehicles in the agent virtual environment as emitter agents and we generate a population

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

of surfer agents executing their behavior, using the follower vehicle as their target for source attraction behavior. The physical behavior of the vehicle then results from a physics-based model which rules the final motion of the vehicle in the real (or simulation) world.

4.2.1. Emitter: Vehicles Model

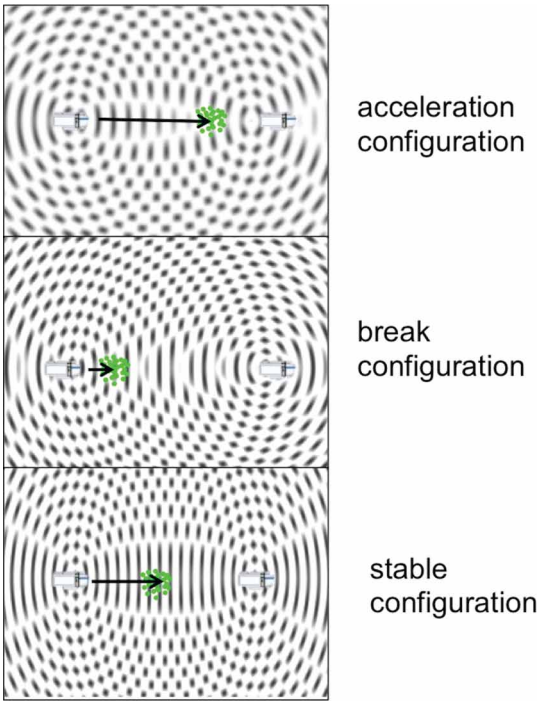
The emitter agent location is determined by the leader position perceived by the follower sensors. Vehicles used in the simulation represent (graphically and physically) the real experimental vehicles of the laboratory. They are equipped with two 270-degree virtual laser range finders, a replica of LMS SICK 200 sensor and with a simulated GPS-RTK receivers required to follow and study trajectories and to estimate the precision of the platoon function. Simulations are performed on a 3-D geo-localized model of a part of the city of Belfort (France).

4.2.2. Surfer Agent for Platoon

Surfer agents for platoon haven't neither a real representation nor a matching with anything in the real-world problem. They are devoted to decision-making and are based on the generic surfer agent definition given previously. These agents have only one simple behavior, they are attracted by the leader, considered as an emitter, in the virtual environment. Agents motion is determined by gravitational-inspired laws. The environment dynamic topography is updated by waves emission and propagations. Surfing toward the waves hollow, surfer agents are collectively describing a balance point that corresponds to the desired system control.

4.3. Simulation

4.3.1. Scenario



This work is a preliminary step toward a complete platoon application. As a proof of concept, we start the experimentation with the design of a simple scenario. The WAVE environment is used to provide a longitudinal platoon regulation command. To validate the approach, we design a simulation where a leading vehicle and a follower are stopped and aligned on the same lane. The leader starts and quickly reach a speed of 30 km/h, remains at this speed during 2 minutes and then stops. The follower is expected to follow the leader with a very stable inter-distance while the vehicles speeds are the same. Figure 5 depicts a view of the environment where the leader and follower vehicles are modeled as wave sources (i.e. emitters with the same parameters: amplitude = 50, wavelength = 100 and frequency = 3). The surfer's agents are attracted by the source, towards the leader position and generates the longitudinal control.

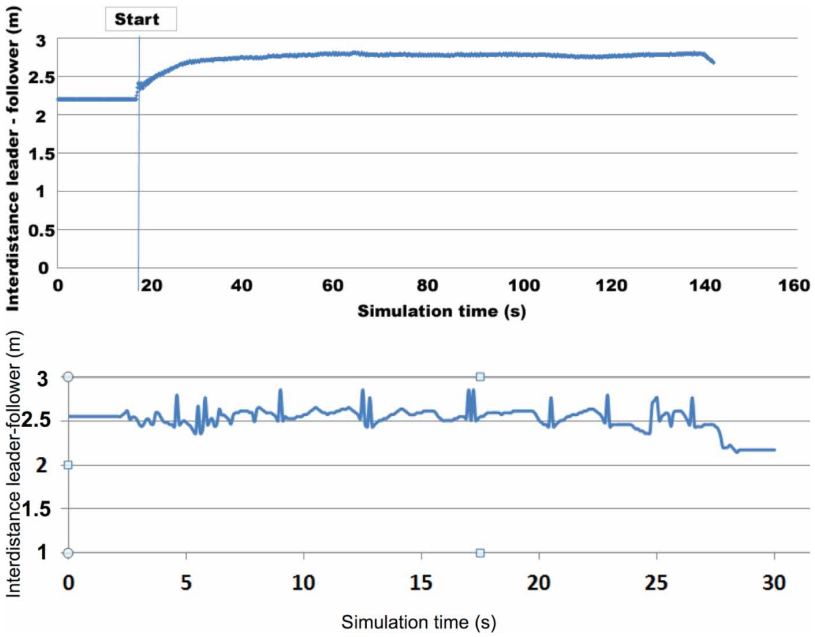
4.3.2. Result

The behavior resulting from WAVE interaction is the longitudinal behavior of the following vehicle. In order to assess the effect of the model on the stability of the generated behavior, one can observe the inter-distance evolution during the designed scenario (Figure 6 (a)). This figure is presenting both the result obtained with the WAVE framework and results obtained with a classical platoon control local method based on a virtual link made of 2 springs (Figure 6 (b)). This classical method has been studied

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 5. Screen-shot of the environment view. The green dots are the Surfer agents, moving along the interference fringe generated from the addition of the waves emitted by the leader vehicle (white) and the follower (blue). The wave amplitude is represented by a gray-scale (from 0 – white – to 100 – black).

in (El-zaher, Contet, Gechter, and Koukam (2012)) and shows good results especially in the respect of the target longitudinal distance. Using the WAVE framework, the inter-distance, initially set to 2.2 m, is increasing after the start of the leader, then it remains very stable (around 2.7 m) during the cruise period, and finally drops to 2.6 m. While the leader and the follower are driven at full speed, the inter-distance remains quite stable. As opposed to these results, while using the 2-spring method, the inter-distance, initially set to 2.5 m, is better respected but the trajectory is presenting more oscillations around this target position. These oscillations are tied to the 2-spring based model used which is not using a damper as we can sometimes find in other virtual-link based models. We consider the mean error, for the 2-spring model, it is close to zero whereas the WAVE approach is presenting an offset of 0.5 m.



By contrast, the WAVE approach is showing few oscillation making the platoon more comfortable for the passengers. Even if these results are confirming the potential of the use of the pattern generated in the virtual WAVE environment, some improvement are required so as to obtain a good platoon control algorithm comparable to those.

5. CONCLUSION AND FUTURE WORK

Platoon control algorithms are widespread in literature. This platoon function can be considered as a first step towards high automated vehicles that are behaving together as a transportation system. The main issue of the platoon function is tied to the quality of the longitudinal control in terms of respect of the

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 6. Inter-distance between leading and following vehicles in a platoon configuration driven in straight line where the longitudinal control is regulated by a WAVE environment with a target longitudinal distance of 2.2 m (a) compared to the result obtained with a longitudinal regulation made with an interaction model based on 2 springs with a target longitudinal distance of 2.5 m (b)

target distance and in stability. The goal of this paper was to present an alternative to the classical local approaches, which are based whether on regulation loops or on virtual physical links, taking inspiration from wave mechanics. In this model, vehicles are generating waves in a virtual environment that together produce emergent pattern as interference fringes. A first implementation in the WAVE environment for platoon control highlights the potential of the use of physics-based individual agent behavior to generate a complex and stable decision making. As compared to other local approaches based on physics inspired interaction function using for instance virtual springs, the wave approach is providing more stability (i.e. less oscillations) but a less precise respect of the target longitudinal distance. Moreover, as a first step, the experimentation framework has been kept simple and shows some limitation of the model such as the difficulty to provide a matching between agents' environment and real world parameters.

In future work, we plan to integrate more high-level characteristics of the waves patterns as a new source of interaction for the agent. Thus, we can expect to extend the decision taken by the WAVE environment to the lateral distance control this being not dealt yet in the model. We also plan to apply this model to other examples to build up a more generic definition.

Chapter 13
A Geometric Dynamic Temporal Reasoning Method with Tags for Cognitive Systems

ABSTRACT

Temporal reasoning is one of the cognitive capabilities humans involve in communicating with others and everything appears related because of temporal reference. Therefore, in this paper a geometric dynamic temporal reasoning algorithm is proposed to solve the temporal reasoning problem, especially in autonomous planning and scheduling. This method is based on the representation of actions in a two dimensional coordination system. The main advantage of this method over others is that it uses tags to mark new constraints added into the constraint network, which leads the algorithm to deal with pending constraints rather than all constraints. This characteristic makes the algorithm suitable for temporal reasoning, where variables and constraints are always added dynamically. This algorithm can be used not only in intelligent planning, but also computational intelligence, real-time systems, and etc. The results show the efficiency of our algorithm from four cases simulating the planning and scheduling process.

1. INTRODUCTION

The notion of time is obvious in any activity that requires intelligence (Pani & Bhattacharjee, 2001; Wang, 2014). The temporal reasoning is one of the cognitive capabilities humans involve in communicating with others (Stock, 1998). Everything appears related because of temporal reference (Pani & Bhattacharjee,

2001). Therefore, cognitive models or intelligent systems have to be developed to mode this capability of representing time and reasoning about temporal relationship (Stracuzzi, Li, Cleveland, & Langley, 2009; Wang & Patel, 2009). Certainly, it is also important many possible application of computer-based systems, for instance planning actions in the real world which is one of high cognitive abilities, scheduling within a complex system (Cervantes, Rodríguez, López, Ramos, & Robles, 2013; Stock, 1998).

This paper takes the application of temporal representation and reasoning in autonomous planning and scheduling as an example to specify our work, because concepts about time are very important when people are talking about actions or events. In real world, actions are not instantaneous but have start times, end times and durations. An important challenge in current planning and scheduling research is time dimension management to allow for the simultaneous execution of non-instantaneous actions (M. C. Cooper, Maris, & Régnier, 2013). The sequential nature of classical plans is often too restrictive to cope with a temporal plan that consists of a set of instances of durative actions (M. Cooper, Maris, & Régnier, 2014). Therefore, time and temporal constraints must be considered in planning and scheduling methods.

Plan-space planning is well suited to temporal planning problems (Cushing, 2012). In plan-space planning, temporal reasoning is needed to check whether a simple temporal problem (STP) instance is consistent once a flaw and conflict is solved (Barták, Morris, & Venable, 2014). It means the temporal reasoning algorithm is called for many times. So improving the efficiency of temporal reasoning in dynamic environment can make the performance of the planning and scheduling method better. Therefore, the authors are interested in dynamic reasoning, namely whenever a new constraint or variable is asserted, this paper wants to maintain a solution of the STP rather than recomputing it using a "static" algorithm (Gerevini, 2005). The static algorithm, such as the Floyd-Warshall algorithm (Aini & Salehipour, 2012), leads to computation cost, because when the value of local variables changes or a variable/constraint is added to an STN, the whole network needs to be propagated again (Xu, 2004).

The most commonly used method is based on a simple temporal network (STN) and there is a list of algorithms. Xu et al. (2004) has proposed a dynamic algorithm which only computes the partial network influenced by the new introduced constraint rather than the whole network with the worst time complexity of the algorithm. Mouhoub and Yip (2002) presented a comparative study of dynamic arc-consistent algorithms in the case of temporal constraint problems and shown the efficiency of AC-3.1|DC algorithm. Planken et al. (2010) presented a brief survey of existing incremental algorithms and proposed a new algorithm that incrementally enforces partial path consistency. Gerevini (2005) proposed a collection of new polynomial algorithms to incrementally decide satisfiability, to maintain a solution, or to update the minimal representation of the CSP. This approach based on STN also has been used in several planning and scheduling systems in order to solve real-world problems, such as the Heuristic Scheduling Testbed System of Deep Space 1 (Muscettola, 1994), the EUROPA system (Barreiro et al., 2012; Bresina, 2015; Iwig et al., 2015), IxTeT (Lemai, 2004) and VHPOP (Younes & Simmons, 2003).

The authors aim to propose an efficient dynamic temporal reasoning algorithm to determine the consistency of the STP and to eliminate possible values to variables in planning and scheduling problems. In order to verify the efficiency of our algorithm, the authors compare it with the temporal reasoning algorithm in EUROPA. It provides incremental algorithms e. g. adaptive Bellman-Ford algorithm to detect a negative cycle which is sufficient for backtrack-free search (Chandrachoodan, Bhattacharyya, & Liu, 2001). On the one hand, the authors want to solve planning and scheduling problems in the future, so it is more suitable and convenient to select a reasoning algorithm having used in planning and scheduling system. On the other hand, the algorithm in EUROPA is actually efficient in temporal reasoning.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Durative actions are 2-dimensional (2-D) in nature, making their 1-dimensional (1-D) representation ambiguous (Rit, 1986). Therefore, in order to solve problems above and take advantage of the 2-D nature, this paper introduces a geometric method to represent durative actions based on our prior work (Li, Xu, Cui, Xu, & He, 2016) and proposes a dynamic algorithm using tags on constraints to propagate temporal constraints.

This paper is organized as follows. First, the authors introduce related work to help readers understand our method, including defining the planning and scheduling problems and the basic representation of actions in the 2-D space. Then, details of the geometry-based dynamic temporal constraint reasoning algorithm are described. In the fourth section, the authors present experiments to verify the performance of our method compared with that of the algorithm in the EUROPA system.

2. RELATED WORK

2.1. Problem Statement

Planning and scheduling techniques have been improved thanks to the application of constraint satisfaction models and tools (Barták, Salido, & Rossi, 2010). In order to apply the efficient constraint satisfaction techniques to planning and scheduling, our problems can be described as constraint satisfaction problems (CSPs) (Tsang, 2014).

Definition 1: A planning and scheduling problem $P=<P,O,C,s_0,g>$ consists of:

- A set of variables $V=\{v_1,v_2,\ldots,v_m\}$, and $v\in D_v$, where D_v is the variable range;
- A set of actions $O=\{o_1,o_2,\ldots,o_n\}$ where an action o has a start time s, an end time e, and a duration d; in other words, $o=\{d,s,e\}$;
- A set of constraints C, namely temporal constraints between two actions, such as $C(o_x,o_y)$ = "o_x *Cons* o_y";
- An initial state s_0;
- A goal state g.

A solution to a planning and scheduling problem P is the result of scheduling all actions to satisfy all constraints, in which each action is assigned an execution time. Therefore, the representation of actions and temporal constraints between them and then the propagation of the temporal constraints are essential tasks for solving a P.

2.2. Geometric Representation

The representation of actions and temporal constraints is the basis of temporal reasoning. Because actions are 2-dimensional (2-D) in nature, making their 1-dimensional (1-D) representation ambiguous (Rit, 1986), this paper takes advantage of geometric representation of durative actions in a 2-D coordinate system to represent actions and temporal constraints.

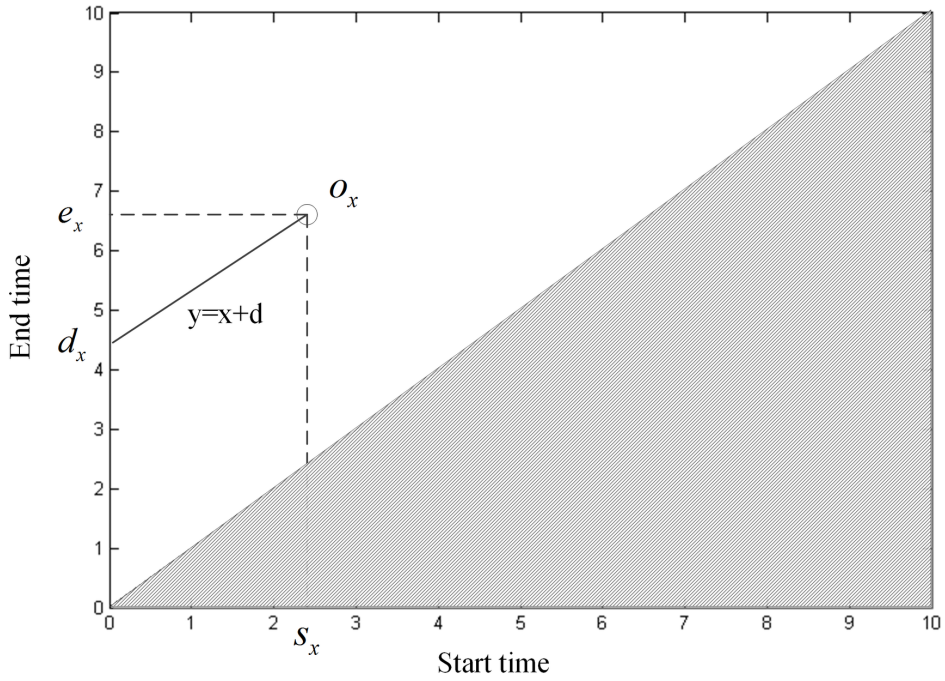
Rit (Rit, 1986) proposed a graphical representation of constrained set of possible occurrences first. He also described a constraint propagation algorithm which is a Waltz-type filtering algorithm. Pujari, Kumari and Sattar later discussed this type of representation (Rit, 1986), while other works have only

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

briefly mentioned it (Aigner & Miksch, 2006; Duftschmid, Miksch, & Gall, 2002). Recently, Ullberg used this method to represent and propagate several simple quantitative constraints to solve the context recognition problem (Ullberg & Pecora, 2012).

2.2.1. Representation of Actions

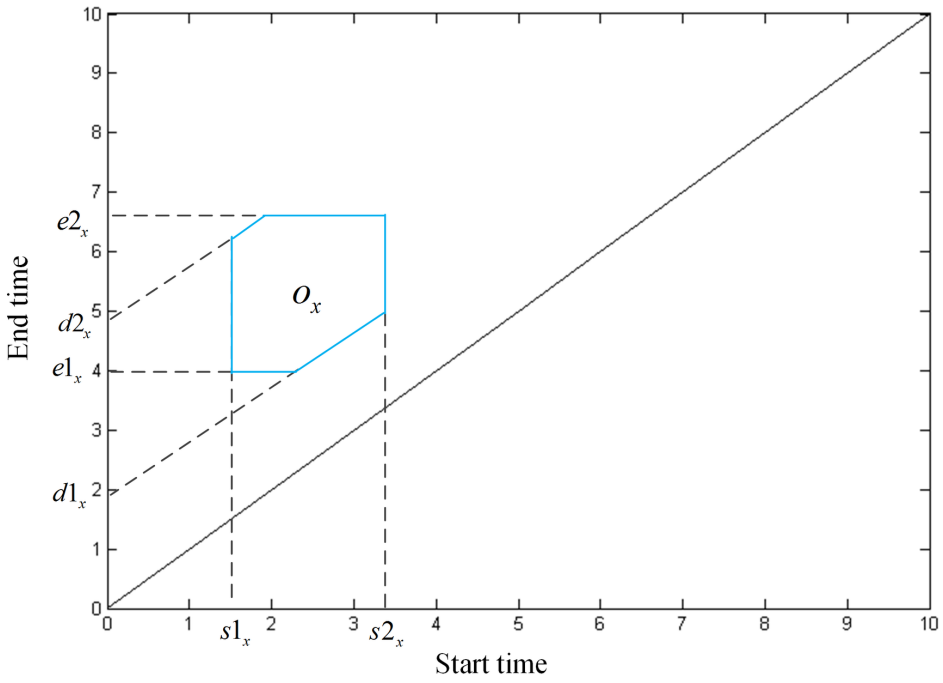
The most straightforward way of representing durative actions would be to interpret an action as a single point in a 2-D graph as in Figure 1. The x-axis defines the action's start-time and the y-axis defines the end-time. An action is not permitted to end before it has started, so no point is in the shadow region.



In the planning and scheduling process, actions usually have flexible range for their start time, end time and duration to deal with uncertainty in execution. Figure 2 shows the representation of an action $o_x = \{s_x, e_x, d_x\}$ with flexible domain $s_x \in [s1_x, s2_x]$, $e_x \in [e1_x, e2_x]$ and $d_x \in [d1_x, d2_x]$. If there is a relative zero point, then $s2_x \geq s1_x \geq 0$. Similarly, $e2_x \geq e1_x \geq 0$ and $d2_x \geq d1_x \geq 0$. The bounds of domain are represented using lines in the 2-D system.

Compared with the simple temporal network (STN) representation method, the geometric method takes an action as a whole while the STN method has to use two points to represent one action. This may reduce time to propagate constraints between two actions.

2.2.2. Representation of Constraints



Constraints between actions consist of qualitative and quantitative constraints. This paper focuses on quantitative constraints. Assume there are two actions o_x and o_y which belong to the set of actions $O = \{o_1, o_2, \ldots, o_n\}$, and $o_x = \{d_x, s_x, e_x\}$, $o_y = \{d_y, s_y, e_y\}$. The constraint between o_x and o_y is represented by $C(o_x o_y)$

Figure 1. Representation of an action in the 2-D system

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. Representation of an action o_x with flexible domain

= "o_x *Cons* o_y". *Cons* has four elements including [*ss*1,*ss*2], [*se*1,*se*2], [*es*1,*es*2] and [*ee*1,*ee*2]. [*ss*1,*ss*2] means that the action o_x starts from *ss*1 to *ss*2 earlier than o_y starts. [*se*1,*se*2] means that the action o_x starts from *se*1 to *se*2 earlier than o_y ends. [*es*1,*es*2] means that the action o_x ends from *es*1 to *es*2 earlier than o_y starts. [*ee*1,*ee*2] means that the action o_x ends from *ee*1 to *ee*2 earlier than o_y ends. According to the domain of action o_x and constraints, the domain of o_y can be got. As an example, Figure 3 shows the domain of o_y according to constraints [*se*1,*se*2] and [*es*1,*es*2], respectively.

3. GEOMETRIC DYNAMIC TEMPORAL REASONING ALGORITHM

During planning and scheduling, the deletion and addition of actions or constraints will lead to the dynamic changes of the constraint network. Recomputation every time may cause massive cost computation. Therefore, in this section, a geometry-based dynamic reasoning algorithm (GD) is proposed to check the consistency of the network and give the minimal range of the start time and end time of all actions as well, shown in Figure 4.

The inputs of the GD algorithm include the set of actions O, the set of action pairs R, the set of constraints C and the set of tags *Tags*. O and C are defined in the section 2. There is a one-to-one correspondence between R and C, i. e. R contains all action pairs ($o_x o_y$) that have constraints contained in C such as $C(o_x o_y)$ = "o_x *Cons* o_y". Tags are the key role in dynamic propagation. Every action pair has a tag contained in *Tags*. The domain of a tag is (0, 1). If *Tags*(i)=1, it indicates that the action pair $R(i)$ needs processing. If *Tags*(i)=0, it is unnecessary to process $R(i)$ because neither of actions in $R(i)$ changes. At the beginning, all values of *Tags* are initialized to 1.

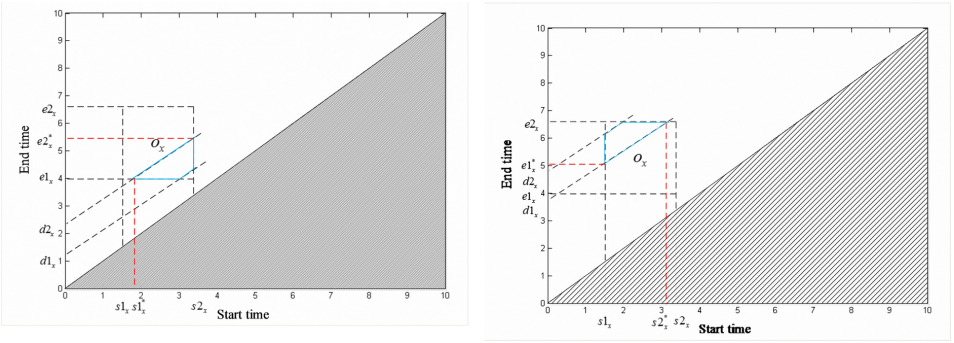
3.1. Evaluating Domain of Actions

At first, the algorithm checks weather all actions exist using function *Evaluate Action*(o_i), where $o_i \in O$. For the simplify of specification, this paper uses graphical method to describe steps in *Evaluate Action*(o_i). Here, assume there are two actions o_x and o_y, and $o_x=\{d_x,s_x,e_x\}$, $o_y=\{d_y,s_y,e_y\}$. In Figure 2, the final region in blue is equal to the initial domain of action o_x. If:

$$[y1_x - s2_x, y2_x - s1_x] \cap [d1_x, d2_x] = \varnothing$$

The action o_x does not exist and the constraint network is not consistent.

Shown in Figure 5(a), if the line $y=x+d2_x$ intersects with the line $y=e1_x$ between $x=s1_x$ and $x=s2_x$, the domain of s_x is changed into $s_x \in [s1_x^*, s2_x]$; if the line $y=x+d2_x$ intersects with the line $x=s2_x$ between $y=e1_x$ and $y=e2_x$, the domain of e_x is changed into $e_x \in [e1_x, e2_x^*]$. Similarly, the line $y=x+d1_x$ can also change the domain of s_x and e_x as shown in Figure 5(b).



In a conclusion, points of intersection of the six lines $x=s1_x$, $x=s2_x$, $y=e1_x$, $y=e2_x$, $y=x+d2_x$ and $y=x+d1_x$ determine the final domain of action o_x.

3.2. Propagation of Constraints

This section is based on the authors' prior work (Duftschmid et al., 2002) and it gives details of propagation of constraints between actions using the function *Propagate*(o_x,o_y,$C(i)$). Here, this paper only uses the conclusion and gives the brief introduction.

Constraints $C(o_x,o_y)$ between two actions $o_x=\{s_x,e_x,d_x\}$ and $o_y=\{s_y,e_y,d_y\}$ are called a constraint pair. A constraint pair includes four elements, i. e. the constraint [$ss1$,$ss2$] placed by the start time of o_x on the start time of o_y, the constraint [$se1$,$se2$] placed by the start time of o_x on the end time of o_y, the constraint [$es1$,$es2$] placed by the end time of o_x on the start time of o_y and the constraint {$ee1$,$ee2$] placed by the end time of o_x on the end time of o_y. Here, the paper gives the method of using the domain of o_x and constraint pair $C(o_x,o_y)$ to calculate all possible values of action o_y directly. This paper will refer to this set as $D^*(o_y)$ and use it to geometrically intersect the previous domain of o_y so as to remove inconsistent values.

Figure 5. Diagram of the influence of domain of d_x on domain of s_x and e_x

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

The possible domain of the start time of o_y is shown in (1):

$$D^*(s_y) = [s1_x + ss1,\ s2_x + ss2] \cap [e1_x + es1, e2_x + es2]$$

The possible domain of the end time of o_y is shown in (2):

$$D^*(e_y) = [s1_x + se1, s2_x + se2] \cap [e1_x + ee1, e2_x + ee2]$$

Calculation of the possible domain of the duration of o_y is a little complex as follows:

$$D^*(d_y) = d1 \cap d2 \cap d3 \cap d4$$

$d1$, $d2$, $d3$ and $d4$ can be obtained by:

$$\begin{cases} d1 = [se1 - ss2,\ se2 - ss1] \\ d2 = [ee1 - es2, ee2 - es1] \\ d3 = [d31, d32] \\ d4 = [d41,\ d42] \end{cases}$$

where:

$$d31 = \min(d1_x - ss1 + ee1, d1_x - ss1 + ee2,\ d1_x - ss2 + ee1, d1_x - ss2 + ee2)$$

$$d32 = \max(d2_x - ss1 + ee1, d2_x - ss1 + ee2,\ d2_x - ss2 + ee1, d2_x - ss2 + ee2)$$

$$d41 = \min(-d1_x - es1 + se1, -d1_x - es1 + se2,\ -d1_x - es2 + se1, -d1_x - es2 + se2)$$

$$d42 = \max(-d2_x - es1 + se1, -d2_x - es1 + se2,\ -d2_x - es2 + se1, -d2_x - es2 + se2)$$

The final step of propagating one constraint pair is removing redundant values of o_y using (5):

$$D^{new}(o_y) = \{D^*(s_y) \cap [s1_y, s2_y],\ D^*(e_y) \cap [e1_y, e2_y],\ D^*(d_y) \cap [d1_y, d2_y]\}$$

3.3. Analysis of Algorithm

In plan-space planning, the initial plan is incomplete and the aim of planning and scheduling is to fill the plan with actions or states. When an action is added in the plan, some temporal constraints may also be added into the constraint network besides points. The propagation algorithm will be called every time

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

when actions are added into the plan in order to check the consistency of the constraint network. Only when the network is consistent can the next step of planning continues. Therefore, the efficiency of the propagation algorithm has a significant impact on that of planning and scheduling.

The GD algorithm is dynamic because of the introduction of tags on action pairs. Unlike the traditional method that needs to process all constraints every time, the GD algorithm only needs to process the marked constraints. In other words, if new actions and their constraints are added to the constraint network, action pairs related to new constraints are marked with $Tags(i)=1$, and then the GD algorithm process these action pairs at the beginning. This brings the advantage of reducing the number of pending constraints.

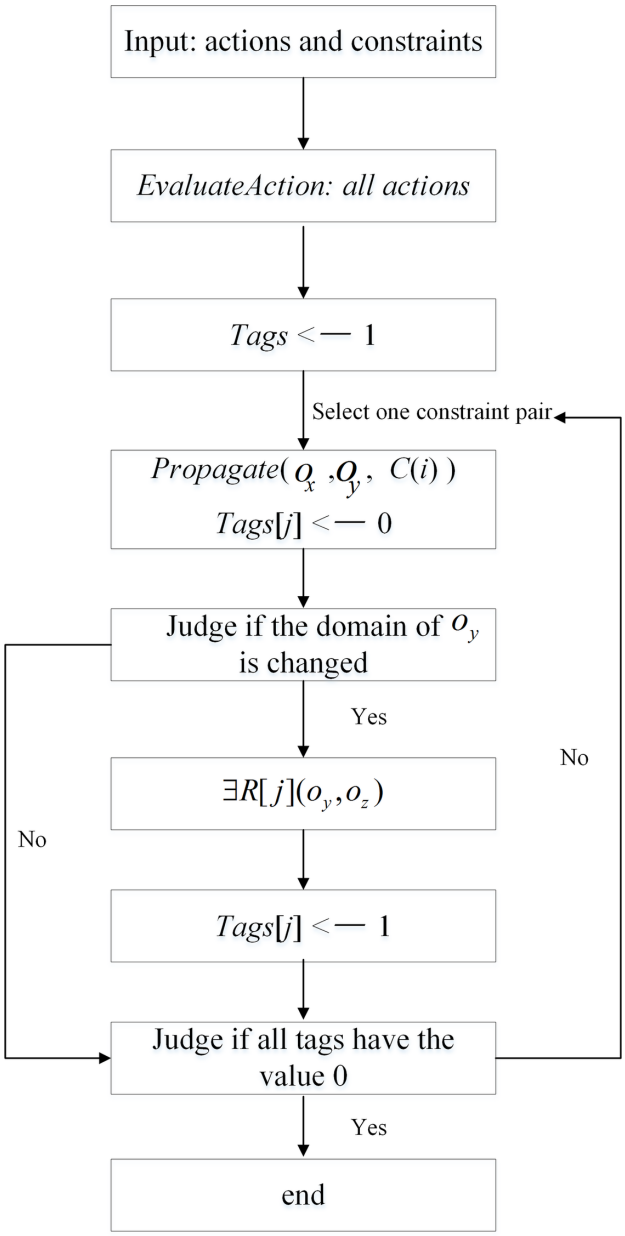
Figure 6 is the flow diagram of the GD algorithm. Actions and constraints are inputs of the algorithm. First, the function *Evaluate Action* is used to check weather all actions exist. Then, all constraints are tagged with the value 1 and one constraint is selected to be propagated using $Propoagate(o_x,o_y,C(i))$. At the same time, the value 0 is assigned to the tag related to $C(i)$. If the domain of o_y is changed because of the constraint, tags of all constraints related to o_y will get the value 1. Perform the function *Propagate* until all tags have the value 0. At last, the consistency will be judged and minimal domain of start time and end time of all actions will be got.

Figure 7 is the diagram to show the dynamic characteristic of the algorithm. New constraint pairs are added in the list above, which are marked red. The values of their tags are 1. After new action pairs are processed, the domain of action o_2 may be changed. If it happens, actions pairs related to o_2 have to be checked with the tag from 0 to 1 marked red in the list below.

4. EXPERIMENTAL EVALUATION

In this section of the paper we compare the performance of the GD algorithm against the results that can be obtained using the temporal reasoning algorithm in the EUROPA system, which provides incremental algorithms e. g. adaptive Bellman-Ford algorithm to detect a negative cycle which is sufficient for backtrack-free search (Barták et al., 2010). Here, the algorithm in EUROPA is called EU algorithm for simplify. The data used for this evaluation comes from the reference (Planken, De Weerdt, & Van Der Krogt, 2012). For reflecting the planning and scheduling process, four cases are considered, which demonstrates the efficiency of our algorithm from multiple perspectives.

Both algorithms were implemented in C++. Experiments were conducted with Microsoft Visual Studio 2008 on Intel Core i7-2600 CPUs running 32-bit Windows. The run times were averaged over 10 runs for each point in the simulation diagrams. Details about data are stated in each case.



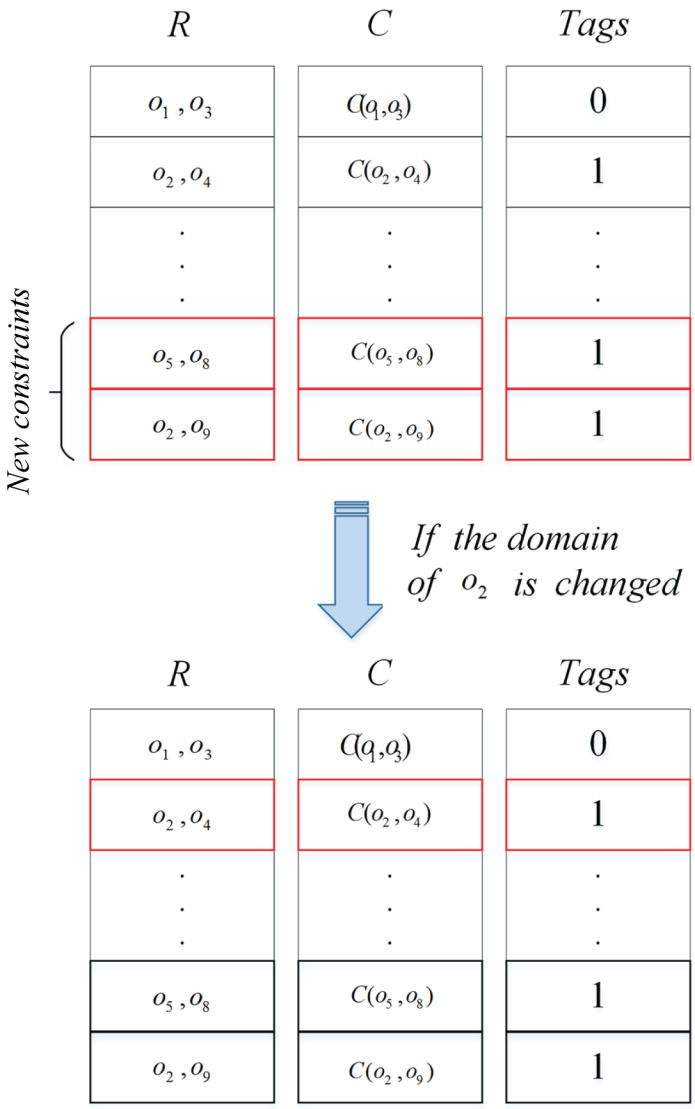
4.1. Case 1

In this case, we want to verify how the number of constraint pairs added can influence the performance of algorithms. The initial constraint network has 250 variable points and 3800 constraint edges. When new constraint edges are added every time, the number of variable points and constraint edges of the initial constraint network remain the same. The number of new constraint edges added is from 10 to 1000 with the interval 10.

Figure 8 shows the results, in which the value of x axis is the sum of the number of initial constraint edges, 3800, and that of the added constraint edges. For example, in the x-axis, 3900 means that 100

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 6. The flow diagram of the GD algorithm



constraint edges are added into the constraint network with 3800 edges; in the same way, 4000 means that 200 constraint edges are added into the network with 3800 edges. Table 1 gives data of six points in Figure 8, which is more specific to show the run time.

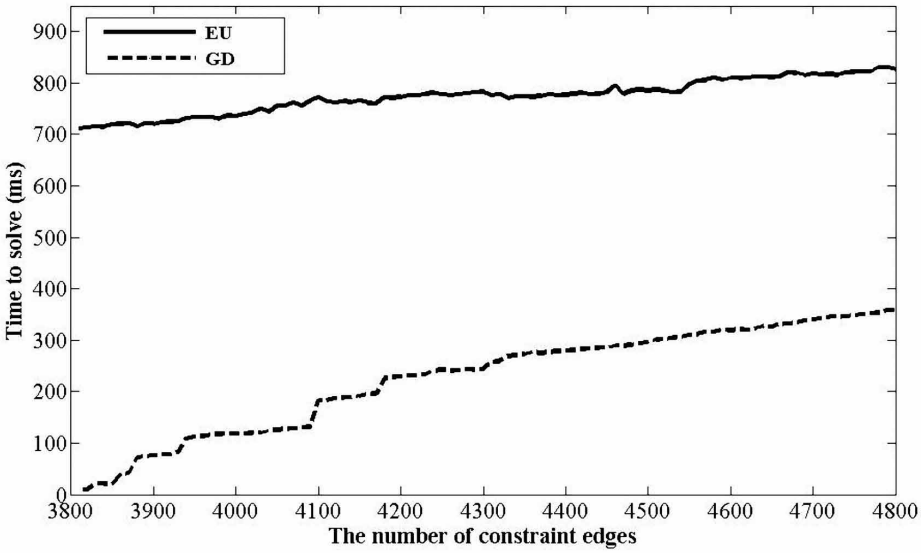
From Figure 8 and Table 1, we can see that run time of both two algorithms increases with the increment of added constraint edges. The GD algorithm is more efficient, especially when the number of added constraints is small. For example, in Table 1, when the number of constraint edges is 3810, the run time of GD is faster by two orders of magnitude.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 7. Diagram of the dynamic characteristic

However, the growth rate of GD is larger. Maybe when the number of new constraints added is very large such as 10000, the EU algorithm will be faster than GD. But it is unusual that a large number of constraints is added into the constraint network at the same time in planning and scheduling. Therefore, the GD algorithm has a certain advantage on this case.

4.2. Case 2



The case 1 has verified that the number of added constraints has influence on run time. In this case, we focus on the influence of the initial network on run time. The initial network is same with that of case 1 where it has 250 variable points and 3800 constraint edges. When new constraint edges are added into the network, the number of points stays same, but the number of constraint edges changes. For example,

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 1. Data of six points in case 1

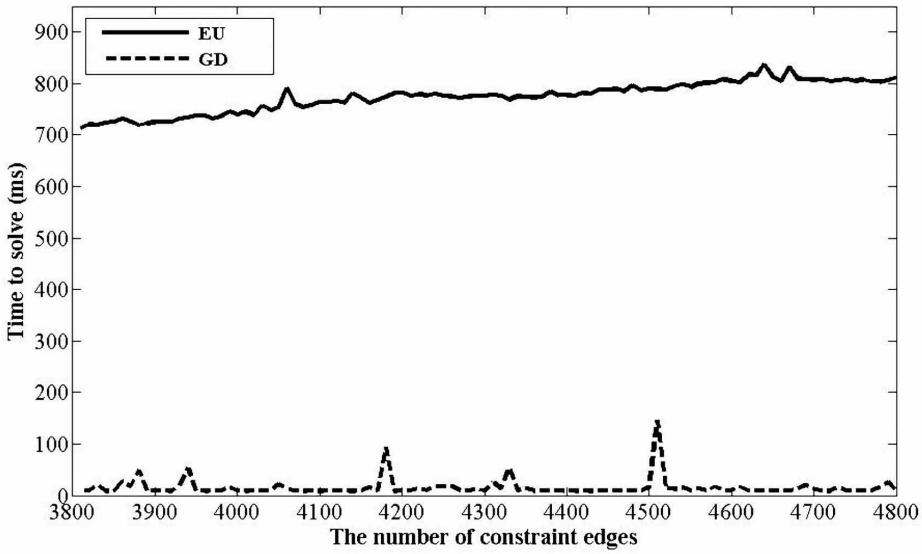
Number of constraint edges		3810	4000	4200	4400	4600	4800
Run time / ms	*EU*	712	736	773	777	809	827
	GD	8	119	229	280	319	359

Figure 8. Comparison of the run times of the GD and EU for case 1

ten constraint edges are added at the first time into the network with 3800 constraints. At the second time, another ten constraint edges are added into the network with 3900 constraints, that is to say the ten constraint edges added last time are not removed. Therefore, the basic number of the constraint network changes every time when ten new constraints are added.

The results of this experiment can be found in Figure 9. Specific data is shown in Table 2. Here we should note that the x axis has the same value with Figure 9, but the way of changing the number of constraint edges is different. The reason has been stated above.

We observe that the efficiency of the GD algorithm is significantly better than that of the EU. The run time of the GD remains about the same while that of EU has a slight increase. From Table 2, we can see that all run time of GD is faster by two orders of magnitude than that of the EU.



Combined with the result in case 1, we also conclude that the number of added constraints has lager effect on run time of the GD while the number of initial constraints of the network has little influence. However, for the EU algorithm, both the number of added constraints and initial constraints can influence its run time.

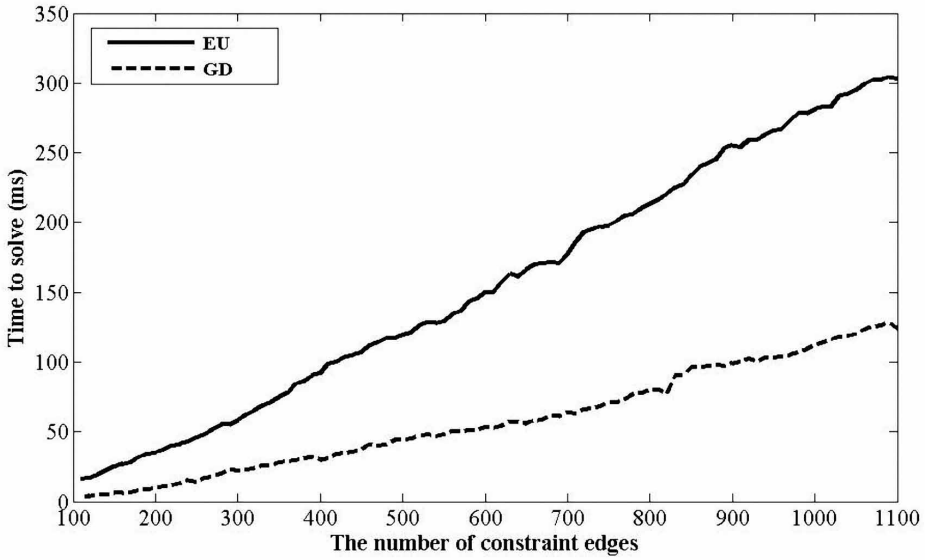
	GD	9	9	10	9	10	10

Figure 9. Comparison of the run times of the GD and EU for case 2

4.3. Case 3

For simulating planning and scheduling process, we design the third experiment. In planning and scheduling, actions with constraints are added into the plan constantly. Therefore, not only new constraint edges are added into the constraint network, but also variable points. In this case, the initial network T_0 contains 45 variable points and 100 constraint edges. The initial network does not change and 10 - 1000 constraint edges with interval 10 are added every time. For example, we add ten constraints into the initial network at the first time and then at the second time we add twenty constraints into the same initial network. Three to five variable points are added into the network with the addition of ten constraint edges.



The results are shown in Figure 10 and Table 3 has the specific data. With the increase of the number of added constraints, run time of both algorithms increases and advantages of the GD are highlighted. From Table 3, we can get that run time of the GD algorithm is less than half of that of EU algorithm. Compared the results with that in case 1, we can conclude that the EU algorithm is influenced by both the number of variable points and constraint edges.

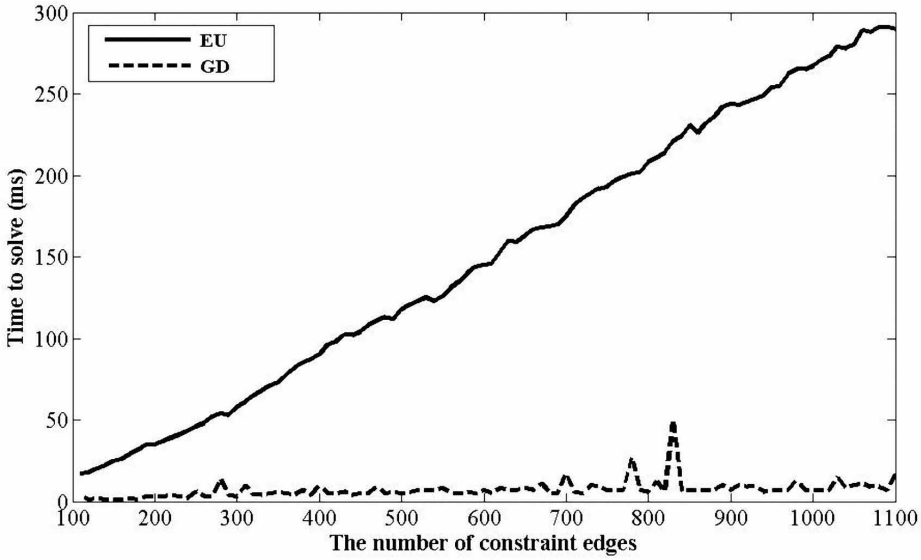
4.4. Case 4

The case is the one most closely associated with planning and scheduling. The initial network T_0 is the same with that in case 3. But when new constraints and variable points are added into the network, they will not be removed. For example, ten constraint edges and 3 points are added into the network with 100 constraints at the first time and then the new network T_1 has 110 constraints and 48 points. Next, another ten constraint edges and 3 points are added into the network T_1. It is a superposed process.

Figure 11 shows the results of this experiment as a function of the number of constraint edges of the constraint network. Table 4 gives the specific data. Like the case 2, the GD algorithm is not influenced by the added constraints. From this case, we can also get that our algorithm is not influenced by variable points. However, the efficiency of the EU algorithm is associated with the number of variable points and constraint edges, so it increases with the addition of new constraints and points.



In a conclusion, in all cases above, our dynamic method has obvious advantages in the efficiency over the EU algorithm. It is more suitable for temporal constraint reasoning in planning and scheduling.

5. CONCLUSION

In this paper, we focus on temporal reasoning which is one of cognitive capabilities people involve in communicating with others and the reference of everything changing. Here, planning and scheduling is taken as an example to specify our topic and method.

we use our prior work to represent actions and filter redundant values of actions in a 2-D coordination system. For reducing the influence of addition of constraints or actions on the efficiency of temporal reasoning algorithm, a dynamic algorithm with tags based on geometric representation (the GD algorithm) is proposed. This approach was described in detail and also evaluated against the algorithm in EUROPA. In the evaluation, we found that our algorithm is more efficient when new constraint edges and variable points are added into the constraint network.

Future work will implement the GD algorithm on the planning and scheduling system to check the consistency of temporal constraint network and give the minimal domain of the start time and end time of all actions. Furthermore, we want to evaluate the performance of our algorithm in other computer-based systems. Also, the formal properties of the GD algorithm remain to be analyzed.

ABSTRACT

Aim of this article is to investigate the potential of Artificial Intelligence (AI) in the discrimination between benign and malignant endometrial nuclei and lesions. For this purpose, 416 histologically confirmed liquid-based cytological smears were collected and morphometric characteristics of cell nuclei were measured via image analysis. Then, 50% of the cases were used to train an AI system, specifically a learning vector quantization (LVQ) neural network. As a result, cell nuclei were classified as benign or malignant. Data from the remaining 50% of the cases were used to evaluate the AI system performance. By nucleic classification, an algorithm for the classification of individual patients was constructed, and performance indices on patient classification were calculated. The sensitivity for the classification of nuclei was 77.95%, and the specificity was 73.93%. For the classification of individual patients, the sensitivity was 90.70% and the specificity 82.79%. These results indicate that an AI system can have an important role in endometrial lesions classification.

INTRODUCTION

The endometrium is a human system with inherent complexity because it undergoes cyclic regeneration under estrogen effects during each menstrual cycle. These effects, as well as sex steroids, oncogene products, growth factors and various peptides (Murphy, Murphy, & Friesen, 1987; Shyamala & Ferenczy, 1981) may cause premalignant and malignant transformation of the endometrium. Early diagnosis is crucial because it is associated with patient management and therapy. However, and despite that in the last decades the incidence of endometrial cancer has increased (Jemal et al., 2006), there is still not a global and well-established screening method for the early detection of endometrial cancer. Moreover, there is no automated procedure.

Artificial Intelligence (AI) techniques are not new in medicine (Adams, Bello, & Dumancas, 2015; Darcy, Louie, & Roberts, 2016; Foran, Chen, & Yang, 2011; Grabe et al., 2010; Karakitsos et al., 1996; Luo et al., 2015; Seffens, Evans, Minority Health, & Taylor, 2015; Su, Xu, He, & Song, 2016). During the last decades, numerous applications have been reported; these involve the use of classical statistical models (Karakitsos et al., 2004), as well as more advanced techniques, such as neural networks. In the field of oncology related medical disciplines there are numerous efforts (Cruz & Wishart, 2006; Hassan, Ruusuvuori, Latonen, & Huttunen, 2015; Karakitsos et al., 1997; Kourou, Exarchos, Exarchos, Karamouzis, & Fotiadis, 2015; Pouliakis et al., 2016; Simões et al., 2014). However, the literature related to endometrial cytological material evaluation by AI and especially publications reporting the comparison of machine learning performance are rather poor.

In this article, a methodology aiming to classify endometrial lesions based on cell nuclei morphometry data will be presented. Initially, the morphometrical features and their biological relation will be described and then the construction of machine learning systems classifying individual nuclei will be outlined. Furthermore, according to the nuclei classification results, a second stage classifier aiming to categorize individual cases will be constructed. The validation of the results will be based on the histological result, which will be considered our gold standard. The applied Machine Learning Algorithm (MLA) was the Learning Vector Quantizer (LVQ) ANN and was selected because it has the capability to provide solutions by creating clusters. The applied classifier was compared with the performance of the cytological outcome.

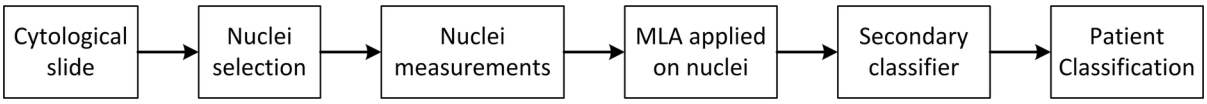
MATERIALS AND METHODS

Biological Sample, Material Collection and Diagnoses

For this study, cytological samples from the endometrial cavity were collected from 416 female patients. The biological material was taken using the EndoGyn® Sampler (Biogyn S.n.c., Mirandola, Italy). Subsequently, the sampling device was withdrawn, and the material was immersed into a vial containing CytoLyt® solution (Cytyc Corporation). The use of this methodology (i.e. Liquid Based Cytology - LBC) for material collection and preservation is essential, not only because it facilitates the cytological diagnosis through the microscope, but also provides a clear material for subsequent image analysis, as required by this study and therefore ensures a constant sample quality. The vials with the biological material were used to prepare a single cytological slide via an automated slide processor (ThinPrep® TP2000, Cytyc Corporation). TP2000 prepares a smear in a 2 cm diameter area containing cells in a single layer with almost no overlap in 90 seconds. Each slide was stained with Papanicolaou stain, using an automated staining machine (Varistain® 24-3 Thermo Electron Corporation [formerly Shandon], Runcorn, U.K.).



Both the cytological and histological examination results were available for every patient included in this study. The histological examination was performed on biological material harvested via endometrial curettage and/or surgically. Women without histological examination results were excluded from the study. Histological confirmation is imperative, as it is the golden standard and the lack of it makes it impossible to have an accurate final diagnosis and therefore evaluate the results and performance of the proposed methodology.

The cytological diagnosis was based on a new classification scheme introduced in the Department of Cytopathology of University General Hospital "Attikon" (Margari et al., 2016) and the histological diagnosis was in accordance with the International Society of Gynecological Pathology (Blaustein & Kurman, 2011) classification. We only considered cases for which the cytological result was in agreement with the histological conclusion; otherwise, the data were excluded from the study. That was due to the aim of this study to include cell nuclei that have a certain histological type exclusively.

Image Analysis System, Measurements, and Their Biological Relation

The process applied for the classification of individual patients is depicted in Figure 1. The workflow starts with the patient's cytological slide; this is analysed via the image analysis workstation. Following the identification of individual nuclei and their measurements, the MLA was applied; the MLA outcome is the classification of every identified nucleus in the slide as benign or malignant. The final stage is the application of a secondary classifier; this classifies a patient into the benign or malignant category on the basis of the classification results for the nuclei after their measurement and subsequent classification by the MLA.

Figure 1. Work flow for the classification of patients

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

From each slide we selected about 100 representative nuclei via a manual selection/segmentation process; this requires about 10 - 20 minutes, in practice, this is a process of definition of nuclei borderline. The characteristics measurement time following nuclei selection is negligible and was performed massively through software built in the programming language of ImagePro Plus. In total, were 38,326 nuclei from the 416 slides were measured. The features are summarized in Table 1 and details for the applied algorithms can be found in the literature (Baak, 1991; Russ, 1995; Sonka, Hlavac, & Boyle, 1993; Varlatzidou et al., 2011).

These features were selected because they are related to the characteristics that cytopathologists examine during the routine microscopic examination. Specifically, cytopathologists during slide screening examine the nuclear size, boundary abnormalities, elongation of nuclei, and other shape based characteristics of the nuclei. Moreover, nucleus density (i.e. darkness), the distribution of DNA in the nucleus centre or membrane as well as the texture caused by chromatin distribution (i.e. the existence of coarse or fine dots of chromatin in the nucleus) are important diagnostic characteristics (Margari et al., 2016).

Classification Targets

The primary target during diagnosis both in the cytological and histological material is to discriminate between benign and malignant cases. Thus, the data were categorized into these two broad categories: a) benign cases: i.e. histologically normal cases including atrophy, secretory and proliferative endometrium, disordered endometrium, polyps and hyperplasias without atypia, and b) the group of malignant cases composed of the hyperplasias with atypia and the carcinomas (endometrioid, serous and adenocarcinomas).

Training and Test Sets

In order to obtain a similar distribution of the data to the relevant histological categories, 50% of the patients/cases (along with their nuclei) were randomly selected and were used as a training set; the remaining nuclei (from the rest 50% of the cases) formed the test set. The distribution of the cases and the nuclei into the two sets is presented in Table 2. By this methodology, it was ensured that a) representative nuclei obtained via cytological material from all histological groups were included in both sets b) there was no mixing of patients' nuclei between the training set and test set and c) there was a balance between the training and test set.

Artificial Intelligence Systems

The Learning Vector Quantization (LVQ) classifier (Teuvo Kohonen, 1989) was selected as a tool for nuclei classification. It was implemented within the MATLAB v2011b environment and the available programming language (The MathWorks, Inc. Natick, Massachusetts, U.S.A.).

ANNs are complex mathematical models inspired by the human brain structure; they are capable of learning and pattern recognition (Duda, Hart, & Stork, 2001; Theodoridis & Koutroumbas, 2009). This capability is suitable for classification and prediction tasks in numerous practical situations. The core component of ANNs is the artificial neuron (Figure 2). Neurons are inspired and have similarities with brain dendrite cells, where each neuron cell is interconnected with other neurons through synapses. In ANNs neurons perform a relatively simple task: the inputs (i_1- i_n) are multiplied one by one by synaptic weight (w_1- w_n), the products are added, and the result is passed via a nonlinear function which represents the artificial neuron output.

Table 1. Nuclear morphometry features involved in the study

	Feature	Description
Characteristics of nucleus shape	Nucleus area	The area occupied by a nucleus expressed in square μm
	Nucleus major axis	The length of the major axis of an ellipse fitted o the nucleus (expressed in μm)
	Nucleus minor axis	The length of the minor axis of an ellipse fitted o the nucleus (expressed in μm)
	Aspect ratio	The ratio of the major and minor axis considering that an ellipse is fitted to the nucleus (expressed as number without units)
	Maximum caliper	Maximum distance between two perimeter points while the nucleus is between two parallel lines (expressed in μm)
	Minimum caliper	Minimum distance between two perimeter points while the nucleus is between two parallel lines (expressed in μm)
	Average value of calliper	The mean value of the distances measured between two perimeter points while the nucleus is between two parallel lines (expressed in μm)
	Maximum nucleus radius	The highest distance between the nucleus centroid and the nucleus outline (the nucleus centroid is the center of nucleus mass when considering that the nucleus is uniform) (expressed in μm)
	Minimum nucleus radius	The minimum distance between the nucleus centroid and the nucleus outline (expressed in μm)
	Radius ratio	The ratio between the maximum and minimum radius (expressed as a number without units)
	Nucleus perimeter	The length of the nucleus boundary (expressed in μm)
	Nucleus roundness	Defined by the formula (Perimeter*Perimeter)/(4π*Area), it is an indication of the nucleus circularity, an absolutely circular nucleus has roundness equal to 1 while anything not perfectly circular has higher roundness, for example, the roundness of a square is 4/π=1.27 (expressed as a number without units)
	Fractal dimension	The fractal dimension of the nucleus boundary is an indication of repetitive patterns in the nucleus outline (Mandelbrot, 1983)
Density characteristics	Integrated optical density	The sum of the pixel values of the nucleus (when color is not considered) if the nucleus intensity is light and the area is large then integrated optical density becomes higher. Can be calculated the formula (Area)*(Mean optical density)
	Mean value of nucleus red color	The average value of the nucleus pixels values of the red color plane, it is a number between 0 and 255
	Mean value of nucleus green color	The average value of the nucleus pixels values of the green color plane, it is a number between 0 and 255
	Mean value of nucleus blue color	The average value of the nucleus pixels values of the blue color plane, it is a number between 0 and 255
	Mean value of optical density	The average value of the nucleus pixels when color is not considered, it is a number between 0 and 255
	Maximum value of optical density	The maximum value that has pixels inside the nucleus, it is a number between 0 and 255
	Minimum value of optical density	The minimum value that has pixels inside the nucleus, it is a number between 0 and 255
	Standard deviation of optical density	The standard deviation of the nucleus pixels when no color is considered, it is an indication of the range of grey values that has the nucleus
	Margination	The percentage of nucleus pixels that deviate more than 10% from the mean value of the nucleus density
	Heterogeneity	An index of homogeneity between the center of the nucleus and the borders, a homogeneous nucleus (i.e. all nuclei pixels have the same value) has heterogeneity = 0.33 while nuclei with the brighter center have higher heterogeneity. Heterogeneity is indicative of the distribution of DNA in the center or the nucleus membrane

	Disorder	2	2	4	181	180	361
	Polyp	12	12	24	1,214	1,096	2,310
	Hyperplasia without atypia	26	26	52	2,577	2,520	5,097
Malignant	Hyperplasia with atypia	10	10	20	773	870	1,643
	Endometrioid carcinoma	62	62	124	5,503	5,091	10,594
	Serous carcinoma	5	5	10	367	457	824
	Adenocarcinoma	9	9	18	792	949	1,741
	Total	**208**	**208**	**416**	**18,938**	**19,388**	**38,326**

Figure 2. The standard model of an artificial neuron, inputs (i_1- i_n) are multiplied by weights (w_1- w_n), subsequently the products are summarized (block Σ) and finally the output is produced as the response of the nonlinear function

The capability of the ANNs to learn is due to the neurons' weights, and the capability to address complex problems is due to the nonlinear function and architectures that interconnect many neurons together in several layers and the use of training (learning) algorithms.

The LVQ is a supervised classifier; during the training phase LVQ creates partitions of the feature space, each partition is characterized by a vector in the centre of the partition being called codebook vector; the class of the codebook vector characterizes the class of the entire partition. During training the codebook vectors are modified to represent the full feature space; passing of all the training vectors

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

to the classifier several times and by the application of a training algorithm LVQ based MLAs store the knowledge in the network components (i.e. in the codebook vectors) (Teuvo Kohonen, 1989; T. Kohonen, Kangas, Laaksonen, & Torkkola, 1992).

During a test or operational phase, unknown vectors are presented to the LVQ, the class of each unknown vector is determined to be the same to the class of the partition that the unknown vector resides. This class is determined by identifying the codebook vector that is nearest to the unknown vector.

Method for the Classification of the Cases

We constructed case classifiers based on the result of nuclei classification by the LVQ using a method similar to a system proposed in the past for the classification of thyroid lesions (Varlatzidou et al., 2011), endometrial lesions (Makris et al., 2017) as well as for HPV methylation analysis (Kottaridi et al., 2017). This second stage classifier is built on the basis of the percentage of nuclei classified as malignant from the LVQ. During training of second stage classifier, the aim is to find a threshold that optimizes patients' classification based on the training data. For this purpose, we evaluated the case classification results for a broad range of thresholds; starting from 0% and increasing up to 100% (indicating the percentage of the patient's malignant nuclei as assigned by the MLA) the increment step was 0.1%. For each threshold value the number of cases that were true positive was calculated, true negative and false positive or false negative, thus it was possible to calculate the various performance indexes: sensitivity, specificity, Positive Predictive Value (PPV), Negative Predictive Value (NPV), False Positive Rate (FPR), False Negative Rate (FNR), Overall Accuracy (OA), odds ratio and Yuden's index. As an optimum threshold was selected the threshold that maximized the overall accuracy on the training cases. The software for the logic of the cases' classifiers and the performance indices was implemented within the MATLAB environment.

RESULTS AND DISCUSSION

Results are reported in two levels: a) the nuclei classification level where the LVQ was trained by the measurements obtained from the 18,938 nuclei of the training set (208 cases) and tested on the nuclei from the remaining 208 cases (19,388 measured nuclei) and b) the case classification level where the thresholds for the case classifiers were found on the basis of the training results obtained from the LVQ and subsequently tested on the rest of the cases.

Performance on Nuclei Classification

In terms of architectural characteristics of the LVQ ANN, the number of the nodes (codebook vectors) representing the number of clusters used to separate the data was 300, the results of the clusters' layer were fed to a second layer with 2 nodes in order to discriminate into the two target categories (benign and malignant); the number of iterations on the training data set was only 3. As training algorithm, it was used the LVQ.1 algorithm (T. Kohonen et al., 1992). The ANN was trained and evaluated on the training set and subsequently assessed on the test set, the performance is presented in Table 3.

NPV	89.35%	90.77%
FPR	25.69%	26.06%
FNR	25.95%	22.05%
OA	74.24%	74.96%
Odds Ratio	8.25	10.03
Yuden Index	48.36%	51.89%

Case Classification Results Analysis and Performance Metrics

The case classifier based on the results of the LVQ outcome missed 14 malignant cases and 37 benign cases (Table 4) leading to a sensitivity and specificity of the test set equal to 90.70% and 82.79% respectively (Table 5).

CONCLUSION

Endometrial carcinoma is the most common malignancy of the female genital tract (Papaefthimiou, Symiakaki, Mentzelopoulou, Tsiveleka, et al., 2005; Parazzini, La Vecchia, Bocciolone, & Franceschi, 1991); it affects women at reproductive age and after menopause as well. The mean age of diagnosis in the USA is 60 years (American Cancer Society, 2005), in the UK is 61 years (Soliman et al., 2005) and in European countries is 63 (Colombo et al., 2013). The most frequent symptom of endometrial carcinoma is postmenopausal bleeding (ACOG, 2005) but, only 10% of the women with postmenopausal bleeding have endometrial carcinoma (Iatrakis et al., 1997; Taskin, Bozaci, Seval, & Unlu, 2006); moreover 5-10% of endometrial carcinoma cases are asymptomatic (Smith-Bindman et al., 1998). According to the American National Institute of Health (NIH), and specifically the Surveillance, Epidemiology and

Table 4. Cross tabulation of the assignment of the cases for the LVQ classifier according to the histological group. Results are presented separately for the training and test sets

	Case classifier based on the LVQ ANN			
	Histological result	Benign	Malignant	Grand Total
Training set	Benign	106	16	122
	Malignant	6	80	86
Test Set	Benign	101	21	122
	Malignant	8	78	86
	Grand total	221	195	416

Table 5 Performance indices of the cases classified on the basis of the LVQ outcomes (training and test sets)

	Training set	Test set
Sensitivity	93.02%	90.70%
Specificity	86.89%	82.79%
PPV	83.33%	78.79%
NPV	94.64%	92.66%
FPR	13.11%	17.21%
FNR	6.98%	9.30%
OA	89.42%	86.06%
Odds Ratio	88.33	46.89
Yuden Index	79.91%	73.48%

End Result (SEER) program, the number of new cases of endometrial cancer for 2016 is estimated to be 60,050 with 10,470 deaths. The age-adjusted rate, based on 2009-2013 data, was 25.4 endometrial cancers per 100,000 women per year. The number of deaths is 4.5 per 100,000 women per year. Moreover, the lifetime risk of developing endometrial cancer is approximately 2.8% for women who will be diagnosed with endometrial cancer at some point during their lifetime (based on 2011-2013 data). In 2013, it was estimated that 635,437 women were living with endometrial cancer in the United States. According to the World Health Organization, there are, worldwide, 188,000 new endometrial carcinomas every year. According to GLOBOCAN, the endometrial cancer age standardized rate for 2012 is 8.2 per 100,000 for the world and for Japan (a single country that is applied endometrial cancer screening) the incidence is significantly reduced to 3.9 per 100,000.

According to various studies (Karakitsos et al., 2002; Papaefthimiou, Symiakaki, Mentzelopoulou, Giahnaki, et al., 2005; Papaefthimiou, Symiakaki, Mentzelopoulou, Tsiveleka, et al., 2005) morphological characteristics of nuclei have an important role in endometrial cytology diagnosis irrelevant of the technique (conventional or LBC); in addition, characteristics of structures formed by the observed cells (contextual characteristics) are important as well.

The application of LBC is in line with the objectivity requirements and quality control and assurance, as advantages of LBC are related to common diagnostic approach, because there is a standardized procedure related to fixation, transfer and cyto-preparation of the biological material; additionally observed cellular overlap is linked to the real 3 dimensional structures and not due to the slide preparation methods; finally the cells are layered in non- overlapping sheets, a fact that facilitates their measurement. The proposed methodology introduces new objectivity in two levels: first cell nuclei are measured in a reproducible method (a procedure facilitated by LBC), and secondly, these characteristics are evaluated via computerized algorithms.

Obviously, the performance of the LVQ on nuclei classification is worse than the performance of the complete system for the classification of cases. For instance, the sensitivity of the test set for nuclei classification was 77.95%, and the PPV 50.50% (Table 3), while the sensitivity of the complete system of case classification was 90.70% and the PPV 78.79% (Table 5). This performance improvement is due to the second stage classification system and the application of the optimal threshold that maximizes the overall accuracy (on the training set).

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

The presented results are concordant to the wider context of encouraging findings related to the performance of cytology in the diagnosis of endometrial cancer (Norimatsu et al., 2006; Papaefthimiou, Symiakaki, Mentzelopoulou, Giahnaki, et al., 2005; Sams, Currens, & Raab, 2012; Yanoh et al., 2009). Nuclear morphological characteristics seem to play a central role in this context, a finding which has been observed in previous studies as well (Karakitsos et al., 2002; Makris et al., 2017; Papaefthimiou, Symiakaki, Mentzelopoulou, Giahnaki, et al., 2005; Papaefthimiou, Symiakaki, Mentzelopoulou, Tsiveleka, et al., 2005; Pouliakis et al., 2014; Zygouris et al., 2014). The rationale behind this is the fact that carcinogenesis destroys the cellular structure and the in particular nucleoskeleton, thus resulting in nuclear deformations. Shape characteristics reflect such changes, while the second group of density characteristics reflects nucleus DNA changes. Although nuclear morphological characteristics can be evaluated both by conventional and liquid- based cytology, the latter contributes towards standardization due to lysis of mucus and blood using a standardized procedure, standardized fixation, transfer and cytological preparation of the biological material and in this study by improving image analysis due to the reduction of cell overlapping.

Concluding, the proposed objective approach using ANN, gave promising results in the discrimination between malignant and benign endometrial cases; the MLA showed encouraging results; the integration of this technique in the laboratory routine might become a useful adjunct in the future leading towards a more objective diagnosis of endometrial malignancies.

Chapter 15
Expanding Bloom's Two-Sigma Tutoring Theory Using Intelligent Agents:
Application to Management Education

Owen P. Hall Jr.
Pepperdine University, USA

ABSTRACT

This article describes how management education is engaged in significant programmatic reforms in response to the business community's call for web-savvy, problem-solving graduates. Web-based intelligent tutors provide a readily accessible vehicle for enhancing business students' learning performance as well as prepare them for the rigors of the global marketplace. A primary goal of these AI-based systems is to approach Bloom's two-sigma learning performance standard. Bloom found that average students tutored one-to-one with mastery learning techniques performed two standard deviations better than students who learned via conventional teaching methods. Intelligent tutors can also be used to identify students at risk, to formulate appropriate intervention plans, and to support team learning. The purpose of this article is to highlight the growing potential for using intelligent tutors to enhance student and team learning opportunities and outcomes and to outline strategies for implementing this revolutionary process throughout the management education community of practice.

INTRODUCTION

Business leaders, accrediting bodies, and management educators alike are calling for a paradigm shift in the content and delivery of management education because of globalization, unprecedented economic uncertainty, changing demographics, and new learning technologies (Buil, 2016; Hall, 2013; Rubin, 2013; Thomas, 2012). Business schools are beginning to recognize that digital technology can play an important role in improving both the learning process and learning outcomes (Bowen, 2014; Mohapatra, 2015; Spada, 2014). Specifically, the rapid growth in Web 2.0+ technologies has ushered in a new era

for management education including: virtual learning environments, intelligent tutors, web-based collaborative learning groups, and crowdsourcing. Additionally, the ubiquitous availability of mobile devices has encouraged educators to utilize this technology as a vehicle for accessing context-based materials, without the constraints or limitations of time, location and pace (Aljohani, 2012). The increased use of learning technologies can help narrow the gap between a graduates' skill set and the ever-changing requirements of business. For example, an MBA Roundtable survey found that many business schools do not emphasize the skills desired by most hiring managers (Hanover, 2013). These included evidence-based decision-making, ethics, and a focus on results and quality.

A number of the concerns such as the lack of integration and too little emphasis on problem finding, international dimensions, entrepreneurship, and practical experience have seemingly not been widely addressed. Nor have many of the other competencies considered important by employers, e.g., motivation and commitment to the firm, creativity, quality focus, customer focus, ethics–integrity, teamwork, flexibility, and interpersonal skills (Herrington, 2013).

With globalization under increased scrutiny and an unpredictable economy, the business community is increasingly focusing on adaptive and sustainable positioning strategies (Waddock, 2013). The business community is looking for web-savvy graduates that are both problem-solving and entrepreneurial oriented. This is the ongoing challenge faced by the management education community. Even the business accrediting organizations have gotten into the act of critiquing business education. A report from the Association to Advance Collegiate Schools of Business (AACSB, 2016) found:

- A larger share of degree-based education will be delivered in flexible formats (modular, part-time) across providers, with students having more control over their curriculum
- Business schools will struggle to align the pace of curriculum development with the pace of evolution in business practice
- A shift toward more experiential learning and business engagement
- Business schools will be increasingly called on to serve the common good

Digital technology provides a vehicle that can be used for addressing these trends. More specifically, providing customized learning opportunities can enhance both student learning outcomes and preparation for the transition to the business community. The mastery of management education material lies at the heart of this proposition. In a 1984 study, Benjamin Bloom found that the average student tutored one-to-one using mastery learning techniques performed two standard deviations better than students who learn via conventional instructional methods (Bloom, 1984). The task at hand is to find technological-based methods of instruction that are scalable, which is not the case with the traditional Bloom model, and that approach the effectiveness of one-to-one human tutoring. Intelligent tutors represent one promising possibility (Anastassakis, 2014; Niu, 2012; Yeh, 2013). These systems, which consist of a combination of hardware devices and software programs, are designed to provide learners with both customized content and instructional feedback at a performance-driven pace. Intelligent tutors can be used to replicate the role of a one-to-one tutor on a massive scale and thus move toward the goal of approaching Bloom's Two-Sigma standard. To be effective, an intelligent tutoring system requires a pedagogical framework that is based on the latest learning constructs and that can justify its choice of activities, presentation

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

formats, and decisions (Bagheri, 2015). In recent years, a range of educational technologies have emerged throughout the business school universe including: homework support agents, simulations, massive open online courses (MOOCs), and conditional content release systems (Bassi, 2014; Chin, 2010).

Learner's attitude toward affective computing, agent tutor's expressiveness, emotion recognition accuracy, number of emotions recognized by agent tutor, pedagogical action and ease of system use have significant influence on learner's satisfaction (Mao, 2010).

These same learning support technologies can also be applied to team learning. For example, sensing technologies are now able to assess each team member's behavior and level of engagement. This data along with individual and team outcome metrics provides the agent with the required inputs to enhance the overall learning process. Accurate individual and team statistics (e.g., exam performance) turn out to be key factors for the agent to identify optimal learning strategies for enhancing overall performance (Holden, 2011). This paper is organized as follows: 1) a review of intelligent tutoring systems (ITS) in management education and 2) an overview on ITS implementation strategies. This article's primary contribution to management education is to identify how intelligent agents can be used to enhance student learning opportunities and outcomes and thus better prepare students for the growing demands of the business universe.

Management education has always striven to inculcate a culture that is both practical and responsive to society's needs. Every tension the industry has experienced in its past continues to affect it today—and will reverberate into its future (Spender, 2016).

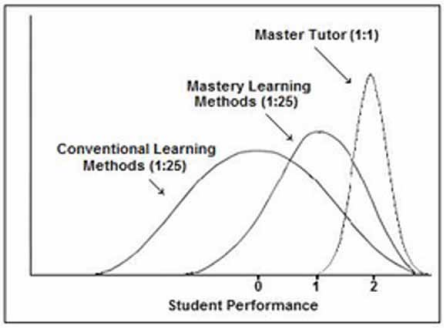
INTELLIGENT TUTORS IN MANAGEMENT EDUCATION

The changing demands placed on the management education universe by the business community continues at a torrid pace. Many students now entering a management degree program, especially at the graduate level, often lack the prerequisite skills and know-how to successfully compete and complete their course of studies, thus leading to less than satisfactory employment results (Pianin, 2014).

Nearly three-quarters of hiring managers complain that millennials – even those with college degrees – aren't prepared for the job market and lack an adequate work ethic (Bentley University, 2014).

These competency issues can be addressed using the intelligent tutoring paradigm outline in this paper. An intelligent tutoring systems (ITS) is defined as a learning construct that provides feedback and support during each phase of the learning process or exercise (e.g., hints) as well as an overall assessment at the end of the process. ITS represent a natural extension to the classical computer assisted learning systems in that they are step-phased oriented allowing the student to advance to the next learning level only after they demonstrate a certain level of proficiency. Additionally, these systems can further enhance the learning process by making it more personalized based on the learner's characteristics, background, desired learning pace, and business requirements (Dixit, 2013; Xu, 2014). ITS can acquire real-time information and knowledge via the web to support the learning process. The fundamental challenge is

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use



to identify the most effective ITS delivery mode for a given learning application. Again, the goal of incorporating tutors into the curriculum is to improve learning outcomes, which in turn, should lead to greater employment options (Zahid, 2013).

If learning goals are not properly aligned with managerial competencies, education and accreditation processes based on those goals are for naught. (Costigan, 2015).

Bloom Basics

Some thirty years ago, Benjamin Bloom observed that students receiving individualized tutoring in combination with corrective instruction tended to perform two standard deviations better than students receiving conventional classroom instruction. This suggests that the tutored students out-performed 98 percent, or about two-sigma, of the students engaged in a traditional learning environment (Guskey, 2007). Bloom also pointed out that master-based individual and team tutoring do not lend themselves to economies of scale, attesting that one-to-one tutoring would be too expensive for most schools to deploy on a wide scale basis. Accordingly, Bloom called for alternative learning strategies, which when used in combination might approach his two-sigma target. These included but were not limited to: 1) mastery learning, 2), proactive classroom participation, 3) time on task, and 4) cooperative engagement (i.e., team collaboration). Of these, mastery learning was found to yield the largest effect size (i.e., one-sigma). In mastery learning, the class size remains the same as in the traditional classroom setting, but learning pace for each student can vary. The goal of mastery learning is for each student to achieve general competency for a given topic (e.g., descriptive statistics) before moving on to the next, more advanced subject (e.g., inferential statistics). In mastery learning, the student is given the time needed to achieve the specified level of expertise, even though it may take longer than other students. Two challenges associated with the mastery learning paradigm are: 1) preserving consistency among multiple course sections and between different business disciplines and 2) maintaining the course pace for the entire class. Specifically, what happens to a student that is unable to complete the course requirements by the end of the term? Figure 1 highlights the basic construct behind Bloom's Two-Sigma paradigm. The numbers in parenthesis represent the ratio of instructor to class size. Notice that in both the one-sigma and two-sigma cases, the variability in performance is substantially reduced. Significantly increasing performance while reducing variability lies at the heart of the Bloom two-sigma paradigm and as such is viewed by many as the *Holy Grail* of modern education.

Figure 1. Bloom's two-sigma paradigm

Intelligent Tutoring Systems

The proposal to utilize computer-based tutors to enhance the learning process is not new, but was first introduced in the late 1990s (Rickel, 1999). Today, the state of the art in intelligent tutoring systems (ITS) has improved dramatically since those early days (Rus, 2013). Specific advancements include:

- Inhabits the environment with the student, thus providing increased potential for "physical" collaboration (e.g., telepresence)
- Communicates nonverbally, for example through gestures and facial expressions
- Tracks learners in new ways, for example their visual attention and physical movements
- Maintains learning records over the course of the study program
- Establishes progressive learning goals
- Provides for team collaboration

Typically, ITS embodies a wide range of web-based learning formats including videos, simulations, interactive cases, homework, games, voiceover slide shows and streaming text. Two recent meta-studies examined the efficacy of ITS (Kulik, 2016; Ma, 2015). The former study found, based on 50 evaluations, that performance scores were raised to 0.66 standard deviations from conventional levels, i.e., 50th to the 75th percentile. This study did observe that performance increases varied based on locally developed or standardized testing methodologies. The latter study, based on a sample size of 107, found a 0.42 sigma increase in student performance across a broad range of subject domains. The first study utilized Glass's effect size estimator while the second study employed Hedges's g. Both these statistics are related to the more common Cohen's d, which translates 0.2 to a small effect, 0.5 to a moderate effect, and 0.8 to a large effect. This scale has been extended to 2.0, very large effect, to encompass Bloom's standard (Sawilowsky, 2009). Unfortunately, neither study broke out the results by business category (e.g., finance, marketing). MBA programs, by their very nature, not only embody a broad range of diverse disciplines (e.g. ethics to analytics) but also are highly interdisciplinary. Accordingly, finding the effect per discipline therefore, is particularly important given the continuing interdisciplinary trends associated with many management education programs (Jacob, 2015). The average of the two meta-studies yielded a 0.5 sigma improvement in student performance. It should be noted that these two meta-studies contain performance data that is based on earlier intelligent tutor technology and usage plans. Furthermore, both studies involved K-12 and post-secondary students.

A basic tenant of this paper is that intelligent tutors will continue to improve student performance as new learning technologies are introduced that tend to mimic more human behaviors and qualities.

The past fifteen years have seen considerable AI advances in education. Though quality education will always require active engagement by human teachers, AI promises to enhance education at all levels, especially by providing personalization at scale. Similar to healthcare, resolving how to best integrate human interaction and face-to-face learning with promising AI technologies remains a key challenge. Over the next fifteen years the use of intelligent tutors and other AI technologies to assist teachers is likely to expand significantly, as will learning based on virtual reality applications (Stone, 2016).

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Recent research suggests that the new generation of management education students face serious concentration, engagement, and socialization issues (Karakas, 2015). This, of course, represents a major issue for business schools in terms of preparing students for the job market. To that end, a well-designed ITS should be able to modify both the lesson plan and content level according to specific student characteristics (Clemente, 2014; Diziol, 2013; Felijakowski, 2014). Faculty, administrators, designers and practitioners of management education need to develop coherent and reliable assessments of this ITS learning paradigm. Agents can support an adaptive, exploratory learning environment for learning using a multi-layered interface design. Each layer's mechanisms and supportive resources are tailored to facilitate learning for a given situation. Based on a student's background and performance, the agent would select the most appropriate interface layer for that context. For example, if a student is having difficulty mastering a particular subject (e.g., basic statistics) as detected by testing or self-assessment, then the tutor would prescribe specific additional learning content to the student. This content can take the form of videos, computing tutorials, or simulations.

Education-based intelligent tutoring systems should possess the following four basic characteristics: autonomy, pro-activity, adaptability, and sociability. An important feature of an effective tutor is to identify something positive in a student's response (i.e., positive reinforcement). Furthermore, intelligent tutors can be used to identify students at risk and to formulate an appropriate intervention plan for students that are challenged. Specifically, Purdue University's Signals Project has applied analytics to the problem of improving student success within a course and, hence, to improving retention and graduation rates (Pistilli, 2012). This project has led to the development of student success data mining algorithms with intervention messages sent to students based on performance via dashboards. These tools, which often include decision trees, rule induction, and neural networks, can be employed to 1) select student groups with similar characteristics and reactions to learning strategies; 2) detect student misuse and lurking; 3) identify students who, in certain types of test formats, are hint-driven; 4) locate students who exhibit low motivation and find alternate means of reaching them; and 5) predict probable student outcomes (MacFayden, 2010; Shahiri, 2015). The domain variables for data mining usually include previous course grades, class test grades, individual assignment performance, admission exam scores, and team assessments (Baradwaj, 2011).

An integrative education is about blending knowledge and skills from different disciplinary areas; putting knowledge in to practice, considering multiple perspectives to advance collaborative problem solving, adapting the skills learned in one situation to problems encountered in another, reflecting upon connections made over time among academic, co-curricular and pre-professional experiences and across-the-curriculum integration of skills with learning in disciplinary or interdisciplinary settings (Khan, 2015).

The emergence of big data and cloud analysis technologies can be used to develop enhanced ITS, which would assess why students are failing or struggling in a particular course. Typically, students fail or struggle for a variety of reasons including a lack of active participation and inadequate background in the subject material. Intelligent tutors should assess whether the lack of performance is an isolated incident or a reoccurring phenomenon. Big data-driven ITS can be transferred to new student populations, which in turn can be used to provide even more customized learning interventions and educational innovations. In this regard, ITS can adapt to individual differences in both student know-how and level of experience (Baker, 2013, Suhadi, 2016).

Team Tutoring

Student team work has had a long history throughout management education. The empirical evidence suggests that students engaged in team activities (e.g., homework, presentations) exhibit improved learning outcomes (Hsiung, 2012). Many students view their team as a personnel trainer. In this team oriented learning universe, faculty become designers, coordinators, moderators, mediators, and mentors, rather than pure instructors, whereas students assume a proactive role including supporting team activities (Lee, 2015). Students with working group experience tend to be better prepared for placement in the business community (Erenli, 2011).

Teamwork competencies are becoming a vital part of a student's preparation for the global workplace. Identifying specific challenges and describing how students engage offer useful insights. This in turn provides added perspectives into how teaching might further support student learning (Gonzalez, 2014).

The United States military has seen an increase in the use of intelligent tutors, particularly as related to team training (Spain, 2012). The U.S. military's training requirements continue to expand in scope and complexity due to the ongoing introduction of new technology and the changing nature of warfare. In response to these challenges, the military is increasingly relying on an adaptive training paradigm. For example, the United States' Tactical Language and Culture Training Systems assists students to acquire functional skills in foreign languages and cultures in a flexible and timely manner (Johnson, W., 2009). Presented below are some specific military-based team-oriented organizational principles for enhancing the learning process, which can be applied to management education (Soetanto, 2012):

- Obliged to rely on one another to achieve specific goals
- Tasked with doing their share of the group assignment
- Charged with providing one another with feedback and support
- Encouraged to develop and practice trust-building leadership skills
- Motivated to facilitate changes in the team process as conditions warrant

The overall aim of these principles is to enable group members to monitor their progress and that of their peers in performing specific learning exercises. In addition, practitioners of this strategy can utilize intelligent tutors with information about each trainee's problem-solving behavior and group engagement for assessment and instructional purposes (Caballé, 2010). Currently, most military ITS focus on well-defined domains where procedures have explicit steps, ordering, measures, and standards (Sottilare, 2010). Ill-defined domains remain a serious issue in both the military space as well as the business universe. For example, hostage negotiations can be considered "ill-defined" since there could be several successful outcomes based on various strategies. One potential approach to overcome these obstacles is to combine team-based simulations with intelligent agents. Team-based business simulations, which are used extensively throughout the management education community, tend to provide limited external guidance while intelligent tutors usually require a structured knowledge domain. However, combining these two pedological platforms where agents provide advice, based on game conditions, to each team over the course of the simulation could prove to be extremely useful from a team learning perspective, particularly in business simulations involving multi-targets (e.g., market share, stock price).

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

In some instances, multi-agents can be used where each agent learns from other agents, which will help improve the overall consulting tasks (Jumadinova, 2014). This combination approach is illustrative of the experiential learning process, which is receiving increased attention throughout schools of business.

Experiential learning is an interdisciplinary approach based on management, education and psychology. It is particularly powerful in connection with management education as it is perceived to be effective in support of training and education in fields as diverse as talent management, leadership performance, competence development, change management, community involvement, volunteering, cross-cultural training and entrepreneurship (Bevan, 2012).

MANAGEMENT EDUCATION ITS EXAMPLES

The previously cited two meta-studies contained a paucity of business management courses. Another meta-study on ITS, which was limited to secondary students not enrolled in a professional program, reported an effect size, using Hedges's g, of a modest 0.26 for three business related subjects (Steenbergen-Hu, 2014). To be clear, many of the reports included in the meta-study were over ten years old, which obviously does not reflect the current state-of-the art in ITS technology. Some additional insights into the efficacy of ITS as pertains to specific business management courses is presented in Table 1. Unlike other educational sectors, the number of studies that have assessed the impact of ITS within the management education universe remains somewhat sparse. The first example was extracted from the first cited meta-study (Phillips, 2011). In this case, both groups received support beyond the traditional textbook and lecture modalities. The resultant effect size of 0.32 suggests a small to moderate impact. However, had the control group only received the traditional instructional support the effect mostly likely would have been somewhat larger. The next study investigated how enforcing the prerequisites impacted course outcomes in intermediate accounting. The prerequisites were enforced using a proficiency test administered online in a system that also offered tutoring to remedy any learning shortfalls, this study reported an effect size of 0.30 (Sargent, 2013). The application of an ITS in an information technology course revealed an effective size of 0.50 (Wang, 2014). The results indicated even larger performance improvement for those students with low-levels of prior subject knowledge. The next example involved an operations management course where the experimental student group was exposed to a series of tutorial videos (Winch, 2015). The resultant effect size was a moderate 0.66. In the supply chain management (SCM) course, the authors noted that the simulation-based, intelligent tutoring system, yielded an effect size of 0.78 (Bhuiyan, 2015). In this ITS application, a survey of both groups was conducted after completing the course. The survey results indicated that students participating in the simulation reported statistically higher levels of confidence and satisfaction than those that did not use the ITS. The use of an ITS in an introductory management course revealed a modest effect size of 0.37. Perhaps more significant was that those students exhibiting a minimal understanding of the material covered in the class at the pre-test phase showed the most improvement after utilizing the ITS (Stonebraker, 2016). The next example exhibited an ITS that offered an adaptive learning strategy in a database design course that selected the type of subsequent task based on the level of assistance the student received in previous problems (Najar, 2016). The results indicated that students using the ITS learned significantly more than their peers who were exposed with a fixed sequence of problem sets ($d = 0.58$). The last example

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 1. Selected ITS business course examples

Discipline	Effect Size[1]
Financial Accounting (Phillips,2011)	0.32
Intermediate Accounting (Sargent, 2013)	0.30
Information Technology (Wang, 2014)	0.53
Operations Management (Winch, 2015)	0.66
Supply Chain Management (Bhuiyan, 2015)	0.78
Introductory Management (Stonebraker, 2016)	0.63[2]
Database Design (Najar, 2016)	0.58
Project Management (González-Marcos, 2016)	0.67

[1]Cohen's d was used in these examples, because Hedges's g was not reported in all cases.
[2]Effect size from the one significant experimental group.

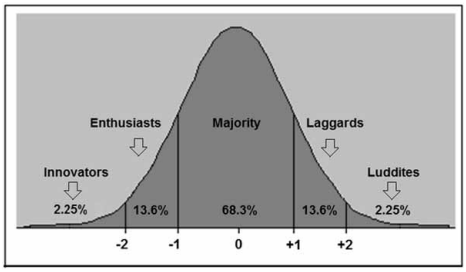
featured a course in project management experimental group where the experimental student group had access to an ITS-based Project Management Information System (González-Marcos, 2016). The resultant Cohen's d of 0.67 was based on final grade scores.

The overall performance improvements reported in Table 1 are consistent with the outcomes delineated in the previously reference meta-studies. The general upward trend in effect size over time does suggest that the one-sigma goal of mastery learning is within reach. However, the lack of standardized assessment methods and small to modest sample sizes makes assessment comparisons somewhat challenging. Furthermore, some uses of ITS within a program of management education have not result in improved learning performance results (Hahn, 2013). This case was very similar in design and content to the first example given in Table 1. The lack of consistent assessment methodologies is one area that is ripe for future research. In contrast, a completely different set of performance outcomes was reported in a fourth ITS meta-study (VanLehn, 2011). The analysis revealed an effect size of 0.76 for ITS and a corresponding effect size of a mere 0.79 for human tutoring (Cohen's d). Clearly, if these observations stand the implications on both further research and system implementation are significant. To this end, one of the significant problems in evaluating ITS performance is establishing and using a consistent definition of content mastery and standardized assessments, e.g., 90 percent.

Students must understand and use learning targets, set their own learning goals, select effective learning strategies, and assess their own learning progress. And as students develop into more confident and competent learners, they become motivated (energized) to learn, increasingly able to persist during demanding tasks and to regulate their own effort and actions when they tackle new learning challenges (Hills, 2015).

IMPLEMENTATION STRATEGIES

The rate at which technology is adopted in organizations varies considerably. The Rogers' diffusion of technological innovation model, which was first used for predicting the introduction rate of hybrid corn seed, provides a helpful paradigm for better understanding the adoption process (Rogers, 2003). Apply-



EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

ing Rogers' model to academia suggests that a significant proportion of faculty tend to react slowly in embracing technological innovation (Fathema, 2015; Sahin, 2006). Figure 2 depicts a slight variation to the basic Rogers' adoption distribution model. This format incorporates a fifth category – Luddites. In a commercial setting the ultimate incorporation of new technologies throughout the organization, for the most part, centers on economics. In academia, this is not always the case. There are some faculty members who most likely will not adopt new learning technologies no matter the nature of the incentives and disincentives and, in fact, may erect road blocks just as their namesakes did some 200 plus years ago. This reality is the primary reason for adding the Luddite category. The Rogers' model is based on the Empirical Rule gleaned from statistics. The Empirical Rules states that approximately 68 percent of the population resides within ± one standard deviation from the mean, while 95.5 percent are contained within ± two standard deviations. Figure 2 shows less than 16 percent of the faculty can be regarded as innovators or enthusiasts during the early phase of new technology adoption. Innovators and early adopters tend to embrace new learning modalities based on their own initiative and technical background without the need for significant institutional support. The emergence of ITS may provide sufficient motivation for these two groups to embrace this technology. Clearly, this percentage does not represent a critical mass. According to Rogers, the majority, which constitutes a little over two-thirds of the population, will begin to embrace new technology only after some period of consideration. This can present a problem with the speed at which new educational technology is being introduced (Rajasingham, 2011).

In general, adoption will significantly increase if the majority are recognized as a distinct group within the community and are made a part of the planning and policy making process. A technological innovation, such as ITS, must be demonstrated as both an effective and easily applied solution to a specific learning need. The motivation for the majority to adopt new learning technologies may not be the same across disciplines. Innovation by laggards is more likely to occur through ongoing majority involvement and continued administrative support in the form of incentives. Laggards will adopt only if they are certain that it will not fail and that there will be no negative consequences to themselves (e.g., negative student evaluations). The luddite segment, as the name implies, can be the source of potentially significant disruptions in the overall adoption process.

User based agents significantly help reduce the administration duties of the course and focus on responding to users' questions or preparing training materials. The agents have been used in many areas of learning. Yet, there remains a myriad of contexts where agents can be incorporated to make learning more efficient and fundamentally change the way education is being delivered (Jawahar, 2015).

Figure 2. Modified Rogers' adoption distribution model

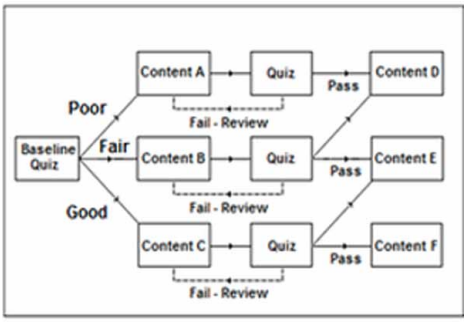
EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

One way to address these adoption concerns in an educational setting is to employ systems that are easy to use, that minimize potential problems, and that yield early success. In this regard, two promising ITS implementing vehicles are learning management system (LMS) based conditional release technologies and standalone authoring design tools. Typically, both of these approaches utilize an inner and outer loop format. The function of the inner loop is to execute the steps associated with the task at hand (e.g., taking a quiz). The inner loop can provide feedback and hints at each step. The inner loop also assesses the student's competence in terms of task performance, which is used by the outer loop to select the next task that is appropriate for the student, e.g., return to review the current material or advance to new more challenging material. Additional loops can be added (Niraula, 2015). However, both system complexity and implementation problems will dramatically increase.

Conditional Release Technologies (CRT)

Conditional release technologies (CRT) incorporated within an LMS provide a specific vehicle for offering students a wide variety of learning options based on progressively delivered, customized content (Li, 2015; Gardner, 2011). CRT can be defined as data-driven algorithms that release content based on student performance and characteristics. It is generally recognized that students entering a program of management education possess a wide range of experiences and capabilities, CRT allows customization of content based upon such differences. Three of the most significant advantages of integrating the ITS based CRT inside the LMS are: 1) ease of implementation, 2) maintenance of student performance records over the course and beyond, and 3) flexibility in providing customized content to meet the needs of a wide portfolio of management education programs. CRT offer the capability to assist students in overcoming specific learning challenges by assessing their performance and providing customized content.

The same technology that supports learning activities can also gather data that can be used for assessment. As students work, the system can capture their inputs and collect evidence of their problem-solving sequences (Bienkowski, 2012).



In this regard, students tend to participate more in learning systems that are content rich and that feature a wide variety of delivery modes, which is a hallmark of conditional release technologies. Recent research on the use of CRTs revealed that students (Fisher 2014):

- Recognized that videos provided the highest degree of choice since they can select which segments to watch at their convenience
- Selected tutorials that gave them the highest level of bandwidth and engagement without technological interference or latency
- Noted that on-line quizzes were the most challenging activity
- Expressed more interested in tutors that were based on their level of technological readiness

Figure 3 depicts a simplified CRT structure. In this application setting the student takes a baseline quiz to determine the appropriate content level based on test performance. Based on the initial baseline quiz results specific content is then presented. After reviewing the web-based content the student is presented with a quiz. If the student passes the quiz a new learning module is displayed, otherwise, the student is directed back to the previous material for further review or given additional supplemental

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 3. CRT design schematic

materials based on the quiz results. In some applications, additional review material can be provided via a variety of delivery modes, e.g., videos, interactive games, slideshow. This process can be further refined by including the student's prior background with the subject material and specific characteristics. While quizzes represent an important and easily implemented performance rubric they can also be augmented by discipline based simulations as conditions warrant. Figure 3 also illustrates incorporation of the two loops in the ITS. In this example, the quiz represents the inner loop while returning the student to the recently review content or providing the student with new content highlights the outer loop. One approach for incorporating additional information, beyond mere quiz scores, into the ITS is through the use of data mining models (Raju, 2016). For example, Bayesian networks can provide enhanced accuracy in the diagnostic of student' knowledge possession (Ramírez-Noriega, 2017). The Bayesian network is continuously updated as additional information about the student's interaction with the ITS is gleaned. These revised probabilities offer further insights into student learning behavior, which in turn allows for the identification of more effective learning content.

Authoring Tools

Authoring tools represent another approach for developing and deploying ITS. These systems have been shown to decrease the amount of time and resources needed for the development of intelligent tutoring systems (Adetokunbo, 2014). Typically, the tutor designer has two classic options: acquire the authoring systems or obtain an already existing tutoring system that can then be modified to meet the specific needs of the learning application. An authoring system, which are usually designed for non-programmers, is a software package that provides the capability to create courseware, multimedia applications, and the corresponding navigational appliances. Authoring tools provide the course designer with more flexibility and thus more creativity than the traditional CRT approach. This capability allows the designer to incorporate more complex and dynamic learning alternatives. Presented in the following are some specific attributes associated with an effective authoring system (Brawner, 2012; Koedinger, 2012).

- Supports the development of cognitive-based, example-tracing, and collaboration tutors
- Accommodates a wide range of application and technical domains
- Incorporates a dynamic and varied learning environment
- Utilizes the latest empirical evidence and learning techniques
- Skeptical of the student's level of understanding

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Rule-based cognitive tutors are designed to capture how students perceive, think, acquire knowledge, and solve problems and are being increasingly used throughout higher education as reported earlier. Example-tracing tutors assess learning performance by comparing student responses against examples of correct and incorrect responses. Typically, this class of tutors provide step-by step guidance on complex problems and situations, such as business cases, and tend to be less costly to develop than rule based systems (Aleven, 2016). Collaborative authoring tools represent a natural and important extension to the classical ITS in the sense that it provides for multiple user assessments (Olsen, 2014). To author a collaborative tutor each of the steps to create an individual tutor are followed for each member of the collaboration. Depending on the type of collaboration activities and roles depends on if different tutor interfaces and behavior graphs need to be made for each student in the group or if the same files can be used.

While the goal of this article is not to evaluate authoring tools, Table 2 lists of some of the better-known development systems. This list is by no means comprehensive. Furthermore, as mentioned earlier, it may be more cost-effective to acquire an existing ITS application than develop one using one or more of these tools.

Illustrative Business Course ITS Example

The Accounting Education Change Commission (AECC), among other bodies, has been active in calling for the incorporation of both innovative teaching as well as active learning paradigms into accounting courses (Larsen, 2014). Accounting principles courses, in particular, are well suited to an ITS learning environment, because they tend to be highly rule-based. To illustrate the use of an authoring tool based ITS, consider the following learning objectives for an entry-level accounting principles course:

- Prepare and analyze an income statement, balance sheet, and statement of cash flow.
- Evaluate the annual report of a public company.
- Assess emerging issues such as revenue recognition and restructuring costs.
- Appreciate the ethical, global and regulatory issues of accounting.
- Understand and use the information technology of accounting.

The ITS can be used to identify and deliver the most effective web-based resources to as illustrated in Table 3.

Table 2. Selected ITS authoring tools

System	Source
Situated Pedagogical Authoring (SPA)	University of Southern California
Cognitive Tutor Authoring Tools (CTAT)	Carnegie-Mellon University
Extensible Problem Specific Tutor (PST)	Iowa State University
Authoring Software Platform (ASPIRE)	University of Canterbury (NZ)
AutoTutor Script Authoring Tools (ASAT)	University of Memphis
Generalized Intelligent Framework for Tutoring (GIFT)	US Army Research Lab.

Table 3. Example delivery modes

Topic	Content Delivery Mode
Income Statement	Computing Template
Annual Report	PowerPoint Presentation
Net Present Value (NPV)	Consultation
Ethics	Simulation
Information Technology	Streaming Video

Figure 4. Illustrative authoring tool format (NPV Example)

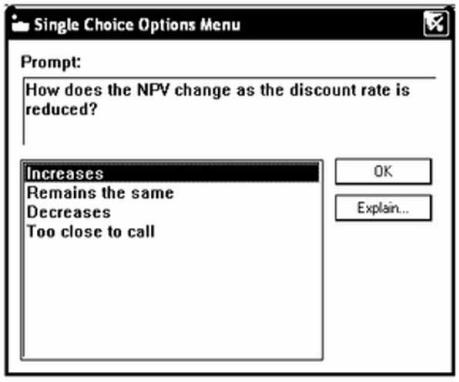

Figure 4 shows a sample consultation for a net present value learning application, which was developed using an authoring tool. In this example application, the student is guided through a series of prompts regarding the case and explanations are provided for each prompt. The consultation can be taken more than once since, among other things, many of the prompts are randomized. The use of this expert system is not limited to entering students requiring preparatory work but can also be used as a refresher by continuing students. For example, a student that is struggling with the notion of net present value (NPV) would be directed to a consultative system that outlines the basic NPV process and that provides more specific content.

Implementation Guidelines

Presented in the following are some guiding principles for implementing ITS in support of management education (Blas, 2014; Brew, 2014; Starke-Meyerring, 2008):

- **Early success**: Learning innovations, like intelligent tutors, are most likely to be accepted and used by the majority of management educators if success is experienced early on. Early on success extends to the peer network, both within and outside the institution, thereby magnifying the impact on adoption and diffusion.
- **On-going peer support**: Live and virtual peer support not only serves as a repository of encouragement; but also contributes diffusion throughout an educational community.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

- **Real learning activities**: Initiatives designed to introduce and use ITS should address real activities and requirements. Furthermore, they should support adaptive learning strategies based on students' responses and backgrounds.
- Using intelligent tutors to access to information and resources can address many of today's management educational challenges and requirements.
- **Design philosophy**: Intelligent tutors are fit for purpose. The purpose determines how the tutors are structured and used.
- **Multi-user collaborations**: Intelligent tutors should support collaborative learning environment which improves student and team opportunities and outcomes.

To reap the full potential of integrating ITS throughout management education universe, the design must be more than simply "attaching" a series of standalone tutors to the curriculum. Generally, the program/course structure must be redesigned to provide a seamless transition between face-to-face learning and the ITS. Some specific administrative implementation tasks include: 1) training faculty for successful system deployment and usage, 2) providing high quality and consistent system access, 3) setting specific performance goals and metrics, 4) preparing students for entry and ongoing use, 5) sustaining system operation, and 6) establishing and maintaining the overall culture (Denton, 2013; Duff, 2014.). An internalized only approach may not take advantage of the ongoing developments in technology. Developing institutional partners represents one possible strategy that helps overcome some of these issues. The current state-of-the-art in ITS technology will continue to improve and learning applications, some of which are at the present time unknown, will continue to unfold. For example, the recent partnership between IBM-Watson and Pearson Publishing, which is designed to apply artificial intelligence to enhancing the education learning process (Luckin, 2016).

The ultimate goal of the field of artificial intelligence in education (AIED) is not to promote artificial intelligence, but to promote education. The leading systems in AIED seem to represent a different paradigm than the classic paradigm of intelligent tutoring systems (Baker, 2016).

CONCLUSION

The management education community is engaged in significant programmatic reforms in light of the business community's call for web-savvy, problem solving graduates. Today the demands from a globalized economy are causing a sea change in the way business education is being delivered. The traditional one-size-fits-all educational approach of the past is being replaced with a customized and flexible learning paradigm that focuses on student outcomes and performance. Web-based intelligent tutoring systems provide a readily accessible vehicle for enhancing business students' learning performance as well as preparing them for the rigors of the global marketplace. To support these goals, intelligent tutors should be designed to perform three basic functions: 1) perception of the dynamic conditions in the learning environment, 2) formulation of problem solving actions, and 3) implementation of the identified actions. Furthermore, they need to exhibit both a user-friendly and adaptive format as a vehicle for enhancing student learning outcomes.

The empirical evidence to date suggests that ITS performance, in the management education universe, is approaching the one-sigma standard (i.e., mastery learning). However, Bloom's two-sigma goal still remains elusive. Moreover, the actual use of ITS on a wide scale basis throughout the community of practice is still in an incipient stage. This should not be surprising since the rate at which technology is adopted in organizations varies considerably. The Rogers' diffusion of technological innovation model provides a helpful paradigm for better understanding the adoption process in business management. Applying Rogers' model to academia suggests that a significant proportion of faculty tend to react slowly in embracing technological innovation. Rogers' model suggests that less than 20 percent of the faculty can be regarded as innovators or enthusiasts during the early phase of any new technology adoption, such as intelligent tutoring systems. Some specific research areas to help accelerate the ITS adoption process include improving the effectiveness of authoring tools to reduce development costs and time, enhancing ITS assessment methodologies to provide improved consistency, reducing students and student teams cognitive overload, and enriching adaptation methodologies with a focus on student learning behaviors.

Chapter 16
A User-Aware and Semantic Approach for Enterprise Search

Giacomo Cabri
University of Modena and Reggio Emilia, Italy

Riccardo Martoglia
University of Modena and Reggio Emilia, Italy

ABSTRACT

This article describes how in addition to general purposes search engines, specialized search engines have appeared and have gained their part of the market. An enterprise search engine enables the search inside the enterprise information, mainly web pages but also other kinds of documents; the search is performed by people inside the enterprise or by customers. This article proposes an enterprise search engine called AMBIT[1]-SE that relies on two enhancements: first, it is user-aware in the sense that it takes into consideration the profile of the users that perform the query; second, it exploits semantic techniques to consider not only exact matches but also synonyms and related terms. It performs two main activities: (1) information processing to analyse the documents and build the user profile and (2) search and retrieval to search for information that matches user's query and profile. An experimental evaluation of the proposed approach is performed on different real websites, showing its benefits over other well-established approaches.

INTRODUCTION

Enterprises produce and rely on a large amount of information. A small part of information is available by public web sites, while the most part is exploited by employees of the enterprise itself by means of intranet, and by customers of the enterprise who have access to some information for business purposes.

In this scenario, the capability of searching for needed information plays a fundamental role. On the one hand, enabling internal employees to find the needed information in a short time is not only useful to speed up their work, but also to avoid or decrease the frustration of long and unsuccessful searches. On the other hand, precise and relevant answers to customers that exploit the company web sites for both searching and interacting can grant a high degree of customer satisfaction.

In this scenario, the authors point out two aspects that can improve the use of search engines in an enterprise context by providing more relevant search results: user-awareness and semantics. Existing studies and surveys in general information management contexts have highlighted the benefits that can be brought to search results by the former (Xiang et al., 2010) and latter (Mangold, 2007). User-awareness means to exploit the knowledge of the user in terms of profile and context to effectively tailor the search on the base of the available information. Semantics can be useful to overcome the limitations of a syntactic approach, which is often exploited but does not consider similar pieces of information expressed in different ways. As far as the authors know, there are no enterprise search engines that exploit both aspects in a single approach.

Starting from the above considerations, the general semantic foundations introduced in (Martoglia, 2015) are exploited to proceed towards the goal of achieving a user-aware semantic enterprise search engine. The search engine is called AMBIT-SE (AMBIT Search Engine). It is not a generic search engine, but a search engine dedicated to searches in an enterprise scenario. The AMBIT-SE approach improves search results by:

- Taking advantage of textual information, including user information. Indeed, text is the primary component of the documents that should be presented / suggested to users, and also one of the main information characterizing user profiles. Consider, for instance, the contents of user browsing history, the description of users' interests, and so on;
- Exploiting semantic techniques: instead of a pure syntactic matching between the query keywords and the words in the available documents, it relies on their meaning and takes into account synonyms and related terms.

