Chapter 60
Socio-Economic and Environmental Impacts of Poor Paper Management at Higher Education Institutions in Ethiopia:
Evidence From Hawassa University

Akalewold Fedilu Mohammed
Hawassa University, Ethiopia

Abdurahman Hamza Ibrahim
Hawassa University, Ethiopia

Degwale Gebeyehu Belay
Hawassa University, Ethiopia

ABSTRACT

Currently there are 34 universities in Ethiopia which enrolled hundreds of thousands of students which generated large volume of waste paper a year. Therefore, this article has an objective of assessing the socio-economic and environmental impacts of poor paper management at higher education institutions of Ethiopia with a particular focus on Hawassa University. The findings of the study revealed that a large volume of paper is consumed for different academic purposes. Due to the poor management of paper consumption as well as poor waste management practices, the university faced socio-economic and environmental problems. By 2015/16 academic year a total of 94,025 reams of paper were used at Hawassa University. This has created a large volume of waste paper at offices, which resulted in un-pleasant working environment. Incineration is the only means of waste paper disposal, which created environmental pollution and health risks to the university community. Moreover, the university also lost a significant amount of money which would have been gained from selling to paper recycling industries.

INTRODUCTION

Increases in literacy, GNP and population in developing countries results in continued growth of paper and paperboard consumption, at a faster rate than in developed countries. Following this consumption level, the waste paper generation is increasing highly, so do the economic and environmental impacts. Hence, the demand for recycling and reduction of the volume of waste paper generated increases as well (Van Beukering and Bouman, 2001).

As it is indicated by Rutgers (2004) cited in Randall (2005), the amount of paper printed in a University with a campus population of ten thousand students is more than one million sheets of paper per month. Correspondingly, paper products make up a large proportion of the solid waste generated by universities, due to their educational and academic endeavours (Modzelewski, 2007).

Paper that does not contain any recycled material is produced from timber (Modzelewski, 2007). A sheet of paper made from wood consumed seventeen watts per hour of electricity (Randall, 2005). It asserts that paper production leads to forest depletion and consumption of energy. Moreover, it has a significant negative impact on biodiversity (Armstrong et al., 1998). However, paper and paper products are regarded as cheap products, often undervalued, and much paper is wasted with no or minimal re-use.

In addition, paper consumption does not only refer to the paper used either for printing or photocopying but also the costs of printing, storage, transporting, disposal and recycling (Randall, 2005). Considering this, formulating comprehensive solid waste management policy and programs in the university based on the generating source are imperative (Armijo de Vega et al., 2008).

Like many developing countries, there is an increasing consumption of paper in Ethiopia. When we compare the consumption level, the education sector especially universities and colleges are the primarily users of papers. This can be explained by the rising number of students who are enrolled every year in these sectors. Currently, Ethiopia has thirty-four public universities. The government has also planned to build eleven additional universities in the second growth and transformational Plan (GTP-II) of 2015/2016-2019/2020. This expansion brings high paper consumption as well as large volume of waste paper generation which leads to environmental problems if there is no proper consumption and waste paper management. Though it is very difficult to find a study conducted on paper consumption and waste paper generation of these universities, one can estimate that every year the consumption and waste paper generation can increase at an alarming rate due to the increasing number of students.

Therefore, this study is aimed at assessing the socio-economic and environmental impacts of poor paper management by taking Hawassa University as a case study.

The Case Study Institution, Hawassa University

Hawassa University is one of the public higher education institutions in Ethiopia located at Hawassa City in Southern Nations, Nationalities and Peoples Regional State. Hawassa is 273 km south of Addis Ababa. The University is among the first-generation universities in Ethiopia and has 5 campuses (The university main campus, the College of Medicine and Health Science, the College of Agriculture, the College of Forestry and Natural Resource, the College of Business and Economics). Hawassa University offers programs at bachelor degrees, master degrees and doctoral degrees levels in several areas of study. According to data from Planning Directorate of Hawassa University (2016), the university had 1393 academic staffs of which 377 were on study leave, and 55 were expatriates. It had also 176 technical assistants, 4998 administrative staffs, 680 health officers, and 91 contractual workers. There was a total

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

of 39660 students (at masters and under graduate level in different programs) (interview with Planning Directorate of Hawassa University, 2016).

Like any other academic institutions, Hawassa University has educational and academic endeavor, and hence it has high consumption of papers for preparing exams, course outlines, handouts and other miscellaneous activities. This makes paper products to be a large proportion of the solid waste to be generated by the University.

The university has no a recycling practice and/or linkage with companies which recycle paper, which makes incineration a widely used practice of waste paper management, which again creates environmental pollution as well as health risks. The university has also no effective environmental policy regarding waste management that in turn leads the university not to properly carry out its responsibility for sustainable protection of the environment and wise use of resources.

In this University, the mismanagement of papers at different offices is quite common. There are a collection of undistributed course outlines, exam papers, students' assignment papers, handouts, letters, and the like which are hoarded for many years. This shows the improper and ineffective handling mechanism of different used papers. Due to this, it is common to listen complains of many students due to loss of their exam papers and grades.

REVIEW OF RELATED LITERATURES

Solid Waste Management

A solid waste is any discarded material which is abandoned and inherently waste-like. An abandoned material is something which is being disposed and incinerated. It is the unwanted or useless solid materials generated from combined residential, industrial and commercial activities in a given area. It may be categorized according to its origin (domestic, industrial, commercial, construction or institutional); according to its contents (organic material, glass, metal, plastic, paper, etc.); or according to hazard potential (toxic, non-toxin, flammable, radioactive, infectious, etc.) (Ajith, 2014). As indicated in Ministry of Urban Development and Construction of Ethiopia (2012), solid waste includes any garbage, refuse, and sludge, and other discarded material including solid and semi-solid wastes.

Waste management is control of waste related activities which ultimately aimed at conserving and protecting human health and the environment (Pongracz et al., 2004). Solid waste management is the discipline associated with the control of generation, storage, collection, transfer, and transport, processing and disposal of solid waste by considering issues of socio-economic and environment (Ministry of Urban Development and Construction of Ethiopia, 2012). Management of solid waste reduces or eliminates adverse impacts on the environment and human health and supports economic development and improves quality of life (Thompson and Wilson, 1994).

Comprehensive solid waste management programs are one of the greatest means to achieve institutional sustainability. Effective solid waste management requires a complete understanding of the composition of a waste stream as well as the activities that determine its generation (Farmer *et al*., 1997). Armijo de Vega and his colleagues stated that tailoring solid waste management programs is important which considers the ground reality than mimicking it from somewhere else (Armijo de Vega et al., 2008).

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Methods of Waste Paper Management

Methods of waste management include 3Rs; reduce, reuse, and recycle (Ajith, 2014; Mohanty, 2011; Peprah et al., 2015). There are many environmental benefits that can be derived from the use of these methods. They reduce or prevent greenhouse gas emissions, reduce the release of pollutants, conserve resources, save energy and reduce the demand for waste treatment technology and landfill space.

Reduction

Waste reduction and reuse of products are both methods of waste prevention. They eliminate the production of waste at the source of usual generation and reduce the demands for large scale treatment and disposal facilities. Reducing the amount of the product to be purchased is the most significant of all the options to manage waste. The key is to only purchase goods that we need and in the right amount (Abdul-Rahman, 2014).

As indicated in Clean Up (2009), principles of reducing paper consumption include double-side printing, write notes and notices on a communal whiteboard, taking notes on a laptop or tablet instead of paper; distributing memos via email or post one copy to a bulletin board; sending, requesting, storing, circulating, editing and filing electronic copies of documents and assignments instead of paper versions, creating an electronic mailing list for newsletters and notices, copy texts as many times as possible per sheet, submit your work by email or electronic delivery systems like Google docs, Dropbox, Moddole, and the like.

Reuse

Reuse refers to using materials repeatedly. According to Abdul-Rahman (2014:3), the process of reusing starts with the assumption that the used materials that flow through our lives can be a resource rather than refuse. "Waste, after all, is in the eye of the beholder. One person's trash is another person's treasure…" As stated in Peprah et al. (2015), reuse involves secondary and subsequent uses of waste materials either in part or whole which is achieved through sorting done at source rather than disposal site and, through detailed processes of checking, cleaning, refurbishing, repairing whole items or spare parts.

Reusing paper is another important principle which includes purchasing paper with 100 percent recycled content that is third party certified, using printed paper as scrap or packing material, sharing print copies of documents, manuals or directories, keeping pieces of paper that have been printed or written on and write notes or print drafts on the blank side (Clean-Up, 2009).

Recycling

Recycling is a practice which is applied for waste materials which cannot be reused directly but can be converted to new products or raw materials (Peprah et al., 2015). Recycling is important to save energy, reduce raw material extraction and combat climate change. Recycling our rubbish is better for the environment rather than incinerating or land-filling it (Friends of the Earth, 2008; DECCW, 2010). Soil and water pollution increases as practices of incineration and landfill increases.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Paper recycling saves the natural wood, decreases the operation and capital cost to produce virgin paper, and decrease water consumption. It also gives rise the environmental conservation (Cabalova, *et al*., 2011).

Benefits of Paper Recycling

Paper recycling has various benefits which include environmental, social, and economical.

Environmental Benefits

Recycling is well-known for its environmental benefits, which include resource conservation, energy conservation, and reductions in water and air pollution, including reductions in greenhouse gas generation (New Jersey Waste Wise Business Network, 2013; Clean Up, 2009; Department of Ecology State of Washington, 2015).

It reduces the demand for wood, requires less total energy to manufacture than virgin paper, and reduces solid waste and greenhouse emissions created by disposing paper in landfill (Clean Up, 2009). Department of Ecology State of Washington (2015) also stated that recycling is also important to save raw materials.

Socio-Economic Benefits

Recycling is an important segment of the national economy; creates jobs and saves money for generators of waste. It helps local industries to grow and to create employment opportunities. As far as energy is concerned, there is 28 -70 percent less energy consumption in producing recycled paper compared to virgin paper. Every tone of recycled paper saves approximately 4 barrels of oil, 4200 KW house of energy (New Jersey Waste Wise Business Network, 2013). Paper recycling also helps to create job opportunities (Bekiroglu and Elmas, 2017; European Environment Agency, 2011). According to European Environment Agency (2011) recycling creates employment opportunities in terms of collection, materials handling and processing to manufacturing products, particularly for low skilled workers.

Paper Production and Its Impacts

Despite predictions that the digital revolution would make paper as obsolete as the type writer, paper remains central to our lives. Instead, global paper consumption has increased dramatically over the last decade, and will continue to rise, especially in developing countries. Paper is one of the most important and widely used consumer materials with an endless ability to be transformed. Paper products are ubiquitous in a society which used for newspapers, magazines, catalogs, office paper, packaging and tissue products (Robert, 2007; Clean Up, 2009).

The primary raw material for paper production is pulps fibers obtaining by complicated chemical processes from natural materials mainly from wood. This fibers production is very energy demanding and it uses many of chemicals which are very problematic for environmental protection. Modern paper production involves mechanical, chemical - or a combination of both - pulping to convert raw materials

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

into various paper products. These processes consume large amounts of energy and use valuable natural resources, including trees and water. Certain processing techniques such as bleaching are also known to be environmentally harmful (Bajpai, 2015).

One of the most significant impacts of the paper industry is climate change. Every phase of paper's lifecycle contributes to global warming, from harvesting trees to production of pulp and paper to eventual disposal. It is estimated that 42% of the industrial wood harvest is used to make paper (Robert, 2007). As stated in Clean Up (2009), paper production consumes trees and water, release CO2, and generate landfill. Trees are the main resource in the paper production, a tone of paper consumes approximately 20 full-grown trees while recycling 1 tone of paper saves 13 trees. Moreover, to make just one tone of paper out of virgin material over 90,000 liters of water are used which will fill 450 rain barrels. Each tone of paper that is recycled saves: almost 13 trees, 2.5 barrels of oil, 4100 kWh of electricity, 4 cubic meters of landfill and 31, 780 liters of water.

Sustainability at Higher Education

Sustainable University is defined as:

…a whole or as a part, that addresses, involves and promotes, on a regional or a global level, the minimization of negative environmental, economic, societal, and health effects generated in the use of their resources in order to fulfill its functions of teaching, research, outreach and partnership, and stewardship in ways to help society make the transition to sustainable lifestyles… (Velazquez et al., 2006, p. 812)

Sustainability in relation to HEIs is associated with carrying out activities that are ecologically sound, socially and economically viable, and that they will continue to be so for future generations. Universities have a moral and ethical obligation to act responsibly for the environment (Armijo de Vega et al., 2008) and its inhabitants (Armijo de Vega et al., 2003). Alshuwaikhat and Abubakar (2008) claim that HEIs should not only educate, but also demonstrate environmental principles and stewardship by taking action to understand and reduce impacts that result from their activities.

HEIs' role in promoting sustainability is of paramount importance for various reasons. In the first place, HEI can take the advantage of professional with wide range of field of study that is vital for achieving the objectives of sustainable development (Forrant and Pyle, 2002). Secondly, they are places where students who are forerunners in achieving sustainable development are found in large number (Thompson and Green, 2005). Thirdly, it is also expected that they can be role models for the society thereby influence the actions of the society (Stephens et al., 2008).

Waste characterization studies at colleges and universities identify campus specific and regionally relevant opportunities for waste reduction and recycling, representing an essential step towards greening the campus (Creighton, 1998). When carefully planned, campus waste characterization studies are relatively inexpensive and can generate administrative support, cooperation among students, faculty and staff and inspire further involvement in campus sustainability issues (Beringer et al., 2008). In addition to the overall desire to become green, rising campus waste disposal costs and shrinking landfill space often demand waste minimization approaches at IHE (Noeke, 2000).

MATERIALS AND METHODS

The study employed both quantitative and qualitative approaches. A descriptive research design based on cross-sectional survey was applied. The design is appropriate to assess the current status of paper use and waste paper management at Hawassa University. Moreover, this method could yield rich data that can be inferred about other universities in Ethiopia. The qualitative approach helps to gather data about how academic staffs in particular and the university in general consume paper and manage waste papers. Besides, it helps to understand how waste paper management affects the socio-economic and environmental conditions in the university.

For this study, a total of 144 respondents were supposed to be selected randomly from the total academic staff list of 72 schools (2 respondents from each school/department) found in different colleges and Institute of Technology at Hawassa University as shown in Table 1. However, questionnaires distributed to 6 departments/schools (12 questionnaires) were incomplete and hence discarded, and the remaining 22 questionnaires distributed to 10 schools/departments were not returned. Hence, the analysis is made using 110 respondents.

In addition, a total of 35 key informants and one focus group discussion with instructors (one from each college/institute); which consists of 8 members were incorporated from Hawassa University. These respondents were selected purposively based on their exposure with regard to paper consumption and waste paper management (see Table 2).

Quantitative data was collected using questionnaires which were distributed to 110 respondents. The type of questionnaires was dominantly close-ended. Before the actual administration of the data collection process, questionnaires were pretested and corrections were made accordingly. Moreover, qualitative data was collected using key informant interview, observation, FGD, and document analysis. To do this a semi-structured key informant interview questions were developed to the relevant respondents from respective units of the university. Observation was made in order to understand the management of used papers in office of the academic staffs, students dormitory and within the compound in general, the time and the means of waste paper disposal. Data from secondary sources was collected from different articles, and other published and unpublished sources.

Table 1. Sample size selected from colleges and Institute of Technology

College/Institute	No. of Schools	Total Sample From Each College/ Institute
Institute of Technology	10	19
College of Natural and Computational Science	7	13
College of Medicine and Heath Science	4	7
Hawassa College of Agriculture	9	15
Wondogenet College of Forestry and Natural Resource	9	18
College of Business and Economics	8	16
College of Social Science and Humanity	9	18
College of Law and Governance	2	4

Table 2. List of key informants from Hawassa University

Key Informants	No.	Description
Heads of schools	16	Two from each college/Institute
Instructors	8	One from each college/Institute
Duplication Centers	5	One from each campus
Campus Beautification Directors	5	One from each campus
Continuing Education Program (CEP) coordinator of the university	1	
Total	35	

Source: Fieldwork, 2016

Besides Campus Beautification and Facility Management Directorate Directors of other 32 Ethiopian Public Universities were interviewed via phone call in order to understand their waste paper management practices.

Quantitative data is analyzed by using descriptive statistics like percentage and frequency. Moreover, the qualitative data was narrated and summarized to support the quantitative data.

RESULTS

Paper Use at Hawassa University

In Hawassa University, paper is used for both academic and administrative purposes (i.e. writing letters, notice, duplicating cost-sharing forms, training manuals, evaluation forms etc). However, this study focused only on paper used for academic purpose. Accordingly, Table 3 shows that Papers are used for printing and copying exams, handouts, course outlines, worksheets, and the like. Among the different purpose of paper in the academic division, exams (53.6%) consume more sheets of papers followed by handouts (39.1 percent).

Table 3. The purpose of paper consumption at Hawassa University

No.	Purpose	No.	%
1	For exam	59	53.6
2	For handout	43	39.1
3	For exam and handout	3	2.7
4	For exam and course outline	2	1.8
5	For exam, course outline and handout	3	2.7

Consumption Level of Paper at Hawassa University

Consumption level of the university is computed by taking the total number of courses of a program, the responses of instructors about their consumption level for course outlines, quizzes, mid exams, final exams, and assignments in each program, and the number of students in that program.

Table 4 shows the average amount of paper consumption at Hawassa University by 2015/16 academic year. Accordingly, for 16225 regular students, 3520 reams of paper were used for duplication of course outlines, 9872 reams for quizzes, 2793 reams to duplicate worksheets, and 8129 reams to duplicate final examinations. The table also shows that for its extension programs (both weekend and evening), the university used 975 reams to duplicate course outlines, 1848 reams to duplicate mid exams, and 2981 reams to duplicate final exams for 7411 students. For 7830 students who attend summer education program, the university consumed 1323 reams of paper to duplicate course outlines, 1662 reams to duplicate mid exams, and 2440 reams to duplicate final examinations. That means, the university used 13550 reams of paper to duplicate final exams, 9872 reams of paper to duplicate quizzes, 5818 reams of paper to duplicate course outlines, 3510 to duplicate mid exams, and 2793 reams of paper to duplicate worksheets for 31466 students. Generally, 35543 reams of paper were used by Hawassa University for academic purposes for 31466 students by the 2015/16 academic year.

Beyond this, large volume of paper is also consumed by the students to duplicate handouts and to write assignments. As indicated in Table 5, regular students used 52256 reams of paper to duplicating handouts, to write individual assignments (437 reams), and group assignments (122 reams).

Table 4. Paper consumption level at Hawassa University by 2015/16

Program	No. of Students	Average Consumption					
		Course Outline	Quizzes	Mid Exam	Work Sheet	Final Exam	Total
Regular	16225	3520	9872	*	2793	8129	24,314
Extension (Weekend + Evening)	7411	975	*	1848	*	2981	5804
Summer	7830	1323	*	1662	*	2440	5425
Total	31,466	5,818	9,872	3,510	2,793	13,550	35,543

Source: (Fieldwork, 2016)

*: refers to modes of assessments which are not applicable to the respective programs.

Table 5. Paper taken into the university

Program	Handout	Ind. Assignment	Gr. Assignment	Total
Regular	52,256	437	122	52, 815
Extension	*	1898	760	2,658
Summer	*	1640	1229	2,869
Total	**52,256**	**3975**	**2111**	**58,342**

Source: Fieldwork, 2016

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Generally, 52815 reams of paper are consumed by the regular students for the aforementioned purposes. Extension students in both weekend and evening programs consumed 1898 reams of paper to write individual assignments and 760 reams to write groups assignments. Similarly, summer students also consumed 1640 reams of paper to write individual assignments and 1229 reams of paper to write group assignments. Generally, Table 5 shows that total of 583342 reams of paper are used by the students (all regular, extension, summer) for the purposes of handout duplication[1], and write-up of assignments. As shown in Table 4 and 5 a total of 93,885 reams of paper become waste at Hawassa University by 2015/16.

Paper Management Practice at Hawassa University

In this section, paper management refers to practice of duplicating exams and course outlines, habit of printing and duplicating double-side, using back side of papers for different purposes, proper management of paper outside offices, the proper management of modules administered by CEP, and waste paper management.

Duplication of Exams and Course Outlines

In order to use papers efficiently, duplicating exams and course outlines based on the exact number of students is vital. As shown in Table 6, 68.1 percent of respondents replied that they know the number of students they teach by counting them in class. Key informant interview made with teachers reveals that attendance sheets also helps to count the number of students in a class. However, such means are not effective to know the exact number of students:

Attendance sheets and counting students in class are not effective ways to know the number of students since some students do not regularly attend the class. There are also some students who add some courses but not attend the classes. (Interview with an instructor from Technology Institute, 2016)

The major problem is the registrar doesn't send the list of students to each school and respective staff immediately after their registration. Sometimes, we [Instructors] voluntarily go to the registrar to get the list of our students. Unless it is based on our estimation that we duplicate exams and course outlines. (Interview with an instructor from College of Law and Governance, 2016)

Key informant interviews with teachers and school heads revealed that sometimes departments and schools might not have the data about students of each batch:

The school doesn't get the list of students of each batch at the beginning of academic years. The registrar sends the grade submission which contains the list of students at the end of each semester. (Interview with Head of School of Governance and Development Studies, 2016)

This leads teachers to duplicate some more course outlines and exams. It is only 18.2 percent of the respondents who might know the exact number of student by taking data from the registrar (15.5%), and from the school (2.7%).

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 6. Means to know the number of students before duplicating course outlines and exams

No.	Ways to Know No. of Students to Duplicate Materials	No.	%
1	By counting their numbers in the class	75	68.1
2	By taking the data from the registrar	17	15.5
3	By estimation	13	11.8
4	By asking other instructors who teach in that program	2	1.8
5	By taking data from the school	3	2.7
	Total	**110**	**100.0**

Source: Fieldwork, 2016

Habit of Instructors to Use Duplex and the Back Side of Papers

In order to reduce paper use at campus, it would be necessary to get much information on each page as possible and also users should always print and copy double sided (EAUC, 2010). As indicated in Sarantis (2002), many organizations have had savings of thousands or even millions of dollars through their paper use reduction efforts. Heather Sarantis further stated that approaches such as double-side copying or printing, may address the ways that people use paper every day. However, as it is depicted from Table 7, it is only when teachers print and duplicate course outlines that they do have often a good habit of using double-side of the paper (76.4 percent). Data from focus group discussants revealed that double side duplication of course outlines is not to have proper consumption of paper:

We don't have an issue of wise use of paper, because the university doesn't have shortage of papers. Hence, we use double side particularly to duplicate exams for large number of students. This is not to save paper but for easily handling and stapling. For example, if you have 8 pages of an exam, then you can staple only four sheets of papers. It is good particularly for common courses. (Summery from FGD, 2016)

The above anecdote shows that instructors do not have attention to wise use of paper. Paper is seen as a cheap resource within the university. However, this study found out that Wondogenet College of Forestry and Natural Resource forced its staffs to print as well as duplicate duplex:

The duplication center doesn't have its own paper. Instructor should bring papers from their respective school/department based on the number of students. we force instructors to bring the number of students as well as the total number of pages to be duplicated before providing sheet of papers. Even the duplication center doesn't make one-side duplication. (Interview with Head of School of Wondogenet Natural Resource Management, 2016)

This study also found that Wondogent college of Forestry and Natural Resource is the only College of Hawassa University which uses paper efficiently.

Table 7 also shows that there are instructors who never or rarely use double-side while they are printing and duplicating course outlines (5.6 percent), worksheets (17.6 percent), exam papers (21.8 percent), and handouts (40 percent).

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 7. Habit of using double-side of the paper

Frequency of Distribution	Exam Papers		Handouts		Course Outlines		Worksheets	
	Freq.	%	Freq	%	Freq.	%	Freq.	%

Source: Fieldwork, 2016

Unable to print and duplicate double side refers that the back side of the paper becomes empty. Proper management of paper includes using this back side of used papers for different purposes. As indicated in Table 8 it is only 20 percent of the respondents who do have a good habit of using the back side of used papers:

I use the back side of used paper for write short notes, to take attendance of students, and to print drafts of research proposals. (Interview with an Instructor from school of Mathematics and Statistics, 2016)

However, 28.2 percent of respondents infrequently use the backside of used papers, and 20 percent have never had such experience. Table 8, hence, portrays that in addition to having weak experience of using-double side to print and duplicate materials, poor management of paper use is exacerbated by poor experience of instructors to use the back side of a used paper which again creates high paper consumption.

Management of Leftover Course Outlines and Exams

As shown in Table 9, 61.8 percent of the respondents replied that there are occasions in which duplicated exams and course outlines are left undistributed. Data from key informants and FGD revealed that exams are left undistributed when questions are stolen as well as when there are extra exam papers

Table 8. Experience of instructors to use backside of used papers

duplicated. This is particularly common in common courses (like Communicative English, Civic and Ethical Education, Logic and Reasoning skill).

As it can be observed from Table 9, 41.8 percent of respondents replied that they put undistributed exam papers somewhere in the office. Some instructors tear it and put into the dustbin (27.5 percent) followed by those who give it to office cleaners for incineration (12.7 percent).

Duplicated course outlines are left when all students are not available in the day-one-class one time. Key informants further replied that instructors often do not distribute the remaining course outlines for absent students in the next class:

In the day-one-class-one time, it is few students who appear in the class. Hence, many course outlines are not distributed. In the next-day class, I don't want to carry the left course outlines. Just I put it in my office. (Interview with an instructor from school of behavioral science, 2016)

Source: Fieldwork, 2017

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

It is clear that leftover papers at office increase the volume of waste paper which makes proper management of waste papers challenging. Significant number of respondents (43.6 percent) replied that undistributed exams and course outlines are put somewhere in the office without any use. However, 29.1 percent of the respondents replied that they keep undistributed course outlines for another semester.

Duration of Keeping Used Papers at Office

Proper management of used papers is partly subject to the period of keeping used papers at office among other things. Table 10 shows instructors' experience of how long they keep exam papers at office. 52.7 percent of the respondents replied that they keep it for less than a year. While 25.5 percent of them replied that they keep exam papers from one to two years. The remaining 21.8 percent of the respondents keep exams for more than two years.

Regarding the periods of keeping exam papers, Hawassa University Senate Legislation 2015 Article 83(5) stated that *'Copies of all exams, tests and quizzes.... shall be kept with the instructor for at least one year*'. This statement doesn't tell the maximum period of keeping exam papers. This has its own repercussion on the mismanagement of papers at staff offices since it creates fear among the staff to dispose exam papers and hence keep it for more than one year. Coupled with absence of enough shelves, this creates unsuitable working environment at offices.

Used Paper Management at Offices

Table 11 shows that the overall management of used paper at offices. Accordingly, 56.3 percent of respondent replied that there is not proper management of used papers at offices. Interviews with instructors revealed that this poor management has results paper mess at offices, loss of students records and other relevant files.

Data from observation, FGD, and key informant interviews revealed that poor management of used papers at offices is caused by absence of mechanisms to dispose waste papers timely, absence of centers to amass waste papers, lack of adequate shelves at offices, presence of exam and assignment papers kept for long periods, lack of adequate and sufficient dustbins, and collection of MA/Msc Thesis and senior essays for many years (see Figure 1):

Table 10. Periods of keeping exam papers at office

Period of Keeping	Freq.	%
Less than six month	14	12.7
seven month-12months	44	40.0
13 months-24 months	28	25.5
More than 24 months	24	21.8
Total	**110**	**100.0**

Source: Fieldwork, 2016

Table 11. Management of used papers at offices

Management Level	Freq.	%
Very good	10	9.1

Figure 1. Mismanagement of papers at office of instructors (Fieldwork, 2016)

Where do I put my used papers? Nowhere! Look at my desk; it is full of used papers. It doesn't looks like an office. I fell that this affects my personal and professional image. Sometimes, I left some relevant documents including students' exam papers. I do have many complaints from students due to loss of their exam papers. (Interview with an instructor from school of Business and Economics, 2016)

Paper Management by CEP

As part of the curriculum of summer program, students are expected to take modules back home and read the modules during the winter time. Nonetheless, there are problems associated with duplication, storage and distribution of these modules. This is due to untimely duplication and distribution of modules by CEP which contribute for wastage of papers. According to the interview with coordinator of the duplication center and CEP coordinator, it is associated with shortage of papers to duplicate modules resulted from the delay of paper purchase. Even in some cases modules are duplicated by estimation. This is the result of absence of clear communication between the registrar and CEP unit. It is also associated with lack of adequate and qualified workers in the duplication center. Despite summer students are supposed to collect modules for the coming winter tutorials, modules are duplicated after summer students left the campus; hence many of copies are left uncollected.

Moreover, modules which are left from the past year or before are not counted properly. As a result, every year CEP orders duplication of modules without taking into account the number of uncollected modules from the previous years. Figure 2 shows some undistributed modules for summer students.

Means of Disposing Waste Papers at Hawassa University

Interviews with the directors of facility and campus beatification centers of the five campuses of the university reveals that the university does not have a practice of waste characterization. Different wastes are collected and taken into incinerating sites of the respective campuses. Office cleaners collect the papers every morning and whenever there is demand from offices to incinerate used papers (see Figure 3). Incineration sites are not far from staff offices which would have serious health risks. Outside offices, there are no dustbins. From our personal observation and interviews with proctors, students left their course outlines, handouts, exercise books and other paper products within their dormitories and around, particularly at the end of each semester. At the end of each semester, janitors collect left exercise books, text books, and handouts of students and incinerate it. This shows the university does not have clear environmental policy for appropriate use or disposal of wastes in general and waste paper in particular.

According to data from phone interviews with Campus Beautification and Facility Management Directorate Directors of 32 Ethiopian public universities, incineration is the only means of disposal of waste papers. It is only Adama University which has a link with Ethiopian Pulp and Paper S.C (EPPSC) that recycles waste papers. The university has established a system to supply waste papers to EPPSC with a price of 1.75 birr per Kg of waste paper. Annually, the university supplies around 3700kg of waste papers to the industry and earns 6, 475 Birr. According to interview data from Adama University, creating such a link with paper recycling companies has different socio-economic and environmental benefits which include income generation, reducing incineration practice that reduces air pollution and associated health risks, creating conducive working environment, and employment creation.

Paper Recycling Practice in Ethiopia is in an infant stage. During the time of this study, there were only two recycling companies which are found at national level. These are Anmol product Ethiopia PLC, and Ethiopian Pulp and Paper S.C which are located in Addis Ababa. These companies purchase used papers from different organizations and recycle it. The outputs of recycled papers from these companies include papers used to duplicate national exams, cartons, classer, hard papers used as patients' card in hospitals and clinics, and exercise books.

Figure 3. Mess of papers around the building of teachers' offices and incineration (Source: Fieldwork, 2016)

DISCUSSION

Wise management of papers would have immense contribution to the socio-economic and environmental development at university and country level. It can reduce consumption and waste generation. Recycling is one of the 3Rs of waste management which saves energy, reduce raw material extraction and combat climate change (Friends of Earth, 2008). However, incineration which is the only mechanism of waste paper disposal at Hawassa University in particular and other Ethiopian public universities in general, has many socio-economic and environmental impacts.

As indicated in ID2 Communications (2009), producing one sheet of A4 size paper consumes 0.012 percent of a tree and 122 ml of water. Likewise, 6.8 g of CO2 is released into the atmosphere, and 0.5 g of land waste is generated. That means to produce 93885 reams of paper (See Table 4 and 5), 5631.3 trees, and 5725155 liters of water are required, 319.1tones of CO_2 released to the atmosphere, and 23463.75 kg land waste is created. Since 2012/13, a national harmonized modular curriculum was implemented in all public universities. Moreover, the number of students enrolled each year at these universities is more or less similar. This makes the level of paper consumption is relatively similar across universities. This has an implication that Ethiopian higher education institutions demand large amount of paper per year which contribute environmental degradation at large. Hence, practicing wise use of paper at universities which consumed large amount of paper can reduces the consumption level which again reduces the required tree and water, CO_2 and land waste produced, and other chemicals.

As stated in Sarantis (2002), reducing paper consumption can improve efficiency and reduce costs. Heather Sarabtis further stated that beyond being efficient and effective, organizations also would get reputation for being environmentally conscious. However, as shown in Table 4 and 5, a total of 93855 reams of paper are used at Hawassa University each year. This volume of waste paper would have been reduced if the university had had the habit of waste paper management practices of reducing and reusing waste papers.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Recycling is the last option of the 3RS of waste management hierarchy. However, as discussed above, incineration is the only means of disposal at Hawassa University and other Ethiopian public universities. Selling the above mentioned volume of paper to industries that recycle paper would have generated money to the university. According to Ethiopian Pulp and Paper Share Company, the company can pay 2.50 to 3.00 Ethiopian Birr to purchase 1 kg of waste paper. Hence, Hawassa university has lost economic gain of 586,593.75 to 703, 912.50 Ethiopian Birr by 2015/16 since it incinerates its waste paper. Considering this case, Ethiopia lost large amount of money due to absence of practicing recycling waste papers across its public universities.

In addition to the aforementioned environmental and economic impacts, poor management of papers has resulted different social impacts like regular student complaints due to loss of their exam papers, poor working environment, and poor professional image to instructors. Lack of a center to collect waste papers each year has created unpleasant working environment to instructors, and other university community. It is common to see loss of exam papers of students at offices due to hoard of waste papers for many years.

CONCLUSION

This study had an overarching objective of assessing the socio-economic and environmental impacts of poor paper management at Hawassa University. The findings of this study revealed that paper is used for different academic purposes in Hawassa University. Quizzes and final exams consume large volume of paper in the University followed by duplicating course outlines.

Proper management of paper is vital particularly for academic institutions. Nevertheless, in Hawassa University, there is no proper management of used and waste papers due to lack of organized system which resulted in different socio-economic and environmental impacts.

Paper recycling practice in Ethiopia is very infant. Except Adama University, other public universities did not have linkage with companies which recycle waste papers. This makes incineration as the only means of waste paper disposal. Moreover, used exam papers are also kept for three and more years at offices partly due to vague statement of the university legislation; exam papers should be kept for 'at least one year.' This creates unpleasant working environment at offices.

The study also revealed that there are slight experiences of printing and/or duplicating materials duplex. However, this study explored that the main reasons behind double side printing and duplicating is to reduce time and energy spent for stapling, and to minimize the number of papers for easy handling. This makes the practice of duplex to be subject to the volume of paper to be printed and duplicated. Beyond this, instructors did not have good habit of using the blank side of used papers. This shows that application of the principles of 'reduce' and 'reuse' of waste are not applied in the university.

The paper use, the volume of waste paper generated and the management practice in the other public universities is not different from Hawassa University. Therefore, the findings of this study entail the need for integrating waste paper management issues in legislations of universities to reduce socio-economic and environmental impacts of poor waste paper management.

ACKNOWLEDGMENT

The authors would like to acknowledge Hawassa University for funding to conduct this research. Authors also would like to thank academic staffs and administrators of Hawassa University who participated in this study. Moreover, we would like to thank our key informants of other Ethiopian public universities.

ABSTRACT

This chapter addresses a case study of long-term assessment of a field application of environmental nanotechnology. Dense Non-Aqueous Phase Liquid (DNAPL) contaminants such as Tetrachloroethene (PCE) and Trichloroethene (TCE) are a type of recalcitrant compounds commonly found at contaminated sites. Recent research has focused on their remediation using environmental nanotechnology in which nanomaterials such as nanoscale Emulsified Zerovalent Iron (EZVI) are added to the subsurface environment to enhance contaminant degradation. Such nanoremediation approach may be mostly applicable

to the source zone where the contaminant mass is the greatest and source removal is a critical step in controlling the further spreading of the groundwater plume. Compared to micro-scale and granular counterparts, NZVI exhibits greater degradation rates due to its greater surface area and reactivity from its faster corrosion. While NZVI shows promise in both laboratory and field tests, limited information is available about the long-term effectiveness of nanoremediation because previous field tests are mostly less than two years. Here an update is provided for a six-year performance evaluation of EZVI for treating PCE and its daughter products at a Superfund site at Parris Island, South Carolina, USA. The field test consisted of two side-by-side treatment plots to remedy a shallow PCE source zone (less than 6 m below ground surface) using pneumatic injection and direct injection, separately in October 2006. For the pneumatic injections, a two-step injection procedure was used. First, the formation was fluidized by the injection of nitrogen gas alone, followed by injection of the EZVI with nitrogen gas as the carrier. In the pneumatic injection plot, 2,180 liters of EZVI containing 225 kg of iron (Toda RNIP-10DS), 856 kg of corn oil, and 22.5 kg of surfactant were injected to remedy an estimated 38 kg of chlorinated volatile compounds (CVOC)s. Direct injections were performed using a direct push rig. In the direct injection plot, 572 liters of EZVI were injected to treat an estimated 0.155 kg of CVOCs. Visual inspection of collected soil cores before and after EZVI injections shows that the travel distance of EZVI was dependent on the method of delivery with pneumatic injection achieving a greater distance of 2.1 m than did direct injection reaching a distance of 0.89 m. Significant decreases in PCE and TCE concentrations were observed in downgradient wells with corresponding increases in degradation products including significant increases in ethene. In the pneumatic injection plot, there were significant reductions in the downgradient groundwater mass flux values for chlorinated ethenes (>58%) and a significant increase in the mass flux of ethene (628%). There were significant reductions in total CVOCs mass (78%), which was less than an estimated 86% decrease in total CVOCs made at 2.5 years due to variations in soil cores collected for CVOCs extraction and determination; an estimated reduction of 23% (vs.63% at 2.5 years) in the sorbed and dissolved phases and 95% (vs. 93% at 2.5 years) reduction in the PCE DNAPL mass. Significant increases in dissolved sulfide, volatile fatty acids (VFA), and total organic carbon (TOC) were observed and dissolved sulfate and pH decreased in many monitoring wells. The apparent effective destruction of CVOC was accomplished by a combination of abiotic dechlorination by nanoiron and biological reductive dechlorination stimulated by the oil in the emulsion. No adverse effects of EZVI were observed for the microbes. In contrast, populations of dehalococcoides showed an increase up to 10,000 fold after EZVI injection. The dechlorination reactions were sustained for the six-year period from a single EZVI delivery. Repeated EZVI injections four to six years apart may be cost-effective to more completely remove the source zone contaminant mass. Overall, the advantages of the EZVI technology include an effective "one-two punch" of rapid abiotic dechlorination followed by a sustained biodegradation; contaminants are destroyed rather than transferred to another medium; ability to treat both DNAPL source zones and dissolved-phase contaminants to contain plume migration; ability to deliver reactants to targeted zones not readily accessible by conventional permeable reactive barriers; and potential for lower overall costs relative to alternative technologies such as groundwater pump-and-treat with high operation and maintenance costs or thermal technologies with high capital costs. The main limitations of the EZVI technology are difficulty in effectively distributing the viscous EZVI to all areas impacted with DNAPL; potential decrease in hydraulic conductivity due to iron corrosion products buildup or biofouling; potential to adversely impact secondary groundwater quality through mobilization of metals and production of sulfides or methane; injection of EZVI may displace DNAPL away from the injection point; and repeated injections may be required to completely destroy the contaminants.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

INTRODUCTION

Chlorinated volatile organic compounds (CVOCs) such as tetrachloroethene (PCE) and trichloroethene (TCE) are dense non-aqueous phase liquid (DNAPL) contaminants widely found in groundwater at Superfund sites in the U.S. They have very low maximum contaminant levels (MCL) for drinking water set up by the US Environmental Protection Agency (EPA) (0.005 mg L^{-1} for both PCE and TCE). There is an urgent need to develop and verify cost-effective methods for groundwater remediation. During the past decade, a novel approach called nanoremediation has gained support from both environmental research and application communities. Nanoremediation is an environmental nanotechnology that uses nanomaterials for environmental cleanup. It has the potential to decrease the overall costs of site remediation, reduce cleanup time, eliminate excavation and disposal of contaminated soil, and reduce contaminant concentration, and it can be done *in situ* (Karn et al., 2009). Of the nanomaterials explored for remediation, nanoscale zerovalent iron (NZVI) has been the most widely used in both laboratory and field studies for groundwater and hazardous waste treatment (Zhang, 2003; Li et al., 2006; Zhan et al., 2011; Tang and Lo, 2013; Guo et al., 2015). A pioneer field test showed potential applications of the nanoscale Fe/Pd bimetallic particles for treating groundwater chlorinated ethenes such as TCE (Elliott and Zhang, 2001). A latter field study conducted in Taiwan confirmed the effectiveness of Pd/Fe bimetallic particles for dechlorination of vinyl chloride (Wei et al., 2009). Other field studies have tested uncoated NZVI (Lacina et al., 2015) and a variety of stabilized and composite NZVI nanomaterials such as palladium-catalyzed and polymer-coated NZVI (Henn and Waddill, 2006) and carboxymethyl cellulose stabilized NZVI (Bennett et al., 2010; He et al., 2010) for groundwater remediation of chlorinated solvents with promising results.

Recent progress has been made in several key areas that has deepened our understanding of the merits and uncertainties of NZVI-based remediation applications. These areas include the materials chemistry of NZVI in its simple and modified forms, the NZVI reactivity with a wide spectrum of contaminants in addition to the well-documented chlorinated solvents, methods to enhance the colloidal stability and transport properties of NZVI in porous media, and the effects of NZVI amendment on the biogeochemical environment (Yan et al., 2013, O'Carroll et al., 2013). Nevertheless, concerns about the safety (the long-term fate, transformation, and ecotoxicity of NZVI in environmental systems) and efficiency of the NZVI technology have limited its applications (Crane and Scott, 2012). The extent and type of NZVI technology applications differ between Europe and the USA (Mueller et al., 2012). Europeans have been more conservative and only three full-scale remediations with NZVI had been carried out up to year 2012, while NZVI has become an established treatment method in the USA. Bimetallic particles and emulsified NZVI, which are extensively used in the USA, have not yet been applied in Europe. Economic constraints and the precautionary attitude in Europe raise questions regarding whether NZVI is a cost-effective method for aquifer remediation. Challenges to the commercialization of NZVI include mainly non-technical aspects such as the possibility of a public backlash, the fact that the technology is largely unknown to consultants, governments and site owners as well as the lack of long-term experiences (Mueller et al., 2012). A more recent review shows that nanotechnology is more effective for removing emerging contaminants and treatment cost of some nanotechnology is comparable to that of conventional methods (Adeleye et al., 2016).

A special formulation of ZVI, namely emulsified zerovalent iron (EZVI) was developed using a surfactant, biodegradable vegetable oil, water, and nanoscale or microscale zero valent iron (ZVI) particles in an emulsion (Geiger et al., 2003; Quinn et al., 2005). The emulsion droplets enhance contact between

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

the ZVI and the DNAPL. The ZVI provides rapid abiotic degradation of the DNAPL constituents and the oil provides an immediate sequestration of the DNAPL constituents as well as a long-term electron donor source to enhance further biodegradation. The EZVI was field tested and monitored for up to two years to treat source-zone CVOCs dominated by TCE at a site in the Cape Canaveral Air Force Station, FL (Quinn et al., 2005; O'Hara et al., 2006). Results showed that EZVI injection into a source area containing TCE using pressure pulse technology had decreased the mass flux of dissolved phase TCE from the DNAPL source zone, and decreased the amount of free-phase DNAPL mass over time. Most of the field tests involving NZVI have been monitored in a short-term fashion (several months to two years) and long-term monitoring is lacking. There is a continuing need for long-term assessments of groundwater remedial systems and some efforts have been made to meet such needs. One example is a field test of permeable reactive barrier of ZVI for treating groundwater hexavalent chromium [Cr(VI)] and TCE that had been continually monitored for 14 years (Wilkin et al., 2014) and is still being monitored today.

Built on previous EZVI success, Su et al. (2012, 2013) further tested EZVI injection using pneumatic fracturing injection and direct injection methods for treating source-zone PCE contamination at Parris Island, South Carolina, USA, and reported a two-and-a-half-year performance evaluation. Here we present an update on the treatment efficiency after six years of operation. Such long-term performance evaluation will help fill the knowledge gaps of such technology and help design cost-effective strategies for site remediation and closure.

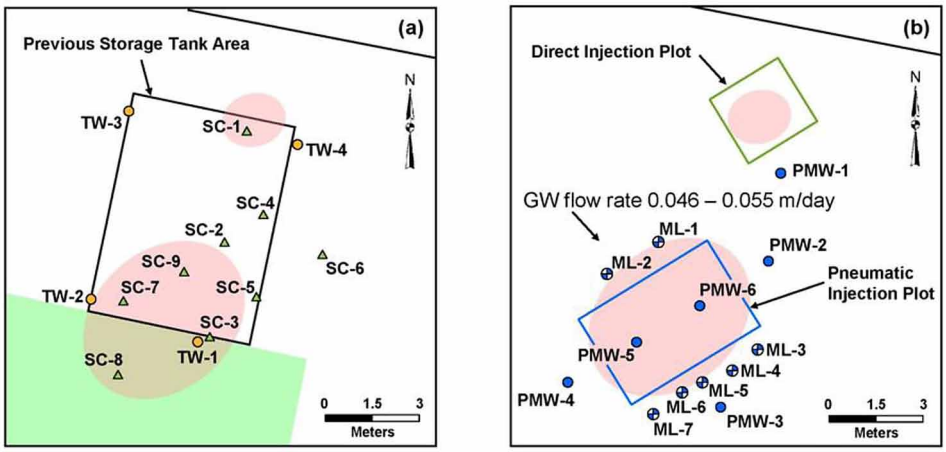
BACKGROUND

Groundwater contamination to depths of approximately 5.8 m below ground surface (bgs) by PCE occurred from a 1994 spill at the Marine Corps Recruit Depot (MCRD), Parris Island, South Carolina, superfund site (Vroblesky et al., 2011; Su et al., 2012). A PCE DNAPL source area was delineated in field investigations conducted in 2005 and 2006 (Figure 1a). Groundwater table is about 1.3 m bgs with small seasonal variations. Groundwater flow follows a northwest-southeast path with very slow velocity at about 0.046–0.055 m day^{-1}. Containment and treatment of the source zone was critical in controlling the migration of the contaminant plume. EZVI technology was chosen due to its previous success at the National Aeronautical and Space Administration (NASA)'s Launch Complex 34 (LC34) located on the 45th Space Wing's Cape Canaveral Air Force Station, FL (Quinn et al., 2005; O'Hara, et al., 2006). EZVI was injected using pressure pulse technology in that study resulting in uneven distribution of the injected EZVI although a decrease in TCE mass flux and TCE DNAPL mass were achieved. Following that study NASA tested four techniques (pneumatic fracturing, direct injection, hydraulic fracturing, pressure pulsing) for separately delivering 379 liters of EZVI to depths of 4.9 to 5.8 m below ground surface (bgs) in an open field near the original injection location. NASA concluded that pneumatic injection and direct injection methods allowed for more controlled injection without loss of EZVI above or below the target depth interval. In the present study, an additional field test was conducted to provide more field demonstration data to improve the EZVI delivery approach and to confirm and validate the technology for widespread use for DNAPL source zone treatment.

Two types of performance monitoring wells (six fully screened and seven multilevel monitoring wells) were installed in two test plots at the site in June 2006 (Figure 1b). Five 5.79-m deep and 5.08-cm diameter monitoring wells (PMW-2, PMW-3, PMW-4, PMW-5, and PMW-6) were installed, screened from 1.22 to 5.79 m bgs in the pneumatic injection plot where an estimated 38 kg of CVOCs was pres-

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. Left panel (a) shows locations of soil cores (green triangles) and temporary wells (orange circles) collected in June 2005 and June 2006 to further evaluate contaminant distribution. The demolished building is shown by the green area. Right panel (b) shows locations of fully screened monitoring wells (blue circles) and multilevel monitoring wells (quartered circles) installed in June 2006 to target the source areas shaded by pink color.



ent. Additionally, seven multilevel monitoring wells (1.27-cm diameter) were installed, with each well screened at seven depth intervals (mid-screen depths at 1.22, 1.98, 2.74, 3.51, 4.27, 5.03, and 5.79 m bgs for ML3, ML4, ML5, and ML6; mid-screen depth at 1.07, 1.83, 2.59, 3.35, 4.11, 4.88, and 5.64 m bgs for ML2 and ML7). In the direct injection plot where an estimated 155 g of CVOCs were present, one 4.11-m deep and 5.08-cm diameter monitoring well (PMW-1) was installed, screened from 1.07 to 4.11 m bgs.

Baseline soil core and groundwater sampling and analyses were conducted before EZVI injection. Eight soil cores (SC-1 through SC-8, Figure. 1a) were collected from ground surface to a depth of 6.10 m bgs at the site during the June 2005 site investigation to evaluate the CVOC mass distribution following the procedures as described by Quinn et al. (2005). An additional soil core (SC-9) was collected from within the pneumatic injection test plot in June 2006 to complete the baseline CVOC mass evaluation. Soil cores were sub-sampled in 0.61-m long sections and CVOCs were extracted and preserved on-site from each section using methanol. The 200 to 300 g wet soil sample was collected and placed in a pre-weighed 500 mL glass container. After capping, the container was reweighed to determine the wet weight of the soil. The container was then filled with 250 mL of reagent grade methanol. The container was then weighed a third time to determine the weight of the methanol added. After the container was filled with methanol and the soil sample, it was agitated by hand for approximately 10 minutes. After shaking, the container was re-weighed to ensure that no methanol was lost during the agitation period. The container was then placed upright and suspended soil matter was allowed to settle for at least 30 minutes. Following the settling period, methanol extract was decanted into glass VOA vials using disposable pipettes. The vials were then capped and stored in a cooler on ice at 4°C until they were shipped on ice to an analytical laboratory. The dry weight of each of the soil samples was determined by sending a subset of the core to the laboratory for moisture content analysis. The final concentrations of VOCs were calculated per the dry weight (105 °C dry basis) of the soil.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Test plot dimensions of 4.57 m wide, 3.05 m long, and 3.66 m in vertical thickness (1.83 to 5.49 m bgs) were used for the VOC mass estimate calculations in the Pneumatic Injection test plot (these are the same test plot dimensions used for VOC mass estimate calculations during the Environmental Security Technology Certification Program or ESTCP demonstration). PCE DNAPL mass was estimated from threshold PCE soil concentrations using equation (1) below to evaluate the presence of DNAPL:

$$C_t = C_{water} (K_d \rho_b + n)/\rho_b \quad (1)$$

where:

C_t = maximum PCE concentration in the dissolved and adsorbed phases (mg Kg^{-1})
C_{water} = PCE Solubility; 240 mg L^{-1}) at 20°C
ρ_b = bulk density of soil (g cm^{-3}): clay/silty clay = 0.98; sand = 1.55; peat = 0.3 (from soil core SC-9)
n = porosity (unitless): clay/silty clay = 0.625; sand = 0.281; peat = 0.844 (from soil core SC-9)
K_d = partitioning coefficient of PCE in soil (mg Kg^{-1}) = $K_{oc} f_{oc}$
K_{oc} = organic carbon partition coefficient for PCE (L Kg^{-1}): clay/silty clay = 447; sand = 355; peat = 631 (Montgomery, 2000)
f_{oc} = fraction organic carbon (unitless): clay/silty clay = 0.045; sand = 0.00088; peat = 0.25 (from soil core SC-9)

Measurements of soil porosity, bulk density, and fraction of organic carbon were performed on select soil samples from soil core SC-9 to further refine CVOC mass estimates.

CVOC and ethene mass flux estimation was made using groundwater concentrations in the upgradient (ML-1 and ML-2) and downgradient (ML-3 through ML-7) multilevel well transects by assuming an effective cross sectional area (perpendicular to groundwater flow) for each multilevel well screen. CVOC and ethene mass flux was also made using the integral pump tests (IPTs) performed downgradient of the pneumatic injection test plot in well PMW-3 prior to EZVI injection in October 2006, March 2009, and at the end of the performance monitoring period in September 2012.

Groundwater samples were analyzed off-site within the limits of sample holding times for CVOCs [PCE, TCE, cis-1,2-dichloroethene (cDCE), trans-1,2-dichloroethene (tDCE), 1,1-Dichloroethene, and vinyl chloride (VC)], dissolved hydrocarbon gases (DHGs) (acetylene, methane, ethene, and ethane), and volatile fatty acids (VFAs) (acetic, CH_3-COOH; butyric, CH_3-CH_2-CH_2-COOH; lactic, CH_3-CHOH-COOH; propionic, CH_3-CH_2-COOH; and pyruvic acids, CH_3-CO-COOH). For CVOCs, groundwater samples (preserved by acidification using concentrated H_2SO_4 to pH less than 2 and cooled to 4 °C on ice) were analyzed by EPA Method 8260B using gas chromatography-mass spectrometry. For DHGs, groundwater samples were measured by gas chromatography (Kampbell and Vandegrift, 1998). For VFA analysis, groundwater samples were collected in 250-mL amber glass jars and preserved by adding concentrated H_3PO_3 to achieve pH 2 and refrigerated to 4 °C. Samples were filtered through a 0.45-µm membrane and a subsample of 50-mL aliquot was injected directly into the high-pressure liquid chromatography (HPLC), separated by a chromatography column, and the eluting compounds were measured with a UV detector. Total organic carbon (TOC) and total inorganic carbon (TIC) in groundwater samples were determined using a carbon analyzer (Dohrmann DC-80). Dissolved anions (chloride, sulfate, and fluoride) were measured using capillary ion electrophoresis (CE, Waters Quanta 4000E). Samples were collected, filtered with a 0.45-µm filter (Gelman Aquaprep) and acidified to pH less than 2 with HNO_3 (Optima,

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Fisher Scientific) for total dissolved metals plus Si and S. Analyte concentrations were determined using inductively coupled plasma-optical emission spectrometry (ICP-OES) (PerkineElmer Optima 3300DV). Analytical quality assurance was practiced during sample collection, storage, and analyses. Detailed information about detection limits, recovery rates, and standard materials was provided in the standard operation procedures for each analyte, for example, method detection limit was 0.17 mg L^{-1} for PCE, 0.20 mg L^{-1} for ethene, 0.39 mg L^{-1} for acetic acid, and 0.263 mg L^{-1} for chloride. The percentage of recovery ranged generally between 95% and 105%. For evaluating reproducibility of groundwater analysis, one replicate groundwater sample was collected and analyzed for every 10 samples.

The EZVI was synthesized on-site by combining 10% by weight NZVI (RNIP-10DS from Toda Kogyo Corporation, 35–140 nm, and a composition of 66% Fe^0 and 34% Fe_3O_4), 51% tap water, 38% corn oil and 1% surfactant (Span 85). The EZVI injections were carried out between October 14 and 18, 2006. Detailed injections were described previously (Su et al., 2012, 2013). Briefly, in the pneumatic injection plot, 2180 liters of EZVI containing 225 kg of iron (Toda RNIP-10DS), 856 kg of corn oil, and 22.5 kg of surfactant were injected to remedy an estimated 38 kg of CVOCs. In the direct injection plot, 572 liters of EZVI were injected to treat an estimated 0.155 kg of CVOCs. The CVOC total mass change was estimated from pro- and post-demonstration soil cores. Daylighting of injected EZVI occurred at several locations but the total amount of daylight was less than 10%.

Groundwater sampling and analyses after EZVI injection were conducted in November/December 2006; January, March, and July 2007; January and July 2008; March 2009; September 2010; and October 2012. For each sampling event, groundwater samples were collected from select fully screened and multilevel monitoring wells and analyzed for either some or all of the parameters initially tested during baseline sampling activities. All of the monitoring wells were sampled for the October 2012, last event.

In October 2012, four post-demonstration soil cores was also collected in the pneumatic injection test plot from locations adjacent to the baseline soil cores (less than 0.3 m away), and cores were analyzed for CVOC concentrations to determine post-demonstration CVOC mass estimates. As was done during baseline sampling, post-demonstration CVOC concentrations from wells PMW-5 and PMW-6 were used to calculate estimates of dissolved phase CVOC mass in the southwestern and northeastern halves of the pneumatic injection test plot, respectively and the estimate of the sorbed and DNAPL mass was determined using the soil cores.

EZVI PERFORMANCE EVALUATION

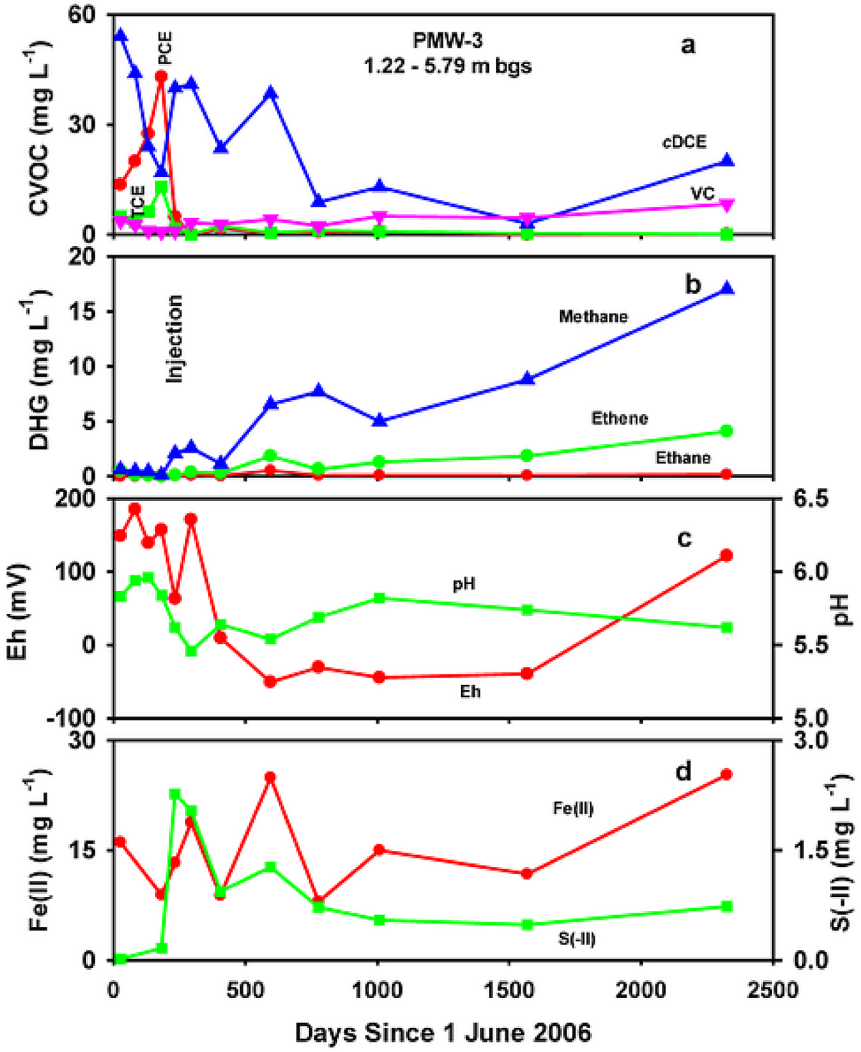
Concentrations of CVOCs and Ethene in Relation to Geochemical Parameters

Baseline data show that PCE and *c*DCE were the predominant CVOCs in downgradient well PMW-3 in the pneumatic injection plot (Figure 2a). The presence of *c*DCE indicates reductive dechlorination of PCE through natural attenuation processes had been occurring. After EZVI injection, concentrations of PCE and TCE temporarily increased but quickly decreased; whereas, *c*DCE showed an increase then decrease after 21 months (Figure 2a). Concentrations of VC were mostly lower than those of *c*DCE. Concentration of *c*DCE was the lowest four years after EZVI injection then it bounced up after that. The rebound of *c*DCE may be a result of near exhaustion of added carbon sources for microbial dechlorination since the NZVI had corroded completely about three months after injection (Su et al., 2013). This also indicates that one single EZVI injection was able to maintain the activity of dechlorination for as

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

long as four years. Dissolved ethene and methane also increased after injection (Figure 2b). Dissolved DHGs were in the order: methane > ethene > ethane > acetylene (not shown but less than 0.12 mg L^{-1}). Eh values showed steady decrease from about 150 mV to -45 mV then rebounded after four years; whereas, pH values showed a minimum of 5.46 five months after injection and then rebounded to 5.82 thirty months after injection followed by a slight decrease afterwards (Figure 2c). Dissolved Fe(II) was variable and sulfide concentrations showed a spike three months following injection and then slowly decreased (Figure 2d). Dissolved sulfate concentrations decreased after injection likely as a result of microbial reduction (data not shown). TOC showed a spike after EZVI injection (data not shown) likely due to organics released by the breakdown of the corn oil and surfactant components of the EZVI. DO levels were between 0 and 1.5 mg L^{-1}.

Figure 2. Temporal changes in monitoring well PMW-3 (1.22–5.79 m bgs, downgradient of the pneumatic injection test plot) of VCOC (a), DHG (b), Eh and pH (c), and dissolved ferrous iron and sulfide (d) before and after EZVI injection.

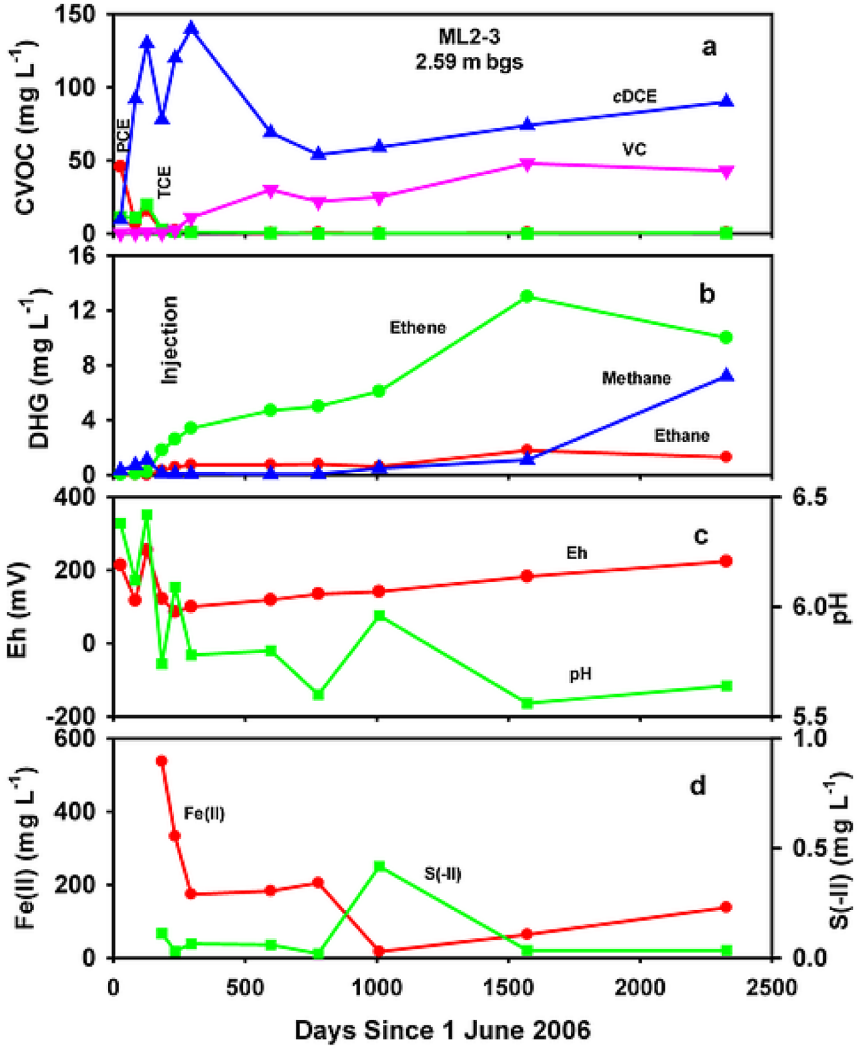


EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Prior to EZVI injection, *c*DCE and PCE showed the highest CVOCs concentrations in the upgradient multilevel monitoring well ML2-3 in the pneumatic injection plot, which was similar to other upgradient wells (Figure 3a). Natural attenuation of PCE was occurring by the presence of PCE degradation products of TCE, *c*DCE, and vinyl chloride (VC). After injection, concentrations of PCE and TCE decreased to low levels, and *c*DCE peaked then decreased before rebounding; whereas, VC increased over time to reach steady state (Figure 3a). The DHGs especially ethene increased dramatically after injection (Figure 3b) indicating enhanced dechlorination of CVOCs upon EZVI addition.

Slightly different trends were observed in the downgradient well ML7-5. Concentrations of *c*DCE increased after injection, reached a plateau from year three to year four, and finally declined thereafter (Figure 4a). Dissolved DHGs increased after injection and were in the order: methane > ethene > eth-

Figure 3. Temporal changes in monitoring well ML2-3 (2.59 m bgs, upgradient of the pneumatic injection test plot) of VCOC (a), DHG (b), Eh and pH (c), and dissolved ferrous iron and sulfide (d) before and after EZVI injection.

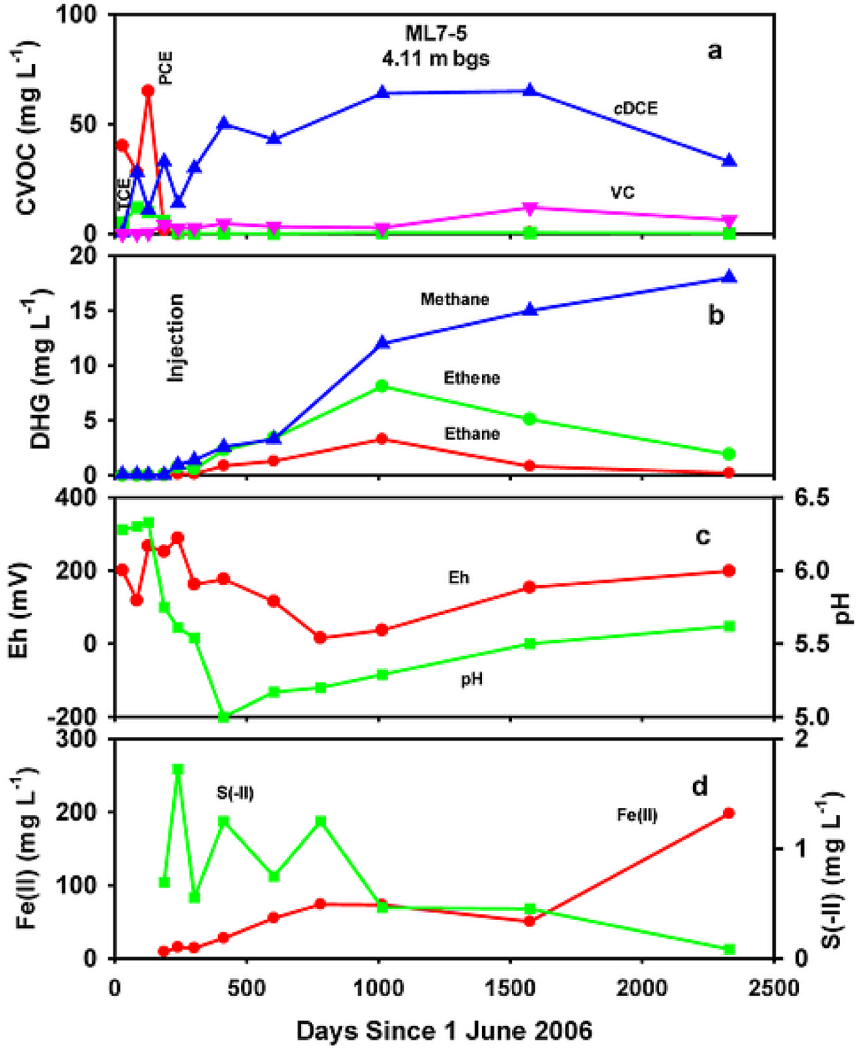


EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

ane > acetylene (not shown but less than 0.12 mg L^{-1} (Figure 4b). Greater decreases in CVOCs were observed in downgradient well PMW-1 in the direct injection plot (data not shown) and PMW-3 in the pneumatic injection plot. Redox potential in the upgradient well ML2-3 decreased right after EZVI injection (Figure 3c); whereas, Eh values in downgradient well ML7-5 showed a slower (time lag) but smaller decrease over time (Figure 4c). The pH values decreased from 6.4 to the lowest value of 5.6 for ML2-3, and to the lowest value of 5.0 for ML7-5 (Figure 4c) before rebounding back.

Dissolved Fe(II) concentrations was estimated to be from 2 to 21 mg/L from total dissolved Fe measurement assuming all the dissolved Fe is ferrous iron in monitoring well ML2-3. Dissolved Fe(II) reached 538 mg L^{-1} after injection then decreased over time (Figure 3d). Dissolved sulfide was low pos-

Figure 4. Temporal changes in monitoring well ML7-5 (4.11 m bgs, downgradient of the pneumatic injection test plot in the direct injection test plot) of CVOC (a), DHG (b), Eh and pH (c), and dissolved ferrous iron and sulfide (d) before and after EZVI injection.



EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

sibly due to precipitation with Fe(II) to form iron sulfides. Dissolved Fe(II) increased over time after EZVI injection reaching 200 mg L^{-1} at year six. Changes in geochemical parameters generally agreed with other field studies (for example, Wei et al., 2010).

Significance of pH Changes

The pH is a master variable in biogeochemistry that is controlled by a combination of multiple reactions and vice versa. The aquifer at the site is slightly acidic before EZVI injection. It became even more acidic after injection. Such decrease in pH after injection could be a result of several biogeochemical processes simultaneously taking place. The fermentation of organic compounds in the corn oil produces VFAs that generates H^+ ions. PCE undergoes abiotic dechlorination by NZVI to produce ethene, magnetite, HCl, and hydrogen gas as indicated in Eq. (2).

$$3C_2Cl_4 + 12Fe^0 + 16H_2O \rightarrow 3C_2H_4 + 4Fe_3O_4 + 12\ HCl + 4H_2\ (g) \quad (2)$$

X-ray diffraction results for the iron corrosions products collected from purging water in monitoring wells and from soil cores showed that magnetite was a major NZVI corrosion product identified in this field study (Su et al., 2013) although other minerals such as green rust and siderite cannot be ruled out. Bacterial reductive dechlorination using H_2 gas (McCarty, 1997; Smidt and de Vos, 2004) derived from iron corrosion could also generate HCl as shown in Eq. (3).

$$C_2Cl_4 + 4H_2\ (g) \rightarrow C_2H_4 + 4HCl \quad (3)$$

The VFAs such as acetic acid can be used by microbes in biological dechlorination to produce HCl and CO_2 (gas) that lower the groundwater pH (Borden, 2007) as shown in Eq. (4).

$$C_2Cl_4 + CH_3\text{-}COOH + 2H_2O \rightarrow C_2H_4 + 4HCl + 2CO_2\ (g) \quad (4)$$

The pH decrease and concentrations of chloride ions increase in monitoring wells are additional evidence of the active dechlorination of CVOCs taking place in groundwter at the site due to EZVI injection. An optimal pH of 4.9 was reported for abiotic TCE degradation by zerovalent iron (Chen et al., 2001); whereas, the optimum pH values of 6.8 to 7.6 were reported for the maximum microbial reductive dechlorination (Zhuang and Pavlostathis, 1995). The pH values observed in the source area were mostly above pH 4.9 and below pH 6.8. Nevertheless, microbial reductive degradation was not prohibited under the lower-than-optimum pH conditions in the source area. There was no need to artificially adjust the pH of the aquifer for the optimal performance of EZVI at this site. The pH values in most monitoring wells showed an increasing trend between 2.5 and six years after injection due to soil buffering effect as shown in an example for ML7-5 (Figure 4c). This rebound in pH should provide a more favorable environment for the dechlorinating microbes to do their work over long periods of time after EZVI injection.

Dissolved VFAs

Typical distribution of dissolved VFAs is shown for downgradient multilevel cluster ML-7 wells at three depths (Figure 5). VFAs were negligible before EZVI injection and were dramatically increased

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

for three of the five VFAs measured. Dissolved propionic acid, acetic acid, and butyric acid were the dominant acids with lactic acid and pyruvic acid showing only trace amounts. The acid concentrations were highest at the shallow depth than at the bottom depth, probably because the lighter corn oil (relative to water) from disintegrated EZVI emulsions tended to migrate (float) towards the top portion of the saturated subsurface where it was used most by microbes as a food source. Corn oil as a component in the EZVI formulation seemed to supply a variety of electron donors such as VFAs that persisted in the source area subsurface over a prolonged period of time up to six years due to the very slow groundwater velocity (0.046 – 0.055 m day^{-1}). An earlier study showed similar VFA distribution trends when emulsified soybean oil was used in a study to enhance anaerobic bioremediation of a TCE source area (Borden et al., 2007). In that study, no NZVI was used. Although vegetable oil itself is a good carbon source for the dechlorinating bacteria, vegetable oil alone may not be as effective as a combined vegetable oil and NZVI. NZVI helps a rapid establishment of reducing conditions that is favorable to the microbial dechlorination. In addition, NZVI provides additional iron that can be transformed to form iron sulfides. Iron sulfides can abiotically degrade CVOCs (He et al., 2015).

Mass Flux

Results of pre-injection and post-demonstration mass flux estimates calculated using CVOC concentrations from the five multilevel wells ML-3 through ML-7 on the downgradient side of the test plot revealed significant reductions in mass flux of the parent compounds PCE and TCE, and of the degradation product *c*DCE (data not shown). In contrast, the mass flux of the degradation products VC and ethene increased significantly over the test period. The increase in ethene mass flux indicates that the reduction in PCE, TCE, and *c*DCE concentrations were due to degradation and not just displacement of water or DNAPL out of the plot.

Total CVOC Mass Reduction

It was estimated from the baseline groundwater and soil sampling events that the total mass of target CVOCs in the pneumatic injection test plot was approximately 38 kg, of which roughly 29 kg (or ~76%) is attributed to PCE DNAPL (Table 1). Post-demonstration sampling results were used to calculate a CVOC total mass of approximately 8.3 kg (Table 1) in the pneumatic injection test plot, of which roughly 1.4 kg (or ~17%) is attributed to PCE DNAPL. Injection of EZVI into the pneumatic injection test plot resulted in approximately 95% reduction in the estimated mass of PCE DNAPL, and approximately 78% reduction in the total mass of target CVOCs. This is lower than an estimated 86% reduction in the total mass of target CVOCs made two and a half years after EZVI injection as reported by Su et al. (2012). Variability of soil cores collected for CVOCs extraction and determination may have contributed to the difference. Nevertheless such reduction is significant from a single EZVI injection event. Repeated EZVI injections could have been used to more completely degrade CVOCs in the source zone but this was not an objective of this field test. Because a single injection was able to maintain active removal of CVOCs for at least four years (Figure 2a), repeated injections may be arranged four years apart to achieve a more cost-effective injection schedule for complete source remediation.

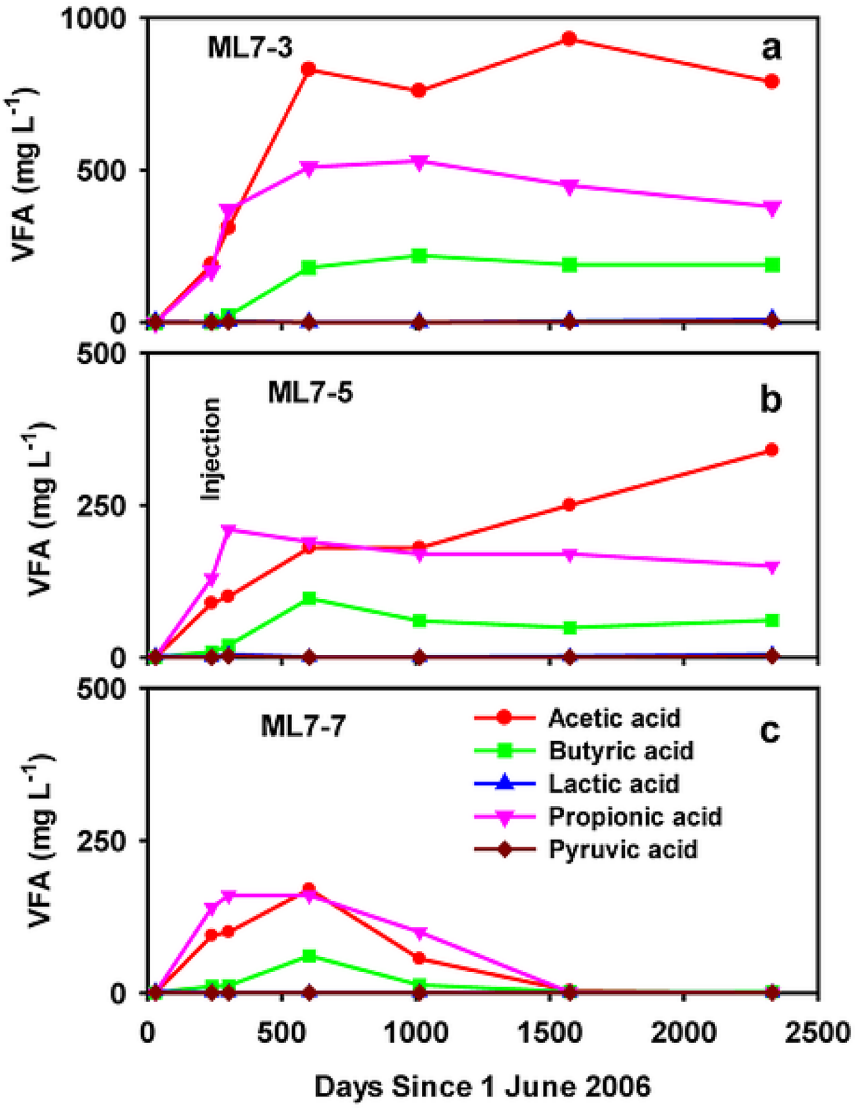
Figure 5. Temporal changes in dissolved volatile fatty acids in monitoring well ML7-3 (2.59 m bgs) (a), ML7-5 (4.11 m bgs) (b), and ML7-7 (5.64 m bgs) (c) downgradient of the pneumatic injection test plot before and after EZVI injection.



PROCESSES OF DECHLORINATION IN THE SOURCE AREA

Mechanisms and pathways of dechlorination in the source area involve several processes that were likely responsible for the accelerated CVOC degradation in the present study. This field test further shows that the EZVI provided multiple reactions for reduction in CVOC mass including rapid abiotic dechlorination resulting from the NZVI and a slower biological dechlorination resulting from the presence of the vegetable oil that was sustained for a more prolonged period of time; however, it is difficult to assess how much contributions of CVOC degradation are from abiotic and biotic pathways. The injected NZVI creates reducing conditions that result in immediate abiotic dechlorination of CVOCs and these condi-

tions are consistent with the reduced redox required for biological reductive dechlorination processes. Anaerobic and aerobic corrosions of NZVI also causes a small increase in pH (Eqs. (5) and (6)) that can be beneficial in buffering the production of acid that can be associated with biological processes such as fermentation producing VFAs and other biological reactions (e.g., Eqs. (3) and (4)).

$$Fe^0 + 2H_2O \rightarrow Fe^{2+} + H_2 + 2OH^- \text{ anaerobic corrosion} \quad (5)$$

$$2Fe^0 + 2H_2O + O_2 \rightarrow 2Fe^{2+} + 4OH^- \text{ aerobic corrosion} \quad (6)$$

The influence of the NZVI on the redox conditions in the bulk fluid in the vicinity of the injected EZVI will be less significant than if the NZVI was injected in the absence of the emulsion but as the corn oil and surfactant components of the EZVI breakdown and the NZVI is no longer shielded within the emulsion, the beneficial impact of the NZVI will become more significant. In general, there is strong indication that biological dechlorination is significant at both test plots. This generalization is supported by: (1) presence of daughter products of PCE (TCE, *c*DCE, and VC) at elevated concentrations prior to EZVI injection; and (2) *c*DCE and VC as major dechlorination products after EZVI injection. Similar biological processes also have been shown in a previous field test using Pd-catalyzed and polymer-coated nanoiron suspension to treat TCE, *c*DCE, and VC (Henn and Waddill, 2006). Microbial analysis was performed using soil cores collected from the source area, and in agreement with another study in the southern groundwater plume area (Vroblesky et al., 2009), the results revealed the presence of microbes (*Dehalococcoides* sp. and *Dehalobacter* sp.) known to degrade chlorinated solvents. A variety of microbes can degrade PCE and TCE, but only microbes related to the genus *Dehalococcoides* are known to degrade *c*DCE and VC to ethene (He et al., 2003 a, b; Schmidt and de Vos, 2004). Complete sequential dechlorination of PCE to ethene has been observed for *Dehalococcoides etheneogenes* (Maymo-Gatell et al., 1997). Microcosm studies show no deleterious effect on total bacterial abundance from NZVI (Kirschling et al., 2010). There is no evidence of adverse impact to microbial communities

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

after EZVI injection; in contrast, population of dehalococcoides was increased from less than 10^3 cells per g of fresh soil in the saturated zone to up to 10^7 cells per g of fresh soil with a 10,000 fold increase after injection in this study, in agreement with an earlier field study (Kirschling et al., 2010). It is likely that a collection of dechlorinators are involved in the degradation of PCE and its chlorinated daughter products in the source area.

ADVANTAGES AND DISADVANTAGES OF THE EZVI TECHNOLOGY

EZVI holds promise in remediating sites cost effectively and addressing challenging site conditions, such as the presence of DNAPL. Based on the previous and present work, the following general statements can be made with regard to the pros and cons, or strengths and weaknesses of the EZVI technology. The main advantages of the EZVI technology over other treatment technologies (pump-and-treat, thermal, conventional PRBs) include:

- An effective "one-two punch" of rapid abiotic degradation followed by slower biological degradation;
- Contaminants are destroyed rather than transferred to another medium;
- Ability to treat both DNAPL source zones and dissolved-phase contaminants to contain plume migration;
- Due to the enhanced reactivity and fast corrosion potential of NZVI, EZVI is most suitable for treating the source-zone DNAPL where the greatest economic benefits can be made;
- Ability to deliver reactants to targeted zones not readily accessible by conventional PRBs; and
- Potential for lower overall costs relative to alternative technologies such as groundwater pump-and-treat with high operation and maintenance costs or thermal technologies with high capital costs.

The main disadvantages of the EZVI technology are:

- Difficulty in effectively distributing the viscous EZVI to all areas impacted with DNAPL;
- Potential decrease in hydraulic conductivity due to iron oxide buildup or biofouling;
- Potential to adversely impact secondary groundwater quality through mobilization of metals and production of sulfides or methane if excess electron donor, in the form of the vegetable oil, is added;
- Injection of EZVI may displace DNAPL away from the injection point; and
- Repeated injections of EZVI may be required to completely destroy the contaminants.

FUTURE RESEARCH DIRECTIONS

It is still a challenge to deliver NZVI to a targeted subsurface zone in a uniform fashion. EZVI injection may be more applicable to deeper aquifers than the shallow aquifers that may help minimize daylighting. Research is needed to explore more effective injection technologies to minimize preferential flow and daylighting at sites with varying lithological and hydrogeological conditions. Formulation of NZVI

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

to make it injectable while maintaining its reactivity can be further improved. Injected nanoiron was shown to transform to iron oxides (with greater particle size) mostly within three months (Su et al., 2013). Fate and transport of NZVI in the subsurface during expanded periods up to many years are still poorly understood. Corrosion products of NZVI such as green rusts, iron sulfides, and magnetite may offer additional benefits for CVOC degradation – such abiotic pathways and their relative contributions to the overall contaminant contamination need to be evaluated in detail in both laboratory and field studies. Being consistent with other field studies, the results of the current field applications with respect to contaminant reduction are promising, and no major adverse impacts on the environment have been observed so far. It is thus expected that these tests will contribute to promoting the technology in other geographical places such as Europe (Mueller et al., 2012).

CONCLUSION

Positive results have been obtained from a six-year field test using a single EZVI injection event for source zone remediation at a Superfund site contaminated with DNAPL PCE. Addition of EZVI resulted in more reducing conditions that stimulated dechlorinating bacteria (dehalococcoides); there is no evidence of adverse effect to the microbial communities. High dissolved VFA concentrations were sustained in the shallow monitoring wells even after six years of EZVI injection, indicating the excellent sustainability of the EZVI technology at this site where groundwater flow is slow. There were significant reductions in the downgradient groundwater mass flux. There were significant reduction in total VOC and DNAPL. A combination of abiotic (from NZVI and its corrosion products) and biotic (from bacteria) pathways lead to contaminant degradation through dechlorination reactions. EZVI technology can be successfully applied to treat source zone DNAPL.

ACKNOWLEDGMENT

This project is a collaboration among the United States Environmental Protection Agency through its Office of Research and Development, Geosyntec Consultants Inc., NASA, and the Naval Facilities Engineering Service Center. Funding was provided by the Environmental Security Technology Certification Program (ESTCP) (project ER-0431) and the U.S. EPA. Although the research described in this article has been funded partly by the U.S.EPA, it has not been subjected to the Agency's peer and administrative review and, therefore, does not necessarily reflect the views of the Agency, and no official endorsement should be inferred. Mention of trade names or commercial products does not constitute endorsement or recommendation for use. We are grateful to the following individuals and organizations: Deborah Schnell, Cornel Plebani, and their team of Pneumatic Fracturing, Inc. (Alpha, NJ) for high-pressure pneumatic injection of EZVI, Andrew Thornton and Corey Gamwell of Vironex Environmental Field Service (Golden, CO) for direct push injection of EZVI, Drs. Cherie Geiger and Christian Clausen of the University of Central Florida for assisting with on-site preparation of EZVI, Mr. Tim Harrington of MCRD at Parris Island and Ms. Bridget Toews (Independent Contractor) for providing logistical support, Messrs. Justin Groves, Brad Scroggins, Ken Jewell, Russell Neil, Tim Lankford, and Pat Clark of EPA, and Steve Randall of Geosyntec for field support, Ms. Lynda Callaway and Kristie Hargrove and Mr. Mark White of EPA for TOC/TIC and anions analysis, Messrs. Steve Markham and Andrew

KEY TERMS AND DEFINITIONS

Abiotic Dechlorination: Dechlorination by inorganic reactants such as elemental iron and sulfides.

