Library of Congress Cataloging-in-Publication Data

Names: Information Resources Management Association, editor.
Title: Waste management : concepts, methodologies, tools, and applications / Information Resources Management Association, editor.
Other titles: Waste management (Engineering Science Reference (Publisher))
Description: Hershey, PA : Engineering Science Reference, an imprint of IGI Global, 2019. | Includes bibliographical references and index. | Summary: "This book examines the management of different types of wastes and provides relevant theoretical frameworks about new waste management technologies for the control of air, water, and soil pollution"-- Provided by publisher.
Identifiers: LCCN 2019026534 (print) | LCCN 2019026535 (ebook) | ISBN 9781799812104 (hardcover) | ISBN 9781799812111 (ebook)
Subjects: LCSH: Refuse and refuse disposal.
Classification: LCC TD791 .W22584 2019 (print) | LCC TD791 (ebook) | DDC 628.4/4--dc23
LC record available at https://lccn.loc.gov/2019026534
LC ebook record available at https://lccn.loc.gov/2019026535

Table of Contents

Preface xx

Volume I

Section 1
Fundamental Concepts and Theories

Chapter 1
Introduction to Solid Waste and Its Management 1
Hamidi Abdul Aziz, Universiti Sains Malaysia, Malaysia
Salem Abu Amr, Universiti Sains Malaysia, Malaysia

Chapter 2
The Role of Waste Management in the Green Economy: An Empirical Analysis of Economic Data of the Business 25
Massimo Saita, University of Milano Bicocca, Italy
Maria Vittoria Franceschelli, University of Milano Bicocca, Italy

Chapter 3
Effective Waste Water Treatment and its Management 49
Sakthivel Lakshmana Prabu, Anna University, India
TNK Suriyaprakash, Al Shifa College of Pharmacy, India
Ruckmani Kandasamy, Anna University, India
Thirumurugan Rathinasabapathy, International Medical University (IMU), Malaysia

Chapter 4
The Fundamentals of Water and Natural Waters 73
Benjamin Cuker, Hampton University, USA
George Bugyi, Pennsylvania State University, USA

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Chapter 5
Chemical and Biological Processes for Nutrients Removal and Recovery 102
Dafne Crutchik Pedemonte, University of Verona, Italy
Nicola Frison, University of Verona, Italy
Carlota Tayà, University of Vic-Central University of Catalonia, Spain
Sergio Ponsa, University of Vic-Central University of Catalonia, Spain
Francesco Fatone, University of Verona, Italy

Chapter 6
Introduction of Environmental Materials 139
Takaomi Kobayashi, Nagaoka University of Technology, Japan

Chapter 7
Introduction to Leachate Treatment 157
Amin Mojiri, Shanghai Jiao Tong University, China
Siti Fatihah Binti Ramli, Universiti Sains Malaysia, Malaysia
Wan Izatul Saadiah Binti Wan Kamar, Universiti Sains Malaysia, Malaysia

Chapter 8
A Review of Emerging Contaminants in Water: Classification, Sources, and Potential Risks 177
Alexandros I. Stefanakis, University of Brighton, UK
Julie A. Becker, University of the Sciences, USA

Section 2
Development and Design Methodologies

Chapter 9
Integrated Leachate Treatment Technology 204
Zawawi Daud, Universiti Tun Hussein Onn Malaysia, Malaysia
Halizah Awang, Universiti Tun Hussein Onn Malaysia, Malaysia

Chapter 10
Structure Development for Effective Medical Waste and Hazardous Waste Management System 221
Nilgün Cılız, Boğaziçi University, Turkey
Hacer Yıldırım, Boğaziçi University, Turkey
Şila Temizel, Boğaziçi University, Turkey

Chapter 11
Design and Operation of Semi-Aerobic Landfill 246
Mohd Suffian Yusoff, Universiti Sains Malaysia, Malaysia
Mohd Faiz Muaz Ahmad Zamri, Universiti Sains Malaysia, Malaysia

Chapter 12
Items of Consideration in the Design of a Malaysian Landfill 259
Mohamad Razip Selamat, Universiti Sains Malaysia, Malaysia
Hamidi Abdul Aziz, Universiti Sains Malaysia, Malaysia

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Chapter 13
An Approach to Sustainable Watershed Management: Case Studies on Enhancing Sustainability with Challenges of Water in Western Maharashtra 286
Sneha Kumari, Symbiosis International University, India
Yogesh Patil, Symbiosis International University, India
Prakash Rao, Symbiosis International University, India

Chapter 14
Characteristics of Chitosan Nanoparticles for Water and Wastewater Treatment: Chitosan for Water Treatment 306
Cayla Cook, Mississippi State University, USA
Veera Gnaneswar Gude, Mississippi State University, USA