The approach presented in this paper brings the following novel contributions with regard to the initial idea of an enterprise search engine sketched in (Cabri, 2016) and to the state of the art:

- Differently from the state of the art on available enterprise search engines, it is able to combine semantics and user-awareness without requiring any manual work (e.g. for annotating documents, describing user profiles, etc.). Novel semantic and user-aware techniques allow the engine to go beyond standard syntactic search in a completely automatic way;
- The semantic text analysis techniques are adapted and refined from previous authors' studies on the effectiveness of semantic text management in specific subject areas such as software engineering (Bergamaschi et al., 2015; Martoglia, 2011), agricultural (Beneventano et al., 2016) and user-centric cultural enhancement data (Martoglia, 2015). In the presented approach, the techniques are generalized to work in a non-specialized enterprise search setting with general purpose ontologies and new weighting schemes, allowing them to be directly compared to the new class similarity contribution;
- The strength of the semantic text analysis contribution is added to the new contribution given by semantic categorization. Categorization classifies documents on the basis of a well-known taxonomy (defined by IPTC[2]) in order to provide improvements in the retrieval effectiveness. To this end, a novel class similarity metric is introduced, with a weighting scheme exploiting the novel concept of inverse (document) class frequency;

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

- A novel ranking selection/fusion technique is employed, producing a final document ranking which: (1) reflects both the query and user profile in a flexible and customizable proportion; (b2 fuses both class and text similarity contributions in the case they are judged as significant; (3) otherwise, it is able to automatically exclude one of the two contributions from the final result.

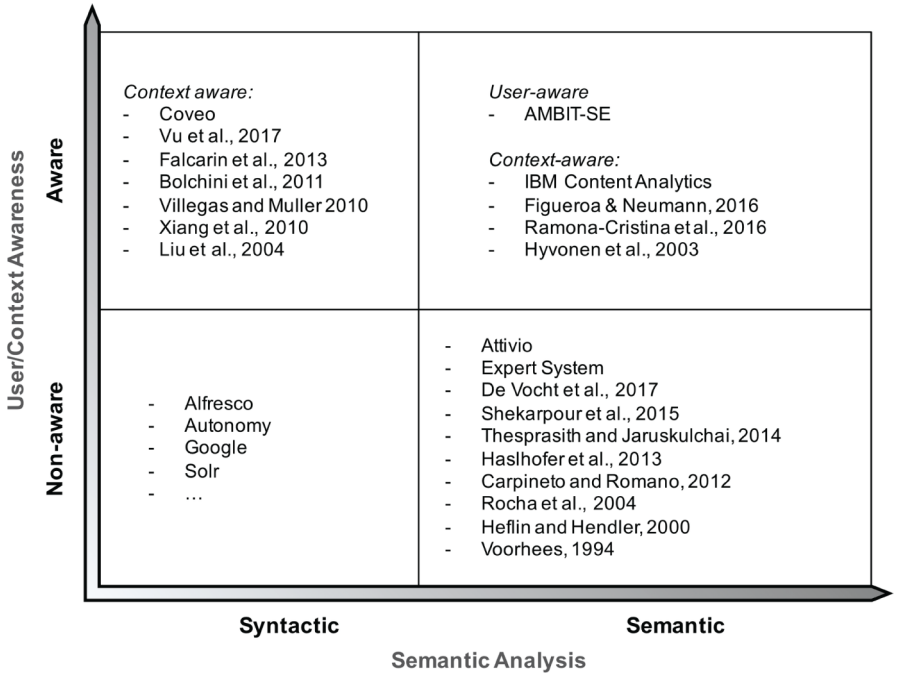
The combined text analysis, user-aware and semantic retrieval techniques ultimately provide enhanced searching effectiveness over standard search techniques, as also shown in the experimental tests. Moreover, the approach is devised for IT Small and Medium-sized Enterprises (SMEs), providing them with easy-to-apply methods that allow them to query for the information they need in the way they are used to.

This paper is organized as follows. First, a related work analysis is presented (Section "Related Work"). Then, Section "Search Engine Architecture" describes the architecture of the proposed search engine. Section "Information Processing" explains how the presented approach processes the documents that can be "searchable" by the users. Section "Search and Retrieval" illustrates how the system defines a ranking of retrieved documents to satisfy the user's query. Finally, the results of the experiments carried out on the system are reported, before the conclusions (Section "Conclusions"), in Section "Experimental Evaluation".

RELATED WORK

This section presents a review of the existing approaches related to user-aware semantic enterprise search engines. The authors have considered both academic and commercial approaches, and have classified them on the base of two aspects: the user-awareness and the semantics; the resulting taxonomy is reported in Figure 1.

Most of the approaches do not consider together these aspects and/or cannot be classified as enterprise search engines. For these reasons, related work will be presented in three separate subsections: semantic approaches, user-aware approaches and enterprise search engines.



Semantic Approaches

The Semantic Web is likely to be the field where most of the approaches for semantic document retrieval has been proposed, as reported in (Mangold, 2007). It is a survey which covers approaches that exploit domain knowledge to process search requests. The authors discuss a large variety of domain knowledge utilization that include automatic query expansion and ontology-driven document retrieval.

The possible ineffectiveness of information retrieval systems is mainly due to the inaccuracy with which a query formed by a few keywords models the actual user information need. One well known method to solve this problem is automatic query expansion, whereby the user's original query is augmented by new features with a similar meaning (Carpineto & Romano, 2012). Differently from the approach presented in this paper, complex query expansion techniques, such as the ones discussed, usually require different parameters to be specified (as also stated in (Abdou & Savoy, 2008)). For instance, the method proposed in (Voorhees, 1994) involves a set of parameters specifying for each run and for each relation type included in the ontology the maximum length of a chain of that type of link that may be followed. Generally, there is no single theory capable of finding the most appropriate values (Abdou & Savoy, 2008) and therefore a long process of manual tuning is needed.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. Taxonomy of user-aware semantic approaches

More and more document retrieval systems make use of ontologies to help users better specify their information needs and produce semantic representations of documents. (Haslhofer et al., 2013) proposes a Simple Knowledge Organization System (SKOS) based term expansion and scoring technique that leverages labels and semantic relationships of SKOS concept definitions. The Hybrid spreading activation approach (Rocha et al., 2004) requires tight coupling between the document base and the ontology, which is a graph where concepts and properties are nodes and edges, respectively. The set of nodes that match the given query terms is used as the start nodes of a spreading activation algorithm: documents with highest activation are ranked highest in the result set. Differently from the presented approach, the mentioned systems have no notion of user context.

Given the need for manual intervention, typical semantic retrieval techniques obtain a good degree of effectiveness only on manually annotated collections and/or with explicit user intervention. (Savoy, 2005) compare the retrieval effectiveness of different search models in a bibliographic database context. These models are founded on automatic syntactic text-word indexing or on manually assigned controlled descriptors. (Thesprasith & Jaruskulchai, 2014) proposes a query expansion technique working on MEDLINE documents that have been manually assigned to controlled MeSH (Medical Subject Headings) vocabularies. The indexing and retrieval approach proposed by AMBIT-SE, instead, exploits the semantics of the text while remaining completely automatic.

(De Vocht et al., 2017) presents a semantic search engine focusing in particular on integration of different sources of data in the science research field. To increase the precision of the results, the authors annotated and interlinked structured research data with ontologies from various repositories exploiting a semantic model. That approach does not consider user-awareness and requires annotation.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

(Figueroa & Neumann, 2016) focuses on the search in the context of Community question answering (cQA) platforms. It induces the semantic classes of question-like search queries by means of the contextual information. Context is set up or represented by inferred views of their respective search sessions, namely views modelling previous queries entered by the same user. The idea of introducing semantic classes and of combining them with contextual information is very interesting, but in that work is limited to a specific field (cQA).

SINA (Shekarpour et al., 2015) is a scalable keyword search system that can answer user queries by transforming user-supplied keywords or natural-languages queries into conjunctive SPARQL queries over a set of interlinked data sources. In this case, differently from the scenario considered in this paper, data are expressed in graph format. The system exploits semantics to improve search over different data sources, but does not take into consideration user information to refine queries.

User-Aware Approaches

The advantages of taking into consideration the context has been point out several times in the literature (Bolchini et al., 2011; Cabri et al., 2003; Falcarin et al., 2013; Xiang et al., 2010; Vu et al., 2017). In particular, a few works concern context modelling, representation, and effective handling. For instance, (Bolchini et al., 2011) proposes to design a context management system which is not application-dependent, (Falcarin et al., 2013) proposes an architectural framework for context data management, while (Villegas & Müller 2010) reports the result of a study on various context modelling and management approaches. (Xiang et al., 2010) addresses the problem of integrating context information into a ranking model. (Liu et al., 2004) proposes a method to derive a user profile based on the search history and on pre-determined category hierarchies. (Vu et al., 2017) proposes a personalised query suggestion framework for Intranet search, relying on two temporal user profiles.

Most of these approaches primarily focus on specific aspects such as external conditions or location, they do not consider the semantics of the context and/or they rely on manual work in order to classify and categorize users and documents. General purpose search engines, such as Google, typically provide only very simple localization of search results on the base of the IP-address.

Enterprise Search Engines

Many enterprise search engines have been proposed in the literature or are sold by companies. Most of the proposals do not provide an ontology-based semantic analysis, relying instead on syntactic and hand-coded rules. Some examples are Alfresco[3], Autonomy[4], Solr[5]. Google[6] is also an example of a syntactic search engine that can be exploited in a enterprise search context.

There are, of course, exceptions to this rule. The SHOE project (Heflin & Hendler, 2000), which requires a domain-ontology where document types correspond to ontology concepts. Attivio[7], a product which manages information in the RDF format, providing search results and alerts. Expert System's Cogito[8], which provides automated disambiguation, classification, entity extraction, and metadata. Nevertheless, these systems provide no notion of user context. Instead, Coveo[9] is a tool specifically oriented to exploit contextual knowledge for dealing with information related to customers and agents, but it does not exploit semantic information.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Considering the semantic and context information, there are few systems that exploit it, even if in a sometimes-limited way. The Ontogator system (Hyvonen et al., 2003), part of an image management and retrieval system, provides an interactive recommendation system that allows the user to browse images based on ontological properties. To exploit user contexts, it introduces views to the ontology that rely on different concept hierarchies, called "facets". Each view represents a specific information-need. PrEmISES, proposed in (Ramona-Cristina et al., 2016), is a framework that aims at addressing information management needs of SMEs relying on ontologies to add semantically enabled information integration. The framework definition is still in a very preliminary phase; therefore, semantic and context-sensitive features are currently only sketched. Another example is IBM's Content Analytics with Enterprise Search[10], which exploits a framework called Unstructured Information Management Architecture (UIMA), in order to build analytic applications and to find meanings, relationships and relevant facts hidden in unstructured text. Context information is provided by means of manual annotations. These approaches require manual intervention on the documents and/or adopt a still limited notion of context, i.e. they do not exploit all of the data potentially available related to the user, such as the contents of any web page visited, attachment downloaded, and similar documents.

DISCUSSION

The authors have reported several researches that are connected to the approach presented in this paper. They point out that there is no existing approach that addresses all the following aspects at the same time:

- **Semantics:** Exploitation of semantic techniques to improve the results of the query;
- **User-awareness:** Exploitation of user information to customize the results of the queries;
- **Generality:** Capability of being applied to general sources of information, not to a specific field;
- **Automation:** No need for manual annotation of the information.

Starting from the above analysis, the AMBIT-SE approach aims at addressing all the above-mentioned aspects. In the next section, the architecture of AMBIT-SE is presented.

SEARCH ENGINE ARCHITECTURE

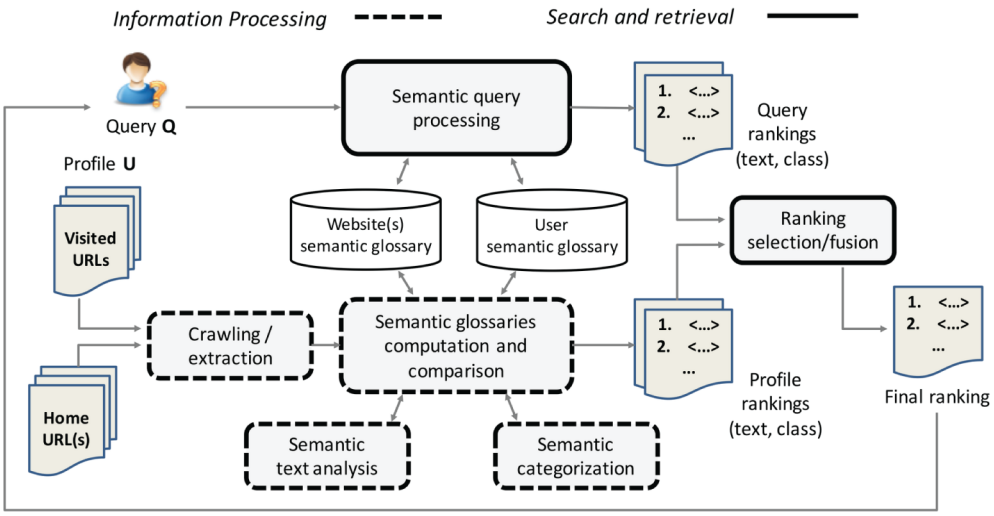
Figure 2 shows the architecture of the proposed search engine, the main activities and the related modules. In (Cabri et al., 2016) the authors tackled in detail many text pre-processing issues such crawling techniques, paragraph identification and text tagging. In this paper, the focus is on defining the semantic text analysis and the novel semantic categorization techniques (described in Section "Information Processing") The general architecture is also significantly extended in order to manage the output of both kinds of techniques and to exploit it in the actual search (Section "Search and Retrieval"). The architecture highlights two main activities:

1. **Information processing (dashed line in figure):** This activity is applied to both the documents to be retrieved (e.g. web pages for a given site) and the documents useful to determine the user's profile (such as e-mails, web pages viewed, profile information, past search queries, etc.). The avail-

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

able information is extracted (crawled) and indexed by means of ad-hoc techniques, also exploiting external knowledge sources. The data structures containing all the information processing results will be referred to as "semantic glossaries", one for the website(s) and one for the user profile. Both glossaries are then compared ("Semantic glossaries computation and comparison" in the figure) with ad-hoc document similarity algorithms, detailed in Section "Search and Retrieval". The generated "Profile rankings" symbolize how relevant the retrievable documents are in relation to the user's profile;

2. **Search and retrieval (solid line in figure):** This activity provides useful answers to the user by retrieving the most relevant documents with regard to the user query, also taking into account its pre-computed profile information. This is achieved ("Semantic query processing") by determining the "Query rankings" of the query with regard to the available documents (semantic similarity discussed in Section "Search and Retrieval"). Query rankings are finally fused with profile rankings in order to provide the final ranking.



These two main activities are detailed in the next two sections.

INFORMATION PROCESSING

Information processing is common to both the documents of the website(s) to be indexed and the user profile documents. Each of them will contribute to a semantic glossary structure containing the results of the analysis.

The first step of the information processing is crawling: web/file crawling is performed in order to retrieve the raw data (e.g., Title, Content, URL, File Name, Meta Description, Meta Keywords) of the documents that will be further analysed by the subsequent steps. All of the crawling operations are handled by the open-source enterprise-class search engine software, OpenSearchServer[11].

Figure 2. An overview of the AMBIT-SE architecture

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Semantic Text Analysis

As single existing tools do not allow sufficient configuration and extension options, the authors designed a customized Semantic text analysis module, which exploits several open source libraries to perform specific actions. The analyser allows us to extract the contents (and meanings) of the processed information, by means of:

- Text extraction, an operation that can vary greatly depending on the format of each document; this is taken care of by components of the open-source software GATE[12];
- Tokenization, the terms are identified and punctuation is removed;
- Stemming and Part of Speech (POS) Tagging, the tokens are "normalized" and "stemmed", i.e., they are reduced to their base form (managing plurals and inflections) and "tagged" with POS tags (i.e., nouns, verbs, etc.); this is taken care of by the TreeTagger[13] library;
- Composite term identification, possible composite terms (such as "production area" or "wine tasting") are identified by means of a simple state machine and of POS tags information;
- Word Sense Disambiguation (WSD), the meaning of the keywords resulting from the previous steps is made explicit with regard to a reference thesaurus (typically, WordNet[14], (Miller, 1995)); in particular, the relevant synsets are extracted and associated;
- Weight computation, keywords are finally enriched with weight information (see below).

The extracted information enables the retrieval of the most relevant information for the user in the search and retrieval phase. In particular, the proposed approach exploites the semantic information from the thesaurus and the similarity functions described in Section "Search and Retrieval". Thanks to them, AMBIT-SE will be able to retrieve documents on the basis of synonyms and related keywords; for instance, documents about "dogs" are considered as relevant to a query about a "terrier". Moreover, by means of WSD, documents about a "pet" in the sense of "domesticated animal" will not be mixed up with those where "pet" means "a special loved one".

For the weight information, text analysis exploits a variant of the standard "tf-idf" weighting scheme. This is introduced to convey the information of the classic scheme while also keeping the weights normalized in the range of [0,1]: this enables an effective ranking comparison and fusion (more on this in Section "Search and Retrieval"). Given a document D^x, each keyword $k_i^x \in D^x$ is assigned a *keyword weight* kw_i^x defined as:

$$kw_i^x = \overline{kf}_i^x \cdot \overline{idf}_i \tag{1}$$

where:

$$\overline{kf}_i^x = \frac{f_i^x}{\max_l f_l^x} \tag{2}$$

$$\overline{idf}_i = log\left(\frac{N}{n_i}\right) / max_l\left(log\left(\frac{N}{n_l}\right)\right) \tag{3}$$

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

$\overline{kf}$ and $\overline{idf}$ are normalized keyword frequency and inverse document frequency: f_i^x is the raw frequency of keyword k_i in document D^x, N is the total number of indexed documents and n_i the number of documents where keyword k_i appears. Note that, by definition, $0 \leq \overline{kf}_i^x \leq 1$ and $0 \leq \overline{idf}_i \leq 1$.

Semantic Categorization

Besides semantic text analysis, a semantic categorization process is also applied to the documents in order to tag each document with appropriate subject classes. The Media Topic NewsCodes taxonomies and vocabularies provided by IPTC are adopted. These are well-known taxonomies offering a very good level of detail and coverage of a wide range of topics. In this case, the starting point is the output of ad-hoc categorization tools from Expert System[15], where each class tag is given a score $s(c_i)$, $0 \leq s(c_i) \leq 1$; the higher the weight the more relevant the class is for the document. For instance, a document about the typical "Terrier food products" will presumably have "Pet product and service" among its highest scoring associated tags. However, the authors deem that if most of the documents of the collection are tagged with the same class, this class will not be particularly distinctive and useful in the retrieval phase. Therefore, this fact is captured by going beyond the plain score and by defining a new weighting scheme for the classes inspired by the text analysis scheme (Equation 1): given a document D^x, each class tag $c_i^x \in D^x$ is assigned a class weight cw_i^x defined as:

$$cw_i^x = s\left(c_i^x\right) \cdot \overline{icf}_i \tag{4}$$

where:

$$\overline{icf}_i = log\left(\frac{N}{t_i}\right) \Big/ max_l \left(\log\left(\frac{N}{t_l}\right)\right) \tag{5}$$

$\overline{icf}$ stands for *inverse (document) class frequency*; N is the total number of documents and t_i is the number of documents tagged with class c_i.

Website(s) and User Semantic Glossaries

By applying batch information processing to the document collection, the *website(s) semantic glossary* is automatically generated. Conceptually, it consists of a *global view* (all keywords/classes together with their occurrences and additional extracted data), and a *per-document view* (keywords/classes occurrences in each document with their statistics). A simplified sample of the latter view is shown in Table 1-left and Table 1-right). In particular, "Document" is the list of the documents IDs in which each keyword/class occurs, "Synsets(s)" are the synsets selected as the output of WSD, while "KF", "KWeight" and "CWeight" are the weights illustrated in Equations (1) and (2).

Each time a user logs in AMBIT-SE, a batch analysis is also scheduled on the data of her profile U in order to generate/update its *user semantic glossary* (which shares the same structure of the website semantic glossary discussed above). In particular, the profile contains *action history data* including a list

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 1. Sample portions of the extracted Document Semantic Glossary: per-doc view for keywords (left) and classes (right)

Document	Keyword	Synset(s)	KF	KWeight		Document	Class	CWeight
P02001	Terrier	00919240-n	0.445	0.277		P02001	Pet product and service	0.645
P02005	Veal	00414222-n	0.210	0.131		P02005	Food industry	0.442
…	…	…	…	…		…	…	…

of past accessed documents and past searches performed on the website. The idea is that such data can be analysed in the same way as the website documents, therefore exploiting all the power of the document text analysis and categorization in order to associate meaningful keywords and classes to users; these will provide more for relevant results to their queries in the search phase. Due to their complexity and so the need for computational power, all the analyses are performed when no users are logged in; they will be available in order to process future requests from the same user in a more accurate way.

SEARCH AND RETRIEVAL

When a user U submits a query Q, AMBIT-SE has to answer it as effectively as it can. The technique illustrated in this section aims to produce the most effective ranking $\hat{\tau}$ of the indexed documents $D \in D$ with regard to both U and Q. This is done by taking into account all the information available in the semantic glossaries produced by the analysis process (text analysis and classification) and by means of the following ad-hoc similarity metrics between two generic documents (i.e. keyword sets) D^x and D^y:

- The similarity *TextSim*(D^x,D^y), considering *keyword* information;
- The similarity *ClassSim*(D^x,D^y), considering *class* information.

In particular, *TextSim* and *ClassSim* will be applied to both:

- The user profile U (i.e.,) with regard to each indexed document (as performed on past navigated data): this produces the profile rankings τ^U_{text} and τ^U_{class};
- The query Q (i.e.,) with regard to each document; this produces the query rankings τ^Q_{text} and τ^Q_{class}.

In the final part of this section, the authors will show how this ranking information is exploited in *ranking selection/fusion* in order to produce the final ranking $\hat{\tau}$. Next, the *TextSim* and *ClassSim* similarity metrics will be defined.

Text and Class Similarity Metrics

Building on previous research on text retrieval for specific subject areas as software engineering (Bergamaschi et al., 2015; Martoglia, 2011), agricultural (Beneventano et al., 2016) and user-centric cultural enhancement data (Martoglia, 2015), the text similarity *TextSim*(D^x,D^y) formula between documents D^x and D^y is defined as:

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

$$TextSim\left(D^x, D^y\right) = \frac{\sum_{k_i^x \in D^x} max_{k_j^y \in D^y} \left(KSim\left(k_i^x, k_j^y\right)\right) \cdot kw_i^x \cdot kw_j^y}{\left|D^x\right|} \quad (6)$$

where the weighting scheme illustrated in Equation (1) is exploited and *KSim* is a term similarity formula (see later) taking into account the semantic information extracted from the semantic glossary. Simply put, the similarity $TextSim(D^x,D^y)$ between two documents D^x and D^y is determined by summing the maximum keyword similarity scores $KSim(k_i,k_j)$ between each pair of keywords k_i and k_j belonging to different documents, multiplied by the weights of both. As to $KSim(k_i,k_j)$, in AMBIT-SE semantic framework, k_i and k_j can be:

1. *Equal or synonyms*: $KSim(,)= 1$;
2. *Related*, i.e. the thesaurus hypernymy path similarity between the keywords'synsets exceeds a given threshold *Th* (Bergamaschi et al., 2015): $KSim(,)= r$, where r is an arbitrary value between 0 and 1, default 0.7;
3. *Unrelated* otherwise: $KSim(,)= 0$.

Please note that, since both $0 \leq KSim(,) \leq 1$ and $0 \leq kw \leq 1$, then $0 \leq TextSim(,) \leq 1$. This will be useful in the ranking selection/fusion phase (Section "Ranking Selection / Fusion").

In addition to document keywords, the classes associated by the semantic classifier can also significantly help in retrieving useful documents. This is obviously true if both documents are strongly characterized by a common IPTC class (e.g. "process industry"); however, also documents about cola factories tagged with a similar class "food industry" would be of interest. This is achieved through $ClassSim(D^x,D^y)$, which quantifies the similarity of D^x and D^y on the basis of their associated IPTC classes $c_i^x \in D^x$ and $c_j^y \in D^y$:

$$ClassSim\left(D^x, D^y\right) = \frac{\sum_{c_i^x \in D^x} max_{c_j^y \in D^y} \left(CSim\left(c_i^x, c_j^y\right)\right) \cdot cw_i^x \cdot cw_j^y}{\left|\left\{c^x \in D^x\right\}\right|} \quad (7)$$

As for Equation (6), $CSim(c_i,c_j)$ between classes c_i and c_j ranges between 1 (equal classes), r (similar, i.e. "near" on the IPTC taxonomy, classes) and 0 (otherwise). Again, since $0 \leq CSim(,) \leq 1$, then $0 \leq ClassSim(,) \leq 1$.

Ranking Selection/Fusion

As previously seen, given a profile U, Equations (3) and (4) induce rankings τ_{text}^U and τ_{class}^U on each document $D \in D$ with regard to U, respectively. Similarly, when the two equations are computed with regard to a query Q, rankings τ_{text}^Q and τ_{class}^Q are induced on the same documents. The aim of the *ranking selection/fusion* process presented in this paper is to exploit the information of those rankings in order to obtain the final ranking $\hat{\tau}$. The aims are the following:

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

1. The final ranking $\hat{\tau}$ should reflect both Q and U, and it should be possible to define the relevant importance of the query Q with regard to the profile U (for instance, to privilege the information contained in Q);
2. The final ranking $\hat{\tau}$ should be flexibly defined so to reflect both text and class information (Equations. 3 and 4, respectively), possibly in a customizable proportion. Moreover, the system should be able to automatically decide if one of the two kinds of rankings (text, class) is not significant, for instance due to very low similarities, which would only negatively affect the final ranking, therefore excluding it from the fusion;
3. The *score* of each document D, and not only its position in the rankings, should be taken into account in order to directly reflect its relevance in the final ranking.

Let us see how AMBIT-SE achieves these points. By means of a linear combination score fusion method, the scores inducing the fused rankings τ_{text} and τ_{class}, which take into account both U and Q, are defined as:

$$s^{\tau_{text}}\left(D\right) = \alpha_Q \cdot s^{\tau_{text}^{Q}}\left(D\right) + \left(1-\alpha_Q\right) \cdot s^{\tau_{text}^{U}}\left(D\right) \tag{8}$$

$$s^{\tau_{class}}\left(D\right) = \alpha_Q \cdot s^{\tau_{class}^{Q}}\left(D\right) + \left(1-\alpha_Q\right) \cdot s^{\tau_{class}^{U}}\left(D\right)$$

where $0 \leq \alpha_Q \leq 1$ is a preference weight determining the relevant importance of Q with regard to U. The default value is $\alpha_Q = 0.7$, meaning that the information in Q is typically more significant than that in U; this can be varied, for instance, by the system administrator depending on the actual usage scenarios.

The above defined τ_{text} and τ_{class} rankings are eventually fused in a final ranking $\hat{\tau}$, which takes into account both text and class contributions as of Equation (8):

$$s^{\hat{\tau}}\left(D\right) = \beta_{text} \cdot s^{\tau_{text}}\left(D\right) + \left(1-\beta_{text}\right) \cdot s^{\tau_{class}}\left(D\right) \tag{9}$$

where $0 \leq \beta_{text} \leq 1$ is a preference weight determining the relative importance of τ_{text} with regard to τ_{class}. The default value is 0.5. Note that ranking selection is implemented in the following way: if $\sum_D s^{\tau_{text}}\left(D\right) \gg \sum_D s^{\tau_{class}}\left(D\right)$ then β_{text} is automatically set to 1 in order to exclude the contribution of τ_{class} (and vice-versa), therefore avoiding possibly detrimental noise. Only documents that are part of all rankings will appear in the final ranking.

EXPERIMENTAL EVALUATION

This section presents the results of several tests performed on different kinds of websites. This paper is focused on effectiveness evaluation; for readers interested in time performances, the current prototype has a response time of 40 ms on average on a standard single-node configuration.

Five websites were selected for evaluation purposes; for each one of them, appropriate information needs were established by examining common searches performed in the past.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

The choice of the website was driven by the aims of the proposed approach. First, the sites are all representative of real and typical business-relevant sites. Moreover, the sites were selected so as to cover a number of different topics (e.g. health, cars, recycling, etc.) and thus different terminologies and text content. Finally, they have different features in terms of structure. This is in line with the main goal of this section, i.e. to evaluate the effectiveness and the flexibility of an enterprise search engine.

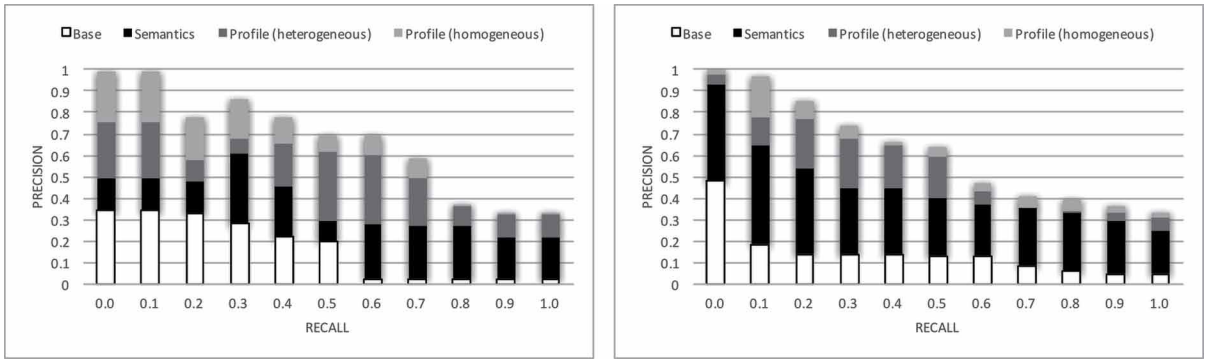
As to possible experimental comparisons, as anticipated in the related, there are currently no approaches that can be directly compared with the proposed one. In particular, among the approaches whose implementation was publicly available, those offering semantic features require unavailable manual annotations and/or were strictly designed to work on specific ontologies (Haslhofer et al., 2013; Thesprasith & Jaruskulchai, 2014; De Vocht et al., 2017). This is also true for semantic enterprise search engines (Cogito, Attivio, Content Analytics). The considered user-aware search engines do not exploit the semantics (Bolchini et al., 2011; Cabri et al., 2003; Falcarin et al., 2013; Xiang et al., 2010; Vu et al., 2017). Also, the publicly available approaches working on context information are restricted to aspects such as time and location (Falcarin et al., 2013; Xiang et al., 2010; Villegas & Müller 2010) or very specific scenarios (e.g. agent management for Coveo, image search for Ontogator, cQA for (Figueroa & Neumann, 2016)) which makes them not applicable to the considered case. Summarizing, the reason that prevents direct comparisons are: first, only a few number of approaches exploit both semantics and user awareness; second, most of the approaches focus on a specific application field and cannot be applied to general websites; third, several approaches are not freely available to be tested. Anyway, for reference, the final part of this section is devoted to a direct comparison with Google search engine; even if it does not exhibit all the features of AMBIT-SE, the authors considered it an important benchmark in the field.

Table 2 reports, for each website, the address, a brief description of its contents and an example of a considered information need. In the context of the information needs of each website, 50 plausible queries were submitted to the system. Moreover, two options for user profiles are considered: a simpler setting, where the profile contains only documents relevant to the information need ("homogeneous profile"), and a more complex one, where the profile contains also an equal number of irrelevant documents ("heterogeneous profile").

Table 2. Experimental setting: details of the five business-relevant websites selected for evaluation purposes

Website	Description	Examples of Information Needs
http://www.cobat.it/	A relatively small website that provides information and services for disposing and recycling four problematic waste categories: batteries and accumulators, tires, electric and electronic devices, and photovoltaic panels.	Retrieve documents pertaining to the disposal of batteries and accumulators.
http://evergreensmallbusiness.com/	A Blog that publishes different kinds of information and advice for small businesses, all classified in categories such as business taxes, management, personal finance, etc.	Retrieve articles pertaining to bookkeeping.
http://www.bagnolottanta.it/	A journalistic website with several thematic columns such as history, culture, theatre, etc.	Retrieve articles in specific columns such as books.
http://truegoods.com/	An Indie online shop that specializes on healthy and natural products.	Retrieve information on products belonging to the pet-care category.
http://www.gruppozatti.it/	An authorized car dealer which sells several brands of both new and used cars.	Retrieve different information about cars belonging to the used category.

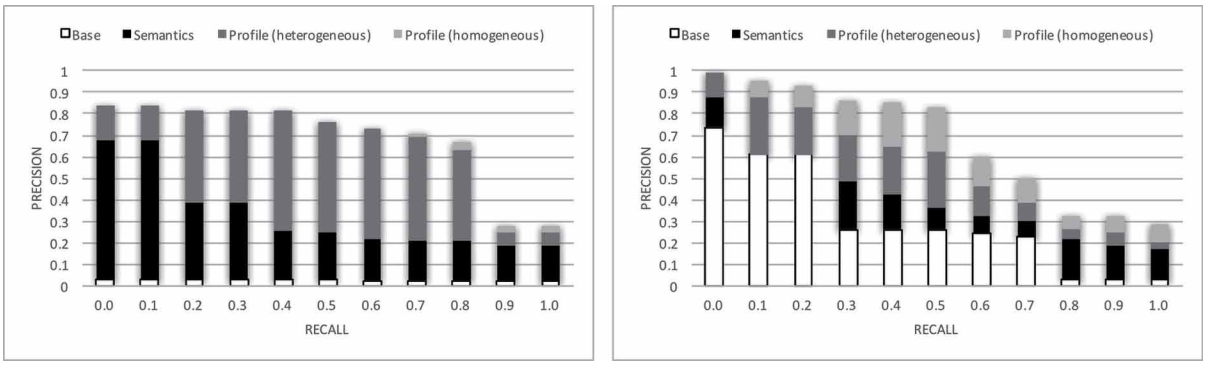
EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use



In each situation, the output of AMBIT-SE is compared with a "gold standard", i.e. relevant answers manually selected from the websites, and precision and recall are assessed; in particular, the tests compute interpolated precision at 11 recall levels of 0.0, 0.1, 0.2, ..., 1.0 (0, 10, 20, ..., 100 percent) (Baeza-Yates & Ribeiro-Neto, 1999), thus taking into account not only the relevance of the results but also their position in the returned ranking. Moreover, a "stable" situation is assumed, where users and documents have been already automatically processed and their relevant keywords and classes stored in the Semantic Glossaries. All the parameters are set at default.

Figures 3 through 5 depict the results (averaged on all the queries) obtained by AMBIT-SE, compared with the baseline of a syntactic retrieval method ignoring synonyms, related terms and class information. In particular, this baseline is representative of the document retrieval techniques commonly exploited by most commercial systems and standard enterprise search engines (e.g. Alfresco, Autonomy, Solr). Further comparisons with available systems (e.g. Google) will be discussed in the final part of the experimental analysis. In order to better visualize the difference between AMBIT-SE's results and the baseline, the figures detail the the precision achieved by the different features of AMBIT-SE. In particular, the white bars (at the bottom) represent the precision of the syntactic method (baseline); the contributions on top are the improvements achieved by means of the semantic (black) and user-aware features (gray).

As readers can see, the improvements in precision offered by the semantic and user-aware features of AMBIT-SE are significant in each scenario, ranging from 20% to even 80%. Let us start by analysing the http://www.cobat.it/ results (Figure 3 (left)). Here, the semantic features offer an advantage at all recall levels; the results also benefited from the user-aware features, because of the large number of keywords contained within the documents associated to the user profiles. For instance, the use of semantics enables the matching of different but very related terms like "battery" and "accumulator". Those contributions go unnoticed in standard syntactic search.



Considering the second website (Figure 3 (right)), the use of semantics provides even greater benefits: for instance, the use of synonyms and related terms are able to exploit a number of terms correlations such as between "money" and "bookkeeping." This was especially evident in the longer and less direct queries submitted, which are harder to satisfy by a search engine without additional information in the form of synonyms and related terms. Summing up the contribution of the profile analysis, AMBIT-SE reaches in some cases an improvement of nearly 80% in precision.

Figure 3. Test results for http://www.cobat.it/ (left) and http://evergreensmallbusiness.com/ (right)

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

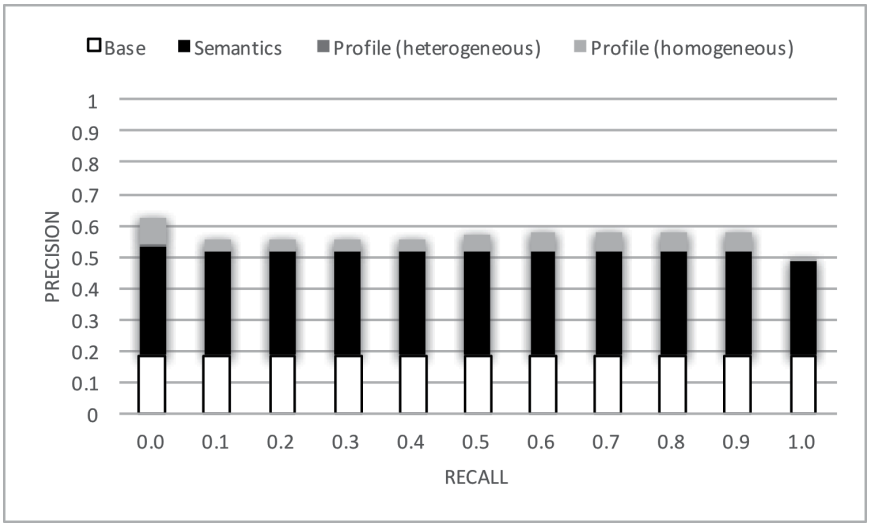


Figure 4. Test results for http://www.bagnolottanta.it/ (left) and http://truegoods.com/ (right)

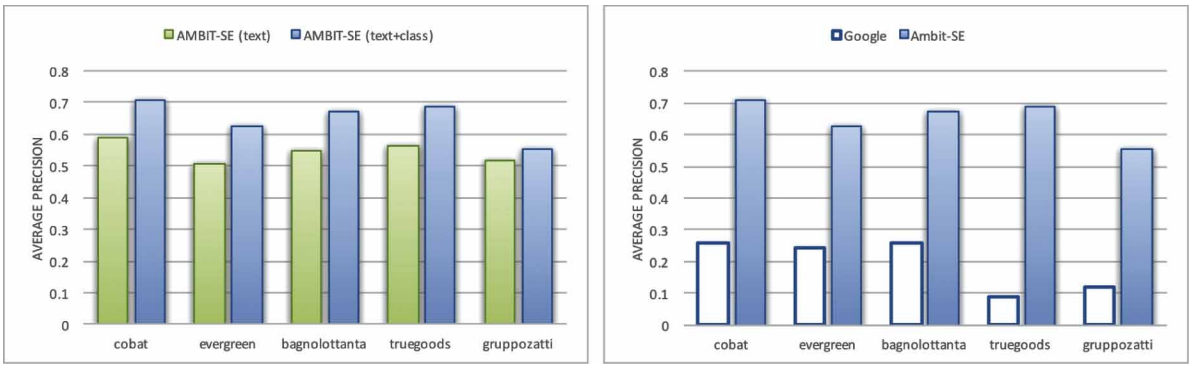
In the test of Figure 4 (left), the authors found that in some cases the queries did not directly benefit from synonyms and related terms management, maybe due to very specific terminology that is used in the pages. Anyway, the use of semantics and the profile analysis provide relevant advantages even in this scenario. Moving to Figure 4 (right), the use of word stems, synonyms, related terms and profile can turn even difficult queries into manageable ones. For instance, in some cases, the syntactic baseline could not retrieve any records since the queries don't include terms that match exactly the ones found in the relevant documents: among the exploited terms correlations, the very frequent one between "pet" and "animal".



The final website considered (Figure 5) is characterized by pages containing very little text, thus providing a different task with regard to the others. Also in this case, a lot of complex queries did not yield satisfactory results for the syntactic baseline, thus providing very consistent advantages from the semantic features (precision improvement of 30% or greater). Due to the peculiar nature of the website, some queries were apparently too difficult even with the additional input provided by the semantics and profiles. Anyway, on average, the effect of the advanced AMBIT-SE features is evident even in this situation.

Figure 5. Test results for http://www.gruppozatti.it/

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 6. Class improvement analysis (left) and comparison with Google (right)

A further test is presented which is aimed at evaluating the impact of the classification features of the presented engine, including the novel ranking selection and fusion capabilities. Figure 6 (left) shows the precision figures (averaged over all the queries and all recall levels) that are achieved by exploiting only the text ranking and similarities (left bars) with regard to the ones achieved by the complete setup presented in this paper. The benefits are usually in the order of more than 10% of improvement. Looking at specific cases, the fused ranking was able to take the best from the class and text rankings, together capturing the user interests more completely.

In order to complete the evaluation, the authors performed a quantitative comparison with a state-of-the-art search engine and a discussion about results is reported in the following. The chosen search engine was Google, as mentioned before.

Figure 6 (right) shows the results of the system compared with those obtainable through the Google search engine. Indeed, Google is one of the most widely used search engines also in the enterprise search area. Similarly to AMBIT-SE, Google is completely automatic and requires no manual work (e.g. annotation) on the documents to be processed. In this case, the considered document set has been restricted to the specific considered website pages. Differently from AMBIT-SE, Google does not perform semantic analysis of the texts, however it employs text processing techniques such as stemming. Multiple users were simulated in Google through different search sessions. The results show that the average precision achieved by Google (in the range of 10-30%) is quite lower than the one achieved by AMBIT-SE (always above 55%). In particular, Google offers a level of performance that is only marginally better than the syntactic baseline discussed in the previous tests.

CONCLUSION

Search engines represent a means essential for a lot of activities. This is especially true in an enterprise context, where the success of the enterprise is often strictly dependent on the ability of its employees and customers to find the needed information.

In this context the authors have proposed AMBIT-SE, an enterprise search engine approach that relies on two aspects, user-awareness and semantics, jointly exploited. First, it builds a profile of the user, which is exploited to search for the information that best matches with her needs. Second, semantic techniques enable the retrieval of interesting information that could not be considered exploiting a

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

standard syntactic search. The experimental evaluation has shown that the presented approach performs better than traditional search methods.

In the future, further ways of exploiting semantics and user information in the search will be considered, for instance by adapting some of the ideas coming from past works in different contexts (e.g., semantic search in heterogeneous and dynamic graph data (Catania et al., 2013) and multimedia data (Grana et al., 2013)).

ACKNOWLEDGMENT

Chapter 17
Use of Chaotic Randomness Numbers: Metaheuristic and Artificial Intelligence Algorithms

Alper Ozpinar
Istanbul Commerce University, Turkey

Emel Seyma Kucukasci
Istanbul Commerce University, Turkey

ABSTRACT

The timeless search for optimizing the demand and supply of any resource is one of the main issues for humanity nearly from the beginning of time. The relevant cost of adding an extra resource reacts by means of more energy requirement, more emissions, interaction with policies and market status makes is even more complicated. Optimization of demand and supply is the key to successfully solve the problem. There are various optimization algorithms in the literature and most of them uses various algorithms of iteration and some degree of randomness to find the optimum solution. Most of the metaheuristic and artificial intelligence algorithms require the randomness where to make a new decision to go forward. So this chapter is about the possible use of chaotic random numbers in the metaheuristic and artificial intelligence algorithms that requires random numbers. The authors only provide the necessary information about the algorithms instead of providing full detailed explanation of the subjects assuming the readers already have theoretical basic information.

INTRODUCTION

Most recent optimization problems of recent years is not only limited to balancing the classical supply and demand problems as well searching for the common optimization problems related with the real-world challenges. Those challenges can be listed as sustainable energy management, logistics, transportation, production, manufacturing, consumption, healthcare, education, financial, telecommunication, cloud

computing, smart grids, internet of things and even genetic research. Most of these studies can be solved by using combinatorial optimization problems (COPs) and most of them are classified as NP-hard type problems. These real-life COPs are frequently characterized by their large-scale sizes and the need for obtaining high-quality solutions in short computing times, thus they require the use of metaheuristic and also artificial intelligence algorithms (Juan, Faulin, Grasman, Rabe, & Figueira, 2015).

In practice initializations of the stochastic and combinatorial optimization algorithms are based on the random number sequences and feeds. The modifications on the initialization directly affect the later phases and the success of the applied metaheuristics algorithm. Moreover, some of the algorithms do selections in regard to random numbers to search the solution space during the iterations. The performances of the evolutionary algorithms are asserted to be improved by using qualified random number generators (Bastos-Filho, Oliveira, Nascimento, & Ramos, 2010; Caponetto, Fortuna, Fazzino, & Xibilia, 2003).

In order to solve the complex and big domain complex problems it's a preferred way to solve them in distributed and parallel within high performance computing systems and supercomputers. The main problem steps distributed among those computing machines which are the members of the distributed system. The term computing machine refers either a single computer with multiple core CPU's, a high performance computing cluster, a supercomputer or may be a distributed grid structure formed by many computing nodes. A good distributed computing structure requires the higher level of transparency. In general transparency refers to operation which does not requires a common operation set, synchronized time settings between nodes, share of memory and variables. Many multi-core processors are homogeneous hardware architectures by means of shared-memory and direct memory access properties, meaning that all cores are identical however heterogeneous configurations of multi-core systems also exist in various computing centers (DAngelo & Marzolla, 2014). The required transparency within the high performance computing and cloud computing applications, requires the ideal case that is all the computing inventory acting like a single system even it does not.

A common problem here is increasing the number of devices results in the increasing the coincidences related with the random computing. Due to the logic and circuit system foundations the outcome of the computers is always acting in the same way unless affected by some an external feedback or source. They can create a random number by using an algorithm and mostly by implementing a deterministic function. Without a dynamic input or bias this double team never makes a surprise to its user. For example in most of the programming courses a lecture is generally includes some practical daily examples about generating random numbers with computers for lottery or card games. A simple example for shooting n random numbers with the simplest code in the computer laboratory, all the students in the lab will get the same lucky numbers in the same order. Some programming languages like c, a seeding number can be used to change the process of random number generation however this time the students using the same number for seeding sequence also gets the same numbers.

Using current time as a continuous changing and non-repeating type of seeds also does not solve the uniqueness problem of random numbers. This is the sensitive and crucial point about solving the problems in parallel and distributed. Considering the top list of super computers with more than million cores the probability of coincidence for obtaining same random numbers increase with the decrease of the quality of the random numbers. As a result either computational performance is decreased or limited search domain obtained for solution progress, which is not desired. In conclusion a good quality random number generation progress is required. The following sections explain this idea in detail with definitions and applications.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

RANDOM NUMBER GENERATORS

To generate independently identically distributed random variables with good statistical properties there are algorithms which provide random numbers that mimic most features of the truly random numbers. The purpose of these algorithms is to produce sequences of numbers or objects whose behavior is very hard to distinguish from that of their "truly random" counterparts, at least for the application of interest (Gentle, 2004).

There are two main types of random number generators available for use in computational operations. The first one is Pseudo-Random Number Generators (PRNGs), based on algorithms that use mathematical methods like linear congruential method or preset data to produce sequences of numbers. Therefore standard microcontrollers and computers without a special modification or upgrade can be classified as PRNGs type. PRNGs can operate with high performance and speed when required to generate ordinary random numbers which are sufficient enough to use in daily operations that does not require high security, uniqueness and complexity.

A pseudo-random number generator (PRNG) can be defined as an algorithm enabling to generate sequences of numbers with some properties of randomness.(Francois, Grosges, Barchiesi, & Erra, 2014) The TRNG derives its output from a physical noise source whereas a PRNG expands a relatively short key (possibly from a TRNG) into a long sequence of seemingly random bits based on a deterministic algorithm (Tsoi, Leung, & Leong, 2003). This determinism brings about the name pseudo-random instead of random. Additionally, the initial inputs of the equations are the "seeds" which are also random numbers. Let S be a set and $s \in S$ be the randomly selected seed number. Also let f be an invertible function from S to S. The pseudo-random number sequence is such that $\{s, f(s), f^2(s), f^3(s), \ldots\}$.

Another option is to use True Random Number Generators (TRNGs) as a hardware or as a software service instead of classical random number function of the computers. The need for a true random number generation is not only limited to metaheuristics and artificial intelligence. Another essential are is to secure any type of communication between electronic devices and in cryptography.

TRNGs can be performed based on different sources like electrical noise, jitter, chaos, entropy change, some irrelevant information noise, weather conditions, traffic congestion or even from elliptic curve operations and biometric sources. (Szczepanski, Wajnryb, Amiga, Sanchez-Vives, & Slater, 2004; Lee & Wong, 2004; Cicek, Pusane, & Dundar, 2014) Those sources mostly based on a natural physical phenomenon and the properties of independence as well as the unpredictability of the generated values are guaranteed by physical laws (Marton, Suciu, & Ignat, 2010). Since true randomness and true random generators do not practically exist, the name physical random number generator is also preferred in the literature. Although TRNGs provide non-predictable random sequences which cannot be repeated, the generation process is too slow and it depends on the specifications of hardware.

CHAOTIC RANDOM NUMBER GENERATION

Random numbers are useful for a variety of purposes, such as generating data encryption keys, simulating and modeling complex phenomena and selecting random samples from larger data sets (Kumar, Shukla, Prakash, Mishra, & Kumar, 2011). Additionally, qualified random numbers are also needed in Monte Carlo techniques (Gentle,), system dynamics (Eberhart & Shi, 2001; Uchida, 2012) and metaheuristics (Alatas, 2010; Bastos-Filho et al., 2010; Jahan & Akbarzadeh, 2012; Mukhopadhyay & Banerjee, 2012;

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Reese, 2009). Random number generation is to find an independent identically distributed sequence with property of non-repeatability where at each repeat, a different sequence must be obtained.

Recently, different random number generators are proposed in the literature based on quantum devices, elliptic curves, cellular automata and different map functions (Akhshani, Akhavan, Mobaraki, Lim, & Hassan, 2014; dos Santos Coelho, 2009; Karimi, Hosseini, & Jahan, 2013; Pivoluska & Plesch, 2015; Reyad & Kotulski, 2015; Wang, Yu, Ding, & Leng, 2008). Random number generators are selected to be used for these applications based on desired application-specified statistical quality. There are physical generators and computational algorithms that imitate the physical generators. Additionally, random numbers can also be generated exploiting chaos theory, where the chaotic behavior of the output provides necessary statistical and computational properties.

The defined function f can also be a chaotic function and the obtained pseudo-random sequence is a chaotic pseudo-random sequence if and only if f has the following properties (Keller & Wiese, 2007):

- f reacts sensibly to changes in s, i.e. even small changes to the value of s result in large changes of the sequence,
- f is topologically transitive, i.e. almost every element of S can be connected to almost every other element of S by a finite sequence,
- f is topologically dense, i.e. even small intervals of S contain periodic points of f.

Chaotic pseudo-random number generators (CPRNG) are preferred since after a certain period length, a pseudo-random sequence repeats itself. The idea of applying discrete chaotic dynamical systems, intrinsically, exploits the property of extreme sensitivity of trajectories to small changes of initial conditions (Lozi & Taralova, 2014).

Aim of this chapter is to explain he use of Chaotic pseudo-random number generators (CPRNGs) in suitable metaheuristic and artificial intelligence algorithms on the other hand search for new generations, new weights, new distances or new parameters based on a previous step and also a randomized touch to scatter, change, improve, mutate the results for new frontiers to the solution and problem set. (Gilli, Maringer, & Schumann, 2011)

CHAOTIC MAPS

Chaotic dynamic system behavior can be described by using several map functions. The chaotic time series sequences can be obtained by using polynomial nonlinearities or piecewise linear maps (Afrabandpey, Ghaffari, Mirzaei, & Safayani, 2014; Caponetto et al., 2003; Jin & Ryu, 2012; Kim, Bok, & Ryu, 2013; May, 1976). Simple linear equations, the initial random value and the knowledge of the parameters are sufficient to generate the chaotic pseudo-random sequences. The following map functions are the mostly used goal-oriented chaotic sequences.

1. **Logistic Map:** A nonlinear function that describes the dynamic behavior of the biological populations is proposed (May, 1976). The logistic difference equation is

$$x^{t+1} = a\, x^t (1 - x^t)$$

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

where t is the iteration number and $a > 0$ is the biotic potential and the generated sequence is in (0,1) if $x_0 \in (0,1)$.

2. **Tent Map:** Similar to logistic map, tent map is a nonlinear function that takes as an input the previous output and generates chaotic sequences in (0,1) with the following form (Peitgen, Jürgens, & Saupe, 2006)

$$x^{t+1} = \begin{cases} x^t \,/\, 0.7, & if\ \ x^t < 0.7, \\ 10 \,/\, 3x^t\left(1 - x^t\right), & otherwise. \end{cases}$$

3. **Cubic Map:** The famous cubic map which has a wide range of applications is formally defined as (Rogers & Whitley, 1983)

$x^{t+1} = \pi\, x^t\, (1 - (x^t)^2)$

with the parameter $\pi = 2.59$. The generated chaotic sequence is in (0, 1).

4. **Gauss Map:** This map is generally utilized for testing the features of the generated sequences by using the following equations

$x^{t+1} = G(x^t)$

$$G\left(x\right) = \begin{cases} 0, & for\ \ x = 0, \\ \dfrac{1}{x} mod\left(1\right), & for\, x \epsilon \left(0,1\right). \end{cases}$$

5. **Circle Map:** This is an iterative nonlinear function that maps the circle onto itself and has the behavior of a simple sinusoidal oscillator (Essl, 2006). The simple circle map function is as follows

$$x^{t+1} = x^t + b - (a/2\pi)\sin(2\pi x^t) \bmod \quad (1)$$

6. **Sinusoidal Map:** The equation for the famous sinusoidal iterator is the following (Peitgen et al., 2006)

$x^{t+1} = a(x^t)^2 \sin(\pi x^\tau)$.

If the sequence begins with $x^0 = 0.7$ and we also have $a = 2.3$, then the equation is simplified as

$x^{t+1} = \sin(\pi x^t)$.

7. **Henon Map:** This nonlinear map is also used for testing purposes and has two parameters a and b. The representation of the map is described as

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

$x^{t+1} = 1 - a(x^t)^2 + bx^{t-1})$

where a=1.4 and b=0.3 are the suggested parameters.

8. **Lozi Map:** This map is the simplified version of the Henon map with a two-dimensional piecewise linear function given by

$$(x^{t+1}, y^{t+1}) = H\left(x^t, y^t\right)$$

$$H\left(x^t, y^t\right) = \left(1 + y^t - a\left|x^t\right|, bx^t\right)$$

where a=1.7 and b=0.5 are the suggested parameters.

9. **Baker's Map:** Another two dimensional function represents Baker's map which defined as (Fridrich, 1998)

$$B\left(x\right) = \begin{cases} \left(2x, 2y\right), & for\, 0 \le x < 0.5, \\ \left(2 - 2x, 1 - \dfrac{y}{2}\right), & for\, 0.5 \le x < 1. \end{cases}$$

A one dimension of the Baker's map gives another representation which is similar to tent map given by

$$x^{t+1} = \begin{cases} 2x^t, & for\, 0 \le x^t < 0.5, \\ 2 - 2x^t, & for\, 0.5 \le x^t < 1. \end{cases}$$

10. **Arnold's Cat Map:** A two dimensional map is proposed in (Arnold & Avez, 1968) where an image of a cat is used to illustrate the chaotic behavior of the map. The representation of this map is

$$x^{t+1} = x^t + y^t \bmod \quad (1)$$

$$x^{t+1} = x^t + 2y^t \bmod \quad (1)$$

where $x^t \in (0,1)$ and $y^t \in (0,1)$.

11. **Lorenz Map (Lorenz Attractor):** Lorenz Map first introduced in (Lorenz, 1963) for a simplified model for atmospheric convection. Lorenz map is similar to logistic map and accepted as a generalization of circle homeomorphisms from zero entropy to positive entropy.(Cui & Ding, 2015) So the Lorenz map has two leaves, or branches, separated by a singular point at y=0.(Gilmore, 2015) Lorenz system based on definition of the system with three non-linear equations

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

$$\frac{dx}{dt} = a\left(y - x\right),\ \frac{dy}{dt} = x\left(b - z\right) - y,\ \frac{dz}{dt} = xy - cz$$

where a, b and c are constants. An example set is (10,28,8/3) and (28,46.92,4).

STATISTICAL TESTS FOR RANDOMNESS

Every PRNG should have a reasonably long period before its output sequence repeats itself, and its output sequence should pass statistical test suites so that it sufficiently resembles a truly random sequence (Keller & Wiese, 2007). The generated random numbers must have forward unpredictability property such that it is not possible to predict the future evolution of the system. Also, it must be shown that the generated pseudo-random numbers cannot be distinguished from truly random numbers. Hence, the statistical tests are proposed to justify the reliability of the generated random bit sequences.

If a pseudo-random number generator passes the next bit test then it passes any statistical test, i.e., no randomized polynomial-time algorithm can distinguish the generated pseudo-random numbers from truly random numbers (Graham, 1995). An ideal random number generator is infinite, aperiodic, uniform, uncorrelated, and computationally efficient (Phatak & Rao, 1995). For each type of algorithm, the selection of the suitable chaotic map and its parameters (i.e. initial values and control parameters) to generate the random numbers must depend on the statistical test results. Quantitative performance measurement of the chaotic driven random selections is provided by incurring most famous statistical tests (Beker & Piper, 1982; Chan, Chan, & Cheng, 2001) which are enumerated below.

1. **Frequency (Monobit) Test:** The frequencies of the 0 and 1 values in a binary sequence are tested such that they must be approximately equal. The frequency test checks that the number of ones in the sequence is not significantly different from half of the length of the sequence (Kanso & Smaoui, 2009)
2. **Serial (Two-Bit) Test:** Random sequences must have the property that value of each element of a sequence must be independent from the value of its predecessor. Hence, the frequencies of the different transitions in a binary sequence such that 11, 10, 01 and 00 must be approximately equal.
3. **Runs Test:** To test the hypothesis of the independence, the arrangement of numbers in a sequence is examined. After the serial test is passed, the number of runs in the sequence also must be checked to be a dichotomous sequence of values.
4. **Poker Test:** This test determines whether the sequences of different lengths each appear approximately the same number of times in the sequence as it is expected from a random sequence (Karimi et al., 2013). Obviously, the frequency test and the serial test are contained in the poker test.

USE OF CHAOTIC RANDOMNESS IN SELECTED ALGORITHMS

In this section of the chapter, the possible use of Chaotic pseudo-random number generators (CPRNG) for proper metaheuristic and artificial intelligence algorithms has explained. As mentioned in the beginning of this chapter there are vast number of research papers and books about different implementations and descriptions of the algorithms therefore instead of providing the detailed technical and theoretical

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

background only sample solutions for adapting CPRNG's is provided. (Draco, Petrowski, Siarry, & Taillard, 2006; Glover & Kochenberger, 2003; Gonzalez, 2007; Luke, 2009; Souza, Omkar, & Senthilnath, 2012; Talbi, 2009; Yegnanarayana, 2009).

Metaheuristic and artificial intelligence optimization algorithms search for an optimum in the problem domain without trapping in to local optimums, avoiding fall in to infinite loops and careful about early victories due to memorization or other issues. The main reason behind those is optimization is different from modelling or learning. Most of the optimizations based on searching for an unknown solution set. This uncertainty in algorithm sometimes gives a candidate optimum with the possibility of the local optimum accepted as a global or searching for the neighbors sometimes results in missing the optimum next to your current location. So there are also optimum parameters in the algorithm which searches the optimum of the problem. Also computational and algorithmic complexity is another concern while working with computers, high performance computing machines as well as the supercomputers and cloud computing where the computational limits far beyond normal acceptance. A balance of amount of resources like CPU, ram and computational time versus the possible algorithms available has to be obtained in order to solve the optimization problem.

In most of the methods two common function types can be used, one of them is to produce a direct random variable with "CPRNG" methods and normalize if necessary and the second one is "CPRNGTweak" method that will change and modify the original or candidate value with a degree of modification and a random number obtained from CPRNG.

CPRNG Generation

```
CPRNGRandom <- PRNGRandom number from ordinary equations
t <- initialization for chaotic map
repeat
test_status <- true
repeat t times do
 map(t+1) <- chaotic_map_function(map(t))
 CPRNGRandom <-map(t+1)
 repeat all_tests do
 if test fails then
 test_status=false
 break
until test_status is true or time limit reached
return CPRNGRandom
```

Simple Methods and Random Search

Simples search algorithms like Gradient Ascent, Newton's Method, Steepest Ascent Hill-Climbing and Random Search methods are the easy and simple methods to start with. All of these methods start with an initial random point or candidate point within the search domain. The rest is more or less in common, search the optimality and the validity of the candidate, if the stopping criteria is not satisfied then change the candidate a little with a random affect and return to the loop. A search based on pure random candi-

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

date for each time is not a good way of searching, instead using a brute force or combinatorial search is better. Searching in in single, parallel or multi node computing adapting by replacing the random number operator with CPRNG will improve the solution diversity and performance.

Improved Hill-Climbing with Random Restarts with CPRNG

```
time_interval <- distribution of possible time intervals
candidate <- A Random CPRNG Candidate
optimum <- candidate
repeat
time <- a random time in near future from time_interval set
repeat
 mid_candidate <- CPRNGTweak (candidate)
if Quality(mid_candidate) > Quality (candidate)
then
candidate <- mid_candidate
 until stopping criteria satisfied with candidate, time is up or timeout
 if Quality(candidate) > Quality (optimum)
then
 optimum <- candidate
 candidate <- A Random CPRNG Candidate
until stopping criteria satisfied with optimum or timeout
Improved Random Search with CPRNG
optimum <- A Random CPRNG Candidate
repeat
candidate <- A random CPRNG Candidate
if quality(candidate) > quality (optimum)
then
optimum <- candidate
until stopping criteria satisfied with optimum or timeout
```

Simulated Annealing (SA)

Simulated Annealing is another global search algorithm for global optimization similar the Hill-Climbing with the difference of changing the candidate and intermediate candidate. Annealing is actually a heat application process in manufacturing and materials science that changes the physical and chemical properties of a material in order to obtain harder more ductile products. The Annealing process initially heating up the material above a suitable critical temperature where the material starts recrystallization and forms better bigger crystal structures which provides the ductility and hardness. After that the process continues with waiting for a proper time which allows slowly cooling so the crystal atoms becomes stable and forms new crystal structure.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Improved Simulated Annealing with CPRNG

```
T <- a high temperature value //melting
candidate <- A Random CPRNG Candidate
optimum <- candidate
repeat
mid_candidate <- CPRNGTweak (candidate)
if quality(mid_candidate) > quality(candidate) or
CPRNG[0..1] < exp((quality(mid_candidate)-quality(candidate))/T)
then
candidate <- mid_candidate
decrease t //cooling
if quality(candidate) > quality (optimum)
then
optimum <- candidate
until stopping criteria satisfied with optimum, T<=0 or timeout
```

Tabu Search (TS)

Tabu Search is a search algorithm using an imaginary memory of the recently tested candidate solutions by putting them on a list called tabu list with a predefined capacity m of storing them. Like memories, tabu lists are volatile based on the time passed or list fully filled with candidates with FIFO principle. It is based on a local search of the neighbors and checking the list if visited before or not. n modified and tweaked candidate children is generated in each step but the ones in the memory is not considered.

Improved Tabu Search CPRNG

```
m <- tabu list length //memory size
n <- number of tweaked candidates desired for sample the gradient
candidate <- some initial candidate solution CPRNG Candidate
optimum <- candidate
tabu_list <-{} a tabu list of length m //FIFO based
enqueuer candidate to memory
repeat
if tabu_list.LEN = m
then
apply FIFO remove the oldest from tabu_list
mid_candidate <- CPRNGTweak (candidate)
for n-1 times do
dummy_candidate <- CPRNGTweak (candidate)
if dummy_candidate not in tabu_list and
quality(W)> quality(mid_candidate) or mid_candidate is in tabu_list
then
mid_candidate <- dummy_candidate
```

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

```
if mid_candidate is not a member of memory and
quality(mid_candidate)> quality(candidate)
then
candidate <- mid_candidate
 enqueue mid_candidate to memory
if quality(candidate) > quality (optimum)
then
optimum <- candidate
until stopping criteria satisfied with optimum or timeout
```

Particle Swarm Optimization (PSO)

Almost the same as the inspiration of the nerve cells particle swarm optimization motivated/brought about from the behaviors of the different huge numbers in the nature like birds, fishes, ants. Particle swarm optimization thought about/believed as population based optimization and can be improved by using chaotic random number modified members, crossovers and mutations. In general PSO a set of computer instructions is used for optimization where candidate solution sets or working limits/guidelines for the population modelled according to the general behaviors. These candidate solution sets which are called particles in solution swarm, live together and change and get better at the same time based on knowledge sharing with close-by particles. Each particle acts individually and also in coordination with the other particles. So each particle creates a solution based on the problem statement and initial starting point. In each turn all the particles changes their location, limits/guidelines, settings by using a speed vector to reach its next position in the solution space. Each particle changes its speed in order to reach a better position than the previous one by using its own best previous experience data and also the best previous experience data from the neighbors within the swarm.

Particles update their velocities as shown in equations below

$$v_{t+1}^{i} = w_t v_t^i + c_1 r_1 \left(p_t^i - x_t^i \right) + c_2 r_2 \left(p_t^g - x_t^i \right)$$

and the new positions according to

$$x_{t+1}^{i} = x_t^i + v_{t+1}^i$$

where x_t^i represents the current position of particle i in solution space and subscript t indicates an iteration, p_t^i is the best-found position of particle i up to iteration count t and represents the cognitive contribution to the search velocity v. Each component of v_t^i can be limited to the range [$-v_{\max}$,$v_{\max}$] to control excessive roaming of particles within the problem domain and creating unfeasible solutions. p_t^g is the global best-found position among all particles in the problem domain up to iteration count t and forms the swarm information flow to the velocity vector; r_1 and r_2 are random numbers uniformly distributed in the interval (0,1), where the chaotic random numbers will be replaced, while c_1 and c_2 are the

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

cognitive and social scaling parameters depending on the structure of problem. Finally w_t is the particle inertia, which is reduced dynamically to decrease the search area in a gradual fashion. The variable w_t is updated as

$$w_t = \left(w_{max} - w_{min}\right) * \frac{t_{max} - t}{t_{max}} + w_{min}$$

where, $w_{\max}$ and $w_{\min}$ denote the maximum and minimum of w_t respectively; $t_{\max}$ is a given number of maximum iterations. So the swarm members repeated the communication and changed their parameters until a time limit or a stopping criteria values reached.

Improved Particle Swarm Optimization

```
for each candidate particle in the candidate particle set
Initialize particle with working parameters
End
repeat
for each particle
Calculate fitness value for better
if the fitness value is better than the best fitness value (p_Best) in history
set current value as the new p_Best
End
Choose the particle with the best fitness value of all the particles as the
g_Best
for each particle
Calculate particle adapting velocity using
update particle working parameters r_1 and r_2 using CPRNG
end
until stopping criteria satisfied with optimum or timeout
```

Genetic Algorithms (GA)

Genetic algorithm (GA), is the most widely used version of evolutionary algorithms in the metaheuristic. Similar to the inspiration from the nature as well as ANN and PSO, genetic algorithms used the structure of evolution in order to reach the perfect solution that fits in to the energy environment. As in the nature every individual member of the has set of properties and working parameters which differs that device among the rest of the solutions in the domain.

These properties and working parameters corresponds to the chromosomes or genotypes similar to the ones in the living organisms (John, 1992).

As the nature changes and gets better in the time domain with new generation reproduced or composed of their parents or family relatives or things that existed long, long ago genotypes by crossover and change. Each new next generation member has a possible chance to better fit to its surrounding conditions. The rules of related to tiny chemical assembly instructions inside of living things sets of

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

computer instructions can be changed to fit optimization problems. Most of the numerical adaptations of the problems numerical values decoded as binary strings so easy to make different levels and sources of crossovers and mutations (Kumar & Mohan, 2011). The common steps of genetic algorithm is as follows

1. **Representations:** Proper coding of the optimization problem in to mathematical chromosomes while the decision variables within a solution (chromosome) are genes. The possible values of variables (genes) are the alleles and the position of an element (gene) within a chromosome is named locus. Most common representation is based on bits. Binary, discrete and permutation representations are available in the literature.
2. **Population Initialization:** Using the representation coding an initial state of the problem settings created and represented as defined on the first step. As to continue from the previous step, initial population contains some power stations are operational and some are not in a particular initial timing.
3. **Objective Function:** Proper coding of the optimization problem in to mathematical chromosomes which will be used to calculate the goodness of the solution.
4. **Selection Strategy:** The best parameter sets or working plans which fit in to the objective function selected for the next round of reproduction. In the rank based selections, without looking the proportions best n solutions selected for the reproduction. Roulette Wheel Selection, Stochastic Universal Sampling, Tournament Selection, Rank-Based Selection are common selection methodologies.
5. **Reproduction with CPNRG:** Using the current solutions sets best solutions will produce the next generation alternatives by the use of chaotic random numbers
    a. **Chaotic Crossover:** Crossover is used to increase the diversity of the possible solutions.
    b. **Chaotic Mutations:** New genetic material into the gene at some minor ratio. With a small probability, randomly chosen bits of the offspring genotypes change from '0' to '1' and vice versa for binary coded strings. This will increase the possibility of the new searches in the domain.
6. **Replacement Strategy:** The best solutions which fit in to the objective function selected for the next round of reproduction
7. **Stopping Criteria:** The best solutions which fit in to objective function selected for the next round of reproduction

Like most of the other artificial optimization methods genetic algorithm can be used for complex problems.

Improved Genetic Algorithms with CPRNG

```
generate an initial population with CPRNG
repeat
Repeat
If crossover condition satisfied Then
select parent chromosomes
choose crossover parameters
perform crossover with CPRNGCrossover
End if
```

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

```
If mutation condition satisfied Then
choose mutation points
perform mutation with CPRNGMutation
End if
evaluate fitness of offspring
Until sufficient offspring created;
select new population;
until stopping criteria satisfied with optimum or timeout
```

Ant Colony Algorithm (ACO)

Ant Colony Optimization (ACO) is an another swarm intelligence based metaheuristic algorithm that is inspired by the pheromone trail laying and tracking of the remaining of ants while finding their way to food or home. Use of artificial ants in ACO for optimization problems are stochastic solutions that build possible candidate solutions for the optimization settings and parameters of the smart grid by adapting the artificial pheromone in other words fitness information. ACO mostly used for discrete optimization problems. The real ants uses stigmergy which is a form of indirect communication by modifying the environment for further usage or communication. In case of the ACO, stigmergy based on the pheromone trails leaved by the ants while passing through a path or way.

Improved Ant Colony Optimization with CPRNG

```
Initialize the base efficiency and fitness (attractiveness), τ, and visibil-
ity, η, for each solution set ;
repeat
for each ant do
choose CPRNGTweak(previous equation) the next state to move into
add that move to the tabu list for each smart agent
repeat until each smart agent completed a solution for dynamic response
End
For each ant that completed a solution do
update fitness τ for each edge that the ant traversed;
End
if (local best solution better than global solution) then
save local best solution as global solution;
End
until stopping criteria satisfied with optimum or timeout
```

Chaotic Crossover

In crossover is the operation of mixing and matching the genes of two parents in to new generations. Mixing and matching is totally random based on some rules. A good quality random numbers will increase the variety of the possible new generations and increase the search domain. In the general application there are three possible crossovers available as one-point, two-point and uniform crossovers. In all of these crossovers random locations selected for crossover.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Improved Single Point Crossover with CPRNG

```
parent_a_dna <- genetic coding of the problem to the representation
parent_b_dna <- genetic coding of the problem to the representation
c <- a CPRNG random integer chosen uniformly from 1 to length of dna
if c<> 1 then
for I from 1 to c-1 do
swap the values of parent_a_dna(i) and parent_a_dna(i)
Improved Two Point Crossover with CPRNG
parent_a_dna <- genetic coding of the problem to the representation
parent_b_dna <- genetic coding of the problem to the representation
c1 <- a CPRNG random integer chosen uniformly from 1 to length of dna
c2 <- a CPRNG random integer chosen uniformly from 1 to length of dna
if c1>c2 then
swap c1,c2
if c1<>c2 then
for i from c1 to c2-1 do
swap the values of parent_a_dna(i) and parent_a_dna(i)
```

Improved Uniform Crossover with CPRNG

```
swap_probability < - setting a 1/length_of_dna, <=0.5
parent_a_dna <- genetic coding of the problem to the representation
parent_b_dna <- genetic coding of the problem to the representation
for i from 1 to length_of_dna do
if p>= CPRNG[0..1] then
swap the values of parent_a_dna(i)and parent_a_dna(i)
```

Chaotic Mutation

Mutation is an operator used to maintain many different kinds of possible solutions from one generation of a problem set to the next. It is the same as change of values in a from its initial state. In mutation, the solution may change wholly from the previous solution. Hence GA can come to a better solution or sometimes an unfeasible solution. If the degree of mutation it is set too high, the optimization will turn into a random search. A simple mutation operator is the bit-flip operator for binary coding's.

Improved Bit-Flip Mutation with CPRNG

```
flip_probability < - setting a probability of flipping a bit
parent_dna <- genetic coding of the problem to the representation
for i from 1 to length_of_dna do
if p>= CPRNG[0..1] then
flip the values of parent_a_dna(i) as 1>0, 0>1
```

FUTURE RESEARCH DIRECTIONS

The application of true random number generations with modified chaotic maps planned by the authors for the future research directions. The main idea behind the progress is to modify the nature inspired events and conditions with chaotic map functions and generate a hybrid version of semi TRNGs and semi CPRNGS.

CONCLUSION

Metaheuristic and artificial intelligence algorithms are widely used in different optimization, modelling and learning problems. Stochastic optimization and search algorithms require the use of random number for initialization of the problem set and tweaks of the current variables to the next calculation step. Increasing the uniqueness and the quality of the random numbers will eventually increase the processing time and the goodness of the solution. This is a more obvious requirement in parallel and grid computing based calculations where the probability of the coincidence of the same random numbers occurring in the system increased in using ordinary PRNGs. The use of TRNG is a possibility with increasing the computational complexity which costs energy and time. This chapter makes a common review of the subjects and gives examples of selected methodologies. As can be seen from the selected examples any algorithm that starts with random initial position, random variables and random modifications within the routine can be modified with chaotic pseudo random number generators and functions.

KEY TERMS AND DEFINITIONS

Chaotic Crossover: An evolutionary crossover based on the chaotic random numbers.

Chaotic Mutation: An evolutionary mutation based on the chaotic random numbers.

Chaotic Pseudo-Random Number Generators (CPRNG): PRNG based on chaotic maps and chaotic functions.

CPRNG Tweak Function: A modification function that uses the original value and a random number from CPRNG to tweak and modify the value.

Pseudo-Random Number Generators (PRNGs): A process for generating random numbers based on deterministic algorithms.

Random Number Generation: A process for generating tested random numbers for different purposes.

True-Random Number Generators (TRNGs): A process for generating random numbers based on non-deterministic random number generation.

Chapter 18
The Media-Sphere as Dream
Researching the Contextual Unconscious of Collectives

Stephen Brock Schafer
Digipen Institute of Technology, USA

ABSTRACT

The psychological nature of the electronic media environment is a virtual reality that—according to Jungian principles—is dreamlike. Perhaps it can be analyzed with Jung's Analytical Psychology. Science is experiencing a paradigm shift into a reality of mediated illusion, and psychological research on this illusion has become the human imperative. It may be stipulated that physics has abolished matter, conceding that "reality is organized mind stuff." If cosmos is structured holographically and the brain is structured holonomically, it is probable that "mind stuff" is structured holographically. The Jungian concept of Psyche is a good place to begin researching the Media-sphere as mind stuff. Cognitive sciences are probing the brain and nervous system in search of the template for cognitive organization, and the salient features have already emerged. It appears that both conscious and unconsciousness cognitive dimensions have dramatic form. This dreamlike structure can be employed to analyze the media dream, and to foster coherent psychological states in contextual collectives.

INTRODUCTION

Carl Jung used symbolic patterns occurring in dreams to promote understanding of contextual meaning residing in a patient's unconscious. Jung equated the patterns of the unconscious with atomic structure and called them archetypes. Dream symbols were understood to be projections from unconscious dimensions, but because they were relatively conscious, Jung called the projections archetypal representations which—as projections—mirrored their source. In this way, discovery of unconscious meaning not only becomes possible, it becomes measurable according to degrees of coherence. Based on a number of correlations between Jungian dreams and media dreams, the hypothesis of this chapter is that the metaverse constitutes a dreamscape, and its holographic images constitute contextual media dreams.

As this chapter will document, according to Jungian depth analysis, a series of dreams will disclose unconscious patterns of meaning of which a patient is unaware. The psychiatrist can use principles of Analytical Psychology to extrapolate the meaning of dream symbols for the purpose of providing feedback to the patient as to the meaning of dream symbols. Given this feedback, the patient is positioned to gain meaningful insight that can have healing affect—much like biofeedback. Though Jung's research was empirically based, more recent cognitive research on heart-rate coherence—to be documented later—has verified that media dreams are susceptible to scientific measurement. Therefore, just as a psychiatrist provides feedback to a patient and as advanced algorithms provide feedback as to a computer user's preferences, research addressed to specific (contextual) target groups could provide mediated feedback designed to foster healing insight to contextual collectives

According to Jung, dream sequences (Jung, 1933, p 14) provide a medium for communication between conscious and unconscious cognitive dimensions:

Dreams give information about the secrets of the inner life and reveal to the dreamer hidden factors of his personality. As long as these are undiscovered, they disturb his waking life and betray themselves only in the form of symptoms. This means that we cannot effectively treat the patient from the side of consciousness alone, but must bring about a change in and through the unconscious. (Jung, 1933, p. 16)

So—in Jungian practice—dreams are not negative. Even if they are nightmares, dreams have a benign function because they hold the keys to meaningful insight that can result in multi-functional (physical, mental, emotional, spiritual) healing. Accordingly, even if the mediated dreams of the metaverse—psychologically multi-functional images—are symbolically saturated with sex, violence, and nightmarish threat, these patterns must be understood as positive, potentially therapeutic messages from the contextual unconscious. If recognized as such, these "dreams" can promote meaningful insight that could lead to unprecedented healing of collective personae. Contextual collectives are much like target groups and come in many formats—great and small—such as Rockets fans, Coca Cola drinkers, stay-at-home-pops, African Americans, white supremacists, environmentalists, Republicans, Buddhists, females, Germans, etc..

It would be safe to say that technological media research in the context of holographic cognitive function—though incipient—is advancing apace. The technological media has long been the prime mover in the creation of modern human reality, but now it becomes clear that using that immense power wisely will not be easy. There can be no doubt that this media power is rooted in the capacity to reach into the *cognitive unconscious* of individuals and demographic groups in order to alter their perceptions of reality by reframing archetypal patterns. The fact that commercial and political motives have skewed the programming of mass media for at least half a century need not be argued.

In advertising, politics, and education, though much is already known about the psychological power of the mass media, proportional efforts to manifest positive potentials for the power of psychological mass media have not been forthcoming. The primary purpose of this chapter is to discuss these potentials in necessarily innovative terms: Dreams, functional coherence, learning, healing, and even transcendence.

Taking a prospective view of benign media purposes, Internet potentials for education, healing, and maintaining coherent states in dimensions of the cognitive unconscious are just beginning to emerge. In *Amusing Ourselves to Death*, (1995) Neil Postman argued that any research on media should recognize that each medium has its own personality, its deficits, and its potentials. In *The Media Equation*, (1996) Stanford researchers Byron Reeves and Clifford Nass concluded that at unconscious levels and in all demographics, people perceive media as "real"—that is to say—unconsciously—all people experience

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

media in terms of personality and psychological experience based in social interaction. These incipient works began to establish parameters for a millennial study of the media dream. More recently, the Immersive Education Initiative, an offshoot of MediaGrid (2015), continues a global effort to advance understanding of the uses of technological media in educational contexts.

Jung says that "dreams have a purpose" (Jacobi, 1973), so if the media dream has Jungian veracity, the media dreamscape is imbedded with the holographic patterns of that purpose in fractal form. Most importantly, the path to Jungian *Individuation*—symbolized by the archetypal Journey of the Hero as process—consummation of which may be understood as the ultimate purpose of all human evolutionary (transcendent) experience, lies latent in the digital/virtual field that is energetically correlated with the Jungian collective unconscious.

In other words, if the mathematics of Fourier transforms can demonstrate recursive correlation between energy configurations (archetypes) in the collective unconscious and the energy images they project in dreams (archetypal representations) energy patterns in digital programs (algorithms) can be correlated with images in the metaverse (dreamscape). How would this be accomplished? With research, of course! The chapter will argue that the use of psychecology games as dream analogs allows for the use of Fourier transforms to interrogate correlations between real-time neuro-biological images (EEG, ECG, MEG, fMRI, etc) and images on the game monitor. Even in 1991, research had already confirmed that some human sensory perceptions are based on Fourier mathematics (Talbot, 1991, pp. 27-29; Lashley, 1950, pp 454-82; Collier, Burkhardt, & lin, 1971; Pollen & Tracktenberg, 1972, p. 109; DeValois, Karen K. & DeValois, Russel L., 1979, pp. 483-505; Chopra) and it is well known that *Fourier Transforms* serve as transducers in the digital dreamscape.

If the correlation between dreams and monitor images stands, all the benefits of Jungian dream analysis may accrue to analysis of the media dream. Then what? Ultimately, such analysis could lead to a documentable understanding of unconscious dimensions of collective personae including a definition of contextual purpose—collective *self realization*—as well as discovery of contextual psychological obstacles that obscure and block that state of harmonious self-realization. Analyzing the media dream "successfully" could eventually lead to harmonization of Earth's psyche and the literal introduction of the vaunted "Golden Age."

If correlates can be established between the holographic-dramatic structure of dreams and the holographic-dramatic structure of mediated images, that structure provides a framework for research with which to analyze digital "dream" illusions as if they were "psychic" dream images. In the emergent reality of psychological electronic media, a *Psych*ecology (an ecology of psyche) may be contemplated as a dreamscape. Ample research evidence exists (see below) in order to hypothesize that—like Jungian Psyche—the *metaverse* is holographic and that its computational patterns correspond to archetypal patterns of Psyche. The terms psychecology and metaverse are similar, but the metaverse is manmade and increasingly digital, while the psychecology is primordial. If this is so—and this is why we must refer to myth—archetypal images projected from the psychecology become archetypal representations in the metaverse. Because projections are essentially recursive, the patterns imbedded in archetypal representations can be used like patterns imbedded in dream images. So archetypal patterns can be employed to discover meaning, to diagnose collective mental disorder, and to apply therapy using media feedback targeted to fostering coherent states in contextual subject groups.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

BACKGROUND

It may be stipulated that psychological dynamics of advertising and propaganda have been very successful, but that the profit motive underlying advertising and the power motive underlying propaganda have been largely responsible for fostering the horrors of the nuclear age, the arms race, wars and rumors of wars, the insanity of the Cold War, black ops and covert political action, fear-based dehumanization, genocide, and devaluation of natural life. (Curtis, 2009; Moyers, 1987)

It may be argued that advertising and political agendas have monopolized the technological media. Notwithstanding the power of all media as catalysts for human evolution, the modern media have functioned as prime movers throughout the latter half of the twentieth century and have amply demonstrated their psychological power to alter human values, choices, and behaviors using psychological tools. (Curtis, 2009) Increasingly, sub-optimization, power-lust, and profit have characterized media policy to a catastrophic degree, and political advertising has intruded itself on national governance. Though opinions vary, the recent Supreme Court decision known as Citizens United—a U. S. constitutional case dealing with the regulation of campaign spending by organizations—is having a profoundly detremental influence on U. S. elections because wealthy corporations can now buy unlimited advertising.

For a variety of reasons—well argued by Adam Curtis (2009)—psychological media power has been closely held by the elites of academia, industry, and government, but these entities—apparently preferring the negative Freudian perspective and fear of the collective unconscious (Curtis)—have refused to embrace many of the positive evolutionary neuro-cognitive potentials of mass media. Even the Public Broadcasting System has been cannibalized and exists in a constant state of attack. One consequence of this sub-optimizing stance is that media potentials for learning and healing have neither been supported nor trickled down and been assimilated by the general populace.

There can be no doubt that today incipient human "cognition"—including thoughts, feelings, memories, and perceptions—that expresses itself through language, science, art, law, technology, and all things cultural—has a powerful influence upon the course of planetary evolution. Due to cognitive plasticity, the digital media have a profound and evolving influence on human perceptions of reality, morality, ethics, and learning. Meanwhile, the Internet provides a constant stream of intelligence relative to the nearly incredible advances in computer technology. The MIT Review is especially adept at reviewing new intelligence. Recently, The Review reported that large corporate entities like Face Book have begun expending vast sums in order to better understand cognitive process for neuro-marketing purposes. The rapidly evolving ecosystems associated with personal data is creating an entirely new field of scientific study, (Geril, Philippe, 2014c; Claes, Zane, 2014; Simonite, Tom, 2015d & 2014; 2015; Demers, 2015)

Industrial-governmental interest in "mapping" the brain is becoming pervasive. Based on a twelve year effort involving dozens of research institutes using supercomputers to create a simulation of how the human brain works, the European Union agreed last year to invest more than one billion Euros in the Human Brain Project (HBP). However, a letter from dissenting scientists has charged that the project employs opaque management and the pursuit of goals not widely shared by neuroscientists. The letter says, "We believe the HBP is not a well-conceived or implemented project and that it is ill suited to be the centerpiece of European neuroscience." (Regaaldo, Antonio, 2014; Simonite, Tom, 2014c)

The European Union is not alone. Governments, including those of the United States and China, have all launched large neuroscience projects to study the brain. But having roughly 86 billion neurons and trillions of connections, the brain is so massively complex that there is little consensus on how to

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

study it. (Human brain project, 2014) Related to this interest in cognitive dynamics is Microsoft's heavy investment in Holographic research and the dynamics of machine intelligence. (Simonite, Tom, 2014) A new trajectory of research on deep cognitive dynamics in the metaverse is the modern human mandate.

EVOLUTION OF THE MEDIA AS DREAM CONCEPT

Long ago, in *The Tempest*, Shakespeare observed that, "We are such stuff as dreams are made on." More recently, Sir Arthur Eddington said, "The stuff of the world is mind-stuff," (Foster, 1985, p7-12) Deepak Chopra has argued that, "We are experiencing the final stages of the overthrow of the superstition of materialism," (Chopra, 1995) and Lewis Carroll asked, "Is all our life, then, but a dream? Taken together, these statements sound a keynote not only for study, but for survival in the emergent age of virtual illusions.

The importance of dreams has reverberated from time immemorial, and characteristics of the dreamscape resound in the metaverse that is synonymous with the media dream. Primary correlates between dreams and media are language, metaphor, and symbolism. In this regard, myth provides important precedent not to be ignored by scientists. Not withstanding Fritjof Capra in his *Tau of Physics* (1976), many physicists including Arthur Eddington, James Jeans, Bertrand Russell, Alfred North Whitehead, and J. Robert Oppenheimer have made note of the correlations between quantum physics and myth. (Foster, 1985) According to most myth, the source of dreams is other-dimensional—a "spiritual" dimension that employs symbolic language as a medium between humans and spirit. The Bible Hub quotes John 1:1 (The Holy Bible), "In the beginning was the Word, and the Word was with God, and the Word was God." That's saying a lot, and one commentator, Mathew Henry, accurately clarifies the matter saying, "The plainest reason why the Son of God is called the Word, seems to be, that as our words explain our minds to others, so was the Son of God sent in order to reveal his Father's mind to the world." (Bible Hub, 2015) Without going into great theological commentary and analysis, if they are understood as symbols, words are the quintessential media. This principle is basically true of the trinities in most myths. As documented by Manley T. Hall (2003), Huston Smith (1958), and Joseph Campbell (1968), it is safe to say that all myths are based on symbolic systems, and the "Word" takes many oracular forms including Odinian runes, the Confucian I Ching, the Cabalistic Sephiroth, Pythagorean numbers, Alchemical symbolism, Hermetics, Tarot cards, the Zodiac, ad infinitum.

What the ancients understood as creation by Spirit, moderns may understand as creation with energy. Not coincidentally, the two pillars upon which Jungian theory are based—psychic totality (coherence) and psychic energism—are also consistent with fundamental principles of physics including the unified field, non-locality/synchronicity, and interactivity. Such factors constitute fundamental correlations between physics and myth. As to cognitive correlation among individuals and collective personae, Jung says:

For every piece of conscious life that loses its importance and value—so runs the law—there arises a compensation in the unconscious. We may see in this an analogy to the conservation of energy in the physical world, for our psychic processes have a quantitative aspect also. No psychic value can disappear without being replaced by another of equivalent intensity. This is a rule which finds its pragmatic sanction in the daily practice of the psychotherapist; it is repeatedly verified and never fails. Now the doctor in me refuses point blank to consider the life of a people as something that does not conform to psychological law. A people, in the doctor's eyes, presents only a somewhat more complex picture of psychic life than the individual. (Jung 1933, p 209-210)

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

For purposes of digital knowledge engineering, Jungian dreams appear to be holographic. Though opinions differ, as mentioned above, exploration of the holographic model has been comprehensively researched by Michael Talbot. (Talbot, 1991) If the basic principles of Psyche are unity and energy (Jacoby, 1973, p. 2), and if dreams are the archetypal representations of archetypal energy and information patterns, the "conversation" between archetypal patterns and projected images as archetypal representations may be understood as the basic form of mediation. Relative to discovery of the meaning embedded in dreams, that meaning may be divulged—as in any conversation—with insight and an understanding of the contextual language—the Word. If the media-sphere may be understood as a holographic conversation in contextual-symbolic dream language between unconscious and conscious dimensions, archetypal patterns of the collective unconscious may be understood to correspond with unconscious algorithmic patterns of digital software articulated as Fourier Transforms. The structure and purpose of projected images in the metaverse can then be correlated with dreams that Jung defined as archetypal representations.

Like film projections, archetypal representations are recursively structured and constitute a symbolic language between conscious and unconscious dimensions of Psyche. In other words, the dream is an accurate projection of unconscious multifunctional patterns. The term multi-functional refers to the four classical human functions (physical, emotional, mental, spiritual) that Jung called Sensing, Feeling, Thinking, and Intuiting. Because they consist of frequencies of energy, these functions cannot actually be separated. Human functions can be correlated with Aristotle's dramatic functions. The psychological functions constantly influence one another in ways consistent with Aristotle's definition of "dramatic unities," and these dramatic structures and unities can be used as a fundamental point of reference for cognitive research. For example, George Lakoff explains the chemical processes in the nervous system relative to semantic "scripts". (Lakoff, 2008) Lakoff cites Roger Shank and Robert Abelson (Lakoff, 2008, p. 249) in his paraphrase, "Complex narratives—the kinds we find in everyone's life story, as well as in fairy tales, novels, and dramas—are made up of smaller narratives with very simple structures." Lakoff says:

The neural circuitry needed to create frame structures is relatively simple [neural binding circuitry, neural signatures, event structures] and so frames tend to structure a huge amount of our thought…Each frame has roles (like a cast of characters), relations between the roles, and scenarios carried out by those playing the roles." (Lakoff, 2008, p. 22; Goffman, 1974) There is a protagonist, the person whose point of view is being taken. The events are good and bad things that happen. And there are appropriate emotions that fit certain kinds of events in the scenarios. (Lakoff, 2008, p. 23)

Citing Goffman, Dr. Lakoff also observes that words are all defined relative to conceptual frames: "Groups of related words, called 'semantic fields,' are defined with respect to the same frame. Thus words like 'cost,' sell,' 'goods,' price,' buy,' and so on are defined with respect to a single frame," (Lakoff, 2008, p 22; Goffman) and the roles of Buyer, Seller, Goods, and Money, form a narrative field context for the frame. Sounding remarkably like Jung who observed that dreams have dramatic action that can meaningfully be broken down into the elements of a Greek play (Jacoby, 1973, p. 83), both Jung and Lakoff understand the importance of the functional unities of cognition.

Symbolic patterns in dreams can be analyzed to discover their message—their purpose—so perhaps, digital images in the media-sphere can be analyzed like dream images in order to diagnose and treat collective mental disorder. Diagnosis would depend on "engineering" the knowledge management software according to principles of cognitive framing, and treatment would involve multifunctional

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

mediated biofeedback based on extensive research. By employing the compensational processes Jung calls the Amplification Method, a Jungian psychiatrist can mentor a patient by providing feedback as to the meaning of dream symbols. If successful, the process leads to meaningful (healing/coherent) insight on the part of the patient. In cognitive terms, unconscious cognitive frames can be adjusted into more coherent frames by providing media feedback. The psychological feedback/association process has been validated by advertising and propaganda, but the process of Jungian feedback is much different, more sophisticated, and differently motivated.

Adjusting cognitive frames in the collective unconscious of targeted personae with feedback in the form of interactive media content could foster meaningful insight and the achievement of coherent states among contextual collectives. The Jungian process of compensation is essentially a process of metaphorical extension, but it is based upon intense empathy with the patient on the part of the psychiatrist. The question of whether such empathy can be incorporated into digital simulations must be addressed with research, and such research lies within the realm of dramatic unities, their integrated archetypal functionality, and their degree of coherence. Because the psychiatrist must have extensive and empathetic knowledge about the patient, s/he is enabled to provide feedback to the dreamer relative to the dreamer's contextual psychic state. Feedback takes the form of suggestions about the meaning of symbolic patterns in the patient's dreams. When a patient (or learner) has insight as to the meaning of a dream, insight becomes learning and healing. According to this same process, media content targeted to contextual subject groups could foster a collective state of coherence (meaningful insight).

The dream speaks in images, and gives expression to instincts, that are derived from the most primitive levels of nature. Consciousness all too easily departs from the law of nature; but it can be brought again into harmony with the latter by the assimilation of unconscious contents. By fostering this [amplification] process we lead the patient to the rediscovery of the law of his own being. …The way of successive assimilations reaches far beyond the curative results that specifically concern the doctor. It leads in the end to that distant goal (which may perhaps have been the first urge to life), the bringing into reality of the whole human being—that is, individuation. (Jung 1933, p 26)

A fundamental assumption in the chapter is that the *Psych*ecology and--as archetypal representation—the media-sphere function in accordance with the rules of dream dynamics observed by Carl Jung. Directly relevant to this media dream-likeness is that humans have finally verified that so-called "material reality" is—in fact—illusion. Therefore, the universal axiom of myth and philosophy has also become scientific fact verified by quantum physics, and echoed by cognitive neuroscience. So, hypothetically, the *Media Dream* can be researched from the perspective of its curative potential. (Schafer & Yu; 2011) It may be understood that precisely like Jungian dreams, mediated digital dreams arise from the collective *unconscious* that is directly correlated with the digital unconscious and ultimately exists as a unified field of energy and information where human functions are unified according to principles of dramatic unity. Both cognitive and digital patterns take the form of frequencies of energetic force that, according to cognitive-psychiatric research, clothe themselves in linguistic-dramatic images and are projected as "dreams" (illusions).

During the past twenty years, research in neurological plasticity has reached a degree of agreement about the existence of this narrative-metaphorical structure of Psyche by studying the electro-chemical dynamics of the nervous system, integrating them with principles of physics, and researching neurobiological processes with technologies such as EEG, ECG, fMRI, MEG, etc. Drama is a more accurate

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

term than narrative for cognitive-linguistic structure because drama is electro-chemically interactive; i.e., actors on the stage and people in the audience perceive drama according to a fourfold matrix of functional components that have always been used to gauge human behavior and experience. To reiterate, Carl Jung called these functions reason, emotion, sensing, and intuition. Jung observed that dreams have dramatic structure, and modern cognitive researchers like George Lakoff have observed that the cognitive unconscious has dramatic structure to which we all refer our projected realities. The roles we play in life have their origin at unconscious levels and provide us with a template for understanding ourselves, our context, our exposition (statement of the problem), and our *lysis* (resolution of the problem). In other words, we live out our unconscious narratives, and—for example—we use the same part of our brains to see, imagine we are seeing, remember seeing, and understand language about seeing. (Lakoff, 2008, p. 39) The four functions are integrated in drama, and this dynamic explains why—when people have vicarious experience such as dreams, film, and video games—they experience emotions appropriate to the film/game story and access unconscious moral patterns. (Lakoff, 2008, p. 63) This effect is usually understood as immersion or suspension of disbelief.

While research on this emergent reality is yet in its infancy, it is certainly apparent that it constitutes a paradigm shift. Therefore, a better understanding of psychological health, morality, ethics, and laws appropriate to the shift become the human mandate. Researching the reality of the media dream according to dream dynamics becomes the human imperative. Though the most recent cognitive research seems to be entirely consistent with the principles of psyche and dream analysis established by Carl Jung, his research opus is more comprehensive and has provided a universal (and often unattributed) framework for computer engineering—memory—and analysis of cognitive research (neural networks, connectionism, holographic computing, etc.). As a recommendation and suggestion of future prospects, this paper addresses the Media Dream primarily from the standpoint of its potential for discovery of unconscious meaning at psychological levels of cultural collectives. Such meaning resides in the imbedded symbolism of mediated images.

Contextual Dream Patterns in War and Entertainment

A significant trend in current virtual reality research is sponsored by the military, and battlefield training courses are intended to be as realistic as possible—a clear example of the paradigm shift into the reality of the metaverse. From the cognitive perspective addressed above, these battle exercises are perceived by trainees as real (Reeves & Nass). Being "immersive" they also impact trainees at unconscious functional cognitive levels. In other words, the contextual group of trainees experiences virtual training exercises as real experience, and this experience changes unconscious "archetypal" cognitive frames at all functional levels including values. Presently, these training "dreams" are being programmed precisely for these reasons. The military wants its trainees to have "warfigher" values.

Warfighters

Just one example of this may be found online at the Naval Office of Research site as reported by EUROSIS, "ARLINGTON, Va.—Marines were able to turn a lush golf course into a hostile battleground complete with tanks, mortar fire and smoke. (Crawford, Katherine H., 2015) This "dream" was made possible by a newly developed augmented reality technology. "The Augmented Immersive Team Trainer (AITT) moved one step closer to its ultimate goal of giving warfighters glasses that can be worn to en-

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

hance augmented reality training scenarios." (Crawford) The reporter makes a distinction between the terms "augmented reality" and "virtual reality". The former refers to "a live environment onto which virtual images are superimposed. Think of watching a football game on television and seeing the yellow first-down line added to the screen you're watching." (Crawford) A "virtual reality" is different because it "is a wholly computer-generated environment in which users immerse themselves." However, according to Peter Squire, a program officer with ONR's Expeditionary Maneuver Warfare and Combating Terrorism Department, says that the AITT system, "which can support a wide array of live, virtual and constructive training scenarios, is 'only limited by the imaginations of those using it,'" (Crawford) For the purposes of this chapter, this is a clear sign of the trend that employs virtual reality to alter unconscious cognitive frames.

Virtual Humans

Another example of the trend to employ contextual dreams to alter experience-based cognitive frames at unconscious levels is the following. Online, we find that: "Research and technology are essential for providing the best capabilities to our warfighters." (Bellman, Orli, 2015) An online article, Researchers Create Virtual Humans, quotes Dr. Laurel Allender, director of the ARL Human Research and Engineering Directorate as saying, "This is especially so for the immersive and live-training environments we are developing to achieve squad overmatch and to optimize Soldier performance, both mentally and physically." The Army and USC are, "exploring the potential of developing a flexible multi-modal human-robot dialogue that includes natural language, along with text, images and video processing." (Bellman)

If this online article is analyzed as part of a more general dream sequence, it may disclose unconscious meaning. The more general sequence has to do with the scientific passion for virtual realities and robotics. We should be asking the question, "Where will this passion lead?" With the emergence of the brave new world of illusion being created by technological media, "virtual humans" are just one form of the denizens projected to inhabit the Metaverse. In the Metaverse, "real" people are expected to express themselves increasingly as avatars—in the same way as game players project their persona into a video game protagonist. The implicit concept underlying the Metaverse is that real life is a metaphor and that virtual life is reality. The term is being used to describe the concept of a future iteration of the internet, made up of persistent, shared, 3D virtual spaces linked into a perceived virtual universe—a virtual reality-based successor to the Internet. (Smart, J.M., Cascio, J. and Paffendorf, J., 2007) Whether "reality" is metaphorical or virtual, both are illusions, and the symbolism in the dreams can promote meaningful insight.

Artificial Intelligence and Robotics

Virtual humans and avatars exemplify the explosion of artificial intelligence applications which are enabling an incipient virtual age. Artificial intelligence algorithms underlie research on *robotics*, so Artificial intelligence and robotics are essentially synonymous. As suggested above, much AI research is being sponsored by governments—with research done by universities—for purposes of waging war. A conclusion is implicit; Just as the video game genre called *First-Person-Shooters,* in which the game player's avatar is first person, have achieved overwhelming popularity in video games, virtual realities based on warfare and "warfighters" have become a priority aspect of media age illusion. Because a

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

basic assumption of this chapter is that all experience, including virtual experience, alters the cognitive patterns in the personal and collective unconscious, the following example of the explosive trajectory of research in robotics becomes a prospective dream that is susceptible to analysis.

The US Defense Advanced Research Projects Agency (DARPA) has launched a new program to help small businesses, and individuals who have not previously worked with the federal government, develop new robotics capabilities. Dubbed Robotics Fast Track (RFT), the program aims to enable rapid, cost-effective development of new robotics capabilities designed to respond to, and even anticipate, quickly emerging warfighter requirements. (Geril, 2015a)

More ominous than the DARPA project is the following report from The U.S. Army that computer simulations improve lethality by understand the effects different caliber ammunition will have on targets. The research center at Picattiny Arsenal in New Jersey, "handles nearly 90 percent of the Army's lethality projects and all conventional ammunition for joint warfighters." (Kowal, Eric, 2015) The research center works with organizations like the U.S. Army Research Laboratory and the Survivability/Lethality Analysis Directorate at Aberdeen Proving Ground, Maryland.

Kowal points out that though large caliber system analysis has taken advantage of computational simulation tools for years, in order to improve consistency and performance with newly released smaller caliber enhanced performance rounds (EPR) a combination of modeling, simulation and testing was employed. "The use of newer, faster computers made critical portions of that effort possible. Some data was statistical, some physical and some probabilistic, but all done using physics-based models to simulate ballistics on soft targets" (Kowal). An "up-side" of simulating soft-target wounds might be that many who study survivability and lethality such as program executive officers and program managers, users, testers, the Army's independent evaluator and other "customers" would not see this as ominous because the research supports milestone decisions that might save lives. Another aspect of the "up-side" is that prototypes can cost millions of dollars a piece. "Modeling and simulation can save money by avoiding costly prototypes and testing" (Kowal).

Obviously, DARPA is not the only government agency interested in warfighters. "Several US government agencies including the army, navy, the department of homeland security, and the National Aeronautics and Space Administration have expressed interest in validating successful RFT projects and performers for use in their operations" (Geril, 2015a).

Research on robotics is not all about warfare. The Europe 2020 Initiative: Digital Agenda for Europe, "Scientists have created underwater robot swarms that function like schools of fish, exchanging information to monitor the environment, searching, maintaining, exploring and harvesting resources in underwater habitats." (Cocoro, anon., 2015) In ten experimental demonstrations, autonomous robots interact with each other and exchange information, resulting in a cognitive system that is aware of its environment. The European Union supported the COCORO project that explored and developed collective cognition in autonomous robots. COCORO's scientists used nature as a model. For example, observing how honeybees cluster, helped scientists develop the BEECLUST algorithm that they used to aggregate robots at a specific location. "Robot swarms not only look like schools of fish, they behave like them" Cocoro, par. 2).

Increasingly, the research on "robotics" involves the use of algorithms based on cognitive function. (Simonite, Tom, 2015b). As Neil Jacobstein, head of the Singularity University told the BBC:

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Artificial intelligence agents are already involved in every aspect of our lives - they keep our inboxes free of spam, they help us make our web transactions, they fly our planes and if Google gets its way will also soon drive our cars for us. "AI's are embedded in the fabric of our everyday lives. They are used in medicine, in law, in design and throughout automotive industry." And each day the algorithms that power away, making decisions behind the scenes, are getting smarter. It means that one of the biggest quests of the modern world - the search to make machines as intelligent as humans - could be getting tantalizingly close. (Wakefield, Jane, 2014)

In another recent report, the MIT Technology Review reports on an algorithm that can help robots heal themselves without human intervention. Researchers say that:

The robots learn with an "evolutionary algorithm.' This means that it will run repeated trial and error steps—building on a list it created before being deployed that details the things it can do and how valuable each one is—to determine a new way to get around. It's like a simplified version of what humans do: if you sprain an ankle, you use memory and experimentation to figure out how to hobble around in the most efficient and least painful way. (Garling, 2015, par. 6)

Though researchers' examples such as the Mars Rover or search and rescue robots are still far from real-world scenarios such as fighting fires or rescuing people, they are a significant aspect of the metaverse. Researchers Jean-Baptiste Mouret and Antoine Cully say these learning algorithms will soon be tested outside the lab on bigger robots. Perhaps they will be tested on virtual humans; this raises considerable ontological, epistemological, and ethical questions relative to the reality of the metaverse. "While watching the six-legged robot figure out a new method of movement inevitably brings about visions of the Terminator and evil robots, Mouret says researchers have plenty of time to build in proper safeguards to prevent robots from implementing behaviors that could harm people" (Garling).

Thinking of contextual collectives in terms of target groups is more a hop than a quantum leap. The use of focus groups in advertising to tap buy buttons in target groups is longstanding and very successful procedure. Now, AI research on demographics—from virtual humans to autonomous robot swarms—employs smart algorithms based on cognitive mapping. The Virtual Worlds Report for March 2015 defines "contextual" demographics, attitudes, and preferences: "The aim of this study was to enhance our understanding of demographics, attitudes, activities and play preferences across a variety of non-game, social virtual worlds, also referred to as metaverses" (Geril, 2015b).

Entertainment

In another framework of the psychological media sphere, the entertainment industry has always been about illusion addressed to contextual collectives. From musicals to war films, drama is based on appeal to contextual collectives, and these collectives are multi-faceted. For example, films of the WWII era were propagandistic and appealed to entire cultures as well as to subsidiary collectives. It may be stipulated that entertainment—to use a vastly general term—has always been a powerful source for acculturation. The idea that the entertainment industry has enormous influence on culture at large: cultural values, individual & cultural choices, and behaviors, need not be extensively documented. (Curtis, 2009)

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Entertainment and the Internet are becoming ever more closely linked as the age of illusion unfolds in a kaleidoscopic phantasmagoria of wireless applications. In answer to the question, "Where is the entertainment industry going?" we discover that Star Trek has provided the pre-eminent paradigm, in the form of the 'holodeck', the virtual reality facility on the Starship Enterprise. The holodeck was a box of a room where crewmembers could immerse themselves in an array of virtual illusions, like distant planets, and interact with aliens without ever leaving their spacecraft. However, mapping consumer demand against industrial innovation is questing beyond the holodeck:

Producing immersive entertainment experiences will require a whole suite of tools and underpinning technologies: in computer vision, positional and spatial audio, smart content creation, compression and real time rendering. Other advances will be needed in capabilities outside the range of even the leading audio-visual production studios. These will include 3-D display, augmented reality, holography, surround sound and haptic technologies. (Geril, 2015b)

Whether a virtual reality is a dream, a memory, a fantasy, a film, television, the Internet, or a video game, the research-based understanding of virtual-cognitive reality is that it has dramatic structure—even at quantum levels. According to Jung and Lakoff, the cognitive structures in unconscious dimensions are *projected* into so-called "real-life" contexts. (Jacobi, 1973; Lakoff, 2008; Goffman, Erving, 1974; Schafer & Yu, 2011) As already mentioned, Jung called the structural patterns of the unconscious *archetypes*, and Lakoff calls them *cognitive frames*. Cognitive-level processes that explain precisely *why* dramatic structure is important for an understanding of virtual illusion—of both conscious and unconscious (immersive) dimensions of *reality*— are not well-known except in fields of cognitive research. Nevertheless, researchers have been exploring linguistic issues of the unconscious for decades. Whether understood from cognitive levels or not, in diverse fields ranging from law enforcement to psychiatry, the value of narrative is practical and well known. Always interested in the poetic dimensions of drama, now the entertainment industry—especially the game industry—is becoming interested in cognitive dimensions as well. For example:

21st century storytelling will require not just enabling technologies, but also story tellers: professionals with expertise in interaction, human experience and story design to create content and experiences to be developed and consumed on these platforms. This in turn may necessitate new organizational structures, management systems and business models to enable innovations and the merging of technologies across films, games and media industries. (Boyd, Frank, 2015)

Recursive Holography and the Metaverse

From these brief references to massive cultural trends, contemplating the media illusion as a dreamscape and using dream analysis to psychoanalyze collective personae for purposes of harmonization and healing does not seem entirely crazy. An increasingly popular term for the media dream is the metaverse which is the global holographic projection of interactive images including Internet, film, video games, television and all the technological paraphernalia presently available. Our fundamental hypothesis is that the digital software (AI) sources of mediated *dream images* is analogous to the archetypal energy/information that is the cognitive source of dreams. Accordingly, the holographic projections of computer engineered archetypes (programs) are analogous to what Carl Jung calls "archetypal representations."