Biotic Dechlorination: Dechlorination by microbes such as *Dehalococcoides* sp. and *Dehalobacter* sp.

Chlorinated Volatile Organic Compounds: Compounds that contain chlorine atoms and are volatile. Examples include tetrachloroethene or perchloroethene (PCE) and trichloroethene (TCE).

Dense Non-Aqueous Phase Liquid: A denser-than-water NAPL, i.e. a liquid that is both denser than water and is immiscible in or does not dissolve in water.

Groundwater: Liquid water that seeps through the soil or rocks underground.

Groundwater Remediation: The process that is used to treat polluted groundwater by removing the pollutants or converting them into harmless products.

Mass Flux: The rate of mass flow per unit area.

Maximum Contaminant Levels: Standards that are set by the United States Environmental Protection Agency (EPA) for drinking water quality. An MCL is the legal threshold limit on the amount of a substance that is allowed in public water systems under the Safe Drinking Water Act.

Non-Aqueous Phase Liquids or NAPLs: Liquid solution contaminants that do not dissolve in or easily mix with the water. Examples are oil, gasoline, and petroleum products.

Nanoremediation: An environmental nanotechnology that uses nanomaterials for environmental cleanup.

National Priorities List (NPL): The list of national priorities among the known releases or threatened releases of hazardous substances, pollutants, or contaminants throughout the United States and its territories. The NPL is intended primarily to guide the EPA in determining which sites warrant further investigation.

Superfund Site: An uncontrolled or abandoned place where hazardous waste is located, possibly affecting local ecosystems or people. Sites are listed on the National Priorities List (NPL) upon completion of Hazard Ranking System (HRS) screening, public solicitation of comments about the proposed site, and after all comments have been addressed.

Chapter 62
Government's Role in Setting Optimal Policies for Green Supply Chain

Kalicharan Sabat
Vignana Jyothi Institute of Management, India

ABSTRACT

In the last two decades lot of research was done in the area of Green design and Green supply chain management. But very few researchers have really tried to study the government's role in the implementation of Green designs and Green supply chain in any nation. In this paper simple general equilibrium model is used to analyze the benefits from taxes, and subsidies by government for green disposal efforts such as waste reduction, waste recycle, remanufacturing, and disposal on both the manufacturers and household consumers.

INTRODUCTION

In every year since 1993 has been in the top 20 warmest years on record[1]. Environmental degradation and increasing resource depletion has compelled the governments across the globe to set policies on green practices such as Green design, Green procurement, Green manufacturing, Green packaging, Green distribution and Green disposal for all the manufacturing companies. Furthermore, with a global concern to environmental issues, various countries have framed stringent laws on disposal of goods, and are imposing green barriers while importing commodities from the global markets.

Fullerton and Wu (1998) in the paper "Policies for green design" initiated the discussion on how the government can use different mix of policy instruments to deal with various organizational and market failures in managing household waste. They suggested in the absence of a market for recycled goods, the mix of consumption tax, packaging tax and recyclability subsidy on producers of different industrial and household products can lead to minimizing the amount of waste generated and maximization of reuse and recycling of material. Similarly, if household and industrial waste is collected free of charge, then the

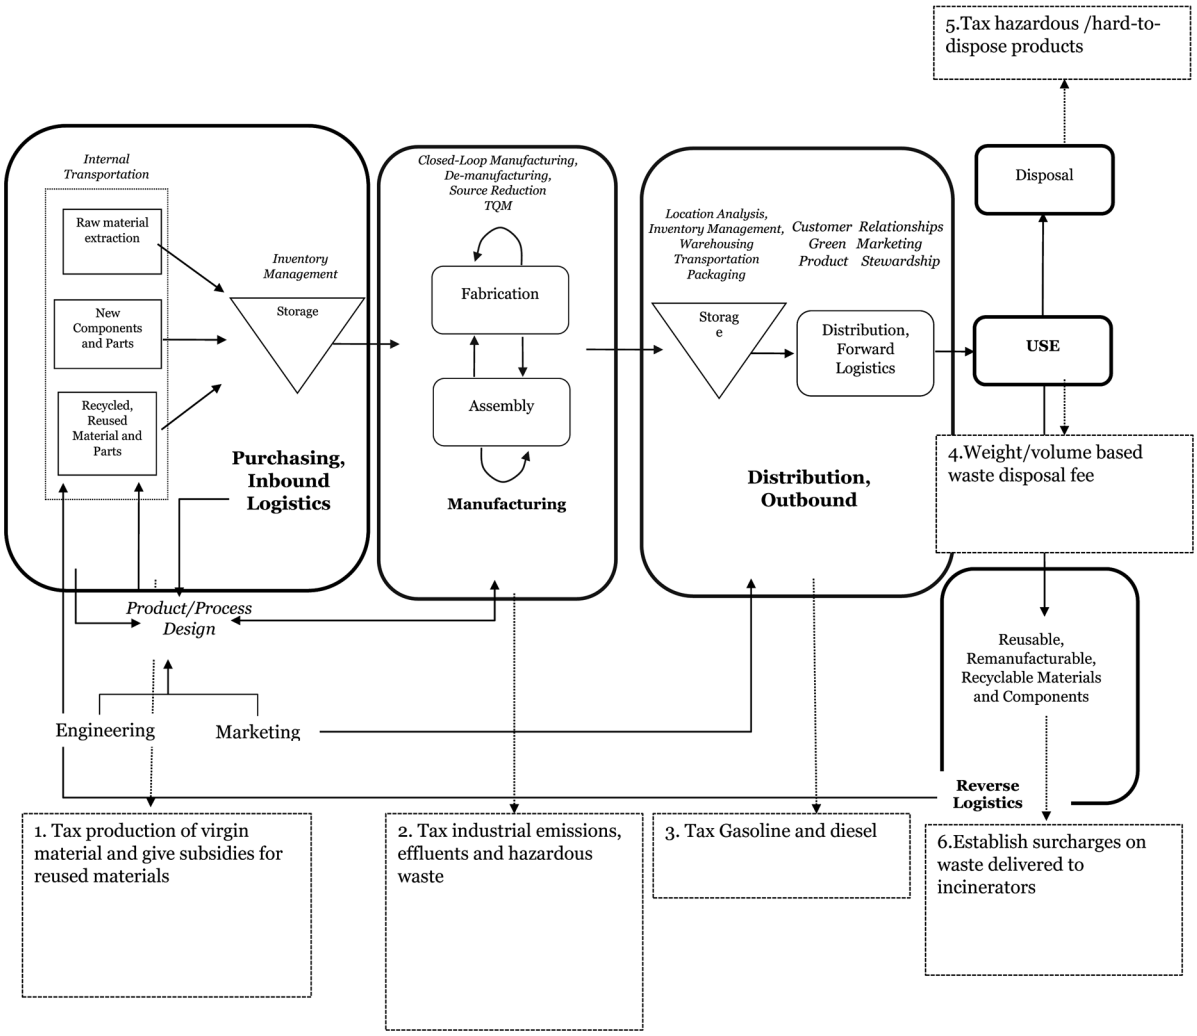
Figure 1. Government policies for manufacturers and consumers at different stages of supply chain



combined effect of consumption tax, packaging tax and recyclability subsidy on producers may lead to optimize the amount of waste in the entire product-life-cycle starting from design, to production, packaging, sales, use and disposal. Figure-1 shows how the government policies can target different stages in the product life cycle. Policies that affect product design will also affect product disposal and vice versa.

BACKGROUND

The concept of Green Supply chain Management was first put forward in US Michigan State University in 1996 (Zhou, 2009). Since then the scholarly interest in the area of Green Supply chain Management has rapidly developed across the world. Benita M. Beamon, (1999), in her Paper "Designing the green supply chain, Logistics Information Management", gave a new aspect to the Supply chain management by taking environmental challenges to production and manufacturing into thought. She insisted on re-

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

ducing waste and minimizing the use of resources at each stage of the supply chain. Also to lower the environmental damage all the supply chain members should examine their "ecological footprint" and make Green supply chain as a practice for lowering the ecologic footprint of supply chains (van Hoek, 1999).

Organizations have started viewing many of these environmental programs like technological and organizational development projects, as possible alternatives for gaining a competitive advantage (Sarkis, 2002). Subhajit Mazumder and Anand Chatterjee in the paper "Green Supply Chain as a competitive advantage enabler in the FMCG sector" have said that cost strategy (low cost) and Evolving strategy (focus) are now out dated and for sustaining in the aggressive market they need to improve the supply chain efficiency and should become more environmentally conscious. A number of green practices were suggested by Srivastava (2007) likes green design, reverse logistics, product recovery, logistic design, solid waste management and so on. Sanjeev Swami and Janat Shah (2011) in the paper "Channel Coordination in Green Supply Chain Management: The Case of Package Size and Shelf-Space Allocation" addressed the benefits of vertical coordination in a green supply chain between the players at the upstream and downstream levels of the chain and to reduce the pack size of products that helps in saving environmentally costly transportation cost.

Aref A. Hervani, Marilyn M. Helms, Joseph Sarkis, (2005), in their paper "Performance measurement for green supply chain management", tried to design a Performance measuring system for GrSCM. In the paper they said in supply chains with numerous vendors, producers, distributors, and retailers the Green performance measurement is very challenging because it is difficult to attribute performance results to any one particular entity within the chain. And the problem gets amplified if the member organizations don't follow any standardized data, poor technological Integration among partners, cultural dissimilarities, lack of understanding of organizational plan, differences upon metrics, or unclear understanding of the needs for inter-organizational performance Measurement, etc. They suggested Environmental performance indicators can be used in evaluating the environmental performance of activities, processes, hardware and services.

GREEN INITIATIVES BY DIFFERENT GOVERNMENTS

As part of its commitment to improve the environment and the quality of life of its citizens, the Canadian government on April 1, 2006 made the policy of green procurement mandatory for all its government purchases.[2] On November 26, 2008 United kingdom (UK) government enacted the climate change act to improve carbon management and help the transition towards a low carbon economy in the UK.[3] The Japanese government is planning to introduce a new tax to curb carbon emissions from fiscal year 2016. Similarly in 2012 china announced increases in resource taxes on six minerals, such as tin, iron ore, and in February 2013, the US Department of Energy announced USD150 million in Advanced Energy Manufacturing Tax Credits for clean energy and energy efficiency manufacturing projects across the US.[4] Also the European Union (EU) too has waste management policies with aim to reduce the environmental and health impacts of waste and improve Europe's resource efficiency.[5] With most governments from the developed nations actively trying different green practices, the impacts from their efforts need to be evaluated.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

A SIMPLE MODEL FOR ANALYSING WASTE REDUCTION AND WASTE REUSES EFFORT

The model is derived from the model suggested by Fullerton and Wu (1998) with the assumption that household consumer can also dynamically support the government's efforts in reducing waste. It is assumed that all the different manufacturers produce identical goods and all the household consumption is identical. A representative firm produces a consumable goods with the cost function $c(q, e)$, where $q \geq 0$ is the quantity of goods produced and $e \geq 0$ is the effort put by the firm to reduce waste at the source, such as reduced use of virgin toxic materials, minimizing material use for production, economic packaging, reverse logistics, etc. Any household in a nation has the utility function $u(q, a) – (m + d)$, where $q \geq 0$ is the quantity of goods produced and $a \geq 0$ is the amount of effort by the household in reducing waste, and 'm' is the monetary cost incurred in the consumption of q and 'd' is the cost incurred while disposing the waste. Household cost incurred in the disposal of waste (d) may include reuse, remanufacture, and recycle of products.

The amount of waste needed to be disposed after consumption will depend on $q, e, a,$ and may be denoted by $w(q, e, a)$. Disposing waste may incurs two different types of cost. The first is the tangible cost of collecting, transporting, shorting, recycling and reuse of waste, denoted by "T" per unit of waste. The second type of cost is the intangible cost on environment and society, and is denoted by "I" per unit of waste. All the above functions are twice differentiable, so as to satisfy $cq > 0$, $ce > 0$, $uq > 0$, $ue < 0$, $wq > 0$, $we < 0$, $wa < 0$ and guarantying an unique solution to the problem.

The policy instruments available to the government are 1) unit consumption tax (t) 2) unit subsidy on waste disposal (λ), 3) unit subsidy on manufacturers waste reduction effort (γ), and 4) Governments direct investment for waste reduction and recycling facilities (θ).

Optimized Social Impact and Decentralizing Efforts

Due to quasi-liner preferences, the first optimal solution for the above model is maximizing household utility, less the cost of production, and cost of waste disposal by household, manufacturer, and the government. Then the objective function becomes $u(q, a) - c(q, e) - (T + I)\, w(q, e, a)$ and the first order condition for interior maximum are

$$uq – cq - (T + I)wq = 0, \tag{1}$$

$$- c_e - (T + I)we = 0, \tag{2}$$

$$ua – (T + I)wa = 0 \tag{3}$$

Each of the above conditions equates marginal social costs to marginal social benefits.

The following are the outcomes from decentralized market efforts. Let's assume the price for a unit consumable good is 'p' and the price of waste disposal per unit waste is 'χ'. If the above mentioned subsidies and taxes are implemented on household consumers, the objective function becomes $u(q, a) - (p + t)q - (\chi + \lambda)\, w(q, e, a)$. The first order conditions for maximum household consumer's utility are

$$u_q - (p + t) - (\chi + \lambda)w_q = 0 \tag{4}$$

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

$$u_a - (\chi + \lambda)w_a = 0 \quad (5)$$

From the given price and government policy variables, the producer's profit function may be derived as $pq - c(q, e) + (\gamma + \theta)e$ and then the first order conditions for profit maximization are

$$p - c_q = 0 \quad (6)$$

$$- c_e + \gamma + \theta = 0 \quad (7)$$

If Optimal Policies for Passive Household Waste Reduction Effort – a = 0

If the household consumers are not pro-active with respect to waste reduction effort, then the equations *(3)* and *(5)* are not applicable. Now if we compare the remaining equations for social optimal results and decentralized outcomes, we can easily find that they are equal if and only if $t + (\chi + \lambda)\, w_q = (T + I)\, w_q$ and $\gamma + \theta = - (T + I)\, w_e$. These conditions may lead to a series of optimal policies as the three parameters to be considered, $t, \lambda, \gamma + \theta$ are needed to be calculated using two equations.

One of the possible optimal government policy may be obtained by setting $t = 0, \lambda = T + I - \chi$ and $\gamma + \theta = - (T + I)w_e$. In this case the combined effort of unit subsidy on household waste disposal and a unit subsidy on the manufacturers and governments waste reduction effort can achieve the social optimal. If the waste disposal service to the household is provided at marginal cost so as $\chi = T$, then the unit tax for household waste disposal will be equal to the pre unit social and environmental cost of waste, ie., Pigouvian tax[6]. Instead suppose the household waste disposal is provided free of charge then, $\chi + \lambda = 0$, is possible because the problem of illegal waste disposal which is very common in most of the counties can be controlled. Once the illegal waste disposal problem is curbed then the remaining policy instruments can be implemented to achieve social optimum. That is, $t = (T + I)w_q$, $\gamma + \theta = - (T + I)w_e$ along with $\lambda = - \chi$ may also lead to social optimal. Again we can use consumption tax and waste reduction subsidy on manufacturers in the Pigouvian way.

If Optimal Policies for Passive Household Waste Reduction Effort - $a \geq 0$

Once the household start active waste reduction efforts, then the comparison for social optimal conditions in the *equations (1-3)* and the decentralized efforts in the *equations (4-7)* will lead to three equations:

$$t + (\chi + \lambda)w_q = (T + I)\, w_q \quad (8)$$

$$\gamma + \theta = - (T + I)\, w_e \quad (9)$$

$$(\chi + \lambda)w_a = (T + I)\, w_a \quad (10)$$

Now there will be only one unique combination of policy devices that implement the social optimal: $t = 0, \lambda = T + I - \chi$, *and* $\gamma + \theta = - (T + I)\, w_e$. The reason for such uniqueness in the optimal policy is purely because government has only three policy devices to control the three private variables.

The optimality of the above policy can be automatically explained. Free waste disposal (or a fixed payment for waste disposal) does not provide the household or manufacturer any incentives to make any

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

waste reduction effort. Everyone in the society (manufacturer, households, institutions, etc.) expect some kind of return on investment (ROI) from their efforts for reducing or safe disposing the waste. This is why most governments are charging taxes at Pigouvian rates.

CONCLUSION

From the above discussions we can conclude that even in the absence of active involvement from household consumers on waste reduction efforts, the governments are capable in setting policy procedure. The reasons behind governments' flexibility in setting policy is the availability of three policy instruments *(t, λ, γ+θ)* to target the two private variable *(q,e).* The role of the waste disposal tax and subsidies becomes more significant only when the household consumers and the manufacturers actively start reducing waste, and reusing/ remanufacturing/ recycling materials.

Chapter 63
Green IT Adoption Practices in Education Sector:
A Developing Country Perspective

Alexander A. Hernandez
Technological Institute of the Philippines, Philippines

ABSTRACT

Green IT is a resource efficient and effective consumption to reduce organizations processes impacts to the environment using information technology. This article aims to explore GIT practices of higher education institutions in the Philippines, where a qualitative multiple-case study is used. The study found that higher education institutions Green IT adoption covers the use of paperless and digital archiving systems, resource efficient IT equipment, responsible electronic waste disposal, recycling and reuse, and initiated awareness programs to educate the employees about Green IT and sustainability. The study also found that these practices are in its early stage of adoption in higher education institutions in the Philippines. This article also presents practical and research implications to further the uptake of Green IT in higher education institutions.

1. INTRODUCTION

Green IT (GIT) is a resource efficient and effective consumption through the use of IT infrastructure and systems. It also involves managerial and individual's practices towards sustainable environment (Lei and Ngai, 2013). It is an approach to encourage stakeholders' participation in solving environmental problems, and strategic focus for organizations to achieve sustainability (Loeser et al., 2017). Essentially, this approach is expected to reduce business operations cost, wastes and emissions of carbon footprint, thus, minimizing the overall impact of IT usage in the environment (Gholami et al., 2013).

Although there are different approaches to achieve GIT benefits, both for organizations and environment (Asadi and Dahlan, 2017), a handful of studies explored on GIT practices in organizations, more specifically, the education sector. First, the education sector researchers are actively involved in the

growing literature of GIT exploring private and public organizations. To date, limited studies have been published on exploring the practices of GIT in higher education institutions (HEI). Second, there is a growing appreciation of GIT adoption in higher education institutions in developed countries. However, there is an inadequate investigation of evidence of GIT in developing countries. Third, higher education institutions have started offering programs on sustainability and environment. It presents a challenge of how universities adopt to GIT as a way to foster environmentally sustainable efforts. Thus, this study is motivated by these concerns that the literature lacks in-depth investigation of the GIT practices, issues, and challenges faced by higher education institutions. Hence, this study fills the gap of understanding Green IT adoption practices in higher education institutions.

This study contributes to growing literature on GIT adoption in higher education institutions, more specifically, in a developing country perspective, the Philippines. Also, it offers new insights on the state of Green IT adoption covering the practices and potential challenges faced by higher education institutions, and approaches to achieve sustainability. Thus, this research is guided by the research question: "*What are Green IT adoption practices towards sustainability?*" To achieve the goal of the study, a qualitative approach using multiple case studies was employed involving higher education institutions in the Philippines. Hence, this study argues that the understanding of GIT adoption in HEIs not only significant to the Philippines, and is similarly important to other rising economies.

The remaining sections of this paper are presented as follows: GIT in education and overview of the Philippine higher education institutions, discussion of the research methodology, the data analysis is presented, discussion of findings, explanation of implications to both research and practice, and conclusion and future work.

2. REVIEW OF LITERATURE

2.1. Green IT

The environmental challenges covering the rising carbon footprint emissions, depletion of natural resources and increasing waste ending in landfills is gaining more attention and discussion among public and private stakeholders (Hilty and Aebischer, 2015). These challenges resulted in the formation of accords in various regions to understand the implications of human safety, business, technology development, and environmental sustainability (Nisha et al., 2013). Conversely, it is a significant area of research in the information systems and environmental education. Thus, sustainability through Green IT was conceived as an important strategic focus for organizations today. GIT is an efficient resource consumption using IT infrastructure as well as applying managerial and human practices, and organizational policies towards sustainability (Molla et al., 2014). To date, many organizations have been proposing their GIT agenda (Ardito and Morisio, 2014), and anchoring it to the sustainability mission and vision (Hernandez and Ona, 2016), to realize the full benefits of GIT, both for economic and environmental performance. Previous studies suggest that adoption of GIT in organizations have been very limited (Khor et al., 2015), especially in developing countries (Hernandez and Ona, 2015). It requires technological and organizational readiness, and support from the external environment to progress from simple to broad – complex GIT adoption activities (Deng and Ji, 2015). Hence, there is a greater need to explore and initiate GIT adoption in organizations.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

2.2. Green IT Practices in Education

The role of education sector has been realized for both research and practice, more importantly, in introducing innovations. Sovacool et al. (2017) state that the education sector should not only introduce new concepts or researches, however, it should also respond to the need for sustainability. Thus, the education sector is seen to thrive in institutionalizing sustainability practices, and allow generation of ideas and spur involvement among students, faculty members, and employees to achieve the goals of GIT (Thongmak, 2012).

Previous studies suggest that the education sector has initiated GIT adoption. First, a growing practice on energy-consumption reduction and conservation were initiated by higher education institutions. Nazari and Karim (2011) found that a university in shifted to energy-efficient ICT operations to reduce energy consumption by 35 percent, whereby, personal computers used was set to optimum energy saving option through end-user pc power management software. Similarly, the University of Edinburgh measures IT power consumption as an approach to making students, faculty members, and employees aware of their role and contribution towards energy conservation (Dovi et al., 2009). It was also a good platform to remain relevant in addressing energy saving needs, through some energy-conservation strategies and use of systems (Van Bokhoven and Bloem, 2013). These practices were developed through the availability of procurement procedures which allows the provision to buy energy-efficient IT equipment. Conversely, Bala et al. (2008) noted that the provision for GIT in organizational procurement procedures and practices resulted in rising interest to minimize environmental impacts of IT. More specifically, it means that higher education institutions were evaluating purchased computers based on a variety of GIT criteria, ranging from energy-consumption, extended life options, and eventual disposal alternatives (Ho et al., 2010). Further, these practices address the need for lesser toxicity and hazardous materials level, which is easily recycled, and end with lesser e-waste. Hence, the HEIs initiated a growing number of GIT efforts to save energy and reduce its equivalent carbon footprint.

Second, consolidation of IT equipment and systems were on the rise in HEIs. Suryawanshi and Narkhede (2013) found that printer consolidation was significant in addressing the need to reduce paper use and IT infrastructure setup of HEIs. Essentially, it reduces the number of physical setups. Therefore, it produces lesser carbon footprint and could lessen power use. Similarly, some universities initiated server consolidation and virtualization, through cloud computing. Okai et al., (2014) noted that cloud computing is a priority to greening IT infrastructure. It was evident that disasters, power growth, and issues became a recovery challenge for organizations. Thus, this GIT practice does not only result in financial budget savings, however, addresses the cost of downtime, patching and power issues during a disaster situation (Khambayat et al., 2015). More recently, virtualization through cloud computing became a major platform to reduce physical storage requirements by 40 percent, and decommissioning of servers with cooling equipment was expected to reduce IT power consumption by 35 percent annually (Suryawanshi and Narkhede, 2012).

Third, the HEIs also began with unified communication systems to reduce employees' dependence on multiple communication software and devices. Ramachandiran (2012) found that improving the use of unified communication software resulted in an increasing participation of employees in ideation, resolving customer concerns, and efficient, responsive feedback needs. For instance, Bolton et al. (2017) note that unified communication software allows efficient access and sharing of files on a range of mobile and desktop devices, thereby saving paper use and printing solutions. Similarly, it allows employees to communicate and work remotely with others in the education institutions, thereby, enabled inclusive

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

participation for mobile workers (Silic et al., 2016). On the other hand, these technologies could result in increased productivity among all employees in the education institution (Boyd et al., 2017). Also, workflow outcomes become more integrated, efficient, and requires fewer resources, therefore, decreases business operations costs.

Finally, HEIs were more concerned about electronic waste (e-waste) disposal, recycling, and reuse options. E-waste is a global concern, and a threat to occupational safety, public health, and environment. Moreover, the growing e-waste contributes to carbon footprint emissions and toxicity, and depletion of natural resource used to produce electronic equipment. However, HEIs started their efforts to green e-waste disposal. For instance, a university in the United Kingdom allows disposal of e-waste more responsibly by letting suppliers collect e-waste disposals (Chai-Arayalert & Nakata, 2011). The employees were advised to dispose their mobile handsets and batteries to suppliers. It is legal to accept e-waste from employees as a practice. The employees were aware of the environmental implications of ending their e-waste in a landfill, and not be disposed to prevent the emission of toxic substances (Elsaadani, 2015). Moreover, the university allows segregation of wastes using colored bags as part of e-waste management with special focus on IT waste.

Likewise, a university concentrated on conducting e-waste audit to measure avoidance from carbon footprint and toxic materials (Geng et al., 2013). E-wastes were accounted, monitored and controlled annually (Ansari et al., 2010). The collected e-waste was sent to accredited formal recycling stream or service provider and paid by the university to recycle and recover components which can be recovered. Gomez et al. (2017) noted that the HEI also encourages the donation of e-waste for refurbishing and recycling efforts. These practices allowed the employees to take part and become responsible for their respective unit's e-waste. Moreover, a GIT committee was formed to tackle the growing concerns on e-waste and other sustainability needs of the university (Shea et al., 2017). Hence, these GIT practices were initially started by HEIs to cope with the growing need for sustainable waste management, thereby, reducing the impacts of e-waste on occupational health, safety, and environment.

2.3. Overview of Higher Education Institutions in the Philippines

The Philippine higher education system consists of two segments, private and public universities. In the segment, 88 percent or equivalent to 1,700 accounts for private, and only 12 percent or equivalent to 224 public higher education institutions (Ricafort, 2009), catering around 3.8 million of students. In the past, the Philippine higher education system was in a challenging state as the quality of education continually declines due to some factors such as (a) availability of qualified-competent faculty members, (b) lack of up-to-date facilities for research, and lacking years of primary education (c) among others (Chapman and Sarvi, 2017). Thus, the Philippine government started working on education policies and programs to address these concerns, and continuously enhance the quality of education. For instance, Outcome(s)-Based-Education (OBE) was implemented in the last 2010 to align the desired outcomes of program offerings to the needs of the employers and industry, and allow Filipino students to access global education opportunities (Borsoto et al., 2014; Rogers et al., 2017) as well as the recent implementation of K12 program (Adarlo and Jackson, 2017), thus, ensuring graduates become globally competitive. Also, these government efforts transpired into global recognition of some colleges and universities program offerings in the field of Engineering, Computing, and Business.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

However, these higher education institutions were also challenged by the need for sustainability. Hence, these HEIs confronted this global challenge by allowing them to introduce sustainability efforts on a day to day operations, and financial resources, and environment. Thus, these consequent events lead to the introduction of green efforts to attain sustainability (Ogundele and Laguador, 2017). To date, some universities focused on infusing green practices to gradually shift from traditional to sustainable activities (Commission on Higher Education, 2014). Furthermore, HEIs have recently started offering programs and relevant courses on sustainability. Likewise, the Sustainable Development Goals (SDG) was considered part of the HEIs' efforts to attain sustainability (De La Salle University, 2014).

3. METHODOLOGY

3.1. Multiple Case Studies

The goal of this study is to identify the GIT adoption practices by Philippine higher education institutions. This study employs qualitative approach through multiple case studies to explore on GIT phenomenon by exploring the experiences of the participants within the universities. Multiple case studies are preferred compared with a single case study as it offers a compelling, robust and intuitive approach to investigate GIT adoption phenomenon (Yin, 2013; Stake, 2013). Thus, it provides a comprehensive understanding of the emergence of GIT adoption practices, processes, and experiences of the participants.

GIT is adoption relatively new concept in higher education institutions in both developed and developing countries, thus, exploring the experiences of the participants is relevant to elicit a better understanding of the phenomenon. An interview is a widely accepted data gathering procedure in qualitative research. It offers in-depth information about the phenomenon involved. Thus, it allows gaining comprehensive insights about GIT adoption experience within higher education institutions. This study utilizes open-ended to semi-structured interview questions to allow the participants to freely communicate their ideas, thoughts, and opinions about GIT adoption within the organizations.

3.2. Questionnaire Development

The interview questionnaire was developed based on Yin (2013). There were two versions of the questionnaire, a detailed version of a guide of the interviewer, and a short version for the participants. The interview questionnaire covers three sections: (1) demographic profile of the participant, (2) background on GIT adoption, (3) practices and processes on GIT. The first version of the interview questionnaire was piloted to a single case study to reduce the risk that the interview questionnaire will not produce results. It also aimed to reduce the problems and biases, hence, ensuring that the questions were understandable to the participants. The first revision was meant to verify the appropriateness of wordings and relevance of the GIT adoption practices questions. Lastly, the final version of the interview questionnaire was validated by experts and used after the pilot test.

3.3. Data Gathering, Validity and Reliability

The Chief IT Officers or similar roles ranging from Management Information Systems Manager, Head of Information Technology Services, and or Senior IT Manager were interviewed as they play an es-

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

sential role in decision-making and implementation. Moreover, this study considered the participation of employees which had direct involvement and knowledgeable on the adoption of GIT practices within the higher education institutions. Thus, the participants with GIT adoption experience served as key informants during the data collection activities.

Table 1 presents the participating higher education institutions with program offerings specialization. This study involved three universities: (1) a university specializing in engineering education, (2) university with specialization information technology education, and (3) a university specializing in both engineering and information technology education. A short background of the universities selected is available in the Appendix. These universities were identified to have initiated sustainable practices through GIT adoption in the past three years.

Face to face interviews were conducted, and each interview session spanned 60-90 minutes. Each participant had at least three interview sessions, digitally recorded, and transcribed for analysis. Also, follow-up interviews were initiated to clarify the practices further, and cover all areas of GIT adoption. The interviews were conducted from June to November 2016. To address the reliability and validity of the data collected, the participants verified the transcribed data, the results, and conclusions drawn from all interviews conducted.

4. DATA ANALYSIS

4.1. Paperless Transactions and Digital Archiving Systems

The participants of University A revealed that 80% of their day to day business transactions ranging from academic systems, planning and monitoring of financial budget and spending, quality and knowledge management resulted in 65% paper reduction across all departments in the university. This paperless implementation was elaborated by the Chief IT Officer:

We have upgraded our software to allow integration of information and efficient collaboration. Now, we seldom print documents. Instead, we created PDF version, and use it for processing. It is more convenient, easy to maintain and mandatory for all us.

Table 1. Profile of participants

University	Participant	Year(s) in Position
A	Chief IT Officer	11 years
	Purchasing Officer	7 years
	Facility In-charge	4 years
B	MIS Manager	5 years
	Facility and Pollution Officer	9 years
C	Head of IT Services	6 years
	Purchasing Head	15 years
	Facility Officer	7 years

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

In University B, utilization of electronic systems was widely accepted as major GIT practice. Most of the work procedures were performed in electronic form, digital approval systems, and payments processing with suppliers were implemented in conjunction with electronic channels to reduce costs in handling business transactions with customers. Also, the university has been implementing digital archiving systems in the past three years to convert paper-based data and provide real-time access to information needed by the stakeholders of the university. This situation was described by the MIS Manager:

We have 80% work processes in digital format. Our employees are more aware about environment than before. I think, it's because of the of the climate change caused by carbon footprint in business. It leads to our decision to do our business online and taken seriously. We respond to it positively.

In University C, a major process streamlining effort was conducted to identify business process inefficiencies resulting 35% savings in human resource requirement, IT equipment, and associated costs. Similarly, the University also introduced the use integrated communication tools and video conferencing systems allowing more employees, students, and faculty members to engage in university-wide initiatives including online discussions on research project proposals with foreign collaborators, attendance to web-based technology-driven training, and participation in forums. It was elaborated by the Head of IT Services:

We always conduct process improvement, we try to throw away of inefficient process and make them streamlined. We are challenged to identify a business process concern which leads to inefficiency, and then solve it. For instance, we now have integrated communication systems, before, every communication was scattered in different software application. It's not making our work productive and inconvenient.

These efforts resulted in a change of attitude and behavior of the employees towards GIT adoption. This success was attributed to the top management support and strategic direction in achieving sustainability.

4.2. Resource Efficient IT Equipment

The interviews conducted with University A participants revealed a strong utilization of energy-efficient IT equipment. The university procurement policies and guidelines on IT equipment were changed to cover a necessary provision on purchasing IT equipment that conforms to energy-efficiency, allowable greenhouse gas, and related footprint. It was elaborated by the Purchasing Officer of the university:

I will continue to apply GIT and support it, as long as it adds value, and not harm our environment. We certainly prefer energy-efficient IT devices, as it brings more savings and fewer footprints.

In University B, the purchasing personnel together with planning officer were trained in assessing and evaluating electronic and IT equipment compliant with environmental regulations and standards. This effort resulted in the conversion of all old electronic equipment into efficient resource equipment, more specifically, this approach was made through a leasing agreement with a multinational equipment vendor. It allows the university to continually upgrade their IT equipment and related resources based

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

on newer environmental and energy standards, which resulted in 65 percent reduction in operating costs and better IT asset management in the university. This practice was explained by the Facility and Pollution Officer of the university:

Our employees are interested in GIT, as such, we are trying to do our purchasing using greener policies and standards. We are aware of the key benefits of green purchasing.

Similarly, University C confronted the need for resource-efficient IT equipment due to the rising electricity costs in the Philippines, as well as the growing energy-consumption of IT equipment through an analysis conducted. The university also significantly promotes the use of environment-friendly office equipment including multi-function printing devices, virtual fax, toner-saving solutions, and integrated IT asset management solutions. This action was transpired in one of the interviews with the Purchasing Head of the university:

…75% of our deployed IT equipment our Energy-Star certified. Some have energy-management software to take control of energy while achieving an optimum performance and lesser waste.

Also, the university widely accepted that transitioning to GIT to address sustainability can be achieved through the use of resource efficient equipment, and use of environmentally-friendly IT products. Most energy inefficient systems were retired, and data center cooling and airflow management were enhanced to apply newer standards in energy-efficiency. Thus, the university is more likely to prefer suppliers and vendors that have a green track record and offers end of life schemes, such as take back options.

4.3. IT Waste Disposal, Recycling and Reduction

In University A, the IT services team designed an IT waste disposal strategy to handle toxic and or hazardous components of electronic equipment sold or have reached its end of life. The university was providing an incentive program to employees for waste reduction. The employees were provided with e-waste bin in which they can donate and dispose of their IT waste regularly. This effort resulted in a growing recognition of the importance of responsible waste disposal among employees of the university. On the other hand, the organization performs a waste audit on a quarterly basis to monitor its potential environmental impacts and minimize wastes in the university. It was better explained by the Facility In-Charge of the university:

I know that there are environmental issues with regard to e-waste. I have been sent to trainings to gain knowledge about mobile devices, PC, and batteries, which have related environmental issues.

In University B, the employees were guided by the implementation of e-waste management policy aims to encourage active participation in waste reduction efforts in the university. The employees were a prime source of portable electronics, mobile phones, digital cameras, batteries, and laptops. The goal of this program is to achieve zero e-waste in all offices that are potentially harmful to the environment. This practice also offers convenience and accessibility to all employees to participate in the environmental awareness and education program of the university. It was highlighted by the Facility and Pollution Officer in one of the interview sessions:

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

At first, I am not aware of the hazards of e-wastes. Proper disposal of e-waste is necessary. We can destroy our environment, but, I can at least help by not throwing garbage anywhere.

In University C, a major GIT practice towards e-waste includes recycling through re-use of assets and consumables. The employees were all encouraged and practiced recycling to achieve major cost reduction and introduce change in handling e-waste in the university. Also, the university encourages the electronic distribution of bulletin of information such as university program offerings, tuition fees, and customer evaluation among others. In the past three years, an average of 65 percent of paper use was reduced, likewise, its toner solutions. It was explained by the Facility Officer:

Our employees understand very clearly the effects of using too much paper, before they don't care about it. We know at this time how to save it, instead of letting them in shredders.

More recently, the university implemented a waste reduction scheme through recyclable outlets positioned in the different areas of the university in which employees, students, and faculty members can donate used, damaged or unwanted electronic items for recycling. This scheme resulted in the enhanced participation of the university stakeholders in training the younger generation of students and employees in environmental sustainability and education.

4.4. Awareness and Environmental Stewardship

The environmental awareness and steward remains imperative to University A. The employees were provided with environmental sustainability training emphasizing individual's role in assisting the university in making a difference on environmental issues, for instance, reducing energy-consumption and waste disposal. Also, the university employs a dedicated officer-in-charge for sustainable use of IT resources to cover awareness and education efforts. Significantly, these initiatives contribute to change the employees' perspective towards sustainable environment behavior gradually. For instance, more employees are actively engaged in turning off or shutting down PC display screens during lunch breaks or shutting off for unused IT equipment. The Chief IT Officer elaborated on this matter during one of the interview sessions:

We are aware because of the training programs about energy-savings as part of our green IT practices. We participate to it seriously.

In University B, a structured environmental education program was launched two years ago. The goal of this program is to encourage all employees to actively participate in environmental stewardship, develop the necessary skills and attitude, and respond to the growing appreciation of sustainability goals in the Philippines, as initiated by the government. More specifically, an environmental leadership circle was commenced to serve as a platform to develop environmental leaders to work with the academic group including faculty members and students and community-based organizations with environmental sustainability agenda. It is a voluntary undertaking and full commitment from the employee. An environmental leader receives a certificate after demonstrating the desired outcomes of the program. It was elaborated by MIS Manager in the university:

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

We are more motivated by GIT as it definitely addresses environment concerns. We respond to it by attending seminars and workshops, and it was designed to capture our attention and apply it. I firmly believe, not all employees will agree with GIT, but, I see big change right now, they are more particular with GIT practices.

In University C, the environmental, safety and pollution group piloted the "Resources Rethinking," a web-based platform encouraging employees to facilitate the discussion of environmental sustainability approaches, issues, and challenges, and hold regular events relevant to environmental sustainability. For instance, this group initiated the development of a mobile application introducing e-waste collection system encouraging employees to dispose of e-waste more responsibly through an accredited e-waste collector, electronic equipment retailer or reseller visiting the university campus on a regular basis. The collected e-waste from the employees is converted to cash or redeemable points, an example of charge-back effort, as elaborated by Facility Officer:

Our awareness on e-waste was raised when saw e-waste bins in our campus. It was interesting that more employees disposit their e-waste, and prepare for e-waste collection. They also earn from it, and plus, they donate when possible.

This effort allows the employees to understand that they can contribute to a positive and significant change within their university and future communities. Moreover, a way to design action projects that offer real perspective for understanding environmental sustainability concerns within their community.

5. DISCUSSION OF FINDINGS

5.1. Paperless Transactions and Digital Archiving Systems

The three universities significantly adapt to paperless transaction processing as major GIT practice. Similarly, it reduces the number of papers for procurement leading to savings and enhances efficiencies on data processing requirements by stakeholders of the universities. Arney et al. (2012) found that paperless processing requires a major shift in digitally doing business. However, it brings positive impact not only reducing costs as well as to the environment. This study proved that the universities in the Philippines are striving to go for paperless transaction processing, therefore, setting the groundwork of other universities to adopt it, as the growing benefits become more observable and quantifiable within these universities. Hence, a major carbon footprint reduction is along with these efforts.

It is also found that user education on paperless processing and digitization efforts improved the efficiency of core business processes. Most organizations strategically highlight paperless processing to pursue new approaches of doing business, and harness the opportunities to communicate business ideas across multiple channels, and attract new customers, and increase revenue (Chen et al., 2012). Conversely, these efforts assisted the universities in workflow automation, document security, increase efficiency and immediate access to the most relevant data of the universities, decrease its environmental impact by eliminating unnecessary paper processing, therefore, reducing the carbon footprint.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

5.2. Resource Efficient IT Equipment

The results of the study indicate that the universities involved substantially deployed resource efficient IT equipment. These universities initiated the replacement of IT assets to increase the efficiency of management. All IT asset purchases were driven by the need for energy efficiency to help the universities monitor their energy consumption and green gas house emission, which is aligned with the GIT governance and management program. The results also revealed that there were rules related to purchase and use of environment-friendly IT equipment. Therefore, this IT equipment conforms to WEEE (Waste of Electrical and Electronic Equipment), Energy-Star, and or Restriction of Hazardous Substances (RoHS) which greatly consider the environmental impact while and after use.

Similarly, Jin et al., (2013) found in his study that server virtualization and use energy-efficient IT equipment is significant to realize reduced environmental impacts. The top management discussed GIT issues as a priority considering the concerns with environmental impacts of IT use, waste and green gas house emissions.

Also, the universities initiated efforts on energy-conservation through switching off unused IT resources, it is seen that the three universities have the culture of use of energy as per need and educates employees as prime responsible to conserve natural resources. Likewise, the universities also planned to sustain the energy-efficiency efforts by exploring options from suppliers through constant collaboration and communication of the universities IT equipment needs. Lastly, the universities encouraged extending the lifespan of IT equipment to maintain resource efficiency through scheduled performance maintenance audits and monitoring activities.

5.3. IT Waste Disposal, Recycling and Reduction

The results of the study indicate that IT waste in three universities was managed in a centralized and decentralized approach. First, each university IT services team conducts IT waste disposal through an accredited e-waste service provider to take account of all items disposed of. Second, employees were encouraged to participate in e-waste donation and collection campaign using the e-waste bins strategically positioned within the university premises. The universities also initiated resource reduction scheme through electronic data interchange systems to facilitate the major reduction of resources. Lastly, a more accountable approach to IT waste disposal, recycling, and reduction covers influencing all employees to actively involve themselves in awareness and education efforts to enhance personal responsibility towards GIT adoption. Hence, the universities were becoming more responsive to the need for conservation of natural resources needed to create an electronic equipment, and reduction of e-waste disposed to the natural eco-systems or landfills.

5.4. Awareness and Environmental Stewardship

The three universities managerial support and commitment towards enhancing awareness and environmental education considerably affects the attitude and behavior of the employees towards GIT adoption practices and processes. Most the participants revealed a formal system is in place to educate the employees on the effects of GIT adoption as sustainability effort to achieve economic, environmental and social benefits.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

The main emphasis of the awareness and education program is to enhance personal responsibility and commitment towards collective efforts on GIT adoption. Although Green IT is on infancy stage in the universities, individual support and commitment were significant in spurring efforts that further top management strategic actions in designing, implementing, assessing and evaluating relevant programs which were measurable through individual's contribution. Conversely, the awareness efforts remain acceptable across these universities. It could be attributed to the fact the positive attitude contributes to a rapid adoption of innovation. Bose and Luo (2012) state that attitude towards innovation signified similar positive actions and participation in innovation adoption. Therefore, by providing awareness and education programs considerably affects the perception of employees towards having a positive perspective towards GIT adoption.

6. IMPLICATIONS

6.1. Theoretical Implications

This study aims to explore the GIT practices of three universities in the Philippines. The findings suggest that GIT practices could further the achievement of sustainability goals of the universities. Thus, the results could be used to develop a conceptual model of GIT practices, and factors influencing its adoption. It could be used as an initial understanding and develop frameworks relevant to the Philippines, as an example of a developing country. Moreover, developing economies such as the Philippines have considerable economic and socio-cultural differences which may affect the rate of adoption in universities. Hence, it could give better insights as to how these factors, enablers or disablers influence the adoption of GIT in organizations. Also, this study was able to identify some links as to why the universities adopt GIT such as attitude, the formal structure of IT unit in the university, and managerial support. Thus, this could be further investigated from a theory perspective. Overall, this study contributes to theory building in many ways.

6.2. Practical Implications

Regarding practical implications, the findings of this study could be used to develop policies and guidelines toward the adoption of GIT across all higher education institutions in the Philippines. More specifically, it aims to accelerate GIT adoption level by allocating resources, designing more relevant approaches and strategies, applying standards, practices, and assessing its benefits and impacts in a more structured way. To date, the Philippine higher education sector is struggling to stay competitive; this study could lead other universities to initiate GIT as a university practice and tackle the participation of stakeholders in full implementation of widely accepted GIT practices.

Moreover, the Philippine higher education sector experiences a constant decline in global rankings of top universities as researches is not becoming a platform to improve the quality of education and likely limited. Hence, these universities could use GIT as a research area to explore its potential opportunities to enhance the quality of researches toward sustainability. Also, Institutional Sustainability Assessment (ISA) is becoming a standard for HEIs in the Philippines and a requirement by the Commission on Higher Education (CHED), thus, GIT adoption, an area of assessment could lead to exploiting the potentials and opportunities towards a more sustainable university through the development of relevant GIT agenda,

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

strategy, and assessment. More recently, the ISA framework introduced IT infrastructure and support services whereby green practices were embedded to shift from traditional delivery of instructions to using digital platforms such as e-learning and other forms of learning management systems.

7. CONCLUSION AND FUTURE WORK

This study aims to explore the GIT adoption practices of three universities in the Philippines. First, GIT adoption practices spanned in the areas of paperless and digital archiving systems, use of resource efficient IT equipment, responsible IT waste disposal, recycling and reduction, and awareness and education. These areas of GIT adoption practices insinuate that HEIs have started their efforts to green their practices and procedures, and responsibilities are defined within each GIT initiative. Second, HEIs adopt GIT to achieve its benefits and stay sustainable. However, a clear green agenda could strategically enhance its adoption to provide a comprehensive understanding of its challenges, opportunities, and directions. Lastly, there are considerable GIT practices. However, individual contribution is not measured and do not offer any substantial reward or incentive program to encourage full participation from all employees. Hence, GIT emerged as a practice and appear to achieve an initial stage of adoption.

Despite the contributions of this study to literature, it is also not free from limitations. First, the study explores GIT adoption in three universities within the Philippine context. The universities in the Philippines have different characteristics, IT infrastructure setup, program offerings, and commitment to sustainability, therefore, a study involving other universities with different GIT adoption and sustainability perspective would reveal additional insights on the current state of GIT adoption practices in higher education in the Philippines. Second, this study did not explore the internal and external factors which affect the rate of adoption in universities. For instance, regulatory agencies may have roles developing policies and guidelines, monitoring, and evaluation of universities in GIT adoption. By exploring on these factors, new insights could emerge regarding GIT adoption. Third, this study did not include students and faculty members of the universities. Thus, future work may elicit experiences of these participants to offer new insights in this emerging field. Lastly, this research only covered a limited number of case studies. Therefore, it is not generalizable for the Philippine context, although, the findings are interpreted carefully based on a relevant perspective. For future research, investigating GIT adoption in a more statistical approach could result in a GIT model covering the counter-intuitive or interesting experience of the universities in the Philippines.

APPENDIX

Profile of the HEIs

University A: One of the largest universities in the Philippines with an average of 25,000 students, both in the undergraduate and graduate levels. It specializes in engineering, science and technology, business, and education. The university has some programs recognized by international accreditation agencies. To date, it is one of only few universities in the Philippines that institutionalized sustainability framework and initiatives to respond to the need for reduction of energy-consumption, waste management, and natural resource conservation. The HEI initially developed a sustainability framework in which objectives, procedures and metrics are implemented across all organizational units and engage employees in GIT adoption.

University B: One of the only few HEIs in the Philippines with strong emphasis on sustainability. It is one of leading universities in the Philippines with a good research track and experts, employer reputation, and wide range of programs ranging from arts, social science, business, education, engineering and technology. The university started its sustainability efforts in 2013 by assigning a dedicated officer to handle GIT practices and initiatives within the university. A sustainability agenda was presented to the employees during its 1st year of implementation. University B also transitioned to the use of green building, to accommodate natural lighting, recycling of waste water, and use of solar energy as source of power. The employees were also involved with GIT practices such as digitization, e-waste donation drive, and consolidation of IT equipment and other related resources.

University C: has a good mix of local and international students, both in the undergraduate and undergraduate level. The HEI has an average of 38,000 students enrolled in various programs including science, arts, engineering and technology, education, business, agriculture, and marine sciences, among others. The university is one of the few pioneers of environmental management education, and have successful experience in implementing sustainability initiatives within the university and to its adopted communities, including coastal areas, low income communities with limited source of electricity, and partnered with government for waste management research and initiatives. To date, the university developed its sustainability framework aligned with the mission vision of institutionalizing green practices and initiatives. The university encourages research and constantly seeks external funding to work on green source of energy, waste management, and utilization of IT infrastructure and resources. It transformed from paper-based to digitized information management, accounting for 75% of its operations. To date, the university also proactively participates and supports the Sustainable Development Goals by the government and external parties, both private and public agencies.

This research was previously published in the International Journal of Sociotechnology and Knowledge Development (IJSKD), 9(3); edited by Lincoln Christopher Wood and Brian J. Galli; pages 1-16, copyright year 2017 by IGI Publishing (an imprint of IGI Global).

Chapter 64
Selecting Demolition Waste Materials Disposal Alternatives Using Fuzzy TOPSIS Technique

Mohamed Marzouk
Cairo University, Egypt

Mohamed Abd El-Razek
Arab Contractors Company, Egypt

ABSTRACT

This article describes how in developing countries, millions of tons of construction and demolition wastes (CDWs) are lost every year due to lack of knowledge of recycling significance and/or procedures. Despite the high value of CDWs, high percentage of this waste is either dumped illegally or disposed in the landfills. Disposal methods should consider saving natural resources and maintaining the environmental conditions through maximizing the value of CDWs. This article aims at choosing the most sustainable disposal alternative using Multi-Criteria Decision Making (MCDM) Process, considering several sustainability measure indicators. The research introduces a list containing the most relevant and significant sustainable indicators that affect the selection of alternative for disposal of CDWs. Then, fuzzy TOPSIS technique is applied considering the significant indicators on each alternative to rank and choose the best alternative for disposal of CDWs.

1. INTRODUCTION

In the developing countries, demolition wastes range from 20% to 30% of the total annual solid wastes (Al-Ansary, 2002), which can express how big the problem is. Construction and Demolition waste (CDWs) doesn't contain much hazardous waste compared to what found in municipal solid waste but CDWs still has its own problems. One of the major problems is the huge bulk of CDWs, without regard to the very long lifetime of CDWs which means occupied landfill for extremely long time before moldering of CDWs (Dantata et al., 2004). EPA (2002) has organized a composition for CDWs materials into a list of eight groups. This paper is concerned with only on the first group "concrete, bricks and tiles".

Peng et al. (1997) presented a hierarchy of CDWs managing options; including reduce, reuse, recycle, compost, incinerate and landfill. Reduce refers to any activity to avoid waste creation, Design stage is considered as the most effective stage in Project Life Cycle to implement waste reduction. At this stage, designer can consider using of re-usable materials or design a building with a long lifespan. Reusing is the next stage of waste management options; it can be described as using the same material more than once without the need for reprocessing. Recycling is the third option, which means the reprocessing of a reclaimed material and converting it into a new material or use. Composting is the next option; the term 'compost' refers to the organic material that can be used as a soil amendment or as a medium to grow plants. Incineration is considered the fifth option of waste management; the CDWs are burned to recover electrical energy or heat. Wood and plastic wastes are considered as the most applicable CDWs in this phase. The last option for CDWs management is a landfill. A landfill is a place where material is dumped as an end-stage.

Choosing the wrong alternative for demolition waste disposal will cause not only high economic losses, but also hazardous environmental and social impacts as well. That's won't be an easy task for decision maker, since it's affected by several indicators, for that reason MCDM have been introduced to aid the decision maker to choose the right decision. MCDM is a tool that can be implemented in optimizing the decision-making problems considering a number of criteria (Kahraman 2008). MCDM techniques have been developed long time ago. Nowadays, there is such a wide list of these techniques; each of them has its own features and weakness. Of the many MCDM methods, Technique for Order Preference by Similarity to Ideal Solution (TOPSIS) has been applied in different application areas.

TOPSIS method is a technique to evaluate alternatives' performance, considering the similarity with the ideal solution (Behzadian et al., 2012, Krohling and Campanharo, 2011). TOPSIS is capable to combine between different indicators with various units simultaneously (Ekmekçioğlu et al., 2010); However, TOPSIS in its standard form is deterministic and doesn't consider uncertainty which is considered as one of its main weakness (Gavade 2014). This encourages several attempts to introduce the term "Fuzzy/Uncertainty" in TOPSIS technique (Jahanshahloo et al., 2006, Jahanshahloo et al., 2009, Krohling and Campanharo, 2011). Determining the exact value for the elements of decision matrix (weights or performance values) aren't reachable in many practical cases as they pass through human judgments which could be vague or including fuzzy or interval data.

Uusitalo et al. (2015) have been reported that the uncertainty of environmental model outcomes needs to be estimated when they are utilized for decision support. The Fuzzy Logic Technique is based on the Fuzzy Set theory that has been proposed by Zadeh (Zadeh 1965). The membership function is used to assign a grade of membership which ranges from zero to one. In order to provide a better understanding of the theoretical foundations of the Fuzzy Logic, a comparison between ordinary (Crisp) set and fuzzy set shall be represented. In the Crisp Logic, variables are provided with the value: "true" or "false", black or white; however in real life applications there is a place for a gray zone which includes all of imprecise, uncertain, and vague data provided by human judgments. This gray zone can be described as Fuzzy Set. This paper proposes a modified fuzzy TOPSIS methodology to make a multi-criteria selection among demolition waste disposal alternatives (reusing, recycling into three different products, and landfilling). An application in the demolition waste disposal options area of Cairo is presented in order to demonstrate the potential of this methodology.

2. SUSTAINABLE INDICATORS

Flowchart of the proposed model is depicted in Figure 1. The indicators take into consideration for this study are summarized in Figure 2 and are described in more detail below. Figure 2 represents the three pillars of sustainable development, which include social, environmental, and economic aspects. These indicators/sub indicators are numbered from C1 to C15, and are classified into Objective Group and Subjective Group. Objective group deals with quantitative terms (can be expressed numerically), while subjective group represent the indicators that have been failed to be expressed as numerical numbers, and are expressed in terms of judgments instead.

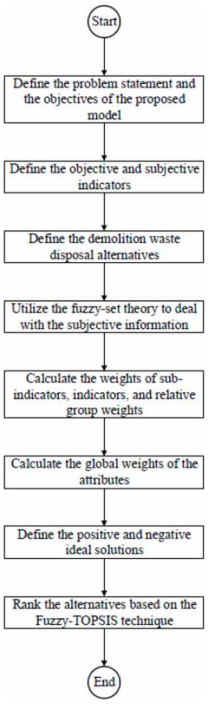
2.1. Objective Group

2.1.1. Energy Consumption

This indicator referred to the Total Energy that was consumed during the process of recycling/disposal of CDWs. It includes energy consumption in electric forms (e.g. electric equipment & crushing plants). Energy consumption can be obtained through Equation (1):

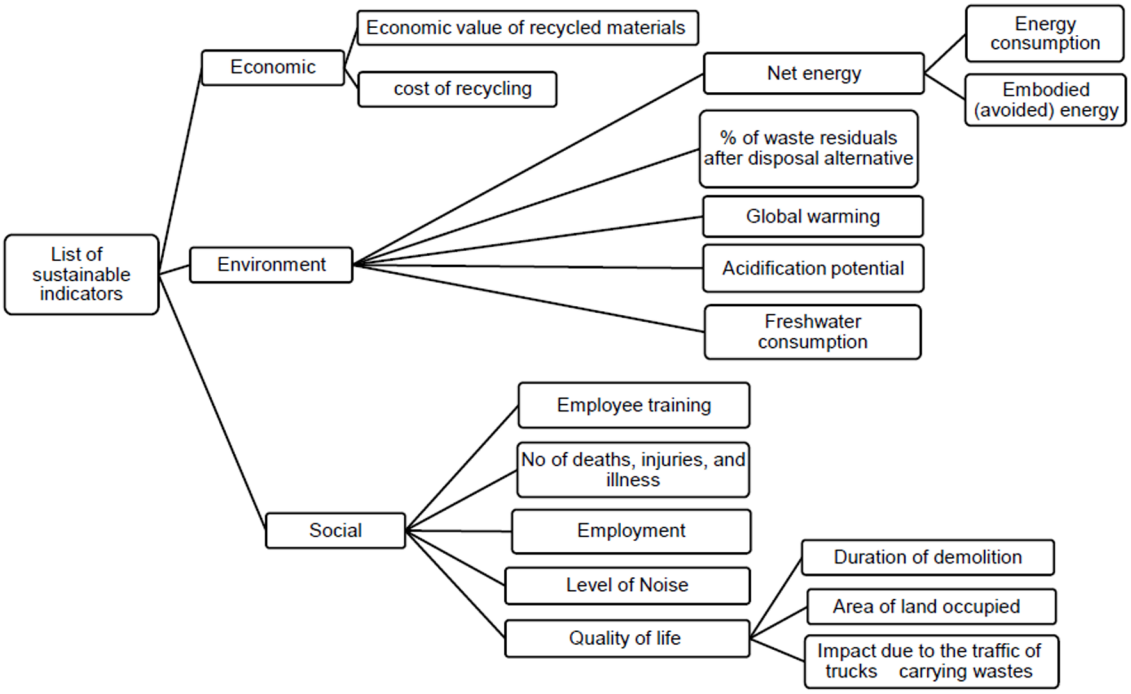
$$\text{Energy Consumption(mega joule)} = \text{Horsepower(hp)}*\text{duration})/(2.684) \quad (1)$$

Figure 1. Flowchart of the proposed model



EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. Indicators taking into consideration for sustainable disposal alternatives of CDWs



2.1.2. Avoided Energy Consumption

The Avoided Energy Consumption represents the avoided initial energy investment necessary for the construction products which includes: energy consumed in both forms of direct fuel and electricity consumption associated with raw material extraction and manufacturing, fuel consumption for transportation (Roussat et al., 2009). The Avoided Energy Consumption can be calculated using Equation (2):

Avoided Energy Consumption = Volume of Material*Embodied Energy (2)

2.1.3. Global Warming Potential

Greenhouse Gases warm the Earth by absorbing energy and slowing the rate at which the energy escapes to the space where they act like a blanket insulating the Earth (EPA, 2008). Global Warming Potential can be presented as kilograms of CO2 equivalents. It consists of the following three components of Equation (3) which can be found in (Petho et al., 2011, EPA, 2008):

CH4=0.5*Fuel Consumption (diesel)

N2O=0.22*Fuel Consumption (diesel) (3)

CO2=10.1*Fuel Consumption (diesel)

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

After introducing components of global warming potential, the following Equation (4) that is found in Acquaye and Duffy (2010) is used to calculate global warming potential:

$$\text{Total Global Warming Potential} = CO2 + (21*CH4)/1000 + (310*N2O)/1000 \quad (4)$$

where the unit of the equation is in (kg of CO2 equivalents).

2.1.4. Acidification Potential

Some compounds released in the air, for example (SO_2, NO_x) may be oxidized and transformed into rains. Then, the acid compounds are present in streaming waters and in watercourses resulting in a decrease in the pH-value of rainwater. This leads to significant damages on the eco-systems. The Acidification Potential is given in Sulfur dioxide equivalents (SO_2-Eq.) (OCED, 2005). Acidification Potential which can be presented as pounds of SO_2 equivalents consists of the following two components of Equation (5) that are found in (USEPA, 1995):

$$SO2 = 0.00205*\text{Power}*\text{Duration}$$

$$NOx = 0.031*\text{Power}*\text{Duration} \quad (5)$$

Equation (6) shows how to combine the foregoing two components as found in Veleva and Ellenbecker (2001):

$$\text{Total Emissions} = SO2+0.7*NOx \quad (6)$$

2.1.5. Duration of Demolition

Duration of Demolition is considered as a sub-indicator of "Quality of Life" indicator. Duration of Demolition represents the total time for a demolition activity which is considered significant since it takes into consideration the nuisances for the local residents due to demolition. Equation (7) shows how to calculate the demolition duration:

$$\text{Demolition Duration} = \frac{\text{volume of demolished material}}{(\text{productivity}*\text{no of crews})} \quad (7)$$

Impact due to the traffic of the trucks carrying the CDWs is an indicator that belongs to the "Quality of Life" group, which represents the traffic jams that could occur due to the passing of CDWs' trucks in the urban and inter urban area. Equation (8) is used to represent this impact (Roussat et al., 2009):

$$\text{Impact} = \text{Number of Trucks}*(\text{interurban distance} + 5*\text{urban distance})*10^{-4} \quad (8)$$

where, the factor (5) represents the ratio of population density between the urban area and the interurban area in Cairo:

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

$$\frac{\text{population density in Cairo City/km2}}{\text{population density in suburbs/km2}} = \frac{35000}{7000} = 5$$

2.1.6. Level of Noise

This indicator refers to the noise produced by various sources (labors/equipment) in different activities of disposal alternatives' processing (e.g. demolition process, size reduction process, crushing) which may lead to serious problems that affect both labor and resident health. The Level of Noise can be calculated through Equation (9) which found in Marzouk et al. (2008):

$$E\ Noise = 10\log\left(\frac{\sum_{i=1}^{n} 10^{\left(\frac{Li}{10}\right)}}{N}\right) \tag{9}$$

where 'E Noise' is equivalent to sound level; Li is noise level of source i at receptor point, and N is total number of sources. The List of noise level of different sources for Equation (9) can be found in (European Commission, 2006; Federal Highway Administration, 2006).

Economic Benefit Generated by Recycled is an indicator that aggregates all the benefits that could be generated from selling the recycled materials, economic benefit. The indicator can be calculated using Equation (10) given by Hsiao (2002):

Economic Benefits = Volume of Material * unit cost of recycled material (10)

In order to obtain the absolute benefit value, cost of land filling residuals after recycling shall be subtracted from the value of economic benefit for each alternative.

2.1.7. Financial Cost for Recycling Alternatives

This indicator aggregates all the possible costs which different alternatives could go through. It includes the following components (Zhao et al., 2009):

1. Annual Fixed Investment, which expressed the total investment of equipment including fixed equipment cost which can be obtained through price quotations. It worth to be mentioned that this cost shall be divided by the number of working years (6-7 years) in order to represent the annual fixed equipment cost, where:

Annual fixed equipment cost = 0.15 * Fixed equipment cost

Maintenance cost = 0.06 of Total equipment price

Insurance = 0.01 of equipment price

2. Electricity consumption

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

3. Fuel cost
4. Labor wages
5. Miscellaneous, Structural, electrical, starters, chutes
6. 6. Lab & office cost:

Cost for Recycling = Annual Fixed Investment + Electricity Consumption + Fuel Cost + Labor Wages + Miscellaneous + Lab and Office Cost (11)

2.1.8. Job Opportunities

This indicator represents the number of jobs provided through different disposal alternatives.

Percentage of CDWs residuals after disposal alternative is an indicator that represents the percentage of CDWs which could not return back to recycle after the initial processing due to contamination or improper size, and which goes directly to the land fill area.

2.2. Subjective Group

Subjective Indicators tend to have linguistic/ qualitative definition. The rest of sustainable indicators are considered subjective.

2.2.1. Fresh Water Consumption

This indicator refers to the estimation of Fresh water quantities used in the process of different disposal alternatives.

2.2.2. Area of Land Occupied

This indicator takes into account the diminishing land space due to the incremental quantities of demolition wastes which leads to increasing the area of landfill. It also takes into consideration the area needed for sorting, size reduction, crushing, and storage of the recycled products.

2.2.3. Average Number of Hours Used for Employee Training

This indicator refers to the number of hours that actually being consumed in acquisition the basic skills for trainees.

2.2.4. Probability of Occurrences of Injuries, Death

This indicator refers to the possibility of injuries between employees for different activities in various disposal alternatives.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

3. DEMOLITION WASTE DISPOSAL ALTERNATIVES

In this study, five demolition waste disposal alternatives specifically for bricks are presented through research (Sadek, 2008). Each alternative has different environmental, economic, and social consequences, eventually they are evaluated through the fifteen foregoing indicators. The demolition waste disposal alternatives are determined as reusing, recycled tennis surface court, recycled aggregate, recycled fill material, landfilling. These alternatives will be described briefly in Table 1.

4. FUZZY TOPSIS METHODOLOGY

A triangular membership function is considered as one of the most popular functions in representing fuzzy set problems, due to its simplicity and fast computation. Therefore, it has been chosen to be implemented in this research, but there are some important basic definitions based on recent work of Ding (2011) which are introduced first.

Definition 1: In a universe of discourse X, a fuzzy subset A of X is defined by a membership function $f_A(x)$, which maps each element x in X to a real number in the interval [0, 1]. The function value $f_A(x)$, represents the grade of membership of x in A.

Table 1. List of alternatives of the proposed model

Alternative Name	Alternative Description
Reusing blocks (A1)	In this alternative, walls are dismantling using an electric saw in order to maintain the condition of the brick unit for reusing, then a cleaning process is taken place to remove mortar residuals from brick units, after that loads of the cleaned bricks are transported to distributors (estimated distance = 25 km) while residual mortar are transported to landfill (estimated distance = 50 km). At the end of process, produced bricks can be packaged.
Recycled tennis surface court (A2)	Dismantling of walls and cleaning process tend to be manually, since there is no need to maintain brick units as long as bricks particles won't be contaminated, then loads of the cleaned bricks are transported to recycle center (estimated distance = 50 km), while residual mortar are transported to landfill (estimated distance = 50 km), after that a manual reduction of particles size is taken place before going to the crusher system. The next step brick particles are landed through loader into hopper, which transfers loads to the crusher through a conveying belt. The rate of crushing of this belt shall not exceed rate of crushing of the jaw crusher to avoid the jamming of the crusher. After crushing, the crushed bricks are transferred through the conveyor belt to the vibrating screen to separate the crushed particles from other particles. While bigger particles will be transferred back to crusher through third conveying belt, proper sized particles are transferred to milling process. The grinder of the European hammer mill is used with maximum inlet size of 40 mm and producing smaller size particles of 3 mm, which could be appropriate for producing tennis court surface.
Recycled aggregate (A3)	In this alternative, walls are dismantled manually, then loads of the demolished bricks are transferring to the recycle center (estimated distance = 50 km), after that a manual reduction of particles size is taken place before going to the crusher system, finally it ends with crushing process where the proper sized particles are transferred to storage facility.
Recycled fill material (A4)	The only difference between alternative A3 and A4 is that in recycled fill material there is no need for crushing process, since it has less restrictive specification about size control, so manual reduction of particles size will be sufficient.
Land filling (A5)	This alternative is considered the worst scenario since it's' salvage value equals zero. This research takes this alternative into account just to spotlight the volume of losses that occurred when the decision maker selects the wrong decision. It simply involves two actions, dismantling of walls manually, then transferring loads into landfill (estimated distance = 50 km).

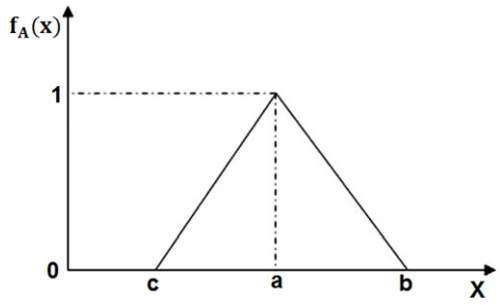
Figure 3. Triangular fuzzy number A = (c, a, b)



Definition 2: A fuzzy number A in real line $\Re$ is a triangular fuzzy number if its membership function $fA:\Re\to[0,1]$ is:

$$\mathrm{F(x)}=\begin{cases}\dfrac{x-c}{a-c} & c\le x\le a\\ \dfrac{x-b}{a-b} & a\le x\le b\\ 0 & \text{otherwise}\end{cases} \tag{12}$$

With $-\infty<c\le a\le b<\infty$. The triangular fuzzy number can be denoted by (c, a, b) as shown in Figure 3.

Definition 3: Let A1 = (c1, a1, b1) and A2 = (c2, a2, b2) be fuzzy numbers. According to the extension principle, the algebraic operations of any two fuzzy numbers A1 and A2 can be expressed as:

$$A1\oplus A2=\left(c_1+c_2,a_1+a_2,b_1+b_2\right) \tag{13}$$

$$k\otimes A2=\left(kc_2,ka_2,kb_2\right)\qquad k\in\Re,k\ge 0 \tag{14}$$

$$A1\otimes A2\cong\left(c_1c_2,a_1a_2,b_1b_2\right)\qquad c_1\ge 0,c_2\ge 0 \tag{15}$$

$$\left(A1\right)^{-1}=\left(c_1,a_1,b_1\right)^{-1}\cong\left(\frac{1}{b_1},\frac{1}{a_1},\frac{1}{c_1}\right)c_1>0 \tag{16}$$

$$A1\varnothing A2\cong\left(\frac{c_1}{b_2},\frac{a_1}{a_2},\frac{b_1}{c_2}\right)c_1\ge 0,c2>0 \tag{17}$$

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Definition 4: Let A1 = (c1, a1, b1) and A2 = (c2, a2, b2) be fuzzy numbers. Then, the Modified geometrical distance can be denoted by:

$$\delta_M\left(A_i + A_j\right) = \sqrt{\left[\frac{1}{4}\left(\left(c_i - c_j\right)^2 + 2\left(a_i - a_j\right)^2 + \left(b_i - b_j\right)^2\right)\right]} \tag{18}$$

The procedure for ranking alternatives using fuzzy TOPSIS methods follow:

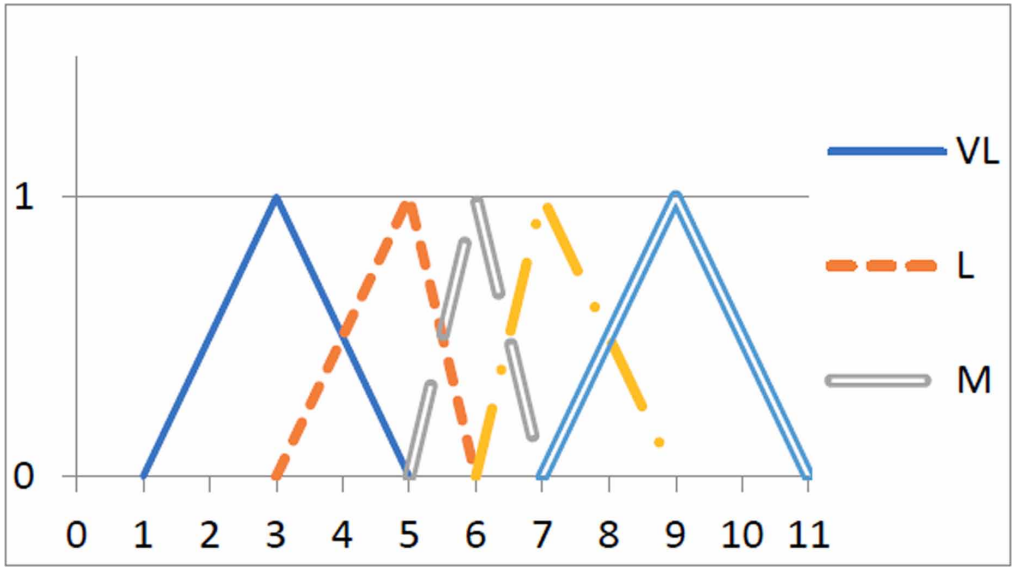
Step 1. Classifying the Sub-Indicators Above the Alternatives Layer Into Subjective and Objective Categories: Indicators are classified into Objective Group and Subjective Group, while objective group deals with quantitative terms (can be expressed numerically), the subjective group is for those indicators that have been failed to be expressed as numerical numbers, and will be expressed in terms of judgments instead.

Step 2. Computing the Global Weights of All Sub-Indicators Above the Alternatives Layer Through Applying the Analytical Hierarchy Process (AHP): The AHP is used to decompose the problem into a hierarchy of sub problems which can more easily be comprehended and subjectively evaluated. Global weights can be determined through multiply local weight by group's relative weight.

Step 3. Estimating the Superiority of Alternatives Versus All Sub Indicators: As mentioned earlier indicators that influenced alternatives selection are classified into subjective indicators and objective ones. The calculations of performance values for subjective indicators are differed from the objective indicators.

Case I. Subjective Indicators Calculations: The subjective indicators tend to be more of qualitative data, and there are no means for numerical measurements. Linguistic values (e.g. high, medium, and low) will be used instead. Triangular Fuzzy Numbers are used to express linguistic values as shown in Figure 4.

Figure 4. Superiority of alternatives versus subjective indicators



EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

As shown in Figure 4, Very Low (VL), Low (L), Medium (M), High (H), and Very High (VH) are the linguistic values, while the corresponding triangular fuzzy numbers for these linguistic values are Very Low (1,3,5), Low (3,5,6), Medium (5,6,7), High (6,7,9), Very High (7,9,11), respectively.

Case II. Objective Indicators Calculations: Estimating the superiority of alternatives versus objective indicators is implemented through numerical calculations and can be expressed by numbers, thoughfuzzy rates is essential to be applied for objective indicators, since it takes into consideration historical records or estimated values (Ding 2011). As an illustrative example of how fuzzy data can be implemented for the objective indicators, let x_1, x_2… x_n represent the quantities of demolition waste for different years, then the fuzzy rating of the quantities of the demolition waste could be used by the geometric mean method to express the fuzzy values (c, a, b) as shown below:

$$c=\min_i(x_i),\ a=\sqrt[k]{\Pi_{i=1}^{k} x_i}\ ,\ b=\max_i(x_i), \text{ where } i=1,2\ldots n, \text{ and } k=n \tag{19}$$

Step 4. Normalization of the Constructed Fuzzy Matrix: It is worth noting that fuzzy superiority (performance) values are converted to dimensionless indices in order to ensure compatibility between the fuzzy ratings of objective indicators and linguistic ratings of subjective indicators. The fuzzy ideal values with minimum values in negative (cost) indicators or maximum values in positive (benefit) indicators should have the maximum rating.

Based on the principle stated above, normalization can then be achieved through the following Equations:

In case of positive indicators, Equation 5-9 is utilized:

$$\text{Sij} = \left\{\frac{cij}{\alpha ij}, \frac{aij}{\alpha ij}, \frac{bij}{\alpha ij}\right\} \text{ where } \alpha ij = \max \text{ of } bij \text{ (for each criterion)} \tag{20}$$

For negative indicators, Equation 5-10 is utilized:

$$\text{Sij} = \left\{\frac{\beta ij}{bij}, \frac{\beta ij}{aij}, \frac{\beta ij}{cij}\right\} \text{ where } \beta ij = \min \text{ of } cij \text{ (for each criterion)} \tag{21}$$

Step 5. Calculating the Fuzzy Ideal Solution and Anti-Ideal Solution: In order to determine the fuzzy ideal and anti-ideal solution, there is a need first to defuzzify the fuzzy normalized decision matrix, since it would be simpler to compare between crisp values instead of fuzzy ratings. The Graded Mean Integration Representation (GMIR) Method is used to defuzzify the triangular fuzzy numbers. For calculating GMIR let S_i= (c_i.a_i,b_i), i.= 1, 2... m be a triangular fuzzy number. By the GMIR method, the (GMIR) R (S_i) of S_i is:

$$R\left(S_i\right) = \frac{cij + 4aij + bij}{6} \tag{22}$$

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

The alternative with max value of $R(S_i)$ or each indicator will represent fuzzy ideal value S_i^+. while alternative with min value of $R(S_i)$ for each indicator will represent fuzzy anti-ideal value S_i^-. Finally, define the fuzzy ideal and anti-ideal solution through the following Equations:

$$I^+ = \left(S_1^+, S_2^+, \ldots, S_j^+, \ldots, S_n^+\right) \quad AI^- = \left(S_1^-, S_2^-, \ldots, S_j^-, \ldots, S_n^-\right) \tag{23}$$

Step 6. Computing the Distance of Different Alternatives Versus the Fuzzy Ideal Solution and Anti-Ideal Solution: In order to obtain the distance between different alternatives and the fuzzy ideal and anti-ideal solution, the Global Normalized Weights of Indicators shall be taken into consideration. Let w_j (j = 1, 2… n) be the global normalized weights of (j) indicators that have been calculated through AHP technique; then the distance between alternative S_{ij} and the fuzzy ideal solution can be obtained by considering the weights of indicators into Equation (24) as follows:

$$Dj^+ = \sqrt{\sum_{j=1}^{n} \left\{ w_j^{\,2} * (\delta m\left(Sj^+, Sij\right))^2 \right\}} \tag{24}$$

where, by the same consideration, the distance between alternative S_{ij} and the fuzzy anti-ideal solution can be obtained using Equation (25):

$$Dj^- = \sqrt{\sum_{j=1}^{n} \left\{ w_j^{\,2} * (\delta m\left(Sj^-, Sij\right))^2 \right\}} \tag{25}$$

where:

$$\delta m\left(Sj^-, Sij\right) = \sqrt{0.25 * \left(cj^- - cij\right)^2 + 2 * \left(aj^- - aij\right)^2 + \left(bj^- - bij\right)^2}$$

Step 7. Calculating the Relative Approximation Value of Each Alternative: The relative approximation value can be obtained by calculating RAVi using Equation (26). The best alternative is the alternative that has the highest value of RAV_i, since it is the closest to the positive fuzzy ideal solution and the farthest away from the fuzzy anti-ideal solution:

$$RAVi = \left(\frac{d_i^-}{d_i^- + d_i^+} \right) \tag{26}$$

5. STUDY AREA

In Egypt, the daily quantity of Construction and Demolition (C&D) Waste has been estimated to be 10,000 tones. This is equivalent to one third of the total daily municipal solid wastes generated in Egypt

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

(Ansary, 2004); however most of this generated waste is not currently properly disposed. Egypt suffers from lack of data concerning quantities of CDWs and imprecise of the existing ones which may be either over exaggerated or less than expected. Furthermore, there is no available data for distribution of these quantities for different CDWs materials, which cause an obstacle for any attempts of using other disposal alternatives instead of landfilling.

A modified model was presented by El-Nouhy (2004) to estimate the general rubble is re-considered to give an approximate composition for different demolition waste materials in residential buildings. It's assumed that typical building consisted of 56 units with dimension (M*M), where the value of "M" ranges between "3, 3.25, 3.5 … 6" meter. As reported by CAPMAS (2011), there are about 220 buildings in average being demolished annually in Cairo. Using data from the estimation model and multiply it by (220) "number of demolished building" creates a wide breakdown of various materials quantities for different values of module size (M), however these values need to be more specific in order to be applicable in fuzzy TOPSIS technique. A Module Size of M equals 4.6 m, which is equivalent to average quantity of demolition waste is chosen to represent data from the estimation model along with the lower module size of M equals 3 m, and the upper size of M equals 6 m. these three values for module size (M = 3, 4.6, 6 m) are used as fuzzy rates for acquiring values of objective indicators against different alternatives.

Table 2 shows the annual quantities for demolition waste materials in residential buildings in Cairo for the forgoing module sizes (M = 3, 4.6, 6 m), however the main interest in this paper is brick quantities for different values of M.

6. RESULTS AND DISCUSSION

After determining the evaluation Indicators and the alternative set convenient for disposal of demolition waste, the steps of the modified fuzzy TOPSIS algorithm are executed. Indicators are classified into: Objective Group and Subjective Group. While subjective indicators include: fresh water consumption, area of land occupied, average number of hours used for employee training, and probability of occurrences of injuries, death and any other kind of accident, the rest are considered objective ones.

The second step is to compute the global weights of all sub-indicators above the alternatives layer through applying the analytical hierarchy process (AHP). Several research papers have been gathered to represent relative importance for the foregoing indicators. These relative weights are found in (Ekmekçioğlu et al., 2010; Bakhoum and Brown, 2012). Data gathered from those papers have been implemented through analytical hierarchy process to acquire both local weight and the integrated weight. First, sustainable indicators shall be divided into three groups: environmental, economic, and social. These groups are considered the first level of hierarchy, while indicators within each group represent the 2nd level; similarly sub indicators represent the 3rd level.

Table 2. Estimated annual demolished waste quantities (tons) in Cairo

Module (m)	Concrete	Steel	Brick	Tiles	Sand	Sanitary	PVC pipes	Wood	Sum
3	53774	4839	49116	8219	5322	172.5	65.1	4468	125,978
4.6	117984	10619	80550	18779	12513	172.5	65.9	8963	249,646
6	209893	18890	108055	31495	21289	172.5	66.3	14448	404,310

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

6.1. Calculation of Global Weights

There are six pairwise comparison matrices that represent the comparison among the three levels. Table 3 shows the local normalized weights or indicators/sub-indicators with their corresponding global weights, where global weights are calculated as per Equation (27):

global weights = (group relative weight*local weights)*subindicators weights (27)

As per Table 3, the weights of the three main groups, i.e., environmental, social, and economic indicators are the same. Global warming has the highest global weight in the environmental group with 9.9%. Accident hours sub-indicator has the highest global weight in the social group with 15.7%. The two sub-indicators in the economic group are of equal weight.

After acquiring indicators weights (eigenvector), there is a need to check consistency for comparison matrix through calculation of consistency ratio C_R. Saaty (2008) argued that, if C_R (A) ≤ 0.1, the pairwise comparison matrix is considered to be consistent enough. Consistency ratio (C_R) for all six pairwise comparison matrices is calculated and found to be in range "0 to 0.04", which are less than 0.10. Thus, the comparison results can be considered consistent and convenient for an AHP procedure.

Table 3. Overall weight distribution

List of Groups	Weights of Relative Group	List of Indicators	Local Weight	List of Sub-Indicators	Sub-Indicators Local Weights	Global Weights
Environmental	0.333	Energy	0.328	Consumption	0.5	5.5%
				Avoided	0.5	5.5%
		Acidification potential	0.077	Acidification potential	1	2.6%
		Global warming	0.274	Global warming	1	9.1%
		Waste percentage	0.264	Waste percentage	1	8.8%
		Water consumption	0.057	Water consumption	1	1.9%
Social	0.333	Job opportunities	0.115	Job opportunities	1	3.8%
		Level of noise	0.052	Level of noise	1	1.7%
		Training hours	0.115	Training hours	1	3.8%
		Accident occurrence	0.470	Accident occurrence	1	15.7%
		Quality of life	0.249	Demolition duration	0.2	1.7%
				Impact traffic	0.4	3.3%
				Land occupied	0.4	3.3%
Economic	0.333	Cost of disposal	0.5	Cost of disposal	1	16.7%
		Benefit from disposal	0.5	Benefit from disposal	1	16.7%

6.2. Estimation of the Superiority of Alternatives

Next step is to estimate the superiority of different alternatives against all indicators, a large fuzzy decision matrix (15x5) has been developed assembling all the fuzzy values of all indicators related to the five alternatives. This matrix is depicted in Table 4; indicators are classified into two groups: Benefit Group of indicators which includes (avoided Energy, Job opportunities, Economic value of recycled materials, and Training hours) and Cost Group that includes all other indicators.

To obtain the fuzzy ratings of objective indicators in fuzzy decision matrix, these calculations shall be implemented for the different values of estimated demolished brick quantities (49115, 80550, 108055 ton), which represents the minimum, average, and the maximum values of the module size (M) in the

Table 4. Fuzzy Decision Matrix (sustainable indicators versus possible alternatives)

Indicators	Reuse Blocks (A1)	Recycled Tennis Court Clay Surface (A2)	Recycled Aggregate (A3)	Fill Material (A4)	Landfill (A5)

estimation model. On the other hand, linguistic values are used to express superiority values of different alternatives versus subjective indicators. Table 5 represents the fuzzy normalized matrix, which is obtained by applying Equations 20 and 21 to the benefit and cost indicators' performance values that are listed in Table 4. After Normalization of the constructed fuzzy decision matrix, fuzzy TOPSIS technique is applied.

Fuzzy ideal and anti-ideal solution are determined through implementing Graded Mean Integration Representation (GMIR) method for defuzzication process, then alternative with max value of $R(S_i)$ for a certain indicator will represent the fuzzy ideal value S_i^+ for this indicator and vice versa.

By applying Equation (22) to the fuzzy values in Table 5, the different values of $R(S_i)$ are obtained, where fuzzy ideal solution will be the corresponding fuzzy values for R max of each indicator, and vice versa for the anti-ideal solution. Table 6 presents the calculated GMIR method and the fuzzy ideal/anti-ideal solution, respectively. Distances between different alternatives and fuzzy ideal/anti-ideal solution can be determined by applying Equations (24) and (25) which has taken into consideration the global normalized weights of indicators that have been calculated through AHP technique. Results for applying of this Equation are listed in Tables 6.

6.3. Ranking of The Alternatives

The final step in determination the rank of disposal alternatives for demolition waste is to obtain Relative Approximation Value (RAV). This could be implemented by applying Equation (26) on the values of Table 7. Relative Approximation Values (RAV) is used for ranking the suggested alternatives, where the higher value of *RAV* is, the better alternative will be, since it is closer to the fuzzy ideal solution and

Table 8. Ranking of demolition waste disposal alternatives

Alternatives		RAV	Rank
A1	Reuse Blocks	0.564	1
A2	Recycled Tennis Court Clay Surface	0.559	2
A3	Recycled Aggregate	0.412	3
A4	Fill Material	0.369	4
A5	Landfill	0.332	5

farther away from the fuzzy anti-ideal solution. Results of relative approximation value (RAV) for each alternative, as well ranking of these alternatives are represented in Table 8. The results indicate that the most sustainable (preferred) alternative out of the five suggested alternatives is the first alternative A1 (i.e. Re-using Blocks). These results contribute in strengthening the hierarchy presented by Peng et al (1997) of disposal options for C&D waste, which sets the reusing option in a higher rank, followed by recycling and land filling respectively.