Chapter 15
Life Cycle Costing on Waste Management 336
Sami Gören, Umm Al-Qura University, Saudi Arabia

Chapter 16
A Decision Support System for Sustainable Waste Collection 347
Mattias Strand, University of Skövde, Sweden
Anna Syberfeldt, University of Skövde, Sweden
André Geertsen, University of Skövde, Sweden

Chapter 17
SCOR Model and the Green Supply Chain 366
Ulas Akkucuk, Bogazici University, Turkey

Chapter 18
Participation Framework to Sustainability: The Undercurrents in Bottled-Water Production and Consumption 383
Taksina Chai-Ittipornwong, Muban Chombueng Rajabhat University, Thailand

Chapter 19
Water Quality Impacts of Abattoir Activities in Southern Africa 405
Never Mujere, University of Zimbabwe, Zimbabwe

Chapter 20
Green Manufacturing: The Need of the Hour for Developing Nations – A Case Study 416
Saurabh Sen, Sunbeam College for Women, India
Ruchi Sen, Sunbeam College for Women, India

Chapter 21
Applications of Nanomaterials for Water Treatment: A Future Avenue 423
Anupreet Kaur, Punjabi University, Patiala, India

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Chapter 22
Determination of Rate of Medical Waste Generation Using RVM, MARS and MPMR 436
J. Jagan, VIT University, India
Pijush Samui, VIT University, India
Barnali Dixon, University of South Florida St. Petersburg, USA

Chapter 23
Decision Insights for Shipbreaking using Environmental Impact Assessment: Review and Perspectives 454
Joshin John, Indian Institute of Management, India
Rajiv Kumar Srivastava, Indian Institute of Management, India

Chapter 24
Advanced Nanomaterials for the Removal of Chemical Substances and Microbes From Contaminated and Waste Water 475
Kamlesh Shrivas, Guru Ghasidas Vishwavidyalaya, India
Archana Ghosale, Guru Ghasidas Vishwavidyalaya, India
Pathik Maji, Guru Ghasidas Vishwavidyalaya, India

Chapter 25
Constructed Wetlands: Description and Benefits of an Eco-Tech Water Treatment System 503
Alexandros I. Stefanakis, University of Brighton, UK

Chapter 26
Systems Based on Physical-Chemical Processes: Nutrient Recovery for Cycle Closure 526
August Bonmatí-Blasi, GIRO Joint Research Unit IRTA-UPC, Spain
Míriam Cerrillo-Moreno, GIRO Joint Research Unit IRTA-UPC, Spain
Victor Riau-Arenas, GIRO Joint Research Unit IRTA-UPC, Spain

Volume II

Chapter 27
Constructed Wetlands for Industrial Wastewater Treatment and Removal of Nutrients 559
David de la Varga, Sedaqua, Spain
Manuel Soto, University of A Coruña, Spain
Carlos Alberto Arias, Aarhus University, Denmark
Dion van Oirschot, Rietland bvba, Belgium
Rene Kilian, Kilian Water, Denmark
Ana Pascual, AIMEN, Spain
Juan A. Álvarez, AIMEN, Spain

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Section 3
Tools and Technologies

Chapter 28
Economic Instruments for Sustainable Environmental Management 589
Günay Kocasoy, Bogazici University, Turkey

Chapter 29
Water Quality Prediction Using Statistical Tool and Machine Learning Algorithm 609
Arun Kumar Beerala, S. R. Engineering College, India
Gobinath R., S. R. Engineering College, India
Shyamala G., S. R. Engineering College, India
Siribommala Manvitha, KITS, India

Chapter 30
The Contribution of ICTs to Sustainable Urbanization and Health in Urban Areas in Cameroon..... 624
Adolphe Ayissi Eteme, University of Ngaoundéré, Cameroon
Justin Moskolai Ngossaha, University of Ngaoundéré, Cameroon

Chapter 31
Advanced Nanomaterials for Water Engineering and Treatment: Nano-Metal Oxides and Their Nanocomposites 642
Rabia Nazir, Pakistan Council of Scientific and Industrial Research Laboratories Complex, Pakistan

Chapter 32
Geopolymer Sourced with Fly Ash and Industrial Aluminum Waste for Sustainable Materials 676
Sujitra Onutai, Nagaoka University of Technology, Japan
Sirithan Jiemsirilers, Chulalongkorn University, Thailand
Takaomi Kobayashi, Nagaoka University of Technology, Japan

Chapter 33
Removal of Emerging Contaminants from Water and Wastewater Using Nanofiltration Technology 697
Yang Hu, University of Waterloo, Canada
Yue Peng, Georgia Institute of Technology, USA
Wen Liu, Auburn University, USA
Dongye Zhao, Auburn University, USA
Jie Fu, Georgia Institute of Technology, USA