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

As discussed above, an important aspect of such representations—especially images—is that they are essentially recursive; i.e. they have the same dramatic structure as "archetypes" that inhabit the personal and collective unconscious. Though research is necessary to verify, the translation from archetype to archetypal representation appears to be based on recursive frequency analyzers known as Fourier transforms (Talbot, 1991, p. 27). It has been verified that human sensory mechanisms are based on Fourier mathematics (Talbot, p. 27; DeValois, Karen, DeValois, Russell L., Yund W. W., 1979 pp. 483-505), but the specific connection to archetypal-quantum structure remains to be validated.

The term "recursive" may be understood in terms of the "fractal" forms of physics, or in terms of the Gestalt perceptual principle of "Invariance". Invariance is the property of perception whereby simple geometrical objects are recognized independent of rotation, translation, and scale. Another psychological aspect of recursion includes such perceptions defined by Gestaltists as "Multistability" or multistable perception (the tendency of ambiguous perceptual experiences to pop back and forth unstably between two or more alternative interpretations), and "Reification" (the *constructive* or *generative* aspect of perception, by which the experienced percept contains more explicit spatial information than the sensory stimulus on which it is based).

This recursive dynamic of perception allows for the computational modeling of what appears to be randomly fluctuating symbols and pixilated images in both dreams and computer monitors. In other words, a quantum flux of archetypes that inhabit the personal and collective unconsciousness as defined by Carl Jung are projected as recursive archetypal representations in a neurobiological-holographic media-sphere. (Schafer & Yu, 2011; Schafer, 2011; Schafer, 2012)

Research on issues of the relationship between the holographic cosmos and the holonomic (holographic) brain is longstanding, and it's early proponents (Penfield, Wilder, 1975; Lashley, Karl, 1950, pp.454-82; Pribram, Karl, 1977, p. 75; Pribram, Karl, 1977, p. 123 & 169; Goleman, Daniel, 1971, pp. 71-72; Collier, J., Burckhardt, C. B.,& lin, L. H., 1971; van Heerden, Pieter, 1970, pp. 410-11; Pietsch, Paul, 1981, p. 78; Pollen, Daniel A. & Tractenberg, Michael C., 1972, p. 109; DeValois, Karen K., DeValois, Russell L., & Yund, W.W., 11979, pp. 483-505; Dossey, Larry, 1982, pp. 108-9; Restak, Richard, 1981, p. 19; Restak, Richard, 1979, p. 253; et al.) are well documented in Michael Talbot's *The Holographic Universe* (1991)

Holographic Coherence

The most recent research evidence that verifies this connection between quantum dimensions and their projections as "consciousness" is the discovery by Stuart Hameroff and Sir Roger Penrose of quantum vibrations in "microtubules" inside brain neurons. "They suggest that EEG rhythms (brain waves) also derive from deeper level microtubule vibrations, and that from a practical standpoint, treating brain microtubule vibrations could benefit a host of mental, neurological, and cognitive conditions." (Hameroff & Penrose, 2014) These researchers based their discovery on two decades of previous research on "orchestrated objective reduction" (Orch Or) which suggests that quantum vibrational computations (microtubules) are orchestrated by synaptic inputs and memory stored in microtubules. (Hameroff & Penrose, 2014) The term "orchestration" suggests the potential to harmonize conscious patterns with archetypal patterns according to the principle of coherence. Coherence is a measurable harmonious neurobiological state that has been studied extensively by the Heartmath Institute. (McCraty, Rollin & Childre, Doc (2010); McCraty, Deyhle, & Childre (2012).

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Coherent states appear to have the same characteristics as Carl Jung's "Compensational" states and "Flow". (Csíkszentmihályi, 1990) Compensation is the fundamental Jungian principle that makes discovery of unconscious meaning possible using the process of symbolic analysis on projected archetypal energy patterns in dream images. As images, dreams and computer graphics have structural correlates. The entirety of Carl Jung's psychiatric theory and practice is based on symbolic images in dreams, so interpretation of the underlying meaning in dream-computer images measured in terms of coherence has identical potential.

Correlated Images

Dream images and computer monitor images are directly correlated as to structure, perception, and leaning-healing potential. These correspondences are a primary component for qualifying psychecology games as a dream analog. (Schafer, 2011; Schafer, 2012) Therefore, psychecology games can be used as a cognitive research instrument in conjunction with MEG, EEG, ECG, fMRI, etc. for measuring real-time neurobiological activity in subject game players. (Schafer & Yu, 2011; Schafer, 2011; Schafer, 2012; Trafton, Anne, 2014) Research methodologies must be contextualized to various media and to myriads of demographics, but the dynamics of dream analysis remain constant. Though the media dream includes multi-functional sensory data that is integrated at levels of the unconscious, this chapter emphasizes the primarily visual symbolism in images.

Jung is not the only observer to say that the changing human perceptions of reality—what he calls the Spirit of the Age (Jung, 1933, pp. 175,196-220)—have been thrust upon us so rapidly that throughout the twentieth century it has disoriented and traumatized human collectives throughout the world. At base, the changes derive from discoveries in the realms of physics, psychology, and computer science. It is a well established fact that the psychological dynamics and structure of advertising and propaganda entail utilizing unconscious demographic patterns to sell their "products". This chapter develops the hypothesis that because the discoveries in these sciences have been incorporated into the holographic, psychological metaverse, its contextual projections can be analyzed like dreams.

THE MEDIA DREAM: REALITY AS ILLUSION

Researching the nature and dynamics of this illusory paradox of human beingness, human creativity, and human responsibility is critical to planetary survival. The arguments and details of why human existence—specifically material existence—is an illusion and a paradox is an issue of physics and psychology that has been well developed by many of humanity's ablest exemplars. Our argument emphasizes Jungian dream parameters as a basis for addressing the importance of the media dream as illusion that appears real. Based on the two pillars of Jungian psychiatry—psychic totality and psychic energy—this chapter postulates correlations among the unified fields of physics, psyche, and the technological media-sphere. (Schafer & Yu, 2011; Schafer, 2012) Though ongoing research constantly adds to the verification of the hypothesis, it is already an authentic premise in diversified scientific fields and is being addressed by an increasingly evolutionary neuroscience. Moreover, scientists and scholars including Eddington, Jeans, Whitehead, Capra, Radins, Oppenheimer, and many others have observed the connections that exist between myth and physics and which are central to Jungian principles of symbolic-metaphorical dream analysis and the process of Compensation through Amplification. Many have recognized the

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

correlations between physics and psychology. Perhaps the most prominent of these is the scholar of myth, Joseph Campbell who asserted that, "Myth is psychology." Campbell was referring specifically to Jungian psychology.

Functional Interactivity

Based in physics, the most promising candidate for dream dynamics and structure is holography—a science that is just coming into its own. (Talbot, 1991) Accordingly, because of their corresponding structure and dynamics, it may be argued that both dreams and media dreams are holographic. Both realities share the principles of energy patterns, wholeness, linguistic structure, functionality, and—most importantly—interactivity. (Schafer & Yu, 2011) The entire framework of Jungian analysis and treatment is founded on his observation that dreams are interactive. (Jacoby, 1973) In other words, the symbolism and context of dreams change according to a patient's evolving need for psychic meaning. These changing patterns resulting from interactive experience manifest as bio-energetic phenomena in the nervous system. We will detail this research in a later chapter. For now, this same bio-energetic interactivity can be imaged and measured in real time as a player makes choices leading to a game-win while playing drama-based video games.

Because non-local bio-energetic processes are now being applied to research using a plethora of electronic devices that contribute to understanding the cognitive connection to holographic media, the collective unconscious is being impacted with the digital unconscious generated by complex algorithms. The fundamentally interactive nature of dreams has already become nearly pervasive—though not recognized—in the media dream. In ways that are correlated, increasing interactivity in media domains allows people to use the Internet, television, smart phones, and a growing array of apps to access contextual meaning from almost anywhere in the virtual domain of the holographic media dream—action at a distance. The electro-chemical neural processes associated with this pervasive interactivity may be calculated mathematically employing sophisticated engineering sets and components such as finite element analysis, fluid dynamics, Discreet Fourier Transforms, efficient algorithms of fast Fourier Transforms, and a variety of other calculations for articulating the paradigm shift. (Schafer, 2011) To reiterate, for decades, scientists from various fields have speculated that the human brain and the universe itself are holographic. (Talbot, 1991; Bohm, 1951; Mishlov, 1998) So holography becomes an increasingly relevant metaphorical model that has the potential to verify the media dream hypothesis.

Deepak Chopra has explained reality is "a socially programmed hypnosis," and promised that ours is an age of the "overthrow of the superstition of materialism." (Chopra, 1995) In a scientific environment where Wilder Penfield has searched for the "thinker of the thought," and others have researched "cellular memory," we have made important strides in the aggressive study of cognition and consciousness, (Chopra, 1995), but we have not yet accepted the ramifications or the psychological impact of the media dream as a primary aspect of human reality. Our research has studied this premise from a variety of angles including the enhancement of psychological coherence in contextual collectives (Schafer, 2011), serious games for articulating the paradigm shift (Schafer, 2011), ethical design of social influence marketing (Schafer & Palamedes, 2011), the use of drama-based video games as a research instrument for creation of meaningful media (Schafer & Yu, 2011), and optimizing cognitive coherence and learning in contextual collectives. (Schafer & Yu, 2011) The arguments in these publications and many conference presentations assert the concept that the technological media-sphere is dynamically and structurally analogous with the unified field of energy and information known to physics and has virtually the same dynamics as dreams defined by the Analytical Psychology of Carl Jung.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

As mentioned above, this analog extends to the structure and dynamics of psychecology games. Defining target groups with subjective data for advertising purposes has been very successful. Using more sophisticated personality profiling like Myers-Briggs and Big 5 profiles to define game player functionality would contribute greater scientific authenticity to the process of defining target (contextual) groups. During drama-based video game play, player choice patterns could be stored and studied using sophisticated headsets or virtual reality technologies to track electro-magnetic and chemical activity in the nervous system. Such research will then contribute to understanding of distributive functions and unconscious motivations in collective personae. Correlating neuro-linguistic dynamics experienced by game players with neuro-linguistic dynamics experienced by users of the media dream could lead to a much better understanding of the "positive" uses of media content, media policy, and media education. This would provide a key that could open the portal of opportunity. Opening the door and crossing the threshold of opportunity would constitute a critical initiation in the human perception and understanding of what is real. We would begin to appreciate the reality of illusion as portrayed in the Media Dream. This would be our crisis of departure from the superstition of materialism. Now we have an opportunity to address the psychological crisis of the media age before we lose track of reality and become immersed in psychotic reaction to illusion—the symbols and symptoms of which are now rampant in the Media Dream. (Schafer, 2012)

According to the dynamics of holography, our technological media provide insight—like a hall of mirrors—to the collective unconscious, while video games have the potential to provide highly specific access to neurobiological function. If neural processes can be correlated with archetypal states of the cognitive unconscious where archetypes form a magnetic field and energy center recursive with the projection of images, a wealth of Jungian principle and research will become available for timely use. "The dream is a statement, uninfluenced by consciousness, expressing the dreamer's inner truth and 'reality as it really is.'" (Jacoby, 1973) "Thus for Jung the manifest content of a dream is not a façade but a fact which always reveals what the unconscious has to say about the situation and which always says exactly what the unconscious means." (Jacoby, 1973) Therefore, the imbedded symbolism in images can be analyzed—as it is in Jungian dream analysis—to access contextual meaning that resides in both the cognitive unconscious and the digital unconscious. (Schafer, 2011) Such access to the personal and collective unconscious can be employed to reinforce cognitive coherence. (Schafer, 2012)

In today's reality of statistics and target groups, it may be stipulated that—at least metaphorically—human groups have "personalities," (ethnic, religious, political, corporate) that are defined by normative-conceptual cognitive structures imbedded in the energy and information fields of the collective unconscious. Jung discusses cognitive structures in terms of archetypal patterns, and George Lakoff discusses them in terms of "neural recruitment" which is a process for strengthening neural synapses. (Lakoff, 2008) Employing the process of Jungian Amplification (symbolic-metaphorical extension), these energy/information patterns of the unconscious are susceptible to harmonization (measured in terms of heart rate variability as a signifier of coherence).

By all indications, Jungian Compensation is synonymous with "coherence". It is our contention that with the application of Jungian principles to the Media Dream, coherent psychological states can be induced in collective personae by pre-measuring how target groups can be predisposed to functionally coherent states. McCraty and Childre discuss the nature of coherence, how it can be measured and reinforced with biofeedback, and applied to harmonization of psyche in all its functions—physical, emotional, rational, and spiritual. "In globally coherent systems such as human beings, there is an incredible amount of activity at every level of magnification or scale that spans more than two-thirds of

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

the 73 known octaves of the electromagnetic spectrum." (McCraty & Childre, 2010) The functions cited by McCraty and Childre correspond to the Jungian functions of psyche—sensing, feeling, thinking, and intuiting. It is these functions that can be integrated into experimental design in order to foster cognitive coherence. As cited by Michael Talbot in *The Holographic Universe*, researchers (DeValois, 1979 pp. 483-505) have discovered that the brain uses Fourier mathematics to translate patterns of the sensory function. For example, the visual cortex responds to frequencies of various wave forms. (Talbot, p. 28) Subsequently, their research has been expanded to confirm that the other sensory functions are based on Fourier mathematics (Talbot, 1991). Moreover, though much more research is necessary to expand our understanding of the dynamic, Lakoff confirms that the functions are integrated by the process of narrative and metaphor. "There is a protagonist, the person whose point of view is being taken. The events are good and bad things that happen. And *there are appropriate emotions* that fit certain kinds of events in the scenarios (italics mine)." (Lakoff, 2008, p. 23)

Characteristics of compensation and coherence are also consistent with characteristics of the "Flow" phenomenon researched by Mihály Csíkszentmihályi. "Flow is the mental state of operation in which the person is fully immersed in what he or she is doing by a feeling of energized focus, full involvement, and success in the process of the activity." (Csíkszentmihályi, 1990) Components of flow include clear goals, concentration and focus, diminished self-consciousness, loss of the sense of time passage, and a sense of personal control and intrinsically rewarding action are aspects of immersion in games and—perhaps—suggestions of contact with an altered cognitive state.

As this dynamic of functionally coherent, compensational, flow becomes more generally accepted—making it a global fact of everyday reality—the human reality will shift in benign ways. Emergent changes in human perceptions of reality and human responsibility will evoke the imperative to generate coherent patterns relative to morality, law, responsibility, privacy, and an entire gamut of social interactions that are presently obscure. Gradually, as we achieve this new understanding of the "real", we will mark a breakthrough in the human sense of responsibility for the direct power humans wield with the energy of their thought and desires. Certain oft-reiterated truths will be clarified: "Thoughts are things." (Plato); "As a man *thinketh* in his heart, so is he." (Christ); "A man is what he thinks." (Buddha); "Our thoughts are epochs in our lives." (Thoreau); "Nurture your minds with great thoughts. To believe in the heroic makes heroes." (Disraeli); "The greatest events of an age are its best thoughts. Thought finds its way into action." (Boice). Greater understanding of the media dream may mark a crossing of the initiatory threshold comparable to the discovery of fire.

From these brief references to massive cultural trends, contemplating the media illusion as a dreamscape and using dream analysis to psychoanalyze collective personae for purposes of harmonization and healing does not seem entirely crazy. A popular term for the media dream is the metaverse which is the global holographic projection of interactive images including Internet, film, video games, television and all the technological paraphernalia presently available. Our fundamental hypothesis is that the digital software, AI, sources of mediated *dream images* is analogous to the archetypal energy/information that is the cognitive source of dreams. Accordingly, the holographic projections of computer engineered archetypes (programs) are analogous to what Carl Jung calls "archetypal representations." An important aspect of such representations—especially images—is that they are essentially recursive; i.e. they have the same dramatic structure as "archetypes" that inhabit the personal and collective unconscious. Though research is necessary to verify, the translation from archetype to archetypal representation appears to be based on recursive frequency analyzers known as Fourier transforms (Talbot, 1991, p. 27).

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

It has been verified that human sensory mechanisms are based on Fourier mathematics (Talbot, p. 27; DeValois, Karen, DeValois, Russell L., Yund W. W., 1979 pp.483-505), but the specific connection to archetypal-quantum structure remains to be validated.

The term "recursive" may be understood in terms of the "fractal" forms of physics, or in terms of the Gestalt perceptual principle of "Invariance". Invariance is the property of perception whereby simple geometrical objects are recognized independent of rotation, translation, and scale. Another psychological aspect of recursion includes such perceptions defined by Gestaltists as "Multistability" or multistable perception (the tendency of ambiguous perceptual experiences to pop back and forth unstably between two or more alternative interpretations), and "Reification" (the *constructive* or *generative* aspect of perception, by which the experienced percept contains more explicit spatial information than the sensory stimulus on which it is based).

This recursive dynamic of perception allows for the computational modeling of what appears to be randomly fluctuating symbols and pixilated images in both dreams and computer monitors. In other words, a quantum flux of archetypes that inhabit the personal and collective unconsciousness as defined by Carl Jung are projected as recursive archetypal representations in a neurobiological-holographic media-sphere. (Schafer & Yu, 2011; Schafer, 2011; Schafer, 2012)

Research on issues of the relationship between the holographic cosmos and the holonomic (holographic) brain is longstanding, and it's early proponents (Penfield, Wilder, 1975; Lashley, Karl, 1950, pp.454-82; Pribram, Karl, 1977, p. 75; Pribram, Karl, 1977, p. 123 & 169; Goleman, Daniel, 1971, pp. 71-72; Collier, J., Burckhardt, C. B.,& lin, L. H., 1971; van Heerden, Pieter, 1970, pp. 410-11; Pietsch, Paul, 1981, p. 78; Pollen, Daniel A. & Tractenberg, Michael C., 1972, p. 109; DeValois, Karen K., DeValois, Russell L., & Yund, W.W., 11979, pp. 483-505; Dossey, Larry, 1982, pp. 108-9; Restak, Richard, 1981, p. 19; Restak, Richard, 1979, p. 253; et al.) are well documented in Michael Talbot's *The Holographic Universe* (1991).

The most recent research evidence that verifies this connection between quantum dimensions and their projections as "consciousness" is the discovery by Stuart Hameroff and Sir Roger Penrose of quantum vibrations in "microtubules" inside brain neurons. "They suggest that EEG rhythms (brain waves) also derive from deeper level microtubule vibrations, and that from a practical standpoint, treating brain microtubule vibrations could benefit a host of mental, neurological, and cognitive conditions." (Hameroff & Penrose, 2014) These researchers based their discovery on two decades of previous research on "orchestrated objective reduction" (Orch Or) which suggests that quantum vibrational computations (microtubules) are orchestrated by synaptic inputs and memory stored in microtubules. (Hameroff & Penrose, 2014) The term "orchestration" suggests the potential to harmonize conscious patterns with archetypal patterns according to the principle of coherence. Coherence is a measurable harmonious neurobiological state that has been studied extensively by the Heartmath Institute. (McCraty, Rollin & Childre, Doc (2010); McCraty, Deyhle, & Childre (2012).

Coherent states appear to have the same characteristics as Carl Jung's "Compensational" states and "Flow". (Csíkszentmihályi, 1990) Compensation is the fundamental Jungian principle that makes discovery of unconscious meaning possible using the process of symbolic analysis on projected archetypal energy patterns in dream images. As images, dreams and computer graphics have structural correlates. The entirety of Carl Jung's psychiatric theory and practice is based on symbolic images in dreams, so interpretation of the underlying meaning in dream-computer images measured in terms of coherence has identical potential.

This chapter argues that dream images and computer monitor images are directly correlated as to structure, perception, and leaning-healing potential. These correspondences are a primary component for qualifying psychecology games as a dream analog. (Schafer, 2011; Schafer, 2012) Therefore, psychecology games can be used as a cognitive research instrument in conjunction with MEG, EEG, ECG, fMRI, etc. for measuring real-time neurobiological activity in subject game players. (Schafer & Yu, 2011; Schafer, 2011; Schafer, 2012; Trafton, Anne, 2014) Research methodologies must be contextualized to various media and to a myriad demographics, but the dynamics of dream analysis remains constant. Though the media dream includes multi-functional sensory data that is integrated at levels of the unconscious, this chapter emphasizes the primarily visual symbolism in images.

Jung is not the only observer to say that the changing human perceptions of reality—what he calls the Spirit of the Age (Jung, 1933, pp. 175,196-220)—have been thrust upon us so rapidly that throughout the twentieth century it has disoriented and traumatized human collectives throughout the world. At base, the changes derive from discoveries in the realms of physics, psychology, and computer science. It is a well established fact that the psychological dynamics and structure of advertising and propaganda entail utilizing unconscious demographic patterns to sell their "products". This chapter develops the hypothesis that because the discoveries in these sciences have been incorporated into the holographic, psychological metaverse, its contextual projections can be analyzed like dreams.

CONCLUSION

Jungian Dream Analysis

The unconscious aspect of *psyche* is much like a *unified field of physics*. According to Jung:

Sooner or later nuclear physics and the psychology of the unconscious will draw closer together as both of them, independently of one another and from opposite directions, push forward into transcendental territory, the one with the concept of the atom, the other with that of the archetype. (Aion, p. 69; from Jacoby, 1973)

Dreams employ a symbolic language that communicates messages between that part of the dreamer's brain that is conscious and that part that is unconscious. Psychecology games are structurally analogous with the structure of Psyche. Due to the interactive loop between conscious-unconscious player choices a complex cognitive process becomes a recursive monitor image—the interactive process articulates the psychological process. This interactivity represents an important breakthrough that incorporates total functionality in the mediating process.

Functionality should be understood in terms of agency and the consequences of action. In the sense that players make psychological choices that are both conscious and unconscious and take action based on the images (and other sensory data) in their perceived reality, video games can be understood as an authentic simulation of a "real" existence in which causal behavior is generated and consequences of the behavior seem to materialize as images. So doing, players are creating their functional four-dimensional reality based largely on unconscious memories of psychological experiences. Using perceptions of images, they are employing cognitive alchemy and symbolic language to translate the unknown into the known. Imbedded unconscious meaning is translated into meaningful insight—precisely the compensational objective of Jung's Amplification Process.

RECOMMENDATIONS FOR FUTURE RESEARCH

An abundance of current research on Artificial Intelligence, psychological dynamics of global target groups, and robotics is underway. However, the frameworks of research are generally antiquated; i.e. they do not employ a comprehensive understanding of dream dynamics at work in the virtual media-sphere.

Contextual Ecosystems

As reported by EUROSIS—The European Multidisciplinary Society for Modeling and Simulation Technology—and directly relevant to analyzing contextual groups with digital technology, we hear that Facebook has "Like Farms". Emiliano De Cristofaro and colleagues (2014) from the University College London, targeted Facebook users in the US, France, India, Egypt, and worldwide. By measuring "likes" activity on an array of Facebook pages, researchers correlated user profiles with measures of page-popularity. Data relative to understanding "likes" of Facebook users translates to traditional personality profiling of target groups, but does not sufficiently factor unconscious dynamics into conclusions. Though an intuitive sense of the scope of unconscious issues exists, the importance of data relative to page popularity has commercial motivation and is being applied primarily to promote business opportunities. Such studies of contextual collective personae should be employed in more profound ways to promote cognitive coherence.

The study of online social networks has revolutionized the way social scientists understand human interaction on a grand scale. It is based on the assumption that the fundamental unit of interaction is the social tie that exists between individuals. This tie can be a message that one person has sent to another, that one person follows another, that one person "likes" another and so on. (8/1/2014)

The MIT Technology Review (1-11-2015) reports that computer scientists in the emergent science of human-data interaction say, "The rapidly evolving ecosystems associated with personal data are creating an entirely new field of scientific study." (Ecosystems, 2015) Again, the article goes on to illustrate the marketing potentials of this new science instead of the more significant potentials for addressing cognitive coherence:

Back in 2013, the UK supermarket giant, Tesco, announced that it was installing face recognition software in 450 of its stores that would identify customers as male or female, guess their age and measure how long they looked at an ad displayed on a screen below the camera. Tesco would then give the data to advertisers to show them how well their advertising worked and allow them to target their ads more carefully. (Ecosystems, 2015)

A remarkable online article defines three neuromarketing lessons derived from video games. The article explains that:

Games are uniquely adept at leveraging human psychology to motivate behavior. We play them for hours on end and enter into a state of flow with an ease not found in other fields. This is no accident: during my time studying game design and working in the field, neurological language like "dopamine hits" and "social proof" were commonplace. In this post, I'll examine some of the common tools used by video game designers in order [to] insure engagement and ultimately drive sales. (Claes, 2014)

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Another recent article is about *The New Statistics*. In their abstract, authors say that, in response to heightened concern that our published research literature is incomplete and untrustworthy, "We need to make substantial changes to how we conduct research." The article goes on to explain that null hypothesis significance testing (NHST) has recognized flaws, and recommends preferred techniques including estimation based on effect sizes, confidence intervals, and meta-analysis (Cumming, 2013).

Robotics and Artificial Intelligence

Recent advances in robotics research constantly confirm the functional interactivity of physics, mathematics, and cognition. In another fascinating article from the MIT Review (Sept 22, 2014), "Eugene Izhikevich thinks you shouldn't have to write code in order to teach robots new tricks. "It should be more like training a dog," he says. "Instead of programming, you show it consistent examples of desired behavior." For example, to teach a robot to pick up trash, a mentor uses a remote control to repeatedly guide the robot's gripper to perform that task. After just minutes of repetition, the robot takes the initiative and starts doing the task for itself. Izhikevich's startup, *Brain Corporation*, based in San Diego, has developed an operating system for robots called *BrainOS* to make that possible. (Simonite, 2014)

Global Coherence Initiative

Perhaps the most exciting and relevant development in the vast arena of current research is the Global Coherence Initiative (GHI) spearheaded by the Institute of HeartMath. There is strong support for the existence in the earth's ionosphere of a global information field that connects all living systems and consciousness. "Every cell in our bodies is bathed in an external and internal environment of fluctuating invisible magnetic forces that can affect virtually every cell and circuit in biological systems." (McCraty, Deyhle, & Childre, 2012). Progress on the establishment of a global network of monitoring stations for studying these electro magnetic fluctuations portends a quantum leap in the direction of understanding of the media dream and how humans interact with it to create reality.

The scope of integration among all earth's inhabitants is becoming a conscious fact throughout the human population. Though vested interests seem always to marginalize the importance of the natural environment, the pervasiveness and popularity of media paraphernalia must eventually lead to a widespread appreciation of their dynamic impact and integration at all functional levels of human reality. We know something about the sun's influences on the earth—like the fact that without the sun, all life on earth would disappear. However, scientists have been expanding our knowledge with regularity. "The most likely mechanism for explaining how solar and geomagnetic influences affect human health and behavior are a coupling between the human nervous system and resonating geomagnetic frequencies called Schumann resonances, which occur in the earth-ionosphere resonant cavity and Alfvén waves. (McCraty, et al 2012) HeartMath researchers say that, "It is well established that these resonant frequencies directly overlap with those of the human brain and cardiovascular system" (McCraty, et al 2012).

This section on the need for further research is rather long in order to emphasize the vast scope and significance of the subject. The scope of necessary research is ontological, and research must be framed to contemplate the very nature of the paradigm shift into a virtual reality. The chapter takes the perspective—as does Joseph Campbell--that "mythology is psychology", that the Jungian archetypes of mythology are the selfsame energy and information patterns of physics, that the media-sphere or metaverse is analogous with psyche, and that it constitutes a holographic projection of media dreams from the collective unconscious.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Relative to more research, the scope of the chapter is both metaphysical and practical. Realization of the existence of a virtual *correspondence* between individuals and collectives—a sort of fractal bio-energetic relationship between the individual and the group as illustrated in such phenomena as focus groups, target groups, or statistical entities—marks the beginning of a more positive scientific understanding of the cognitive reality of the mediated dream. Many scientists have addressed this subject, and David Foster has provided an excellent overview. (Foster, 1985) Today, the marketing industry applies the correspondence principle constantly. Carl Jung understood the correspondence between individual and collective psyche as a fundamental principle of his therapeutic method. Accordingly, with appropriate adjustments in research methodology, therapy that works on individual levels may also be hypothesized to work at collective levels.

Now the doctor in me refuses point blank to consider the life of a people as something that does not conform to psychological law… "A people, in the doctor's eyes, presents only a somewhat more complex picture of psychic life than the individual," to quote Swedenborg. And so we can draw a parallel: just as in me, a single human being, the darkness calls forth the helpful light, so does it also in the psychic life of a people. (Jung 1933, p 209-210)

The therapeutic efficacy of narrative/drama is ancient and well-documented. (White, 2000) Phenomena such as catharsis have long been studied, so—given the robust interest in the technologies of the media-sphere—drama-based video games and Massively Multi-Player Online Games (MMOG) may provide a portal relative to collective healing and such new-paradigm experiences as epiphany, "metanoia" (Markley, 1972) or psychological critical mass.

KEY TERMS AND DEFINITIONS

Archetypal Representations: Jungian archetypes of mythology are the selfsame energy and information patterns of physics that constitute the source of the media-sphere or metaverse and are analogous with psyche. Archetypes are the psychoenergetic, generative source of holographic projections (archetypal representations) of media dreams from the collective unconscious.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Archetype: Jungian archetypes of mythology are the selfsame energy and information patterns of physics that constitute the source of the media-sphere or metaverse and are analogous with psyche. Archetypes are the psychoenergetic, generative source of holographic projections (archetypal representations) of media dreams from the collective unconscious.

Artificial Intelligence (AI): This field overlaps with electronics, computer science, robotics, mechatronics, nanotechnology, and bioengineering.

Avatar: The doctrine of avatars is a mythical concept in which a deity takes incarnation in human form that embodies a cosmic concept or philosophy in a person; i.e. Jesus embodies the concept of Love, and the Buddha embodies the concept of Compassion. In in the computer world, an avatar specifically refers to a character that represents an online user. Avatars are commonly used in multiplayer gaming, online communities, and Web forums.

Coherence: A single wavelength or frequency with all the waves in phase.

Collective Personae: According to Carl Jung, the persona is the social face the individual presents to the world—a kind of mask that is projected into the world and serves as a mirror of unconscious psychic patterns of individuation. A primary function of the persona is the evolutionary development of a viable, adaptive social persona. Jung was explicit as to the existence of collective personae (much like target groups in advertising) that are functional correspondences to individual personalities.

Compensation: A natural process aimed at establishing or maintaining balance within the psyche. The activity of consciousness is selective and requires direction, but direction requires the exclusion of everything irrelevant. According to Jung, the conscious orientation is one-sided. The psychic contents that are excluded and inhibited by the chosen direction sink into the unconscious, where they form a counterweight to the conscious orientation. As a rule, the unconscious compensation does not run counter to consciousness, but is rather a balancing or supplementing of the conscious orientation. In dreams, for instance, the unconscious supplies all those contents that are constellated by the conscious situation but are inhibited by conscious selection, although a knowledge of them would be indispensable for complete adaptation.

Contextuality: Jung's principle of compensation demands that dream interpretation must incorporate significant familiarity and understanding of the individual or patient who is doing the dreaming. In order for game software to provide authentic compensation, the game must be specifically programmed to the psychological profile or "context" of the player.

Holography: A method of reproducing a three-dimensional image of an object by means of light wave patterns recorded on a photographic plate or film. Holography is sometimes called lensless photography because no lenses are used to form the image. The plate or film with the recorded wave patterns is called a *hologram.* The light used to make a hologram must be coherent, i.e. of a single wavelength or frequency and with all the waves in phase. A coherent beam of light can be produced by a laser. The term is often used as a metaphorical model; i.e. "holographic universe" and "holographic brain".

Interactivity: In computers, interactivity is the dialog that occurs between a human being and a computer program. Programs that run without immediate user involvement are not interactive, but video games are usually thought of as fostering a great amount of interactivity. In the context of the chapter, interactivity extends to the four psychoenergetic Jungian functions (thinking, feeling, sensing, and intuiting). However, order entry applications, channel changing, and many other business applications are also interactive.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Media Dream: The media dream, a term coined by the author, goes beyond the technologically generated virtual realities called the metaverse and provides a comprehensive framework for correlating fundamental dimensions of reality by including multi-functional dynamics of Jungian dreams. The dreamscape of the holographic media-sphere that has the same psychoenergetic structure as Jungian dreams; i.e. dramatic, multifunctional structure.

Metaverse: The Metaverse is a virtual shared space—a collective—created by the convergence of virtually enhanced physical reality and "physically persistent virtual space, including the sum of all virtual worlds, augmented reality, and the internet. The word *metaverse* is a portmanteau of the prefix "meta" (meaning "beyond") and "universe" and is typically used to describe the concept of a future iteration of the internet, made up of persistent, shared, 3D virtual spaces linked into a perceived virtual universe. The term was coined in Neal Stephenson's 1992 science fiction novel *Snow Crash*, in which humans, as avatars, interact with each other and software agents, in a three-dimensional space that employs the real world as metaphor. Stephenson used the term to describe a virtual reality-based successor to the Internet. Concepts similar to the Metaverse have appeared under a variety of names in the cyberpunk genre of fiction as far back as 1981 in the novella *True Names*, Stephenson stated in the afterword to *Snow Crash* that after finishing the novel he learned about *Habitat*, an early MMORPG which resembled the Metaverse" (Smart, J.M., Cascio, J. and Paffendorf, J., 2007).

***Psych*ecology:** The unified field ecology of psychoenergetic, multidimensional reality.

***Psych*ecology Video Games:** These drama-based, psychoenergetic games should not be unduly associated with video games in their present state of development. Rather, they constitute an emergent game genre that is characterized by advanced principles of cognitive dynamics and story-telling art. These games have all the components of dreams, physics, the media, and interactivity with which to research the fourth dimension.

Psychological Functions: The classical four dimensions of human reality are 1) sensory/material, 2) emotional, 3) mental/rational and 4) spiritual. Jung called them 1) Sensing, 2) Feeling, 3) Mental, and 4) Intuitive. These dimensions are symbolized by 1) earth, 2) water, 3) air, and 4) fire.

Recursion: The process of repeating items in a self-similar way. For example, when the surfaces of two mirrors are exactly parallel with each other, the nested images that occur are a form of infinite recursion. The term has different meanings specific to a variety of disciplines ranging from linguistics to logic. The most common application of recursion is in mathematics and computer science, in which it refers to a method of defining functions. The term function refers to a relation between a set of inputs and a set of permissible outputs in which the function being defined is applied within its own definition. The functional relationship between Jungian archetypes and archetypal representations (projections) is analyzed in dreams according to symbolic images that are projections of unconscious psychoenergetic patterns. Recursion may also apply to metaphorical resonance that can be coded mathematically.

Robotics: A branch of engineering that involves the conception, design, manufacture, and operation of robots. This field overlaps with electronics, computer science, artificial intelligence, mechatronics, nanotechnology, and bioengineering.

This research was previously published in Exploring the Collective Unconscious in the Age of Digital Media edited by Stephen Brock Schafer; pages 232-260; copyright year 2016 by Information Science Reference (an imprint of IGI Global).

Chapter 19
On the Use of Bayesian Network in Crime Suspect Modelling and Legal Decision Support

O. E. Isafiade
University of Cape Town, South Africa

A. B. Bagula
University of the Western Cape, South Africa

S. Berman
University of Cape Town, South Africa

ABSTRACT

Predictive policing (Pp) relates to identifying potentially related offences, similar criminal attributes and potential criminal activity, in order to take actionable measures in deterring crime. Similarly, Legal Decision Making Process (LDMP) considers some level of probabilistic reasoning in deriving logical evidence from crime incidents. Bayesian Networks (BN) have great potential in contributing to the area of Pp and LDMP. Being based on probabilistic reasoning, they can assess uncertainty in crime related attributes and derive useful evidence based on crime incident observations or evidential data. For example, in a particular context of crime investigation, BN based inference could help collect useful evidence about a crime scenario or incident. Such evidence promotes effective legal decision making process and can assist public safety and security agencies in allocating resources in an optimal fashion. This chapter reports on various application areas of BN in the crime domain, highlights the potential of BN and presents "thought experiments" on how offender characteristics could be modelled for decision support in legal matters. The chapter further reports on the performance of empirical analysis in the legal decision support process, in order to elucidate the practical relevance and challenges of using BN in the crime domain.

1. INTRODUCTION

The foundation and motivation for repeat victimisation study (RVS) relates to the fact that repeat crime is much more likely to happen in a short interval of time after the first incident, and often within a close proximity (Evett et al., 2006 & Riesen et al., 2009). RVS is also associated with the notion that crime is mostly initiated and perpetuated "where and when" there is a "conducive" environment for a potential offender and the presence of a suitable (vulnerable) target victim. This notion is corroborated by the long-established routine activity theory (RAT) in criminology depicted in Figure 1 (Clarke et al, 1993), which stipulates that a crime can only be committed when three specific criteria are involved. These criteria are that there must be a motivated offender, a suitable target or vulnerable victim (available at an appropriate location and time), as well as the absence of a capable guardian. RAT is a sub-field of crime opportunity theory that focuses on situations or circumstances of crimes. Jury members also consider such circumstances when probing crime scenarios, in order to justify the legal decision process.

Furthermore, judges or jury members often make legal decisions based on their instinct and/or experience (Milgram A., 2013). Such legal decision making process considers some level of probabilistic reasoning in deriving logical evidence, although the mathematical rigour for such probabilistic evidence is sometimes ignored or ill-defined.

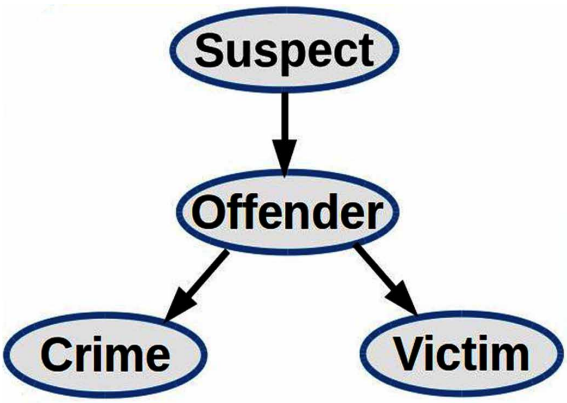
One aspect that stimulates interest is whether a crime X that previously occurred or repeatedly happens in location K is committed by the same individual suspect in that location, another location of close proximity or geographically close domestic dwellings, given observations of certain exculpatory or incriminating evidence or findings. For example, exculpatory or incriminating evidence could be footwear or footprint marks found at both points of entry of the crime scenes, particular items recovered from the points of entry at both crime scenes, type of victim information repeatedly reported and Modus Operandi (MO) involved. The degree of similarity between the evidence in two crimes can further motivate a number of research questions:

1. How does the evidence transfer between previous and current crimes?
2. To what extent can we attribute the crime observations or offender characteristics in the current crime to the previous one, for example in terms of MO reported?

Figure 1. A model of routine activity theory

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Such probing or investigative research questions are also at the intersection of efforts in predictive policing.



Predictive policing deals with the usage of analytical and predictive techniques in law enforcement to identify and curb potential criminal activity. Existing software technology called PredPol is a good sample application in the area of predictive policing (Predpol, 2013). However, PredPol does not predict a potential offender, but helps in identifying and preventing potential crime incidents by predicting the next probable crime location. Predictive policing approaches are categorised into four distinct methods, these are:

- Methods for predicting perpetrators' identities,
- Methods for predicting offenders' characteristics,
- Methods for predicting crimes,
- Methods for predicting victims of crime.

It is widely recognised that Bayesian Networks (BNs), also known as Bayesian belief networks (BBNs), or Probabilistic Directed Acyclic Graphical Model (PDAGM), have great capacity for contributing to the area of predictive policing and crime suspect modelling (Zoete et al, 2014). Being based on probabilistic reasoning, they can derive useful probabilistic dependencies and inferences about the crime subject. Such probabilistic inference can ultimately assist public safety agencies in identifying mitigation priorities and allocating security resources in an optimal fashion, during investigative crime procedures. The terms Bayesian network (BN) and Bayesian belief network (BBN) shall be used interchangeably throughout the chapter.

A BN is a graphical mathematical model that encodes probabilistic relationships and conditional independence relationships between crime variables in the graph structures. A BN can be used to model suspect/offender behaviour as presented in Figure 2, a simple (4-nodal) BN, where a crime "suspect" variable encodes information about who the "offender" would most likely be, and the offender has a direct influence on both crime type and victim(s) involved. The offender encodes information about the crime committed and has a direct impact on the victim.

Figure 2. A simple (4-nodal) Bayesian network

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

A Bayesian network is potentially useful in the following ways:

- Acquiring useful knowledge (probabilistic dependencies) from crime data.
- Assessing uncertainty in crime related attributes or characteristic features.
- Combining crime knowledge sources or observations.
- Deriving actionable crime evidence and mitigation priorities.

BNs are of practical significance in real life scenarios, especially where domain experts are not available or in limited supply for knowledge acquisition. Its usefulness is further evident in the fact that it is a compact representation of the joint probability distribution over the crime variables and encodes the conditional independence relationships between the variables in the graph structure (BN).

Current criminal justice systems and legal decision making processes are mostly dependent on a jury's intuition and experience. Judges have the best interest of the community at heart when they make legal decisions, but decisions made with instincts and/or experience have not significantly helped to promote the public safety of many nations (Milgram, 2013). However, a BN can assist a jury with reasoning under uncertainty (Sjoerd et al, 2014), in order to make a decision that makes the community and nation at large safer.

BNs have received widespread acceptance in academia and industry and proven useful as practical applications of artificial intelligence in solving real-life problems. For example, BNs have practically and successfully been adopted in speech recognition (Nefian et al., 2002), spam filtering/text mining (Raghuram et al., 2009), image classification systems (Jayech et al, 2010) and smart home activity prediction (Nazerfard, 2013), to mention a few.

Furthermore, BNs have over the years received much attention in the public safety and crime domain, and successfully been applied in the areas of offender behavioral modeling (Baumgartner et al., 2008), predicting victimisation (Riesen et al, 2009), crime linkage analysis (Zoete et al, 2014) and Forensic science (Sjoerd et al, 2014), among others. The BN approach to crime profiling typically draws on the fields of criminology, offender modeling and knowledge-based systems. The adoption of probabilistic networks make it practical to represent multidimensional relationships between all relevant crime or offender variables that may be identified at a crime scene. Hence, a valid BN model is a probabilistic directed acyclic graphical model (PDAGM) and can be used to predict unknown crime variables composing an offender profile based on observational variables from a crime scene.

1.2 Contributions and Outline

BNs have been employed for deriving crime knowledge from information in various capacities. This chapter explores various implementation of BN for crime knowledge discovery and delivery, and presents "thought" experiments that focus on understanding the underlying arguments regarding crime or offender modeling using BNs, as well as support in legal decision making process.

The organization of the chapter is as follows: Section 2 presents a brief review of background concepts on BN and further reports on current implementation or adoption of BN in the public safety and crime domain. Section 3 describes methods of exploring the application of BNs in modeling a simple offender scenario. In section 4, a more complex scenario is presented alongside the types of knowledge that can be derived from the BN. The performance of the empirical analysis in legal decision support is also reported. Section 5 summarizes and concludes the chapter.

2. BACKGROUND CONCEPTS AND RELATED STUDY

2.1 Theory and Notation of Bayesian Network Models

A Bayesian belief network (BBN) is a directed acyclic graph (DAG), that encodes probabilistic quantities to derive statistical inference based on probabilities (Jensen, 1996). Essentially, a BBN combines graph theory and probability theory to map variable interdependences in a stochastic system. Nodes in the network (graph) depict variables, while edges represent conditional dependencies between those variables (Vlek et al., 2013a). The DAG $\nabla=\{\chi,\gamma\}$ comprises a set of directed arcs γ that denote the dependencies among a set of nodes (variables) $\chi=\{X_1,\ldots,X_n\}$ such that:

$$\gamma=\left\{\left(X_i,X_j\right);X_j\in\chi\wedge X_i\neq X_j,j>i\right\}.$$

Given a set of discrete random variables $X_1\ldots X_n$ in the Bayesian network, their joint probability density distribution is mathematically defined as follows, in Equation 1:

$$P\left(\chi\right)=p\left(X_1,\ldots,X_n\right)=\prod P\left(X_i=x_i\;/\;Parents\left(X_i\right)\right) \tag{1}$$

where *Parents*(X_i) represent the values of the parents of the node X_i with respect to the graph. Bayesian probability, from Bayesian statistics, is the underlying concept in Bayesian networks. Bayesian probability is based on the assumption that probabilities are dependent on prior events or incidents. It then follows that in a Bayesian crime network, the strengths of the conditional crime dependencies would be calculated with the help of the Bayes' Rule equation. The probabilities $P(X_i)$ are derived from Bayes' theorem (Equation 2) and correspond to degrees of belief of a crime observation. Bayes' rule allows the computation of the probability of a crime event, given prior knowledge of a variable that the event is conditionally dependent on. As new information regarding a crime is obtained, the probabilities of certain characteristics of the unidentified subject are updated with Bayes' Rule.

Bayes' theorem is mathematically stated in Equation 2 as follows:

$$P\left(X\;/\;Y\right)=\frac{P\left(Y\;/\;X\right)P\left(X\right)}{P\left(Y\right)} \tag{2}$$

where *X* and *Y* are "effect" and "cause" events respectively.

- $P(X)$ and $P(Y)$ are independent probabilities of *X* and *Y*.
- $P(X/Y)$ is the conditional probability of *X* given that *Y* is true.
- $P(Y/X)$ is the conditional probability of *Y* given that *X* is true.

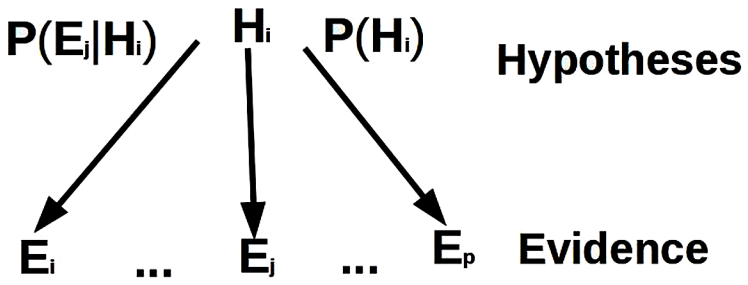
EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

BN application in a crime domain typically relies on four major steps, which are

1. Identify crime variables of interest, which become nodes in the network.
2. Specify prior probabilities over observable crime scenarios or incidents.
3. Compute posterior probabilities based on prior specifications, using Bayes' rule and all observed crime information.
4. Make predictions or inference according to the posterior quantities.

Figure 3 is a depiction of how crime evidence is influenced by hypothesis (i.e. extracting inference from crime observations or scenarios).

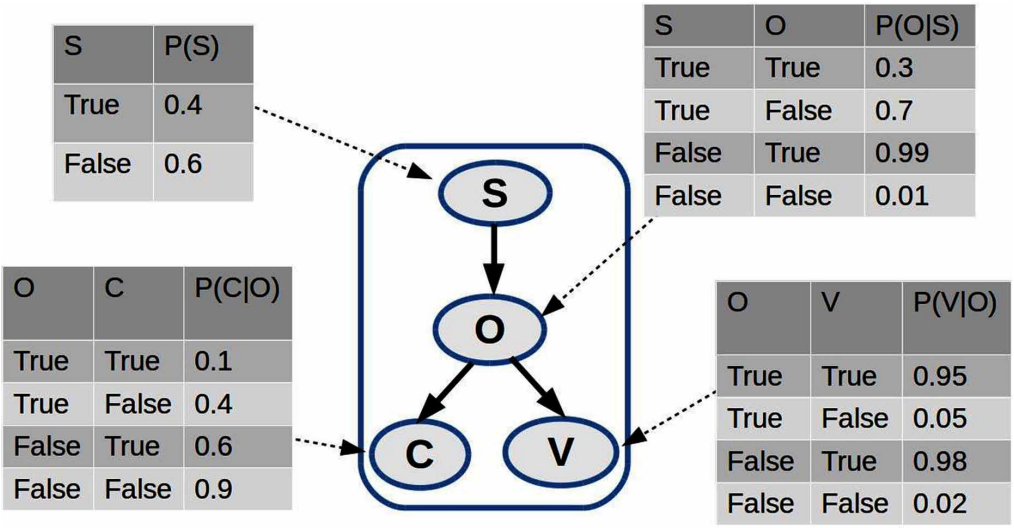
Given the following:



- Evidence/manifestations of crime: $E_1 \ldots E_p$,
- Hypotheses/observed crime features: $H_1 \ldots H_n$

Suppose we know the prior probability of the hypothesis $P(H_i)$ and the conditional probability $P(E_j/H_i)$ and want to compute the posterior probability $P(H_i/E_j)$, applying Bayes' theorem from Equation 2 results in Equation 3

$$P\left(H_i / E_j\right) = \frac{P\left(E_j / H_i\right) P\left(H_i\right)}{P\left(E_j\right)} \tag{3}$$



For a simple Bayesian investigative reasoning, the goal is to determine the hypothesis H_i with the highest posterior, i.e. $\text{Max}_i P(H_i/E_1 \ldots E_p)$. However, the simple Bayesian inference is limited in handling very large sets of crime information or data. In spite of their significant power and potential to address inferential procedures, there are some inherent limitations and liabilities to Bayesian networks (Fenton et al, 2014). It is computationally expensive, and sometimes specifying an appropriate or actual prior is not straightforward. Some researchers often just specify a convenient prior for computational purposes, not the actual prior. Further problem centers on the quality and extent of the prior beliefs used in Bayesian inference processing. A BBN is only as useful as the strength or reliability of such prior knowledge or belief. Either a pessimistic or an excessively optimistic expectation of the quality of these prior beliefs could distort the entire network and invalidate the results. Vlek et al. (Vlek et al, 2013c) noted that

Figure 3. Model setting of investigative Bayesian inference

constructing a BN for complex scenarios is sometimes cumbersome and proposed a tool for exploring crime scenarios in a step-wise manner by building a BN in a step-by-step fashion. This notion exploits unfolding crime scenarios with variations. The idea only focuses on crime scenarios of interest at any given time of the investigative procedure and expands each scenario as crime event or evidence unfolds. Such an approach therefore results in a relatively more rigorous network of crime incident observations.

Using a Bayesian network to compute probabilities is called inference. Figure 4 presents a representation of Figure 2 with the conditional probability distribution for each variable of interest, where the names of the variables have been abbreviated to S = Suspect, Offender (O), Crime (C) and Victim (V). Each node X_i (in Figure 4) has a conditional probability table (CPT) representing its probability distribution $P(X_i/Parents(X_i))$, which quantifies the effect of the parents on the node or relationship between variables. The parameters are the probabilities in the CPTs. Therefore, for a given combination of values of the parents *O* in the analogy, the entries for $P(C=true/O)$ and $P(C=false/O)$ must add up to 1, satisfying one of the axioms of probability as shown in Equation 4 below (Vlek et al., 2013a).

$$P(C = true/O=false) + P(C = false/O = true) = 1 \quad (4)$$

In this case for example, *C* is the "evidence variable" while *O* is the query "variable". It is important to note that the probabilities in Figure 4 are chosen for illustrative purposes of a conditional probability table (CPT). Also, note that suspect information (depicted as "*S*" in the table) is the so-called "root node" with no parent(s), so there is only a single probability distribution for the node, *S*, while for nodes with parents there is a conditional distribution for each possible instantiation of its parents. Hence the varying CPTs in Figure 4.

2.2 Practical Applications of BN Model in Crime Domain

There is a wealth of research in the field of crime data mining and with a number of different techniques and approaches for achieving different tasks in this field. Figure 5 presents different techniques or approaches of data mining available for exploration.

The strength of Bayesian Belief Networks (BBNs) as a powerful predictive probabilistic model (PPM) in the crime domain is evident in its different areas of real world application (Vlek et al, 2013b), which includes criminal profiling, forensic science, prediction of victimization characteristics, crime linkage and crime series detection, to mention a few. Furthermore, there exists a number of software technologies available for building and/or modeling BN (Korb et al, 2011). These include Netica, software used to program BNs in Java (Woodberry et al, 2015), CaMML (Causal discovery via Minimum Message Length), a machine learning program used for learning causal BNs from data (Chris et al, 1999), HUGIN model-based decision support software, and BayesiaLab software, to mention a few. It is important to note that most of these are however commercial (not free) software. There are a few open source BN tools available, such as the BN implementation in the Weka Machine Learning Workbench for data mining (Hall et al, 2009). We hereafter present a non-exhaustive summary of existing application areas of BN in the crime domain.

Figure 5. A taxonomy of crime data mining techniques

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

2.2.1 Criminal Profiling

BNs offer several advantages in criminal profiling and received significant attention in this area (Stahlschmidt et al, 2013). Criminal profiling deals with identifying the attributes or behavioural characteristics of an unknown offender, what motivates the crime committed and principal personality from a crime scene (Baumgartner et al, 2008). As such it is an important consideration in crime investigation since it provides useful gain in psychological and social profiling of the suspect. This generally promotes crime detection and criminal identification (CDCI), since identified characteristics of the offender can narrow the number of potential suspects and reduce investigative efforts by excluding those not showing the specific traits inferred. For example, if a crime investigator initially has three suspects on his list to investigate, and thereafter realises that only two of the suspects match all the crime observations he has gathered to date, he can easily focus more of his attention on those two whose characteristics correlate with his current observations.

Security agencies do background work by filtering or sniffing through a crime scene for observational evidence, because they have some degree of belief that careful observation and analysis of the crime scene can produce useful information that could help apprehend an unknown offender or understand "why" such crime occurred. Essentially, the three major approaches to modeling reasoning with evidence are argumentative, narrative and probabilistic approaches. The work of Vlek et al. (Vlek et al, 2014) reports that integrating these three approaches could arguably enhance the communication between an expert and a judge or jury. Their approach combined the three techniques (argumentative, narrative and probabilistic) in order to form a design method for constructing a Bayesian network based on narratives. Related research has however proposed techniques to represent narratives in a Bayesian network and to use narratives as a basis for systematizing the construction of a Bayesian network for a legal case (Sjoerd et al, 2015).

While Stahlschmidt et al (Stahlschmidt et al, 2013) report on using BN for criminal profiling and prediction in sex-related homicides, the work of Baumgartner et al. present a novel Bayesian network approach to criminal profiling (Baumgartner et al, 2008). Their approach learns a BN model from crime data, which is one of the options for constructing a BN, and then implements the model for profiling means. The variables used as nodes include "offender" and "evidence" variables. The offender variables are characteristics of the offender, which includes attributes such as military history and sex crime history. Evidence variables are characteristics of the crime scene, such as possibility of committing arson, stabbing the victim, and so on. The strengths of edges between nodes are calculated using a combination of a database of offender and crime data and expert knowledge from actual criminal profilers. The more data, the more iterations of Bayes' rule can be applied, and the more accurate the interdependences between offender variables and evidence variables. Once the preliminary conditional probabilities have been calculated, the network can be instantly used to narrow down criminal profiles in unsolved cases in an automated structure. Once evidence/crime scene data are supplied as input, characteristics/attributes that are closely correlated to the variables of interest are observed. Conditional probabilities are re-computed based on new crime data. Their research presents a significant use of BN and Bayes' rule in real world scenarios.

2.2.2 Prediction of Victimisation Characteristics

Riesen et al. (Riesen et al, 2009) developed a Bayesian network classifier for predicting a victimisation attribute value from a crime data set. They identified that a scoring function, suitable structure-learning algorithm and parameter learning algorithm are necessary in order to induce a Bayesian network from a dataset. The dataset they considered was the National Crime Victimisation Survey dataset with 216,000 and 250 data points and attributes respectively. Their model implemented the local hill-climbing and k2 algorithms in the parameter and structural learning phase using the Weka machine learning software workbench, while ensuring reasonable bounds for time-space complexity (Hall et al, 2009).

Related work of Axelrad et al (Axelrad et al, 2013) focuses on predicting insider threat using a BN model. Their paper which consists of five different phases reports on a Bayesian network model for the prediction of level of interest in a malicious insider. Authors investigate the motivation and psychology of the malicious insider by first developing an initial model based on results in the research literature, thereby highlighting essential variables for the prediction of level of interest in a potentially malicious insider. Second, a survey was conducted to measure these predictive variables in a regular sample of normal participants. Third, the original model was used to construct a structural equation model. The model was updated based on a split-half sample of the empirical survey data and validated against the remaining half of the dataset. Fourth, the Bayesian network was updated in view of the results of the empirical analysis. Lastly, the updated model was used to develop an upper limit on the quality of model predictions of its own simulated data. When empirical data regarding psychological predictors were input to the model, predictions of counterproductive behavior approached the upper bound of model predictiveness.

To validate the BN constructed, a hypothesized structural equation model (SEM) was developed, which incorporated as many of the variables from the Bayesian network as it was feasible to measure. Then the data was split in half, randomly assigning cases to a development sample and a holdout sample. SEM was then fit to the first data sample and model adjusted in light of the results so as to test it on the holdout sample. Data was then aggregated to fit a final structural model.

2.2.3 Crime Linkage

Crime linkage focuses on identifying possibly related crime incidents in relation to perpetrator attribute characteristics, different (incriminating) crime scene observations such as Modus Operandi, and victim information. When two distinct similarities are identified in two or more different crimes, it becomes of interest to know whether the crimes were committed by the same culprit or group of culprits. Bayesian networks can be used to model varying evidential structures in linking two or more crimes using different crime attributes as metrics.

Space and time metrics have been considered as parameters for estimating crime linkage. Tonkin et al (Tonkin et al., 2012) used crime location and time between two crime events as yardsticks for identifying linked and unlinked crime cases. They focused on how far apart (in time) were two crimes committed or length of space between two related crimes. They resolved that temporal and/or spatial proximity and/or crime incident locations can achieve statistically significant levels of discrimination between crimes that are linked and unlinked. A related attempt by Zoete et al (Zoete et al, 2014) also reports on modeling crime linkage using Bayesian networks. Their work is motivated by the lack of adequate mathematical treatment in defining the degree of crime similarity in practical casework. They

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

investigated how evidential information derived in one case can influence the probability of hypotheses about who the offender is in another case. It was reported that the usual procedure in law enforcement where only cases with evidence pointing to a suspect are considered and other cases discarded, could be misleading because those discarded cases can generate evidence with important practical consequences if considered.

2.3 Limitations and Challenges of Bayesian Network

A BN has a significant computational cost (an NP hard task) because one needs to explore all parent crime nodes or variables, in order to explore an unknown crime network. Missing dependencies could affect crime results or evidence provided. It potentially requires initial knowledge or prior probabilities of certain crime variables, which may be extremely difficult to obtain and is sometimes falsified. Furthermore, it is sometimes insufficient to derive conclusions for a specific case from an initially developed network (Vlek et al, 2013c). Often there is a need to further explore sub-scenarios of crime in order to update the developed model or network and uncover new crime evidence, especially in a very complex BN model. Furthermore, since each crime is unique, there is a need to investigate how useful a scheme for a general situation is, when dealing with a peculiar crime situation.

3.0 BAYESIAN NETWORKS ADOPTION IN OFFENDER MODELLING

In this section we present a "thought experiment" on how a BN can be used to model a simple offender's behaviour and present a scenario of offender modelling in the subsequent section. We focus more on the logic of the argumentation which presents the essence of the problem and application of BN in reality. There exist various methods of obtaining Bayesian Network (e.g have an expert design it or learn it from data), but that is not the focus of this chapter. We refer the reader to comprehensive textbooks on Bayesian networks for more theoretical arguments or information on BN (Korb et al, 2011 & Woodberry et al, 2015).

3.1 A Simple Case of Offender Modelling

One of the major goals of offender modeling is to identify mitigation priorities in the crime investigation procedure. When related characteristics of an offender are identified it helps to narrow down an investigative procedure by eliminating suspects with characteristics unrelated to those in the identified profile list. Suppose two separate crimes have been committed, not necessarily by the same offender, and you are trying to determine whether an individual is a serial criminal who committed both (Evett at al, 2006 & Zoete, et al, 2013). You observe the following (how likely a suspect is a serial offender given certain conditions, for example prior offences, prior arrests):

- The suspect appears to have previously committed "crime "A".
- The suspect appears to have previously committed "crime "B".
- The suspect appears to have previously committed "crime "C".

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Note that we are not 100% certain that the person is a serial offender because of these "observations". Thus, we are dealing with uncertainty at this stage. While there is no similarity evidence at this point of observation, one would assume that knowledge of the culprit or offender in case A would not necessarily affect the uncertainty related to case B or C.

Consider the simple Bayesian offender modeling (from Figure 2). Given a set of observations (evidence (E)), we have the following hypothesis for a single crime scenario:

H1: The suspect (S) is the offender (O).
H2: The suspect (S) is not the offender (O).

3.1.1 Properties of a Hypothesis

1. Must be mutually exclusive (non-overlapping).
2. Must consider all possible scenarios (i.e. exhaustive).

In a "two-crime scenario" (crime A and crime B), however, the following hypothesis is considered (Zoete et al, 2014).

H1: The suspect (S) is the offender (O) in both crime cases.
H2: An unknown person (U) is the offender (O) in both cases.
H3: An unknown person (U) is the offender in the first case and the suspect is the offender in the second case.
H4: The suspect is the offender in the first case and an unknown person (U) is the offender in the second case.
H5: An unknown person (U) is the offender (O) in the first case and another unknown person (U') is the offender (O) in the second case.

In any case, the goal is to find the hypothesis (H_i) with the highest posterior probability. The resulting output further strengthens, weakens or nullifies the *a priori* belief regarding the initial hypothesis considered. In light of the fact that BN is a PPM, it has the capability of approximating the posterior probability distribution of any attribute of interest in a crime domain (Riesen et al, 2009).

In general, each of the five hypotheses (crime propositions) has a unique probability. In theory the probabilities must sum up to one. However, one is much more interested in how the probabilities would change as they are updated with corresponding evidence. The question that follows then is "how does the *posterior* probability $P\left(H_1 \,/\, E, A\right) = k'$ change or evolve as it is updated with the computation from the prior probability $P(H_1/A)=k$, where H_1 is the hypothesis, A is the crime scenario considered and E is the evidence.

Going by Bayes' rule, we obtain the following equation:

$P(H_1/E,A) \propto p(E/H_1,A)P(H_1/A)$.

The same expression could be derived for the remaining joint propositions or hypotheses. For example, if the *posterior* value $k' > k$, then it becomes clear that there is a higher chance that hypothesis

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

H_1 is true, i.e. the suspect is most likely to be the offender in both cases. The *posterior* probability is being updated as new evidence is derived, computed and updated; eventually an effective decision would result.

It is important to note that more work needs to be done in terms of modeling complex scenarios of crime using BN. Such effort has been demonstrated in the work of Vlek et al (Vlek et al, 2013c), which deals with unfolding (sub) crime scenarios in an attempt to make a scenario more precise. This precision is achieved by modeling several connected sub-scenarios to enhance the network and derive more inclusive evidence. They implemented a three-stage approach idiom which exploits "scenario", "sub-scenario" and "merged-scenario" idioms, in order to further complement and strengthen the derived evidence. This is one of the ways by which inference could be extracted from observations in a BN, which greatly relies on prior belief and observations from a crime scene or about a specific crime. Depending on the level or strength of the incriminating evidence, the jury may then be able to reach one of the following decisions:

1. Charge the suspect with case 1; drop case 2.
2. Charge the suspect with case 2; drop case 1.
3. Charge the suspect with both cases.
4. Drop both cases.

3.2 Complexity of Inference in Bayesian Belief Networks

Inference in a BBN corresponds to calculating the conditional probability, $P[A/B=b]$, where $A, B \subset \left\{X_1, \ldots, X_n\right\}$ are sets of latent and observed crime variables, respectively. Cooper (Cooper, G. F., 1990) proved that exact inference in BBNs is NP-hard. In general, the size of the problem is given by the total size of the probability tables needed to represent the BN. Dagum and Luby (Dagum, P., Luby, M.,1993) further showed that even approximate inference is NP-hard (note: the mathematical detail of the proof is not explicitly highlighted in this chapter).

There exist three main inference tasks for BBNs. These include:

1. **Inferring Unobserved Variables:** Since BN is a PDAGM, it can be used to answer probabilistic queries about variables and their relationships. It therefore helps in deriving probabilistic inference, which is a process that derives updated knowledge of the state of a subset of crime variables when other variables (the *evidence* variables) are observed.
2. **Parameter Learning:** It is necessary to specify for each node *X* the probability distribution (CPT) for *X* conditional upon *X*'s parent, in order to fully specify the BBN and therefore completely represent the joint probability distribution of the random variable. The conditional distributions sometimes include unknown crime parameters which must be estimated from the available crime data, sometimes using the maximum likelihood approach.
3. **Structure Learning:** The structures of BBNs are either learned from data or specified by an expert in the corresponding domain and afterwards used to perform inference. In applications where the task of defining the network is too complex for humans, the network structure and the parameters of the local distributions are usually learned from data. An alternative method of structural learning uses optimization based search, which requires a scoring function and a search strategy. A typical scoring function is *a posterior* probability of the structure given the training crime data.

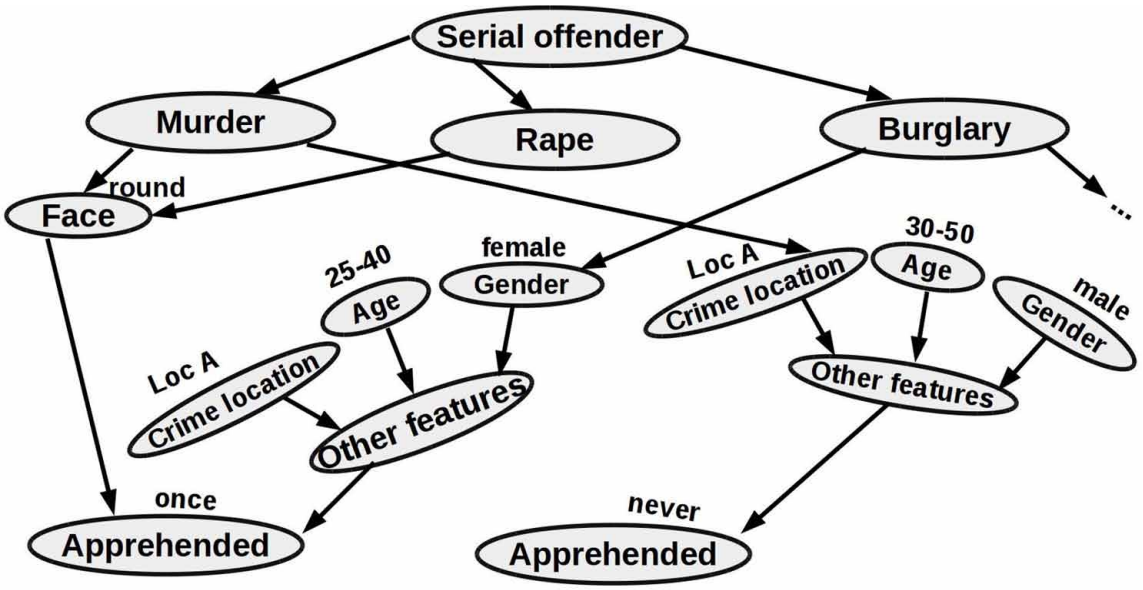
4.0 COMPLEX SCENARIOS OF BAYESIAN LEARNING AND OFFENDER MODELLING

In this section, we present relatively more complex scenarios of offender modeling using Bayesian networks and corresponding implications for deriving valid results.



More generally, BN probabilistic reasoning can result in a powerful combination of predictive, diagnostic and explanatory reasoning. Considering the fact that several levels of scenarios could be explored in the figurative explanation of a relatively complex BN (Figure 6), which may also have different levels of precision, it is worth noting that the validity of evidence that can be derived would to a large extent depend on the level of this exploration.

The general approach to a complex crime scenario or offender information, such as in Figure 6 usually considers evaluating different kinds of evidence. Such evidence includes information from crime attractors (e.g. vulnerable victims), eye witnesses, scientific processes and results and alibis, to mention a few. Most of the evidence is usually not quantified but could be used by the jury to follow a quantitative means of reaching a fair and effective decision, among several.

The BN in Figure 6 can be used to derive useful inference such as the following:

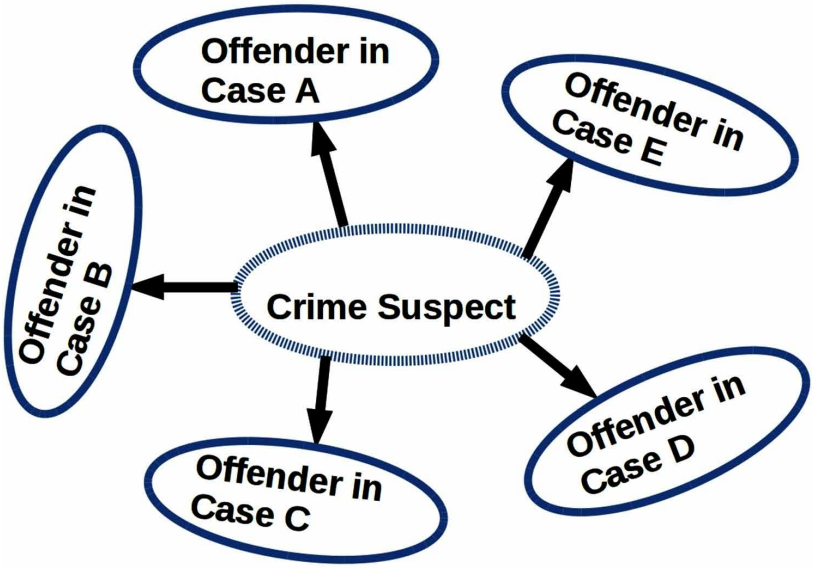
1. Can combine evidence from various crime attributes.
2. Can predict a crime suspect from the observational crime features.
3. Can explain the model's belief in a crime investigation scenario.
4. Can identify specific characteristics of suspects based on the nature of their crimes.
5. Can model information such as the crime spatial dispersion pattern and suspect apprehension.

Figure 6. A more complex Bayesian network of suspect modelling

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

4.1 Generating Candidate and Extraction Rules

Candidate items in our "thought experiment" refer to attributes of crime incidents of interest, which a jury or crime analyst is very much interested in investigating or probing further. Consider five different crime scenarios or types as follows: Crime A, Crime B, Crime C, Crime D, Crime E, with Figure 7 depicting how each crime might be linked to a suspect.



Now, for each scenario, suppose we are interested in how many crimes relate to a particular suspect (e.g identifying a serial offender), assuming we already have prior knowledge of certain incriminating evidence or observations from each crime scene. In real life scenarios, one may observe that residential burglars tend to return to previously victimized locations, or to their close vicinities, after having acquired information on the schedules of inhabitants, the properties, and possible surveillance systems. For example, in Figure 6, a once apprehended offender may be suspected of another related crime in a location of close proximity to the previous crime.

However, depending on how much incriminating evidence is attributed to a suspect, the jury may then be able to make one or more of the following decisions:

- The suspect is not guilty of any of the crimes.
- The suspect is guilty of only one crime, say crime k, $k \in \{A,B,C,D,E\}$.
- The suspect is guilty of only two of the crimes, say crimes A and B, etc.

We could model possible scenarios of allegations that can be made to a suspect in a 5-crime scenario as presented in Table 1. Since there are five crimes, then there are $S=2^5$ possible states related to the suspect in question. Variables A,B,C,D,E depict the five different crime types thought to have been committed by the suspect, S_i, $i \in \{1,2,\ldots,32\}$.

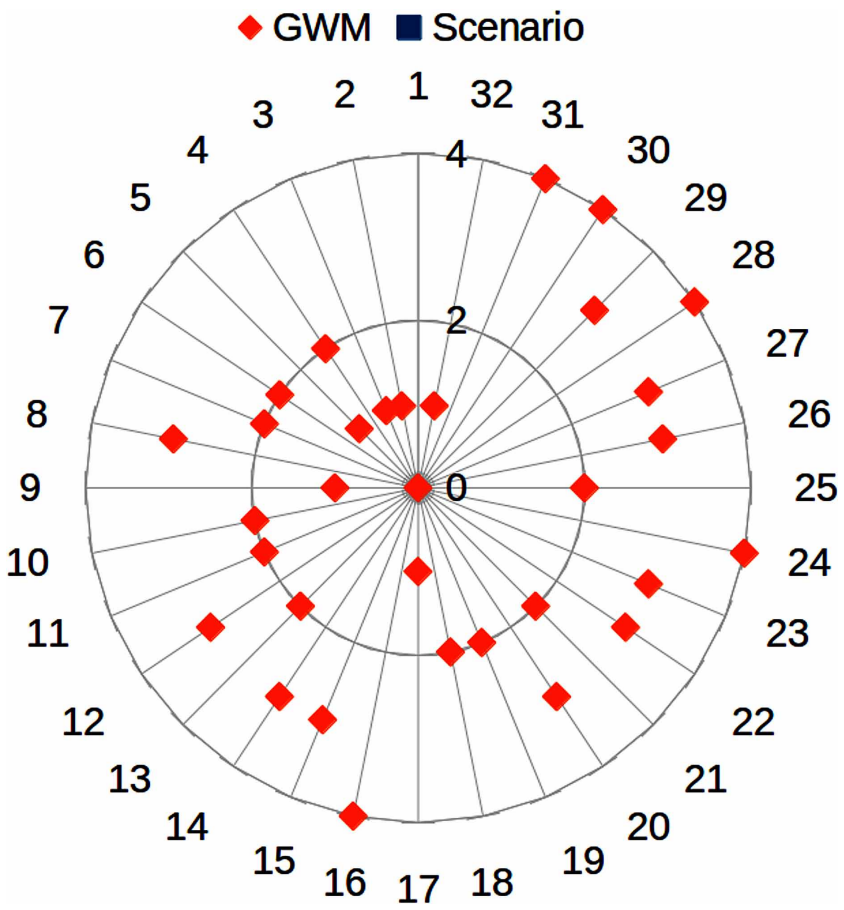
S32	G	G	G	G	G	5/5 = 1

Variables *G* and *N* in Table 1 represent *guilty*:*G* and *not guilty:N* respectively. Note that certain allegation scenarios states S_i, $i \in \{1,2,\ldots,32\}$ appear to share the same value in terms of general weight measure (GWM), where $0 < GWM \leq 1$. They may however not necessarily share the same aggregate weight measure (AWM). There are two "exceptional" cases S_1 having no weight since the suspect is not guilty of any of the (five) crimes and S_{32} where the suspect is guilty of all allegations. For example scenarios

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

S_2, S_3, S_5, S_9, S_{17} have a general weight measure (GWM) of 1 in 5 crimes. However, suppose the unique weight (w) for each crime is depicted as W_A, W_B, W_C, W_D, W_E respectively. Then each scenario S_i would have different weight values. A special case would then be if all the crimes have the same weight measure, in which there is a high probability that a suspect has committed a crime repeatedly five times. In summary, we have the following states or scenarios sharing the same GWM as presented in Figure 8 and Equations 5, 6, 7, and 8. However, note that every scenario has only one GWM.



$$1/5 = \{S_2, S_3, S_5, S_9, S_{17}\} \tag{5}$$

$$2/5 = \{S_4, S_6, S_7, S_{10}, S_{11}, S_{13}, S_{18}, S_{19}, S_{21}, S_{25}\} \tag{6}$$

$$3/5 = \{S_8, S_{12}, S_{14}, S_{15}, S_{20}, S_{22}, S_{26}, S_{27}, S_{29}\} \tag{7}$$

$$4/5 = \{S_{16}, S_{24}, S_{28}, S_{30}, S_{31}\} \tag{8}$$

Figure 8. Correlated GWM of possible scenarios of suspect allegation

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Thus the Aggregate Weight Measure (AWM) for each state S_i is computed as the sum of the corresponding weights $c_W \in \{W_A, W_B, W_C, W_D, W_E\}$ for which the suspect is guilty (G), as depicted in Equation (9)

$$AWM_{\{S_i\}} = \sum_{G_i} \{C_W\} \tag{9}$$

The weight information could be regarded as indicating the gravity of the crime committed, which is further defined by the AWM for every suspect scenario S_i, especially for a serial offender. The suspect could then be charged for correspondingly identified scenario(s) accordingly. It is important to recognise that the reported idea does not eliminate or exclude the jury's intuition but serves to complement their overall decision.

5. SUMMARY AND CONCLUDING REMARKS

The public safety agencies collect a great deal of crime information which can be explored for evidence-based solutions in deterring crime. Also legal cases involve, to a great extent, reasoning with evidence. Thus, employing Bayesian networks (BNs) in the crime domain is a recognised application that can model different crime scenarios and assist in mitigation priorities or investigative procedures for solving crime, since it is based on probabilistic reasoning.

The strength of BNs as a Predictive Probabilistic Model (PPM) is evident in its wide acceptance and application in solving real world problems, both in academia and industry. A BN is particularly useful for classification and prediction tasks and has thus received significant attention in several domains, including the crime domain. This chapter has described various means by which BNs have been employed in the crime mining domain. The various applications areas discussed include crime suspect modeling, crime linkage, criminal profiling and repeat victimisation studies, which can assist in understanding criminal identification or apprehension, crime control and legal decision processes.

This chapter further highlighted the strengths and limitations of BNs and also reported a "thought experiment" on simple and "near-complex" offender modeling cases using BN probabilistic reasoning, with discussions of the logic of evidence interpretation and decision making. While BNs have been explored in different capacities in the crime domain, it is important to recognise that there is still room for exploring its capability in modeling complex crime scenarios and advancing the strength of the technique, as it has some inherent limitations such as computational difficulty in its current application. It is worth noting that inference from BNs is quite convenient and feasible in small to medium sized networks and could be very time consuming in large networks. However, researchers resort to various techniques for approximating inference, which are more reliable and faster.

Also the resulting BN model is not intended to make final decisions or conclusions about a crime case, but to assist in the investigative process and advise or assist a jury or judge in legal decision making. This means that we do not propose eliminating the judge's instinct and experience in legal decision making and crime control. We however present the fact that judge's instinct and experience can be complemented and strengthened using BN, as presented in current applications of BN in the crime domain. There is a great deal more to BNs when building an actual network of any complexity, which can be studied in depth in Bayesian Network focused textbooks. This work illustrates the future potential and opportuni-

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

ties of applying Bayesian Networks in this field and can be explored further in different forms in future practical research. This chapter however could further serve as a reference guide to understanding key issues and underlying framework of BN application in Crime Detection and Criminal Identification (CDCI) or crime mining field in general.

KEY TERMS AND DEFINITIONS

Bayesian Network: A directed acyclic graph that encodes probabilistic reasoning of an event or a compact representation of probability distribution over a set of propositional random variables.

Crime Linkage: The process of verifying whether two or more crimes, say A and B, committed at possibly separate times and/or locations are linked by some related features.

Criminal Profiling: The process of identifying behavioural characteristics of a crime offender and motivations for committing the crime.

Crime Pattern: An observable recurring trend of crime attributes or characteristics.

Crime Tactical Analysis: A crime analysis that is carefully planned in order to combat a specific crime.

Dynamic Bayesian Networks (DBNs): These are Bayesian networks that include directed edges pointing in the direction of time.

Modus Operandi: This characterises the process or mode of operation of an offender or group of offenders.

Probabilistic Reasoning: The process of summarising uncertainty from various sources or using probability theory and information about interdependencies to derive statistical inference.

Serial Crime: A set of two or more related crimes identified to have been committed in a successive time interval and mostly within close proximity.

Serial Offender: An offender that has been identified to commit related crime offences in a successive time interval, mostly with the same Modus Operandi.

Victimization Prediction: The process of identifying principal attributes, characteristics or features that surrounds a crime victim and using such observation to identify potential victims.

Chapter 20
Information Extraction for Call for Paper

Laurent Issertial
Osaka Prefecture University, Japan

Hiroshi Tsuji
Osaka Prefecture University, Japan

ABSTRACT

This paper proposes a system called CFP Manager specialized on IT field and designed to ease the process of searching conference suitable to one's need. At present, the handling of CFP faces two problems: for emails, the huge quantity of CFP received can be easily skimmed through. For websites, the reviewing of some of the main CFP aggregators available online points out the lack of usable criteria. This system proposes to answer to these problems via its architecture consisting of three components: firstly an Information Extraction module extracting relevant information (as date, location, etc...) from CFP using rule based text mining algorithm. The second component enriches the now extracted data with external one from ontology models. Finally the last one displays the said data and allows the end user to perform complex queries on the CFP dataset and thus allow him to only access to CFP suitable for him. In order to validate the authors' proposal, they eventually process the well-known precision / recall metric on our information extraction component with an average of 0.95 for precision and 0.91 for recall on three different 100 CFP dataset. This paper finally discusses the validity of our approach by confronting our system for different queries with two systems already available online (WikiCFP and IEEE Conference Search) and basic text searching approach standing for searching in an email box. On a 100 CFP dataset with the wide variety of usable data and the possibility to perform complex queries we surpass basic text searching method and WikiCFP by not returning the false positive usually returned by them and find a result close to the IEEE system.

INTRODUCTION

With today's technology any type of information accessibility has greatly increased and this is also true for our domain of study: Call For Papers (CFP). It has never been so easy to find information on conference usually via numerous websites or simply by email. However, this profusion of information has also its downside. Handling CFP can be seen as a really time consuming task. Regarding the emails, many CFP are received every day and most of them will only be skimmed through or forgotten by lack of time or attention. As for the web, it is possible to find many websites where you can browse a wide range of CFPs such as WikiCFP (2014) or ConferencePartner (2014), or others bound to different institutions like IEEE (2014) or ACM (2012). Nevertheless these sites have several weak points. They do not allow the user to use CFPs obtained by external sources (e.g. Email) ; thus a new research have to be done on a totally different database, sometimes with less information you could actually find in your CFP email. Moreover, conferences research parameters can be really basic and not handle a request more complex than searching different strings of characters (e.g. conference about X topic in Y country with a Z deadline). Those are the issues we propose to handle with our system: CFP Manager.

In one of our previous work (Issertial & Tsuji, 2011), we proposed the concept of a text mining system able to extract relevant information from a group of CFP. In another one concerning visualized comparison of CFP datasets (Issertial, Saga, & Tsuji, 2012), we introduced the idea of extracted data enrichment via the utilization of ontology, another one (Issertial & Tsuji, 2013) focused on the query and interface system along with the different kind of output that can be obtained from the set of relevant data previously collected. This paper proposes to focus on the case of a final user who's looking for information about conferences suited to him and how our proposed system will ease this process. We will do so by reviewing current web-services proposing this functionality and comparing their theoretical results with our proposed system on different queries. This will be introduced along with the description of our system and numerical experimentations proving its good working. CFP will be subject to rule based text mining algorithms in order to extract relevant information. These very data will be enriched via ontology models with concepts close to the ones found in the CFP. Finally, using the previously collected data, we form the base of a user interface system with an intuitive query system allowing the user to perform complex queries.

PROBLEM DESCRIPTION CFP HANDLING PROBLEM

Our problematic can be divided in three parts; how to extract, manage and display relevant data. CFP is already an active subject of research to make the handling of CFP easier. Nevertheless these researches focus on displaying (Sacco, 2005), gather (Jaimez-Gonzalez & Luna-Ramirez, 2013) and creating end-user application (Xin, Li, & Tang, 2007) or web crawler (Yang, 2009) from available sources and do not take an Information Extraction approach as we intend to do. The Information extraction field is a well-known area and many techniques and algorithms have been used to solve this kind of problem like classifiers (WHISK), sequence model (Hidden Markov Chain) or written rules (NLP algorithm) (Feldman & Sanger, 2007) historically support by completion based conferences as MUC (Message Understanding Conference) (Chinchor & Sundheim, 1993). The application of IE to CFP can be traced back up to 1998 (Lazarinis, 1998). From this time researches focusing on extracting relevant information from CFP applying different algorithms as SVM (Support Vector Machine) (Ireson et al., 2005), CRF

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

(Conditional Random Field) (Scnheider, 2006; Cox, Nicolson, Finkel, Manning, & Langley, 2005) or rule induction (Ireson et al., 2005; Li, Rastan, Shepherd, & Paik, 2013) can be found. These researches give relatively good results in term of accuracy but always lake of diversity and precision in term of extracted data. For example even if deadline related information is extracted, precise information like which type of deadline for which type of paper is not provided.

CFP could be seen as a simple type of document, they are semi-structured data possessing internal data structures as shown in Figure 1; for example important dates as paper submission, deadline, etc… are often represented in a paragraph titled *Important Dates* with similar structures (type of event and date). Conference date and location are often found together with similar pattern of location enumeration. Even conference titles share some writing patterns. Therefore we decide to use rule based algorithms searching these patterns to extract relevant data.

In addition, we can also acknowledge that information contained in data can be extended to more general concepts but not expressed for several reasons. This can be seen in two different points in CFP files. The first one is the obvious data not mentioned by lack of usefulness; a good example could be location of conference. Location level upper than country are never mentioned in a CFP for evident reasons. However this information could be sometimes useful for queries. The second type is 'generalization': the way very specific information can be generalized to a wider term. In the CFP case, it can be found in conference topics when the topics are rather specific in order to be as exhaustive as possible. However if we could generalize these terms, we could discover and observe relations between conferences easily. Thus, we enhance the extracted data via external data stored in two ontologies, one for locations and another for topics as shown in one of our previous work (Issertial et al., 2012), as this kind of knowledge representation is close to our needs and have been used numerous times to represent conference linked subject (Sure, Bloehdorn, Haase, Hartmann, & Oberle, 2005; Jeong & Kim, 2010). This feature should improve the capacity to make meaningful queries for the user.

Current Systems Review

There are already plenty of systems handling and presenting conference and CFP to users searching for conference suiting their interest. Consequently we decide to take into account some of these systems and to compare them to our system in terms of data usability and functionality, namely WikiCFP (2014), Semrex (Call For Paper) (Yuan et al., 2013), Conference Partner (2014), Conference Alerts (2014), ACM Conference Calendar (2014), IEEE Conference Search (2014), and Microsoft Academic Search (Jacso, 2011). The first three are general CFP aggregator for computer science related conferences. The following one is the same kind but with a broader field, from social science to economics. The following two gather only the conferences linked to their own organization respectively ACM and IEEE. The last one is just slightly related to CFP and focus more on publication. We finally add the basic research that can be executed in an email box as shown in Table 1.

As we can see, the strong point of our system is the variety of data handled by it, especially the different events' date. Except for the IEEE Conference Search, most of the systems are limited to gather CFP without providing the necessary tools to explore them. As for the topic row, it shows the range of topics available as a list and which also are linked to the CFP, i.e. the term don't have to appear in the CFP itself. However some mistakes or double can be found, for example with "AI" and "Artificial Intelligence" categories in WikiCFP, or many nonsensical categories in Semrex. Concerning the additional functionality, like aforesaid, beside IEEE (who also allows the use of wildcard) these systems do not give the opportunity to use Boolean operators and thus to perform complex queries. Finally our system shows three theoretical weak points with the impossibility to find if a conference exists in series, to use wildcard in queries, and to display if a deadline is extended or not.

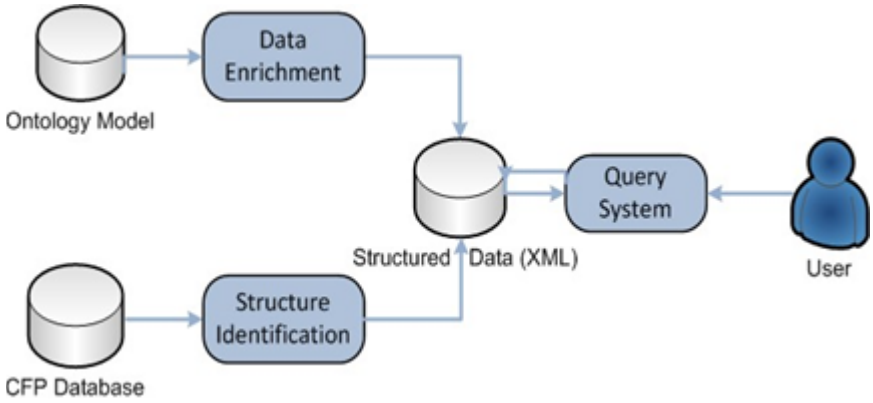
SYSTEM OVERVIEW

As shown in Figure 2, the CFP Manager system is composed of three main parts, information extraction from CFP, enrichment of these data via external ontologies and the query system.

Information Extraction

The information extraction part is based on the GATE framework developed by the University of Sheffield for text mining (Cunningham, Maynard, Bontcheva, & Tablan, 2002) as shown on Figure 3. Before using the text mining part the collected documents go through a pre-processing phase in order to extract the text body from an email document or a webpage. It also appeared that some CFPs are multi lingual so we extract the English part for the following phases, for this purpose we use basic pattern recognition and regular expression. From this point we use successively different GATE modules for text tagging that can be based on information tagged by previous modules; we begin by using six modules namely an English Tokenizer, a sentence Splitter, a Gazetteer for location, a Part of the Speech Tagger and finally a Named Entity Transducer.

Figure 2. CFP Manager Overview



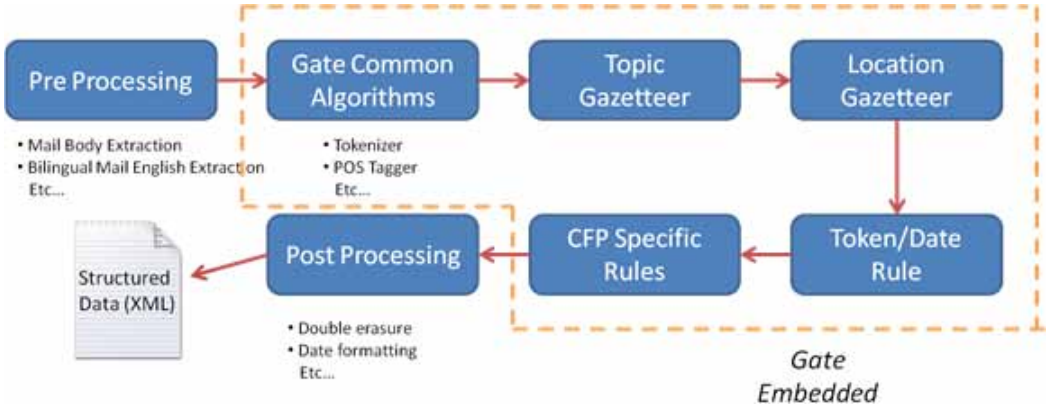


Figure 3. Information Extraction processing

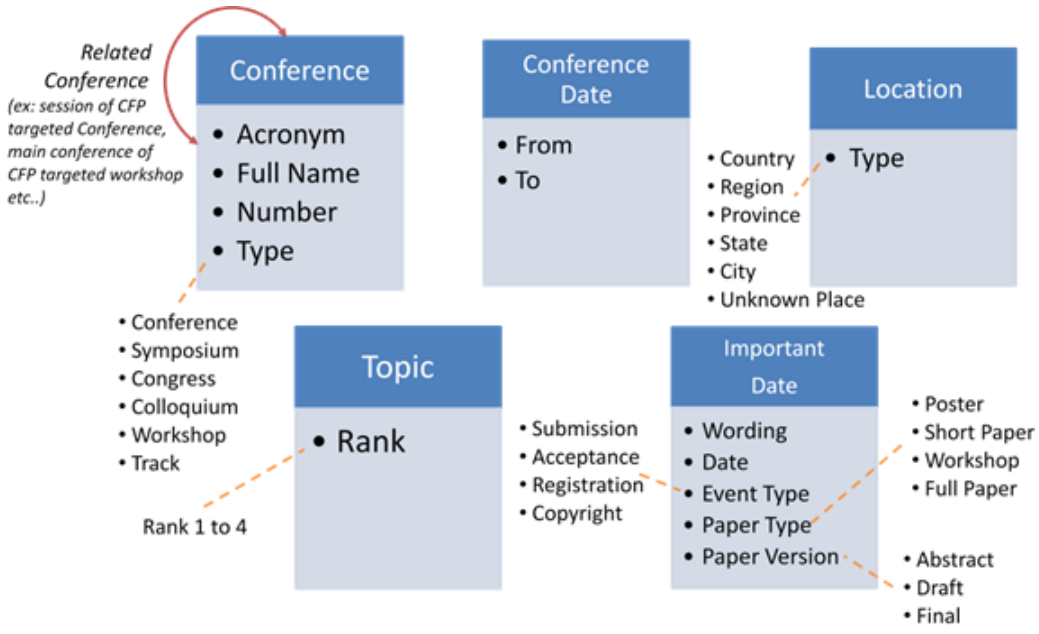


EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

This phase is followed by two gazetteers tagging respectively computer science related topics with a dictionary of 1085 terms divided in four different ranks based on ACM computing classification system (2012) and location forgot in the common algorithm phase (mainly USA states). Even if the basic GATE algorithms give a good base of useful annotations, we notice that some date and token needed for the following phases were not correctly annotated. Thus we add a phase with a set of 20 rules tagging date and token forgotten by the common algorithms. Then we finish the GATE phase with a set of rules specific to CFP in order to extract relevant data to our case. This phase is itself divided in 37 sub-phases processing 120 rules. All the data collected by the algorithm such as conference location, date, event (as shown on Figure 4) are then post processed. Data are ordered (put sub data with its affiliated one, like Date of a particular event), all extracted double are deleted, and if data already exists (in case of the same conference but with an extended deadline for example) we merge the two. Finally the result is stored in a structured data XML file.

As shown on Figure 4, we want to extract five types of data from CFP. Firstly the conference that can be divided in two labels *Acronym* and *Full Name*; from the *Full Name* we get the number and the type (symposium, workshop, etc…). Note that we are also interested in extracting related conferences; mostly conference holding the workshop advertised in the CFP, but it can also be a poster session just mentioned in the CFP conference or more rarely two conferences held together. From this we have the classic conference date and location, with location divided in five groups: country, region, province, state, city and unknown place. *Unknown Place* standing for place identified by rules but not present in our gazetteer like university, hotel or city to small to be in our gazetteer. *Important Date* represents every deadline link to the conference like submission or notification. We extract for this one the event and its date and make distinction between the different types of event and in the case of a paper, which type of paper and which version is needed. Finally topics are divided in four ranks as explained in the next part.

Figure 4. Extracted Data

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

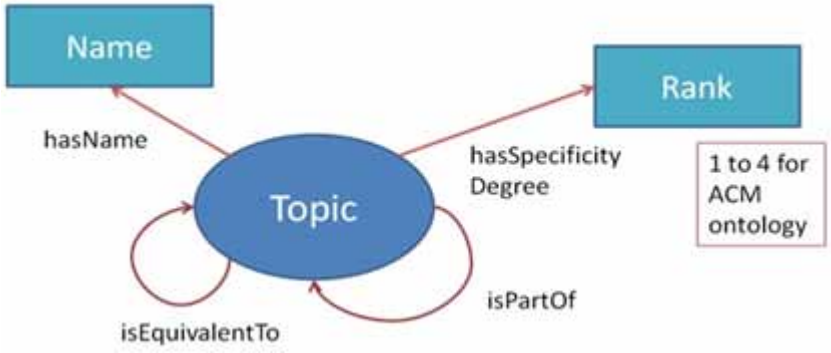
Ontology Enrichment

Input data can be further improved via external data linked to the extracted one. We enrich our model via external ontology model. We use two of them for location and topic data, searching for linked information in the ontology and adding it in the structured data.

Location Ontology

Based on the FAO (Food and Agriculture Organization of the United Nation) geopolitical ontology (Iglesias-Sucasas, Kim, & Viollier, 2013), it provides information about geographical region and especially country upperlocations in the form of the five continents and twenty two continent subdivisions (Western Europe, Eastern Asia, etc.). It provides upper location information from country extracted in CFP.

Topic Ontology



Based on the ACM computing classification system (2012), we use it to classify research topics with different layers. From this classification system we create an ontology model with four topic layers becoming more and more specific as shown on Figure 5. Thus we create relation between a given topic from the CFP and an equivalent or upper level one and so forth to the top level.

This improvement helps to link specific topics to more general and understandable ones. Even if, a given conference has only very specific topics tagged in its structured data file, this improvement allows us to access and classify it easily.

User Interface

The user interface allows the user to perform complex queries on his dataset and display it in various forms (CFP list, graphs, etc…), however we will focus only on the query part. As shown on Figure 6, the user can choose a date span for time sensitive data (like conference venue or deadline) or list plain text criteria (like topic or location) because more than looking for a conference name, the user tends to look for a conference regarding these constraints.

Figure 5. Topic Ontology Model

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 6. Example of GUI Query

The user thus can apply to selected criteria the three basics Boolean operations AND, OR, NEG. The set of color represents the AND and OR operations: criteria with the same color are linked by a AND relation, thereby different colors stand for OR relation. The NEG is represented by a text in italic. Thus the query shown in Figure 6 should be read: (With First Draft From the 6th March 2014 to the 29th March 2014) AND ((Japan AND Text Mining AND NOT Artificial Intelligence) OR (Eastern Asia AND Data Mining)).

EXPERIMENTS

In order to validate our approach we set two experiments. The first one validates data extraction via precision and recall measures. The second measures the superiority of our approach in term of query results compared to other systems.

Text Mining Validation

The information extraction field has really strong links with the MUC (Message Understanding Conference) series (Chinchor & Sundheim, 1993), thus we use the well-known metrics introduced by it, Precision, Recall and F-Measure on two different criteria, strict and lenient, showing the utilization or not of partial result, defined as:

Strict:

$$Precision = \frac{Correct}{Correct + Spurious + Partial} \tag{1}$$

$$Recall = \frac{Correct}{Correct + Missing + Partial} \tag{2}$$

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Lenient:

$$Precision = \frac{Correct + Partial}{Correct + Spurious + Partial} \tag{3}$$

$$Recall = \frac{Correct + Partial}{Correct + Missing + Partial} \tag{4}$$

$$F - measure = \frac{(\beta^2 + 1) Precision * Recall}{\beta^2 Precision + Recall} \tag{5}$$

Where:

- Partial stands for annotation sharing a same span of text without being exactly the same
- Spurious indicates when a span of text is tagged in the gold standard and not in the tested one
- Missing indicates when a span of text is tagged in the tested model and not in the gold standard
- β is the weighting between Precision and Recall

We use these metrics and compare the tagging results of our system with a gold standard manually tagged on 100 CFP as shown on Table 2 showing the number of correct missing, spurious and partial data along with the recall (Equation 2,4), precision (Equation 1,3) and Fmeasure (Equation 5) on strict (s) and lenient (l) settings. Since this paper focus particularly on WikiCFP and IEEE on the next experiment, we repeat the same experiment on two 100 CFP datasets built exclusively with CFP from WikiCFP and IEEE respectively in Table 3 and Table 4. Note that we set the F-measure (Equation 5) weighting to 1 and the bottom line for summary calculates the precision, recall and F-measure for each document and then calculate the average.

We can divide the different extracted annotations in three different groups. The first one is crucial information used in query colored in white on Table 2 like *Conference Location*. For them we are expecting a score of 0.95 in precision and 0.90 in recall, the non apparition of the data being somehow preferable to the false one, the final user being able to access the original file anytime he wants. The second one in yellow represents information already inside another annotation like *Important Event Date* being a part of *Important Event*. For these annotations patterns are easily findable and the big part of the work has already been done. For these reasons we require a precision and recall rate near to the encompassing annotation, taking account of case of typo or unusual presentation. The last group in green represents data we don't really use at present but could be useful especially for linking conferences/CFP together and create an ontology from CFP. As we did not focus as much on this information for the moment, we conclude that a reasonable threshold should be set at 0.7 for both metrics.

As shown on Table 2, we successfully extract 1698 important data from our dataset with an F-measure of 0.92 and 0.94 respectively on strict and lenient settings. The reason why there is so many extracted data is due to the extraction of multiple instances of the same data in each document allowing us to discover more information (a conference acronym can have multiple spelling, a suit of location can give

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

more information than a previous one, etc…) As we can see most of the extracted data give satisfactory results within the threshold we previously fixed, especially in term of precision. In this case partial data counted as 18% of all the errors making a difference of 0.01 to 0.02 in summary result. However they are mostly shared between *Important*

Event and *Conference Full Name*, both of them exceeding our threshold in strict setting. *Related Conference Full Name* and *Conf Unknown Place* show also bad results. The former shows especially bad results in term of recall and it is intrinsically linked to the way it appears in rules. Its related rules are only triggered in combination with conference acronym leaving single full name in the text untagged and the same apply for *Conference Full Name*. Incidentally, the improvement of *Related Conference Acronym* retrieval should also improve its score. The latter represents every places tagged by our system only by rules and without a Gazetteer thus is make it more difficult to properly tag it and to know where it begin and end has shown by it missing and partial score. We can thus confirm the rules' tendency to be strict with low case of spurious and partial data and a majority of errors (48%) coming from missing data.

The WikiCFP dataset give in summary a little (0.01 to 0.02) worst result on recall and a slightly better result on precision (0.02 to 0.03). The repartition of error stay approximately the same for partial's one but increased for Missing going to 67%. Beside this, the results of the different extracted data remain close to the previous ones. We can guess that *Conf City*, *Conf Country* and *Important Event* results have slightly increased thanks to the WikiCFP template making these data more accessible.

The IEEE dataset gives a result roughly identical to the first one. The type of error proportion is the same and the metrics for the summary give almost the same result with plus 0.01 on lenient precision. Finally, the extracted data result pattern and weak points are the same. As we shown on Table 3 and Table 4 the differences between the three datasets are really subtle and the same pattern can be found in the three experiments, we can infer that our system can handle the heterogeneity of CFP data sources, furthermore we can compare our system to the WikiCFP and IEE one introduced in the next part.

Comparison with Other Systems

After we confirmed our system extracts a reasonable amount of data, we will focus on the relevance of its query system. As a final user who wants to find a conference according to his preferences, do our query system and our system as a whole provide a suitable experience? To answer that we compare our CFP Manager with other systems we described previously. We choose the 3 systems: basic email searching (text searching), WikiCFP and IEEE Conference Search. The first two are representative to the way information on a broader type of CFP is currently provided. The later, by its various functionalities, represent the goal our system tends forward in terms of query.

We compare the response to each system to a series of queries done on a 100 CFP dataset. However, since using these systems per se is quite difficult we decide to simulate their working. For example, as shown on Table 1, WikiCFP cannot handle queries on deadline so this part of the query will be simply ignored, however, it use its own set of topics to classify CFP so we use it instead of extracted topics. Because of these variations, we will use different dataset for this case, with only CFP from WikiCFP. For the two others a combination of various CFP can be used. The tables will also present results with and without the help of the ontologies.

WikiCFP

As shown on Table 5, WikiCFP shows some weak points compared to our system. First of all on topics, it does not use CFP body text and thus misses some conferences (cf. *data mining* and *artificial intelligence* queries). It also misses seldom topics like *network protocols* or *wireless communication*. The impossibility to use Boolean operator leads to false positive as in the *China and artificial intelligence* request and, as said before, the impossibility to use deadline also leads to false positive. However our system using only topics from the topic ontology creates some problems when we want to use simple terms as *wireless*.

Basic Searching (Pseudo Email)

The basic text searching that stand for email shows the weakness we could predict from this kind of searching: the impossibility to understand the context. Thus it creates double in *data mining* for example as it don't understand the difference between a CFP and one of its updated version (for example extended deadline) and incidentally also creates false positives for deadline. Same for location found in CFP emails that aren't the conference location and thus creates false positive for *artificial intelligence and China* query. Finally without structure we cannot use date type so use a simple text query instead (*deadline march 2012)* however it miss the CFP because of the different ways the information is writing.

China	9	0	9	23(11)
Artificial Intelligence	9	30	39	10
Artificial Intelligence in China	3	2	5	3(1)
Data in march 2012 (deadline march 2012)	1	0	1	0(1)
Wireless communication	1	0	1	1
Wireless	X	X	X	9

IEEE Conference Search

As seen previously, the IEEE system already possesses many features to find a conference and thus give reasonable results. On the downside, it can only use date for conferences or final version but can't find notification, or draft types (cf. *Artificial Intelligence With Draft in May 2012*) contrary to our system.

CONCLUSION

This paper has introduced a Call For Papers manager system aimed at helping researcher to handle the daily flow of CFP and ease their research of a suitable conference. We have introduced the different systems currently available online to access CFP and pointed their main flaw as the lack of usable criteria to perform a request. Therefore, we have presented the main characteristics of our system: the extraction

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 7. CFP Manager / IEEE Conference Search Comparison

Query \ Result by System Positive (False Positive)	CFP Manager			IEEE
	TM	Onto	Total	
Data Mining	27	0	27	27
China	9	0	9	9
Artificial Intelligence	20	41	61	20
Artificial Intelligence in China	2	4	6	2

Wireless communication	2	0	2	2
Network protocols	2	0	2	2

of relevant data from CFP dataset using text mining algorithms, mainly rule based ones; the enrichment of these data via ontology models for conference location and topics; and finally the utilization of these data by the final user to find a suitable conference via interface allowing complex queries.

In order to validate our approach, we have set two experiences. The first one has measured via precision and recall, the efficiency of information extraction offering satisfactory results with 0.95 for precision and 0.91 for recall on average on our three dataset with strict and lenient setting. The second one has compared the number of results obtain on different queries with four systems: WikiCFP, IEEE Conference Search, basic text searching and our system with and without the ontology enrichment. We found that our system has surpassed WikiCFP and basic text searching by eliminating the false positive they returning.

As future work, the system still need improvement like the amelioration of information extraction especially for *Related Conference Full Name* and *Related Conference Acronym* or also the extraction of new type of data like conference website for example. The contribution of the ontology model should also be reviewed and the use of bigger ontology could be considered. From this point we could consider different application, for instance we could continue our research concerning data providing and implement a calendar to the system. We could also look at the other side of the problem and implement the extraction part as a tool to upload contentaware CFP on existing platform. Even if the result gives a good glimpse of the system capacity to handle heterogeneous sources of CFP, additional tests on bigger dataset should be performed.

Chapter 21
Word Sense Based Hindi-Tamil Statistical Machine Translation

Vimal Kumar K.
Jaypee Institute of Information Technology, India

Divakar Yadav
Jaypee Institute of Information Technology, India

ABSTRACT

Corpus based natural language processing has emerged with great success in recent years. It is not only used for languages like English, French, Spanish, and Hindi but also is widely used for languages like Tamil, Telugu etc. This paper focuses to increase the accuracy of machine translation from Hindi to Tamil by considering the word's sense as well as its part-of-speech. This system works on word by word translation from Hindi to Tamil language which makes use of additional information such as the preceding words, the current word's part of speech and the word's sense itself. For such a translation system, the frequency of words occurring in the corpus, the tagging of the input words and the probability of the preceding word of the tagged words are required. Wordnet is used to identify various synonym for the words specified in the source language. Among these words, the one which is more relevant to the word specified in source language is considered for the translation to target language. The introduction of the additional information such as part-of-speech tag, preceding word information and semantic analysis has greatly improved the accuracy of the system.

INTRODUCTION

Natural language processing (NLP) is a part of artificial intelligence which interacts with the systems (computer) through natural languages to perform desired actions. It deals with understanding and analyzing human languages in order to perform various functionalities which can enhance the interaction between the machine and the humans. There are various widely used algorithms under NLP, especially statistical natural language processing but each algorithm has its own bottleneck. These algorithms are usually based upon the analysis of large textual corpora and then calculating probabilities in order to

achieve the desired results. According to linguistics, corpus refers to large structured texts consisting of numerous words which are used for statistical analysis of the text. Generally, the corpus should be annotated to provide an efficient statistical analysis. The Corpus consists of each and every word in every sentence used for the language analysis. These words are added to the corpus along with the information about its part of speech such as: verbs, adjectives, nouns, and adverbs etc., which are called as POS tags. Corpus based NLP techniques have emerged with great success in the recent years. It is not only used for languages like English, French, Spanish, and Hindi but also is widely used for languages like Tamil, Vietnamese etc.

Numerous algorithms have been introduced in statistical machine translation to provide various intelligent functionalities for human-computer interaction. All these algorithms parse the sentences and then group the words before the translation process. Parsing of free word order languages such as Indian is also a bottleneck in these methods (Bharati et al., 2009; Bharati & Sangal, 1993). Local word grouping (LWG) is basically used in Indian languages since there is a need for grouping the words based on the context in which it is used and the meaning of those words will be clear only when it is grouped together (Bharati et. al, 1991; Ray et. al, 2003; Balaji et al., 2014). In these existing technologies related to corpus based NLP, the statistical analysis for machine translation makes use of a parallel corpus. In a parallel corpus, each word in the source language is mapped parallel with its corresponding word in the target language. In addition to parallel corpus being used for translation, the part-of-speech of the words is also considered for machine translation. Also, in statistical machine translation, the target texts are generated on the basis of statistical models and these models are derived from the analysis of the text corpus of the two languages. Generally, a document is translated to a probable sentence in the target language according to the probability distribution $P(t|h)$ which refers to the probability of string t in the target language (for example, Tamil) given the string h in the source language (for example, Hindi).