7. CONCLUSION

This research is focused on waste materials resulted from the demolition stage of residential buildings. The first objective of this study is to present the indicators that measure sustainability between various demolition waste disposal alternatives. These indicators are taken into consideration the three clusters of sustainability development; Economic, Social, and Environmental aspects. The second objective of this study is to compare between different disposal alternatives in terms of sustainable indicators using fuzzy TOPSIS technique. TOPSIS method is particularly adapted for sustainable development problems, as it defines the ideal solution and anti-ideal one which represent the best and worst results against all indicators respectively, then it be used as a measure tool to express closeness of each alternative to ideal and negative ideal solution, however this study is used fuzzy TOPSIS to manage combination between all of imprecise, uncertain, and vague data provided by human judgments and objective results from equations. The results from fuzzy TOPSIS technique showed that the most sustainable (preferred) alternative out of the five suggested alternatives is Re-using. Also, it proves the superiority of reusing over recycling and for recycling over land filling. The current research can be extended to include more indicators and sub-indicators. Moreover, more demolition waste disposal alternatives can be investigated. Finally, other MCDM can be utilized and compared with the fuzzy TOPSIS such as grey relational analysis (GRA), Elimination and Choice Translating Reality (ELECTRE I), Preference Ranking Organization Method for Enrichment Evolution (PROMETHEE II), etc.

Chapter 65
Toward Achieving Environmental Sustainability in the Computer Industry

Nayem Rahman
Portland State University, USA

ABSTRACT

The computer industry has come under increasing scrutiny in terms of energy consumption, the carbon emissions and e-waste. Shipment of e-waste to developing countries where it is often disposed of in unsafe ways is another major issue. Organizations and individuals have a tendency to throw away or store their aging computer technology assets which is not environmentally sustainable and or cost effective. Implementation of an end-to-end computer and related products' sustainability management strategy by incorporating the reuse of existing technology can make a major impact on the environment. Computer industry sustainability management includes design and development of energy efficient computer products, refurbishing of computer assets, purchasing of green or refurbished components and providing sustainability metrics procedures. By implementing sustainability programs, organizations can contribute in reducing the amount of energy spent to develop new computer technology products, help in reducing carbon emission, keep e-waste out of landfills and recycle them. This paper discusses different aspects of sustainable computer industry program and proposes that computer makers take ownership of disposing of e-waste by following safety standards. The paper also proposes adopting reverse supply chain process for possible reuse, recycle or disposal of computers.

1. INTRODUCTION

The information technology (IT) industry accounts for approximately 2 percent of global carbon dioxide (CO_2) emissions (Gartner, Inc. 2007). About 75% of the ecological footprint comes from IT products usage and 25% constitute embodied carbon in IT products (The Climate Group, 2008). IT products include data centers, servers, personal computers (PCs), telecoms networks and devices, and printers. This paper limits the scope of this research to Personal Computers (PCs).

Research firm, Gartner, Inc. (2015) reported that worldwide combined shipments of devices (PCs, tablets, ultra-mobiles and mobile phones) for 2015 are estimated to reach 2.5 billion units, an increase of 3.9 percent over 2014. This projected number of computer device sold indicates how much energy would be consumed worldwide. This also references materials used to build these computer products. Energy consumption, carbon emissions, natural resources consumption and landfill of computers (after end of life) are the key concerns. Given the intensity of natural resources and energy consumption by computer products indicates the need for the computer industry to be environmentally sustainable.

The term sustainability has been defined in many different ways by different people, institutions and organizations. One widely accepted definition is from the Brundlandt Report, "sustainable development is the development that meets the needs of present without compromising the ability of future generations to meet their own needs" (World Commission on the Environment and Development, 1987). Sustainability is "a characteristic of a process or state that can be maintained at a certain level indefinitely" (Jabareen, 2008). The major driving force for sustainability is the public concern about the environmental impact of the present fossil fuel based energy system (Rahman and Akhter, 2010). We need to satisfy our needs by judiciously using renewable resources, recycling wastes, and reversing environmental degradation (Duan et al. 2009).

Sustainability starts from a sustainable design. Sustainability can and should be a central focus of interaction design (Blevis, 2007). A sustainable approach to design and engineering involves evaluating where a product or system has the greatest environmental impact and then prioritizing strategies which reduce that impact (Gaughran et al. 2007). Intelligent manufacturers must take into account all the indicators of energy demands and supply in planning their chain supply, and processing strategies. All these apply to computer products. Reduction of waste including energy waste shows not just corporate responsibility, but is also seen to make sound economic sense (Gaughran et al. 2007).

Nidumolu et al. (2009) assert that sustainability should be taken as one of the main drivers of innovation. Instituting sustainability starting from design (sustainable products and services) helps a company to be compliant with regulations enforced by countries in different regions. In fact forward looking companies take compliance as an opportunity to make their products follow regulations set by countries globally. They add sustainability to value chains – supply, operations, and returns (reuse returned products).

Our research was based upon a few questions. Can the computer industry improve environmental sustainability to help contribute to a greener planet? Where do computers go after end of use? Are they recycled or hoarded or go to landfill? To answer to these questions, we did an extensive review of existing literature. We went through research and industry papers written by researchers, practitioners, and environmental sustainability advocacy group. Based on insights drawn from academy and industry papers we propose measures that needs to be adopted to achieve sustainability in terms of environmental, energy and material consumption.

2. LITERATURE REVIEW

The computer industry is an important area from an environmental sustainability standpoint. Sustainability has been a research topic for more than three decades. The research is mostly related to ecological, economic and social aspects of sustainability. Tukker (2003) suggests there is the potential of CO_2 reduction from household consumption by fulfilling final consumer needs by Product-Service Systems (PSS).

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Edward Deming (Neave, 1990) advocates the understanding of change through the System of Profound Knowledge (SOPK). He professes that the prevailing style of management must change and is necessary but not sufficient. We must understand what changes to make. To understand what and how to change one first needs to understand the subject matter in terms of theory. Deming maintains that without comprehending the theory there is no comprehensive knowledge to effect change to the environmental problems related to the computer industry. In this paper we may think of computer industry's product life cycle analysis in terms of systems thinking, which is a unique approach to problem solving, in that it views certain 'problems' as part of the overall system so focusing on these outcomes will only further develop the undesired element or problem. A comprehensive systems approach is proposed by Fiksel (2006), to better understand the dynamic, adaptive behavior of complex systems and their resilience in the face of disruptions.

Krajnc et al. (2008) discuss the cultural influences and barriers to the rational use of energy. The suggestions for reducing energy consumption come mainly from a technical innovations standpoint, but there is also a need to pursue all other possible approaches to tackle this problem. Sustainable consumption is a link between economic prosperity and resource conservation. In rich countries, the population needs to build a habit of adequate consumption as opposed to excessive consumption. It does not make sense to have a computer connected to power outlets on a twenty four by seven basis. Education has been given a crucial role when shifting from unsustainable to sustainable consumption patterns (Krajnc et al. 2008).

Advances toward sustainability will require system specific metrics to assess both current performance and the impact of operational, technological or regulatory changes on that performance (Rahman and Akhter, 2010; Atlee and Kirchain, 2006). Currently, there are few operational metrics by which to practically assess progress toward sustainability. We think that there are opportunities to use reliable performance indicators towards achieving sustainability in development, manufacture, and use of computer products (Rahman and Akhter, 2010).

In order to reduce environmental footprints caused by computer industry business organizations need to embrace strategic transformation which includes business model development, redesign of business processes (Sherringham, 2011; Ghose et al., 2009), and development of effective communication of environmental improvement activities within industry (Parker et al., 2010). Banerjee et al. (2013) propose a theoretical framework that includes management, technological, marketing, financial and regulatory elements as part of motivations to have non-green organizations in adopting green information and communications technology (ICT). For smaller organizations Capra et al. (2013) propose achieving green objectives with a more incremental approach to deal with infrastructure and significant upfront investment requirements. Kongar (2010) proposes Data Envelopment Analysis (DEA) model to calculate and rank the technical efficiencies of conventional and alternative green initiative-based energy sources by taking into consideration such factors as economies of energy sources and other environmental criteria including CO_2, emissions and damage cost.

Mouchet et al. (2014) propose using carbon footprint auditing tool for individual ICT organizations which can motivate them and support decision making to adopt sustainability activities. Their research also called out the need for consistent management of hardware in ICT organizations. Philipson (2011) reports that most organizations are unable to identify which areas to address to achieve environmental sustainability. To help ICT organizations achieve green ICT sustainability the author proposed a comprehensive green ICT framework consisting of four pillars including lifecycle, end-user-IT, enterprise and data center IT and IT as a low-carbon enabler. Then he proposes five dimensions including attitude, policies, practices, technologies and metrics under each of those four pillars. Adopting this framework would encourage organizations to measure and compare metrics among one another.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Rahman and Akhter (2010) propose a comprehensive sustainability metrics against which ICT organizations could measure carbon footprint reductions activities and capture benchmarks. Fostering such comprehensive metrics will allow organizations to measure and compare metrics amongst one another. Pradhan (2011) propose leveraging ISO standard in carbon footprint assessment. The ISO 14001 helps an ICT organization to maintain an environmental management system (EMS) to plan, execute and review environmental performance.

Verguts et al. (2016) propose utilizing industrial symbiosis as sustainable development strategy. "Industrial symbiosis (IS) is the coordination of energy and material flows among geographically proximate firms to increase economic performance while reducing environmental impact" (Verguts et al., 2016). Muduli et al. (2016) propose that green supply chain management minimize wastes and emissions and enhance performance. Metaxas and Tsavdaridou (2014) report that CRS was adopted amongst some European companies to tackle issues of recycling, environmental pollution, energy conservation, and environmental education.

Lindahl et al. (2016) propose an analytical framework for exploring pathways to sustainability. They propose five steps towards exploring pathways: identify actors, explore actors' frames, explore actors' activities, analyze institutions and governance, and explore alternative pathways to sustainability. Galia et al. (2015)'s study indicate that investment in environmental innovation is influenced by internal factors of the farm. These factors include size, performance, training, cooperation and openness that contribute to significant impact on green innovation. Bradford and Saad (2014) suggest that absorptive capacity is a key that speaks for a firm's ability to recognize the value of, acquire, internalize, and exploit external new knowledge and apply.

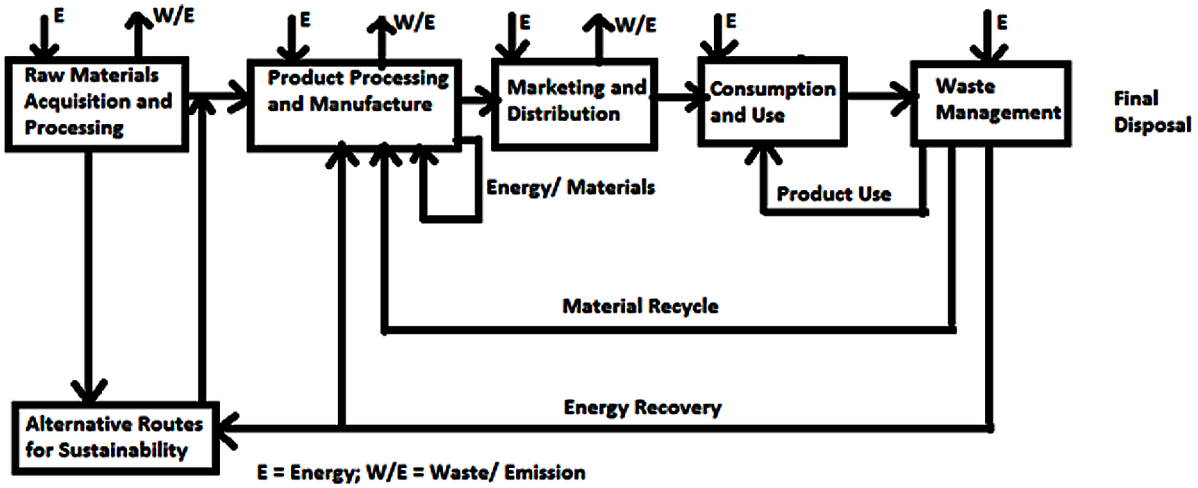
3. SUSTAINABILITY OF THE COMPUTER INDUSTRY

In order to achieve sustainability PC makers have been adopting different active programs including recycling, sustainable manufacturing, and compliance regulations of foreign countries. For example, Dell has programs to reduce hazardous substances in its computers while a global consortium of computer companies, including AMD, Dell, IBM, and VMware made an alliance with the goal of improving energy efficiency in computers and data centers (Kurp, 2008). Nonetheless, societies and governments are concerned about increasing environmental impact of energy usage, carbon footprints and toxic waste caused by computer industry given computer usage has significantly been in increasing all over the world (Cater-Steel and Tan, 2010; Araujo, 2012). Computer industry needs to come up with comprehensive measures to address environmental concerns (Rahman and Akhter, 2010; Murugesan, 2008). Measures need to be taken to decrease the use of toxic-heavy metals and technology innovation is needed to reduce energy consumption (Son et al., 2016).

In computer industry sustainability programs include actions to reduce the use of physical resources, the adoption of reuse, refurbish and recycle programs, the use of renewable rather than deplete-able resources, the redesign of production processes and products to eliminate the production of toxic materials, the protection and restoration of natural habitats and environments valued for their livability or beauty. Figure 1 shows energy consumption and e-waste/emission points of a product's life cycle. Measures need to be taken in each of these phases to ensure environmental sustainability.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. Examples of process loops identifying sustainability pathways (Culaba and Purvis, 1999)



A desktop uses about 600 kWh and emits 175 kg of CO_2 per year (energyguide.be, 2016) when it runs for eight hours a day. On the other hand a laptop that is on for eight hours a day uses between 150 and 300 kWh and emits between 44 and 88 kg of CO_2 per year (energyguide.be, 2016).

The U.S. Environmental Protection Agency (EPA) (2016) has Energy Star programs that strengthen requirements for computers earning the Energy Star certifications. In order to certify computers and workstations as energy efficient these products must meet maximum power consumption requirements. To be compliant with energy use guidelines the computers must have "off" and "idle" operations. EPA gradually sets stringent requirements for computers to be ENERGY START certified. Computer manufactures have motivation in getting this certification for their products as it helps in product marketing and promotion. The EPA estimated that if all computers that are sold in the United States were Energy Star certified that would incur a savings of more than one billion dollars energy costs per year. That would also prevent about 15 billion pounds of annual greenhouse gas emissions.

The U.S. Environmental Protection Agency (EPA) should have computer life time standards for PCs to ensure PCs could be used for at least five years. The EPA also needs to enforce other important requirements such as amount of toxic content a PC might emit and percentage of materials that could be extracted for re-use or recycling.

3.1. The Material Aspects of Sustainability of the Computer Industry

Life-cycle analysis (LCA) studies show that manufacturing and use of computer devices are of the highest environmental importance. Manufacturing devices such as the integrated circuits (ICs) and the Liquid Crystal Display (LCD) are contributing most to the environmental impact (Duan et al, 2009). To achieve ecological sustainability the design aspects of PCs need to be continuously evaluated. Currently, computers have life span as low as 2-3 years (Rahman and Akhter, 2010; Kahhat and Williams, 2009). The expanding user base of computers and continual buying of new computers every two or three years prevents society from reaching ecological goals.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

What percentage of energy savings is achieved through energy efficiency measures? How much increase of efficiency is achieved in PCs? How much savings achieved through process redesign and exergy analysis in the LCA? All these initiatives by PC makers could speak for proactive efforts to improve energy efficiency through technological improvements of processes (Rahman and Akhter, 2010).

AT&T, Advanced Micro Devices (AMD) and Cisco are transitioning from excessive consumption to impressive designs to take advantage of potential improved business opportunities. As a result these companies are bringing productivity leaps to the non-digital economy. AMD expects a 2,500% gain in energy productivity for its computer processors by 2020 (Shireman, 2015). In each phase of manufacturing process energy efficient design and reusability must be adopted. Most of the computer parts must be made so that they are reusable and recyclable. Computer life-time needs to be increased from 2-3 years to at least five years. To achieve that goal computer parts must be made of good quality. Computer manufactures might want to consider standardizing the product parts.

Not everyone will be willing to give up the materialism that drives unsustainable behaviors. Therefore, design must influence more sustainable consumption and the computer industry must find tools that can allow designers to do so. They must embrace principles of designing according to the perspective of sustainability. Blevis (2007) proposed a set of design principles that include linking invention and disposal, promoting renewal & reuse, promoting quality and equality, de-coupling ownership and identity, and using natural models and reflection. To minimize the environmental impact of e-waste all efforts must be made to increase useful materials recovered from the waste before it goes to landfills. Design for environmental (DFE) tools need to be used for creating products which makes it easy to recover, reuse, or recycle PCs. This type of tools help in examining environmental effects during design phase (Hart, 1997). PC makers need to have a sustainability vision that will promote product stewardship, pollution prevention, and efficient technology to move them toward sustainability.

3.2. E-Waste of Computer Products

Industrial nations are shipping millions of obsolete computers to developing countries which has been causing ever-growing set of global environmental change (Rahman and Subramanian, 2012; Williams et al., 2008; Nnorom and Osibanjo, 2008b). Some companies (both exporting and importing) might consider it a significant business opportunity, given the volumes of e-waste being generated and the content of both toxic and valuable materials in them. The fraction including iron, copper, aluminum, gold and other metals in e-waste is over 60%, while pollutants comprise 2.70% (Widmer et al. 2005). Developing countries are becoming environmentally polluted very fast. Iles (2004) proposes an environmental justice approach that will help illuminate the impacts of technology and material flows. The author advocates a framework that takes into consideration global production systems, development models, and regulatory actions (Iles, 2004).

Given the developed countries use poor countries as a dumping place for the obsolete computers the author proposes that exports from the developed to the developing world be completely banned. This notion is supported by other researchers as well (Kahhat and Williams, 2009). One compelling reason for this ban is that in developing countries e-waste is not disposed of properly. A good number of researchers reported that in those countries they do ‘informal’ recycling’ or ‘backyard’ recycling which causes potential emissions of toxics from disposal in poorly managed landfills and impacts workers and communities involved. (Williams et al., 2008).

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Despite excessive consumption of energy and materials, in developed countries the levels of pollution are relatively low (Hart, 1997). This is because of stringent environmental regulations, the greening of industry, and the relocation of the most polluting activities (such as commodity processing and heavy manufacturing) to the developing nations. Hart (1997) called out that this greening of the developed world is at the expense of environmental degradation in developing countries. On the other hand, Meadows et al. (2004) reported that "environmental degradation often affected the poorest groups in society, as they were unable to protect themselves from the environmentally destructive activities of richer and more powerful people."

According to Electronics Takeback Coalition (2014), in 2010 423 thousand tons (51 million units) of computers were disposed of out of which 255 thousand tons (31 million units) were trashed and 168 thousand tons (20 million units) were recycled. That means only 40% of those computers were actually recycled and the rest ended up in landfills. On the other hand, 595 thousand tons (35 million units) of monitors are disposed of, 401 thousand tons (24 million units) trashed and only 194 thousand tons (11 million units) of monitors recycled (recycling rate, 33%). A report by the EPA (Skye, 2016) shows that by 2010 computers and other e-waste consisted of 70% of heavy metals found in U.S. landfills. EPA report stated that computer and other electronics are fastest growing types of waste in the U.S.

Keeping electronics out of landfills is recommended by the EPA since they contain materials such as lead, nickel, cadmium and mercury which can be a risk to individuals' health as well as the environment (Moss and Scheer, 2015). As for laptops, recycling one million of them could save energy equal to the electricity used by 3,657 homes a year. Recycling one million cell phones would save us 35,274 pounds of copper, 772 pounds of silver, 75 pounds of gold, and 33 pounds of palladium (Moss and Scheer, 2015).

E-waste can be minimized by increasing recovery from the waste stream through reverse supply chains (Kahhat and Williams, 2009; Williams et al., 2008). "Reverse supply chain is a process by which a manufacturer systematically accepts previously shipped products or parts from the point of consumption for possible reuse, remanufacturing, recycling, or disposal" (Rahman and Subramanian, 2012). The domestic reverse supply chain of PCs takes into consideration extensive collection, reuse, and recycling (Kahhat and Williams, 2009). Ravi et al. (2005) propose determining the "key reverse logistics variables, which the top management should focus on to improve the productivity and performance of computer hardware supply chains."

Research suggest that availability of resources, coordination and integration of recycling tasks and the volume and quality of recyclable materials, are critical for computer recycling operations (Rahman and Subramanian, 2012). Studies emphasize on on-site waste minimization and associated sustainability characteristics in relation to environmental impact assessment and process improvement (Culaba and Purvis, 1999). One way of minimizing the environmental impact of e-waste is to increase the amount of product materials recovered from the waste stream through recycling operations (Rahman and Subramanian, 2012).

Formal recycling of e-waste using efficient technologies and state-of-the-art recycling facilities are rare in most of the countries of the world. Most of the countries of the world including developed countries adopt some inappropriate methods after their life span. These include holding them in closets of the house (health hazard), backyard of the house, and disposing in open dumps or surface waters (Nnorom and Osibanjo, 2008a). Similarly, there is no integrated framework regarding the monitoring and management of toxic and hazardous materials and wastes in underdeveloped countries (Nnorom and Osibanjo, 2008a).

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

There needs to be an easy system of computer disposal to encourage users to sell or trade-in their computer products in a timely manner so they can be refurbished and used for another few years before they are transformed into raw materials (Nealson, 2015). Recycling of these items could be the last option. Back in 2010 Americans disposed about 384 million consumer electronics according to EPA (Nealon, 2015). Some of these materials contain hazardous materials such as cadmium, lead, and mercury. This is an issue because these toxics can leak from the electronic devices and enter drinking water supplies.

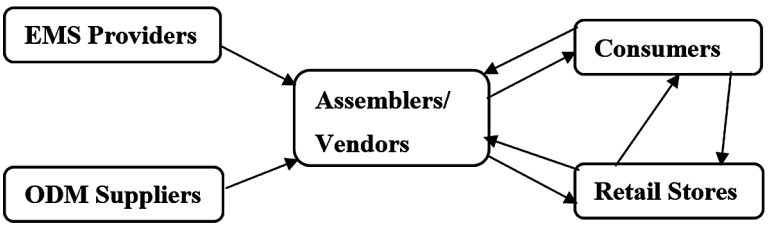
Governments of each country must promulgate required laws and enforce them strictly. The first and foremost law could be to make it compulsory that computer manufactures have to take responsibility for collecting their end-of-life items from the users. Rules and regulations need to be adopted to compel computer stores (retail, wholesale, etc.) to receive end-of-life from users. That way users are expected to deposit their end-of-life items to stores which will eventually be collected by computer manufactures to perform proper disposal such as reuse, refurbish and recycle. Manufactures have obligations to retake and dispose of. Kahhat et al. (2008) propose a solution for e-waste that will be electronically registered and tracked via a radio-frequency identification device (RFID) placed on the product." Figure 2 shows paths to return end-of-life computer products to assemblers/ vendors as part of reverse supply chain program.

Computer makers get their laptops built by contract manufacturers (CM), original design manufactures (ODM), or Electronic manufacturing services (EMS) (Akhter and Rahman, 2014). The top ten ODM companies include Pegatron, Quanta Computer, Compal Electronics, Wistron, Inventec, Lite-On Technology, Cal-Comp Electronics & Communications, Qisda Corporation, MiTAC Holdings, and Wistron NeWeb. Leading EMS companies include Foxconn, Flex, Jabil, FIH Mobile, Sanmina, Celestica, Advanced Semiconductor Engineering, Plexus, Benchmark Electronics, and SIIX. Most of these ODM and EMS companies are located in China and the rest are in other Asian countries including Taiwan.

State governments might employ auditors to audit the disposal processes of computer manufactures. This is expected to help significantly in reducing environmental emission, pollution and health hazards. It is reported that Best Buy, an electronics retailer, offers a complete appliance and electronics recycling program in America (Moss and Scheer, 2015). Best Buy offers free recycling and accepts all appliances, regardless of where they were purchased. This indeed speaks for corporate social responsibility.

To achieve sustainability individual companies, government agencies, and industry groups need to collaborate and provide recommendations on best practices, metrics, and technologies that will improve PC and data centers' energy efficiency" (Kurp, 2008). Sikder (2007) proposes considering sustainability in terms of global, regional, institutional or business, and technological sustainability systems. Global sustainability should take care of issues that involve multi-national efforts. Regional systems are meant to resolve sustainability at local level using regulatory means. The institutional or business

Figure 2. High-level flow of end-of-life PC's return to assemblers/vendors



EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

system should tackle multinational and local issues via legal and ethical framework of the institution or business organization. Technological sustainability systems should address sustainability concerns by product stewardship and process improvements (Sikder, 2007). Morelli (2011) suggests that achieving regulatory compliance should be the critical role of the environmental manager in industry. Research suggests that government legislation compels computer makers to take environmental sustainability efforts. Due to regulations in Australia computer makers such as Dell and Toshiba, two original equipment manufacturers entered into strategic alliance in order to reducing e-waste by implementing reverse logistics processes to end-of-life (EOL) computers (Rahman and Subramanian, 2012).

4. SUSTAINABILITY AND CONSUMER HABITS

To achieve complete sustainability in the computer industry, efforts should be made to not only make improvements in extraction, manufacturing, and distribution, reuse and recycle but also in consumption patterns. A complete ''sustainable consumption'' policy should not only include ecological but also social aspects. Purchase limit of computer products per family needs to be considered. Computer products need to be turned off when not used. It would not be enough to minimize energy consumption at production level, while allowing it unrestrained at the consumption level. Keeping computers turned on twenty-four-by-seven cause huge energy consumption. These habit needs to be changed. A social movement is needed to encourage private and public offices and individual citizens not misuse energy.

"Does technological innovation to improve the efficiency of energy-using products and systems lead to lower energy consumption and hence reduced environmental impacts? The answer given by economists since the mid-19th century is 'no'" (Herring and Roy, 2007). This means that energy consumption reduction efforts by PC makers is not enough. Similar effort needs to be made from consumer side as well to make sure computers are not turned on unnecessarily and thus avoid excessive energy consumption. PC makers' promoting technical innovation to reduce energy consumption and emissions will be defeated unless consumers show certain degree of responsibility and sustainability measures. Experts in this field suggest that other policies such as taxation or regulation are required (Herring and Roy, 2007; Zaccai, 2008).

In 1994, at a Norwegian government hosted symposium on 'sustainable consumption' Gro Harlem Brundtland reported in her keynote address that: "An average person in North America consumes almost 20 times as much as a person in India or China, and 60 to 70 times more than a person in Bangladesh. It is simply impossible for the world as a whole to sustain a Western level of consumption for all." (Meadows et al., 2004).

"Capitalism, notoriously, depends on the creation of new desires and new markets for its dynamic." (Meadows et al., 2004). Kopnina (2016) observed that, "environmental unsustainability is due to both structural features and historically specific characteristics of industrial capitalism resulting in specific patterns of production and consumption." The author also reported that sustainability literature is critical of the established corporate and political power hegemonies that are interested in maintaining economic growth, but on the other hand individual citizen-consumers are compromising with that by virtue of not taking counteract measures or being ethical enough to address unsustainability (Kopnina, 2016). Suki (2015)'s research findings based on a survey in Malaysia found consumers are supportive of environmentally sustainable products or green products.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Panchal and Moschandreas (2015) emphasize that public literacy is an important factor of sustainable development. They identify three domains of responsibility for sustainability: global responsibility (national governments) local responsibility (state, city or municipality governments), and individual responsibilities (individual citizens, non-experts). In regards to individual responsibility the authors assert that, sustainability is not all about technology and regulations. Regulators and scientists alone cannot achieve global sustainability. Non-expert individuals, the majority of citizens, must be drawn in to understand their responsibilities and act accordingly (Panchal and Moschandreas (2015).

El Idrissi and Corbet (2016) propose the idea of modernity perspective of green IS research in which one of the patterns includes the importance of individuals' participation in solving environmental sustainability issues. The authors suggest that, "individuals' comprehension of the impact of their behavior is as important factor in moving toward a more sustainable future." Foth et al. (2009) compare environmental responsibility into issues of personal moral choice which should start at the point of consumption (for example, in the supermarket). An organizational level consumption should be measured and be compliant with sustainability. For example, "Intel IT is engaged in developing a broad, ongoing sustainability strategy to help Intel consume fewer resources and emit less waste" (Wellsandt and Snyder, 2009). Intel also developed a sustainability framework and defined a set of metrics to measure and help ensure success with addressing consumption and waste, setting challenging goals, redesigning business processes, and encouraging participation (Wellsandt and Snyder, 2009).

5. CONCLUDING REMARKS

Computer industry has an important role to play in achieving environmental sustainability given that desktop and laptop computers use huge material and energy resources. The computer industry needs to take a holistic approach in reducing environmental footprints. In this paper, we elaborated the energy and material consumption and e-waste aspects of computer products. We have pointed out that computer design and manufacturing need to be done with technological innovation and efficiency. The manufacturing of computer devices significantly contributes to environmental pollution. Each of the manufacturing phases needs to adopt energy efficient design and reusability measures. Computer products need better design to ensure less raw material usage and judicious use of natural resources. Computer designs need to address issues of energy consumption and carbon emission. To achieve ecological sustainability the design aspects of computers need to be continuously evaluated.

The computer industry must embrace different measures to reduce the global carbon dioxide emissions. Consumers must recycle and/or dispose of computer products appropriately. Regulation of recycling and proper disposal system must be adopted by the governments to prevent e-waste. All kinds of e-waste exports from developed countries to developing countries must be banned. Laws could be enacted to make it compulsory for computer manufactures to take responsibility for taking back end-of-life items from the users.

The computer makers need to work towards a sustainability portfolio (Hart, 1997) that takes clean technology into consideration, achieve major improvements through new technology, prevent significant waste and emission streams from existing operations and reduce costs and risks by eliminating wastes in source and manufacturing processes. The computer industry needs to have a vision to solve sustainability issues in terms of lowering hazardous waste, preventing natural resource depletion and decreasing toxicity

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

potentials from heavy metals (Son et al., 2016). They need to maintain a stewardship in product design and all phases of product's life cycle. The responsibility to ensure sustainability falls on the shoulder of the computer industry. At the same time consumption patterns also needs to move toward sustainability.

Chapter 66
Remanufacturing, an Added Value Product Recovery Strategy

Adnan Corum
Bahcesehir University, Turkey

ABSTRACT

Organizations offer a variety of products to the market with affordable prices. The popularity of a product rapidly disappears with the introduction of a new one and consequently end-of-life products and waste disposal rates increase. In the past, there were not strict regulations and sufficient public awareness about the disposal of products. Companies had limited concern for the consequences of their products sold. Nowadays there are economical and environmental motivations for organizations to look for alternative ways to value their end-of-life products. For that reason, alternative means of disposals of these products such as recycling, direct reuse, repair, refurbishing, and remanufacturing have growing attention. Among these only in remanufacturing used products are brought at least to the original equipment manufacturer performance specification. Worn-out parts are removed and replaced. It conserves the product identity and seeks to bring the product back into like-new condition. In this chapter the features of remanufacturing is presented.

INTRODUCTION

Green production and resource efficient systems are major issues today. Scarce resources make organizations look for alternative ways to value end-of-life products and turn waste into a resource. Alternative product recovery options have growing attention. In the past there were no regulations and public concern about the end-of-life products, firms did not feel any obligation for the consequences of the products after sold to customers. Today, both customers and authorities make firms to be concerned about their used products. Cost reduction is always a reason for change and to look for new methods but today product recovery has been receiving growing attention not only because of cost reduction and value recovery from the used products but also regulations, consumer awareness, social responsibilities and environmentally consciousness. These days better environmental image is important for organizations due to consumer awareness. Intending to reduce the needs for raw materials and energy in production,

recovered products are good for business, for customers, and for the environment. In addition, because it integrates waste back into the manufacturing cycle, it is also a method for avoiding waste limitation penalties (Subramoniam et al, 2013).

Defined product or component recovery options in the literature are: Recycling, direct reuse, repair, refurbishing, and remanufacturing (Thieery et al., 1995; Oh & Hwang, 2006; King et al., 2006a). Each of the recovery options involves collection of used products and components, reprocessing, and redistribution (Thiery et al., 1995).

- **Recycling:** Series of activities by which discarded materials are collected, sorted, processed and used in the production of new products (King et al., 2006a). In recycling, the identity and functionality of products and components is lost. The purpose of recycling is to reuse materials from used products and components (Thieery et al., 1995).
- **Direct Reuse:** No components or materials are replaced. Products are reused directly or after minor maintenance and cleaning.
- **Repair:** Damaged parts are replaced or upgraded to working order (Tang & Naim, 2004). It is the correction of specified faults in a product. The quality of the repaired product is inferior compared to remanufactured and refurbished products (King et al., 2006a). It usually requires only limited product disassembly and reassembly (Thierry et al., 1995).
- **Refurbishing:** Used products are disassembled into modules then all critical modules are inspected and fixed or replaced. Approved modules are reassembled into refurbished products. The purpose of refurbishing is to renovate and bring used products up to specified quality where quality standards are less precise than those for new products (Thierry et al., 1995).
- **Remanufacturing:** In remanufacturing used products are completely disassembled and all modules and parts are extensively inspected (Thierry et al., 1995). Worn-out parts are removed and replaced to bring the quality standard of final product to like-new condition. It conserves the product identity and seeks to bring the product back into like-new condition by carrying out the necessary disassembly, overhaul, and replacement operations (Oh & Hwang, 2006). It preserves most of the added value by giving a second life to the product and reduces the use of energy by eliminating production steps (Bernard, 2011). It is the only product recovery method where used products are brought at least to the original equipment manufacturer performance specification (King et al., 2006a). See Table 1 for different characteristics, and main differences between the product recovery options.

Table 1. Comparison between product recovery options (Thieery et al., 1995)

	Level of Disassembly	Quality Requirements	Resulting Product
Repair	To product level	Restore product to working order	Some parts fixed or replaced by spares
Refurbishing	To module level	Inspect all critical modules and upgrade to specified quality level	Some modules repaired/replaced; potential upgrade
Remanufacturing	To part level	Inspect all modules and parts and upgrade to as new	Used and new modules/parts combined into new product; potential upgrade
Recycling	To material level	High for production of original parts; less for other parts	Materials reused to produce new parts

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Repair, refurbishing, and remanufacturing upgrade used products in quality and/or technology. These options differ with respect to the degree of upgrading. Repair involves the least upgrade while remanufacturing involves the most (Thierry et al., 1995). Repair returns a used item to working order. Refurbishing brings an item up to a specified quality while remanufacturing brings an item up to a like-new quality (Teunter, 2001a). Remanufacturing is distinctly different from repair and refurbishing operations, since products are disassembled completely and all parts are returned to like-new condition. Remanufacturing focuses on added value recovery, rather than just materials recovery (recycling) (Guide, 2000). There is a major distinction between material recovery (recycling) and added value recovery (remanufacturing) (Kenné et al., 2012). Selecting the most advantageous product recovery option depends on (Thierry et al, 1995): (1) Technical feasibility; (2) Supply of suitable used products and components; (3) Demand for reprocessed products, components, or materials; (4) Economic and environmental costs and benefits.

The concept of product recovery is not new, and remanufacturing has been more and more common industrial activity since the Second World War. However, after the late 1970s interest in remanufacturing as an academic research topic began to emerge with Prof. Robert Lund's original studies of the remanufacturing industry (Hatcher et al., 2011). Gungor and Gupta (1999) later Ilgın and Gupta (2010) present a comprehensive summary of the environmentally conscious manufacturing and product recovery literature. They organized the literature into four main areas: (1) Product design; (2) Reverse and closed-loop supply chains; (3) Remanufacturing; (4) Disassembly. Also Fleischmann et al. (1997) review the extant literature and their paper is one of the most cited review paper in the field of product recovery. They subdivided the field into three main areas: (1) Distribution planning; (2) Inventory control; (3) Production planning.

OECD and Eurostat defines eco-industries as: *Activities which produce goods and services to measure, prevent, limit, minimize or correct environmental damage to water, air and soil, as well as problems related to waste, noise and eco-systems. This includes technologies, products and services that reduce environmental risk and minimize pollution and resources*. The estimated total turnover of eco-industries in the EU is €227 billion. The largest national markets for eco-industries are France and Germany which make 49% of total turnover in 2004. The three following countries are UK, Italy and the Netherlands that make 24% (EU, 2006). Based on this definition remanufacturing is part of the eco-industry.

OECD began to work on a program called Extended Producer Responsibility (EPR) in 1994 which is an environmental policy approach under which the responsibility of producers for their products is extended to the stage where products get to its end-of-life. EPR is applied both to industrial wastes and to packaging and post-consumer waste (OECD, 2001; Smith, 2005; OECD, 2014). The goal of EPR program is (OECD, 2014): (1) Increased collection and recycling rates; (2) Reduction of public spending on waste management; (3) Reduction in overall waste management costs; (4) Design for environment innovations. It is increasingly recognized worldwide as an efficient waste management policy to help improve recycling and reduce land filling of products and materials. Producers assume responsibility for managing the waste generated by their products put on the market. Since its first developments in the early 1990s, it has contributed to significant increases in recycling rates and reductions on waste management cost in many countries (OECD, 2014).

Two features of EPR is (OECD, 2001): (1) Producers of products should take responsibility (physical and/or financial) from government or municipal units; (2) To provide incentives to producers to consider environment from design to disposal stages of their products. The ultimate objective is to reduce the amount of landfill and hazard caused by the end-of-life products. In order to realize these objectives, policy makers have a range of policy instruments. There are four broad categories of EPR policy instru-

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

ments (OECD, 2014): (1) Product take-back requirements: Take-back policies require the producer or retailer to collect the product at the post-consumer stage; (2) Economic and market-based instruments: These include measures such as deposit-refund schemes, advanced disposal fees, material taxes, and upstream combination tax/subsidy that incentivize the producer to comply with EPR; (3) Regulations and performance standards: Such as minimum recycled content. (4) Accompanying information-based instruments: These policies aim to indirectly support EPR programs by raising public awareness.

Under conventional waste management practices for household wastes, the collection and disposal of end-of-life products is typically under the responsibility of local or municipal governments, and the cost is somehow charged to households. In comparison with this conventional system of waste management, EPR involves a number of distinctive differences (Smith, 2005): (1) EPR shifts direct financial responsibility (fully or partially) for the costs of waste management upstream to the producer, and away from the municipality and taxpayer; (2) EPR often involves the producer in some physical aspects of waste management (such as waste collection, or the management of collective waste management organizations), in addition to its financing; (3) EPR is designed to make the producer deal with the costs of end-of-life disposal of their products, and thereby to make the producer to take account of these future costs while designing and marketing their products.

When products can be freely discarded by consumers without any responsibility and waste management costs are carried by municipalities, producers can design and market products which will have high end-of-life future waste management costs. Requiring producers to carry financial responsibility for the end-of-life products can make them produce and market products that will have low end-of-life waste management costs. Producers who can reduce these costs may benefit in higher profits or in higher market share if they can reduce their selling prices relative to their competitors (Smith, 2005). Many EPR programs in operation have three common elements (Smith, 2005): (1) Physical or financial obligations on the producer concerning the collection (take-back) of product packaging or end-of-life products; (2) Responsibility for the costs of proper waste management of the collected products and materials; (3) Rules or targets conducting the policy, actions, affairs, and methods of waste management of recovered products, for example specifying minimum required rates of reuse or recycling.

OECD began to work on EPR program in 1994 and in 2001 published a guidance manual for conducting the policy, actions, and affairs on EPR that provides the key issues, general considerations, and the potential benefits and costs associated with EPR. Most OECD countries have now implemented EPR policies in key sectors such as packaging, electronics, batteries, and vehicles. Certain emerging economies in Asia, Africa, and South America have also started to develop EPR programs in recent years. EPR is an effective policy instrument to engage producers in going for green growth and a resource efficient economy (OECD, 2014).

EPR requirements first appeared in policy and law in the early 1990s in several European countries, including Germany, Sweden, and France. Today, EPR programs have spread and developed rapidly around the world. Policy makers in OECD and emerging economies are now implementing EPR policies as an efficient target oriented environmental tool along with traditional instruments and regulations such as landfill taxes or emission standards for waste treatment facilities (OECD, 2014).

The current status of EPR applications in the world is as follows (OECD, 2014): At the *EU* level, all member countries have implemented EPR schemes on the four waste streams: Packaging, Batteries, End-of-Life Vehicles, and Electrical and Electronic Equipment. In addition, a number of member countries have put in place additional schemes for products like tyres, graphic paper, oil, and medical waste that are not directly addressed in EU-wide legislation. In the US and Canada, EPR programs cover a wide

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

group of products and the rules and regulations are set and implemented by states and provinces. In the US, there is no federal law governing EPR so that individual states have developed and implemented their own policies depending on local conditions and each state's specific political dynamics. Between 1991 and 2011, US states have performed more than 70 EPR laws, which generally require manufacturers to implement EPR programs. In parallel, producers have themselves implemented voluntary programs to organize the collection and recycling of their products. In Latin America and the Caribbean, several countries including OECD members Chile and Mexico, as well as Brazil, Argentina, and Colombia have implemented their first EPR schemes in recent years, in particular covering the large markets for potentially hazardous electronic waste market. The current situation of EPR in Asia varies significantly across countries and between OECD and non-OECD members. Industrialized OECD economies like Japan and the Republic of Korea have already well established EPR schemes and regulations on the key waste streams, supported by a solid monitoring and enforcement framework. Some rapidly emerging economies, such as the People's Republic of China, India, and Indonesia have started to develop EPR programs even though these are generally not yet fully implemented and functioning.

Apart from OECD's EPR program, in the US many of the electronics companies have voluntary take-back programs. Having a voluntary program means offering take-back and recycling options even when there is no law requiring it. Some of the examples from the industry are (electronicstakeback.com)**:** Acer let customers drop off old Acer products at collection points operated by third party collector, and they reimburse the collector for the costs of collection, transportation, and recycling. This is an example of retailer/manufacturer partnership. Apple has a trade in program for working iPhones, iPads, and Mac or PC desktop and notebook computers. If item has any reuse value, customers can send it to Apple and have an Apple gift card in return. This program is run by a third party organization. Besides, Apple takes any brand of computer and monitor for free recycling. The program works with third party recycling company. Customers get no gift or discount in return for non-Apple products but make their end-of-life products recycled for free shipping. Apple also accepts iPods for recycling in their stores and customers get a 10% discount towards a new one. Customers can also mail back iPods and cell phones (any brand) for free without any discount coupon or trade in value. Asus has a mail-back recycling program for free shipping contracting with third party recycling company. Dell takes back Dell product for free shipping. HP is working with third party organization for collecting used products. Customers can take back many products to any location of the company in the US. HP also has a mail-back program for free recycling and shipping for HP products. Customers can also ship non-HP products, but it's not for free. They also offer free recycling and free shipping of used toner or inkjet cartridges. Canon has a mail-back take-back program for all of their consumer products and some of small office/home office product lines. But it is not for free. Kodak offers a mail-in trade-in/recycling program for its used printers, cameras, and lenses. The program works with a third party recycler. Lenovo has a free mail-back recycling program for Lenovo equipment, including free shipping. LG's program includes take-back of some TV types. To recycle an LG TV for free, customers can drop off products at LG's designated collection sites. The program works with a third party recycler. Microsoft partners with Dell's reconnect program to offer collection sites for recycling Microsoft products. Microsoft also has a mail-back take-back program for its Xbox games, consoles, computer accessories, and Zune players for free shipping. Xerox has a mail-back recycling program, but shipping is not for free. Toshiba takes back laptops and other smaller electronics using a third party company which allows customers to trade in their products for cash. Customers pay to ship them to company, and if products have value, company sends customers a check in return. To recycle Toshiba TVs and other larger Toshiba electronics for free, customers

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

have to take them to one of the collection sites operated by third party recycling program. To recycle Samsung Televisions, Digital Cameras, Camcorders, Home Theater, Blu-ray and DVD players, printers, monitors, notebooks for free, customers must take them to one of Samsung's recycling locations. The program works with a third party recycler. Panasonic has laptop recycling and reuse program with shipping cost. Also old laptop may have a trade in value while buying a new one. To recycle Panasonic TVs or other Panasonic consumer electronics for free, customers must take them to one of the collection sites operated by the third party recycling program. Mitsubishi participates in third party operated recycling system. To recycle a Mistubishi TV for free, customer must drop it off at a designated collection site.

The rest of the chapter is organized as follows. In Section 2, reverse logistics is defined. In Section 3 remanufacturing industry is described. In Section 4 the production system with remanufacturing included which is called hybrid manufacturing/remanufacturing system is described and different policies used are defined within the system. In Section 5 the paper is concluded with final remarks.

REVERSE LOGISTICS

Collecting and recovering products leads to numerous complicated logistical activities. In the literature these backward activities is called Reverse Logistics (RL) which is a broader term and encompasses collection, transportation, inspection and sorting, inventory management, and production planning and scheduling of returned products. Logistics is defined by The Council of Logistics Management as (Rogers & Tibben-Lembke, 1998): *The process of planning, implementing, and controlling the efficient, cost effective flow of raw materials, in-process inventory, finished goods and related information from the point of origin to the point of consumption for the purpose of conforming to customer requirements*. RL includes all of the activities that are mentioned in this definition above. The difference is that reverse logistics encompasses all of these activities as they operate in reverse. Therefore, RL is (Rogers & Tibben-Lembke, 1998): *The process of planning, implementing, and controlling the efficient, cost effective flow of raw materials, in-process inventory, finished goods and related information from the point of consumption to the point of origin for the purpose of recapturing value or proper disposal*. More precisely, RL is the process of moving goods from their typical final destination for the purpose of capturing value, or proper disposal. Product recovery is a part of RL. It is clear that the overall amount of RL activities in the economy is large and still growing. See Table 2 for common RL activities.

In the literature there are two categories of reverse logistic systems (Kenne et al, 2012): Open and closed-loop, depending on whether the return operations are integrated or not with the initial operation. Also there are four basic types of returns (Östlin et al., 2008): (1) End-of-Life Returns: These are returns that are taken back from the market to avoid environmental or commercial damage. These used products are often returned as a result of take-back laws; (2) End-of-Use Returns: These are used products or components that have been returned after customer use. These used products are normally traded on an aftermarket or being remanufactured; (3) Commercial Returns: These returns are linked to the sales process. Other reasons for the returns include problems with products under warranty, damage during transport or product recalls; (4) Re-Usable Components: These returns are related to consumption, use or distribution of the main product. The common characteristic is that they are not part of the product itself, but contain and/or carry the actual product.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 2. Common RL activities (Rogers & Tibben-Lembke, 1998)

Material	RL Activities
Products	Return to Supplier
	Resell
	Sell via Outlet
	Salvage
	Recondition
	Refurbish
	Remanufacture
	Reclaim Materials
	Recycle
	Landfill
Packaging	Reuse
	Refurbish
	Reclaim Materials
	Recycle
	Salvage

Savaskan et al. (2004) consider three options for collecting returned products: (1) One can collect them himself directly from customers, for instance Xerox corporation provides prepaid mailboxes so that customers can easily return their used copy or print cartridges to Xerox without incurring any costs. The company also remanufactures copiers. The used copiers are collected directly by Xerox as new ones are installed; (2) One can provide suitable incentives to an existing retailer (who already has a distribution channel) to make the collection. For instance Kodak Company receives single use cameras from large retailers that also develop film for customers. Each time a camera is returned to Kodak the retailer is paid a fixed fee per camera and the transportation costs; (3) One can subcontract the collection activity to a third party. In the auto industry, independent third parties are handling used product collection activities for the original equipment manufacturers.

RL has received considerable attention due to potentials of value recovery from the used products. Besides, legislations and directives, consumer awareness and social responsibilities towards environment are also the drivers for RL. Research on RL has been growing since the Sixties. The RL activity that has attracted most attention of the researchers is inventory management. Starting from repairable item inventory management in the 1960s, a lot of research effort has been put in so far for managing inventory of recoverable products and components (Mitra, 2007). Research on strategies and models on RL can be seen in the publications in and after the Eighties. The focus on RL is on waste management, material recovery through recycling, parts or product recovery through refurbishing or remanufacturing (Pokharel & Mutha, 2009).

Not all reverse supply chains are identical. However, most return supply chains are organized to carry out five key processes (Blackburn et al., 2004): (1) Product acquisition: Obtaining the used product from the user; (2) RL: Transporting the products to a facility for inspecting, sorting, and disposition; (3)

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Inspection and disposition: Assessing the condition of the return and making the most profitable decision for reuse; (4) Remanufacturing: Returning the product to original specifications; (5) Marketing: Creating secondary markets for the recovered products.

REMANUFACTURING INDUSTRY

Ebersole (1997) states that the symbol of 20th century industry was the assembly line, the symbol of 21th century industry may be the disassembly line. Many organizations like Xerox Co. and Eastman Kodak Co. design products not only for assembly but also for disassembly. Xerox remanufactures many parts and machines each year. Kodak collects millions of single use cameras, microfilm machines, photographic film base, etc., each year from different countries for remanufacturing. During the Second World War the remanufacturing industry increased, especially in the US since many manufacturers were focusing on military production (Östlin et al., 2008). Most developed countries have environmental regulations for manufacturers, generators, and users of chemicals regarding properly dispose of chemical wastes. In the mid-1980s this was commonly known as *cradle-to-grave* resource management. Today, modern environmental management makes sustainable manufacturing practices focusing on recovery of resources, recycling, and reuse which can be described as *cradle-to-cradle* resource management (Kumar & Putnam, 2008). Remanufacturing studies have increased after the 1980s, and researches have been studying on this subject since then (Sasikumar et al., 2010).

Environmental legislation is becoming increasingly strict, particularly in Europe. There are recent developments such as the Waste Electronics and Electrical Equipment (WEEE) and End-of-life Vehicle (ELV) directives and standards such as Germany's VDI 2243 and the UK's BSI 8887, Japanese Specified Home Appliances Recycling Law (SHARL), Japanese PC Recycling System, and state specific e-waste take-back programs in twenty four states in the US (Esenduran et al., 2012; Hatcher et al, 2011). Companies can meet these legislations with remanufacturing effectively in a profitable manner.

A material recovery system which may be named as a recoverable product environment, includes strategies to increase product life by means of: Repair, refurbishing, remanufacturing, and recycling of products. A major part of the recoverable product environment is the recoverable manufacturing system that focuses on the repair, refurbish, and remanufacture of products (Guide et al., 1997a). These systems are economic, environmentally friendly, and designed for sustainable development. Recoverable manufacturing is an economical way to achieve many of the goals of sustainable development. Recoverable manufacturing systems minimize the environmental impact of industry by reusing materials, reducing energy use, and reducing the need to landfill industrial products (Guide et al., 2000). A recoverable system is essentially a closed-loop industrial system with discarded items used in place of virgin materials as much as possible. While these systems are more complex to manage than traditional systems, the rewards for organizations are correspondingly higher (Guide et al., 1997b).

Remanufacturing is environmentally conscious and efficient as it aims to use less energy and materials compared to traditional manufacture with new raw materials. Since end-of-life materials are taken back the amount of landfill is decreased. Remanufacturers are a well doing and valuable set of companies. They create economic value in micro and macro level. Top remanufacturers are characteristically flexible and adaptable. Many need a wide skill set which can be hard to find. Workers in these businesses

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

more often find their work motivating and interesting. They need to be capable of: Sourcing end-of-life products (cores), inspection and classification on arrival, disassembly, component testing, remediation, repair or replacement, re-assembly, assembly, testing, and dispatch (remanufacturing.org.uk).

Remanufactured products are cheaper than the traditionally manufactured products. Remanufacturing is practiced in many industries including photocopiers, computers, telecommunication equipment, automotive parts, office furniture, and tires. The actual process of remanufacturing is generally less expensive than producing a new product as many parts and components can be reused (Ferguson, 2009). The cost of remanufacturing is typically 40% to 60% of the cost of manufacturing a new product with only 20% of the effort. This is nice when the remanufactured product is in like-new condition and can be sold with warranty (Mitra, 2007). A remanufactured product can be sold for 45% to 60% of the price of a new one (Lund, 1996). In their recent studies Lund and Hauser (2010) state that they know of 113 product areas in which remanufacturing occur in the US. The major product areas are motor vehicle parts, electrical motors and generators, pumps, transformers, laser toner cartridges, industrial machinery, tires, industrial valves, and office furniture. The price of a remanufactured product is normally between 45% and 65% of the price of a comparable new product.

According to Kerr and Ryan (2001) sustainable production and consumption is only possible with closed loop systems in which resources are recovered from the used products. However, a system that closes the loop through recycling is less environmentally and economically efficient since in each stage of a closed recycling system energy is expended. Returning and reusing manufactured components or subcomponents rather than recycled raw materials is much more efficient. Remanufacturing is also preferable in comparison with other product recovery options, since the geometrical form of the product is retained and its associated economic and environmental values are preserved (Östlin et al., 2008).

There are various motives for product remanufacturing (Seitz & Peattie, 2004): Increased profitability, ethical responsibility, legislation, secured spare part supply, increased market share, and brand protection. Ferguson (2009) states that if a firm does not choose to remanufacture it may lose its environmentally conscious customers. Firm can find itself facing costly regulatory restrictions and government disposal fees in the future. This is already occurring in the electronics and automotive industries. One regulation requires a certain percentage of each automobile be recyclable (EU End-of-Life Vehicle Directive). Other regulation forces the electronic equipment producers to fund the take-back and proper disposal of their products (WEEE Directive).

Xerox Corporation, a global company offering products and services in printing business, is the pioneer company in remanufacturing. According to Kerr and Ryan (2001) Xerox has one of the most widely reported remanufacturing systems. It has recovered used equipment since the 1960s, but developed a more formal remanufacturing system in the late 1980s and early 1990s to maximize the profitability of remanufacturing operations. Today, by remanufacturing used photocopiers, Xerox has saved millions of dollars in raw material and waste disposal costs. It remanufactures used photocopiers and print and toner cartridges all around the world. It has remanufacturing facilities in the US, UK, Netherlands, Australia, Mexico, Brazil, and Japan, which helped Xerox to enhance its image as an environmentally conscious company. The integration of remanufacturing into the company's overall business strategy has also been critical to Xerox's success. Ferguson (2009) states that in 1991 Xerox obtained savings of around $200 million by remanufacturing copiers returned. Equipment remanufacture and the reuse and recycling of parts prevent millions of pounds of waste from entering landfills each year, 48,000 metric tons in 2008 alone (xerox.com). Xerox routinely offers new, newly manufactured, remanufactured, and certificated repaired versions of their products (Atasu et al., 2010). According to Murray (1995) Chairman and

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Chief Executive Officer of Xerox Corporation states that *environmental protection is considered by people from around the world to be one of the most critical issues of the 1990s. Xerox shares the public's concern about the environment and has integrated that concern into their business activities, making environmental values a key part of the Xerox corporate culture*.

On the other hand, there are other global companies that remanufacture. Ferguson (2009) presents three examples: Kodak is one of the classic examples of an original equipment manufacturer that has created a fully integrated manufacturing and remanufacturing strategy around its reusable camera line. Caterpillar is changing its strategy from only manufacturing and selling construction equipment to a leasing and remanufacturing strategy. This allows Caterpillar to create a new market among contractors who cannot afford to buy a Caterpillar product but prefer leasing. Caterpillar established a remanufacturing division that sells both equipment and parts. In 2007, this division had over $2 billion in sales and was the fastest growing division out of all Caterpillar's divisions. In 2007, the Global Asset Recovery Solutions division of IBM collected over one million units of used information technology equipment that was converted to billions of dollars in revenues on the second hand equipment, parts, and materials markets. According to Atasu et al. (2010) the imaging and printer group at Hewlett Packard (HP) has various contracts with third party remanufacturers and logistics providers to recover some of the costs associated with the substantial volumes of commercial returns from its inkjet printer lines. HP practices product recovery primarily to be good corporate citizen and as a way to avoid the environmental burden from land filling the returns. Reduced production cost also attracts independent remanufacturers (IRs). In 2005, IRs represented 54% of the aftermarket for automotive parts in Europe and 66% worldwide (Bernard, 2011).

Auto parts are the most remanufactured materials in the world. Up to two-thirds of remanufacturing businesses globally is estimated to involve auto parts. The remanufactured auto parts primarily include engines, turbo chargers, alternators, starters, compressors, transmissions, and steering units (Matsumoto & Umeda, 2011). Bernard (2011) states that alternators and starters represent 80% of remanufactured auto parts. Valeo and Bosch are two important alternator producers in Europe. They started remanufacturing activities in the early 1990's. Remanufacturing process requires a lot of handling (dismantling, sorting, cleaning, etc.), the removal of the hazardous content is a technological constraint that has made alternator remanufacturing commercially viable. In its lifetime, the same car goes through two or three alternators. Remanufactured alternators and starters cover more than 90% of the replacement market. They are produced with less cost compared to the original one: On average they require 14% of the energy and 12% of the material necessary for the production of new ones. In the alternator industry, more than 90% of the aftermarket is filled with remanufactured products.

Bourgeosi (2004), research associate in Renault Trucks, states that remanufactured parts (labeled Renault 100%) accounted for 16% of Renault Trucks' parts revenues in 2001. Remanufactured parts provide vehicle owners with a low cost, like-new replacement component, and added benefit of environmental consciousness. The most advantage of a remanufactured part over an original one is its price. For most components of Renaults Trucks, remanufactured versions are 30% to 50% cheaper. Remanufactured components, especially engines, often benefit from recent technology upgrades, which sometimes make them more efficient than the original component. Remanufacturing is quicker than rebuilding and provides cost savings over purchasing a new part. In 2000 Renault remanufactured parts turnover had reached $64 million (170000 units) with a product margin of $19 million. To compare, Renault trucks' turnover from its total parts business in 2000 was $488 million, with a product margin of $192 million.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Lund and Hauser (2010) state that the remanufacturer not only competes with other remanufacturers, but is increasingly in competition with lower-priced new products, often imports. Robert Bosch Tool, North America offers remanufactured versions of its Bosch and Skil products. In addition to variety of reasons including cost saving, remanufacturing is also a way to reach customers who would not buy expensive new products but buy lower priced remanufactured version. With the price advantages coming with remanufacturing, company can compete with inexpensive imports. Bosch managers consider remanufacturing to be a core part of the business (Atasu et al., 2010). Kerr and Ryan (2001) attempt to quantify the life cycle environmental benefits achieved by incorporating remanufacturing into a product system, based on a study of Xerox photocopiers in Australia. The study finds that remanufacturing can reduce resource consumption and waste generation over the life cycle of a photocopier by up to a factor of three. They claim that reductions will be greater if a product is designed for disassembly and remanufacturing.

In the UK the range of products that are being remanufactured includes (remanufacturing.org.uk): Machine tools, electrical motors and compressors, starter motors, automatic transmissions, car and truck engines, office photocopiers, excavation equipment, power bearings, defense equipment, computer and telecoms equipment, air-conditioning units, pumps, industrial food processing equipment, aerospace, carpet tiles, and rolling stock. Lund and Hauser (2010) state that remanufacturing enterprises exist in a number of different forms. They have defined three categories to encompass all forms: (1) Conventional firms: They purchase cores, remanufacture them and sell them to new owners; (2) Contract firms: They agree with the owner of a product to remanufacture it and return it to the owner; (3) Original Equipment Manufacturers: They are manufacturers of a product who also remanufacture their product for resale. Original Equipment Manufacturers typically sell their remanufactured products through their dealer networks. Conventional remanufacturers may sell directly to individual customers, through distributors, or through retailers. Contract remanufacturers may provide products to individual owners. They may sell to customers with fleets, such as trucking companies (tires), airlines (engines), or banks (printers).

Matsumoto and Umeda (2011) investigate Japanese remanufacturing industry which is an important player in this sector and provide valuable information: Japanese remanufacturing practices are advanced in some product areas like photocopiers and single-use cameras, and lagging in fields like auto parts. Three major OEMs of photocopy machines in Japan are Fuji Xerox, Ricoh, and Canon. They account for about 90% of Japan's photocopier market and they are remanufacturing their used products. Fuji Xerox started remanufacturing in 1990s, and Ricoh and Canon began selling remanufactured machines in the 2000s. In Ricoh, 93% by weight of a typical remanufactured photocopy machine is composed of reused parts, its price is 30% to 50% of a new product, and profits from remanufactured machines are larger than those from newly produced machines. In Fuji Xerox's remanufacturing process, reused components are incorporated in new products. Thus, all products may include reused components and there is no distinction between new and remanufactured products. However Xerox in the US and Europe remanufactured products are distinguished from new products like in Ricoh and Canon.

Remanufacturing of single-use cameras is very common. Single use cameras began to appear in 1986 and in 1987, OEMs began to collect used products and recycle them. Fuji Film, Kodak, and Konica are the major Japanese camera OEMs. Fuji Film developed an automated production line for single-use cameras in 1992 and work on product designs that enabled recycling and remanufacturing. In 1998, it developed a remanufacturing line that fully automated all processes of product disassembly, parts cleaning, parts inspection, parts replenishment, reassembly, and final testing. The company reports that they reuse or recycle more than 82% by weight of all camera components.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

In Japan, 200 million ink cartridges are sold annually, primarily for use in personal printers. Remanufactured cartridges account for 15 million in sales. Ecorica, an independent remanufacturer (IR) founded in 2003, is Japan's largest ink cartridge remanufacturer, shipping approximately 10 million remanufactured products annually. Ecorica collects used cartridges from end-users, and remanufactures and sells them. 30 million toner cartridges are sold annually in Japan, mainly for office printers, 5 to 6 million of them are remanufactured. There are a number of independent toner cartridge remanufactures; 33 IRs formed the Association of Japan Cartridge Remanufacturers, and member companies account for 90% of remanufactured toner cartridges sold in Japan. Some OEMs do remanufacturing of printer cartridges. But most of remanufacturing in the product areas is done by IRs, and OEMs generally respond negatively to such activities by IRs as they earn most of their profit from selling ink and toner cartridges. Recently, OEMs began to recover used ink cartridges. Six OEMs, Epson, Canon, Hewlett-Packard, Brother, Dell, and Lexmark, collaborated to collect used ink cartridges. However, since remanufacturing ink cartridges costs more than manufacturing new cartridges, OMEs are not active remanufacturers but recycle the collected cartridges.

Ferguson (2009) states that despite all of these benefits from remanufacturing, most firms continue to ignore any remanufacturing or reuse of their used products. Many original equipment manufacturers spend the majority of their time and resources focusing on their new product sales, and thus simply not consider remanufacturing as a viable business model. Even some original equipment manufacturers that seriously consider remanufacturing may also do not remanufacture because they do not feel that they have the infrastructure and expertise to collect the used units and remanufacture them in a profitable manner. There are often significant costs associated with the logistics of remanufacturing.

Not all products are suitable for remanufacture. For example, if technology changes very quickly, or fashion causes a high turnover of designs and styles, or if the product is durable but basic, then remanufacturing will be hard to justify. Under these circumstances consider the role of secondary markets (remanufacturing.org.uk). Remanufactured products usually have shorter lead times. However, the high variability of remanufacturing operations makes the use of traditional operations management techniques difficult (Ilgın & Gupta, 2010). Individual repair requirements for every product returned, and coordination of several interdependent activities makes production planning complicated. Comparing to traditional manufacturing systems, no well-determined sequence of production policies exist in remanufacturing (Kenné et al., 2012). Labor is the major factor in remanufacturing, ranging from 34% to 45% of product cost. The cost of cores is an important cost factor, but for most companies it is lower than the cost of replacement parts and other materials needed to bring products to like-new condition (Lund & Hauser, 2010).

Guide (2000) reports on managerial remanufacturing practices via a survey of production planning and control activities at remanufacturing firms in US and identify seven complicated characteristics of remanufacturing: (1) Uncertainty in the timing and the quantity of returns; (2) Balancing returns with demands; (3) Disassembly; (4) Uncertainty in materials recovered; (5) Reverse logistics; (6) Materials matching requirements, (7) Routing uncertainty and processing time uncertainty. These uncertainties make resource planning, scheduling, shop floor control, and material management more difficult than in traditional manufacturing environments. Production planning in a remanufacturing system environment is very complex especially with uncertainties (Kenné et al., 2012). King et al. (2006b) explain and illustrate the process Xerox uses at its United Kingdom factory to return old photocopiers to a like-new product. They state that although Xerox has made a profitable business from remanufacturing, there are many barriers to its wider development. An original equipment manufacturer has a number of decisions

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

to make in remanufacturing environment that are not present in a traditional manufacturing environment. See Table 3 to compare the recoverable manufacturing environment with traditional manufacturing environment by area of responsibility for the managers in different functions of business.

A verity of factors must be taken into account when making the remanufacturing decision (Atasu et al., 2010): Remanufactured product introduction timing, competition, supply constraints, last time buy decisions, and legacy systems. The original equipment manufacturer has more advantages over the independent manufacturer in terms of establishing the relationship with used product suppliers, remanufacturing operations, and marketing of the remanufactured products (Saavedra et al., 2013). If the marginal cost to remanufacture a used unit is lower than the price the remanufactured product can be sold at, and the profit generated from this effort over a certain time period exceeds any fixed cost investment required to set up a remanufacturing operation and sales channel, then the firm should choose to do remanufacturing (Ferguson, 2009). Subramoniam et al. (2013) develop a remanufacturing decision making framework (RDMF) to assist original equipment suppliers on their strategic decision-making processes.

Study of the link between product cannibalization and remanufacturing opportunities is also important in the remanufacturing sector (Vasudevan et al., 2012). According to Atasu et al. (2010) cannibalization occurs when the purchase of a remanufactured version of a product displaces the sale of a new product. It becomes concern when the remanufactured and new products are differentiable to customers. This is the case when a firm offers a remanufactured version of a product with a different price than the new version of that same product. The sales of remanufactured products may then reduce the sales of new product.

Table 3. Comparison of recoverable and traditional manufacturing environment (Guide et al., 2000)

Factors	Recoverable Manufacturing Environment	Traditional Manufacturing Environment
Environmental focus	Seeks to prevent post production waste	Environmentally conscious design and manufacturing, focus on pre production Pollution prevention and remediation
Logistics	Forward and reverse flows	Open forward flow
	Uncertainty in timing and quantity of returns	No returns
	Supply driven flows	Demand driven flows
Production planning and control	Need to balance demand with returns	No such need
	Material recovery uncertainty	Certainty in planned materials
	Stochastic routings and processing times	Fixed routings and more stable processing times
	Manufacturing system has three major components: disassembly, remanufacturing and reassembly	Manufacturing system has two major components: fabrication and assembly
Forecasting	Forecast both core availability and end product demand	Forecast only end products
	Must forecast part requirements because material recovery rates are uncertain	No parts forecasting needed
Purchasing	Highly uncertain material requirements due to variable recovery rates	Material requirements deterministic
	Cores and parts, components, replacement parts	Raw materials, new parts, and components
Inventory control and management	Types: cores, remanufactured parts, new parts, new and remanufactured substitute parts, original equipment manufacturer parts	Types: raw materials, work-in-process, finished goods
	Must track and provide accounting for all part types	Must track and provide accounting for work-in-process and finished goods

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

On the other hand Atasu et al. (2010) states that cannibalization is not a major concern when remanufactured versions are perfect substitutes for new products. A perfect substitute means the remanufactured product cannot be distinguished by a customer. This allows the original equipment manufacturers to use remanufactured components and parts, reducing material costs, and does not require the firm to offer lower selling price. A firm in this situation can benefit from lower manufacturing costs and higher profit margins.

Ferguson (2009) claims that, most firms seem to have the fear that product cannibalization will reduce the demand for the firm's new product. For example, Bosch Power Tools restricted remanufacturing to products where the firm had less than a 50% market share. Their thinking behind this rule of thumb is that for products with more than a 50% market share, the remanufactured product will cannibalize sales of the firm's new product but if the market share is less than 50% then it will cannibalize the sales of their competitors.

Atasu et al. (2010) state that, although there are some cannibalization concerns, Bosch managers attempt to focus the introduction of remanufactured products to markets where Bosch does not hold a majority share, and use secondary channels. HP managers strongly believe remanufactured products cannibalize new product sales. Additionally, one manager at a global computer manufacturer informed Atasu et al. (2010) that for every four remanufactured products sold, one new product sale was cannibalized. According to Ferguson (2009) products do cannibalize the sales of new products but probably not to the degree that many firms fear.

All of these characteristics mentioned up to this point, make harder to manage the operations of such a production system with remanufacturing comparing to traditional regular production system. It causes researchers to develop models which solve the problems regarding production planning and control of these systems.

HYBRID MANUFACTURING/REMANUFACTURING SYSTEM

Many researches refer to the definition of remanufacturing made by Lund (1983): *Remanufacturing is an industrial process in which worn-out products are restored to like-new condition. Through a series of industrial processes in a factory environment, a discarded product is completely disassembled. Useable parts are cleaned, refurbished, and put into inventory. Then the new product is reassembled from the old and, where necessary, new parts to produce a fully equivalent and sometimes superior in performance and expected lifetime to the original new product*. During this process, the core passes through a number of remanufacturing operations like; inspection, disassembly, component reprocessing, reassembly, and testing to ensure meeting the desired product standards (Östlin et al., 2008).

Each of the processes in a remanufacturing systems is strongly dependent on each of the other processes. The remanufacturing system is composed of three highly dependent subsystems (Guide et al, 1999): A disassembly area, a processing area, and a reassembly area. A production planning and control of these systems have additional complexity of coordinating.

RL and remanufacturing are a customer relationship management challenge. Remanufacturing is typically discussed as a production and logistical challenge added on to a conventional system of consumption (Seitz & Peattie, 2004). There are three important and critical limitations that a remanufacturing

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

firm needs to overcome: (1) Limited access of cores leaving the use phase; (2) Limited feasibility of product remanufacturing; (3) Limited market demand for the secondary output from remanufacturing (Geyer & Jackson, 2004).

The question of acquiring cores is an important issue for the remanufacturer in order to be able to satisfy the demand for remanufactured products to increase the performance of the remanufacturing system. Management of different types of relationships with the customer and suppliers is an important factor for the performance of the remanufacturing system. Regarding core acquisition, one of the most important issues is to focus on identifying different sources of cores and rating them according to their characteristics. Forecasting core availability is critical in order to balance supply and demand (Östlin et al., 2008).

There are a number of possible shop structures available for a remanufacturing facility. The most common type of remanufacturing facility is a general purpose remanufacturing shop with characteristics of both open and closed job shops with reassembly operations (Guide et al, 1999). Remanufacturing requires a lot of manual work. It is difficult to automate operations as they are not common for all remanufactured products.

In the literature a recoverable manufacturing system where it is possible to do direct manufacturing or remanufacturing depending on the system requirement, is called as a hybrid manufacturing/remanufacturing system. Integration of manufacturing and remanufacturing operations require realignment of the manufacturing process, information systems, and handling of returns for remanufacturing (Pokharel & Mutha, 2009).

The hybrid manufacturing/remanufacturing system is illustrated in Figure 1. The system works as follows (Tang & Naim, 2004; Zanoni et al., 2006; Corum et al., 2014): Cores collected from customers come to recoverable inventory from the collection points. They are remanufactured depending on the policy used. The remanufactured products are sent to serviceable stock and treated as like-new regular manufactured products. New customer demands are filled from serviceable stock. It is also possible to do regular manufacturing to fill the serviceable stock when needed. Demand and return are not correlated as the product has not yet reached the end of its life-cycle, there are typically more demands than returns. Hence some demands have to be satisfied by manufactured products (Teuter, 2001a). The main production strategy options for the hybrid manufacturing/remanufacturing systems are Push and Pull controlled hybrid systems. Other systems defined in the literature are extension of them.

The (R_m, Q_m, Q_r) Hybrid Push Strategy

Under the hybrid push strategy defined by Van Der Laan et al. (1999), remanufacturing starts when the recoverable inventory level reaches to Q_r which is the remanufacturing batch size. These Q_r products are batched and pushed to remanufacturing process which has a lead time of L_r per batch. The inventory level drops to zero in recoverable stock and increases by Q_r in the serviceable stock. When the inventory drops to R_m, manufacturing takes place in batches of Q_m with lead time of L_m per batch where s_m represents the safety stock. The timing of remanufacturing operations is completely return driven. As soon as sufficient returned products are in recoverable stock, these products are batched and pushed into the remanufacturing process. In this strategy remanufacturing operations are scheduled as early as possible. The timing of manufacturing operations is based on the serviceable stock position. See Figure 2 (a) for illustration.

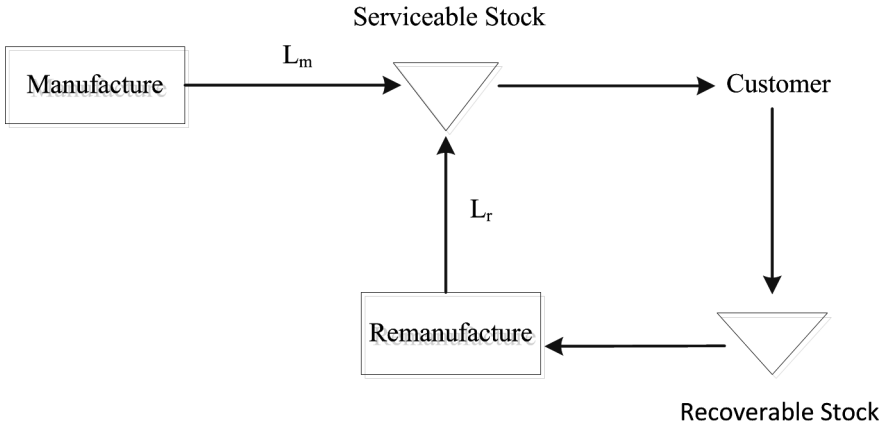
Figure 1. Material flow in a simple manufacturing/remanufacturing system
(Corum et al., 2014).



The (R_m, Q_m, R_r, Q_r) Hybrid Pull Strategy

Under the hybrid pull strategy defined by Van Der Laan et al. (1999), remanufacturing starts with two conditions one leading the other: First the inventory level of serviceable stock drops to R_r and second there is sufficient inventory level of Q_r to send to remanufacturing process. When these two conditions are satisfied the Q_r products are batched and sent to remanufacturing process having a lead time of L_r per batch. The inventory level drops by Q_r in recoverable stock while increases by Q_r in the serviceable stock. When the inventory drops to R_m ($< R_r$), manufacturing takes place in batches of Q_m with lead time of L_m per batch where s_m and s_r represent the safety stocks. The timing of remanufacturing operations depends on a composite of returns, future expected demands, and inventory positions. In this strategy remanufacturing operations are scheduled as late as suitable. The timing of manufacturing operations is based on the serviceable stock position. See Figure 2 (b) for illustration.

It is essential to accurately value the assemblies that influence holding cost rates while comparing inventory strategies in average cost models. Correct valuation method is critical to find the correct order batch size in hybrid manufacturing and remanufacturing systems. Teunter (2001b) proposes a method for valuing new, recoverable, and recovered assemblies (products, components, parts, etc.) in production systems with RL so called *RL Valuation Method:* The value of a new or an as good as new remanufactured assembly is the cost price of a new assembly. The value of a recoverable assembly is its net profit.

Total inventory cost is calculated as described in Teunter et al. (2000): Holding cost for recoverable item is $h_r = C_{core}*i$. Holding cost for serviceable items are based on holding cost rates of manufactured (weight 1-r) and remanufactured items (weight r), $h_s = i*[C_{reman}*r+C_{man}*(1-r)]$. Where;

i= Interest rate
C_{core}= Cost of returned products (cores)
C_{reman}= Unit remanufacturing cost
C_{man}= Unit manufacturing cost

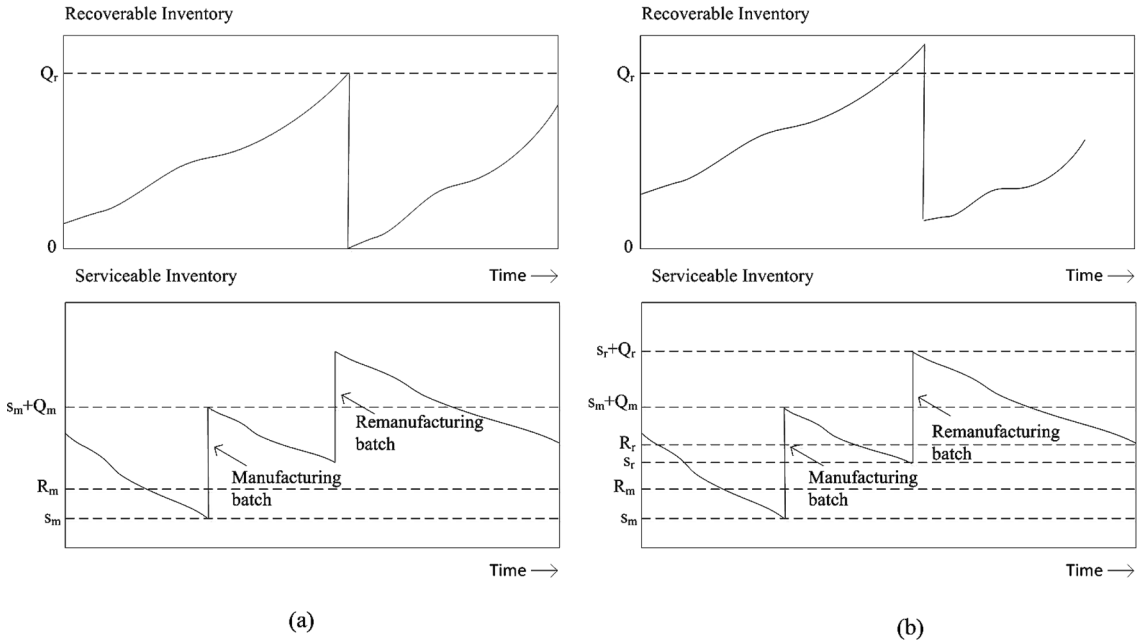
Figure 2. Push and pull controlled hybrid systems: (a) push control strategy (b) pull control strategy (Corum et al, 2014).



Pull system outperforms the Push system with respect to the total inventory costs when recoverable stock is valued *lower* than serviceable stock (Van Der Laan et al., 1999). Although Pull system is less costly than Push system, but management can still prefer Push system because it is relatively simple and easy to run it. Push system has independently controlled recoverable and serviceable inventory; the remanufacturing decision is based on only recoverable inventory level and the decided batch size. Pull system has dependently controlled recoverable and serviceable inventory; the remanufacturing decision is based on both recoverable and serviceable inventory levels and the decided batch size.

CONCLUSION

Recently, product recovery is one of the most important issues for the organizations. There are many motivations behind: Value recovery from the used products, the new regulations, and globally growing customer awareness, and environmental consciousness. Organizations consider different material recovery systems. One of them is remanufacturing where worn-out parts are removed and replaced. It is the only process where the quality standard becomes as good as a new product. A recoverable manufacturing system where it is possible to do direct manufacturing or remanufacturing depending on the system requirement, is called as a hybrid manufacturing/remanufacturing system. It is always complex to plan and control these systems because of the uncertainty existing in different stages of manufacturing. Management should take the remanufacturing decision after a detailed study. It is important to set up an effective and efficient collection system and plan the entire remanufacturing process. There can be hidden operating costs.

KEY TERMS AND DEFINITIONS

Disposal: The action or process of throwing away or getting rid of something.

Hybrid Pull System: Production system where demand is satisfied both with manufacturing and remanufacturing. Collected used items are pulled for remanufacturing when end item stock level decreases to a certain level.

Hybrid Push System: Production system where demand is satisfied both with manufacturing and remanufacturing. Collected used items are pushed to remanufacturing.

Manufacturing: Produce something on a large scale using machinery.

Product Recovery: The action or process of regaining the possession of the lost value of a product.

Product Return: Return of used product to add a value.

Recycling: Series of activities by which discarded materials are collected, sorted, processed and used in the production of new products.

Refurbishing: To renovate and recondition a used product to a certain level.

Remanufacturing: Completely to disassemble a used product and inspect all modules and parts. Worn out parts are removed and replaced to bring the quality standard of final product to like-new condition.

This research was previously published in the Handbook of Research on Waste Management Techniques for Sustainability edited by Ulas Akkucuk; pages 347-367, copyright year 2016 by Information Science Reference (an imprint of IGI Global).

Chapter 67
Applicability of ANN in Adsorptive Removal of Cd(II) from Aqueous Solution

Nirjhar Bar
University of Calcutta, India

Sudip Kumar Das
University of Calcutta, India

ABSTRACT

Cadmium is frequently used and is extremely toxic in relatively low dosages and is one of the principal heavy metals that is responsible for causing kidney damage, high blood pressure, renal disorder, destruction of red blood Cells and bone fracture. Permissible limit to discharge in the inland surface water is 2.0 mg/l, discharge in public sewers is 1.0 mg/l and drinking water is 0.01 mg/l. Adsorption is the only user-friendly technique for the removal of heavy metal. We have developed an ANN model for prediction of percentage removal of Cd(II). A multilayer perceptron with a single hidden layer has been learnt separately by three different algorithms: Backpropagation, Levenberg-Marquardt and Scaled Conjugate Gradient algorithms for analysis purpose. Optimization for each one of the four standard transfer functions (in a single hidden layer) has been carried out in all three cases. The ANN model with Backpropagation algorithm, with the second transfer function and 25 processing elements gives the best predictability of the outlet concentration.

INTRODUCTION

The presence of heavy metals in the environment is a major concern as they are toxic in nature. Heavy metal pollutants are non-biodegradable hence environmentally persistent. Heavy metal exists in environment as natural components, and also their concentration has increased in the last century due to industrial revolution after World War II (Nriagu, 1979). As the heavy metals are non-biodegradable in nature, they are accumulated in the food chain via water–plants–animals–humans (Sciban & Klasnja, 2003). Hence

the presence of heavy metal ions in water bodies, groundwater and soils from industrial waste water can pose a significant threat to ecological systems and also human health (Sen et al. 2002). For the protection of public health the heave metals removal from wastewater and water bodies are necessary. Heavy metal contamination exists in aqueous waste streams of many industries, such as metal plating facilities, mining operations and tanneries etc. Hence a cost-effective treatment for metals-contaminated wastewater is required, as environmental laws become stringent (Singha & Das, 2012, 2013).

Cd(II) is non-biodegradable and have great environmental impact for its presence in wastewater (Brower et al., 1997; Cay et al., 2004). Cadmium is introduced into the water bodies from different industrial activities like metal mining, plating, cadmium–nickel batteries, smelting, phosphate fertilizers, alloy industries pigments, stabilizers and sewage sludge etc. It is observed that the average Cd(II) concentration from metal plating industries are nearly 15–20 mg/l, and as high as 1000 mg/l concentration in lead mine acid drainage. The harmful effects of Cd(II) include acute and chronic metabolic diseases like testicular atrophy, disorders, renal damage, hypertension, emphysema and itai–itai disease, (Zhou et al. 1993; Chakravarti et al. 1995, Naiya et al. 2009a). Due to toxicity, the recommended maximum tolerance intake of Cd(II) by IS 10,500 for discharge in inland surface water and public sewers are 2.0 and 1.0 mg/l, respectively (IS 10500 1992, CPCB, 1995). The tolerance limits for heavy metal concentration in potable water and discharge into inland surface waters is shown in Table 1 (IS 10500 1992, EPA, WHO).

Cd(II) Removal Techniques

In general, various techniques are used for heavy metal removal effectively from the aqueous solution and they are the reduction and precipitation, coagulation, flotation, adsorption, ion-exchange and reverse-osmosis or electro dialysis, etc. (Zouboulis et al., 1997; Ravindran et al. 1999; Esalah et al. 2000; Canet et al. 2002; Pacheco et al., 2006; Sharma et al. 2009; Zhang & Fang, 2010; Gajda & Bogacki, 2012, Singha & Das, 2013). However it is observed in some instances, that these methods don't work properly with good efficiency. Many of these remediation technologies are expensive and time consuming and also have limitations particularly at low concentration of metal ions (Bhattacharya et al., 2006; Pacheco et al., 2006; Naiya et al., 2009a,b; Naiya et al., 2009). The precipitation method involves higher cost for heavy meal removal as voluminous sludge is produced which must be treated and disposed off properly (Hao et al., 2010). Ion-exchange and reverse-osmosis are effective and efficient, but expensive because of its high operational and maintenance cost. Adsorption, on the other hand, is a simple and cost-effective technology that has been widely used for remediation of numerous contaminants in waters, wastewaters, and soil (Stietiya & Wang, 2014). Adsorption onto activated carbon is considered as an effective technique and was extensively used in the last few years (Yiaocumi & Tien, 1995; Kandah, 2004). But considering the cost economics, recent research has focused on the development of low-cost readily

Table 1. Tolerance limits for heavy metal concentration in drinking water and discharge into inland surface water

available alternatives using various agricultural, industrial, natural/biological waste materials including synthetic, modified model adsorbents. Several contributions have made in this area utilizing number of materials are reported in literature (Ferro-García et al., 1988; Low et al., 2000; Yalcinkaya et al., 2002; Bhattacharya et al., 2006; Memon et al., 2007; Bhattacharya et al. 2008; Naiya et al. 2009a,b; Naiya et al. 2009; Singha & Das, 2011, 2012, 2013).

Large electroplating facilities generally employ precipitation technique and it is in the form of either sulfide, carbonate, hydroxide precipitation or some combinations of these treatments for wastewater treatment (Peters et al., 1985). Peter and Ku (1984) reported the batch precipitation of cadmium as hydroxide and sulfide for various operating condition like pH, reaction time etc. They observed that cadmium hydroxide is colloidal in nature, and extremely low residual Cd(II) concentration had been obtained. But it generates large amount of sludge of relatively low density and create disposal problem. The carbonate precipitation occurs at lower pH than hydroxide precipitation but they are denser and hence easy to filter. For sulfide precipitation Na_2S used as precipitating agent for heavy metal by Bhattacharyya et al. (1979) and reported that the Cd(II) ion removal was more than 99% for copper smelting wastewater. Sulfide precipitation can be achieved by wide pH range (Bhattacharyya et al., 1979). The disposal of sulfide sludge is problematic as they are prone to oxidize and Cd(II) ions re-entered into the wastewater. In alkaline condition emission of hazardous H_2S gas is observed, hence pH must be properly monitored during the entire precipitation process. However the removal efficiency is more that 99.99% (Peters et al., 1984). Brantner and Cichon (1981) concluded that the precipitation techniques for Cd(II) removal is very effective method.