Chapter 34
Physical Treatment Technologies for Landfill Leachate: Performance and Limitation..... 717
Mohammed J. K. Bashir, Universiti Tunku Abdul Rahman, Malaysia
Nurazim Ibrahim, Universiti Sains Malaysia, Malaysia
Muhd Nazmi Ismail, Politeknik Sultan Abdul Halim Mu'adzam Shah, Malaysia
Muhammad Azan Tamar Jaya, Universiti Sains Malaysia, Malaysia

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Chapter 35
Heavy Metal(loid) Remediation Using Bio-Waste: A Potential Low-Cost Green Technology for Cleaning Environment 754
Sukanta Rana, University of Kalyani, India
Jatindra Nath Bhakta, University of Kalyani, India

Chapter 36
Biological Treatment Technology for Landfill Leachate 775
Husnul Azan Bin Tajarudin, Universiti Sains Malaysia, Malaysia
Mohd Firdaus Bin Othman, Universiti Sains Malaysia, Malaysia
Noor Aziah Binti Serri, Universiti Sains Malaysia, Malaysia
Muhammad Redzwan Bin Tamat, Universiti Sains Malaysia, Malaysia

Chapter 37
Scientific Insights Into Modified and Non-Modified Biomaterials for Sorption of Heavy Metals From Water 807
Tawfik A. Saleh, King Fahd University of Petroleum and Minerals, Saudi Arabia
Salawu Omobayo Adio, King Fahd University of Petroleum and Minerals, Saudi Arabia
Prakash Parthasarathy, Independent Researcher, India
Gaddafi I. Danmaliki, King Fahd University of Petroleum and Minerals, Saudi Arabia

Section 4
Utilization and Application

Chapter 38
Waste Disposal: Sustainable Waste Treatments and Facility Siting Concerns 829
Hossein Farraji, Universiti Sains Malaysia, Malaysia
Nastaein Qamaruz Zaman, Universiti Sains Malaysia, Malaysia
Parsa Mohajeri, Universiti Sains Malaysia, Malaysia

Chapter 39
Assessment of Available Technologies for Hospital Waste Management: A Need for Society 860
Alok Rai, Babasaheb Bhimrao Ambedkar University, India
Richa Kothari, Babasaheb Bhimrao Ambedkar University, India
D. P. Singh, Babasaheb Bhimrao Ambedkar University, India

Chapter 40
Mystery of Recycling: Glass and Aluminum Examples 877
Yasin Galip Gencer, Bogazici University, Turkey

Chapter 41
Sustainable Environmental Service - Knowledge Management: A Case of Bangkok MSW Management 897
Pitchayanin Sukholthaman, Japan Advanced Institute of Science and Technology (JAIST), Japan
Kunio Shirahada, Japan Advanced Institute of Science and Technology (JAIST), Japan

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Chapter 42
Leachate Generation, Transport, and Control 918
Mohamed Shahrir Mohamed Zahari, Universiti Malaysia Terengganu, Malaysia
Shahrul Ismail, Universiti Malaysia Terengganu, Malaysia
Izan Jaafar, Universiti Malaysia Terengganu, Malaysia

Chapter 43
Bioremediation of Agricultural, Municipal, and Industrial Wastes 948
Shivani Garg, Kurukshetra University, India

Chapter 44
Polymer Consumption, Environmental Concerns, Possible Disposal Options, and Recycling for Water Treatment 971
Tawfik A. Saleh, King Fahd University of Petroleum and Minerals, Saudi Arabia

Preface

As global waste generation increases at a rapid rate, there is a dire need for waste management practices such as collection, disposal, and recycling to protect from environmental pollution. Improper disposal methods such as open-air burning and unsafe recycling have led to significant public and environmental health issues including respiratory disorders, resource depletion, and infant mortality. Adopting new waste management techniques is a necessity in order to preserve the health of the global community and ecosystem.

The field of waste management is evolving, especially as the world's population continues to grow and more solid and liquid waste are being generated by society. Staying informed of the most up-to-date research trends and findings is of the utmost importance. That is why IGI Global is pleased to offer this three-volume reference collection that will shed light on critical issues on the management of different types of wastes and new waste management technologies by providing both broad and detailed perspectives on cutting-edge theories and developments. This reference is designed to act as a single reference source on conceptual, methodological, and technical issues, as well as to provide insight into emerging trends and future opportunities within the field.

Waste Management: Concepts, Methodologies, Tools, and Applications is organized into seven distinct sections that provide comprehensive coverage of important topics. The sections are:

1. Fundamental Concepts and Theories;
2. Development and Design Methodologies;
3. Tools and Technologies;
4. Utilization and Applications;
5. Organizational and Social Implications;
6. Critical Issues and Challenges; and
7. Emerging Trends.