Naive Bayes algorithm is one of the existing algorithms which are based on statistical analysis of the existing bilingual corpus. The algorithm uses probability of occurrence of words for translation from one language to another. For a particular word, its probability is calculated based upon the frequency of occurrence of the word in the corpus. The meaning which has maximum occurrence in the target language will be the probable translation for the input word. The mathematical representation of this algorithm is:

$$\mathrm{P}\left(\frac{x}{y}\right) = \mathrm{P}\left(\frac{y}{x}\right) * \mathrm{P}(x) / \mathrm{P}(y)$$

Since P(y) will not affect the result, the equation is equated as shown below:

$$\mathrm{P}\left(\frac{x}{y}\right) \cong \mathrm{P}\left(\frac{y}{x}\right) * \mathrm{P}(x)$$

This mathematical representation signifies that there is translation model and language model being used to perform the translation process. Translation model analyzes the translation between source and target language whereas the language model analyzes the target language being used. These statistical algorithms can further be improved by considering the tag information of the word under consideration but still there will be lack of efficiency and accuracy. Also, ambiguity is one of the concerns of these

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

algorithms. In order to overcome this ambiguity issue, an analysis on these languages has been made and found that the sense of word can be used to eradicate this ambiguity issue. Certain word has different translations based on its part-of-speech which has been included in this Naïve Bayes model. There are words that have multiple translations based on the context in which it is used and this can be identified using word sense disambiguation over the sentence. Thus, the objective of this system is to improve the efficiency of the statistical machine translation by providing additional information such as the part-of-speech of the word to be translated as well as the information about the preceding words and also to make use of the word's sense in the translation process. Since this translation process takes in to account the word's part-of-speech (syntactic information) as well as the word's sense (semantic information) during the machine translation, it improves the efficiency and accuracy of the translation.

Rest of the contents of this paper is arranged as follows: Section 2 discusses the existing works, researches and technologies which have been prevalent in the field of machine translation. It also discusses about challenges faced and solutions proposed in the respective field. Section 3 consists of a detailed description of the algorithm introduced, theory, implementation and mathematical interpretation. The results and its analysis are described in section 4. Finally, in section 5, it concludes the work along with some future directions.

RELATED WORK

Various techniques have been proposed in the sub field of inter language translation under the umbrella of natural language processing (NLP). Cross linkage of words from two different languages have empowered NLP facilitating bilingual dictionaries and other practical applications. This can be a challenging task as the linkage needs to be balanced and two languages can be varied on grounds of culture, meanings etc. Hindi to English linkage suffers from kinship relations (uncle in English can be mama or chacha in Hindi), musical instruments, grains, kitchen utensils etc. Direct and hypernamy linkage can cater to such challenges. Also, manual linking of two languages can be facilitated using WordNet SynsetMatcher tool (Saraswati et al., 2010; Alguliyev, et al., 2017).

Annotation in Hindi and English varies highly as both the languages differ in terms of grammar. The two techniques for tagging can be: linking all possible words in both source and target language, or, linking least possible words in both source and the target language. Since exact correspondence is hard to find and word to word translation is possible for very few words, thus remaining words are translated based on the combination of words. Thus, annotation can follow certain guidelines such as following fuzzy, regular and null links in punctuation which can lead to desired results (Yadav & Gupta, 2010; Hema & Geetha, 2016).

A system, ANUBHARTI which follows an approach of machine aided translation having the combination of example based and corpus based approaches with some elementary grammatical analysis is been developed for corpus generation (Bharati et al., 1997). In ANUBHARTI the traditional EBMT approach has been modified to reduce the requirement of a large example based corpus. ANUBHARTI-II in 2004 uses Hindi as a source language for translation to other Indian language.

A machine translation system which translates pure (standard) Hindi to pure English was implemented in 2004 by incorporating additional level to AnglaBharti-II and AnuBharti-II. The system gives satisfactory results in more than 90% cases (Sinha & Thakur, 2005; Sinha, 2004).

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

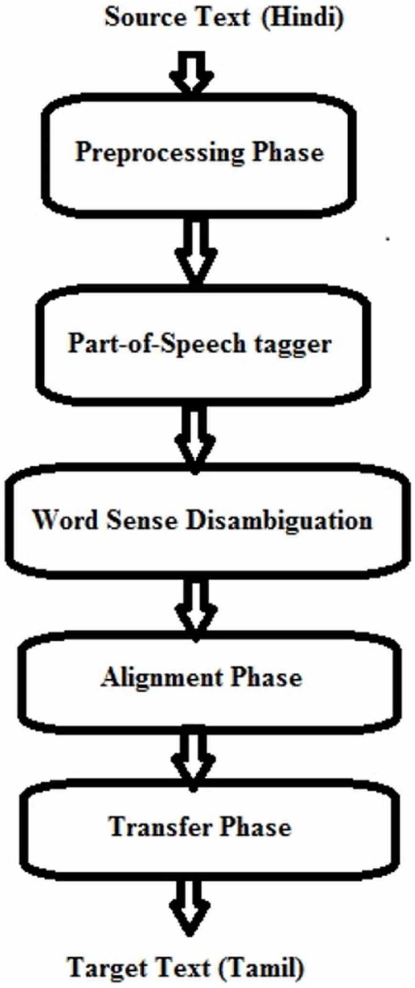
Vishal Goyal and G.S. Lehal (2010) proposed a machine translator from Hindi to Punjabi. The methodology used for the translation was direct translation and later on improving the language learning modules for the enhancement of the quality of the system. The accuracy of the translation is approximately 95%. The web tool developed has many application areas like over internet for the particular community of peoples, for the newspapers and sending e-mails from Hindi to Punjabi or vice versa (Goyal, 2010; Goyal & Lehal, 2010).

The performance of the multilingual information retrieval employing dictionary based strategy for query translations have been measured and analyzed by several articles reported in the literature (Korra et al., 2011; Abbache, 2016). The experimental result shows that the performance of the multilingual information retrieval system enhances over the monolingual information retrieval system by 31.4%.

For English to Hindi statistical machine translation, the key challenge is that the Hindi language is richer in morphology than the English language. Reordering of English source sentences in accordance with Hindi language and/ or making use of suffixes of Hindi words are the two strategies that can facilitate reasonable performance. Since Indian languages and English differ in word order, morphologically rich Indian languages and unavailability of huge parallel corpora for two languages make the above two strategies more challenging to derive the desired results with reasonable performance (Ananthakrishnan et al., 2009).

PROPOSED METHOD

This proposed method performs translation at the word level and it follows a step by step procedure. The paper focuses on a system which makes use of a translation model and a language model. The translation model is developed to provide the translation from one language to another, based on the analysis of both the languages. Since the translation process depends on the grammatical sequence of words in the source language, an analysis of grammatical structure of the source language is performed and a language model is developed for the same. It is identified for the languages under consideration that the word's sense also matter during the translation process, the word's sense is identified using the semantic analysis. The system architecture is as shown in Figure 1.



Following are the detailed description about the various phases of this proposed translation system.

Preliminary Phase: Corpus Generation

The text corpus is a large set of structured text electronically stored in the database. The corpus is used for the statistical analysis within the language territory. In this algorithm, a multi-lingual database is built for the language model and translation model by traversing over a big textual corpus in both the languages provided by Technology Development for Indian Languages (TDIL) Programme, Department of Information Technology (DIT), MC&IT, Govt of India. The database is made in accordance to the part-of-speech tagging for individual words in the source language (Hindi) along with semantically equivalent of the target word (Tamil). Additionally, words' frequency of occurrence in the text corpus is also stored. This is one part of corpus generation which is required for the translation model. Another database is built for Tamil text by traversing a Tamil corpus and storing values in the database for preceding words, current word, and their frequencies. This database signifies the language model required for the statistical system

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. System architecture

Pre-Processing Phase

Since this system is a word level translation system, the preprocessing phase is to tokenize the input text in to individual sentences. These sentences are further tokenized to extract the words and these words are passed on to the next phase of the translation system which is the part-of-speech tagging phase.

POS Tagging Phase

In machine translation, the part-of-speech tagging has to be performed that refers to the marking of the words for information based upon the context of the word and also the relationship between the word and the adjacent words. It refers to the identification of words as nouns, verbs, adjectives, adverbs etc. Part-of-speech tagging is generally of three types namely: rule based part-of-speech tagging, transformation based part-of-speech tagging and probabilistic based part-of-speech tagging. Ambiguity is one of the major problems that come across while performing part-of-speech tagging. This system uses the well-

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

known HMM based POS Tagging. The tagger considers the preceding word information to improve the tagging process that reduces the ambiguity. As the proposed system considers the tagging information during translation, the accuracy of the system depends more on this phase of the translation process. In case the tag assigned to a particular word is wrong, then the system's translation won't be proper.

Word Sense Disambiguation using Hindi Wordnet

This phase uses the Hindi Wordnet dictionary to identify the various senses for the particular word with its identified part-of-speech. Semantic analysis between the words under consideration over the various senses of the word provides a score of its relevance. The high scored senses are used further in the translation. For the sense disambiguation, the latent semantic analysis (LSA) technique is used. LSA technique is a singular value decomposition method which decomposes the term-frequency matrix in to three different matrices namely left singular matrix (L), right singular matrix (R) and singular diagonal matrix (D). Left singular matrix is a matrix which has the Eigen vectors of the term matrix and its transpose and this matrix is also called as term matrix. Right singular matrix is one which contains the singular values of the term frequency matrix as the diagonal elements and it is also called as concept matrix. Whereas the singular diagonal matrix has the Eigen vectors of the transpose of term-frequency matrix and this matrix is known as concept by document matrix.

$$\begin{bmatrix} f_{t1}^{1} & f_{t2}^{1} & \ldots\ldots & f_{tn}^{1} \\ f_{t1}^{2} & f_{t2}^{2} & \ldots\ldots & f_{tn}^{2} \\ \ldots & \ldots & \ldots & \ldots \\ f_{t1}^{m} & f_{t2}^{m} & \ldots\ldots & f_{tn}^{m} \end{bmatrix} = L * R * S$$

where, f_{tn}^{m} - indicates the frequency of n^{th}-term in m^{th}-sentence

The term frequency of words is arranged in the form of a matrix with column as different terms (words) used in the text and row of the matrix as the sentence identification numbers. After the decomposition of this matrix, the product of the right singular matrix and singular diagonal matrix gives the frequency of semantically similar words in different sentences and the similarity between two sentences is found using cosine similarity over the product of right singular vector and singular diagonal vector of the sentence considered (Kumar et al., 2015). The cosine similarity is calculated using the below mentioned in the equation:

$$\cos\theta = \frac{\sum_{i=1}^{n} x_i * y_i}{\left(\sqrt{\sum_{i=1}^{n} x_i^2} * \sqrt{\sum_{i=1}^{n} y_i^2}\right)}$$

At this phase, the system has identified the relevant senses for the word, now the system has to rearrange the sentence since the naïve Bayes method requires the proper sequence in the target language.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Alignment Phase (Syntactic Restructuring)

Based on the analysis, it is found that Hindi language follows Subject Object Verb (SOV) sequence that is same as in Tamil. The transfer phase makes use of the target language model and considers the preceding word information in the target language level. Since, the text which is in source language follows the grammatical correctness of the words in target language; there is no need for rearranging the words based on the target language grammar under certain exceptional cases such as compound sentences, which gives emphasis on the restructuring of sentences in the target language Tamil. In Tamil language, there are various affixes being used in a sentence which doesn't exist in Hindi language. Accordingly, the grammatical restructuring of the words in source language happens such that the source language sentence is aligned with the grammar as in the target language. This is achieved by applying the statistical based alignment algorithm. Basically, this system makes use of GIZA++ (a tool for word alignment). This tool generates the alignment table which is required for the statistical method. The sample alignment table is as shown in Table 1 which has the position in target language, source word position, length of Hindi sentence and length of its corresponding Tamil word.

Naïve Bayes model is applied over this alignment table to identify the probable alignment in target language for the given sentence in source language. The one which has the higher probability will be used for aligning these source language words.

Transfer Phase

The basic model of language translation, also called as parallel translation, finds every individual target language word of the source language word in a list and substitutes this word with the equivalent target language word. But this method does not ensure accurate results as the relationship followed between words in source language and in target language are often one-to-many, instead of one-to-one. This is due to that a word in source language can give different equivalent translations in the target language based on the context where it is being used. Solutions for increasing the accuracy of the results are to distinguish the word on the basis of its part-of-speech and also on the basis of word's sense. In this proposed system, the part-of-speech of the word is used to identify the category of words and in the particular category a word can have multiple senses which are further identified using LSA and Wordnet tool. The sense of the word is used in our statistical translation model.

Probability serves a major role to analyze any complex data. This system follows analysis for translation by taking it into account the probability of target word given the source word and its corresponding part-of-speech. The probability can be represented as mentioned below:

Table 1. Sample alignment table

S.No	J (Word's Position in target language)	I (Word's Position in Source language)	L (Source Sentence Length)	M (Target Sentence Length)	Frequency
1	4	3	8	10	252
2	7	7	10	10	231

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

$$P\left(W_t \mid W_s, W_{tag}\right) = \arg\max_{j \to 0 to N} P\left(W_j, W_{tag} \mid W_t\right) * P\left(W_t\right)$$

Where, N indicates the total number of senses identified for word W_s

$$P\left(W_s, W_{tag} \mid W_t\right) = P\left(W_s \mid W_t\right) * P\left(W_{tag} \mid W_t\right)$$

$$P\left(W_s \mid W_t\right) = \frac{count\left(W_s, W_t\right)}{count\left(W_t\right)}$$

$$P\left(W_{tag} \mid W_t\right) = \frac{count\left(W_{tag}, W_t\right)}{count\left(W_t\right)}$$

$$P\left(W_t\right) = P\left(W_t \mid W_{prev_word}\right)$$

$$P\left(W_t\right) = \frac{count\left(W_t, W_{prev_word}\right)}{count\left(W_t\right)}$$

The above-mentioned formulae are used for finding the probable translation for one sense of the word in the source language. To find the most probable translation for that context in which it is being used, the above equation is applied over all the various senses of the word and the one which has the maximum probability value is selected as the best translation for the word. Sample tagged transfer database is as shown in Table 2. This database has Hindi words, its corresponding Tamil words based on the POS tag of the Hindi word along with the frequency of occurrence. In Table 2, the word अच्छी (*AACHCHI*) appears in 89 sentences out of which it is converted to நல்ல (*NALLA*) in 49 sentences and the rest of the sentences it is converted as நன்றாக (*NANDRAGA*). From this it is evident that the words' part of speech can be used to distinguish the target word translation. The same word appearing as adjective, has two different equivalent words in Tamil in *60* cases and in such cases, it can be narrowed to one particular word by considering its preceding word information as well as the word's sense.

Table 2. Sample transfer database

Hindi word	Tamil word	Tag	Frequency
अच्छा	நல்ல	JJ	53
अच्छी	நன்றாக	RB	29
अच्छी	நன்றாக	JJ	11
अच्छी	நல்ல	JJ	49
उत्पादक	உற்பத்தியாளர்	N_NN	24

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 3. Sample precedence database

Precedence word	word	frequency
^	நல்ல	18
மிகவும்	நல்ல	25
^	நன்றாக	13
இது	நன்றாக	15
^	உற்பத்தியாளர்	4
நல்ல	உற்பத்தியாளர்	12

There comes the need for a precedence database whose sample is as shown in Table 3 and this database has the details about the preceding word for any given Tamil word along with its frequency. The use of ^ symbol for precedence word denotes that the word occurs in the beginning of any sentence.

For Example

Consider the input text, **"**ताजा साँसें और चमचमाते दाँत आपके व्यक्तित्व को निखारते हैं।**"**

After preprocessing the text, individual words are identified as unique tokens from the input text. This tokenized text is subjected to POS Tagging. The tagged sentence output is ताजा\JJ साँसें\N_NN और\CC_CCD चमचमाते\JJ दाँत\N_NN आपके\PR_PRP व्यक्तित्व\N_NN को\PSP निखारते\V_VM हैं\V_VAUX ।\RD_PUNC. This tagged text is considered for syntactic restructuring but in this case there won't be any change in the order of the sentence so the same output is fed to statistical transfer phase and is described as follows,

Considering the word *"*ताजा\JJ*"*,

From the wordnet the various senses that are found for (ताजा as Adjective) are - ताज़ा, ताजा, अम्लान, अशुष्क, आला, गरमागरम, टटका. These words are further subjected to word sense disambiguation using LSA. For the latent semantic analysis, the sentences formed using these various senses and the given word is converted in to term-frequency matrix which is used in the latent semantic analysis. The LSA algorithm identifies that ताजा and ताज़ा are the relevant words for the given input word.

Case-1: When source word W_s is "ताजा" and Tag W_{tag} is "JJ" and target word W_t is "புத்தாணர்ச்சியான" (Puthunarchiyana means Fresh), then $P(W_s, W_{tag}|W_t) = 30/34$

Also, when the target word W_t is "புத்தாணர்ச்சியான" and precedence is nothing, then $P(W_t) = 22/30$

So combined probability $P(W_t|W_s, W_{tag}) = (30/34)*(22/30) = 0.647$

Case-2: When source word W_s is "ताज़ा" and Tag W_{tag} is "JJ" and target word W_t is "புதுப்பித்த" (Puthupithu means New), then $P(W_s, W_{tag}|W_t) = 8/10$

If the target word W_t is புதுப்பித்த and precedence is nothing, then $P(W_t) = 1/10$

So combined probability $P(W_t|W_s, W_{tag}) = (8/10)*(1/10) = 0.08$

Out of these probabilities first one is highest so the target text is "புத்தாணர்ச்சியான".

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Similarly, the other words are translated. The final translated output will be பாத்தாணர்ச்சியான\JJ சாவாசம்\N_NN மற்றாம்\CC_CSD பளபளப்பான\JJ பற்கள்\N_NN தங்களின்\PR_PRP தோற்றத்தை\N_NN நிர்ணயிக்கிறதா\V_VM_VF .\RD_PUNC

RESULTS AND EVALUATION

This system has been evaluated using various sentences (restricted to health domain) and the Bilingual Evaluation Understudy (BLEU) score is calculated to be 0.68. The precision and recall of the system are found to be 0.85 and 0.7 respectively. As shown in the Table 4, the system is found to give very good results by introducing word sense based translation which is compared with its counterpart without word sense disambiguation (WSD). The precision and recall gradually improves with increase in corpus size. This is due to inclusion of additional words to the corpus which makes it mature enough compared to the lesser corpus size.

CONCLUSION

The basic advantage is that the algorithm considers the sense of the word during translation process. In addition to that, the introduced algorithm also tends to increase accuracy of the translation as compared to parallel translation or any other existing methods for language translation. The algorithm calculates probability of occurrence for individual word, precedence word and tagging of words during the translation. The precision and recall of the algorithm are 87% and 86.5% respectively, which shows considerable improvement compared to the system without word sense disambiguation, whose precision and recall are found to be 83% and 79% respectively.

Although the algorithm tends to improve the results, but still there is scope for modifications that can further improve the accuracy of the output. One of such modifications can be introducing good part-of-speech tagging in the source language. Another modification can be making the algorithm machine intelligent so that if the input word is not contained in the corpus, the algorithm intelligently derives proper translation. These further modifications, if implemented in future can improve results in machine translation from Hindi to Tamil.

Table 4. Comparison of the precision and recall

S. No.	Corpus Size (in number of words)	Statistical Machine Translation(with WSD)		Statistical Machine Translation(without WSD)	
		Precision (in %)	Recall (in %)	Precision (in %)	Recall (in %)
1	10000	65	63	58	57
2	20000	76	72.5	71	72
3	30000	87	86.5	83	79

Chapter 22
Exploiting Chi Square Method for Sentiment Analysis of Product Reviews

Nilesh M Shelke
Priyadarshini Indira Gandhi College of Engineering, India

Shrinivas P Deshpande
DCPE, HVPM, India

ABSTRACT

Sentiment analysis is an extension of data mining which employs natural language processing and information extraction task to recognize people's opinion towards entities such as products, services, issues, organizations, individuals, events, topics, and their attributes. It gives the summarized opinion of a writer or speaker. It has received lot of attention due to increasing number of posts/tweets on social sites. The proposed system is meant to classify a given text of review into positive, negative, or the neutral category. Primary objective of this article is to provide a method of exploiting permutation and combination and chi values for sentiment analysis of product reviews. Publicly available freely dictionary SentiWordNet 3.0 has been used for review classification. The proposed system is domain independent and context aware. Another objective of the proposed system is to identify the feature specific intensity with which reviewer has expressed his opinion. Effectiveness of the proposed system has been verified through performance matrix and compared with other research work.

INTRODUCTION

As the publication of posts/opinion/thoughts/tweets on social sites/blogs/forums became easy, internet sites are flooding with product reviews. Reviews are useful to customers for taking decisions for purchasing, institutes/companies for branding, politicians for making image in the public, etc. This public generated review holds sentiments for various products/persons/movies etc. But their browsing is tedious as they are huge in number. Sentiment Analysis from text is multi-facetted research issue. Even though

there are tremendous challenges and many difficulties in sentiment analysis from text; its contribution and applications to industry is not ignorable. Because sentiment analysis bases its results on factors that are so inherently humane, it will become one the major drivers of many business decisions in future. Practical applications of sentiment analysis are huge. Sentiment analysis can be successfully applied to learn user preferences and interests from users' personal writings. These methods are often studied for consumer feedback analysis. Similarly, e-learning systems can benefit from affective tutoring approaches.

Sentiment Analysis is an extension of data mining which employs Natural Language Processing and Information Extraction task to recognize people's opinion towards entities such as products, services, issues, organizations, individuals, events, topics and their attributes. Sentiment Analysis analyze each text and detect which part contain opinionated word, which is being opinionated and who has written the opinion. It gives the summarized opinion of a writer or speaker. Sentient analysis can be done at word level, sentence level and document level. In a broader sense, sentiment analysis is focused to detect the attitude of a speaker or a writer with respect to some topic or about overall coverage of a document (Zhao et al., 2015). Sentiment can be defined as

Sentiment:= $<o_j, f_{jk}, so_{ijkl}, h_i>$,

o_j is the target: what/whom the sentiment is expressed to.

f_{jk} is a feature of the object o_j,

so_{ijk} is the sentiment value of the opinion of the opinion holder h_i *on feature* f_{jk} *of object* o_j*;* so_{ijkl} *is +ve,-ve, or neutral, or a more granular rating.*

*hi is h*older: who expresses the sentiment (Pawar, 2016).

Identification of sentiments or moods embedded in the (written) natural language is critical and a challenging issue. Researchers are attempting to apply different approaches and techniques and extract useful information from this data.

As such demand of sentiment analysis applications is increasing rapidly. Primary tasks in sentiment analysis is finding the "aspects" or "features", finding their corresponding sentiments, identifying the intensity of the sentiments and finally calculating the overall opinion of the reviewer. Consider some actual reviews from the dataset.

1. The bread is top *notch* as well.
2. In fact, this was not a Nicosia salad and was *barely eatable*.
3. I have to say they have one of the *fastest* delivery times in the city.
4. The food is always *fresh* and *hot* - ready to eat!
5. Did I mention that the coffee is *outstanding*?
6. Certainly not the *best* sushi in New York, however, it is always *fresh* food, and the place is *very clean, sterile*.

In the above example reviews, underlined terms are the product features and italic terms indicates the sentiments about those features termed as sentiment features.

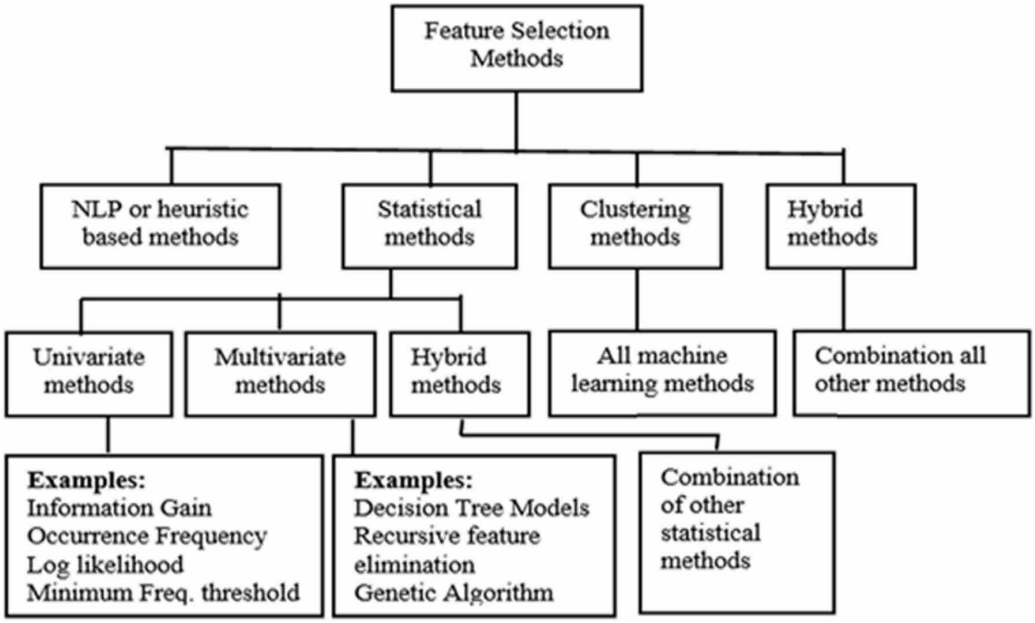
This paper is intended for exploiting chi square method for sentiment analysis. Major contributory research work on chi square method for exploiting feature selection from text do not occur. Researchers have used chi square method mainly in statistics for verifying the interdependence of two events. In particular, chi square can be exploited to test the dependency of some special terms with specific classes. In sentiment analysis, researcher has employed it for the classification of any review to a particular class like positive or negative or to study the interdependence between feature and a class as by (Janaki Meena et al., 2010). In the proposed system chi square method is employed for feature selection. Chi square method has been exploited for fine feature selection.



This paper is organized as follows: Section II details the work done on sentiment analysis by various researchers; Section III introduces proposed system which includes algorithms for feature extraction, the aspect-oriented sentiment analysis; Section IV evaluates the proposed work with existing works and finally conclusion has been provided.

LITERATURE SURVEY

Figure 1 is the summary of feature selection methods researchers worked upon. Natural language processing techniques includes locating the terms near subjective expression which acts as features and take the help of POS Taggers like noun and noun phrases which are feature rich (Heeryon et al., 2016).

Statistical methods are highly popular for feature extraction. Univariate works one at a time on attributes. These techniques are computationally efficient. Demerit of these techniques is that they do not work upon interaction amongst the attributes. Univariate methods like Information Gain for feature extraction are implemented by (Gao, 2014; Ghosal, 2016; Ferruh, 2014; Jiamin, 2015). Study has coined a new term, Maximum Discrimination (MD) a statistical method for implementation of feature selection (Tang, 2016).

Figure 1. Summary of features selection techniques

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Statistical feature selection multivariate methods like Decision Tree Model has been used (Hwang, 2002). Statistical binary bat algorithm has been implemented (Rani and Rajlakshmi, 2015). Recursive feature elimination method has been implemented by (Abualigah, 2016). Previous studies have employed genetic algorithm for feature selection. Only drawback of multivariate methods is that they are computationally expensive unlike univariate methods. Multivariate methods word on group of attributes. Hybrid techniques use univariate, multi-variate and other methods for high accuracy (Zhao and Yafei Wang, 2010; Ahmad, 2015; Singh and Kakkar, 2015).

Feature clustering for feature extraction using PMI has been proposed (Jeyadurga, 2004). Depending upon frequency, a head word of the cluster is selected. This head word is then compared with other word for PMI similarity and thus features are decided. However, drawback of such technique is that feature clustering loses minor features and can collect major features only (Zhang, 2011).

Many researchers achieved this task of feature selection by machine learning Approaches (Su, 2018; Zhang, 2011; Masashi, 2016; Zhang, 2012; Lu, 2009; Zhai, 2011; Kharde, 2016). Conditional Random Fields (CRF) also can be applied for feature extraction (Batcha and Azi, 2013). However, demerit of machine learning approaches is that they require huge data and techniques which are data dependent.

(Wu et al., 2014) found better results with statistical machine learning than semantic approach and accuracy increases with increase in training dataset. Work was done for financial website Sina Finance. Study could establish the relationship between stock price volatility and sentiments expressed by the stakeholder. (Xinjie Zhou et al., 2016) tried experiments on Chinese CMSAE dataset. Proposed system called CMiner is used for aspect orientation and opinion summarization. However, methodology proposed is data dependent and work has been done for Chinese reviews only.

The mutual information measure (PMI) method has been employed by the researchers for identifying the correspondence between the features and the classes. The point-wise mutual information (PMI) gives the co-occurrence strength. This is the basic PMI. Another mostly used feature selection technique is Latent Semantic Indexing, accompanied by Principal Component Analysis wherein, reduced dimensionality technique is used by (Walaa Medhat, 2014). (Baumgarten et al, 2013) attempted sentiment mining for twitter using keywords. But this attempt carries with an inherent problem of keywords like *Ambiguity in Keyword Definitions, Incapability of Recognizing Sentences without Keywords*, *Lack of Linguistic Information and* Poor recognition of affect when negation is involved.

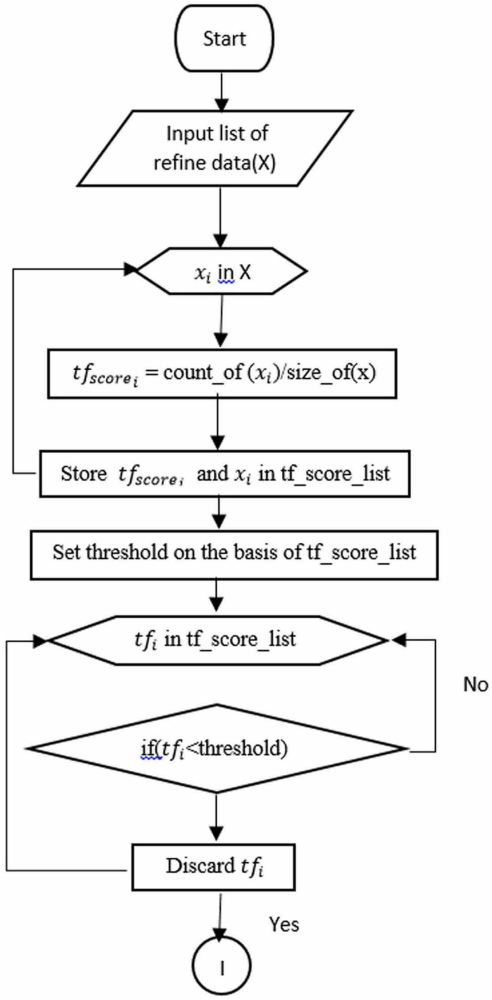
PROPOSED SYSTEM

Figure 2 depicts architecture of the proposed system. Reviews collected from amazon.com is of varying domains like restaurants, camera, computer, antivirus, vehicles. Reviews are un-structured data with slangs, abbreviations like TTYL, B4N! …, Gr8.., CU, … and noise like smiley, special Symbols (!, ?, ….). This necessitates slang conversion and care of symbols in the beginning. After pre-processing input comment is given to feature selection method which outputs features of products about which author has expressed his/her reviews. Feature selection is done by term frequency parameters. Figure 3 depicts the flowchart for feature selection by Term Frequency. Term frequency for every term is calculated by the formula

$$tf_{scorei} = \text{count_of}(x_i)/\text{size_of}(x)$$

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. Architecture of the proposed system



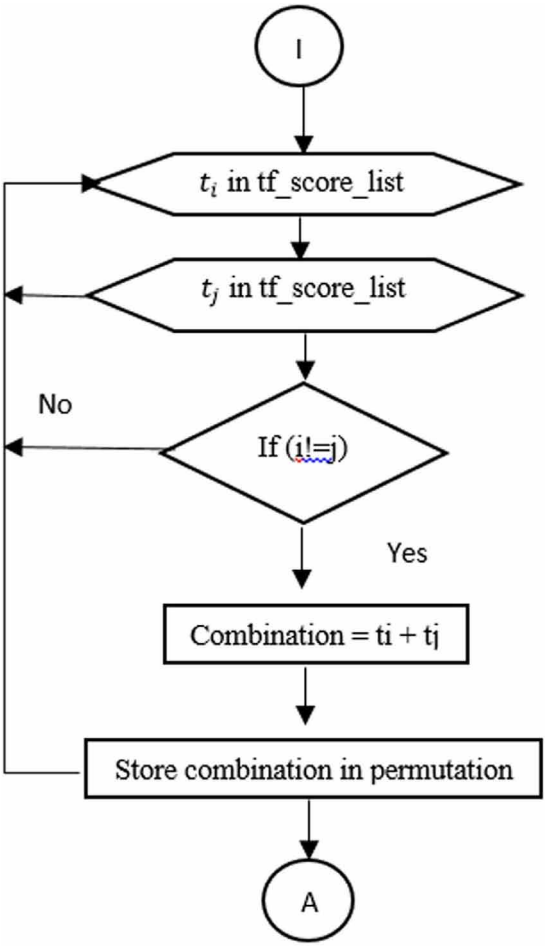


Figure 3. Feature Selection using TF-IDF score

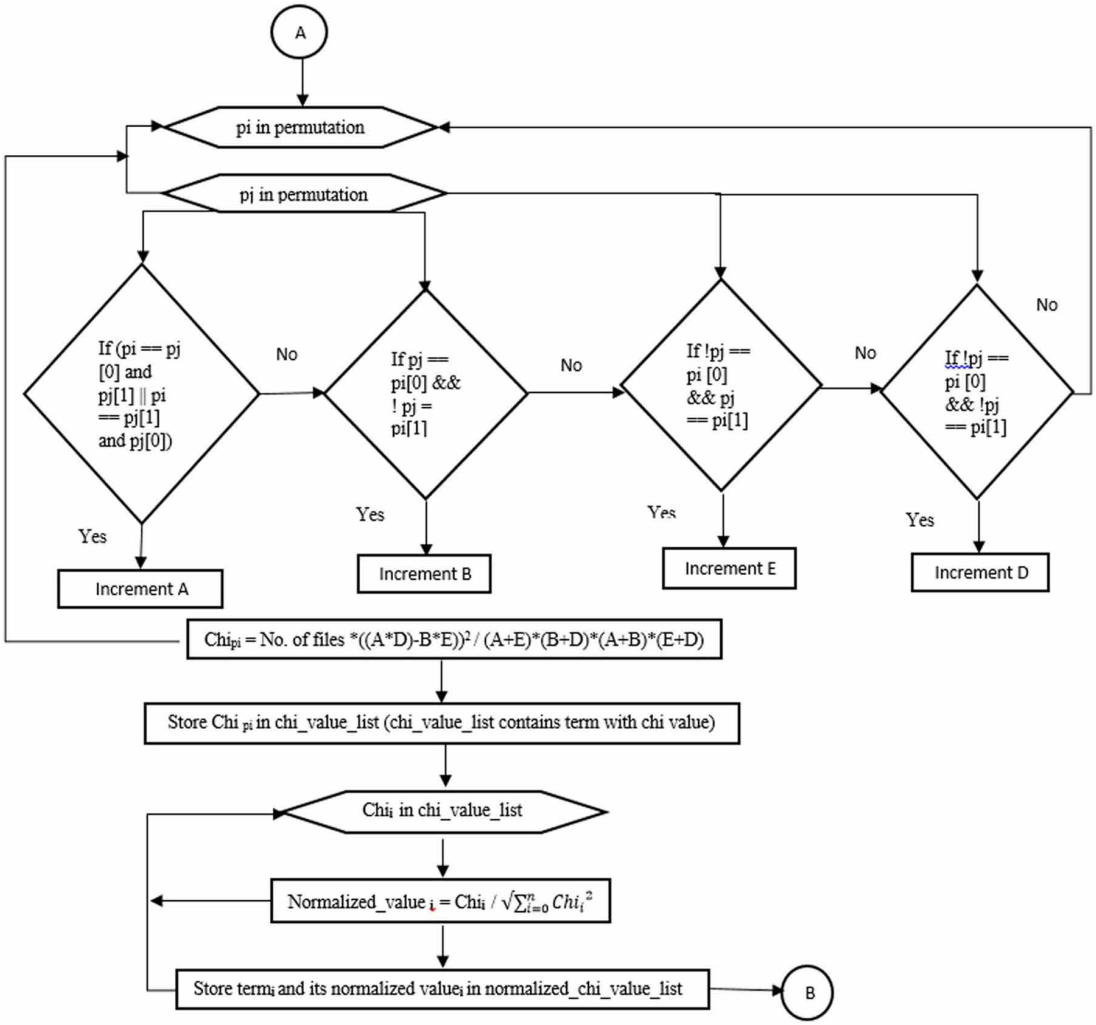

Term frequency score of every term is stored in tf_score_list. A threshold for term frequency score is decided. Terms with frequency score below this threshold are removed. This helped to remove noisy features. Further pruning of the features is done by chi square method. Chi square method has been applied in a novel way for fine pruning of the features. Figure 4 shows permutation and combination of the probable features obtained from Figure 3. Figure 4 and Figure 5 shows the mechanism of chi square method. Figure 6 depicts the flowchart for normalizing chi score values. Chi square values are fed for calculation of sentiment scores of all the features. SenitiWordNet 3.0 has been used for calculation of sentiment score. Figure 7 provides flowchart for calculation of sentiment score for the features of product reviews with proper polarity and intensity.

Mechanism of feature selection through chi square method is explained here with actual reviews from the dataset. Intentionally short reviews are taken for the sake convenience of explanation. Actual reviews contain 4-5 statements also. Feature with a character less than 3, could not observe in the dataset. Hence those words are omitted along with adjectives and adverbs from the candidate features list.

Permutation = mention coffee, A = 2, B = 1, E = 1, D = 111, feature = mention, chi value = 4.326

Permutation = coffee mention
A = 2, B = 1, E = 1, D = 111, feature = coffee, chi value = 4.326194019274377

- **Normalise all the chi values**
  feature = bread, normalized score = 0.14531439742822497
  feature = notch, normalized score = 0.14531439742822497
  feature = fact, normalized score = 0.1780572139105606
  feature = fact, normalized score = 0.05448712750170592
  feature = nicoise, normalized score = 0.1780572139105606
  feature = nicoise, normalized score = 0.05448712750170592
  feature = salad, normalized score = 0.05448712750170592
  feature = salad, normalized score = 0.05448712750170592
  feature = mention, normalized score = 0.55447660037437
  feature = coffee, normalized score = 0.55447660037437
- Finally, find maximum Chi value for a feature
  feature = bread, max chi value = 0.14531439742822497
  feature = notch, max chi value = 0.14531439742822497
  feature = fact, max chi value = 0.1780572139105606
  feature = nicoise, max chi value = 0.1780572139105606
  feature = salad, max chi value = 0.05448712750170592
  feature = mention, max chi value = 0.55447660037437
  feature = coffee. Max chi value = 0.55447660037437
  // Chi Test ends

Those terms which have more than one normalize chi value, their maximum score have taken into consideration. Thus this process outputs fine product features. Flow of this mechanism is depicted in Figure 4 and Figure 5.

For calculation of sentiment scores of features, SentiWordNet 3.0 (SWN) is exploited which publicly available freely. SWN contains a word with many senses as found by (Apoorva et al., 2016) Hence, only those senses are considered which POS tag matches with sentiment feature expressed in the review. If still multiple senses occur, then following formula is used for calculation of sentiment score.

Score= (1/2) (1st score from SWN)*(1/3) (2nd score from SWN)…….

This mechanism is depicted in Figure 6. In case sentiment feature expressed in review is not available in SWN, it's all synonyms are searched. In case of unavailability of synonym its hypernyms are searched. Synonym or hypernym with maximum score is selected. Flowchart 7 is used for polarity classification.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

ALGORITHM: Determining the Polarity of Reviews
Input: Single Comment.
Output: Polarity, Intensity.

Step 1: Select Comment.
Step 2: Apply POS tagging using Stanford POS tagger.
Step 3: Get features from feature selection algorithm
Step 4: Take Noun phrase and verb Phrase using Stanford parser.
Step 5: If it is Noun phrase then for every Noun Phrase, check Noun and Adjective. If it is a Noun then calculate the polarity with the formula
PolarityN=$\Sigma^{i}_{k=0}$ $[(1-Ni)*Ni]$
and if it is adjective then calculate it with the fomula
PolarityA= $\Sigma ik^{=}_{0[}(1-Ai)*Ai]$
Setp 6:
If it is a Verb phrase, then for every Verb phrase, check for verb and adverb.
If it is a verb, calculate the polarity as
PolarityV=Σ $ik^{=}_{0[}(1-Vi)*Vi]$ and
if it is adjective, calculate it as
PolarityA=Σ $ik=0_{[(1}-Advi)*Advi]$
Step 7: Intensity= polarityN + polarityA;
Step 8: classification
If intensity>0
Positive;
Else
Negative;

ALG**ORITHM 5.2: Fe**ature Calculation and Score Calculation

Step 1: Get N,A,V,Adv as word
Step 2: find word in to SentiWordNet
If(found)
Score=(1/2)(1st score from SWN)*(1/3)(2nd score from SWN)…….
Return score;
Step 3: Else
Apply stemming and get set of synonyms from WSD
For each synonym
Calculate score for each word.
End for.
End else
Step 4: Return max (score);
Step 5: end

RESULT ANALYSIS

The results obtained from the implemented methods and their comparison with existing approaches are discussed here. The proposed approaches are implemented using NetBeans IDE 8.0.2. 200 reviews each of camera, computer, Norton Antivirus and more than 600 reviews of restaurant are tested. For clarity and uniformity, results of average of 100 reviews are shown here. Figures 8 and 9 show graphs with improvement of work and accuracy comparison. Tables 1-4 show information regarding restaurant domain.

The performance of a developed model is determined by how good the classifications (predictions) reflect the actual events. There are two possible predicted classes: "POSITIVE" review and "NEGATIVE" review (AlShahrani, 2017).

- **True Positives (TP):** These are cases in which proposed system predicted POSITIVE (they are positive reviews), and they are actually the POSITIVE reviews.
- **True Negatives (TN):** System predicted NEGATIVE, and they are actually NEGATIVE reviews.
- **False Positives (FP):** System predicted POSITIVE, but they are actually NEGATIVE reviews.
- **False Negatives (FN):** System predicted NEGATIVE, but they actually are POSITIVE reviews (Dey, 2016).

There is a list of rates that are often computed from a confusion matrix for a binary classifier: (Saba et al, 2016; Virmani et al, 2016; Nath et al, 2016).

- **Accuracy:** Overall, how often the classifier is correct can be calculated by

$$A = \frac{\left(TP + TN\right)}{\left(TP + TN + FP + FN\right)}$$

- **Recall**

$$R = \frac{\text{No: of sentences correctly classified as class } x}{\text{Actual No: of sentences of class } x}$$

- **Precision:** When it predicts POSITIVE, how often is it correct?

$$P = \frac{\text{No: of sentences correctly classified as class}}{\text{No of sentences classified as class } x}$$

- **F Score:** This is a weighted average of the true positive rate (recall) and precision.

$$F - score = \frac{2 * Precision * Recall}{\left(Precision + Recall\right)}$$

Proposed work is the extended work done in (Nilesh Shelke et al., 2016). Proposed method outperforms the previous work.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Methods	Precision	Recall	FM	Accuracy
Previous work (Nilesh Shelke et al., 2016)	0.8732	0.7126	0.7847	0.87
Proposed System	0.9277	0.8651	0.8953	0.89

CONCLUSION

The major contribution of the research work is extraction of features from product reviews for which chi square method has been implemented. Another contribution is that the methodology applied is dataset independent i.e. same method is useful for all the datasets of product reviews. Feature selection task addressed through chi square method is context aware also. It has been observed that feature position is more important than feature frequency. The proposed system is an extended work done in (Nilesh Shelke et al, 2016). Spurious features could observe in the previous work. Hence, they have been pruned by TF-IDF measure and then by employing chi-square method. These methods could extract concrete features from the reviews.

Table 3. Comparison with (M. Govindarajan, 2014)

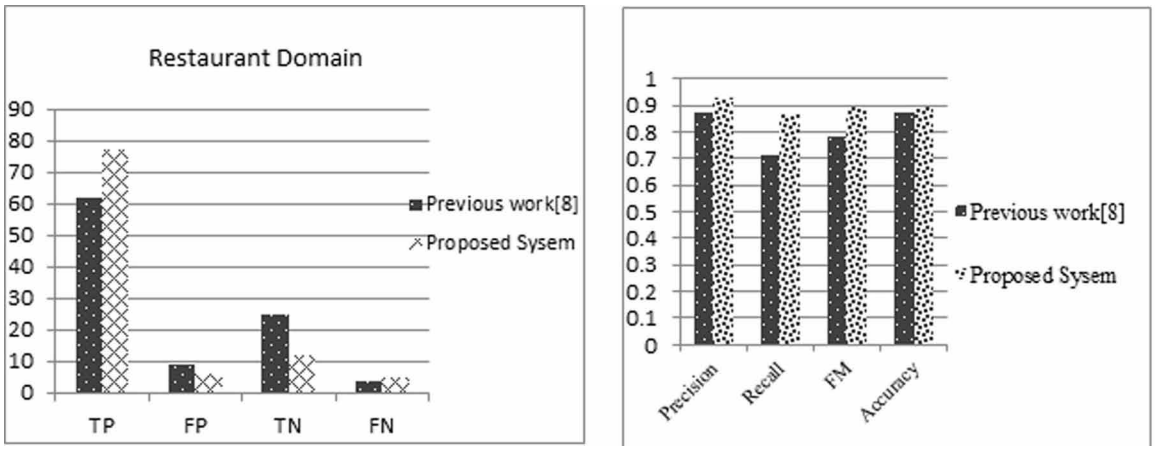
Algorithm	Accuracy
Naïve Bayes	85
Support Vector Machine	85.2
Genetic Algorithm	85.3
Previous work (Nilesh Shelke et al., 2016)	87
Proposed System	89

Table 4. Proposed work compared with (Aishwarya Mohan, 2014)

Methods	Precision	Recall	FM	Accuracy
Naïve Bayes	0.851	0.85	0.85	0.85
KNN	0.866	0.865	0.865	0.865
Previous work (Aishwarya Mohan, 2014)	0.8732	0.7126	0.7847	0.87
Proposed System	0.9277	0.8651	0.8953	0.89

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 8. Graph showing improvement over the previous work done by (Nilesh Shelke et al., 2016)



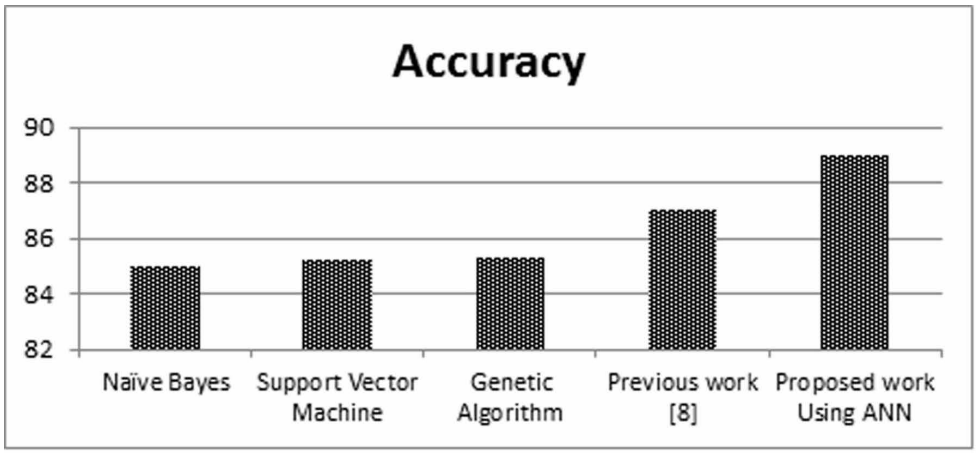


Figure 9. Graph showing Accuracy comparison with (M. Govindarajan, 2014)

Some of the limitation of the proposed system is that it cannot handle the implicit features. For example, 'this camera is very heavy', leads to the weight feature. Also work needs to be done on negative sentences like 'camera is too big'. Moreover, there are limitations in categorizing an opinion in comparative sentences. One has to be dependent on the order of words in comparative sentences to determine the opinion e. g. The review, "Restaurant Taj is better than restaurant Haldiram" depicts completely different opinion from "Restaurant Haldiram is better than restaurant Taj". Concept based methods needs to be incorporated for such types of feature extraction. There are enormous future perspectives to extend the proposed work. Building information retrieval models, designing Human-Computer Interfaces (HCI) affective interfaces, building educational dialog systems, developing expressive text-to-speech synthesis, conducting subjective natural language processing tasks, improving text summarization or machine translation, and including affective semantics for foreign language learning etc. can be possible with exploration of sentiment analysis and emotion extraction.

Chapter 23
Business Applications of Deep Learning

Armando Vieira
Redoctopus, UK

ABSTRACT

Deep Learning (DL) took Artificial Intelligence (AI) by storm and has infiltrated into business at an unprecedented rate. Access to vast amounts of data extensive computational power and a new wave of efficient learning algorithms, helped Artificial Neural Networks to achieve state-of-the-art results in almost all AI challenges. DL is the cornerstone technology behind products for image recognition and video annotation, voice recognition, personal assistants, automated translation and autonomous vehicles. DL works similarly to the brain by extracting high-level, complex abstractions from data in a hierarchical and discriminative or generative way. The implications of DL supported AI in business is tremendous, shaking to the foundations many industries. In this chapter, I present the most significant algorithms and applications, including Natural Language Processing (NLP), image and video processing and finance.

1. INTRODUCTION

Artificial Intelligence (AI) is a relatively new area of research – that started in the 50's – marked by some successes and many failures. The initial enthusiasm originated in the materialization of the first electronic computer, soon fade away with the realization that most problems that the brain do in a blink are in fact very hard to solve by machines. These problems include, locomotion in uncontrolled environments, language translation, or voice and image recognition. Despite many attempts, it also become clear that the traditional approach to solve complex mathematical equations was insufficient to solve the most basic situations that a 2 years old toddler had no difficulty – like understand basic language concepts.

This lead to the so-called long "AI winter", where many researchers simply gave up of creating machines with human level cognitive capabilities – despite some successes in between, like the IBM machine Deep Blue that become the best Chess player in the world, or the application of neural networks for hand writing digits recognition in late 80's.

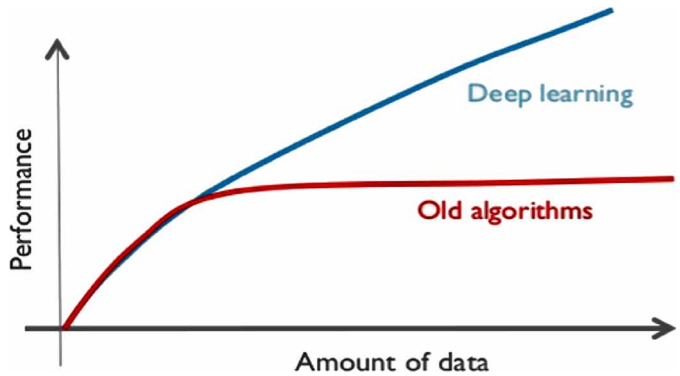
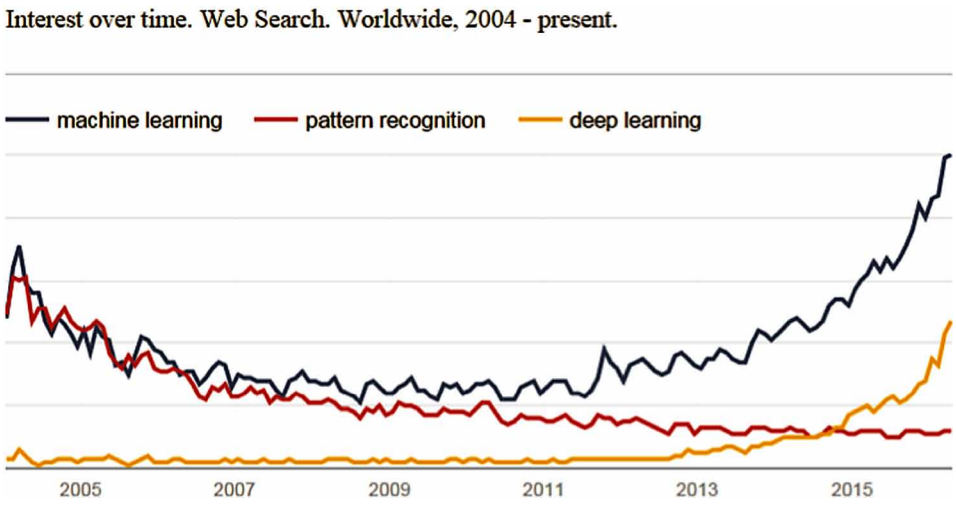
But AI is today one of the most exciting research fields with plenty of practical applications, from autonomous vehicles to drug discovery, robotics, language translation and games. Challenges that seemed insurmountable just a decade ago have been solved – sometimes with super-human accuracy - and are now present in products and ubiquitous applications, like voice recognition, navigation systems, facial emotion detection and even in art creation, like music and painting. For the first time, AI is leaving the research labs materializing in products that may seems to have emerged from Science Fiction movies.



How this revolution became possible in such a short period of time? What changed in recent years that puts us closer to the General AI dream? The answer is more a gradual improvement of algorithms and hardware than a single breakthrough. But certainly on the top of the list is Deep Neural Networks, or commonly referred Deep Learning (DL) (I. Goodfellow 2006).

Artificial Neural Networks is hardly a new field. They were around for about 50 years and got some practical recognition after mid 80's with the introduction of a method (Backpropagation) that allowed training of multiple layers neural networks. However the true birth on Deep Learning may be traced to the year of 2006, when Geoffrey Hinton (R. S. G. E. Hinton 2006) presented an algorithm to efficiently train deep neural networks in an unsupervised way – data without labels. They called them Deep Belief Networks, and consisting of staked Restrictive Boltzmann Machines. They differ from previous networks since they were generative models capable to learn the statistical properties of data being presented without any supervision.

Inspired by the depth structure of the brain, deep learning architectures have revolutionized the approach to data analysis (R. S. G. E. Hinton 2006) (I. Goodfellow 2006) (Schmidhuber 2015, Schmidhuber 2015). Deep Learning networks have won a paramount number of hard machine learning contests, from voice recognition, image classification, Natural Language Processing (NLP) to time-series prediction – sometimes by a large margin. Traditionally AI relied on heavily handcrafted features, for instance, to have decent results in image classification, several pre-processing techniques have to be applied, like filters, edge detection, etc. The beauty of DL is that most, if not all, features can be learned automatically from the data – provide enough (sometimes million) training data examples are available.



Being essentially non-supervised machines, deep neural architectures can be exponentially more efficient than shallow ones. The number of computational elements is only limited by the number of training samples – which can be of the order of billions. Deep models can be trained with hundreds of millions of weights and therefore tend to outperform shallow models such as SVMs. Moreover, theoreti-

Figure 1. DL has a higher capacity to learn from large amounts of data

Source: Google Trends

cal results suggest that deep architectures are fundamental to learn the kind of complex functions that represent high-level abstractions (e.g. vision, language, semantics), characterized by many factors of variation that interact in non-linear ways, making the learning process difficult.

1.1. From a Long Winter to a Blossom Spring

Today it's difficult to find any AI based technology that do not rely on Deep Learning. The implications of DL in technological applications of AI will be so profound that we may be on the verge of the biggest technological revolution of all times.

One of the remarkable features of DL neural networks is their (almost) unlimited capacity to accommodate information from large quantities of data without overfitting – as long as strong regularizers are applied. DL is much of a science as of an Art and, while it's very common to train models with billions of parameters, on millions of training examples, that is only be possible with carefully selection and fine-tuning of the learning machine.

The main characteristics that make DNN unique can be summarized in the following points:

1. High learning capacity (since DNN have millions of parameters, they don't saturate easily - the more data you have the more they learn).
2. No feature engineering required (learning can be performed end-to-end – being robotic control, language translation or image recognition).
3. Abstraction representation (DNN are capable of generating abstract concepts from data).
4. High Generative capability (DNN are much more than simple discriminative machine – they can generate unseen - but plausible - data based on latent representations).
5. Knowledge transfer (this is one of the most remarkable properties – we can teach a machine in one large set of data - images, music or biomedical data – and transfer the learning to a similar problem where less data is known. One of the most remarkable examples is DNN that capture and replicate artistic styles).

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

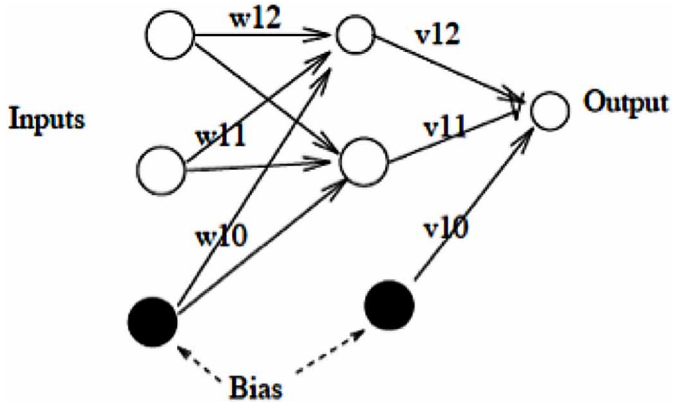
6. Excellent unsupervised capabilities (as long as you have lots of data, DNN can learn hidden statistical representations without any labels required).
7. Multimodal learning (DNN can integrate seamlessly disparate sources of high-dimensional data, like text, images, video and audio to solve hard problems like automatic video captions generation and visual questions and answers).
8. They are relatively easy to compose and embed domain knowledge to handle uncertainty.

The less appealing aspects of DNN models are[1]:

1. They are hard to interpret - despite the ability to extract latent features from the data, DNN are black boxes that learn by associations and co-occurrences. They lack the transparency and interpretability of other methods, like decision trees.
2. They are only partially able to uncover complex causality relations or nested structural relationships, common in domains like biology.
3. They can be relatively complex and time consuming to train, with many hyper parameters that require careful fine-tuning.
4. They are sensitive to initialization and learning rate – its very easy the network to be unstable and not converge. This is particularly acute for recurrent neural networks.
5. A loss function has to be provided - sometimes is very hard to find a good one.
6. Knowledge is not incremental – each dataset has to be trained from scratch.
7. Knowledge transference is possible for certain models, but its specific for each problem.

1.2. Why DL Is Different?

Machine Learning (ML) is a vague but hardly new concept. It can be summarized in one simple sentence: finding patterns in data. These patterns can be anything from cycles in the stock market to distinguish images of cats from dogs. ML can also be described as the art of teaching machines how to make decisions. Yes, an art; perhaps more than a science.



ANNs started with a work by McCullogh and Pitts who showed that sets of simple units (artificial neurons) could perform all possible logic operations - thus capable of universal computation. This work was concomitant to Von Neumann and Turing who first dealt with statistical aspects of the information processing of the brain and how to build a machine capable of reproduce them. Frank Rosembalt invented the Perceptron machine to perform simple pattern classification. However, this new learning machine was incapable of solving simple problems, like the logic XOR. In 1969 Minsky and Papert showed that Perceptrons had intrinsic limitations that could not be transcended, thus leading to a fading enthusiasm for ANNs during the 70's.

1.3. The Multilayer Preceptron

The Multilayer Preceptron (MLP) was proposed to solve problems that were not linearly separable, i.e., categories that cannot be separate by a set of straight lines. An example of a multilayered perceptron MLP is shown in next Figure:

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 3. The multilayer preceptron

The ANN consists of a set of inputs, connected to a set of hidden unities through weights w. The hidden unities are connected to the output through weights v. Initially all the weights and the bias term are set to random numbers. The activity in the network is propagated forwards via weights from the input layer to the hidden layer where some function of the net activation is calculated, normally the transfer functions are sigmoid, *tanh* or, more recently, rectified linear unities (*ReLU*). Then the activity is propagated via more weights to the output neurons.

Two sets of weights must be updated: those between the hidden and output layers and those between the input and hidden layers. The error due to the first set of weights is calculable by Least Mean Square rule. To propagate backwards that part of the error due to the errors in the second set of weights (W) we used the backpropagation algorithm, that simply states that the errors should be proportional to the weight contribution. The algorithm has two main parameters: learning rate and momentum (to avoid traps in local minima). Also the number of unities in the hidden layer is an important input (more hidden unities will increase the computational power but it could also compromise the generalization capabilities).

The choice of the network parameters is normally performed by *n*fold cross validation: fixing *n*-1 parts of the training data for training and the remaining for testing, and then swapping these segments.

The key insight that makes this procedure relatively efficient for feedforward networks is that—simply by applying the chain rule from basic calculus—the derivatives of the error with respect to filter values in a given layer can be efficiently computed from those in the layer just above. Derivative computations thus start at the top layer and then propagate backwards through the network down to the first layers.

Another important technical innovation enabling large-scale backpropagation is stochastic gradient descent (SGD). SGD involves breaking training data into small, randomly chosen batches. Gradient descent is done on each batch in sequence until the training data are exhausted, at which point the procedure can begin again, usually on newly chosen random batches. SGD enables backpropagation on much larger data sets.

2. DEEP NEURAL NETWORKS

So, why all the excitement about AI powered by Deep Learning? As mentioned before, the difference of DL is both quantitative (an improvement of 5% in voice recognition makes all the difference between a useful user interface or a useless one) and qualitative (how DL models are trained, the subtle relations they can extract from high-dimensional data and how these relations can be integrate into an unified perspective).

It was long known that ANN with more hidden layers (deeper) could have a higher computational power and be better suited to solve classification or regression problems (D. E. Rumelhart 1986). The challenge was how to train them, i.e., learn the weights or connections that link a layer of neurons to the others. The backpropagation algorithm worked fine for ANN with a single layer, but it strives to generalize for deeper architectures due to the so called vanish gradient problem – i.e., the correction signal from the output was dissipated as it travels to lower layers.

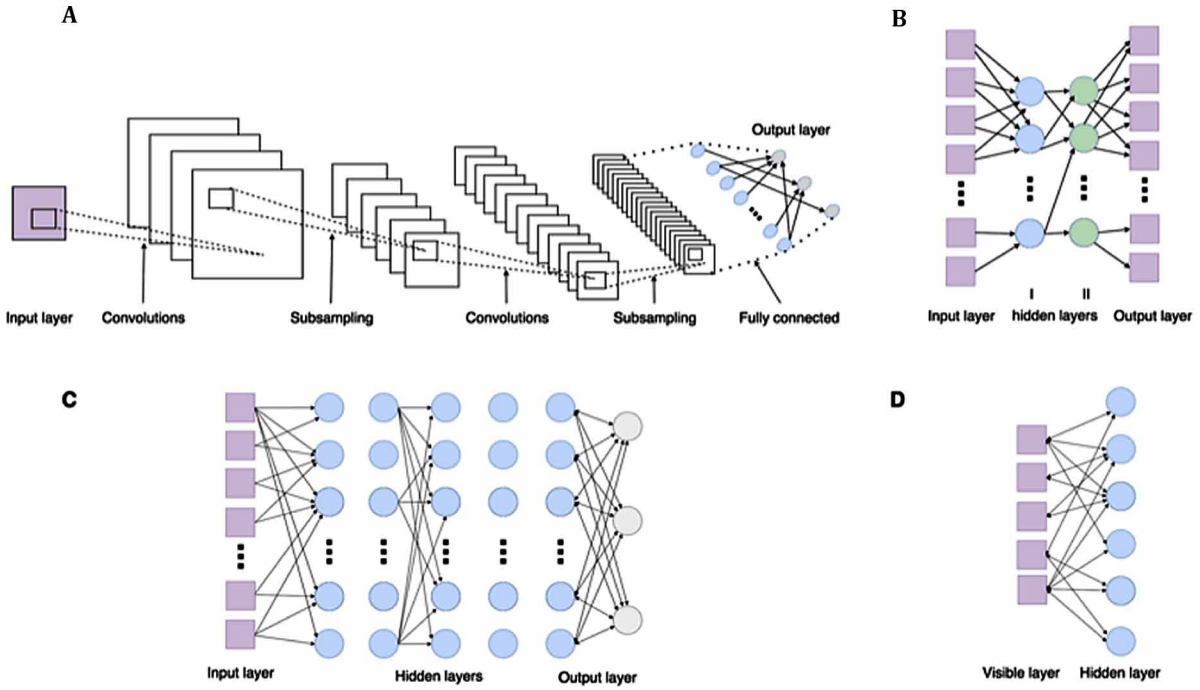
However, in 2006, Hinton et al. proposed an unsupervised learning algorithm using a method called Contrastive Divergence, that was successful in training deep generative models known as Deep Belief Networks (DBN) (R. S. G. E. Hinton 2006). A DBN is composed of a stack of Restricted Boltzmann Machines (RBMs) trained by a greedy, layer-by-layer learning algorithm (contrastive divergence). They are normally used for unsupervised tasks, but that could be fine-tuned to perform supervised learning by attaching a Softmax layer to the top layer.

There are many DL approaches and architectures, but most of the DNNs can be classified into five major categories:

1. Networks for unsupervised learning, designed to capture high-order correlation of data by capturing jointly statistical distributions with the associated classes - when available. Bayes rule can later be used to create a discriminative learning machine.
2. Networks for supervised learning. These networks are designed to provide maximum discriminative power in classification problem are trained only with labeled data - all the outputs should be tagged.
3. Hybrid or semi-supervised networks, where the objective is to classify data using the outputs of a generative (unsupervised) model. Normally, data is used to pre-train the network weights to speed up the learning process prior to the supervision stage.
4. Reinforcement learning - the agent interact and changes the environment and receives feedback only after a set of actions are completed. This type of learning is normally used in the field of robotics and games.
5. Generative Neural Networks - Deep generative models are a powerful approach to unsupervised and semi-supervised learning where the goal is to discover the hidden structure within data without relying on labels. Since they are generative, such models can form a rich imagery the world in which they are used: an imagination that can harnessed to explore variations in data, to reason about the structure and behavior of the world, and ultimately, for decision-making. A great advantage of these models is there is no need to supplement an external loss function as they learn the structure of the data autonomously.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Despite all the hype around deep learning, traditional models still play an important rule in solving machine learning problems, especially when the amount of data is not very large of the input features are relatively "clean". Also, if the number of variables is large compared with the number of training examples, SVMs or ensemble methods, like Random Forest or Extreme Gradient Boosting trees (XGBoost), may be simpler, faster and better options.



The most popular types of DNN architectures are: stacked denoising autoencoders (SdAE), Deep Belief Networks (DBN), Convolutional Neural Networks (CNN) and Recurrent Neural Networks (RNN). Many advances in machine vision were achieved using CNNs - making this DNN type the standard for image processing. However, there are many flavors of DNNs that are applicable to the various business applications, depending on architecture, connectivity, initialization, training method and loss functions being used.

Figure 4 presents a brief summary of these popular DNN architectures. Following is a brief guideline to the terminology and the most popular types of deep neural networks.

2.1. Convolutional Neural Networks (CNN)

A CNN is composed by several blocks composed by different types of layers. Each module consists of a convolutional layer and a pooling layer. These modules are often stacked up with one on top of another, or with a softmax logistic layer on top of it, to form a deep model. The CNN uses several tricks that

Figure 4. Four of the most popular classes of deep learning architectures in biological data analysis: a) convolutional neural network (CNN) has several levels of convolutional and subsampling layers optionally followed by fully connected layers with deep architecture; b) stacked autoencoder consisting of multiple sparse autoencoders; c) deep belief network (DBN); d) restricted Boltzmann machine (RBM) architecture includes one visible layer and one layer of hidden units

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

makes them well suited for image processing like weight sharing, adaptive filters and pooling. Pooling takes subsamples of the convolutional layer to feed the next layer - acting as a powerful regularizer. Weight sharing and pooling schemes (most usually a max pooling), allow the CNN to generate conservation properties like translation invariance. CNNs are highly effective and have been commonly used in computer vision and image recognition.

CNNs operate on what should be considered a signal stream rather than a feature vector. That is, fully connected neural nets consist of activation units bound to all inputs of the feature vector. Every unit has a weight specific to each feature in the input. Convolutional layers, on the other hand, utilize weight sharing by sliding a small (trainable) filter of weights across the input vector (or 2D input map, as CNNs are often used on images) and convolving each overlayed region of input with the filter.

CNNs with max-pooling are powerful enough to mimic low-level stages of primates visual cortex having biologically plausible feature detectors, such as Gabor filters. However, once trained, the CNN acts a simple feedforward machine with frozen weights.

2.2. Deep Autoencoders

An autoencoder is a DNN having as outputs the input data input itself. If they are trained with some added noise, these architectures can act as generative models and are called denoising autoencoders. An autoencoder can be trained with a greedy layer-wise mode, much like the DBNs, to form a deep model.

Autoencoders can be stacked to form a deep network by forwarding the outputs of the autoencoder in the layer below as input to the layer above. The unsupervised pre-training is done a layer at a time and each layer is trained to minimizing the error in reconstructing of its input. After pre-trained, the network can be fine-tuned by adding a softmax layer and applying supervised backpropagation - as if they were multilayer perceptrons.

Stacked denoising AutoEncoders (SdAE) is a stochastic version of AE obtained by adding noise to the input in order to prevent learning of the identity map. They try to encode the input while undo the effect of a corruption capturing the statistical dependencies in the inputs.

Variational AutoEncoders (VAE) are composed by an autoencoder with extra constraints on the encoded representations being learned – it learns a latent stochastic model to generate its input data and a function to approximate sampling from latent variables – thus it's a generative model.

The parameters of the model are trained via two loss functions: a reconstruction loss forcing the decoded samples to match the initial inputs (just like a normal autoencoders), and the KL divergence between the learned latent distribution and the prior distribution, acting as a regularization term. You could actually get rid of this latter term entirely, although it does help in learning well-formed latent spaces and reducing overfitting to the training data. See this tutorial and some examples of code applied to the MNIST dataset on the Keras blog.

2.3. Deep Belief Networks

A Boltzmann Machine formed by two layers - one of visible units and other of hidden units with no lateral connections is called a Restricted Boltzmann Machine (RBM). A Deep Belief Network (DBN) is a probabilistic generative model formed by several stacked hidden layers (normally binary). The top two layers are symmetrically connected through indirect connections. Each layer receives a directed connection from the layer below. DBN are trained by greedy layerwise strategy using the Contrastive

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Divergence (CD) algorithm proposed by Hinton et al. Apart from providing good initialization points for the weights of the network, the DBN also have other interesting properties: 1) we can use all data, even unlabeled datasets; 2) it can be seen as a probabilistic generative model, very useful within the Bayesian framework; and 3) the over-fitting problem, can be effectively alleviated by the pre-training step and other strong regularizers, like dropout.

2.4. Recurrent Neural Networks

Traditional ML methods, like Support vector machines, logistic regression, and feedforward networks, have proved useful without explicitly modeling time in temporal process – by projecting time as space. This assumption, however, is incapable to model long-range dependencies and has limited usability in complex temporal patterns. Recurrent Neutral Networks (RNNs) are a rich family of models differentiable end-to-end, thus amenable to gradient-based training, latter regularized via standard techniques, like dropout or noise injection. Recurrence is key to solve hard problems, like language, as it seems to be present in most of the brain mechanisms.

The first structures of RNN were introduced by Jordan as feedforward networks with a single hidden layer extended with special units. Output node values were fed to the special units, which then feed these values to the hidden nodes at the following time step. If the output values are actions, the special units allow the network to remember actions taken at previous time steps. Additionally, the special units in a Jordan network are self-connected.

RNN are a class of unsupervised or supervised architectures to learn temporal, or sequential, patterns. A RNN can be used to predict the next data point in a sequence using the previous data samples. For instance in text, a sliding window over previous words is used to predict the next word or set of words in the sentence. RNNs are generally trained with Long Short Term Memory (LSTM) algorithm proposed by Schmidhuber (Schmidhuber 2015) or GRU (gated recurrent units). The flip side is that they are difficult to train in capturing long-term dependencies due to the well known gradient vanishing or gradient explosion problems and great care required in optimizing hyper parameters.

RNN have become recently very popular, especially with the introduction of several tricks, like bidirectional learning (forward and backward sequence prediction) and attentive mechanisms that allow the use of dynamic size sliding windows, especially useful to build language models.

2.5. Training DNNs

Almost all DL neural networks are trained evolving the optimizing a loss function, like likelihood maximization. The loss function may assume many forms depending on the problem. The likelihood of a set of parameter values, θ, given outcomes x, is the probability of those observed outcomes given those parameter values, $P(x|\theta)$. For a classification problem, it's typically defined as the log likelihood, given the observations of labels y, we want to generate a model with a probability distribution than maximizes the $\log(P(y|x))$. This is equivalent to minimizing the cross-entropy, a measure of similarity between two distributions P and Q: the sum of the entropy of P and the Kullback–Leibler divergence between Q and P (also known as the relative entropy of Q with respect to P):

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

2.5.1. Initialization, Overfitting, and Regularization

Deep Neural Networks are relatively large and complex machines - models with 100 million or even billions of parameters are not uncommon. Models with a large number of free parameters can describe very complex relations within data but extreme caution should be taken that they are able to generalize properly. Traditional ways to regularize DNN include cross validation, noise addition, L2 regularization and, more recently, dropout, i.e., removal of a randomly subset of connections - a very simple but effective technique.

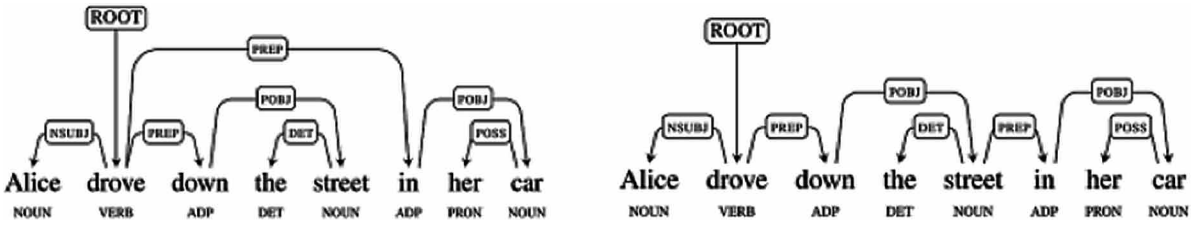
Learning, i.e., adjusting the weights of the neuron connections, is normally performed with backpropagation using Stochastic Gradient Descendent (SGD) in batch mode, with a very small (and decaying) learning rate and a some momentum term. Getting a neural network learning properly is hard. A proper initialization of weights is important to guarantee convergence – normally we should start with a set of small random values in the interval [-1/a, 1/a] where *a* is the number of connections to the neuron.

The learning rate should be small - depending of the network architecture, complexity of the problem and size of the dataset – the higher the lowest the learning rate. A value between 0.01 and 0.001 is normally a safe choice. The number of epochs is typically in the order of thousands and the batch size not less than 100 – again highly dependent of the problem.

2.6. DL as a Service

2015 may well be considered the year of Deep Learning. Remarkable innovations were achieved, like Microsoft neural net of 152 layers (where 6 or 7 layers was the norm) that lead to the winning of the ImageNet competition - with superhuman accuracy.

At the same time all big players are creating their own DL platforms and open sourcing some of their core algorithms – the era of AI-as-a-service. Amazon, IBM, Google, Facebook, Twitter, Baidu, Yahoo, and Microsoft. Google is offering TensorFlow for free. Next table presents a summary of the principal services offered by these companies.



Deep Learning is moving to open source and the Cloud. Google, Facebook, IBM, Amazon and Microsoft are trying to establish ecosystems around AI services provided in the cloud. “This technology will be applied in pretty much every industry out there that has any kind of data—anything from genes to images to language”

Table 1. Main machine learning platforms

Company	Cloud-Based ML Platform	DL Technology (Open Sourced)
Amazon	Amazon Machine Learning	DSSTNE
Baidu	-	Deep Speech 2 PaddlePaddle
Facebook	-	TorchNet, FastText
Google	NEXT Cloud	TensorFlow
IBM	Watson	IBM system
Microsoft	Azur	CNTK
Twitter	-	Cortex

Figure 5. Parsing a sentence: two possibilities

3. APPLICATIONS TO NATURAL LANGUAGE PROCESSING

Deep Learning is having a tremendous impact in Natural Language Processing (NLP). Language understanding is one of the oldest, and probably the hardest problem for machines. However, as large corpus of data become available on the Internet, DL is a natural option to solve innumerous problems related to understanding human language.

Parsing is a central problem for NLP. It consists in decomposing a sentence in its components (nouns, verbs, adverbs, etc.) and built the syntactic relation between them – the parsing tree. It is a very complex problem due the ambiguity in possible decompositions. For instance the sentence "Alice drove down the street in her car" has at least two possible dependency parses:

The first corresponds to the (correct) interpretation where Alice is driving in her car; the second corresponds to the (absurd, but possible) interpretation where the street is located in her car. The way humans disambiguate these options is through "common sense" – they know that streets cannot be located in cars. For machines incorporating this world information is very challenging.

Google launched a recent tool SyntaxNet (code based on Tensorflow available at Github SyntaxNet) to solve the hard parsing problem – a 20 to 30 words sentence can have thousands of syntactic structures (see the blog post on Google research Google parser). They used a globally normalized transition-based neural network model that achieves state-of-the-art part-of speech tagging, dependency parsing and sentence compression. The model is a simple feed-forward neural network that operates on a task-specific transition system, yet achieves comparable or better accuracies than recurrent models. The SyntaxNet English language parser, Parsey McParseface, is considered the best parser surpassing, in some cases, human level accuracy. Recently they expand the service to cover about 40 languages.

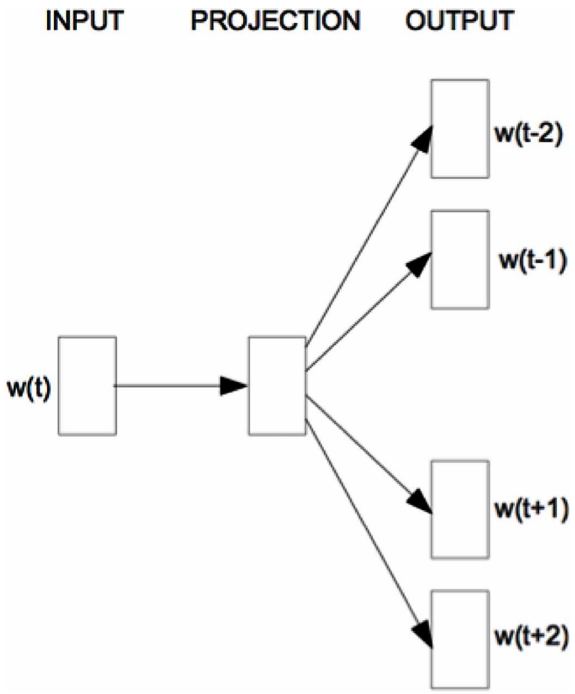
3.1. Distributed Representations

One of the core problems in NLP is related to the high-dimensionality of data, thus a huge search space) and inference of grammatical rules. Hinton (D. E. Rumelhart 1986) was one of the first to propose the idea that words could be represented via distributed (dense) representations. The advantage of distributed representations is that semantics can easily be accessible and knowledge be transferred from different domains - even on different languages.

Learning a distributed (vectorized) representation for each word is called word embedding. Word2vec is the most popular approach to create a distributed representation of words; It's a publicly available library providing an efficient implementation of skip-gram based vector representations for words. The model and implementation is based on the work of Mikolov et al. (Mikolov & Sutskever 2013). In addi-

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

tion to the implementation, the authors also provide vector representations of words and phrases learnt by training this model on Google News Dataset (about 100 billion words). Vectors can be up to 1000-dimensional containing 3 million words and phrases. An interesting feature of these vector representations is that they capture linear regularities in the language. For example the result of the vectorized words equation: "Madrid" - "Spain" + "France" is "Paris".



After the "bag of words" (BOW) - with the TFIDF trick - Word2vec is probably the most used method for NLP problems since it's relatively easy to implement and very useful in understanding (in an unsupervised way) hidden relations in the data. There is a very good and well-documented Python implementation of word2vec, Gensim. It can be used with pre-trained vectors or trained to learn the embeddings from scratch given a large training corpus - normally on the order of million of documents.

Le et al. also proposed a method to encode whole (variable size) paragraphs using a similar technique; they called it Paragraph Vector. The paragraph vector is shared across all contexts generated from the same paragraph but not across paragraphs. Each word vector is shared across paragraphs. Kiros et al. (R. Kiros 2015) introduced the idea of Skip-Though Vectors using unsupervised learning to encode sentences. The model used a RNN to reconstruct the surrounding sentences of an encoded passage.

3.2. Language Translation

Natural Language Translation is a very hard problem that has been defeating a satisfactory solution since the eve of AI in the 50's. Traditional DNNs have some limitations in dealing with this problem, like the requirement that the inputs and targets should be encoded with vectors of fixed dimensionality.

Figure 6. The schematic representation of word2vec algorithm—word W(t) is used to predict context words W(t-2)…W(t+2)—here a context window of K=5 is considered

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

For sequences of arbitrary length this is a serious limitation[2]. Unlike the traditional statistical machine translation, recent DNN models create a single neural network to jointly represent the distributions of both languages and maximize the translation score. Most models use a scheme of encoder–decoders and encode a source sentence into a fixed-length vector from which a decoder generates the respective translation. The most common model consists of RNN with LSTMs unities that process input sequences and compress it into a large, but fixed, dimensional vector. This vector is later used by another LSTM to extract the output sequence. The second LSTM is essentially a recurrent neural network language model except that it is conditioned on the input sequence.

Sutskever et al. (I. Sutskever 2014) used this approach to achieve state-of-the-art performance of the conventional phrase-based machine translation system on an English-to-French translation task - a BLEU score of 34.81, outperforming the best previous neural network NLP systems, and matching the best published results for non-neural network approaches. When their system is used to re-rank candidate translations from another system, it achieved a BLEU score of 36.5. The implementation involved eight GPUS and training took 10 days to complete.

3.3. Voice Recognition

Automatic Speech Recognition (ASR) is the problem of translating voice transcripts into pioneer the application of Deep Bidirectional LSTM to this problem achieving top results in the TIMIT database. Graves et al. applied applied Deep Bidirectional LSTM to this problem achieving top results in the TIMIT database. They used end-to-end designed for discriminative sequence transcription with recurrent neural networks, namely Connectionist Temporal Classification and Sequence Transduction. These methods do not require forced alignments to pre-segment the acoustic data, as they directly optimize the probability of the target sequence conditioned on the input sequence and are able to learn an implicit language model from the acoustic training data.

A Baidu team recently proposed an advanced Automatic Speech Recognition (ASR) system for translating voice into text (Amodei 2015). The improvement performance of the algorithm is due to deep learning replacing feature extraction modules with a single neural model. The Baidu system, called *Deep Speech 2*, consists of a pipeline that approaches the accuracy of humans in several languages. This system was built on end-to-end deep learning using bidirectional RNN trained in clean and noise environments. In English the speech system was trained on 11,940 hours of speech, and in Mandarin for 9,400 hours. Data synthesis was used to augment the data during training. Training a single model at these scales requires tens of exaFLOPs that would require 3-6 weeks to execute on a single GPU. A recent experiment showed that users, using this system on smartphones, input text faster by speaking then typing.

4. APPLICATIONS TO IMAGE AND VIDEO PROCESSING

Probably the area where most advances were made by DL was in image processing. The human visual perceptual system achieves remarkable object recognition performance even in noisy environments or under geometric transformations or background variation. Recent advances in DNN, particularly using Convolutional Neural Networks, lead to a revolution in image processing and analysis achieving, or even surpassing, human level performance. In this section we will show some applications of deep learning into image processing.

Table 2. Performance of deep speech 2 compared with humans

Read Speech			
Test Set	**DS1**	**DS2**	**Human**
WSJ eval '92	4.94	3.60	5.03
WSJ eval '93	6.94	4.98	8.08
LibriSpeech test-clean	7.89	5.33	5.83
LibriSpeech test-other	21.74	13.25	12.69

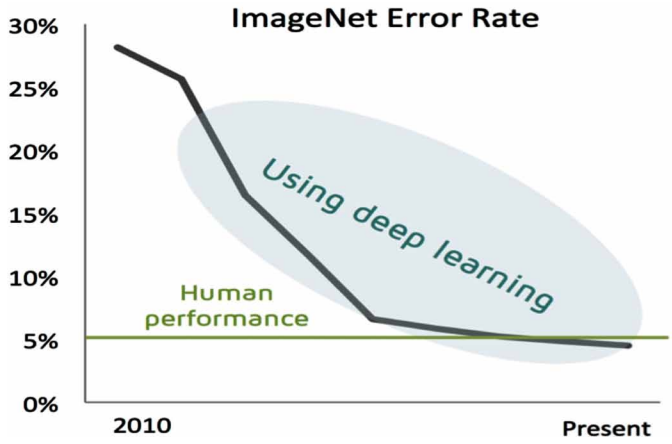
4.1. From ImageNet to Caption Generation

CNNs were one of the first deep learning models - biologically inspired by the mammal visual cortex. In a CNN each unit takes its input from a local receptive field on the layer below forcing it to extract local features. Furthermore units within a plane or feature map are constrained to share a single set of weights, this makes the operations performed by a feature map to be shift invariant. The weight sharing technique also reduces the number of free parameters, thus reducing risk of overfiting. The features of CNNs can be summarized as:

- Convolutional neural network with a sequence of convolution and pooling layers.
- Use convolution to extract spatial invariant features.
- Subsample using spatial average of maps.
- Multilayer neural network (MLP) as a final classifier.
- Sparse connection matrix between layers (weigh sharing) to avoid large computational cost and reduce overfitting.

Complete CNNs are formed by stacking together multiple convolutional layers (each with feature-maps planes and local receptive fields). Sub-sampling layers are also added improving invariance to shift and distortions. During 1990's it become evident that deeper networks perform better. However, larger networks required lots of computational resources and overfit easily since not much data was available.

Krizhevsky et al. (A. Krizhevsky 2012, R. Kiros 2015, Amodei 2015) pioneered the use of a graphical processor units (GPUs) for a fast implementation of a CNN containing 650,000 neurons and 60 million parameters – by contrast LeNet-5 had 60,000 - winning with a top-5 error rate of 15.3% - a far better result than the state of the art technique techniques that reached only 26.2%. Besides using larger data set and bigger networks, these authors used aggressive regularizations techniques to avoid overfitting, like data augmentation (applying slight distortions in shapes, rotations and colours) and dropout to shrink co-adaptions of neurons. This last technique allows a single neuron to learn more robust features without relying on other neighbour neurons.



A trained CNN can be used for classification on the ImageNet data set replacing the final classification layer with a regression network. This regression network is simply an MLP with two hidden layers of 4,096 and 1,024 units, connected finally to the output layer of 4 units which predicts the coordinates of the bounding boxes. The final layer is class-specific having 1,000 versions (one for each class) while the rest of the regression network shares weights. During localization only the regression network's weights are updated, and the remaining larger network only acts as a feature extractor.

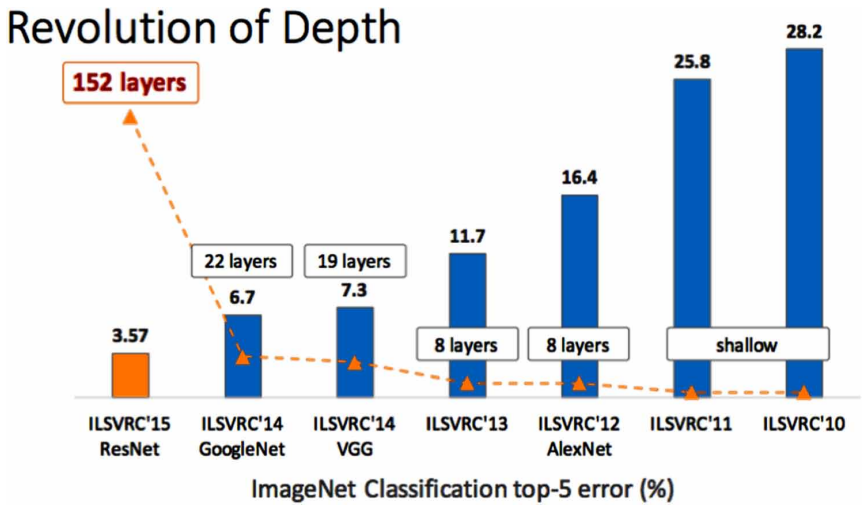
Figure 7. Image captioning with CNN

Figure 8. Performance evolution on ImagNet competition

In 2014, Google introduced Inception5 (Google LeNet), a very deep CNN (with 20 layers) that won the ImageNet contest with an error rate of only 6.7% - this work showed the importance of using very deep models to abstract higher level features from the images.



Recently, a Microsoft team achieved a super-human performance on ImageNet with an error rate of only 3.7% with a network named ResNet (residuals network) (K. He 2015) as well as MS COCO data set – the code is available on github. ResNet is based on a simple idea: feed the output of two successive convolutional layer bypassing the input to the next layers - bypassing a single layer did not give much improvements while two layers can be seen as a classifier itself. They were able to train networks of up to 1000 layers.

4.2. Video and Satellite Images

Donahue et al. investigated a CNN model with RNN and proposing a recurrent convolutional architecture for end-to-end large-scale visual challenging task, like activity recognition, image captioning, and video description. This model departs from fixed visual representations and was able to learn compositional

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 9. Deep residual learning for image recognition (from He, Zhang, Ren, & Sun, 2016)

representations in space and time. The model is a fully differentiable RNN, capable to learn long-term dependencies, and very appealing since it can map variable-length videos to natural language text. The model is fully trained with backpropagation. The authors show that this model can achieve good results for discriminative or generative text generation tasks. They evaluate the model on TACoS multilevel dataset containing 44,762 video/sentence pairs obtaining a BLUE score of 28.8.

In Mamoshina (2016), the authors combined a CNN and a LSTM for jointly learn the embedding of video and text in order to generate automatic annotation of videos. Due to lack of datasets, the authors relied on photo annotation data and used knowledge transfer techniques. They achieved good accuracy in the subject, verb, and object (SVO) metrics but still far from human level – probably due to the lack of training data.

Satellite image classification is a complex problem involving remote sensing, computer vision, and machine learning. The problem is challenging due to the high variability of the data. Basu et al (S. Basu 2015) proposed a method based on Deep Belief Networks and careful preprocessing of satellite image achieving 97.95% accuracy in two public datasets. One dataset consists of 500,000 image patches covering four broad land cover classes: barren land, trees, grassland and other; 400,000 patches were chosen for training and the remaining 100,000 for testing.

Cargometrics is a startup that uses VHF radio tracking as well satellite images processing through deep learning algorithms to analyze maritime traffic data in order to help predict commodity prices – it tracks the movement of 120 000 ships across the world. Their work is being used by hedge funds to identify pricing and securities opportunities.

Terrapattern uses DL to perform similarity based search for unlabeled satellite photos. It provides an open-ended interface for visual query-by-example, the user clicks in a spot on Terrapattern's map and it will find other locations that look similar.

Vicarious developed deep learning algorithms for vision, language, and motor control. They are mainly focused on visual perception problems, like recognition, segmentation, and scene parsing. They claim that their system requires orders of magnitude less training data than traditional machine learning technique in deploying generative probabilistic models.

5. OTHER APPLICATIONS

5.1. Self-Driven Cars

Deep Learning plays a consider role in Self-driving cars technology by analyzing a disparate set of signals, being video the most challenging. Following the recent success of Google driverless car, almost all carmakers are considering this option in future versions of they cars. Some models under test are Toyota Prius, Audi TT, and Lexus RX450h. Tesla S3 will probably be the first production car with self-driving capabilities included by default. All of these models rely on Deep Learning technology for object recognition, planning, routing and object avoidance.

Google has developed its own custom vehicle relying on a 64-beam laser detector that allows the vehicle to generate a detailed 3D map of its environment. The algorithm use these maps and combines them with high-resolution maps of the world, producing a sufficiently detailed model for self-navigation. Google tested their fleet of vehicles over 2 million km – Tesla tested their own vehicles on more than 130 million km.

Nvidia launched a GPU specific for these cars and Baidu plans to start self-driving cars tests on roads in the United States over 2016 - the core technology is based on DL algorithms. Baidu and Google are pushing towards governmental regulation of self-driven cars claiming it only requires minor changes in actual infrastructure. The goal of Baidu is to run a shuttle service in Chinese cities by 2018.

Autonomous driving requires intuitive psychology. The self-driving car needs to have some common sense understanding or inferring pedestrian behavior and beliefs (do they think it is safe to cross the street? Are they paying attention?) as well as desires (where do they want to go? Are they in a rush?). Similarly, other drivers on the road have similarly complex mental states underlying their behavior (do they want to change lanes or ass another car?). This type of psychological reasoning, along with other types of model-based causal and physical reasoning, are likely to be especially valuable in challenging and novel driving circumstances for which there is little relevant training data.

A recent study concluded that self-driving taxis could reduce the traffic in cities as much as 90%.

5.2. Chatbots

Chatbots, also called Conversational Agents or Dialog Systems, are algorithms designed to have human level conversation capabilities. The goal of bots is to achieve a level of natural conversations indistinguishable from humans. There are two types of bots, Retrieval-based, that use a repository of predefined responses and some heuristics to pick an appropriate response based on the input and context and Generative models that generate automatically responses from past experience and context. Most of the latter rely on Deep Learning technology.

Generative models can be quite sophisticated and learn from creating latent representation of data. They are very flexible but require a large corpus of text (training data). Sequence-to-Sequence learning methods like (I. Sutskever 2014) has a great potential, but most production systems are still based on hard rules for dialogue retrieval. Short text conversations are easier to optimize, especially in closed domain knowledge where the space of possible inputs and outputs is somewhat limited to a specific context.

Vinyals et al. used the sequence-to-sequence framework to create a conversational model able to predict the next sentence given previous sentences in a conversation (O. Vinyals 2015). It was designed as an end-to-end model requiring few crafted features. They trained it in a large conversational dataset and it

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

was competent enough to deliver good advice using an IT helpdesk dataset while showing common sense reasoning in a movie conversational dataset. However, the bot fails to be consistent in the conversations.

Generative models are very powerful, but grammatical mistakes can be costly, so companies still rely on old retrieval technologies. However, as companies get more data, generative models will become the norm - but probably with some human supervision to prevent them from "inappropriate behavior", like happened to the Microsoft Twitter chatbot, Tay

Most big companies are using, testing or considering the implementation of chatbots in their services and operations. Using its experience with its personal assistant Cortana, Microsoft has recently opened a development framework for Chatbots implementation and also released Luis.ai an API for language understanding. Facebook has launched M, a chatbot for its message service and acquired Wit.ai, a company that works on voice recognition technology. IBM has also available a very simple API to embed its powerful knowledge inference machine, Watson, into a conversational bot. Most of these services can be easily incorporated in conversational services like Twitter, Whatsapp, Skype, WeChat, Telegraf or Slack. For instance, Slack allow simple or complex conversation automating based on hard or soft rules.

Retail banks and FinTech start-ups are now exploring the use of Chatbots for digital experiences for checking bank account balances, finding nearby ATMs, making payments and even advising how to spend your money more wisely. Tractica predicts US$ 40.6bn will be spent on artificial intelligence systems for enterprises from 2015 to 2014. Zendesk launched a chatbot to automate answers to customer queries, after other competitors, like Slack, start automate some conversations. Deep learning for chatbots on Wildml, offfers an excellent tutorial on how to build bots from scratch using Ubuntu forum data.

In a recent post (Hybrid Intelligence) Clarie Corthell stated that: "humans will always be part of the system. So we shouldn't focus on how to replace humans in a system, rather how to optimally integrating the contributions of humans and computers." I partially agree: humans will definetly have to be in the loop for the next years, but as technology evolves we have to change.

5.3. Art

Perhaps the most extraordinary achievements of DL were obtained in an unsuspicious area: art. Gatys et al. applied Convolutional Neural Networks to obtain a representation of the style of an artist (input image) using the feature space originally designed to capture texture information. By including the feature correlations of multiple layers, they obtain a stationary, multi-scale representation of the input image. They proved that the representations of content and style in the Convolutional Neural Network are separable. Both representations can be independently manipulated to produce new, perceptually meaningful images. To demonstrate this finding, they generate images that mix the content and style representation from two different source images – see Figure 10 (see a demo online on Ostagram).

A Swedish company, Peltarian, released a neural network that can perform sophisticated computer generated choreography by extracting high-level features from raw sensor data. The system, called chor-rnn, uses Recurrent Neural Networks for generating novel choreographic material in the nuanced choreographic language and style of an individual choreographer. It also can create higher-level compositional cohesion, rather than just generating sequences of movement. The neural network is trained on raw motion capture data and that can generate new dance sequences for a solo dancer.

In literature, Hitoshi Matsubara, used a DL based algorithm to generate a short story that was shortlisted, among 10 others, from more than 1000 human written pieces.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 10. Artificial generated images using CNNs trained on two sets of images

In music, Google Brain's creative AI launched a project Magenta dedicated to the creation of music and art through machine learning. They released the first music track - which show the potential ANN to generate creative music.

5.4. Biomedical

In the era of Big Data, modern biology and medicine are confronted with a massive scale of data that requires novel computational tools for analysis and translation of the results. Success of the analysis depends on the ability to interpret such complex and biased data.

5.4.1. Biomarkers and Genomics

One of the main directions of biomedicine is the transition from biological data to valid biomarkers that reflect phenotype and physical state of the body. Biomarkers are critical in measuring clinical trials outcomes, detecting diseases, and monitoring disease states, particularly for diseases as heterogeneous as cancer (see Mamoshina, 2016, for a review).

Exponential growth in modern genomics technology, particularly with the introduction of Next Generation Sequencing (NGS), allows production of a massive amount of genomics data by reducing cost and time consumption of sequencing. Analysis of sequencing data implies analysis of the function and structure of genome. All of this could be performed *in silico* using modern computational approaches.

Analysis of transcriptomics includes analysis of various types of transcripts (mRNA, IncRNA, miRNA, etc.) that carry various types of functional information, from splicing code to biomarkers of various diseases. Transcriptomics data are often obtained from different types of platforms (various microarray platforms, sequencing platforms) that differ by the gene set measured and method of signal detection. Cross-platform analysis requires normalization techniques, which can be a major challenge[22]. DNNs are particularly well-suited for cross-platform analysis with their generalization ability and as such have great potential to benefit transcriptomics data analysis.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Some startups working on these areas are:

- Stratified medical.
- Atomwise.
- Quantitative Medicine.
- Insillico medicine.
- Deep Genomics.

5.4.2. Healthcare

Deep Learning in already having a strong impact in healthcare industry due to: i) increase capacity and accuracy of learning algorithms and ii) wide availability of large sets of healthcare data – made possible through the digitalization of (structured and unstructured) medical records, as well as personal genetic data and other personalized data originated from mobile devices.

Having achieved human level performance on object identification or facial recognition, DANN have a great potential in processing medical imaging, an area where subjectivity interpretation is common and contextualization is key to disambiguate several possible explanations.

DL is being applied to images—which remains its primary application today. Some companies—like Enlitic—are applying DL to recognize cancer in medical images, like X-rays and many automated image recognition tools are already used in hospitals. Diagnoses based on processing of medical images is, however, just a tiny fraction of the potential of DL in medical sector.

Some startups have emerged to apply deep learning to medical imaging such as BayLabs, Imagia, MD.ai, AvalonAI, Behold.ai or Kheiron Medica. iCarbonX has a near term goal of predicting the onset of diseases from genomic, medical and lifestyle data.

DL was also extensively used for model and understanding complex biomedical processes like protein interactions, RNA decoding.

6. CONCLUSION AND FUTURE DIRECTIONS

We are experiencing a revolution in Artificial Intelligence. This fast-moving wave of technology innovations powered by AI is impacting business and society in such a velocity that is hard to predict its implications. One thing is sure: cognitive computing powered by AI will be able to perform most tasks and empower humans even in creative tasks. AI will impact jobs that had seemed impossible to automate a few years ago, from doctors to legal clerks.

By 2020, the market for machine learning applications will reach $40 billion, IDC, a market research firm, estimates - 60 percent of those applications, the firm predicts, will run on the platform software of four companies (Amazon, Google, IBM and Microsoft) most of it relying on Artificial Intelligence.

Probably the most immediate impact of GAI supported by DNN will not be in self-driving cars or robotics but in customer service. Services like sending a specific email, a mobile push, or a customer pass for a specific shop or event; predictive analytics to help support decisions and call centers. Contact centers deal with very mundane interactions that soon will be serviced through automated messaging like chat bots and personal assistants. AI can help suggest how to deliver a conversation; user interests and product. It can even use the data for secondary proposes, like risk assessment based on previous interactions.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

6.1. Research

From the point of view of technology, I would like to highlight three key research areas I found the most promising:

- Deep Generative Adversarial Neural Networks (GANs).
- Recurrent Neural Networks.
- Multimodal learning models.

GANs are a powerful approach to explore unsupervised and semi-supervised learning where the goal is to discover the hidden structure within data without relying on external labels. One of the most interesting models is Generative Adversial Networks (GANs) where a generative networks is trying to confuse a discriminative one in distinguish real data from faked (generated) one (Alexey Kurakin 2016)14]. The Deep generative models have widespread applications including probability density estimation, image denoising and inpainting, data compression, scene understanding, representation learning, 3D scene construction, semi-supervised classification, and hierarchical control.

New methods to train Recurrent Neural Networks and Multimodal Learning (learning from different data types – video, image, voice, text) are presently very active areas of research and very promising in solving problems related with control and object manipulation, image and video caption and text processing.

6.2. Risks

DL is a powering this tremendous transformative AI technology. A study by Carl Benedikt Frey and Michael Osborne, published in 2013, found that 47% of jobs in America were at risk of being replaced in a near term. More recently Bank of America Merrill Lynch predicted that by 2025 the "annual creative disruption impact" from AI could amount to $14 trillion, including a $9 trillion reduction in employment costs thanks to AI-enabled automation of knowledge work; The McKinsey Global Institute says AI is contributing to a transformation of society "happening ten times faster and at 300 times the scale, or roughly 3,000 times the impact" of the Industrial Revolution.

6.3. Startups

In 2015 only 1% of software have AI capabilities. In 2020 that number will be 50%. DL thus represents a huge opportunity for Startups and investors. In a recent review by The Economist, Nathan Benaich stated that "In 2015 a record $8.5 billion was spent on AI companies, nearly four times as much as in 2010, according to Quid, a data-analysis company. The number of investment rounds in AI companies in 2015 was 16% up on the year before, when for the technology sector as a whole it declined by 3%."

Accel, a venture capital firm headquartered in Palo Alto, announced a $500 million fund for early stage companies and $1.5billion fund for late stage businesses. Of their nine areas of focus for the future, Artificial Intelligence topped the list of priorities. New Enterprise Associates, also a worldwide venture capital firm, is the second top investor in Artificial Intelligence. The firm has invested in WellTok's CafeWell.com website which combines social networking technology with knowledge of healthcare, making recommendations based on health goals allowing users to take control of their wellbeing.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Most AI based venture capital deals were in deep learning/machine learning. Naveen Rao, founder and Chief Executive of Nervana Systems explains, "the method allows computers to process tasks through 'neural networks', systems that mimic the structure of the human brain in order to learn, improve and, in the case of AlphaGo, become capable of decision-making that resembles human intuition more than it does brute computation."

Chapter 24
Agreement Technologies for Conflict Resolution

ABSTRACT

Recently, artificial intelligence, has emerged as a new source of scientific works in conflict resolution. The interest in conflict resolution lies in diverse reasons. One of the main reasons is that computational systems have gradually shifted towards a distributed paradigm where heterogeneous entities should include computational conflict resolution mechanisms, such as proposed by agreement technologies. This chapter gives an overview of these technologies, which are needed in order to ensure the accomplishment of the global system goal and to solve conflicts. Among agreement technologies, automated negotiation is proposed as one key mechanism in conflict resolution due to its analogous use in human conflict resolution. Automated negotiation consists of an automated exchange of proposals carried out by software agents on behalf of their users. Another key technology is argumentation, which provides a fruitful means of dealing with conflicts and knowledge inconsistencies. Agents can reach agreements by engaging in argumentation dialogues with their opponents in a discussion.

INTRODUCTION

Agreement Technologies (AT) is a new discipline, which covers a range of specific techniques for dealing with interactions in dynamic, open environments (Ossowsky, 2013; Sierra, Botti & Ossowski, 2011). They address issues such as finding ways to negotiate, agree and cooperate with other agents, and developing appropriate means of forming and managing coalitions. These aspects are extremely related with the concept of conflict resolution. Conflict is an omnipresent phenomenon in human society, which is related with the necessity to achieve an agreement between entities. Conflict spans from individual

decision making trade-offs such as deciding what to do next (sleep, eat, work, play), to complex scenarios including politics and business. Over the last decades, computer science has tried to study conflict from a computational perspective. Conflict is a ubiquitous phenomenon and arises in many areas of our lives. It arises and needs to be dealt with in social settings, such as a group of friends deciding on a vacation or contract negotiation in business and politics (Browder, 2000), as well as in individual settings related to action selection (e.g., how to weigh one's preferences and decide what product to buy). Even if we are not aware of it, we are continuously facing conflict and attempting to solve it.

Different proposals based on agreement technologies have been developed with conflict resolution as their main research goal. For instance, automated negotiation approaches have been proposed as set of algorithms and protocols whose mission is providing effective deals in electronic marketplaces (Jennings et al, 2001; Parsons, Rodriguez-Aguilar & Klein, 2011; Sanchez-Anguix, Julian, Botti, & García-Fornes, 2013). Researchers in argumentation aim to solve conflicts by means of dialogue games, speech particles and information rebuttal (Rahwan et al, 2003). Works in cooperation and coordination try to give a joint solution to a problem, usually with no global information or control (Rebollo, Carrascosa, & Palomares, 2014). Reputation is another way to solve conflicts when an entity must to decide about other entities (Pinyol, Sabater-Mir, 2013). Finally, agent organizations, inspired by the metaphor of human organizations, allow achieving global goals (and solve conflicts) by using norms, plans and structures formally specified (Argente et al 2011; Hübner, Sichman & Boissier).

This chapter explores in detail several works done in the area of agreement technologies, which can be used as a way to engage new conflict resolution approach along with new challenges to face by these technologies. During the chapter we discuss different types of agreement and agreement processes related to conflict resolution, describing and relating the different technologies and application areas involved. First, the different related technologies are briefly introduced. After this, a detailed analysis of negotiation and argumentation technologies is introduced in the following sections.

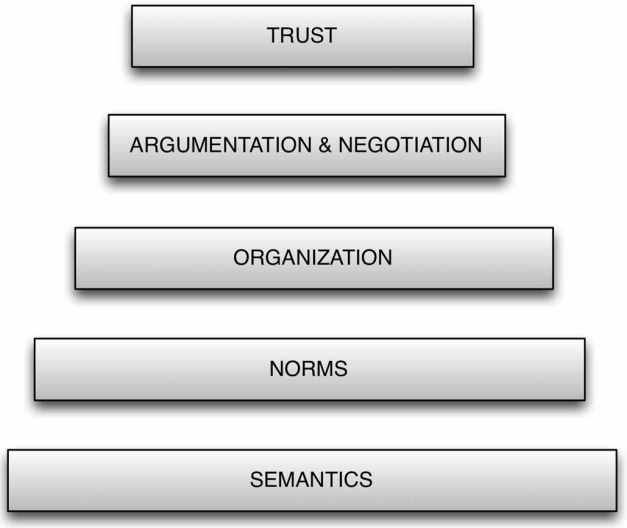
AGREEMENT TECHNOLOGIES

Open multi-agent systems are distributed systems where heterogeneous agents, with their own goals, can enter and leave the system during the life of the system (Hewitt, 1991). For instance, we can think of an electronic commerce platform as an open system where users, human or even automated software, act according to their own interests: in the case of sellers to maximize their own profits, and in the case of buyers to acquire some goods at relatively good price. Since agents have different goals, act based on their goals, and they can be heterogeneous (i.e., humans and software agents may show different behaviors), it is feasible to find situations where an agent's goals conflict with other agents' goals. If we refer ourselves to the example of electronic commerce, the buyer may want to buy the product at a low price, while the seller may want to maximize its revenue. In these situations, mechanisms that allow agents to coordinate, regulate their behavior, and solve conflicts are needed.