Nilsson (1971) reported the coagulation/flocculation method using aluminium sulfate and calcium hydroxide for the cadmium removal from wastewater. Mahvi and Bazrafhan (2007) studied electro coagulation process for cadmium removal using aluminum electrode. They observed that the applied current density is a major parameter to dictate the cadmium removal efficiency. Cadmium-cynide and nickel-cyanide containing wastewater from electroplating industry was successfully treated by using electrocoagulation method using iron plate electrodes in a electrochemical reactor by Kobya (2010). The main drawback of these processes is the huge sludge formation and high chemical consumption.

In wastewater treatment flotation plays an important role for the removal of heavy metals. Foam flotation, dissolved air flotation, ion flotation, precipitation flotation and adsorbing colloid flotation are mainly used (Fu and Wang, 2011). In foam flotation a surfactant is used which promote the non-surface active material to surface active and foaming the product to be removed by air bubbling. Huang et al. (1988) and Jurkiewicz (2006) demonstrated the useful application of flotation for Cd(II) separation. In ion flotation the metal ions are made to be hydrophobic by the use of proper surfactants and then removed by air bubbling. Yuan et al. (2008) studied this technique to remove Cd(II), Pb(II) and Cu(II) from the aqueous solution using tea saponin, a bio-surfactant. Salmani et al. (2013) studied the removal capability of cadmium(II) using sodium dodecyl sulphate as surfactant and ethanol as frother in ion flotation technique. Sabti et al. (2002) used adsorbing colloid flotation for the effective removal of heavy metals, Zn(II), Cu(II), Cd(II) and Pb(II) from dilute solutions. Sodium dodecyl sulphate and sodium oleate were used in single or mixed form as surfactant and $Fe(OH)_3$ as flocculant for colloid formation. The advantages of this methods are the removal capability of trace metal ions from natural and industrial wastewater streams, choice of proper surfactant and flocculant make the process highly metal selective and high removal efficient, rapid processing, simple design, small volume of final solution,

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

concentrated sludge production, flexible operation (Sabti et al., 2002). But the major disadvantages are the high initial cost, high operation and maintenance costs, difficult to regulate as the process depend on several operating parameters.

Cementation is a powerful technique for removing heavy metals from wastewater. It consists of displacing the toxic metal ions from the wastewater by a more non-toxic metal. General reaction for cadmium cementation with other metal ions is represented as,

$$Cd^{2+} + M = M^{2+} + Cd \quad (1)$$

where M is a bivalent metal.

Gould et al. (1986) and Ku et al. (2002) reported that cadmium could be removed by cementation with magnesium and zinc powder respectively. Nosier (2003) reported the removal of Cd(II) ions by cementation on zinc in a batch stirred tank reactor lined with zinc sheet. The cementation process is a diffusion control chemical reaction and hence the removal efficiency depends on the operating parameters like stirrer speed, initial Cd(II) concentration, temperature and cementation time. The reactor is simple in design and operation, can operate in batch and/or continuous mode. The cadmium is deposited on zinc surface as a fine powder and can be collected by scraping the zinc surface. Thus saleable cadmium product improves the economy of the process. Younesi et al. (2006) reported the cementation of cadmium ions at pH 5.2–5.4 by zinc powder in a batch reactor and observed first-order reaction kinetics.

Ion exchange is basically an adsorption process where charged molecules, i.e., ions, in a solution are exchanged for another ions at the surface of adsorbant or resin either synthetic or natural solid. The common cation exchanger resin contain either strong acid like sulfonic acid group (-SO_3H) or weakly acid like carboxylic acid group (-COOH). Cadmium ions are exchanged for the hydrogen ions during the ion-exchange process as (Fu & Wang, 2011),

$$2R - SO_3H + Cd^{2+} \rightarrow \left(R - SO_3^-\right)_2 Cd^{2+} + 2H^+ \quad (2)$$

$$2R - COOH + Cd^{2+} \rightarrow (R - COO^-)_2 Cd^{2+} + 2H^+ \quad (3)$$

The exchange of metal ions on the ion exchange resin depends on different operating parameters, like pH, temperature, initial metal ion concentration and contact time (Gode and Pehlivan, 2006). This process has high selectivity, high treatment capacity, high removal efficiency, fast kinetics, wide applicability range of pH values and high regeneration potential (Kang et al., 2004). Researchers used different types of ion exchange resins (Koivula et al, 2000; Martinez et al., 2006; Pehlivan & Altun, 2006; Zhu et al., 2007a,b; Wong et al., 2014; Alyüz & Veli, 2009). Many researchers studied cadmium removal using different resins such as Amberlite IRC 718 (Malla et al., 2002), Dowex 50 W (Pehlivan & Altun, 2006), Amberlite IR 120 (Kocaoba, 2007), dolamite (Kocaoba, 2007) etc. Ion exchange process requires a high capital investment for equipments and also high operational cost due to the use of chemicals for resin regeneration.

Fu and Wang (2011) reported that the membrane filtration process has a great promise for cadmium removal due to their high removal efficiency, easy to operate and space saving unit. Researchers reported membrane filtration, including microfiltration (MF), ultrafiltration (UF), nanofiltration (NF) and reverse osmosis (RO) for cadmium removal using different pressure and pore sized membrane to

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

physically retain cadmium. Ritchie et al. (2001) used polycysteine and polygloutamic acid functionalized MF membrane for high concentration of cadmium solution. Zeng et al. (2009) reported the cadmium separation by the hybrid complexation-ultrafiltration process using ployacrylic acidsodium salt as complexing agent with polysulfone membrane. Han et al. (2012) used composite membrane prepared from hyperbranched polyamidoamine and polysulfone for removal of Cd(II). Salehi et al. (2012) immobilized 8-hydroquinone as a multi-dentate chelating agent on the PVDF MF membrane and observed Cd(II) adsorption was more favorable than other metal ions. Qdais and Moussa (2004) reported the removal of Cd(II) by RO and NF. They observed that for RO much higher pressure was required compare to NF. Saljoughi and Mousavi (2012a,b) developed an asymmetric polysulfone membrane for Cd(II) removal and obtained more than 98% separation. Bennani and M'hiri (2015) studied heavy metal separation using two commercial nanofiltration membranes (DL and DK) from industrial wastewater. They showed that the maximum rejection of heavy metal was obtained at 4 bar transmembrane pressure and cadmium rejection was 86%. The advantages of NF are ease of operation, comparatively low energy consumption, reliable in operation and high removal efficiency. The effectiveness of the membrane techniques is limited by their low permeate flux and high costs (Ballet et al., 2004). Sribudda et al. (2015) studied the separation of Cd(II) from industrial wastewater via hollow fiber supported liquid membrane (HFSLM). They examined the effect of pH of feed and stripping solutions, type and concentration of extractants and observed 97.08% extraction.

The use of electrodialysis technique for Cd(II) removal from synthetic water was demonstrated by Marder et al. (2003). In this process the metal ions were removed as solid metallic form, can be reuse. Ali et al. (2014) studied the removal of cadmium from brackish water by electrodialysis. They observed that the efficiency of this process depends on the demineralization rate, the removal rate and the transport flux of cadmium, the current efficiency and the specific power consumption. The advantages of this process are that there is no need to use other chemicals and hence there is no sludge formation. But this process is inefficient at low cadmium concentration (Rao et al., 2010).

Liquid-liquid extraction from aqueous solution using selective solvent is another technique for the cadmium removal (Nrogueia & Delmas, 1999; Gupta et al., 2001; Jia et al., 2004; Reddy et al., 1996). Reddy et al. (1996) used bis-2-ethylhexyl sunphoxide in benzene as solvent for Cd(II) and Zn(II) removal from thiocyanate solution. Reddy et al. (2006) used phosphorus based extractants such as TOPS 99, Cyanex 923, Cyanex 272, Cyanex 302 and Cyanex 301 diluted in kerosene for the solvent extraction to recover Cd(II), Co(II) and Ni(II) from the sulphate leached liquor of spent Ni-Cd batteries wastewater. The disadvantages are the use of large amount of solvent, costly stripping step to regenerate the solvent and very high recovery cost of cadmium if the concentration is very low.

All the techniques reported earlier have their own limitations such as at less effective at low concentration, sensitive operating condition, sludge production and problems of disposal, costly initial and operating cost etc. Another powerful technique is adsorption for the removal of toxic and heavy metals from wastewater stream. The advantages of the adsorption process are the use of low cost and easily available adsorbent, utilization of industrial and agricultural waste, low operating cost, ease of operation, regeneration and disposal of used adsorbents. Hence, adsorption is environmental friendly, cost effective and feasible method. Last few decades large amount of research have been reported in literature for the removal of toxic metals, cations, anions, organics and dyes etc. The adsorbents used are activated carbon; synthetic metal oxide like, activated alumina, silica, titanium oxide; polymers; nano materials; natural minerals and industrial waste, agricultural and plant materials; microbial materials etc.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Activated carbon has been a widely used adsorbent and the adsorption capacity depends on the nature of the adsorbent, concentration and pH of the adsorbate solution. Activated carbon is used for various applications like heavy metal ions, other cations and anions, dyes and organic removal from wastewater (Purkayastha et al., 2014).

The activated carbon prepared from different raw materials having high carbonaceous materials, like bone char (Cheung et al., 2001), peanut husks (Ricordel et al., 2001), bagesse (Mohan & Singh, 2002), activated carbon prepared from almond husk (Hasar & Cuci, 2000), coconut shell carbon (Aziz et al., 2005), Wood (Rao et al., 2006), granulated activated carbon (Minceva et al. 2007), activated carbon (Wasewar et al., 2010), *Sesamum Indicum* Carbon (Venkatesan et al., 2014), neem oilcake carbon (Hema & Srinivasan, 2010), charcoal, rock melon activated carbon (Nurdin et al.,2015) etc. used for Cd(II) removal.

Synthetic metal oxide like mixed oxides of iron and aluminum (Srivastava et al., 1998), aluminum oxide (Sen & Sarzali, 2008; Naiya et al., 2009), manganese dioxide (Mishra & Tiwary, 1998; Tonkin et al., 2004; Zaman et al., 2009), etc. are used for Cd(II) removal. Other oxides like low grade ores containing metal oxide, sludges, fly ashes etc. are used for Cd(II) removal from aqueous solutions. These materials include calcite (Mcbridge, 1980), chabazite and clinoptilolite (Kesraoui-Ouki et al., 1993), natural and activated bentonite (Prsdasp et al., 1994), kaolinite (Angove et al., 1997), the montmorilonite (Barbier et al., 2000), goeteite (Christphi & Axe, 2000), activated kaoline (Yayuz & Aslan, 2002), clinoptilolite (Sprynskyy et al., 2006), Zeolite 4A (Rao et al., 2006)), Naural zeolite (Minceva et al., 2007**),** kaolinite, montmorillonite and their acid-activated forms (Gupta and Bhattacharyya, 2009), clarified sludge (Niaya et al., 2008), basic oxygen furnace slag (Xue et al., 2009), red mud (Apak et al., 1998; Han et al., 2002; Gupta and Sharma, 2002; Zhu et al., 2007a), coal fly ash (Apak et al., 1998; Mohan & Gandhimathi, 2009; Koukouzas et al., 2010), bottom fly ash (Khan et al., 2009), activated clay (Wasewar et al., 2010) etc.

Agricultural waste materials usually contain lignin, cellulose, hemicelluloses, lipids, many other compounds containing functional groups like, surface –OH, carboxyl groups, alcohols and esters, saturated and unsaturated groups, phenolic, amido, amino, -SO_3 groups, sulfonic acid, phosphoric ester group etc. (Singha & Das, 2011). These groups are responsible for the metal binding. These agro materials are saw dust, bark, peel, husk, leaves of different origin.

Saw dust of pinus sylvestris (Taty-Costodes et al., 2003), papaya wood (Saeed et al., 2005), poplar wood (Sciban et al., 2007), teak wood (Naiya et al., 2009), sunflower stalks (Sun and Shi,1998), maize cob (Abia et al. 2005), cassava waste (Abia et al., 2003), banana pith (Low et al., 1995) medicago sativa (Alfalfa) (Gardea-Torresdey et al., 1998), natural and $KMnO_4$ modified myrtus communis leaves (Dhabab et al., 2014), peels of banana (Anwar et al., 2010), rice husk (Ajmal et al., 2003; Kumar et al., 2010; Nhapi et al., 2011), base treatment of juniper fiber (Min et al. 2004), raw and EDTA modified maize husk (Igwe and Abia, 2007) Corn straw and corn cobs (Jamil et al., 2009), *Calotropis procera* root (Ramalingam et al., 2013), coconut shell (Khorasgani, 2013), magnetically modified peanut husk (Rozumova et al., 2013), eucalyptus bark (Ghodbane et al., 2008), neem bark (Naiya et al., 2009), orange peel (Li et al., 2007), mango peel (Iqbal et al., 2009), pine bark (Al-Asheh & Duvnjak, 1997), rice husk (Ajmal et al., 2003; Kumar & Bandyopadhyay, 2006), neem leaf (Sharma & Bhattacharya, 2005), olive tree leaf (Hamdaoui, 2009), *Hevea brasiliensis* leaf (Pandey et al., 2008), *Psidium guvajava* leaf (Rao et al., 2007) etc. used for Cd(II) removal from wastewater.

ANN Techniques

Artificial Neural Networks (ANNs) are extensively studied in different fields of engineering, finance etc. with a basic objective of achieving prediction, classification, function approximation etc. It is a very powerful tool to identify underlying highly complex relationships from input-output data and represent both linear and non-linear relationship. It can learn this relationship directly from the data this is the reason it is a important tool for data mining. But Individual relations between the input variables and the output variables are not developed by scientific or engineering judgment. So far from the literature survey it is clear that the use of multilayer perceptron with backpropagation, Levenberg-Marquardt and Scaled Conjugate Gradient algorithms for various predictions had been very popular in the recent past (Bar et al., 2010a, 2010b, 2011; Bar and Das, 2011, 2013; Mitra et al., 2014; Singha et al., 2014; Das et al., 2015; Singha et al., 2015). The prediction of percentage removal for Cd(II) ion using ANN is very rare and not much of research had been done in this field as evident from literature review. This chapter discuss the adsorptive removal of Cd(II) ions from aqueous solution in batch and applicability of ANN for the predictability of the removal.

MATERIALS AND METHODS

ANN Methodology

In this chapter we have developed an ANN model for percentage removal of Cd(II). The adsorbent used are Saw dust of teakwood origin, Neem bark, Rice husk, Clarified sludge, Fly ash, Activated alumina and Fuller's earth. The effect of different operating parameters on the selectivity and sensitivity were reported. A multilayer perceptron with backpropagation (BP), Levenberg-Marquardt (LM) and Scaled Conjugate Gradient (SCG) algorithms have been used for the analysis. Four different standard transfer functions in a hidden layer and a linear output function are used. The analyses with each transfer function has been separately carried out in all cases and the network was optimized before final prediction.

RESULTS AND DISCUSSION

Characterization of Adsorbents

The adsorbents were subjected to characterization by a variety of methods such as X-ray diffraction (XRD), chemical analysis, thermo gravimetric analysis (TGA), particle size, BET surface area, and scanning electron microscope (SEM). Figure 1 shows the SEM micrographs (Model S415A, Hitachi, Japan) of all the adsorbents. It indicated that the surface was porous in nature for all adsorbents.

The constituents of activated alumina, rice husk ash, fly ash, clarified sludge were studied by using X-ray diffractograms (XRDs) obtained from an X-ray diffractometer (Model No. XRD 3000P, Seifert, Germany). The X-ray diffraction was analyzed by using Cu Kα as a source and Ni as a filter media, K radiation maintained at 1.52 Å. The diffraction pattern is shown Figures 2-6. The Brunauer–Emmett–Teller nitrogen adsorption technique (BET) was used to determine the surface area (Model 1750

SORPTY, Carlo Erba, Italy). The particle size of 250–350 μm is analyzed in particle size distribution analyzer (Model 117.08, MALVERN Instruments, USA). The point of zero charge of the adsorbents was determined by the solid addition method (Srivastava et al., 2006; Singha and Das, 2012).

The properties of adsorbents are shown in Tables 2 and 3. FT-IR (FTIR RX-1, PerkinElmer, USA) spectrometer was used to determine the type of functional groups in saw dust and neem bark responsible for metallic adsorption.

Table 4 represents the shift in the wave number of dominant peak associated with the fresh and Cd(II) loaded saw dust and neem bark. These shift in the wave number indicated that there was metal binding at the surface of the adsorbent (Pravasnt et al., 2006; Naiya et al., 2009a). The shift of wave number of 1033.66 cm^{-1} (fresh saw dust) to 1031.73 cm^{-1} (Cd(II) loaded) and 1026.91 cm^{-1} (fresh neem bark) to 1027.87 cm^{-1} (Cd(II) loaded) indicated surface -OH is one of the functional group responsible for adsorption. Other major functional groups responsible for the adsorption are carboxylic acid N-H stretching and C-O stretching for saw dust and carboxylic acid N-H stretching for neem bark; amide C-O stretching and sulphonate S-O stretching for both adsorbents.

Effects of Initial pH on the Adsorption

The effect of pH on adsorption behaviour of cadmium by different adsorbents was shown in Figure 7. The pH of the solution varies from 2 to 8. The Cd(II) ions in the aqueous solution may undergo solvation and hydrolysis as follows,

$$Cd^{2+} + nH_2O = Cd\left(H_2O\right)_n^{2+} \tag{4}$$

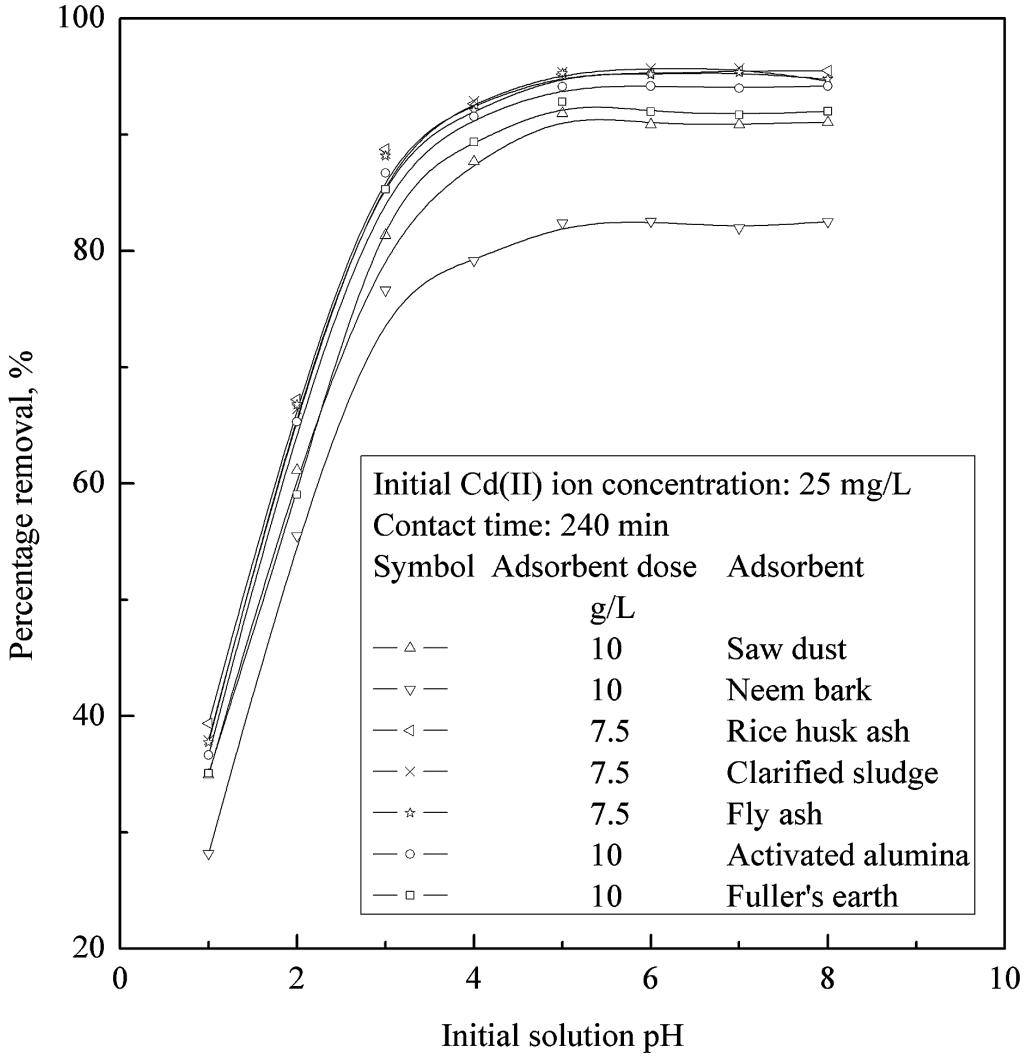
Figure 7. Variation of the initial solution pH on the removal of Cd(II)



$$Cd^{2+} + nH_2O \rightleftarrows \left[Cd\left(H_2O\right)_{n-1}\left(OH\right)\right]^{+} + H^{+} \tag{5}$$

The pK_a value is 10.1 for Equation (5). The oxides of silica, calcium, alumina and iron present in rice husk ash, clarified sludge, fly ash, activated alumina and fuller's earth which develop charge in contact with water. Zero point charge (pH_{ZPC}) of SiO_2, CaO and Fe_2O_3 are 2.2, 11.0 and 6.7 respectively (Srivastava et al., 2006). Hence, a positive charge develops on the surface of oxides of ashes in an acidic medium as,

$$-MO + HOH \xrightarrow{H^+} M - OH^{2+} + OH^- \tag{6}$$

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

The sorption at low pH ranges take place with low removal efficiency. This occurs because there was a high concentration of proton in solution and the proton competed with metal ions in forming a bond with the active sites on the adsorbents (Srivastava et al., 2006). As the initial pH of the system increases, the number of positively charge sites decreases and negatively charge sites increases, hence electrostatic attraction increases on the surface of ash. The mechanism can be expressed as

$$-MOH + OH^- \xrightarrow{H^+} -MO^- + H_2O \tag{7}$$

$$2 - MO^- + Cd^{2+} \xrightarrow{H^+} M - O - Cd - O - M \tag{8}$$

Similar theories are also proposed by other researchers Viraraghaban and Rao (1991) and Mathialagan and Viraraghaban (2002). The similar trend has also been reported by other researchers using different adsorbents (Horsfall and Abia, 2003; Hawari and Mulligan, 2006; Hasan et al., 2006; Memon et al., 2007). Increase in adsorption with increase in pH can also be explained on the basis that hydrolysed species have a lower degree of hydration that is less energy is necessary for the molecules upon binding sites. At a further increase of pH (6-9) the solubility of Cd(II) decreases enough for precipitation to occur.

The adsorption of Cd(II) ions onto the surface of saw dust and neem bark can probably be explained by an ion-exchange mechanism based on the surface complex formation model, which is facilitated by the dissociation of different functional groups present and resulting in the formation of metal complex (Khalid et al. 2005; Naiya et al., 2009a)

$$m\left[RO_7\left(OH\right)_{11}\right] \rightleftarrows m\left[RO_7\left(OH\right)_9\left(O^-\right)_2\right] + mH^+ \tag{9}$$

$$Cd^{n+} + m\left[RO_7\left(OH\right)_9\left(O^-\right)_2\right] \rightleftarrows Cd\left[RO_7\left(OH\right)_9\left(O^-\right)_2\right]_m^{n-m} \tag{10}$$

The overall reaction can be represented by:

$$Cd^{n+} + m\left[RO_7\left(OH\right)_{11}\right] \rightleftarrows Cd\left[RO_7\left(OH\right)_9\left(O^-\right)_2\right]_m^{n-m} + mH^+ \tag{11}$$

where, Cd^{n+} and $-RO_7(OH)_{11}$ are the cadmium ion with n+charge and the acidic part of the adsorbent respectively and R represents the matrix part of the adsorbents. The reaction is reversible. The enhanced adsorption of Cd(II) ions with an increase in pH may possibly due to the condensation reaction between the hydrolysis products of sorbate ions and the sorbent carrying the –OH groups (Benes and Majer, 1980; Khalid et al. 2005; Naiya et al., 2009a). Hence the Cd(II) adsorption onto the saw dust and neem bark are mainly due to the ion-exchange mechanism involving combine effect of site binding adsorption and also complexation phenomena. To ensure only adsorptive removal all subsequent experiments were carried out at pH 5.

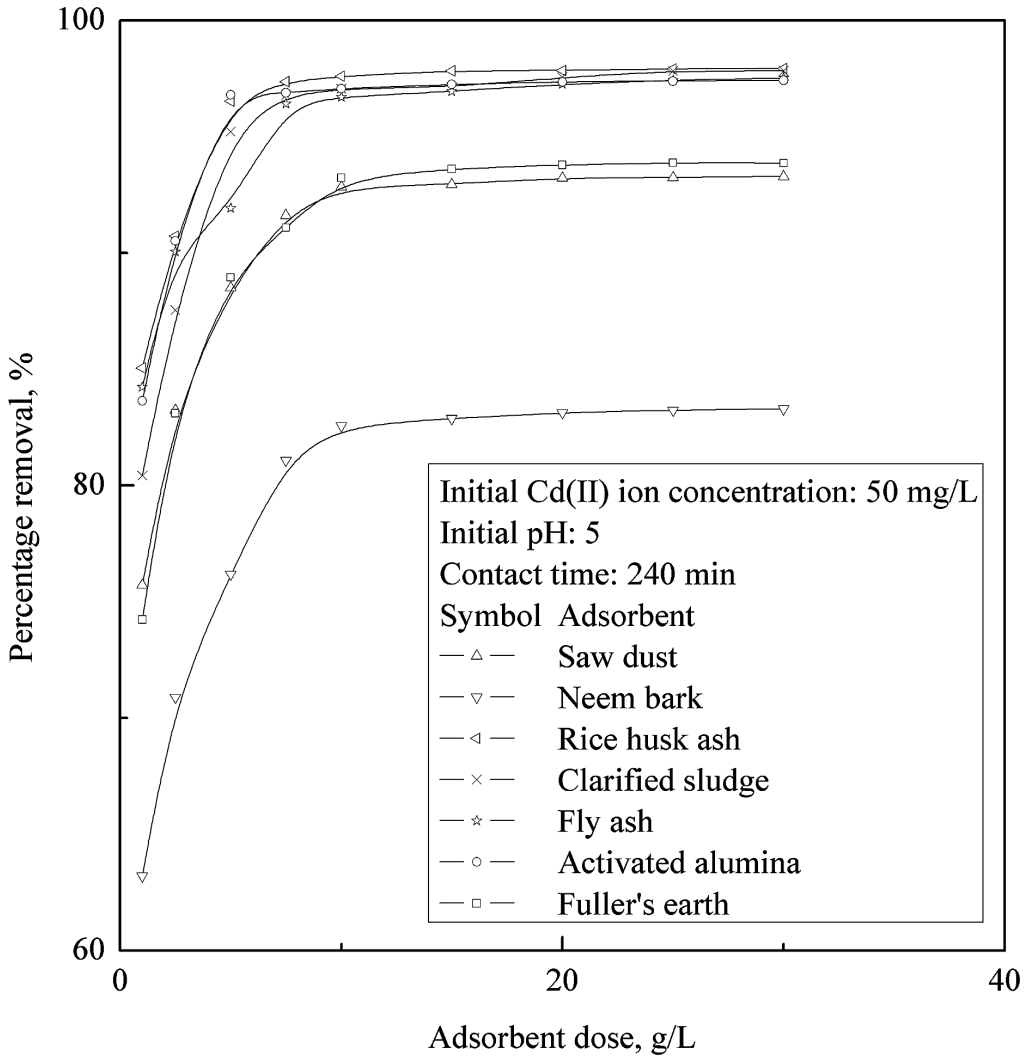
Effects of Initial Metal Ion Concentration on the Adsorption

Figure 8 shows the effect of initial Cd(II) concentrations on the removal efficiency by both the adsorbents. The efficiency of metal ions removal is also affected by the initial concentration of metal ions in aqueous solutions. Removal percentages of Cd(II) from aqueous solution decreases as concentration increases from 3 to 100 mg/L at constant pH. As the metal ion/adsorbent ratio increases, the higher energy sites are saturated and adsorption begins on lower energy sites, resulting in decrease in the adsorption efficiency (Zouboulis et al. 2002; Kadirvelu and Namasivayam, 2003; Bhattacharya et al. 2006; Naiya et al. 2009a, Singha and Das, 2013).

Figure 8. Variation of the adsorbent dosage on the removal of Cd(II)

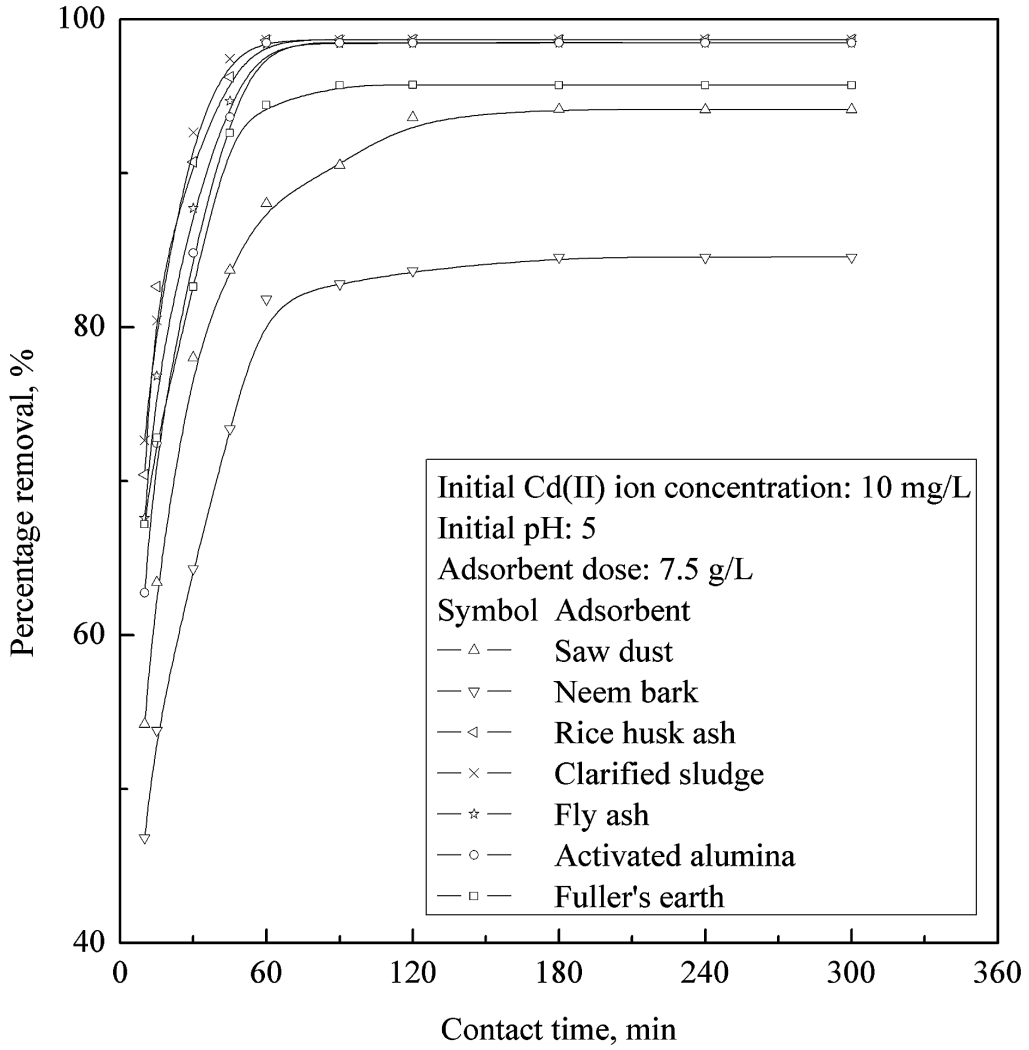


EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Effects of Adsorbent Concentration on the Adsorbent

Figure 9 illustrates the effect of adsorbent dosage on the adsorption of Cd(II) onto rice husk ash. The removal of Cd(II) was found to increase significantly with an increase in adsorbent dosage from 1–5 g/L. After adsorbent dosage level of 7.5 gm/L the metal ion removed almost remain unchanged. With increase the adsorbent dosages the availability of adsorbent sites and surface area increases hence adsorption increases, i.e., metal ion uptake by the adsorbents increases. For adsorbent dosage of 5 g/L, the incremental metal ion removal becomes very low as the surface metal ion concentration and the solution metal ion concentration comes to equilibrium with each other. For higher adsorbent dosage of 7.5 g/L, the removal efficiency becomes almost constant for the removal of Cd(II) ions onto rice husk ash.

Figure 9. Variation of contact time on the removal of CD (II)



EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Effects of Contact Time on the Adsorption

Figure 10 shows the variation of contact time on the removal of Cd(II) ions. The effect of contact time for the removal of Cd(II) showed rapid adsorption of Cd(II) in the first 45 min; thereafter, the adsorption rate decreased gradually and adsorption reached equilibrium in about 2 h. Therefore, at 2 h of contact time, the steady state approximation was assumed and a quasi-equilibrium situation was accepted. Accordingly all the batch experiments were conducted for a contact time of 2 h under isothermal and shaking conditions at 120 rpm.

ANN PROCEDURE AND PERFORMANCE

Table 5 gives the range of data for ANN analysis. The threshold value for the minimum value of cross-validation MSE was 1×10^{-4}. This value is kept same for analysis using all 3 networks. For the networks that was used for Backpropagation (BP) algorithm (Gradient descent or Momentum), each run was set for a maximum of 32000 epochs. The value of cross-validation MSE were dependent upon the capability of improvement within 10000 epochs, i.e., convergence towards the threshold value, otherwise the training was set to stop.

From the literature servey it is clear that the initial values of α and μ for BP algorithm are not mentioned in some of the papers where these algorithms are successfully used (Übeyli and Güler, 2004; Ozkan et al., 2010; Bonakdari et al., 2011). Although in some papers the values of above mentioned parameters are given (Karnin, 1990; Maier and Dundy, 1998; Udelhoven and Schutt, 2000; Yildiz et al., 2002; Desai et al., 2005; Ho, 2009). From the above literature survey it is clear that the values are

Table 5. Range of data

Measurement Type		Range
Input Parameters	Number of adrorbent	1 to 7
	pH	1 to 8
	Adsorbent Dosage (g/L)	1.0 to 30.0
	Initial Concentration C_o (mg/L)	3.00 to 100.00
	Time T (min)	10 to 300
Output Parameter	Percentage Removal (%)	27.23 to 99.82
Total number of data points		600

Table 6. Optimum numbers of processing elements in the hidden layer for four different transfer functions

Transfer Function in Hidden Layer	Equation	Algorithm	Optimum Number of Processing Elements
Transfer Function 1	$f_{1h}(x) = \tanh \beta x = \frac{e^{\beta x} - e^{-\beta x}}{e^{\beta x} + e^{-\beta x}}$	BP	24
		LM	22

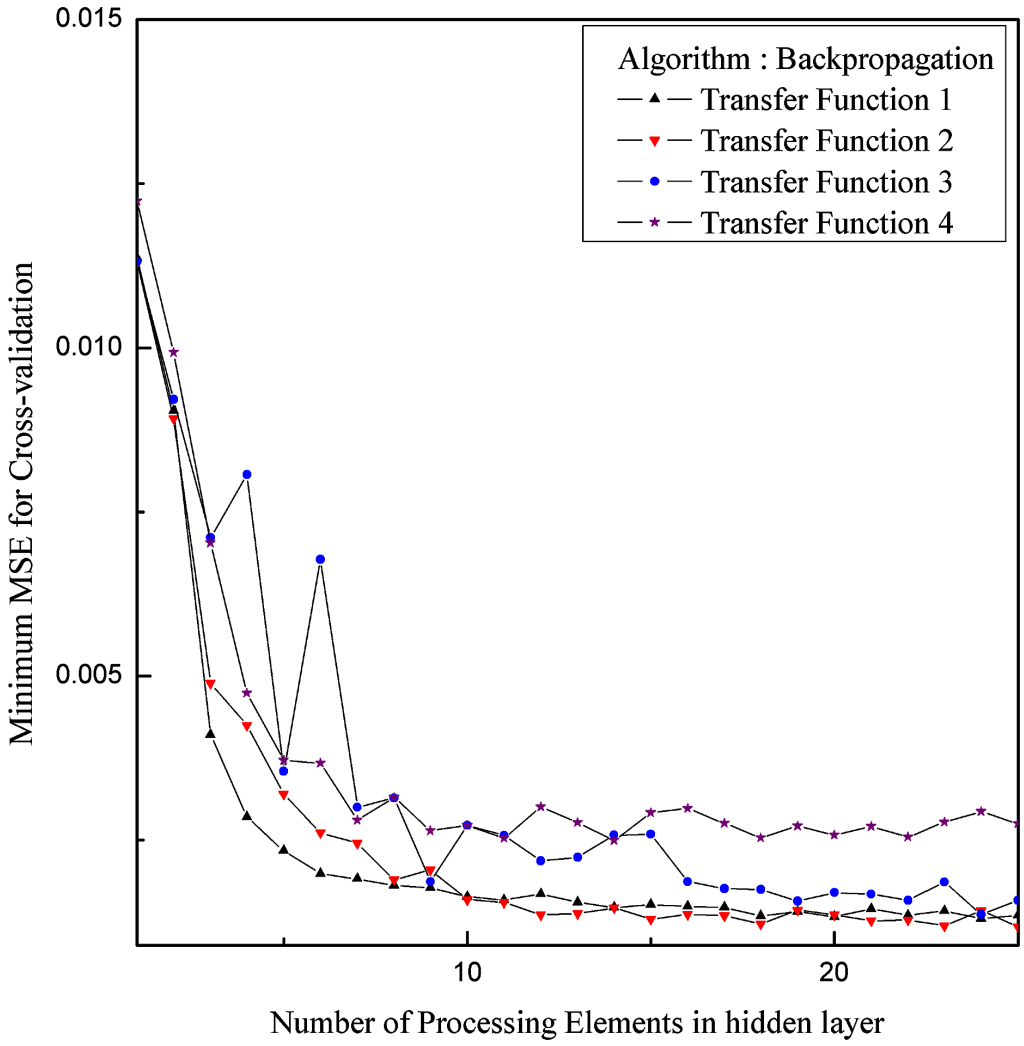
Transfer Function 3	0.001373	0.005997	0.002325
Transfer Function 4	0.002498	0.000763	0.001326

Figure 11. Variation of cross-validation MSE with the number of processing elements in the hidden layer

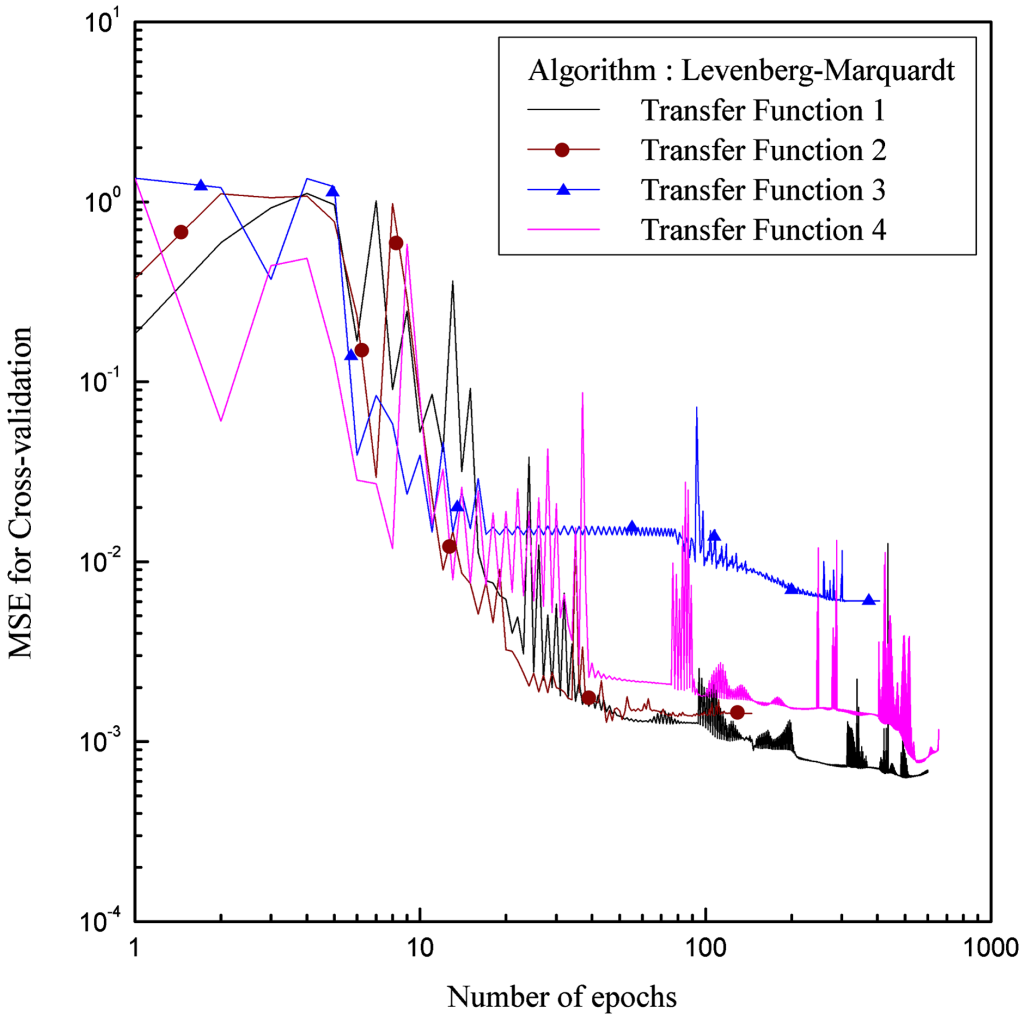


EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

randomly chosen. So it is clear that these values are dependent on the problem it deals with. The initial values of these constant parameters mentioned for training of BP are kept constant throughout this analysis. A few of these values of α and μ for BP algorithm are kept common for this study and the studies by Karnin (1990), Maier and Dundy (1998), Udelhoven and Schutt (2000), Yildiz et al. (2002), Desai et al. (2005) and Ho (2009). So, for the hidden layer of BP network the value of learning rate was 0.7 and momentum coefficient was 1. Similar procedure had been successfully applied in our earlier work (Bar et al., 2010a, 2010b, 2011; Bar and Das, 2011, 2013; Mitra et al., 2014; Singha et al., 2014; Das et al., 2015; Singha et al., 2015).

For network using Levenberg-Marquardt (LM) algorithm each run was set for 1000 epochs. The value of cross-validation MSE were dependent upon the capability of improvement within 100 epochs, otherwise the training was set to stop. Similar type of procedure had been followed in our earlier work (Bar and Das, 2011, 2013; Mitra et al., 2014; Singha et al., 2014; Das et al., 2015).

Figure 12. Cross-validation curve for Levenberg-Marquardt algorithm



EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

For network using Scaled Conjugate Gradient (SCG) algorithm each run was set for 32000 epochs. The value of cross-validation MSE was dependent upon the capability of improvement within 5000 epochs, otherwise the training was set to stop. Similar procedure have been followed in our earlier work (Bar and Das, 2011, 2013; Mitra et al., 2014).

The determination of optimum value for the number of nodes in the hidden layer was necessary for the best result. This value was determined during training and cross-validation phase (which was done simultaneously) for BP, LM and SCG algorithm respectively. The value of number of nodes for which the MSE of cross-validation is minimum was considered to be optimum. Table 6 presented the optimum value of number of nodes or transfer functions in the hidden layer for the respective transfer functions for which the minimum value of cross validation MSE had been achieved. Table 7 presented the value of the minimum value of cross-validation MSE reached during training. The variation of minimum value of cross-validation MSE with the number of processing elements in the hidden layer for BP network is represented in Figure 11.

A typical presentation of a cross-validation curve for LM algorithm is represented in Figure 12. From the curve it can be observed that for transfer function 1 and 2 the value of cross-validation MSE had

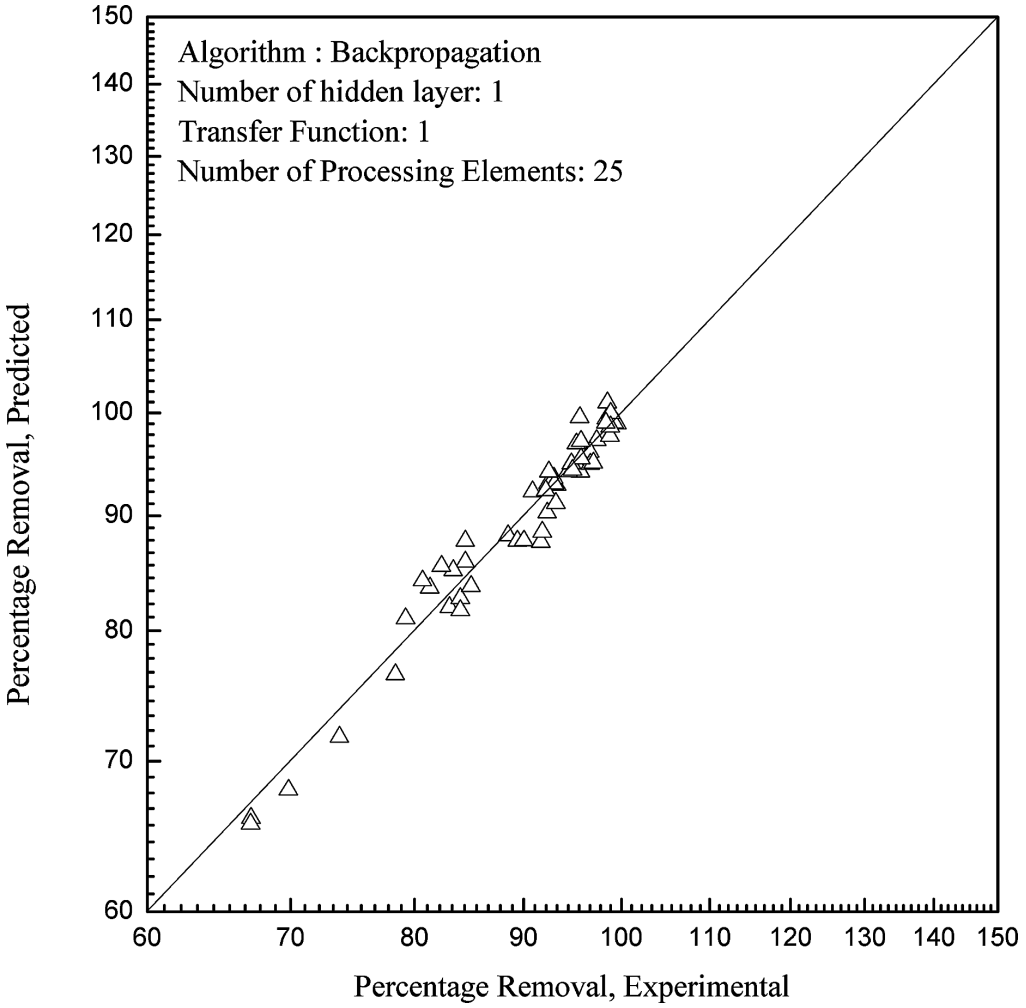
Figure 13. Comparison between the Experimental Data to be predicted from ANN



increased near the end of termination of training, i.e., the value of MSE increased in the last 100 epochs and showed no improvement during that period. For transfer function 3 and 4 the value of cross-validation MSE remained constant for the last 100 epochs, so the training was terminated.

Table 8 gives the comparison of all the statistical error parameters related to final prediction. The accuracy is evident from the observation of the low values of various statistical parameters related to the error, e.g., AARE, SD (σ). In all cases the values of R, i.e., cross correlation coefficient (CCC) were found close to unity, i.e., 0.99 and above. To draw conclusion of all the results the χ^2 test was conducted and is represented in Table 8.

The observation of all the results of the χ^2 test from the Table 8 it is clear that the ANN model with Backpropagation algorithm, using a hidden layer with transfer function 2 and 25 processing elements gives better predictability of the percentage removal. Thus, the successful prediction capability was understood from Figure 13 which is the comparison between the values of percentage removal of experimental and ANN prediction.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

CONCLUSION

The sorption of Cd(II) ion onto different adsorbents in batch mode are reported. Effects of different operating parameters on the removal efficiency are investigated. We have developed an ANN model for prediction of percentage removal of Cd(II). A multilayer perceptron with backpropagation and Levenberg-Marquardt algorithm and four different standard transfer functions in a hidden layer and a linear output function has been used for all cases. The ANN model with Backpropagation algorithm, using a hidden layer with transfer function 2 and 25 processing elements gives better predictability of the outlet concentration.

APPENDIX: NOMENCLATURE

C_o: Initial Cd(II) concentration (mg/L)
C_t: Cd(II) concentration at time t (mg/L)
m_s: Amount of adsorbent added in g
N: Number of data points
q_t: Amount (mg) adsorb per g of adsorbent

R: Cross correlation coefficient, $R = \dfrac{\sum_{i=1}^{N}\left(x_i - \overline{x}\right)\left(y_i - \overline{y}\right)}{\sqrt{\sum_{i=1}^{N}\left(x_i - \overline{x}\right)^2 \sum_{i=1}^{N}\left(y_i - \overline{y}\right)^2}}$, dimensionless

V: Volume of the solution in ml
x: Experimental value of % removal of Cd(II)
y: ANN predicted value of removal of Cd(II)

MSE: Mean Squared Error, $\frac{1}{N}\sum_{i=1}^{N}\left(x_i - y_i\right)^2$, dimensionless

AARE: Average Absolute Relative Error, $AARE = \frac{1}{N}\sum_{i=1}^{N}\left|\dfrac{\left(y_i - x_i\right)}{x_i}\right|$, dimensionless

Greek Letter

χ^2: $\chi^2 = \sum_{i=1}^{N}\dfrac{\left(x_i - y_i\right)^2}{y_i}$, dimensionless

σ: $\sigma = \sqrt{\sum_{i=1}^{N}\dfrac{1}{N-1}\left[\left|\dfrac{\left(y_i - x_i\right)}{x_i}\right| - AARE\right]^2}$, dimensionless

Chapter 68
Occurrence and Treatment of Micropollutants in Landfill Leachate

Muhammad Umar
The University of British Columbia, Canada

ABSTRACT

Micropollutants have emerged as a new challenge to the scientific community over the past decade. This chapter discusses the occurrence of various micropollutants in landfill leachate. Phthalic acid esters (PAEs) are one of the most investigated compounds in landfill leachate and are therefore given special focus in this chapter. The potential treatment options for these micropollutants are discussed with relevance to the estrogenicity potential of micropollutants. The potential of leaching of micropollutants from landfill sites is discussed to emphasize on the requirements of appropriate liners to avoid such exposure to the surrounding environment. Biological treatment in particular membrane bioreactors have been successfully used to remove some of the micropollutants. Advanced oxidation processes such Fenton and photo-Fenton have limited application reported in literature whereas other physic-chemical processes such as coagulation and adsorption have been demonstrated to be effective in the removal of micropollutants.

INTRODUCTION

Increasing population growth, changes in social and resource-use habits, and significant industrial and technological progress have led to an increase in the generation of municipal and industrial solid waste worldwide (Ojeda-Benítez & Beraud-Lozano, 2003; Renou et al., 2008). Landfills are one of the most affordable and acceptable means of final disposal of solid waste worldwide. Solid waste in a landfill is degraded by both aerobic and anaerobic processes. Once waste is placed in a landfill, it undergoes many physical, chemical and biological processes. These processes lead to production of landfill leachate and gas. Landfill leachate is a complex mixture with markedly varying composition depending largely on

the type of waste and age of the landfill. Leachate production poses serious environmental concerns such as pollution of groundwater and surface water if not properly managed, collected and treated. These concerns are particularly serious, where waste is deposited in unlined landfills (Umar, 2010).

Landfill leachate is generally very high in organic matter (both biodegradable and refractory to biodegradation), with humic-like matter making up an important group, as well as ammonia–nitrogen, heavy metals, chlorinated organic and inorganic salts. Although much lower in concentration (μg/L to ng/L) when compared with conventional contaminates, micropollutants constitute an important group of contaminants in landfill leachate. Over the last few decades, there has been an increasing concern on their occurrence due the increasing concentration originating from a wide range of sources including pharmaceutical, chemical engineering and personal care product industries in rivers, lakes, soil and groundwater. Micropollutants are subjected to various processes such as distribution between different phases, biological and abiotic degradation in environment (La Farre et al., 2008). These processes contribute to their elimination and affect their bioavailability. The role of the aforementioned processes in micropollutants' fate depends on their physico-chemical properties (polarity, water solubility, vapor pressure) and the type of the environment (natural or mechanical), where the micropollutants are present (groundwater, surface water, sediment, wastewater treatment systems, landfill leachate, drinking water facilities) (Virkutyte et al., 2010). As a result, different transformation reactions can produce metabolites that often differ in their environmental behavior and ecotoxicological profile from the parent compounds. Micropollutants may include two classes of contaminants: (1) legacy contaminants of which toxic effects have been established, and control measures have been developed; (2) contaminants of emerging concern that are not currently regulated and are thought to have potential threats to environmental ecosystems or human health and safety (La Farre et al., 2008).

Persistence of micropollutants in the groundwater down gradient of landfills has been reported by in various studies (Barnes et al., 2008; Buszka et al., 2009). In fact, landfill leachate contaminated groundwater had been shown to have the highest median concentrations of micropollutants (Lapworth et al., 2012). As a result, landfills have been recognized as one of the primary sources of contamination in groundwater and surface water (Barnes et al., 2008; Befenati et al., 2003; Buszka et al., 2009; Holm et al., 1995; Stuart et al., 2012). Pharmaceutical and personal care products (PPPCs) and endocrine disrupting compounds are a great concern with regard to landfill leachate as these compounds have the potential to contaminate both surface and ground water. Because pharmaceuticals are biologically active substances designed to cure or prevent diseases, they can interfere with biological systems and their toxic effects can affect every hierarchical ecological level: subcell, cells, organs organisms, populations, ecosystems, and ecosphere (de Witte et al., 2011). Endocrine disrupting compounds disrupt the endocrine system of aquatic biota (multiple-appendaged amphibians, feminization of fish, etc.) (Yang et al., 2014). Recently, evidence from field research has indicated adverse reproductive and developmental effects in wildlife (Kidd et al., 2007).

Treatment of landfill leachate is therefore, an important part of leachate management strategy. Several physicochemical and biological techniques are used for the treatment of landfill leachate, such as coagulation, flotation, chemical precipitation, adsorption, membrane filtration and various biological processes (i.e., sequencing batch reactors, anaerobic sludge blanket) (Garcia-Lopez et al., 2014; Ince et al., 2010). A combination of physicochemical and biological processes is generally needed to treat landfill leachate to an acceptable level. Conventional treatment approaches can be ineffective for the treatment of micropollutants. As a result, there is an increasing interest in alternative novel approaches that are efficient in removing such toxic compounds and to remove potential estrogenicity. A combination

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

of conventional and novel processes is in particularly, promising considering the increasingly stringent regulations related to quality of treated leachate prior to discharging to receiving waters. The objective of this chapter is to provide an assessment of the presence of micropollutants in landfill leachate and to look into the effectiveness of various methods for their removal.

BACKGROUND

In recent decades, the types of waste materials deposited in landfills have changed, mainly as a result of higher demand and better quality of consumer products. For example, batteries, paints, oils, electrical products and micropollutants that are potentially deposited at landfills contain additives that can negatively impact the environment and human health (Eggen et al., 2010). Micropollutants in landfill leachate include a variety of organic contaminates including compounds used in household and industrial applications and consumer products that include fecal and plant sterols, food additives, soaps and detergents, solvents, cleaning agents, fire retardants, plasticizers, perfumes, pesticides and pharmaceuticals (Andrews et al., 2012). Their presence in landfill leachate can be a consequence of the direct use of these compounds and their successive discharge or their leaching from discharged products (Loffredo et al., 2014). Pharmaceutical compounds may occur in concentrations of approximately 8.1 mg/kg in typical MSW (Musson & Townsend 2009). Having been discarded in landfills, micropollutants may be degraded/metabolized, adsorbed to solids, or dissolved in leachate (Musson and Townsend 2009).

Leaching of organic micropollutants from landfills to groundwater and/or disposal to surface water is a an important environmental problem, considering these compounds are potentially toxic, estrogenic, and carcinogenic to both terrestrial and aquatic organisms (Cozzarelli et al. 2011; Huset et al. 2011; Matejczyk et al. 2011). Some studies have reported that mixtures of dilute concentrations of micropollutants in water may deleteriously affect human health, as had been previously shown for aquatic biota (Sharpe & Skakkebaek 1993; Lye et al. 1999; Pomati et al. 2006; Tillitt et al. 2010).

Although most modern landfills have leachate collection and pumping systems to collect leachate into lined holding pits or lagoons, leaks through liners, caps, and leachate collection systems could lead to some of its escape from containment systems into the surrounding environment (Andrews et al., 2012). Furthermore, leachate collected in containment systems generally is drained into sewer lines that discharge to municipal Wastewater Treatment Plants (WWTPs). As existing WWTPs were not designed to remove micropollutants, varying proportions micropollutants could be discharged with treated waste water back into the receiving streams (Ternes 1998; Snyder et al. 2007).

Understanding the occurrence and removal of micropollutants in wastewater and develop effective ways to safe levels is critical in assessing their environmental and public health risk and determining safe levels. As the reclamation and reuse of a range of wastewaters is an emerging approach to mitigate the stress from water scarcity in many regions of the world, one of the main concerns in water recycling is the risk resulting from micropollutants at trace concentrations. As a result, there is now a strong need for the enhanced removal of micropollutants using alternative approaches which are efficient and cost effective.

One of the major limitations in determination of trace organic contaminants has been the difficulties in analyzing these compounds considering their very low concentration. This has been more relevant to complex matrices such as landfill leachate. However, recent analytical advancements have now made it possible to detect compounds at very low level to be determined in most wastewater matrices. Although landfill leachate has been extensively investigated for the presence and removal of dissolved organic

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

carbon (DOC), ammonium, methane, and heavy metals, there is a limited data on the type and concentration of micropollutants present in landfill leachate. Consequently, there is little data available on their removal from landfill leachate using conventional and novel approaches.

Occurrence of Range of Micropollutants in Landfill Leachate

The U.S. Geological Survey recently conducted the first national assessment of the range of micropollutants in landfill leachate in United States (Masoner et al., 2014). Leachate was collected form 19 active landfill sites and analysed it for 202 chemicals across a wide range of uses, including pharmaceuticals, hygiene products, home-use chemicals, pesticides, plastics etc. Out of those, a total of 129 compounds including 62 prescription pharmaceuticals, 23 industrial chemicals, 18 nonprescription pharmaceuticals, 16 household chemicals, 6 steroid hormones, and 4 plant/animal sterols were detected in landfill leachate. Concentration of the chemicals found varied widely. Steroid hormone concentrations generally ranged from 1 to 100s ng/L, prescription and non-prescription pharmaceuticals concentrations generally ranged from 100 to 10,000 ng/L, whereas home-use and industrial chemicals ranged from 1,000 to 1,000,000s ng/L.

Organic compounds identified by GC-MS full scan analysis of leachates from three landfills (landfill A, B, and C) was carried out by Eggen et al. (2010). They classified organic compounds into substance groups to facilitate interpretation of leachate composition. The non-target analysis indicated hundreds of compounds per sample of which, about 80% could be classified into substance groups. The authors performed qualitative and semi-quantitative overviews on the substances released and transported via the landfill leachate. Total organic load of leachate samples collected from landfills B and C was approximately 4 and 1.5 times higher than those from landfill A, respectively. At landfill A, leachate of the fresh active part releases about 10-fold more organic substances than leachate from the old, inactive dump. The authors also identified chemicals in the landfill and their transport downstream of a sandy aquifer was reported at landfill A. The amount of organic substances decreased in the wells downstream of the landfill, although 100 m downstream was at the same level as active part. In addition to variation in the total organic content, the composition of pollutant mixtures was different for each site and also between samples at landfill A. The ratio of PAHs to cycloalkanes, alkanes, and iso-alkanes could indicate the degradation potential in landfills. The highest proportion of alkanes was measured in leachates from landfill C and in 50 m downstream at landfill A. In general, these indicate different sources of waste and probably different biodegradation potential of the landfills. The proportion of cyclic or unsaturated hydrocarbons was reported to be high in leachates from landfills B and C.

Alkylated phosphates, both chlorinated and non-chlorinated, were found in all leachate samples (approximately 2–10% of total organic content) and triethylphosphate and tris(chloropropyl)phosphate (TCPP) were detected in all leachates samples, except in the operational part of the landfill A (Eggen et al., 2010). Tri(2-chloro-ethyl)phosphate (TCEP) and tris(1-chloro-2-propyl) phosphate (TCPP), were reported in landfill leachate by several other authors (Barnes et al., 2004; Paxéus, 2000; Schwarzbauer et al., 2002). According to these authors, the TCEP, TCPP and Tri-iso-butylphosphate were found in ranges of 220-240,000, 4000–50,000 and 110,000–350,000 ng/L, respectively.

Some of the widely used insecticides such as N,N-diethyl toluamide (DEET), benzothiazole, and N-butyl benzenesulfonamide (NBBS), were reported in leachate samples by several authors (Barnes et al., 2004; Paxéus, 2000; Schwarzbauer et al., 2002; Welander, 1997). The polar properties of these substances with log K_{ow} (ratio of the concentration of a chemical in n-octanol and water at equilibrium at a specified temperature) values of 2.2 (DEET), 1.99 (benzothiazole), and 2.1 (NBBS) (Westerhof et

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

al., 2005), contribute to their spread in aqueous environment. For example, while NBBS is a naturally occurring substance that is used commercially as plasticizer in the polymerization of polyamides and has previously been shown to be neurotoxic (Strong et al., 1991), DEET is an insect repellent and is frequently detected in leachates at µg/L level (Eggen et al., 2010). NBBS has also been measured in landfill leachates at µg/L range (Welander, 1997) and standardized OECD tests have classified this compound as persistent. Considering the polarity of TCPP with log K_{ow} 2.59–3.33 (OECD), TCEP with log K_{ow} 1.4, DEET (2.2) and NBBS (2.1), these compounds are not expected to bioaccumulate in the environment, however their recalcitrant nature and high polarity render them potentially readily transportable through conventional landfill treatment systems.

Perfluorinated compounds (PFCs) have a widespread application in a myriad of products, including household cleaning agents, carpets, textiles, paper coatings, cosmetics, fire-fighting foams and packaged-food containers (Hekster et al., 2003). Presently, little data on their occurrence in landfill leachate is available, however, some studies have shown that landfill leachate may represent a significant source of PFCs (Bossi et al., 2008; Kallenborn et al., 2004; Woldegiorgis et al., 2006; Busch et al., 2010). Contrary to many persistent organic pollutants with a medium to high hydrophobicity, many PFCs are mainly found in the water phase (Schultz et al., 2006), and efficient removal of these compounds becomes challenging during leachate treatment (Eggen et al., 2010). Quantitative analyses of PFCs in water and particle phases were performed for leachates from two landfills and sediment samples from another landfill by Eggen et al. A comparison of the concentrations of PFCs measured in 2004 and 2006 showed that their concentration was generally greater in 2006, where the majority of PFCs were found in the aqueous phase. In the 2004 leachates, perfluorooctanoic acid (PFOA) was the predominant compound with concentration respective ranges of 23–118 and 5.8–157 ng/L in water and particle phase.

In a study by Busch et al. (2010), the sum of PFCs was in the range of 31–12,819 ng/L (average 5777 ng/L) in untreated leachate samples, 15–129 ng/L (average 42 ng/L) in reverse osmosis treated leachate, 9–4079 ng/L (average 723 ng/L) in active carbontreated leachates (n=8), 621 and 1257 ng/L (n=2) in nanofiltrated leachates, 1992 and 4610 ng/L in wet air oxidation treated leachates, and 4023 and 8059 ng/L in biologically treated leachates. Polycyclic musk compounds are used in various household products and cosmetics. The occurrence of polycyclic musk compounds in landfill leachate was investigated by Eggen et al. (2010). The authors reported the highest concentration of polycyclic musk compounds in leachates from the closed and vegetated part of the landfill with concentration of 482,000 ng/L in the water phase.

Bisphenol A (BPA), also known as 2,2-bis-(4-hydroxyphenyl) propane or 4,40-isopropylidenediphenol, is an endocrine disrupting compound (EDC) that has been widely studied due to its extensive use in making polycarbonate plastic and epoxy resins, which are used in polycarbonate baby feeding bottles and epoxy food-can linings. BPA has been shown to have some similarity of chemical structure with estrogen, and exhibits affinity with estrogen receptors. BPA has been classified as an EDC by the USEPA (1997) and is found in a wide range of aquatic environments. BPA has also been reported in landfill leachate of 7 out of the 10 landfill sites by Yamamoto et al. (2001) with concentrations ranging from 1.3 to 17,200 µg/L. The mean concentration of BPA in that study was 276 µg/L which is in agreement with that reported by Boonnorata et al. (2014). However, Kalmykova et al. (2013) reported a lower concentration (up to 107 µg/L) of BPA than aforementioned studied.

Li et al. (2014) investigated the presence of polybrominated diphenyl ethers (PBDEs; additive flame retardants) at 4.0–351.2 ng/L level, with an average of 73.0 ng/L in landfill leachate in a city in North China. The authors reported that BDE-209 dominated the congeners in most of the samples, followed

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

by BDE-47 and BDE-99. Greater PBDEs concentrations were reported in leachate from young landfill sites located in the urban area. The authors performed a Pearson correlation analysis which demonstrated a potential dependence of the concentration of PBDEs on landfill age, suspended solids and DOC concentration.

Phthalic Acid Esters (PAEs)

Phthalic acid esters (PAEs) can be highly concentrated in landfill leachate (Schwarzbauer et al., 2002) and are one of the most extensively investigated micropollutants in landfill leachate. Phthalates has been detected in leachates from landfills in several studies (Table 1). As noted in Table 1, a wide range in the concentration of PAEs was reported ranging from 0.10-470 µg/L. PAEs are classified as endocrine disrupting compounds that are known to adversely impact the reproductive, neuro developmental, and immune system of both humans and wildlife. Dissolved organic matter (DOM) facilitated transport of PAEs is an important transport mechanism from solid waste (Bauer & Herrman, 1997). The distribution of three PAEs including diisobutylphthalate (DIBP), di-n-butylphthalate (DnBP) and bis(2-ethyl) hexylphthalate (DEHP) in humic acid (HA), fulvic acid (FA) and hydrophilic fractions (those having an affinity to water and are usually charged or have polar side groups to their structure) of leachates from sanitary or bioreactor landfills was evaluated by Zheng et al. (2007). The results showed that the PAEs were bound mainly to the HA fraction in leachate, irrespective of landfill age or leachate recirculation. Molecular weight of DOM correlated well with PAEs partition. Considering the presence of phenolic, carboxyl or amide groups in DOM fractions, the interactions between PAEs and leachate DOM were expected to be mainly due to hydrogen bonding. The peptide groups in the HA fraction was likely explanation of the strong affinity of PAEs for HA. The fluorescence excitation-emission-matrix spectra demonstrated that the hydrophilic fractions shared similarities with HA-like substances with regard to their molecular structure, partly explaining why PAEs exhibited a clear sorption to the hydrophilic fractions.

Another study conducted by Xiaoli et al. (2010) showed that the association of humic substances (HS) with PAEs depends greatly both on the properties of the PAEs and the source of HS. Greater association of DnBP, which has a high log K_{ow} and low water solubility suggests that non-specific hydrophobic interactions between PAEs and HS could have an important role in their abiotic association. The HS, with higher aromatic content and a larger molecular weight, has a strong association with DnBP, indicat-

Table 1. Concentration of various phthalate esters in landfill leachate

Compound	Concentration (µg/L)	Reference
bis (2-ethylhexyl) phthalate	<1.0-23	Kalmykova et al. (2013)
bis (2-ethylhexyl) phthalate	180	Rocha et al. (2013)
bis (2-ethylhexyl) phthalate	293	Boonnorata et al. (2014)
Diethyl phthalate	<0.10-22	Kalmykova et al. 2013
Diethyl phthalate	130	Boonnorata et al. (2014)
Di-n-butyl phthalate	<0.10-1.8	Kalmykova et al. 2013
Di-n-butyl phthalate	275	Boonnorata et al. (2014)
Di-n-butyl phthalate	470	Rocha et al. (2013)

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

ing that the hydrogen-bonding between the H-donating aromatic groups of HS with the H-acceptors in the PAE molecules may be involved in the association reaction between PAEs and HS. Occurrence of DEHP, DBP, and di-ethyl phthalate (DEP) (grouped as benzenedicarboxylic acid esters and contributing 5–20%) were detected in at least three leachate samples collected from three different landfill sites.

Potential of Leaching of Micropollutants from Landfill Sites

In addition to the micropollutants in leachate produced, there is a strong potential of the contamination of the groundwater and reservoirs due to their leaching specifically in the vicinity of landfills. This problem is particularly severe in countries where solid waste is landfilled or has been landfilled without separation/pre-treatment as this could result in enhanced release of contaminants, posing potential contamination of the surrounding environment.

Several antibiotic compounds (e.g., sulfamethoxazole, lincomycin, and erythromycin) have been detected in groundwater in Europe and North America, with maximum concentrations in the range of 5.7–2×10^3 ng/L (Lapworth et al., 2012; Peng et al., 2014). Moreover, a variety of industrial chemicals (e.g., detergents, fire retardants, and plasticizers), pharmaceuticals and personal care products (PPCPs) (e.g., anti-inflammatories, β-blockers, drugs of abuse, antiseptics, preservatives, and sweeteners) and their metabolites have been observed in groundwater (Lopez-Serna et al., 2013; Loos et al., 2010; Osenbruck et al., 2007). The occurrence of various PPCPs including antibiotics, azole anti-fungals, non-steroid anti-inflammatory drugs, lipid regulators, parabens, antiseptics, and bisphenol A, was investigated in groundwater and reservoirs in the vicinity of two municipal landfills in the metropolis of Guangzhou, South China by Peng et al. (2014) Dehydroerythromycin, sulfamethoxazole, fluconazole, salicylic acid, methylparaben, triclosan, and bisphenol A were the mostly frequently detected PPCPs in the groundwater at low ng/L levels. Lapworth et al. (2012) found that landfill leachate contaminated groundwater had the highest median concentrations of a range of emerging organic contaminants.

The pharmaceuticals, paracetamol, phenazone, and gemfibrozil were not detected in any of the samples in a study conducted by Eggen et al. (2010), while the non-steroidal anti-inflammatory drug (NSAID), ibuprofen, was detected in all leachate samples. The highest ibuprofen concentration of 166,624 ng/L, was measured in leachate from the inactive part of the landfill, decreasing to 96.9 ng/L at inlet to treatment plant. Naproxen, another NSAID, was measured in the leachate from the active part of the landfill at a concentration of 282 ng/L. Compared to ibuprofen, the lower concentration level of naproxen probably reflects a lower deposition volume and/or a faster degradation with shorter half-life (9–14 days) compared to ibuprofen (32 days) (Araujo et al., 2009; Tixier et al., 2003). The neuroleptic drug carbamazepine applied as an anti-epileptic drug and anti-depressive was measured at trace concentration of 8.6 ng/ L in the active phase of the landfill and at inlet to the treatment plant at 0.8 µg/L. Despite these trace levels, carbamazepine is one of the most distributed drugs in the environment (Clara et al., 2004; McClellan & Halden, 2010; Zhang et al., 2008). Due to its persistence and semi-polar properties, carbamazepine can reach groundwater and has been detected in drinking water (Donn et al., 2008).

The concentration of polycyclic musk compounds was reported to decrease downstream of the landfill. Considering their more hydrophobic properties (HHCB (1,3,4,6,7,8-hexahydro-4,6,6,7,8,8-hexamethylcyclopenta-γ-2-benzopyran) log K_{ow} 5.9, AHTN (6-acetyl-1,1,2,4,4,7-hexamethyltetraline) log K_{ow} 5.7) (Balk & Ford, 1999), these polycyclic musk substances are adsorbed on surfaces of suspended matter and detected in both the water and particle phases. The particle-bounded concentration of musk, presented as the sum of AHTN and HHCB, at active part and 200 m downstream of landfill

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

was 9.6 and 17.9 ng/L, respectively. The corresponding water phase concentration was 6.5 and 3 ng/L, respectively. The authors inferred that it indicated transportation of these compounds via both water and particle phases through the sandy aquifer of the landfill. The particle-bound musk contribution in leachates from another landfill, taken at the discharge of the WWTP drainage system, was 27 ng/L. The relatively lipophilic HHCB has been observed in the range of 43–63 mg/kg dry weight sewage sludge in previous studies focusing on the environmental fate of musk compounds (Carballa et al., 2007).

Treatment of Micropollutants in Landfill Leachate

The current scenario related to the occurrence of micropollutants in the receiving waters requires new approaches for their treatment. Unfortunately, conventional wastewater treatment plants are designed to deal with bulk substances that occur regularly and in large quantities (primarily organic matter and the nutrients, i.e., nitrogen and phosphorus). Micropollutants are however, entirely different due to their unique characteristics and behavior in the treatment plant and are not generally eliminated during the treatment. Moreover, their concentration is very low compared with conventional contaminants making them less amenable to elimination. Thus, new measures need to be taken to reduce for their reduction or complete elimination from water and wastewater.

Membrane Bioreactors

A recent study by Boonnorata et al. (2014) investigated the removal of BPA, 2,6-di-tert-butylphenol (2,6-DTBP), 2,6-di-tert-butyl-4methylphenol(BHT), di-ethyl phthalate (DEP), di-butyl phthalate (DBP) and bis-(2-ethylhexyl) phthalate (DEHP) in municipal solid waste landfill leachate using two-stage membrane bioreactor (MBR) in a long term operation of 500 days. These contaminants were effectively removed in both anoxic and aerobic conditions, however, greater removals were obtained under aerobic conditions. The predominant removal mechanism of removal of investigated compounds was biodegradation with removal of up to 99.5%, 99%, 99%, 98%, 97% and 96% for BPA, 2,6-DTBP, BHT, DEP, DBP and DEHP, respectively. Chemical properties of the leachate were considered the main factor affecting the removal efficiency of contaminants. Among the investigated compounds, BPA, 2,6 DTBP, DEP are relatively hydrophilic, their biodegradation rate was higher. The molecular structure of DHEP is more complex and pre-treatment by adsorption and downstream biological treatment could be an effective way of removing such compounds.

Yiping et al. (2008) used anaerobic-membrane bioreactor in order to remove organic micropollutants that were present in the landfill leachate effluent. In their study, 17 organo-chlorine pesticides (OCPs), 16 polycyclic aromatic hydrocarbons (PAHs) and technical 4-nonylphenol (4-NP) were investigated and they found that 4-NP compound were removed by the MBR whereas OCPs and PAHs were mainly removed by the anaerobic process. An overall removal of 94% of OCPs, 77% of 4-NPs and 59% of PAHs was reported by the authors.

A study conducted by Wintgens et al. (2003) investigated two different landfill leachate treatment plants with a variety of process configurations. The xenoestrogenic substances, namely, nonylphenol and bisphenol A were detected in high µg/L-ranges in raw landfill leachate. MBR was capable of removing more than 80% of the nonylphenol load and the final concentrations were reported to range between 1–12

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

µg/L nonylphenol and 3–30 µg/L bisphenol A, respectively. The authors reported that reverse osmosis was less effective for the removal of both nonylphenol and bisphenol A than MBR with downstream polishing stages like nanofiltration and activated carbon adsorption.

Fenton and Photo-Fenton

Rocha et al. (2013) identified more than 40 organic compounds in landfill leachate including benzene (0.09±0.07 mg/L), trichlorophenol (TCP) (0.18±0.12 mg/L), phthalate esters DnBP (0.47±0.01 mg/L), Butyl benzyl phthalate (BBP) (0.36±0.02 mg/L), DEHP (0.18±0.01 mg/L), among others and investigated their removal using solar photo-Fenton oxidation process. Toluene, pentachlorophenol, dimethyl phthalate, diethyl phthalate, and Di-noctyl phthalate were not detected in any of the samples. After treatment, TCP decreased to below the detection limit whereas the benzene concentration increased approximately three fold. Oxidation of 3 phthalate esters namely DnBP, BBP, and DEHP by the solar photo-Fenton process was demonstrated the process to be very efficient for the treatment of DnBP with a reduction of 77% however the reduction of BBP was low (17%) whereas no reduction of DEHP was observed. Overall, the solar photo-Fenton process was considered to be very efficient for the treatment of sanitary landfill leachates, leading to the complete elimination of 24 of the detected micropollutants to levels below their respective detection limits and low to significant abatement of seven other organic compounds, thus resulting in an increase of the leachate biodegradability.

There are limited studies conducted using the Fenton-based processes for the removal of micropollutants from landfill leachate. In addition to the limited investigation of the Fenton and related processes (photo-Fenton, electro-Fenton), there is no data on the types of breakdown products that could form during these treatments. Determination of by-products is significantly important considering some of those by-products are even more toxic than the parent compounds raising concerns related to the toxicity of treated leachate.

Adsorption

Activated carbon is the most commonly used adsorbent for industrial applications, particularly for the elimination of organic compounds from aqueous solution due to its chemical and textural properties (Alslaibi et al., 2013; Ocampo-Pérez et al., 2012). Adsorption on activated carbon has been recommended by the US Environmental Protection Agency as the best available technology for removing non-biodegradable toxic organic compounds from drinking water and industrial wastewater (USEPA, 1997). One of the important aspects of the adsorption processes considering the treatment plant design is the adsorption kinetics (Alslaibi et al., 2014). The overall adsorption rate of phthalic acid, BPA, diphenolic acid, 2,4-dichlorophenoxy-acetic acid, and 4-chloro- 2-methylphenoxyacetic acid on two commercial activated carbons was studied by Ocampo-Pérez et al. The authors used pore volume and surface diffusion model (PVSDM) diffusional and a kinetic model. The PVSDM model considers external mass transport, intraparticle diffusion, and adsorption on an active site whereas the concentration decay data were interpreted by using kinetics models. The PVSDM model satisfactorily fitted the experimental data of adsorption rate onto activated carbon. The contribution of pore volume diffusion represented greater than 92% of intraparticle diffusion, implying that the pore volume diffusion was the controlling mechanism of the overall rate of adsorption and role of surface diffusion could be neglected. Although

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

both diffusional models and kinetic models successfully fitted the adsorption rate experimental data, the authors recommend the use of diffusional models, since the assumptions were closer to the real adsorption process, than those of kinetic models.

The sorption and degradation of petroleum hydrocarbons (PHCs), alkylphenols, BPA, phthalates and PAHs in landfill leachate was investigated by using peat, sand and GAC filters by Kalmykova et al. (2014). It was reported that the removal of the sand filter was insufficient to meet water quality standards. However, sand filter was proposed as a necessary pre-treatment for the precipitated iron to avoid saturation of the filter material and to improve the removal of PAHs and PHCs in peat and GAC filter. Pyrene and DEHP were reported to be removed to a similar extent by sand and GAC filters, whereas the removal efficiency of the higher alkanes was lower for peat and GAC filters. The general trend revealed that PHCs were the most difficult compounds to remove, which was attributed to the colloid-facilitated transport from the peat filter and desorption from the GAC filter.

Coagulation

Coagulation is rarely investigated for the removal of micropollutants which predominantly relates to the ineffectiveness of coagulants to satisfactorily remove such compounds. Six PAEs, namely dimethyl phthalate (DMP), di-ethyl phthalate (DEP), DBP, BBP, DEHP, and di-octyl phthalate (DOP), are listed as priority pollutants by the US Environmental Protection Agency. The removal of these six PAEs by coagulation was evaluated from fresh and partially stabilized landfill leachate by Zheng et al. (2009). The PAEs were partly removed from fresh and partially stabilized landfill leachates (about 30% and 50%, respectively) by coagulation. The PAEs removal efficiencies in the fresh leachate were similar to the reduction of dissolved organic matter (DOM) measured as TOC and relative to the hydrophobicity of PAEs. The humic substances in the partially stabilized leachate facilitate the PAEs removal in a CF process. However, more studies are required to investigate the removal of micropollutants considering coagulation as the most widely and commonly used pre-treatment method in landfill leachate treatment. The use of novel coagulants ($TiCl_4$) and electrocoagulation are potential alternatives to traditional coagulation approaches for the removal of trace contaminants.

Estrogenicity of Landfill Leachate

There is increasing concern about the environmental effects of oestrogens and xenoestrogens that end up in receiving waters (Daughton, 2009). Estrogenic activity of municipal waste landfill leachate was investigated using a reporter-gene-based bioassay with a human breast-cancer-derived cell line (MVLN cells) by Coors et al. (2003). The leachate was processed using two different membrane processes operating in parallel. One process consisted of aerobic biological degradation, ultrafiltration, and downstream adsorption onto activated carbon. The second process used reverse osmosis treatment of the raw leachate. The efficacy of these two processes in removing estrogenicity was compared. Although both treatments removed more than 97% of the estrogenic activity, calculated as estradiol equivalents (EEQs), the treatments were not equally effective; after adsorption onto activated carbon, no estrogenicity was detected, whereas concentrated effluent of the reverse osmosis treatment elicited an estrogenic response in the bioassay potentially due to accumulation of contaminants in the brine. Chemical analysis revealed that bisphenol A was responsible for the majority of the estrogenic response in the raw and treated landfill leachate.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

An in vitro test based on recombinant yeast strains transfected with genes for the human estrogen receptor was adapted to study the occurrence estrogenic and antiestrogenic substances in six Swedish landfill leachates (Svenson et al., 2009). The authors measured the antiestrogenic effects as inhibition of the estradiol induced response with the human estrogen receptor α, and quantified by comparison with the corresponding inhibitory effects of a known antiestrogen, hydroxytamoxifen. The results revealed that the estrogenicity was within the range of that determined in domestic sewage effluents, from below the limit of detection to 29 ng estradiol units/L. Antiestrogenicity was detected in some of the landfill leachates and ranged between 38 and 3800 µg hydroxytamoxifen equivalents/L. Fractionation of leachate revealed that estrogenic compounds were located in two dominant fractions. BPA, estradiol, and ethinylestradiol accounted for the estrogenic activity in extracts of leachates.

CONCLUSION

Emerging compounds identified in landfill leachate include a range of chlorinated alkylphosphates including the possible carcinogenic flame retardant (TCPP), the neurotoxin plasticizer (NBBS), the insect repellent (DEET), PFCs, pharmaceuticals and personal care products such as the NSAIDs (ibuprofen and naproxen) and polycyclic musk compounds. Analysis of micropollutants is becoming increasingly important as well as prevalent and increasing studies have reported their occurrence in landfill leachate. In addition to analyzing the landfill leachate, there is a strong need of future research to correlate the landfill leachate and micropollutants occurrence in the nearby aquatic environments. Despite the contribution of estrogenic load on the aquatic environment seems to be low for treated leachate when compared with that of sewage treatment works, the high estrogenic activity in raw landfill leachate stresses the necessity for the appropriate treatment to minimize such hazards. Long-term fate of micropollutants in landfill leachate has not been extensively studied which is critical considering the recalcitrant nature of some of the micropollutants. Long-term studies of changes with regard to changes in microbial structure and function in environments downgradient of landfills could provide insight into the potential hazards associated with landfill leachate.

Chapter 69
Green Information Technology Usage:
Awareness and Practices of Philippine IT Professionals

Alexander A. Hernandez
Technological Institute of the Philippines, Philippines

ABSTRACT

Green information technology is resource efficient and effective consumption through the use of IT infrastructures to address environmental sustainability. This study aims to understand the level of awareness and practices of IT professionals towards GIT in organizations. A survey questionnaire was used, the study found that participants have a high awareness and practices of Green IT covering the efficient use of computing resources, energy conservation in an office environment, responsible disposal of electronic wastes, and demonstrate an individual contribution and commitment to GIT adoption practices in organizations. The study also found that male IT professionals have better awareness of GIT in organizations. The awareness and practices of IT professionals in GIT offers direction for organizations to strategically integrate GIT within their core business objectives and activities to attain environmental sustainability. Practical and theoretical implications are presented.

1. INTRODUCTION

Green IT is the study and practice of environmentally sustainable computing in organizations. It is an approach to address the growing environmental challenges resulting in detrimental effects to natural resources, increased carbon emissions, and leads to global warming (Bengtsson and Ågerfalk, 2016). These problems are associated with business activities heavily relying on the use of IT. Thus, it resulted in the inception of Green IT (GIT). The goal of GIT is to achieve resource-efficient and low-carbon business activities to minimize its impact on the environment (Loeser et al., 2017. Therefore, GIT remains a significant area of both research and practice.

Previous studies suggest that knowledge of new technology is critical to further technology adoption in organizations (Jenkin et al., 2011; El Idrissi and Corbett, 2016). It is also necessary to understand the role of professionals in the adoption of GIT in organizations and become an integral element of their work culture. Recent information technology (IT) infrastructure spending is crucial to achieving business performance (Chuang and Huang, 2016), however, as this grows, behavioral change among IT professionals is perceived significant to achieve sustainable use of computing resources (Murugesan and Gangadharan, 2012). Therefore, IT professionals have an important role to play in achieving environmental sustainability through their awareness of and practices in GIT in organizations.

The immense perspective to establish the practices of IT users helps to achieve environmental sustainability. More recently, GIT is a global issue for various industries. However, it is also growing concern in developing countries in which lacking educations is observed. The developing countries have been slow in recognizing environmental sustainability concerns and challenges (Hernandez and Ona, 2016; Chugh et al., 2016) in comparison to developed countries with advanced strategies, policies, and technology implementations on GIT. Therefore, developing countries have a significant role to play in GIT adoption (An Hign et al., 2017). It also calls for an urgent introduction to GIT, and take essential actions to engage and increase awareness of employees in organizations.