The following paragraphs provide a summary of what to expect from this invaluable reference tool.

Section 1, "Fundamental Concepts and Theories," serves as a foundation for this extensive reference tool by addressing crucial theories essential to the understanding of waste management. Introducing the book is "Introduction to Solid Waste and Its Management," by Prof. Hamidi Abdul Aziz (Universiti Sains Malaysia, Malaysia) and Prof. Salem S. Abu Amr (Universiti Sains Malaysia, Malaysia): a great foundation laying the groundwork for the basic concepts and theories that will be discussed throughout the rest of the book. Section 1 concludes and leads into the following portion of the book with a nice segue chapter, "A Review of Emerging Contaminants in Water: Classification, Sources, and Potential Risks," by Prof. Alexandros I. Stefanakis (University of Brighton, UK) and Prof. Julie A. Becker (University of the Sciences, USA).

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Section 2, "Development and Design Methodologies," presents in-depth coverage of the conceptual design and architecture of waste management. Opening the section is "Integrated Leachate Treatment Technology," by Prof. Zawawi Daud (Universiti Tun Hussein Onn Malaysia, Malaysia) and Prof. Halizah Awang (Universiti Tun Hussein Onn Malaysia, Malaysia). Through case studies, this section lays excellent groundwork for later sections that will get into present and future applications for waste management. The section concludes with an excellent work by Prof. David de la Varga (Sedaqua, Spain), Prof. Manuel Soto (University of A Coruña, Spain), Prof. Carlos Alberto Arias (Aarhus University, Denmark), Prof. Dion van Oirschot (Rietland bvba, Belgium), Prof. Rene Kilian (Kilian Water, Denmark), Prof. Ana Pascual (AIMEN, Spain), and Prof. Juan A. Álvarez (AIMEN, Spain), "Constructed Wetlands for Industrial Wastewater Treatment and Removal of Nutrients."

Section 3, "Tools and Technologies," presents extensive coverage of the various tools and technologies used in the implementation of waste management. The first chapter, "Economic Instruments for Sustainable Environmental Management," by Prof. Günay Kocasoy (Bogazici University, Turkey), lays a framework for the types of works that can be found in this section. The section concludes with "Scientific Insights Into Modified and Non-Modified Biomaterials for Sorption of Heavy Metals From Water," by Prof. Tawfik A. Saleh (Department of Chemistry, King Fahd University of Petroleum and Minerals, Saudi Arabia), Salawu Prof. Omobayo Adio (King Fahd University of Petroleum and Minerals, Saudi Arabia), Prof. Prakash Parthasarathy (Independent Researcher, India), and Prof. Gaddafi I. Danmaliki (King Fahd University of Petroleum and Minerals, Saudi Arabia). Where Section 3 described specific tools and technologies at the disposal of practitioners, Section 4 describes the use and applications of the tools and frameworks discussed in previous sections.

Section 4, "Utilization and Applications," describes how the broad range of waste management efforts has been utilized and offers insight on and important lessons for their applications and impact. The first chapter in the section is "Waste Disposal: Sustainable Waste Treatments and Facility Siting Concerns," written by Prof. Hossein Farraji (Universiti Sains Malaysia, Malaysia), Prof. Nastaein Qamaruz Zaman (Universiti Sains Malaysia, Malaysia), and Prof. Parsa Mohajeri (Universiti Sains Malaysia, Malaysia). This section includes the widest range of topics because it describes case studies, research, methodologies, frameworks, architectures, theory, analysis, and guides for implementation. The breadth of topics covered in this section is also reflected in the diversity of its authors, from countries all over the globe. The section concludes with "Bioremediation of Pharmaceutical Wastes," by Prof. Alka Bali (Panjab University, India), a great transition chapter into the next section.

Section 5, "Organizational and Social Implications," includes chapters discussing the organizational and social impact of waste management. The section opens with "Legislation for Solid Waste Management," by Prof. Azhar Abdul Halim (Universiti Kebangsaan Malaysia, Malaysia) and Prof. Siti Hafizan Hassan (Universiti Sains Malaysia, Malaysia). This section focuses exclusively on how these technologies affect human lives, either through the way they interact with each other or through how they affect behavioral/workplace situations. The section concludes with "Human Overpopulation and Water Pollution: Reduction of Microbial Pollution by Vertical Flow Constructed Wetland," by Prof. Gargi Sharma (Malviya National Institute of Technology, India) and Prof. Pravin Kumar Mutiyar (National Mission for Clean Ganga, India).