Electronic commerce is not the only application where conflict may make act of presence. For instance, in the last few years, grid computing (Foster, Kesselman & Tuecke, 2001) has emerged as a new paradigm of computation where different entities collaborate to accomplish several tasks. In grid computing, entities share several resources: from hardware resources (e.g., computing nodes) to software resources (e.g., services). How should those resources be distributed among the different tasks or users of the system? Presumably, users want the best response time for their tasks, and resource owners want

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

to take the highest profit of their resources. Resource allocation is a delicate matter, especially when collaboration requires cross-boundary relationships. Software mechanisms that solve conflict in these scenarios are needed.



Even purely cooperative applications like rescue applications (Kitano & Tadokoro, 2001) are not alien to conflict. In multi-robot systems for rescue applications, information is usually distributed among the different robotic agents. Coordination among these entities is a problem itself, which becomes more acute when agents' opinions and information conflict. How should these entities solve conflict and rescue as many persons as possible while making an efficient use of the computational resources? Again, software tools and mechanisms are necessary to tackle with conflicts.

The concept of Agreement Technologies (Luck & McBurney, 2008; Ossowsky, 2013; Sierra et al 2011) has been coined in the last few years as an umbrella term for addressing all of those technologies that are envisioned to collaborate, directly or indirectly, to the resolution of conflicts in software systems, and specifically in MAS systems. Even though which works can be considered agreement technologies are arguable (since the contribution to the resolution of a conflict may be indirect), some authors distinguish between several challenges that need to be solved in the so-called agreement technologies.

In this chapter, we position ourselves with the taxonomy/challenges introduced by Sierra et al (2011). Despite the fact that negotiation and argumentation will be the focus of this chapter, we think that it is important to briefly describe every technology involved in agreement technologies. Next, we briefly describe each of the challenges mentioned by Sierra et al. (see Figure 1): (i) Semantics: The current trend of service-oriented computing (Papazoglou & Georgakopoulos, 2003) has changed the way in which complex systems are built. Nowadays, software is built by using diverse services offered by very different providers. Given the heterogeneity of service providers, it is logic to think that service information is provided in different communication languages, and even using different terms to address the same concept (i.e., different ontologies). Whenever a software system needs to cooperate or solve a conflictive situation with other systems, it requires of mechanisms that allow understanding other software systems by matching and aligning ontologies and semantic concepts (Noy, 2004) (Choi, Song & Han, 2006); (ii) Norms: Most distributed applications are no longer static but open, and agents can exhibit a varied spectrum of behaviors. One possible way of "solving" conflict is avoiding conflict, establishing mechanisms that preclude agents of reaching a conflictive situation. Normative systems (Boella, Van Der Torre & Verhagen, 2006; Criado, Argente, & Botti, 2013) are envisioned with such purpose (among others). The society of agents is regulated by norms, which define which actions/states are to be punished in the system (e.g., to avoid conflict) and which actions/states are to be rewarded (e.g., promote actions that avoid conflict); (iii) Organizations: Agents usually have limited computational capabilities. Therefore, if a complex problem needs to be solved, agents need to join together as a group and coordinate to reach such complex goal. Agent organizations (Argente et al, 2011; Esparcia & Argente, 2011; Horling & Lesser, 2008) may be seen as large and implicit coordination mechanisms that establish the roles to be played by agents and the interaction protocols to be carried out among organizational members. In this sense, agent organizations may conflict by strictly defining the structure and interactions of the group; (iv) Trust: Trust mechanisms (Sabater & Sierra, 2005; Such, Espinosa, Garcia-Fornes & Botti, 2011), usually used in concordance with reputation models, are devised to help agents to select whom they should interact with. Trust is formed from one's own past experiences with other agents. To put it simply, positive experiences should bias one agent to collaborate and interact with the other party, whereas negative experiences should bias one agent to avoid interactions with the other party. Reputation is built according to the opinion that agent societies have on individuals. Trust and reputation mechanisms may

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. Agreement technologies architecture

help to reduce conflict by interacting with good partners; and, finally, (v) Negotiation & Argumentation, which can be considered the main components, from the point of view of conflict resolution. For this reason, these two topics will be explained in detail in the following sections.

NEGOTIATION

Negotiation is the main technology of agreement technologies that makes possible for agents to solve conflicts. In this case, imitating how humans solve conflicts, agents negotiate looking for an agreement that is acceptable for all of the involved entities. It would not be possible for agents to solve conflict without this technology, at least not in an efficient way. Despite negotiation being crucial for solving conflicts, it should be highlighted that it requires of other technologies as semantics, norms, organizations, and trust to help in the resolution of conflicts. Semantics may help heterogeneous agents to form a negotiation domain (e.g., negotiation problem) that is understandable by all of the parties involved in the conflict situation. Then, society's norms may be used to formally force agents to respect established agreements. Otherwise, agents would violate agreements whenever it suits them. Organizations establish a framework where roles and possible interaction protocols are formalized, giving room negotiations with clear rules of interaction (e.g., negotiation protocols), and helping agents to identify and search conflicting agents based on the information provided by roles (e.g., sellers and buyers are classical roles in conflict). Trust and reputation may guide agents to select negotiation opponents that are more likely to guarantee a good service. Hence, every technology in agreement technologies collaborates along negotiation in leading conflict situations towards good terms. Despite being part of a new topic like agreement technologies, automated negotiation has been studied by scholars for a few years.

Negotiation can be defined as a process in which two or more parties make a joint decision. The parties first verbalize contradictory demands and then move towards agreement by a process of concession-making or search for new alternatives (Pruitt, 1981). Analogously, automated negotiation consists of an automated

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

search process for an agreement between two or more software parties. Two different research lines can be distinguished in automated negotiation models: game-theoretic models and heuristic models. Since the decade of the 50's, automated negotiation has been studied in game theory. Game theory researchers focus on reaching optimal solutions under assumptions of unbounded computational resources, complete/partial information regarding the strategies and preferences of other parties. Some of the most important theoretical results come from game theory, like the work of Nash (1950), Rubinstein (1982), Binmore et al (1986), and more recent studies like Fatima et al. (2004) and In and Serrano (2003). Although game theory studies are interesting from a theoretical point of view, most of them make strong assumptions that may not hold in real applications. For instance, computational resources are of extreme importance for agents since they may be scarce and shared among different tasks. Thus, negotiation should not always assume un-bounded computational resources. Additionally, since agents are heterogeneous, not all of the agents know the same strategies. Identifying which strategies each agent knows may be a hard task that can only be successful after several negotiations. The same goes for the knowledge regarding the opponents' preferences, reservations values, and so forth. Hence, models that tackle uncertainty and limit the use of computational resources are mandatory for some situations.

Heuristic models tackle the problem mentioned above. They do not calculate the optimum agreement, but they obtain results that aim to be as close as possible to the optimum. Heuristic models assume imperfect knowledge regarding the opponent and the environment, and aim to be computationally tractable while obtaining good results. The reader is assumed to have some working knowledge on heuristic models for automated negotiation. In other case, the reading of several introductory texts and reviews like (Guttman, Moukas & Maes, 1998; Beam, Segev, 1997; Kraus, 1997; Jennings et al, 2001; Lomuscio, Wooldridge & Jennings, 2003; Lopes, Wooldridge & Novais, 2008) is recommended. The amount of literature in automated negotiation is vast and immense, ranging from bilateral negotiations, to multi-party negotiations. An extensive review of all of the problems in automated negotiation would be an almost non-feasible task. Following, we discuss some of the most important works in the area of automated negotiation and bilateral negotiation.

Concession Strategies

The classic view of artificial intelligence with respect to negotiation in incomplete information settings is that agents need to eventually concede in order to reach an agreement (Faratin, Sierra, & Jennings, 1998; Bui, Venkatesh, & Kieronska, 1999; Hindriks & Tykhonov, 2008). However, agents can concede in very different magnitudes and in different rounds of the negotiation. Concession strategies determine how the agents concede and when these concessions are carried out.

The most influential work regarding concession strategies is, perhaps, the work of Faratin et al. (1998). The authors proposed concession strategies that are a mix of different families of concession tactics. The authors divide concession tactics into three different families:

- **Time-Dependent Tactics:** These tactics take into account the remaining time in the negotiation to carry out concessions. In this family, we can distinguish between linear tactics, boulware tactics, and conceder tactics. On the one hand, linear tactics carry out the same amount concession at each negotiation round until the reservation value is reached. On the other hand, conceder tactics con-

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

ceder very rapidly towards the reservation value in the first interactions, whereas boulware tactics concede very slowly during the first negotiation rounds, but it concedes faster as the negotiation process approaches the deadline.

- **Behavior-Dependent Tactics:** In the case of behavior-dependent tactics, the concession carried out by the agent depends on the negotiation movements performed by the opponent in the previous rounds. The classic tactic in this family is tit-for-tat, which mimics the concession carried out by the opponent in the previous round. Other variants of tit-for-tat include random absolute tit-for-tat, which performs the absolute concession carried out by the opponent in the last offer plus/minus a small deviation, and averaged tit-for-tat which takes the window of past opponent offers and carries out the average concession carried out by the opponent.
- **Resource-Dependent Tactics:** This family of tactics computes concession based on the scarceness of a resource in the environment and resource consumption (i.e., time, product quantity, messages, etc.). In general, the scarcer the resource, the more eager should be the agent to maintain/obtain such resource.

Another classic concession based model for bilateral multi-issue negotiations is the Agent Based Market Place (ABMP) framework proposed in (Jonker, Robu & Treur, 2007; Jonker & Treur, 2001). ABMP is a negotiation framework, based on additive utility functions, where proposed bids are concessions to previous bids. The amount of concession is regulated by the concession factor (i.e., reservation utility), the negotiation speed, the acceptable utility gap (the maximal difference between the target utility and the utility of an offer that is acceptable), and the impatience factor, which governs the probability of the agent leaving the negotiation process. Additionally, the framework includes other remarkable characteristics such as the possibility of sharing preference information with the other party, and guessing heuristics that allows agents to determine the ranking of issues and issue values based on the bid history.

Similarity Mechanisms in Negotiation

One of the traditional mechanisms proposed in the literature for solving conflicts is the use of similarity mechanisms. They can be used to solve a current conflict based on solutions given to previous conflicts or as mechanisms that implicitly approximate offers to opponents' preferences. Basically, the two similarity mechanisms more widely used are Case Based Reasoning (Leake, 1994;(Lopez de Mantaras, 2001) and similarity heuristics (Faratin, Sierra & Jennings, 2002; Lai, Sycara & Li, 2008).

Sycara proposed a mediator that uses case based reasoning for solving conflicts in the labor domain (i.e., PERSUADER) (Sycara, 1989, 1990, 1991). PERSUADER takes as input a set of conflicting goals and outputs an agreed plan of actions. The system keeps track of the agreements found in past negotiations and, once a new conflict situation is present, it looks for the most similar past situation. The retrieved agreement is adapted to the present conflict situation, since the rationale behind this heuristic is that similar conflict situations should yield similar solutions.

Another popular use of similarity mechanisms is implicitly approximating one's own proposals to the preferences of the opponent. This is usually carried out by means of similarity heuristics that look for trade-offs. A trade-off consists in decrementing the benefit obtained from some negotiations issues that are not important for us but are important of the other agent, in order to get the decremented benefit as an equivalent increase in the benefit obtained by other issues that are important for us but are not important for the other agent. Faratin et al. (2002) introduced the use of similarity heuristics in

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

bilateral multi-issue negotiations to compute similarity between pairs of others. Given a certain utility u demanded by one of the agents, this agent proposes the offer with utility u that is the most similar to the previous offer proposed by the opponent. The idea behind this heuristic is that the more similar the offer is to the previous opponent offer, the more acceptable it is for the opponent. For computing the similarity between two offers, a fuzzy similarity criterion between issue values. The main drawback of fuzzy similarity heuristics is that they require domain knowledge regarding the similarity between issue values for the opponent.

The use of similarity heuristics was reintroduced again by Lai et al (2008). In this work, a bilateral negotiation protocol for multi-issue negotiations, where agents are capable of sending up to k different offers per round, is presented. The k offers sent by agents are selected from the iso-utility curve, which contains all of the offers with a certain utility. The offer that is selected is the one that is the most similar to the previous opponent offer that reported the most utility. The other k-1 offers are selected randomly from the iso-utility curve. In this case, the similarity heuristic employed is the Euclidean distance. As a similarity measure, Euclidean distance may be less powerful than fuzzy similarity, but it has the advantage of being more general and not requiring domain knowledge.

Bayesian Learning in Negotiation

When reviewing the use of Bayesian learning in negotiation, we cannot forget about the seminal work of Zeng and Sycara (1998). In this article, authors argue about the benefits of using Bayesian models in negotiation. They study a bilateral negotiation case where the buyer attempts to learn the reservation price of a seller by updating its beliefs with Bayesian learning. Despite the fact that it introduces the use of Bayesian learning in negotiation, the applicability of the article is limited since it only focuses on single issue models.

Bayesian classifiers have been used to model the preferences of negotiating agents. In Bui et al. (1999), the authors propose a multi-party cooperative negotiation mechanism for the distributed meeting scheduling domain. Agents start from an initial set of possible agreements and jointly look for good collective agreements by partitioning the set of possible agreements in a tree until a set with only one agreement (leaf node) that is acceptable by all of the agents is found. From the joint set of possible agreements, each agent proposes a partition of such set where the final agreement will be looked for. Agents decide on which set should be explored from all of the partitions that have been proposed. If all of the agents agree on the partition to be selected, the partition becomes the new joint set of possible agreements and the refinement process continues. Otherwise, agents exchange preferences on the proposed partitions and the partition that maximizes the preferences of the group is selected as the next joint set of agreements. In order to save messages exchanged, the agents employ Bayesian classifiers to learn the preferences of other agents according to the information gathered from the cur- rent and past negotiations. Intervals of utility are used as classes and partitions represent attributes of the Bayesian model.

Genetic Algorithms in Negotiation

Genetic Algorithms (GAs) (Goldberg, 1989) have also contributed to the state-of-art in automated negotiation. They are general optimization and learning algorithms based on the evolutionary processes found in the nature. Candidate solutions for a problem form the genetic population of the algorithm, which gradually converges towards high quality solutions by applying genetic operators like mutation

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

and crossover. GAs are general, which means that they do not rely on a specific problem structure. Additionally, they can be used as an implicit learning and adaptation mechanism in environments where dynamics and structure is also uncertain. This is perhaps what makes GA an adequate approach to negotiation problems, since they can be used to learn and adapt both to the opponent and the environment.

The seminal work of GA's in Automated Negotiation is Oliver et al. (1996). They focused on evolving negotiation strategies for bilateral multi-issue negotiations where agents' preferences are represented by means of additive utility functions. In the proposed negotiation framework, a negotiation strategy is a set sequential rules (i.e., rules that are applied in sequential order according to the round), where a rule is a utility threshold that determines if an offer from the opponent is acceptable and a counter-offer to be made to the other party in case that the opponent's offer is not acceptable. Faratin et al. (1998) introduced a negotiation framework for bilateral negotiations where agents' concession strategies can be classified into time-dependent strategies, behavior-dependent strategies and resource-dependent strategies. Matos et al. (1998) proposed a framework where the concession to be carried out in each negotiation issue is a linear combination of the concession of the families of concessions strategies proposed by Faratin. The main research goal of Matos et al. (1998) is determining which the optimal negotiation strategies in different negotiation environments are. For this purpose, an evolutionary process is proposed where the weights given to the concession strategies for each negotiation issue represent a candidate solution in a genetic algorithm. Populations of sellers and buyers with different negotiation strategies negotiate in a round robin way. After each round robin round, negotiation strategies are assigned a fitness value which takes into account the utility obtained in the negotiations and the numbers of messages exchanged. The highest fitness negotiation strategies for sellers and buyers become the parents of the next population of negotiation strategies, which is obtained by the application of genetic operators like mutation and crossover. Eventually, the population of negotiation strategies for sellers and buyers converges towards an optimal set of strategies for the environment under study. The advantage of this proposal with respect to Oliver (1996) is that the evolutionary process does not depend on the number of negotiation rounds but on the number of negotiation issues, which results in a more tractable search space.

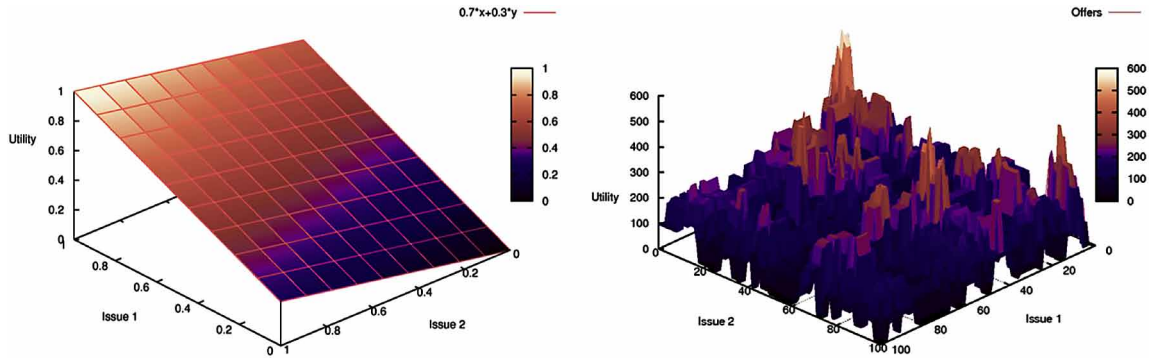
Offline Learning in Negotiation

By offline learning we refer to a learning process that is carried out after or before the negotiation process starts. Hence, the model is not updated during the negotiation and it requires of several iterations of the negotiation game to learn an educated model. From the works that we have already reviewed, we can highlight some works like Buffett and Spencer (2007) where the learning of the Bayesian classifiers is carried out before the negotiation starts. However, there are also other approaches that have advocated for the use of learning before or after the negotiation process.

For instance, Coehoorn and Jennings (2004) propose the use of kernel density (Sheather & Jones, 1991) for the estimation of the weights of the opponent's additive utility function. The negotiation model revolves around the idea that a rational agent gradually con- cedes towards its reservation utility, and a rational agent should concede less on the most important issues at the start of the negotiation and concede more on the least important issues. Given this assumption, the agent calculates for each pair of consecutive offers the concession carried out in each issue, and an educated guess of the weight based on such concession. Each tuple, composed of the difference between pairs of consecutive offers, the estimated weight, and the probability density of the weight, forms a three dimensional kernel that is used along the other kernels to calculate an estimation of the real issue weight.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Another set of approaches that heavily rely on offline learning are those approaches based on Artificial Neural Networks (Carbonneau, Kersten & Vahidov, 2008; Carbonneau, Kersten & Vahidov, 2011). In Carbonneau et al. (2008), authors propose a neural network that takes as input the negotiation history of a bilateral negotiation with continuous issues and an offer to make an estimation of the opponent's counter-offer. The major drawback of this approach is that it requires that an artificial neural network is trained per negotiation case. Similarly, the same authors propose an improvement over their previous work in (Carbonneau, Kersten & Vahidov, 2011). It aims to make a predictive model that does not depend on the negotiation case. The model takes pairs of negotiation issues as inputs of the neural network, where one of the issues is considered the primary issue (i.e., independent variable) and the other issue is considered the secondary issue (i.e., dependent variable). The neural network may also take historical information from each issue like the minimum value, maximum value, average value, etc.



Complex Interdependent Utility Functions

Negotiation processes normally consist in the exchange of proposal between the involved parties. One of the key issues in negotiation strategies is the way in which the agents' preferences are represented. This issue strongly affects how proposals are evaluated and how offers should be generated. In processes where just a single issue is involved, it is quite clear how to evaluate and generate proposals: the value of the issue. However, it is not easy to give a valuation when multiple issues are involved. The multi-attribute utility theory (Wallenius, 2008; Keeney & Raiffa, 1993) comes into play in this case. This theory provides mechanisms for the evaluation of proposals composed of multiple issues. Classic multi-attribute theory has considered that issues are independent. Issue independence means that the value of negotiation issues does not affect the valuation of other issues. Hence, a classic way of representing such preferences is by means of linear additive utility functions. Despite the fact that linear additive functions perform well in some simple domains, there are scenarios where they become poorly suited (Klein, Faratin, Sayama & Bar-Yam, 2003). Just as an example, we could think of a water market domain where two parties negotiate over the exploitation of several water resources. One of the parties' desires to satisfy its water needs whereas the other party has rights over several water exploitations. In this negotiation, the different issues are the water exploitations to be included in the deal. Even though the provider offers a proposal whose amount of water may satisfy the buyer, the value of the proposal may turn into a low utility for the buyer if the water sources are too distant. Thus, some issues have a negative effect over the value of others, and preferences can no longer be represented as classic linear additive utility functions. There is a need to provide complex utility functions that are capable of representing interdependences between negotiation issues.

Negotiation strategies that perform well in domains with linear utility functions may not perform equally in the case of complex interdependent utility functions. In fact, the search space for each agent is much more complicated, needing new negotiation strategies adapted to these complex functions. Figure 2 shows an illustrative example of the search space in the case of linear utility functions and complex interdependent utility functions. The left figure shows the search space of a two issues linear utility function, whereas the right figure shows the search space of a two issues complex interdependent utility function using the model introduced by Ito et al. (2008), which will be reviewed later. As it can be observed, the optimization problem faced by each agent is more complex in the case of interdependent utility functions, leading to the need of new mechanisms that tackle these domains.

Figure 2. An example of linear (left) and complex (right) utility functions

In this section we have review some important works related with automated negotiation, and more specifically in bilateral negotiation. We have analyzed the adequateness of the different models proposed in the literature for conflict resolution, and we identify those mechanisms that may prove more interesting for solving conflicts. Next section introduces argumentation as a complementary technology to achieve success in negotiation processes among intelligent entities.

ARGUMENTATION

The high dynamism of MAS requires agents to have a way of harmonizing the conflicts that come out when they have to collaborate or coordinate their activities. In those situations, agents need a mechanism to argue (persuade other agents to accept their points of view, negotiating the terms of a contract, etc.) and reach agreements. Argumentation provides a fruitful means of dealing with conflicts and knowledge inconsistencies in MAS. Within the history of research done in argumentation in Artificial Intelligence (AI), there have been a wide variety of mutual contributions. The argumentation theory has produced important benefits on many AI research areas, from its first uses as an alternative to formal logic for reasoning with incomplete and uncertain information to its more recent applications in Multi-Agent Systems (MAS) (Bench-Capon & Dunne, 2007; Rahwan & Simari, 2009). Currently, the study of argumentation in this area has gained a growing interest. The reason behind is that having argumentation skills increases the agents' autonomy and provides them with a mechanism to engage in dialogues and to solve conflicts with other agents demonstrating an intelligent behavior.

An autonomous agent should be able to act and reason as an individual entity on the basis of its mental state (beliefs, desires, intentions, goals, etc.). As a member of a MAS, an agent interacts with other agents whose goals could come into conflict with those of the agent. Moreover, if dynamic and open MAS are considered, the knowledge that an agent has about the environment, its neighbors and its mental state can change in the course of time. In addition, agents can have a social context that imposes dependency relations between them and preference orders among a set of potential values to promote/demote. Therefore, agents must have the ability of reaching agreements that harmonize their mental states and that solve their conflicts with other agents by taking into account their social context and

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

values. Argumentation is a natural way of reaching agreements between several parties with opposing positions about a particular issue. The argumentation techniques, hence, can be used to facilitate the agents' autonomous reasoning and to specify interaction protocols between them (Rahwan, 2006).

Argumentation and Artificial Intelligence

From the beginning of AI research, the development of knowledge-bases, reasoning methods and cognitive architectures able to reply human reasoning has been a core area of interest. The work done in such area is typically known as common sense reasoning research. A reasoning method of this kind must include the following features: (i) the ability to reason with knowledge that is assumed to be true or false in the absence of any evidence that shows the opposite, which is called default reasoning; (ii) the ability to manage uncertain knowledge; (iii) the ability to reason quickly over a wide range of domains; and (iv) the ability to reason and take decisions in presence of incomplete knowledge and subsequently, to revise the beliefs and decisions that were taken when concrete knowledge is acquired, which is called non-monotonic reasoning.

Initially, argumentation theory was adopted in AI due to the inability of the classic propositional logic to reason and give explanations in presence of uncertain or imprecise information (Reiter, 1980). The main problem with classical logic is its monotonic condition, which implies that the acquisition of new information cannot modify the conclusions that were inferred to that moment and thus, it is not applicable as common sense reasoning method. This problem already appeared in rule-based expert systems, where several rules could conflict or even be invalidated by the acquisition of new information. The process of drawing conclusions by using rules that can be defeated by new information is called defeasible reasoning. When defeasible rules are linked up to reach to a conclusion, the proofs that support such rules turn into arguments. The arguments can defeat each other, given rise to an argumentation process. To determine the winning arguments, they must be compared by establishing which beliefs are justified. Therefore, argumentation theory has been studied in AI to deal with the process of argument searching and more concretely (Bench-Capon & Dunne, 2007): (i) to distinguish between valid and invalid arguments; (ii) to identify the protocols and rules that manage the argumentation processes; (iii) to define the argument components and their interaction; and (iv) to determine the conditions under which further discussion becomes redundant.

There are several works that provide an extensive review of the argumentation research that has been done in AI throughout history. According to (Bench-Capon & Dunne, 2007) and (Rahwan & Simari, 2009), the foundations of argumentation in AI lie in the studies done to extend non-classical logic to manage argumentation, the argumentation models that are based on dialogue processes and the diagrammatic treatments of the argument structure. We refer the reader to this important work for further details. Nowadays, the argumentation research in AI is experiencing a new reactivation, mainly motivated by recent and interesting contributions developed in MAS. On the one hand, the argumentation theory has been studied in MAS to manage the agent's practical reasoning. Practical reasoning is a well-known area in philosophy, but which historically has received less attention in AI than the theoretical reasoning. This type of reasoning analyses which specific action should be performed in a particular situation, instead of the theoretical reasoning objective of deciding the truthfulness of beliefs. Moreover, practical reasoning does not presuppose, as theoretical reasoning does, that the fact of reaching an objective is always adequate or profitable, but it must select the best objectives to perform and decide afterwards whether their realization is worthwhile. This fits the reality of a MAS, where each individual agent has its own

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

point of view and its particular objectives and interests. However, the theoretical reasoning about the state of the world and the effects of the potential actions to perform is also essential. Therefore, both types of reasoning must be considered in MAS. In (Rahwan & Amgoud, 2006), an argumentation-based approach for practical reasoning has been proposed. In this work, Dung's abstract argumentation framework (Dung, 1995) is instantiated to generate consistent desires and plans to achieve them. Dung's framework is defined as a pair <A, R> where A is a set of arguments and $R \subseteq A \times A$ is a binary attack relation on A. The works developed by Atkinson in her thesis and her subsequent research are also other important contributions to the modelling of argumentation processes that allow the agents to reason about what is the best action to execute (Atkinson, 2005).

Argumentation in MAS

Moreover, the argumentation techniques have been applied to manage the agents' autonomous reasoning and the interaction between them (Rahwan, 2006). In open MAS, the introduction of new information may give rise to new arguments that reinforce or weaken certain beliefs. Therefore, the argumentation techniques can be used as a way of revising the agents' beliefs in presence of incomplete or uncertain information. The work proposed in (Capobianco, Chesñevar & Simari, 2005) applies argumentation to keep the consistency of the agents' mental state in changing environments by using an appropriate representation of the environment and a mechanism that integrates the new information in the beliefs update process. Argumentation has also been applied in MAS as a selection means between conflicting desires (Amgoud, 2003) and objectives (Amgoud & Kaci, 2004), as a qualitative means of reasoning about the expected value of the realization of certain actions (Fox & Parsons, 1998) and as generator of plans (Hulstijn & van der Torre, 2004) (Simari, Garcia & Capobianco, 2004).

Argumentation provides MAS with a framework that assures a rational communication. The dialogue typology of Walton and Krabbe (Walton & Krabbe, 1995) has been adopted in MAS to classify the different types of dialogues between the agents depending on the objective of the interaction. Other concepts of the argumentation theory (i.e. dialogue games (Hamblin, 1970) and argumentation schemes (Walton, 1996) have also been applied to structure the dialogue between agents with different points of view according to the interaction rules that have been previously agreed. A wide range of approaches that formalize interaction protocols by using different dialogue games have been published (McBurney & Parsons, 2002).

Some examples of dialogue game protocols about specific types of dialogues are: inquiry, persuasion, negotiation and deliberation. As pointed out before, argumentation schemes have several characteristics that make them very useful in defining the communication between agents. In the case of Walton's argumentation schemes, the critical questions are arguments that can be presented by an opponent to criticize the claim that the scheme poses, thus providing the argument with a clear structure that reduces the computational cost of generating and evaluating arguments. Reed & Walton (2005) propose a formal framework to specify argumentation schemes for agent's communication by using the markup language AML, based on XML. Also, the work presented in Atkinson and Bench-Capon (2007) provides firm foundations for an approach to practical reasoning based on presumptive argument.

Among current research on argumentation in MAS, to study the effect of argumentation strategies in the interaction between agents is also a recent trend. Here, there are different approaches to the study of strategies in argumentation frameworks. On the one hand, preliminary works studied the concept of strategy as developing heuristics for move selection in argumentation dialogues. A first contribution was

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

provided in Bench-Capon (1998). In this work the author defines a Toulmin dialogue game machine and proposes some heuristics for move selection. The acceptability of the arguments is computed by using some Toulmin-like rules. A similar work is the one presented in Amgoud and Maudet (2002), which proposes heuristics for move selection on the context of persuasion and negotiation dialogues. This research defends a three-level approach of strategy, inspired on naturally occurring dialogues between humans. The levels identified are: maintaining the focus of the dispute, building one's point of view or destroying the opponent's one, and selecting the method to fulfil the objective set at levels 1 and 2.

While levels 1 and 2 refer to strategy (planning the line of argumentation), level 3 refers to tactic (the mean to reach the aims fixed at the strategically level). Then, the account for strategy proposed follows three steps to develop strategies: (i) define some agent profile: agreeable (accept whenever possible), disagreeable (only accept when there is no reason not to), open-minded (only challenge when necessary), argumentative (challenge whenever possible), or elephant child (question whenever possible); (ii) choose to build or destroy; and (iii) choose some appropriate argumentative content.

This work computes argument acceptability by using a more general Dung-like argumentation framework. In a subsequent work, the author studied the notion of strategy for selecting offers during a negotiation dialogue (Amgoud & Kaci, 2005), proposing different agent's profiles and different criteria for the notions of acceptability and satisfiability of offers. Also, in (Amgoud & Hameurlain, 2006) it is argued that there is no consensus on the definition of a strategy and on the parameters necessary for its definition. Consequently, there are no methodology and no formal models for strategies. This work defends that a strategy is a two steps decision process: (i) to select the type of act to utter at a given step of a dialogue, and (ii) to select the content, which will accompany the act. Thus, an agent tries to choose among different alternatives the best option, which according to its beliefs will satisfy at least its most important goals. There are two types of goals: strategic goals, which help an agent, on the basis of the strategic beliefs, to select the type of act to utter; and functional goals, which help an agent to select, on the basis of the basic beliefs, the content of a move. Then, the work proposes a formal model for defining strategies. The model takes as input the strategic and the functional goals together with the strategic and basic beliefs and returns the next move (act plus its content) to play. Then, the model assesses each alternative by constructing the set of supporting arguments for each one and evaluating their quality.

The agent profiles of Amgoud and Maudet (2002) were also considered in Kakas, Maudet & Moraitis (2005) to develop different types of strategies. This work proposes an argument-based framework for representing communication theories of agents that can take into account the conformance to society protocols, private tactics of individual agents, strategies that reflect different types of personal attitudes (agents' profiles) and adaptability to the particular external circumstances at the time when the communication takes place. Although the authors do not provide a clear structure and definition for their notion of agent society, social relations between agents are captured in the form of preference rules that affect the tactic component of an agent and help it to decide the next move in a dialogue.

On the other hand, a different approach follows a game-theoretic view to the study of argumentation strategies. This is the case of the work proposed in Roth & Rotolo (2007), where the probability of a conclusion is calculated using a standard variant of defeasible logic, in combination with standard probability calculus. In this approach the exchange of arguments is analyzed with game-theoretic tools, yielding a prescriptive account of the actual course of play. Other game-theoretic approach for the study or argumentation strategies in negotiation dialogues was presented in Rahwan & Larson (2009). This approach uses the paradigm of Argumentation Mechanism Design (ArgMD) for designing and analyzing

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

argument evaluation criteria among self-interested agents using game-theoretic techniques. Mechanism design (MD) is a sub-field of game theory concerned with determining the game rules that guarantee a desirable social outcome when each self-interested agent selects the best strategy for itself.

The approach analyses strategy-proofness under grounded semantics for a specific type of arguments, the so-called focal arguments (the arguments that agents are especially interested in being accepted). In a preliminary work (Rahwan & Larson, 2008), the authors restricted the analysis to the case where agents use a specific type of preference criteria, the individual acceptability maximizing preference criteria. Following these criteria, every agent attempts to maximize the number of its arguments that are accepted. In further research the ArgMD approach has been applied to more realistic situations in which each agent has a single focal argument it wishes to have accepted. Authors demonstrate for both preference criteria that if each agent's type (characterized as the set of argument that an agent can bring up) corresponds to a conflict-free set of arguments which does not include (in)direct defeats, the grounded direct argumentation mechanism for this argumentation framework is strategy-proof. Opposite to the heuristic-based approaches, the goal of this game-theoretic approach is to design rules that ensure, under precise conditions, that agents have no incentive to manipulate the outcome of the game by hiding arguments or lying (how to ensure the truth in an argumentation framework).

Within this section it has been shown how argumentation techniques have been successfully used to reach agreements and solve conflicts that assure the coherence of the agents' mental state and to structure their interaction in disagreement situations. Parsons et al. (1998) proposed a seminal theoretical framework that unifies argumentation-based reasoning and communication for negotiation in MAS. After that, Rahwan et al. (2003) analyzed this and other argumentation-based negotiation frameworks. A wide review of the situation of the argumentation research in AI was also published in the special issue on argumentation of the journal Artificial Intelligence (Bench-Capon & Dunne, 2007) and in the book Rahwan & Simari (2009). Moreover, an effort to consolidate the work done in argumentation languages and protocols, argument visualization and editing tools and, generally, in argumentation frameworks for MAS, was performed by the ASPIC project. As a result, a new standard for argument interchange in MAS, the Argument Interchange Format (AIF), was proposed to serve as a convergence point for theoretical and practical work in this area (Willmott, 2006). All these advances show how the study of argumentation in AI, and more concretely in MAS, is currently a research area that has a high activity and a growing interest.

CONCLUSION

In this chapter, we have reviewed the state-of-the-art in automated negotiation from the point of view of Agreement Technologies. A special emphasis was put to analyze which current negotiation models are more convenient for conflict resolution. The analysis allowed us to identify that from the point of view of negotiation, the use of time-based concession tactics, the use of complex and interdependent utility functions for representing agents' preferences, and the use of similarity heuristics and genetic algorithms as learning mechanisms may be of interest in order to achieve more efficient automated conflict resolution tools.

Moreover, this chapter has also introduced several concepts and works of argumentation technology that have been applied to model the reasoning and behavior of agents in MAS. Argumentation technology has been proved as a powerful tool for solving conflicts in the context of a society in a MAS. Neverthe-

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

less, the application of argumentation to agent societies is a new area or research with few contributions to date. Commonly, the term agent society is used in the argumentation and AI literature as a synonym for an agent organization or a group of agents that play specific roles, follow some interaction patterns and collaborate to reach global objectives. Many works in argumentation in MAS that refer to the term 'agent societies' follow this approach, which is not targeted to the study of the structure of agent societies and the underlying social dependencies between agents. The influence of the agent group and the social dependencies between agents in the way agents can argue must be further investigated.

KEY TERMS AND DEFINITIONS

Agreement Technologies: All of those technologies that are envisioned to collaborate, directly or indirectly, to the resolution of conflicts in software systems, and specifically in MAS systems.

Argumentation: A verbal, social, and rational activity aimed at convincing a reasonable critic of the acceptability of a standpoint by putting forward a constellation of propositions justifying or refuting the proposition expressed in the standpoint.

Negotiation: Process in which a joint decision is made by two or more parties.

Open Multi-Agent System: A distributed system where heterogeneous agents, with their own goals, can enter and leave the system during the life of the system.

Reputation: What a society says about a target (probably an entity) regarding his behavior.

Trust: An expectation about an uncertain behavior.

Virtual Organization: A set of individuals and institutions that need to coordinate resources and services across institutional boundaries.

Chapter 25
Virtual Soar-Agent Implementations:
Examples, Issues, and Speculations

Jeremy Owen Turner
Simon Fraser University, Canada

ABSTRACT

This chapter provides a brief overview of those virtual agent implementations directly inspired by the cognitive architecture: Soar. This chapter will take a qualitative approach to discussing examples of virtual Soar-agents. Finally, this chapter will speculate on the future of Soar virtual characters. The goals of this chapter are sixfold. The first goal is to explain why cognitive architectures are becoming increasingly important to virtual agent design(s). The second goal is to convey why this chapter focuses exclusively on virtual agents that utilize the Soar architecture. The third goal is to explore some of Soar's technical details. The fourth goal is to showcase a few diverse examples where Soar is beginning to have a design impact on virtual agents. The fifth goal addresses Soar's limitations – when applied to agent design in virtual environments. The final goal speculates on ways Soar can be expanded for virtual agent design(s) in the future.

INTRODUCTION

Cognitive architectures have been around for decades.[1] Many of the more canonical architectures such as CLARION (CLARION webpage, n.d.) and Soar (Soar webpage, n.d.) have been continually updated over the years for agent implementation by external developers, academics and hobbyists. However, most virtual agents (e.g. bots, Non-player-characters [NPCs]) created up to the present day, still do not directly utilize cognitive architectures for interaction with the agent's embodied environment. Instead, such agents often depend on cognition-less systems that may include the use of: finite-state machines, subsumption-level (i.e. reactive) algorithms (Brooks, 1991), hierarchical search interaction trees, heuristic search, and brute-force techniques, or some combination thereof. In recent years, computing power has exponentially increased and this has allowed for a serious reconsideration of cognitive architecture

implementations. This new technological climate is beginning to encourage tractable innovations in artificial general intelligence (AGI) generally, and experimentation with cognitive architectures in particular. Academics and developers are increasingly interfacing cognitive architectures with virtual agents for more deliberation and cognitive potential in their interaction design.

This chapter provides an opportunity to qualitatively discuss and tally some of the state-of-the-art of those virtual agents that employ a particular canonical cognitive architecture, Soar (State Operator And Result)[2] (invented by Laird, Newell & Rosenbloom, ca. 1983). There are numerous cognitive architectures existing today (e.g. ACT-R, CLARION, RASCALS etc.) but due to size and other limitations explained below, Soar will be the focus of this chapter.

The thematic goals of this chapter are sixfold. The first goal is to explain what a cognitive architecture is and why they are becoming increasingly important to virtual agent design(s). The second goal is to convey why this particular chapter focuses exclusively on virtual agents that utilize the Soar architecture. The third goal is to explore some technical details that are uniquely characteristic of Soar's handling of cognition. The fourth goal is to showcase - via a few diverse examples - the continued legacy and design impact Soar is beginning to have on virtual agents. The fifth goal is to address Soar's limitations – when applied to NPC/bot design in virtual environments. The final goal is to speculate on additional ways Soar can be expanded for virtual agent design in the near future.

CAVEAT: VIRTUAL AGENTS MIGHT NOT EVEN REQUIRE COGNITIVE ARCHITECTURES

Design motivations behind whether or not to deploy a cognitive architecture often varies according to whether the virtual agent is meant to academically evaluate embodied and/or extended cognition or instead, to implement a virtual character (NPC) for social and/or ludic entertainment purposes. With these contextual contingencies in mind, most contemporary virtual agents are not required to be cognizant of the visual inputs beyond the raw numerical data underlying each object and path. Basically, a virtual agent can successfully interact and navigate its environment without being directly aware of it in any introspective way. An agent can react to numbers alone. For example, a bit-mapped image or any other virtual object can be represented simply as a stream of numeric representations (e.g. binary digits). These numbers provide the agent with coordinates, proximity-relations, and other manually coded identification data that allow the agent to respond in a completely reactive way. In many video-games, for example, an NPC can appear to be intelligent simply by mindlessly reacting to the changes in numerical inputs afforded by the dynamic changes occurring via game-play interaction. However, cognitive architectural enhancement might be useful for any agent-based cognitive task involving reasoning and mnemonic assistance. Otherwise, a cognitive architecture may only be useful in this numerically-reduced case if we wish to imbue the agent with the ability to contemplate its environment as an "[...] idealized version of the underlying reality" (Best et al., 2006, p. 186). This underlying numerical reality might be modeled to enable embodied, extended, situated, and distributed (EESD) cognition so that virtual agents can actively "[...] structure or manipulate their environments" to "simplify, sequence, or otherwise, support cognitive processes" (Smart & Sycara, 2015, p. 3837).

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

The Need for Integrating Cognitive Architectures with Virtual Agents

Most virtual agents to date – whether embodied in video-games, interaction simulators or social virtual worlds - are not enabled with any cognitive architectures or algorithms modeling deeper cognitive processes. Cognitive representation of some kind is crucial if designers and developers wish to create artificially intelligent agents capable of some manner of introspective thought and deliberation – before executing an action. Due to the simplicity of construction and the current cost of available computational resources, behavioral regulation comes instead in the form of finite-state machines, and/or purely reactive systems where a particular input immediately corresponds to an (observable) output. Some designers see the behavioral affordances of finite-state machine-driven characters as "brittle" (Best et al., 2006, p. 190). Further, as the number of states (and state-transitions) increase in more behaviorally realistic games, the more states the programmers have to manually account for. Further, each of these states would require the programmer to account for an increasing number of pre-programmed responses while entering, transitioning to, or experiencing these additional states. At worst, "[...] human players often learn to game the finite state machine and take advantage of the idiosyncrasies of the opponents" (Best et al., 2006, p. 190). If virtual agents are one day intended to be perceived by gamers and other interacting avatars as "believable characters", then it seems that one should expect an increasing integration in the near-term of cognitive architectures as well as cognition-inspired algorithms and models in a virtual agent's deliberative and behavioral design.

COGNITIVE ARCHITECTURES

A cognitive architecture is semantically distinct from any other system or algorithmic structure that parses and models representations of cognition. To qualify this distinction, one must first clarify those categories that are not considered to be cognitive architectures. Firstly, an agent imbued with cognitive potential might utilize a cognitive architecture as one of many possible modular components for deliberation and (inter)action. However, the agent itself, is not architectural. Cognitive architectures are ontologically distinct from cognitive agents in that they resemble computer architectures. Like computer architectures, cognitive architectures specialize in parsing: "memories, processing and control components, representations of data, and input/output devices" (Laird, 2012, p. 5-6). A cognitive agent using any cognitive architecture ideally involves Artificial General Intelligence (AGI) not for computation's sake, but only for "[symbolic] representation, acquisition, and use of knowledge to pursue goals." (Laird et al., 2012, p. 6). Secondly, a cognitive model resembles a cognitive architecture however, "[...] a number of task-specific cognitive models can be developed that all draw on the same underlying (cognitive) mechanisms [which would comprise an architecture]" (Smart et al., 2014a, p. 3). A cognitive (infra)architecture can summarize a "common set of underlying mechanisms" to unify and explain "[...] a number of otherwise disparate behaviors" (Smart et al., 2014a, p.3).

A cognitive architecture is fundamentally, more general-purpose in that it can be applied towards a host of different agents and multi-agent systems. An agent uses a portion of an architectures' "fixed and task independent" (Smart et al., 2014a, p. 6) attributes. These attributes are customarily identified as: memories, natural-language patterns, data-structures and algorithms. These attributes learn and encode specific knowledge configurations, problem-specifications, rational deliberations, and actions for goal-directed intelligent performance in a stochastic environment (e.g. virtual world) (Smart et al., 2014a,

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

p. 8). Cognitive architects usually understand that their cognitive architecture cannot be so general purpose as to handle every possible contingency and action. Due to the stochastic nature of an external environment,cogntive agents are assumed to "exist in an environment and [...] pursue tasks similar to those we find in the world we inhabit". Therefore, cognitive agents – regardless of architectural type - must be custom tailored to handling situations unique to their task domain (Smart et al., 2014a, p. 28). Some cognitive architectures assert their cognitive influence on a single agent by focusing on introspection and metareasoning capabilities. To clarify, metareasoning is the "process of [recursively] reasoning about [its own] reasoning cycle" (Cox & Raja, 2011, p. 4).The strong AI community traditionally employs a robust cognitive architecture (e.g. Soar) to model an agent's reasoning or metareasoning capabilities in the form of a "decision cycle within an action-perception loop […] (Cox & Raja, 2011, p. 4).

Why Discuss Soar and Not Other Cognitive Architectures?

Other than Soar, there are a few canonical cognitive architectures that can be (and are being used) for tractable virtual agent implementations. The three cognitive architectures - briefly discussed below in chronological order - are by no means representative of all cognitive architectures but are sufficient for encapsulating three basic architectural types as belonging to one canonical corpus.

The most established cognitive architecture for virtual agents is known as ACT-R [Adaptive Control of Thought-Rational] (Anderson ca. 1990)]. ACT-R was an early model for representing brain-like cognition and was re-iterated from previous models known as "HAM" (1973) and "ACT-*" (1983).[3] ACT-R is one of the first cognitive architectures to explore and implement the relationships between deliberation, conceptualization memorization, and action. Further, ACT-R is an early instantiation of a hybrid architecture that dynamically draws from: symbolic, rule-based, and statistically tunable sub-symbolic representations of memory and cognition (Best et al., 2006, p. 188).

ACT-R has been implemented primarily for use by NPCs (non-player characters)[4] in first-person shooter video games for pathfinding, maze navigation, and strategic team communication (Best et al., 2006). Additionally, ACT-R has been occasionally deployed for more cerebral social simulations modeling human cognition and/or human-surrogate attributes.[5] For example, some virtual agents use a centralized intelligence network to send and receive news items in order to semantically interpret and predict terrorist attacks (Smart et al., 2014). The bulk of these particular ACT-R projects are military affiliated and/or directly funded. As mentioned previously, ACT-R is perhaps the most widely used cognitive architecture for virtual agent implementations. Therefore, it was decided that this chapter's contribution would be a focus on a cognitive architecture that is just as canonical as ACT-R but was not quite as popular and whose virtual agent implementations had not yet been summarized into one text.

Another canonical cognitive architecture is CLARION (Connectionist Learning with Adaptive Rule Induction ON-Line) (Sun et al., 2006). CLARION, like ACT-R, is a hybrid architecture that is focused on distinguishing between implicit and explicit cognition by using means of distributed representation.[6] For implicit cognition, CLARION can also parse subconscious processes, sub-symbolic knowledge (Sun, 2006, p. 82-83) and employ tacit knowledge. This implicit knowledge is effectively a priori knowledge which, like ACT-R, is represented and managed using bottom-level functional approximations of neural-nets. CLARION's neural nets are quite elaborate as they can support: back-propagation, feed-forward behaviors (Sun, 2006 p. 82), and Q-learning techniques (Watkins, 1989 in Sun, 2006., p. 83, 85). For explicit cognition, CLARION focuses on levels of: conscious awareness, active introspection, and intentional deliberation. CLARION frequently generates elements of focused top-down knowledge from

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

bottom-up intuition in the form of: deductions, inductions, abductions, hypothesis testing, and explicit symbolic representation (Sun, 2006, p. 83-84). CLARION is also one of the few cognitive architectures capable of representing meta-cognition (Sun, 2006, p. 92-94). Of all the canonical cognitive architectures, CLARION theoretically has the most potential for implementing virtual agents with cognitive faculties for self-awareness, innate motivations and drives, complex strategic deliberation, and even learning from reactive behavior. However, CLARION's issue is the reverse of ACT-R in that there are very few known virtual agent implementations of CLARION. Because of this under-representation, the main active developer of CLARION has even decided to translate its entire code-base from C# into Python in order to entice character designers to use CLARION for their virtual agents.[7] Therefore, a discussion of CLARION will be reserved for a future paper on virtual agent implementations. It is hoped that tractable CLARION examples will become more plentiful over time.

There are many other cognitive architectures. Some of these architectures have emerged from fringe beginnings. However, due to interesting implementations with virtual agents, the occasional architecture had the potential to become canonical in its own right. Take the example of RASCALS (Rensselaer Advanced Synthetic Character Architecture for "Living" Systems) (Bringsjord et al., 2005). The RASCALS cognitive architecture was developed to explore the mathematical modeling of morality in AGI-enabled agents. RASCALS "[...] uses simple logical systems (first-order ones) for low-level (perception & action) and mid-level cognition, and advanced logical systems (e.g., epistemic and deontic logics) for more abstract cognition" (Bringsjord et al., 2005, p. 31). RASCALS' primary virtual agent was a personified embodiment of moral evil existing in the social virtual world Second Life ("Second Life", n.d.)[8] - aptly named, "E". RASCALS has been shown to be technically distinguished from CLARION due to the additional aforementioned emphasis of natural language processing capabilities (Bringsjord et al., 2005, p. 31). RASCALS can also be distinguished from earlier versions of other canonical cognitive architectures based on production rules such as Soar. Once again, RASCALS, like CLARION, has not included many virtual agent examples from which to examine. In fact, the RASCALS project is no longer formally maintained by Bringjord's research team. Therefore, the rest of this discussion will focus primarily on Soar. Soar is an architecture with enough examples to examine and also deserves a higher-profile for its under-represented virtual agent implementations.

Soar

Soar ("State Operator And Result") is a production rule-based AGI cognitive architecture with military and entertainment clientele. However, Soar's creators claim that Soar-agent developers do not need previous programming nor computer-science experience to understand its architectural syntax. Soar is also appealing as a cognitive architecture because it is generalizable enough to handle different: problem-space, tasks, states, and operators. Ultimately, Soar is known for handling multi-faceted problem-domain approaches to a particular task (Laird, 2012, p. 4).

Canonical Features of Soar

Soar is highly scalable to support a large number of rules. In recent versions, Soar has also provided reinforcement learning capabilities. The most recent versions of Soar even have found a way to represent affective states and mental imagery processing (Lathrop & Laird, 2009). Unlike other Rule Based Systems (RBS), Soar-agents have the ability to dynamically update their beliefs about the external

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

environment via "computationally inexpensive truth maintenance algorithms"("SoarTech Corporate Brochure", n.d.). Having a flexible belief system allows a Soar-agent to adapt to multiple ontological commitment opportunities within its particular task-domain. Soar's growing number of memory banks are completely associative, and currently store procedural, semantic, and episodic memories. There is even active speculation that Soar might include a predictive prospective memory bank in the near future (Li & Laird, 2013).

Soar's chunking mechanism is also rule-based and is a form of "explanation based learning" (Laird, 2012, p. 8) that is consolidated in episodic memory. Rule-based chunking allows a Soar-agent to compress a batch of pre-conditions from a specific episodic experience into a single generalized pre-condition for later possible activation of an operator that would be governed by a production rule. Soar's chunking procedure governs all learning from input through deliberation on the object-level and back to output via proposing, then selecting an operator for future action(s) in the external environment. Any novel or unfamiliar real-time episodic event perceived by the agent "returns a result to [the agent's] supergoal" (Laird, 2012, p. 8). The agent's actions and interpretations from this event are immediately "chunked" into a production rule. This chunked rule contains new conditional statements that relate directly to the episodic experience just witnessed and interpreted by the agent. Just like Soar's operators and states, this rule-chunk is stored associatively between the agent's short-term episodic memory and its long-term procedural memory banks for cross-retrieval. These episodic "interpretations" are based on a priori or previously acquired knowledge relating to apparently similar situations. For future interaction scenarios where a similar episodic event matches some of the conditions in that rule-chunk, the agent can retrieve suggested preferences for the most appropriate operators or actions to use in that new situation. Over time, Soar's reinforcement learning feature "[…] tunes the actions of rules that create preferences for operator selection" by rewarding the agent for acting out "good" preferred operators and actions (Laird, 2012, p. 18).

Soar also employs "automatic subgoaling" (an extension of the chunking mechanism). After recognizing a conflict (impasse) during a novel decision-making scenario, the Soar-agent generates a new state known as a "subgoal". As this new state is based on rule-based knowledge, Soar's freshly generated subgoal can oscillate between superstate and substate designations. Soar's corporate literature claims that other Rule Based Systems (RBS) can only deal with one fixed state at a time. The Soar agent automatically generates monitoring substates that "decompose complex operators into similar operators" (Laird, 2012, p. 66). Therefore, Soar's assignment of a monitoring role to these substates implies that Soar also offers rudimentary on-demand metareasoning or self-reflection capabilities (Laird, 2012, p. 66).

Soar's characteristic feature is its decision cycle. Soar's decision cycle is a "fixed processing mechanism that works in five phases: input, elaboration, decision, application, and output" (Lehman, Laird, & Rosenbloom, 2006, p.17). The Soar-agent must be able to parse continuous percepts (e.g. observations, perceptions) from a stochastic environment in order to make informed real-time decisions on which operators to select next. The Soar-agent handles this perpetually updating percept stream of new symbols by temporarily storing them first in a local "perceptual short-term memory" before adding them to a more global and action-driven working memory (Laird, 2012, p. 18). Next, the Soar-agent reflects on recently occurred episodes stored in its short-term working memory by elaborating on the elements of these events as conditions and suggested actions.

The Soar-agent elaborates on these learned episodes by comparing the history of its operator-preferences (thoughts) and operations (actions) it made at the time with conditional statements it had acquired from the rules it had chunked and stored from previous experience into its long-term memory. The Soar-agent

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

then has the opportunity to decide on a course of action. If any rules generated (learned) from a recent episode match with any other remembered rules, those matching rules will fire in parallel. Once these matching combination of rules fire, the Soar-agent will have updated to its next state which contains new "suggestions, or preferences, for selecting the current operator" (Lehman, Laird, Rosenbloom, 2006, p.17). From a list of highly rated and preferred operators, the Soar-agent can then propose, select, and apply the operator to be used for the next action. The programmer also has the luxury of manually preferring operators by adding a "+" symbol to a favored operator. With the reinforcement learning procedure, the Soar-agent updates an operator with a "+" symbol and a corresponding numerical rating value automatically when rewarded for an action that was produced by that operator.

Soar's architecture is known mostly for its ability to simultaneously fire an extremely large number of hard-coded production rules without having these rules initially undergo a matching procedure. Soar's operators and states are also rule-driven. In fact, Soar differentiates itself from other Rule Based Systems (RBS) in that it is most concerned with selecting the best operator that will impact the agent's next state. In other RBS, the focus is on hierarchically rating each rule and sequentially determining which single rule should fire next (Laird, 2012, p. 4). Soar instead determines the best combination of rules to be fired in parallel, given the "knowledge and structure'" of a particular task-context (Laird, 2012, p. 4-5). These operators, states, and rules are completely modular atomic elements and can be recycled from one memorized context to another for action-selection. This means that Soar saves on rule-firing speed and resolves any conflicting logical contradiction or decision impasse by being highly associative with different elements of each of its parallel long and short term memory banks. However, this convenient association and modularity among memorized rules comes at a structural cost. For example, Soar can retrieve any other chunk (concept with data and a form) from one memory bank and automatically turn it into a sub-goal for use in episodic context. This cross-retrieval process is executed without requiring any knowledge of the previous associative context. Consequently, Soar is task-agnostic as it only focuses on how the parallel optimization of a large number of hard-coded rules result in operational changes "[…] to the features and values" in the agent's state (Lehman, Laird, & Rosenbloom, 2006, p. 17).

Soar's Technical Integration with Virtual Agents

This chapter is focused on historical virtual agent implementation examples rather than on their technical interfacing protocols between agent, cognitive architecture and virtual environment. However, it can be stated in passing that generally speaking, integration between Soar and character-driven virtual environments are contingent on the technical affordances of a particular software application. For example, NPCs residing in gaming engines such as Unreal Tournament can be interfaced with Soar using a control methodology and data specifications that are packaged by the company SoarTech as a "Human Behavior Model Interface Standard" (HBMIS, van Lent et al., 2004). It is entirely feasible that this interface standard can be migrated across similar gaming engines such as Unity. The most established gaming engine implementation treats each human behavioral model as an asynchronous external software module that (for now) communicates with a proprietary "UnRealScript" function interface (van Lent et al., 2004, p. 3). Each model exclusively processes Unreal's simulation data through the Soar General Input/Output mechanism (SGIO, Laird et al., 2002) before passing this data through its own decision cycle (van Lent et al., 2004, p. 3). Fortunately, these models are designed so that their processing cycles do not interfere with the game engine's own processing cycles (van Lent et al., 2004, p. 4).

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

SoarTech has made further high-level modifications to this Unreal/SGIO interface to account for state initialization and representation, (multiple) independent procedural threading, and group action sequences (van Lent et al., 2004, p. 3-4). For data control, SoarTech has also created their own low-latency DLL file that is executed once the Unreal engine initializes (van Lent et al., 2004, p. 4). In order to account for Unreal's real-time rendering capabilities, the SGIO mechanism must be able to execute and return game loops at a rapid speed. In fact, deliberative latency might even compromise the virtual environment's frame-refresh rate (i.e. below 30 frames per second, van Lent et al., 2004, p. 4). Therefore, Soar's once impressive ability to refresh a new decision cycle every 50 milliseconds might still prove to be too temporally cumbersome for cognition to believably function at the speed of contemporary game-play (van Lent et al., 2004, p. 4). One of the agent designers mentioned in this chapter has developed a plausible workaround to this interface issue. In this case, the high-level interface virtually encapsulates three selectable lower-level interfaces that operate at run-time instead of real-time (Magero et al., 2004, p. 879). Magerko's research team has optimised the performance capabilities of SGIO by "embedding [...] multiple copies [of] Soar within the UT process using a C API" (Magerko et al., 2004, p. 879).

Gaming engines in general (esp. VBS2, Unity3D and Unreal Tournament) can now be interfaced with Soar using SoarTech's "PoL" ("Patterns of Life") behavior modeling infrastructure (SoarTech, "Entity-Level Patterns of Life for Virtual Environments, promotional brochure, 2013). This PoL infrastructure comes bundled with sample virtual agents for evaluation. These agents feature parameterized and schedulable patterns that correspond to self-monitoring behaviors, beliefs, desires and intentions (SoarTech, "Entity-Level Patterns of Life for Virtual Environments, promotional brochure, 2013).

Outside of the gaming context, other Soar-agent designers have created novel integration solutions such as implementing an elaborate messaging interface that links various technical components and software application components. These disparate software components can even run on different machines, if required. For example, the proprietary components that created the cognition for the first virtual agent example (STEVE, Rickel & Johnson, 2000, p. 11) passed messages between the VIVIDS simulation engine (USC Behavioral Technologies Laboratory, 1997), Vista Viewer (for visual interfacing, Lockheed Martin, 1995), and Entropic's Text-to-Speech software. These messages were dispatched using another piece of proprietary software known as, ToolTalk (SunSoft, 1994).

Soar Examples

These four Soar implementation examples were chosen to showcase the various ways a rule-based cognitive architecture can enhance the interactive and deliberative potential of a virtual agent. These examples are presented chronologically in historical order from 2000-2013. These Soar-agent examples address military (e.g. industrial and cultural sensitivity training), entertainment (e.g. video-games), and fine-arts (e.g. dance) contexts.

The Soar Training Expert for Virtual Environments (STEVE)

The first example involves a US Navy-funded "Soar Training (Virtual) Expert for Virtual Environments" known colloquially by "his" personified acronym, "STEVE" (Rickel & Johnson, 2000). STEVE is a virtual humanoid who interacts with naval officers wearing a head-mounted display (HMD) in a virtual reality (VR) environment (Rickel & Johnson, 2000, p. 101-105). STEVE can respond to text-to-speech queries as well as reason about the motivations and goals for enacting the correct operational procedures

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

for maintaining has turbine engines on naval ships[9] (Rickel & Johnson, 2000, p. 96). In order to carry out these training procedures in a believable manner, STEVE can orient his avatar body, walk around, and point towards salient virtual objects within the turbine-engine simulation while identifying each object by name (Rickel & Johnson, 2000, p. 97). Further, STEVE can shift his gaze from the inquiring officer to the queried virtual objects that he is currently identifying for pedagogical purposes.

STEVE uses a perception module to monitor as well as semantically interpret all of the appropriate messages and events that result in updating the (virtual) world-state (Rickel & Johnson, 2000, p. 106). STEVE constantly relays the current world-state in a way that is continuously interpretable by the STEVE's cognition module (ie. where Soar resides) (Rickel & Johnson, 2000, p. 106). This cognition module is then responsible for deciding what STEVE's next action-sequence should be. Once one decision cycle has transpired, STEVE transmits motor-commands to the motor control module which allows STEVE's voice to speak and avatar body to move (Rickel & Johnson, 2000, p. 107). STEVE's cognition module carries out serial procedures independently from the other modules while the perception and motor control modules work in parallel (Rickel & Johnson, 2000, p. 107). STEVE is unique from many other virtual agent implementations because Soar in this case, does not supply STEVE's virtual mind with higher-level cognitive processes (e.g. cerebral deliberation and meta-cognition). By contrast, Soar represents STEVE's lowest level of cognition (Rickel & Johnson, 2000, p. 106-107). Soar was only modeled for lower-level cognition because the original Soar architecture was never optimized to assist with those demonstration and conversational activities more familiar to the perceptual and actuational (motor-control) modes of operation (Rickel & Johnson, 2000, p. 106-107)

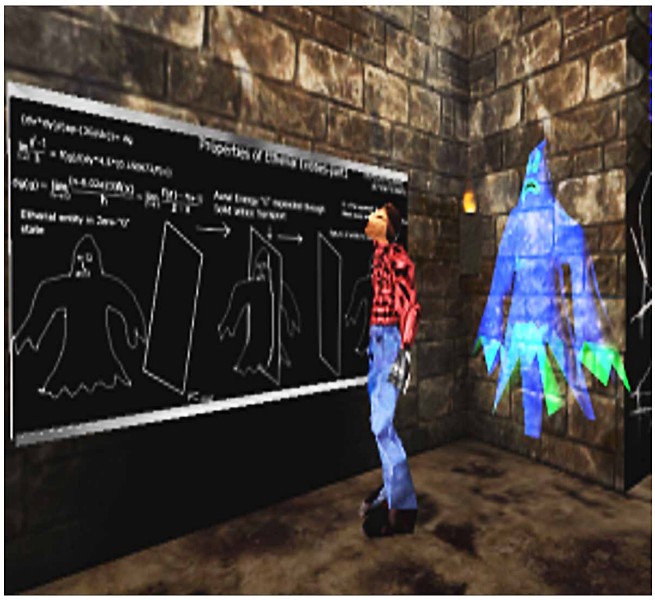
Permission granted by the author (Rickel & Johnson, 2000)

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

STEVE repeatedly deployed his cognition module to choose the next appropriate action (Rickel & Johnson, 2000, p. 114). STEVE engaged the cognitive module by perpetually looping Soar's trademark decision cycle. Based on the hardware specifications circa 2000, STEVE used to complete up to ten decision cycles per second (Rickel & Johnson, 2000, p. 106-107). Even back then, STEVE appeared to be very responsive to his environment (Rickel & Johnson, 2000, p. 115). From each percept received by the perception module, STEVE responds to a trainee's question or demonstrates a new procedure by executing a behavioral operator. These operators are represented by production rules that effect a change in the world-state and might even influence the next sequence of proposed operators themselves (Rickel & Johnson, 2000, p. 116). Once an operator has been applied, STEVE then determines which preferred operator to select and apply for the next time-step. These operators conform to action-categories related to: object manipulation, object-movement, self-proximity, and condition checking while the actions themselves correspond with STEVE's communicative faculty (Rickel & Johnson, 2000, p. 116). STEVE hierarchically compares, prefers, selects and then applies operators based on their contextual priority. STEVE's first priority is usually to answer the trainee's queries. However, if there are no queries, STEVE might instead attempt to steer the conversation towards focusing on more of his own verbal explanations and demonstrations of the training course (Rickel & Johnson, 2000, p. 114-115). In other cases, production rules might prompt STEVE to move to the next appropriate demonstration location or compel him to point at a particular object of immediate importance (Rickel & Johnson, 2000, p. 114-115). STEVE's communicative acts are in the form of Soar production-rules but ultimately have the restricted interactive characteristics of finite-state machines (Rickel & Johnson, 2000, p. 115).



Soar-NPCs in Unreal Tournament

These virtual Soar-agents are NPC (Non-Player Character) humans that use the Soar General Input/Output (SGIO, Laird et al., 2012) interface in order to communicate with Soar's architecture and the Unreal custom video-game environment (Magerko et al., 2004, p. 879). In this video game known as "Haunt 2", the player is the ghost and the player's goal is to uncover the mystery behind his/her death by subtly haunting the rule-driven NPCs using a limited ethereal mode of non-verbal communication. The player also cannot directly manipulate objects in the game and so, can only psychologically influence the haunted human NPCs to manipulate objects on behalf of the ghost's otherworldly will (Magerko et al., 2004, p. 878). The player-as-ghost can either scare the NPC into acting on the ghost's behalf or temporarily possess a more psychologically receptive NPC. When an NPC is in a possessed state, the ghost-player can actually observe and directly manipulate the NPC's Soar-mediated cognitive processes as they occur (Magerko et al., 2004, p. 878). However, each NPC has its own idiosyncratic psychological tolerance, bias, goals, motivations, needs (e.g. comfort), drives (e.g. hunger, thirst etc.), and a unique knowledge-representation of the background context (Magerko et al., 2004, p. 879).

Plot points in Haunt 2 are divided into preconditions and postconditions that can be optimally mediated by Soar operators to address both general and specific narrative outcomes. Preconditions describe "[…] what has to be in true in the world in order for this plot point to be relevant". In contrast, postconditions describe "[…] what actions should take place once these conditions are met" (Magerko et al., 2004, p. 880-881). In Haunt 2, there is no explicit mention of in-conditions which would describe what should be continually happening in the world to retain the truth of that particular condition. The closest thing to in-conditions in Haunt 2 is a "timing constraint" that provides situations when certain plot points lose their relevance over time (Magerko et al., 2004, p. 881). In addition to the player-character (PC)

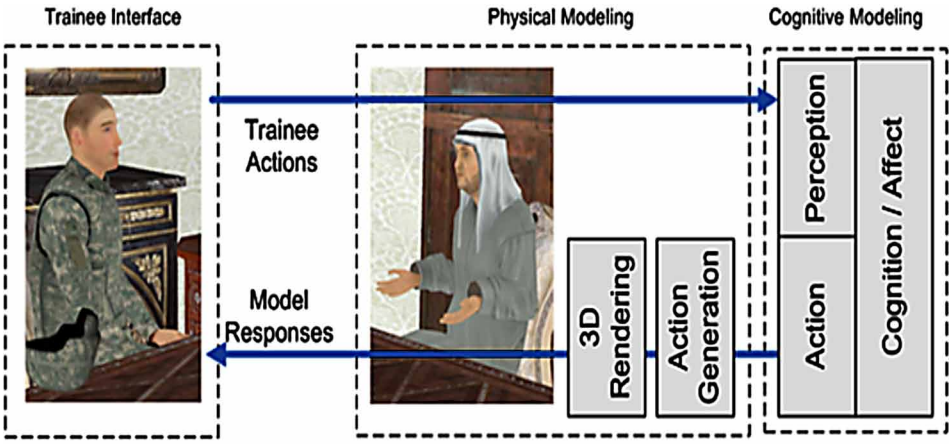
Figure 2. A screenshot of the player haunting Soar-NPCs as a ghost in the video-game HAUNT 2 Permission for this image granted by the author. Accessed online from http://ai.eecs.umich.edu/~Soar/sitemaker/projects/haunt/images/blackboard.jpg on March 16, 2015
(Magerko et al,2004).

and NPC, Haunt 2 has a "Director" that runs a simulation modeling the player's actions in order to hypothesize over "[…] what declarative knowledge [the ghost] is acquiring through his [event triggered or time-lapsed] experiences [by keeping] an up-to-date internal structure describing the state of the world" (Magerko et al., 2004, p. 882). For example, the Director can alter the NPC's communication style (e.g. to be more outwardly "social"), and/or control the NPC's motor-functions and available text-strings for dialogue with other NPCs (Magerko et al., 2004, p. 880). The Director determines the success or failure of a world-state hypothesis depending on whether the player advances the story's plot points towards the expected narrative conclusion or instead, thwarts the activation of a plot-point by ignoring some particular pre-condition (Magerko et al., 2004, p. 880).

Virtual Soar-Agents using the Cultural Cognitive Architecture (CCA)



Some Virtual Soar-agents have been designed to interpret and communicate the complex ethnographic nuances of behavioral protocols, values, and social norms from other cultures. The military contractors known as "SoarTech" ("SoarTech", n.d.) have designed a Cultural Cognitive Architecture (CCA) within SOAR[10] in order to cognitively enhance conversational virtual agents for cross-cultural training purposes (Taylor & Sims, 2009, p.1). Soar in particular was chosen for its: "scalable long-term memory, […] associative memory activation [functions], mixed automatic and deliberative reasoning [capabilities], goal-directed, problem-solving behavior, ability to incorporate multiple reasoning methods, […], and graph-based working memory, which maps well to Scripts/Frames approaches to schema representation" (Taylor et al., 2007, p. 2; Minsky, 1975; Schank & Abelson, 1975).

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Built upon the Cultural Schema Theory (CST), the CCA draws from an ontology that contains a growing corpus of embodied ethnographic knowledge (Taylor et al., 2007, p. 4). Outside of virtual environments, this ethnographic knowledge is usually acquired when human agents are embedded within a particular culture for a sufficient length of time (Taylor & Sims, 2009, p. 1). The cultural schema itself encodes the social hierarchies, known protocols, predicted social outcomes, culturally salient features of the environment as well as the particular contextually-sensitive goals that are likely to drive characters from particular ethnographic backgrounds (Taylor & Sims, 2009, p. 5). A culturally instantiated schema is subject to "[…] a process of activation, decay, and deactivation based on relevance to events perceived in the environment" (Taylor et al., 2007, p. 4). SoarTech claims that the CCA and CST are generalizable enough to be applied to understanding various cultures[11]. If any cultural differences cannot be captured with generality, the CCA generates leaf nodes to represent any noticeable cultural idiosyncrasies (Taylor & Sims, 2009, p. 5).

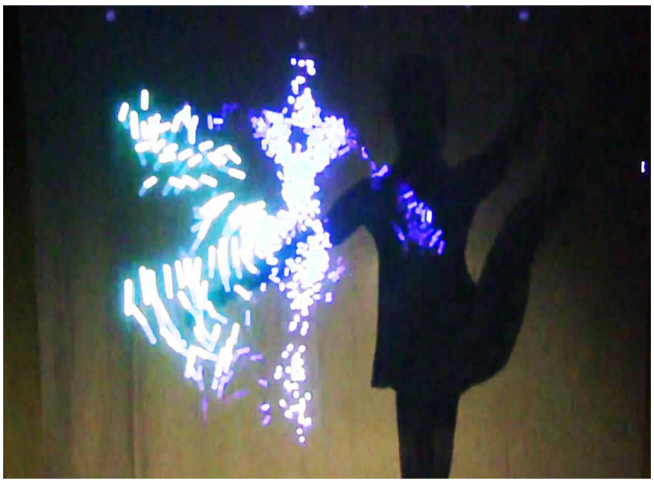
The Soar-CCA implements its virtual agents by balancing an emotional system dealing with an event-dependent appraisal mechanism with a cognitive system that establishes higher-level goals and generated behaviors (Taylor & Sims, 2009, p. 5-6). These conversational virtual agents exist in the 3D animation engine and behavioral simulator, "Vcommunicator". Vcommunicator has access to "[…] over 60 culturally diverse virtual human models as well as 40 facial expressions and 500 gestures, and can automatically lip-sync to over 22 mouth shapes that map to over 100 speech sounds of the International Phonetic Alphabet." (Taylor & Sims, 2009, p. 4). A culturally successful agent will be able to ascertain the relevance of goals, and the benchmark set for societal norms while assessing the relative novelty of a particular ethnographic ritual (Taylor & Sims, 2009, p. 4). SoarTech claims that a virtual agent drawing from the Soar-CCA can dynamically assess the most typical emotional state (e.g. relative standards of "rudeness" and "politeness") based on the episodic sum of the outputs from the emotional system and the appraisal value collected from a specific cultural encounter (Taylor & Sims, 2009, p. 4). Overall, each virtual character receives both the recommended action-sequence and the expected emotional state while having parameterized control over situations where the relative emphasis of certain culturally appropriate gestures is required (Taylor & Sims, p. 2009, p. 7).

Figure 3. This image depicts a virtual soldier attempting cross-cultural negotiations with a Middle-Eastern Soar-CCA Virtual Agent. Permission to use this image granted by the author (Taylor & Sims, 2009, SoarTech).

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

The SoarTech team has conceded to some challenges regarding virtual character implementations of the CCA. For one, it was difficult for the team to determine the ideal granularity for cognitive and physical actions. Dealing with the granularity at the atomic level might be well-tailored to very specific cultural instances but would likely not be generalizable enough to be interoperable with multiple cultural contexts. More generalized models are easier to engineer. However, if the models are too generalized, then this would create a culture-agnostic character which might not be seen as believable or realistic (Taylor & Sims, 2009, p. 9).

In theory, but not entirely realized in practice, the CCA-agents are potentially scalable to handle rich data models and a fluent understanding of various natural languages. However, with increasing complexity and size comes an equal increase in available computational resources. Within the virtual world context, this poses no real obstacle because the "[…] fidelity of the data would be only as good as the fidelity of the interactions available in the virtual world" and most virtual world data is limited to culturally unrealistic gestures and inauthentic chat-responses anyway (Taylor & Sims, 2009, p. 9). To date, however, there does not appear to be any firm evidence of Soar-agents (including CCA-agents and any other AI-enhanced agents) that have sufficiently transcended the limitations of finite-state organization to handle natural language understanding and generation at an adult human level. At the very least, some noteworthy attempts (see Lindes et al., 2015) have been made to use Soar for grounded language acquisition and linguistic mapping. In one particular case, a Soar-agent can "[…] associate the sentence 'put a large red block in the table' with an instantiated operator which will achieve the intended goal" (Mohan et al., 2012., p. 124).



CAA-agents are similar to the Director in Haunt 2 as it can select goals that will encourage following the currently activated narrative script towards its ritualistic conclusion (Taylor et al., 2007, p. 4). Soar's impasse threshold-breaking mechanism is mirrored in CAA's ability to prefer, apply, and fire those current script-relevant operators and rules from working memory that already have the highest activation potential (Taylor et al., 2007, p. 3-4). The issue here is that the CAA-agent will always act based on what is determined to be the most culturally appropriate action rather than in its own self-interest (Taylor et al., 2007, p. 3-4).

A Virtual Soar-Agent using Augmented Reality for Improvised Choreography

VAI (Viewpoints Artificial Intelligence, Jacob et al., 2013) is an augmented reality virtual Soar-agent designed for interactive improvised choreography in real-time. VAI is projected onto a 2D surface in order to interact with human-participants in a turn-taking manner (Jacob et al.,, 2013, p. 4). VAI is influenced by the collision physics of the human participant's shadow and can learn movement sequences that are scanned from a human's skeletal vertex points acquired via a Microsoft Kinect system ("Kinect for Windows", n.d.). Cognitively, VAI accesses "perception, reasoning and action modules" in order to calculate relative vertex values of: joint position, tempo (pacing), energy[12] levels, and velocity. These values are conveniently represented for Soar as "predicates" (Jacob et al., 2013). These Soar-ready predicates convert VAI's ambient movements into color values when gestures are being made at low-acceleration rates (Jacob et al., 2013, p. 4). VAI stores all input and output gestures into an "internal interaction history" (Jacob et al., 2013, p. 4) which likely encompasses various stages of Soar's working memory. VAI either randomly accesses these working memory elements – composed of various dance-sequence durations - in order to determine the best movement operator to propose, select, and apply, or ignores the interaction history entirely (Jacob et al., 2013, p. 4). In response, VAI can choose between refusing

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 4. A snapshot of VAI taking turns improvising a dance routine with a human participant. Permission for this image granted by the author
(Jacob et al., 2013)

to apply an operator, repeat the input gesture (i.e. mimicking the dancing human participant), or perform some novel choreographic variation on said gesture. VAI's creators have asserted their desire to enable the possibility for VAI to propose and apply operators based on instances of similarity based reasoning principles (i.e. the similarity between "source and target […] predicates", Jacob et al., 2013, p. 5). VAI also has a heuristic for showing an awareness of the human participant's presence and dance-movement choices while also showing the capacity for improvisation and creative autonomy. This heuristic allows VAI to follow a human participant's repeated gesture twice (consecutively) before performing an improvised gestural variation of its own devising (Jacob et al., 2013, p. 5).

VAI's limitations were more the result of its perceived levels of interaction and not so much due to any cognition parsing issues produced by Soar. For example, some people were too impatient with the turn-taking approach to VAI's choreographed interactions (Jacob et al., 2013. p. 4-5). Otherwise, some human participants either found VAI's interactions to be arbitrary (random), or merely copying the human movements. In fact, some human participants were deluded into thinking the VAI agent possessed more deliberative capabilities than were actually present under-the-hood (Jacob et al., 2013, p. 4-5). The latter can be seen as beneficial for those designers wishing to elicit conceivable rather than accessible interactive states in the mind of the interactor.[13]

Criticism of Soar-Implementations

Current versions of Soar – although centered on rules – work best with a robust knowledge base containing a large number of hand-coded productions. Ultimately, Soar works best for purely deterministic simulated environments but has been criticized for not being able to solve even rudimentary logic problems based on hidden, partially observable or incomplete empirical knowledge (Bringsjord et al., 2005, p. 35). For many virtual agent implementations, cognitive architectures such as Soar do not usually require full scale logic operations. This is because they are usually "[…] too slow for real-time perception-and-action-heavy computation" (Bringsjord et al., 2005, p. 35) anyway. Soar might be scalable while keep-

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

ing the computational cost relatively low but eventually, Soar's cognition lags when a large number of production-rules need to successfully interpret a dynamically changing virtual environment. Basically, Soar's chunking mechanism can optimize limited computational resources but a stochastic simulation modeled after the "real world" will cause the automatic-subgoaling mechanism to gradually tax the Soar's working and long-term memory capabilities.

The general issue of abstracting out semantically-appropriate information from a stochastic virtual environment and "specifying the [symbolically represented] conditions under which productions can apply" (Best et al., 2006, p. 212) provides ongoing engineering challenges to those particular cognitive architectures that are production rule-driven (esp. Soar). At best, a production-oriented cognitive architecture can cope with generalized symbolic approximations of environmental conditions through some rudimentary form of case-based reasoning process. In this instance, a cognitive agent can focus on a single "canonical case" that can be applied to most particular interactive scenarios where conditional decision making applies (Best et al., 2005, p. 213). Culturally speaking, cognitive elements representing a "canonical case" – and its associated natural language structures - might not even be sufficiently decomposable into production rules and rule-chunks.

In virtual environments optimized for multi-agent system interactions, cognitive architectures are usually under-represented as they are criticized for neglecting multi-agent implementations. This is because cognitive architectures were originally to focus on the egocentric cognitive concerns of a single agent instead of allocentrically mapping the overall cognitive climate of interacting agents. According to Smart et al., developers of these multi-agent swarms, usually "[...] assume that individual agents have very rudimentary cognitive processing capabilities, and in some cases, aspects of agent cognition (e.g., beliefs or attitudes) are represented by simple numerical values that do not respect the constraints imposed by the human cognitive system" (Smart et al. 2014a., p. 1).

Speculations for Future Virtual Soar-Agent Implementations

Overall, the above examples are diverse enough from each other to address the range of Soar's potential and limitations when cognitively interfacing with a virtual agent. It is up to each of the above researchers whether or not they wish to re-iterate their virtual agents with newer Soar-related features. Regardless, there are some plausible research directions these and other researchers could take to develop the next-generation virtual Soar-agents. For example, STEVE could utilize Soar's reinforcement learning capability to emergently discover how to train naval officers with equipment operating in unknown or hostile virtual simulations (e.g. a war-zone). In addition, the NPCs in Haunt 2 could be modified to explicitly model separate "in-conditions" from pre and post conditions. Further, CCA-agents could do with a connectionist representation in future versions of Soar – similar to CLARION - where cultural sensitivities can be gradually learned in a supervised manner using tunable weights and/or with reinforcement signals. Perhaps, a virtual-agent can be incrementally rewarded and/or have neural connections solidified (i.e. Hebbian learning activity increased) for producing behaviors (as well as internal thoughts) that seem to match the protocols of other cultures (e.g. scripts for culturally "correct" postures, semantic relationships, and routines). This would be a compelling alternative to classically tuning Soar's rules and operators themselves. Ideally, the issue of a virtual agent's "self-interest" situated within an uncertain cultural context would be more elaborately addressed if Soar was modified to draw from a software ontology (Noy et al., 2001) that contained recursive predicates and slots that dealt with "self-awareness". Monitoring substates is sufficient for finding common ground between complex operators (Laird, 2012.,

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

p. 66). However, operators themselves are not necessarily a tractable representation of what one culturally would consider to be a form of self-awareness. As for VAI, it may prove difficult to have Soar's decision cycle operate in a non-serial manner. Turn-taking, however, was an issue for some impatient human participants so VAI's creators might consider either advocating more parallelism in Soar and/or implementing VAI with a different cognitive architecture more suited to parallel decision making.[14]

Generally speaking Soar's current endeavor to develop additional affective-state models and mental imagery (i.e. imagination) representations is encouraging. Soar will also likely be adopted by a newer generation of virtual agent designers once a distinct prospective memory store is finally implemented in future iterations. Imagination resides in episodic memory[15] as a list of proposed (but not preferred) operators, rules, and actions. These proposed rules, operators and, actions are the atoms of imagination in Soar. These atoms can be further elaborated on via fictional metadata stored in semantic memory, or as plausible (but untested) interactivity algorithms, and/or heuristics stored in procedural memory. Alongside speculations of a prospective memory Soar implementation, a parallel sub-component of episodic memory known as "elaborative memory" or "fantasy memory"[16] would generate imagined novel episodes as myths/fictions. These episodes would propose equally fictional operators, rules, and actions.[17] The elaborative memory would be driven by sub-goals and sub-states. Elaborative memory would determine which sub-goals/sub-states should be rapidly retrieved from other memory banks. Chunking would involve elaboration by fabricating memories, operators, rules etc. The rule firings themselves could even resemble mirror neurons as they could be simulated internally without actually firing to express cognitive deliberation (Maffre et al., 2001).

Prospective memory on its own would definitely benefit those aforementioned virtual Soar agents that navigate semi-deterministic virtual spaces. The possibility of Soar including a prospective memory as one of its features would be even more impressive if the virtual Soar-agent interface this type of memory with a robust logic component – autonomous from the authority of production rules. Further, a future version of Soar could have its own equivalent representation of CLARION's *rule-extraction refinement algorithm"* (aka. RER, Sun 2006., p. 86). Soar could approximate how CLARION actually connects declarative and procedural knowledge. Like CLARION, Soar's own version of the RER algorithm could be encoded as an explicit knowledge element for use by CLARION's deductive and inductive logic components in the service of actionable inference. In other words, Soar can understand in its own way how CLARION's showcased RER algorithm has enabled a CLARION-agent to learn from sub-symbolic knowledge and find ways to convert this knowledge into logic and/or ontology symbols. If the implicit knowledge component is sufficiently salient and capable of semantic refinement, base empirical experience can even be converted into a Soar production rule. Prospective memory combined with logical inference and a new representation of the RER algorithm may even be able to predict future world-states in a stochastic environment with some actionable degree of confidence.

CONCLUSION

In conclusion, this chapter has showcased the various ways in which Soar can be integrated with virtual agents representing multi-faceted roles such as: military trainers, video-game NPCs, culturally sensitive interpreters, and improvised choreographers. This chapter has discussed the relevance for using a cognitive architecture in the first place and has contextualized the strengths and weaknesses of implementing virtual agents with Soar.

Soar's legacy remains as an established scalable and stable production-rule architecture still maintained by an active development team seeking further iteration and improvement to its fundamental design. The speculations mentioned in this chapter merely serve to inspire cognitive architects to push the boundaries of interactions driven by mental-processes even farther than anticipated.

KEY TERMS AND DEFINITIONS

Bot: Social virtual world slang for a Virtual Agent.
Chunk: Episodic associations compressed into a singular generalized concept.
Cognitive Architecture: A unified collection of cognitive models used to regulate mental processes.
Declarative Knowledge: Memorized Information that pertains to factual information.
NPC: Video-game slang for a "Non-Player Character" (aka. a Virtual Agent).
Production: A type of rule that is dynamically governed by alterable conditional statements.
Virtual Agent: The academic name for an artificially intelligent entity in a virtual environment.

ENDNOTES

[1] Since at least 1971. For one of the earliest cognitive-architecture flow-charts, see page 3b & 5b of Atkinson, R. C., & Shiffrin, R. M. (1971). The control processes of short-term memory. Technical report no. 173. Institute for Mathematical Studies in the Social Sciences, Stanford University. 23 pages.

[2] Soar was originally treated as an acronym. Therefore, Soar would normally be capitalized as SOAR. However, there is now evidence to suggest that the Soar community no longer uses the acronym convention to describe this cognitive architecture (Ritter, Kim, and Sanford, 2012).

[3] For more historical contextualization, read Anderson 1996 & Best et al. 2006 (in Sun, 2006, p. 187-189).

[4] Of note, the creator of ACT-R has interfaced his architecture a 2D virtual space-ship that is the main player-avatar of the videogame "Space Fortress" (Bothell, 2010). However, to limit the scope of this paper, a space-ship will, in in this case, not be considered as a "character". See Moon & Anderson, 2012.

[5] Smart et al. (2014) make the distinction that their abELICIT agents designed by Smart et al. (2014) for ACT-R are not really "[…] based on a cognitive architecture that is modeled after the human cognitive system" (Smart et al. 2014a, p. 5).

[6] For more information, see van Gelder, T. (2001). "Distributed vs. Local Representation" (pp. 236-*238).* In R.A. Wilson., F.C. Keil., [Eds.]. The MIT Encyclopedia of Cognitive Science (MITECS). Cambridge, MA: MIT Press. 964 pages.

[7] Based on email correspondence with the lead CLARION developer, Michael Lynch on March 04, 2015.

[8] Second Life is the most popular social virtual world with its own proprietary "Linden Scripting Language" (LSL) for virtual agent AI implementations.

[9] Apparently, STEVE can draw from different declarations related to other domains that support virtual worlds and associated objects, if needed (Rickel & Johnson, 2000, p. 96). Also, STEVE can re-tailor his training demonstration by to adjusting his plan to world-state changes and "failure modes" induced by human-interactors in the VR world (Rickel & Johnson, 2000., p. 97).

[10] To clarify, SoarTech developed a "[…] hybrid symbolic-numeric model" that is part of more comprehensive sub-architecture built entirely within Soar. (Taylor et al., 2007, p. 8).

[11] This research was intended to analyze and interpret Middle-Eastern (esp. Arabic) cultural protocols.

[12] Energy in this context, represents the "amount of movement" (Jacob et al., 2013, p. 4).

[13] An inverse of the "common-sense" idea of privileging accessible over conceivable states (advocated by Crawford, 2003).

[14] With Soar, only the decision cycle runs serially. The rules themselves can fire in parallel.

[15] In future Soar versions, the imagination will likely also reside in prospective memory.

[16] These are my terms to describe what should be future memory components in Soar.

[17] For example, Soar's syntax might include "elaborate-operator" as well as "propose-operator".

This research was previously published in Integrating Cognitive Architectures into Virtual Character Design edited by Steve DiPaola, Michael Nixon, Jeremy Owen Turner, and Ulysses Bernardet; pages 181-212; copyright year 2016 by Information Science Reference (an imprint of IGI Global).

Chapter 26
Applications of PNC in Artificial Intelligence

Dariusz Jacek Jakóbczak
Technical University of Koszalin, Poland

ABSTRACT

Interpolation methods and curve fitting represent so huge problem that each individual interpolation is exceptional and requires specific solutions. Presented method is such a new possibility for curve fitting and interpolation when specific data (for example handwritten symbol or character) starts up with no rules for polynomial interpolation. The method of Probabilistic Nodes Combination (PNC) enables interpolation and modeling of two-dimensional curves using nodes combinations and different coefficients γ. This probabilistic view is novel approach a problem of modeling and interpolation. Computer vision and pattern recognition are interested in appropriate methods of shape representation and curve modeling. PNC method represents the possibilities of shape reconstruction and curve interpolation via the choice of nodes combination and probability distribution function for interpolated points. It seems to be quite new look at the problem of contour representation and curve modeling in artificial intelligence and computer vision.

INTRODUCTION

Probabilistic modeling is still developing branch of the computer science: operational research (for example probabilistic model-based prognosis) (Lorton, Fouladirad & Grall, 2013), decision making techniques and probabilistic modeling (Pergler & Freeman, 2008), artificial intelligence and machine learning. There are used different aspects of probabilistic methods: stochastic processes and stochastic model-based techniques, Markov processes (Cocozza-Thivent, Eymard, Mercier & Roussignol, 2006), Poisson processes, Gamma processes, a Monte Carlo method, Bayes rule, conditional probability and many probability distributions. In this chapter the goal of probability distribution function is to describe the position of unknown points between given interpolation nodes. Two-dimensional curve (opened or closed) is used to represent the data points. So problem statement of this chapter is: how to reconstruct

(interpolate) missing points of 2D curve having the set of interpolation nodes (key points) and using the information about probabilistic distribution of unknown points. For example the simplest basic distribution leads to the easiest interpolation – linear interpolation. Apart from probability distribution, additionally there is the second factor of proposed interpolation method: nodes combination. The simplest nodes combination is zero. Thus proposed curve modeling is based on two agents: probability distribution and nodes combination. Curve interpolation (Collins, 2003) represents one of the most important problems in mathematics and computer science: how to model the curve (Chapra, 2012) via discrete set of two-dimensional points (Ralston & Rabinowitz, 2001)? Also the matter of shape representation (as closed curve-contour) and curve parameterization is still opened (Zhang & Lu, 2004). For example pattern recognition, signature verification or handwriting identification problems are based on curve modeling via the choice of key points. So interpolation is not only a pure mathematical problem but important task in computer vision and artificial intelligence. The chapter wants to approach a problem of curve modeling by characteristic points. Proposed method relies on nodes combination and functional modeling of curve points situated between the basic set of key points. The functions that are used in calculations represent whole family of elementary functions with inverse functions: polynomials, trigonometric, cyclometric, logarithmic, exponential and power function. These functions are treated as probability distribution functions in the range [0;1]. Probabilistic modeling represents a subject arising in many branches of mathematics, economics and computer science. Such modeling connects pure mathematics with applied sciences. Operations research similarly is situated on the border between pure mathematics and applied sciences. So when probabilistic modeling meets operations research, it is very interesting occasion. Our life and work are impossible without planning, time-tabling, scheduling, decision making, optimization, simulation, data analysis, risk analysis and process modeling. Thus, it is a part of management science or decision science. This comprehensive and timely publication aims to be an essential reference source, building on the available literature in the field of probabilistic modeling, operational research, planning and scheduling, data extrapolation in decision making, probabilistic interpolation and extrapolation in simulation, stochastic processes, and decision analysis. It is hoped that this text will provide the resources necessary for economics and management sciences, also for mathematics and computer sciences. Decision makers, academicians, researchers, advanced-level students, technology developers, and government officials will find this text useful in furthering their research exposure to pertinent topics in operations research and assisting in furthering their own research efforts in this field. Proposed method, called Probabilistic Features Combination (PFC), is the method of 2D curve interpolation and extrapolation using the set of key points (knots or nodes). Nodes can be treated as characteristic points of data for modeling and analyzing. The model of data can be built by choice of probability distribution function and nodes combination.

PFC modeling via nodes combination and parameter γ as probability distribution function enables value anticipation in risk analysis and decision making. Two-dimensional curve is extrapolated and interpolated via nodes combination and different functions as discrete or continuous probability distribution functions: polynomial, sine, cosine, tangent, cotangent, logarithm, exponent, arc sin, arc cos, arc tan, arc cot or power function.

BACKGROUND

An important problem in machine vision and computer vision (Ballard, 1982) is that of appropriate shape representation and reconstruction. Classical discussion about shape representation is based on the problem: contour versus skeleton. This chapter is voting for contour which forms boundary of the object. Contour of the object, represented by contour points, consists of information which allows us to describe many important features of the object as shape coefficients (Tadeusiewicz & Flasiński, 1991). In the chapter contour is dealing with a set of curves. Curve modeling and generation is a basic subject in many branches of industry and computer science, for example in the CAD/CAM software. The representation of shape has a great impact on the accuracy and effectiveness of object recognition (Saber, Yaowu & Murat Tekalp, 2005). In the literature, shape has been represented by many options including curves (Sebastian & Klein, 2003), graph-based algorithms and medial axis (Liu & Geiger, 1999) to enable shape-based object recognition. Digital curve (open or closed) can be represented by chain code (Freeman's code). Chain code depends on selection of the started point and transformations of the object. So Freeman's code is one of the method how to describe and to find contour of the object. An analog (continuous) version of Freeman's code is the curve α-*s*. Another contour representation and reconstruction is based on Fourier coefficients calculated in Discrete Fourier Transformation (DFT). These coefficients are used to fix similarity of the contours with different sizes or directions. If we assume that contour is built from segments of a line and fragments of circles or ellipses, Hough transformation is applied to detect contour lines. Also geometrical moments of the object are used during the process of object shape representation (Choraś, 2005).

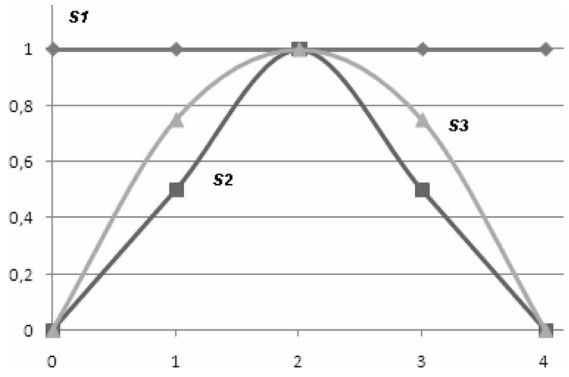
Nowadays methods apply mainly polynomial functions, for example Bernstein polynomials in Bezier curves, splines (Schumaker, 2007) and NURBS (Rogers, 2001). But Bezier curves don't represent the interpolation method and cannot be used for example in handwriting modeling with key points (interpolation nodes). In comparison PNC method with Bézier curves, Hermite curves and B-curves (*B-splines*) or NURBS one unpleasant feature of these curves has to be mentioned: small change of one characteristic point can result in unwanted change of whole reconstructed curve. Such a feature does not appear in proposed PNC method. Numerical methods for data interpolation are based on polynomial or trigonometric functions, for example Lagrange, Newton, Aitken and Hermite methods. These methods have many weak sides (Dahlquist & Bjoerck, 1974) and are not sufficient for curve interpolation in the situations when the curve cannot be build by polynomials or trigonometric functions. Also there exists several well established methods of curve modeling, for example shape-preserving techniques (Dejdumrong, 2007), subdivision algorithms (Dyn, Levin & Gregory, 1987) and others (Kozera, 2004) to overcome difficulties of polynomial interpolation, but probabilistic interpolation with nodes combination seems to be quite novel in the area of shape modeling. Proposed 2D curve interpolation is the functional modeling via any elementary functions and it helps us to fit the curve during the computations. The method of Probabilistic Nodes Combination (PNC) enables interpolation and modeling of two-dimensional curves using nodes combinations and different coefficients γ: polynomial, sinusoidal, cosinusoidal, tangent, cotangent, logarithmic, exponential, arc sin, arc cos, arc tan, arc cot or power function, also inverse functions. This probabilistic view is novel approach a problem of modeling and interpolation. Computer vision and pattern recognition are interested in appropriate methods of shape representation and curve modeling. PNC method represents the possibilities of shape reconstruction and curve interpolation via the choice of nodes combination and probability distribution function for interpolated points. It seems to be quite new look at the problem of contour representation and curve modeling in artificial intelligence

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

and computer vision. Function for γ calculations is chosen individually at each curve modeling and it is treated as probability distribution function: γ depends on initial requirements and curve specifications. PNC method leads to curve interpolation as handwriting modeling via discrete set of fixed knots. So PNC makes possible the combination of two important problems: interpolation and modeling. The method of Probabilistic Features Combination (PFC) enables interpolation and modeling of high-dimensional *N* data using features' combinations and different coefficients γ: polynomial, sinusoidal, cosinusoidal, tangent, cotangent, logarithmic, exponential, arc sin, arc cos, arc tan, arc cot or power function. Functions for γ calculations are chosen individually at each data modeling and it is treated as *N*-dimensional probability distribution function: γ depends on initial requirements and features' specifications. PFC method leads to data interpolation as handwriting or signature identification and image retrieval via discrete set of feature vectors in N-dimensional feature space. So PFC method makes possible the combination of two important problems: interpolation and modeling in a matter of image retrieval or writer identification. Main features of PFC method are: PFC interpolation develops a linear interpolation in multidimensional feature spaces into other functions as *N*-dimensional probability distribution functions; PFC is a generalization of MHR method and PNC method via different nodes combinations; interpolation of *L* points is connected with the computational cost of rank $O(L)$ as in MHR and PNC method; nodes combination and coefficients γ are crucial in the process of data probabilistic parameterization and interpolation: they are computed individually for a single feature. Proposed method, called Probabilistic Features Combination (PFC), is the method of *N*-dimensional data interpolation and extrapolation using the set of key points (knots or nodes). Nodes can be treated as characteristic points of data for modeling and analyzing. The model of data can be built by choice of probability distribution function and nodes combination. PFC modeling via nodes combination and parameter γ as probability distribution function enables value anticipation in risk analysis and decision making. *N*-dimensional object is extrapolated and interpolated via nodes combination and different functions as discrete or continuous probability distribution functions: polynomial, sine, cosine, tangent, cotangent, logarithm, exponent, arc sin, arc cos, arc tan, arc cot or power function.

PNC IN OBJECT RECOGNITION

This chapter consists of some examples with PNC applications in Artificial Intelligence (Zhang & Lu, 2004). First example is dealing with PNC method in MHR version.



Object Recognition via Contour Reconstruction

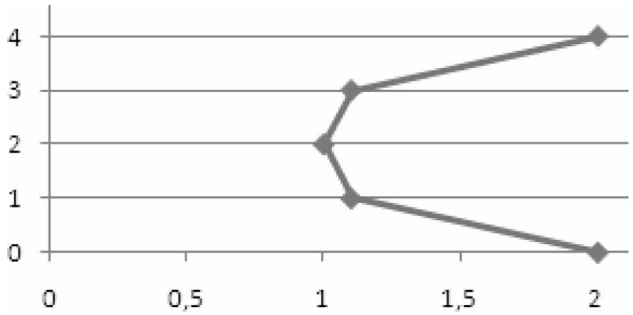
The Example: Models

Assume that one part of *OBJECT1* contour is described by the set of points $\boldsymbol{S}_1 = \{(x_0, y_0^{(1)}), (x_1, y_1^{(1)}), \ldots, (x_M, y_M^{(1)})\}$ for $x_j < x_{j+1}$. Also one part of *OBJECT2* contour is described by the set of points $\boldsymbol{S}_2 = \{(x_0, y_0^{(2)}), (x_1, y_1^{(2)}), \ldots, (x_M, y_M^{(2)})\}$. Additionally exists $k = 0,1,..., M$ that $y_k^{(1)} = y_k^{(2)}$ (at least one common point of models). These sets of nodes $\boldsymbol{S}_1$ and $\boldsymbol{S}_2$ are models of contour fragment for *OBJECT1* and *OBJECT2*. For example $M = 4$: $\boldsymbol{S}_1 = \{(0;1), (1;1), (2;1), (3;1), (4;1)\}$ and $\boldsymbol{S}_2 = \{(0;0), (1;0.5), (2;1), (3;0.5), (4;0)\}$. Of course it is possible to deal with more models $\boldsymbol{S}_i$: let there is given the set $\boldsymbol{S}_3 = \{(0;0), (1;0.75), (2;1), (3;0.75), (4;0)\}$ for *OBJECT3*.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. The sets of nodes S_1, S_2, S_3 and contour fragments of three objects

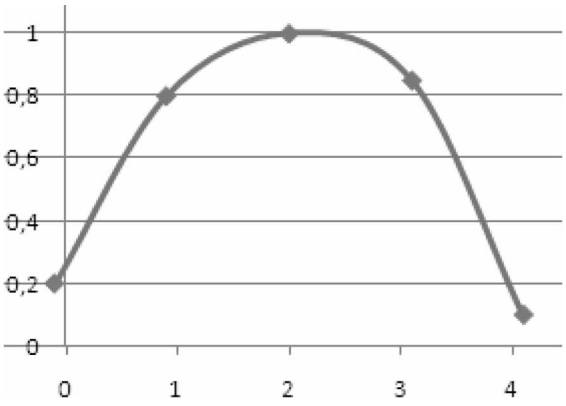
The nodes from Figure 1 are monotonic in coordinates x_i. MHR method is also working with nodes monotonic in coordinates y_i. For example here are three other models of three other objects: $\boldsymbol{S_1}'$={(1;0), (1;1), (1;2), (1;3), (1;4)}, $\boldsymbol{S_2}'$ = {(3;0), (2;1), (1;2), (2;3), (3;4)}, $\boldsymbol{S_3}'$ = {(2;0), (1.1;1), (1;2), (1.1;3), (2;4)}.



Five nodes is the minimum number for MHR method to find points between the nodes. Curves of the contour are smooth (Figure 1) or not smooth (Figure 2). The number of nodes influences precise reconstruction of the curve.

Detection

The unknown object (one part of its contour) is described by detected interpolation nodes according to MHR method: $\boldsymbol{S} = \{(x_0',y_0'), (x_1',y_1'),\ldots, (x_m',y_m')\}$ for $x_j' < x'_{j+1}$. Also assume: exists $i = 0, 1, ..., m$ that $(x_i',y_i')\in \boldsymbol{S_1}$, $(x_i',y_i')\in \boldsymbol{S_2}$ (common point of models and recognized object) and $x_0' \le x_0$, $x_m' \ge x_M$ because of using all nodes of $\boldsymbol{S_1}$ and $\boldsymbol{S_2}$ to recognition. Another part of the contour could be described by detected interpolation nodes monotonic in coordinates y_i: $\boldsymbol{S}' = \{(\underline{x}_0',\underline{y}_0'), (\underline{x}_1',\underline{y}_1'),\ldots, (\underline{x}_l',\underline{y}_l')\}$ for $\underline{y}_j' < \underline{y}'_{j+1}$. Number of models $\boldsymbol{S_i}$ is determined for $i = 1, 2, 3, 4...$ Let there is given the set $\boldsymbol{S}$= {(-0.1;0.2), (0.9;0.8), (2;1), (3.1;0.85), (4.1;0.1)} for unknown object.



How the unknown object from Figure 3 can be recognized as *OBJECT1*, *OBJECT2* or *OBJECT3* from Figure 1?

Figure 2. The set of nodes S_3' and contour fragment of the object

Figure 3. The set of nodes S and contour fragment of unknown object

Recognition

Contour points of unknown object have to be calculated by MHR method: (x_0,y_0), (x_1,y_1),…, (x_M,y_M). The criterion of object recognition for models $\boldsymbol{S}_j$, $j = 1,2,3\ldots$ is:

$$\sum_{i=0}^{M}\left|y_i - y_i^{(j)}\right| \to \min .$$

How does this criterion work for models $\boldsymbol{S}_1$, $\boldsymbol{S}_2$, $\boldsymbol{S}_3$ and for the set of contour points $\boldsymbol{S}$? According to characteristic points (x_i,y_i) of unknown object from Figure 3 have to be computed for $x_i = 0, 1, 3, 4$. MHR calculations are done as follows:

1. For nodes (-0.1;0.2), (2;1) OHR operator (1)

$$M_0 = \begin{bmatrix} 0.494 & 0.125 \\ -0.125 & 0.494 \end{bmatrix},$$

for nodes (0.9;0.8), (3.1;0.85) OHR operator

$$M_1 = \begin{bmatrix} 0.322 & 0.165 \\ -0.165 & 0.322 \end{bmatrix},$$

for $c_1 = 0$:

$$\alpha = \frac{0.9 - 0}{0.9 - (-0.1)} = 0.9 ,$$

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

$c_2 = \alpha\bullet 2 + (1-\alpha)\bullet 3.1 = 2.11,$

$$M_2 = \alpha \cdot M_0 + (1-\alpha)\cdot M_1 = \begin{bmatrix} 0.477 & 0.129 \\ -0.129 & 0.477 \end{bmatrix},$$

$$M_2 \cdot \begin{bmatrix} 0 \\ 2.11 \end{bmatrix} = \begin{bmatrix} 0.272 \\ 1.006 \end{bmatrix},$$

for $c_2 = 3$:

$$\alpha = \frac{3.1-3}{3.1-2} = 0.091,$$

$c_1 = \alpha\bullet(-0.1) + (1-\alpha)\bullet 0.9 = 0.809,$

$$M_2 = \alpha \cdot M_0 + (1-\alpha)\cdot M_1 = \begin{bmatrix} 0.338 & 0.161 \\ -0.161 & 0.338 \end{bmatrix},$$

$$M_2 \cdot \begin{bmatrix} 0.809 \\ 3 \end{bmatrix} = \begin{bmatrix} 0.756 \\ 0.883 \end{bmatrix};$$

2. For nodes (0.9;0.8), (3.1;0.85) OHR operator

$$M_0 = \begin{bmatrix} 0.322 & 0.165 \\ -0.165 & 0.322 \end{bmatrix},$$

for nodes (2;1), (4.1;0.1) OHR operator

$$M_1 = \begin{bmatrix} 0.116 & 0.187 \\ -0.187 & 0.116 \end{bmatrix},$$

for $c_1 = 1$:

$$\alpha = \frac{2-1}{2-0.9} = 0.909,$$

$c_2 = \alpha\bullet 3.1 + (1-\alpha)\bullet 4.1 = 3.191,$

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

$$M_2 = \alpha \cdot M_0 + (1-\alpha) \cdot M_1 = \begin{bmatrix} 0.303 & 0.167 \\ -0.167 & 0.303 \end{bmatrix},$$

$$M_2 \cdot \begin{bmatrix} 1 \\ 3.191 \end{bmatrix} = \begin{bmatrix} 0.835 \\ 0.801 \end{bmatrix},$$

for $c_2 = 4$:

$$\alpha = \frac{4.1-4}{4.1-3.1} = 0.1\,,$$

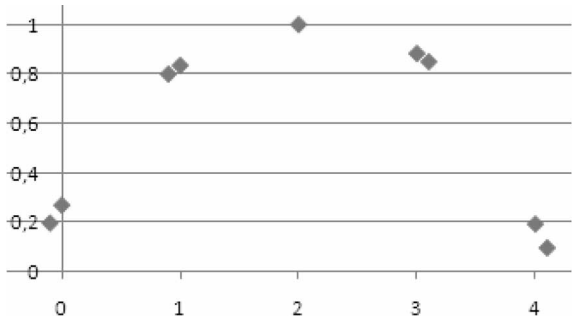
$c_1 = \alpha \bullet 0.9 + (1-\alpha) \bullet 2 = 1.89,$

$$M_2 = \alpha \cdot M_0 + (1-\alpha) \cdot M_1 = \begin{bmatrix} 0.136 & 0.185 \\ -0.185 & 0.136 \end{bmatrix},$$

$$M_2 \cdot \begin{bmatrix} 1.89 \\ 4 \end{bmatrix} = \begin{bmatrix} 0.998 \\ 0.196 \end{bmatrix}.$$

So here are computed points to use in criterion: (0;0.272), (1;0.835), (3;0.883), (4;0.196).
The criterion gives the results:

1. For *OBJECT1* and set $\boldsymbol{S_1}$: $\sum_{i=0}^{4} \left| y_i - y_i^{(1)} \right| = 1.814$;
2. For *OBJECT2* and set $\boldsymbol{S_2}$: $\sum_{i=0}^{4} \left| y_i - y_i^{(2)} \right| = 1.186$;
3. For *OBJECT3* and set $\boldsymbol{S_3}$: $\sum_{i=0}^{4} \left| y_i - y_i^{(3)} \right| = 0.686$ = minimum.