To date, studies on exploring the awareness of employees in GIT and practices are mostly focused in developed countries. However, a handful of studies investigating this phenomenon in developing countries such as the Philippines is not evident in the literature. Considering the growing economy and population of the country, therefore, this study attempts to fill this gap and offer new insights on GIT awareness and practices of IT professionals, which could be integrated as part of IT professionals' roles in achieving environmentally sustainable work practices in organizations.

This study aims to present the findings of a survey that explores the environmentally sustainable practices by Philippine IT professionals. To attain the goal of the study, a survey was used to determine the level of awareness and practices in GIT among IT professionals. The remaining parts this research covers the following sections: (2) discussions on the roles of IT professionals in environmental sustainability and overview of the Philippine IT industry, (3) discussion of the research method and considerations in adopting a survey instrument, (4) the results of the study and presentation of findings, (5) discussion of the theoretical and organizational contributions and lastly (6) the conclusions and research limitations are discussed.

2. LITERATURE REVIEW

2.1. Overview of the Philippine IT Industry

As of 2016, the total IT companies in the Philippines was at an average of 646 with different business activities supporting local and international customers (IBPAP, 2016). Moreover, the IT sector continues to grow due to the international demands and developing economies. In 2015, the IT sector posted USD 22 billion in revenues, thus, making it the second largest source of income in the Philippines (Magkilat, 2015) and accounts for 9% of the gross domestic product in 2016 (IBPAP, 2016). The IT sector labor market and productivity increased by 1.2 million direct jobs. The stable growth of the IT sector is attributed to the foreign direct investments, the numerous expansions and projects in the past five years (Manning et al., 2016). Recently, the IT sector encourages partnership with government agencies

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

and academe to harness research and development (Hernandez and Ona, 2015), co-develop industry champions and participate in environmental sustainability programs. Similarly, the IT sector embarked to greener business activities such as GIT as one of the focus areas for rapid growth and sustainability (Department of Information and Communications Technology, 2016). Specifically, the professional associations and organizations in the IT sector developed GIT roadmap and strategy together with the design of guidelines on its implementation (Hernandez and Ona, 2016). Overall, through GIT, the IT sector contributes to achieving a more sustainable business and environment.

2.2. Roles of Information Technology Professionals in Environmental Sustainability

The Philippines Information Technology-Business Process Management (IT-BPM) sector experience sustained growth in the last five years (Department of Information and Communications Technology, 2017), however, as an indirect result, greengas house emissions and energy consumption continuously rise (Department of Science and Technology, 2013). These results contribute to the long term environmental degradation. Thus, organizations in the Philippines proactively adapt to GIT and sustainable practices as IT infrastructure continues to grow (Komatsuzaki, 2016) in many industries. Santiago (2013) reported that GIT and sustainability initiatives spending in the Philippines would reach USD 2.5 billion by year 2020. It manifests the gap in GIT and sustainability adoption and slower as compared to other developing countries as Philippine organizations lack strategic directions and approaches to further GIT adoption (Deloitte, 2015). Moreover, major problems and issues confronting the Philippines on sustainable environment from an IT perspective covers (a) rising electronic waste (Terazono et al., 2017), (b) ignorance (Roumasset et al., 2016), rising energy costs (Roxas and Santiago, 2016), (d) increasing carbon footprint (Holden et al., 2017), and depletion of natural resources (Khan et al., 2016).

These problems prompt serious threat to environmental sustainability, public health and safety, thus, a strategic approach is necessary to address these problems (Lee et al., 2013; Khor et al., 2015; Terazono et al., 2017). The establishment of GIT based strategic business approach, guidelines, integration of IT infrastructure, and systems are critical in the primary business procedures of an organization to achieve resource-efficiency and effectiveness and reduce environmental footprint (Montabon et al., 2016). The goal of GIT is to address technology inefficiencies essentially, focus on searching for available best options, and more effective strategies. Environmental sustainability may be referenced alongside different measures, but, in the perspective of GIT, it is commonly concentrated in the reduction of energy consumption in the entire business lifecycle (Deng and Ji, 2015), decreasing greenhouse gas emissions, better environmental knowledge and governance (Mithas et al., 2010), the usage of technology efficient equipment, and electronic waste reduction from IT industry (Luthra et al., 2014). Prior works proved that GIT adoption reduces costs (Tseng et al., 2013; Harmon and Auseklis, 2009; Chitra, 2011). It can also increase profit by 45% of organizations (Gullo and Haygood, 2010). Considering GIT adoption is an essential aspect in addressing sustainability associated concerns. Similarly, Hilty and Aebischer (2015) stated that IT use can positively persuade environmental concerns. However, the beneficial outcomes of GIT adoption were recognized concerns worthy of further investigation.

Disposal of IT waste responsibly is a significant measure towards encouraging environmental sustainability (Afroz et al., 2012). Electronic waste can come from used and damage electric and electronic devices that reached the end of life. The IT industry contributes 36% of electronic wastes generated in the Philippines (Terazono et al., 2017). Thus, electronic waste is now a major concern both in quantity

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

and toxicity in nature (Li et al., 2017). Most organizations and households are unaware of responsible electronic waste disposal schemes, except for firms with in-placed waste management policies (Yoshida et al., 2016). In support of this growing problem, managerial support and commitment, and organizational culture hinder environmentally friendly practices (Zaman and Sedera, 2016). Therefore, investigating the practices of IT professionals as well as organizations perspective with the sustainable environment could promote responsible electronic waste disposal within the IT industry.

The IT industry generates nearly 740 million metric tons of carbon emissions annually (Gelenbe and Caseau, 2015) in which carbon footprint also increases (Kanemoto et al., 2016). Hence, IT professionals can take the initial step to reduce carbon footprint in their organizations. The continuous growth of IT industry in the Philippines has led to the growing IT practitioners in the industry. The Philippines employs nearly 1.2 million of IT professionals working in IT-BPM industry (Hernandez and Ona, 2015). Considering the growing number of employees, it is essential to introduce awareness on GIT practices as to further GIT adoption in organizations (Hernandez and Ona, 2016). The IT industry is largely consuming energy and engaged in maintaining related products in various sectors (Hernandez and Ona, 2016). Hence, the practices IT employees adopt can have implications on environmental sustainability. The behaviors of IT employees also constitute an essential enabler on sustainable environmental practices. Moreover, GIT awareness emerged significantly in different industries (Makela and Luukkainen, 2013). Given the employees' awareness of GIT, it signifies a real foundation of change in behaviors with a greater focus on environmental sustainability (Baggia et al., 2017). Employees can take action and influence others to adopt GIT practices by changing some of their existing IT activities (Gan et al., 2017). However, GIT adoption practices are limitedly discussed in the literature (Loeser et al., 2017). It presents the necessity to adopt further GIT practices through the IT professionals' uptake through their knowledge and ability to apply these practices. Hence, investigating the level of sustainable computing knowledge remains an important aspect of information systems research and practice.

A key driver of sustainability investments within firms was employees' knowledge, support, and commitment towards sustainable computing practices (Yang et al., 2017). Front liners including employees and managers were considered crucial in adapting to sustainable computing activities (Al-Shemmeri and Naylor, 2017). Molla et al. (2014) in their study of IT professionals found that more concerns were focused on rising environmental challenges and their positive perspective about GIT. It was also concluded that it professionals were gradually changing their behaviors on GIT through paper-saving activities, however, in doubt of firm's awareness, practices, and policies on GIT. In a study of Philippine IT professionals to determine the significance of environmental issues, 35 percent of the respondents indicated that environmental sustainability was incorporated into their business activities (Hernandez and Ona, 2016). However, GIT is missing from the employees' perspective. Conversely, there were some sustainability practices covering switching off unused computers (Hernandez and Ona, 2016) and 3R (recycle, reuse, reduce) (Widjaja et al., 2011; Terazono et al., 2017), reducing the brightness of desktop displays (Chow and Chen, 2009), and common understanding about sustainable computing practice (Watling and Zhou, 2011) as well as reducing printed business documents.

The main point of the literature review highlights the concerns on sustainable computing activities. These issues and challenges were investigated comprehensively, thus, mostly conducted in developed nations, covering small to large scale organizations (Weng and Lin, 2011; Zailani et al., 2014; Abdullah et al., 2014; Cuerva et al., 2014, Lim et al., 2015), however, as stated in the introduction, a handful of studies have been available in the literature exploring the environmentally sustainable practices of IT

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

professionals in the Philippines. Hence, this research explores on both awareness and practice as there is little work in this area despite the critical roles of IT practitioners in the design, manufacturing, use, and disposal of IT infrastructure and related systems.

Finally, this study aims determine the green behaviors (Jenkin et al., 2011) of IT employees (Murusegan and Gangadharan, 2012) in a developing country perspective (Lee et al., 2013), by specifically exploring awareness (Chuo and Chuo, 2012) and practices in GIT (Seidel et al., 2010). Figure 1. presents the awareness of and practices in GIT of Philippine IT professionals. The components identified were from the previously discussed literature review in the section.

3. METHODOLOGY

The purpose of this research is to determine the level of awareness and practices of Philippine IT professionals towards GIT. The succeeding sub-sections discuss the survey questionnaire, demographic profile of the participants and data collection activities. This study used a validated survey questionnaire from the literature with three sections and sixteen items (Chugh et al., 2016). The questionnaire uses Likert's scale using a five-point scale for awareness and GIT practices with categories such as (a) demographic information, (b) awareness of environmental sustainability and (c) environmentally sustainable practices adopted by respondents and their organizations.

The survey questionnaire was distributed to thirty-eight firms of different sizes. The respondents were invited to participate through an email sent to the firm's IT manager containing the web survey link. The data was gathered from October – December of 2016. The survey was distributed to IT professionals as they were considered as knowledge workers (Gullo and Haygood, 2010) and were involved in GIT practices at the professional and individual level. The IT professionals were also considered as they were users and driver of GIT initiatives. Purposive and snowball techniques were used to ensure that the respondents were only IT professionals of different participating organizations. The IT managers were requested to distribute the survey to the selected IT professionals and encourage them to submit a completed survey. However, the identities of the respondents were not solicited from these organizations.

The survey questionnaire was sent through email with 108 completed survey received and only 104 were considered usable. Considering the exploratory and initial research on environmental sustainability awareness and practices, this study analyses IT employees' awareness regarding GIT practices from a chosen group of thirty-eight companies. It is considered that the selected group of IT professionals was valid representatives of the IT sector in the Philippines. The demographic characteristics of the IT professionals are presented in Table 1.

4. RESULTS AND DISCUSSION

Table 2 presents the mean score of the survey among all age groups; the results indicate that age group thirty-five and older are more aware of emissions and implications to the environment. Likewise, they perceived greater importance in renewable resources and understanding on electronic waste. Also, the results indicate age group thirty-five and older have higher agreement on their responsibility to act on environmental issues. However, age group twenty to twenty-four have a higher awareness of the increasing costs of energy use of IT equipment, and consistent on turning off computers after office hours.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. Green IT awareness and practices of Philippine IT professionals

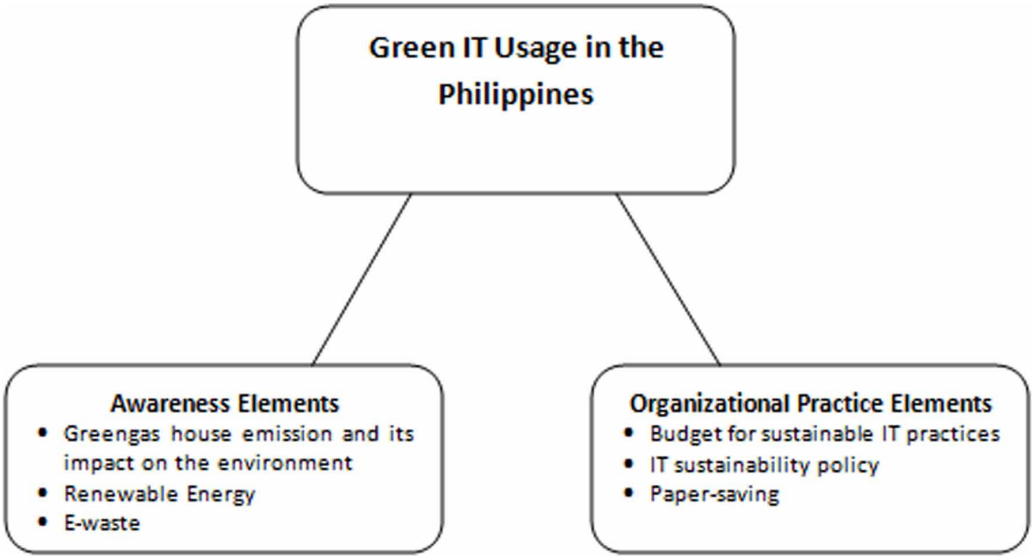

Table 1. Demographic profile of IT professionals

Characteristics	N (%)
Age – Group	
20-24 25-29 30-34 35 and older	15 (14.42%) 41 (39.43%) 26 (25%) 22 (21.15)
Gender	
Male Female	79 (75.96%) 25 (24.04%)
Number of Employees in the Firm	
Less than 1000 More than 1000	48 (46.15%) 56 (53.85%)

Meanwhile, all age groups have almost similar awareness in switching-off lights. The results also show that thirty-five and older have noted that their organizations have sustainability policy, and employ an in-charge for sustainable practices, and put emphasis on paper-saving activities.

Based on the results of the survey (see Table 3), the comparison between male and female groups has little difference in most of the items. Both male and female groups have similar agreement on shutting down of computers when not used in their firms, allocates budget for sustainable IT practices, and highlights paper-saving activities. The male group had a higher awareness of renewable resources, considers individual responsibility on sustainable environment challenges including electronic waste disposal, switching-off lights, and energy use of equipment. The male group also recognized the relevance of sustainable ICT guidelines and considered designating a member of the organization to further GIT

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 2. Comparison of the mean score among age groups

Statement	Age Group				
	20-24	25-29	30-34	35 and Older	Average
I am aware of greenhouse gas emissions and its impact on the environment	3.4	3.3	3.5	3.6	3.5
I am aware of renewable energy	3.3	3.7	3.5	3.8	3.6
I have knowledge of e-waste	2.6	3.1	3.2	3.4	3.1
I take responsibility to assist in making a difference on environmental issues, for instance, energy consumption and e-waste disposal	3.1	3.2	3.5	3.7	3.4
I am aware of the increasing cost of energy consumption in desktop computers	3.3	3.1	3.3	3.2	3.2
I shut down my personal computer after work day.	3.6	3.2	3.1	3.1	3.3
I switch-off lights when not be used.	3.5	3.7	3.5	3.5	3.6
My company provides budget for sustainable IT practices	3.0	3.5	3.3	3.5	3.3
My company has an IT sustainability policy	3.1	3.3	3.2	3.5	3.3
My company has a dedicated person responsible for ICT sustainable practices	3.5	3.4	3.5	3.6	3.5
My company highlights paper-saving	3.3	3.6	3.4	3.7	3.5

practices. Therefore, it could be explained that male professionals observed better understanding and awareness of sustainable environmental practices and proactive behavior. Overall, GIT practices among female and male groups were similar within the organizations involved in this study.

The results of the survey present (see Table 4) the comparison between two groups: organizations with less than one thousand employees and organizations with more than one thousand employees. Overall, organizations with less than one thousand professionals have lower GIT practices covering (a) greenhouse gas emission, (b) consideration of renewable resources, (c) electronic waste understanding,

Table 3. Comparison of the mean score among the genders

Statement	Gender	
	Male	Female
I am aware of greenhouse gas emissions and its impact on the environment	3.7	3.5
I am aware of renewable energy	3.8	3.4
I have knowledge of e-waste	3.6	3.2
I take responsibility to assist in making a difference on environmental issues, for instance, energy consumption and e-waste disposal	3.3	3.5
I am aware of the increasing cost of energy consumption in desktop computers	3.5	3.3
I shut down my personal computer after work day.	3.9	3.3
I switch-off lights when not be used.	3.7	3.4
My company provides budget for sustainable IT practices	3.3	3.3
My company has an IT sustainability policy	3.8	3.2
My company has a dedicated employee responsible sustainable IT practices.	3.8	3.6
My company highlights paper-saving	3.5	3.5

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 4. Comparison of the mean score among different size of organizations

Statement	Size of the Organization	
	Less than 1000 Employees	More than 1000 Employees
I am aware of greenhouse gas emissions and its impact on the environment	3.1	3.4
I am aware of renewable energy	3.1	3.5
I have knowledge of e-waste	3.0	3.2
I take responsibility to assist in making a difference on environmental issues, for instance, energy consumption and e-waste disposal	3.1	3.7
I am aware of the increasing cost of energy consumption in desktop computers	3.0	3.4
I shut down my personal computer after work day.	3.1	3.5
I switch-off lights when not be used.	3.3	3.9
My company provides budget for sustainable IT practices	3.1	3.4
My company has IT sustainability policy	3.1	3.4
My company has a dedicated employee responsible sustainable IT practices.	3.5	3.4
My company highlights paper-saving	3.2	3.8

(d) individual responsibility and contribution to addressing environmental challenges, and (e) issues on the rising energy use of IT equipment. It is also observed that most of these organizations have a lower budget for IT practices, sustainability policy. The results also indicate that organizations with more than one thousand employees have an emphasis on the importance of switching-off lights, and paper-saving activities as an element of sustainable practices as compared to smaller organizations.

5. THEORETICAL IMPLICATIONS

This paper provides a significant contribution to the Green IT literature. First, it is evident that a handful of studies are available investigating the awareness and practices on environmental sustainability among Philippine IT professionals. Prior studies were essentially persistent to understanding the factors and practices on applying information technology to enhance corporate environmental sustainability (Hernandez and Ona, 2015), however, lacks further exploration on understanding employees' perception regarding their role in sustainability through GIT adoption. This study offers new insight on the awareness, perception, and practices of Philippine IT professionals towards sustainability. The results of the survey suggest that 89% percent have good or very good awareness regarding emissions and its environmental impacts. This understanding relates to firms attempts to adapt to sustainable environmental programs. Likewise, if employees are aware of GIT practices, then, these could be more adopted by the IT professionals and become optimistic to further GIT efforts (Mariani and Imam, 2012).

Second, a handful of studies on GIT practices in developing countries, such as the Philippines, in which IT spending by firms constantly increased. To the date, the IT industry of the Philippines constantly contributes to carbon emissions due to the increasing investments in IT infrastructure. Investigating the Philippine IT professionals GIT practices can offer essential perspectives that can assist in developing

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

much significantly needed GIT practices for Philippine IT organizations. A study suggests that knowledge of IT professionals on GIT practices contributed to addressing environmental issues (Molla et al., 2014). It also suggests that sixty-nine percent of respondents had a fair, good or very good awareness to make a difference on the environment.

Third, male employees exhibited higher awareness and understanding of sustainable environment challenges and their responsibility towards addressing these concerns. Nonetheless, both male and female groups have largely similar adoption of environmentally sustainable practices. These findings are in contrast with Molla et al., (2014) which found both male and female groups were similarly aware of GIT practices, and its significance to attaining environmental sustainability.

The results of the survey also indicate that nearly fifty percent of the respondents signified concern in the increasing resources needed for desktop and server energy consumption. The rising electricity cost is a result of suppliers' imposition of additional electricity charges. However, there is an extent of reducing these costs through environmentally sustainable practices through shutting down of computers when unused and switching off lights after working hours. It is expected that firms must design relevant policies and guidelines to further GIT adoption. However, these organizations need to be GIT champions to spur the adoption of these practices by the employees (Antonioli et al., 2013). However, the results indicate that only forty nine percent of the respondents had dedicated an employee to oversee GIT practices within their organizations. Assigning a dedicated employee could further improve GIT adoption practices among IT professionals in organizations.

To date, the Philippine spending on GIT is not yet formalized as part of the national budget (DTI, 2017). This situation also reflects the commitment of organizations to allocate financial budget for GIT adoption, however, the results also indicate an average of 3.4 mean score which suggests that a few organizations in the Philippines have allocated budget to further the adoption of GIT. Therefore, lacking budget is a major concern in some organizations in the Philippines. However, the results also indicate that only seventeen percent disagreed that their organizations have allotted budget to support GIT efforts. It reflects that firms may have allocated some budget, however, but these were not promoted effectively within the firms. Hence, requires a new way to encourage budget spending to adopt these GIT practices continuously.

This research opens new opportunities for employees to further GIT adoption within organizations. It also emphasizes the need to develop a framework to apply GIT practices. Lastly, this paper offers new insight into the awareness of Philippine IT professionals on GIT adoption. This work will build on the growing appreciation of firms on GIT adoption as an area of research and practice of environmental sustainability within organizations. The outcomes of the research could be used to promote the proactive participation of employees on GIT practices, therefore, as this research considered a multidimensional construct of investigating Philippine IT professionals practices and awareness level of GIT, and support future researches in this area.

5.1. Organizational Implications

The study suggests that IT professionals employed in large firms in the Philippines have better awareness and knowledge of GIT practices. The findings of this study are consistent with Ansari et al. (2010) about GIT awareness and practices in Bangladesh. Although organizations aim to adapt to GIT practices, however, employees need sufficient knowledge to adopt and may lead to better participation. Hence,

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

small organizations need to provide capacity building and education programs to their employees on GIT adoption including awareness in carbon emissions, responsible electronic waste disposal, and use of information systems to integrate roles in GIT adoption practices.

The role of an economic, social and environmental partnership is critical to the success of GIT adoption in firms (Stankeviciute and Savanneviciene, 2013). Although capacity building equips employees about GIT adoption, it cannot always assure individual participation. Previous studies suggest that culture and individual's attitude remains a barrier and hinder GIT adoption. The study of Gholami et al. (2013) found that managers have an important role to play in adapting to GIT practices. Similarly, the lack of managerial support becomes a significant barrier to the successful GIT adoption in organizations (Buchalcevova and Gala, 2013). Prior studies suggest that innovative culture is attained from top managers to entry level employees, hence, senior managers attitude and ability to persuade employees on GIT practices (Guerci and Pedrini, 2014; Robbins et al., 2014). Certainly, there is the potential of changing the firms' culture and modify individual's actions (Robbins et al., 2014) by developing appropriate GIT guidelines. Conversely, it requires better managerial support, commitment, and responsibility. Organizational policies can spur positive actions to managers going to the staff to motivate them to proactively contribute to sustainable business and environment improvements (Guerci and Predini, 2014).

Despite the implementation of policies, procedures, and facilities to further GIT adoption in organizations, this study also found the lacking budget allocation towards GIT practices, which also come backs with managerial support and behavior. Also, rewards and incentive systems can play a critical role in employees' behavior to continue adopting GIT in organizations (Lim et al., 2013). Likewise, rewards and incentive programs can result in positive implications on enhancing employees' participation in GIT adoption. Interestingly, the results of the survey indicate an equal awareness of GIT adoption and knowledge on sustainable practices among age groups. However, Philippine IT professionals thirty-five and older had better knowledge and awareness of GIT practices and responsibility on environmental issues. This finding is consistent with Molla et al. (2014). Nevertheless, it is an important finding that younger IT employees in developed countries such as Australia are involved with GIT adoption activities than older IT employees.

6. CONCLUSION AND FUTURE WORK

GIT adoption practices play a critical role in spurring environmental performance, however, may not warrant positive outcomes. Conversely, this can be attained by developing appropriate policies and education program aiming to improve the rate of participation and roles of employees, thus, achieving the goals of environmental sustainability. Prior studies found the significance of individual's understanding can influence in enhancing the rate of participation towards GIT. Hence, it presents the necessity to determine the awareness level that can be useful to develop strategic approaches for engaging employees to implement environmentally sustainable business activities. This study is the first to offer insights on exploring the awareness and environmental sustainability of IT employees in the Philippines and presented deeper understanding and perception regarding GIT adoption practices. The insights presented from this research can offer direction in encouraging and developing practices to sustain GIT adoption in Philippine IT organizations.

This study used a survey to understand the awareness level on GIT adoption practices of Philippine IT professionals. The findings suggest conclusion which can be valuable to firms in designing strategies, guidelines, programs, are presented. First, this study found that IT professionals aged thirty-five

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

and over have a higher understanding of environmentally sustainable practices as compared with other age groups. Significantly, employees aged twenty to twenty-four have lower awareness of GIT practices. The awareness gap between age groups can be explained through the length of stay and experience in IT and their organizations.

This study also offers new insights on GIT practices to achieve environmental sustainability and also recognize the need for further research. Furthermore, IT professionals with prior understanding in regards to GIT adoption can significantly contribute by introducing changes and encourage other employees to adopt by sharing and communicating their positive experience, insights, and outcomes. Also, promote the significance of adopting to GIT practices to attain environmental sustainability within their peers. The study also found that male IT professionals had better awareness on environmentally sustainable practices. However, both male and female groups had a largely similar adoption rate of GIT within their firms.

Lastly, organizations with one thousand IT professionals and above have advanced awareness on the sustainable environment compared to smaller firms. It is also found that firms with one thousand IT professionals have a greater emphasis on shutting down of unused computers, switching off lights and paper-saving initiatives as part of their sustainable environmental practices as compared to smaller organizations involved in this study. This work suggests that smaller organizations are laggard in GIT practices education drive, as employees are the asset of the firms. Therefore, it is necessary to provide sufficient education for them to realize the potential and beneficial outcomes of adopting to environmentally sustainable practices.

Although this study offers new insights about the awareness of Philippine IT professionals on environmentally sustainable practices, this study is not also free from limitations. First, the study only covered Philippine IT professionals, which lacks a global opinion. Hence, the findings and suggestions from this study are only applicable to Philippine IT firms or countries with similar characteristics. This research suggests further studies on exploring the knowledge of IT professionals in several developed and developing countries. Second, this study is based on a survey of respondents of only in IT organizations, future studies can deal with a large number of respondents across sectors and industries in which different insights can be obtained and can assist in designing new strategies and policies to achieve a low-carbon economy, thus, resulting in sustainable business and environment. Finally, exploring the experience of IT professionals through qualitative studies could further reveal meaningful insights in GIT adoption in organizations.

ACKNOWLEDGMENT

The author gratefully acknowledges the constructive and helpful comments of three anonymous reviewers and associate editor on the earlier version of the manuscript which helped to improve the presentation of the article considerably.

Chapter 70
Revisiting the Conflicts between 'Environmental Taxes vs Standard' in the Context of International Trade:
The Role of Waste Recycling

Nilendu Chatterjee

Tonmoy Chatterjee
Ananda Chandra College, India

ABSTRACT

The present paper throws light on the famous "tax versus standard" debate in the sphere of environmental economics by using general equilibrium framework and tries to examine which of the two, i.e., tax or standard is the better way to deal with pollution. It has done so in the presence of a waste recycling sector which is the unique feature of it and has shown the impact of tax and standard separately on different polluting and non-polluting sectors of the economy. The study has developed a unique as well as an interesting result that in the presence of a waste recycling sector in the economy, both pollution tax and environmental standard have the same impact.

1. INTRODUCTION

Over the last two and a half decades, perhaps the most relevant, worrying and most thought over issue worldwide has been global warming and the root cause of it, environmental pollution and how to deal with it for the sake of saving this planet. There may be no wrong in saying that an upsurge in the population growth and an urge for rapid development have contributed to the present scenario of environmental degradation. But the need for development cannot be denied either considering the fact that over two third of the population worldwide still belongs to developing economies. In order to become developed, it is necessary to fasten the production process and other economic activities and here lies the tragedy of the poor nations because such activities are contributing to the devastating environmental pollution. For sustainable development, it is therefore necessary to adopt proper measures that can continue the production process yet do not create pollution to an extreme level. The measures which are available to the controlling authority for dealing with pollution have given birth to the famous debate of environmental economics: "tax versus standard", that is, the authority can either impose tax on the polluting industries or they may reduce the maximum allowable level of pollution for the sake of environment. Developed countries, with their good capital base, have started using those technologies that will not create pollution. This technology may be referred to as "green technology" or "green capital." Developing nations, mostly, do not even possess such technology for being poor. Therefore, they either cannot use such sophisticated technology or even if they can, they use it in selected; few areas, not in all sectors of the economy because of lack of capital. Developing economies largely either imposes tax or restricts the emitting level and, if possible, uses "green technology" in very few areas.

Green technology generally enters in developing economies through the inflow of foreign capital or foreign investment and in the presence of globalization[1] this trend is expected to grow where a developing nation would come across foreign entrepreneurs possessing pollution free technical knowhow. So the use of "green technology" in a developing nation initiates mainly through foreign investment. There are empirical evidences in support of this argument.[2]

One more important aspect that has gained momentum and earned respect in the modern world is the recycling and reusing a product. During the production process, there may be few things which become obsolete but there may be few things which may be re-used and may be given the shape of another product through the process of recycling. Recycling is the process of separating, collecting and remanufacturing or converting used or waste products into new materials. The recycling process involves a series of steps to produce new products. Recycling helps to extend the life and usefulness of something that has already served its initial purpose by producing something that is useable. Recycling has a lot of benefits and importance not only to us humans but especially to our planet. Recycling is very important as waste has a huge negative impact on the natural environment. A few of these impacts are:

1. Harmful chemicals and greenhouse gasses are released from rubbish in landfill sites. Recycling helps to reduce the pollution caused by waste;
2. Habitat destruction and global warming are some the effects caused by deforestation. Recycling reduces the need for raw materials so that the rainforests can be preserved;
3. Huge amounts of energy are used when making products from raw materials. Recycling requires much less energy and therefore helps to preserve natural resources.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Recycling is essential to cities around the world and to the people living in them because we have no space for waste. Our landfill sites are filling up fast. Recycling reduce financial expenditure in the economy. Making products from raw materials costs much more than if they were made from recycled products. It also preserves natural resources for future generations.

Presently in India, about 960 million tonnes of solid waste is being generated annually as by-products during industrial, mining, municipal, agricultural and other processes. Of this, 350 million tonnes are organic wastes from agricultural sources; 290 million tonnes are inorganic waste of industrial and mining sectors and 4.5 million tonnes are hazardous in nature. There are many evidences that output or may be wastage of one sector is used by that sector or by a different sector to form a new product.[3] So the dirty goods[4] may contribute to the formation of pollution free goods. But the process of recycle and re-use needs the presence of sound, advanced technology which again generates the necessity of 'green technology".

The main motivation behind this study generates from the fact that there are only a few empirical works are there on the issue of pollution control through pollution tax or setting standard. From the theoretical angle, also there are only few works to mention and even in this regard perhaps no work has been done by comprising the famous debate of "tax versus standard" in the presence of recycling sector in a general equilibrium framework. The only exception in this regard is the work by Gupta (2012). He has examined the trade-off between tax and standard in a general equilibrium framework. This model helps us in understanding the inter-sectoral linkages and also to examine whether there is actually any trade-off between tax and standard in the presence of recycling.

This study is based on a small open economy general equilibrium structure that has been used by several authors for dealing with environmental and trade related issues.[5] The present study considers the impact of both pollution tax as well as setting environmental standard by regulating the level of emission in the presence of a recycling effect. The concept of green capital is also incorporated without categorising the different sectors of the economy into formal or informal sectors.

The paper is organised in the following sub sections. Section 2 considers the basic model. Comparative static analysis is done in section 3. Finally, the concluding remarks are made in section 4.

2. THE BASIC MODEL

We consider a small open economy with four sectors: a sector that requires no green capital and they need not recycle wastes (sector X), the sector which requires green capital to recycle wastes (sector Z), the polluting-manufacturing sector (sector Y) and the fourth sector is the waste-generating, non-traded intermediate good sector (sector V)[6]. This sector also uses green-capital. Its output is independent of the output of sector y. Wastes are generated by sector y during the process of producing its own output and by sector v from solid wastes of the community or from consumers. As sector v uses green capital, the wastes generated by this sector are all recycled by sector Z. In other words, as sector V uses green capital, the wastes generated by this sector are not harmful for the economy as they can always be used for the purpose of recycling. Sector X and sector Z together can be considered as "non-polluting" sectors within the economy. The assumption of small open economy implies that apart from the non-traded sector v, for all other sectors the product prices are fixed as the economy is a price-taker in the in the international market.[7] Production function in each sector exhibits constant returns to scale (CRS), variable co-efficient technology and diminishing marginal productivity to the variable factors. Sector x and

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Sector Y use traditional capital, K, which is perfectly mobile between these two sectors. Sector z and sector V use much advanced, sector-specific "green capital" K_G which is perfectly mobile between these two sectors. The use of K_G by these two sectors implies the use of better, advanced, non-polluting technology by these sectors. Labour is assumed to be perfectly mobile among all the four sectors. Sector X and Sector V employ labour at a fixed wage rate $\bar{w}$ .The remaining workers are used by the other two sectors, that is, sector Y and sector V, at the competitive wage rate w, which is assumed to be flexible and lower than $\bar{w}$. The workers who fail to get a work in sectors x and sectors z are absorbed in sectors y and v. So, there exists full employment in the labour market. The product of sector x is regarded as a numeraire and its price has been set equal to unity. A pollution tax α is imposed on per unit of output of sector y, which is the polluting-manufacturing sector.

The following notations are used in the formal presentation of the model:

a_{Li} = Labour-output ratio in the i-th sector, i = x,y,z,v

a_{Ki} = Capital-output ratio in the i-th sector, i = x,y,z,v

P_i = Price of the product of the i-th sector, i = x,y,z,v

w = Competitive wage rate of sector y and sector v

$\bar{w}$ = Fixed wage rate of sector x and sector v

X = Output of sector x

Y = Output of sector y

Z = Output of sector z

V = Output of sector v

r = Rate of return on traditional capital

R = Rate of return on green capital

L = Total endowment of labour in the economy

K = Total endowment of traditional capital

K_G = Total stock of green capital

α = Tax rate on per unit of output of sector y

Ω = Maximum allowable pollution

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

λ_{ji} = Use of j-th factor by i-th sector with respect to total factor endowment (j=L,K; i=x,y,z,v)

θ_{ji} = distributive share of the j-th input in the i-th sector

2.1. Equational Structure of the Model

The competitive equilibrium conditions of the four sectors are given as:

$$\bar{w}\, a_{LX} + r\, a_{KX} = 1 \tag{1}$$

$$w\, a_{LY} + r\, a_{KY} = P_Y - \alpha = P_Y' \tag{2}$$

$$\bar{w}\, a_{LZ} + R\, a_{KZ} + P_V a_{VZ} = P_Z \tag{3}$$

$$W a_{LV} + R a_{KV} = P_V \tag{4}$$

The relationship between the waste-generating intermediate sector v and waste recycling sector z is given as:

$$a_{VZ} Z = V \tag{5}$$

Mobility of traditional capital between sectors x and sector y is given as:

$$a_{KX} X + a_{KY} Y = K \tag{6}$$

Full employment condition of the labour market is given by:

$$a_{LX} X + a_{LY} Y + a_{LZ} Z + a_{LV} V = L \tag{7}$$

The mobility of green capital between sector z and sector v is given by:

$$a_{KZ} Z + a_{KV} V = K_G(\Omega) \text{ where, } K_G' < 0 \tag{8}$$

In Equation (8) the reason behind $K_G' < 0$ is that when there is an improvement in the standard of environment, that is, when the maximum allowable pollution level is reduced, there is an increase in the use of green capital as the producers are compelled to adopt environment-friendly technology.

2.2. Working of the Model

The working of the model is simple. From Equation (1) we can solve for r. Using the value of r in Equation (2) we can get w. From Equation (4) we can express R in terms of P_V. As R can be expressed in terms of P_V, by using this relation, from Equation (3) we can get the value of P_V, using which again in Equation (4) one can get the value of R. From Equation (5) we can express V in terms of Z, by using this

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

relationship in Equation (8), one can get the value of Z and again by using the value of Z in Equation (5) we can get the value of V. Thus, both Z and V becomes known. Now we are left with two equations, that is, Equation (6) and Equation (7), and two unknowns – X and Y. So, we can solve for the values of X and Y from these two equations.

3. COMPARATIVE STATISTICS

Here we would like to examine the impact of a strict environmental policy in the form of improvement in the environmental standard (by imposing reduction in maximum allowable pollution) and also in the form of an increase in the tax rate on output of the polluting sector. Both the measures can be interpreted as a drive towards an improvement in environmental quality of the economy.

First, we would like to examine the impact of a strict environmental policy, that is, a reduction in the maximum allowable level of emission in all the economy. A strict environmental policy implies a reduction in Ω. When we examine the change in Ω, then the system or the model becomes decomposable as the input-output co-efficients can be determined independent of the output system. From Equation (5) we can see that V can be expressed in terms of Z. So Equation (8) can be expressed in terms of Z only. In Equation (8), as Ω falls because of a tough policy, we see that K_G rises. To maintain the equilibrium, it implies that Z should also increase. As $\hat{Z} = \hat{V}$, it also implies that V should rise.[8] This is shown by the following two equations that express change in Z and V with respect to change in Ω:

$$\frac{\hat{Z}}{\hat{\Omega}} = \frac{\varepsilon}{\left(\lambda_{KZ} + \lambda_{KV}\right)} \tag{9}$$

and:

$$\frac{\hat{V}}{\hat{\Omega}} = \frac{\varepsilon}{\left(\lambda_{KZ} + \lambda_{KV}\right)} \tag{10}$$

Both the two equations above show an inverse relationship between Ω and output of sector Z and sector V because ε is negative (less than zero) in sign. So as Ω falls, the output levels of both sectors v and sector z increase, it implies that the availability of effective labour decreases in rest of the two sectors, that is, in sector X and sector Y. This creates a *"Rybczynski effect"* for which output of the capital intensive sector or sector X rises and that of the labour intensive sector or sector Y falls. Mathematical expressions of these results are shown below (see Appendix for detailed derivations):

$$\frac{\hat{Y}}{\hat{\Omega}} = \left\{ -\frac{\left(\lambda_{KZ} + \lambda_{KV}\right)\lambda_{KX}}{\left(\lambda_{LX}\lambda_{KX} - \lambda_{KY} + \lambda_{LY}\lambda_{KX}\right)} \frac{\varepsilon}{\left(\lambda_{KZ} + \lambda_{KV}\right)} \right\} \tag{11}$$

and:

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

$$\frac{\hat{X}}{\hat{\Omega}} = \lambda_{KY}\left\{\frac{\left(\lambda_{KZ}+\lambda_{KV}\right)}{\left(\lambda_{LX}\lambda_{KX}-\lambda_{KY}+\lambda_{LY}\lambda_{KX}\right)}\frac{\varepsilon}{\left(\lambda_{KZ}+\lambda_{KV}\right)}\right\} \tag{12}$$

Again as ε is negative in nature, the above two equations express a direct relation between Y and Ω and an inverse relation between X and Ω, respectively.

These findings can be expressed with the help of following proposition:

Proposition 1: A strict environmental policy in the form of a reduction in the maximum allowable pollution increases the supply of green capital and also increases the production of wastes and output of waste recycling sector. It increases output of the non- polluting sector and reduces output of the polluting sector, given that the non-polluting sector is more capital-intensive than the polluting sector.

So far we have discussed the effect of change in environmental standard. Now, we would like to see the effect of change in tax rate (α) on the output of all the sectors as well as on the input prices.[9]

From Equation (13)[10] we find that the price of the waste-generating intermediate sector (sector v) and price of the price of the polluting sector (sector y) is given as:

$$\frac{\hat{P}_V}{\hat{P}_Y'} = \frac{\theta_{KZ}}{\theta_{LY}\left(\theta_{KZ}+\theta_{VZ}\theta_{KV}\right)} \tag{13}$$

The above expression is positive, so, the relation between $\hat{P}_V$ and $\hat{P}_Y'$ is direct, that is, as $\hat{P}_Y'$ falls, $\hat{P}_V$ falls. The economic interpretation is simple. An increase in the tax rate on the output of the polluting sector reduces effective price of the product of the polluting sector, $P_Y{}'$, as r is already determined from Equation (1), a fall in, $P_Y{}'$ causes a fall in w, as we find from Equation (2). For given $P_{V,}$ a fall in w causes a rise in R from Equation (4). However, P_V is not given as sector v is the non-traded sector. This is evident from Equation (3) where we find, for given P_Z, a rise in R implies a fall in P_V. So we conclude a fall in $P_Y{}'$ causes a fall in P_V. As R increases, it implies that a_{KZ} and a_{KV} also falls, as a result of which Z increases and consequently V also increases, (as $\hat{Z}=\hat{V}$) it is shown by the following equation:

$$\frac{\hat{Z}}{\hat{P}_Y'} = \left\{-\frac{\left(\lambda_{KZ}A_2+\lambda_{KV}A_1\right)}{\left(\lambda_{KZ}+\lambda_{KV}\right)}\right\} = \frac{\hat{V}}{\hat{P}_Y'} \tag{14}$$

As w falls (for given r), w/r falls or we can say that r/w increases. It also results in a fall in a_{KX} and a_{KY} for given X and Y. So, there is excess supply of capital. From Equation (7) we see that a fall in w results in an increase in a_{LY} and a_{LV}. It results in a reduction in the availability of labour for sector x and sector y as $\{L-(a_{LZ}+a_{LV}a_{VZ})Z\}$ falls. This is known as *"Rybczynski-type effect."* This will result in an increase in the output of sector x and a fall in that of sector y, given that x is the capital-intensive sector than sector y. We thus have:

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

$$\frac{\hat{X}}{\hat{P}_Y'} = \frac{A_5\lambda_{KY} - \lambda_{LY}A_6}{\lambda_{LX}\lambda_{KY} - \lambda_{KX}\lambda_{LY}} \tag{15}$$

and:

$$\frac{\hat{Y}}{\hat{P}_Y'} = \frac{\lambda_{LX}A_6 - \lambda_{KX}A_5}{\lambda_{LX}\lambda_{KY} - \lambda_{KX}\lambda_{LY}} \tag{16}$$

These results are presented by the following proposition:

Proposition 2: An increase in the tax rate on the output of the polluting sector increases the output of waste-generating intermediate sector as well as the output of waste recycling sector, it also increases the output of non-polluting capital-intensive sector but decreases the output of the labour-intensive polluting sector.

4. CONCLUDING REMARKS

In this paper we build up a model, using the H-O-S general equilibrium structure, assuming the presence of four sectors in the economy. Out of these four, two sectors are "non- polluting" and other two are "polluting". One sector from each category use green capital, that is, use advanced sophisticated, pollution free technology. A "non-polluting" sector takes the help of green technology to recycle wastes and a polluting sector does so to generate wastes for the purpose of recycling. In such a set up we have shown that the regulating authority possess the dual instrument to deal with pollution, that is, they may impose a pollution tax on the price of the product of the polluting industry and also they can reduce the maximum allowable level of emission which would compel industries to go for green technology. In this paper, we have shown the effects of both a reduction in the maximum allowable level of pollution as well as an increase in the tax rate on the output of the polluting sector.

In both the cases we have come across same results. In both the cases, we have seen that, either due to an increase in tax rate or because of a reduction in the maximum allowable emission level, the output levels of waste generating intermediate good sector and waste recycling sector have increased. We have also shown expansion of the non-polluting capital-intensive sector and contraction of the of the labour-intensive polluting sector. So, output levels of three of the four sectors go up out of which two are "non-polluting" in nature and that of the remaining sector goes down. One thing to be noticed here is that sectors which use green technology have expanded.

These results are significantly different to other findings in the field of "tax versus standard" studies. Most of the studies in this sphere have recommended either increase in pollution tax as superior to the reduction in the maximum emission level or vice-versa, depending upon their respective areas, under focus, which the impact of these two means are compared upon. But, our study reveals that both the measures would provide us the same result under some reasonable conditions.

ENDNOTES

1. The term "globalization" is used in a broad sense in a developing nation where "greater integration of the world economy through heightened trade and investment flows and greater mobility of factors" are expected.
2. The investigating works of Mansfield (1961, 1968) may be mentioned.
3. See Pappu, Saxena and Asolekar (2006) for details.
4. "Dirty goods are those goods that create pollution during the production process.
5. See Chichilnisky (1994), Chaudhuri and Gupta (2004) for details.
6. Moreover, sector V produces an waste augmented intermediate product and the entire output of sector V have been demanded by sector Z.
7. Apart from sector V, all other sectors produce final commodities in this model.
8. See Appendix at the end of this chapter for detailed mathematical derivations.
9. Here we have shown the impact of a change in tax rate α in terms of change in the price of the polluting sector (sector Y) after tax being imposed, that is, in terms of $\hat{P}_Y^{'}$. As α rises, $P_Y^{'}$ falls. So, α and $P_Y^{'}$ have an opposite relation between them. This can be proved very easily. We know that $P_Y - \alpha = P_Y^{'}$ (see equation 3.2). Differentiating this expression with respect to $P_Y^{'}$, we get, $-\frac{da}{P_Y^{'}} = \frac{dP_Y^{'}}{P_Y^{'}}$, Or, $-\frac{a}{P_Y^{'}}\frac{da}{a} = \hat{P}_Y^{'}$, Or, $-\frac{a}{P_Y - a} = \hat{P}_Y^{'}$, Or, $-\gamma\hat{a} = \hat{P}_Y^{'}$ and $\gamma = \frac{a}{P_Y - a}$, So the nature or sign (positive or negative) of any relationship which is expressed in terms of $_{KY}$ will become

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

exactly of the opposite nature or sign (positive or negative) when expressed in terms of P_Y-α. For example, if the impact of $\hat{P}_Y^{'}$ on $\hat{Z}$ is negative, it will become positive when expressed in terms of $\hat{\alpha}$. This inverse relationship between $\hat{P}_Y^{'}$ and $\hat{\alpha}$ and its verbal explanation will be applicable on all those mathematical expression that shows a change in any variable with respect to a change in $\hat{P}_Y^{'}\left(\hat{P}_Y^{'}\right)$.

[10] Equation (13) and Equation (4.1) (in the Appendix) are same, only for the sake of the simplicity, it is numbered differently, first, here and later in the Appendix.

APPENDIX A

Mathematical Expressions of the Basic Model

$$\bar{w}\, a_{LX} + r\, a_{KX} = 1 \tag{1}$$

$$w\, a_{LY} + r\, a_{KY} = P_Y - \alpha = P_Y' \tag{2}$$

$$\bar{w}\, a_{LZ} + R\, a_{KZ} + P_V a_{VZ} = P_Z \tag{3}$$

$$W a_{LV} + R a_{KV} = P_V \tag{4}$$

$$a_{VZ} Z = V \tag{5}$$

$$a_{KX} X + a_{KY} Y = K \tag{6}$$

$$a_{LX} X + a_{LY} Y + a_{LZ} Z + a_{LV} V = L \tag{7}$$

$$a_{KZ} Z + a_{KV} V = K_G(\Omega),\ K_G' < 0 \tag{8}$$

APPENDIX B

Detailed Derivations of Different Expressions

Derivations of equations considering change in the environmental standard, that is, a change in the maximum allowable level of emission (Ω).

Differentiating Equation (1) we get:

$$a_{LX}\, d\bar{w} + \bar{w}\, d\, a_{LX} + a_{KX} dr + r d\, a_{KX} = 0$$

as $\bar{w}\, d\, a_{LX} + r d\, a_{KX} = 0$ (By Envelop Theorem) and $d\,\bar{w} = 0$, we get,

$$\hat{r}\ \theta_{KX} = 0 \text{ or, } \hat{r} = 0 \tag{1.1}$$

Differentiating Equation (2) we can get:

$$a_{LY}\, dw + w d\, a_{LY} + a_{KY} dr + r d\, a_{KY} = d\, P_Y'$$

Again by using Envelop Theorem ($w d\, a_{LY} + r d\, a_{KY} = 0$) from the above equation we get:

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

$$\hat{w}\theta_{LY} = \hat{P}_Y' \text{ or } \hat{w} = \frac{\hat{P}_Y'}{\theta_{LY}} \tag{2.1}$$

Differentiating Equation (3) and using Envelop theorem we get:

$$\hat{R}\theta_{KZ} + \hat{P}_V\theta_{VZ} = 0 \text{ or } \hat{R} = -\hat{P}_V \frac{\theta_{VZ}}{\theta_{KZ}} \tag{3.1}$$

From Equation (4) we get:

$$\text{wd } a_{LV} + a_{LV}\text{dw} + \text{Rd } a_{KV} + a_{KV}\text{dR} = 0$$

By applying Envelop Theorem in the above expression we can get:

$$\hat{w}\theta_{LV} + \hat{R}\theta_{KV} = \hat{P}_V$$

Using the value of $\hat{R}$ from Equation (3.1) in the above expression we get:

$$\hat{w}\theta_{LV} - \hat{P}_V \frac{\theta_{VZ}}{\theta_{KZ}}\theta_{KV} = \hat{P}_V$$

Again, using the value of $\hat{w}$ from Equation (2.1) in the above expression we get:

$$\frac{\hat{P}_Y'}{\theta_{LY}} = \hat{P}_V\left(1 + \frac{\theta_{VZ}\theta_{KV}}{\theta_{KZ}}\right) \text{or } \frac{\hat{P}_V}{\hat{P}_Y'} = \frac{\theta_{KZ}}{\theta_{LY}(\theta_{KZ} + \theta_{VZ}\theta_{KV})} \rangle 0 \tag{4.1}$$

Using Equation (4.1) in Equation (3.1) we can get another expression of $\hat{R}$, expressed as:

$$\hat{R} = -\hat{P}_Y' \frac{\theta_{VZ}}{\theta_{LY}(\theta_{KZ} + \theta_{VZ}\theta_{KV})} \tag{4.2}$$

From Equation (5) we see that as a_{VZ} is fixed, we can say:

$$\hat{Z} = \hat{V} \tag{5.1}$$

From (6) we find that:

$$a_{KY}\,\text{dX} + \text{X d } a_{KY} + a_{KY}\text{dY} + \text{Y d } a_{KY} = 0$$

$$\text{or X } \frac{a_{KX}}{k}\frac{dX}{X} + \frac{Xa_{KX}}{k}\frac{da_{KX}}{a_{KX}} + \frac{Ya_{KY}}{k}\frac{dY}{Y} + \frac{Ya_{KY}}{k}\frac{da_{KY}}{a_{KY}} = 0$$

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

or $\lambda_{KX}\hat{X} + \lambda_{KX}\hat{a}_{KX} + \lambda_{KY}\hat{Y} + \lambda_{KY}\hat{a}_{KY} = 0$

or $\lambda_{KX}\hat{X} + \lambda_{KX}\hat{a}_{KX} = -(\lambda_{KY}\hat{Y} + \lambda_{KY}\hat{a}_{KY})$

From Equation (1) and Equation (2) we get: $\hat{a}_{KX}$ and $\hat{a}_{KY}$ are fixed,

so, $\lambda_{KX}\hat{X} + \lambda_{KY}\hat{Y} = 0$ or $\hat{X} = -\frac{\lambda_{KY}}{\lambda_{KX}}\hat{Y}$ (6.1)

From Equation (7) we get:

$$a_{LX}\,\mathrm{dX} + \mathrm{Xd}\,a_{LX} + a_{LY}\mathrm{dY} + \mathrm{Yd}a_{LY} + a_{LZ}\mathrm{dZ} + \mathrm{Zd}a_{LZ} + a_{LV}\mathrm{dV} + \mathrm{Vd}a_{LV} = 0 \quad (7.1)$$

As $\hat{a}_{LX}$, $\hat{a}_{KY}$ and $\hat{a}_{LZ}$ are fixed from Equations (1), (2) and (3) respectively and by using elasticity of substitution from Equation (4), we can express $\hat{a}_{LV}$ as a function of $\hat{P}_Y'$. It is proved in equation (4.B.3), (proven later). But here we are dealing with change in maximum allowable emission level or Ω and therefore the effect of pollution tax rate, α, is held constant. So, $\hat{P}_Y'$ which shows the price after tax (P_Y – α) can be considered as zero. So, we can say $\hat{a}_{LV} = 0$. By using $\hat{a}_{LX}$, $\hat{a}_{KY}$, $\hat{a}_{LZ}$ and $\hat{a}_{LV} = 0$ in Equation (7.1) we get:

$$\lambda_{LX}\hat{X} + \lambda_{LY}\hat{Y} + \lambda_{LZ}\hat{Z} + \lambda_{LV}\hat{V} = 0$$

Using the result of Equation (5.1), in the above expression we can get:

$$\lambda_{LX}\hat{X} + \lambda_{LY}\hat{Y} + \lambda_{LZ} = 0 \text{ or } \lambda_{LX}\hat{X} + \lambda_{LY}\hat{Y} = \left(\lambda_{LZ} + \lambda_{LV}\right)\hat{Z}$$

Using the value of X from Equation (6.1) in the above expression we get:

$$\lambda_{LX}\left(-\frac{\lambda_{KY}}{\lambda_{KX}}\hat{Y}\right) + \lambda_{LY}\hat{Y} = -\left(\lambda_{LZ} + \lambda_{LV}\right)\hat{Z}$$

or,

$$\hat{Y} = -\frac{\left(\lambda_{LZ} + \lambda_{KV}\right)\lambda_{KX}}{\left(\lambda_{LX}\lambda_{KX} - \lambda_{KY} + \lambda_{LY}\lambda_{KX}\right)}\hat{Z} \quad (7.2)$$

From Equation (8) we get:

$$a_{KZ}\,\mathrm{dZ} + \mathrm{Zd}\,a_{KZ} + a_{KV}\mathrm{dV} + \mathrm{Vd}\,a_{KV} = K_G' \text{ or } \lambda_{KZ}\hat{Z} + \lambda_{KZ}\hat{a}_{KZ} + \lambda_{KV}\hat{V} + \lambda_{KV}\hat{a}_{KV} = \varepsilon\hat{\Omega}$$

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

as $\hat{Z} = \hat{V}$ (from equation 5.1), the above equation can be written as $\hat{Z}(\lambda_{KZ} + \lambda_{KV}) + \lambda_{KZ} = 0$.

Here also, like the previous case, we can get the value of from Equation (3) and the value of from Equation (4) in terms of . The fact that and can be expressed in terms of is proved in Equation (3.B) and in equation (4.B.2) respectively (proven later). Repeating the reasoning of the last case used after Equation (7.1), we can say that the values of and are zero (0) in this case as we are dealing with change in Ω and not in α . So, from the above equation we can get:

$$\hat{Z} = \frac{\varepsilon\,\hat{\Omega}}{\left(\lambda_{KZ} + \lambda_{KV}\right)} \tag{8.1}$$

Again, by using the result obtained in Equation (5.1), we get:

$$\hat{V} = \frac{\varepsilon\,\hat{\Omega}}{\left(\lambda_{KZ} + \lambda_{KV}\right)} \tag{8.2}$$

Using Equation (8.1) in Equation (7.2) we get:

$$\hat{Y} = \left\{ -\frac{\left(\lambda_{KZ} + \lambda_{KV}\right)\lambda_{KX}}{\left(\lambda_{LX}\lambda_{KX} - \lambda_{KY} + \lambda_{LY}\lambda_{KX}\right)} \frac{\varepsilon\,\hat{\Omega}}{\left(\lambda_{KZ} + \lambda_{KV}\right)} \right\} \tag{7.3}$$

We use the above expression in the Equation (6.1) and get:

$$\hat{X} = -\frac{\lambda_{KY}}{\lambda_{KX}}\hat{Y}$$

$$\text{or, } \hat{X} = -\frac{\lambda_{KY}}{\lambda_{KX}} \left\{ -\frac{\left(\lambda_{KZ} + \lambda_{KV}\right)\lambda_{KX}}{\left(\lambda_{LX}\lambda_{KX} - \lambda_{KY} + \lambda_{LY}\lambda_{KX}\right)} \frac{\varepsilon\,\hat{\Omega}}{\left(\lambda_{KZ} + \lambda_{KV}\right)} \right\}$$

$$\text{or, } \hat{X} = \frac{\lambda_{KY}}{\lambda_{KX}} \left\{ \frac{\left(\lambda_{KZ} + \lambda_{KV}\right)\lambda_{KX}}{\left(\lambda_{LX}\lambda_{KX} - \lambda_{KY} + \lambda_{LY}\lambda_{KX}\right)} \frac{\varepsilon\,\hat{\Omega}}{\left(\lambda_{KZ} + \lambda_{KV}\right)} \right\}$$

$$\text{or, } \hat{X} = \lambda_{KY} \left\{ \frac{\left(\lambda_{KZ} + \lambda_{KV}\right)}{\left(\lambda_{LX}\lambda_{KX} - \lambda_{KY} + \lambda_{LY}\lambda_{KX}\right)} \frac{\varepsilon\,\hat{\Omega}}{\left(\lambda_{KZ} + \lambda_{KV}\right)} \right\} \tag{6.2}$$

APPENDIX C

Detailed Derivations of Different Expressions

Derivations of equations considering change in the environmental pollution tax rate, that is, a change in α.

From Equation (2) we get:

$$wa_{LY} + ra_{KY} = P_Y'$$

$$wda_{LY} + rda_{KY} = 0$$

or,

$$\theta_{LY}\hat{a}_{LY} + \theta_{KY}\hat{a}_{KY} = 0 \text{ or } \hat{a}_{LY} = -\frac{\theta_{KY}}{\theta_{LY}}\hat{a}_{KY} \text{ (2.B)}$$

again,

$$\sigma_Y' = \frac{\hat{a}_{KY} - \hat{a}_{LY}}{\hat{w} - \hat{r}} \text{ or } \sigma_Y'\hat{w} = \frac{\hat{a}_{KY}}{\theta_{LY}} \text{ (as } \hat{r} = 0)$$

Using the value of $\hat{w}$ from Equation (2.1) in the above expression we get:

$$\hat{a}_{KY} = \sigma_Y'\hat{P}_Y'$$

Now from Equation (2.B) we get the value of $\hat{a}_{LY}$ as:

$$\hat{a}_{LY} = -\frac{\theta_{KY}}{\theta_{LY}}\sigma_Y'\hat{P}_Y' - \text{(2.B.1)}$$

From Equation (3) we get:

$$Rd\, a_{KZ} + P_V d\, a_{VZ} = 0$$

or,

$$\theta_{KZ}\hat{a}_{KZ} + \theta_{VZ}\hat{a}_{VZ} = 0 \text{ or } \sigma_Z = \frac{\hat{a}_{VZ} - \hat{a}_{KZ}}{\hat{R} - \hat{P}_V}$$

as $\hat{a}_{VZ} = 0$, we can say, $\sigma_Z = \frac{-\hat{a}_{KZ}}{\hat{R} - \hat{P}_V}$

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

or, $\sigma_Z\left(\hat{R}-\hat{P}_V\right)=-\hat{a}_{KZ}$

or, $\hat{a}_{KZ}=\sigma_Z\left(\hat{P}_V-\hat{R}\right)$

or, $\hat{a}_{KZ}=\sigma_Z\left\{\frac{\hat{P}_Y'\theta_{KZ}}{\theta_{LY}\left(\theta_{KZ}+\theta_{VZ}\theta_{KV}\right)}+\frac{\hat{P}_Y'\theta_{VZ}}{\theta_{LY}\left(\theta_{KZ}+\theta_{VZ}\theta_{KV}\right)}\right\}$

or, $\hat{a}_{KZ}=\hat{P}_Y'\sigma_Z\left\{\frac{\theta_{KZ}}{\theta_{LY}\left(\theta_{KZ}+\theta_{VZ}\theta_{KV}\right)}+\frac{\theta_{VZ}}{\theta_{LY}\left(\theta_{KZ}+\theta_{VZ}\theta_{KV}\right)}\right\}$

or, $\hat{a}_{KZ}=\hat{P}_Y'\,\mathrm{A}_1$ (3.B)

where, $\mathrm{A}_1=\sigma_Z\left\{\frac{\theta_{KZ}}{\theta_{LY}\left(\theta_{KZ}+\theta_{VZ}\theta_{KV}\right)}+\frac{\theta_{VZ}}{\theta_{LY}\left(\theta_{KZ}+\theta_{VZ}\theta_{KV}\right)}\right\}$, $\mathrm{A}_1>0$.

Again from Equation (4) we get:

wd $a_{LV}+\mathrm{Rd}\,a_{KV}=0$ or $\sigma_V=\frac{\hat{a}_{KV}-\hat{a}_{LV}}{\hat{w}-\hat{R}}=$ (4.B)

Again, wd $a_{LV}+\mathrm{Rd}\,a_{KV}=0$ also implies:

$\theta_{LV}\hat{a}_{LV}+\theta_{KV}\hat{a}_{KV}=0$ or $\hat{a}_{LV}=-\frac{\theta_{KV}}{\theta_{LV}}\hat{a}_{KV}$ (4.B.1)

Using the above relation in the Equation (4.B) we get:

$\hat{a}_{KV}=\theta_{LV}\sigma_V(\hat{w}-\hat{R})$

or, $\hat{a}_{KV}=\theta_{LV}\sigma_V\left\{\frac{\hat{P}_Y'}{\theta_{LY}}+\frac{\hat{P}_Y'\theta_{VZ}}{\theta_{LY}\left(\theta_{KZ}+\theta_{VZ}\theta_{KV}\right)}\right\}$

or, $\hat{a}_{KV}=\theta_{LV}\sigma_V\hat{P}_Y'\left\{\frac{1}{\theta_{LY}}+\frac{\theta_{VZ}}{\theta_{LY}\left(\theta_{KZ}+\theta_{VZ}\theta_{KV}\right)}\right\}$

or, $\hat{a}_{KV}=\mathrm{A}_2\,\hat{P}_Y'$ (4.B.2)

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

where, $A_2 = \theta_{LV}\sigma_V \left\{ \frac{1}{\theta_{LY}} + \frac{\theta_{VZ}}{\theta_{LY}\left(\theta_{KZ} + \theta_{VZ}\theta_{KV}\right)} \right\} > 0.$

Using equation (4.B.2) in equation (4.B.1) we get:

$$\hat{a}_{LV} = -\frac{\theta_{KV}}{\theta_{LV}}\hat{a}_{KV}$$

or, $\hat{a}_{LV} = -\frac{\theta_{KV}}{\theta_{LV}} A_2 \hat{P}_Y'$

or, $\hat{a}_{LV} = A_3 \hat{P}_Y'$ (4.B.3)

where, $A_3 = -\frac{\theta_{KV}}{\theta_{LV}} A_2 < 0$

Again Equation (8) gives us:

$Zda_{KZ} + a_{KZ}\,dZ + Vda_{KV} + a_{KV}\,dV = 0$

or, $\lambda_{KZ}\hat{Z} + \lambda_{KZ}\hat{a}_{KV} + \lambda_{KV}\hat{V} + \lambda_{KV}\hat{a}_{KV} = 0$

Using $\hat{Z} = \hat{V} =$ and the values of $\hat{a}_{KZ}$ and $\hat{a}_{KV}$ from Equations (3.B) and (4.B.2) respectively in the above expression, we get:

$$\hat{Z} = \left\{ -\frac{(\lambda_{KZ}A_2 + \lambda_{KV}A_1)}{(\lambda_{KZ} + \lambda_{KV})} \hat{P}_Y' \right\}$$

or, $\hat{Z} = A_4 \hat{P}_Y'$ (8.B)

where, $A_4 = \{ -\frac{(\lambda_{KZ}A_2 + \lambda_{KV}A_1)}{(\lambda_{KZ} + \lambda_{KV})} \} < 0$. (As, $A_1 > 0$ and $A_2 > 0$).

By differentiating Equation (7) we get:

$a_{LX}dX + Xda_{LX} + a_{LY}dY + Yda_{LY} + a_{LZ}dZ + Zda_{LZ} + a_{LV}dV + Vda_{LV} = 0$

or, $\lambda_{LX}\hat{X} + \lambda_{LX}\hat{a}_{LX} + \lambda_{LX}\hat{Y} + \lambda_{LY}\hat{a}_{LY} + \lambda_{LZ}\hat{Z} + \lambda_{LZ}\hat{a}_{LZ} + \lambda_{LV}\hat{V} + \lambda_{LV}\hat{a}_{LV} = 0$

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

or, $\lambda_{LX}\hat{X} + \lambda_{LY}\hat{Y} + \lambda_{LY}\hat{a}_{LY} + \lambda_{LZ}\hat{Z} + \lambda_{LZ}\hat{a}_{LZ} + \lambda_{LV}\hat{V} + \lambda_{LV}\hat{a}_{LV} = 0$ (as $\hat{a}_{LX} = 0$)

or, $\lambda_{LX}\hat{X} + \lambda_{LY}\hat{Y} + \lambda_{LY}\hat{a}_{LY} + \hat{Z}(\lambda_{LZ} + \lambda_{LV}) + \lambda_{LV}\hat{a}_{LV} = 0$ (as $\hat{Z} = \hat{V}$)

or, $\lambda_{LX}\hat{X} + \lambda_{LY}\hat{Y} + \hat{Z}(\lambda_{LZ} + \lambda_{LV}) + \lambda_{LY}\hat{a}_{LY} + \lambda_{LV}\hat{a}_{LV} = 0$

or, $\lambda_{LX}\hat{X} + \lambda_{LY}\hat{Y} + \mathrm{A}_4\hat{P}_Y'(\lambda_{LZ} + \lambda_{LV}) + \lambda_{LY} - \frac{\theta_{KY}}{\theta_{LY}}\sigma_Y\,'\hat{P}_Y' + \lambda_{LV}\ \mathrm{A}_3\hat{P}_Y' = 0$

{by using the values of $\hat{Z}$, $\hat{a}_{LY}$, $\hat{a}_{LV}$ from Equations (8B), (2.B.1), and (4.B.3) respectively}

or, $\lambda_{LX}\hat{X} + \lambda_{LY}\hat{Y} = -\mathrm{A}_4\hat{P}_Y'(\lambda_{LZ} + \lambda_{LV}) + \lambda_{LY}\frac{\theta_{KY}}{\theta_{LY}}\sigma_Y\,'\hat{P}_Y' - \lambda_{LV}\ \mathrm{A}_3\hat{P}_Y'$

or, $\lambda_{LX}\hat{X} + \lambda_{LY}\hat{Y} = \hat{P}_Y'\{-\mathrm{A}_4(\lambda_{LZ} + \lambda_{LV}) + \lambda_{LY}\frac{\theta_{KY}}{\theta_{LY}}\sigma_Y\,'- \lambda_{LV}\ \mathrm{A}_3\}$

or, $\lambda_{LX}\hat{X} + \lambda_{LY}\hat{Y} = \hat{P}_Y'\,\mathrm{A}_5$ (7.B)

where, $\mathrm{A}_5 = \{-\mathrm{A}_4(\lambda_{LZ}+\lambda_{LV}) + \lambda_{LY}\frac{\theta_{KY}}{\theta_{LY}}\sigma_Y\,'- \lambda_{LV}\,\mathrm{A}_3\} > 0$ (as $\mathrm{A}_4 < 0$ and $\mathrm{A}_3 < 0$)

Again, by differentiating Equation (6) we get:

$a_{KX}\mathrm{dX} + \mathrm{X}\,\mathrm{d}a_{KX} + a_{KY}\mathrm{dY} + \mathrm{Y}\,\mathrm{d}a_{KY} = 0$

or, $\lambda_{KX}\hat{X} + \lambda_{KX}\hat{a}_{KX} + \lambda_{KY}\hat{Y} + \lambda_{KY}\hat{a}_{KY} = 0$

or, $\lambda_{KX}\hat{X} + \lambda_{KY}\hat{Y} + \lambda_{KY}\hat{a}_{KY} = 0$ (as $\hat{a}_{KX} = 0$)

or, $\lambda_{KX}\hat{X} + \lambda_{KY}\hat{Y} = -\lambda_{KY}\hat{a}_{KY}$

or, $\lambda_{KX}\hat{X} + \lambda_{KY}\hat{Y} = \mathrm{A}_6\hat{P}_Y'$ (6.B)

Equations (6.B) and (7.B) can be written in the matrix form as:

$$\begin{bmatrix} \lambda_{LX} & \lambda_{LY} \\ \lambda_{KX} & \lambda_{KY} \end{bmatrix}\begin{bmatrix} \hat{X} \\ \hat{Y} \end{bmatrix} = \begin{bmatrix} \hat{P}_Y' & A_5 \\ \hat{P}_Y' & A_6 \end{bmatrix}$$

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

$$\Delta = \lambda_{LX}\lambda_{KY} - \lambda_{KX}\lambda_{LY}$$

$|\Delta| < 0$ as X is the capital intensive sector and Y is the labour intensive sector.

By using Cramer's rule we get the value of $\hat{X}$ and $\hat{Y}$ in terms of $\hat{P}_Y'$ as:

$$\hat{X} = \frac{\Delta_1}{\Delta} = \frac{A_5\lambda_{KY} - \lambda_{LY}A_6}{\Delta}\hat{P}_Y' \text{ and } \hat{Y} = \frac{\Delta_2}{\Delta} = \frac{\lambda_{LX}A_6 - \lambda_{KX}A_5}{\Delta}\hat{P}_Y' \text{ (6.B.1)}$$

Chapter 71
Access to Safe Drinking Water: A Low Income Sustainable Water Purification System

Robert Cecil Willems
Leamis International Ministries, USA

Steve A. MacDonald
Dare County Schools, USA

ABSTRACT

The focus of this chapter is to demonstrate that providing safe drinking water to communities in Majority World countries, specifically Kenya, Africa, is easily accomplished. Any water system, in order to be successfully constructed in impoverished Majority World communities, must be simple and inexpensive and the benefiting community must have a vested interest and ownership for the system to be effective. Establishing a vested interest by water recipients requires that the people providing the water purification technology understand the culture and worldview of the water system recipients. This approach is supported by literature review but more so by empirical evidence gathered by both authors.

INTRODUCTION

The World Health Organization (WHO) reports that diarrhea is a waterborne disease that kills around 760,000 children each year and is the second leading cause of death in children under five years old. There are nearly 1.7 billion cases of diarrhea each year. Diarrhea is both preventable and treatable (World Health Organization [WHO], 2015). WHO lists access to safe drinking water as the first key measure to prevent diarrhea.

Safe water supplies, hygienic sanitation and good water management are fundamental to global health. The global disease burden could be reduced by approximately 2.7% by increasing access to safe drinking water, improving sanitation and hygiene, and improving water management to reduce risks of waterborne infectious disease, especially diarrheal disease (WHO, 2015). Efforts to improve water, sanitation and

hygiene interact with each other to boost overall health. Access to sanitation techniques such as simple latrines in communities that lack water treatment systems prevents drinking water contamination from human waste and reduces infection. High-tech public health measures may not necessarily be the best practice while frequent hand-washing with soap and safe storage of drinking water are low-cost, high-impact practices. Investment to improve drinking water, sanitation, hygiene and water resource management systems makes strong economic sense. The Stockholm International Water Institute reported in 2004 that there is a potential for a three to thirty-four United States Dollar (USD) benefit to be realized for every one USD invested in reaching the United Nations Development Program Millennium Development Goals for safe drinking water (Sanctuary, Tropp & Berntell, 2004). In addition to the value of saved human lives, other benefits include higher economic productivity, more education, and increased healthcare savings.

Historically speaking, the developed, western countries have viewed Africa as an impoverished continent that required an immense amount of help to alleviate the suffering of its people. To that end governments and faith based and non-government organizations (NGO) have poured an immense amount of economic aid into Africa looking to correct problems that prevent those countries from becoming economically stable and self-sufficient. According to Development Initiatives, $5.9 trillion US dollars are being spent each year in more than half of all developing countries (Development Initiatives, 2013). While recognizing that these expenditures are intended to be of major benefit to Majority World countries, most of the programs contain elements of paternalism which creates dependency and a sense of entitlement.

There are five types of paternalism: resource, where the solution to poverty is grounded in financial and material resource donation; spiritual, where the benefactor believes the materially poor can be taught much about spiritual concerns; knowledge, where the assumption is that the poor do not have good ideas about how to do things; labor, when the work is done for those who can do for themselves; managerial, where a time and efficiency model is the most expedient (Corbett & Fikkert, 2009). Corbett and Fikkert (2009) contend that paternalism must be avoided at all costs.

The colonialism of Africa, which started in the mid1800s and continued till the 1970s, changed the face of the economic, political and social fabric of the colonized countries forever (Settles, 1996). Oliver and Atmore reported that economic development and education were left up to the private sector (as cited in Settles, 1996, p. 9) but the colonizing countries controlled the foreign trade tax which was designed to benefit the colonizing country, not the colony (as cited in Settles, 1996, p. 9). This situation persisted after the end of colonialism and the effects are still felt today. The infrastructure of transportation and human services in Kenya, most notably in sanitation and water supply, is extremely underdeveloped by western standards. This infrastructure underdevelopment is due to the withdrawal of colonizing country control in the 1960s and an African worldview that interrupts the western process of development. This African worldview will be discussed in following sections.

The objective of this chapter is to present a specific example of an extremely effective way of making safe drinking water available to millions of people in the Majority World. Simple, cost effective, and empowering preventative solutions, such as the system discussed here, can lead to safe, reliable water supplies for all. These solutions need not involve intervention by the major economic and political powers. Providing safe water will require a decentralized process that involves participation and sustainability (Marshall, 2011).

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

BACKGROUND

Diarrhea is a symptom of infection caused by a host of bacterial, viral and parasitic organisms, most of which can be spread by contaminated water. It is most common when there is a shortage of clean water for drinking, cooking and cleaning. Basic hygiene is important in the prevention of waterborne sickness. Water contaminated with human feces from municipal sewage, septic tanks, pit latrines or a lack of sanitation facilities is a major concern. Animal feces, which can enter the water system from a number of sources, also contain microorganisms that can cause diarrhea. Diarrhea can be spread from person to person where poor personal hygiene exists. Food is another major cause of diarrhea when it is prepared or stored in unhygienic conditions. Water can contaminate food during irrigation, and fish and seafood harvested from polluted water may also contribute to the disorder.

Africa is estimated to be the world's second largest and second most populous continent with more than 1.1 billion people living in about 30 million square kilometers of land (World Atlas, 2015). Kenya's population in 2013 was 41.8 million (Kenya National Bureau of Statistics [KNBS], 2015). According to the WHO/UNICEF Joint Monitoring Programme (2014) report, of those millions, 38% of them did not have access to safe drinking water and 70% are restricted to shared, open defecation or other unimproved sanitation facilities. Compare those numbers to the United States where 99% of the population in 2014 had safe drinking water available to them (World Bank, 2015). How sanitation and disease are dealt with is influenced by the African worldview, as explained below.

The African Worldview

Munza (2008) explains the African worldview in the following way.

A worldview is usually not something that is deliberately taught, it is simply a way of living. Our African worldview is absorbed. At nights we would have competitions in story telling that also taught traditional African values and worldview. When I was growing up within the Luba tribe my father was a chief, and he carefully instructed me in the traditions of my culture. Although he repeatedly told me that he was sending me to the white man's school, he wanted me never to forget the misumba. (The word misumba means literally the hunting or fishing camps that one occupies temporarily.) He wanted me to learn what I needed in order to make it in the world. 'Misumba ibidi hatanda, wasatwe keuyukene.' is a proverb which means, 'There are two camps in the world, but the third is unknown.' (p. 7)

Munza relates that the mother's womb is the first camp and the physical existence of the current world is the second camp. The third, unknown camp is the spiritual realm that follows death and cannot be known but is one's real home. The belief is that this existence is cyclical in nature and one may have to go to the other camps occasionally, but one may stay at home. The cyclical nature is born from generations observing the world around them. Munza (2008) states "How did we get this worldview? My father pointed out that the grass dies or is burned and then comes up again when the rains start. The sun disappears every evening and then reappears the next morning. Nature is cyclical, and so are our lives." (p. 8). Simply stated, the traditional faith on which the African worldview is based is an agrarian form of reincarnation which carries with it all the attendant customs, taboos, and rituals. The implications of this worldview are profound and it affects all aspects of life. Development is severely limited by the perception that this world is a *musumba,* which is the singular form of misumba. This perception is a

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

major obstacle to development because to the African it makes no sense to build good houses and roads in a place one will be occupying only temporarily. The concept of development is almost absent. There is also the idea that one is to leave things to others at the time of death just as it was found. This includes style of life, housing, food, power, land or boundaries, and traditions (Munza, 2008).

In the African worldview, spiritual beings are the source of all diseases and therefore, the diseases cannot be satisfactorily treated with medicine and there is little sense of ability for change. Everything happens because one is bewitched or because the spirits predestined it. This affects both development as well as disease management. Traditional African practices toward healing derive major importance from beliefs that existed long before modern medicine was developed. The healers were considered charlatans and biomedicine antagonists who exploited an ignorant population. Each African country supports varying healing practices based on social and cultural traditions and heritages (Kubukeli, 1999).

Closely related to this is the use of a fetish to succeed or the belief that an individual does not have to work at being skillful. There are fetishes for success in school and business, for love in marriage, for security or protection against any action of one's enemies (MacGaffey, 1994).

According to MacGaffey (1994):

The material fetish as an object established an intense relation with, and exerted power over, the desires, actions, health, and self-identity of individuals whose personhood was conceived as inseparable from their bodies: the human body (as the material locus of action and desire) was subjected to the influence of amulets and the like that, although cut off from the body, functioned as its controlling organs at certain moments for example, for healing. (p. 1).

There are several additional traditional beliefs that delay development in Africa. Ancestral heritage is sacred and includes land, power, and traditions. Land boundaries must not be changed. Rights of other tribes or people are irrelevant. It is an unforgivable sin to compromise. Colonialism, as practiced by the European countries during the 19th and 20th centuries, changed boundaries and transferred people groups. Munza (2008) states "When you get meat, share it with your family, or you will not have someone to share with you when you don't have meat" (p. 15). Sharing is a required practice. It involves much more than sharing food or goods or taking care of family. This traditional form of sharing has been expanded to mean power or benefits if one has any social or political position (Munza, 2008)

The deeply entrenched cultural practice of nepotism is revealed in Kenya's political history. Kenya moved to a multiparty political system in 1992 after almost 30 years of independence from Great Britain. Many expected to see the end of political tribalism that was a hallmark for both the Kenyatta and Moi eras. Both former presidents favored their own tribes economically and are reputed to have stolen millions of shillings from the country. Unfortunately, election riots in 2007 showed that Kenyan politics are still divided along tribal lines and may stay that way for generations (Barsby, 2013).

Worldview Conflict

As westerners begin to interact with those individuals still holding tight to the traditional African culture and worldview, there are two things that may begin to happen to the westerner. First, appreciation may grow for how western culture differs from African culture and how thought processes are very different. Or secondly, one can choose at this point to not embrace the differences. For decades the western

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

culture has tried to convert the African people and their culture into a form that resembles the west. This effort has resulted in programs that carry a large burden of paternalism and a sense of entitlement and dependency.

In order to achieve authentic development, Africans and their development partners need to understand that paradigms and strategies the partners suggest, demand, insist on, and force on the people will not work. An indigenous African agenda for development must be the basic principle behind programs (Ohiorhenuan, 2010). A notable deterrent to development are the three levels of culture Hall and Helman identified: behaviors visible to the outsider, behaviors known by the group but not relayed to outsiders, and rules that are known and obeyed by all (as cited in Esegbona-Adeigbe, 2011, p. 492). Hall further argues that the third, or primary level, is less understandable to the outsider, and more resistant to change because of its stability (as cited in Esegbona-Adeigbe, 2011, p. 492). These are the conditions that exist in the African culture of the 21st century.

The chapter authors believe that there needs to be a fundamental shift away from the *misumba* concept of temporary residency. The change cannot be forced on Africa but instead must come from within the African culture. But how can that be accomplished if, as Hall (1984) states "…no matter how hard man tries it is impossible for him to divest himself of his own culture…"? What must be done to move out of the quagmire of paternalism and attitude of entitlement into a state of unshakable independence? This problem is awaiting a solution.

Western culture derives rules for living from a totally different source than traditional African thought (Munza, 2008). Public service has become a way of life for some Americans and giving seems to have become a part of the national character. For such public service-minded persons the typical worldview includes being good stewards of the environment and the concept that humanity is to treat everyone as a neighbor. But compassionate instincts and generous spirits aren't enough because a disturbing truth is that all too much charity has become toxic, with devastating effects on the very people it's meant to help (Lupton, 2011). This manifests itself in a larger issue regarding the approach the developed (western) countries of the world have historically taken to help developing countries like those on the African continent. While recognizing the good intent of these efforts, often times these efforts do not achieve the expressed goals of the organization financing the effort, and the effort then fosters an atmosphere of paternalism, which may cause dependency. Lupton (2011) states "When we do for those in need what they have the capacity to do for themselves, we disempower them" (p. 3). Lupton (2011) then explains further that "Giving to those in need what they could be gaining from their own initiative may well be the kindest way to destroy people" (p. 4).

THE PROBLEM WITH SANITATION

There are approximately 2.5 million slum dwellers in Kenya's capitol city of Nairobi representing 60% of the Nairobi population. Kibera houses almost 1 million of these making it the largest slum in Africa and one of the largest in the world (The Kibera Law Centre, 2015). Until recently Kibera had no independent water supply so the people living there had to collect water from the Nairobi dam. The dam water is not clean and causes typhoid, cholera, and diarrhea. A study published by the United Nations Development Programme (UNDP, 2011) reports that there were 159 small-scale water providers within Nairobi city. This indicates that water is becoming more available within the city but that same report questions the

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

quality of the water by noting that testing water quality is only done at the initial licensing stage without follow-up testing. The report later examines some serious implications about the water quality that is distributed (UNDP, 2011).

Sanitation is almost non-existent by western standards. One pit latrine (a hole in the ground) is shared by up to 50 to 500 people (Capital Broadcasting, 2015). Once the latrines are full, young boys are employed to empty them by taking the contents to the river. All greywater, water that has been used for other than flushing toilets, and much untreated sewage flows throughout the area in open ditches. Because clusters of pit latrines (four per cluster for 50 shacks) are widely scattered, human waste is often put in a plastic bag and tossed out the door of the shack. This practice is called air latrines and contributes greatly to the vastness of the sanitation problem.

The memory of the atrociousness of Kibera's sights, sounds, and smells may stay with a visitor for a very long time and may also cause a fundamental change in the visitor's attitude toward poverty. If the visitors are westerners they may begin to develop strategies to correct situations perceived as broken. But, maybe, just maybe, Africa is not broken. The LEAMIS training manual for their volunteers (LEAMIS International Ministries, n.d.) emphasizes that something is not necessarily wrong just because it is different. Perhaps each culture looks at the other as broken. Maybe both cultures need each other to correct the misconceptions about each other's world.

REALITY CHECKS: EXAMPLE OF A HELPING RELATIONSHIP THAT WORKS

A LEAMIS (a faith-based organization headquartered in the United States) team made arrangements with Bishop Paul Mbithi, founder and Senior Pastor of the New Life Restoration Ministries International (NLRM), to travel to Nairobi, Kenya in 2004 to establish a relationship that would hopefully have a long-lasting effect on the people of Kenya and the NLRM. Bishop Mbithi predicted that "Once the dust of Africa is on your sandals, you can never get rid of it!" (P. Mbithi, personal communication, June, 2004). The dust of Africa is the richness of the culture, the demand that one understand and live within that culture and the history of the people with all the diversity of family and tribal traditions. The efforts of western countries to lift the people of Africa out of material poverty over the decades can be labeled as a type of colonialism and paternalism and are not considered part of the dust. The LEAMIS team that met with Bishop Mbithi in 2004 was not fully cognizant of the differences between worldviews and the conditions they were introduced to in Nairobi were shocking. The NLRM headquarters is located on the edge of the Kibera slum that was described above.

LEAMIS and NLRM, as a result of the 2004 meeting, entered into an agreement that would help provide villages associated with the NLRM, in Kenya, with water filtration and chlorinating systems. The process for installing the systems that LEAMIS and NLRM established was not in consonance with the decades old approaches of church and non-government organizations that created an entitlement culture in Kenya as well as other countries in Africa. LEAMIS stopped telling people *what to do* and started showing them *how and why to do* for themselves and then allowed their students to make their own decisions. Empowering people is done through communicating what the issues are in a non-patronizing way, explaining why these conditions exist, gaining as much participant input as possible and not being critical of conditions. This approach not only provides valuable training, it builds trusting relationships.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. A typical street on the edge of the Kibera slum in Nairobi, Kenya in 2014.

LEAMIS and NLRM acknowledged the conditions and environment that foster poverty in Kenya, and then developed viable solutions for those problems. These solutions, that could be effective with changes in attitude and lifestyle practices, are based on the idea that personal involvement offers the best way to determine if our charitable investments are being put to good use (Lupton, 2011). However, material poverty cannot be eliminated by a single organization. What was done was not to presuppose solutions but let NLRM determine what some of those solutions might be. One of those solutions was to create a means for villages to gain access to safe drinking water. Establishing safe water supplies is an ongoing development process for both the helped and the helpers. This led also to workshops being created that allowed skills by which the local community constructed clean water filtration and chlorination systems and established cottage industries. LEAMIS encouraged evaluation of the existing conditions to determine which skills were most needed to improve the use of resources. Experiences with waterborne diseases such as typhoid and diarrhea, especially in infants and young children, were also investigated. The most useful result and workshop that came from this collaborative effort was the water filtration and chlorination system discussed further in this chapter. LEAMIS and NLRM have also incorporated the SODIS water purification process in their workshops, which adds another method for providing safe drinking water to the communities.

It is important to note that both authors have helped communities construct and operate these systems in rural African villages. The original Chlorine Production Unit (CPU) has been replaced by a newer, smaller and more energy efficient model. However, both CPUs perform the same function—generating chlorine to make filtered water safe to drink. The following account illustrates the importance of providing clean, safe water to communities around the world.

Kissi is a small town about one hour from Nairobi whose water source is a small pool of water located downhill from the two pit latrines that served this community of about fifty people. As the LEAMIS team prepared for the workshop session, a pastor from another town arrived on foot and proceeded to drink out of this small pool, because it was available. Tests of this water and another source about one

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

half of a mile away confirmed that they were both contaminated and unsafe to drink. The man's use of this water is a very good example of the situation in Majority World countries wherein people will drink water they may know is unsafe because there is no safe water available. Even though the man most likely knew the water was unsafe and he was already infected with typhoid, he still drank the water. Such is the situation in Majority World countries.