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Section 6, "Critical Issues and Challenges," presents coverage of academic and research perspectives on waste management tools and applications. The section contains the chapter "Nanotechnology for Filtration-Based Point-of-Use Water Treatment: A Review of Current Understanding," by Prof. Kathryn Gwenyth Nunnelley (University of Virginia, USA) and Prof. James A. Smith (University of Virginia, USA). The chapter in this section looks into theoretical approaches and offers alternatives to crucial questions on the subject waste management.

Section 7, "Emerging Trends," highlights areas for future research within the field of waste management, opening with "Novel Bioremediation Methods in Waste Management: Novel Bioremediation Methods," by Prof. Charu Gupta (Amity University, India) and Prof. Dhan Prakash (Amity University, India). This section contains chapters that look at what might happen in the coming years that can extend the already staggering amount of applications for waste management. The final chapter of the book looks at an emerging field within waste management, in the excellent contribution, "Reverse Logistics in the Electronics Waste Industry," by Prof. Berk Ayvaz (Istanbul Commerce University, Turkey) and Prof. Ali Görener (Istanbul Commerce University, Turkey).

Although the primary organization of the contents in this multi-volume work is based on its seven sections, offering a progression of coverage of the important concepts, methodologies, technologies, applications, social issues, and emerging trends, the reader can also identify specific contents by utilizing the extensive indexing system listed at the end of each volume. As a comprehensive collection of research on the latest findings related to using technology to providing various services, *Waste Management: Concepts, Methodologies, Tools, and Applications* provides researchers, scientists, environmentalists, engineers, policymakers, government officials, academicians, and all audiences with a complete understanding of the development of applications and concepts in the management of waste products. Given the vast number of issues concerning usage, failure, success, policies, strategies, and applications of protecting the environment through the effective disposal of waste products in countries around the world, *Waste Management: Concepts, Methodologies, Tools, and Applications* addresses the demand for a resource that encompasses the most pertinent research in technologies being employed to globally bolster the knowledge and applications of managing societal waste products.

Chapter 1
Introduction to Solid Waste and Its Management

Hamidi Abdul Aziz
Universiti Sains Malaysia, Malaysia

Salem Abu Amr
Universiti Sains Malaysia, Malaysia

ABSTRACT

Municipal Solid Waste (MSW) disposal has become an increasingly serious problem in many parts of the world. In general, greater economic prosperity and a higher percentage of urban population correspond to a greater amount of solid waste produced. However, less effort has been exerted in the proper management of solid wastes produced by urban dwellers, particularly in developing countries. This chapter introduces the basic MSW rules. MSW composition, production, and collection are also highlighted. Furthermore, the concept of landfilling and waste decomposition is discussed in this chapter.

INTRODUCTION

Growing population and industrial development have increased waste generated by urban areas. Municipal solid waste (MSW) can be defined as the wastes arising from domestic, commercial, industrial, and institutional activities in urban areas (Bartone 1990; Ravindra et al., 2015). In developing countries, MSW disposal has become an ever-increasing problem in many parts of the world, especially in the developing countries (Al-Khatib et al., 2014; Caniato et al., 2014). Generally, the greater the economic prosperity and the higher the percentage of urban population, the greater is the amount of solid waste produced. This tremendous increase in the amount of MSW generated is due to changing lifestyles, food habits and living standards of the urban population. Despite this growth, there has been less parallel effort to properly manage the solid wastes produced by the urban dwellers, especially in the developing countries.

MSW are defined by EPA as a waste consisting of everyday items "used and then thrown away, such as product packaging, grass clippings, furniture, clothing, bottles, food scraps, newspapers, appliances, paint, and batteries," which come from homes, schools, hospitals, and businesses (US EPA, 2013).

Gershman et al. (1986) described MSW as rubbish from residences, institutions, and commercial establishments and non-hazardous light industrial refuse. McBean et al. (1995) defined MSW as residential solid waste produced from the house, and outdoor activities of a single or multi-family house. Dixon and Jones (2005) defined MSW as a mixture of waste primarily originating from residential and commercial establishments. The Malaysian Solid Waste and Public Cleansing Management Act of 2007 (Act 672) defines MSW as any substance requiring disposal because it is broken, worn out, contaminated, or physically spoiled. The management of MSW that has already been generated can be roughly divided into four methods: recycling, composting, thermal treatment with energy recovery, and landfilling. However, the generation of wastes can be reduced by various means, such as a better design of products and packaging, and therefore "Reduction" is placed at the very top of the waste management hierarchy.