It means that unknown object from Figure 3 with the set of nodes $\boldsymbol{S}$ is recognized as *OBJECT3* from Figure 3 with the model $\boldsymbol{S_3}$.

Discussion of the Example

This example is very simple and this chapter goes to first step of application MHR method in object recognition (Ballard, 1982). Models of known objects possess special features: appropriate contour points with characteristic (identical) one coordinate. Also unknown object must have the same one coordinate. And geometrical transformations ought to be considered (translations, rotations, scaling): if unknown object is transformed, then models of the object (points) have to be also transformed and then MHR recognition is possible.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

OFFLINE TEXT-INEPENDENT HANDWRITING IDENTIFICATION AND SHAPE MODELING VIA PROBABILISTIC NODES COMBINATION

Handwriting identification and writer verification are still the open questions in artificial intelligence (Choraś, 2005) and computer vision (Tadeusiewicz & Flasiński, 1991). Handwriting based author recognition offers a huge number of significant implementations which make it an important research area in pattern recognition (Lorton, Fouladirad & Grall, 2013). There are so many possibilities and applications of the recognition algorithms that implemented methods have to be concerned on a single problem. Handwriting and signature identification represents such a significant problem. In the case of writer recognition, described in this chapter, each person is represented by the set of modeled letters or symbols. The sketch of proposed method consists of three steps: first handwritten letter or symbol must be modeled by a curve (Sebastian & Klein, 2003), then compared with unknown letter and finally there is a decision of identification (Liu & Geiger, 1999). Author recognition of handwriting and signature is based on the choice of key points and curve modeling. Reconstructed curve does not have to be smooth in the nodes because a writer does not think about smoothing during the handwriting. Curve interpolation in handwriting identification is not only a pure mathematical problem but important task in pattern recognition and artificial intelligence (Saber, Yaowu & Murat Tekalp, 2005) such as: biometric recognition (Pergler & Freeman, 2008), personalized handwriting recognition, automatic forensic document examination, classification of ancient manuscripts. Also writer recognition in monolingual handwritten texts is an extensive area of study and the methods independent from the language are well-seen. Proposed method represents language-independent and text-independent approach because it identifies the author via a single letter or symbol from the sample. This novel method is also applicable to short handwritten text.

Writer recognition methods in the recent years are going to various directions: writer recognition using multi-script handwritten texts, introduction of new features, combining different types of features, studying the sensitivity of character size on writer identification, investigating writer identification in multi-script environments, impact of ruling lines on writer identification, model perturbed handwriting, methods based on run-length features, the edge-direction and edge-hinge features, a combination of codebook and visual features extracted from chain code and polygonized representation of contours, the autoregressive coefficients, codebook and efficient code extraction methods, texture analysis with Gabor filters and extracting features, using Hidden Markov Model (Cocozza-Thivent, Eymard, Mercier & Roussignol, 2006) or Gaussian Mixture Model. But no method is dealing with writer identification via curve modeling (Dyn, Levin & Gregory, 1987) or interpolation (Kozera, 2004) and points comparing as it is presented in this chapter.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Handwriting Modeling and Author Identification

PNC method enables signature and handwriting recognition. This process of recognition consists of three parts:

1. **Modeling:** Choice of nodes combination and probabilistic distribution function for known signature or handwritten letters;
2. **Unknown Writer:** Choice of characteristic points (nodes) for unknown signature or handwritten word and the coefficients of points between nodes;
3. **Decision of Recognition:** Comparing the results of PNC interpolation for known models with coordinates of unknown text.

Modeling: The Basis of Patterns

Known letters or symbols ought to be modeled by the choice of nodes, determining specific nodes combination and characteristic probabilistic distribution function. For example a handwritten word or signature "*rw*" may look different for persons A, B or others (Dejdumrong, 2007). How to model "*rw*" for some persons via PNC method? Each model has to be described by the set of nodes for letters "*r*" and "*w*", nodes combination h and a function $\gamma=F(\alpha)$ for each letter. Less complicated models can take $h(p_1,p_2,\ldots,p_m) = 0$ and then the formula of interpolation looks as follows:

$$y(c) = \gamma \bullet y_i + (1 - \gamma) y_{i+1}.$$

It is linear interpolation for basic probability distribution ($\gamma = \alpha$). How first letter "*r*" is modeled in three versions for nodes combination $h = 0$ and α=0.1,0.2…0.9? Of course α is a random variable and $\alpha \in [0;1]$.

Person A: Nodes (1;3), (3;1), (5;3), (7;3) and $\gamma = F(\alpha) = \alpha^2$ (see Figure 5).
Person B: Nodes (1;3), (3;1), (5;3), (7;2) and $\gamma = F(\alpha) = \alpha^2$: (see Figure 6)
Person C: Nodes (1;3), (3;1), (5;3), (7;4) and $\gamma = F(\alpha) = \alpha^3$: (see Figure 7)

These three versions of letter "*r*" (Figures 5-7) with nodes combination $h = 0$ differ at fourth node and probability distribution functions $\gamma = F(\alpha)$. Much more possibilities of modeling are connected with a choice of nodes combination $h(p_1,p_2,\ldots,p_m)$. MHR method (Jakóbczak, 2007) uses the combination h with good features because of orthogonal rows and columns at Hurwitz-Radon family of matrices (Jakóbczak, 2010):

$$h(p_i, p_{i+1}) = \frac{y_i}{x_i} x_{i+1} + \frac{y_{i+1}}{x_{i+1}} x_i$$

and then

$$y(c) = \gamma \cdot y_i + (1 - \gamma) y_{i+1} + \gamma(1 - \gamma) \cdot h(p_i, p_{i+1},).$$

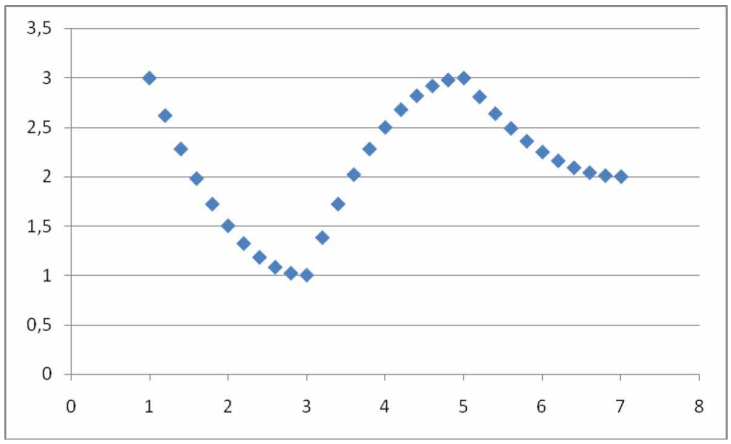

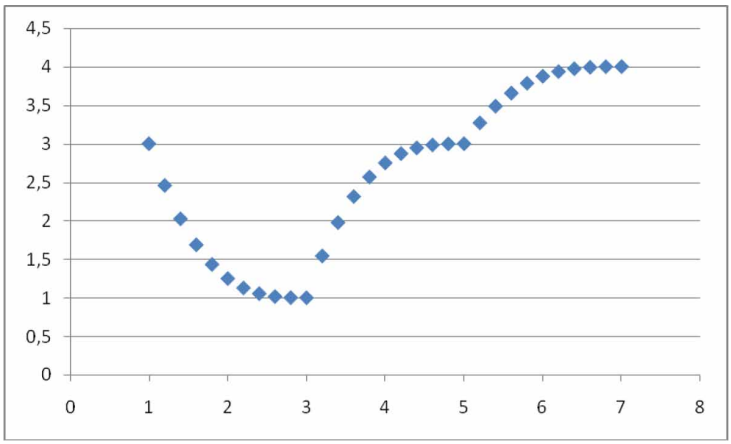

Figure 7. PNC modeling of handwritten letter "r"

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

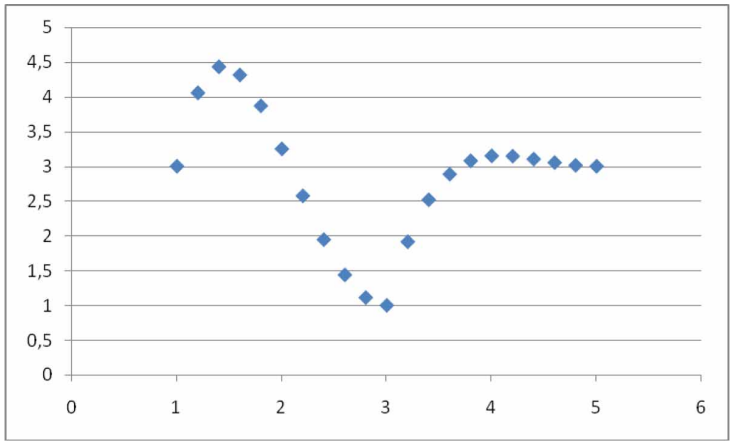
Here are two examples of PNC modeling (Jakóbczak, 2011) with MHR combination.

Person D: Nodes (1;3), (3;1), (5;3) and $\gamma = F(\alpha) = \alpha^2$: (see Figure 8)
Person E: Nodes (1;3), (3;1), (5;3) and $\gamma = F(\alpha) = \alpha^{1.5}$: (see Figure 9)

Figures 5- 9 show modeling of letter "*r*". Now let us consider a letter "*w*" with nodes combination $h = 0$.

Person A: Nodes (2;2), (3;1), (4;2), (5;1), (6;2) and $\gamma = F(\alpha) = (5^{\alpha}-1)/4$: (see Figure 10)
Person B: Nodes (2;2), (3;1), (4;2), (5;1), (6;2) and $\gamma = F(\alpha) = sin(\alpha \cdot \pi/2)$: (see Figure 11)
Person C: Nodes (2;2), (3;1), (4;2), (5;1), (6;2) and $\gamma = F(\alpha) = sin^{3.5}(\alpha \cdot \pi/2)$: (see Figure 12)

Figure 8. PNC modeling of letter "r" with three nodes



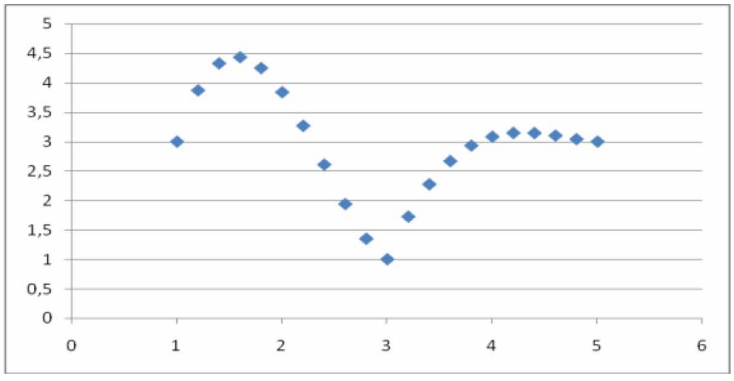


Figure 9. PNC modeling of handwritten letter "r"

Figure 10. PNC modeling for nine reconstructed points between nodes

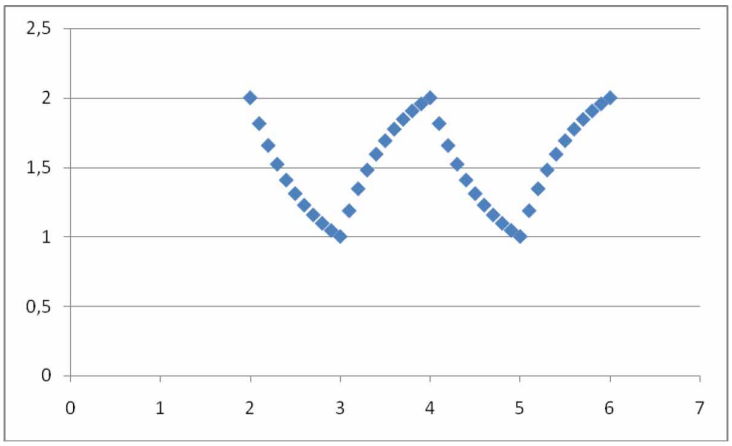

Figure 11. PNC modeling of letter "w" with five nodes

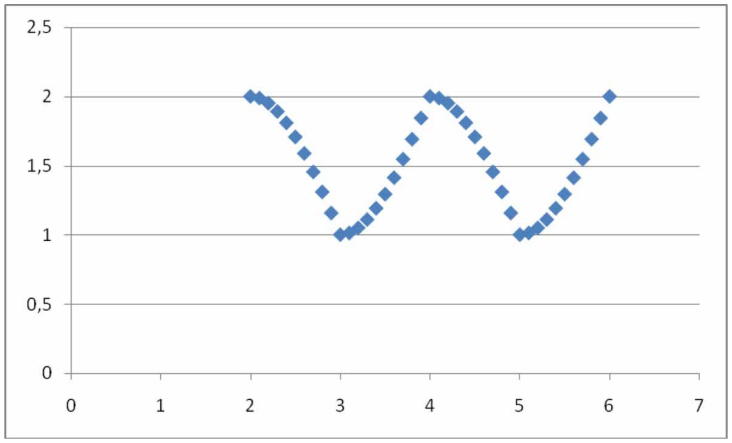

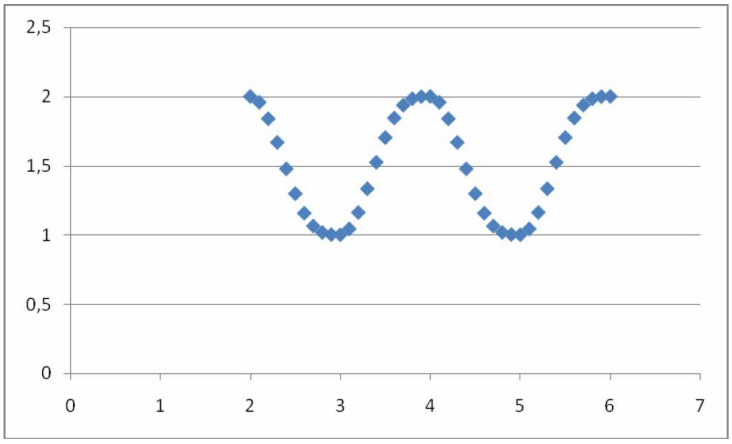

Figure 12. PNC modeling of handwritten letter "w"

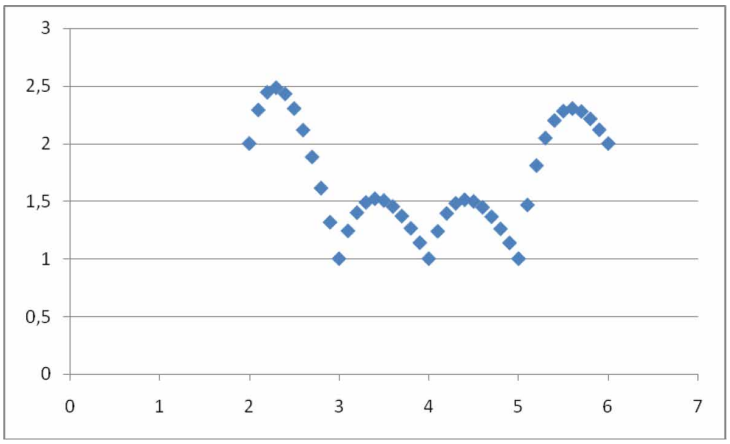
EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

These three versions of letter "*w*" (Figure 10-12) with nodes combination $h = 0$ and the same nodes differ only at probability distribution functions $\gamma = F(\alpha)$. Figure 13 is the example of nodes combination h formula from MHR method.



Person D: Nodes (2;2), (3;1), (4;1), (5;1), (6;2) and $\gamma = F(\alpha) = 2^{\alpha}$-1: (see Figure 13)

Examples above have one function $\gamma = F(\alpha)$ and one combination h for all ranges between nodes. But it is possible to create a model with functions $\gamma_i = F_i(\alpha)$ and combinations h_i individually for a range of nodes $(p_i;p_{i+1})$. It enables very precise modeling of handwritten symbol between each successive pair of nodes. Each person has its own characteristic and individual handwritten letters, numbers or other marks. The range of coefficients x has to be the same for all models because of comparing appropriate coordinates y. Every letter is modeled by PNC via three factors: the set of nodes, probability distribution function $\gamma = F(\alpha)$ and nodes combination h. These three factors are chosen individually for each letter, therefore this information about modeled letters seems to be enough for specific PNC curve interpolation, comparing and handwriting identification. Function γ is selected via the analysis of points between nodes and we may assume $h = 0$ at the beginning. What is very important-PNC modeling is independent of the language or a kind of symbol (letters, numbers or others). One person may have several patterns for one handwritten letter. Summarize: every person has the basis of patterns for each handwritten letter or symbol, described by the set of nodes, probability distribution function $\gamma = F(\alpha)$ and nodes combination h. Whole basis of patterns consists of models $\boldsymbol{S}_j$ for $j = 0,1,2,3\ldots K$.

Unknown Writer: Points of Handwritten Symbol

Choice of characteristic points (nodes) for unknown letter or handwritten symbol is a crucial factor in object recognition. The range of coefficients x has to be the same like the x range in the basis of patterns. Knots of the curve (opened or closed) ought to be settled at key points (Schumaker, 2007), for example local minimum or maximum (the highest point of the curve in a particular orientation), convexity changing or curvature maximum and at least one node between two successive key points (Rogers, 2001). When

Figure 13. PNC modeling for nine reconstructed points between nodes

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

the nodes are fixed, each coordinate of every chosen point on the curve (x_0^c,y_0^c), $(x_1^c,y_1^c),\ldots,(x_M^c,y_M^c)$ is accessible to be used for comparing with the models. Then probability distribution function $\gamma = F(\alpha)$ and nodes combination h have to be taken from the basis of modeled letters to calculate appropriate second coordinates $y_i^{(j)}$ of the pattern $\boldsymbol{S}_j$ for first coordinates x_i^c, $i = 0,1,\ldots,M$.

Figures 14-16 present a reconstructed signature or a handwritten symbol of unknown writer for 17 nodes (red dots). These three interpolations (Figure 14-16) are calculated for PNC method in MHR version where probability distribution function is $\gamma = F(\alpha) = \alpha^2$. Figure 14 is computed for Hurwitz-Radon matrices of dimension $N = 2$ (MHR-2) and nodes combination h with four ($2N$) points:

$$h(p_1,p_2,p_3,p_4) = \frac{1}{x_1^{\,2}+x_3^{\,2}}(x_1x_2y_1 + x_2x_3y_3 + x_3x_4y_1 - x_1x_4y_3) + \frac{1}{x_2^{\,2}+x_4^{\,2}}(x_1x_2y_2 + x_1x_4y_4 + x_3x_4y_2 - x_2x_3y_4)$$

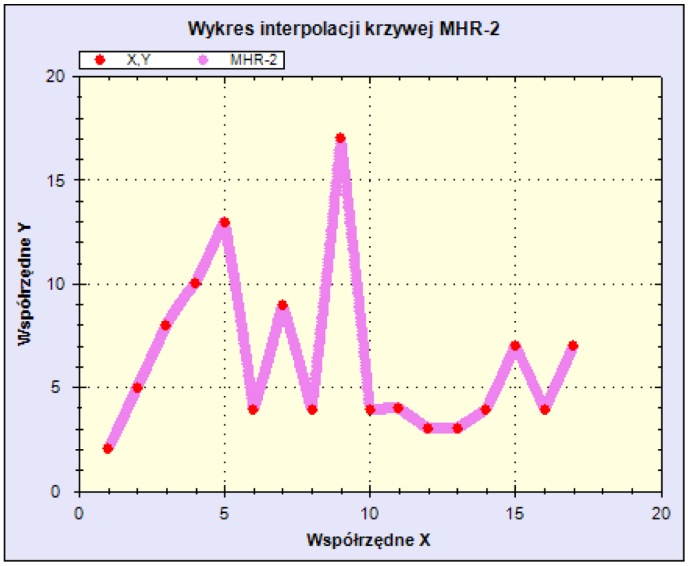


Figure 15 is reconstructed for unknown author with $h(p_1,p_2,\ldots,p_8)$ build similarly for Hurwitz-Radon matrices of dimension $N = 4$ (MHR-4) and eight ($2N$) successive nodes.

Figure 16 is reconstructed with $h(p_1,p_2,\ldots,p_{16})$ build similarly for Hurwitz-Radon matrices of dimension N=8 (MHR-8) and sixteen ($2N$) successive nodes.

Figure 17 represents the comparison of three curves from Figures 14-16. There are minimal differences between MHR-2, MHR-4 and MHR-8 because of orthogonal Hurwitz-Radon matrices. Important feature of MHR and then PNC method is the stability of calculations.

Figures 18-20 consist of Lagrange (Ralston & Rabinowitz, 2001) classical polynomial interpolations (Collins, 2003) for the same 17 nodes as Figures 14-17. Figure 18 represents four splined polynomials (Chapra, 2012) of degree 4, each polynomial is built for five successive nodes.

Figure 14. MHR-2 curve modeling for 99 reconstructed points between nodes

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 15. MHR-4 interpolation with 99 reconstructed points between nodes

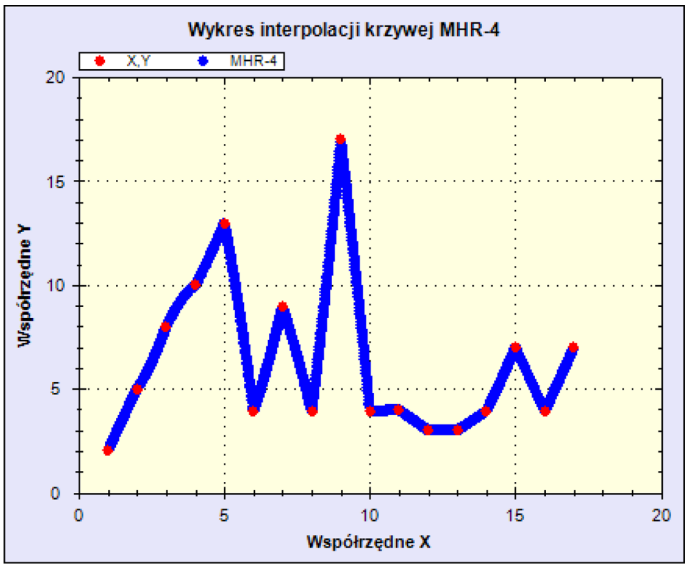

Figure 16. MHR-8 method for 99 reconstructed points between nodes

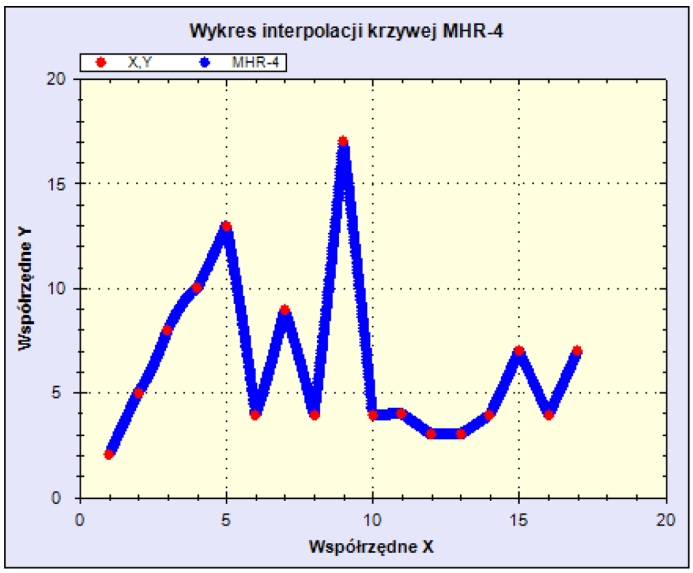

Figure 19 represents two splined polynomials of degree 8, each polynomial is built for nine successive nodes.

Figure 20 represents the polynomial of degree 16, which is built for all 17 nodes.

Polynomials of high degree (more then 4) are often useless because of some bad features (Dahlquist & Bjoerck, 1974): roots (zeros), Runge phenomenon and others. PNC modeling is more accurate then polynomial or spline interpolations. After interpolation it is possible to compare given handwritten symbol with a letter in the basis of patterns.

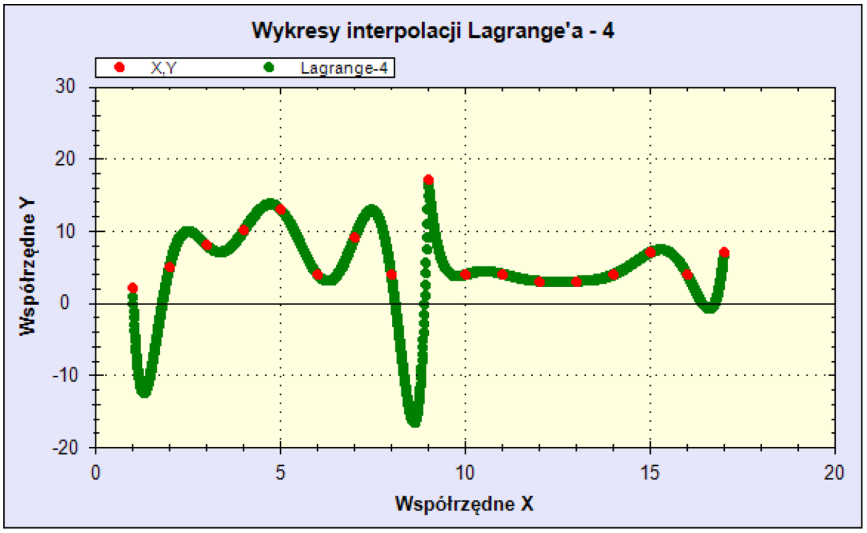
Decision of Recognition: The Author

Comparing the results of PNC interpolation for required second coordinates of a model in the basis of patterns with points on the curve (x_0^c,y_0^c), (x_1^c,y_1^c),…, (x_M^c,y_M^c), we can say if the letter or symbol is written by person A, B or another. The comparison and decision of recognition is done via minimal distance criterion. Curve points of unknown handwritten symbol are: (x_0^c,y_0^c), (x_1^c,y_1^c),…, (x_M^c,y_M^c). The criterion of recognition for models $\boldsymbol{S}_j = \{(x_0^c,y_0^{(j)}), (x_1^c,y_1^{(j)}),\ldots, (x_M^c,y_M^{(j)})\}$, j=0,1,2,3…K is given as:

$$\sum_{i=0}^{M}\left|y_i^{\,c} - y_i^{\,(j)}\right| \to \min .$$

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 19. Two splined interpolation polynomials of degree 8



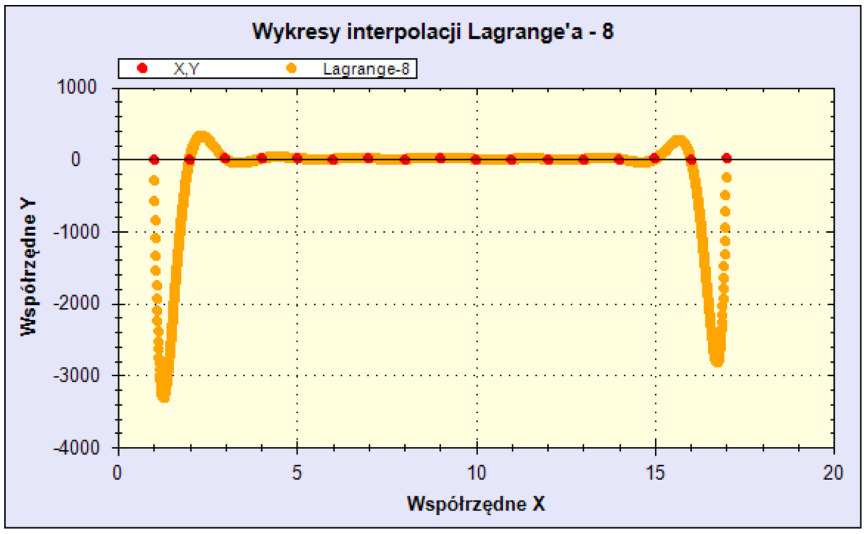


Figure 20. Interpolation polynomial of degree 16

Figures 21 and 22 show how the criterion is used for $M = 1600$ (number of reconstructed points together with nodes in Figure 14-16 is 1601) and $j = 0{,}1$ (an easy example with two persons S_0 and S_1 in the basis of patterns). Figure 21 with the model S_0 presents less differences between graphs (or between coordinates) then Figure 22 with the model S_1. So using two persons from the basis of patterns, our unknown writer (pink curve) is recognized as the pattern S_0 from Figure 21 (orange curve).

Minimal distance criterion helps us to fix a candidate for unknown writer as a person from the model $\boldsymbol{S_0}$.

SOLUTIONS AND RECOMMENDATIONS

Proposed method, called Probabilistic Features Combination (PFC), is the method of 2D curve interpolation and extrapolation using the set of key points (knots or nodes). Nodes can be treated as characteristic points of data for modeling and analyzing. The model of data can be built by choice of probability distribution function and nodes combination. PFC modeling via nodes combination and parameter γ as probability distribution function enables value anticipation in risk analysis and decision making. Two-

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

dimensional curve is extrapolated and interpolated via nodes combination and different functions as discrete or continuous probability distribution functions: polynomial, sine, cosine, tangent, cotangent, logarithm, exponent, arc sin, arc cos, arc tan, arc cot or power function.

FUTURE RESEARCH DIRECTIONS

Future trends will go to various directions: how to fix the best probability distribution function for the nodes, how to calculate the most appropriate nodes combination and what extrapolation is the most valuable in decision making and risk analysis.

FINAL CONCLUSION

Providing relevant and current research, this book and its author'individual publications would be useful for academics, researchers, scholars, and practitioners interested in improving decision making models and business functions. Probabilistic modeling represents a subject arising in many branches of mathematics, economics and computer science. Such modeling connects pure mathematics with applied sciences. Operations research similarly is situated on the border between pure mathematics and applied sciences. So when probabilistic modeling meets operations research, it is very interesting occasion. Our life and work are impossible without planning, time-tabling, scheduling, decision making, optimization, simulation, data analysis, risk analysis and process modeling. Thus, it is a part of management science or decision science. This book looks to discuss and address the difficulties and challenges that occur during the process of planning or decision making. The editors have found the chapters that address different aspects of probabilistic modeling, stochastic methods, probabilistic distributions, data analysis, optimization methods, probabilistic methods in risk analysis, and related topics. Additionally, the book explores the impact of such probabilistic modeling with other approaches.

This comprehensive and timely publication aims to be an essential reference source, building on the available literature in the field of probabilistic modeling, operational research, planning and scheduling, data extrapolation in decision making, probabilistic interpolation and extrapolation in simulation, stochastic processes, and decision analysis. It is hoped that this text will provide the resources necessary for economics and management sciences, also for mathematics and computer sciences. Decision makers, academicians, researchers, advanced-level students, technology developers, and government officials will find this text useful in furthering their research exposure to pertinent topics in operations research and assisting in furthering their own research efforts in this field. Proposed method, called Probabilistic Features Combination (PFC), is the method of 2D curve interpolation and extrapolation using the set of key points (knots or nodes). Nodes can be treated as characteristic points of data for modeling and analyzing. The model of data can be built by choice of probability distribution function and nodes combination. PFC modeling via nodes combination and parameter γ as probability distribution function enables value anticipation in risk analysis and decision making. Two-dimensional curve is extrapolated and interpolated via nodes combination and different functions as discrete or continuous probability distribution functions: polynomial, sine, cosine, tangent, cotangent, logarithm, exponent, arc sin, arc cos, arc tan, arc cot or power function.

Risk analysis needs suitable methods of data extrapolation and decision making. Proposed method of Hurwitz-Radon Matrices (MHR) can be used in extrapolation and interpolation of curves in the plane. For example quotations from the Stock Exchange, the market prices or rate of a currency form a curve. This chapter contains the way of data anticipation and extrapolation via MHR method and decision making: to buy or not, to sell or not. Proposed method is based on a family of Hurwitz-Radon (HR) matrices. The matrices are skew-symmetric and possess columns composed of orthogonal vectors. The operator of Hurwitz-Radon (OHR), built from these matrices, is described. Two-dimensional data are represented by the set of curve points. It is shown how to create the orthogonal and discrete OHR and how to use it in a process of data foreseeing and extrapolation. MHR method is interpolating and extrapolating the curve point by point without using any formula or function.

Proposed method, called Probabilistic Nodes Combination (PNC), is the method of 2D curve interpolation and extrapolation using the set of key points (knots or nodes). Nodes can be treated as characteristic points of data for modeling and analyzing. The model of data can be built by choice of probability distribution function and nodes combination. PNC modeling via nodes combination and parameter γ as probability distribution function enables value anticipation in risk analysis and decision making. Two-dimensional curve is extrapolated and interpolated via nodes combination and different functions as discrete or continuous probability distribution functions: polynomial, sine, cosine, tangent, cotangent, logarithm, exponent, arc sin, arc cos, arc tan, arc cot or power function. Novelty of this book consists of two generalizations: generalization of previous MHR method with various nodes combinations and generalization of linear interpolation with different (no basic) probability distribution functions and nodes combinations. Computer vision needs suitable methods of shape representation and contour reconstruction. One of them, invented by the author and called method of Hurwitz-Radon Matrices (MHR), can be used in representation and reconstruction of shapes of the objects in the plane. Proposed method is based on a family of Hurwitz-Radon (HR) matrices. The matrices are skew-symmetric and possess columns composed of orthogonal vectors. 2D shape is represented by the set of successive nodes. It is shown how to create the orthogonal and discrete OHR operator and how to use it in a process of shape representation and reconstruction. Then MHR method is generalized to Probabilistic Nodes Combination (PNC) method.

This work clarifies the significance and novelty of the proposed method compared to existing methods (for example polynomial interpolations and Bézier curves). Previous published papers of the author were dealing with the method of Hurwitz-Radon Matrices (MHR method). Novelty of this monograph and proposed method consists in the fact that calculations are free from the family of Hurwitz-Radon Matrices. Problem statement of this book is: how to reconstruct (interpolate) missing points of 2D curve having the set of interpolation nodes (key points) and using the information about probabilistic distribution of unknown points. For example the simplest basic distribution leads to the easiest interpolation – linear interpolation. Apart from probability distribution, additionally there is the second factor of proposed interpolation method: nodes combination. The simplest nodes combination is zero. Thus proposed curve modeling is based on two agents: probability distribution and nodes combination. Significance of this chapter consists in generalization for MHR method: the computations are done without matrices in curve fitting and shape modeling, with clear point interpolation formula based on probability distribution function (continuous or discrete) and nodes combination. This book also consists of generalization for linear interpolation with different (no basic) probability distribution functions and nodes combinations. So this chapter answers the question: “Why and when should we use PNC method?”.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Curve interpolation represents one of the most important problems in mathematics and computer science: how to model the curve via discrete set of two-dimensional points? Also the matter of shape representation (as closed curve-contour) and curve parameterization is still opened. For example pattern recognition, signature verification or handwriting identification problems are based on curve modeling via the choice of key points. So interpolation is not only a pure mathematical problem but important task in computer vision and artificial intelligence. The book wants to approach a problem of curve modeling by characteristic points. Proposed method relies on nodes combination and functional modeling of curve points situated between the basic set of key points. The functions that are used in calculations represent whole family of elementary functions with inverse functions: polynomials, trigonometric, cyclometric, logarithmic, exponential and power function. These functions are treated as probability distribution functions in the range [0;1]. Significant problem in machine vision and computer vision is that of appropriate 2D shape representation and reconstruction. Classical discussion about shape representation is based on the problem: contour versus skeleton. This monograph is voting for contour which forms boundary of the object. Contour of the object, represented by successive contour points, consists of information which allows us to describe many important features of the object as shape coefficients. 2D curve modeling and generation is a basic subject in many branches of industry and computer science, for example in the cad/cam software. The representation of shape can have a great impact on the accuracy and effectiveness of object recognition. In the literature, shape has been represented by many options including curves, graph-based algorithms and medial axis to enable shape-based object recognition. Digital 2D curve (open or closed) can be represented by chain code (Freeman's code). Chain code depends on selection of the started point and transformations of the object. So Freeman's code is one of the method how to describe and to find contour of the object. Analog (continuous) version of Freeman's code is the curve α-*s*. Another contour representation and reconstruction is based on Fourier coefficients calculated in discrete Fourier transformation (DFT). These coefficients are used to fix similarity of the contours with different sizes or directions. If we assume that contour is built from segments of a line and fragments of circles or ellipses, hough transformation is applied to detect contour lines. Also geometrical moments of the object are used during the process of object shape representation. Contour is also applied in shape decomposition. Many branches of medicine, industry and manufacturing are looking for methods connected with geometry of the contour.

Why and when should we use MHR and PNC methods? Interpolation methods and curve fitting represent so huge problem that each individual interpolation is exceptional and requires specific solutions. PNC method is such a novel tool with its all pros and cons. The user has to decide which interpolation method is the best in a single situation. The choice is yours if you have any choice. Presented method is such a new possibility for curve fitting and interpolation when specific data (for example handwritten symbol or character) starts up with no rules for polynomial interpolation. This chapter consists of two generalizations: generalization of previous MHR method with various nodes combinations and generalization of linear interpolation with different (no basic) probability distribution functions and nodes combinations. The method of Probabilistic Nodes Combination (PNC) enables interpolation and modeling of two-dimensional curves using nodes combinations and different coefficients γ: polynomial, sinusoidal, cosinusoidal, tangent, cotangent, logarithmic, exponential, arc sin, arc cos, arc tan, arc cot or power function, also inverse functions. This probabilistic view is novel approach a problem of modeling and interpolation. Computer vision and pattern recognition are interested in appropriate methods of shape representation and curve modeling. PNC method represents the possibilities of shape reconstruction and curve interpolation via the choice of nodes combination and probability distribution function

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

for interpolated points. It seems to be quite new look at the problem of contour representation and curve modeling in artificial intelligence and computer vision.

Function for γ calculations is chosen individually at each curve modeling and it is treated as probability distribution function: γ depends on initial requirements and curve specifications. PNC method leads to curve interpolation as handwriting modeling via discrete set of fixed knots. So PNC makes possible the combination of two important problems: interpolation and modeling. Main features of PNC method are:

1. The smaller distance between knots the better;
2. Calculations for coordinates close to zero and near by extremum require more attention because of importance of these points;
3. PNC interpolation develops a linear interpolation into other functions as probability distribution functions;
4. PNC is a generalization of MHR method via different nodes combinations;
5. Interpolation of L points is connected with the computational cost of rank $O(L)$ as in MHR method;
6. Nodes combination and coefficient γ are crucial in the process of curve probabilistic parameterization and interpolation: they are computed individually for a single curve.

What is the most important feature of MHR and PNC methods? Interpolation methods and curve fitting represent so huge problem that each individual interpolation is exceptional and requires specific solutions. PNC method is such a novel tool with its all pros and cons. The user has to decide which interpolation method is the best in a single situation. The choice is yours if you have any choice. Presented method is such a new possibility for curve fitting and interpolation when specific data (for example handwritten symbol or character) starts up with no rules for polynomial interpolation. This chapter consists of two generalizations: generalization of previous MHR method with various nodes combinations and generalization of linear interpolation with different (no basic) probability distribution functions and nodes combinations. The method of Probabilistic Nodes Combination (PNC) enables interpolation and modeling of two-dimensional curves using nodes combinations and different coefficients γ: polynomial, sinusoidal, cosinusoidal, tangent, cotangent, logarithmic, exponential, arc sin, arc cos, arc tan, arc cot or power function, also inverse functions. This probabilistic view is novel approach a problem of modeling and interpolation. Computer vision and pattern recognition are interested in appropriate methods of shape representation and curve modeling. PNC method represents the possibilities of shape reconstruction and curve interpolation via the choice of nodes combination and probability distribution function for interpolated points. It seems to be quite new look at the problem of contour representation and curve modeling in artificial intelligence and computer vision. Function for γ calculations is chosen individually at each curve modeling and it is treated as probability distribution function: γ depends on initial requirements and curve specifications. PNC method leads to curve interpolation as handwriting modeling via discrete set of fixed knots. So PNC makes possible the combination of two important problems: interpolation and modeling. The method of Probabilistic Features Combination (PFC) enables interpolation and modeling of high-dimensional N data using features' combinations and different coefficients γ: polynomial, sinusoidal, cosinusoidal, tangent, cotangent, logarithmic, exponential, arc sin, arc cos, arc tan, arc cot or power function. Functions for γ calculations are chosen individually at each data modeling and it is treated as N-dimensional probability distribution function: γ depends on initial requirements and features' specifications. PFC method leads to data interpolation as handwriting or signature identification and image retrieval via discrete set of feature vectors in N-dimensional feature

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

space. So PFC method makes possible the combination of two important problems: interpolation and modeling in a matter of image retrieval or writer identification. Main features of PFC method are: PFC interpolation develops a linear interpolation in multidimensional feature spaces into other functions as *N*-dimensional probability distribution functions; PFC is a generalization of MHR method and PNC method via different nodes combinations; interpolation of *L* points is connected with the computational cost of rank $O(L)$ as in MHR and PNC method; nodes combination and coefficients γ are crucial in the process of data probabilistic parameterization and interpolation: they are computed individually for a single feature. Future works are going to applications of PFC method in signature and handwriting biometric recognition: choice and features of nodes combinations *h* and coefficients γ.

Proposed method, called Probabilistic Features Combination (PFC), is the method of *N*-dimensional data interpolation and extrapolation using the set of key points (knots or nodes). Nodes can be treated as characteristic points of data for modeling and analyzing. The model of data can be built by choice of probability distribution function and nodes combination. PFC modeling via nodes combination and parameter γ as probability distribution function enables value anticipation in risk analysis and decision making. *N*-dimensional object is extrapolated and interpolated via nodes combination and different functions as discrete or continuous probability distribution functions: polynomial, sine, cosine, tangent, cotangent, logarithm, exponent, arc sin, arc cos, arc tan, arc cot or power function. The method of Probabilistic Features Combination (PFC) enables interpolation and modeling of high-dimensional data using features' combinations and different coefficients γ as modeling function. Functions for γ calculations are chosen individually at each data modeling and it is treated as *N*-dimensional probability distribution function: γ depends on initial requirements and features' specifications. PFC method leads to data interpolation as handwriting or signature identification and image retrieval via discrete set of feature vectors in N-dimensional feature space. So PFC method makes possible the combination of two important problems: interpolation and modeling in a matter of image retrieval or writer identification. PFC interpolation develops a linear interpolation in multidimensional feature spaces into other functions as *N*-dimensional probability distribution functions. Future works are going to applications of PFC method in biometric recognition, computer vision and artificial intelligence. Nodes are treated as characteristic points of data for modeling and analyzing. The model of data can be built by choice of probability distribution function and nodes combination. PFC modeling via nodes combination and parameter γ as probability distribution function enables value anticipation in risk analysis and decision making. Two-dimensional object is extrapolated and interpolated via nodes combination and different functions as discrete or continuous probability distribution functions: polynomial, sine, cosine, tangent, cotangent, logarithm, exponent, arc sin, arc cos, arc tan, arc cot or power function. Functions for γ calculations are chosen individually at each data modeling and it is treated as 2-dimensional probability distribution function: γ depends on initial requirements and features' specifications. PFC method leads to data interpolation as handwriting or signature identification and image retrieval via discrete set of feature vectors in 2-dimensional feature space. So PFC method makes possible the combination of two important problems: interpolation and modeling in a matter of image retrieval or writer identification. PFC interpolation develops a linear interpolation in multidimensional feature spaces into other functions as two-dimensional probability distribution functions. Future works are going to applications of PFC method in biometric recognition, computer vision and artificial intelligence.

Future works are going to: application of PNC method in signature and handwriting recognition, choice and features of nodes combinations and coefficient γ, implementation of PNC in computer vision and artificial intelligence: shape geometry, contour modelling, object recognition and curve parameterization.

KEY TERMS AND DEFINITIONS

Artificial Intelligence: Intelligence of machines and computers, as a connection of algorithms and hardware, which makes that a man – human being can be simulated by the machines in analyzing risk,

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

decision making, reasoning, knowledge, planning, learning, communication, perception and the ability to move and manipulate objects.

Contour Modeling: Calculation of unknown points of the object contour having information about some points of the object contour.

Curve Interpolation: Computing new and unknown points of a curve and creating a graph of a curve using existing data points – interpolation nodes.

Data Extrapolation: Calculation of unknown values for the points situated outside the ranges of nodes.

Hurwitz – Radon Matrices: A family of skew – symmetric and orthogonal matrices with columns and rows that create, together with identical matrix, the base in vector spaces of dimensions $N = 2, 4$ or 8.

MHR Method: The method of curve interpolation and extrapolation using linear (convex) combinations of OHR operators.

OHR Operator: Matrix operator of Hurwitz – Radon built from coordinates of interpolation nodes.

Chapter 27
Fair Use Defences During Copyright Litigation:
Is the Success of a Fair Use Defence Strategy Predictable?

Michael D'Rosario
Deakin University, Australia

ABSTRACT

The prediction of legal outcomes and other legal domain related variables has served as the basis of a number of recent studies. While recent studies have estimated standardised variables and dichotomous outcomes such as the outcome of a judicial decision process, few studies have employed dichotomous data and categorical data to predict the basis of a legal defense strategy or the likelihood of trial success. Empirical research within the judicial sciences continues to employ a limited subset of empirical methods. This article reasserts the benefits of several artificial intelligence based non-parametric techniques that are better suited to the discipline than many of the common methods employed within the literature. The article considers the predictability of fair use defense within the U.S. during copyright infringement proceedings, and the likelihood of trial success.

INTRODUCTION

The prediction of judicial processes has been the subject of much research in recent decades. There is a general acceptance of traditional economic methods within the sphere of legal research[1] (Barker, 1996). The application of economic and econometric methods in the legal domain is ever increasing. Artificial intelligence (AI) methods are generating substantial interest with the legal community. Some might argue that the interest has been a long time coming given the advent of such technologies over three decades ago. Indeed the more practical advent of new methods, such as AI technologies in recent years has made such technologies more accessible to those within the legal domain[2].

The advent of such technologies has not met with positivity from all practitioners. But the potential has resulted in a heightened sense of importance and a desire to develop greater familiarity that is palpable[3]. This occurrence is perhaps warranting some moderation of the evidenced euphoria about such methods in legal practice[4]. While some contend that AI methods have the potential to replace practitioners, the present article takes a contrarian view and argues that AI technologies shall serve to supplement traditional legal information sources, and inform trial strategy. There is also scope for the emergence of a secondary market for data-driven legal services.

Professor Art Cockfield moderated a recent discussion where participant innovator and legal graduand Addison Cameron Fuff offered some insightful comments. "I think the change is people being more proactive. Right now lawyers are very reactive; somebody has an issue, and a lawyer researches it using books and databases. There is an opportunity for software to make that first pass, to highlight new issues. When a new case comes out, you shouldn't have to wait weeks for a newsletter. It should come into your inbox. That proactive aspect is something computers can deliver, because no lawyer on the planet could possibly read all of the cases, laws and regulations that come out. Depending on your scope, you could be talking municipal, provincial, federal, international…"[5]

Jordan Furlong in contributing to the same recent AI and Law dialogue asserts that; "we're going to see the adoption of AI in the legal market, more broadly speaking, rather than in the legal profession for quite some time to come. Lawyers are sort of naturally disinclined, for cultural reasons, to disrupt the way they work and go about their jobs. Technology tends to generate that aversion"[6]. The present article offers an example of just how effective such methods and technologies might be in support of legal practitioners.

Within the legal domain the regulatory framework and its support structure are evolving, capturing more data and enhancing courts administration and judicial accountability.

Richardson (1989) posited the advantageousness of optimisation methodology, specifically of the economic flavour when discussing the role of analysis within the courts, the author's claims remain similarly valid to Artificial intelligence methods. Essentially courts and concerned with the allocation of resources and the behaviour of individuals. While somewhat reductionist there truth in the claim.

It is therefore logical to assume that the rules and models of sanction should be framed while having regard for the potential incentives and disincentives these rules and pronouncements create, and their likely impact on future resource allocations (Richardson, 1989). The current article considers the extant empirical research employed within the literature positing an alternative to the common logit methods employed within legal research.

Advances of empiricism within the law and economics sub-disciplines serve as the starting point for the subsequent precis on research methods. Arguably, the most acceptance of empiricism has been observed in Intellectual property research and judicial decision-making research. This is noteworthy given the present article's focus on both I.P. law and judicial process outcomes. For brevity's sake, these spheres of research shall be surveyed as they represent emergent bodies of research employing empirical methodologies to legal challenges.

EMPIRICISM WITHIN INTELLECTUAL PROPERTY LAW

There is limited literature on the success of fair use defenses and empirical fair use research generally (Sag, 2012). Consequently we review the broader fair use and empirical Intellectual Property literature.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Siebeck et al (1990) offers unique insight into the economic benefits of strengthen IPRs within non-developed countries. The study reviewed the extant literature both encompassing both theoretical and empirical studies. The study claims that the body of literature pertaining to industrialized economies suggests that increases in IPR protections increase R&D activities to the extent that the social cost of having IRP protections is offset.[7] Notably, all surveyed research employed traditional regression methodologies, none of the reviewed studies employed artificial intelligence methods.

Cotropia & Gibson (2015) In "Copyright's Topography: An Empirical Study of Copyright Litigation" claim that one of the most important ways to measure the impact of copyright law is through empirical examination of actual copyright infringement cases (Ibid, 2015). The authors respond to the dearth through the analysis of differences between copyright and non-copyright litigation. The study employs traditional regression methods.

Menell (2016) considers the laws of fair use as they relate to mashups. The author contends that "the appropriate inquiry is whether an allocation mechanism achieves the best overall resolution of the trade-offs among authors' rights, cumulative creativity, freedom of expression, and overall functioning of the copyright system. By adapting the long-standing cover license for the mashup genre, Congress can support a charismatic new genre while affording fairer compensation to owners of sampled works, engaging the next generations, and channeling disaffected music fans into authorized markets." The author analyses fair use employing a conventional economics approach.

Chen (2005) considers the complex trade-off that exists between developing nations pursuing active innovation or choosing to imitate or mimic foreign rivals. The author shows that innovation within a deloping country context gives rise to increases in domestic intellectual property protections. Moreover, the countries development statas influences its level of IPR protection. The author employs a panel of data for 64 developing countries to "confirms both the positive impact of IPRs on innovations in developing countries and the presence of a U-shaped relationship between IPRs and economic development"(Chen, 2005).

Richardson (1991) in building upon general economic development studies asserts the worthwhile contribution associated with protection of IPRs within the framework of a closed economy; and considering the complexity deriving from the international nature of IPRs and innovation. The author provides a short exposition on the nature of the current U.S. practices and framework for IPR protection and enforcement particularly in relation to the interactions and model of sanctions employed on the basis of the national origin of an infringing service or product. The study contends that it is inapt to an employ a subsidy based approach to providing incentives for R&D to promote shifting profits to U.S. firms (Richardson, 1991). The noteworthy study employs traditional economic methodology within the analysis.

McCalman (2005) titled International Diffusion and Intellectual Property Rights: An Empirical Analysis is a noteworthy study rejecting "…traditional thinking about intellectual property rights (IPR) suggests a monotonically increasing relationship between property rights and the speed of diffusion of new products and technology. Our analysis of data on the international release pattern of Hollywood movies suggests a more complex story: although moderate standards of IPR encourage the spread of movies, either weaker or stronger property rights tend to decrease the speed with which American movies are released abroad. This empirical finding is consistent with a variety of specifications, including controlling for countries' self-selection of IPR standards. Overall, it appears that while some IPR recognition may encourage diffusion, very strong IPR may actually retard the speed of diffusion…" (McCalman, 2005). The study employs traditional regression methodology consistent with the broader literature.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Glass & Saggi (2002) explore the role of FDI and IPR's in moderating innovation and imitation. The authors develop a model based on product life cycle with endogenous innovation while accounting for FDI and imitation. The authors "find that stronger IPR protection keeps multinationals safer from imitation, but no more so than Northern firms. Instead, the increased difficulty of imitation generates resource wasting and imitation disincentive effects that reduce both FDI and innovation. The greater resources absorbed in imitation crowd out FDI. Reduced FDI then transmits resource scarcity in the South back to the North and consequently contracts innovation." (Glass & Saggi, 2002).

McCalman (2002) conducts an analysis of TRIP's agreement implementation focusing on the costs, benefits, and incentives associated with the agreement. The authors determined that "the static costs of raising the standards of patent protection are captured by the transfers of income between countries, with the majority of countries estimated to make net payments abroad, the United States being a major beneficiary. To offset these transfers the model provides estimates of the dynamic benefits from the greater incentive to innovate, revealing that there is potential for all countries to benefit from the TRIPs agreement in the long run. However, the distribution of these benefits is highly skewed towards developed countries." (McCalman, 2002).

The study of Gould & Gruben (1994) considers the theoretical relationship between IPRs and economic growth. This matter is frequently considered within econometrics research. Employing panel data, the study considers this relationship while accounting for country-specific considerations, such as trade, patent protections, and other country-specific factors, determining that rights and protections are strongly and positively associated with economic growth, which is consistent with the broader literature.

A further study by Yang and Maskus (2001) sought to respond to the shortage of research in intellectual property rights literature employing contemporary empirical methods such as panel data approaches and GMM estimation. The study sought to assess the linkage between licensing agreements and support for Intellectual Property rights IPRs. The study identifies the countries that are employing stronger patent protections and those that value patent rights generally attract a larger arm's length volume of licensed technology.

Employing traditional regression methods, Landes & Posner (2003) claimed that the extension of copyright had nominally positive but statistically insignificant effect on copyright registrations. Utilising pooled panel data the study is a noteworthy contribution, but due to the due to the somewhat restrictive methods utilised the study cannot account for interaction effects.

The present study response to the dearth of research employing non-parametric estimation techniques in analysis the interplay between intellectual property regulation, judicial decision making, and fair use litigation.

EMPIRICISM WITHIN JUDICIAL DECISION MAKING

The literature is replete with exploratory studies conducted considering the predictability of judicial decision making employing traditional linear OLS, GLS and logistic regression methods. Burton (1976) offers what is arguably the first systematic and extensive application of cross-judicial methodology. The authors examine the seminal accounts of the members of the Rehnquist Court (1986–94 terms) contrasting them with "…the prior appellate court experience to discern any correlation with their Supreme Court behaviour in terms of non-consensual opinion writing and voting…"

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

The authors make the remarkable discover that judges change markedly. The authors assert that the judges … become less consensual as justices than they were as judges in the lower court. Importantly, this finding holds after controlling for such institutional differences between the two court levels as size, ideology, case types, stare decisis, and norms. Consistent with the neo-institutional perspective, we surmise that this behaviour change is due to the modern Supreme Court being unique, a court on which the members feel it is desirable, necessary, and possible to express policy disagreements with the majority via separate opinions and votes.[8] The study authors employ conventional regression methods in the analyses. The underlying complexity of the decision process implies that it may be non-linear in the opinion of the author.

Billica (1997) is an example of a quantitative study considering the judicial decision-making process. Specifically, Billica considered the process in the United States, by which 'states are pushed into the courts for review and interpretation.'[9] The study considered statutes across a 28-year period through the 86th and 99th congresses from 1959-86. Through the use of a randomly selected subset of statutes from the main dataset, the study tracks statutes that have been challenged by the courts, considering the issues addressed by the courts in interpreting statutes.[10]

Sisk el al (1998) considers the quandary faced by judges in 1998 when hundreds of federal district judges were suddenly confronted with the need to render a decision on the constitutionality of the Sentencing Reform Act and the newly promulgated criminal Sentencing Guidelines. Never before has a question of such importance and involving such significant issues of had constitutional law mandated the immediate and simultaneous attention of such a large segment of the federal trial bench. The authors assert that the event serves as an archetypal model for understanding the influence of key factors such as social background, ideology, judicial role and institution, and other factors on judicial decision making[11].

The authors have produced what is described as "…unprecedented empirical study of judicial reasoning in action. By exploiting this treasure trove of data, the authors have looked deeper into the judicial mind and observed the emergence of influences upon the manner in which a judge examined the constitutional issues, adopted a constitutional theory, and engaged in legal reasoning." The seminal account employs traditional regression methodology.

Yoon (2006) offers a unifying account of judicial tenure. The author claims that; Analysing judicial turnover, year by year, this article finds that judges have increasingly synchronized their departure from active service with qualifying for their judicial pension. By comparison, political and institutional factors appear to have little influence on turnover rates. These findings contradict much of the existing scholarship on judicial turnover and also offer more viable alternatives for judicial reform. The study is a further example of the style of research necessary within the legal domain[12].

Martin, Quinn, and Epstein consider the matter of median justice identification.[13] Adapting the method framed by Martin and Quinn,[14] the study develops an improved quantitative method for median justice identification based on conventional regression techniques.[15] 'The Median Justice' is an exemplary study of interdisciplinary law and decision sciences research. Nonetheless, there remain relatively few predictive studies within law and economics, particularly in relation to judicial decision-making.

Epstein et al. consider the pertinent matter of how judicial decision making is impacted by threats to national security.[16] The study employs a large dataset, incorporating every civil rights and liberties case from between 1945 and 2005. The study indicates that during periods of conflict, when national security is threatened the justices are 'substantially more likely' to curtail rights.[17]

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

The study is a further example of the benefits of quantitative methods in judicial decision-making research. Like much of the research surveyed in this paper, the extant literature employs one of several popular estimation techniques. In the noted studies, logit and probit-based parametric estimation techniques are employed. The present study, as such, is a worthwhile departure from the norm, adopting a perceptron models to robustly identify associations between judicial experience and judicial outcomes and develop potentially more accurate predictive models.

Calderia and Wright consider the participation of the various parties that participate in judicial processes as Amici curiae within the U.S. Supreme courts, pursuant to petitions for writs of certiorari and jurisdictional statements, in addition to decisions based on merits. The authors employ a large dataset constituted by all cases involving amici since 1982. The study employed traditional regression methodologies.

Collins and Martinek contribute to the judicial decision-making literature by considering whether ideology mediates the impact of amicus curiae briefs on the decision making in the U.S. courts of appeals. The authors contend that amicus briefs afford the judges with critical information that influences their voting decisions. Employing conventional econometric methodology the authors assert that the amicus briefing influences judicial decision-making, but the influence is contingent on the judge's ideology.

The noted studies are broadly representative of the scope of works within the sphere of judicial decision-making research, from a methodological perspective, all employing traditional regression methodologies. [18] Herein an alternative is introduced, the multi-layer perceptron, detailing potential applications within empirical legal research.

The noted studies all employ logistic or probit modelling techniques. The most commonly used method employed in empirical judicial sciences research is logistic regression, largely because it is well suited to the dichotomous dependent variables that serve as the subject of many studies within the judicial sciences. While the contributions to empirical judicial research have been apt, many complex nonlinear problems have not been considered empirically. The present article proffers an alternative method asserted to be parsimonious for research in the judicial sciences, representing a viable alternative to the commonly employed logit model.

THE NEXT WAVE OF LEGAL EMPIRICISM, ARTIFICIAL INTELLIGENCE WITHIN THE LEGAL DOMAIN

Richardson & Hatfield (1989) describes this renewed focus on empiricism as the second wave of law and economics, with the first wave as claimed by the author evidencing only limited use of empirical methods[19]. While there remains the need for further acknowledgment of the benefits associated with parametric estimation methodology within the law and economics field of research amidst the so-called second wave of law and economics, it is apparent that novel non-parametric methodologies made possible by modern computing technologies represent an equally important sphere of inquiry (D'Rosario, 2016). These non-parametric methods offer insights not possible when employing traditional parametric regression. In particular, the advantages of multi-layer perceptron models in comparison to logit models when modelling complex nonlinear processes are pertinent to consider (D'Rosario, 2017).

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

A Survey of Artificial Intelligence, Specifically Perceptron Models, and Expert System Methodology Within the Legal Domain

The Multi-layer perceptron model is asserted to be a viable supplement, and where data is limited, or relationships are complex, bi-directional and nonlinear, a superior alternative to the logit model because it offers a more accurate framework for prediction. Consider some of the challenges associated with alternative parametric techniques. Firstly, there are obvious issues associated with predictive analysis where the process is nonlinear. Logit and Probit models are relatively less capable of modelling nonlinear decision processes. MP-ANN overcomes this challenge through the application of weighted, aggregative nonlinear values based estimation. Neural networks have been advocated as an alternative modelling technique to logistic regression within the applied sciences. However there is a dearth of research considering the viability of such methods within law and economics research.

Within law and economics research, logistic regression is by far the most commonly employed method, given its suitability to dichotomous dependent variables. Within the applied sciences many more complex alternatives are being adopted. These methods present as viable alternatives to logit and probit modelling.

As asserted by Tu (1996) neural networks offer a number of advantages over logistic regression, including the ability to implicitly detect complex nonlinear relationships between dependent and independent variables, the ability to detect all possible interactions between the specified predictor variables, and the availability of multiple training algorithms. Driesietl and Ohno-Machado (2002) offer a formal methodological review of each modelling technique, noting the formal association between the techniques. The multi-layer perceptron model can be seen as an abstraction of the logistic model, employing a sigmoid function. A more apt description, however, would be that the logistic model is a simple single layer perceptron model, that does not employ a second (layer) weighted aggregate input set.[20] The following are studies employing artificial intelligence and expert systems methodology within the legal domain. The summation is not exhaustive but rather an outline of indicative studies worthwhile for legal scholars.

Zeleznikow (1995) contend that argument structures proposed by Toulmin can be used to represent legal knowledge in a manner that enables rule-based reasoning to be integrated with neural networks. The authors employ this approach for the construction of a system known as Split-up which predicts the outcome of property disputes in the domain of Australian family law.

Bellucci, Lodder and Zelznikow (1994) contend that current research in developing negotiation support systems focuses upon argumentation, artificial intelligence and game theory[21]. These techniques are rarely used in tandem. The authors argue that truly intelligent negotiation support systems require the integration of such techniques. The authors integrate the argumentation techniques of Lodder and the combined artificial intelligence/game theory approach of Bellucci and Zeleznikow to develop an online system of negotiation.

Oatley et al. (2005) summarises research within the sphere of crime prediction outlining both the authors own work and experiences as an employee of the United Kingdom police force[22]. The study incorporates detailed explanatory notes from the spheres of spacial statistics and forensic psychology that serve to inform the case based reasoning and logic programing within the presented models[23]. The crime matching techniques used are case-based reasoning, logic programming and ontologies, and naïve Bayes augmented with spatio-temporal features (Ibid, 2005). The crime prediction techniques are survival analysis and Bayesian networks (Ibid, 2005). The techniques present favourably against traditional methods in terms of ease of interpretations and enable predictive estimation not possible with traditional methods.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Bellucci (2001) conducts expert systems research centered upon the sphere of Australian Family Law[24]. The authors analyse, detail and critically appraise four systems that have built in their specialized laboratory, specifically *Family_Negotiator, Split_Up, AdjustWinner* and *DEUS*. In doing so, we learn the complexities of the negotiation domain and investigate modelling issues for construction of an intelligent negotiation support tool.

The research has centered upon the study of negotiation strategies, specifically how to construct decision support technologies to help support human actor decision making and strategy formulation. The authors hope that their discoveries will result in future research involving multi-criteria decision making, the application of genetic algorithms and graph theory to build more efficacious Negotiation Decision Support Systems (NDSS).

D'Rosario (2017) seeks to identify whether trial representation experience possessed by lawyers within the U.S. Supreme Court impacts upon judicial decision making through the formulation of a predictive model. The author notes that a number of relatively recent studies within the extant literature have considered the role of experience in influencing judicial decision-making[25]. The D'Rosario study responds directly to the seminal work of McGuire[26]. McGuire is a significant study into the impact of the experience of competing trial lawyers on judicial decision making, employing traditional logistic regression methodologies[27]. The McGuire study found that trial experience possessed by trial lawyers was associated with favourable trial outcomes. The D'Rosario study extends upon McGuire, assessing the robustness of the original study employing a series of more advanced parametric estimation techniques (D'Rosario, 2017). The study then uses the McGuire logistic model framework to develop a model of prediction, employing a backward propagation, multilayer perceptron network model (D'Rosario, 2017).

D'Rosario (2016) asserts that significant methodological and theoretical contributions have been made to the extant intellectual property law and economics literature. The author asserts that 'in recent years, a number of studies have considered the impact of IPRs on software piracy, specifically TRIPS and more recently U.S. USTR 301 reporting, pursuant to the Trade Act' (D'Rosario, 2017). The noteworthy study of Shadlen (2005) is broadly supportive of the notion that IPR reforms directly influence rates of copyright infringement. The D'Rosario (2017) study extends upon Shadlen (2005), contrasting the traditional pooled panel model framework evidenced to a novel alternative model, a backward propagation, multilayer perceptron network model. The analysis conducted within the study focuses directly on ASEAN member countries. The study identifies the importance of IPRs and governance variables as well as presenting substantially improved predictive accuracies and goodness of fit measures.

Each of the noted studies incorporates the MP-ANN method in place of traditional estimation, to elucidate understanding in legal analysis and judicial sciences research. Pertinently each paper employs different data frameworks and variable structures. The studies incorporate binary, continuous, categorical and ordinal data, and as such introduce scholars to the treatment of each variable type. Each is written in a manner that is accessible to a non-technical audience.

STUDY DATA, HYPOTHESES, AND METHODOLOGY

The data was procured from Sag (2012).[28] Sag's seminal study compiled trial data and litigant data from the U.S. district courts, consider the main battle ground for copyright disputes, over a 33 year period between 1978 and 2011. The present study employs consolidated court determination data as derived by

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 1. Variable descriptions

Variable	Variable Description	Type
Win_fu	The success of the defendant employing a fair use defense	Binary
reform	The level of advantage of the petitioner relative to the defendant (employee pool size)	Binary
UseShift	The transformative use status of the copyrighted work	Binary
Unpublished	The published status of the work	Binary
Commuse	The commercial status of the defendant	Binary
Partial	Whether the usage was partial or full	Binary
Year	The year of the case	Binary
Natural_cr	The status of the claimant as a natural person	Binary
Natural	The status of the defendant as a natural person	Binary
Repeatplayer_cr	The repeat litigation status of the claimant	3 point ordinal
Repeatplayer	The repeated litigation status of the defendant	3 point ordinal

Sag (2012), and from the United States Supreme Court Judicial database, as presented in the Sag (2014) seminal study. A total of 222 cases *(n=222)* were included in the study.

Win_fu is the dependent variable denoting a successful or unsuccessful fair use defense. Rel_firm denotes the relative firm sizes of each of the litigants. Repeatplayer is the critical repeat action variable denoting whether a defendant has appeared previously. Useshift accounts for a shift in the usage of the media, essentially transformative usage. Unpublished is a binary/Boolean variable denoting the publication status of the media. Commuse denotes the usage status of the media, either commercially on non-commercially. Partial is a variable denoting the degree of replication either full or partial. Year denotes the year of the trial. While natural denotes the natural person's status of the defendant (see Table 1).

A number of factors are likely to have influence, aside from those considered herein, the model specifications seek to determine the critical association between litigant advantage, amicus curie and, critically, judicial experience with petitioner success. The manner with which this relationship is explored appears to be the first unique contribution of the current study, extending upon the existing work of Sag (2012).[29]

It is postulated herein that the relative firm size of litigants is a key determinant of judicial outcomes when accounting for litigant natural person status. A further postulate is that transformative use is positively and significantly associated with copyright fair use defense failure. The latter postulate is consistent with Sag (2012).[30] Consequently, we test the following hypotheses:

H1: Where a defendant is larger relative to the claimant in firm size terms this position shall be positively and significantly associated with litigant fair use defense.

H2: Where the defendant engages in transformative use this action shall be positively and significantly associated with fair use defense success.

The Sag (2014) study adopted a traditional logistic regression framework to build a predictive model. Herein, three predictive models are constructed using in the first instance the same methodology as employed by Sag, and then two alternative non-parametric estimation technique capable of more accurate predictive outcomes based on neural networks theory. Firstly, a multilayer perceptron network structure

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

based on artificial neural networks theory is adopted to predict fair use defense success. Then a hybrid logit-MPANN is employed, utilising a backward propagation technique for model training. The following hypotheses pertain to the different methods of estimation:

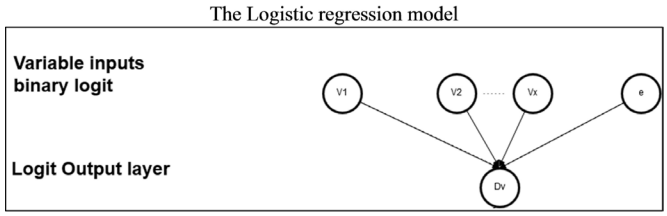
H3: It is posited that the Perceptron shall achieve higher predictive accuracy than the traditional logit regression.

H4: The Hybrid Logit-MPANN shall achieve higher predictive accuracy than traditional logit regression and the standalone MPANN.

The MPANN approaches lend themselves well to the nature and structure of the available data. The dearth of research considering these matters is addressed by the present study which seeks to respond to omissions in the extant literature by framing a potentially more robust and accurate collection of the predictive model. A brief introduction to each of the techniques noting their benefits is detailed in the subsequent section.

This study adopts a logit model, a perceptron model and a hybrid model with the intention of understanding the impact of Repeat player status and Firm advantage on trial success and with the intent of predicting the likelihood of defence success where a fair use defence is successful, this latter task is where the multilayer perceptron model may afford the most significant benefit.

The employed data is binary, as such the excepted approach for statistical robustness all things being equal is logit regression or multiple discriminant analysis. It is posited within a number of recent studies that that such approaches are relatively less capable of accommodating dynamic and non-linear relationships. It is asserted herein that threshold effects relating to independent variables and interaction effects between independent variables cannot be estimated without knowledge of the relationship in logit specifications. A brief summary or precis on methods is provided for those unfamiliar with any of the methods, and particularly because of the new hybrid model proposed herein.



The Logit Model

Logistic regression is a common method in empirical research, sometimes called logit modeling. The method is employed where an outcome is dichotomous in nature. When logit is employed the log odds of the dichotomous outcome is modeled as a linear combination of the predictor variables. Logistic regression seeks to measure the relationship between the dichotomous dependent variable and a vector of one or more independent variables, through the estimation of coefficients as with linear regression but by estimating probabilities using a logistic function. The logistic function has a cumulative logistic distribution.

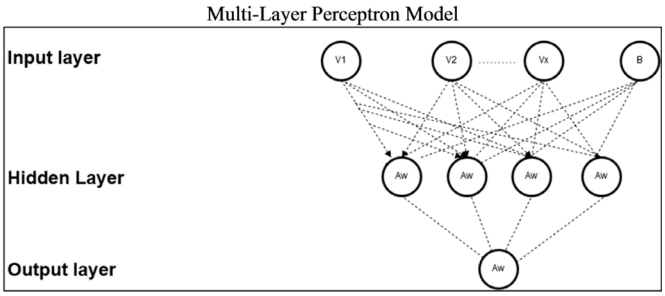
The logistic regression model is essentially a special instance of the generalised linear model and consequently, shares a level of association with linear estimation. The underlying assumptions of the logistic regression model differ markedly from those of linear regression. The most pertinent difference relates to underlying distribution structures. The logistic regression employs a Bernoulli distribution rather than a Gaussian because the dependant variable is a dichotomous binary variable. Additionally, the predicted values of the logistic specification are probabilities and therefore seek to determine outcome values of either 0 or 1 because the output variable is binary. The logit may also be conceptually viewed as a single layer perceptron. Essentially a special instance of the perceptron without a hidden layer (see Figure 1).

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. Conceptual drawing of the logit model (Note: Here V1…Vx are the independent variables (input variables), and e denotes the error term (referred to as bias traditionally within the machine learning). Dv denotes the Dependent variable Winfu. The solid lines denote the sigmoid/logistic regression process. Dv evidences a Bi-nominal distribution).

Model Structure

Equation (1) summarises the econometric structure of the estimation. Recall that Win_fu is the dependent variable denoting a successful or unsuccessful fair use defense. Rel_firm denotes the relative firm sizes of each of the litigants. Repeat player is the critical repeat action variable denoting whether a defendant has appeared previously. Use shift accounts for a shift in the usage of the media, essentially transformative usage. Unpublished is a binary variable denoting the publication status of the media. Commuse denotes the usage status of the media, either commercially on non-commercially. Partial is a variable denoting the degree of replication or the subject matter, copyrighted work either full or partial. Year denotes the year of the trial. While natural denotes the natural person status of the defendant, where it indexes each data item across time:



$$Winfu_{it} = a + \beta.Relfirm_{it} + \beta.Partial_{it} + \beta.Transform + \beta.Commuse_{it} + \beta.Unpublished_{it} + \beta.Repeatplayer_{it} + \beta.Natural_{it} + \beta.Repeat_cr_{it} + \beta.Natural_cr_{it} + \varepsilon_{it} \quad (1)$$

The Multilayer Perceptron Network Model

The article given both its interdisciplinary nature and focus introduces a number of technical concepts that are likely to be unfamiliar to non-technical audiences and in particular those with a largely jurisprudential background. In the interest of engaging with the broadest audience, the following precis on neural network methodology[31] is provided. The multilayer perceptron model is simply a form of the artificial neural network model (herewith MP-ANN) [32], a nonparametric predictive model[33] that seeks to replicate the structure of a biological neuron as it occurs in nature[34]. More plainly, it is a series of weighted, aggregative, non-linear values[35]. Neural network models emerged out of the body of research on artificial intelligence[36] that should attempt to model the human process of learning through the development of a modeling framework resembling the structure of the human brain.[37] The MP-ANN model has the potential to provide more accurate predictive outcomes than traditional parametric estimation techniques and is therefore well suited to the present research questions, any criticisms of legal realist logic notwithstanding[38]. Moreover, the methods appear more suited even accepting any legal realist underpinnings (see Figure 2).[39]

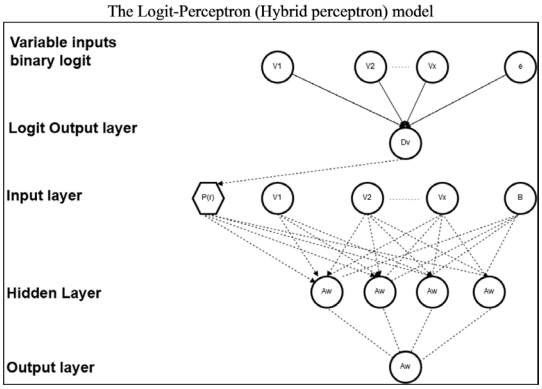
EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. Conceptual drawing of the multi-layer perceptron model (Note: Here V1…Vx are the independent variables (input variables), x denotes the number of variables and b denotes the error term (referred to as bias traditionally within the machine learning). Dv denotes the Dependent variable Winfu. Aw denote the hidden layer nodes, and the latter Aw denotes the aggregate weight at the output layer).

Model Structure

The sigmoidal function was chosen given the data structure, and its dichotomous nature. Hidden layer size was determined based on Heaton (2011) recommendations. Optimality generally exists between the number of input layers and output layers.[40] Hidden layer structure was based on optimisation. Two hidden layers offered no additional optimisation benefit. Moreover, two hidden layers may be useful when employed in situations where modeling data evidences discontinuities. Within the present dataset, this is not the case.

The use of an additional hidden layer increased computational resources required and offered no improvement to the model. A single hidden layer model is employed to avoid a greater risk of converging to an incorrect local minima. One potential shortcoming of the selected methodology relates to the efficiency of ANN models in accommodating non-numeric variables, commonly referred to as dummy variables in economics. This is, however, only the case where non-numeric variables can take a large number of values, which is not the case in the present study.



Data reduction and data pruning techniques were not necessary to improve model resolution, and the model performed efficiently and robustly absent of any node reduction. As such, the input values remain the same as those employed in Sag (2014). This is pertinent as it ensures that each predictive modeling framework can be compared on equal terms employing the same parameter set.

The Hybrid Perceptron Network Model

The hybrid multilayer perceptron model is a new form of the artificial neural network model (herewith MP-ANN), incorporating initial logit pre-processing. The logic behind the hybrid approach is rather simple, where the perceptron has a tendency to overfitting, pre-processing may be beneficial. Herein the proposed logit-perceptron derives initial probabilities from the logit model that serve as an input for the perceptron[41]. Employing this method the series of weighted, aggregative values derive input from the existing vector set of variables as well as the logistic regression probability estimates. While neural network models emerged out of the body of research on artificial intelligence that should attempt to model the human process of learning through the development of a modeling framework resembling the structure of the human brain.[42] The MP-ANN model has the potential to provide more accurate predictive

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 3. Conceptual drawing of the Hybrid perceptron model (Note: Here V1…Vx are the independent variables (input variables), and e denotes the error term (referred to as bias traditionally within the machine learning). P(r) denotes the probabilities associated with the logit specification outputs. B denotes the bias function at the input layer. Dv denotes the Dependent variable Winfu. Aw denote the hidden layer nodes, and the latter Aw denotes the aggregate weight at the output layer).

outcomes than traditional parametric estimation techniques and is therefore well suited to the present research questions[43]. While this article may not be the first instance where hybrid methods such as this have been employed, it appears to be quite plausibly the first within the legal domain (see Figure 3).

The MP-ANN is selected as a viable alternative to the Sag (2014) logit [44] model because it offers a more accurate framework for prediction. Consider some of the challenges associated with alternative parametric techniques. Firstly, there are obvious issues associated with predictive analysis where the process is non-linear. Logit and probit models are relatively less capable of modeling non-linear decision processes robustly. MP-ANN overcomes this challenge through the application of weighted, aggregative non-linear values-based estimation. The MP-ANN model appears superior when modeling complex relationships, such as the relationship between judicial experience variables and judicial outcomes.

Neural models appear more consistent with judicial decision making[45]. Members of the judicial system carefully weigh alternative criteria, balancing competing criteria and implicitly employ these weighted considerations in their decision making. While the process may not be explicit, it is nonetheless essential to judicial decision making. Neural networks are more capable of replicating complex decision criteria and decision weighting than the commonly employed logistic regression.

The Layers of a Hybrid Neural Network

The first layer is the logit input layer. Here standardised and unstandardized logit inputs are employed in a logit specification. They are employed to specify a logit function representation of the relationship between the variables and litigation success. The output is a non-Gaussian distributed, Bernoulli distribution of litigation success. The logit specification classification probabilities are then captured and specified as an input in the next layer. The next layer is the first layer is the perceptron, an input layer. The perceptron input layer processes and standardises a vector of the predictor variables. This process loosely resembles the process of "saltatory conduction" with a biological neuron.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

The standardised vector values of the predictor variables, reach the perceptron hidden layer. At the hidden layer, their standardised values are multiplied by a weight, with the weighted values aggregated and passed forward to the transfer function. The values from the transfer function are passed to the output layer.

The output layer accepts the values from the hidden layer, multiplying the values by weights, with the weighted values aggregated and passed forward to the transfer function. The values from the transfer function are the model outputs. As the target variable is the outcome for the petitioner, there are *2* neurons in the output layer producing *2* values, one for each of the categories of the target variable.

The hidden layer size was determined based on model optimisation, and Heaton (2011), noting optimality usually exists between the number of input layers and output layers.[46] Moreover, two hidden layers may be employed when modeling data that evidence discontinuities, such as a saw-tooth wave pattern (D'Rosario, 2016). Given the nature of the underlying dataset, this is not the case. The use of an additional hidden layer reduces estimation efficiency and offers no improvement to the model in this instance. Herein, a single hidden layer model is employed to avoid a greater risk of converging to an incorrect local minima.

Data pruning techniques were not employed to improve model resolution, and the model performed efficiently and robustly absent of any node reduction. As such, the input values remain the same as those employed in Sag (2014). This is pertinent as it ensures that each predictive modeling framework can be compared on equal terms employing the same parameter set.

MODEL FINDINGS

Considering first the logit specification, the findings indicate that relative firm size as measured by employees, the claimant's status as a natural person and whether the defendant was a repeat player are significant at the 1% level (relsize, cl_natural) and 10% level (df_repeat). These findings are in contrast with the earlier Sag (2014) study that identified both the amount copied, transformative use, the plaintiff status and the defendant's underdog status as all significant at either the five or one percent level. The contrary findings are likely due to the inclusion of the relsize variable which captures both underdog status and arguably more accurately represents firm level advantage. The substantially improved goodness of fit measures strongly supports this claim.

The multilayer perceptron findings offer some insight into independent variable importance. Remarkably, usage shifting and unpublished status are found to be relatively less important than the status of a defendant as a repeat player, the claimant status as a natural person, whether the infringing act involved partial or full copying and most pertinently the relative size variable which is asserted to be the most important determinant of fair use claim litigation success, employing the methods of Garson (1991) and Goh (1995) (see Table 2). These findings are in stark contrast with those of Sag (2012), the differences are likely due to the inclusion of the relsize variable and the method of estimation. The perceptron is capable of modeling complex non-linear processes and capturing variable interaction effects (Garson 1991, Goh 1995).

The hybrid model findings are largely consistent with the multi-layer perceptron findings, however the logit probabilities largely ranked first across all iterations of the hybrid model indicating that logit pre-processing was indeed worthwhile the relsize variable and the claimant and defendant status as repeat players were also found to be important employing the methods of Garson (1991) and Goh (1995).

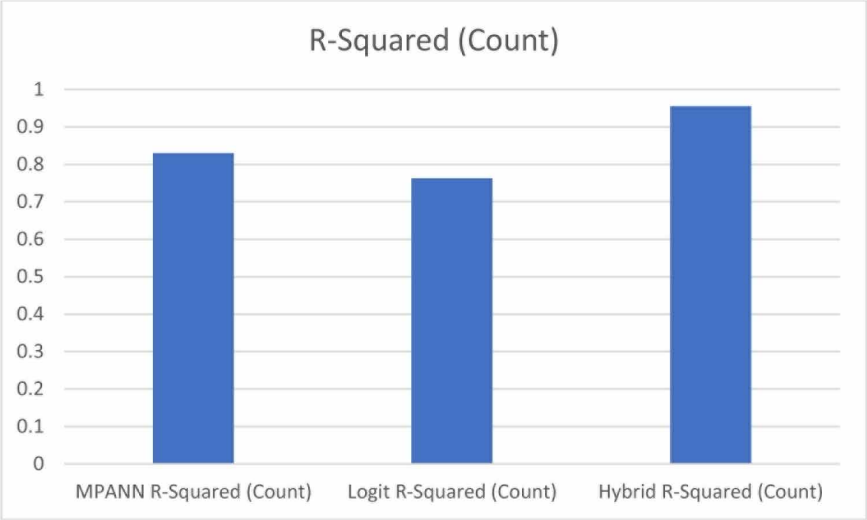
Note – This table summarises the co-efficient, t statistics, and associated probabilities for all variables within the specification

Figure 4. Efron's R-squared goodness of fit measures

Goodness of Fit and Predictive Accuracy

We employ Efron's method of determining goodness of fit because of its ease of interpretation (see Figure 4). Unlike other measures of goodness of fit Efron's method enables the resultant R-squared to be interpreted as a measure of explained variability within the specification. The ratio is the proportion of variability explained by the model specification. It is also mathematically the square of the correla-



EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

tion between the actual values and those predicted by the model. Consequently, this measure observes a range from minus one to plus one. This is consistent with the equivalent non-pseudo R-squared values employed in OLS regression.

The initial multi-layer perceptron model evidence an Efron's R-squared of 0.2401. This is substantially higher than the R-squared values observed within the extant literature. In Sag (2012), R-squared values vary between 0.095 and 0.215. These logit specifications were replicated to ensure consistency when framing the alternative logit, MPANN and hybrid logit/MPANN. This represents an 11.67% increase in goodness of fit between the full form logit model in Sag (2012) and the equivalent MPANN. Considering again the models presented above, we observe a shift in predictive accuracy and goodness of fit through the inclusion of a re-specified variable relsize denoting relative firm size. The inclusion of relsize, is in the logit model gives rise to substantial improvements in the logit model goodness of fit measures. Efron's R-squared, increases from 0.215 to 0.2714 a 26.25%. However, the increase in goodness of fit is not as substantial within the MPANN specification, increasing from 0.2401 to 0.2540.

The application of the hybrid method results in some remarkable efficiency gains in terms of computational time as well as goodness of fit and predictive accuracy. Through the use of the logit model as a pre-processing method, the MPANN incorporating the logit probabilities evidences an Efron's R-squared of 0.7208 representing a 201% increase in goodness of fit, when compared with the MPANN in isolation, and 184% increase in goodness of fit when compared with the logit used in isolation. While there is no perfect measure to assess model goodness of fit, all of the indicia suggests the hybrid method (logit-MPANN) offers the most robust specification. Considering now the central question of predictive accuracy, the findings indicate that the multi-layer perceptron and the hybrid method results in far greater predictive accuracy. Consider the count R-squared values for each of the models, essentially the percentage of observations predicted correctly by each model specification (see Figure 5). The traditional logit gives rise to a count R-squared of 0.763, while the multi-layer perceptron evidences a count R-squared of 0.83 equating to approximately 9.1% increase in predictive accuracy through the use of multi-layer perceptron. Through the application of the logit model as a pre-processing technique, the hybrid multi-

Figure 5.Count R-squared values for each model specification

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

layer perceptron achieves a predictive accuracy level of 0.9553, a substantial increase in predictive accuracy of 15.1 to 25.2% when compared with the logit and multi-layer perceptron respectively.

Considering the posited hypotheses, the findings are broadly consistent with the stated hypotheses. Each of the posited hypotheses is noted below:

H1: Where a defendant is larger relative to the claimant in firm size terms this position shall be positively and significantly associated with litigant fair use defense.

The findings across all specifications suggest that relative firm size is one of the most significant determinants of litigation success. Within the logit, perceptron and hybrid-perceptron models, the coefficient and independent variable importance analysis indicate that relsize ranks first in importance terms and is the most statistically significant within the logit specification.

H2: Where the defendant engages in transformative use this action shall be positively and significantly associated with fair use defense success.

In relation to transformative use the findings are mixed. Useshift is found to be nominally important within the perceptron models and positively associated with fair use defense success during litigation. However, it is found to be statistically insignificant.

H3: It is posited that the Perceptron shall achieve higher predictive accuracy than the traditional logit regression.

H4: The Hybrid Logit-MPANN shall achieve higher predictive accuracy than traditional logit regression and the standalone MPANN

Hypotheses 3 and 4 shall be considered concurrently. The perceptron and hybrid-perceptron achieved vastly superior predictive accuracy than the logit model. The hybrid-perceptron achieved the highest predicative accuracy overall, consistent with the stated hypotheses.

As such, in relation to the central consideration, the framing of a predictive model of fair use litigation success, the findings strongly favour the use of non-traditional methods specifically the multilayer perceptron and the hybrid multilayer perceptron. This is consistent with a number of studies incorporating discussion and/or analysis of logistic regression and machine learning methods (Tu, 1996; D'Rosario, 2016). There is however, a genuine dearth of research incorporating an analysis of hybrid methods and traditional methods within the legal domain. The present study appears to be the first within the area of litigation analysis.

CONCLUSION, LIMITATIONS, AND SCOPE FOR FUTURE RESEARCH

A number of studies have evidenced the benefits of artificial intelligence and machine learning methods within the legal domain. The current study extends upon this literature offering a unifying account, and detailing a new method of estimation not utilised within the legal domain previously. Through the use of a new specified variable capturing relative firm size it was identified that the status of the claimant as a natural person, defendant repeated status and relative firm size are identified as of significance to

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

litigation success. The perceptron and logit-perceptron offered deeper insights. The logit-perceptron is shown to achieve better predictive accuracy and better goodness of fit outcomes than the conventional regression methods employed within the extant literature.

Moreover, through the use of the perceptron and logit perceptron the variable relsize was found to be the most significant determinant of litigation success. The defendant status as repeat players was also found to be important employing the methods of Garson (1991) and Goh (1995). The findings appear to validate and further endorse the use of these contemporary non-parametric methods. The study does have some limitations worth noting specifically the limited available data and the absence of a singularly accepted method for determining robustness. Clearly, as more data becomes available, subsequent studies shall respond to the former issue in relation to the latter the use of Efron's R-Squared and the count R-Squared method appear to be the most valid and allow for the most coherent comparison of the parametric and non-parametric methods.

While economic methods are employed consistently within legal research, the use of non-parametric methods such as those within the domains of artificial intelligence and machine learning are relatively under utilised within the legal domain. The present study seeks to advise the next wave of interdisciplinary legal research, typified by applications of machine learning within the legal domain. We refer to this next wave as the third wave of legal empiricism in honour of Richardson & Hatfield (1989). We offer the conjecture that legal empiricism shall be strongly influenced by machine learning methodology, particularly as such technologies become more accessible to those within the legal domain. As this study makes evident, there is a dearth of research considering the relationship between law and machine learning. While this study responds directly to this shortage, further research is necessary. It would be worthwhile to consider the importance of judiciary member characteristics on judicial decision making as well as considering the legal domain beyond intellectual property. Such studies would serve to inform legal practice regulatory policy and our understanding of judicial decision making. Such studies would serve to inform the development of even more accurate and robust machine learning methods; and it is hoped that such studies are inspired and informed by the present study.

[33] D'Rosario (2016) "Rosenblatt posited the perceptron model, framing the concept of the retina layer with distributing input values. The work of Rosenblatt owed much to the initial work of Hebb, and also McCulloch, and Pitts. The work of Marvin Minsky and Seymour Papert asserted a number of the limitations of the perceptron model, and their work brought about a diminution of interest in perceptron modelling. The key challenge evidenced in the perceptron model as posited by Rosenblatt was the step function approach that made neural network models problematic to train. However interest in the field was renewed with the advent of techniques to moderate the issues associated with neural network training. A revival of sorts occurred as a result of the work of Rumelhart, Hinton and Williams, whose seminal paper 'Learning Internal Representations by Error Propagation' offered resolution. Their work enabled the effective training for a multilayer neural network. The backpropagation training method and a viable algorithm was first asserted in Rumelhart, Hinton and Williams, and was the first practical method for training neural networks. Herein, a gradient descent backpropagation training method is used for efficiency."

[34] Within a biological neuron, the synaptic signals are received by the soma (cell body) and dendrites and transmitted through the axon. Within an artificial neuron the vector of the variable is passed from one, neuron in the input layer to another neuron with the assignment of synaptic weights (weighted values). Transfer occurs through the assistance of a transfer function, the synthetic axon.

[38] It is necessary to discuss the criticisms of neural network methodology within legal research of which there appear to be few of a unique nature. Dan Hunter details the problems of using statistical sub-symbolic techniques in a symbolic field of research (D'Rosario, 2017a). At the outset it is apparent that such criticisms are relevant to all quantitative methods not merely machine learning. Hunter, is highly critical legal realist philosophy insofar as machine learning methods such as

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

perceptron models and artificial intelligence methods derive from them (D'Rosario,). It is evident that Hunters assertions are based on what Hunter considers to be inapt realist claims about the focus of network applications in his view and not the methods directly (D'Rosario, 2017). Hunter rightly and notably claims that useful applications are likely to be observed in latter studies (Hunter, 1994). It is hoped that the present study is such a study. It is also worth acknowledging that at the time that Hunter's paper article was authored, computing technologies did not enable the use of complex multi-layer perceptron models, nor was it possible to account for independent variable importance and as such the methods available now are far more useful in accommodating symbolic and sub symbolic languages as well as the open texture within legal research. Herein, as with D'Rosario (2016, 2017a) the author agrees with the claims of Hunter only to the extent that legal realists espouse that neural networks can provide normative assessments of legal outcomes and jurisprudence. No such claim is made herein. However, Neural networks methodology does enable a fuller analysis of judicial outcomes, jurisprudence and the importance of different variables in relation to such determinations.

[39] Consider the statements of Warner (1989), plausibly the most ardent proponent of this position, "While our language dictates a sequential description of the (legal reasoning) process, the process is in fact parallel. Many aspects of the problem resolution process are carried out simultaneously. The problem domain is defined by the initial statement of the problem. That initial problem is then resolved into a number of issues... the solution to which will be sought within the problem domain utilizing a sub symbolic paradigm that is not rule based…"
When accounting for even this staunch position, or when ascribing to the Hunter (1994) view position, the view of Warner does not coincide with the correct interpretation of legal reasoning as a process, neural networks nonetheless remain superior in methodological terms within legal research pertaining to legal reasoning; when compared with traditional regression methodology. This is because traditional regression models such as logit models are incapable of modelling dynamic nonlinear functions and as previously noted accounting for the interaction between variables (D'Rosario, 2016, 2017).

[43] For the initial theoretical propositions that served as the basis for the methodology see Hebb, D.O. (1952). *The organisation of behaviour: a neuropsychological theory*. Wiley.

[44] The multi-layer perceptron model shares a level of association with the logistic model, employing a logistic/sigmoid function. A more apt description however would be that the logistic model is a simple single layer perceptron model, that does not employ a second (layer) weighted aggregate input set.

Chapter 28
A Graphical Tool for the Creation of Behaviors in Virtual Worlds

Andrea Corradini
Design School Kolding, Denmark

Manish Mehta
Accenture Technology Lab, USA

ABSTRACT

Typically, the creation of AI-based behaviors for Non-Playing Characters (NPC) in computer games is carried out by people with specialized skills in the broad areas of design and programming. This book chapter presents Second Mind (SM), a digital solution that makes it possible for novice users to successfully author behaviors. In SM, authors can use a graphical interface to define the behaviors of virtual characters in response to interactions with players. Authors can easily endow NPCs with behavior capabilities that make them act in different possible roles such as e.g. shopkeepers, museum hosts, etc. A series of user tests with human subjects to evaluate the behavior authoring process shows that Second Mind is easy to understand and simplifies the process of behavior production.

INTRODUCTION

In order to increase player experience, the virtual characters that populate video games and virtual worlds should exhibit believable behaviors (Umarov, Mozgovoy, & Rogers, 2012). This does not apply only to the player characters, which are the characters that are controlled by the player, and as such are meant as more of a player's extension. This also applies to any other character that is controlled by the game, usually through artificial intelligence, such as townsfolk, vendors, enemies, allies, historical figures, bystanders, quest givers, etc. All these latter characters are referred to as non-player characters (NPCs) and are an integral part of the game. They exist to interact with the player characters, other NPCs, and the environment in a way that reflects their own distinct personalities and dialog capabilities.

In the context of synthetic characters, believability is all about making the users believe they are interacting with a living agent, whose existence is consistent with the virtual world the character is situated in. In essence, believability is the ability to suspend the users' disbelief, by providing an illusion of life (Bates 1994).

Creating behaviors for NPC usually requires specialized skills in both design and programming well beyond the skills of the average person (Magerko, Laird, Assanie, Kerfoot, & Stokes, 2004). Hence, the intrinsic nature of the behavior generation process is restricted to the individuals who have a certain expertise in this specific area. To date, there is little understanding of how individuals without programming and design experience (whom we will refer to as "novice users" throughout this paper) can carry out the behavior authoring process.

The behaviors of NPCs are usually scripted and are automatically triggered by certain actions, events, or dialogue. In that sense, player characters play the game, while NPCs display some facet of the game and help to further the storyline making the game what it is (Gillies & Ballin, 2004). In early digital games, NPCs display only basic non-interactive dialogue capabilities. Monologues realized with screens of text, floating text, voiceovers, cutscenes, text clouds and other non-branching dialogue techniques made it possible for NPCs to convey only an immediate impression of their personality in reaction to or to initiate interaction with the player. However, this lack of interactivity turns the player into a mere passive consumer of content. More recent, advanced games allow for interactive dialogue where the player can engage in a compelling conversation with NPCs that results in witty and dramatic storylines that fit the context at hand. In those games, a conversation is typically modelled using dialogue trees (Adams, 2012) where the player is presented with and can choose from a limited list of interaction options in response to an NPC's action. Each choice affects the course of the game in a different way since each of them may result in a different response from the NPC. Moreover, the possibility to choose between different options makes it necessary for the game designer to customize the NPCs' behaviors by modifying their default scripts or by creating entirely new ones.

Branching the overall storyline puts the player in charge of learning about the game by engaging him in conversation with NPCs. In this way, uncovering the storyline becomes part of an increased overall player experience (Li, Thakkar, Wang, & Riedl, 2014). Besides engaging interactive narrative experiences (Yu & Riedl, 2014) with unfolding storylines, it is also necessary to have the tools that make it possible to design and create the appropriate behaviors. This is not just about making them funnier. It is also about creating more surprising and unpredictable behaviors within the game constraints so that two interactions with an NPC never turn out to be the same.

Digital games have much to gain from adopting artificial intelligence (AI) techniques to author complex behaviors. This is however, a difficult task for it requires a great deal of competence and resources. Usually, only the game creators or the people with specialized skills in both design and programming can carry out such a task. As a result, authoring behavior can even become a bottleneck in the process of creating the content displayed within digital worlds.

In this paper, we present Second Mind, a digital authoring tool solution that helps any players to populate virtual worlds with NPCs that can exhibit believable interactive behaviors. Our solution is based on a study that we carried out using paper prototypes to investigate how individuals without programming and design experience carry out the behavior authoring process. That study reveals some major limitations that we account for in the development of Second Mind. In Second Mind, novice users can easily design the behavior of graphical characters that impersonate different tradesmen such as shopkeepers, museum hosts, etc. in virtual worlds.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

The rest of the paper is organized as follows. In the next section, we discuss related works and the challenges that behavior authoring poses to users, with particular focus on novice users. Thereafter, we present the results of the user study that we ran with 40 novice users to evaluate the feasibility of a paper-based prototype authoring system in a restricted context. We then detail the architecture of the digital authoring solution that we developed for novice users based on the findings discovered in running the user study. Eventually, we conclude with an outline of the work in process and our ideas for further improvement.

BACKGROUND AND RELATED WORK

Believable characters play an important role in many interactive stories and digital games (Rickel, Marsella, Gratch, Hill, Traum, & Swartout, 2002) because they can contribute to the overall narrative. Thus, the improvement and the control of their behaviors is propaedeutic to an increased game experience for players.

To ensure believability, virtual agents usually integrate multiple cognitive abilities of people such as language, gesture, emotion, and the problems associated with real-time navigation in and interaction with a simulated virtual world. Moreover, they also simulate many of the embodied and social aspects of human behavior as well as the need of autonomous behaviors, consistent with the character's personality, motivational state, and world context. Such an autonomy is usually implemented with an internal structure that allows the agent to have its own needs, motivation and interests. Based on these needs and interests the character can then dynamically select and generate goals that eventually result in autonomous behavior. An architecture to represent and manage internal driving factors in intelligent virtual character, using the concept of motivation, has been presented in (Avradinis, Panayiotopoulos, & Anastassakis, 2013). Because of the integration of human cognitive capabilities, virtual characters are gaining interest also as a methodological tool for studying and validating theories in human cognition (Gratch, Hartholt, Dehghani, & Marsella, 2013). At the same time several cognitive architectures have been put forward also for applications with virtual agents (Langley, Laird, & Rogers, 2009, Laird, 2008, Langley & Choi, 2006, Nuxoll & Laird, 2007, Sun 2007, Gluck 2010).

Common methods for authoring behaviors rely on heavy scripting, where a blend of dialogue scripts, hand-coded animation scripts, motion-captured characters, and hard-coded behaviors is used to exhibit a character's features. Usually, artists, designers and programmers must work together to detail a character-attitude and to portray the appropriate character's movements given a set of constraints. However, scripting is labor intensive, rigid because it does not adapt to all variations induced by interaction, and requires programming and design skills. An alternative approach is to use artificial intelligent (AI) techniques to adapt character behaviors in response to the different contexts that are induced by different interaction sessions. Despite its own inherent limitations, AI technology has been increasingly applied with success to digital game design and interactive narrative both to enhance interaction and to create novel gameplay scenarios (Riedl & Zook, 2013). AI techniques have been explored with diverse focus on character believability and expressivity in terms of e.g. synchronization of verbal and non-verbal modalities (Cassell, 2001, Corradini, Mehta, Bernsen, & Charfuelan, 2005), portrayal of emotion and personality (Allbeck & Badler, 2004, Aylett, Louchart, Dias, Paiva, & Vala, 2005), and so on.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

The ease of the actual process of behavior creation has been given less relevance and explored by fewer researchers. The language ABL (Mateas & Stern, 2004) is an early effort in this direction. ABL is a Java-like programming language that can be used to manually script behaviors (Mateas & Stern, 2003, Gomes & Jhala, 2013). The production costs are high and the use of ABL requires advanced programming skills. Finite State Machines (FSMs) have also been used in digital games for many years as an alternative to scripting. However, FSMs can quickly become difficult to maintain and do not scale well with increasing game complexity (Schwab, 2009). Various FSMs modifications have been proposed to bypass part of these problems (Isla, 2005, Champandard, 2007). The use of AI techniques such as Layered Statechart-based AI (Dragert, Kienzle, & Verbrugge, 2012), Behavior Trees (Tomai & Flores, 2014), automated planning and scheduling strategies (Coman & Munoz-Avila, 2012, Kadlec, Toth, Cerny, Bartak, & Brom 2012, Kelly, Botea, & Koenig, 2008), has been explored as well. All these works require human intervention and a great deal of effort and skills to create and to debug the scripted behaviors. A recent attempt at eliminating manual scripting in favor of automatic script generation is presented in (Zhao & Szafron, 2014) where the content creation for cyclic behaviors is facilitated using a tiered behavior architecture model. This model features a scheduling algorithm to determine the objectives of virtual characters and to specify the roles that satisfy these objectives dynamically during game play. The results of a user study that compares the creation of manually scripted behaviors with the behaviors generated by an implementation of their model is also presented. Three metrics, and notably behavior completion time, behavior completeness, and behavior correctness, are used as a measure for assessing behavior reliability and designer efficiency.

Differently to most of the works presented previously, our solution provides a graphical user interface with different constraint types. While a few graphical interfaces have also been put forward to help people create scripts, these tools are aimed at story designers and at people who want to learn to program. Our implementation targets any person who wishes to create behaviors with no prerequisites in terms of skills and experience.

THE AUTHORING PROCESS AS A MENTAL ACTIVITY

Illustrative Example

Steven is an enthusiastic digital game player without any programming and design background. Steven is essentially an average end user and game player. He likes to buy interactive story games. Lately he has been playing an online game recently released that is based on the story "*And then there were none*" (Figure 1).

The story context is that the player has been invited to have dinner at a manor house. When the dinner is about to start, the player discovers that one of the guests has been murdered. After the introduction, the player is free to move around and interact with the other characters in the house. The goal of the game is to find out who committed the murder among the guests in the house.

After one of his many playing sessions, Steven wants to show off his creative skills by adding a set of simple scenes to the game in order to add more variability for other online players. Steven has a few scenes in mind that involve only characters with a particular personality, personal traits, emotions, and background. Authoring such experience is an example of the creative process that we wish to understand and enhance.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Using the traditional approach (i.e., hand-authoring scripts) would require a tremendous effort in authoring each one of the individual characters. Moreover, game companies usually provide toolkits to create only scenes/maps. The behavior creation is commonly carried out through scripts in a programming language, which restricts the process to people with a certain degree of programming skill. Steven does not have such a programming experience and thus he cannot add this kind of new content and experience to the game. If there was an environment that would allow more people like Steven to be involved in extending the game, it would provide them an opportunity to exercise their creative skills and make them available for other players. Consequently, the gameplay experience would improve given a larger base of users creating content and sharing it with each other.

AI Behavior Construction by Novice Users

Novice users bring little or no programming experience to the behavior construction task. However, they can employ a combination of real-world experiences, experience with other software, computers and electronic gadgets in general to understand the construction task. One of the fundamental capabilities of human cognition is the ability to relate something new to something similar that was already encountered and/or experienced.

Familiar interaction design approaches that allow users to create correspondences with a more familiar domain (Heckel, 1984) have been used in product design and have been shown to make a product or interface easier to understand. The key question, therefore boils down to identifying the right interaction design approach that can be employed as part of the presentation of the authoring process that can help novice users understand the construction process.

An AI behavior construction process requires an underlying representation formalism and vocabulary that is used to represent behaviors. Representation formalisms have been a keenly studied topic within the AI field for quite a long time. In fact, several representational formalisms have been put forward, ranging from predicate calculus through frames and scripts to semantic networks and more (Brachman

Figure 1. A snapshot of the commercial interactive story "And then there were none"

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

& Levesque, 2004, Russell & Norvig, 2010). An AI scientist, who is familiar with the vocabulary of the underlying representational formalism, is adept at translation between the domain that is being represented and the formal language used to describe it. A novice user, however, would not have the necessary background to use the formal representational language. Several criteria can be utilized to classify different AI representation formalisms: expressivity is one of the most common among them. Clearly, the more expressive the formalism is, the easier it is to represent something with it. In our context though, the key requirements for the representation formalism and the corresponding vocabulary, are understandability and ease of use. Our idea is to forsake some level of expressivity for better understandability and ease of use. We contend that the representation vocabulary should speak the user's language and use words, phrases, and concepts familiar to the user, rather than terms more familiar to an AI scientist.

Assuming that a design solution that will enable novice authors to construct AI behaviors should provide the right interaction design approach and representation vocabulary to support them in the authoring activity, the main question that we have to address is what is a design solution that enables novice users to easily create AI behaviors for NPCs in a virtual world?

For the sake of simplicity, we focus on the construction of particular kinds of AI behaviors situated in a particular domain. Namely, we confine the scope of AI behavior creation as sequence of actions to NPCs impersonating tradesmen in a virtual world.

Representation Vocabulary

As a starting point in the process to identify the basic vocabulary and terminologies, we used an existing reactive architecture that we presented in (Corradini, Mehta, Bernsen, & Charfuelan, 2005, Zang, Mehta, Mateas, & Ram, 2007). The key property of such kind of architectures is their reactivity and responsiveness response to time-critical events, such as emergencies in a robot assistance domain, or dodging and avoiding unexpected obstacles in real-world navigation domains. This reactivity to time critical events makes them ideally suited for creating interactive avatars. Examples of reactive architectures include the Reactive Action Packages (Firby, 1987), the Gapps formalism (Kaelbling & Rosenschein, 1990), the Procedural Reasoning System (Georgeff & Lansky, 1987), the Soar architecture (Laird, 2012), and many more. A notable example of reactive architecture specifically developed for interactive believable characters is the A Behavior Language (ABL) (Mateas & Stern, 2004). ABL has been successfully used to author the central characters Trip and Grace for the interactive drama Facade (Knickmeyer & Mateas, 2005).

Based on our existing architecture and taking inspiration from the architectures previously mentioned, we identified the following terms:

- **Scene:** Provides a social context under which the behaviors of the virtual characters can be described. An example of a scene might be "a boy meeting a girl at the park for a date". Scenes may contain one or more characters, and can be of arbitrary length.
- **Behavior:** Represents the activities that the avatar can accomplish. Behaviors can be considered similar to plans in a traditional AI planning paradigm. An example of a behavior within the scene "a boy meeting a girl at the park for a date", the boy avatar could perform a "flirt with a girl" behavior. In general, behaviors consist of a sequence of other behaviors and actions so that "flirt with a girl" may contain e.g. the behavior "smile to a girl".

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

- **Action:** Represents the lowest level behaviors that can be performed by the avatar in the world and cannot be further decomposed. They represent the elementary units on which all behaviors are further built on.
- **Personality:** Represents a character's overall way of conducting himself. The personality is manifested in the way a specific avatar goes about performing the scenes through the kind of behaviors he can pursue, the way he carries out these behaviors and the way he conducts the basic actions.
- **Emotion:** Represents the avatar feelings in response to things happening in the environment.
- **Percept:** Represents basic events that the avatar detects from the environment.
- **Like/Dislike:** Represents things that the virtual characters likes or dislikes.

Behaviors are further associated with the following set of conditions:

- **Pre-Condition:** Detects when the behavior needs to be activated and carried out.
- **Success-Condition:** Detects when a behavior has been successful. This information is needed to identify when a behavior needs or not to be pursued again.
- **Non-Progress-Condition:** Detects when a behavior is not progressing well. If a behavior is not progressing well, the character would try to repair the situation by different means such as pursuing a different behavior to achieve the same or a similar behavior and/or have an emotional reaction in response.
- **Failure-Condition:** Detects if the behavior has failed to achieve its purpose.
- **Advancing-Condition:** Keep a check on whether the behavior is progressing well or not.

Success-condition and failure-condition are mutually exclusive. As such, they can be thought of as opposite to each other. They are used separately to provide more flexibility to the user to use either of them as needed. A similar reasoning went into providing the Non-progress-condition and the Advancing-condition as separate entities. As part of the authoring process, these conditions can be created by using basic sensory information through mathematical and logical operations that can be detected from the virtual world.

In our framework, the behaviors are defined bottom-up meaning that each behavior must resolve into a series of basic actions. Hence, during the authoring activity, a novice user must define each behavior in terms of its constituent actions. Likewise, in order for the framework to detect the conditions associated with a behavior, these conditions need to be defined in terms of the basic set of events that can be detected within the virtual world.