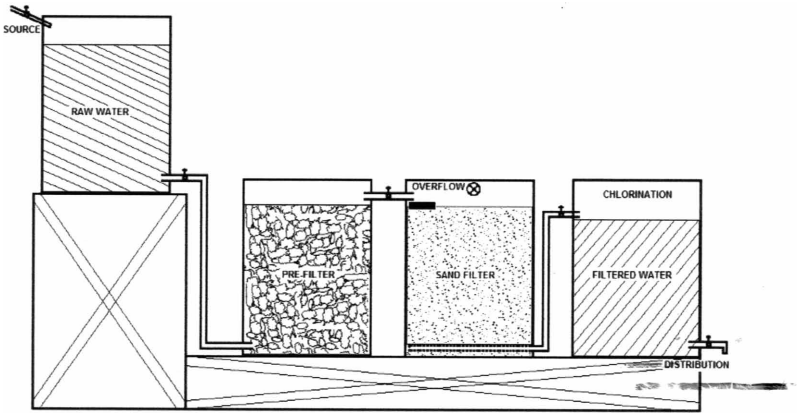
A PRIMARY SOLUTION: WATER FILTRATION AND CHLORINATION

The water filtration system developed in response to the requests of LEAMIS and NLRM is a three stage system based on the process common wetlands utilize to filter and clean water naturally. The first stage filters particulates with a rock or gravel component that is made of first large rocks then smaller rocks that capture smaller and smaller unwanted materials. The next stage is sand which creates a microbial biofilter that uses the biological flocculation process which allows living organisms such as bacteria, zooplankton, diatoms and algae to eliminate pathogens in the water (Tarsi, 2008). The sand filter is a microcosm of wetlands that occur in nature. Wetlands are extremely efficient in filtering water and can actually purify contaminated water and render it safe to drink. The third stage includes using chlorine to treat the water to remove pathogens not removed by the filtration and to kill parasites.

All of the containers in an ideal system are the same size to allow for uniformity of water distribution through the system. The recommended size of the containers is between 30 and 50 gallons. The first container is used to house the raw water. The second, Pre-filter, is filled with clean, 1-1.5 inch diameter pebbles or gravel. Raw water is piped in at the bottom of the pre-filter by hydrostatic pressure and allowed to percolate up to the top where it is piped onto the top of the second stage sand filter. The purpose of the pre-filter is to remove as much organic material as possible. Over time, this filter may clog and the gravel will need to be thoroughly cleaned or replaced.

The Sand Filter is filled with clean sand the texture of fine beach sand or sand that is used for mortar. There is a deflection rock on top of the sand to prevent the sand being stirred. About two weeks after initial use a microbial layer will form. This is why this filter is effective. This layer is made up of liv-

Figure 2. Elements of a filtration/chlorination system. Figure created by chapter author Robert Willems, 2014.



EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

ing organisms that naturally occur. Over time this layer will become denser and actually slow the water percolation. At that point a few inches the top layer of sand needs to be removed and new sand added. There is a perforated pipe in the bottom of this filter that will discharge filtered water into the third stage collection container where the water will be chlorinated.

Chlorination currently occurs by one of two methods. The first method is by bubbling chlorine gas through the filtered water. The chlorination unit uses ordinary table salt or unrefined rock salt. Water is added to the device and it is connected to a standard 12 volt car battery. The salt is broken down into sodium and chlorine which are given off as gasses. The byproducts that are captured by the unit are highly concentrated Clorox-type bleach on one side and a strong sodium hydroxide solution on the other. The chlorine gas is injected into the filtered water while the sodium is vented to the atmosphere or captured for other use. The former, when diluted, is ideal for use as an effective antibacterial cleaning agent and the latter is ideal to deodorize pit latrines, effectively removing their odor. The time required to bubble chlorine gas through the filtered water to raise the concentration to a level that will kill bacteria is approximately one minute for fifty gallons of water. According to the WHO (2003) the chlorinated water must contain a chlorine concentration level between 0.2 and 1.0 parts per million (ppm) to be considered safe for consumption. If the chlorine concentration drops under that, the water must be re-chlorinated and retested. The concentration level may be determined by using an ordinary swimming pool test kit. A very effective and dependable chlorine generating unit has been designed and patented by New Life International, www.waterfortheworld.com, where the units are available.

The second method of chlorination is to manufacture liquid chlorine by passing salted water through a Chlorine Producing Unit (CPU) and treating the filtered water with the chlorine. One of the most recent units installed in villages in Kenya is the Khlor Gen System (Hayes Pure Water, 2014). The Khlor consists of a chlorine producing unit powered by a motorcycle sized 12 volt dc battery and a solar panel to keep the battery charged. The complete system currently costs $365 US and is expected to last five

Figure 3. Original four barrel water filtration system installed in New Life Restoration Ministries church and orphanage in Nairobi, Kenya

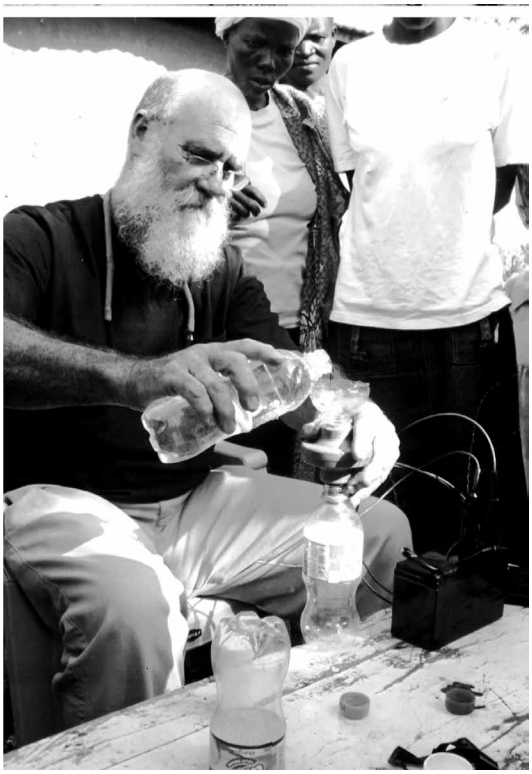
Figure 4. Chapter author Steve MacDonald demonstrating the newest Khlor Gen System to villagers in Kenya in 2014 during the LEAMIS Water Purification Workshop



years under normal usage. The inventor of the Khlor reports that more than 4000 units have been installed worldwide (Hayes Pure Water, 2014). The system is easily transported in airline checked baggage and is simple enough to use that very little training is required. With exception of the chlorination unit all other materials for the systems can and should be purchased locally to assist the local economy and prevent creating a situation of paternalism or sense of entitlement.

The workshop that was developed to train members of the community in the operation of the filtration system is followed up with construction of a system by residents of the village. This ensures that those trained in the operation of the system will have ownership of the system and the community is empowered with the knowledge necessary to teach the concepts to others. Periodic maintenance and troubleshooting of the system is also included in the workshop. The entire process from workshop to completed filtration system can be accomplished in as little as two days. However, the experience of both authors has been that the process takes three to four days.

The reader is strongly encouraged, at this point, to visit the LEAMIS website at www.leamis.org to watch "2010 KENYA Trip" (found under the "Watch Our Videos" tab) which portrays the passion felt for bringing this technology and these systems to groups such as New Life Restoration Ministries. To date every system that has been installed in Kenya has completely eradicated waterborne disease (P. Mbithi, personal communication, March 3, 2014). The reader is also encouraged to visit Vimeo on-line video library and watch http://vimeo.com/76944942 to learn more about New Life Restoration Ministries and see how they have upgraded the original system installed in 2004.

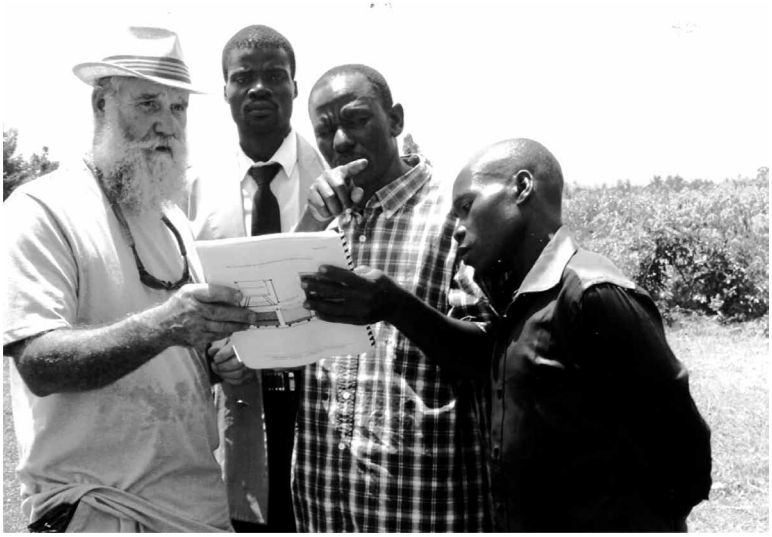
Figure 5. A group of NLRM members consult with one of the authors during the construction of a water purification system



SODIS: A Value Added Process

Solar Water Disinfection (SODIS) is a simple, environmentally sustainable, low-cost solution for treating drinking water at the individual level for people consuming microbiologically contaminated raw water. SODIS uses solar energy to destroy pathogenic microorganisms causing waterborne diseases and therewith it improves the quality of drinking water. Pathogenic microorganisms are vulnerable to two effects of the sunlight: radiation in the spectrum of Ultraviolet A (UV-A) light with a wavelength between 320 and 400 nanometers and heat. Eawag (2015) lists 42 scientific publications that discuss the SODIS method of water purification. The mortality of the microorganisms found in untreated water increases when they are exposed to both higher temperature and UV-A light at the same time. SODIS is ideal to disinfect small quantities of water of low turbidity, which is a measurement of the clarity of water. Contaminated water is filled into transparent plastic bottles and exposed to full sunlight for a minimum of six hours. During the exposure to the sun the pathogens are destroyed. If turbidity is greater than 50%, the plastic bottles need to be exposed to direct sunlight for two consecutive days in order to produce water safe for consumption. Filtering the water through clean cloth will reduce the turbidity which will increase the available water that can be successfully treated. The treatment efficiency can be improved if the plastic bottles are exposed to sunlight on reflecting surfaces such as aluminum or corrugated iron sheets.

SODIS is well suited for small households or individuals because of the simplicity of the process and that it uses plastic bottles that are usually very plentiful. There are two forms of plastic, polyethylene terephthalate (PET) and Polyvinyl chloride (PVC). PVC can be harmful through chemicals that leach into the water as the bottles age and are exposed to sunlight. The PET plastic bottle is much less volatile as it degrades in sunlight and is therefore much safer from a health standpoint.

Turbidity and availability of usable bottles are issues. If the raw water is too turbid the water cannot be treated. A simple test has been devised to confirm that the turbidity is low enough that the water can be treated. The test is to determine if the word “SODIS”, printed on a sheet of white paper, can be read

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

looking through the water in the bottle. If the turbidity is low enough to classify the water as treatable, "SODIS" can be read. Availability of bottles can be a minor issue because of the recycle potential of PET which gives it a marketable value and bottles may be scavenged from debris piles. Eawag, The Swiss Federal Institute of Environmental Science and Technology, in cooperation with the Department of Water and Sanitation in Developing Countries (SANDEC), have perfected this inexpensive yet dependable water disinfecting technique.

One additional benefit of conducting both filtration/chlorination and SODIS workshops simultaneously is that in the event a CPU should cease functioning for any reason, the SODIS treatment of the filtered water will provide users with safe drinking water.

RECOMMENDATIONS

Reliable and safe water supplies must be developed if there is to be a reduction in the global disease burden. Individuals and NGOs interested in helping communities develop a safe water supply should carefully consider exactly how to help those communities without creating a situation where paternalism and entitlement become the norm. A suggestion is to study cultural competence information before attempting an encounter to assist Majority Word peoples. According to Ansuya (2012) Leininger's Culture Care Theory is one such useful basis for understanding the importance of culture in an individual's health and other behaviors. Leininger's work was written for nursing originally, but could be easily broadened to assist anyone seeking to implement health improvements in Majority World locations. Some of the essential elements of cultural competence include: valuing diversity, preforming cultural self-assessment, being conscious of dynamics of cross-cultural interactions, having cultural knowledge of the service area and developing adaptations of service delivery reflective of that cultural knowledge (Ansuya, 2012).

FUTURE RESEARCH DIRECTIONS

Several efficient, simple and cost effective water filtration and chlorination systems have been developed in the last decade. Consultations with leading authorities in the proper implementation of those systems will help ensure successful development of healthier communities. Further research directions could be focused on variations of the water systems that would work better in different communities. Also relationship building methods that assist in successful delivery, installation and on-going operation of water purification systems can be further developed.

CONCLUSION

Having access to clean, safe drinking water is a large scale problem for a majority of the world's population. Contaminated water is responsible for too many deaths each year, especially young children. Finding clean, pure and potable water is a life-sustaining necessity worldwide. Many people have to travel miles just to find water which much of the time is polluted and leaves the population victim to waterborne disorders such as typhoid and diarrhea.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

LEAMIS was instrumental in the development of an extremely effective, simple, cost effective, and empowering preventative solution that lead to safe, reliable water supplies for all. This has been accomplished without the intervention of major economic and political entities and the countless monies spent trying to save the continent. This very successful program relies on a decentralized process that insists on the participation of those benefiting from the water treatment systems. More than thirty systems based on the original system installed in Kibera have been installed in NLRM communities in Kenya since 2004. "The water purification systems LEAMIS has so far managed to install at various church locations here in Kenya have been quite revolutionary. Waterborne diseases have effectively been eradicated and children at our school in Kibera have been one of the greatest beneficiaries" (P. Mbithi, personal communication, March 3, 2014). When the installation of a system is accompanied with proper training and bolstered by a relationship such as the one enjoyed by NLRM and LEAMIS, the health and well-being of the community members are greatly increased.

KEY TERMS AND DEFINITIONS

Dependency: The state of being when someone constantly relies on a person or organization for economic, political or emotional support. Those that are dependent often do not do for themselves what they can because some else will do it for them.

Flocculation: A chemical process occurring in biofilters that results in pathogens coming out of solution and attaching themselves to solids in the filter.

Majority World: Those countries that have traditionally been labeled underdeveloped or third world. The majority of the world's population resides in these countries.

Misumba: The hunting or fishing camps that an African temporarily occupies while living on the earth. The concept of a Misumba is one of the major components of the African worldview that hinders development.

Paternalism: A policy or practice of treating or governing people in a fatherly manner, especially by providing for their needs without giving them responsibilities.

Safe Drinking Water: Water that is either naturally potable or has been filtered and chemically treated to render it potable.

SODIS: A water purification process that capitalizes on the susceptibility of microorganisms to ultra violet light and heat.

Workshop: An informal training conference designed to transfer knowledge to attendees.

This research was previously published in Impact of Water Pollution on Human Health and Environmental Sustainability edited by A. Elaine McKeown and George Bugyi; pages 304-318, copyright year 2016 by Information Science Reference (an imprint of IGI Global).

Chapter 72
Increase of Transportation Efficiencies and Emission Reduction within a City

Christian Jenne
University of Duisburg-Essen, Germany

ABSTRACT

On a worldwide scale population is increasing, necessitating efficiencies in transportation essential for a modern and healthy environment. Most cities have already reached their limitations on population and vehicle movement. Street layouts and cycling lanes, which were initially planned for a certain number of inhabitants, are now not able to cope with increasing demand. The same applies for fresh water supply and effluent treatment which have limitations also. With an increasing population in urban areas, restriction levels in these regions can be reached very quickly, creating a problem which needs to be addressed. A smarter city can only be developed when there is pre-planning on all of these issues, when there is an understanding of newly developed human behaviours, and when new inventions and technologies in urban areas can adapt to these changes.

INTRODUCTION

In order to develop a good eco-society, there are a number of elements that need to be in place before a city can be labelled as a "smart city". Refuse collection, recycling infrastructure and recycling amenities, low smog concentration, traffic flow of vehicles and people, substantial investment in renewables, and energy efficiencies will all have a major influence in achieving a smart city status.

Industrially developed cities are fighting against pollution by increased decarbonisation programmes. Supporting energy efficient systems with the help of renewable energy technologies, while at the same time carefully targeting the spending of those investments, is a key part of this strategy. This chapter will focus mainly on methods and technologies in the transportation sector which until now have been ignored but which play a major role in the pollution of cities. Transportation emissions are a major contributor to smog levels and therefore need to be addressed in any assessment of this problem.

In order to have a modern eco-society, planners and engineers have to reassess their city in every area, evaluate required steps and take critical action against those problems identified. This chapter will highlight potential pitfalls and will demonstrate state of the art developments across the globe, enhancing a city's lifestyle and associated environmental management system accordingly.

BACKGROUND

Urban population is increasing at an alarming rate which, over time, will result in traffic flow problems, increased pollution density, crowded public transport, exhaustion of land availability for future property developments, and consequently a reduction of available social parks and woodlands. Reduced green zones in built-up areas result in a subsequent increase in CO_2 emissions, particles measured in parts per million (PPM), and noise levels.

According to the "Bevölkerungsfonds der Vereinten Nationen", the world population is predicted to reach 9.6 billion people by 2050, by which time more than two thirds of this population (approximately 6.4 billion inhabitants) will be residing within urban areas and cities (Malte Laub, 2015). This shocking prediction highlights the urgent need for more efficiency in cities, smarter traffic planning and innovative living accommodation.

In India, 30 people currently move from a rural area to a city every minute. This growth trend is expected to continue for the next 20 years. Experts are predicting that there will be a development of approximately 500 new cities within India in the next two decades (Heckel, 2015). This movement of people from rural to urban will result in enormous lifestyle changes, with a much greater proportion of people's lifestyle requirements having to be met in a smaller living space.

- **Issues:** With the constant growth of cities on a global scale, ownership of properties is becoming more limited and requires more land area. This demand on properties will increase rent and limit affordability, which will trigger higher living expenses in these cities. A higher population density for a city which has not been designed initially for this explosion of people puts pressure on waste disposal, the resources of treatment plants, and parking spaces for vehicles, and also leads to a surge in noise and emissions. This has a huge impact on current layout designs, beginning with traffic flow problems, public transportation systems, postal delivery, nearby parks and forestry, fresh water supply, and available grocery stores.
- **Controversies:** Living accommodation can be very limited and expensive in a growing city which consequently requires more housing solutions. This can apply when looking for new property developments while reducing social green field spaces like parks, amenities and small forests or nearby developments. Reducing social spaces will not please everyone, but doing nothing against a growing number of inhabitants won't solve the problem either.
- **Problems:** Some cities are not designed for rising population numbers and need to reinvent in order to adapt. In some cases not every city and urban area can deal with these until-now unknown problems and they will require professional help. Focus groups, advisors and other specialists are needed to deal with the above mentioned problems like waste treatment, water supply, the parking situation, limited public service transport, required rental properties, and other related pollution factors.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

- **Solutions:** Pre-planning in response to forecasts of increased population is essential for a stable city design. Every city should have a planning and design team focusing on a specific area with the help of a focus group. These groups need to analyse current system setups, address current and future issues, and evaluate possible options. The forecast data, which will include expected population numbers, is essential for a pre-planning procedure. Available land area and lead time to build properties must be considered when pre-planning, as it can take up to three years from filing a planning application to initial completion.

Transportation efficiencies and emission reduction are very important topics, which must and will be explored by many cities. Growing urban areas have come under pressure, as these problems have only recently been taken seriously.

Research Statement

The expression "smart city" is in very common usage nowadays to cover a very broad range of areas stretching from sustainable living, eco-friendly dwellings, smart integrated solutions via mobile phone applications, modern waste water treatment facilities using the off-gas for power and electricity production, and smartly controlled traffic flow guided junctions. All of this integrated technology has already changed behaviours and will certainly shape the coming years and even decades. Computer assisted guiding systems for disabled and elderly people, and robots serving food and accomplishing easy tasks like cutting lawns when required, are already a reality. This evolution is all part of becoming a more connected environment, helping in decision making processes, which will subsequently lead to higher efficiency. Televisions integrated into mirrors in bathrooms, informing people of breaking news, is not a future idea any more. This all is part of a smarter city structure, embedded in various fragments of this system.

This section however deals mainly with transportation related topics ranging from traffic flow design, energy saving innovations, new technology developments, and efficient system integration using public transport services. A comprehensive framework of innovative strategies has been introduced. Those technologies will highlight what deficiencies exist in the process of transforming a smart city to the next level. Best practice and examples from around the world which demonstrate the potential of each city have been researched.

Small Solutions Can Make a Huge Difference

There is not just one solution to reducing urban waste and pollution. Several small changes have the potential to have a major impact on these problems. There is enormous room for efficiency and improvements and, when all enhancement programmes are running concurrently, there could be a noticeable change. Below is a list of suggestions using different technologies and inventions, some of which are still on a pilot scheme basis.

Action Against CO_2 Reduction Requires Several Steps

Traffic systems and public transport need to be constantly re-evaluated for future action which may be required. The newest available technology has to be used, keeping traffic flow moving despite the fact

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

that the population in urban areas is growing. "Smart traffic light systems", higher efficiency with parking spaces, more public transport incentives, and an increase in cycling lanes, car sharing, and usage of electric vehicles are all things that can make a city smarter. All these improvements will have the effect of decreasing carbon dioxide and other emissions due to higher effectiveness. This will also positively impact on the health and quality of life of people living in those areas mentioned.

Renewable Systems Will Play a Major Part of an Eco-City

Hot water solar panels that can produce free hot water in combination with photovoltaic panels can generate localised electricity as has been done widely in mainland Europe. This is one of the key elements that can contribute to reducing emissions in cities. Energy efficiency, architectural design of south facing buildings in the northern hemisphere and north facing buildings in the southern hemisphere, and draught and heat loss reductions supported by thermal coated triple-glazed windows will enhance sustainable living. These improvements will also reduce heat load and electricity bills, which can then lead to reduced emissions due to lower energy requirements from public, domestic and industrial premises. These combined with highly efficient electrical devices will conserve electricity consumption which is traditionally produced by nuclear power or peat, coal, oil and gas power plants. Therefore, electricity reduction is one of the best methods of saving by reducing the emissions and environmental pollution of energy production.

Smarter Building Design Integrated with Innovative Renewable Technology has been Enforced by Tougher Building Regulations

Most counties in Europe have a localised standard of building regulations. In order to get planning permission, buildings need to meet those standards, and technology and some type of renewable energy contribution need to be installed to comply with these standards. In order to compare different system types, energy performance of dwellings are measured in Maximum Permitted Energy Performance Coefficient (MPEPC). This performance certificate indicates the emissions produced and the quality of insulation in the house. For each m^2 of living space there is a certain heat and energy requirement. The better a house is insulated, the lower the heat demand; therefore, efficiency is increased. Nowadays, these certificate values are indicated in kWh/m^2 per annum. With this system the buyer and property developer know exactly what energy costs will be expected after purchase. In Germany, these certificates have to be renewed every 10 years in order to include new technologies and modernisation improvements which were carried out in the intervening years.

Energy performance certificates for houses used for letting and sales are mandatory in Germany since 2008. This energy and house performance certificate (Energieverbrauchsausweis) indicates the energy requirement as a value but also has, for the less technical person, a scale in letters ranging from A+ to H (dena, 2009). A house with an energy rating of "H" would be the worst performing house with literally no insulation and poor window glazing. A house with the "A+" accreditation would be classified as a passive house which does not require any import of heat and electricity. In another words, an A+ house produces its own required heat and more electricity that it consumes. Most passive houses have solar thermal panels for hot water production and photovoltaic panels for electricity production. If the annual electricity production is greater than their need, surplus electricity will be exported. Electricity could be used for geothermal heat pumps and, therefore, no fossil fuel is consumed. It could also be

used for wood pellet boilers, igniting the fire, powering the wood pellet auger and circulating the hot water for domestic heating purposes. Passive house designs are always costlier than normal dwellings, but eventual running costs are less over the life cycle of the building and it can be seen as an emission free house all year around (Figure 1).

Start and Stop Function in Trucks and Vehicles

Newer cars have a start/stop function which will stop the engine when the car is not moving, the gears are engaged and the clutch is not activated. This technology can reduce emissions in a traffic jam and will have the added bonus of saving fuel. All these systems work similarly and are ubiquitous on hybrids. When the car comes to a stop, the engine computer cuts spark and fuel. When the brake is dis-engaged, or the clutch engages, the engine fires back up. The engine starter has to be stronger than in normal engines to withstand the markedly increased on-off cycling. A more powerful battery is also required to satisfy the car's entire electrical needs with its more frequent engine off cycles. Otherwise, stop-start is about as easy a fuel-saving technology as driving downhill (Colwell, 2015).

This technology will help during traffic jams, reducing delay times at traffic lights and other situations where longer idling time is encountered before proceeding in driving off. Depending on the vehicle model, fuel type and engine size, the rule of thumb is that if the engine is switched off for more than 5 seconds a fuel saving will occur. This applied technology in cars is known as "blue motion technology", which has been developed for exactly these kind of situations. Most of the newer mid-range specification vehicles manufactured after 2009 will have this feature as standard.

Increased Road Tax Fees for Cars with High Emissions

It is generally becoming more common throughout Europe that road tax systems are based on emission levels only. The higher the emissions of a vehicle/truck, the higher the running costs and associated road tax. This will incentivise vehicle owners to invest in more modern engine technology which will lead

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

subsequently to less road tax expenditure. Road tax is based on emissions of various fuel types like petrol, diesel, LPG, electricity, hydrogen, LNG and CNG due to various fuel densities and associated emission values. The higher the tax for a vehicle the more likely the owner will change it. Cars older than 10 years must also undergo an annual roadworthiness inspection which incentivises the vehicle owner to drive a newer automotive. This will help in reducing emissions and will likewise lead to less fuel consumption.

Travelling Ban for Amber and Red Emission Labels in City Centres

Particulate emission bands for vehicles in cities in Germany are classified in three categories: green, amber and red. Vehicles, therefore, have been classified into different emission bands, which must be denoted by a sticker displayed on the front windscreen. The vehicle registration office will issue those stickers according to the emissions of the vehicle. More than 50 cities in Germany have introduced areas where only low emission vehicles are permitted. Other locations are less restricted and allow amber coloured labels. A green labelled vehicle can drive through the city without any limitations, amber labelled vehicles are limited to certain areas and red labelled vehicles are prohibited from entering the city centre (ÖAMTC, 2014). This system has been in operation since January 2013 and will keep emissions lower in busy cities. Compliance is strictly controlled and any violation is prosecuted with a hefty fine.

Traffic Information for Vehicles and Public Service via Mobile App and Satellite Navigation

Commuters can be notified via mobile phone app, radio data systems or satellite navigation about current traffic status, enabling them to pre-plan required journeys and routes in a more efficient way. This has the potential to reduce traffic jams, making traffic flow more efficient, with the aim of reducing travelling time and emissions. Some companies are very efficient in this area, developing their own software and networks. One of the company developments is based in Zaragoza in Spain (Figure 2).

The Vehicle Traffic Monitoring Platform, part of the Libelium Smart Cities solution is a platform capable of sensing the flow of Bluetooth devices in a given street, roadway or passageway differentiating hands-free car kits from pedestrian phones. Sensor data is then transferred by a multi-hop ZigBee radio, via an internet gateway, to a server. The traffic measurements can then be analysed to address congestion of either vehicle or pedestrian traffic (Gascón, 2015).

Intelligent Streets Lights and Public Places Illumination

Most street lights in cities are switched on at sunset and switched off at sunrise. This technology is dated and not conducive to energy savings. There are several ways of developing smarter street lights whereby the first step should be changing the light bulb to a LED lighting unit. The second step should be that streets lights are switched on and off automatically, measuring lux rate, and when light is required should be dimmed to a programmed light emittance. This will prevent lighting up when not required or during daylight. In addition to this, light sources should be upgraded with a presence sensor, detecting moving objects, so that the light can be dimmed when full light output is not required (Leccese, 2014).

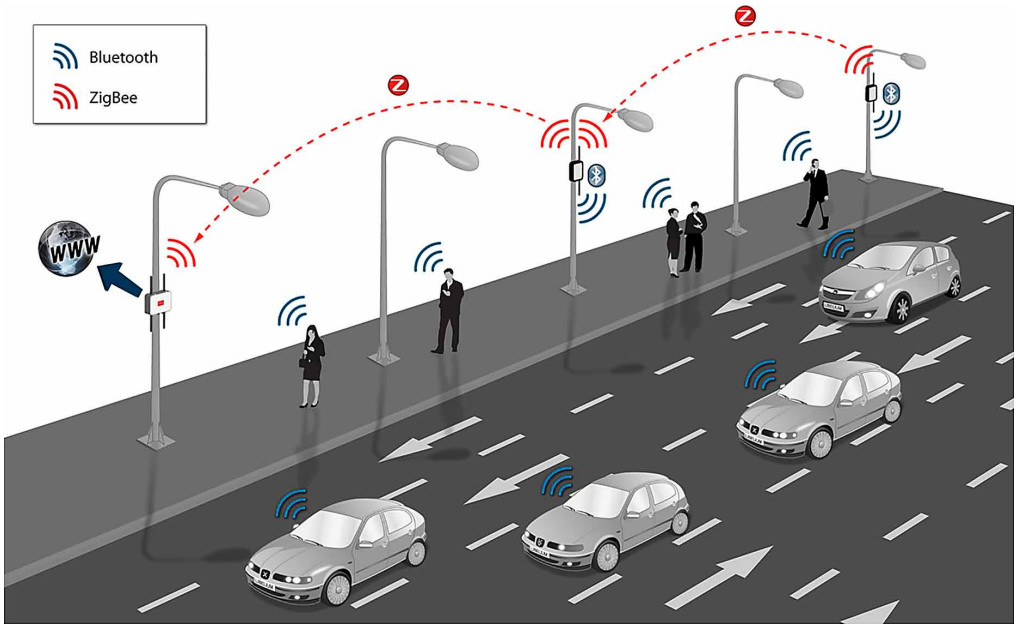
Figure 2. Vehicle traffic monitoring platform with Bluetooth Sensors over ZigBee, 15.05.2015



Smart Junction Crossings and Traffic Light Systems

The first traffic light was erected in Berlin in Germany in 1914. More than 100 years ago it was a unique innovation. Nowadays a city without traffic light systems is not imaginable or practicable. In some situations, waiting for a green light can take up to several cycles depending on the traffic situation and road layout. Sometimes despite having no other traffic in the vicinity a driver has to wait on a red light. This is a typical situation where a smart traffic light would be very beneficial.

Smart traffic lights work in conjunction with small sensors that have been integrated into the street, measuring the traffic flow, and can therefore calculate the travelling speed of oncoming vehicles. These systems can also predict the time of arrival at a particular junction and as a result have the ability to switch the traffic light to green if optimal conditions prevail. In addition, autonomous cameras are connected to this system, recognising emergency vehicles like ambulances, fire brigade vehicles, police vehicles, etc. and regulating the traffic lights for priority. This makes journeys for emergency staff safer and has the potential to decrease travel time in reaching the emergency situation, when seconds can make a difference between life and death. This technology will automatically reduce passing-through times at traffic junctions, reduce "stop and go" behaviours, increase throughput of vehicles and eventually reduce particle emissions, thereby reducing the emission levels within cities. All sets of traffic lights are connected with sensors and smart technology, enabling communication between the various sets of traffic junctions.

According to Carlos Gershenson, a researcher from Universidad Nacional Autónoma de México in Mexico, the estimated upgrading cost for a full functional junction is in the region of only 25,000 US dollars which is approx. 19,000 Euro. Politicians in Mexico City are in talks with a researcher group in upgrading major traffic junctions and therefore reducing costs due to mass production down to 2,000 to 4,000 US dollars (Gershenson, 2015). This will enable smaller councils to afford this smart technology, reducing emissions and noise levels in their area.

Available Parking Space Display and Mobile App Functions

A mobile app should be designed for individual locations fed with live data, identifying empty parking spaces and locations, and notifying customers when a parking space becomes available. This will reduce time and effort for the vehicle driver looking for a free parking space, make parking space searches more efficient and reduce vehicle numbers on the road. Bigger car parks should have a display board outside their premises informing customers about the current number of car spaces available. The app could also inform electric vehicle (EV) owners about free parking spaces to charge up their vehicles. In the future these apps could also be used for charging point pre-bookings. This technology would secure an available parking space for an EV driver knowing the exact location and time of arrival in advance.

Photovoltaic (PV) Solar Panel Cycling Lane for Smarter Emission Free Electricity Production

The Dutch government has designed and installed the world's first photovoltaic solar panel cycling lane which was opened to the public in December 2014. This cycling lane has the potential to produce electricity during daylight while at the same time functioning as a cycling lane. The electricity production of this trial solar cycling lane has already excelled during the winter months, according to a recent announcement by the solar road spokesperson (Wit, 2015). The 70 metre test track has inserted solar panel crystalline cells into a cast concrete base instead of tarmacadam. This is protected by a tempered 10 mm safety glass. This surface is also proven to be slip resistant. The surface was tested with various protection coatings to compare their chemical properties but no complaints were submitted and reaction to this new innovation is very positive. Further investment and installations are expected by the end of 2015 with expansion to major towns in the Netherlands.

Horizontal PV on cycling lanes has the potential to produce emission free electricity, necessitating less need for oil rich tarmacadam and with no required uptake of available land space with conventional PV solar farms. This form of renewable energy production has been gaining acceptance by the Dutch community with no complaints filed so far (Figure 3).

Figure 3. Horizontal PV renewable energy

Freephone Traffic Engineering Hotline

Since 2009, the City of Cologne in Germany has a Freephone hotline connected to the traffic engineering office where commuters can make suggestions on any traffic improvements they feel would be advantageous for the city. On average, the engineering office receives approximately 900 calls per annum with some very valuable ideas coming from people who are dealing with these traffic problems on a daily basis. Since this traffic efficiency initiative has begun, commuting in the city of Cologne has improved noticeably (Verkehrsdienst, 2015). There was one particular traffic junction about which motorists complained regularly. At one particular time during heavy traffic in the morning, waiting time was more than 8 minutes. Trams and Metro have priority before cars, followed by cyclists and finally pedestrians. After the traffic light setup was assessed and adjusted in conjunction with other surrounding traffic lights, the waiting time was adjusted to an average of 110 seconds, which was archived with an impressive waiting reduction time of more than 400%. These improvements show clearly the need for an efficient system like this. Initially, this hotline was only introduced as a trial phase for 6 months but, after a successful take up by the citizens, the service is still running.

Tax Incentives for Low Emissions Cars

In the USA there are fast lanes in place enabling cars and car pooling commuters to drive in the fast lanes once the car has more than three or more occupants. This incentivises car sharing in driving to work, for example, which correspondingly reduces the number of cars on the road. The same principle is being applied in Germany for hybrid and electrically propelled cars. Any violation of these rules can be prosecuted, with hefty fines imposed.

High-Occupancy Vehicle Lane (HVO) on Motorways

High-occupancy vehicle lanes are also known as HVO lanes, transit lanes, 2+ lanes and diamond lanes, and are designed to increase the enthusiasm for sharing vehicles on the way to work, for example. These lanes are normally less busy, vehicles can drive faster and, because they carry less traffic, they create a more relaxed driving experience. They are designed for peak times and can only be used for carpooling with at least two occupants in the vehicle. Depending on country and state there are other vehicle exemptions imposed for school buses, emergency and law enforcement vehicles, motorcycles, and low emission vehicles. These lanes are created with the intention of reducing the numbers of cars on the road and increasing average occupancy numbers in cars while reducing congestion on the roads (Figures 4 and 5).

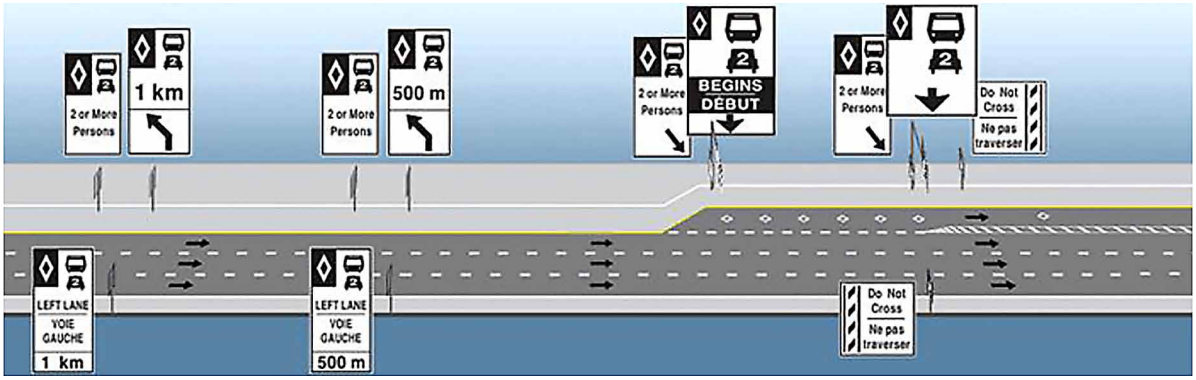
BENEFITS IN USING HVO LANES

- **Save Time:** It can avoid congestion and arrive at destination more quickly than those who don't carpool
- **More Reliable Commute:** Avoiding congestion means a quicker and more consistent commute time
- **Save Money:** It costs less to ride a bus or to share a ride than to drive alone every day. Regular carpooling could cut fuel costs by 50%

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 4. High-occupancy vehicle lanes
Source: (Christopher K. Leman, 1994)

Figure 5. High-occupancy vehicle lanes
Source: (Transportation, 2015)



- **Conserve Fuel:** less fuel waste sitting in traffic
- **Less Stress:** Letting someone else drive while relaxing on the drive to work

BENEFITS FOR CITIES

- **Manage Congestion:** An HOV lane can handle a lot of growth in demand. Once a general traffic lane reaches capacity, it becomes congested and moves fewer vehicles
- **Make Better Use of Infrastructure:** One highway lane can carry 1,500 to 2,200 vehicles each hour. A lane full of buses and carpools moves many more people than a standard traffic lane.
- **Transit Priority:** Buses and transit occupants have priority. A single transit bus can replace 57 single-occupant cars!
- **Provide Choices:** HOV lanes make carpooling and public transit more effective and reliable choices for commuters

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

- **Support Mobility:** Taxis and airport limousines that use HOV lanes can return to duty faster after dropping off a fare or arrive sooner to pick up a fare
- **Support Electric Vehicles:** Electric vehicles with green plates can use HOV lanes until June 30, 2016
- **Re-Thinking HOV:** High Occupancy Vehicle Facilities and the Public Interest (Ontario, 2013)

According to an analysis by the U.S. Census Bureau in 2004, the share of people carpooling was 12.2 percent in 2000, which accounts for the second largest share: 77 percent of people drive alone; 4.7 percent use public transit (Hideo Konishi, 2010).

Road Tax Exemption for Electric Vehicles

The German government has also extended road tax exemptions for any electrically propelled vehicles, initially agreed for five years, which has recently been extended to 10 years until 2025. This will also help to get more electric vehicles (EVs) registered, with the aim in having 1,000,000 EVs on the road by 2020.

Other countries in Europe have similar incentives to stimulate the EV market. Due to very high investment costs for EVs, mainly due to the high purchase cost of the battery, it is evident that market growth cannot be achieved without some form of incentive. For that reason, many countries have schemes to stimulate the EV sales market. In the Netherlands for example they have a low private motor vehicle and motorcycle tax called "BPM" for EVs, which is divided into various categories related back to the CO_2 emission band. The highest tax for emission > 110 gram/km is set with 25% BPM and pure EVs are only charged a tax of 4% if < 50 gram/km (TACA, 2015). Therefore, not all EVs have a low tax band, but the lower the emissions the less tax charged, and consequently the greater the incentive for introducing environmentally friendly vehicles (ACEA, 2015).

Tax incentives can be introduced in different formats, like a tax rebate when purchasing an EV, the introduction of road tax exemption, tax reduction for companies reducing their liabilities/annual circulation tax, and top-up grants. Some countries also differentiate CO_2 bands, which are then linked to associated support levels, while some countries have no incentive scheme in place. This highlights the fact that certain countries have no interest in supporting EVs, while others are very inventive with a broad range of incentive schemes introduced.

Most EVs are classified as emission free or CO_2 neutral but this is not a comprehensive reflection of the situation. This does not apply to EVs if they are using regular sockets where the electricity is only supplied from the national grid to charge vehicles. Countries have various emission levels depending on how electricity is produced, i.e. coal, turf, oil, gas, waste, etc. In reality, only an emission free EV is CO_2 neutral when charged by photovoltaic, wind, hydro, geothermal, and biogas-produced electricity which produce literally no emissions. It could be argued that some fossil fuel energy was required to build those systems but this equally applies to traditional fossil fuelled power stations. Many companies in Austria and Germany are charging their EVs on site with electricity produced from their own installed photovoltaic roof panels, which represents a totally CO_2 emission free charge.

Park and Ride Systems

Park and Ride (P&R) systems are a very effective way of reducing the numbers of vehicles in a city. This commuting system, whereby vehicle owners can park their vehicle at a car park outside the city free of charge, is very common in Germany. These car parks can accommodate a couple of hundred vehicles. The intention is that urban and rural commuters will travel to a P&R location, park their vehicle on that site and travel the rest of their journey by public transport to their intended destination. This system minimises the number of vehicles driving directly into the centre of the city, thereby reducing traffic flow, noise, pollution, and fuel emissions. This makes the centre of the city a more pleasant environment for tourists and shoppers and also for residents.

Gigaliner Trucks for Long Haul Logistics

Depending on the availability and cost, cargo can be transported by airplane, ship, truck and/or train. A combination of multiple shipping solutions is also possible but this depends very much on the timeframe for goods. If goods are transported via trucks, there might be a clever way of dealing with this delivery by road. Long haul goods which have to be shipped more than 250 miles can be carried in so called "super liner", "gigaliner" or "giant" trucks. These trucks are longer and heavier, and therefore specifically designed for long distances. The maximum total weight of these giant trucks, which are 25.25 metres long, and is 60,000 kg. Two of these trucks can replace three ordinary long distance trucks due to a higher storage capacity. This makes the running costs of fuel, insurance, the number of qualified drivers required, and maintenance cheaper and therefore more competitive. Currently, there is only one section of the German motorway approved by the government which has a special license for testing these trucks on the motorway.

These gigaliner trucks are longer than regular trucks by as much as 7.5 metres and therefore more dangerous for overtaking, as they create a longer obstacle for any overtaking vehicle. One hundred trucks have been granted special permission in Germany for a trial period beginning in 2012 and ending in 2016 (Figure 6).

The aim of these trucks is to transport goods from the collection point to a central collection location close to the destination. These huge trucks are prohibited from driving inside the city and only designed for long haul journeys. At this central point, or "Umschlagepunkt", which is naturally located outside bigger cities, delivery goods can be reloaded to smaller vans and delivery trucks. Delivery to nearby places can be arranged with electric vans with few emissions coupled with shorter journeys.

Within the frame of the Logistics Action Plan, the European Commission is analysing the impacts of a potential introduction across the EU of Longer and Heavier Vehicles (LHVs), i.e. vehicles measuring up to 25.25 m and weighting up to 60 tons. Such vehicles are expected to improve the efficiency of the road freight sector but their impacts on the environment, infrastructure and safety need to be analysed in more depth. The present study aims at providing an overview of the technical aspects associated with LHVs regarding energy efficiency, infrastructure (road wear and bridges) and safety issues. This is carried out at vehicle level based on a comparison with standard 40t heavy duty vehicles (HDVs). Some technologies that can potentially improve the performance and reduce the damage caused by LHVs are described and issues that require further and detailed research are also identified (Leduc, 2009)

Tax Saver Commuting Ticket Scheme

Since 2000, Ireland has introduced a commuting tax saving scheme incentive for public transport, which can have a total tax saving for employees of up to 51%. This incentive reduces tax on the total gross income while travelling to work using a multi ticket valid for bus, train, Luas or ferry pass for one year from purchase.

Cycle to Work Scheme

The Irish government has also introduced a second incentive aimed at health conscious professionals and has found a unique advertising strategy for this incentive. The scheme is officially called "Burn Calories Instead of Emissions" which has proven popular over the last number of years. Any regular/electrified bicycle or Pedelec can be purchased up to a total value of €1,000 including safety equipment, with tax savings of up to 51% similar to the tax saver commuting ticket.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Bicycle Rental from Multiple Points within a City

In various cities across Europe bicycle rental schemes are available. These schemes are very effective for tourist cyclists, enabling them to discover the city emission free. Cities usually have several bicycle hubs spread around the city centre, facilitating customers in collecting and dropping off bicycles whenever suits them. Any person can hire a bicycle for a day, three days or a full week depending on the user's requirements. In order to take a bicycle, the customer has to register at a hub, using a booking terminal while giving their credit card details as a deposit for security. This registration process normally takes less than 5 minutes and rental fees are in the region of €10 to €20 a day which is equivalent to $12 to $24. Those central hubs usually have more than 15 bicycles available and most cities offer a free app for mobile phones as well. These apps can show the nearest hub location for picking up or returning bicycles. This is a very attractive, environmentally friendly and healthy option for discovering a city with a great degree of flexibility. This has a big advantage in that cyclists can be flexible in their cycling trips with the option of not cycling back to their starting point if unable to do so.

Eco-Label Introduction in Pubs, Hotels and Restaurants

Pubs, bars and restaurants could introduce an eco-label showing customers their commitment to producing and sourcing sustainable food. Eastern located countries have already an embedded tradition of buying food and groceries from the local market. This reduces transportation emissions while avoiding unnecessary imports of food and also impacts positively on local employment. At the same time, it strengthens the local community and keeps money in the local economy. The idea is to reduce waste and packaging to a minimum, and this can then be displayed in the form of a certificate which will be issued annually.

All restaurant customers can see the benefits of using locally produced food for the same price and most customers would opt to frequent these particular restaurants. This in not only a marketing incentive, but also a sustainable way of sourcing local food with low packaging requirements, electricity coming from renewables, 80% of light bulbs fitted with energy Ratings of A, etc. (Commission, 2009). Achieving an eco-label is not easy and will take some time and effort but customers will certainly appreciate it. Spot checks and annual inspections are just one part of ensuring standards are met. There are several criteria that have to be achieved in getting this certification with a 34 point questionnaire. Depending on the size of the business, some smaller hotels need to fulfil 5 fewer points if they do not have a leisure centre/spa on their property.

Efficiency of Public Transport

Public transport also has to be affordable, efficient and convenient, making it easy for people to choose this form of commuting. Only an efficient and reliable transportation system can be attractive for customers, which means that expectations are set high. Affordability is also one of the major factors in decision making when choosing public transport. It goes without saying that reliability would be a number one priority. Affordability would be the second consideration in attracting customers followed by frequency of trains, buses, metros and so on. Comfort and modern layout would also be an optimum feature when choosing public transport systems. Modern technology like free Wi-Fi broadband on board will certainly attract business people on their way to work or on business trips.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Incentivise Compressed Natural Gas and Biogas Powered Vehicles and Trucks

Compressed Natural Gas (CNG) powered vehicles have much fewer emissions when compared to petrol and diesel powered vehicles. The savings on emissions have been scientifically proven ranging from 12% up to 99% on carbon monoxide, carbon dioxide, soot, nitrogen oxide, hydrocarbon and sulphur. Biogas, when measured in kWh in comparison to fossil fuels, is also cheaper in almost all countries, is cleaner, and creates less engine noise and, in Germany, for example, road tax is lower due to lower emissions. Also quieter noise levels for early morning delivery vehicles is becoming increasingly popular in cities.

Low CO_2 Footprints for Packaging and Wrapping of Food/Goods

Low emissions with reduced oil rich packaging content for wrapping of goods is becoming important for many people. Therefore, companies using environmental eco wrapping need to focus on promoting the environmental benefits when advertising. Reducing emissions is even more important for multinational companies which need to show their efforts on their websites and inform people of how environmentally responsible they are (Figure 7).

Customers will naturally prefer a certain product if there is little or no price difference. This eco driven behaviour is good for the environment and certainly reflects an attitude change in Europe which has been noticed over the last number of years.

One of these multinational companies could be, for example, DHL. This company has a separate ordering section for environmentally connected customers who want to send a parcel emission free. This is good for the environment and is also good public relations. A CO_2 emission free parcel order has the advantage of a "feel good factor" for the consumer and helps the company in reducing their generated

Figure 7. Green logistics

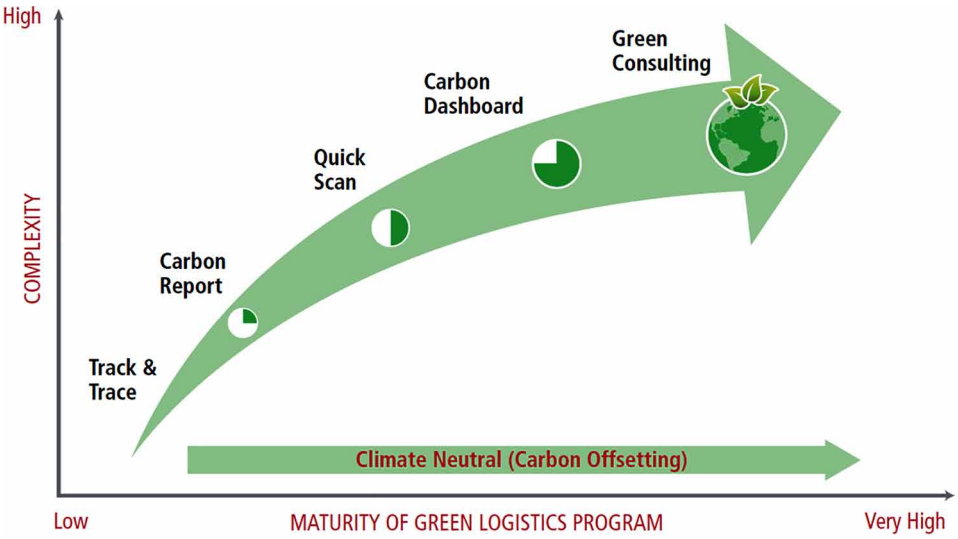
Figure 8. Maturity of Green Logistics Program
Source: (Department, 2014)



emissions. These "green logistic shippings" are a little bit costlier but in return the company is doing something to offset emissions like planting a tree, supporting a project in a third world country, etc. (Figure 8).

Automatic Waste Collection Notification

Waste bins should be fitted with weight sensors whilst transmitting a collection notification to the nearest waste provider when required. This technology would reduce unnecessary collection journeys picking up partially filled waste bins. This system has the potential to increase efficiency and subsequently reduce fuel consumption when applied to the waste collection fleet, including all waste, recycling, paper, and food waste collection bins. These intelligent systems are costlier than a regular waste bin but, with fewer collection intervals and greater fuel savings, this will have the advantage of recouping the higher investment cost very quickly. With the implementation of this technology, waste collection noise due to less frequent collections can reduce noise levels, which will also improve the quality of life for residents.

Soot Filters and Emission Limitations for Industrial Buildings in Germany

Air pollution in urban areas can cause health issues, and other associated problems. For that reason the German government has introduced a legislative law enforcement introducing tighter restrictions on particulate filters on vehicles and for industry. The automotive industry has developed particulate filters, first for petrol and later for diesel powered engines, and these have become much more effective in keeping these emissions trapped inside the particulate filter (Melkonyan D. A., 2012). The industry has also had to comply with legislation, which has improved the air quality in urban areas significantly. There are three major reasons for the improved air quality in industrialised areas. Firstly, the quality improvement was linked to very strict law enforcement. Secondly, the filter technology improved during

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

research, with newer materials and better practical applications. Thirdly, an allowed "grace period" for industries concluded in the early 1980s, followed by lower emissions on a year by year basis (Figure 9) (Erste Verordnung zur Durchführung des BundesImmissionsschutzgesetzes - Verordnung über kleine und mittlere Feuerungsanlagen - 1.BImSchV, 2010).

Since the early 80s, soot filters installed at commercial premises have reduced smog levels significantly in Germany. The impact on coal and oil fired businesses for steel processing, aluminium smelting and major energy consumers was especially noticeable. This was due to cleaner air, fewer smog emissions and brighter days in cities, which also improved the health and quality of life of citizens.

District heating coming from power plants is also a very efficient way in using exhaust heat from incineration plants, for example. This heat has already been produced in burning waste which can then be used further in supplying heat via heat exchange to buildings. This heat is also known as by-product, which means that heat was produced during incineration which was subsequently consumed further via heat transfer. These are smart ways in using a by-product for something useful, making heating systems affordable.

Reduction of Emissions Coming from Vehicles are a Major Step Forward in Having a Cleaner City

Car manufacturers are also obliged to reduce their emissions, which has required more research on the engine efficiency of their cars over the last few decades. The European Economic Community as it was known at the time was initially formed by six industrial countries after the Second World War, namely Belgium, Germany, France, Italy, Luxembourg and the Netherlands, with more countries joining over

Figure 9. Steel industry in Qian City in North China
(Source: Spiegel online, 01.07.2015)

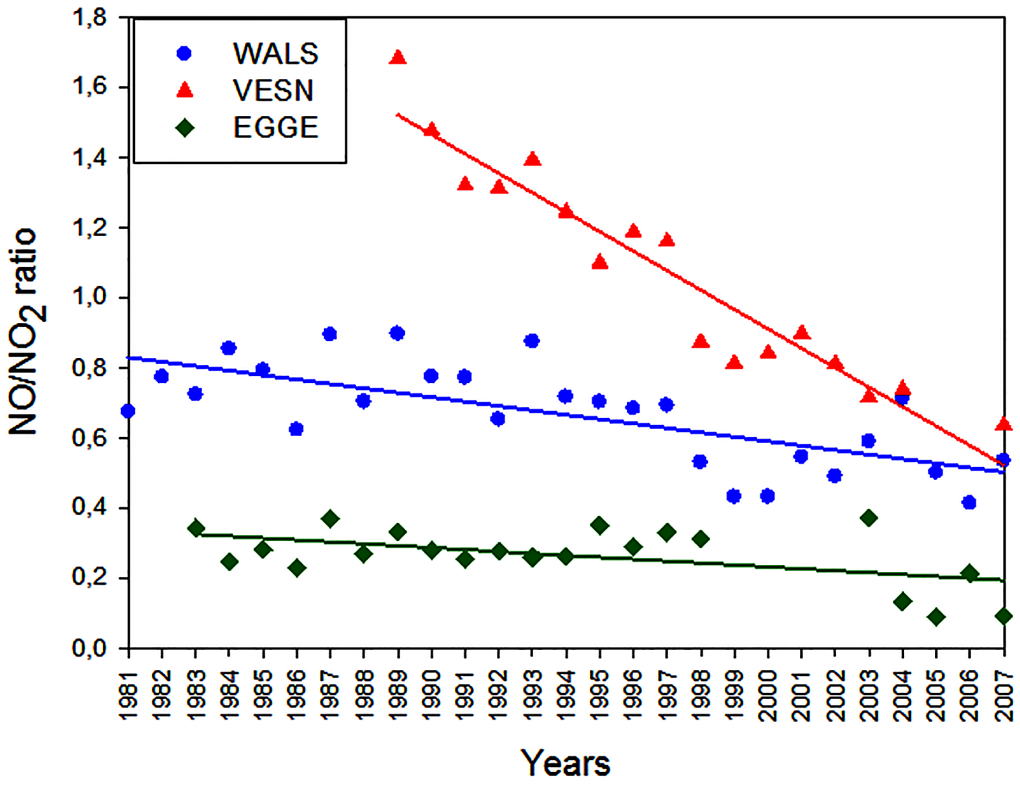
EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

the years (Commission, Erst sechs, dann 28 - Europäische Nachbarschaftspolitik und Erweiterungsverhandlungen, 2015). At the moment there are 28 Member state partners in the EU (European Union). The EU members' medium term plan is that the proposed legislation will be agreed, with a universal regulation for all EU member states eventually in place. Since January 2015, heavy goods vehicles cannot be registered at the licencing office if they do not comply with the newest Euro particulate 6 norm. The same rule applies for vehicles below 2,610 kg in total weight but the deadline for those vehicles to comply was September 1st 2015 (Wolkenstein, 2014). The Euro 6 norm for diesel powered engines, known as the 715/2007/EC document, requires lower emissions of mg of NOx /km. Flexi-fuel vehicles with a bioethanol mix of 75% and more have different emission ratios as well as petrol powered vehicles (Industry, 2006). Emission ratios are measured in seven different categories, based on engine fuel requirements and vehicle type – for example, passenger cars, light duty vehicles, heavy duty vehicles, etc.

The impact of these stricter requirements is evident and can be seen in the chart below. Emission measurements from three different locations in the state of North Rhine Westphalia in Germany were taken over a time period of 26 years and accumulated accordingly. The three different colours and locations indicated in red (busy motorway), blue (industrial area) and green (local forest) suggest a very similar indication of emission reductions (Figure 10).

Emission levels within urban areas can fluctuate very much depending on time of day and day of week. The graph below illustrates that there is a noticeable NOx increase during mid-week which takes place between 5.00 and 8.00 a.m. This incline from low to peak can reach up to 250% from early morning

Figure 10. Yearly emissions emittance in Duisburg of NO/NO_2
Source: (Melkonyan D. H., 2015)



EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

emission levels. This emission chart represents the traffic frequency of vehicles on the road. The traffic participation is more distributed and, even on a Saturday and Sunday, traffic increased only slightly after 4.00 p.m. It can be concluded that weekend traffic behaviour is totally different to weekdays. Mid-week traffic is therefore mostly related to working commuters travelling to work in the morning and returning back home in the evening (Figures 11 and 12).

It needs to be highlighted that over the last 30 years high emission reductions have been possible even though vehicle registration numbers are increasing.

Green Logistics and Eco-Friendly Parcel Delivery

Major logistics companies have seen a huge opportunity in advertising their products with a green label. They are promoting their delivery of goods with a positive message, while at the same time the customer can trace back the produced emissions depending on the importance of the arrival time of ordered goods. DHL, for example, have a special section on their website informing customers on emission loading per delivery. If an express delivery within 24 hours has been selected, air freight is considered, which will increase emission factors by 3 to 10 times in comparison to trucks. The best and lowest emission delivery is by rail with a much lower emission ratio. So, in this case, the customer has the power in choosing emissions produced, depending solely on their delivery selection.

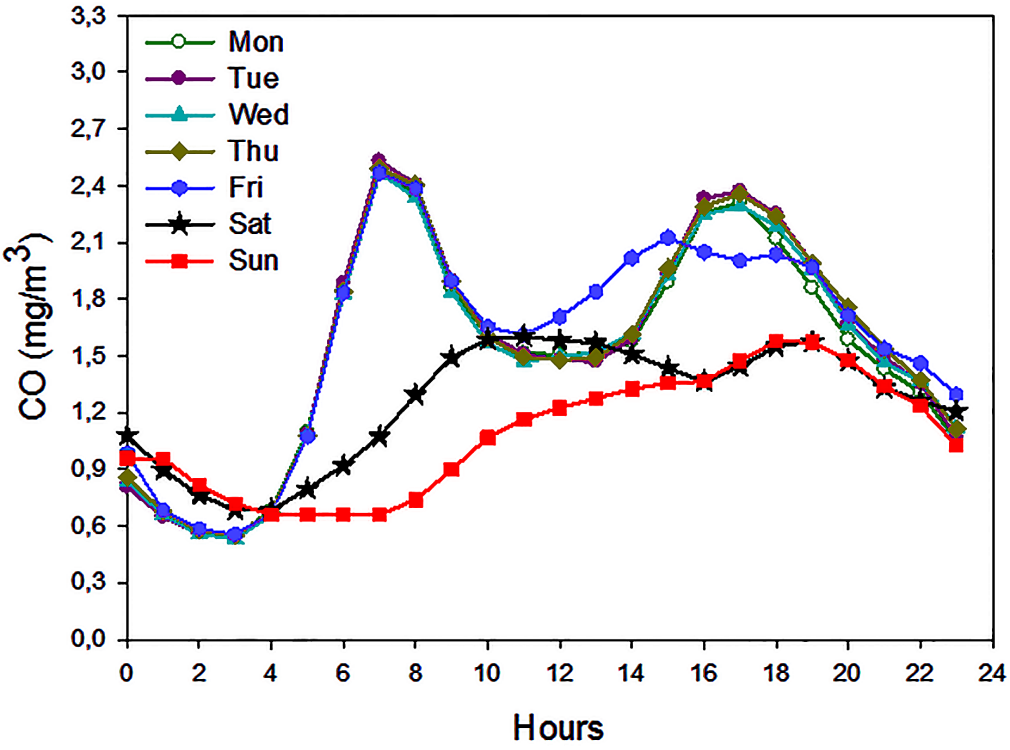
Figure 12. Hourly emissions of CO in urban areas within one week
Source: (Melkonyan D. A., 2012)



For even more environmentally oriented customers, DHL can offer an innovative CO_2 neutral product of delivery, due to the fact that they will reinvest money in projects offsetting those emissions produced. The delivery of these parcels are approx. 5% to 10% more expensive, but money will be reinvested in sustainable projects like wind turbine farms, tree planting, electric delivery vans, etc. Since its introduction, this idea looks as if it will have huge potential on a long term basis. If companies are using this type of service, they can also highlight their contribution in reducing emissions and therefore they can show this commitment to their own customers.

Green logistics are seen to be reducing emission impacts and action on the environment. The main activity in green logistics is coordination of activities within a supply chain in such a way that emissions are kept as low as possible. This all comes down to economics, which has an impact on low emission goods delivery, which can only be achieved in pre-planning routes in a very efficient way. In the past the haulage industry focused on having low running costs while making high profits. This business model has changed direction dramatically. Nowadays, customers are much more selective in picking delivery companies. The cost for air pollution, dumping waste and packaging costs, climate change contribution, soil degradation, noise, emissions and selective transportation methods now appears in the calculated cost.

Logistics need ICT - The use of the most modern information and communication technologies (ICT) plays a significant role in logistics: Information and communications technology became the trigger and guarantor for efficient solutions and processes. The internet of things and cyber physical systems are heralding another new era in logistics (Hompel, 2015).

A Small City Powered with More Than 950 Environmentally Friendly Biogas Buses as a Leading Example

Malmö is a small city in the south-westerly part of Sweden with a population of close to 300,000. Due to its geographically advantageous location, Sweden has electricity production from hydro power. Because of this the electricity price in Sweden is very competitive. In spring 2015, Sweden had a surplus electricity production from hydro power, supplying their own and the European market as a whole with affordable electricity. This is one of the major reasons why Sweden is not producing electricity from biogas, opting instead for converting biogas as a fuel for their bus fleets. The first biogas production and upgrading process started in the early 90s. This decision was taken 20 years ago and made Sweden an expert in biogas conversion and usage in the transportation sector. Most other European countries are producing electricity from biogas which needs less treatment, is easier to handle, and involves no transportation and storage issues but, because Sweden already has ample production from hydro power, it is not financially worthwhile for them to convert biogas to electricity.

Skånetrafiken is the name of a district in Sweden which regulates the public transportation market, a semi-state organisation funded by the taxpayer in Skåne County, which is one of 25 counties in Sweden. This organisation does not have an active role in owning, maintaining or running these transport vehicles; its role is of a supervisory nature. At the moment there are 10 contractors operating approximately 950 buses of which 98% are biogas/natural gas and biodiesel buses, 5 electric buses and 20 ordinary diesel buses (Sörensson, 2015). The aim of this particular region is to have 100% environmentally friendly buses replacing natural gas and diesel buses with biogas and electric buses by 2020.

A new innovation has also been introduced – a hybrid bus which can carry more people using only one instead of two buses for popular routes and peak time compensation which is powered by biogas and electricity. This is a 24-meter hybrid CNG-electric bus, using regenerative braking power charging a battery which, when accelerated, produces electricity which can then be used to power the bus, which subsequently reflects positively on fuel consumption (Cody, 2009). This bus is able to carry up to 151 passengers and uses smart technology, saving electricity where available. The doors, for example, open only if passengers are pushing the door opening button and sophisticated software shows the bus driver's daily performance, fuel consumption ratios between recouping electricity by braking and biogas. The company is also able to trace back each individual driver's performance which can be easily measured and improved with training (Figure 13).

Delivery Restriction for Trucks within Malmö Which has a Huge Impact on Their Future Businesses

Malmö has even more ambitious plans for reducing traffic journeys from heavy goods vehicles by introducing a very strict enforcement for companies driving through the city. Several politicians and environmental groups are supportive of this idea. Currently they are working on how this can be implemented without impacting on business negatively. The premise of this proposal is that trucks will only be allowed to enter the city if their load storage capacity is greater than 90%. This would mean that several businesses would need to do a joined-up thinking in sharing one truck for different deliveries. This will reduce transportation movements which will also improve profitability due to there being fewer trucks in the fleet and more efficient delivery systems. Plans and proposals have been discussed and the system is currently under review.

Nowadays the Choice of an Environmentally Friendly Taxi is in the Customers' Power

Since 2010, Malmö central train station has a highly sophisticated taxi rank system in place. Customers can select their taxi of choice on a touch screen terminal, choosing the size – normal or multi-seater – and fuel type individually. On the display it will be shown if there are any taxies available and if not how long the estimated waiting time will be. Initially when this eco-friendly taxi initiative (Miljöbil) was introduced, it was more for promotional purposes and seen as experimental, but is now being readily accepted. It started off with a couple of eco powered taxies; which can be hybrid, gas, biodiesel, bioethanol or electric vehicles, but nowadays these taxies are the preferred choice for the majority of customers. This shows that consumer behaviour is changing, leading towards a more environmentally friendly focused future. Taxi fares for all choices are the same but the customer can clearly dictate their support for those requested services. Since the introduction of this system, customer choice has dictated that eco vehicles can, if offered for the same fare, be the preferred choice.

CO_2 Neutral Produced Electricity from Renewable Energy Sources

Electricity suppliers also have a large variety of environmentally supportive products that the consumer can select. In Germany, for example, there are more than 1,100 electricity providers competing with each other in offering the best possible deal for customers. Again, the consumer can select the production source of electricity coming from wind power generation, solar photovoltaic farms, hydro, geothermal, up to biogas produced electricity. Over the last decade, electricity production costs from renewable sources have gone down and are currently very competitive. In some cases, renewable energy production can be even more cost effective than nuclear and coal fired power plant production with the benefit of producing few or no emissions.

Some electricity providers can also indicate the location where electricity is produced. A mix of various renewable energy systems are also possible for those who do not care where the electricity comes from as long as it comes from a sustainably produced source. This enables ordinary customers who do not have the knowledge about this technology to select a good product from a climate friendly source.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

From this it is obvious that the customer has a large selection of choices and the power to make an active decision on emission production. According to an existing European law, all electricity providers need to show the CO_2 emissions produced per unit which is given in kWh. If electricity is produced from nuclear power this also has to be displayed as waste production measured in weight per produced kWh. Customers with a sustainable mindset can see on their monthly bill an indication of zero emissions produced. This positive message is a good motivator in supporting this type of industry for a similar price with the benefit of getting locally produced, clean, emission free electricity.

Energy Cities in Europe

Energy Cities, which is a trade mark, is operated by a European semi-state organisation based in Brussels. It has the aim of developing an existing or new city in a more sustainable, motivated environment. This presents the advantage of living in a more environmentally friendly area, with less pollution, more cycling lanes and electricity which is generated by a greater share of renewables. Water harvesting systems and waste water treatment plants are designed to use a limited amount of chemicals and work with natural plants like Norfolk water reed.

Since the unification of Europe more cities are representing themselves as eco cities offering a new way of sustainable living. "Energy Cities" was an initiative which was established more than 25 years ago, and has achieved great success, with astonishing participation rates. Since 2009 more than 6,000 city mayors have signed the "covenant of Mayors" and committed to go beyond the EU's CO_2 reduction target (Roumet, 2015). The principle behind this competition is to bring people together, sharing ideas, improving their living situations in the city, and learning from each other. There are several categories that any individual city can apply for, and nowadays more than 1,000 cities and local authorities from over 30 countries participate in this annual competition, highlighting their best show cases. Cities can be found on a "virtual" map, and it is possible to do searches for particular projects with associated contact details (Cities, 2015).

There is also promotional literature assisting cities and policy makers in preparing for these competitions. One particular document, "The big five", explains the five most important steps which are:

1. Include cities in energy policies and in international climate negotiations
2. Set new investment priorities to increase energy security
3. Use local resources to tap the full efficiency potential
4. Involve all actors to foster social innovation
5. Design future-proof cities with radical reduced energy needs

These guidelines are assisting cities – even with no previous knowledge of this innovation – to enter the competitions with the aim of fostering smarter living in their particular city.

FUTURE RESEARCH DIRECTION

Taking into account all possible technologies and lifestyle choices that can make a difference, more research is this area is required. Future research should focus on the green economy and sustainability. Transportation of goods is also a very crucial factor when emission reduction is concerned. Every situation and circumstance is different; consequently, technology needs to be adapted to individual environments.

Discussion Section

This chapter predominantly deals with transportation systems and technologies. Every individual citizen can make a lifestyle choice even without actively doing something other than making positive selections. Decisions need to be made every day, but the crucial question is whether someone would sometimes like to go for a sustainable option for the same price as one that does not contribute positively to the environment.

Fuel and emissions pollution from transportation vehicles is unhealthy, noxious and not good for the environment. Therefore, every effort needs to be made in reducing those levels caused by traffic. Car-pooling, travelling by train instead of taking a short distance flight, cycling to the next bakery instead of taking the car, and electricity purchase from a local sustainable source are all choices we can make without huge sacrifices.

Older diesel engines are heavy polluters - Exhaust fumes from older diesel vehicles are the main source of fine particulate matter in cities. Some 1.7 million diesel cars in Austria are not equipped with particulate filters as standard, and older Lorries emit vast amounts of fine particulate matter. If the pollution levels in Vienna stayed below the WHO threshold for fine particulate matter (PM 2.5), people who are 30 years old today would live nine months longer. Living near busy roads causes a number of chronic diseases: One in three cases of coronary heart disease and one in four cases of chronic obstructive pulmonary disease in over 65-year-olds in Vienna can be attributed to traffic pollution (Gansterer, 2013).

CONCLUSION

All incentives need to be assessed carefully from a social, technical, political, and practical point of view with the objective of contributing towards a more environmentally friendly society as a whole. In order to complete these suggestions positively, a special project group should be in charge of coordination, implementation and project revision. It is also advisable to engage with communities during open days, theme days and workshops to include citizens in this project as much as possible. Support of those proposed improvements will only be visible if a high level of people engagement is present. These schemes should also have a deadline towards which all participants can work.

Education of young pupils and students in sustainable lifestyle choices is also vital. As mentioned in this section, there are feasible options without compromising lifestyle in any way. It is not a question of what we should do; what is more important is how we can do this without harming the environment.

Engineers and planners have the power to make changes in the city due to legislation and enforcement. There are so many showcases on a worldwide scale that some of these technologies can be introduced on a small trial basis and, when successfully completed, expanded on a national scale. A comprehensive

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

framework for innovative strategies was emphasised to give the reader a more in-depth knowledge about various technology implementations across the world. Some improvements could be achieved within a couple of months while others need to be planned for a longer period.

This chapter as a whole has dealt with efficiency improvements in the transportation sector with the aim of reducing pollution from engine fuel emissions. It can be seen that, in order for this change to come about, behaviour and urban planning changes rather than financial input are required. Sometimes it is easier to achieve a solution if the solution required is financial rather than one requiring a radical change in behaviours and attitudes. However, in order to see progress in this area, urban planners and city councils will have to be open minded and proactive in relation to a different way of urban planning. It is probable that the expected increase in migration towards cities will force planners to consider alternative solutions for reducing urban waste and pollution.

The aim for this chapter was to cover all important areas of environmental reduction impacts, ranging from modern transportation systems, emission reduction of industries, residential heat and electricity production coming from renewables, tax incentives for eco vehicles, car sharing options and eco-label introductions for restaurants to smart building designs. These efficiency proposals cover a vast range but they have already been introduced by all participating cities successfully. It has been observed that, once transition has taken place gradually, moving away from petrochemical fuels towards more sustainable alternative solutions like hydrogen, electricity and biogas powered vehicles, subsequent consumer behaviour can have a positive impact in emission reductions. This has the effect of enriching air quality. With only limited fuel and energy resources available, every positive impact can help improve environmental quality and help conserve precious natural resources on this planet.

KEY TERMS AND DEFINITIONS

Eco-Society: A cultural driven society, focusing on environmental, efficient and health orientated civilisation.

Gigaliner: A haulage truck that is specially designed for long haul journeys with a total length of 25.25 metres and weighing up to 60 tons. These trucks are only allowed on specialised licensed motorway sections for a trial period until 2016.

Green Economy: Buildings and infrastructure are designed to be environmentally friendly and economically sustainable, made up from local sources and alternative biofuels.

Logistical Urban Central Hubs: Can be used for parcel delivery for distances of less than 5 miles, whereby the delivery vehicle will be electrically powered.

Semi-Central Urban Hubs: Logistics centres designed for short haul deliveries within a 20 mile20-mile radius of their customers.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Smart City: Sophisticated, well designed and efficient living environment within a highly densely populated city.

Smart Traffic Light Systems: This is a new technology suitable for infrequent traffic, whereby traffic lights are controlled by sensors switching lights, depending on traffic flow.

This research was previously published in Smart Cities as a Solution for Reducing Urban Waste and Pollution edited by Goh Bee Hua; pages 91-125, copyright year 2016 by Information Science Reference (an imprint of IGI Global).

Chapter 73
Human Overpopulation and Water Pollution:
Reduction of Microbial Pollution by Vertical Flow Constructed Wetland

Gargi Sharma
Malviya National Institute of Technology, India

Pravin Kumar Mutiyar
National Mission for Clean Ganga, India

ABSTRACT

The increased human population is threatening the natural water resources by reducing flows and deteriorating quality. High levels contamination of fecal microbes in Indian water resources is one of the worst impact on natural environment. The incomplete sewage treatment in existing STPs is the root cause it, along with disposal of untreated sewage. Fecal microbes even after the secondary treatment demands the further reduction, hence, an alternative method of vertical flow constructed wetland was adopted to examine the efficiency of the system. The study was aimed to primarily to suggest the suitability and comparative performance of wetland species, P. australis and C. indica. Study revealed the importance of fibrous rooting system of C. indica which helps to enhance aerobicity within the system and cause the reduced number of microbes. The additive enhancement of physical mechanism as well as competition among microflora within the wetland system and excretions from roots of C. indica plant might have been the reason of the significant highest removal of microbial indicators.

INTRODUCTION

The water demand supply gap is increasing continuously due to population explosion and alternate source of water are being explored to fill this gap. Reuse of treated effluents for non-potable purposes could significantly reduce this gap, as huge volume of wastewater is being generated and treated in urban metros and class II cities, but the incomplete treatment in STPs is polluting the existing water resources and thus

high level of coliforms were found during monitoring of various rivers' water quality in India (Jamwal & Mittal, 2009; CPHEEO, 2013). Coliforms levels has been even reported in groundwater aquifers, considered generally safe which are being used directly for potable water in areas around Delhi (Mutiyar et al., 2013). In Rajasthan, where the study was performed, the general trend for treated wastewater disposal has been either for irrigation purposes or into recreational lakes as there are not many rivers around. Since, with both these reuse applications, public health is at risk due to presence of microbial contaminants, there is a need to find solution to mitigate this risk and the importance of studying microbial removal as tertiary treatment. Hence, this research was classified as "Applied research" that often comes from a practical need to know or find a possible solution to a real world problem with real world challenges.

The idea behind this research was to find an applicable solution for the reuse of treated wastewater within the existing semi-arid weather conditions to overcome the public health risk of abovementioned reuses. The wetlands have been reported to be efficient in terms of microbiological contaminants removal though no such study has been reported for investigating as well as comparing the survival of different plants, which were used for the study, in treated wastewater during tertiary treatment in semi-arid climatic conditions prevailing in Rajasthan with their performance vis-a-vis microbial reduction. Additionally, the cities are now expanding as a part of growing urbanization, the wastewater plants have now come within the city limits and high land demand for horizontal flow wetlands is becoming a constrain for application of wetlands in sewage treatment. To reduce the land requirement in wetlands, therefore the vertical flow constructed wetland system, which requires less land area, as a tertiary treatment step and to assess its suitability especially with a focus on microbiological contaminants was chosen for the study.

EXPERIMENTAL

Experimental Setup

Experimental setup was established at Civil Engineering Department, Malviya National Institute of Technology, Jaipur, India. The experiments were performed for 25 weeks during the months of November to April, followed by the acclimatization period of 12 weeks and then by physico-chemical analysis of 13 weeks. The historical average minimum and maximum temperatures during April are 21.8°C and 37.2°C, respectively, which is suitable for the plants growth - optimum temperature for growth of *Phragmites australis* is 30-35°C, for *Canna indica* is 12-32°C and for *Typha latifolia* is ~35°C. Four CW units were constructed using sintex tanks made up of polypropylene material, having dimensions 29 cm×25 cm×70 cm and has approx. 55 cm of packed bedding with an empty space of 2-5 cm at the top for aeration purpose. Initially, only three units, UN-ph, UN-cn and UN-ct, were constructed which were similar in terms of bed media configuration but different in terms of plantation (Figure 1a). After identifying that the unit planted with *Canna* (UN-cn) was more efficient than the other two units, the next objective was to further explore if the removal efficiency of this unit can be improved by improvising on the media. Hence, a layer of finer material (sand) was introduced in the system. In order to maintain the total height of the system as earlier in initial three units, after introduction of the sand layer the thickness of the coarse bottom gravels (16-20mm) was decreased from 29.2cm to 15cm (Figure 1b). It was considered necessary to keep the gravel layer for supporting the sand layer and also as a barrier between influent system and sand. The complete removal of gravels would have had operational challenges. Among the coarse (16-20mm) and finer (8-12mm) gravels layer, the coarse layer was reduced

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

for a smooth gradation from finer to coarse material considering efficiency has been positively affected by the finer material. Figure 1 shows the transverse section of media distribution for all four CW units and Table 1 gives the detailed design configuration of the experimental set up for all the CW units. All plantations were allowed to acclimatize for about two to three months (13 weeks) before the experimental analysis starts. After the acclimatization stage, units were allowed to run for 38 weeks continuously with a constant flow rate of 6.8lt/day. The microbial analysis was performed for 25 weeks out of 38 weeks, while rest was performed for physico-chemical analysis.

Study Site and Flow Distribution

The secondary treated wastewater was sourced from the sewage treatment plant located in south Jaipur throughout the study period. The effluent from the field was brought to ensure actual effluent quality

Figure 1. Transverse cross section of two different types of constructed wetland units (a) Distribution of media for UN-ph, UN-cn and UN-ct (b) Distribution of media in UN-cn-sd

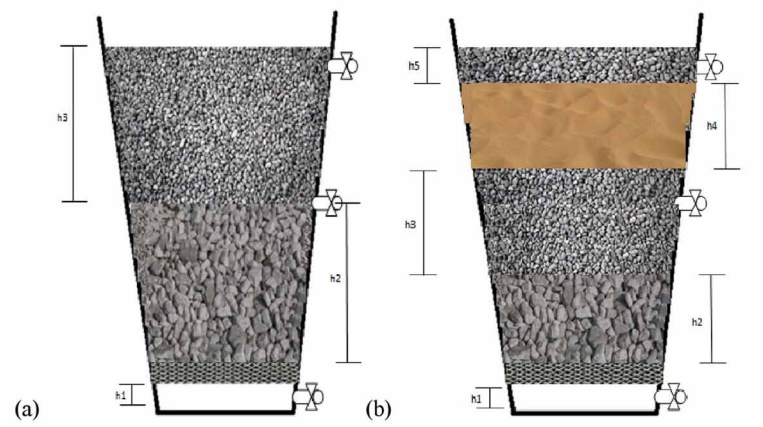

Table 1. Design configuration of experimental setup

Constructed Wetland Unit	Height and Type of Media				
	H1	**H2**	**H3**	**H4**	**H5**
UN-ph Planted with *Phragmites australis*	Inlet chamber	Media – Gravel Size - 16-20mm Height - 29.2cm	Media – Gravel Size - 8-12mm Height - 22.9cm	-	-
UN-cn Planted with *Canna indica*	Inlet chamber	Media – Gravel Size - 16-20mm Height - 29.2cm	Media – Gravel Size - 8-12mm Height - 22.9cm	-	-
UN-ct Control unit No plantation	Inlet chamber	Media – Gravel Size - 16-20mm Height - 29.2cm	Media – Gravel Size - 8-12mm Height - 22.9cm	-	-
UN-cn-sd Planted with *Canna indica* with sand layer	Inlet chamber	Media – Gravel Size - 16-20mm Height - 15cm	Media – Gravel Size - 8-12mm Height - 25cm	Media – Sand Size - 1-2mm Height - 15cm	Media – Gravel Size - 8-12mm Height - 1-2cm

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

of STPs. So, to maintain the actual conditions for the study, the treated sewage was carried every third day to the study site, it was finally kept in a feeding tank of 100 liters capacity and used to feed all the connected CW units. Each treatment unit was separately connected to the feeding tank via peristaltic pump (Make: Enertech-ENPD victor 100; range: 0.3 - 450 ml per minute) and silicon piping of 2 mm inner diameter and 4 mm outer diameter.

A steel sieve was kept at 12 cm (H1) above from the bottom in each of the treatment unit, to separate the inlet chamber from treatment bed which also helps in uniform distribution of water throughout the treatment bed (Figure 1). The treated wastewater first flows into the inlet chamber via inlet valve, then rises upwards to the treatment bed to allow for continuous flow and is finally collected from outlet ports.

Sampling and Analysis

Sampling frequency was twice in a week wherein the time difference between the inlet and outlet sample according to the HRT of 2-3 days for every week. The influent samples were collected from inlet port located at the bottom and the effluent samples were collected from the outlet ports placed at the top of the units where the treated water flows out. Further, to confirm the role of finer material (sand) in the microbial removal in UN-cn-sd, the unit with sand was further analysed at middle point. Water samples of approximately 100ml were collected from influent and effluent to evaluate the performance of constructed wetland units. The sample collection was made using acid pre-washed PVC bottles and prepared by sterilization through autoclave before each sampling. For microbiological analysis, two species - *Total coliform* (being the most common indicator) and *Fecal streptococci* (more resistant to environmental stress and known as secondary indicator) were used. Such analysis of indicators organisms was performed using multiple-tube fermentation according to the method given in APHA (1998; 9221B and 9330B) within 2 hours of sampling.

The concentrations of microbial species were observed as MPN (most probable number) per 100 milliliters (MPN/100ml) according to the table 9221: IV in APHA 1998. Such MPN values were converted to log scale. The performance efficiency of the proposed system was calculated in terms of concentration removal observed for all parameters.

The log removal for microbial removal was calculated as: $\log_{10}(Ci) - \log_{10}(Co)$, where Ci and Co represent the influent pathogen concentration and effluent pathogen concentration, respectively.

Further, a statistical analysis was performed using two tailed t-test to determine the significance level at $p<0.05$ for different sets of experimental data.

RESULTS AND DISCUSSION

Removal of Microbial Indicators

Mean influent concentrations of *Total coliform* and *Fecal streptococci* were observed to be 5.49 and 4.87 log MPN/100ml, respectively. The mean effluent concentrations of these microbial species are presented in the Figures 2 and 3. Accordingly, the mean log removal from UN-ph was 1.01 and 1.01 log units, from UN-cn was 1.87, and 1.82 log units, and from UN-ct was 1.24 and 1.03 log units for *Total coliform* and *Fecal streptococci,* respectively. Interestingly, since the UN-cn-sd was designed as an improved system, showed the minimum mean outlet concentrations of indicator species (*Total coliform*

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. Comparative insight of mean influent and effluent concentrations (logMPN/100ml) for the Total coliform from all four treatment units

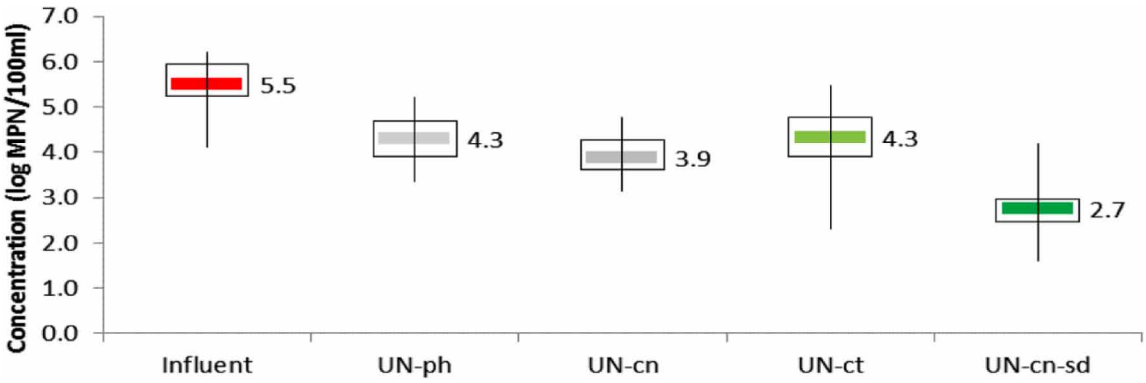

Figure 3. Comparative insight of mean influent and effluent concentrations (logMPN/100ml) for the Fecal streptococci from all four treatment units

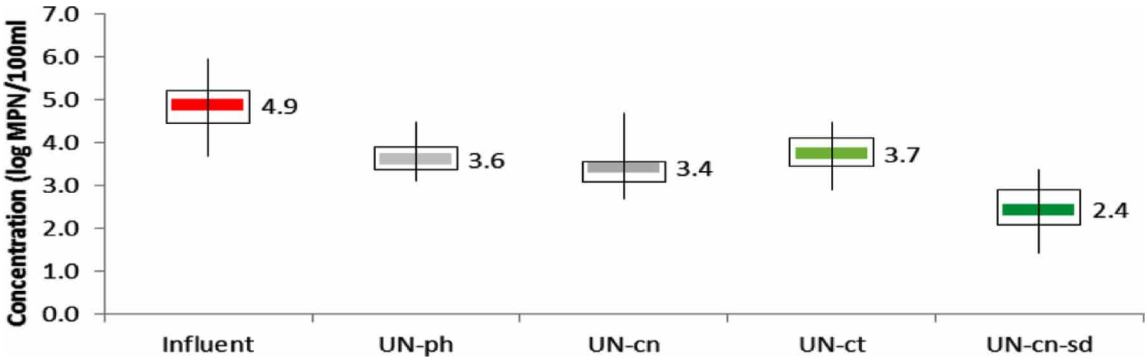

and *Fecal streptococci*) were observed in the effluent from UN-cn-sd as depicted in Figure 2 and 3. The log removal from the UN-cn-sd unit is found to be highest with 3.01and 2.80 log units for *Total coliform* and *Fecal streptococci,* respectively. These results revealed that the maximum log removal of indicators from UN-cn-sd followed by UN-cn, UN-ct and UN-ph, in decreasing order.