SOLID WASTE PRODUCTION

Solid waste generally refers to unused solid materials generated as a result of human activities. Many of these items can be considered as waste such as domestic rubbish, sewage sludge, wastes from manufacturing activities, packaging items, discarded cars, discarded electronic devices, garden waste, old paint containers etc. Accordingly, all human daily activities can give rise to a large variety of different wastes arising from different sources (Ngoc & Schnitzer, 2009). Based on their sources, solid waste can be classified into various types which include MSW, hazardous waste, agricultural waste and industrial waste (Tchobanoglous et al., 1993). In Malaysia; the generation of MSW has significantly increased in recent years, ranging between 0.5 - 2.5kg per capita per day (or a total of 25000 - 30000 tons per day). More than 70% of the generated wastes are collected using both curbside and communal centers with a collection frequency varying from daily to every two days (Johari et al., 2014).

MSW defined as a waste collected from households, in addition to the commercial waste collected by a municipality but it generally excludes hazardous wastes. Because urbanization and population growth have rapidly increased the rate of MSW production and disposal in many cities of the world, the management of MSW has emerged as a major concern around the world particularly the rapidly developing countries.

According to Tanaka (2006), the generation of solid waste is expected to increase steadily along with economic growth if we continue the lifestyle of mass production, mass consumption and mass disposal (Figure 1).

It has been reported by Chong et al. (2005) that solid waste is one of the biggest environmental problems in Malaysia and the generation rate of solid waste is expected to increase tremendously due to the rapid increase in population and economic growth in the country.

Table 1 illustrates the annual MW generation in tons by weight in South East and East Asian Countries. China has the highest waste generation in the region, followed by South Korea, Japan and Indonesia. Currently, there is no data on municipal waste generation at the national level for Cambodia and Mongolia. But in Phnom Penh, the capital of Cambodia, the amount of municipal waste is observed. Actual statistics of municipal waste generation is illustrated in countries like Brunei Darussalam, Phnom Penh - Cambodia, PR China, Indonesia, Republic of Korea, Lao PDR, Mandalay in Myanmar, Singapore, Thailand and Vietnam. Most of the member countries do not have the data and information on the actual municipal waste generation, so that estimated and/or projected amount of municipal waste generation

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. Predicted solid waste generation (Tanaka, 2006)

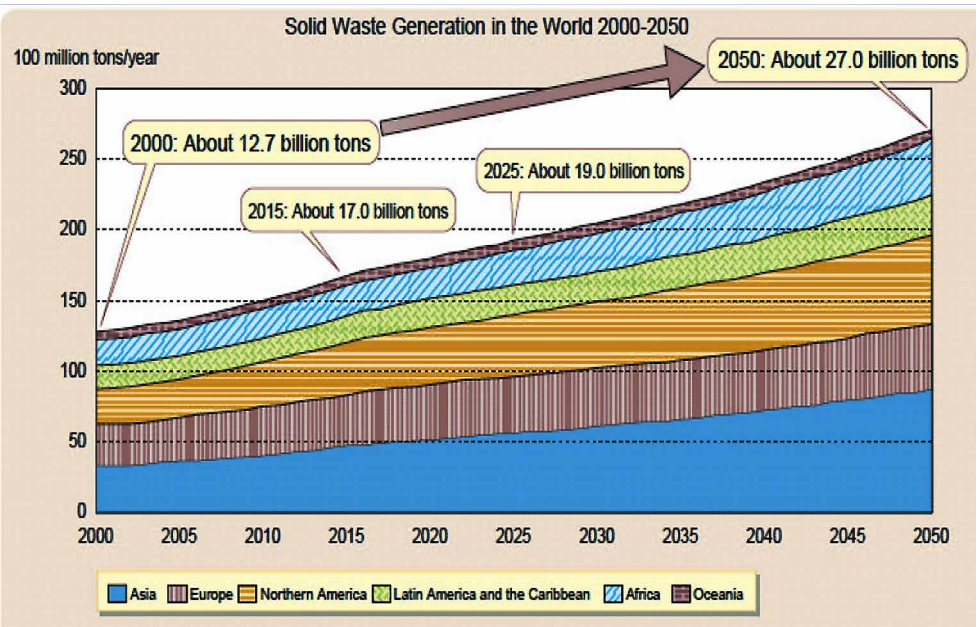

Table 1. Municipal Waste Generation and population in East, West, South and North Zone (Velumani et al., 2009)

Zone	Number of Houses	Population	MSW Generated in Tons / Day			
			Degradable	Recyclable	Inert	Total
East	63,355	2,87,553	102	7.2	22.4	131.6
West	59,838	2,66,717	114.4	7.9	21.4	143.7
South	46,509	2,38,571	120.4	8.1	19.1	147.6
North	59,007	3,01,047	109.4	7.8	23.9	141.1
Total	2,28,709	10,93,888	446.2	31.0	86.8	564.0

can be noticed. This is so in countries like Malaysia and Philippines' Metro Manila. The MW recycled is the highest in South Korea, followed by Singapore while other member countries do not have sufficient data on recycled MW.