Next, we discuss the authoring process that we envisioned for the authors to carry out.

The Envisioned Authoring Process

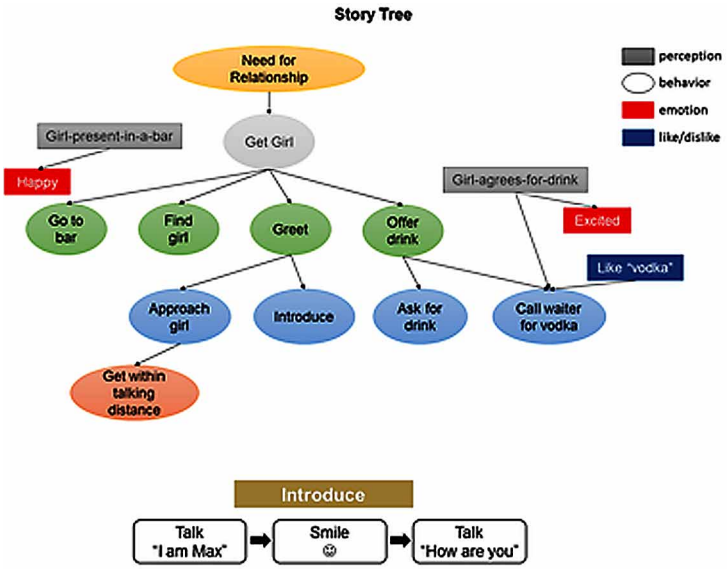
The envisioned authoring activity is based on our previous works on the generation of interactive characters using reactive planning languages (Corradini, Mehta, Bernsen, & Charfuelan, 2005, Corradini, Mehta, & Charfuelan, 2005, Zang, Mehta, Mateas, & Ram, 2007). It can be carried out following three main steps.

The first step involves the creation of scenes with a hierarchical behavior structure. Scenes may contain one or more characters, and be of arbitrary length. As an example, we can consider a scene called "boy flirting with a girl in a bar". The given scene consists of two avatars: one representing a girl and

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

the other representing a boy. The boy might be assigned a personality trait called "flirtatious" and "enthusiastic". The female character may be assigned a personality trait of being "shy". For such a scene, the behavior tree is shown in Figure 2 (top). The top-down structure linking the lowest level behaviors in terms of basic actions that can be carried out in the virtual world is also defined by the authors as shown in Figure 2 (bottom) for the behavior "Introduce". Such a behavior is made up of three actions in sequence, namely, a parameterized "Talk" action (the parameter being e.g. "I am Max"), followed by a "Smile" action, and concluded with another "Talk" action with parameter "how are you".

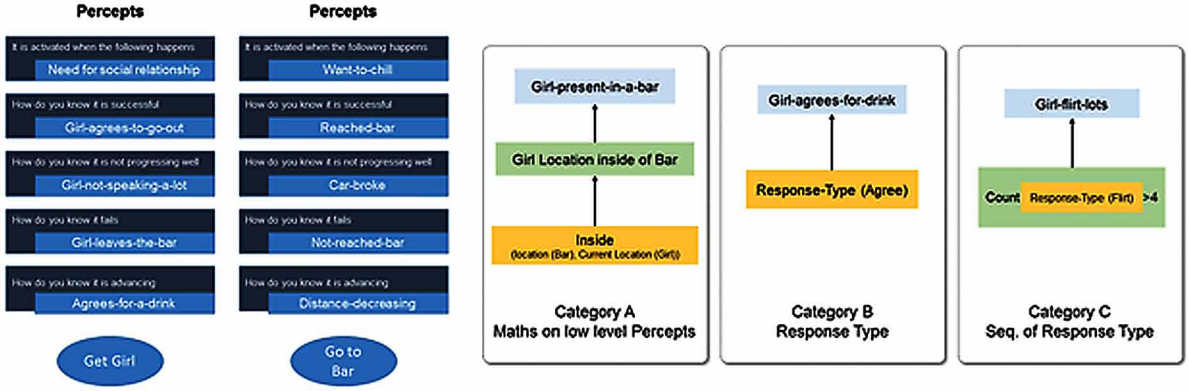
The second step in the authoring process consists in defining the various conditions for the behaviors as mentioned in the previous section. Various conditions for two example behaviors are shown in the Figure 3 (left). For example, the behavior "Go to a bar" is associated with an activation condition that the boy wants to chill out.



The third and final step involves linking higher level conditions with the basic level percepts available in the virtual world. For example, the condition "Girl is present in a bar" can be detected by performing an inside operation on location of bar and location of the girl as shown in Figure 3 (right). An exhaustive list of basic actions and percepts that are available to authors can be found in (Mehta, 2012).

User Study: A Paper-Based Authoring Prototype

We conducted a user study in order to identify if novice users would be able to understand the representational vocabulary and carry out the authoring process following the steps listed above.



The user study was carried out using paper prototypes. We were particularly interested in figuring out which parts of the representation vocabulary are difficult for users to understand, what parts of the authoring process are difficult to conceptualize, and possibly what are the points at which the authoring process becomes tedious.

Figure 2. (top) Graphical representation of the behavior tree structure created for a scene; (bottom) the behavior "Introduce" as linked sequence of basic actions available in the virtual world

Figure 3. (left) Example of conditions for two behaviors; (right) percepts from the virtual world

We recruited forty participants (referred to as P1 through P40): 10 females and 30 males. The participants were pre-screened to make sure they did not have any programming and design background. The participants ranged across multiple races, education levels, and ages (from 22 to 40 with an average age of 28). Each subject was paid 10 USD per hour rounded up to the nearest hour. Players signed a consent form at the beginning of the session. The authoring task was described to participants through example forms (as shown in Figure 2 and Figure 3).

Each participant was given a brief description of the scene setting. Two such scene settings were provided to the participants. The first scene was about a boy taking a girl to prom, while the second scene involved an armed robber who holds someone up. The list of basic actions and basic events that can be detected from the environment was also provided to the user. The participants were then asked to conduct the authoring activity using the paper-based prototype interface forms.

These forms were blanked out versions of the filled forms similar to those shown in Figure 2 and Figure 3.

During the authoring session, a researcher observed the player's interaction with the paper prototype and took notes. This included any unusual things such as "unable to fill a condition", or "having difficulty creating behaviors". On an average, a complete player interaction lasted approximately one hour. At the end of their interaction, subjects were asked to fill out a quantitative questionnaire. Moreover, an open-ended interview about the authoring experience was conducted with each participant immediately thereafter.

To perform the analysis, we transcribed both the user responses from the interviews and the actions observed during the authoring process. We analyzed the data obtained with focus on the qualitative analysis of the authoring process. To that extent, as qualitative analysis method we chose the well-known Grounded Theory (Strauss & Corbin, 1990). Using grounded theory principles, the transcriptions were processed, first in order to take open-ended notes and second to highlight more salient ideas expressed by each subject.

We generated codes, such as "User not able to fill precondition" or "User not able to complete scene creation process", and listed multiple user quotes for each category in an Excel spread-sheet. We then grouped related codes: for instance, all codes that referred to the problem of creating behaviors were initially grouped together into related concepts. We went through an iterative process of describing each concept and conceptually linking them to each other. We formed a single hierarchy of the concepts, and

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

organized the same concept with a paragraph to describe each concept along with the top two to three quotes for it. This hierarchical organization of concepts served as an outline for the qualitative findings.

We also analyzed the results from the forms filled out by the users during the authoring process to identify any further issues during the authoring process and to get a better understanding of issues that emerged from the interview session.

The analysis of data collected during the study provided several key insights that can summarized into the following categories.

Conceptualization of Behaviors

The data analysis indicated that users had difficulty conceptualizing the behavior creation process as a hierarchical, top-down process. To that regards, P16 states:

..When you think of a scenario where X needs to happen, you can think of a few things that would happen, like A would happen and then B could happen and so on. Here (using the authoring interface) I am thinking of things in a different way. I am thinking like A would happen and then in order to accomplish A, I need to do these two other things and then I would have to break them down, that is kind of hard..

When users visualize the creation process, it seems very hard for them to think in a top down fashion and they seem more used to thinking in a sequential fashion. Subject P23 stated:

..When I do things, I do them in a very sequential fashion, it would be hard for me to plan out like I would do this and then it would be doing these other two things which would then involve other activities..

The difficulty of creating hierarchical structures is confirmed by high ratings extrapolated from the quantitative questionnaires. To the question of difficulty level in creating behaviors, our subjects provided an average rating of 4.03 (with 5 indicating "very difficult").

Feedback on Created Scene

Several users reported that they had difficulty seeing the results of their authoring process. Creating the behaviors on a paper prototype did not give them the opportunity to evaluate what they just created. Subjects mentioned that it would have been easier for them to create behaviors if the system could "play back a simulation of the behavior" (P13) so that they could "verify or correct their creations"(P15). Subject P2 mentioned:

..I was imagining how things would go when someone does these things, I could see that there could be some things which might not work exactly, I would say it would have been easier if things played out in a game, that would give good ideas on what works and what doesn't..

Users mentioned that they would want to see how "*the scene they had created would work in actual practice*" (P10). They felt that the scene "*might come out funny or some gesture might not work*" (P24). Looking at the avatar acting out the created behaviors would be very helpful in finding how well things would work in actual practice. Subject P19 mentioned:

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

..Seeing my creation being acted out would be great. That would tell me how well it works from the performance perspective..

During the authoring process, it is very hard for users to take into account all the possible situations that might occur in reality during gameplay. This task becomes even harder for novice users as they are new to carrying out the design task. Thus, it is very likely that while designing behaviors, the users would forget to take into account certain situations. It would be helpful if the users were able to observe a simulation of the created behaviors to identify immediately any issues with them.

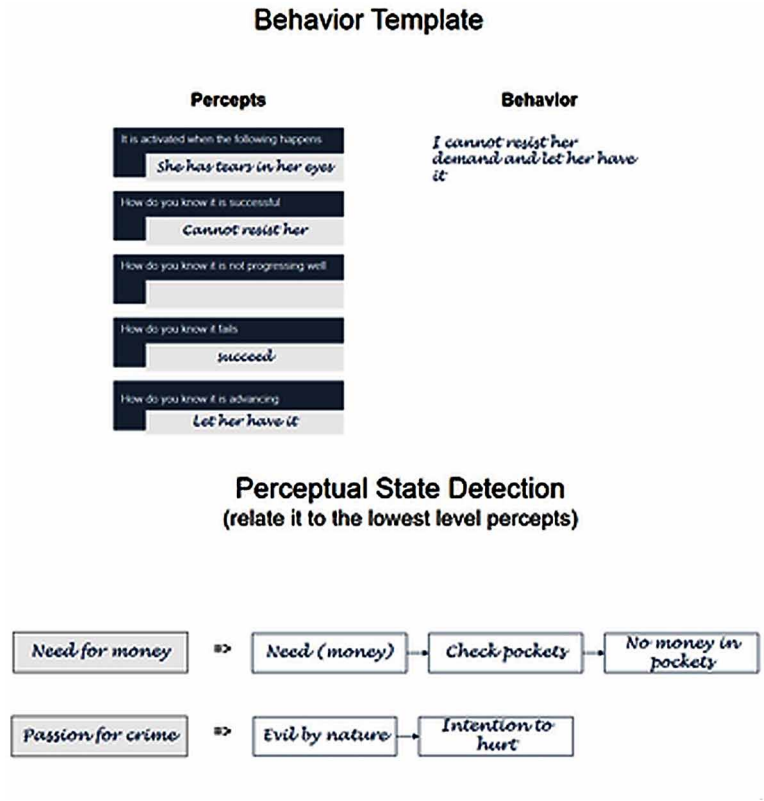
Behavior Conditions

Some parts of the behavior condition creation process were left empty by the subjects. They had difficulty identifying things like the "progress-condition" (30 out of 40 users) and "failure-condition" (34 out of 40 users), the "advancing condition" (28 out of 40 users), and the "success-condition" (26 out of 40 users). Figure 4 (top) shows an example behavior condition form filled by one user who did not fill some of these conditions and provided only a very vague description for some of the others. Subject P24 mentioned:

..When my behavior needs to be activated was clear. I know when I want my character to perform something. Some of the other things were difficult like success condition. I may not be able to know whether my behavior is successful or not by looking at things in the environment..

On the question of difficulty level in creating advancing condition, users provided an average rating of 4.1 (with 5 indicating "very difficult"). Similarly, for difficulty level in creating failure, success and progress condition users provided an average rating of 4.28, 4.35 and 4.55, respectively (with 5 always indicating "very difficult").

On the one hand, a simple way to address this problem would be to reduce the set of conditions. On the other hand, we are aware that this also takes away some of the expressivity of the system. Having novice users as target group, we decided to reduce the set of conditions in order to make the authoring process more accessible for them.



Additionally, subjects had difficulty linking behavior conditions with lowest level sensory information that was available in the environment. As P32 mentioned:

..Sometimes I could say when my behavior fails. But in general I wasn't sure if I could see these things in terms of what that was available in the environment..

The perceptions could become very abstract and users had difficulty relating it to sensory information that can be detected from the environment. Figure 4 (bottom) shows an example where "need for money" is broken down to "money in pocket" which a subject could not relate to the sensory information describing "no money in someone's pocket". Apart from that, in order to concretely connect the sensory information obtained from the world to higher level behavior conditions, mathematical operators needed to be defined in certain situations and contexts. Most of the times, subjects skipped this process. Subject P6 reported that "..creating mathematical formulas was the most difficult part..".

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 4. (top) A paper form related to behavior conditions as filled out by one user; (bottom) example of behavior condition that users had difficulty in connecting to sensory information from the environment

Similarly, subject P25 explicitly expressed that authors need technical skills in order to carry out this step:

..Defining it mathematically in terms of the lowest level things that are happening in the environment was unclear. I would think someone who has the technical skills would be able to understand it better than me..

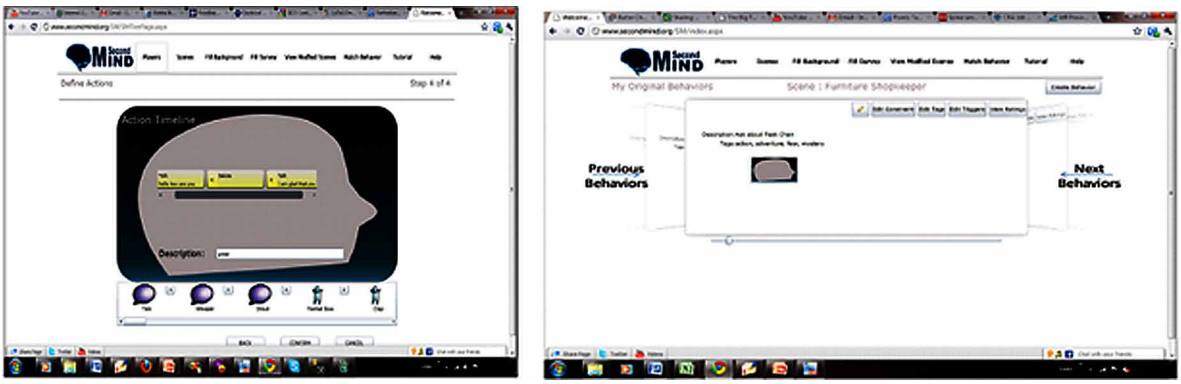
One possibility would be to remove the notion of complex conditions defined using mathematical operators over the basic sensory information could be to provide a base set of parameterized conditions that can be used individually or combined together to result in more complex conditions.

SECOND MIND: A SYSTEM FOR BEHAVIOR AUTHORING

Rationale and Context

The previous user study explored a design solution that would enable novice users to successfully author AI behaviors. That study provided, among others, the following key insights and design directions for creating the authoring interface:

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use



- The process to link behavior constraints to lower level percepts must be as simple as possible; the conditions themselves must be limited, clearly understandable and should be expressed with an easy-to-use formalism.
- The authoring task should be presented as a sequential process and not rely on deep hierarchical structures.
- Authors need continuous feedback on the authoring activity so that they can see the results of their ongoing process and thus promptly identify possible problems.

On one hand, reducing the set of conditions takes away some of the expressivity of the system, but on the other hand, it allows keeping the authoring process simple. Conditions help the avatar identify when, what, and how a certain behavior must be carried out.

We express conditions using what we refer to as triggers. We provide a set of triggers that can be used individually or combined together to define more complex constraints. An example of trigger is "User Clicks on (button label)", which can be used when the player wants the avatar to perform a behavior in response to a button click ("button label" is a placeholder that must be provided during the authoring process). Many other triggers are also provided such as "Avatar Close to (object name)", "Avatar Touches (object name)", "Player Close to (object name)", "Player Touches (object name)", "Behavior Ends (behavior name)", "Pause after Behavior Ends (behavior name, time)", "Run Event (event name)", and so on. Triggers can be composed using logical operators. For instance an "Trigger And(A, B)" can be used to specify a behavior for the avatar to perform when both a given trigger A and trigger B are specified.

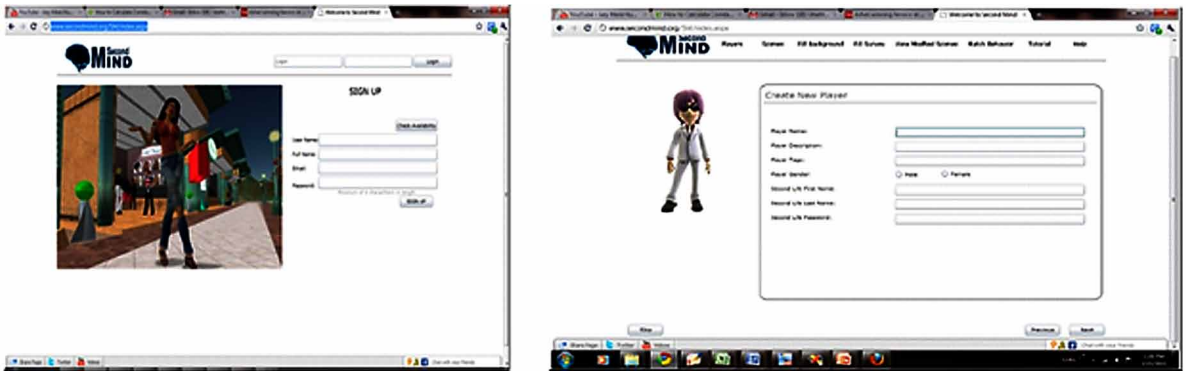
In order to present the behavior creation task as a sequential process, we applied the notion of timelines. Timelines indicate a left-to-right sequential sequence, where each event occurs in chronological order. Various storyboard-authoring tools like Adobe Director and Apple's Garageband Timelines as well as AI-based interactive story authoring tools like Scribe (Medler & Magerko, 2006), U-Create (Sauer, Osswald, Wielemans, & Stifter, 2006) and Viper (Agamanolis & Bove, 2003) employ timelines as an interaction design approach. We use timelines to represent the ordering of story segments in a left-to-right sequence while also allowing story segments to be re-ordered on the timeline. In order to help the user conceptualize the task concretely, the authoring activity along the timeline is presented in a mind-like shape (Figure 5).

Figure 5. (left) Authoring of a greeting behavior as a left-to-right sequence of the basic actions "talk (text)", "salute" and "talk (text)" on the timeline; (right) Behaviors are shown in a sequence using the cover-flow approach

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Eventually, in order to comply with the need to provide a continuous feedback to the user, we connect our authoring environment to an online virtual world named Second Life (Rymaszewski, 2009) where avatar's behaviors can be executed and displayed graphically in 3D. In Second Life, users can create, design and build their own clothes, buildings, artifacts, landscape, pets and much more. We chose Second Life as platform to display 3D-based user-generated content because it has a large user base, it allows for easy connection to external controllers through an API, and it provides a rich set of basic actions for the avatar in the form of emotions and physical actions. Using our authoring interface Second Mind, authors can create behaviors, execute them in Second Life, and immediately see the effects of their authored artifacts.

The Authoring Process in Second Mind



In order to use Second Mind, the user needs to create an account where to store, among other things, his/her Second Life login credentials. Once the account is created, the user is guided through a tutorial, which explains the terminology used in the authoring interface (like triggers, scenes, behaviors, actions, etc.). The user then can define one or more characters in Second Mind and connect each of them to a different avatar in Second Life.

At this stage, the user is ready to create a scene and its corresponding behaviors. A scene provides a social context such as, e.g. a furniture shop where the avatar acts as a shopkeeper whose goal is to sell furniture items. The author creates a description of the scene by entering some information like the name, a description and by selecting one of the characters created in earlier steps (see Figure 6). The user also associate constraints a limited set of constraints. For instance, a constraint to apply to the scene in the shopkeeper context could be "likeable" or "salesman skills".

Beside the contextual constrains, all scenes are associated by default with two additional general constraints, namely "overall experience" and "avatar performance". The author uses a set of sliders to specify matching values on a 0 to 5 point scale for each of the constraints s/he wants to set. Moreover, the user can associate semantic tags to the scene. Now, avatar behaviors can be added within the scene.

Similarly, to the scene creation process, the author can create a complex behavior from a list of simple elementary behaviors. To define a new behavior, the author needs to enter a name that uniquely identifies it followed by the list of behaviors that make it up and by the specification of the constraints that characterize the behavior as a whole.

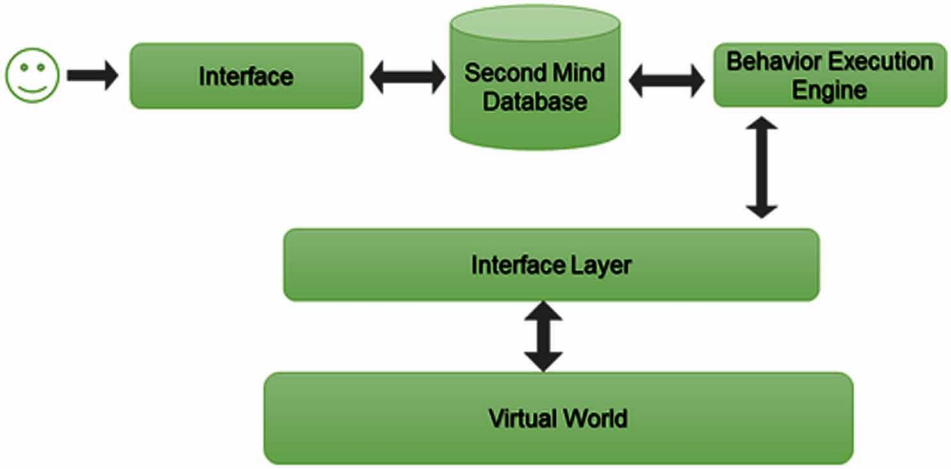
Figure 6. (left) Screenshot of the web version of Second Mind; (right) initial steps for the creation of a scene

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 7. The player interaction with an avatar can be initiated by clicking on the device carried by the avatar on his left shoulder; clicking on the device causes a graphical interface to pop up with various scenes to choose from

Using a set of sliders, the author can specify the values for the constraints. For example, in order to have an "enthusiastic" and "pushy" shopkeeper for a "greeting behavior", the user has to select first the corresponding values for those two constraints that give an idea of the avatar personality. These values influence the way (e.g. speed, spatial extension, etc.) a certain behavior is rendered. The user then can assign triggers to the behavior in order to specify the context in which it should be carried out by the avatar. The process is iterative, in the sense that each of the steps can be applied to define an even more complex behavior as well as to each single behaviors that are used to define the complex one. During the creation of a specific behavior, the author can also define a constraint for which it is the avatar that initiates the interaction. Once a behavior is created, the user can immediately play it out in Second Life and test its 3D graphical representation.

In order to interact with an avatar in Second Life, the player must click on an attachment on the avatar's left shoulder (see Figure 7). Upon clicking, the player is presented with a GUI containing buttons labeled with the names of the scenes that have been previously authored for the avatar (see Figure 7). Each of these buttons represents one "User Clicks on (button label)" trigger that is associated with the behaviors of a scene. To interact with the avatar, the player must simply click on a button.



System Architecture

With a basic understanding of the authoring activity, we can delve into the system architecture. As shown in Figure 8, Second Mind architecture has four core components and one application-specific component. The four core components are:

- **Second Mind Database:** A MS-SQL server based database that stores scenes, players, behavior elements such as triggers, basic action, etc.
- **Behavior Execution Engine:** An execution engine that loads the behavior elements and executes them in the external world. The behavior execution engine connects to the external world through the interface layer that is specific to the world that Second Mind is connecting to.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

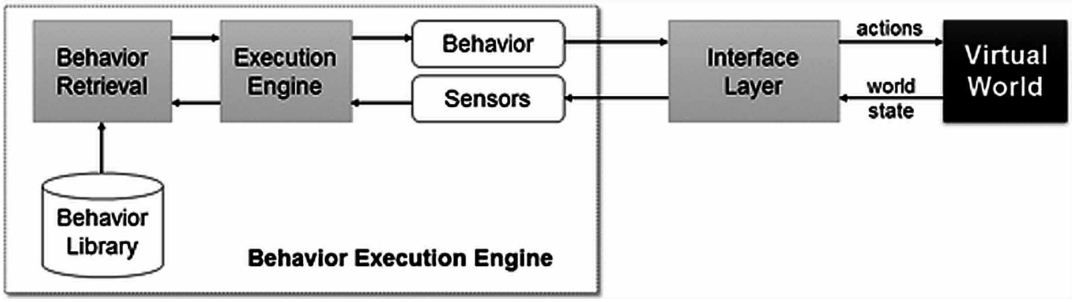
Figure 8. Overview of Second Mind overall architecture

- **Graphical Interfaces:** Provides the interfaces for creating user account, scenes and behaviors as described in the previous section.
- **Behavior Recommendation Engine:** Provides suggestions during the behavior-authoring task.

In addition, in order to apply Second Mind to a given graphical world, one application-specific components is required: are:

- **Interface Layer:** The architecture of Second Mind is domain-independent and can be connected to different virtual world simulations via a custom interface layer. The interface layer provides the ability to connect Second Mind to the simulation platform, such as Second Life or other virtual world. The interface layer requires the definition of percepts, actions, and other application-specific elements along with the APIs to connect Second Mind to the simulation.

Behavior Execution Engine



The behavior execution engine (see Figure 9) loads the behaviors corresponding to the currently active scene, identifies the behavior(s) to carry out based on the current perceptual information from the world, and sends the information about these behaviors to the graphical world for execution through the interface layer.

The behavior execution engine can be correspondingly broken down into three main modules: interface:

- **Behavior Library:** It is part of the Second Mind database that holds behavior elements for a specific application domain. For example, if the application domain were Second Mind in an educational setting, the library would contain personalities corresponding to teachers, students, etc. If instead the application domain were a household robot, the library would contain personality elements corresponding to cooking food, cleaning the house, etc.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 9. Overview of behavior execution engine architecture

- **Behavior Retrieval:** It is responsible for loading all the behaviors corresponding to the active scene from the behavior library. The active scene is the scene that the player selected when s/he was presented with all possible authored scenes associated with a certain avatar.
- **Execution Engine:** It receives the currently active domain independent sensors from the interface layer and checks the triggers for the behaviors corresponding to the active scene to see if any of the behaviors were activated. It also takes the current active behavior and sends it through the interface layer to the virtual world for the avatar to perform it.

Interface Layer

The Interface layer parses the domain dependent perceptual state into a set of domain independent sensors (see Figure 10). The domain dependent perceptual state from Second Life contains the following items:

- **Object Info:** Contains the information about various objects in the environment such as their current position, rotation, type (whether an avatar or a passive object), region to which the object belongs, etc.
- **User Button Click Info:** Contains information regarding button clicks made by the player while interacting with the avatar.
- **Event Info:** Contains the information regarding various events happening in Second Life such as the player moving around in the environment, the player touching an object, etc. Objects in the environment can send various events to communicate with the avatar. If there are behaviors that have "Event happens (event name)" as triggers, avatar can react to events with name "event name".

The world specific information is parsed into a set of domain independent sensors that correspond to various triggers. This information is then sent to the execution engine, which checks the sensors against the triggers corresponding to the current set of behaviors to identify if any new behavior(s) has become activated. The interface layer module also receives the action corresponding to the active behavior and sends it to the virtual world. The interface layer provides an abstraction layer and maps the action name received from the execution engine to virtual world specific action name. For example, an action "*laugh*" in Second Mind is mapped to actions that express "*express_laugh*", which is the specific name used by Second Life virtual world. Table 1 shows the mapping of a few action names in Second Mind with the corresponding names in the virtual world Second Life.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 10. The interface layer parses the world state in second life into domain independent sensors

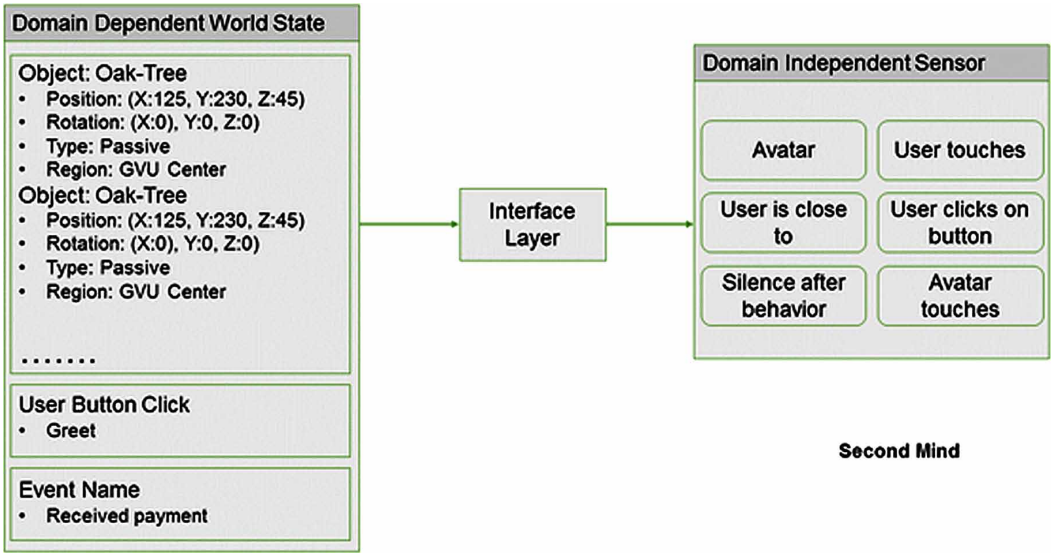


Table 1. Action names in SM and corresponding virtual world action names in second life

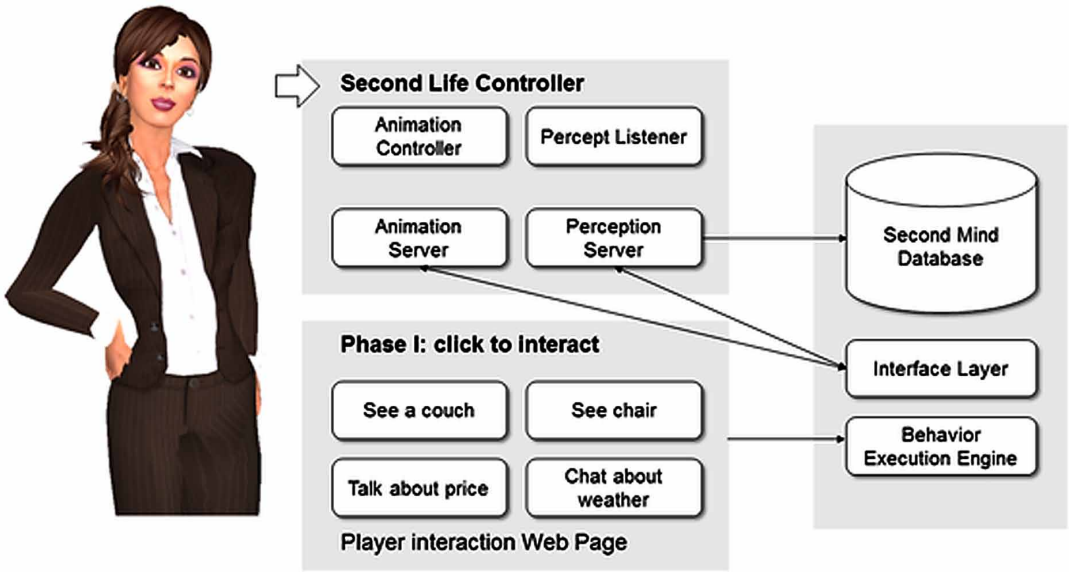

Domain Independent Action Name	Virtual World Action Name
Laugh	express_laugh
Shrug	express_shrug_emote
Bow	avatar_hold_bow

Initially, in order to connect Second Mind to Second Life, we modified an open source version of Second Mind clients. We soon realized though that not all Second Mind users are willing to installed a modified version of Second Life as well. Therefore, we instead created scripts in Second Life's proprietary scripting language named Linden Scripting Language (LSL). Those scripts make it possible to send and to receive information through the Second Mind interface layer from/to Second Life for controlling the avatar with any genuine Second Life client (Figure 11).

The collection of scripts is packaged in a component called Second Mind Controller and distributed through the Second Life marketplace. Second Life marketplace is a social web portal from Second Life where all the items from various vendors are listed and available for purchase. Second Mind controller is listed on the Second Life marketplace and is available for free. In order to have their avatar controllable through Second Mind, players need to download it from the Second Life marketplace. Purchasing items from Second Life marketplace is a common activity performed by Second Life users. Once users have bought the items from Second Life marketplace. Second Mind controller is downloaded automatically onto their avatars, which they can then attach to their avatar in Second Life.

Figure 11. Scripts organization for the connection of second mind and second life

Behavior Recommendation

During the behavior authoring process, once the name of the behavior is entered, the user is presented with a list of recommended behaviors that he can use as a starting point. The behaviors are suggested based on similarity between the behavior name specified for the currently authored behavior and existing behaviors in the database. The semantic similarity is calculated using a WordNet-based algorithm (Simpson & Dao, 2014).

CONCLUSION AND FUTURE DIRECTIONS

In this paper, we have presented the results from a user study conducted to evaluate a paper-based prototype version of the authoring activity. The findings from the user study, made it possible for us to identify and modify early design flaws that we accounted for and incorporated into the current version of the digital authoring tool, which employs Second Life (Rymaszewski, 2009) as the concrete virtual world where the behaviors can be executed. To address the issue of having concrete feedback on the authoring activity, the authoring interface was connected with a concrete virtual world, Second Life, so that author can view the created behaviors and any possible problems with them. In order to simplify the steps required to link behavior conditions to lower level percepts, we provided to the user a base set of triggers that can be used individually or combined together to make more complex triggers. In order to present the authoring task as a sequential one, instead of deep hierarchies, we used a left to right sequential action creation approach represented on a timeline. Eventually, we outlined the authoring steps necessary to create and run a behavior along with the system architecture and its four core components.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

We evaluated the Second Mind approach to check whether it can be understood and easily used by non-programmers. In order to evaluate our approach, we invited 65 subjects to create a certain set of behaviors for an avatar (e.g. act as a shopkeeper) on a Second Life island using the authoring system. We divided the subjects into three broad categories: User Interface designers, non-programmers, and programmers (with experience in Java). We transcribed data from the subjects' responses to interviews as well as from the notes taken while observing subject actions during the authoring process. To analyze this vast quantity of data collected from the user study, we adopted a combination of qualitative and quantitative analysis. Specifically, we employed again a Grounded Theory (Strauss & Corbin, 1990) approach to perform the qualitative analysis. A detailed report on the evaluation of the system is outside the scope of this paper. However, for the sake of completeness, the evaluation results show that non-programmers were able to easily create behaviors using the scaffolding provided by Second Mind. Moreover, no relevant statistical difference was noticed in the quantitative measures used to asses authoring skills among the different subject categories. This seems to indicate that designers, programmers, and non-programmers perform very similarly while authoring behaviors with Second Mind.

There is much work left to do in Second Mind, some of which is research, some of which is in development. There are still numerous open questions that form possible avenues of future directions for this research. Authoring support through demonstrating behaviors is something we are considering. Learning from demonstration is also a point we would like to investigate. Human learning is often accelerated by observing a task being performed or attempted by someone else. These capabilities of the human brain are also evident in computer games where players go through a process of training and imitating experienced players. These results have inspired researchers in artificial intelligence to study learning from imitation techniques. By observing an expert's actions, new behaviors can quickly be learnt and then successfully performed.

ACKNOWLEDGMENT

We would like to thank Ms. Maria Kikidou for the integral role she played in helping us with the editing process and the creation of the images in this book chapter.

Chapter 29
Contour Reconstruction:
2D Object Modeling

Dariusz Jacek Jakóbczak
Technical University of Koszalin, Poland

ABSTRACT

The method of Probabilistic Features Combination (PFC) enables interpolation and modeling of high-dimensional N data using features' combinations and different coefficients γ: polynomial, sinusoidal, cosinusoidal, tangent, cotangent, logarithmic, exponential, arc sin, arc cos, arc tan, arc cot or power function. Functions for γ calculations are chosen individually at each data modeling and it is treated as N-dimensional probability distribution function: γ depends on initial requirements and features' specifications. PFC method leads to data interpolation as handwriting or signature identification and image retrieval via discrete set of feature vectors in N-dimensional feature space. So PFC method makes possible the combination of two important problems: interpolation and modeling in a matter of image retrieval or writer identification. Main features of PFC method are: PFC interpolation develops a linear interpolation in multidimensional feature spaces into other functions as N-dimensional probability distribution functions.

INTRODUCTION

Probabilistic modeling is still developing branch of the computer science: operational research (for example probabilistic model-based prognosis) (Lorton, Fouladirad & Grall, 2013), decision making techniques and probabilistic modeling (Pergler & Freeman, 2008), artificial intelligence and machine learning. There are used different aspects of probabilistic methods: stochastic processes and stochastic model-based techniques, Markov processes (Cocozza-Thivent, Eymard, Mercier & Roussignol, 2006), Poisson processes, Gamma processes, a Monte Carlo method, Bayes rule, conditional probability and many probability distributions. In this chapter the goal of probability distribution function is to describe the position of unknown points between given interpolation nodes. Two-dimensional curve (opened or closed) is used to represent the data points.

So problem statement of this chapter is: how to reconstruct (interpolate) missing points of 2D curve having the set of interpolation nodes (key points) and using the information about probabilistic distribution of unknown points. For example the simplest basic distribution leads to the easiest interpolation – linear interpolation. Apart from probability distribution, additionally there is the second factor of proposed interpolation method: nodes combination. The simplest nodes combination is zero. Thus proposed curve modeling is based on two agents: probability distribution and nodes combination.

Curve interpolation (Collins, 2003) represents one of the most important problems in mathematics and computer science: how to model the curve (Chapra, 2012) via discrete set of two-dimensional points (Ralston & Rabinowitz, 2001)? Also the matter of shape representation (as closed curve-contour) and curve parameterization is still opened (Zhang & Lu, 2004). For example pattern recognition, signature verification or handwriting identification problems are based on curve modeling via the choice of key points. So interpolation is not only a pure mathematical problem but important task in computer vision and artificial intelligence. The chapter wants to approach a problem of curve modeling by characteristic points. Proposed method relies on nodes combination and functional modeling of curve points situated between the basic set of key points. The functions that are used in calculations represent whole family of elementary functions with inverse functions: polynomials, trigonometric, cyclometric, logarithmic, exponential and power function. These functions are treated as probability distribution functions in the range [0;1]. Curve interpolation represents one of the most important problems in mathematics and computer science: how to model the curve via discrete set of two-dimensional points? Also the matter of shape representation (as closed curve-contour) and curve parameterization is still opened. For example pattern recognition, signature verification or handwriting identification problems are based on curve modeling via the choice of key points. So interpolation is not only a pure mathematical problem but important task in computer vision and artificial intelligence. The monograph wants to approach a problem of curve modeling by characteristic points. Proposed method relies on nodes combination and functional modeling of curve points situated between the basic set of key points. The functions that are used in calculations represent whole family of elementary functions with inverse functions: polynomials, trigonometric, cyclometric, logarithmic, exponential and power function. These functions are treated as probability distribution functions in the range [0;1]. Significant problem in machine vision and computer vision is that of appropriate 2D shape representation and reconstruction. Classical discussion about shape representation is based on the problem: contour versus skeleton. This monograph is voting for contour which forms boundary of the object. Contour of the object, represented by successive contour points, consists of information which allows us to describe many important features of the object as shape coefficients. 2D curve modeling and generation is a basic subject in many branches of industry and computer science, for example in the cad/cam software. The representation of shape can have a great impact on the accuracy and effectiveness of object recognition. In the literature, shape has been represented by many options including curves, graph-based algorithms and medial axis to enable shape-based object recognition. Digital 2D curve (open or closed) can be represented by chain code (Freeman's code). Chain code depends on selection of the started point and transformations of the object. So Freeman's code is one of the method how to describe and to find contour of the object. Analog (continuous) version of Freeman's code is the curve α-s. Another contour representation and reconstruction is based on Fourier coefficients calculated in discrete Fourier transformation (DFT). These coefficients are used to fix similarity of the contours with different sizes or directions. If we assume that contour is built from segments of a

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

line and fragments of circles or ellipses, hough transformation is applied to detect contour lines. Also geometrical moments of the object are used during the process of object shape representation. Contour is also applied in shape decomposition. Many branches of medicine, industry and manufacturing are looking for methods connected with geometry of the contour. Why and when should we use MHR and PNC methods? Interpolation methods and curve fitting represent so huge problem that each individual interpolation is exceptional and requires specific solutions. PNC method is such a novel tool with its all pros and cons. The user has to decide which interpolation method is the best in a single situation. The choice is yours if you have any choice. Presented method is such a new possibility for curve fitting and interpolation when specific data (for example handwritten symbol or character) starts up with no rules for polynomial interpolation. This book consists of two generalizations: generalization of previous MHR method with various nodes combinations and generalization of linear interpolation with different (no basic) probability distribution functions and nodes combinations. The method of Probabilistic Nodes Combination (PNC) enables interpolation and modeling of two-dimensional curves using nodes combinations and different coefficients γ: polynomial, sinusoidal, cosinusoidal, tangent, cotangent, logarithmic, exponential, arc sin, arc cos, arc tan, arc cot or power function, also inverse functions. This probabilistic view is novel approach a problem of modeling and interpolation. Computer vision and pattern recognition are interested in appropriate methods of shape representation and curve modeling. PNC method represents the possibilities of shape reconstruction and curve interpolation via the choice of nodes combination and probability distribution function for interpolated points. It seems to be quite new look at the problem of contour representation and curve modeling in artificial intelligence and computer vision. Function for γ calculations is chosen individually at each curve modeling and it is treated as probability distribution function: γ depends on initial requirements and curve specifications. PNC method leads to curve interpolation as handwriting modeling via discrete set of fixed knots. So PNC makes possible the combination of two important problems: interpolation and modeling. Nodes are treated as characteristic points of data for modeling and analyzing. The model of data can be built by choice of probability distribution function and nodes combination. PFC modeling via nodes combination and parameter γ as probability distribution function enables value anticipation in risk analysis and decision making. Two-dimensional object is extrapolated and interpolated via nodes combination and different functions as discrete or continuous probability distribution functions: polynomial, sine, cosine, tangent, cotangent, logarithm, exponent, arc sin, arc cos, arc tan, arc cot or power function. Functions for γ calculations are chosen individually at each data modeling and it is treated as 2-dimensional probability distribution function: γ depends on initial requirements and features' specifications. PFC method leads to data interpolation as handwriting or signature identification and image retrieval via discrete set of feature vectors in 2-dimensional feature space. So PFC method makes possible the combination of two important problems: interpolation and modeling in a matter of image retrieval or writer identification. PFC interpolation develops a linear interpolation in multidimensional feature spaces into other functions as two-dimensional probability distribution functions. Future works are going to applications of PFC method in biometric recognition, computer vision and artificial intelligence.

BACKGROUND

Shape Representation and Curve Reconstruction

An important problem in machine vision and computer vision (Ballard, 1982) is that of appropriate shape representation and reconstruction. Classical discussion about shape representation is based on the problem: contour versus skeleton. This chapter is voting for contour which forms boundary of the object. Contour of the object, represented by contour points, consists of information which allows us to describe many important features of the object as shape coefficients (Tadeusiewicz & Flasiński, 1991). In the chapter contour is dealing with a set of curves. Curve modeling and generation is a basic subject in many branches of industry and computer science, for example in the CAD/CAM software.

The representation of shape has a great impact on the accuracy and effectiveness of object recognition (Saber, Yaowu & Murat Tekalp, 2005). In the literature, shape has been represented by many options including curves (Sebastian & Klein, 2003), graph-based algorithms and medial axis (Liu & Geiger, 1999) to enable shape-based object recognition. Digital curve (open or closed) can be represented by chain code (Freeman's code). Chain code depends on selection of the started point and transformations of the object. So Freeman's code is one of the method how to describe and to find contour of the object. An analog (continuous) version of Freeman's code is the curve α-*s*. Another contour representation and reconstruction is based on Fourier coefficients calculated in Discrete Fourier Transformation (DFT). These coefficients are used to fix similarity of the contours with different sizes or directions. If we assume that contour is built from segments of a line and fragments of circles or ellipses, Hough transformation is applied to detect contour lines. Also geometrical moments of the object are used during the process of object shape representation (Choraś, 2005).

Nowadays methods apply mainly polynomial functions, for example Bernstein polynomials in Bezier curves, splines (Schumaker, 2007) and NURBS (Rogers, 2001). But Bezier curves don't represent the interpolation method and cannot be used for example in handwriting modeling with key points (interpolation nodes). In comparison PNC method with Bézier curves, Hermite curves and B-curves (*B-splines*) or NURBS one unpleasant feature of these curves has to be mentioned: small change of one characteristic point can result in unwanted change of whole reconstructed curve. Such a feature does not appear in proposed PNC method. Numerical methods for data interpolation are based on polynomial or trigonometric functions, for example Lagrange, Newton, Aitken and Hermite methods. These methods have many weak sides (Dahlquist & Bjoerck, 1974) and are not sufficient for curve interpolation in the situations when the curve cannot be build by polynomials or trigonometric functions. Also there exists several well established methods of curve modeling, for example shape-preserving techniques (Dejdumrong, 2007), subdivision algorithms (Dyn, Levin & Gregory, 1987) and others (Kozera, 2004) to overcome difficulties of polynomial interpolation, but probabilistic interpolation with nodes combination seems to be quite novel in the area of shape modeling. Proposed 2D curve interpolation is the functional modeling via any elementary functions and it helps us to fit the curve during the computations.

This chapter presents novel Probabilistic Nodes Combination (PNC) method of curve interpolation. This chapter takes up new PNC method of two-dimensional curve modeling via the examples using the family of Hurwitz-Radon matrices (MHR method) (Jakóbczak, 2007), but not only (other nodes combinations). The method of PNC requires minimal assumptions: the only information about a curve is the set of at least two nodes. Proposed PNC method is applied in curve modeling via different coefficients: polynomial, sinusoidal, cosinusoidal, tangent, cotangent, logarithmic, exponential, arc sin, arc cos, arc

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

tan, arc cot or power. Function for PNC calculations is chosen individually at each interpolation and it represents probability distribution function of parameter $\alpha \in [0;1]$ for every point situated between two interpolation knots. PNC method uses two-dimensional vectors (x,y) for curve modeling-knots $p_i = (x_i,y_i) \in \boldsymbol{R}^2$ in PNC method, $i = 1,2,\ldots n$:

1. PNC needs 2 knots or more ($n \geq 2$);
2. If first node and last node are the same ($p_1 = p_n$), then curve is closed (contour);
3. For more precise modeling knots ought to be settled at key points of the curve, for example local minimum or maximum and at least one node between two successive local extrema.

Condition 3 means for example the highest point of the curve in a particular orientation, convexity changing or curvature extrema. So this chapter wants to answer the question: how to interpolate the curve by a set of knots (Jakóbczak, 2010)?

Algorithm of PNC interpolation and modeling (1) looks as follows:

Step 1: Choice of knots p_i at key points.
Step 2: Choice of nodes combination $h(p_1,p_2,\ldots,p_m)$.
Step 3: Choice of distribution $\gamma = F(\alpha)$ (continuous or discrete).
Step 4: Determining values of α: $\alpha = 0.1, 0.2\ldots0.9$ (nine points) or $0.01, 0.02\ldots0.99$ (99 points) or others.
Step 5: The computations.

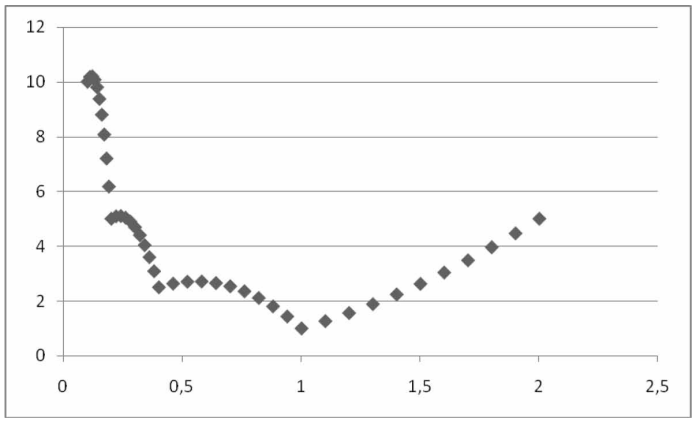
These five steps can be treated as the algorithm of PNC method of curve modeling and interpolation. Without knowledge about the formula of curve or function, PNC interpolation has to implement the coefficients γ, but PNC is not limited only to these coefficients. Each strictly monotonic function F between points (0;0) and (1;1) can be used in PNC modeling.

HANDWRITTEN CHARACTER AND SHAPE MODELING

Issues

Curve knots $p_1 = (0.1;10), p_2 = (0.2;5), p_3 = (0.4;2.5), p_4 = (1;1)$ and $p_5 = (2;5)$ are used in some examples of PNC method in handwritten character modeling. Figures 1-8 represent PNC as MHR interpolation (Jakóbczak, 2011) with different γ. Points of the curve are calculated with no matrices ($N = 1$) and $\gamma = \alpha$ in example 1 and with matrices of dimension $N = 2$ in examples 2-8 for $\alpha = 0.1, 0.2,\ldots,0.9$.

Example 1: (refer to Figure 1)



PNC curve interpolation for $\gamma = \alpha$ and

$$h(p_1, p_2) = \frac{y_1}{x_1} x_2 + \frac{y_2}{x_2} x_1 .$$

For $N = 2$ (examples 2 – 8) MHR version (Jakóbczak, 2011) as PNC method gives us:

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. PNC character modeling for nine reconstructed points between nodes

$$h(p_1,p_2,p_3,p_4)=\frac{1}{x_1^{\,2}+x_3^{\,2}}(x_1x_2y_1+x_2x_3y_3+x_3x_4y_1-x_1x_4y_3)$$
$$+\frac{1}{x_2^{\,2}+x_4^{\,2}}(x_1x_2y_2+x_1x_4y_4+x_3x_4y_2-x_2x_3y_4)$$

Example 2: (refer to Figure 2)
PNC sinusoidal interpolation with $\gamma = sin(\alpha \cdot \pi/2)$.
Example 3: (refer to Figure 3)
PNC tangent interpolation for $\gamma = tan(\alpha \cdot \pi/4)$.
Example 4: (refer to Figure 4)
PNC tangent interpolation with $\gamma = tan(\alpha^s \cdot \pi/4)$ and $s = 1.5$.

Proposed method, called Probabilistic Nodes Combination (PNC), is the method of 2D curve interpolation and extrapolation using the set of key points (knots or nodes). Nodes can be treated as characteristic points of data for modeling and analyzing. The model of data can be built by choice of probability distribution function and nodes combination. PNC modeling via nodes combination and parameter γ as probability distribution function enables value anticipation in risk analysis and decision making. Two-dimensional curve is extrapolated and interpolated via nodes combination and different functions as discrete or continuous probability distribution functions: polynomial, sine, cosine, tangent, cotangent, logarithm, exponent, arc sin, arc cos, arc tan, arc cot or power function. Novelty of this book consists of two generalizations: generalization of previous MHR method with various nodes combinations and generalization of linear interpolation with different (no basic) probability distribution functions and nodes combinations. Computer vision needs suitable methods of shape representation and contour reconstruction. One of them, invented by the author and called method of Hurwitz-Radon Matrices (MHR), can be used in representation and reconstruction of shapes of the objects in the plane. Proposed method is based on a family of Hurwitz-Radon (HR) matrices. The matrices are skew-symmetric and possess columns composed of orthogonal vectors. 2D shape is represented by the set of successive nodes. It is shown how to create the orthogonal and discrete OHR operator and how to use it in a process of shape

Figure 2. Sinusoidal modeling with nine reconstructed curve points between nodes

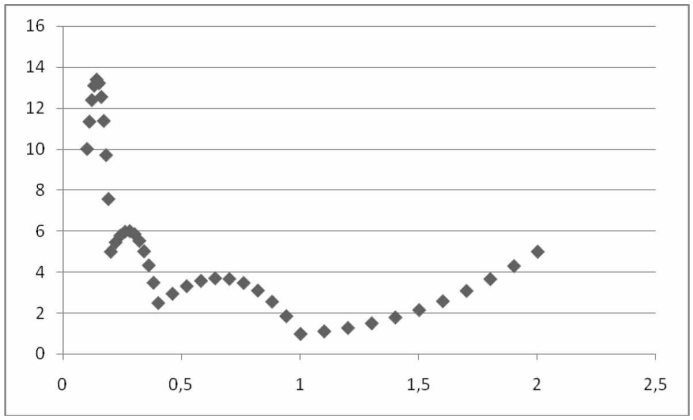

Figure 3. Tangent character modeling with nine interpolated points between nodes

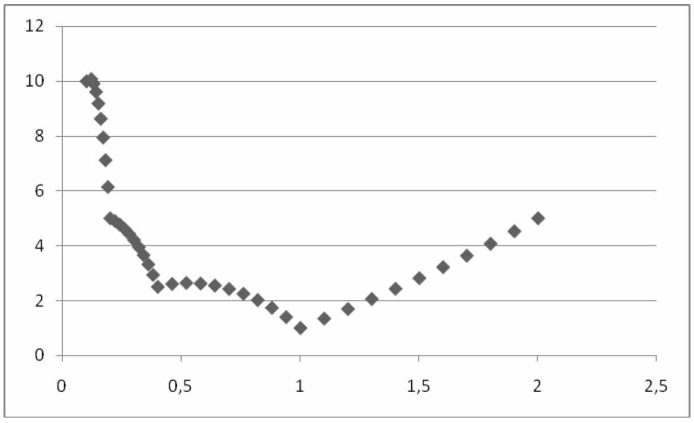

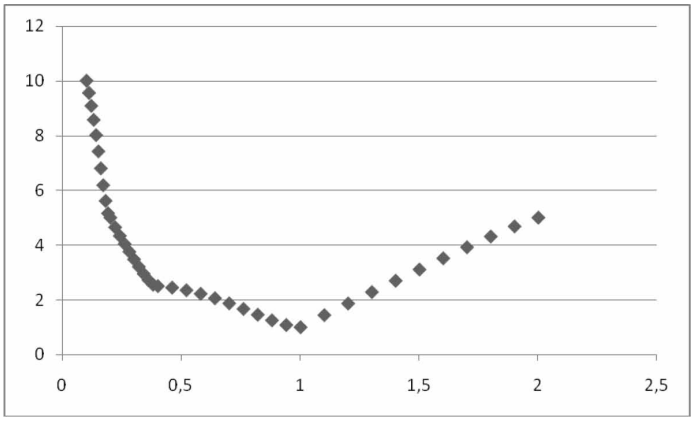

Figure 4. Tangent curve modeling with nine recovered points between nodes

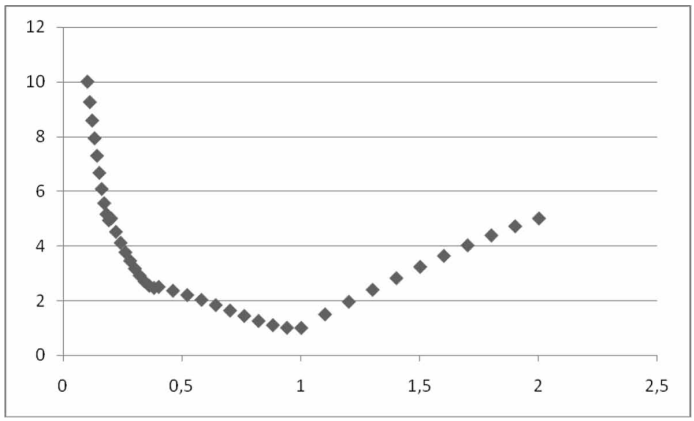
EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

representation and reconstruction. Then MHR method is generalized to Probabilistic Nodes Combination (PNC) method.

Example 5: (refer to Figure 5)
PNC tangent curve interpolation for $\gamma = tan(\alpha^s \cdot \pi/4)$ and $s = 1.797$.
Example 6: (refer to Figure 6)
PNC sinusoidal interpolation with $\gamma = sin(\alpha^s \cdot \pi/2)$ and $s = 2.759$.
Example 7: (refer to Figure 7)
PNC power function modeling for $\gamma = \alpha^s$ and $s = 2.1205$.
Example 8: (refer to Figure 8)
PNC logarithmic curve modeling with $\gamma = log_2(\alpha^s + 1)$ and $s = 2.533$.

These eight examples demonstrate possibilities of PNC curve interpolation and handwritten character modeling for key nodes in MHR version. And here are other examples of PNC modeling (but not MHR):

Figure 5. Tangent symbol modeling with nine reconstructed points between nodes



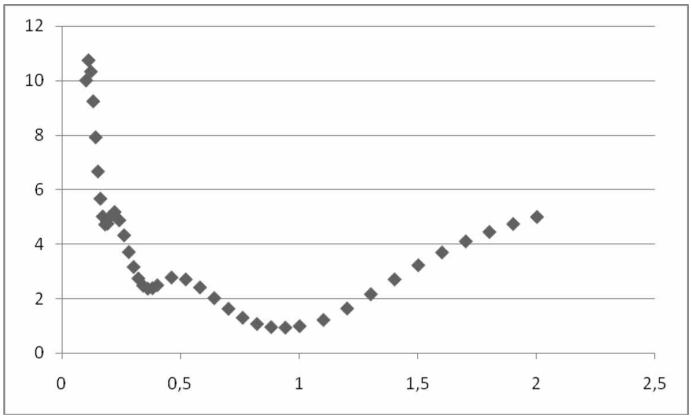


Figure 6. Sinusoidal modeling with nine interpolated curve points between nodes

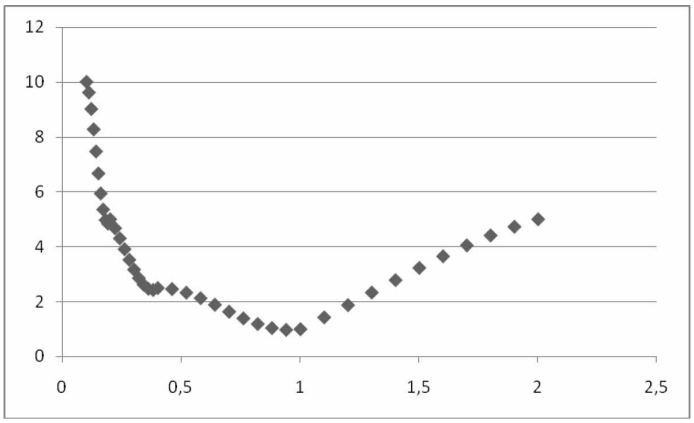
EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 7. Power function curve modeling with nine recovered points between nodes



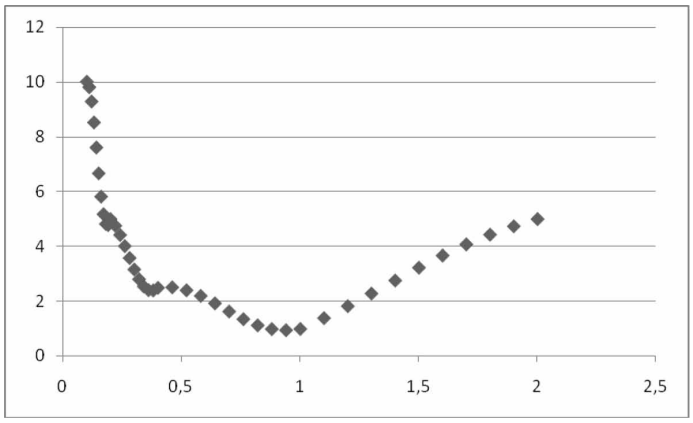


Figure 8. Logarithmic character modeling with nine reconstructed points between nodes

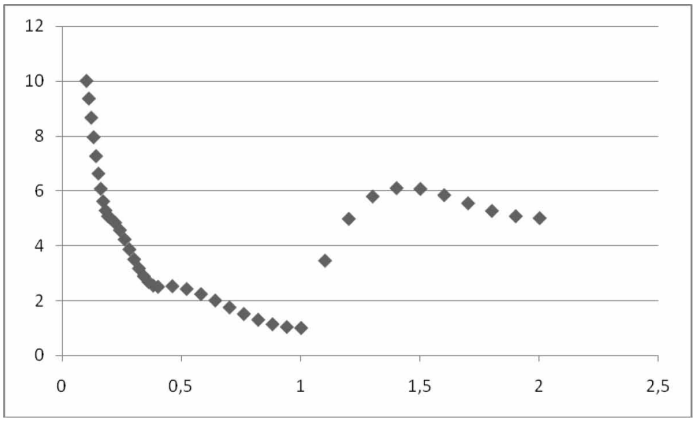


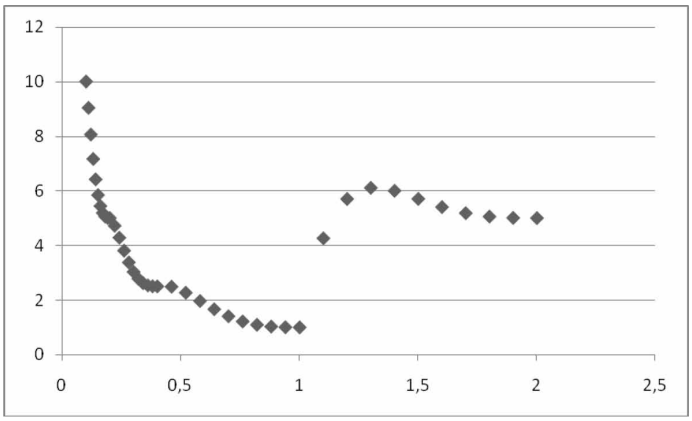
Example 9: (refer to Figure 9)

PNC for $\gamma = \alpha^2$ and $h(p_1,p_2) = x_1,y_1 + x_2y_2$.

Curve interpolation represents one of the most important problems in mathematics and computer science: how to model the curve via discrete set of two-dimensional points? Also the matter of shape representation (as closed curve-contour) and curve parameterization is still opened. For example pattern recognition, signature verification or handwriting identification problems are based on curve modeling via the choice of key points. So interpolation is not only a pure mathematical problem but important task in computer vision and artificial intelligence. The monograph wants to approach a problem of curve modeling by characteristic points. Proposed method relies on nodes combination and functional modeling of curve points situated between the basic set of key points. The functions that are used in calculations represent whole family of elementary functions with inverse functions: polynomials, trigonometric, cyclometric, logarithmic, exponential and power function. These functions are treated as probability distribution functions in the range [0;1].

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 9. Quadratic symbol modeling with nine reconstructed points between nodes



Example 10: (refer to Figure 10)
PNC for $\gamma = \alpha^3$ and $h(p_1,p_2) = x_1,y_1 + x_2y_2$.

If we consider Figure 1 as closed curve (contour) with the node $p_6 = p_1 = (0.1;10)$ then examples 8 and 9 give the shapes:

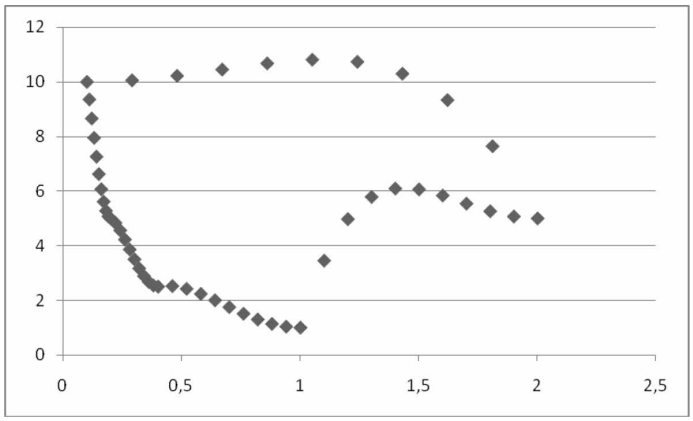
Example 11: (refer to Figure 11)
PNC for $\gamma = \alpha^2$ and $h(p_1,p_2) = x_1,y_1 + x_2y_2$.
Example 12: (refer to Figure 12)
PNC for $\gamma = \alpha^3$ and $h(p_1,p_2) = x_1,y_1 + x_2y_2$.

Every man has individual style of handwriting. Recognition of handwritten letter or symbol need modeling and the model of each individual symbol or character can be built by choice of γ and h. PNC modeling via nodes combinations h and parameter γ as probability distribution function enables curve interpolation for each specific letter or symbol.

Figure 10. Cubic character modeling with nine reconstructed points between nodes

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 11. Quadratic contour modeling with nine reconstructed points between nodes



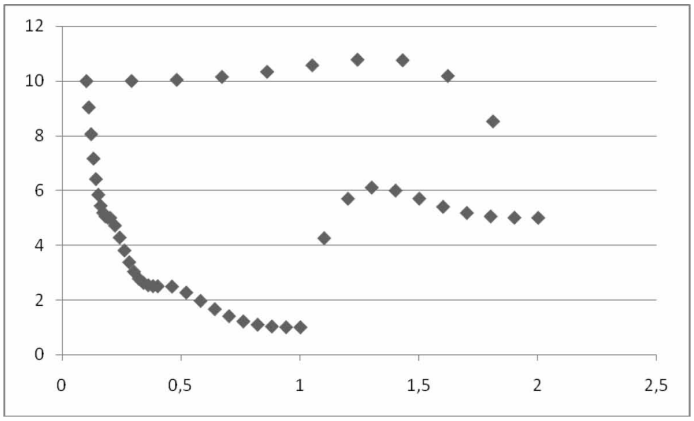


Figure 12. Cubic shape modeling with nine reconstructed points between nodes

Number of reconstructed points depends on a user by value α. If for example $\alpha = 0.01, 0.02,\ldots,0.99$ then 99 points are interpolated for each pair of nodes. Reconstructed values and interpolated points, calculated by PNC method, are applied in the process of curve modeling. Every curve can be interpolated by some distribution function as parameter γ and nodes combination h. Parameter γ is treated as probability distribution function for each curve.

Beta Distribution

Basic distribution ($\gamma = \alpha$) with nodes combination $h = 0$ turns PNC interpolation (1) to linear interpolation. What about PNC in the case of yet another distribution on the range [0;1]: beta distribution? Power functions as γ used in examples 1, 7 and 9-12 are also connected with beta distribution. Here are the examples of PNC modeling for beta distribution with nodes combination $h = 0$.

Example 13: (refer to Figure 13)

PNC for $\gamma = 3\alpha^2-2\alpha^3$ and $h(p_1,p_2)=0$.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Example 14: (refer to Figure 14)
PNC for $\gamma = 4\alpha^3\text{-}3\alpha^4$ and $h(p_1,p_2)=0$.
Example 15: (refer to Figure 15)
PNC for $\gamma = 2\alpha\text{-}\alpha^2$ and $h(p_1,p_2)=0$.

Examples 9-12 represent beta distribution with $h(p_1,p_2) = x_1,y_1 + x_2y_2$.

Exponential Distribution

Exponential distribution is dealing with random variable ≥ 0, but in PNC interpolation random variable $\alpha\in[0;1]$. Then exponential distribution is represented by distribution function:

$\gamma = F(\alpha) = 1 - (1\text{-}\alpha)e^{\alpha}$.

Example 16: (refer to Figure 16)
PNC for $\gamma = 1\text{-}(1\text{-}\alpha)e^{\alpha}$ and $h(p_1,p_2)=0$.
Example 17: (refer to Figure 17)
PNC for $\gamma = 1\text{-}(1\text{-}\alpha)e^{\alpha}$ and $h(p_1, p_2) = \frac{y_2}{y_1} + \frac{x_2}{x_1}$:

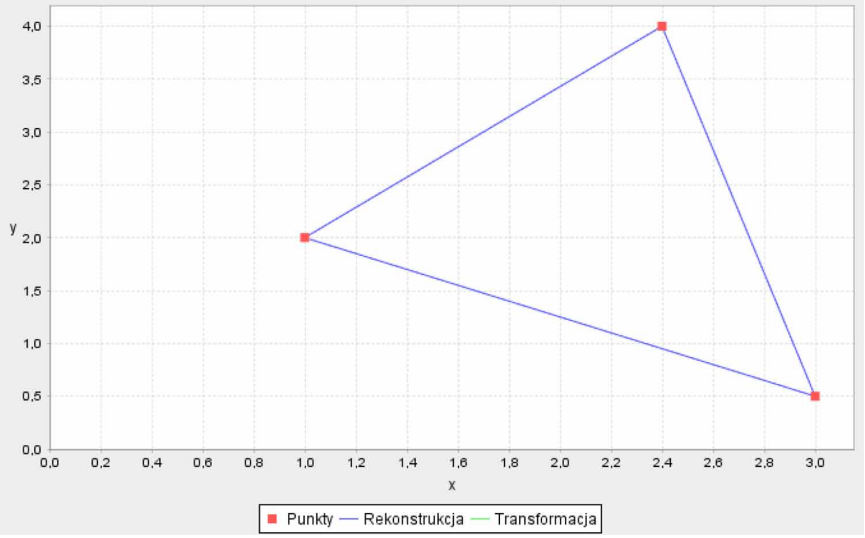
These examples show the variety of possibilities in curve modeling via the choice of nodes combination and probability distribution function for interpolated points.



2D OBJECT MODELING

What about contours – closed curves? The only assumption is that first node and last node are the same. The simplest way is the linear interpolation for h=0 and $\gamma=\alpha$. (Figure 18).

Proposed method, called Probabilistic Nodes Combination (PNC), is the method of 2D curve interpolation and extrapolation using the set of key points (knots or nodes). Nodes can be treated as characteristic points of data for modeling and analyzing. The model of data can be built by choice of probability distribution function and nodes combination. PNC modeling via nodes combination and parameter γ as probability distribution function enables value anticipation in risk analysis and decision making. Two-dimensional curve is extrapolated and interpolated via nodes combination and different functions as discrete or continuous probability distribution functions: polynomial, sine, cosine, tangent, cotangent, logarithm, exponent, arc sin, arc cos, arc tan, arc cot or power function. Novelty of this book consists of two generalizations: generalization of previous MHR method with various nodes combinations and generalization of linear interpolation with different (no basic) probability distribution functions and nodes combinations. Here are examples of shape modeling for five (or rather six) nodes:

Significant problem in machine vision and computer vision is that of appropriate 2D shape representation and reconstruction. Classical discussion about shape representation is based on the problem: contour versus skeleton. This monograph is voting for contour which forms boundary of the object. Contour of the object, represented by successive contour points, consists of information which allows us to describe many important features of the object as shape coefficients. 2D curve modeling and generation is a basic subject in many branches of industry and computer science, for example in the cad/cam software. The representation of shape can have a great impact on the accuracy and effectiveness of object recognition.

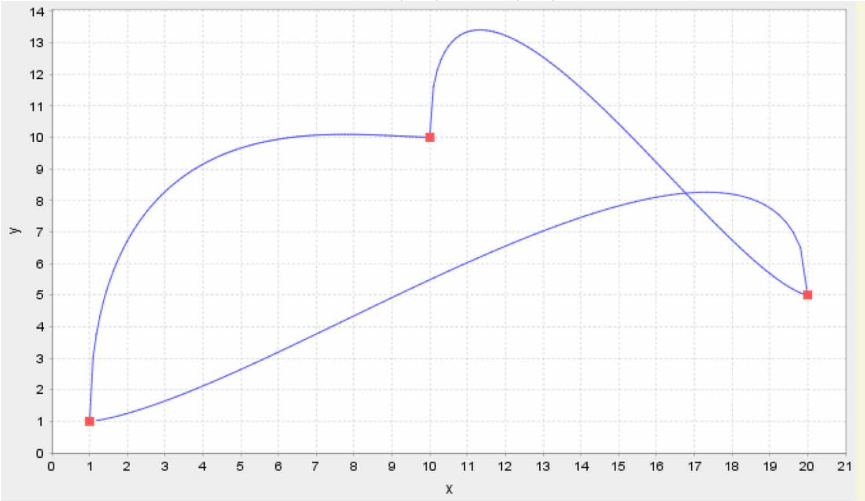
These examples of shape modeling and contour reconstruction show the variety of PNC interpolations via chosen parameters and set of nodes.

RESULT ANALYSIS

PFC method is interpolating a curve between each pair of nodes using modeling function $\gamma = F(\alpha)$ and nodes combination *h*. The simplest way of comparing PFC with another method is to see the example. Here is the application of PFC method for function $f(x)=1/x$ and nine nodes: $y = 0.2, 0.4, 0.6, 0.8, 1,$

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 35. Object modeling with s = 1.4, $h = y_1\left(\frac{x_2}{x_1}\right) + y_2\left(\frac{x_1}{x_2}\right),\ \gamma = 1 - \frac{2}{\pi} * \arccos\left(\alpha^s\right)$



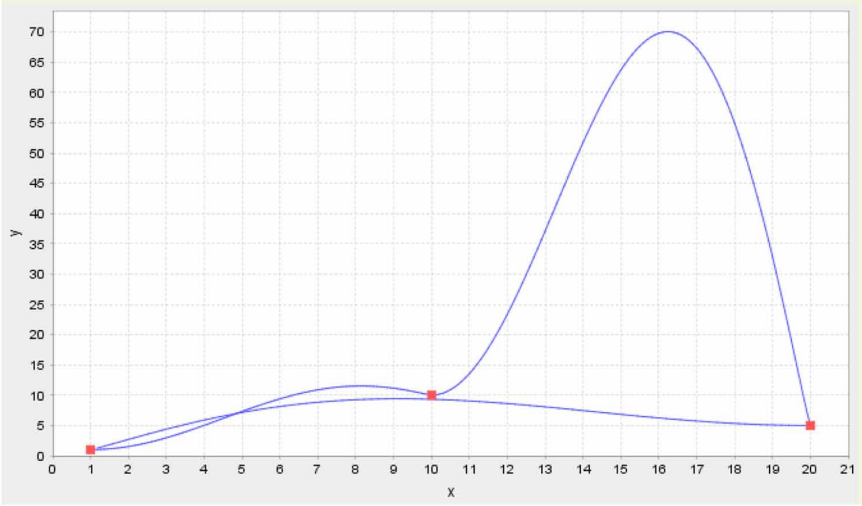


Figure 36. Shape interpolation with s = 1.1, h= $x_1x_2 + y_1y_2,\ \gamma = \sin\left(\alpha^s * \frac{\pi}{2}\right)$

1.2, 1.4, 1.6, 1.8. PFC represents (Figure 42) much more precise interpolation than Lagrange or Newton polynomial interpolation (Figure 43).

PFC interpolation is more accurate than polynomial interpolation by Newton or Lagrange. Very important matter is dealing with closed curves. PFC reconstruction of the contour or shape is done with the same formulas. Another important problem is connected with extrapolation. PFC method gives the tool of data anticipation or prediction.

PFC is a novel approach to the matter of data modeling, reconstruction and extrapolation.

FUTURE RESEARCH DIRECTIONS

Future trends will go to various directions: how to fix the best probability distribution function for the nodes, how to calculate the most appropriate nodes combination and what extrapolation is the most valuable in decision making and risk analysis.

CONCLUSION

The method of Probabilistic Nodes Combination (PNC) enables interpolation and modeling of two-dimensional curves using nodes combinations and different coefficients γ: polynomial, sinusoidal, cosinusoidal, tangent, cotangent, logarithmic, exponential, arc sin, arc cos, arc tan, arc cot or power function, also inverse functions. This probabilistic view is novel approach a problem of modeling and interpolation. Computer vision and pattern recognition are interested in appropriate methods of shape representation and curve modeling. PNC method represents the possibilities of shape reconstruction and curve interpolation via the choice of nodes combination and probability distribution function for interpolated points. It seems to be quite new look at the problem of contour representation and curve modeling in artificial intelligence and computer vision. Function for γ calculations is chosen individually at each curve modeling and it is treated as probability distribution function: γ depends on initial requirements

and curve specifications. PNC method leads to curve interpolation as handwriting modeling via discrete set of fixed knots. So PNC makes possible the combination of two important problems: interpolation and modeling. Main features of PNC method are:

1. The smaller distance between knots the better;
2. Calculations for coordinates close to zero and near by extremum require more attention because of importance of these points;
3. PNC interpolation develops a linear interpolation into other functions as probability distribution functions;
4. PNC is a generalization of MHR method via different nodes combinations;

Figure 45. Prediction of values left of first node

5. Interpolation of L points is connected with the computational cost of rank $O(L)$ as in MHR method;
6. Nodes combination and coefficient γ are crucial in the process of curve probabilistic parameterization and interpolation: they are computed individually for a single curve.

What is the most important feature of MHR and PNC methods? Interpolation methods and curve fitting represent so huge problem that each individual interpolation is exceptional and requires specific solutions. PNC method is such a novel tool with its all pros and cons. The user has to decide which interpolation method is the best in a single situation. The choice is yours if you have any choice. Presented method is such a new possibility for curve fitting and interpolation when specific data (for example handwritten symbol or character) starts up with no rules for polynomial interpolation. This book consists of two generalizations: generalization of previous MHR method with various nodes combinations and generalization of linear interpolation with different (no basic) probability distribution functions and nodes combinations. The method of Probabilistic Nodes Combination (PNC) enables interpolation and modeling of two-dimensional curves using nodes combinations and different coefficients γ: polynomial, sinusoidal, cosinusoidal, tangent, cotangent, logarithmic, exponential, arc sin, arc cos, arc tan, arc cot or power function, also inverse functions. This probabilistic view is novel approach a problem of modeling and interpolation. Computer vision and pattern recognition are interested in appropriate methods of shape representation and curve modeling. PNC method represents the possibilities of shape reconstruction and curve interpolation via the choice of nodes combination and probability distribution function for interpolated points. KEY TERMS AND DEFINITIONS

Contour: Closed curve.

Curve Interpolation: Computing new and unknown points of a curve and creating a graph of a curve using existing data points – interpolation nodes.

Data Extrapolation: Calculation of unknown values for the points situated outside the ranges of nodes.

Hurwitz – Radon Matrices: A family of skew – symmetric and orthogonal matrices with columns and rows that create, together with identical matrix, the base in vector spaces of dimensions $N = 2, 4$ or 8.

MHR Method: The method of curve interpolation and extrapolation using linear (convex) combinations of OHR operators.

OHR Operator: Matrix operator of Hurwitz – Radon built from coordinates of interpolation nodes.

Shape Representation: Data that are used in shape reconstruction.

Value Anticipation: Foreseeing next value when last value is known.

Chapter 30
Statistical Features for Extractive Automatic Text Summarization

Yogesh Kumar Meena
MNIT Jaipur, India

Dinesh Gopalani
MNIT Jaipur, India

ABSTRACT

Automatic Text Summarization (ATS) enables users to save their precious time to retrieve their relevant information need while searching voluminous big data. Text summaries are sensitive to scoring methods, as most of the methods requires to weight features for sentence scoring. In this chapter, various statistical features proposed by researchers for extractive automatic text summarization are explored. Features that perform well are termed as best features using ROUGE evaluation measures and used for creating feature combinations. After that, best performing feature combinations are identified. Performance evaluation of best performing feature combinations on short, medium and large size documents is also conducted using same ROUGE performance measures.

INTRODUCTION

Day by day the information content on World Wide Web is exponentially increasing (BIG Data) along with the increase in the number of web users. In current scenario volume of information available on World Wide Web exceeded the textual information available in the printed form in libraries. The rapid growth of online information services makes it difficult to retrieve the relevant information quickly. While searching a particular information content, many a times information system users realize that the extracted information using currently available popular tools, that is present in the form of text, is not relevant to their information need at all, even after reading the whole list of text documents. They perhaps only waste their valuable time in reading the irrelevant text document. This problem can be

solved if users can be provided with a summary of the given text document. However, due to a large volume of available text data, that too dynamic in nature, it is very cumbersome for human experts to summarize all the documents manually. This issue leads to the requirement of an automated system that summarize the given text document automatically. This system that condenses the text document automatically and preserving its overall information content using a computer is termed as Automatic Text Summarization (ATS) system. There are numerous applications of automatic text summarization such as a snippet in information retrieval systems, news headlines as replacement to full story of news, electronic program guide in television systems. ATS is widely used for various domains such as business, news, legal and medical domains.

The researchers have classified text summarization systems (Hovy & Lin, 1995; Jones, 1997; Mani & Maybury, 1999; Gupta & Lehal, 2010; Lloret & Palomar, 2012; Nenkova & McKeown, 2012) on the basis of three main perspectives namely input, purpose and output. The third aspect which is most popular among these (i.e. output) considers summarization systems as either extractive or abstractive, and is mostly used by researchers. In extractive automatic text summarization (EATS), a subset of sentences from the original text document is selected for the final summary. Whereas abstractive automatic text summarization (AATS), sentences are fused and regenerated using natural language resources or rules. Abstractive text summarization requires deep knowledge resources, lexical/language resources, parsers and language generators. Because of these resource requirements, it is practically infeasible to use abstractive methods for automatic text summarization. Therefore, researches mainly focused on extractive text summarization instead of abstractive text summarization. The research work carried out is also focused on extractive automatic text summarization.

A typical extractive text summarization process completes in three steps namely pre-processing, sentence scoring, and summary generation. The first step in text summarization is preprocessing the input text document. Preprocessing mainly includes the sentence segmentation, stemming, stopword removal and special symbol removal. In the step which is sentence scoring, a score is assigned to each sentence of the document based on certain specific criteria. In literature various features are defined for sentence scoring such as term frequency, numerical data inclusion, sentence location, etc. After calculating each sentence score, rank is assigned to each sentence based on these scores. The sentences with the higher score are considered more important than the sentences with lower scores and are assigned high ranks consequently. After assigning a rank to each sentence, in third step, top ranked sentences are selected to generate the summary. Total number of sentences in the summary depends on the required length of it.

This chapter is focused on statistical features used in extractive approaches. In this chapter performance of these features is analyzed individually. After that, features that perform well termed as best features using ROUGE evaluation measures are used for creating feature combinations. After that, best performing feature combinations are identified. A deep performance evaluation of best performing feature combinations on short, medium and large size documents is also conducted using same ROUGE performance measures.

The rest of the chapter is organized as follows: After discussing challenges of ATS, background methods are presented followed by features used for sentence scoring. . Next, author discusses generic summarization process used for ATS. This is subsequently followed by evaluation matrices for ATS, followed by proposed impact analysis. Features and their combinations are properly analyzed before the chapter is finally concluded.

GENERAL CHALLENGES IN TEXT SUMMARIZATION

Major issues (Jones, 1998, Mani & Maybury, 1999) in generating automatic extractive text summaries are listed below:

1. **Redundancy:** Extractive text summaries are generated by selecting top scoring sentences from the text document. This sometimes led to the selection of redundant sentences in the final summary.
2. **Cohesion:** Sometimes, top scoring sentences becomes totally different from each other. Each neighboring sentence contains totally different terms without any of context in between. It becomes an issue, because if sentence are not cohesive then it becomes difficult to interpret the intended gist of text.
3. **Coherence:** Textual relationship beyond more than one sentence and through a discourse, if not meaningful then there is no meaning of generated summary. As selected sentences on the basis of some scoring function might not produce quality summary due to lack of coherence in between the selected ones.
4. **Anaphora:** Scoring function do not reproduce sentence as they only select the sentences as it is from the original text, therefore referring pronouns in the resulted summary creates issues in terms of interpretation and resolution.
5. **Coverage:** Extractive summaries do not guarantee that all inherent topics or themes are present in the finally produced summary as selection is purely on the basis of score of sentences obtained using some scoring methodology.

BACKGROUND AND ISSUES

Work in the area of EATS started in the early 1950s, however as of now; no such system is available that can generate summaries as efficient as experts. In early stage, pioneered features such as term frequency (Luhn, 1958), sentence location (Baxendale, 1958), cue words and title similarity (Edmundson, 1969) were proposed for text summarization process. As the time progressed, new features were added for the text summarization process like tf-isf, gain, etc. The basic methodology behind these summarization processes is to assign score to each of the sentences present in the text by using either a single feature or linear sum of features. However, applying features alone do not improve the quality of text summaries significantly, as each feature processes sentences in a different aspect. In literature many feature based statistical, graph based, lexical, machine learning and evolutionary methods for extractive summarization are proposed by researchers.

The key component of the statistical approaches(Rush et al.,1971; Pollock & Zamora, 1975; Brandow et al., 1995; Salton, 1983; Church & Gale, 1995; Hovy & Lin, 1997; Hovy & Lin, 1998; Baldwin & Morton, 1998; Radev et al., 2001; Nobata et al., 2001; Mori, 2002; Nobata et al., 2002; Pingali et al., 2005; Liu et al., 2009) of extractive text summarization is assigning weights to words or sentences based on certain statistics such as frequency of appearance of words in the text. Statistical approaches are simple to use as no knowledge source is required in these approaches. However problems with these approaches are similar to extractive text summarization approaches such as problem of ambiguous references i.e. anaphors (such as pronouns which refers to some words that appears earlier in the text) and cataphors (ambiguous words which signals to word that appears later in the text).

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

In graph based approaches (Michalcea & Tarau, 2004), sentence scores are generated based on the relationship among the sentences. Although graph based approaches work well as graph based approaches do not rely only on the local context of a text unit (vertex), rather take into account information recursively drawn from the entire text (graph). However graph based approaches also have the issue of ambiguous references. In addition to this issue, graph based approaches also have an issue of the requirement of multiple iterations as these approaches require multiple iterations to converge.

Later machine learning methods and evolutionary methods (Kupiec, 1995; Hirao et al., 2002; Varma et al., 2005; Fattah & Ren, 2009; Prasad & Kulakarni, 2010; Xiaoyan et al., 2010; Abuobieda et al., 2013; Abuobieda et al., 2012; Wang & Maches, 2013; Mendoza et al., 2014) were proposed with the increase number of features. These methods, used to identify a suitable set of features and their applicable weights. On the trained data the performance, most of the times, is optimal; however applying the same process to unknown data may result in the generation of poor quality summaries. This issue of generation of poor quality summaries for unknown data is known as the generalization issue. Although machine learning algorithms allow to test performance with a high number of features in an easy way, however at the same time, all these approaches require labelled corpus of sentences. This requirement of labelled corpus becomes a critical issue while summarization because it is difficult to mark summary sentences similar to abstracts, manually. Also these methods are not able to resolve the issue of coherence and cohesiveness.

Semantic methods such as feature based semantic similarity and lexical chains were proposed to alleviate the issue of coherence and cohesiveness. In lexical chain based approaches, lexical chains are constructed after the pre-processing step. Thereafter in the next step, scoring of the chains is conducted. For this purpose various matrices are applied such as chain length, chain distribution in the text, text span covered by the chain, density, graph topology (diameter of the graph of the words) and number of repetitions. The main issue with lexical chain based methods is the requirement of knowledge sources on hand such as WordNet to find semantically related words and chains, and secondly interpretation of semantic information such as semantic similarity threshold. These practical issues limits and puts constraints on the usefulness of semantic methods.

In order to improve the performance of extractive text summarization systems, the information-rich sentences need to be selected to produce the final summary. Hence sentence selection is the most important step of extractive text summarization process. For the purpose a numerical measure of usefulness may be assigned to each of the sentences in the given text. Information rich sentences are then selected according to the specified heuristics. Aforesaid weight assigning process by using a specific heuristic is termed as sentence scoring. For the final summary, sentences are selected on the basis of their scores computed using different scoring methods. Therefore, the overall performance of extractive text summarization system mainly depends on the sentence scoring methods employed to score the sentences. Several other factors like pre-processing, also influences the quality of text summaries.

From early 1960s, researchers are continuously trying to analyze the feature from different perspectives in order to generate efficient text summaries. Rafael et al., 2013 assessed a broader set of features that includes term frequency, tf-isf, upper case, proper noun, word co-occurrence, lexical similarity, cue word, numerical data, sentence length, sentence position, title similarity, aggregate similarity, bushy path and textrank. They tested each and every algorithm for three different datasets. It was concluded that term frequency, tf-isf, sentence length, lexical similarity and text rank are better features for sentence scoring as compared to the rest of the features listed. Later Rafael et al., 2014 analyzed the performance of previously proposed algorithms using different combinations. The proposed methodology was termed

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

as context based summarization and three groups of features were created namely word level, sentence level and graph level. All combinations of intra-group and inter-group word level, sentence level and graph level features are tried to test their impact on sentence scoring. This approach concluded that word frequency; title similarity and sentence location are the best features specifically for News domain. However, in all assessments listed above impact analysis of features such as sentence entropy, sentence to sentence cohesion etc. has not been carried out and a single evaluation measure ROUGE-1 for extracting best feature combinations is used. Moreover, some semantic features are also analyzed with statistical features. However, lack of abundant knowledge sources makes it difficult to use semantic features. This motivated to use exhaustive set of features for impact analysis other than semantic features (due to lack of knowledge sources) and evaluation measures (ROUGE-1, ROUGE-2, ROUGE-L and ROUGE-W).

FEATURE ENGINEERING

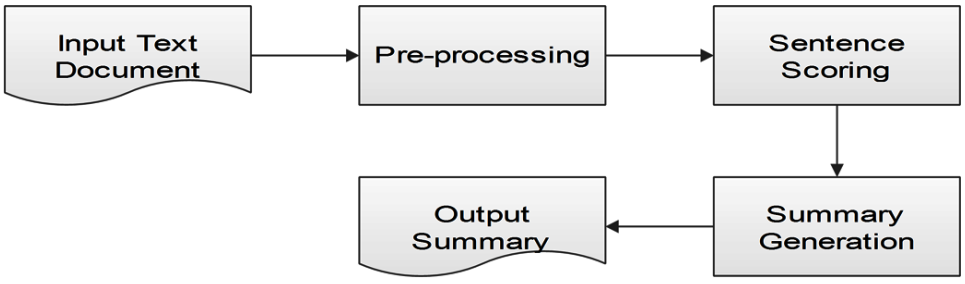
A typical sentence scoring module of extractive automatic text summarization requires various features to score sentences. A number of statistical and linguistics features have been proposed by researchers for the aforesaid scoring process. These features are categorized into three groups of categories according to their processing level. The categories are word level scoring, sentence level scoring and graph based scoring and these are described as following:

1. **Word Level Scoring:** The features used for word level scoring methods score each term present in the given text according to a particular criterion. Sentence score is computed as the sum of each term present in a given sentence.
2. **Graph Level Scoring:** The sentence score in case of graph level scoring method is calculated using the relationship of a sentence with other sentences. If two sentences are linked via some defined parameter, then an edge is established in between them. Their weights are used to generate sentence scores.
3. **Sentence Level Scoring:** The features used for sentence level scoring methods use sentence level statistics for computing score for a given sentence.

All features are summarized in Table 1.

GENERIC SUMMARIZATION PROCESS

A typical extractive text summarization process completes in three steps namely pre-processing, sentence scoring and summary generation. The details of process flow are discussed in the following subsection. Whole generic text summarization process flow consisting of three steps is shown in Figure 1.



1. **Pre Processing:** First step in text summarization is preprocessing the input text document. Preprocessing mainly includes the following steps sentence segmentation, stemming (Porters, 1980), stopword removal and special symbol removal.
2. **Feature Based Scoring:** After preprocessing, the next step in generic text summarization is sentence scoring. In this step, a score is assigned to each sentence of the document based on certain specific

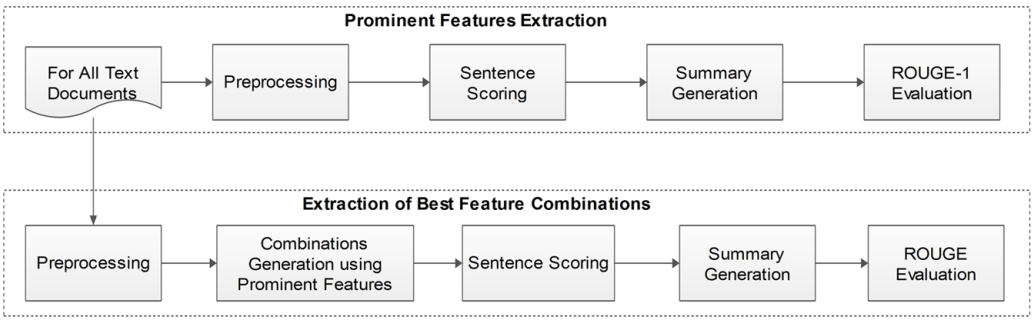
criteria. Various features are defined for sentence scoring such as term frequency, numerical data inclusion, sentence location, etc. After calculating each sentence score, rank is assigned to each sentence based on these scores of the sentences. The sentences with the higher score are considered as more important than the sentences with lower scores. Ranks are assigned to each sentence in the given text according to their scores.

3. **Summary Generation:** After assigning a rank to each sentence, the final step in generic text summarization is summary generation. In this step, top ranked sentences are selected to generate the summary. The number of sentences to be selected depends on the required length of the summary.



Evaluation Matrices

Automatic evaluation of text summaries is a challenging and difficult task. The gold summaries provided by human experts and summary generated by automatic text summarization systems usually do not match exactly. Lin, 2004 proposed Recall-Oriented Understudy for Gisting Evaluation (ROUGE) measures for evaluation of text summarization systems. ROUGE measures are the only available commonly used measures for the purpose of automatic evaluation. ROUGE-1 and ROUGE-2 are versions of ROUGE-N, where N is 1 and 2, respectively. ROUGE-L and ROUGE-W are computed using longest common sub-sequences.

Proposed Impact Analysis

As discussed earlier, extractive text summarization in general completes in three steps namely: pre-processing, sentence scoring and summary generation. Process flow to analyze the impact of feature combinations is shown in Figure 2. Pre-processing is applied on the text document using the process described earlier. Each sentence is then scored using all the features one by one. After sentence scoring, summary is generated using each feature. ROUGE-1 evaluation measure as described in previous section is then applied on the summary and relevant features are further used for generation of feature combinations. These relevant features are termed as prominent features. For each feature combination, a summary is generated. ROUGE evaluation measures (ROUGE-1, ROUGE-2, ROUGE-L, ROUGE-W) are further applied to get the better performing feature combinations which are termed as best feature combinations.

Figure 2.

RESULTS AND DISCUSSIONS ON DUC 2002 DATASET

Document Understating Conference (DUC) 2002 dataset is used for experimental evaluation of proposed impact analysis. This dataset contains News data along with their gold summaries (manual summaries provided by humans). Sixty reference documents sets, each of them consisting of approximately ten documents for the evaluation task are provided in DUC 2002. For each document, DUC 2002 provides two abstractive summaries as gold summaries with about hundred words each.

After summary generation using a specific sentence scoring ROUGE-1, ROUGE-2, ROUGE-L and ROUGE-W scores are computed for each document. Initially, for each feature algorithm precision, recall and f-Measure value is calculated for each document. Thereafter, features that perform well are identified and termed as prominent features. These feature algorithms are then used for generating feature combinations. The feature algorithm combinations which perform well are termed as best feature combinations.

Using prominent feature algorithms, different feature algorithm combinations are generated for sentence scoring. Initially, Best forty combinations for each evaluation measure ROUGE-1, ROUGE-2, ROUGE-L and ROUGE-W are selected. Combinations which are present in the lists of best performing combinations, for each of the four evaluation measures are selected as final best feature algorithm combinations. These combinations are listed in Table 2. The list comprised of features algorithms busy path, cosine similarity with title, depth of the sentence in the tree, lexrank, aggregate similarity, sentence location1, sentence to sentence cohesion and title similarity. Despite having better performance individually, sentence entropy did not produce higher ROUGE scores in combinations with other feature algorithms. All best combinations are renamed as COMB with number in the same order of their respective rank for ROUGE-2 F-measure, for the purpose of comparison in graphical form. For example: first best performing combinations is renamed as COMB1.

Pre-processing is an important step of any text processing system. Final results are very much sensitive to this pre-processing. Comparison of results obtained using ROUGE-1 evaluation measure on all documents for single feature algorithms, with stemming and without stemming is shown in Figure 3.

It is observed that results using stemming are better as compared to results without stemming. The fact that stemming use the root forms of the words, enhances the performance. Comparing terms using their stemmed version gives more number of matches, which ultimately improves the results. Comparison of results obtained using ROUGE-2 evaluation measure on all documents for single feature algorithms, with stemming and without stemming is shown in Figure 4. Here also, the performance of stemmed version is better as compared without non-stemmed version.

Precision, Recall and F-Measure comparisons of best feature algorithm combinations for all documents set using ROUGE-1 and ROUGE-2 are presented in Figure 5 and Figure 6 respectively. Results are sorted on the basis of f-measure. It is observed that their are notable variations in ROUGE scores of precision and recall for some of the combinations. This is primarily due to the size of summary to be produced i.e. compression rate.

In proposed experiments, the compression rate is hundred words. At the time, total words in the summary exceed the limit beyond hundred words, the variation in between precision and recall is visible. More the limit exceeds, more the difference is reported in precision and recall. The smooth curve shows that COMB1 performs better as compared to all other feature algorithm combinations. ROUGE-L and ROUGE-W comparisons for the similar group are shown in Figure 7 and Figure 8, respectively.

Table 2. Best feature algorithm combinations details

S. No.	Combination ID	Features in Combination
1	COMB1	Aggregate Similarity + LexRank + Sentence Location1
2	COMB2	LexRank + Sentence Location1
3	COMB3	Aggregate Similarity + LexRank + Sentence Location1 + Sentence to Sentence Cohesion
4	COMB4	Bushy Path + LexRank + Sentence Location1 + Sentence to Sentence Cohesion
5	COMB5	LexRank + Sentence Location1 + Sentence to Sentence Cohesion + Sentence to Centroid Cohesion
6	COMB6	LexRank + Sentence Location1 + Sentence to Sentence Cohesion
7	COMB7	Depth of the Sentence in the Tree + LexRank + Sentence Location1
8	COMB8	Aggregate Similarity + LexRank + Sentence Location1 + Sentence to Sentence Cohesion + Sentence to Centroid Cohesion
9	COMB9	Depth of the Sentence in the Tree + LexRank + Sentence Location1 + Sentence to Centroid Cohesion
10	COMB10	LexRank + Sentence Location1 + Sentence to Sentence Cohesion + Term Frequency
11	COMB11	Aggregate Similarity + Depth of the Sentence in the Tree + LexRank + Sentence Location1 + Sentence to Sentence Cohesion
12	COMB12	Depth of the Sentence in the Tree + LexRank + Sentence Location1 + Term Frequency
13	COMB13	Aggregate Similarity + Depth of the Sentence in the Tree + LexRank + Sentence Location1
14	COMB14	Aggregate Similarity + LexRank + Sentence Location1 + Sentence to Sentence Cohesion + Term Frequency
15	COMB15	Sentence Location1 + Sentence to Sentence Cohesion
16	COMB16	Aggregate Similarity + Depth of the Sentence in the Tree + LexRank + Sentence Location1 + Sentence to Centroid Cohesion
17	COMB17	Aggregate Similarity + Frequential Sum of Probability + LexRank + Sentence Location1 + Sentence to Sentence Cohesion
18	COMB18	Aggregate Similarity + Sentence Location1 + Sentence to Sentence Cohesion
19	COMB19	Aggregate Similarity + Depth of the Sentence in the Tree + LexRank + Sentence Location1 + Term Frequency
20	COMB20	Depth of the Sentence in the Tree + Sentence Location1 +Term Frequency
21	COMB21	Aggregate Similarity + Sentence Location1
22	COMB22	Similarity + Depth of the Sentence in the Tree + Hamming distance + LexRank + Sentence Location1

Similar to ROUGE-1 and ROUGE-2, it is observed that COMB1 performs better in case of ROUGE-L and ROUGE-W evaluation as well. COMB1 comprised of feature algorithms aggregate similarity (Salton, 1997), lexrank (Erkan, 2004) and sentence location1. This is primarily due to using graph based feature algorithms such as aggregate similarity (Salton, 1997) and lexrank (Erkan, 2004) which focuses on the sentences which have more number of interlinks. In rest of the other combinations, feature algorithms such as depth of the sentence in the Tree (Neto et al., 2002), frequential sum of probability (Torres et al., 2002), hamming distance (Torres et al., 2002) sentence to sentence cohesion (Neto et al., 2002)}, term frequency (Luhn, 1958) and title similarity (Edmundson, 1969) are present other then the three features present in COMB1.

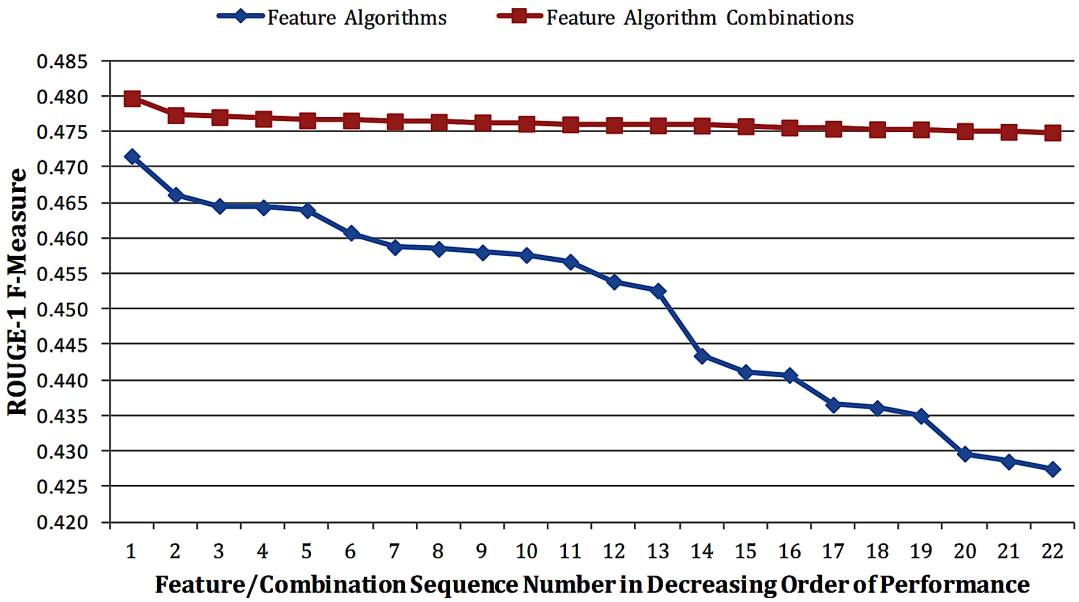
All the best twenty two feature algorithm combinations differ slightly in ROUGE scores. Comparing with individual feature algorithms, these feature algorithm combinations performs better as shown in Figure 9. It is clearly visible that all best feature algorithm combinations performs better as compared to all individual algorithms. Similar to individual feature algorithms, it is not a good idea to use a single feature algorithm combination for summary generation. As different feature algorithm combinations have different inherent properties. In comparison with work carried out by Rafael et al. (Rafael et al., 2013; Rafael et al., 2014) reported best combination is COMB1 contains two graph level and one sentence level features. Moreover, no dependent features such as cue words (Edmundson, 1969), named entity (Nobata et al., 2002) etc. are present in the reported best combinations.



Comparisons in between ROUGE-1 scores for short size, medium size, large size and all set of documents are shown in Figure 10. It is observed from the figure that performance of summarization system decreases as the size of document increases. This degradation is due to increase in the number of sentences because as the number of sentences increases, probability of selection of informative sentences decreases.

ROUGE-2 scores comparisons for short size, medium size, large size and all set of documents are shown in Figure 11. Here also performance decreases with the increase in the size of input text document.

CONCLUSION

In this chapter performance of various individual features algorithms such as bushy path, cosine similarity, cue words etc. is tested using ROUGE evaluation measures. It is observed that single feature algorithms only use specific feature strengths that are not capable of generating efficient summaries. Stemming impact is also analyzed while pre-processing of input text document; it is observed that with stemming performance improves significantly. Thereafter, feature algorithm combinations are generated

using best performing single feature algorithms using ROUGE evaluation measures. A feature algorithm combination which performs well for all ROUGE evaluation measures are reported as best feature algorithm combinations. Their performance is investigated on short, medium and large size documents. It is observed that performance degrades as the size of document increases.

KEY TERMS AND DEFINITIONS

Abstractive Summarization: Extraction of sentences by merging and fusing from the original text.

Extractive Summarization: Retrieval of sentences as its is from the original text.

Precision: Ratio of the relevant sentences retrieved divided by total sentences retrieved.

Recall: Ratio of the relevant sentences retrieved divided by total sentences relevant sentences.

Sentence Features: Any of various abstract entities that specify or combine to specify phonological, morphological, semantic, and syntactic properties of linguistic forms and that act as the targets of linguistic rules and operations.

Stemming: The process of reducing the words to its root form or word stem.

Stopword: Commonly or frequently used words (such as "is") that needs to be ignored at most of the times of processing of text either searching or retrieving.

Text Summarization: A process of condensing the text document automatically by computer system such that the produced summary is no longer than a specified threshold [typically one-third of the size of original text] and covers all the information contents of it.

Chapter 31
Improving Collaborative Filtering Algorithms: Sentiment-based Approach in Social Network

Firas Ben Kharrat
University of Carthage, Tunisia

Aymen Elkhleifi
Paris-Sorbonne University, France

Rim Faiz
University of Carthage, Tunisia

ABSTRACT

This paper puts forward a new recommendation algorithm based on semantic analysis as well as new measurements. Like Facebook, Social network is considered as one of the most well-prominent Web 2.0 applications and relevant services elaborating into functional ways for sharing opinions. Thereupon, social network web sites have since become valuable data sources for opinion mining. This paper proposes to introduce an external resource a sentiment from comments posted by users in order to anticipate recommendation and also to lessen the cold-start problem. The originality of the suggested approach means that posts are not merely characterized by an opinion score, but receive an opinion grade notion in the post instead. In general, the authors' approach has been implemented with Java and Lenskit framework. The study resulted in two real data sets, namely MovieLens and TripAdvisor, in which the authors have shown positive results. They compared their algorithm to SVD and Slope One algorithms. They have fulfilled an amelioration of 10% in precision and recall along with an improvement of 12% in RMSE and nDCG.

INTRODUCTION

Nowadays, the continuous progress of data and communications technologies, the increasing use of digital technologies among the people and the development of the users' lifestyles and norms necessitate innovative types of systems. The success of these systems will rely upon their capability to operate as a unit, to supply services to their users in every place and at any moment as well as to accustom themselves to the changes surrounding their environments. Recommender systems help users to identify their interests and sets of choices by predicting the invalidity of an item or a group of items to these users. They are defined as a special type of information filtering that provide information about which items may be interesting to users. Recommender systems generate a personalized recommendation for users based on a set of previously rating items. However, according to (Baldoni et al., 2011) the social web principles, social network and platforms promote the participation of users in many ways, stimulating the expression of opinions about the contents inserted by other users, by 'Like', 'Share' annotations, star-rating systems... This huge amount of data is a precious information source about perceptions, trends and feelings, and a lot of research is being carried on to identify ways for extracting meaningful information from these data. In fact, the social network could be considered an important source of recommendation. This paper endeavors to combine two types of information respectively called social and semantic information. The main purpose is to compute recommendation lists through making a visit to a limited part of social network.

We have improved the Slope One and SVD algorithms by external knowledge and through some experiment results. The approach has been applied in Java and tested on the MovieLens and TripAdvisor data sets. The results demonstrate that the additional knowledge achieved by the semantic analysis contributes to the amelioration of the quality recommendation in terms of accuracy.

Hence, this study foregrounds two major issues. The first part seeks to gather as well as parse data, while the second one attempts to use external resources to come up with relevant suggestions.

We construct this paper as following: We start with some major research literature on recommendation systems. Next, we highlight our approach via applying user's sentiment in order to raise the value of recommendation algorithm. We clarify the experiment immediately followed by an estimation of our algorithm. In conclusion, we briefly summarize our proposed study providing a few remarks on future works.