The removal of *Total coliform* from the *Canna* planted units, UN-cn (1.87 log units) and UN-cn-sd (3.01 log units), were found to be comparatively higher than the removal of 1.52 log units observed in the study by Gersberg et al. (1989) wherein *Scirpus* was used in planted wetland for treating secondary treated effluent. Such observed removal efficiency of UN-cn and UN-cn-sd in the proposed study, were also found to be higher than 0.7-1.5 log unit observed during the study by Arias et al. (2003). However, the study suggested by Garcia et al. (2003) found higher removal of microbial indicators while using finer media in horizontal constructed wetland that agreements the use of Un-cn-sd. Such comparisons support the higher removal efficiency of microbial contaminants from unit UN-cn-sd containing finer material (sand) as compared to the other units with coarser media. Also, the mean removal of *Total coliform* from the unit UN-cn-sd (3.01 log units) lies in the range of 2.7-4.7 log units as observed in the

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

study by Kadam et al. (2008), where domestic wastewater was treated through vertical flow constructed wetland. And, the removal of *Fecal streptococci* from the same unit UN-cn-sd (2.80 log units) was found to be higher than the range suggested by the author (1.7-2.5 log units).

Influent-Effluent Distribution During Treatment

Figure 4 and 5 are percentile curves, showing distributions of concentrations during the study period, clearly indicates that all the treatment units are significantly efficient in removal of the targeted indicator species from the secondary treated wastewater. The curves shown in Figure 4 clearly show that UN-cn is more efficient than UN-ph and UN-ct for removal of *Total coliform*, wherein the curves of UN-ph and UN-ct was close to each other. Interestingly, the curve for UN-cn-sd stood separately and shows that 90% of the observed effluent concentrations fall within the WHO recommended standard of 1000MPN/100ml (3logMPN/100ml). The mean *Total coliform* concentration in the effluent from UN-cn-sd was found to be 2.75logMPN/100ml whereas the 90th percentile concentration value was found to be 3.03logMPN/100ml. The almost same was observed for *Fecal streptococci,* where its 90% of the observed concentrations fall below the concentration of 2.90logMPN/100ml (Figure 5). These curves confirm the high removal efficiency of coliform as well as *Fecal streptococci* numbers from the secondary treated wastewater for the unit UN-cn-sd. However, the same pattern was observed for both of the indicators but the curves for *Fecal streptococci* were sturdier (less varying) than the curves observed for *Total coliform* which shows that *Fecal streptococci* is more resistant to the changing environmental conditions prevailing within the system.

Statistical Analysis

The results drawn above for both, *Total coliform* as well as *Fecal streptococci*, are also supported by the statistical analysis of the experimental results, where significant difference was found between removal from the units UN-ph and UN-cn but the difference between removal from UN-ph and UN-ct were found to be statistically non-significant. These results indicate that the presence of *Phragmites australis* have negligible impact whereas the presence of *Canna indica* is of significant importance for deciding the

fate of indicator organisms. Furthermore, the significant difference was observed between the removal from UN-cn-sd as compared to UN-ph, UN-cn and UN-ct, finally confirms the result of highest efficiency from UN-cn-sd for these two indicator species, *Total coliform* and *Fecal streptococci* (Table 2).

Analysis of UN-cn-sd for Indicator Organisms: Middle Point Analysis

The Un-cn-sd unit was also studied via middle point along with sampling at inlet and outlet points to know the effect of finer material sand on microbial removal efficiency in different zones. The transverse cross-section of the wetland unit UN-cn-sd shows that below the middle point, a layer of smaller sized (8-12mm) gravels was placed above the larger sized (16-20mm) gravels, such that the smaller sized gravels accounts for only 30% of the total area from inlet to middle point. Whereas above the middle point smaller sized (8-12mm) gravels and finer material sand (1-2mm) occupy the total area. Figure 6 and 7 present the varied concentration of *Total coliform* and *Fecal streptococci* during the monitoring period at inlet, middle and outlet points of the wetland unit. The observed mean concentrations for *Total coliform* were 5.36, 4.89 and 2.72 log MPN/100ml, respectively, and for *Fecal streptococci* are 4.40, 4.13

Figure 6. Concentration of Total coliform (log MPN/100ml) at inlet, middle and outlet points of UN-cn-sd during the monitoring period

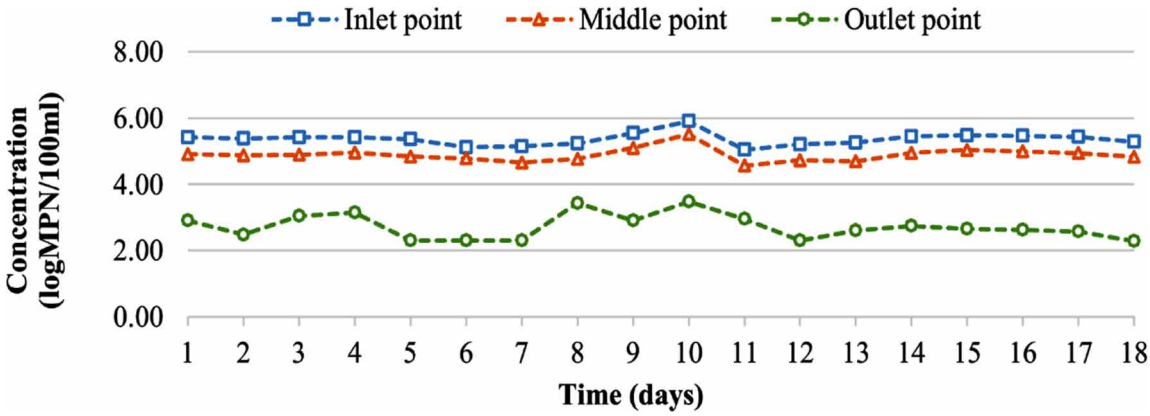

Figure 7. Concentration of Fecal streptococci (log MPN/100ml) at inlet, middle and outlet points of UN-cn-sd during the monitoring period

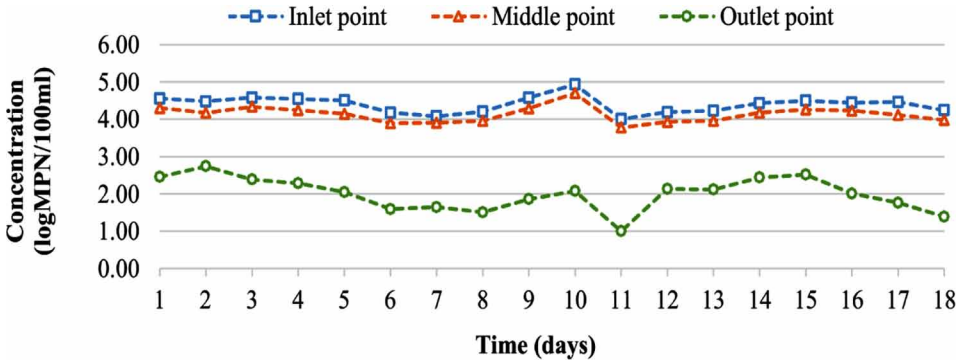


and 2.00 log MPN/100ml at inlet, middle and outlet points of the unit, respectively. Mean log removals for *Total coliform* were 0.48 and 2.64 and for *Fecal streptococci* were 0.27 and 2.40 from middle and end points, respectively. Significantly lower outlet concentrations were observed from the outlet point as compared to the middle point. Such concentration distributions reveal that the incorporation of finer material sand greatly improves the performance of the wetland unit.

Removal Mechanism of Microbial Species

The high performance of *Canna indica* planted unit UN-cn is related to its higher capacity of phytoremediation and to its fibrous rooting system which has capability of high root zone aeration, larger root surface area and high root numbers (Wenyin et al. 2007; Zhang et al. 2007; Bose et al. 2008). The increased root surface area helps to enhance the physical mechanisms such as:

- Aggregation,

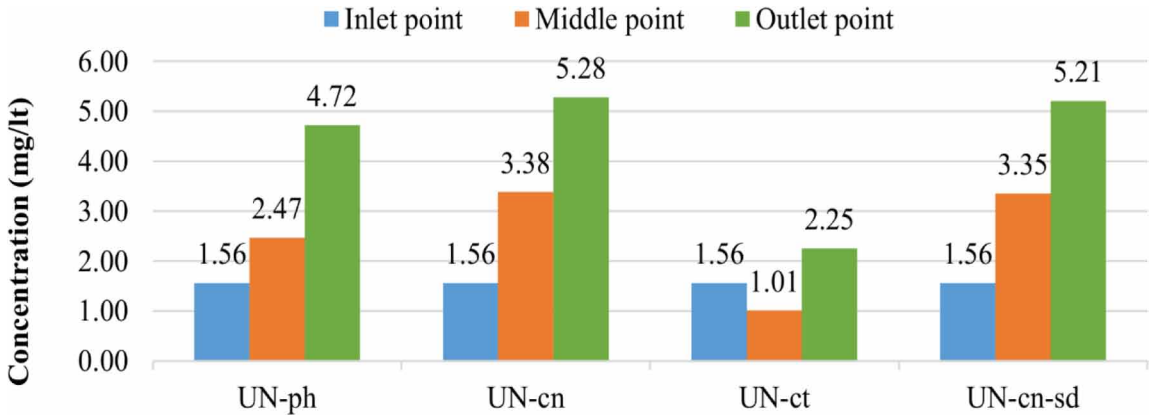
EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

- Adsorption,
- Oxidation,
- Sedimentation,
- Filtration,
- Solar irradiation,
- Straining, and also increases the possibilities of natural death and predation for microbial removal (Gersberg et al. 1989; Williams et al. 1995; Quinonez-Diaz et al., 2001; Stott et al., 2001; Pundsack et al., 2001; Karim et al., 2004; Stevik et al., 2004; Auset et al., 2005).

The major removal of microbes could be occurred due to the release of antimicrobial extract, especially from the rhizomatic part of the plant *Canna indica* (Abdullah et al. 2012; Gaur et al. 2014). The increased surface area along with the enhanced physical mechanisms lead to increased active sites for biochemical reactions to happen and increased area for development of bio-film within the treatment bed. And, in this way, the performance efficiency of the treatment bed is essentially effected by the microbial community present within the bed since the removal of contaminants from wastewater are majorly mediated by microbial activities (Reddy, 1983).

The performance efficiency of wetland systems can also be correlated with the concentration of dissolved oxygen (DO) in the wetland environment; increased bacterial die-off due to increased dissolved oxygen has been already discussed earlier in reported studies (Pearson et al., 1987; Fernandez et al., 1992). The removal mechanism in oxygenic environment is dominated by surface destruction of microbes through oxidation leading to the reduction of oxygen sensitive bacteria (Gross et al., 2007). This effect was dominantly observed for indicator microbial species in the proposed study throughout the monitoring period. As per the results of the study shown in Figure 8, higher DO values were observed throughout the treatment bed of *Canna* planted unit, UN-cn as compared to the units UN-ph and UN-ct. This could be due to the high aeration capacity of *Canna indica* roots which create an unfavorable environment for the microbial population and thus leading to higher removal efficiency of microbial contaminants. The high removal efficiency due to high aeration in planted filters is also suggested by Decamp et al. (1999).

Figure 8. Mean dissolved oxygen (DO) concentrations in mg/l observed for four constructed wetland units at middle and outlet points



EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

The lowest DO values were observed at the middle and outlet points of the unplanted control unit UN-ct, which proves the significance of vegetation in creating an oxygenated environment suitable for higher removal of microbial species. The low DO values in UN-ct is in accordance with the design characteristic of up-flow constructed wetland which have aerobicity at the top followed by anoxic environment at the bottom (Ong et al., 2009; Ghosh and Gopal, 2010). So, the low removal of indicator species from UN-ct might be related to the low concentration of dissolved oxygen for their survival. A deviation from the above discussion was found when it was observed that the planted unit UN-ph, although having a higher DO concentration as compared to the control unit UN-ct, showed lower performance in terms of removal of indicator organisms. This is in agreement with the previously reported studies by Hench et al. (2003) and Vacca et al. (2005). This could be justified through the observation by Torrens et al. (2009), who stated that the presence of *Phragmites australis* could be of less significance in vertical flow wetland as compared to the horizontal flow. The probable reason given for the decreased removal from vegetated wetland as compared to the un-vegetated unit was the presence of enteric bacteria and other competing bacteria, as a part of the rhizosphere communities, around the exudates of *Phragmites australis* (Axelrood et al., 1996; Pierson and Pierson, 1996).

Improved Performance Efficiency of UN-cn-sd Over UN-cn

The higher removal efficiency of UN-cn-sd over UN-cn can be related to the additional benefits provided through the inclusion of sand layer and more gradation of the media layers in the constructed wetland unit. The inclusion of sand layer helps to maintain the moisture content required for rhizosphere and subsequently increases the contact time between water and treatment bed within the system. The incorporation of sand layer significantly enhances the advantages related to the higher root surface area of *Canna indica* discussed earlier, i.e. enhanced physical mechanisms (aggregation, adsorption, oxidation, sedimentation, filtration, solar irradiation, straining), increased possibilities of natural death and predation for microbial removal, increased active sites for biochemical reactions to happen and increased area for development of bio-film within the treatment bed. The whole system functions in order to provide good aeration and removal of enteric microorganism's sensitive to high concentration of oxygen. The bacterial removal is maximized by the physical mechanisms like retention (filtration/ adsorption) and natural death (Ellis &McCalla, 1976; Reddy et al., 1981; Crane & Moore, 1984). Thus, the systematic increment in the favorable conditions for the removal of microbial contaminants in UN-cn-sd, along with the basic properties of UN-cn, makes it possible to achieve the high removal efficiency of the whole treatment system. Figure 9 clearly indicates that the log removal from Un-cn-sd increased from UN-cn by an amount of 60%, 54% and 45% for *Total coliform, Fecal streptococci* and *Salmonella typhi*, respectively. The results obtained are also in good agreement with studies reported by Vacca et al., (2005) and Sleytr et al., (2007) and are favorable when compared with the study given by Torrens et al. (2007), where less than 2 log unit bacterial removal was observed. Such studies favor the incorporation of sand layer, as a good choice of finer material within the wetland treatment beds, in order to enhance the adherence of microbes; Sleytr et al., (2007) also reported high concentrations of microbes in sediments of sand layer.

As far as the final effluent concentration of *Total coliform* is of concern, UN-cn-sd was the only unit capable of bringing down the concentration within the prescribed WHO standard limit for safe disposal into water streams; WHO limit is 3 logMPN/100ml and UN-cn-sd achieved 2.75 logMPN/100ml. The results related to UN-cn-sd suggests that it is highly efficient for the removal of all three microbial species. The above evaluation of results favors the suitability of *Canna indica* being used with sand media

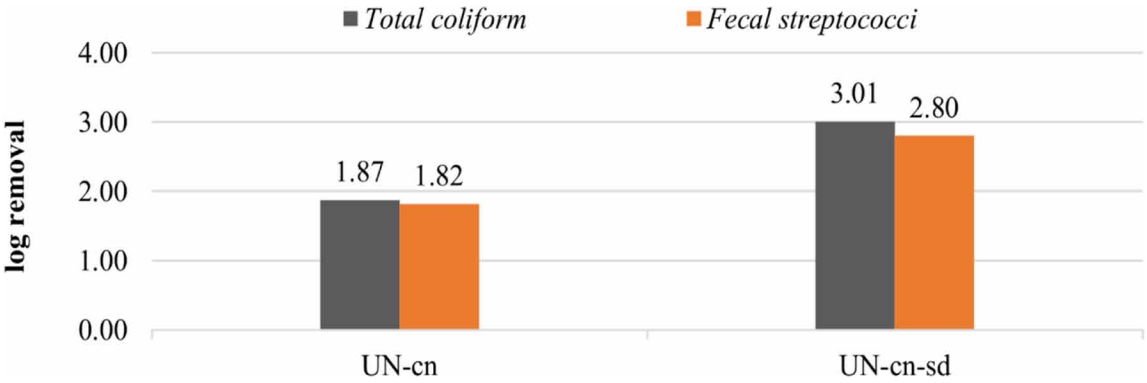
Figure 9. Comparative insight for improved efficiency of Canna indica planted units by incorporation of finer media sand



in vertical flow constructed wetland for post treatment of secondary treated wastewater in semi-arid climatic conditions prevailing in the region of Rajasthan, India. In such climatic conditions a compact and well-designed vertical up-flow constructed wetland unit, constituting fine material sand along with the coarse material gravel, with gradation, is able to reduce the public health risks associated with the disposal of secondary treated effluents.

CONCLUSION

The basic nature of sand and the root pattern of *Canna indica* might have helped during the study for reduction of microbial indicators. These two components increased the physical mechanisms and dissolved oxygen content and secretions of antibacterial substance within the system which may have created unfavorable environment to survive microbial species. So far, this study can be useful for the existing domain of the effluent treatment plants where chemical dosing is their tool to disinfect the secondary treated wastewater. And, the very simple and efficient approach to use of sand and gravel as media and *Canna indica* as a suitable plant species, can reduce their cost of establishment of treatment. This novel approach may be helpful for further studies to challenge the different treatment processes as a post treatment alternative.

ABSTRACT

With significant infrastructure investments required for centralized water treatment, in home treatment technologies, known as point-of-use, have become a popular solution in the developing world. This review discusses current filtration-based point-of-use water treatment technologies in three major categories: ceramics, papers and textiles. Each of these categories has used silver for added antimicrobial effectiveness. Ceramics have had the most development and market infiltration, while filter papers are a new development. Textiles show promise for future research as a cheap, socially acceptable, and effective method. Also, a new method of silver incorporation in ceramics is explored.

INTRODUCTION

Approximately 1 billion people worldwide do not have access an "improved water supply", which is defined by the World Health Organization (WHO) as "a household connection or access to a public standpipe, a protected well or spring, or a source of rainwater collection"(Cosgrove & Rijsberman, 2000). This definition also requires that at least 20 liters per person per day are available within 1 km of a person's home. Because this definition does not refer to water quality, reliability of service, or even cost, it is estimated that an additional 2-3 billion people also have unsafe water supplies, at least for part of the

time (Hutton & Haller, 2004). Studies have also shown that numbers reported by the Joint Monitoring Programme of the proportion of drinking water coming from improved sources are likely substantial overestimations when water quality data is included (Bain et al., 2012). Access as well as quality is key.

The dangers of consuming unsafe water are substantial, particularly for children. The WHO estimates that consuming unsafe water causes the deaths of over 4 million people per year, with more than 1.5 million of these deaths being children under the age of 5. This is about equal to having 10 jumbo jets crashing every day with 90% of the passengers being children (Dillingham & Guerrant, 2004). Not included in this figure are the added health burdens on children who experience cognitive impairment and growth stunting as a result of gastrointestinal infections caused by consumption of water with pathogenic organisms like Shigella, pathogenic strains of *Escherichia coli*, *Vibrio cholerae*, and *Cryptosporidium parvum (Dillingham & Guerrant, 2004)*. People living with AIDS are particularly susceptible to infections from waterborne pathogens because of their weakened immune systems (Dillingham et al., 2006). In many parts of sub-Saharan Africa, there is an unfortunate confluence of low-quality drinking water and high rates of HIV infection. Providing safe water to our global population has been identified as one of the Grand Challenges of Engineering by the National Academy of Engineering.

In most cities and suburban areas of the developed world, water is treated at centralized water-treatment plants and delivered directly to homes through distribution systems with chlorine residual. About 3-4 billion people receive this high level of service, which generally prevents gastrointestinal infections by waterborne pathogens. This service is usually not available in the developing world or even in some suburban and rural areas of the developed world. These regions cannot economically sustain centralized water treatment plants that meet the full demands of the population. A centralized water treatment facility is a very large investment not feasible for many communities. The treatment plants plus the distribution system is not practical in developing rural areas due to the financial and structural requirements for safe treatment and delivery of water. The WHO has suggested that one possible solution is to take a more decentralized approach to water treatment, wherein people treat their water in their households immediately before consumption. This idea, often referred to as point-of-use (POU) water treatment, has the potential to significantly improve the microbial quality of household water and reduce the risk of diarrheal disease and death, particularly among children (Thomas Clasen, Nadakatti, & Menon, 2006). Table 1 shows a summary of some point-of-use systems currently in use and their effectiveness against *Escherichia coli* (*E. coli*).

Ideally, local markets can ideally drive the proliferation of these technologies without reliance on government interventions and/or subsidies. Peter-Varbanets, et al. divides current point-of-use treatments being used into three general categories: heat and UV-based systems (boiling with fuel, solar radiation, SODIS, combined action of heat and solar UV, and UV lamps), chemical treatment methods (coagulation, flocculation and precipitation, adsorption, ion exchange and chemical disinfection), and physical removal processes (sedimentation or settling, filtration, including membranes, ceramic and fiber filters, and granular media filters, including sand filters and aeration).

Rural areas of developing countries have been unable to implement centralized drinking water treatment because it is expensive. This leads to using untreated natural water sources (rivers, lakes, groundwater or rain) (Peter-Varbanets, Zurbrugg, Swartz, & Pronk, 2009). Without centralized treatment and direct piping into the home, there are many steps before consumption including collection from the source, storage, contamination, and treatment (J. E. Mellor, Smith, Learmonth, Netshandama, & Dillingham, 2012). There are three types of conventional methods for treatment including physical, chemical, and biological (Praveena & Aris, 2015). Common practices for point of use water treatment not utilizing

filtration include boiling, chlorination, or solar disinfection. Membrane systems for use in the home have become increasingly popular, but still remain too expensive for the poorest of countries. Microbial pollution is the most threatening issue with water supplies, and fecal contamination of a water supply leads to water-borne diseases. Boiling of water is the most common form of treatment in developing countries, but is not as effective as hoped. A study in semi-urban India found 40.4% of stored drinking water of those who reported boiling their water were contaminated with fecal coliform (Thomas Clasen et al., 2008). In addition, 25.1% had more than 100 fecal coliforms (FC) per 100 mL, while the WHO standard is 0 FC/100mL) (Thomas Clasen et al., 2008). Boiling also creates a high-energy demand and poses the additional problem of deforestation when wood fires are used to boil the water. Assuming that households boiled 6 liters per day, the estimated monthly fuel cost for boiling water in semi-urban India was US $1.50 for households using liquid petroleum gas and US $3.21 for those using wood (Thomas Clasen et al., 2008). The cost is higher for those using wood as fuel because of the opportunity cost of lost time earning money that is instead spent gathering wood. Places like Bangladesh also lack access to the fuel necessary to boil water (A. Huq et al., 1996). Chlorine has been tested as an in-home option and has proven effective, but unpopular; household users complain about the taste and have reported a refusal to drink the water since the smell is similar to that of household bleach (Kirchhoff & McClelland, 1985). Solar disinfection has been proven as effective but requires sunlight and a large supply of plastic bottles while only treating a limited amount of water at one time (D. S. Lantagne, Quick, & Mintz, 2006). When there is limited water quantity, common solutions include groundwater wells and rainwater harvesting. However, groundwater wells are not always well planned and can become polluted, while temporal and spatial variations in rainfall can make rainwater harvesting unreliable in the absence of large-volume storage (Peter-Varbanets et al., 2009).

BACKGROUND

High surface area to volume ratio leads to better bactericidal activity, making nanomaterials excellent adsorbents (Praveena & Aris, 2015). This chapter will focus on one particular nanomaterial, silver. Silver has been used for disinfection for millennia and in wound treatments since the 1960s (LeOuay & Stellacci, 2015). Silver has bactericidal activity in its oxidized state, Ag^+ (Karel, Koparal, & Kaynak, 2015). Silver nanoparticles are between 1 and 100 nm in size (T. A. Dankovich, 2012).

Growth studies of microbial cultures have been performed with both silver and copper nanoparticles. One study showed that silver and copper nanoparticles have great promise as antimicrobial agents against *E. coli, B. subtilis*, and *S. aureus (Ruparelia, Chatterjee, Duttagupta, & Mukherji, 2008). E. coli* is a common choice for testing the effectiveness of a technology since it is a gram-negative, rod-shaped bacterium, 1-2 μm long and 0.1-0.5 μm in diameter, and a common water microbe with strains that cause gastrointestinal infections (Brown, Chai, Wang, & Sobsey, 2012). Silver nanoparticles perform better as an antimicrobial agent against *E. coli* and *S. aureus* than copper. Copper nanoparticles form an oxide layer and demonstrate better antimicrobial activity towards *B. subtilis* than silver, possibly due to a greater affinity to the surface-active groups. Ruparelia et al. admits that the antimicrobial mechanism of the silver and copper nanoparticles is not yet fully established, and a combination of silver and copper nanoparticles may produce a more complete bactericidal effect against mixed bacterial populations that would be more common in actual use (Ruparelia et al., 2008).

Silver is usually in concentrations of approximately 0.1 mg/kg in aquatic systems at subnanomolar levels. Higher silver concentrations in aquatic environments often come from waste streams of commercial or industrial processes. Silver in nature can be monovalent (Ag(I)) or metallic (Ag(0)). Studies have shown that free or hydrated Ag(I) exhibits toxic effects on a variety of aquatic organisms ranging from zooplankton to rainbow trout (Herrin, Andren, & Armstrong, 2001). Several studies have demonstrated that silver ions are selectively toxic for prokaryotic microorganisms, with little effect on eukaryotic cells (Park & Jang, 2003). However, the exact reasons for the antimicrobial ability of the nanoparticles are still unknown. Among all antimicrobial nanomaterials, nanosilver is probably the most widely used (Li et al., 2008). Silver's antimicrobial property is related to the amount and the rate at which it is released. Metallic state silver is inert, but silver will react with moisture in the skin or fluid in a wound to become ionized. Ionized silver is highly reactive, binding to bacterial DNA and RNA by denaturing. The nanoparticles bind to the cell membrane, a vital point of protection, and accumulate to causing irreparable damage (Pradeep & Anshup, 2009). This inhibits a bacterial cell from replication. In binding to tissue proteins, the silver brings structural changes to the cell wall and nuclear membranes causing the cell to distort and die (Rai, Yadav, & Gade, 2009). It has also been found that if the antimicrobial and the bacterial cell (negative charge) have the same surface charge, there is repulsion and less contact (Pradeep & Anshup, 2009). Oxygen presence in a system with bulk silver provides complete destructive oxidation of microorganisms (Pradeep & Anshup, 2009).

Health concerns are the chief barrier to the implementation of new technologies that use silver nanoparticles. Silver release from a treatment material is affected by the water's pH, temperature and chemical composition. Just 60 milligrams can be toxic to humans, while 1.3 to 6.2 grams is lethal (D. S. Lantagne, 2001). The WHO sets a limit to ensure that these technologies do not cause harm, stating that up to .1 mg/L can be tolerated without risk. The United States Environmental Protection Agency sets a maximum silver concentration for drinking water at .1 mg/L (Quang et al., 2013). The retention rate of silver in humans is only 0-10 percent, and silver is mainly stored in the liver and skin. The WHO

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

set a guideline of 10 grams of silver in a lifetime (D. S. Lantagne, 2001). Potential human risks of silver consumption at high levels include high blood pressure, kidney damage, gastrointestinal irritation, cancer and neurological damage, in addition to DNA damage (Praveena & Aris, 2015). The silver levels after treatment must be within a safe range for human consumption. Risks to environment and human health are a rising concern. The technologies discussed in the chapter release silver at levels below the drinking water standard, meaning they are safe and may cause a substantial improvement in water quality and human health, particularly in resource-limited settings. Some of the ceramic technologies are made with silver nitrate instead of silver nanoparticles and thus release silver ions instead of nanoparticles.. There is a strong understanding of the health effects of silver in ion form, but the effects of silver in the nano form are less understood.

CURRENT POINT-OF-USE WATER TREATMENT TECHNOLOGIES

Herein, we discuss current point-of-use water treatment practices that use silver nanoparticles in porous media. The three main categories of treatment type that will be addressed are ceramic, paper and textile. These technologies us e filtration, which benefit from removal of turbidity and are gravity fed, which saves on energy costs (Albert, Luoto, & Levine, 2010). In addition, we present new data on a novel "silver-nanopatch" fabrication technique as applied to ceramic filters.

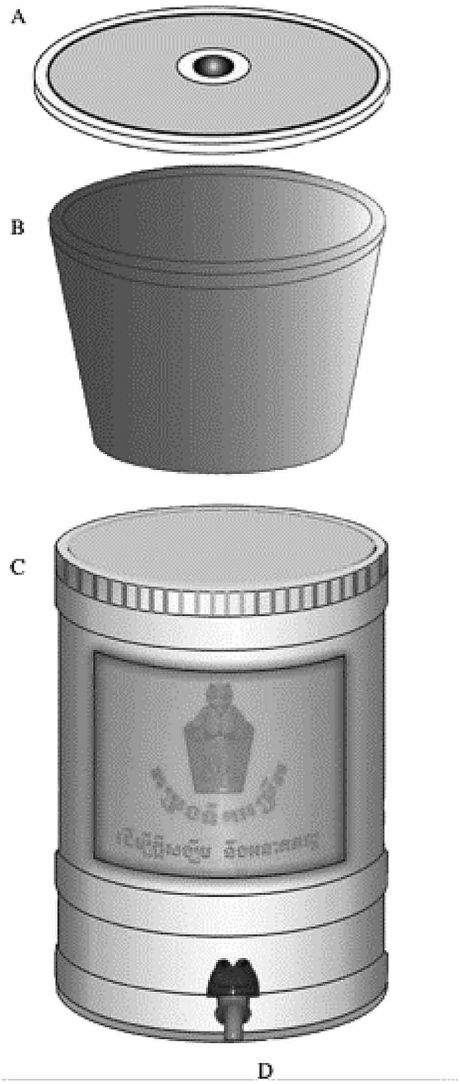
Ceramic

Silver has been imbedded in clay and can be designed to control silver release kinetics (Karel et al., 2015). Silver imbedded clay can also be used with textiles by soaking a textile then oven drying (Kasuga et al., 2011). Although this method has not been used for water, it has been used for air purifiers, and the clay has been used in plates to treat drinking water (Kasuga et al., 2011). Fired clay makes a ceramic that can be used for ceramic filtration which has been shown to have high effectiveness against bacteria and protozoa (D. S. Lantagne et al., 2006). Potters for Peace is a US-based nongovernmental organization (NGO) that has been teaching communities to produce and manufacture ceramic pots that filter water (D. S. Lantagne, 2001). The pots are made from water, clay and a combustible material like sawdust and shaped like a pot. The kiln is typically fired at 900 ˚C for 8 hours, below the melting point of silver (Praveena & Aris, 2015; Ren & Smith, 2013). During firing, the clay forms a ceramic and the sawdust combusts, leaving behind porosity for water flow. Some filter factories then perform a pressure test by submerging the filter to the rim in water for 10 seconds and to see if any wet spots appear on the interior of the filter pot. A wet spot would suggest a macropore that in turn may limit filter performance for pathogen removal (Rayner, 2009). Filters are then soaked and subjected to a flow test. If the filters pass a flow rate test they are then painted or dipped in colloidal silver solution that provides antimicrobial effects (Rayner, 2009). Water containing a colloidal silver has been filtered through as a way to embed the silver in the filters, but has been proven less efficient (D. S. Lantagne, 2001). Also, painting on silver nitrate is less efficient due to high washout, and silver nanoparticles are recommended (Rayner et al., 2013). Mixing in silver nanoparticles prior to firing has shown higher retention of silver in the ceramic and potentially better long term use when compared to the paint on or dipped application method which release silver at high levels quickly during early use (Ren & Smith, 2013). This has not been tested for bacterial disinfection nor has it been field tested, but it could be a promising alternative. The ceramic sits

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

inside a 20-30 liter plastic bucket with a spigot. Figure 1 is a diagram of a completed ceramic water filter (Brown & Sobsey, 2010). These can be manufactured locally and pots are a common storage container for water already, so there is no break to the social norm (D. S. Lantagne et al., 2006). The filtering of water is gravity-fed and would save on energy cost. The clay-to-sawdust ratio by volume of 47% has proven best in optimizing flow rate without losing coliform removal (D. Lantagne et al., 2010). Also, the type of combustible used has been shown to make a difference even if the same size and amount is used, like sawdust versus coffee or rice husk (D. Lantagne et al., 2010).

Figure 1. Schematic of the ceramic water filter produced by Resource Development International—Cambodia (courtesy of Mickey Sampson). The complete filter unit consists of a lid (A), ceramic filter element (B) in a plastic container (C) that gathers treated water and dispenses through a tap at the base (D). *Brown & Sobsey, 2010.*



EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

The silver-impregnated ceramic water filters have shown to be both sustainable and socially acceptable as well as effective with physical filtration and chemical treatment both contributing to pathogen removal (Abebe et al., 2014). The ceramic filter without silver has been shown to successfully remove *E.* coli but the addition of silver improves the water quality of the effluent (Kallman et al., 2011). Porosimetry of the filters has shown that the pores of the ceramic are too big to remove bacteria by only size exclusion-- there are several other mechanisms like depth straining, particle bridging inertial impaction, interception, diffusion and electrostatic attraction that help with capturing bacteria (Matthies et al., 2015). The filter has also been shown to be a preferred option by a study of 400 households in Kenya. Households were given the option of three different technologies, PUR (chlorine-based), Waterguard (chlorine-based) and a ceramic water filter. The households had a two-month trial with each, and then were asked their preference again at the conclusion of the trial. The ceramic water filter was preferred both before and after (Albert et al., 2010).

The method of application of silver does not appear to be a factor affecting disinfection efficiency (D. Lantagne et al., 2010; V. Oyanedel-Craver & J. A. Smith, 2008). Instead the mass of colloidal silver that remains after the saturation period determines effectiveness. The bacterial removal may be helped by the ceramic pores being filled by silver instead of the bacteria in transport. Testing has shown between 97.8 and 100% removal of *E.* coli (V. Oyanedel-Craver & J. A. Smith, 2008). It is also important that the silver release remains below the regulatory limit for silver in drinking water, which is 0.1 mg/L. This level was not exceeded for any of the filters tested after passing water through the filter for about 200 min (V. Oyanedel-Craver & J. A. Smith, 2008). The shape of the filter, flat bottom versus round bottom, also has no effect (D. Lantagne et al., 2010).

Ceramic candles are often used in a gravity-fed, ceramic water filter system. The set up involves two 20 L plastic buckets stacked on top each other with the silver impregnated ceramic candles vertical allowing their effluent to flow to the bottom bucket and be dispensed out a spigot. Each candle can treat 20000 L depending on water quality (THOMAS Clasen, Parra, Boisson, & Collin, 2005). This technique has been associated with 70% lower diarrheal rates, and 92% of users report "feeling better" after using the filter (T. F. Clasen, Brown, Collin, Suntura, & Cairncross, 2004). Ceramic candles have shown that after 16 months, only 48.7% are still operating properly, and 54% of those produce coliform free water (T Clasen & Boisson, 2006). The main problem with this technology is breakage. The ceramic filters are popular with the end user, but with so many parts, any failure commonly leads to discontinued use because of difficulty to repair (T Clasen & Boisson, 2006). It has been found that the treatments are not always done correctly by the user (D. S. Lantagne & Clasen, 2012). This lowers the effectiveness of the technology and therefore does not provide recipients with the safe drinking water they should be receiving. Proper education on use and maintenance of the treatment system is vital (D. S. Lantagne, 2001). Proper maintenance of ceramic water filters can reduce early childhood diarrhea by an extra 45% (J. Mellor, Abebe, Ehdaie, Dillingham, & Smith, 2014). Often the new technology may be provided to a developing country, but with English directions. Keeping methods simple and similar to current practices could improve the utilization phase of treatment processes (D. S. Lantagne & Clasen, 2012).

The benefits of ceramic filtration include its proven effectiveness against bacteria and protozoa, its simplicity, its long-term use, and its low cost due to the ability to locally produce. One study of the ceramic filter reported a 90-99% removal of MS2, a viral pathogen (Brown & Sobsey, 2010), but conversely it has also been claimed that there is a minimal efficiency against viruses (Matthies et al., 2015). But with that, there is a risk of recontamination in the lower reservoir and need for education for optimal use (T. F. Clasen et al., 2004). Ceramic filters provide health improvements, cost-effectiveness

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

and are environmentally friendly, making them sustainable and a better option than a centralized treatment system in the developing world (Ren, Colosi, & Smith, 2013). Unfortunately, ceramic filters have shown a 2% decrease in likelihood of use after each month of ownership with the most common reason being the filter breakage (Brown, Proum, & Sobsey, 2009), and 67% of the discontinued use is because of breakage (Sobsey, Stauber, Casanova, Brown, & Elliott, 2008).

As for human health effects, a study has shown that the use of silver-impregnated ceramic filters reduced diarrhea rates by 49% across age groups and sexes (Brown, Sobsey, & Loomis, 2008), and by 80% among HIV-positive users (Abebe et al., 2014). This is important since individuals who are immunocompromised can be particularly susceptible to gastrointestinal infections from waterborne pathogens (Abebe et al., 2014). There has also been epidemiological research on ceramic filter use and reduction of the hepatitis A virus (T. F. Clasen et al., 2004). Ceramic water filters have been found to reduce early childhood diarrhea by 41% over two years (J. Mellor et al., 2014), but the effectiveness is reduced after 3 years (J. Mellor et al., 2014).

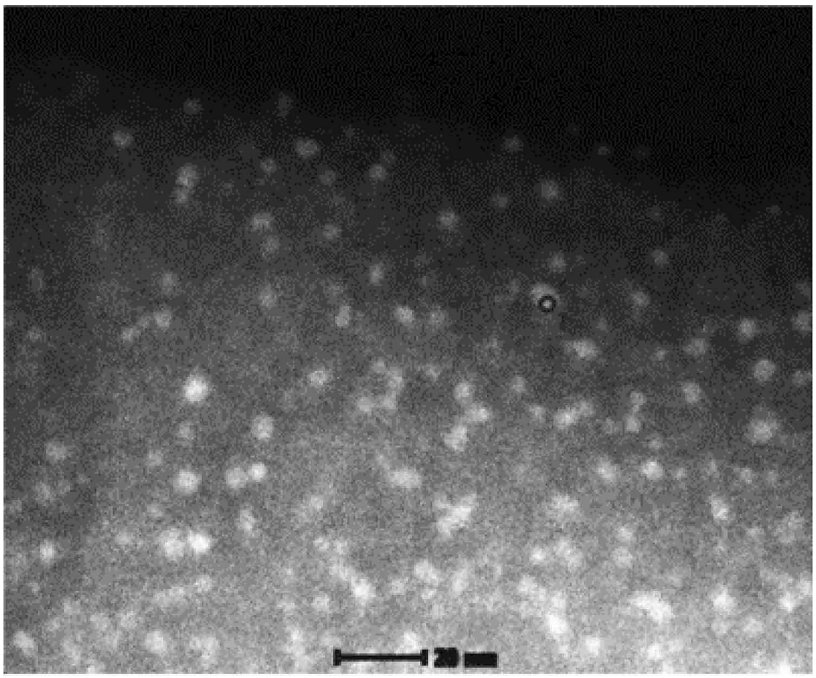
Other ceramic technologies have been developed that do not use filtration. Silver-coated ceramic beads can be used in water, and has been tested by pouring through columns rather than a batch method (Han, Lee, Lee, Uzawa, & Park, 2005; Lin et al., 2013). Recently, a novel method of metallic silver formation in a porous ceramic was reported by Ehdaie et al. (2014). These researchers combined clay, sawdust, water, and silver nitrate, pressed the mixture into the form of a ceramic tablet, and fired the tablet in a kiln at 900 ˚C. During firing, the clay formed a ceramic, the sawdust combusts, and the ionic silver is reduced to metallic silver, forming metallic silver "nanopatches" with an average diameter of 2.71 nm as seen in Figure 2. The ceramic tablet can be added to a 5-15-L household water storage container and it passively releases ionic silver for the inactivation of *E. coli* and other gram-negative waterborne pathogenic bacteria. A 3-log reduction (99.9% removal) was shown for *E.* coli in a 10 L water source after 8 hours. This technology shows promise as a successful stand-alone technology for household water treatment for very low cost, or in combination with other filter or boiling treatments, where recontamination is a common issue (Ehdaie, Krause, & Smith, 2014). Similarly, colloidal silver has been coated on a ceramic brick for suspension in large drinking water storage tanks (Nover, McKenzie, Joshi, & Fleenor, 2013). This provides continuous, low-maintenance disinfection quickly (Nover et al., 2013), but the silver levels may become too high and require attention to residence time and size of the water container (Nover et al., 2013).

In a recent investigation in 2015, we conducted a study on incorporating this new method of silver application to ceramic filters. This study was done at the PureMadi Mukondeni Pottery Cooperative in Limpopo Province, South Africa. Currently, ceramic filters are being made by mixing sawdust, water and clay. The mixture is pressed into the shape of a filter and then fired. After that, a silver nanoparticle suspension is painted on the inside and the outside of the filters. With the help of local potters, filters were made using a new method. The new method of incorporating silver is mixing clay, sawdust and water with $AgNO_3$. During the firing process the Ag^+ reduces to Ag^0 forming small nanopatches, like in Figure 1. Filters were made with 0.3 g Ag (the same silver mass used in the paint on method) and 1.0 g Ag.

Filters were tested at the University of Venda, in Thoyondou, South Africa. Controls (filters fabricated by painting on silver nanoparticles), filters with 0.3 g of Ag, and filters with 1.0 g Ag were compared over 12 days for coliform bacteria removal efficiency. For testing, 4L of challenge water from a local stream was poured into the top reservoir of each filter. This was allowed to percolate and gather in the lower reservoir for 12 hours before collection. Samples were then tested for total coliform and *E. coli* removal using membrane filtration. To calculate results, the log of the effluent concentration (C) divided

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. Transmission electron microscopy image of silver nanopatches in the center of a ceramic tablet using scanning electron microscopy mode. The scale bar represents 20 nm in length
(Ehdaie et al., 2014).



by influent concentration (C_0). Results are displayed in Figure 3. The error bars represent one standard deviation above and below the mean and show there is no statistical difference between using the paint on method and the new silver nitrate method of incorporating prior to firing.

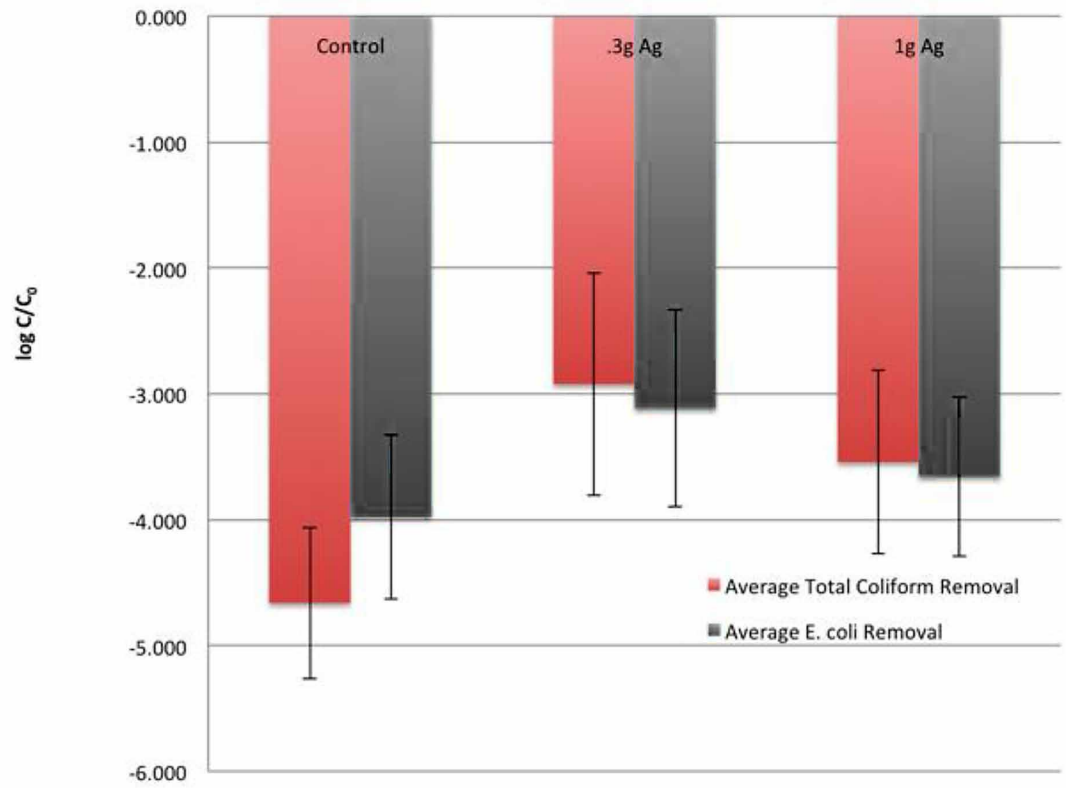
The method is less expensive and easier to manufacture as the painting step is omitted and $AgNO_3$ is much less expensive than silver nanoparticles. Potentially, even more silver in the form of silver nitrate for be added to improve the performance of the filters without increasing filter cost. On the downside, filters that do not pass quality control tests (pressure or flow rate tests) will waste the silver that has been applied to them. Filters that are manufactured conventionally will not receive silver nanoparticle application until passing quality control tests. Further research needs to be done to expand this data set, but these results show promise for an improvement to the technology.

Paper

Paper is mostly made up of cellulose, the most abundant natural polymer. It is readily available, inexpensive, renewable, and biodegradable as well as having a great ability for metal ion sorption (Tang, Meng, Lu, & Zhu, 2009) (T. A. Dankovich, 2012). Paper is a cellulosic non-woven material like some fabrics (Ngo, Li, Simon, & Garnier, 2011). Silver nanoparticles have been formed on cellulose in bandages, clothing, food packaging, and much more. This proves a potential use of paper for water treatment (T. A. Dankovich, 2012). The most common way of synthesizing silver nanoparticles on cellulosic material is *in situ* chemical reduction of metal ions, with a reducing agent commonly being sodium borohydride

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 3. Plot of the average log removal of total coliform bacteria and E. coli by conventional filters manufactured by painting on 0.3 g of silver nanoparticles (Control) and filters fired after mixing with silver nitrate (0.3 and 1.0 g as Ag). During firing, the silver nitrate is reduced to produce silver nanopatches throughout the porous ceramic media.



(T. A. Dankovich, 2012; Tang et al., 2009; Zeng et al., 2007). Dankovich (2012) has described a method of creating silver nanoparticle (AgNP) paper by immersing blotting paper sheets (6.5 cm by 6.5 cm) in 20 mL of silver nitrate solutions at concentrations from 0 to 100 mM for 30 minutes. The sheets are then rinsed with ethanol to remove excess silver nitrate that was not absorbed into the blotter. To form nanoparticles, the paper is placed in aqueous $NaBH_4$ solutions (ranging from 1:1 to 10:1 molar ratio, $NaBH_4/AgNO_3$) for 15 min. Lastly, the paper is soaked in water for 60 min, and dried in an oven at 60° C for 2 to 3 hours (T. A. Dankovich & Gray, 2011).

A microware irradiation method for *in situ* preparation of silver nanoparticles in paper has also been developed. Using a microwave, or a conventional oven, a silver nanoparticle covered paper can be produced in a "green" way. Blotting papers are submerged in aqueous solutions of silver nitrate and glucose (T. Dankovich, Clinch, Weinronk, Dillingham, & Smith, 2014). The papers are then heated in either a microwave or a conventional oven before being soaked in water to remove excess reagents (T. Dankovich et al., 2014). Glucose functions as the reducing agent with higher concentrations leading to smaller, more uniform nanoparticles and a faster reaction time. The average size of the resulting nanoparticles can be measured with TEM images to be 5.5 nm (T. A. Dankovich, 2012). Figure 4 shows scanning

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

electron microscope (SEM) images of AgNP on paper (T. A. Dankovich, 2014). This way of producing the papers is more benign than the use of sodium borohydride as the reducing agent, while being just as effective (T. Dankovich et al., 2014).

Silver nanoparticles have the largest antibacterial effects with the smallest particle sizes, with average diameters under 10 nm being most effective. Results showed the AgNP paper was effective with *E. coli* bacteria suspensions poured through the sheets. After passage through the paper, effluent bacteria was isolated and used for plate counts, showing log 7.6 (±1.3) and log 3.4 (±0.9) reductions of viable *E. coli* and *E. faecalis* bacteria, respectively. Bacteria were reduced by log 0.95 (± 0.5), probably because some bacteria remained on the fiber surfaces in the blotting paper. Graphite furnace atomic absorption was used to measure the silver content in the effluent, which measured 0.0475 (±0.0177) ppm meeting the USEPA guideline for drinking water of less than 0.1 ppm (T. A. Dankovich & Gray, 2011).

Gottesman et al. (2010) describe a way of depositing silver nanoparticles onto paper by ultrasonication. The paper is held immersed in a solution of silver nitrate, ethanol, ethylene glycol and water which is then irradiated with a high intensity ultrasonic horn.. These papers have been shown to have minimal loss of silver from the coated surface, which is important for the longevity of the material. They were also shown to be effective against both gram-negative and gram-positive bacteria. This shows promise for water treatment and the avoidance of cross contamination (Gottesman et al., 2010).

Silver nanoparticles have been imbedded in paper by first immobilizing initiators on a paper's surface. Then a surface-initiated atom transfer radical polymerization technique has been developed to graft poly(tert-butyl acrylate) brushes to cellulose filters. Then the brushes are transferred into poly(acrylic acid) by hydrolyzation. Silver nitrate is then reduced to Ag^+ *in situ* by reducing agent sodium borohydride. These filters display good antibacterial ability against *E. coli* (Tang et al., 2009).

Textile

Silver nanoparticles are commonly used in clothing, especially socks, as an antimicrobial agent (Benn & Westerhoff, 2008). Antimicrobial silver is also popular for improving dressing for burn wounds. An ethanol/water medium with silver nitrate uses cation exchange between silver and sodium from sodium carboxymethyl cotton gauze (Parikh et al., 2005). The use of textiles for filtration is not a new idea. Different types of sari material have been used in Bangladesh as an inexpensive and easily available option for point-of-use water filtration (Colwell et al., 2003; A. Huq et al., 1996). Shesh, a traditional textile of North Africa, and more modern textiles like denim or shower curtains have also been tested for water filtration performance (Saidani-Scott, Tierney, & Sánchez-Silva, 2009). Textiles are very effective at removing turbidity when used for filtration (Tammisetti, 2010). The waterborne pathogen *Vibrio cholerae* often attaches to something larger like zooplankton, particularly copepods (Colwell et al., 2003; A. Huq et al., 1996). This makes for easier removal by fabric filtration. The larger particles are more likely to get filtered out via fabric filtration, while smaller organisms could pass straight through the holes in the fabric. Folding of the fabric is encouraged to increase efficiency so more levels of fabric are used for filtration (Colwell et al., 2003). The simple filtration technique of pouring water through a fabric folded at least four times has been shown to effectively remove zooplankton, most phytoplankton and particulates bigger than 20 micrometers (Colwell et al., 2003). Most importantly, follow up studies have shown that the method is accepted and sustainable by villagers in Bangladesh and also reduced the incidence of cholera by 48% (Anwar Huq et al., 2010). Gram-negative bacterium *E. coli* and Gram-positive bacterium *Staphylococcus aureus* are commonly used for antimicrobial activity with fabric testing and fungus *C. albicans* is also used frequently (Ilic et al., 2010; Ilic et al., 2009; Maneerung, Tokura, & Rujiravanit, 2007; Mecha & Pillay, 2014). Textiles show this promise because without alteration they remove larger suspensions and reduce turbidity.

Radetić (2013) offers a comprehensive overview of nanoparticle-embedded textiles. The quick push for silver nanoparticles in textiles led to a growing industry with lack of insight into the possible environmental effects. Cotton seems to be the original textile of choice, especially pre-dyed or printed. The natural fiber allows for silver application to be commonly done without any prep work. Cotton is also a common fiber that is easily available and widely used. Like paper, sodium borohydride and glucose are common reducing agents used for the formation of silver nanoparticles (Maneerung et al., 2007; Reda M. El-Shishtawy, 2011). Silk has also be used with the reduction of silver nitrate with reducing agents like hydrazine and glucose (Gulrajani, Gupta, Periyasamy, & Muthu, 2008). Wool is also a common fiber,

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

but not as well explored for AgNP applications. It has been shown to have antimicrobial abilities, and its main benefit is said to be the bright brilliant colors it produces (Radetic, 2013). Silver nanoparticle wool composites have been made by the reduction of silver ions in solution by trisodium citrate in solution with merino wool fibers or fabrics (Kelly & Johnston, 2011). This process creates a bind between the silver metal nanoparticles and the amino acids of the keratin protein in the wool fibers with the reducing agent functioning as the linker (Kelly & Johnston, 2011). Cotton fabrics also do not need pre-treatment to be able to load silver nanoparticles efficiently, even though 3-aminopropyltriethoxysilane has been used for surface modification with improved results (Guo et al., 2013; Ilic et al., 2009; Liu, Lee, Norsten, & Chong, 2013), but, the ability of cotton textiles to retain moisture leads to an excellent environment for growing microorganisms (C.-Y. Chen & Chiang, 2008). Because of surface charges, inorganic particles and polymeric materials, like manmade textiles, demonstrate repelling between silver and the fiber at the interface; this requires a modification be made to the surface, but this commonly washes away with laundering leading to leaching (Dastjerdi, Montazer, & Shahsavan, 2009). Chelating monomers, like glycidyl methacrylate-iminodiacetic acid, can be used to graft onto cotton fibers to increase the amount of Ag^+ sorbed. The Ag^+ can then be reduced by UV radiation to form silver nanoparticles on the surface (C.-Y. Chen & Chiang, 2008). Polyester and polyamide offer two synthetic options, and polypropylene fibers (PP) are widely used in the manufacturing of medical and hygienic textile materials where a high level of antimicrobial activity is required (surgical masks, diapers, hygienic bands, etc.) (Radetic, 2013). Figure 5 show untreated PP fiber as well as a PP fiber loaded with silver nanoparticles. Activated carbon fibers have high adsorption capacities and can be impregnated with silver. Because of the high adsorption capacity and large surface area, bacteria will breed on the activated carbon filter (Yoon, Byeon, Park, & Hwang, 2008). Silver-deposited activated carbon filters have been shown to be effective for air filters, but also have a low life expectancy with greatly decreasing performance quickly when used for water filtration (LePape et al., 2002, 2004; Yoon et al., 2008). When designing a method to incorporate silver nanoparticles with textiles, it is key to control the chemistry of the solution including the pH, ionic strength, and surface complexation (Yin, Walker, Chen, & Yang, 2014). A crosslinkable polysiloxane layer can be used to permanently modify the surface of polyester with a polymeric layer on the surface that is resistant to light, heat, chemical and microbial attacks making it safer during washing (Dastjerdi et al., 2009; Dastjerdi, Montazer, & Shahsavan, 2010).

Another way of synthesizing silver nanoparticles in textiles involves using Tollen's reagent; silver nitrate is combined with NaOH to form Ag_2O powder. An ammonia solution is added and sonicated to produce an aqueous solution of Tollen's reagent, a complex ion, $[Ag(NH_3)_2]^+$. Cotton fabric is soaked in a boiling bath of Tollen's reagent solution then washed with deionized water and dried at room temperature forming silver nanoparticles (Montazer, Alimohammadi, Shamei, & Rahimi, 2012). Using electrostatic interactions, cellulose can be modified to be positively charged by using an epoxy substitution reaction on the abundant hydroxyl groups on cellulose to graft ammonium ions. This now positively charged cellulose fiber surface can be involved in adsorption of either negatively charged metal complex ions followed by reduction or with metal nanoparticles capped with negative citrate ions (Dong & Hinestroza, 2009).

In efforts to take a more "green approach", natural extracts from *Eucalyptus citriodora* and *Ficus bengalenis* are used in production of silver nanoparticles. Silver nanoparticles are produced on cotton fibers by an aqueous silver nitrate solution with fresh leaf extract. The leaf broth reduces Ag^+ to silver nanoparticles through the interactions of functional groups present in the leaf extracts (Ravindra, Mohan, Reddy, & Raju, 2010). This does not require any harsh chemicals or dangerous byproducts in the production process. *Curcuma longa* tuber powder and extract have also been used for their water-soluble

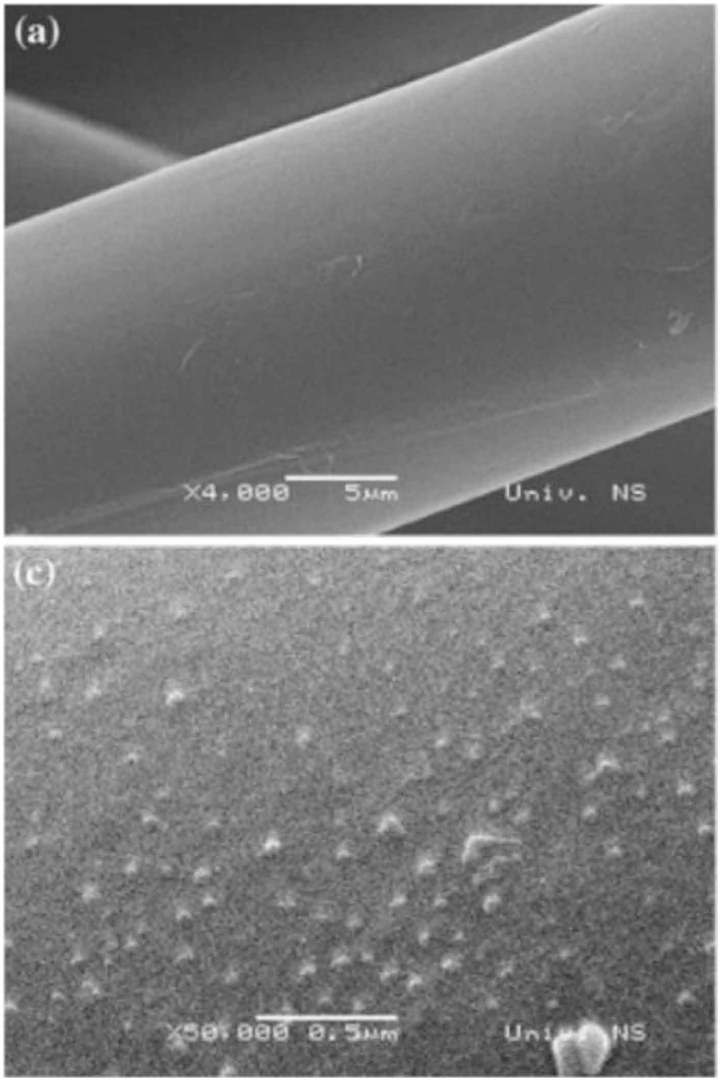
Figure 5. SEM image of untreated PP fiber and PP fiber loaded with AgNP (Radetic, 2013).



organics to reduce silver ions from aqueous silver nitrate to nano-sized silver particles on cotton cloth. The extract works better than the powder since there is more of the reducing agent to form the nanoparticles (Sathishkumar, Sneha, & Yun, 2010).

Low-temperature radio frequency plasma has been used to activate the surface of fibers for improved binding ability of colloidal silver nanoparticles onto polyester fabrics. The plasma treatment reduces the number of coatings necessary for the same level of antibacterial ability in half. These fabrics have been tested for antimicrobial ability as well as laundering ability and have proven to be an improved method. The antibacterial ability was tested against the common Gram-negative bacterium *E. coli* and Gram-positive bacterium *S. aureus* (Ilic et al., 2010).

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

As with papers, the cellulose structure of fabric can be used to soak the fabric in silver nitrate solution followed by either physical (heat/UV) or chemical (sodium borohydride) reduction (Fernández et al., 2009). Microwaves are a way of delivering irradiation and heat after soaking with a reducing agent, like sodium citrate (Guo et al., 2013). Mecha and Pillay uses a modified version of the Dankovich method described in the previous section on woven fabric for microfiltration membranes (T. A. Dankovich, 2014). This is a point-of-use filter that is gravity fed and has coated membranes that are hydrophilic and have high water permeability ($p<0.05$). Filtration of turbid water (40–700 NTU) produced clear permeate (<1 NTU) and treatment of water spiked with bacteria (2500– 77,000 CFU/100 mL *E. coli*) showed the removal efficiency of coated membranes was 100% (Mecha & Pillay, 2014).

It has been reported that silver-nanoparticle-coated textile fabrics possess antibacterial activity against *S. aureus*. Silver nanocomposite fibers have been made containing silver nanoparticles incorporated inside the fabric but scanning electron microscopy has concluded that the silver nanoparticles incorporated in the sheath part of fabrics possessed significantly better antibacterial ability compared to the fabrics with silver nanoparticles in the core. The same results came from silver nanoparticles on polyester nonwovens (Rai et al., 2009). Aqueous silver nitrate has been electrospun with polymers to create a fiber that is then reduce with UV irradiation to create silver nanoparticle fibers (Lala et al., 2007). These fibers could then be woven into a textile for use in filtration. An interesting application method has also been developed for applying silver to TiO_2 thin film. An aqueous solution of 1 M silver nitrate ($AgNO_3$) is mixed with ethanol and a 0.6 mL aliquot of the solution is uniformly cast on the TiO_2 thin film. The film is then irradiated with UV light for 1 min, to deposit Ag nanoparticles in the porous film by photocatalytic reduction of Ag^+. The resulting $Ag-TiO_2$ film is thoroughly rinsed with DI water and dried by blowing air with an electric duster (Naoi et al., 2004). Schoen et al., presents an interesting textile technology that combines several mechanisms into one process. It is a "textile based multiscale device for the high speed electrical sterilization of water using silver nanowires, carbon nanotubes, and cotton" (Schoen et al., 2010). This gravity fed device can operate at 100,000 L/(h m^2) while inactivating >98% of bacteria with only seconds of total incubation time. An electrical mechanism rather than size exclusion, allows for the flow to be fast but effective with a very high surface area and large electric field with silver nanowire (Schoen et al., 2010).

CONCLUSION AND FUTURE RESEARCH DIRECTIONS

Increasing the market penetration of point-of-use (POU) technologies will require continued development of inexpensive, easy to use, socially acceptable technologies that do not change the taste of water. These design efforts must be complimented by education and training. Current filtration technologies possess many of the requisite design criteria. Each of the technologies introduced in the chapter have their own strengths and weaknesses. Ceramics filters are the most widely used technology and have the most market penetration to date, but the fragile nature of ceramics makes brakeage a concern. Fabric filters can successfully remove copepods, reducing cholera, but their effectiveness against other pathogens is unknown. Adding silver to fabrics and evaluating performance and social acceptance would be a significant advancement. Paper filters are the least developed technology but may be effective once the proper way of incorporating the technology into household point-of-use is determined. The new method of silver incorporation by the reduction of silver nitrate in papers and ceramics also shows promise as a way to avoid harsh chemicals and the potential health risks of silver nanoparticles.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Moving forward, important work should also be done to understand the anti-bacterial activity of silver against all classes of bacteria (Pradeep & Anshup, 2009). New POU technologies, in addition to being effective, need to be culturally appropriate to encourage use and motivate the purchasing of the treatment system (D. S. Lantagne et al., 2006). An optimized POU technology should be easy to use, low maintenance, independent of energy and chemicals and have a low cost (Peter-Varbanets et al., 2009). Finding a technology that satisfies all these requirements is challenging. Other nanomaterials have proven effective against other waterborne pathogens and the potential for combination of silver with another metal could improve technologies (Ruparelia et al., 2008). Long term effectiveness is important, making the antifouling ability necessary (Praveena & Aris, 2015). Expanding production of, marketing and distributing any technology will also require research and knowledge of underlying economic factors (Sobsey et al., 2008). It has also been suggested that the introduction of multiple interventions to prevent the transmission of disease is the most effective way to improve the quality of all of the interventions (J. E. Mellor et al., 2012). Solving one point of exposure will not maximize effect. Multiple interventions to improve knowledge and treatments will have the most effect.

Chapter 75
Novel Bioremediation Methods in Waste Management: Novel Bioremediation Methods

Charu Gupta
Amity University, India

Dhan Prakash
Amity University, India

ABSTRACT

Bioremediation technologies are one of the novel methods in the field of waste and environment management and are presently gaining immense credibility for being eco-compatible. Bioremediation using microbes has been well accepted as an environment friendly and economical treatment method for disposal of hazardous petroleum hydrocarbon contaminated waste (oily waste). Besides this, earthworms can be used to extract toxic heavy metals, including cadmium and lead, from solid waste from domestic refuse collection and waste from vegetable and flower markets. Other novel methods used recently for treatment of wastes are plasma incineration or plasma assisted gasification and pyrolysis technology. The technologies applied for conditioning include ultrasonic degradation, chemical degradation, enzyme addition, electro-coagulation and biological cell destruction. Genetic engineering is another method for improving bioremediation of heavy metals and organic pollutants. Transgenic plants and associated bacteria constitute a new generation of genetically modified organisms for bioremediation.

1. INTRODUCTION

It is believed now that wastes are no longer treated as waste and they can be used as a valuable resource. Biomass can interact and confront with water and soil pollutants in both active (live) as well as passive (dead) way, thereby offering numerous opportunities of exploring them for environmental clean-up. With rapid increase in urban populations particularly in the developing world, there is a growing problem of how to manage organic waste and to find alternatives to landfill disposal particularly for domestic food

waste and that from vegetable markets. According to the research team, it is an unfortunate fact of life that much of this waste is currently dumped on the outskirts of many towns and cities and is causing serious pollution, disease risk and general ecological harm. It also represents a considerable wasted resource, whereas the organic matter might be exploited usefully in growing food crops (Glazer & Nikaido, 2007). Besides this, vast number of pollutants and waste materials containing heavy metals are also disposed into the environment per annum. Approximately 6 x 10^6 chemical compounds have been synthesized, with 1,000 new chemicals being synthesized annually. Almost 60,000 to 95,000 chemicals are in commercial use. According to Third World Network reports, more than one billion pounds (450 million kilograms) of toxins are released globally in air and water. The contaminants causing ecological problems leading to imbalance in nature is of global concern. Bioremediation is an option that offers the possibility to destroy or render harmless various contaminants using natural biological activity. As such, it uses relatively low-cost, low-technology techniques, which generally have a high public acceptance and can often be carried out on site (Vidali *et al.,* 2001). Compared to other methods, bioremediation is a more promising and less expensive way for cleaning up contaminated soil and water (Kamaludeen *et al.,* 2003). Bioremediation uses biological agents, mainly microorganisms, e.g. yeast, fungi or bacteria to clean up contaminated soil and water (Strong *et al.,* 2008). It results in the elimination, attenuation and/or transformation of polluting or contaminating substances by the use of biological processes.

1.1 Principles of Bioremediation

Bioremediation is defined as the process whereby organic wastes are biologically degraded under controlled conditions to an innocuous state, or to levels below concentration limits established by regulatory authorities (Mueller *et al.,* 1996). Most bioremediation systems are run under aerobic conditions, but running a system under anaerobic conditions may permit microbial organisms to degrade otherwise recalcitrant molecules. The microorganisms may be indigenous to a contaminated area or they may be isolated from elsewhere and brought to the contaminated site. Contaminant compounds are transformed by living organisms through reactions that take place as a part of their metabolic processes. Biodegradation of a compound is often a result of the actions of multiple organisms. When microorganisms are imported to a contaminated site to enhance degradation, the process is known as bio-augmentation. Since bioremediation mainly utilizes living organisms (plants) including microbes (bacteria and fungi) that degrade or detoxify substances hazardous to human health and environment. Microorganisms secrete extracellular enzymes that attack the pollutants and convert them into harmless products. Therefore bioremediation can be effective only where environmental conditions permit microbial growth and activity; its application often involves the manipulation of environmental parameters to allow microbial growth and degradation to proceed at a faster rate. For degradation it is necessary that bacteria and the contaminants should be in contact. This is not easily achieved, as neither the microbes nor contaminants are uniformly spread in the soil. Some bacteria are mobile and exhibit a chemotactic response, sensing the contaminant and moving towards it. Other microbes such as fungi grow in a filamentous form toward the contaminant. It is possible to enhance the mobilization of the contaminant utilizing some surfactants such as sodium dodecyl sulphate (SDS) (Hetherington et al., 2006). However, contaminants like chlorinated organic or high aromatic hydrocarbons are resistant to microbial attack and they are degraded either slowly or not at all. The main advantage of using bioremediation techniques is that they are more economical than the traditional methods of incineration and some pollutants can be treated on site thereby reducing exposure

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

risks for clean-up personnel and potentially wider exposure as a result of transportation accidents. Since bioremediation is based on natural attenuation it is considered more acceptable than other technologies (Glazer & Nikaido, 2007).

Besides this, earthworms can also be used to extract toxic heavy metals, including cadmium and lead, from solid waste from domestic refuse collection and waste from vegetable and flower markets. Three species of earthworm, *Eudrilus eugeniae*, *Eisenia fetida* and *Perionyx excavates* can be used to assist in the composting of urban waste and to extract heavy metals, cadmium, copper, lead, manganese, zinc, prior to subsequent processing. The process of vermicomposting in this way allows such waste materials to be remediated and the compost can be used subsequently in growing human food without the risk of accumulating heavy metals in crops (Kamarudheen et al., 2014).

2. FACTORS AFFECTING BIOREMEDIATION

The factors affecting bioremediation process include existence of a microbial population capable of degrading the pollutants; availability of contaminants to the microbial population; environment factors (soil type, temperature, pH and the presence of oxygen or other electron acceptors and nutrients).

2.1 Microbial Populations for Bioremediation Processes

Microbes are diverse in their habitat, they will adapt and grow at subzero temperatures, as well as extreme heat, desert conditions, in water, with an excess of oxygen, and in anaerobic conditions, with the presence of hazardous compounds or on any waste stream. Their main requirements are an energy source and a carbon source. Because of the adaptability of microbes they can be used to degrade or remediate environmental hazards. Aerobic bacteria recognized for their degradative abilities are *Pseudomonas*, *Alcaligenes*, *Sphingomonas*, *Rhodococcus* and *Mycobacterium*. These microbes degrade pesticides and hydrocarbons, both alkanes and polyaromatic compounds as they use the contaminant as sole source of carbon and energy (Vidali, 2001; Prescott, 2002). Anaerobic bacteria are not as frequently used for degradation as aerobic bacteria but some of them are used for bioremediation of polychlorinated biphenyls (PCBs) in river sediments, dechlorination of the solvent trichloroethylene (TCE) and chloroform. Ligninolytic fungi such as the white rot fungus *Phanaerochaete chrysosporium* have the ability to degrade an extremely diverse range of persistent or toxic environmental pollutants. They utilize the substrates such as straw, saw dust, or corn cobs.

Methylotrophs grow by utilizing methane for carbon and energy. The initial enzyme in the pathway for aerobic degradation, methane monooxygenase, has a broad substrate range and is active against a wide range of compounds, including the chlorinated aliphatic trichloroethylene and 1,2-dichloroethane (Glazer & Nikaido, 2007).

2.2 Environmental Factors for Bioremediation Processes

The growth and activity of the microorganisms must be stimulated to increase their population for bioremediation. It is achieved through 'bio-stimulation' that involves the addition of nutrients and oxygen to help indigenous microorganisms. These nutrients are the basic building blocks of life and allow microbes to create the necessary enzymes to break down the contaminants. All of them will need nitrogen,

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

phosphorous and carbon for their growth (Prescott, 2002). Microbial growth and activity is affected by pH, temperature and moisture. Although microorganisms have also been isolated in extreme conditions, most of them grow optimally over a narrow range, so that it is important to achieve optimal conditions. Hydrocarbons are readily degraded under aerobic conditions, whereas chlorinated compounds are degraded only in anaerobic ones. To increase the oxygen amount in the soil it is possible to till or spurge air. In some cases, hydrogen peroxide or magnesium peroxide can be introduced in the environment. Soil structure can be improved by adding gypsum and organic matter (Prescott, 2002). Nowadays, there are four main biological techniques used for treating soil and groundwater for stimulation of activity of indigenous microorganisms by the addition of nutrients, regulation of redox conditions, optimizing pH conditions; inoculation of the site by microorganisms with specific biotransforming abilities; application of immobilized enzymes; and use of plants (phytoremediation) to remove or transform pollutants (Vidali, 2001; Gupta, 2012). In the specific methods used for bioremediating contaminated soil and water, landfarming, composting, intrinsic bioremediation and slurry bioreactor are included.

3. BIOREMEDIATION STRATEGIES

3.1 *In-Situ* Bioremediation

Bioventing encourages the *in-situ* biodegradation of POLs (petroleum-oil-lubricants) by providing oxygen to microorganisms in the soil. The system supplies oxygen by injecting air directly into the residual contamination. Bioventing uses low airflow rates to provide only enough oxygen to keep up microbial activity. Optimal flow rates maximize biodegradation as vapors move slowly through biologically active soil while minimizing volatilization of contaminants. A basic bioventing system includes a well and a blower, which pumps air through the well and into the soil (Lee *et al.,* 2006). Biopile treatment is a full-scale technology in which excavated soils are mixed with soil amendments, placed on a treatment area, and bioremediated using forced aeration. The contaminants are reduced to carbon dioxide and water. The basic biopile system includes a treatment bed, an aeration system, an irrigation/nutrient system and a leachate collection system. Moisture, heat, nutrients, oxygen, and pH are controlled to enhance biodegradation. The irrigation/nutrient system is buried under the soil to pass air and nutrients either by vacuum or positive pressure. The treatment time is typically 3 to 6 months (Wu *et al*., 2009).

3.2 *Ex-Situ* Bioremediation

These techniques mainly involve the excavation or removal of contaminated soil from ground. Land farming is a simple technique in which contaminated soil is excavated and spread over a prepared bed and periodically tilled until pollutants are degraded. The goal is to stimulate indigenous bio-degradative microorganisms and facilitate their aerobic degradation of contaminants. In general, the practice is limited to the treatment of superficial 10–35cm of soil. Composting is a process by which organic wastes are degraded by microorganisms, typically at elevated temperatures in the range of 55° to 65°C. The increased temperatures result from heat produced by microorganisms during the degradation of the organic material in the waste. In windrow composting, firstly, contaminated soils are excavated and screened to remove large rocks and debris (Blanca *et al.,* 2007; 2008).The soil is transported to a composting pad with a temporary structure to provide containment and protection from weather extremes. Amendments (straw,

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

alfalfa, manure, agricultural wastes and wood chips) are used for bulking agents and as a supplemental carbon source. Soil and amendments are layered into long piles, known as windrows. The windrow is thoroughly mixed by turning with a commercially available windrow turning machine. Moisture, pH, temperature and explosives concentration are monitored. At the completion of the composting period, the windrows are disassembled and the compost is taken to the final disposal area. Biopiles are a hybrid of land-farming and composting. These are typically used for treatment of surface contamination with petroleum hydrocarbons. They are a refined version of land farming that tends to control physical losses of the contaminants by leaching and volatilization. Biopiles provide a favorable environment for indigenous aerobic and anaerobic microorganisms. Here engineered cells are used for construction of aerated compost piles (Fahnestock *et al.,* 1998). Bioreactors/ slurry reactors/ aqueous reactors are used for *ex situ* treatment of contaminated soil and water. It involves the processing of contaminated solid material (soil, sediment, sludge) or water through an engineered containment system. Slurry bioreactor creates a three-phase (solid, liquid and gas) mixing condition to increase the bioremediation rate of soil bound and water-soluble pollutants as a water slurry of the contaminated soil and biomass (usually indigenous microorganisms) capable of degrading target contaminants. In general, the rate and extent of biodegradation are greater in a bioreactor system than *in situ* or in solid-phase systems because the contained environment is more manageable and hence more controllable and predictable.

The first patent for a biological remediation agent was registered in 1974, being a strain of *Pseudomonas putida* (Prescott *et al.,* 2002) that was able to degrade petroleum. In 1991, about 70 microbial genera were reported to degrade petroleum compounds and almost an equal number has been added to the list in the successive two decades. These organisms belong to at least 11 different prokaryotic divisions (Glazer *et al.,* 2007).

4. NOVEL BIOREMEDIATION METHODS

4.1 Plasma Incineration

A novel method developed and used recently for treatment of wastes is plasma incineration or plasma assisted gasification. It uses plasma that causes the volatilization of solid waste materials under anaerobic conditions. The plasma generates a huge amount of energy which otherwise cannot be produced by nuclear fission/fusion. Under such extreme conditions, waste materials get decomposed and oxidized partially to harmless innocuous products like carbon monoxide, hydrogen and water. During this process the organic matter of waste is converted into synthetic gas called S*ynGas* while inorganic fraction is converted into an inert vitrified glass and thus no ash is left to be land-filled. The major advantages of this technology are that it reduces the production of exhaust gas and thus lessens the air pollution; toxic materials produced are entrapped and encapsulated thereby making easier and safer to handle; and finally equipment is compact so it takes a minimum space for large disposal wastes (Amin et al., 2012).

4.2 Pyrolysis Technology

Another recently developed method for bioremediation is Pyrolysis technology (developed by Energystics Technologies, Ltd). This method involves the use of electromagnetic waves (EM). Direct and concentrated electromagnetic waves are allowed to fall on solid, liquid or gaseous waste. This technology directly

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

couples electromagnetic energy with a target material to produce heat. When EM waves fall on the target, it absorbs energy producing temperature which is above the melting or vaporization temperature of target waste material. Such a high temperature causes the disassociation of strong molecular bonds in waste materials. This technology requires only a relatively small energy input because the technology does not utilize conductive medium. In order to demonstrate the effect of this technology on animal tissues, pyrolysis of beef carcass was done which resulted in complete dematerialization of the tissue leaving no residues or smoke. The major advantages of Pyrolysis technology are that it produces instantaneous but controllable heating and releases no harmful emissions (Shepera, 2004; Jones et al., 2004).

4.3 Conditioning

Conditioning is done to enhance the characteristics of bio-solids for their further processing. There are many conditioning technologies like ultrasonic degradation, chemical degradation, enzyme addition, electro-coagulation and biological cell destruction. These processes modify the inorganic and organic characteristics of waste which is critical to other processes (Hetherington et al., 2006).

4.3.1 Ultrasonic Degradation

This is the first step of the conditioning process. Solid wastes are subjected to acoustic waves to attain extremely high temperatures and pressures within biosolids. This result in the complete destruction of microbial cells due to shear stresses produced as a result of explosion of gas bubbles. This process is adjustable to high frequency and low frequency waves. The major advantages of this technique is that it causes an increase in rate of cell disruption, decrease in anaerobic digestion time, thereby reducing sludge quantity and increases the biogas production (Hetherington et al., 2006).

4.3.2 Chemical Cell Destruction

This process ensures disruption of the cell membrane of microorganisms in waste activated sludge process for the improved efficiency of anaerobic digestion and amount of biogas. The waste material is treated with caustic soda for about one hour. This causes the weakening of cell membrane of microorganisms and also decreases the viscosity of solution. For industrial scale treatment, MicrosludgeTM (Biocell) is used for this purpose. It uses industrial-scale high pressure homogenizer which causes a sudden and enormous pressure drop responsible for causing lysis of microbial cell in the sludge. This sludge is then liquefied, mixed with primary sludge followed by anaerobic digestion to produce biosolids and biogas (Hetherington et al., 2006).

4.3.3 Enzyme Conditioning

Enzyme conditioning is done with the help of microbes (both aerobic and anaerobic) that produces specialized enzymes (usually an enzyme mixture with specific nutrients like humic acids, amino acids) which degrade organic materials converting them into carbon dioxide and water. This method increases the dewaterability of biosolids and also reduces odours during digestion process (Hetherington et al., 2006).

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

4.3.4 Electro-Coagulation

This is the recently developed method where electric current is used to increase the rate of anaerobic digestion of waste material. The electric current so produced dissolves an anode (sacrificial anode) and releases chemically reactive aluminum into the wastewater stream. The positively charged aluminum ions attract very fine negatively charged ions and particles towards them resulting in agglomeration. As a result, the agglomerated particles increase in size and settle down due to their increased weight (Hetherington et al., 2006; Amin et al., 2012).

4.3.5 Biological Cell Destruction

This process involves the use of a chemical agent that possesses strong oxidation properties. The agent weakens the cell wall of bacteria. These processed bacteria are then returned back to the activated sludge process where they decompose into carbon dioxide and water.

4.3.6 Thermophilic Fermentation

This method utilizes the microorganisms to increase the rate of digestion process at high temperatures. Thus sewage sludge and other waste residuals are converted into a fertilizer grade product. Another technology called ThermoMaster™ process has been developed in which auto-heated aerobic digestion is operated at a relatively short residence time (30 hours) to maximize the production of single-cell protein using an influent waste material as a substrate. The solids thus obtained are dried and pelletized (Hetherington et al., 2006; Amin et al., 2012).

4.4 Anaerobic Digestion

The first phase consists of volatile fatty acid digester where digestion takes place at around 35°C. In the next phase, the temperature is further increased in a thermophilic range of 50-56°C where further digestion takes place under anaerobic conditions. In the final phase, the heating is slowed down till temperature reaches around 35°C. Recent advancements in technology have led to the use of ozone treatment for anaerobic digestion. The biosolids are first subjected to anaerobic digestion and then are passed into a reaction tank where they are exposed to low levels of ozone. Studies have shown that only 0.06g of ozone per gram of dissolved solids is sufficient to destroy the biological activity of digested biosolids. The ozone treated waste material is then sent to thickening tank followed and back to digester in which both ozone treated and non-ozone treated waste materials are mixed. After this, waste material is either sent for dewatering or for ozone treatment (Vranitsky & Lahnsteiner, 2002).

4.5 Electro Dewatering of Waste Material

Conventional dewatering technologies, such as centrifuges, belt filter presses, and rotary vacuum filters, are not effective methods for treating sewage sludge with high water content. Alternatively, waste material is subjected to direct current (DC) which in the initial stage causes particles to migrate to the oppositely charged electrode (electrophoresis). Due to electro-osmosis, cake formation occurs as ions migrate to the oppositely charged electrode. This technology is suitable for use in combination with conventional filtration (Kim et al., 2014).

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

4.6 Electroacoustic Dewatering

This is another method of dewatering waste where both electric field and ultrasound waves are used to increase the efficiency of dewatering. Electric field is used for electrophoresis and electro-osmosis whereas acoustic waves (sound waves) are used in maintaining electrical continuity throughout the waste material. The main advantage of using acoustic waves is that they decrease specific energy consumption, increases the filtration rate and helps to keep cathode clean (Hetherington et al., 2006).

4.7 Mechanical Freeze Thaw

In this process, the sludge is frozen followed by crushing and thawing under natural conditions. During freezing, the chemical bonds in the sludge are altered thus making removal of water easier.

The treated sludge is then subjected to conventional sludge dewatering equipment (Amin et al., 2012).

4.8 Hydrothermal Oxidation

This technology is also known as 'Supercritical water oxidation'. In this process, the water is heated and pressurized above the critical point at 374°C and 3,191 pounds per square inch (psi). Consequently, the solubility of organic substances and oxygen into water is significantly increased. The main advantage of this technology is that it decomposes organic matter completely and produces a high quality effluent (Amin et al., 2012).

4.9 Drying of Waste Material

Drying is done to remove the water from the waste residues collected from both domestic, industrial and agriculture waste. This reduces weight and volume with high solid percentage. Drying can be through direct or indirect heating. The different methods of drying are discussed below:

4.9.1 Belt Drying

It involves the use of two or more slow moving belts that are arranged in series. The air is supplied around the belts. The dewatered sludge is spread in the form of a thin layer on a belt to increase the surface area (Amin et al., 2012).

4.9.2 Direct Microwave Heating

This process involves the use of high-efficiency multi-mode microwave system which is specifically designed to remove moisture. It removes water and pathogens from dewatered sludge. This process is highly automated and can dry waste materials having an initial moisture content of 85% to a final moisture content of 10%. This technology has an added advantage that it has the capacity of about 100% pathogen without any change in its nutrient content (Amin et al., 2012).

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

4.9.3 Flash Drying

This method can dry waste material to up to 90% or more solids. Sludge containing water is fed into a centrifuge machine where dewatering takes place and its solid content reach up to 25% concentration. This material is then discharged into thermal stage as a fine-grained spray. Once the particles of solid waste enter thermal cyclone chamber, they get dried up instantly. These dried particles are then taken out of the chamber in a fraction of second, with the help of sweep gas. The sweep gas, drawn through ventilator fan is reheated in hot gas generator before re-entering into dryer loop (Amin et al., 2012).

4.9.4 Fluidized Bed Dryer

After the wet cake is formed, it is passed through the fluidized bed dryer where it comes into contact with already dried granules. Indirect heating is then applied by means of tubular heat exchangers that are immersed in fluidized layer of solids. The major advantages of this technology are that it can dry the sewage material up to 90% solid content (Amin et al., 2012).