The composition of the waste is a description of the contents of the waste. In addition to providing important information about the way to handle the waste, the composition tells us about the people who generated the waste. The composition of waste varies widely from place to place, especially country to country. Table 2 shows the average composition and amounts of waste for low, medium and high-income countries.

The most striking difference that can be seen is the difference in organic content which is much higher in the low income countries than the high income countries and the paper and plastic content which is much higher in higher income countries than low income countries. This shows the difference

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 2. Relative composition of household waste in low, medium and high-income countries (INTOSAI working group on environmental auditing, 2002)

	Parameter	Low-Income Countries	Medium-Income	High-Income Countries
Contents	Organic (putrecible), %	40 to 85	20 to 65	20 to 30
	Paper, %	1 to 10	15 to 30	15 to 40
	Plastics, %	1 to 5	2 to 6	2 to 10
	Metal, %	1 to 5	1 to 5	3 to 13
	Glass, %	1 to 10	1 to 10	4 to 10
	Rubber, leather, etc., %	1 to 5	1 to 5	2 to 10
	Other, %	15 to 60	15 to 50	2 to 10
Physical and chemical properties	Moisture content, %	40 to 80	40 to 60	5 to 20
	Specific weight, kg/m3	250 to 500	170 to 330	100 to 170
	Calorific value, kcal/kg	800 to 1100	1000 to 1300	1500 to 2700

in consumption pattern, cultural and educational differences. In higher income countries, the usage of disposable material, magazines and packaged food is used in higher quantity that results in a waste having higher calorific value, lower specific density, and lower moisture content. In case of lower income countries, the usage of fresh vegetables to packaged food is much higher and mostly materials that are reusable are used. This results in a waste composition that has high moisture content, high specific weight and low calorific value. This shows how waste statistics can be used to describe the life style of the people and also their income.

MUNICIPAL WASTE COMPOSITION

Composition is the term used to describe waste components that comprise a solid waste stream and its relative distribution, which is usually based on weight percentage. Waste components are significantly affected by social and economic factors, including population increase, consumption growth, changes in consumption patterns, and technological development of waste treatment systems (Buttol et al., 2007). Waste composition is influenced by factors such as culture, economic development, climate, and energy sources. Composition affects how often waste is collected and how it is disposed. In the MSW stream, waste is normally classified as organic and inorganic. Waste composition is categorized as organic, paper, plastic, glass, metal, and "others." These categories can be further refined. However, these six categories are often sufficient for general solid waste planning purposes. Table 3 describes the different types of waste and their sources.

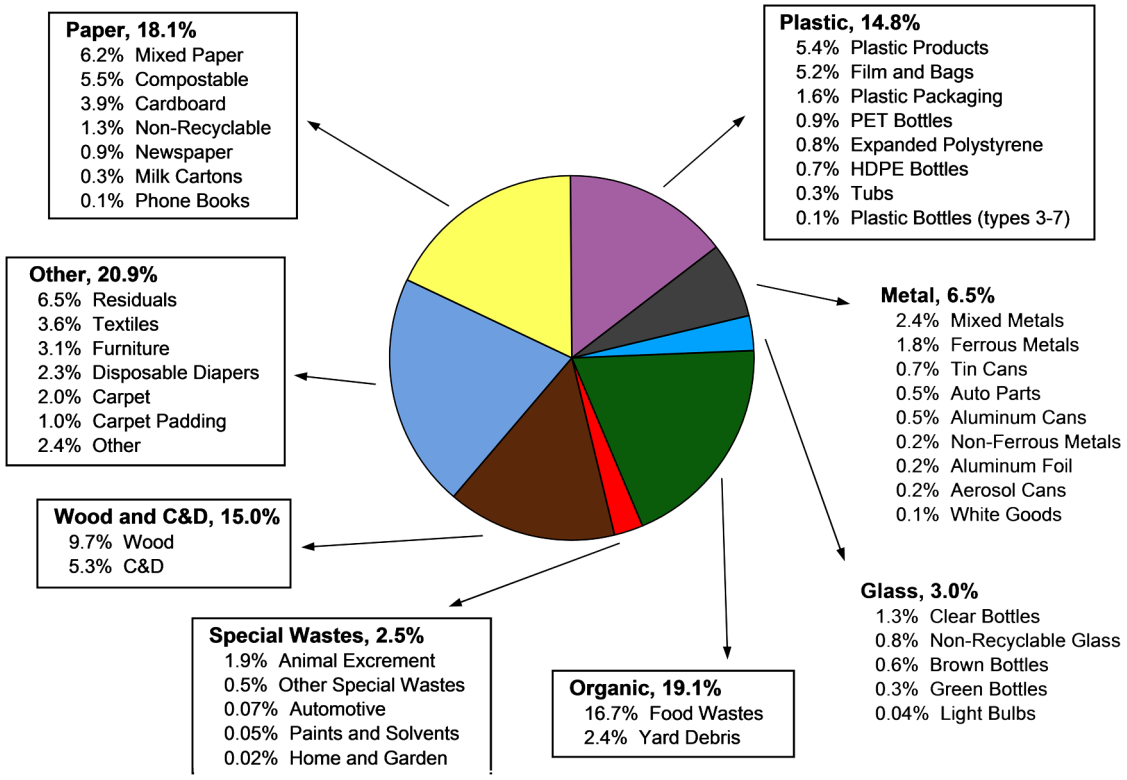
An effective waste management and minimization strategy is practically impossible without reliable information on waste characteristics. Adequate information on waste characteristics is important to assess the effects of different waste types and to estimate the age of landfills. However, dependable information on MSW characteristics is difficult to achieve (Idris et al., 2004). MSW composition is provided in Table 3 and Figure 2.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 3. Type and source of solid waste