EASE OF USE

According to Burke (Burke, 2002), Recommender systems have three fundamental categories: collaborative-filtering, content-based and hybrid. The hybrid recommender system combines the content-based and the collaborative-filtering regarding the kind of advocated data Recommendation types are explained in details with their limitations in this section:

- **Content-based:** It advocates items that are akin to those the users selected on time before (Adomavicius & Tuzhilin, 2005; Burke, 2002). Items like products, services or even people are identified by their related characteristics. User's favorite choices, which are preserved in the user's profile and taking into account those associated criteria, emerge in already estimated items. According to (Schafer et al., 1999) content-based technique is termed item-to–item affinity. We show some usual research on which these traits are revolved around this technique, which are:

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

- NewsWeeder (Lang, 1995) is newsgroup, an internet base-discussion, filtering system. It charges users to rank some not viewed news articles according to their preferences. The applications were built on schematic tree-shaped diagram, sensory network and graphics based on vector.
- Pazzani et al., 1997 suggests a system able to bring forth web sites based on issues that the users have to be involved in regarding to their typical interest. In this experimentation, the applied system is Bayesian classifier.
- Zhang et al., 2002 suggests to differentiate in the midst of queries appropriate files including new data and using Bayesian system.
- **Collaborative Filtering:** CF is also termed people-to-people correlation.
- Tapestry (Goldberg et al., 1992) extracts electronic script on a drafted issue by a particular user.
- Ringo (Shardanand & Maes, 1995) advocated recording of music and artists established by resemblances among user's tastes as well as others.
- Hoaks (Hill & Terveen, 1996; Terveen et al., 1997) proposes home pages from news messages. If followers are interested, the system will not only find the person who got in a touch but also identify the web page.
- GroupLens (Konstan et al., 1997; Resnick et al., 1994) makes an advance in a system that deals with extracting data that assesses newsgroups article.
- Jester (Goldberg et al., 2001) is an online funny recommending the system. It uses a Collaborative Filtering algorithm termed Eigentaste and it is adjacent to algorithm for the disconnected phase. Next, the author utilizes a repetitive rectangular classification method for the offline stage.
- **Knowledge-based:** Advocates items taken from the assumption or the opinion of the user's tastes and choices. Indeed, the user profile comprises useful conception organized and explained in harmony with the inference machine:
- Google (Brin & Page, 1998) proposes the most famous links including the questions given by the users. The system is characterized by probabilistic standard.
- CF is the widely successful recommendation approach and has become used in many e-commerce systems. However, collaborative-based filtering undergoes various drawbacks:
- **Data Sparsity:** Most users rate small numbers of items in the system (Lianga et al., 2006). Therefore, those users may not find similar users.
- **Cold start Problem:** This is referring to the problems occurring with a new item or a new user. On the one hand, a new user who has not rated any items yet will not find similar users to help in finding recommendations. On the other hand, when a new item is introduced into the system and no user has rated it yet, it will be impossible to recommend that item anyway.

In recent works, semantic web mining is used in order to improve recommendations (Blanco et al., 2008; Blanco et al., 2010; Moreno et al., 2010; Kim et al., 2011). This approach is a field of research where it converges the semantic web and the web mining, which are two areas that have been evolving very quickly. Both techniques are contributing to the latest challenges of the WWW in a complementary way. The shortage of structure of most of the web data can be just interpreted by human beings. Whereas, the huge amount of information can only be processed efficiently by machines. The semantic web addresses the first problem by enriching the web with machine-understandable information, while web mining addresses the second one by automatically extracting the useful knowledge hidden in web data (Stumme et al., 2006). Semantic web mining aims at improving the results of recommendation by exploiting the semantic structures in the web as well as building the semantic web making use of web mining techniques (Schroder et al., 2011).

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

In a social network context, the identification of the opinion of users is receiving an increasing attention. It is a striking indicator of the appraisal of topics, people, situations, re-sources and trends. Hence, the development of opinion Mining (Pang & Lee, 2008), of ontologies of emotions and of W3C markup language proposals like Emotion Markup Language (Schroder et al., 2010; Schroder et al., 2011). However, there are few applications that still use the most advanced results in web technology to deal with opinion. Moreover, most of the approaches use emotional ontologies where emotions are individual isolated units (e.g. WordAffect). Such considerations motivated our focus on the ontology of emotions in (Francisco et al., 2007), an OWL ontology where emotions are structured and organized in levels, trying to integrate the results of the most recent psychological models.

Furthermore, on account of the evolution of social network application, recommendation systems in the social network have become more common. Facebook group recommender is proposed in order to make each user join the group that is near to its interests (Baatarjav et al., 2008). The authors proposed a mechanism called Group Recommendation System 'GRS' which uses hierarchical clustering and decision tree techniques. These techniques classify the users according to their features and then provide the recommendation depending on this classification.

Slope One One (Lemire & Maclachlan, 2005) is a CF algorithm. Firstly, it is not sophisticated to put into function or to test it indeed. Secondly, it is updatable in the sense that new estimation may alter expectations immediately. Thirdly, it is useful when we want to question visitors. It is necessary that those queries must be swift to the benefit of storage. Ultimately, the Slope One algorithm expects a little assessment from the first visitors in order to produce authentic recommendations.

Slope One utilizes a measure of similar items akin to Item-based CF. This standard is quiet distinct from the variation of Item-base Collaborative Filtering just as the prediction calculation. In another word, we intend to keep the differential rating values of items in pair.

The following symbols or signs were used to describe schemes adopted by (Lemire & Maclachlan, 2005):

- u_i is the rating of a user given to item i.
- S(u) is the subset of items consisting of all items rated in u.
- Card(S) is the number of elements in S.
- The average of ratings in an evaluation u is denoted $\overline{u}$.
- The set Si(X) is the set of all evaluations u ∈ X as they contain item i (i ∈ S(u)).
- Given two evaluations u, v, we define the scalar product (*u,v*) as $\sum_{i \in S(u) \Delta S(v)} u_i v_i$.

Predictions, P (u), represent a vector where each component is the prediction corresponding to one item: predictions depend implicitly on the training set X.

The similarity in Slope One is defined as the average deviation of items i, j given by:

$$dev(i,j) = \sum_{u \in S_{i,j}(X)} \frac{u_i - u_j}{card\left(S_{i,j}(X)\right)} \tag{1}$$

When new ratings are entered, *dev*(*i,j*) is symmetric and computation time is halved. $dev(i,j) = u_j$ used as a prediction for u_i. Therefore, a usable predictor is the average of all predictions:

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

$$P^{S1schema}\left(a\right)_i = \frac{1}{card\left(R_j\right)}\sum_{j\in R_j}\left(dev\left(i,j\right)+u_j\right) \tag{2}$$

With

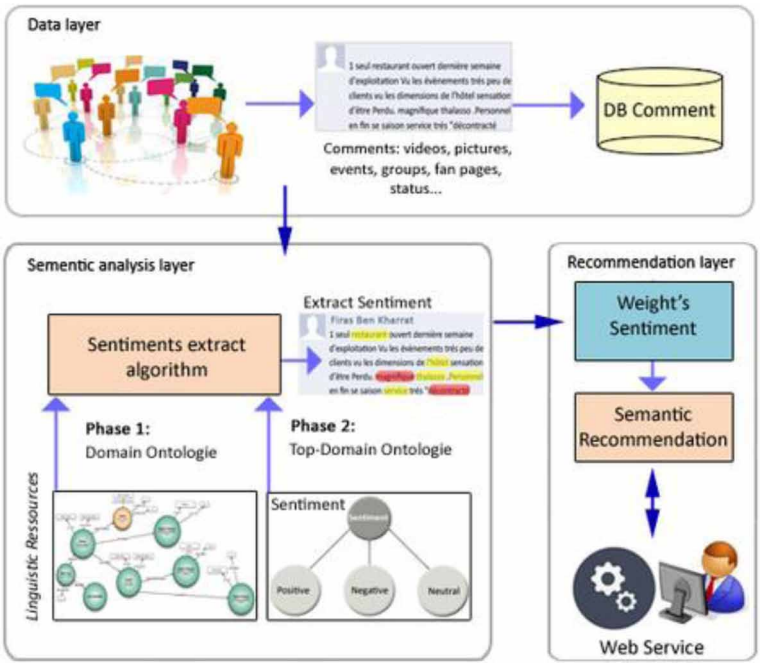
$$R_i = \left\{j|j \in S\left(u\right), i \neq j, card\left(S_{i,j}\left(X\right)\right) > 0\right\}.$$

The authors (Lemire & Maclachlan, 2005) present an approximation based on a dense dataset, where almost all pairs of items i and j were rated, R_i=$S(u)$/(i). Also, in a dense dataset $\sum_{j\,/\,R_i}\frac{u_j}{card\left(R_j\right)}$ is approximately $\overline{u}$. The accurate prediction is:

$$P^{S1}\left(u\right)_j = \overline{u} + \frac{1}{card\left(R_j\right)}\sum_{i\in R_j} dev_{i,j} \tag{3}$$

According to (Koren et al., 2009), Matrix factorization models map both users and items to a joint latent factor space of dimensionality *f*, such that user-item interactions are modeled as inner products in that space. Accordingly, each item *i* is associated with a vector *qi* ∈ R, and each user u is associated with a vector *pu* ∈ R. For a given item *i*, the elements of *qi* measure the extent to which the item possesses those factors, whether positive or negative. For a given user *u*, the elements of *pu* measure the extent of interest the user has in items that are high on the corresponding factors, once again, positive or negative. The resulting dot product, $q_i^T p_u$, captures the interaction between user *u* and item *i.* The user's overall interest in the characteristics of the item. This approximates user u's rating of item *i*, which is denoted by $\hat{r}_{ui}$, leading to the estimate:

$$\hat{r}_{ui} = q_i^T p_u \tag{4}$$



OUR APPROACH

General Architecture

Figure 1. displays the overall architecture of our proposed approach in this current paper. It is based on semantic analysis of user's comment. Our architecture connects the users via the collaborative social network in order to use sentiments in their comments. This system combines the social network analysis comments with the sentiment of item's concepts in one social recommendation algorithm. The suggested system consists of three parts. The first part deals with a comment posted by the user. This comment is stored in the database of comments. We utilize these data to create a user profile. The second part is established on semantic analysis methods that deploy semantic-based techniques. This consists of exploring the semantics of different sentiments, for each user's comment. Next, we calculate user's weight from the extracted sentiment. Finally, the recommendation layer, where the new input is sent to our algorithms.

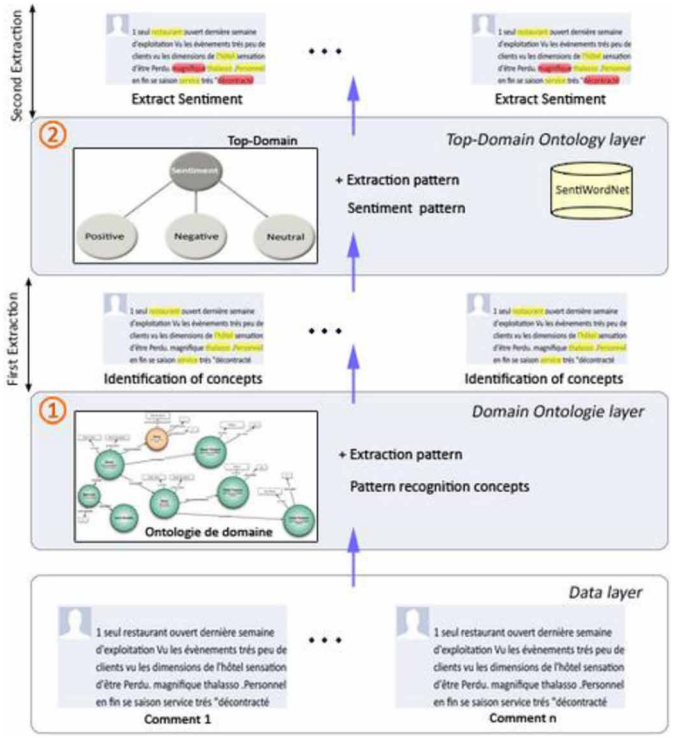
Figure 1. Collaborative recommender systems architecture

Data



The MovieLens dataset is one of the gold-standards for testing collaborative filtering algorithms (Ekstrand et al., 2011). It contains 100,000 real ratings (rє{1,2,3,4,5}) from 943 users on 1,682 movies, which are collected through the MovieLens web site. For purposes of validation, the dataset is organized in five different splits, each containing a training set with 80,000 ratings and a test set with 20,000 ratings.

In addition, we chose to experiment our system in the tourism domain. We created one benchmark data composed by description and comments of many hotels. We developed an extract program based on 'jaunt API.' It's an open source API to draw forth data such as hotel's description, comments, localization, and so on and so forth from tourism website. TripAdvisor is a well-known online website that collects comments and reviews. It is also rated by customers who book hotels throughout the world.

The primary problem that we encountered was that of collecting information from social network. We chose the social network Facebook for our experiment. Then, we set up a script in java in order to gather all necessary comments using 'Facebook Graph API', which included comments related to the topic of movies. We stimulated all MovieLens' users with our profile collection by a simple matching. This matching is based on demographic information about the users like age, gender, occupation and country. For privaetness, both data sparsity and dynamicity were being taken into consideration when tackling with social network data. Furthermore, we have created an online website to collect users profile from Facebook. In the tourism domain, the users of TripAdvisor and Facebook were alike. Ultimately, all users profile was stored in the database.

Figure 2. Semantic analysis layer

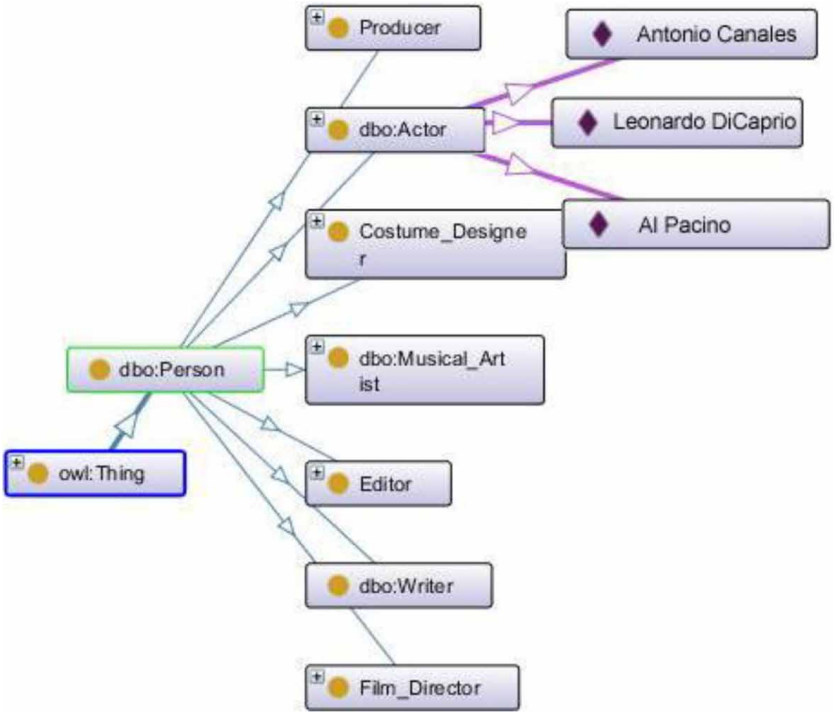
Semantic Analysis

This semantic analysis contributes to a system that allows a comment with reference to a particular item as well as offers sentiment average to each concept in this item. The semantic analysis of the developed system is well elucidated in Figure 2. The suggested approach is divided into two stages. At first, (a) is the application of the domain ontology to filter concepts. At second, (b) is the sentiment analysis on a collection of comments characterized by the concepts and properties and also included in the Top-Domain ontology. These two stages are well depicted afterward.

- **Domain Ontology:** The most important contribution of ontologies is the key role that they have played in extracting concepts from comments. We extended the existing ontologies so as to use a domain of ontologies. Figure 2 and 3 demonstrate a set of concepts which are organized in a hierarchical structure (depending on the domain) to describe objects of items. Our produced system uses an ontology to represent items for description. As we show in Figure 3, the concept `Person' at level 1 is the most general concept in films' ontology, whereas the concept in deeper levels is more specific one.
- **Top-Domain Ontology:** The primary idea behind the proposed approach is to take advantage of a Top-Domain ontology for providing more elaborate sentiment scores regarding the notions contained in a user's comment. In order to rise the underlying semantics, the Top-Domain ontology is enriched with synonyms and hyponyms (SentiWordNet) of the detected attributes, Figure 5.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 3. Films ontology



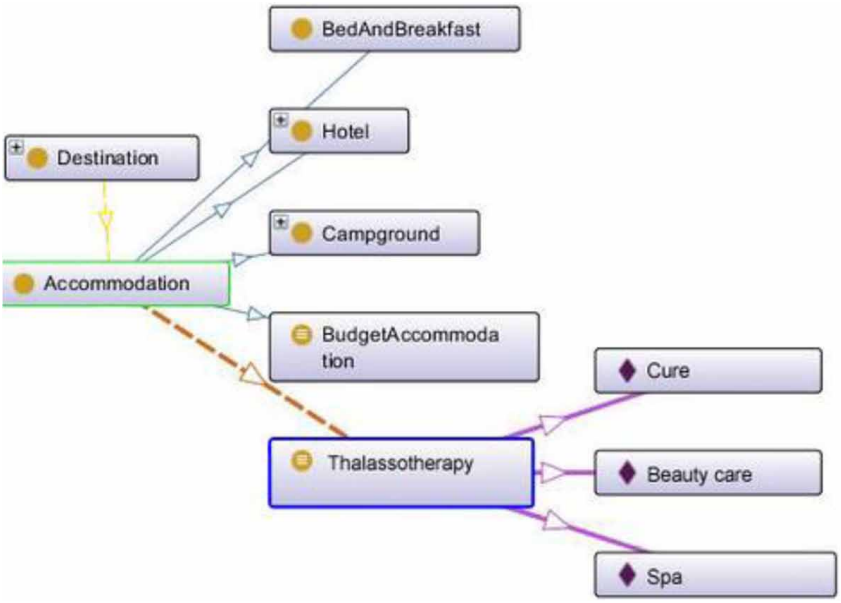


Figure 4. Tourism ontology

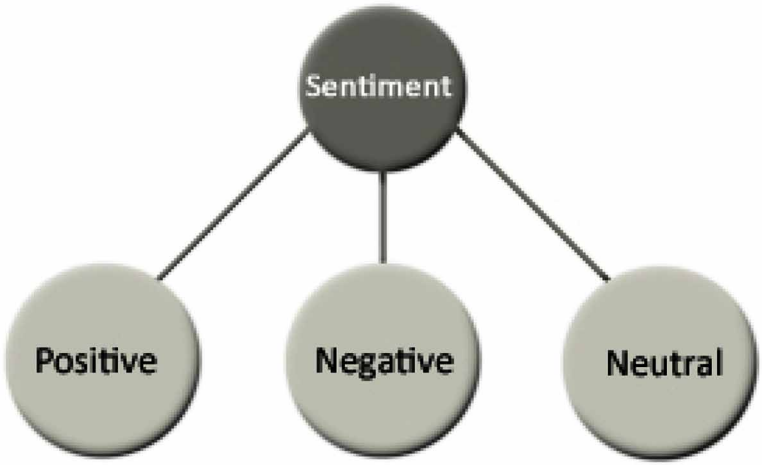
EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Similarly, SentientiWordNet is defined as, a lexical resource for opinion mining. It contains different subsets of effective concepts that group together synsets which denote sentiment states. SentiWordNet assigns to each synset of WordNet three sentiment scores: positivity, negativity, objectivity.

- **Extraction Algorithm of Sentiment:** used to annotate all sentiments in comments. We have two phases of annotation. In the first phase, we annotated concepts. Then, in the second one, we elucidated sentiments on these concepts. Sometimes we found more than two sentiments in the same sentence. In this case, we have defined a priority for the selection of sentiment as follows: Negative, Neutral and positive. Figure 1 described the algorithm that annotated sentiments in our textual corpus, based on both the Domain ontology and Top-Domain ontology.



The users' semantic data is provided by the user's sentiment for distinct concepts of items. In the system, every user has a profile expressed by the sentiment of many concepts, demonstrated in Figure 6. The opinion embodies the user interests applying a comment's semantic analysis. Correspondingly, concepts of every item have a range of preferences regarding the significance of the concept. For instance, an actor in the film is more important than the sound production company. It is important to mention that the user may have different opinions on the same concept in different items.

Recommendation Algorithm

As already explained, the basic idea beyond the proposed approach is to take advantage of a semantic analysis for providing more elaborate semantic scores regarding concepts contained in a comment. We combine the social network analysis measures with the sentiment of the users in one semantic recommendation algorithm.

We divide the step of recommendation into two phases: (a) is the creation of sentiment score (Table 1), and (b) is the integration of sentiment dimension onto recommendation algorithms. These two phases are more described hereunder.

Figure 6. User's profile

For every concept with sentiment, a relevant score is submitted to this concept via table score, described in Table 1. We are also interested in calculating the score for other users of the system. Therefore, we assign a specific score to their concepts that carry sentiment information.

The sentiment of users is given by user profiles, Figure 6. Each user in the system has a profile described by means of concept. The concept represents the item description using the domain Ontology.

Figure 7. shows an example of item's concept and user's sentiment. User 1 has a positive sentiment about the actor 'Leonardo Dicaprio' in the film 'Titanic'. We want to anticipate another film to user 1 with the same actor. We calculated the concept's sentiment to check if we can recommend him the film 'Aviator'.

Table 2. displays two sample pre-processed comments retrieved during this phase as well as their corresponding sentiment score generated from the average of weight.

The formalization of weight for the user *i* and item *j* is as follows:

$$w1_{i,j} = \frac{\sum_{k=1}^{n} \left(\alpha_k \times g_k\right)}{n} \tag{5}$$

Table 1. Sentiment scores

Predict User		Current Users	
Sentiment	**Weight**	**Sentiment**	**Weight**
Positive	2	Positive	1
Neutral	0	Neutral	-1
Negative	-1	Negative	-2

ITEM j

	User1	...	UserN	
Concept1	Positive (+1)		Neutral (-1)	Average of weight
⋮				
Concept K	Negative (-2)		Negative (-2)	

USER i

	Item1	...	ItemM
Concept1	Neutral (-1)		Negative (-2)
⋮			
Concept L	Positive (+1)		Negative (-2)
	Average of weight		

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

With: α_k is the weight of the concept's sentiment *k*. *n* is the number of concept. And g_k is the grade of the concept *k;* $g_k \in]0,1[$ depends on the importance of the concept.

The formalization of weight for system users and item j is:

$$w2_j = \frac{\sum_{k=1}^{n} (\beta_k \times g_k)}{n} \tag{6}$$

With: β_k is the weight of the concept's sentiment *k*, returned from all sentiments of current users.

The proposed recommendation algorithm is based on user's sentiment and the concepts of item.

The new algorithms are defined by an improved Slope One algorithm, described in Equation (7) and an improved SVD algorithm, described in Equation (9).

$$P^{SS1}\left(u\right)_j = \frac{\sum_{i \in R_j} (dev_{i,j} + u_i)}{card\left(R_j\right)} + \log\left(1 + \frac{w1_{u,j} \times w2_j}{1 + w1_{u,j} + w2_j}\right) \tag{7}$$

With:

$$dev\left(i,j\right) = \sum_{u \in S_{i,j}(X)} \frac{(u_i - u_j) \times \left(1 + w1_{u_i,j}\right)}{card\left(S_{i,j}\left(X\right)\right)} \tag{8}$$

The matrix factorization model should integrate all signal sources with enhanced user representation. The idea is to minimize the squared error over all ignored rate:

$$\hat{r}_{ui} = \left[q_i^T + \log\left(\frac{w2_j}{w1_{u,i} + w2_j}\right)\right]\left[p_u + \log\left(\frac{w1_{u,i}}{w1_{u,i} + w2_j}\right)\right] \tag{9}$$

EXPERIMENTATION AND RESULTS

We used the MovieLens dataset with 1k ratings by 943 users on approximately 1682 items. Each user rated at least 20 movies. Then, we used the TripAdvisor dataset with 500 ratings, in which only users who have rated at least 20 hotels are included in our database. We also used the LensKit recommender toolkit for our experiments (Ekstrand et al., 2011). LensKit evaluations are defined with Groovy scripts. Evaluations are organized around tasks such as crossfold (to partition data for cross-validation) and train Test (to run a train-test evaluation over one or more datasets). Tasks can optionally be contained within targets. In this case, their execution is deferred until the target is executed allowing a single evaluation script to define multiple evaluation capabilities.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

We used the following algorithms by identifying parameters revolved around prior results in the literature research and experience tuning LensKit for both the MovieLens and TripAdvisor datasets. Therefore, we will compare Slope One (Lemire & Maclachlan, 2005) algorithm with our improved one, 'SemSlope One,' against Simon Funk's SVD (Funk, 2006) with our enhanced one, 'SemSVD'.

The effectiveness of a given CF Systems established by evaluative Slope One or SVD algorithms can be measured precisely. As an attempt to assess our given approach, we have utilized four standards metrics (Dixit et al., 2013) such as RMSE, nDCG, precision and recall measurements (Fellbaum et al., 1998).

RMSE and nDCG estimate the prediction accuracy of every advocated item. We have observed that these two standards act quite alike in our assessment. In order to create training and tests collections for distinct number of ratings from 1 to 20, we first made set of experimentation and training partitions. Thereby, test users have 20 training items when applying the crossfold method. Next, to produce any other number of ratings, we haphazardly selected a model of a training set of 20 items. This paved us the way to create training collections with a given number of ratings for test users. For example, each profile size is assessed with the same test set.

RMSE is the square root of the mean/average of the square of all of the error. The use of RMSE is very common and it makes an excellent general purpose error metric for numerical predictions. Compared to the similar Mean Absolute Error, RMSE amplifies and severely punishes large errors.

$$RMSE = \sqrt{\frac{1}{n}\sum_{i=1}^{n}\left(y_i - \hat{y}_i\right)^2} \tag{10}$$

Normalized discounted cumulative gain (NDCG) measures the performance of a recommendation system based on the graded relevance of the recommended entities. It varies from 0.0 to 1.0, with 1.0 representing the ideal ranking of the entities. This metric is commonly used in information retrieval and to evaluate the performance of web search engines.

$$DCG_k = \sum_{i=1}^{k}\frac{2^{rel_i} - 1}{log_2\left(i+1\right)} \tag{11}$$

With k is the maximum number of entities that can be recommended. $IDCG_k$ is the maximum possible (ideal) DCG for a given set of queries.

$$nDCG_k = \frac{DCG_k}{IDCG_k} \tag{12}$$

DISCUSSION

This study introduces our algorithm, which is termed SemSlope One. We attempted to examine the anticipation errors of our algorithm. Using the LensKit toolkit (Ekstrand et al., 2011), we divided 'SemSVD' in comparison with the original algorithms 'Slope One' and 'SVD'. We begin the task of separating the collection of data in 5 folds cross-validation configuration. Users are divided into 5 groups. In a random

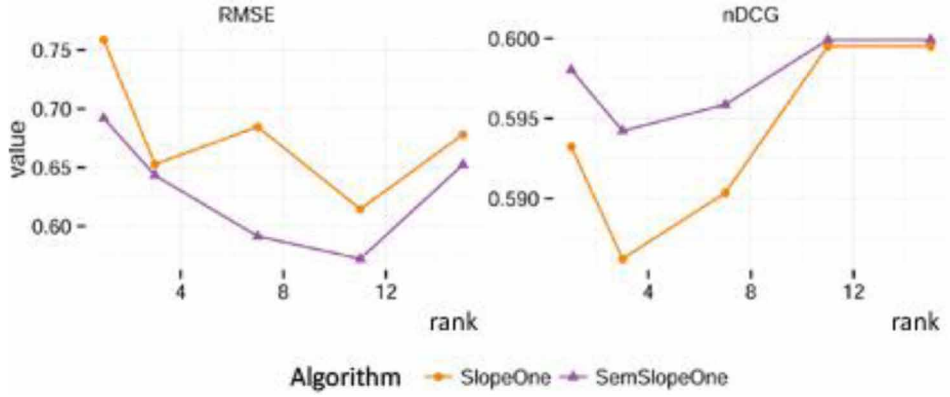

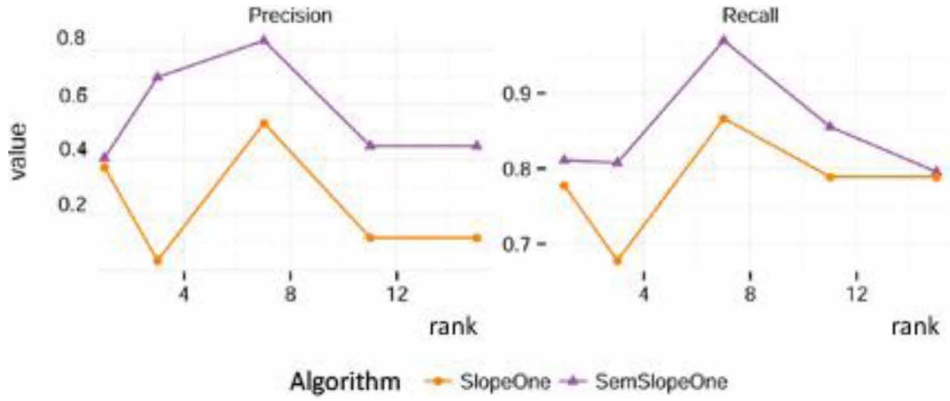

Figure 15. Results of Precision, Recall metrics for algorithms: SemSlope One and Slope One (TripAdvisor)

manner, we picked out 20 of their ranges according to the test to each user in each division. The residual ratings from users combine to create training set. Next, we put into function five recommender algorithms on the data, and recorded the predictions of each algorithm used to each test estimation rating. Thereupon, we compared Slope One algorithm with our enhanced Slope One. But, the task of comparing 'SemSVD' based on matrix factorization with SVD, is rather important. The high-level results from our evaluation are summarized in Figures 8, 9, 10 and 11 using MovieLens dataset and in 12, 13, 14 and 15 applying TripAdvisor dataset. When the number of rates is between 0 and 4, all our improved algorithms perform similarly well. To note, when the number of rating increases, the 'SemSVD' recommender algorithm is the optimal predictor, and it is better than the others. To thoroughly appreciate the importance of our improvement over existing algorithms, it is worth noting that the average progress of our algorithm over the Slope One recommender is 10% and that over SVD is 12%. These are the major progress mainly when compared to the differences that could be attributed to the implementation details, which are shown by the variation in performance between Slope One, SVD and our algorithms.

CONCLUSION AND FUTURE WORK

What we propose in this paper is a fruitful study of a new approach for the recommendation systems based on users' sentiments. This suggested approach is divided into three main stages with an obvious intention to recommend the items.

In the first phase, we selected the comments of the users from the social network using a program called preprocessor. In the second one, we detected sentiment from users' comments. Then, we deduced both user's and item's weight using sentiment from certain selected concepts. The study concludes that the recommendation system is predicted with two algorithms based on Slope One and SVD. The achieved results are promising compared to those reached by the Slope One and SVD algorithms.

The future of algorithm is, indeed, very promising. In the future, we propose to elaborate user's profile using a demographic information. We also aim to extend our study of algorithm to search various connected communities. Besides, we will try to extract data from other resources such as discussion forms, blogs and semantic information in order to improve our assumption about the users in various social networks. Furthermore, we will attempt to extract semantic information from IMDb database to enrich knowledge about items for movies dataset.

Chapter 32
Knowledge-Based Support to the Treatment of Exceptions in Computer Interpretable Clinical Guidelines

ABSTRACT

Clinical guidelines are one of the major tools that have been introduced to increase the rationalization of healthcare processes, granting both the quality and the standardization of healthcare services, and the minimization of costs. Computer interpretable clinical guidelines (CIGs) are widely adopted in order to assist practitioners in decision making, providing them evidence-based recommendations based on the best available medical knowledge. However, a main problem in CIG adoption is the fact that, in the medical context, some degree of uncertainty is often present. Thus, during guidelines executions on specific patients, unpredictable facts and conditions (henceforth called exceptions) may occur. A proper and immediate treatment of such exceptions is mandatory, but most of the current software systems coping with CIGs do not support it. In this paper, the authors describe how the GLARE system has been extended to deal with this purpose. They identify different types of exceptions, considering their "pre-locability" and "pre-plannability". On the basis of such parameters, the authors propose different treatment modalities, consisting of both data structures to model the different types of exceptions, and the algorithms to treat them. The resulting methodology is an innovative one, integrating different Artificial Intelligence techniques (ranging from planning to ontology-based reasoning). Finally, they also discuss how they implemented their system-independent methodology on top of GLARE, and describe its application in the ROPHS project, considering the management of the severe trauma guideline.

1. INTRODUCTION

1.1. Context

The rationalization of the healthcare system is important to grant both the quality and the standardization of healthcare services, and the minimization of costs. *Knowledge* is the cue factor to promote such a rationalization: it may support both strategic *decisions* at the organization level, as well as diagnostic/therapeutic *decisions* concerning specific patients. *Evidence-based* medicine has gained a major role in this context. Clinical Practice Guidelines (CPGs) are one of the major tools that have been introduced to provide *evidence-based medical decision support*. CPGs are, in the definition of the USA Institute of Medicine, "*systematically developed statements to assist practitioner and patient decisions about appropriate health care in specific clinical circumstances*" (Institute of Medicine, Committee on Quality Health Care in America, 2001). In short, CPGs provide evidence-based recommendations to suggest to physicians the set of diagnostic/therapeutic actions to be executed to cope with a specific disease. Notably, the last decision on the activities to be performed on the patient is always left to the user-physician. Thousands of CPGs have been developed in the last decade, or so. For instance, the Guideline International Network (http://www.g-i-n.net) groups 100 organizations of 48 countries, and provides a library of more than 6500 CPGs. Despite such a huge effort, CPGs have not provided all the expected advantages to clinical practice yet. Recent research has shown that Computer Science can help to drastically improve the impact of CPGs in clinical practice, by developing tools to manage computer-interpretable clinical guidelines (**CIG**s henceforth), defined as formal representations of CPGs in some computer format. The adoption of CIGs, and of computerized approaches to acquire, represent, execute and reason with provides crucial advantages to:

1. Patients, enabling them to receive the best quality medical treatments;
2. Physicians, providing them with a standard reference which they may consult, with a way of certifying the quality of their activity (e.g., for insurance or legal purposes), and, above all, with advanced support for their decision-making activity;
3. Hospitals, and healthcare centers, providing them with tools to enable the quality and the standardization of their services, as well as with a tool to evaluate quality, and to take strategical knowledge-based decisions for optimizing costs and resources.

In recent years, the research about CIGs has reached an important role within the Medical Informatics community, and many different approaches and projects have been developed to create domain-independent computer-assisted tools for managing, acquiring, representing and executing them. See e.g. the systems Asbru (Shahar, Miksch, & Johnson, 1998), EON (Musen, Tu, Das, & Shahar, 1996), GEM (Shiffman et al., 2000) GLARE (Terenziani, Molino, & Torchio, 2001) (Terenziani., Montani, Bottrighi, Molino, & Torchio, 2008), GLIF (Peleg et al. 2000), GUIDE (Quaglini, Stefanelli, Lanzola, Caporusso, & Panzarasa, 2001), PROforma (Fox, Johns, & Rahmanzadeh, 1998), and the collections (Gordon, & Christensen, 1995; Fridsma, 2001; Ten Teije, Miksch & Lucas, 2008; Peleg, 2013). One of such approaches is GLARE (Guideline Acquisition, Representation and Execution), which started from 1997 in a long-term cooperation between the Department of Computer Science of the University of Eastern Piedmont Alessandria, Italy, and the Azienda Ospedaliera San Giovanni Battista in Turin (one of the largest hospitals in Italy). Besides supporting CIG acquisition, representation, storage and

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

execution, GLARE is characterized by the adoption of advanced Artificial Intelligence and Temporal Database formal techniques to provide advanced supports for different tasks, including reasoning about temporal constraints (Anselma, Terenziani, Montani & Bottrighi, 2006), the treatment of periodic data (Stantic, Terenziani, Governatori, Bottrighi & Sattar, 2012), guideline versioning (Anselma, Bottrighi, Montani & Terenziani, 2013), model-checking verification (Bottrighi et al., 2010), decision support (based on Decision Theory) (Montani, & Terenziani, 2006; Anselma et al., 2011), CIG contextualization (Terenziani et al., 2004).

1.2. Handling Exceptional Cases

One of the main goals of CPGs (and of CIGs) is to capture medical evidence and to put it into practice. However, from one side, evidence is essentially a form of statistical knowledge, and is used to capture the generalities of classes of patients, rather than the peculiarities of a specific patient. From the other side, demanding to expert committees the elicitation of all possible executions of a CPG on any possible specific patient in any possible clinical condition is an infeasible task. Thus, two conditions are usually implicitly assumed by experts/committees building a CPG:

1. Ideal patients, i.e., patients that have just the single disease considered in the CPG (thus excluding the concurrent application of more than one CPG), and are "statistically relevant" (they model the typical patient affected by the given disease), not presenting rare peculiarities/side-effects;
2. Ideal context of execution, so that all necessary resources are available.

On the other hand, when a specific physician applies a given CPG to a specific patient, the patient and/or the context may not be "ideal". Hence, a CPG cannot be interpreted as a protocol which has to be executed exactly as it is (without any possible modification), and the actions prescribed by CPGs cannot be interpreted as "must do" actions. Informally speaking, given a patient *X* to which a CPG *G* has to be applied in a context *C*, *G* has to be interpreted as a set of default prescriptions: whenever *X* and *C* fit with *G*'s prescriptions, they must be executed, unless some exceptional situation arises. Specifically, *X* (or *C*) may have peculiar features, and unpredictable facts and conditions (henceforth called ***exceptions***) may occur which are not explicitly covered by *G*. In such a case, recommendations in the CIG cannot be followed any more, and additional *knowledge* must be exploited to provide appropriate treatments to the patient.

Ex.1: A patient treated for chronic atrial fibrillation, suddenly presenting massive gastrointestinal bleeding. The **CIG** for atrial fibrillation prescribes to perform anticoagulant treatment. However, the anticoagulant treatment is not performed. Since an unexpected problem threatening the patient's life has arisen, the execution of the CIG is suspended, and the massive gastrointestinal bleeding is treated first.

In general, especially in case of unexpected life threatening problems, the physician has to suspend/stop the "standard" execution of the CG, and to start to cope with such new problems. Henceforth, such problems will be called "exceptions", since they are exception to the "standard" execution of a CIG.

Despite the fact that supporting the treatment of "exceptions" is of dramatic importance for the practical applicability of software tools managing CIGs, only a limited attention has been devoted to such a

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

challenging task until now (see the Related Work Section). In the rest of the paper, we describe an approach to extend current CIG systems to cope with exceptions. Although the methodology we propose is mostly general, in this paper we will focus specifically on the extensions we made to the GLARE system.

The paper is organized as follows. In the second Section, we propose a preliminary discussion of the main features of GLARE. In the third section, we describe our ontology of exceptions, and our representation of exceptions within GLARE. In the fourth section we focus on the treatment of a specific type of exceptions, external exceptions, which involves limited forms of re-planning. In the fifth section, we discuss how GLARE execution engine has been extended to cope with exceptions. In the sixth section, we consider a practical example (the CIG about severe trauma). In the seventh section we discuss related work in the literature and, finally, in the eighth section we propose discussions and conclusions.

2. MAIN FEATURES OF GLARE

GLARE is a long-term project started in 1997 to provide a user-friendly and domain-independent tool to support CIG acquisition, representation and execution, and to provide the physician with a wide range of facilities, helping her/him in decision support or CIG analysis tasks. The main goals of the GLARE systems are:

1. To be domain-independent. In particular, GLARE has been already applied to deal with a wide range of CIG, ranging, e.g., from asthma to ischemic stroke.
2. To be user-friendly. GLARE is intended to be a tool to support physicians (in particular, regarding decision making), not at all to replace them. Such a goal has several implications, including the facts that (i) CIGs representation language must be as close as possible to the physicians' way of looking at it, and (ii) the "technological" complexity of the system must be hidden to the user-physicians, through a user-friendly and easy-to-use interface.
3. To be easily extendable. Indeed, physicians should be provided with plenty of facilities concerning CIG treatment. Thus, the system architecture must be modular and easily extendable.

2.1. GLARE Representation Language

In GLARE, a CIG can be represented as a hierarchical graph, where nodes are the actions to be executed, and arcs are the control relations linking them. GLARE distinguishes between *atomic* and *composite* actions (called *plans*), where atomic actions represent simple steps in a CIG, and plans represent actions that can be defined in terms of their components via the "has-part" relation. To be as physician-friendly as possible, a limited and "physician oriented" number of types of atomic actions have been identified:

- **Work actions**, i.e. actions that describe a procedure which must be executed at a given point of the CIG; *pharmacological actions* are specific subtype of work actions, specifying a drug (or drug category, of active principle) to be administered to the patient, and the posology.
- **Decision actions**, used to model the selection among different alternatives. In GLARE has been introduced a distinction between:
- **Diagnostic decisions**, used to make explicit the identification of the disease the patient is suffering from, among a set of possible diseases, compatible with her findings;

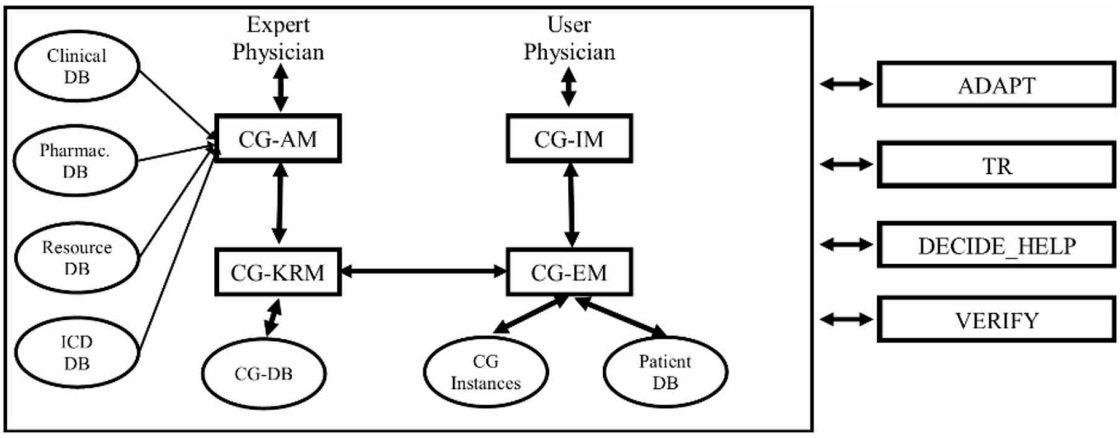
EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

- **Therapeutic decisions**, used to represent the choice between paths in a GL, where each path represents a particular therapeutic process. The choice can be made by evaluating a fixed set of parameters (effectiveness, cost, side-effects, compliance and duration);
- **Query actions**, i.e. requests of information (typically patient's parameters), that can be obtained from the outside world (physicians, databases, patient visits or interviews).
- **Conclusions**, which explicitly identify the output of a decision action.

Each type of action is described by a set of properties. For instance, a *pharmaceutical action* is described by: *Action Type*, which for each action of this category takes the value "Administration of Medicament", *Substance*, which describes the administered drug, *Posology*, which describes the dosage and the modality of assumption.

Actions in a CIG are connected through ***control relations***. Control relations establish which actions can be executed next, and in what order. In particular, the ***sequence*** relation explicitly establishes what is the following action to be executed; the ***alternative*** relation describes which alternative paths stem from a decision action, the ***constrained*** relation establishes temporal constraints between actions to be executed (e.g., one action *during* the other), and the ***repetition*** relation, states that an action has to be repeated several times As well as the modality and periodicity of the repetitions (Anselma, et al., 2006).

2.2. Architecture of the Kernel of GLARE



The core of GLARE (see box on the left of Figure 1) is based on a modular architecture. CG-KRM (Clinical Guidelines Knowledge Representation Manager) is the main module of the system: it manages the internal representation of CIGs, and operates as a domain-independent and task-independent knowledge server for the other modules; moreover, it permanently stores the acquired CIG in a dedicated Clinical Guidelines Database (CG-DB). The Clinical Guidelines Acquisition Manager (CG-AM) provides expert-physicians with a user-friendly graphical interface to introduce the CIG into the CG-KRM and describe them. It may interact with four databases: the Pharmacological DB, storing a structured list of drugs and their costs; the Resources DB, listing the resources that are available in a given hospital (it is therefore used to represent the context-dependent version of a CIG); the ICD DB, containing an international coding system of diseases; the Clinical DB, providing a "standard" terminology to be used when building a new CIG, and storing the descriptions and the set of possible values of clinical findings.

The execution module (CG-EM) executes a CIG for a specific patient, considering the patient's data (retrieved from the Patient DB). Roughly speaking, GLARE execution module starts the execution starting from the first action in the CIG, and goes on, following the control flow described by the control arcs in the CIG. Composite actions (plans) are simply decomposed in their atomic components. The execution of query actions demands for an access to the Patient DB. The execution of diagnostic decisions takes advantage of the data in the patient DB and of the decision criteria, to suggest one or more alternatives. However, the last decision, also in the case of therapeutic decision, is always left to the user physician. CG-EM directly supports the concurrent execution of (possibly temporally constrained) multiple actions, through the *agenda technique* (Terenziani, Mastomonaco, Torchio, & Molino, 2000).

CG-EM stores the execution status in another DB (CG Instances) and interacts with the user-physician via a graphical interface (CG-IM). A more accurate discussion of GLARE execution engine is reported in (Terenziani et al., 2000).

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. Architecture of GLARE. Rectangles represent computation modules, and ovals represents data/ knowledge bases. The left box contains the "core" of GLARE, while additional modules in the right of the figure depict advanced AI support for several tasks.

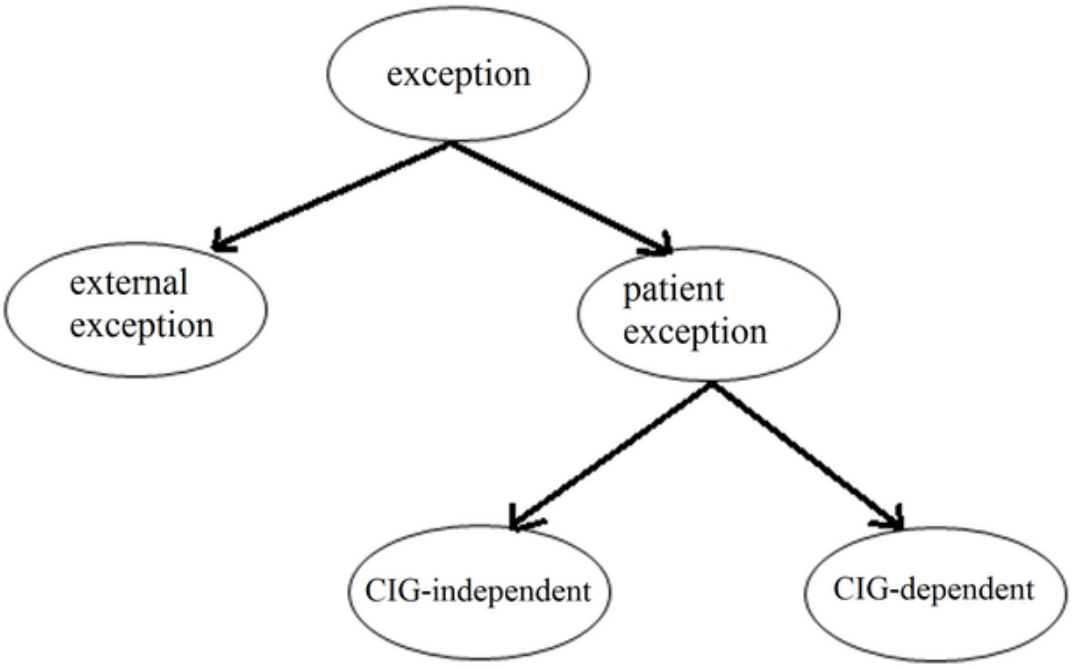
Through the CG-AM and CG-IM modules, GLARE provides user-friendly interfaces to user, achieving the goal of "hiding" them in the internal complexity of the system.

2.3. Extended Architecture

To enhance extendibility, GLARE's architecture is open: new modules and functionalities can be easily added to the system if\when necessary. In recent years, new modules and\or methodologies has been added in order to cope with automatic resource-based contextualization (ADAPT module, (Terenziani et al., 2004)), temporal reasoning (TR, (Anselma et al., 2006) and (Stantic et al., 2012)), decision-making support (DECIDE_HELP, (Montani, & Terenziani, 2006) and (Anselma et al., 2011)), and model-based verification (VERIFY, (Bottrighi et al., 2010)).

3. ONTOLOGY AND REPRESENTATION OF EXCEPTIONS

The management of exceptions within a software system managing CIGs arises several difficult challenges. For instance, in general, plans to cope with exceptions cannot be simply represented as new actions in CIGs, for the simple reason that exceptions are unpredictable, so that they can occur at any moment during the execution (or may not occur at all). Thus, an independent (from CIGs) representation of CIGs must be provided, as well as a methodology to combine the treatment of exceptions with the CIG execution. In this section, we focus on representation. First, we identify the "ontology" of exceptions. Second, we propose a formalism to represent the exceptions, and the plans to treat them. Our mechanism to integrate the treatment of exceptions with the "standard" execution of CIGs is then discussed in the following sections.



EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

3.1. Ontology: Different Types of Exceptions

At least two different types of exceptions can be distinguished: exceptions related to the state of the execution of the actions in a CIG, and exceptions related to the state of the patient (see Figure 2). The first type (external-exception henceforth) arises whenever, for any contextual reason, the execution of the current action fails. For instance, the failure may be due to the absence of a resource needed to carry on the action (typically, an instrument). Another typical failure occurs when the deadline for the execution of the current action expires. The second type of exceptions (patient-exception henceforth) arises when the standard execution of a CIG cannot be carried on, due to an unexpected condition in the status of the patient. Indeed, we further distinguish into two subtypes of patient-exceptions: CIG-dependent and CIG-independent. CIG-dependent patient-exceptions are those exceptions that, although are not frequent enough to be explicitly managed in the CIG, can be foreseen to occur at a specific point in the execution of the CIG. For instance, an action of drug administration can raise an exception, in case a patient is allergic to such a drug. On the other hand, CIG-independent patient-exceptions are totally unpredictable, and may occur at any time during the execution of CIGs. For instance, an ischemic stroke may occur, requiring an immediate treatment, regardless of what is the CIG and the specific action in the CIG currently in execution.

The distinction among external-exceptions, CIG-dependent-patient-exceptions and CIG-independent-patient-exceptions is important also from an operational point of view. There are two orthogonal aspects to be considered here: "*pre-locability"* and "*pre-plannability"*. Such aspects deeply affect the treatment of exceptions, both from the point of view of their representation, and from the point of view of how they can be managed.

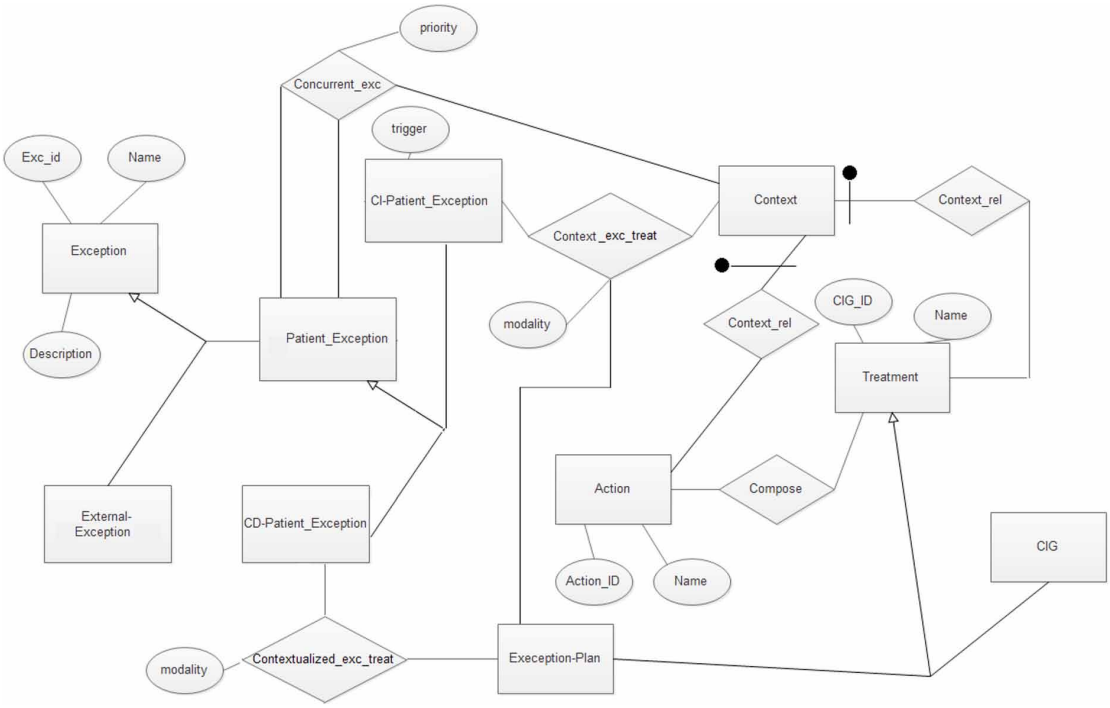
Figure 2. Exception taxonomy

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

With the term "pre-locability" we intend the possibility, for the experts defining a given CIG, to find (one or more) proper locations of the exceptions, at specific points (actions) of the CIG. In this sense, External-exceptions and CIG-dependent-patient-exceptions can be "pre-located". This fact affects the representation of the CIG (since the triggering conditions for such exceptions must be stored within the appropriate actions in the CIG) and the CIG execution engine (since the rise of pre-located exceptions must be verified when such exceptions are encountered, during the execution of CIG actions). On the other hand, CIG-independent-patient-exceptions cannot be "pre-located", since they are totally unpredictable. Thus, triggering conditions will need to be stored in a data structure (library) which is external to the CIG, and must be checked "continuously", by an independent process which may interrupt the execution of the current CIG when a trigger is satisfied.

With the term "pre-plannability" we intend the a-priori availability of a "plan", expressed by a CIG, for the treatment of the exception. Since patient-exceptions (both CIG-dependent and CIG-independent) correspond to general conditions of patients, it is reasonable to assume that expert physicians can provide proper guidelines to cope with them. In this work, we envision the development of a wide body of medical knowledge, consisting of a domain/guideline-independent library of guidelines, coping with patient-exceptions. On the other hand, external-exceptions have a different nature. They do not concern the state of the patient, but depend on "external" contextual situations that are neither under the control of physicians, nor depends on the patient state. Assuming that also in case of External-exceptions expert physicians provide a library of guidelines seems to us quite unrealistic. We thus suggest a more general approach to cope with such exceptions, based on general medical knowledge about the goals of guideline actions, and on a limited form of "planning" on such a knowledge.

3.2. Representation of Exceptions



Until now, we have distinguished among three main types of exceptions. We now focus on their representation. In the following, we propose the representation of exceptions we adopt in our approach. Such a representation involves different parts of the system: CIG representation, Library of Exceptions, and Exception DB.

3.3. CIG Representation

First of all, the description of actions in the CIG has been modified, in order to represent "pre-locable" exceptions. External exceptions are modelled as an additional property (the property <Completed_Execution>) of *work actions*. When executing a work action, the property <Completed_Execution> leads to a request to the user-physician, who has to indicate whether the action has been successfully executed in the external world or not. Of course, in the case of failure, the treatment of external exceptions will be launched. Also, the description of actions is augmented with the <Exception_List> property, which is optional and, if present, indicates the identifiers (<Exc_ID> in the *Exception DB,* see also Figure 3) of the CIG-dependent patient-exceptions that may occur at that point.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 3. Entity relationship model of Exception DB

3.4. Library of Exception Treatments

In our proposal, the plans to cope with "pre-plannable" exceptions are stored in a library (the Exception Treatment Library) which complements the library of available CIGs. As discussed above, also exception treatments can be described using GLARE formalism. This grants for generality, and makes exception execution easier (since exception treatments can be directly managed by the CIG execution module).

3.5. Exception DB

In our approach, all the other pieces of information describing the exceptions are stored into a new database (to be added to the ones shown in Figure 1), the *Exception DB*. In the following, we adopt the Entity-Relationship notation (see Figure 3), to represent the content of such a DB, since, from one side, it grants for the generality of the description and, on the other side, it supports the internal logical and physical representation in the relational model.

Each exception (<Exception> in Figure 3) can be identified by an attribute <Exc_ID>, and is characterized by textual attributes <Name> and <Description> (see the left corner of Figure 3). No additional attribute is needed for the description of external-exceptions (<External-Exception> in Figure 3). Indeed, as discussed above, such exceptions are not "pre-plannable". This means that the actions to recover from such exceptions are not fixed a-priori, but will be determined when needed, on the basis of the available medical knowledge. The recovery actions will be executed instead of the failed action, and, after their execution, the standard execution of the current CIG will be carried on.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

On the other hand, several different aspects must be modelled, considering patient-exceptions: (1) triggers, (2) recovering plan, (3) synchronization, (4) priorities, and (5) context-dependence.

1. **Triggers:** Patient-exceptions arise when specific well-known conditions characterize the state of the patient. Thus, a set of triggering conditions must be associated with each patient exceptions (see the attribute <Trigger> associated with <CI-Patient-Exception> in Figure 3). When such conditions become true, the exception arises for the given patient.
2. **Recovering Plan:** Since patient-exceptions are "pre-plannable", they have an associated recovery plan (<Exception-Plan> in Figure 3). It is worth noticing that, thanks to the expressiveness of GLARE's formalism, exception plans can be represented using the same formalism we adopt in order to specify CIGs (<CIG> in Figure 3). Thus, GLARE supports a library containing both CIGs and Exception-plans. As we will see, this solution allows us to deal in a homogeneous way (through the same execution engine) with both the execution of CIGs and the execution of plans coping with exceptions.
3. **Synchronization:** While in the case of external-exceptions the recovering actions have to substitute the failed action in the CIG, in the case of patient-exception a wider range of possibilities must be taken into account. The attribute <Modality> in Figure 3 specifies what must be the interplay between the execution of the exception plan and the execution of the current CIG. For the sake of generality, we envision five different types of interplay
    a. *Concurrent*. The plan for the exception must be executed concurrently with respect to the current CIG;
    b. *Suspend*. The CIG execution is suspended, and will be resumed after the end of the execution of the plan for the exception;
    c. *Abort*. The current CIG is aborted. Only the plan for the exception is executed;
    d. *Abort&Goto(X,*CIG_i*)*. The execution of the current CIG is aborted. The plan for the exception is executed. After this execution, the execution engine executes the action X of the guideline CIG_i.
    e. *Ignore*. The Exception is ignored; so that the standard execution of the current CIG continues (this modality is useful in cases when the execution of the CIG is crucial for the patient health, while the treatment of the exception is somehow not relevant, given the current CIG).

Notice that the methodology above easily supports the ***nesting*** of CIG-dependent patient-exceptions. The cue idea for facilitating the treatment of nested exceptions is to represent exception plans as CIG themselves. Thus, from the point of view of our system, there is no difference whether an exception arises during the execution of a CIG, or during the execution of an exception plan (which, recursively, may arise during the execution of a CIG, or of an another exception). In all cases, the recovering plan is activated, and is synchronized with the process activating it. Specifically, depending on the chosen modality, such nested exceptions may be run concurrently, or may be suspended, or may abort the execution of the exception plan in which they are nested.

4. **Priorities:** Unluckily, more than one CIG-independent patient-exception might be triggered together, for the same patient. Unfortunately, there seems to be no general rule to identify a unique correct behaviour, covering all possible situations. We thus allow the possibility to specify, for chosen pairs <Ei,Ej> of patient-exceptions, the priority between them (attribute <Priority> of the relationship

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

<Concurrent_exc>; such a relationship will be explained later on). We support different values for such an attribute: (1) E_i may *override* E_j (so that only E_i is executed) or vice-versa, or (2) E_i may be executed *before* E_j (or vice-versa), or (3) E_i and E_j may be executed *concurrently*. Since not all the co-occurrences are known a-priori for each CIG, it is possible to define a minimum set of known general rules as the default behaviour, leaving guideline authors free to override these rules, or to add new ones, to provide different selection strategies for specific CIGs. Furthermore, these rules can be maintained incrementally: after defining a first set, new rules can be added when new exceptions are added to the repository, or each time a new co-occurrence has been experienced by the CIG users and defined as a new rule.

5. **Context-Dependence:** Though the above description of exception is, to the best of our knowledge, the most comprehensive one in the CIG literature, it still neglect a major practical problem: the fact that, unfortunately, the clinical procedures adopted to cope with patient-exceptions are not "absolute", but may change depending on the context (and, in particular, on the specific CIG or action in the CIG which is currently under execution).

3.6. Example

Let us consider an episode of sudden systolic blood pressure decrease (i.e. the value of systolic pressure falls under 90 mmHg). The procedure to cope with this exception during a hemodialysis session suggests a nurse to administer osmotic drugs (e.g. mannitol) to re-establish proper blood pressure levels, which allow the patient to terminate the session. In the severe trauma guideline, instead, different treatments are specified, which are furthermore highly dependent on the current action in the guideline (see the section about the sample CIG implementation).

We propose an innovative approach to the treatment of exceptions, characterized by the fact that we support the possibility of specifying different plans of treatment and different modalities of execution for the same exception, depending on the context when it occurs (i.e., depending on which action of which CIG is being executed when the exception arise). This attention to the context is a major departure with respect to the treatment of exceptions in object oriented programming, as well as in the current approaches to exceptions in the CIG literature. However, this step is extremely important, to cope with practical medical applications.

To cope with such cases, we allow the possibility of specifying context-dependent plans and modalities for patient-exceptions.

Indeed, CIG-dependent patient-exceptions (entity <CD-Patient_Exception>) are, by definition, "contextualized" (since they are associated with a specific action in a specific CIG). They are thus directly associated, through the relationship <Contextualized_exc_treat>, to their <Exception-Plan>. Notice that the <Modality> attribute is associated with such a relationship, to model the synchronization between the current CIG and the exception plan.

On the other hand, several entities and relationships have been introduced in Figure 3 to cope with context-dependence. First of all, <Context> is a weak entity and is identified via the two relationships <Context_rel> connecting it to the entities <Treatment> (which is a super-entity of <CIG> and <Exception-plan>) and <Action> (which represents the actions composing the <Treatment>). In such a way, we define specific contexts of execution by specifying an action, and a treatment containing it. The core notion to represent context-dependence of treatments is the relationship <Context_exc_treat>. It is a ternary relationship connecting (i) a CIG-indepentent patient-exception (entity <CI-Patient-Exception>),

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

a context (<Context>), and an execution plan (<Exception-Plan>). The <Modality> attribute is associated to such a relationship, to model the fact that the treatment of CIG-indepentent patient-exceptions depends on the context, and also the modality of synchronization. Of course, at the implementation level, defaults can be specified, in case the same treatment (and or modality) is applicable to an entire CIG (independently of the current action), or to all the CIGs (context-independent treatment of an exception).

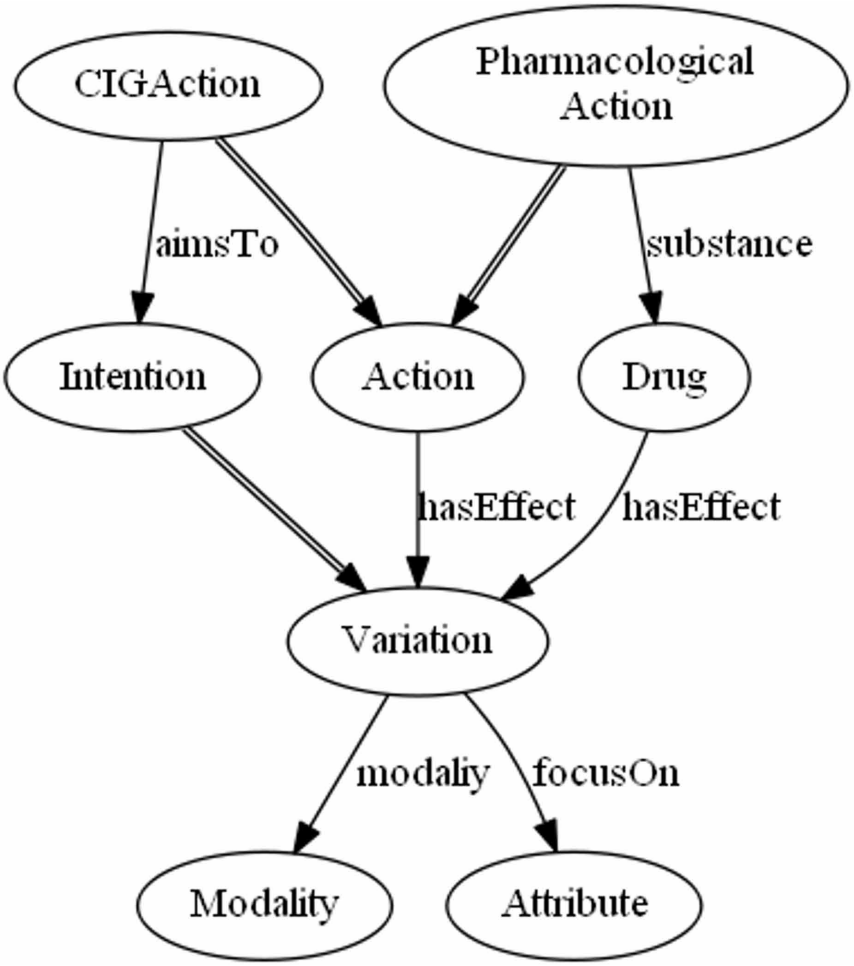
Moreover, the priorities between two exception treatments could depend on the <Context> and thus it is modelled by the attribute <Priority> of the ternary relation <Concurrent_exc>, which involves two exceptions (i.e. the super-entity <Patient_exception> of CI-Patient_Exception and CD-Patient_Exception) and a <Context>.

4. DEALING WITH EXTERNAL EXCEPTIONS

Differently from the other types of exceptions, external exceptions are related to outer factors that, independently of the state of the patient, may lead to a failure of the current action in the CIG. Given their nature, we cannot expect that the treatment of such exceptions can be pre-planned in the library. On the other hand, we aim at proposing a comprehensive approach, supporting user-physician also in the case of external exceptions. To such a purpose, we propose a knowledge-based and goal-based approach, in which a limited form of planning is adopted. The core idea is quite simple. External exceptions arise due to the failure of *work-actions* (see the subsection "GLARE representation language" above). Obviously, each one of such actions is present in a CIG in order to achieve some goals (e.g., decrease blood pressure). If the action fails, it can thus be substituted by other actions that allow one to reach the same goals.

We thus propose a typical Artificial Intelligence approach, in which a knowledge base represents general medical knowledge, specifying actions and their goals, and a goal-oriented form of reasoning is adopted to find the actions to cope with a failure (i.e., to achieve the goals of the failed action). In the following, we first describe our simple ontology of actions and goals, and then we describe our reasoning algorithm.

4.1. A Medical Ontology of Actions and Goals



In the medical domain, decisions are often driven by the synthesis of several knowledge sources. Modelling and exploiting such a knowledge are open problems of the Medical Informatics community. In the ontological extension of GLARE (Piovesan, Molino, & Terenziani, 2014), we decided to represent at least a part of such a medical knowledge through the development of an ontological model of clinical actions and, consequently, also of CIG actions. Our model is an extension of consensus medical ontologies (in our approach, we used SNOMED CT (International Health Terminology Standards Development Organisation)).

The idea underlying our model is that medical actions are not "primitive" elements, but entities that can be described through their relations with, for instance, their goals, their effects, and through their classification in a taxonomy. In the following, we will describe a part of our ontology, which is particularly relevant for this work.

In the ontological extension of GLARE (Piovesan et al., 2014), we characterize clinical actions (concept *Action* in Figure 4) through several properties, including its effects (*hasEffect* arc). We characterize such effects as variations (concept *Variation*), with certain modalities (concept *Modality*; e.g., increase,

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 4. Ontological representation of CIG actions

decrease) of patient state parameters (concept *Attribute*). For instance, the effect "urine alkalinization" (characterizing, for example, the Calcium Carbonate administration) is modelled through the variation "increase" of the attribute "urine pH".

Actions in a CIG (*CIGActions*) have an additional attribute (*aimsTo*) relating them to the goals or intentions (concept *Intention*) they are intended to achieve in the specific CIG. Such intentions are still variations of the state of the patient. However, notice that there is subtle distinction between the (CIG-specific) intentions of CIG actions and the effects of actions "per se" (i.e., independently of any CIG in which they can be considered). For example, while the urine alkalinization is a general effect of the administration of calcium carbonate, in the CIG for the treatment of the gastroesophageal reflux such an administration has the (CIG-specific) goal of decreasing the gastric acidity.

In our model, variations (and intentions) are hierarchically organized in an IS-A and a PART-OF taxonomy. For instance, the intention of "block of calcium channels" is a sub intention (IS-A relation) of "decrease blood pressure", since the first one is a more specific way of achieving the second one. PART-OF relations allows to decompose "composite" intentions into their subcomponents.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

For instance, the intention of "improve lifestyle" can be decomposed into "improve diet", "increase physical activity" and "stop smoking". Intentions are associated with CIG actions at each level of abstraction of the CIGs.

Pharmacological actions (i.e., drug administrations) are of paramount importance in the medical domain. Pharmacological actions are clinical actions (and, of course, may be also CIG actions) that are related with the drug (arc *substance*) they prescribe. Drugs are hierarchically organized following the ATC classification (WHO Collaborating Centre for Drug Statistics Methodology). Also drugs are related to their effects (arc *hasEffect*) and, for integrity purpose, the action of administering a drug has the same effects (or superconcepts of them) of the drug it recommend.

4.2. The Planner for Coping with External-exceptions

In the following, we describe how the previous model can be exploited, in order to identify plans to recover from an external exception. However, before describing it, we have to make some considerations about the adopted solution. Many approaches are present in Artificial Intelligence (AI) literature for the adaptation of plans that failed due to action failures or due to unsatisfied preconditions. However, given the peculiarities of CIGs, only the most conservative approaches can be adopted in real world situations. Indeed, CIGs are developed by experts following the medical evidence, and the solutions proposed by decision support systems must adhere as much as possible to the existing plans. In addition, our experience in the medical domain suggested that physician would not trust "black box" tools that simply output plans without explaining to the user (in an "understandable" way) how such conclusions have been reached.

Considered such desiderata, we decided to face the recovering from external exceptions through a *mixed initiative* (Horvitz, 1999) goal-oriented plan repair strategy. Exploiting our ontology, we developed a tool highly collaborative with the user physicians, supporting her/him in the repairing of the current CIG. It is worth stressing that such approach could potentially be used also for replanning from scratch in case a large part of the CIG fails. However, we intentionally limited it to local (in most cases single-action) repairing, to propose solutions as close as possible to the original (evidence-based) plan.

Our algorithm helps physicians in the navigation of our ontology, finding out the relevant alternatives for the failed action. We distinguish between two possible cases: the recovering involves

1. only one (not decomposable) intention, or
2. more than one intention.

First, let us focus on the first (basic) case (i.e., case (i) above), which occurs when one CIG action failed, and it has only one intention (not decomposable -through the PART-OF taxonomy- into a set of sub-intentions).

For the basic case, we need to retrieve all the actions (*actset*) that satisfy (*hasEffect* arc) the intention *int* of the failed action *a*.

```
algorithm basic_af:
input: CIGAction a;
output: Set<Action>;
Intention int ← aimsTo(a);
Set<Action> actset ← inverseof  hasEffect^noTrans(int);
```

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

```
for each action act ∈ actset
     issuit ← the system asks the
               user if act is a suitable alternative in the specific situation
     if issuit == 'no'
          actset ← actset \ {act}
return actset;
```

The algorithm for the management of the basic case algorithm *basic_af* (basic action finding) is divided in three phases. First, the intention *int* of the failed action a is retrieved from the CIG model. Then, the set *actset* containing all the actions[1] which have as effect (*hasEffect* arc, followed backward) *int* is retrieved from the ontological knowledge. Notice that the set *actset* also includes composite actions (i.e., actions whose components have been specified through the PART-OF taxonomy). Finally, *actset* is pruned by asking the user to discard uninteresting actions, in order to maintain only the relevant results. At the end of the algorithm, *actset* represents the set of possible alternatives to the failed action a, satisfying its intention and considered relevant by the physician.

In case *actset* is empty, there is no direct way to recover from the exception. However, a more flexible treatment of such an exception can be tried, in case the failed action *a* is part of a composite action *a'* in the CIG. In such a case, the basic algorithm can be applied considering *a'* as the failed action. Such a procedure can be recursively applied, until either one (or more) recovery action is found, or the highest level of abstraction in the CIG is reached.

Case (ii) involves the management of more than one intention. There are three different cases in which the treatment of more than one intention is required: (a) if the failed action has itself two or more intentions or (b) if the intention of the failed action is a composite one (so that all its sub-intentions have to be satisfied), or (c) if two or more actions failed, each one with its own intention(s).

The management of case (ii) requires some modifications in the basic algorithm, since two or more intentions must be satisfied by the proposed solution. For the sake of simplicity, we only describe how our algorithm manage the case of two intentions int_1 and int_2

When two intentions int_1 and int_2 have to be satisfied, the procedure of action finding in the ontology described for the basic case is applied separately for the two intentions. Two resulting sets of actions are obtained, named actset1 and actset2. The system then returns the Cartesian product of $actset_1$ and $actset_2$ as possible solutions. Notice that the result of Cartesian product between two sets is a set of sets

$$A = \{a_1, a_2, \ldots, a_n\}, B = \{b_1, b_2, \ldots, b_m\}$$

$$A \times B = \{\{a_1, b_1\}, \{a_1, b_2\}, \ldots, \{a_n, b_m\}\}$$

If two actions $a_i \in A$ and $b_j \in B$ are equal, such couple will produce in the result the element $\{a_i\}$ so that the result does not contain duplicates.

The development of solutions containing two or more actions raises two problems: on one side, interactions between the actions can occur (e.g., drug-drug interactions)[2]; on the other side, no ordering constraints are returned by the system. However, such a kind of issues are very common in the management of the concurrent execution of two or more CIGs (e.g., for the treatment of comorbid patients). Thus, for instance, the techniques presented in (Piovesan, Anselma, & Terenziani, 2015) to cope with concurrent execution of CIGs can be easily adapted for this use.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

5. MANAGING EXCEPTIONS DURING CIG EXECUTION

The execution engine of CIGs (CG-EM in Figure 1; henceforth called *Executor* for the sake of clarity) must be widely extended in order to cope with exceptions. Different extensions are needed, to cope with the different types of exceptions pointed out in the previous section. Indeed, roughly speaking, the *Executor* executes the actions in the CIG, following the flow of control described by the control arcs in the CIG. "Pre-locable" exceptions can be managed at specific points during the flow of execution. Therefore, such exceptions can be directly managed by the Executor, which must be properly extended.

In particular, to cope with **external-exceptions**, the Executor simply checks, at the end of each action, whether it has been accomplished with success, or whether it has failed (in the current version, success and failure are simply signaled to GLARE by the user-physician executing the CIG; i.e. the property <Completed_Execution> of *work action*). In the case of success, the Executor simply continues its standard execution, moving to the next action in the CIG. On the other hand, in the case of failure, the planner for external-exceptions is invoked, having in input the goals of the failed action. The new plan returned by the planner (navigating the ontological knowledge and interacting with the user-physicians, as discussed in the previous section) is then executed by the Executor. After the execution of the new plan, the standard execution is restarted, from the next action in the CIG.

The treatment of **CIG-dependent patient-exceptions** is easier. The basic *Executor* has been modified in such a way that, before the execution of each CIG action, the triggering conditions of the CIG-dependent patient-exceptions associated to the current action (if any) are checked. If an exception is triggered, the proper exception-plan is searched in the library of exception plans, considering the context (current action and current CIG in execution), as well as its synchronization modality. The Executor loads the related exception plan and its modality of execution (as explained in subsection "Representation of exceptions", the modality may be unique for the given exception, or may depend on the current CIG and/or action). Then, depending on the modality, the following actions are performed:

Figure 5. Creation of new operands and associated SQL query using the graphical editor. The names in the right figure refer to real patient's data defined in the RoPHS (Report on the Piedmont Health System) project

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

1. In the case of "*Concurrent*" modality, the Executor inserts in the agenda also the first action in the plan for the exception, and re-start its standard agenda-based execution (it is worth remembering that (1) GLARE's original *Executor* supports the concurrent execution of the actions in the Agenda, and (2) since the plan for the exceptions are represented using the guideline formalism, the CIG Executor itself can be used in order to execute such plans).
2. In the case of "Suspend" modality, the first action of the exception plan is put on top of the Agenda. Thus, the Executor executes this plan first, and then returns to the other actions in the Agenda, recovering the execution of the suspended CIG.
3. In the case of "Abort" modality, the Agenda is first made empty (i.e., all the actions in it are deleted). Then, the first action of the exception plan is put on top of the Agenda. Thus, the Executor executes this plan first, and then terminates (since the Agenda becomes empty).
4. The "Abort&Goto(X,CIG_i)" modality is similar to "Abort", except that, after the completion of the exception plan, the action X of the guideline CIG_i is inserted in the Agenda, forcing the *Executor* to jump to that specific point of the CIG.
5. In the case of "Ignore" modality, the standard execution of the current CIG is simply carried on.

On the other hand, **CIG-independent patient-exceptions** are not "pre-locable": they can arise at any moment, during the execution of a CIG. For such a reason, they cannot be properly associated with any specific point in CIG. On the contrary, their triggering conditions should be continuously monitored, considering the state of the patient (as stored in the patient DB).

For such a reason, the proper treatment of CIG-independent patient-exceptions demands the definition of a new engine, that we call ***Exception-monitor***. Of course, the *Exception-monitor* and the *Executor* run concurrently. The Exception-monitor can interrupt the Executor whenever an exception is triggered. At that point, The *Executor* loads the related exception plan and its modality of execution (they may depend on the current CIG/action, i.e. the contest) and goes on with the execution of the CIG and/or the exception plan, depending on the given synchronization modality (as discussed above for the case of CIG-dependent patient-exceptions).

Before concluding this section, it is worth mentioning two features of the approach we propose.

First of all, the methodology above easily supports CIG-dependent exception nesting. Depending on the chosen modality, such nested exceptions may be run concurrently, or may be suspended, or may abort the execution of the exception plan in which they are nested.

Second, we also support cases in which two CIG-independent exceptions, defined in the exceptions library, are triggered together, through the management of (possibly context-dependent) priorities (see the discussion in the subsection "Representation of exceptions").

5.1. Implementation

This subsection presents a brief description of the exception handling system we developed and its integration with the GLARE system. In the next Section, real world examples, implemented in GLARE using the functionalities of this new exception manager, are provided in the context of severe trauma management, to show the applicability of our strategy in a real context.

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

5.2. System Components Implementation

We implemented the concepts exposed in an exception management system, which has been integrated and tested in GLARE. The exception management system is implemented in Java and is composed by two main components: (1) a graphical editor for user-friendly definition and maintenance of the exceptions library, and (2) proper extensions to the GLARE Executor to allow the CIG-independent patient-exceptions handling. Each exception of this type is associated to a triggering condition, which defines a particular (problematic) patient's state. Exceptions are triggered when the associated triggering conditions become true, independently from the status of execution of the actions in the CIG. To access the patient-related information (e.g. the blood pressure or the body temperature) needed to periodically verify these triggering conditions, the system relies to SQL queries to retrieve the most up-to-date information from the patient's data base.

5.3. Graphical Editor and Exception Repository Maintenance

The exception management system offers a user-friendly graphical editor, which permits the CIG author to: (1) build new triggering conditions combining operators, operands and constant values; (2) create new exceptions and eventually customize the modality of execution of the exception plan for a particular CIG plan (see "Representation" above), and (3) define the rules to be applied by the Executor when two or more exceptions are triggered at the same time (see "Integration of Exception and CIG Executions" above).

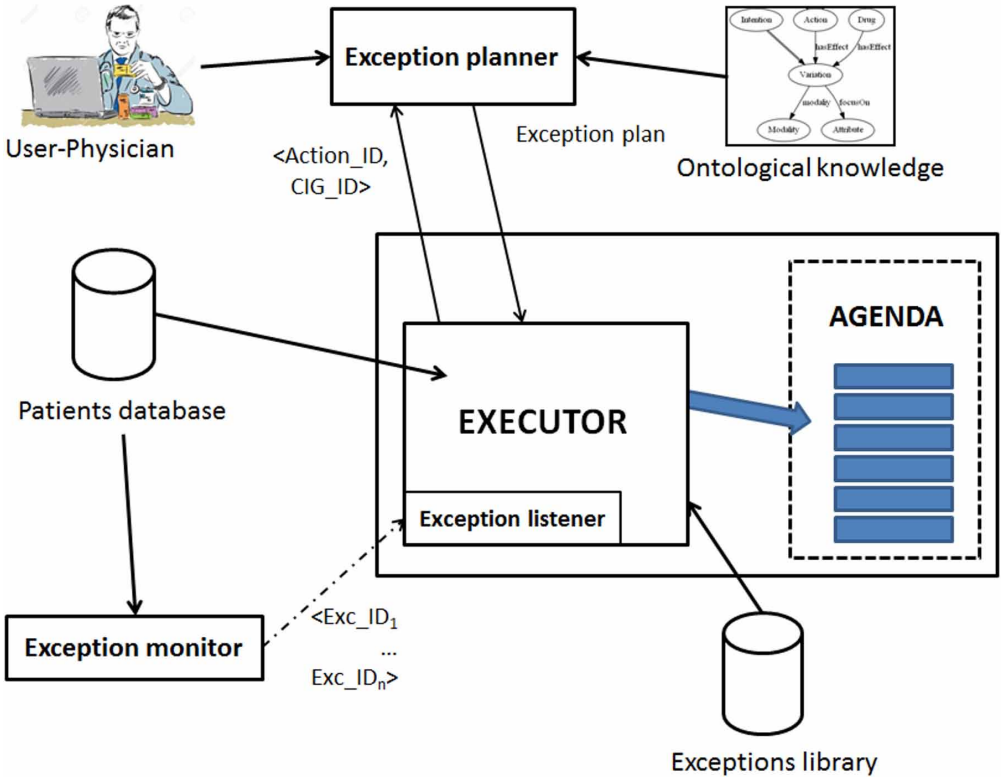
In particular, the graphical editor helps the user in performing these three tasks providing the following features. Considering the task (1), the editor permits the user to define new triggering conditions (for example the condition " 'systolic pressure' <= '90 mmHg' AND 'cardiac frequency' < '45 bpm') or to edit an existing one by combining operators (i.e. arithmetic, logic and comparison), operands (such as 'systolic pressure') and constants (e.g. '90 mmHg') by means of a guided procedure. For each operand (see Figure 5), the editor can automatically build the SQL query which will be used run-time to retrieve the most up-to-date values associated to the considered operand from the patients database, each time this condition must be evaluated. Note that, since in Figure 3 trigger is an attribute of <CI-Patient-Exception>, at the implementation level we have defined a triggering library in order to allow the reuse of a triggering condition, which can be associated with a unique identifier (condition_ID).

Task (2) helps the user in defining new exceptions or in modifying existing ones. An exception is defined as follows: <Exc_ID, name, description, Context_ID, condition_ID, exceptionPlan_ID, modality>, where:

- exc_ID: unique identifier of the exception
- name, description: name and natural language description of the exception
- Context_ID: identifies the context, for which this exception must be checked, see section "Exception DB"
- condition_ID: identifier of the triggering condition to be verified to raise this exception
- exceptionPlan_ID: identifier of the exception plan to be executed to manage this exception
- modality: modality of execution of the exception plan (Concurrent, Suspend, Abort, Abort & Goto, Ignore)

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Once the user has indicated the Exc_ID (or accepted an auto-generated identifier), she/he must: (1) enter name and description of the associated exception, (2) choose a condition from the triggering condition library and an exception plan from the exception plans library. The standard execution modality (if defined) for the chosen plan is automatically loaded, but the user has the possibility to override it, by changing the modality or by customizing it to indicate, for example, to go to a particular action of the CIG plan, in case of Abort & Goto.



Finally, task (3) permits to define, for each pair $<E_i, E_j>$ of exceptions for one Context_ID, the rules to be applied (i.e. one of them overrides or must be executed before or after the other one, or both of them must be executed concurrently) when they happen at the same time.

All the exceptions defined by the user are permanently stored in the Exceptions library, in order to be automatically loaded and used by the Executor, when a new instance of a CIG plan is created and run. This repository can be updated at any time using this graphical editor, adding, deleting or modifying triggering conditions, exceptions and co-occurrence rules.

5.4. CIG Executor Modifications

The CIG Executor of GLARE has been modified and extended to cope with exceptions at run-time. The new version of the Executor now loads and exploits the exceptions saved in the Exceptions library when exceptions arise during the execution of a CIG on a specific patient.

Figure 6. The exception management system's architecture

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

CIG-dependent patient-exceptions are directly managed by the Executor, as discussed in the previous section. On the other hand, the treatment of external-exceptions and CIG-independent patient-exceptions require an extension to the architecture of GLARE. In particular, the architecture extensions are illustrated in Figure 6: while a CIG is executed on a patient the Exception monitor, responsible for checking and raising the CIG-independent patient-exceptions runs concurrently and asynchronously with the CIG Executor, sending messages to the latter as soon as one or more exceptions are raised.

On the other side, the Executor can receive messages from the Exception monitor by means of an integrated Exception listener. Any time a message is received, the Executor stops immediately the execution of the current CIG plan, loads the proper exception plan(s) from the exceptions library and applies the proper steps to allocate it run-time on the agenda, in order to manage the exception(s) risen from the monitor. Finally, the Executor continues the execution of the CIG, augmented with the allocated exception plan(s). This architecture allowed us to obtain a system which is able to react run-time to the CIG-independent exceptions, without modifying the existing GIC Executor (CG-EM in Figure 1).

Additionally, if an external-exception is risen by the failure of the execution of a CIG action, the external-exception planner is invoked. It takes in input the failed action (the couple <Action_ID, CIG_ID> in Figure 6), and navigates the ontology, possibly interacting with user-physicians, in order to identify a new plan, which is sent to the CIG Executor to recover the failed action (Exception-Plan in Figure 6).

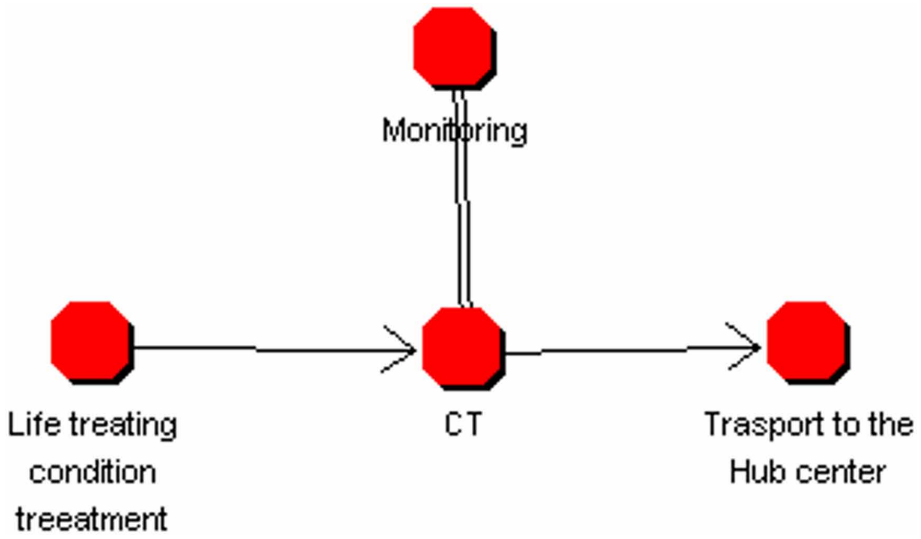
The exception monitor has been implemented as a Java thread (subclass of the *java.lang.Thread* class), and its constructor permits to receive:

1. the set of exceptions to be checked (the set E of tuples <exc_ID, name, description, CONTEXT_ID, trigger, exceptionPlan_ID, modality>, where CONTEXT_ID matches the current context of execution and exceptionPlan_ID identifies the treatment (see CIG_ID in figure 3) to be executed to manage this exception, and
2. the time interval T which must elapse between the check of two successive exceptions. T may also be set to zero, to enforce continuous monitoring of triggering conditions.

In particular, the exception monitor executes the following operations (implemented by overriding the method *run()* of the *Thread* class):

1. Wait for the period T to elapse
2. For each exception *exc* **ϵ** E:
   a. Let P the triggering condition identified by: *exc.conditionID*, associated to the exception *exc.exceptionID*
   b. For each operand *op* **ϵ** P, execute the query *op.query* on the patients database to retrieve the most up-to-date values
   c. Solve the triggering condition P and store its result R (true/false) as a pair <exc_ID, R>
3. If at least one of the couples <exc_ID, R> has R = true, then:
   a. Build a message M containing all the couples <exc_ID, R>, where R = true
   b. Send the message M to the Executor
4. Jump to point 1

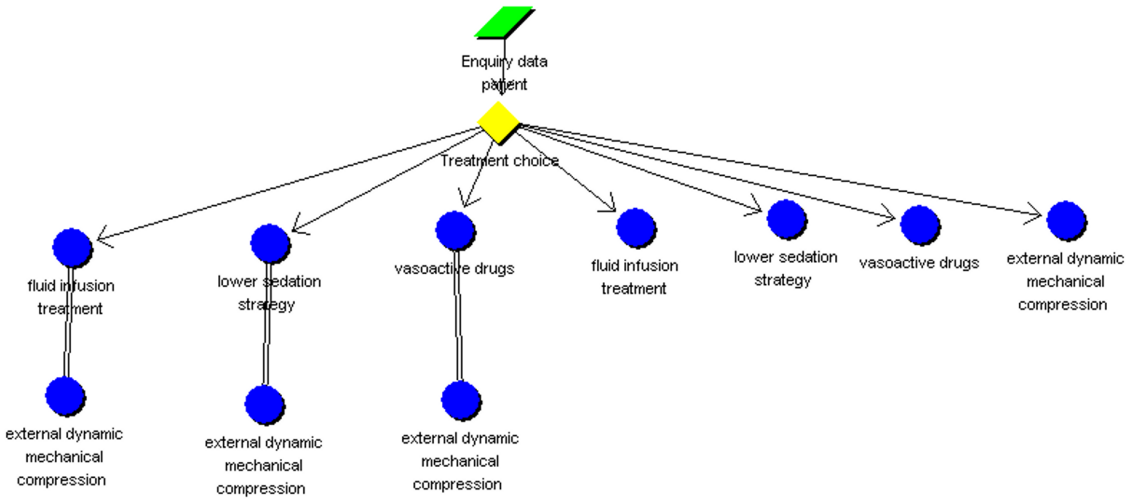
EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use



The exceptions to be risen are defined as all the exc_IDs for which the corresponding value of R is set to true. This set of exceptions will be sent to the Executor through a message containing them, in order to be managed by the Executor itself. The operations from point 1 to point 4 form an infinite cycle, which will be interrupted by the Executor (by interrupting the thread implementing the monitor) only when the treatment of the patient (CIG and –possibly- exception plan executions) reaches its end.

On the other side, the Engine has been modified to receive messages from the Exception Monitor, thanks to an instance of a custom class implementing the MessageListener Java Interface.

The treatment of a patient starts with the execution of the proper CIG. A specific instance of the CIG is created by the Executor, and started on the patient. Meanwhile, the exception monitor starts monitoring the exception rules and the exception listener allows the Executor for continuously listening to potential asynchronous messages arriving from the monitor. While no messages are received from the exception monitor, the Executor continues with no interruptions. As soon as one or more exceptions are detected by the exception monitor, a message is sent to the Executor which, after receiving the message, stops the execution of the current CIG, performs all the operations needed to load the proper exception plans(s) in the Agenda and restarts the execution. The following pseudo-code illustrates this process in detail. Each time the Exception listener receives a message M from the exception monitor, the Executor performs the following steps:



1. Stop executing the current CIG
2. Unpack the message M to retrieve the set of exceptions X= {exc_ID_1, …, exc_ID_n} in M
3. If X contains two or more exceptions, then apply the priority rules to decide what exception E must be managed among all those in X; otherwise, E = the only exception In X
4. Retrieve from the Exceptions library the exception plan(s) to manage the exception X
5. Update the Agenda with the plan(s) retrieved at point 5, accordingly to the policies to be applied to manage the modality of execution associated to the(se) plan(s)
6. Restart the execution of the actions in the Agenda

Figure 7. Fragment of the severe trauma guideline acquired in GLARE

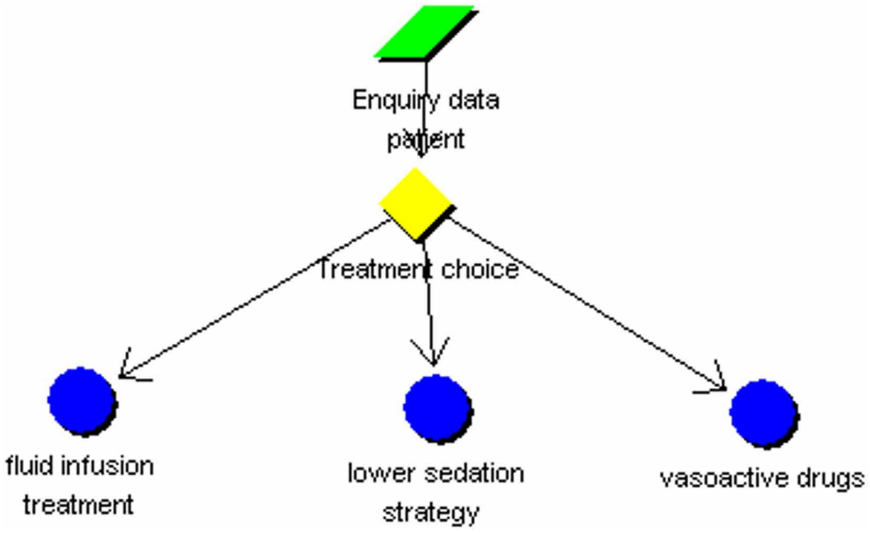
EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 8. The treatment plan for systolic blood pressure decrease exception meanwhile "Life treating condition treatment" plan execution

The steps 1 and 6 are necessary to stop and to restart the execution of the CIG before and after the Agenda has been altered in the steps 4 and 5. After having performed all these operations, the new plan(s) are thus seen by the Executor as part of the (augmented) CIG. The process described continues until the treatment (CIG instance and, possibly, exception plans) reaches its end and, consequently, the Executor shuts down both the exception monitor and the engine.

It is worth noting that through this technique, we obtained a run-time and asynchronous management of the CIG-independent exceptions without modifying the core of the existing Executor. Furthermore, the extensions described are totally transparent to the user, since this important additional service allows the system to execute CIGs in a flexible and more true to life way in a completely automatic fashion. In the case where no exceptions are defined for a particular CIG, the latter will be executed such as no CIG-independent patient-exceptions management system exists.

6. AN EXAMPLE OF CIG IMPLEMENTATION



In this section we describe the application of our approach with real examples in the context of severe trauma treatment. The severe trauma guideline, briefly described in this section, is developed under the RoPHS (Report on the Piedmont Health System) project, funded by the Regione Piemonte.

This guideline is based on the evidence of the need of a synergistic organization to reduce the time of intervention and the excessive delay before hospital admission. In particular, the guideline is based on the following principles:

1. an appropriate clinical out-of-hospital evaluation of trauma patients for a prompt identification of lesions and therapeutic priorities;
2. the ability to perform some effective life-treating actions to support cardiac and pulmonary functions;

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 9. The treatment plan for systolic blood pressure decrease exception after "Life treating condition treatment" has been executed

3. the correct clinical decision must be made to refer the patient to an hospital offering a competent treatment of the trauma, not necessarily the nearest, and
4. the optimum operative linking between the services for the acute management and the rehabilitation hospital.

Moreover, the guideline exploits the "Hub and Spoke" strategy, in order to emphasize the integration of services throughout the various service areas to ensure efficacy of treatment of the trauma patients. The "Hub and Spoke" model relies on a leader center (i.e. the hub), where the trauma patients may be treated for severe neurologic, thoracic, abdominal and vascular traumas. Spoke centers are strategically placed in the territory to ensure an appropriate treatment in the geographical area and are closely linked with their hubs through the emergency system (e.g. the 118 service, in Italy or the 999 and 112 services, in United Kingdom). In the context of the RoPHS (Report on the Piedmont Health System) project, the guideline is developed and applied on Eastern Piedmont. In this area, the Hub center is located in Novara, and the Spoke centers are hospitals located in Borgosesia, Borgomanero, Domodossola, Verbania, Vercelli and Biella.

Different exceptions are defined for this guideline: exceptions which can occur during the execution of the entire guideline, and exceptions which can occur only in specific sections of the guideline. For example, an exception applied on the whole guideline regards the heart failure. In the case that the patient has a heart failure, the current action and the guideline are immediately aborted, (since the <Modality> of this exception is set to Abort), and the treatment plan for heart failure exception is executed.

Considering exceptions occurring in a specific section of the guideline, shown in Figure 7, the "Life treating condition treatment" plan is followed by two concurrent plans: (1) "CT" plan (defining all the actions concerning the choice and the execution of the proper kind of Computed Tomography), and (2) "Monitoring" plan, where the patient is monitored with a multi-parametric monitor to gather information about his/her heart rate, blood pressure, pulse oximetry and saturation. Finally, the patient will be

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

transported in a specialized hospital, called Hub center. During this part of guideline, exceptions on monitored data can happen. For example, an exception to cope with the problem of sudden systolic blood pressure decrease is defined. This exception captures episodes where the systolic pressure falls under 90 mmHg. If the exception monitor, while checking the patient's systolic pressure, verifies that it is lower than 90 mmHg, it raises this exception. The execution engine will finally capture the exception and will start the proper treatment (exception) plan. The treatment plan is dependent from the action executed at the time of the exception, since its management in the severe trauma guideline is context dependent:

- If the current action(s) belong(s) to the "Life treating condition treatment" plan, this plan will be executed concurrently with the exception (i.e. <Modality> is set to Concurrent). This exception is managed by choosing one or more of the following actions: fluid infusion treatment, vasoactive drugs, and lower sedation strategy. These actions can be performed as unique treatments, or can be associated to external dynamic mechanical compression, in order to manage an eventual arterious external bleeding. Moreover, also the external dynamic mechanical compression can be performed as a unique treatment (see Figure 8).
- Otherwise, if the exception is captured after the conclusion of the "Life treating condition treatment" plan, the exception plan, even if executed concurrently with the guideline such as the previous one, relies on a different strategy. The actions to be performed in this plan are: fluid infusion treatment, vasoactive drugs, and lower sedation strategy. Note that there is not external dynamic mechanical compression among them (neither unique treatment nor in combination with one other treatment) since, after the "Life treating condition treatment", the patient's conditions are more stable and arterious external bleeding cannot occur (see Figure 9).

The system GLARE, extended as described above, allowed to cope with all the exceptions needed to properly manage the severe trauma guideline, representing and managing them during the execution of this CIG.

7. RELATED WORK

Considering the generality and relevance of the phenomenon, in the following we discuss the more relevant approaches in the literature, covering exceptions representation and management.

PROforma language (Sutton, & Fox, 2003) allows one to specify exceptions, while the system can set an Exception flag if an abnormal event has occurred in the processing of a guideline operation. However, in our approach, exceptions are hierarchically organized and we distinguish among three different types of exceptions. Moreover, for every exception, it is possible to define a specific treatment plan to manage it.

Tu & Musen (1999) differentiate between normal flow and exceptional flow and contemplate the specification of scenario-based exceptions handlers. Tu & Musen (1999) only consider exceptions regarding the execution of actions in the guideline. In their approach only the current action(s) can generate exceptions (such as our CIGs dependent exception). Our approach is more general, since we also allow to define exception on the basis of the patient's data. Moreover, Tu & Musen (1999) provides only two modalities of interactions between CIGs and exceptions: (1) exceptions leading a patient back to a scenario covered by the guideline (as our Abort&Goto modality), and (2) exceptions where the patient is managed outside the guideline (Abort modality in our approach).

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

Hierarchies of exceptions are managed by (Grando, Peleg, & Glasspool, 2010). They distinguish between "hazards" (concept somehow close to our CIG-independent exceptions) and "obstacles" (as our CIG-dependent exceptions), mainly focusing on what we call External-exceptions, allowing hierarchical refinement. They take into account some of the modalities of interactions between CIGs and exceptions we also pointed out in our approach: parallelExecuting (close to our Concurrent modality), suspending (Suspend in our approach) and discarding (Abort in our approach). However, in their approach, exception treatment is always goal oriented: corrective actions are chosen accordingly to the substitution of the default goal expressed in the CIG. In our approach, such a goal-oriented treatment of exception is adopted just in the case of external exceptions, and is based on ontological knowledge. Additionally, we focus on context-dependent treatments of exceptions, and on both "pre-locable" and not "pre-locable" exceptions.

Quaglini et al. (2001) managed the flexibility of their guideline-based careflow system introducing a classification of exceptions which is similar to our ontology. Exceptions can be expected or unexpected, synchronous or asynchronous and GL-related or unrelated. Our approach differs in the exception handling, since in (Quaglini, et al., 2001) the triggers are requested by the physician who, at a certain point of the CIG execution, asks the system to delay the current action, to substitute the current action with another one or to add a new non-planned action. The system will then manage this trigger to cope with the physician's request. Our system, instead, triggers exceptions when an abnormal patient's state is detected, and automatically loads from the repository a plan to cope with the triggered exception, without the need of human intervention. This difference is justified, because manages exceptions in a careflow management system, where the physician must have the experience (and must be free) to introduce the proper deviations under her/his responsibility. Our system is a CIG-based decision support system, therefore it is responsibility of the system to suggest not only the proper actions to be performed in a normal situation, but also to recognize abnormal states of the patient and to suggest what must be done to treat the patient accordingly.

Peleg, Somekh, & Dori (2009) propose a methodology for eliciting and modelling exceptions. They describe a conceptual model in which exceptions can be expected or unexpected, and are triggered as asynchronous events. Triggers start a synchronous exception management branch during the CIG execution. Peleg et al. (2009) define two types of exception causes: (1) HumanCause, e.g. human errors, malicious actions or non-compliance, and (2) Non-humanCause, e.g. organizational causes, work item failures, deadline expirations. However, they do not distinguish between CIG-dependent and CIG-independent exceptions, and the exception management, briefly sketched, describes an approach similar to our Suspend modality, but goal driven: after the execution of the corrective actions to manage an exception, a set of goals should fulfilled to resume the CIG normal execution otherwise the CIG is aborted. On the other hand, our approach defines a complete exception management system, where different modalities of execution can be defined for each exception plan.

8. DISCUSSION AND CONCLUSION

Computer interpretable clinical guidelines (CIGs) are widely adopted to assist physicians in decision making, providing them evidence-based recommendations based on the best available medical knowledge. However, a main problem in CIG adoption is the fact that, during CIG executions on specific patients, unpredictable facts and conditions (exceptions) may occur. Decision support in the case of exceptions

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

is mandatory, but most current software systems coping with CIGs do not provide it. In this paper, we proposed a general approach to cope with exceptions, showing how software systems coping with CIGs can be extended (in the representation formalism, as well as in the execution module). Moreover, we have demonstrated the feasibility of our approach extending the GLARE system (Terenziani et al., 2008) and applying it the severe trauma guideline developed under the RoPHS (Report on the Piedmont Health System) project.

As discussed in the "Related work" section, some CIG approaches have already faced the treatment of exceptions. However, our approach is quite comprehensive and innovative, distinguishing between different types of exceptions, and proposing a wide range of methodologies to cope with them. In particular, we distinguish between exceptions than can be "pre-planned" or not, "pre-located" or not, considering a wide range of modalities of interactions between CIG and exception execution, and supporting the context-dependence of exception treatments. We also support the goal-based knowledge-based planning of new actions in substitution of CIG actions failed for "external" reasons.

Despite the wide range of phenomena being addressed, several interesting aspects deserve further analysis and work.

The availability of a large library of exception-plans is critical for the practical applicability of our approach. For the moment, we only cope with a very limited number of exception plans in our library. This is because the main goal of our work was that of devising a general methodology, and, only as a proof of concept, of implementing a prototypical version of it. However, an extensive adoption of our methodology in the real world would require the development of an extensive library of "pre-planned" CIGs coping with exceptions. This would require a substantial amount of work of the medical community, to devise evidence-based plans to cope with exceptions, and of the medical informatics community, to encode them into CIG formats. However, given the increasing adoption of computer tools in the medical field, and the increasing focus on CPGs and on exceptions and personalized medicine, it is hopeful that such a wide library can be developed, in the middle\long term.

In the presented methodology, we have proposed a limited adoption of *planning* techniques, to cope only with the substitution of "failed" actions during CIG execution (*external-exceptions*). Indeed, such knowledge-based and goal-based planning techniques could be used much more extensively, to cope also with other forms of exceptions (e.g., to build new complex plans –CIGs– coping with patient-exceptions not covered in the library of "pre-planned" exceptions yet). Such a solution would mitigate the problem of "manually" developing a large library of computerized exception plans. Therefore, such a new line of research is probably worth future investigation. However, our twenty-year experience of cooperation with physicians has taught us that physicians are quite reticent to accept new treatment plans automatically identified by software systems. There are two main reasons for that. First of all, many physicians are naturally diffident towards software tool "fully taking their place" in the definition of medical treatments. But, even more important, the main reason for the adoption of CPGs (and CIGs) is the desire to promote evidence-based treatments. Indeed, automatically generated plans, though "technically" correct and knowledge-based, cannot be evidence-based, since evidence can only be gathered through the definition and study of clinical trials. As a consequence, we try to limit as much as possible to delegate work to the planner, and suggest to exploit as much as possible libraries of evidence-based exception plans.

A further issue concern the treatment of patients affected by multiple diseases (the so-called *comorbid* patients). The treatment of comorbid patients is one of the main challenges for modern healthcare, also due to population aging and the increase of chronic diseases. For example, most of the patients suffering from such chronic diseases, are affected by two or more of them (Gijsen, Hoeymans, & Schellevis,

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

2001). Comorbid patients are not "ideal" patients, since two (or more) CIGs must be combined. Although in many cases one can suppose that all the relevant CIGs to be combined are available, the problem of combining them is a very critical and challenging one, since the interactions between the actions in the different CIGs must be properly analysed and managed. We have recently started to address such a challenging issue, proposing a knowledge-based mixed-initiative approach to support user-physicians in the detection and the analysis of interactions (Piovesanet al., 2014)

However, substantial work will be needed to integrate such a proposal with the current approach, to provide a comprehensive methodology coping with many different types of "exceptional" patients.

ACKNOWLEDGMENT

The work described in this paper has been partially developed within the RoPHS (Report on the Piedmont Health System) project, funded by the Regione Piemonte, and within the GINSENG project, funded by Compagnia San Paolo. The authors are very grateful to. Francesco Della Corte (Department of Translational Medicine, Univ. Piemonte Orientale "A. Avogadro", Novara, Italy) and Dr. Antonio Messina (Azienda Ospedaliera "Maggiore della Carità", Novara, Italy), for their support in the development of the CIG about severe trauma.

ENDNOTES

1 The keyword "inverseof" in the algorithm states that the arc *hasEffect* is followed backward. The superscript "noTrans" in the algorithm states that we do not consider the transitivity of the IS-A property for such query. In other words, only those actions that are directly linked to the effect *int* are returned, while their sub categories do not. Such a choice is adopted in order to limit the dimension of the output, making it manageable by user physicians.

2 Indeed, depending on the nature of the exception (and, thus, of the exception plan), the problem of interacting actions might arise also in the case of exceptions, since new actions (the actions in the exception plan) have to be "merged" with the action in the CIG. If the exception plan is specific of a given CIG (or, even better, of a specific point of a specific CIG –as in the case of "pre-locable" exceptions–), it is reasonable to assume that the possible interactions have been already considered during the definition of the exception plan, so that there is no need to check them when the excep-

EBSCOhost - printed on 2/9/2023 6:08 AM via . All use subject to https://www.ebsco.com/terms-of-use

tion arise. On the other hand, CIG-independent-patient-exceptions cannot be "pre-located". Thus, one cannot know a priori at what point of the execution of a given CIG their exception-plan has to be executed. In such a context, the analysis of the possible interactions between the current actions in the CIG and the one in the exception plan may be of paramount importance. Such an analysis may be carried on through the techniques we have proposed in (Piovesan et al., 2015)