4.9.5 Chemical Drying

This process involves the drying of solids through chemical reaction. The dewatered waste material is allowed to react with ammonium salts or anhydrous ammonia and concentrated organic acids like sulphuric acid and phosphoric acid. The reaction of ammonia with organic acids generates heat and during this reaction sulphates and phosphates are produced. The heat produced from the reaction is utilized for drying of waste materials. During this process, hard granular materials are produced that can be mixed with plant nutrients to raise their nutritive value (Amin et al., 2012).

5. BIOREMEDIATION BY GENETIC ENGINEERING

Biotechnological technique like genetic engineering can be used for improving bioremediation of heavy metals and organic pollutants. Transgenic plants and associated bacteria can be used to create genetically modified organisms for bioremediation by over-expressing the genes responsible for their metal-binding proteins or peptides that in turn enhance their heavy metal accumulation and/or tolerance. Furthermore transgenic algae and microorganisms mutated with bioluminescence genes can be used in bio-monitoring of organic and inorganic pollution. There are several approaches for the construction of GEMs for bioremediation application. First approach is the identification of organisms suitable for modification with the relevant genes, *e.g*. aquatic microbes can be used to develop GEMs for bioremediation of aquatic sources. The use of such organisms would avoid the supplementation of nutrients to the inoculated environment, thereby reducing the costs incurred and maintenance required. Scientists have developed *Anabaena sp.* and Nostoc *ellipsosporum* by the insertion of linA (from *P. paucimobilus*) and fcbABC (from *Arthrobacter globiformis*) respectively (Kulshreshtha, 2013). The second approach is the pathway construction, extension and regulation. GEMs have developed by improving existing catabolic pathways or to extend these pathways to degrade some more compounds which are not possible to degrade by using wild strain. The complete catabolic pathway may be encoded by a single microorganism, or by a consortium of microorganisms, each performing one or more of the stages of bioremediation of

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

xenobiotics. In this way, constructed GEMs possess the degradation capabilities of different microbial communities due to the alteration of gene sequences which further improve the efficiency and efficacy of the catabolic pathways (Kulshreshtha, 2013). Third approach is modification of enzyme specificity and affinity, e.g. *E. coli* strain is genetically modified to express a hybrid gene cluster for the degradation of trichloroethylene (TCE). Fourth approach is bioprocess development, monitoring, and control, and bioaffinity, bioreporter, sensor applications for chemical sensing, toxicity reduction, and end point analysis. Bioluminescence can be easily detected and do not require expensive devices, exogenous addition of chemicals or co-factors. Further, GEMs possess chemical sensors that allow the monitoring of contaminant bioavailability rather than just contaminant presence. Bioluminescence producing GEMs also help us to understand the spread of microbes in the polluted area and end point of the bioremediation (Kulshreshtha, 2013).

In a recent study, a *Pseudomonas putida* strain was genetically engineered for 1,2,3-trichloropropane bioremediation. 1,2,3-Trichloropropane (TCP) is a toxic compound that is recalcitrant to biodegradation in the environment. Attempts to isolate TCP-degrading organisms using enrichment cultivation have failed. Finally, the dehalogenase gene (dhaA31) was cloned and was introduced into the genome of strain MC4 using a transposon delivery system. Growth of the resulting engineered bacterium, *P. putida* MC4-5222, on TCP was observed, and all organic chlorine was released as chloride. The results demonstrated the successful use of a laboratory-evolved dehalogenase and genetic engineering to produce an effective, plasmid-free, and stable whole-cell biocatalyst for the aerobic bioremediation of a recalcitrant chlorinated hydrocarbon (Samin et al., 2014). Transgenic *Chlamydomonas* cells express metallothionin, a metal binding protein. These cells grow at normal rates in the presence of lethal concentrations of cadmium accumulating five-fold more cadmium compared to wild type cells. Mixotrophy in cyanobacteria and microalgae can provide many competitive advantages over bacteria and fungi in degrading persistent organic pollutants (POPs) (Subashchandrabose *et al.,* 2013).

6. BIOREMEDIATION USING EARTHWORMS (VERMICULTURE)

Earthworms could be used to extract toxic heavy metals, including cadmium and lead, from solid waste from domestic refuse collection and waste from vegetable and flower markets. Three species of earthworm, *Eudrilus eugeniae*, *Eisenia fetida* and *Perionyx excavates* are used to assist in the composting of urban waste and to extract heavy metals, cadmium, copper, lead, manganese, zinc, prior to subsequent processing. The process of vermicomposting in this way allows such waste materials to be remediated and the compost can then be used in growing human food without the risk of accumulating heavy metals in crops. Studies have shown that up to three-quarters of the various heavy metals can be removed by the worms from solid waste. The *E. eugeniae* species is the most effective worm at remediating solid waste and producing rich compost. Research has shown that the heavy metal content of such waste can be reduced to levels significantly below the permissible safe limits. The mechanism involved is because of worm's digestive system that is capable of detaching heavy metal ions from the complex aggregates between the ions and humic substances in the waste during the process of rotting. Various enzyme-driven processes leads to assimilation of the metal ions by the worms so that they are locked up in the organism's tissues rather than being released back into the compost as worm casts. The separation of dead worms from compost is a relatively straightforward process allowing the heavy metal to be removed from the organic waste (Science Daily, 2012). In a recent research, phenol bioremediation potential of Earthworms

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

was studied. Earthworms were maintained under proper growth conditions. Different concentrations of phenol ranging from 10ppm to 50ppm were taken for the assays. All the bioremediation assays were done in the soil with phenol dispersed in water and remediation rates were observed for 24 hours, 48 hours, 72 hours, 96 hours and 120 hours. The initial concentration of phenol was increased eventually and the rate of bioremediation was estimated using 4-amino anti-pyrine method. The phenol degradation activity of the gut microflora of the earthworm along with the soil microflora was also observed on a formulated media. The amount of phenol bioremediated was found higher in case of earthworm and not the microflora solely. It was found to be 30 ppm in 48 hours when the initial concentration was 50 ppm (Kamarudheen et al., 2014). In another study, the earthworms' capacity to remediate the quality of soils polluted with heavy metals (Zn, Cu, Mn, Pb) as a result of using the swine residual water in agriculture ($50\ m^3\ ha^{-1}$) was distinguished. The study has been conducted in a Chernozem (FAO System), in a culture of *Zea mays* L. The collected data consisted of soil analyses and tissue analyses to establish the heavy metal uptake by earthworm species. Determination of the heavy metal contents of soil has been realized on two depth intervals: 0-10 cm and respectively 10-20 cm, through the method of flame atomic absorption spectrometry. Earthworm extraction was done using formaldehyde according to the methodology in force at six months since the residual water has been applied on soil. Both for earthworm number and earthworm weight there were significant differences (<0.05) between the values recorded in controls and treatments, i.e. the earthworm number considerably increased in the variants fertilized with swine residual water and also the earthworm weight, which confirm the earthworm preference for the organic matter provided by the residual water. Also there were significant differences (<0.05) between the three analyzed earthworm species regarding the accumulation process of the investigated microelements and, among them, *Lumbricus rubellus* showed in its tissues the lowest concentration of microelements and *Allolobophora rosea* the highest concentrations. There were also much lower concentrations of the studied microelements in the earthworm tissues as compared with the adjacent soil in all analyzed species, and among them there was recorded the lowest content of heavy metals in *Lumbricus castaneus*. This aspect and also the fact that this species has been the best represented as numeric abundance in the experimental soil confirm the good capacity of this species to tolerate the presence of the heavy metals in soil and to metabolize them with the soil ingestion within the feeding process. The results of this study support the idea claiming the earthworms' bioremediator potential of the soils polluted with heavy metals, as a possibility to restore their quality by maintaining in appropriate levels the earthworm populations in the agricultural lands. These findings also come to sustain the specialization of this role on earthworm species (Iordache & Borza, 2012).

7. DUCKWEEDS FOR PHYTOREMEDIATION

Effective wastewater treatments through conventional methods that rely on heavy aeration are expensive to install and operate. Duckweeds are capable of recovering or extracting nutrients or pollutants and are an excellent candidate for bio-remediation of wastewaters. Such plants grow very fast, utilizing wastewater nutrients and also yield cost effective protein-rich biomass as a by-product. Duckweeds being tiny surface floating plants are easy to harvest and have an appreciable amount of protein (15%–45% dry mass basis) and a lower fiber (7%–14% dry mass basis) content. Besides nutrient extraction, duckweeds have been found to reduce total suspended solids, biochemical oxygen demand (BOD), and chemical oxygen demand in wastewater significantly. Depending on the initial concentrations of nutrients, duckweed-covered

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

systems can remove nitrate at daily rates of 120–590 mg NO_3^- m^{-2} (73%–97% of initial concentration) and phosphate at 14–74 mg PO_4m^{-2} (63%–99% of initial concentration). Removal efficiencies within 3 days of 96% and 99% have been reported for BOD and ammonia. Besides several genera of duckweeds (*Spirodela, Lemna, Wolffia*), other surface-floating aquatic plants like water hyacinth (*Eichhornia*) are well known for their phyto-remediation qualities (Gupta & Prakash, 2014). Duckweed culture is an eco-friendly approach of phyto-remediation which will not only help in free-of-cost extraction of nutrients in the form of protein-rich biomass but also bio-remediate the ponds, lakes, and other water bodies and make them a more suitable water resource for aquaculture. Wastewater-duckweed-carp poly-culture makes the perfect integrated package for pollution control and re-use of recovered nutrients. Moreover, in view of increased pressure on land over the years for production of food and fodder (due to ever increasing population, urbanization, industrialization, etc.), utilization of an alternate resource for the purpose makes sense. In this direction, duckweed culture holds ample scope not only for high quality food production through aquaculture but also releasing pressure on the underground water resources (Gupta & Prakash, 2014).

8. MUSHROOMS AND BIOREMEDIATION

Spent mushroom compost is generated as waste after the harvesting of mushroom crop. Recently, it is proposed to call it as "post mushroom substrate" because it is not really spent and has many uses. The composition of spent mushroom substrate varies depending on the type of mushroom to be cultivated and substrate used. It is proved as an excellent source of humus, although much of its nitrogen content has been used up by the growing mushrooms. It remains a good source of general nutrients (N, P, K along with trace elements) which makes it well suited for supporting plant growth (Svoboda et al., 2002). Mushrooms are found to possess the two basic abilities of biodegradation and bioaccumulation for the bioremediation of waste. Biodegradation ability of mushrooms is due to the presence of many enzymes involved in the degradation of pollutants and solid waste residues though the extent and safe level is unknown. Moreover, mushrooms are known for the bioaccumulation of pollutants or heavy metals from the habitat in which they are growing. Mushroom possesses a very effective mechanism that enables them to take up some trace elements from the substrate. Heavy metal accumulation ability of mushroom has been studied by the number of authors (Kala & Svoboda, 2000; Svoboda et al., 2002; Kulshreshtha & Sharma, 2014).

9. BIOREMEDIATION OF PLASTIC AND RUBBER BY ENDOPHYTIC FUNGI

The massive and rapid accumulation of plastic and rubber waste is a problem that cannot be ignored. While there has been an enormous boom in synthetic polymer production, methods of treating these materials after disposal have not been able to keep up. Since several types of plastic and rubber contain the same chemical bonds that are found in natural plant polymers, specific attention is given to the ability of endophytes, organisms that grow symbiotically inside plants, to degrade synthetic plastic and rubber. The endophytic fungus *Pestalotiopsis microspore* has previously been identified in the degradation of the plastic polyester polyurethane. This fungus secretes a small enzyme that is responsible for plastic degradation (Legaspi & Elaine, 2014).

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

10. BIOREMEDIATION THROUGH MICROBES: GROWTH PARAMETERS

Most bioremediation systems work under aerobic conditions, but recalcitrant molecules are degraded by microbial organisms only under anaerobic conditions. Bioremediation depends on various parameters: nature of pollutants, soil structure, pH, moisture content and hydrogeology, nutritional state, microbial diversity of the site, temperature and oxidation-reduction (redox-potential) (Dua *et al.,* 2002). In bioremediation processes, microorganisms use the contaminants as nutrient or energy sources (Tang *et al.,* 2007). Bioremediation activity through microbes is stimulated by supplementing nutrients (nitrogen and phosphorus), electron acceptors (oxygen), and substrates (methane, phenol, and toluene), or by introducing microorganisms with desired catalytic capabilities (Ma *et al*., 2007; Baldwin *et al.,* 2008). Plant and soil microbes develop a rhizospheric zone which is also used as a tool for accelerating the rate of degradation or to remove contaminants. In addition to this, aromatic compounds are persistent environmental pollutants that are widely distributed in the biosphere due to anthropogenic activities. These compounds are highly toxic to living beings; therefore, many of them have been listed as priority pollutants by Environmental Protection Agency. Microbial degradation has emerged as an effective technology to remove these compounds from environment. Many microbial enzymes such as oxygenases, dehalogenases, reductases, hydroxylases and dehydrogenases are involved in the degradation of these environmental pollutants. Among them, oxygenases are the key enzymes for aerobic biodegradation of aromatic compounds because they are involved in the initial reaction of degradation and also catalyze the ring cleavage of the aromatic compounds which is the essential step for the complete mineralization of these compounds (Arora *et al.,* 2009). Oxygenases catalyze insertion of one or two oxygen atoms into the substrates. Two classes of oxygenases have been identified based on number of oxygen atom used in the oxidation: mono-oxygenases and dioxygenases. Monooxygenases incorporate one atom of the oxygen into the substrate whereas dioxygenases add both atoms of the oxygen (Arora *et al.,* 2009).

11. PROS AND CONS OF BIOREMEDIATION

Bioremediation is a natural process and is therefore perceived by the public as an acceptable waste treatment process for contaminated material such as soil. The residues for the treatment are usually harmless products and include carbon dioxide, water and cell biomass. Theoretically, bioremediation is useful for the complete destruction of a wide variety of contaminants. Many compounds that are legally considered to be hazardous can be transformed to harmless products. This eliminates the chance of future liability associated with treatment and disposal of contaminated material. In bioremediation, there is no need of transferring contaminants from one environmental medium to another and the complete destruction of target pollutants is possible. Bioremediation can also be carried out on site, without causing a major disruption of normal activities. This also eliminates the need to transport quantities of waste off site and the potential threats to human health and the environment that can arise during transportation. Bioremediation can prove less expensive than other technologies that are used for clean-up of hazardous waste (Dua et al., 2002).

The major con of bioremediation is that the process is limited to those compounds that are biodegradable. Not all compounds are susceptible to rapid and complete degradation. There are some concerns that the products of biodegradation may be more persistent or toxic than the parent compound. Biodegradation process is a natural phenomenon and is highly specific. There are major site factors required

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

for complete biodegradation that include the presence of metabolically capable microbial populations, suitable environmental growth conditions, and appropriate levels of nutrients and contaminants. Biodegradation is often difficult to extrapolate from bench and pilot-scale studies to full-scale field operations. Research is needed to develop and engineer bioremediation technologies that are appropriate for sites with complex mixtures of contaminants that are not evenly dispersed in the environment. Contaminants may be present as solids, liquids, and gases. Bioremediation often takes longer than other treatment options, such as excavation and removal of soil or incineration. Regulatory uncertainty remains regarding acceptable performance criteria for bioremediation. There is no accepted definition of "clean", evaluating performance of bioremediation is difficult, and there are no acceptable endpoints for bioremediation treatments (Dua et al., 2002).

12. CONCLUSION

Environmental pollution affects quality of life and environmental ecosystem. Since decades, many attempts are being done to reduce environmental pollution. Among these attempts bioremediation is one of the good remedial techniques. Bioremediation technique involves the use of microorganisms to reduce the toxicity of harmful wastes and heavy metals from contaminated wastes water. Some other methods of bioremediation are by using earthworms (vermiculture), duckweeds and mushrooms, thermophilic fermentation or by genetically engineered microbes including endophytic fungi for biodegrading plastic wastes. Recently bioremediation is used in combination with other physical and chemical methods such as plasma incineration, pyrolysis, conditioning, electro-coagulation, electroacoustic dewatering, mechanical freeze thaw, hydrothermal oxidation, flash drying, microwave heating, fluidized bed dryer, and chemical drying. Bioremediation can thus be proved as a problem solving approach in the field of solid waste by detoxifying wastes. Due to its cost effectiveness and lesser environmental impact, it offers an attractive and more conventional clean-up technology.

Chapter 76
Modeling of Polypropylene Modified Bitumen Mix Design Results Using Regression Analysis

Kaval Chhabra
VIT University, India

Divesh Agrawal
VIT University, India

Saladi S. V. Subbarao
VIT University, India

ABSTRACT

This study investigates the effects of mixing Polypropylene waste plastics in the bituminous mix for the design of Flexible Pavement. Since, obtaining Marshall Test results from the bituminous mix is time-consuming, so if the practitioners measure the values of stability and flow by mechanical testing, other computations can be done by applying simple mathematical calculations. So, this study carried out stability and flow tests on different specimens made with varying bitumen and polypropylene plastic content. From the initial test results, the optimum bitumen and plastic contents are found. Further, the test results obtained from Marshall Test are modelled by identifying various input variables, which are various physical properties of the mix such as plastic content, bitumen content, air voids and unit weight. The regression modeling framework is adopted in this study to predict the Marshall stability and flow value. Since the developed models have yielded good results, these can be effectively used in parameter estimation, and thus aids the future researchers.

INTRODUCTION

The rapid growth in industrialization coupled with population growth has led to enormous rise in production of various types of wastes worldwide. In a recent study concerning the top 20 countries that have dumped the most plastic waste into the oceans, India (at 12th) is one of the worst performers. It has dumped up to 0.24 million tons of plastic waste into the ocean every year, thereby polluting the natural resources. One recent study (2014-15) reported that approximately 8 kg of waste plastics dumped by the each individual in India. These plastic wastes are needed to be recycled, if not, it gets disposed by the available waste disposal techniques like Land filling and Incineration. Though these techniques have been widely in use but these too have certain impacts on the environment which are discussed as under.

Land filling refers to a process of disposal wherein the waste materials are buried in a specific area that is situated far away from the city. This process has certain impacts on the environment like affecting water recharge, reducing soil microbial activity, and also it leads to drainage and water line clogging. Such clogging in turn leads to production of gases such as methane, which affects Greenhouse effect. Also, land availability for filling is a major point of concern. Further, Incineration refers to a process of burning the wastes above 700°C. Incineration of polymers like polypropylene, polystyrene, etc. evolves gases like CO_2, CO etc. which in turn causes global warming, pollution. If polyvinyl chloride mixes with the waste, it results in the production of Chlorine, HCl and sometimes Dioxin which is a carcinogenic and a poisonous gas. In fact, this process requires scientific monitoring and it can accentuate pollution problems, if strict standards aren't being enforced.

Since both landfilling and incineration have certain negative impact on the environment. Under these circumstances, an alternate use for the waste plastics is the need of the hour. Several investigations in India and many other countries have revealed that properties of bituminous mixes can be enhanced to meet the present requirements of pavement with the inculcation of certain additives in bituminous mixes. These additives are termed as "Bitumen Modifiers" and the bitumen that is premixed with these modifiers is termed as "Modified Bitumen". Modified bitumen is expected to provide higher strength and durability depending upon the type of additives used and modification process involved. The time period of next renewal is expected to be extended by 50 percent in case of surfacing with modified bitumen in comparison to normal period specified for conventional bituminous mix. Certain Performance analysis studies undertaken under the protection of Central Road Research Institute, New Delhi; Highway Research Station, Chennai; Rubber Board, Kottayam (Kerala); Ministry of Road Transport and Highways, New Delhi; Kerala Public Works Department and Gujarat Engineering Research Institute, Vadodara have revealed that the usage of Modified Bitumen in construction as well as maintenance of bituminous roads is quite cost effective, when life-cycle cost is taken under consideration.

Plastic waste when mixed with hot bitumen, it melts to form an oily coat over the aggregate and the mixture is laid over the road surface as similar as a normal tar road. The plastic waste can be effectively used as a binder material in flexible pavements. They may be used to enhance strength, enhance fatigue resistance to deformation and thus makes the pavements more durable. Plastic coated bitumen can result in higher stiffness than that of conventional bitumen, but without undergoing a large increase in flexibility.

PAST RESEARCH ON MODIFIED BITUMEN

Since last few decades, researchers are focussing more on usage of modified bitumen in pavement construction. In this process, modifying the properties of bitumen by using waste plastics is gaining importance due to its nature of enhancing the strength and economical mix. Kumar et al. (2003) reported that there occurs comparatively plastic bitumen blends less than that of neat bitumen, as observed during thin film oven test, which in turn controls the premature failure of a flexible pavement due to cracking. There is significant improvement in the indirect tensile strength and a considerable reduction in the rutting characteristic of the modified mixes prepared as compared to conventional ones. It has been reported that the Marshall Stability value of modified bituminous mix modified with 5 per cent of waste plastics increased by about 23%. Vasudevan et al. (2006) reported that even though Plastics-Modified-Bitumen (PMB) improves the quality of the roads and associated properties, the process (dry or wet process of mixing) of using these plastics for blending decides the enhanced strength of the bonding. Dry process is far better process than wet process. They also reported that polymer will not be leaching out after laying the road using waste plastic coated aggregate bitumen mix. Rajmane et al (2007) conducted a study on effective utilization of waste plastic in construction of flexible pavement for improving their performance and have found out that Plastic roads would be a boon for India's hot and extremely humid climate, where temperatures frequently cross 50°C and torrential rains create havoc, leaving most of the roads with big potholes.

Vasudevan (2007) has emphasized upon the use of dry process of mixing over wet process because bitumen binding strength in the Wet process is less compared to Dry Process. Reena Gupta et al (2011) worked upon a novel approach to improve road quality by utilizing plastic waste in road construction and have found out that no toxic gas is produced as the maximum temperature to coat the aggregates is 150-160 degree C in technology related to dry process of plastic waste utilization. Jalal J. Jafar (2015) under his study for Utilisation of Waste Plastic in Bituminous Mix for Improved Performance of Roads has proposed a mechanism to explain the effect of the chemical additives on the increase in the stiffness of the bituminous mixture which attributed to an increase in the bonding forces between the aggregates and the bitumen. Further, SerkanTapkın et al (2009) conducted a study on Prediction of Marshall test results for polypropylene modified dense bituminous mixtures using neural networks and have found that the addition of polypropylene fibres results in the improved Marshall Stabilities and Marshall Quotient values.

Though the above studies reported substantial literature on utilization of waste plastics for modifying the properties of bitumen in order to enhance the strength of the bitumen mix, still there is a scope for investigating the changes in properties of bitumen after adding the polypropylene plastics.

PROVEN CASE STUDIES ON UTILIZATION OF MODIFIED BITUMEN IN INDIA

Several live projects have been reported in India for effective utilization of modified bitumen in flexible pavement design. Some of the studies are reported in this section.

1. Laboratory studies have been carried out at the Centre for Transportation Engineering of Bangalore University, in which the waste plastic was used as an additive to heated bitumen in different proportions (ranges from zero to 12% by weight of bitumen). The results from these laboratory inves-

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

tigations reported that, the addition of waste plastic of about 8.8% by weight of bitumen, helps in substantially enhancing the strength, stability, fatigue life and many other desirable properties of bituminous mix, even during adverse water-logging conditions. The addition of 8.0% by weight of waste plastic for the preparation of modified bitumen resulted in a saving of 0.4% bitumen by weight of the mix or about 9.6% bitumen per cubic meter of bituminous mix.

2. In the state of Tamil Nadu, length of roads around 1000 m in various stretches have been constructed using waste plastic as an additive to bituminous mix under the scheme of "1000 km Plastic Tar Road", and it was found that, the performance characteristics of all the road stretches are satisfactory.
3. The performance characteristics of the road stretches constructed using waste plastic in Karnataka are also found to be satisfactory.

The construction of roads using Waste Plastics in the above states was based on the guidelines developed by Bangalore University and College of Engineering, Madurai. However, standard specifications are not available on the use of waste Plastic in Bituminous road Construction. So in this regard, IRC was specially requested by NRRDA for the preparation of such Guidelines for enabling the construction of these Rural Roads under PMGSY using Waste Plastic. In order to facilitate the development of Guidelines for this, an Expert Group was appointed by NRRDA for the preparation of interim guidelines for the usage of plastics which would be sent to IRC for further approval.

It is quite evident that the above studies reported on utilizing the waste plastics in flexible pavement design, but most of these studies followed the laborious experiments for calculating the Marshall Stability and flow value. Hence, by keeping this in mind, this study concentrated on developing a model for the estimation of Marshall Stability, so that the model results serves as an aid for future researches in this area.

GOALS AND OBJECTIVES

Motivation behind the study is too efficiently utilise the waste plastic in a constructive and a cost effective manner so that it can be beneficial to the society. Main objective of the current project work are:

1. To identify the optimum proportion of waste plastic that is to be added in the bituminous mix for getting the desired strength.
2. To compare the experimental results with the conventional pavement details and perform the analysis.
3. To prepare a statistical model to analyse the parameter dependencies and generate a relation between dependent and independent variables.
4. To assess the extent with which various physical properties of constituents affecting the stability and flow.

METHODOLOGY

Plastic Aggregate Bitumen Interaction Model

The shredded plastics when sprayed over the hot aggregate melt and spread over the aggregate in the form of a thin coating at the aggregate surface. When the aggregate is heated around 160°C, the coated plastics remains in the softened state. Over these coated aggregates, hot bitumen (heated at 160°C) is added. The added bitumen then spreads over the aggregate. At this temperature both the coated plastics and bitumen are in the liquid state and so are capable of easy diffusion at the interphase. This process is further aided by the increase in contact area. These observations may be reported as follows- Waste polymers i.e. polypropylene are hydrocarbons with long chains and the bitumen is a complex mixture of asphaltenes and maltenes that are also long-chain hydro carbons. When bitumen gets mixed with plastic coated aggregate a percentage of bitumen diffuses through the plastic layer and binds with aggregates. The plastic layer has already strongly bonded with aggregates. During this phase, a three-dimensional internally cross linked network structure develops between bitumen constitutes and polymer molecules. Therefore, the bonding becomes stronger and removal of bonded bitumen becomes hard.

Materials Used in the Study

1. **Aggregate:** Stones passing through 12.5mm sieve and retained on 10mm sieve; Sand.
2. **Bitumen:** VG30 Bitumen Grade.
3. **Waste Plastic:** Polypropylene (PP) waste plastic in the shredded form (2.36 to 4.75mm).

Process Description

As indicated in the flow chart, the primary step is the material procurement wherein the different constituents like aggregates, bitumen and waste plastic are collected in the desired form and quantity. Aggregates composed of stones that are retained on 10 mm sieve but passed through 12.5 mm sieve; and sand. The grade of bitumen used in this study is VG30 grade bitumen (i.e. 50-70 penetration grade bitumen). Polypropylene waste plastics have been used in shredded form (2.36mm to 4.75mm). Shredding of these plastics has been done in a plastic factory in Vellore. The choice of Polypropylene types of waste plastics was based on the availability, suitability and its efficient properties. Not all types of waste plastics can be used in flexible pavement design. Plastics like Polyvinyl chloride can't be used for this purpose due to the release of harmful gases on its applications.

The next step is to find out various physical properties of the constituents, using laboratory testing. These physical properties of constituents are tested in order to assure that the selected constituents are suitable pavement design. Following this, Marshall Specimens have been prepared varying the percentages of plastic and bitumen and then the results obtained from the modified bitumen have been compared with that of conventional bitumen. The main objective of this test was to obtain the Optimum contents of Bitumen and Plastic in order to get the desired strength. Post analysis have been done using Regression modeling that yielded a relationship between parameters and this relationship was then used to perform sensitivity analysis.

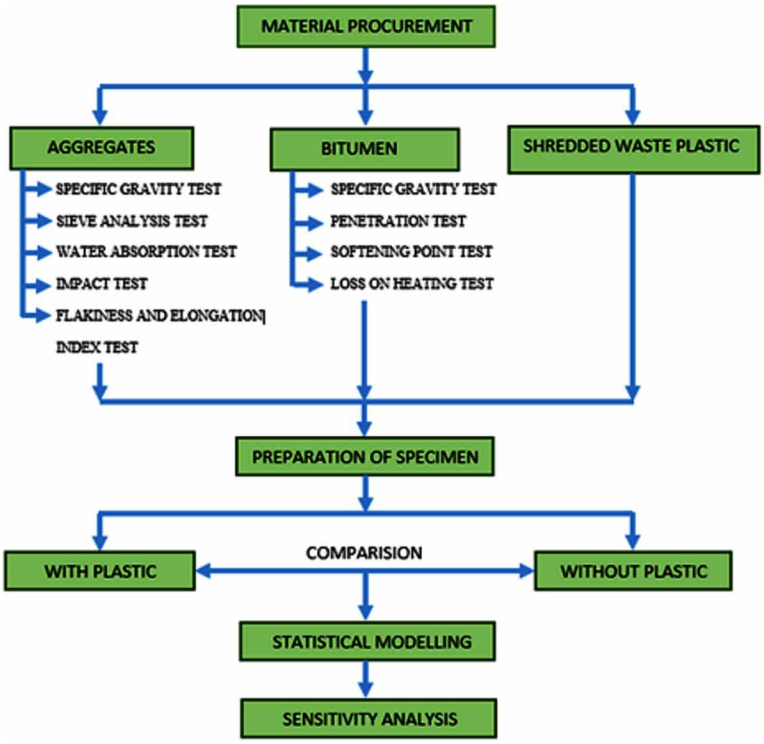
Figure 1. Shows the detailed methodology which was followed in this study



Processes for Manufacturing Bituminous Mix Using Waste Plastic

There are two different processes namely, dry process and wet process used for design of bituminous mix flexible pavement. However, this study uses the dry Process of Mixing due to following reasons:

1. Advantage of Dry Process Over Wet Process:
    a. Harmful gases are not evolved in dry process as no burning of the plastic waste is done.
    b. Dry process is simple while the wet process is complex.
    c. Ease in handling in case of dry process as the dealing is done with the normal dry shredded waste plastic unlike the wet process wherein the dealing is done with the hot molten waste plastic.
    d. Unlike wet process, there is no risk of uneven mixing of molten plastic and bitumen and thus there will not be any loose binding of aggregates.

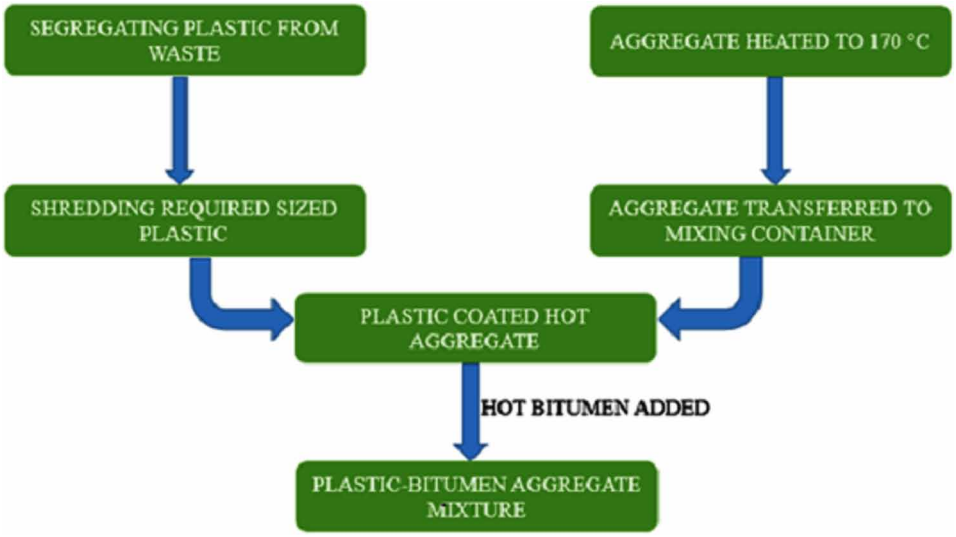
Figure 2. Shows the steps involved in dry process of mixing



EXPERIMENTATION

Tests on Aggregates

1. **Specific Gravity:** It is the ratio of the weight of a given volume of aggregate to the weight of an equal volume of water. It is considered to be a measure of strength or quality of the material. Stones having low specific gravity are generally weaker than those with higher specific gravity values. The specific gravity of coarse aggregates used is found out to be 2.5g/cc. The specific gravity of aggregates normally used in road construction ranges from about 2.5 to 3 with an average of about 2.68.
2. **Sieve Analysis Test:** A sieve analysis (or gradation test) is a laboratory procedure used to assess the particle size distribution (also called gradation) of a granular material. The size distribution is of critical importance as it is an indicative to the way the material performs when in use.
3. **Water Absorption Test:** Aggregate absorption is the increase in mass due to water in the pores present in the material. Aggregate absorption is a useful quality measure because:
   a. High values of water absorption can indicate non-durable aggregate.
   b. Absorption also indicates the amount of asphalt binder the aggregate will absorb.
   c. Water absorption is found out to be 0.9%. According to IRC, the maximum allowable limit of water absorption for any aggregate used in highway construction should not exceed 2% by weight of aggregates.
4. **Impact Test:** Aggregates should be tested for their resistance against shock or impact loads caused due to the movement of vehicles at high speeds. Aggregate impact strength is found out to be 11.64%. According to IRC, the maximum allowable aggregate impact is 30%.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

5. **Flakiness and Elongation Test:** Flakiness index is the percentage by weight of flaky aggregates whose least thickness is less than 0.6 times the average size of the aggregate. Elongation index is the percentage by weight of aggregates whose longest dimension is more than 1.8 times the average size of aggregate. The combined flakiness and elongation index is found out to be 24%. According to IRC, the maximum allowable combined flakiness and elongation indices is 30%.

Tests on Bitumen

1. **Specific Gravity:** It is the ratio of mass of a given volume of bitumen to the mass of an equal volume of water, both taken at a specified temperature. The specific gravity of pure bitumen ranges from 0.97 to 1.02. The specific gravity of bitumen used is found out to be 0.99 g/cc. According to Indian standards (BIS), minimum specific gravity of paving bitumen at 27℃ shall be 0.99.
2. **Penetration Test:** Penetration value is a measure of hardness or consistency of bituminous material. It is the vertical distance penetrated or traversed by the point of a standard needle into the bituminous material under specific conditions of load, temperature and time. This distance is measured in one tenths of a millimetre. This test is an indicative of consistency of bitumen. Higher penetration values implies softer grade bitumen. Penetration value of bitumen used is found out to be 52.
3. **Softening Point Test:** The Softening Point of bitumen is the temperature at which the substance attains particular degree of softening. As per IS: 334-1982, it is the temperature in ℃ at which a standard ball passes through a sample of bitumen in a mould and falls through a height of 2.5 cm, when heated under glycerine or water at specified conditions of test. The binder should possess sufficient fluidity before its application in road uses. The softening point is an indicative of the temperature up to which a bituminous binder should be heated for various road-use applications. The softening point of bitumen used is found out to be 35℃.
4. **Loss on Heating Test:** The loss in weight (exclusive of water) of bituminous materials when heated is called loss on heating of bituminous materials. The loss on heating is observed to be 0.4%. According to IRC, the maximum allowable value of matter loss by heating should not exceed 1%.

Tests Results

From the tests conducted, it can be obtained that the given materials meet the desired specifications and hence can be successfully used in further study.

Table 1. The test results for bitumen tests

S. No.	Tests	Results	Permissible Limits	IS Code
1	Specific gravity test	0.99 g/cc	0.97 g/cc to 1.02 g/cc	IS 1202
2	Penetration test	52	50 to 70 (VG30)	IS 1203
3	Softening point test	35℃	40℃ to 50 ℃	IS 1205
4	Loss on heating test	0.4%	≤ 1%	IS 1212

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 2. The test results for aggregate tests

S. No.	Tests	Results	Permissible Limits	IS Code
1	Specific gravity test	2.5 g/cc	2.5 to 3.0	IS 2386 Part II
2	Sieve analysis test	Uniformly graded	-	IS 2386 Part I
3	Water absorption test	0.9%	≤ 2%	IS 2386 Part III
4	Impact test	11.64%	≤ 30%	IS 2386 Part IV
5	Flakiness and elongation index test	24%	≤ 30%	IS 2386 Part I

Marshall Test

This test is used to measure the resistance to plastic deformation of a compacted cylindrical specimen of bituminous mixture when the specimen is diametrically loaded at a deformation rate of 5 cm per minute. The Marshall stability of a mix is defined as the maximum load carrying capacity of the specimen at a standard test temperature of 60°C. The flow value is defined as the deformation that the test specimen undergoes during loading up to the maximum load. Flow is measured in 0.25 mm units. In this test, Marshall Specimens are prepared varying the bitumen and the plastic content in order to find the optimum bitumen content and the optimum plastic content. All the samples are prepared as per the guidelines given in ASTM D1559. Cylindrical moulds (10cm diameter and 7.5cm in height) consisting of a base plate and collar extension have been used.

Steps of Design

1. Determine the proportion of coarse and fine aggregates to be used as per the desired grading.
2. Determine the specific gravity of each of the constituents: aggregate constitutes, bitumen and the waste plastic.
3. Prepare the trial mixes by varying the bitumen and the plastic content.
4. Measure the specific gravity of compacted specimens.
5. Perform the stability test on specimens.
6. Compute percentage air voids, voids filled with bitumen and voids in mineral aggregates for each specimen.
7. Record the optimum bitumen content and the optimum plastic content from the data obtained.
8. Evaluate the design and perform analysis.

Formulae Used in the Study

$$G_m = \frac{W_a}{W_a - W_w} \tag{1}$$

where,

G_m = Bulk or actual specific gravity (g/cc)

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

W_a = Weight of compacted specimen in air (Kg)
W_w = Weight of compacted specimen in water (Kg)

$$G_t = \frac{W_1 + W_2 + W_3 + W_b}{\frac{W_1}{G_1} + \frac{W_2}{G_2} + \frac{W_3}{G_3} + \frac{W_b}{G_b}} \quad (2)$$

where,

G_t = Theoretical specific gravity (g/cc)
W_1 = Weight of coarse aggregate (Kg)
W_2 = Weight of fine aggregate (Kg)
W_3 = Weight of filler (Kg)
W_b = Weight of bitumen in total mix (Kg)
G_1 = Specific gravity of coarse aggregate (g/cc)
G_2 = Specific gravity of fine aggregate (g/cc)
G_3 = Specific gravity of filler (g/cc)
G_b = Specific gravity of bitumen (g/cc)

$$V_v = \frac{G_t - G_m}{G_t} * 100 \quad (3)$$

where, V_v = Percent air voids in the mix (%)

$$V_b = \frac{\frac{W_b}{G_b}}{\frac{\sum W}{G_m}} * 100 \quad (4)$$

where, V_b = Percent bitumen content in the mix (%)

$$VMA = V_v + V_b \quad (5)$$

where, VMA = Volume of voids in the mineral aggregates (%)

$$VFB = \frac{V_b}{VMA} * 100 \quad (6)$$

where, VFB = Voids filled with bitumen (%)

Tables 3-6 show the Marshall Test results.

Result Analysis and Discussion

Based on the Marshall Test Results, variation of unit weight, air voids, VFB, VMA, stability and flow for each of the plastic content, is plotted against Bitumen content and the analysis is performed as under.

It is quite evident from the Figure 3 and Figure 7 that at the lower bitumen contents, unit weight as well as the stability are less but with the increase in bitumen content, these values attains a peak and afterwards reflects a decreasing trend. At lower bitumen contents, specimens fails at lower loads because the quantity of bitumen mixed with aggregates is not sufficient enough to develop efficient bonding between aggregates to withstand applied loads. On the other hand, specimens with excess quantity of bitumen also fail at smaller loads due to a thick film of bitumen at the interface of aggregates which prevents the effective transmission of loads onto the aggregates. Hence, only at a particular quantity of bitumen (optimum content), maximum values of unit weight as well as Marshall Stability are observed.

From the Figure 4 and Figure 5, it can be observed that as the bitumen content increases, Voids filled with bitumen also increases which in turn leads to decrease in air voids present in the specimen as more and more bitumen tends to fill empty voids in the specimen.

As the bitumen content increases, a slight variation is observed in the values of Voids in mineral aggregates, as reflected in Figure 6. This variation attributes to the adjustment of mineral aggregates with the increased bitumen content.

Flow is the measure of the deformation caused due to applied loads. From the Figure 8, it is observed that the flow increases with the increase in bitumen content because of the presence of a thick bitumen film around aggregates that prevents strong aggregate interlocking.

From the Figure 7, as the maximum stability occurs at 4.5% bitumen content, therefore the Optimum Bitumen Content is 4.5%. Then a curve is plotted between stability and plastic content at the optimum bitumen content and it is observed from the Figure 9 that the maximum stability value occurs at 4.5% plastic content, so the optimum plastic content is 4.5%.

MODELLING OF MARSHALL STABILITY AND FLOW

Regression Analysis

Regression analysis is the technique employed here to model Marshall Stability and flow. Regression analysis is a statistical tool in order to assess the relationship between variables. Regression analysis is widely used for prediction and forecasting purposes. Usually, it is used to ascertain the causal effect of

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 6. Variation in VMA with bitumen content

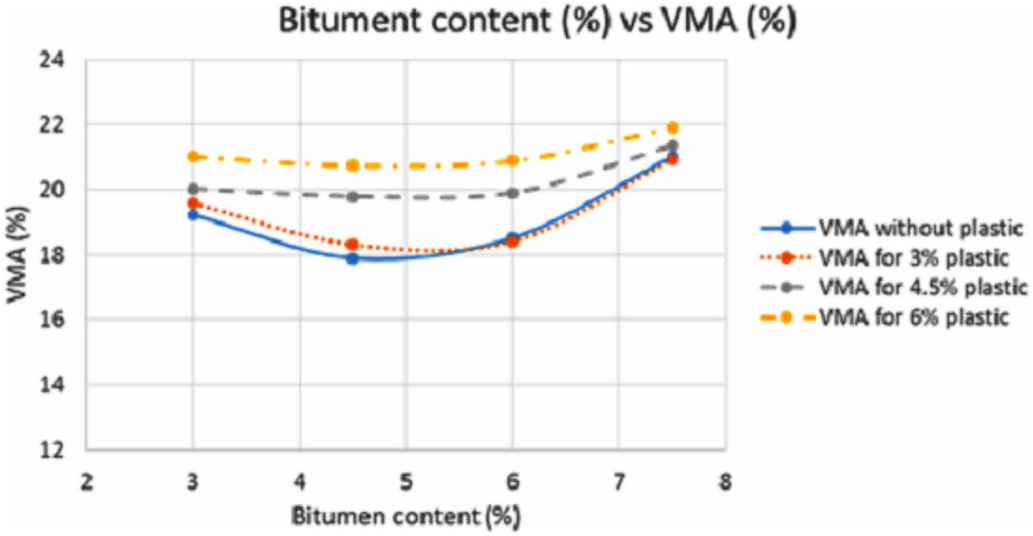

Figure 7. Variation in stability with bitumen content

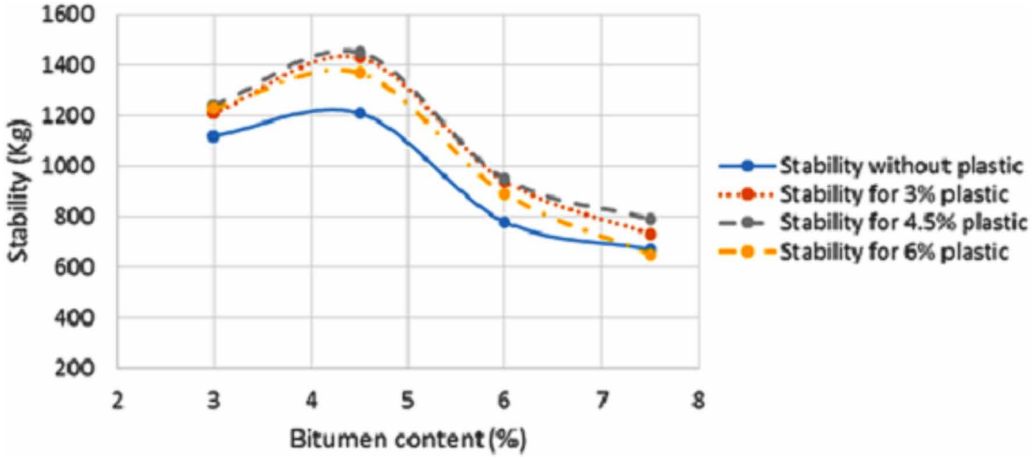

one variable upon another, as for example, the effect of increase in price of a commodity upon its demand, or the effect of change in money supply upon inflation rates. To explore such issues, the data on the underlying variables of interest is assembled and regression is employed to predict the quantitative effect of the causal variables upon the variable that those variable influence. This analysis is also used to assess the 'statistical significance' of the estimated relationships, i.e. the degree of confidence that the true relationship is close to the estimated relationship.

This study inculcated the use of 'Multiple Linear Regression model' since there are multiple parameters involved. Multiple regression analysis is a powerful tool used for predicting the unknown value of a variable from the known value of two or more variables, also termed as 'predictors'.

More precisely, multiple regression analysis helps to predict the value of Y for given values of X_1, X_2, …, X_n.

Figure 8. Variation in flow with bitumen content

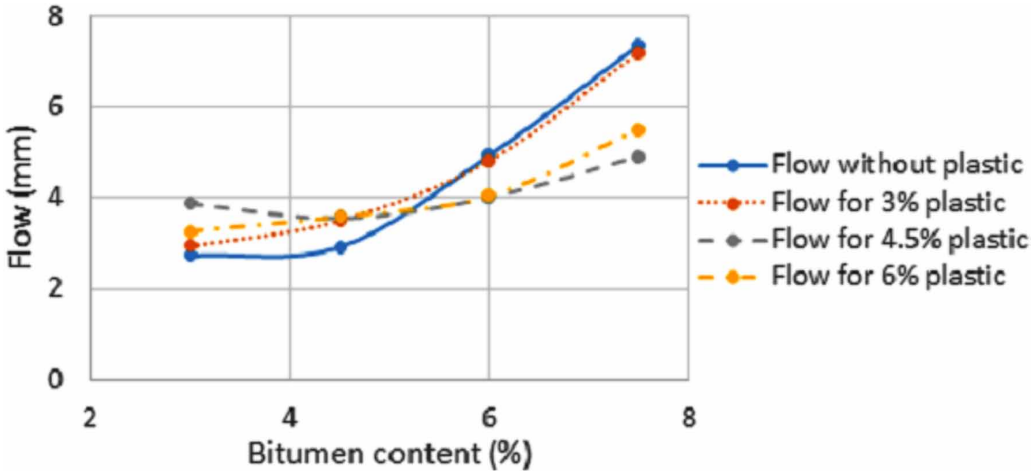

Figure 9. Variation in stability with plastic content

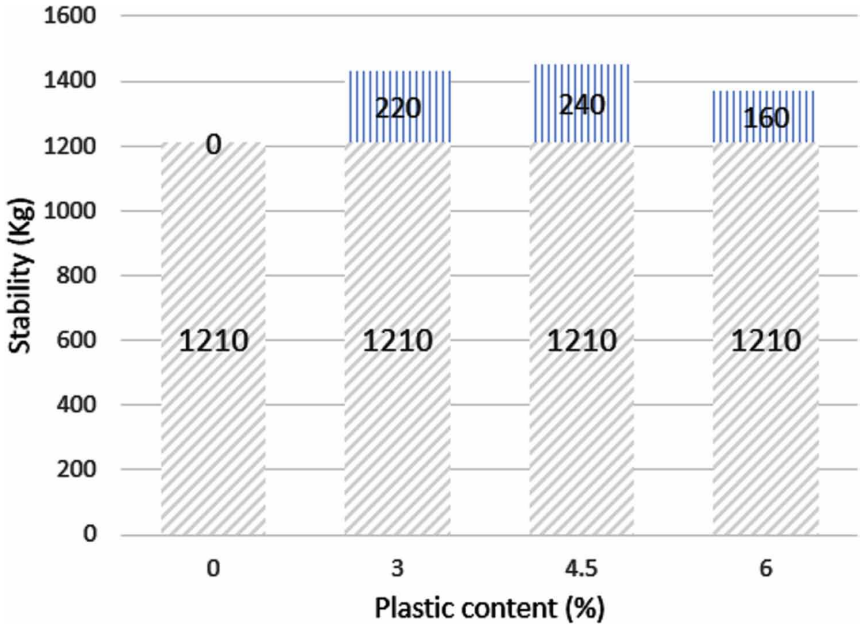

Dependent and Independent Variables

In multiple regression model, there is one dependent variable and two or more independent variables. A dependent variable is one whose value is to be predicted and the independent variables are those whose values are used for prediction. These independent variables are also referred to as 'exploratory' variables.

In general, a multiple regression equation of Y on X_1, X_2, …, X_n is of the form:

$$Y = b_0 + b_1X_1 + b_2X_2 + \ldots + b_nX_n \quad (7)$$

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

where, Y = Dependent variable and X_i = Independent variables (where, i = 1, 2,….n).

Interpretation of Regression Coefficients

Here, b_0 is the intercept and b_1, b_2,….b_n are analogous to the slope in linear regression equation and are also termed as 'regression coefficients'. These could be indicated in similar way as slope. Thus, if b_i = 10, then it implies that Y will increase by 10 units if X_i increased by 1 unit. The appropriateness of the multiple regression model as a whole can be tested by using the t-test in the ANOVA (Analysis of Variance) table. A significant 't value' indicates a linear relationship between Y and at least one of the X's.

Test for Model Significance

In order to assess prediction ability of the developed regression equation, a good practice is to look upon 'Coefficient of Determination' (R^2 value). R^2 lies between 0 and 1. The closer is the value of R^2 to 1, the better is the developed model and its prediction.

In order to assess, if the independent variables chosen individually influences the dependent variable significantly or statistically, to test the null hypothesis that the relevant regression coefficient is zero; a t-test is required.

If the t-test of a regression coefficient is significant, it indicates that the concerned independent influences Y significantly while controlling for other independent variables.

Assumptions for Multiple Linear Regression

1. Multiple regression technique does not test if the data are linear. On the contrary, it proceeds by the assumption that the relationship between the Y and each of the X_i's is linear. Hence, it is a good practice to always look at the scatter plots of (Y, X_i), i= 1, 2,…,n. If any of the plots suggests non linearity, one must use a suitable transformation to attain linearity.
2. Another important assumption is the absence of multicollinearity i.e. the independent variables are not related among themselves. However, this can be tested by the computation of the correlation coefficient between each pair of independent variables.
3. Other assumptions include those of normality and homoscedasticity (i.e. the variance around the regression line is same for all values of the predictor variable (X_i)).
4. Multiple regression analysis is generally useful when one is interested in predicting a continuous dependent variable from a number of independent variables. In the case, the dependent variable is dichotomous, then the logistic regression should be used.

For this study, the dependence of Marshall Stability and Flow upon different variables is assessed. Herein, parameters are chosen based on the correlations between them i.e. there should be significant correlation between dependent and independent variables.

CONCLUSION AND FUTURE SCOPE OF WORK

Conclusion

This study explored the effective utilization of waste plastic (polypropylene) as a binder replacement in the flexible pavement design as the obtained results in case of plastic additive reflects higher strength values as compared to the conventional bituminous mixes. A considerable improvement in other pavement properties is also observed. The use of waste plastics not only helps in enhancing pavement properties, it also aids in curbing the waste disposal. The key findings of the study are the optimum bitumen content of 4.5% and the optimum plastic content of 4.5%. The modelling approach adopted in the study has produced quite satisfactory results. This regression modelling also shows that Bitumen Content is the most significant parameter affecting Marshall Stability and Flow. Since the Coefficient of determination values of both the models are close to 1, which means the predicted results are quite closer to the actual results, so the developed models can be efficiently used for prediction. These models can aid future researchers to obtain the Marshall Stability and Flow values directly from the physical properties of materials which will save a lot of time spent in conducting cumbersome and laborious tests.

Future Research Directions

The findings and the approach from this study can be extended in exploring the efficient utilization of other types of waste plastics as well as the other types of wastes from different industries. Besides, due to availability of less data, the study is limited to Regression modelling, however with the increase in the number of data collection, further advanced modelling can also be adopted to model Marshall Stability and flow which may validate the results more accurately.

Chapter 77
Reverse Logistics in the Electronics Waste Industry

Berk Ayvaz
Istanbul Commerce University, Turkey

Ali Görener
Istanbul Commerce University, Turkey

ABSTRACT

Recently, due to the rapid world population growth, decreasing of natural resources and raw materials, increasing environmental awareness, interesting for wasting raw materials, using produced products more efficiently, and reusing of sources is rapidly increasing. Nowadays, reverse logistics as an important business strategy for profitable and sustainability is becoming important. The effective implementation of reverse logistics gives companies a competitive advantage in sectors. Due to mentioned reasons firms intend to incorporate reverse logistics activities such as the recovery, remanufacturing, recycling or disposal. Reverse logistics has become increasingly important as a profitable and sustainable business strategy. Therefore, more and more manufacturers have adapted the practice of recovering value from returned products and integrate product recovery activities into their processes. The electronic industry is one of the fastest growing manufacturing industries and the main purpose of this chapter is to explore the opportunities for waste returns within this sector.

INTRODUCTION

In recent years, the number of studies about the recovery of the limited sources increase due to rapid population growth, climatic changes, depletion of natural resources and increasing environmental awareness. Reverse Logistics (RL) has become attractive because of raised consumer awareness, the green laws performed by the governments, request of the producers to reduce the cost with lower business capital, increasing of the usage of the recovered containers, increasing of the request of services, raising the quality, re-production, fixing etc. (Sengul, 2009). Also today in many countries, the firms are responsible to collect some of their products back. According to the regulation came into force in Germany in

1991, the firms are responsible to recycle 65%-70% of the packages of their products. Beside the legal sanctions, the consumers are being more conscious every day and they are being more sensitive on environment. Also the green image has become an important selling factor for companies. That situation is forcing many firms to find new ways of recycling and recollecting of their products. The effective implementation of reverse logistics provides competitive advantage to the firms in their sector. Also the economic factors like needing less source of the recycled products compared to new ones is playing an important role in the development of the products. Because of this situation, a logistic network providing an affective flow only to forward is not enough, also proper reverse logistic structures are needed to be installed which provide possibilities for flowing of used and improved products for recovering of the used products. Today, the reverse logistic activities are gaining more importance for the firms as a profitable and sustainable business strategy. Because of that kind of reasons, the firms include the reverse logistics into their systems which provides recovering of the products from customers into the production, recycling of them or disposing of them. The goal is minimizing the harmful impacts of the used products to the environment, reducing the productions cost, gaining competitive advantage, etc. gaining maximum benefits from the used products. Because of all these reasons, the firms like Fuji Film, Hewlett–Packard, IBM Europe and Xerox, etc. have already voluntarily performed participation in the activities of recycling (Qiang et al., 2013).

In the reverse logistics network, there are more units than the ones in the forward logistics network. Supply chain including reverse flow, in addition to all the elements of advanced logistics network, includes 3rd party logistics companies which perform duty as demand point, secondary markets, disposal centers, collecting points and more. Transportation of the products from the customers to the facilities, determination of the settlements for submitting them in to the market from here, plants and the quantity of the products which will be carried, which recycling strategy will be performed to the products are important decisions which must be taken.

In this work, first, the basic elements of the reverse logistics issue have been explained. In pursuit of explaining the activities of the firms performed in the scope of the reverse logistics by the firms, the decision steps and the reasons of the application. At the last part, general characteristics of electrical and electronic goods, their recycling processes under the reverse logistics are described.

REVERSE LOGISTICS

Definition and Scope of the Reverse Logistics

There are different descriptions for “Reverse Logistics” in literature. First terms about the concept of the reverse logistics in scientific literature have been used in 1970’s years by Guiltinan and Nwokoye (1974) and Ginter and Starling (1978). In 1980’s years, the reverse logistics is described as reverse flow opposite to the forward flow in the traditional supply chain, in other words it is described as a wrong way flow (De Brito, 2004). The Council of Logistics Management, has made it first know description on the reverse logistics in 1990’s years. The concept of reverse logistics is “planning, execution and control processes for the purpose of recovering the information of the raw materials, the inventories still in process, the finished goods from the point of consumption to the point of production or disposing them in the correct way” (Yongsheng & Shouyang, 2008).

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Pohlen and Farris (1992) has described "RL" as the flow of the product in distribution channel from the consumers to the producers. The RL description of the USA Reverse Logistics Executive Council is as so: "planning, execution and control processes for the purpose of regaining the information of the raw materials, the in-process inventory, the finished goods from the point of consumption to the point of production or disposing them in a proper way." The reverse logistics activities have an important share in all logistic activities (Rogers & Tibben-Lembke, 1999). Stock (1992) has described the reverse logistics as "the role of the logistics in product returns, reducing sources, recovery, material substitution, reusing of the materials, disposing and burning of the wastes, repairing and remanufacturing. The reverse logistics can be examined from different points. Basically it can be characterized in three ways and the proper description can be defined according to this (Fleischmann, 2000):

1. The reverse logistics is being accepted as the growing element of the logistic systems. The supply chains had been traditionally described as an one-way structure. As Ganeshan et al. (1998) has described as "the most know description of the supply chain is the system consist of the supplier, producer, retailer and costumers. In this system the product flowing is from the supplier to the customer and the information flowing in both ways." The reverse logistics is described as reverse product flowing. But in the organizations it is seen that the material flow is not characterized to below and the logistic network is developed. In this situation, it is not proper to separate the reverse flows from the whole picture.
2. The reverse logistics is being considered as the flow of second products which of original usage has been completed or not able to used. For this reason, the reverse logistics is mentioning about planned and really realized derivatives of past usage. The goal is increasing the economic value of the products released by disposing or some regaining forms.
3. The reverse logistics term is mainly described the receiver side. So, we can say that the reverse logistics is a special situation of the supply logistics.

The reverse logistics is the process of efficient and effective planning, execution and control processes of the second material stores, flow of the material and concerned information for the purpose of regaining of the material or disposing in a proper way in the opposite way to the traditional supply chain (Fleischmann et al., 2001). The reverse logistics is a fact helping to the green logistic activities. Performing scientific methods on the problems about environment and developing methods which will solve these problems has become important for many disciplines, and modern logistic management has taken place in the disciplines concerned with the environment (Erol et al., 2006). The reverse logistics is concern with the remanufacturing, recycling or safe disposal processes of the products moving to the start point of the supply chain because of various reasons (Erol et al., 2008) (see Table 1).

The traditional production cycle has been started to be described as recovery production cycle after entering of the reverse logistics logic into the business structure. In summary, descriptions of RL, has been changed over time from the emphasis of reverse flowing to environmental responsibility. As a result, all these definitions and passed time show us that the reverse logistics has extended its area (De Brito, 2004).

Table 1. Products and the waste samples created by them

Product	Potential Waste
Box Drink	Aluminum box
Detergent	Plastic-based box or package
Ball-point pen	Plastic or metallic sections
Cellphone	Integrated circuit, wire, battery, plastic
Computer	Wire, monitor, cabinet, led
Newspaper	Used paper
Automobile	Engine, metallic parts, tire, plastic, wire

THE ACTIVITIES OF THE REVERSE LOGISTICS

The activities concern with reusing in the scope of the reverse logistics include the following steps:

Collecting

All activities are concerned with the collection of the used products or materials from the consumers for processing and transporting to the place for processing (Fleischmann et al., 2000; Sengul, 2009). For example, collecting back the used carpets from carpet sellers and the used photocopy machines from the users (Fleischmann et al., 2000). The collecting process includes obtaining, transporting and storage of the used products (Kumar & Malegeant, 2006). The collecting work is done by the own facilities of the establishment or the 3rd part providers (Demirel and Gokcen, 2008a).

Inspection and Sorting

Includes the activities determining whether the collected products are proper to re-usage or not and how they can be used. Performing inspection and sorting activities on collected products for several recovery and disposing operations before sending to the producer firm. These operations are also called as local eliminating. The local eliminating is being performed to at the collecting point of the returned products. In this step the decision between reprocessing of the product or disposing is taken (Flesichmann, 2000). In the stage of inspection and sorting, testing, disassembly, separating into small parts, sorting and storage operations are performed (Fleischmann et al., 2000).

Reprocessing or Direct Recovery

The direct recovery is sending again the products to the selling points and again usage without performing any treatment on them. The reprocessing is converting a used product into usable product again. This stage includes different options like recycling, repair and re-manufacturing. In addition to that options, it can also include the steps of cleaning, renovation and re-assembling too. We can give examples as nylon recycling from used carpets, new part production from used photocopy machines and cleaning the waste construction sand for the reprocessing (Fleischmann et al., 2000).

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

The most important difference separating the reverse logistic systems is occurring at this stage (Demirel & Gokcen, 2008a). The reprocessing is the stage in the reverse logistic web which needs the highest investment. Especially the cost of the operations of the re-manufacturing and the recycle is high. The main difference show itself in the stage of the reprocessing. According to this, the processes of the product recovery can be lined as following (Thierry et al., 1995):

- **Repairing:** The goal of the repairing is making the returned product workable or usable (Thierry et al., 1995). The repairing operation of the product includes the repairing of the broken or damaged parts and changing them (Karacay, 2005). The quality of repaired product is less than the quality of a new product (Wadhwa et al., 2009).
- **Refurbishing:** The goal of the product innovation is increasing the quality level of the used product to a certain quality level (Thierry et al., 1995). The facilities of refurbish maintain the quality of the returned products nearly as same as the quality level of a new product (Jarayaman et al., 2003). Generally this operations is performed on expensive products (like military and commercial planes). In the product innovation operations the broken parts are changed with new ones or old parts are changed with ones having more quality according to technology (Sengul, 2009).
- **Re-Manufacturing:** The goal of the re-manufacturing is increasing the quality level of the used product up to the quality level of a new product. All parts of the used product are demounted and all modules and parts are controlled. The worn, outdated and demode parts and modules according to the current technology are changed with new ones. The repairable parts and modules are repaired and tested (Thierry et al., 1995). The re-manufacturing is known as main recovery option because of feasibility and its benefits (Lu & Bostel, 2007).
- **Cannibalization:** The first three options provide highly rated reusage in recovery activities. In here the reusage possibility is limited. The main goal is taking limited numbered usable parts from the used product or component (Thierry et al., 1995).
- **Recycling:** In the product recovery options mentioned above, the main goal is preserving the functions and properties of the used products and components as good as possible. In recycling operation, the products loose its functions and properties. The recycling is obtaining material from used products (Thierry et al., 1995). In the recycling operation the material is regained without preserving the structure of the product (Thierry et al., 1995). The recycling operations are performed on many used products. For example, in many countries like USA, England, Germany, nearly all metallic parts composing 75% of the weight of the scrapped cars are being performed to recycling (Thierry et al., 1995).

Disposing

In this stage needed operations are performed for valueless products which can not be reused because of the technology or economic reasons. The valueless of a waste or scrap depends on not creating any value by reusage of it as technically or economically or not being worth to process. The rejected products in the stage of inspection and sorting because they need very much repairing and the products which can not be used because their expire date has passed can be disposed. There are some options like removal, soil burying and incineration (Fleischmann et al., 2000).

Returning Recourses in Reverse Logistics

If the products don't perform their functions, there is no need for them, then they will be sent back or thrown. We can list the typical reasons of the products as errors, damage caused during transport, the introduction of new models, product replacement with another product, refunds, repairs, recall and incorrect deliveries (Min et al., 2006). At the same time, several returning reasons of the products in the supply chain hierarchy from the production stage to the delivering step to the consumers can be collected in three main groups as following (Dekker et al., 2004):

- **Production Returns:** Sometimes the needed quality can't be gained in the production stage or retaking of the products and components which must be recycled can be described as productions returns.
- **Distribution Returns:** That includes all returns occurred in the stage of distribution in the reverse logistics. That is a reverse distribution activity including product recalls, withdrawal of the product from customers (Jarayaman et al., 2003). The recalls caused by the safety or health risks at the products are initiated by the manufacturer or supplier. Business to business (B2B) commercial returns are caused by the returning options concern with the contract between the retailer and the parent company. Damaged product deliveries, defective products, out-of-lifecycle products, seasonal products which couldn't sold, etc. can be given as example to that category.
- **Returns from the Customers:** These returns consist of the returns after the product has reached to the customer because of several reasons. Warranty returns, service returns (repair, replacement parts), end of usage returns can be evaluated in this scope.

Decision Stages in Reverse Logistics

Transportation of the products from the customers to the facilities for recycling, determination of the settlements for remarketing them from that place, facilities and the amount to be transported between each plant are the important decisions which must be taken (Fleischmann et al., 1997). The periodic decisions in the reverse logistics can be lined as following (De Brito, 2004; Srivastava, 2008b):

- **Long Term Decisions:** Plant layout, facility planning, capacity and design,
- **Middle Term Decisions:** Integration of the operations and choosing which information and technology system will be used,
- **Short Term Decisions:** Inventory, vehicle routing, schedules for re-manufacturing.

Strategic decisions are taken by senior management, tactical decisions are taken by middle level management and the operational decisions are taken by the lower-level management (Sengul, 2009). The reasons of performing the reverse logistics by the companies can be summed under three general titles:

- **Economical Factors:** In today's world in which the competition conditions have become hard, the economic factor play triggering role for the improvement of the products. The companies are trying to find new ways to reduce the production costs. The reverse logistics program can provide direct benefits for the companies by reducing the amount of the raw materials, adding value to the product by recycling or reducing the disposal cost. The indirect benefits of the reverse logistics are

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

as green (environmental) image, improved customer satisfaction, preparation for the laws which will be valid in the future and market protection (Fleischmann, 2000; De Brito, 2004). The investigations show that the re-manufacturing has 25% less cost instead of new production (Linton & Johston, 2000). Previously performing recycling operations of the firms will provide advantage to them for adopting the laws which will be applied in the future (Louwers et al., 1999). The product recycling methods can be performed to make close relations with the customers having environmental sensitivity. So, the firms can gain indirect economic benefit by the established green image (Buyukozkan and Vardaloglu, 2008; Fleischmann et al., 2000).

The direct and indirect benefits of the reverse logistics provided to the firms can be summed as following (Dekker et al., 2004):

- **Direct Benefits:** Reducing the amount of the used materials, reducing the production costs, adding value to the products by recycling.
- **Indirect Benefits:** Laws which will come into force, protecting the market share, green image, developing customer / supplier relationships.
- **Legal Regulations:** Legal regulations are another factor which forces the firms to perform the reverse logistics. These laws force the firms to return and recycle the used products in a certain ratio (Dekker et al., 2004; De Brito, 2004). Nowadays the return products have big importance and responsibilities are given to the producers for the products which have completed their life cycle (Fleischmann et al., 2001). In many countries, companies are being held responsible with collecting back a certain part of the products they produce. Especially the European Union gives importance to the development and implementation of "green laws" for the reduction of the environmental impact even for the elimination (Sengul, 2009). In the scope of the "Germany Waste and Packaging Law" which has entered into force in 1991 in Germany, manufacturers, distributors and retailers must recycle minimum 60%-75% of their packaging wastes (Fleischmann et al., 1997). Again in this country, the manufacturers are responsible for the disposal of the electronic products which have completed their life time (Jarayaman et al., 2003). In Turkey "Packaging and Packaging Waste Control Regulation" has entered into force in the date of 07.30.2004. In the European Union, in January 2003, the "The Waste Electrical and Electronic Equipment " (WEEE) directive (EC, 2003a) has been issued for collecting the electrical and electronic products and supporting recycling of the products like this type. Also the " The Restriction of Hazardous Substances" (RoHS), (2002/95/EC numbered directive) has been issued by the European Union and the usage amount of six hazardous materials (chromium, cadmium, lead, polybrominated biphenyls, mercury and polybrominated diphenyl ether) has been limited at the all production stages of the electrical and electronic devices (EC, 2003b). Because of the laws, every product bought by the government must have recycled materials in Japan. In Netherland, the manufactures are responsible of collecting used refrigerators, washing machines, freezers, televisions and electronic tools and all packages of these products, treating them and providing recycling of them.

Generally these legal regulations are at the way of collecting the products at the end of their life cycle, reusing of them, waste management and encumbering the responsibilities about this on manufacturers, reducing the amount of the wastes, increasing the recycle amount of the products and materials. Some of the legal regulations in our country are as following: Control Regulation of Medical Wastes, Control

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Regulation of Tires which have completed their life time, Control Regulation of Solid Wastes, Control Regulation of Vegetable Waste Oil, Control Regulation of Waste Batteries and Accumulators, Control Regulation of Packaging Wastes, Control Regulation of Hazardous Wastes etc.

- **Environmental Sensitivity:** Environmental sensitivity is one of the performing reasons of the reverse logistics. Including the environmental goals into the reverse logistics applications and strategic plans of the firm provides competitive advantage to the firm according to its competitors. In recent years, the interest in environmental management in supply chain management has been increased (Ravi et al., 2005). As the result of this, producing environment friendly products and recycling of the products has become an important market component (Sengul, 2009). In addition to this, (Ravi et al., 2005) has mentioned from firm citizenship concern with the values required for responsibility of the firms or organizations on the reverse logistics as another performing reason of the reverse logistics. The reverse logistics help improving of the firm image. At this point, Nike firm is converting the used shoes to the materials used in installing of the basketball courts and jogging trails. And this application makes a positive affect to raise the brand value.

DIFFERENCES BETWEEN FORWARD LOGISTICS AND REVERSE LOGISTICS

There are some differences between forward logistics and reverse logistics. At the same time, the reverse logistics cannot be the symmetric reflection of the forward logistics (Fleischmann et al., 1997). The basic difference between the reverse logistics and the forward logistics including some uncertainties of the reverse logistics because of its structure about used products. There are uncertainties about the amount, quality and timing of the returned products, furthermore different return ratios are valid for each products of the firm. In the forward logistics the factors like time, quantity, quality are controllable, so they can be guessed. This is the main property separating these two ones. The differences between forward logistics and reverse logistics can be summed as shown in Table 2 (Tibben-Lembke and Roger, 2002).

Table 2. Differences between forward logistics and reverse logistics

Forward Logistics	Reverse Logistics
Estimates are relatively clear	It is more difficult to make estimations
Transporting is from one center to many centers	Transporting is from many centers to one center
Product quality is uniform	Product quality is not uniform
Product packaging is uniform	Package of the product is damaged
Following route is certain	Following route is not certain
Channels are standardized	It is directed with expectations
Prices are standard	Prices are affected by many factors
Costs are under control with accounting system	Costs are less certain
Consistent inventory management	Inconsistent inventory management
Agreements between actors are clear and simple	Agreements between actors are completed according to conditions
Marketing methods are certain	Marketing methods change according to some conditions
Real-time information is available for tracking items	The traceability process level is lower

RECYCLING OF ELECTRIC-ELECTRONIC WASTES

Electrical and Electronic Equipment (EEE) are one of the most rapidly grown sector in the world (Hischier et al., 2005). Accordingly in recent years, there is a rapid increasing in the production of EEE all over the world. Rapid technological developments and continuously provision of the new products to the market increase the usage of these equipments in daily life in the modern world. Parallel to this situation, The Waste Electrical and Electronic Equipment (WEEE) occur which can cause to new environmental problems (He et al., 2006; Achillas et al., 2012).

EEE are the equipments needing electric current or electromagnetic field, generating that kind of current and area, transmitting, measuring and designed not to exceed usage of 1000 volts alternating current or 1500 volt direct current for their main functions according to EU's Directive 2002/96/EC regulation (Bereketli et al., 2011). WEEE are the wastes of several electric and electronic equipment and materials which don't provide any benefit to their owners or have completed their usage life time, has become inactive because of breakdown etc. (Widmer et al., 2005). According to EU's Directive 2002/96/EC regulation, WEEE are the waste electrical and electronic equipment including all components, subassemblies, consumables which are part of the equipment when the equipment is thrown (Widmer et al., 2005). As an alternative, e-waste term is widespreadly used instead of WEEE (Chancerel and Rotter, 2009).

United Nations Environment Program has calculated that in every year 50 million tons of WEEE are produced all over the world (Bereketli et al., 2011). According to the foresight of European Union Commission, 45% increasing in the amount of e-wastes is predicted between 1995-2020 in European countries (Hischier et al., 2005). In 1998 in West Europe, 6 million tons of WEEE occurred and 3%-5% ratio of increasing at this amount is expected (Cui & Forssberg, 2003). According to the declaration of United Nations University in 2005, 27 countries which are members of European Union have produced 8.3–9.1 million tons e-wastes (Oliveira et al., 2012). It is expected that in 2015 the amount of the e-wastes will be 12 million tons annually. That means 14 kg WEEE per person (Gutierrez et al., 2008). In 2004 in USA, 315 millions items of computers have been completed their life time (He et al., 2006).

In Table 3, the amount of the WEEE produced per person in some countries of the world (Ongondo et al., 2011).

According to 2002/96/EC directives European Parliament and WEEE Council (January 2003) have described WEEE product categories as following (Widmer et al., 2005):

1. Large household appliances e.g. fridges, cookers, microwaves, washing machines and dishwashers.
2. Small household appliances e.g. vacuum cleaners, irons, toasters and clocks.
3. IT and telecommunications equipment e.g. personal computers, copying equipment, telephones and pocket calculators.
4. Consumer equipment and photovoltaic panels e.g. radios, televisions, hi-fi equipment, camcorders ad musical instruments.
5. Lighting equipment e.g. straight and compact fluorescent tubes and high intensity discharge lamps.
6. Electrical and electronic tools – e.g. drills, saws and sewing machines, electric lawnmowers.
7. Toys, leisure and sports equipment e.g. electric rains, games consoles and running machines.
8. Medical devices e.g. (non infected) dialysis machines, analysers, medical freezers and cardiology equipment.
9. Monitoring and control instruments e .g. smoke detectors, thermostats and heating regulators.
10. Automatic dispensers e.g. hot drinks dispensers and money dispensers.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 3. The amount of the WEEE produced per person in some countries

Country	Annual WEEE Amounts Per Person (kg)
Germany	13.3
England	15.8
Switzerland	9.0
China	1.7
India	0.4
Japan	6.7
Kenya	0.2
South Africa	1.2
Argentina	2.5
Brazil	3.5
USA	7.5
Canada	2.7

In additionally, categories of EEE covered by this directive as follows (EC, 2003a):

1. Temperature exchange equipment.
2. Screens, monitors, and equipment containing screens having a surface greater than 100 cm2.
3. Lamps.
4. Large equipment (any external dimension more than 50 cm) including, but not limited to: Household appliances; IT and telecommunication equipment; consumer equipment; luminaires; equipment reproducing sound or images, musical equipment; electrical and electronic tools; toys, leisure and sports equipment; medical devices; monitoring and control instruments; automatic dispensers; equipment for the generation of electric currents. This category does not include equipment included in categories 1 to 3.
5. Small equipment (no external dimension more than 50 cm) including, but not limited to: Household appliances; consumer equipment; luminaires; equipment reproducing sound or images, musical equipment; electrical and electronic tools; toys, leisure and sports equipment; medical devices; monitoring and control instruments; automatic dispensers; equipment for the generation of electric currents. This category does not include equipment included in categories 1 to 3 and 6.
6. Small IT and telecommunication equipment (no external dimension more than 50 cm).

There are three different ways of treatment of WEEE. These are recovery, recycling and disposal options explained in previous sections (Gomes et al., 2011).

Characteristics of WEEE Products in Terms of Recycling

WEEE has a heterogeneous and complex structure in terms of material and component. Developing an affective and qualified environment friendly recycling system is concern with having knowledge of physical properties of valuable materials, harmful wastes and their components. These properties can be classified as following (Cui & Forssberg, 2003):

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Hazardous components: WEEE has inhomogeneous and complex structure in terms of their components and materials (He et al., 2006). These components and materials include precious materials like iron, steel, copper, aluminum, metal, gold, silver, palladium, platinum, plastic, etc. and also there are wastes which are harmful for human health and environment (Wang et al., 2012). If e-wastes are not performed recycling and disposing processes under control, they will be harmful affects for human health and environment. For example, in the content of consumer electronic products 40% ratio of lead material which has harmful effects to the human brain and also triggers to allergic reactions and cancer (Widmer et al., 2005). The harmful materials in WEEE are cadmium, cathode ray tubes, mercury containing components, such as switches, asbestos waste, toner cartridges, liquid, paste and color toner, liquid crystal imagers, and gas discharge lamps, etc. (Cui & Forssberg, 2003; He et al., 2006).

Material composition: In the structure of EEE's there are many different materials more than one thousand. There are considerably precious materials in the structure of WEEE's (Widmer et al., 2005). The basic economic trigger of the recycling of the electronic wastes is the precious materials in them. At the same time, the proportion of the precious metal in the EEE illustrates a growing trend toward reduction (Cui & Forssberg, 2003). In the first generation of computers there was 4 gr gold. Today that amount is nearly 1 gr. One ton of WEEE includes 0,2 ton of copper (Widmer et al., 2005).

Physical properties: As a component of the precious materials, WEEE includes metals as copper, aluminum, gold and also plastic. The key factor in developing mechanic recycling system is effective material separation process based on the differences in physical characteristics (Cui & Forssberg, 2003).

Particle size, shape and separation properties: Particle size, shape, mechanical recycling properties have an important role in mechanical recycling processes. There is a specific particle size range in which nearly all mechanical recycling processes are effective (Cui & Forssberg, 2003).

Examining of E-Wastes (WEEE) in Terms of Regulations

Many countries are preparing regulations for supporting recycling and reducing the amount of disposal (Bereketli et al., 2011). In Europe the situations like disposal of electronic equipment, laying down specific recycling targets, retaking obligations of the products are determined by legal regulations (Thierry et al., 1995). There are two directives as WEEE (EC, 2003a) and RoHS (EC, 2003b) which have been come into force in EU at the date of 13 February 2003 concern with the waste of electrical and electronic equipment (Allsopp et al., 2006). Since the date of 1 January 2006 electrical and electronic products which will be produced and sold in the borders of EU will be proper to RoHS and WEEE regulations.

RoHS

RoHS (Restricting the use of Hazardous Substances) are the rules limiting the usage amount of the hazardous materials in electrical and electronic equipment to prevent the harm of the electrical and electronic equipment given to the environment dictated by EU. The six materials limited in the scope of RoHS are cadmium, mercury, chromium, polibrominl biphenyl, polibrominl diphenyl ether and lead (He et al., 2006). In Table 4 the ratio of materials limited for usage in the scope of RoHS can be seen.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 4. The ratio of materials limited for usage in the scope of RoHS

Material	Amount (As Weight in a Homogeneous Material)
Mercury (Hg)	0.1%
Hexavalent chromium (Cr^{6+})	0.1%
Polybrominated biphenyls (PBB)	0.1%
Polybrominated diphenyl ether (PBDE)	0.1%
Lead (Pb)	0.1%
Cadmium (Cd)	0.01%

WEEE Directives

WEEE-The Waste of Electrical and Electronic Equipment Directives (Directive 2002/96/EC) provides recollecting of the products of the manufacturers and importers in EU and disposal of them without giving any harm to the environment (Ongondo et al., 2011). This directive includes manufacturers, distributors, consumers and all actors in the process of WEEE treating. It has been issued based on 175/1 article of European Treaty and it is only for increasing the environmental protection works. The responsibilities loaded on the actors with WEEE Directive are as following (EC, 2003a):

- Ministries are responsible for checking and controlling e-waste collecting and recycling activities of manufacturers, electronic products retailers, local units, recycling centers.
- Municipalities are responsible for providing every kind of support for the recycling of electrical and electronic equipment and serving to that process. Also they are responsible for providing the collection of domestic wastes and e-wastes separately and controlling the activities of collection and recycle centers.
- Producers are responsible for providing the recycle of a certain percentage of manufactured products, creating the appropriate conditions for the easy implementation of recycling, conducting research and development work on the subject, produced goods to designed to be suitable for recycling, giving priority to be derived from the recycling of raw materials. Also they are responsible for financing e-waste management and sending the products and/or parts which can't be recycled to the companies that provide recycling services.
- Recycling companies (the reverse logistic service suppliers) are responsible for taking certificate of conformity from the ministry, having the proper and developed technology for recycling activities.
- Electronic products distributors are responsible for collecting old and electrical and electronic products removed from usage and components from consumers free of charge or sending to the manufacturers or recycling companies free of charge.
- Consumers are responsible for leaving the electrical and electronic devices which they want to dispose in proper way in the private centers.

The goal of the WEEE directive is reducing the disposal ratio of EEE and healing the environmental performance of EEE products (He et al., 2006). WEEE recycling options have the goal of increasing of the recycling and reducing of the disposal.

KEY TERMS AND DEFINITIONS

Electrical and Electronic Equipment (EEE): Electrical and Electronic Equipment is defined as equipment which is dependent on electric currents or electromagnetic fields in order to work properly and equipment for the generation, transfer and measurement of such currents and fields.

Logistics Management: As defined by the Council of Supply Chain Management Professionals (CSCMP): "Logistics management is that part of supply chain management that plans, implements, and controls the efficient, effective forward and reverse flow and storage of goods, services, and related infor-

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

mation between the point of origin and the point of consumption in order to meet customers' requirements. Logistics management activities typically include inbound and outbound transportation management, fleet management, warehousing, materials handling, order fulfillment, logistics network design, inventory management, supply/demand planning, and management of third party logistics services providers.

Reconditioning: When a product is cleaned and repaired to return it to a "like new" state.

Recycling: When a product is reduced to its basic elements, which are reused.

Refurbishing: Similar to reconditioning, except with perhaps more work involved in repairing the product.

Remanufacturing: Similar to refurbishing, but requiring more extensive work; often requires completely disassembling the product.

Reuse: Using a product again for a purpose similar to the one for which it was designed.

Reverse Logistics: A specialized segment of logistics focusing on the movement and management of products and resources after the sale and after delivery to the customer. Includes product returns for repair and/or credit.

Supply Chain: Starting with unprocessed raw materials and ending with the final customer using the finished goods, the supply chain links many companies together.

Waste Electrical and Electronic Equipment (WEEE): Waste Electrical and Electronic Equipment is defined as EEE which has reached end of life (waste); including all components, subassemblies and consumables which are part of the product at the time of discarding.

This research was previously published in the Handbook of Research on Waste Management Techniques for Sustainability edited by Ulas Akkucuk; pages 155-171, copyright year 2016 by Information Science Reference (an imprint of IGI Global).

sustainable development 20, 27-28, 31, 140-141, 222, 243, 336, 338, 340, 384-385, 417, 455, 477, 633-634, 642, 896, 1125, 1143, 1210, 1272, 1282, 1336, 1383, 1395, 1398, 1413, 1418, 1420, 1426, 1439, 1526
sustainable indicators 1396, 1398, 1402, 1408, 1413
sustainable materials 142, 147-148, 676-677, 696
Sustainable operations 382
sustainable service 897, 899
sustainable society 139-140, 149, 152, 155
sustainable urbanization 624, 626, 637

T

Technology Selection 1064-1065
tetrachloroethene 1352, 1354, 1371
textiles 184, 260, 370, 391, 877-879, 949, 1298, 1496, 1603, 1607, 1614-1615
thermocline 92, 100
thermodynamic and transport properties 1105
Thermohaline Circulation 100
Total coliform 408, 410, 1590-1594, 1596, 1610, 1612
toxic compounds 49, 68, 122, 166, 190, 205, 211, 840, 1016, 1493
toxic heavy metal 148, 156, 427
tracer 928-929
traditional costing 1139, 1142, 1144, 1149
transport 6, 28, 83, 91, 126, 177, 185, 190, 195, 222, 225, 229, 232-234, 239, 245-246, 260-261, 315, 349, 388, 437, 460, 466, 513, 517, 536-538, 592-593, 598, 626, 703, 729, 758, 787, 821, 871, 890-891, 918, 925, 927-929, 931-932, 937, 950, 962, 973, 979, 984, 990-991, 1017, 1020-1021, 1023-1024, 1026-1028, 1058, 1105, 1107, 1109, 1121-1122, 1193, 1222, 1283, 1318, 1333, 1354, 1367, 1437, 1457, 1495, 1497, 1500-1501, 1560-1562, 1570-1572, 1579, 1609, 1639, 1645, 1669
treatment 2, 4, 6-9, 11, 19, 33, 49-56, 58-62, 66-68, 92, 95, 103, 110-111, 114-115, 117, 122-124, 127, 157-159, 162, 164-167, 169-172, 178, 180, 184-189, 191, 193-195, 204-216, 221, 237, 239-241, 243, 245-246, 249, 259, 266, 270, 274-277, 281, 284, 306-307, 312-314, 316, 324-325, 338-340, 374, 377, 407, 410, 412-413, 423, 425, 459, 461, 463, 466, 475-476, 478, 480, 482, 484, 488, 503-520, 524-526, 532-536, 538-540, 545-546, 550, 559-561, 563-564, 567-568, 570, 572, 574-579, 587, 590-593, 597-599, 602, 628, 635, 642-644, 646-648, 650, 653, 657, 697-701, 704-706, 708-709, 717-726, 728, 731-732, 736-745, 754, 765, 767-770, 775-777, 779-795, 797-798, 811-817, 830, 833-835, 838-840, 846, 860-863, 865-868, 870-872, 880-881, 891, 918-919, 933-935, 937-938, 940, 942, 949-950, 952-957, 959-961, 964, 966, 971, 979, 983-985, 1015-1016, 1018, 1020, 1022, 1024-1025, 1028, 1037-1050, 1078, 1083, 1106, 1110, 1112, 1124, 1149, 1151-1152, 1155-1156, 1160-1161, 1169-1178, 1181-1182, 1194, 1205-1209, 1219, 1221, 1226-1227, 1229-1231, 1237-1252, 1266, 1268, 1271, 1283-1284, 1288, 1296, 1310, 1322, 1334, 1353-1355, 1366, 1435, 1454-1456, 1458, 1492-1494, 1496, 1498-1502, 1545, 1554-1556, 1559, 1561, 1579, 1581, 1587-1592, 1595-1597, 1603-1607, 1609-1611, 1614, 1616-1618, 1627, 1630-1633, 1639-1640, 1667, 1673
Treatment Wetlands 504, 506, 509, 511, 513, 517, 560, 567, 579