Organic	Food scraps, yard (leaves, grass, brush) waste, wood, process residues
Paper	Paper scraps, cardboard, newspapers, magazines, bags, boxes, wrapping paper, telephone books, shredded paper, paper beverage cups. Strictly speaking paper is organic but unless it is contaminated by food residue, paper is not classified as organic
Plastic	Bottles, packaging, containers, bags, lids, cups
Glass	Bottles, broken glassware, light bulbs, colored glass
Metal	Cans, foil, tins, non-hazardous aerosol cans, appliances (white goods), railings, bicycles
others	Textiles, leather, rubber, multi-laminates, e-waste, appliances, ash, other inert materials

Figure 2. Waste composition in the world (Thurston county Waste composition study, 2009)



SOLID WASTE STORAGE, COLLECTION, AND TRANSFER

1. **Waste Collection:** Is a part of the waste management_process and involves the transfer of solid waste from the point of use and disposal to the point of treatment or landfill. Waste collection also includes the curbside collection of recyclable materials, which are technically not waste, as a part of a municipal landfill diversion program. A transfer station is a building or processing site that is used for the temporary deposition of waste. Transfer stations are often used as places where local waste collection vehicles will deposit their waste prior to loading into larger vehicles. These larger vehicles will transport waste for recycling or to the endpoint of disposal in an incinerator, landfill,

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

or hazardous waste facility. The waste collection is a process that includes gathering solid wastes and recyclable materials and transporting these materials to either the processing facility, transfer facility, or disposal site. Several types of waste collection are presented as follows (Tchobanolous et al., 1993):

2. **Community Bins:** Bins are placed in convenient locations where community members can throw waste. This method is comparatively cheaper to implement than other methods and is the most widely adopted method in Western countries. For this method to be adopted, bins should be covered, aesthetically presentable, are attended regularly, kept clean, and easy to handle. Moreover, separate bins should be provided for recyclable, mixed, paper, and biodegradable waste materials.
3. **Door-to-Door Collection:** In this process, the waste is placed at the doorstep at a set time when the waste collector arrives. In this method, the waste collector is responsible for collecting the waste separately. This method is highly convenient for householders, although it requires homeowner cooperation and a scheduled service for homeowner cooperation.
4. **Block Collection:** Collection vehicles arrive at a particular place, day, and time to collect waste from households. Household members bring their waste containers and empty them directly into the vehicle. This method requires a higher homeowner cooperation and scheduled service for homeowner cooperation.
5. **Curbside Collection:** The homeowner is responsible for placing their garbage containers at the curb on the collection day and for returning the empty containers to their storage location until the next collection of transfer and transport

Waste materials are transferred from a small collection vehicle to larger transport vehicle. The subsequent transport of waste to a processing or disposal site often takes long distances. Thus, the transfer often takes place at a transfer station. Non-engineered disposal, which involves no controls or only slight or moderate controls, is the most common method of disposal in low-income countries. Waste materials tend to remain for a long time, thus increasing the risk for environmental degradation, including mosquito and rodent infestation, water pollution, and land degradation.

A sanitary landfill is a fully engineered disposal option that can avoid the harmful effects of uncontrolled dumping by spreading, compacting, and covering the engineered wasteland. The four minimum requirements for setting up a sanitary landfill are full or partial hydrological isolation, formal engineering preparation, permanent control, and planned waste placement and covering. Land filling relies on waste containment rather than waste treatment (for control). Appropriate liners for groundwater protection, leachate collection and treatment, well monitoring, and appropriate final cover design are integral components of an environmentally sound sanitary landfill.

In the future, transfer stations could be equipped with material recovery facilities and with localized mechanical biological treatment systems to remove recyclable items from waste streams.

SOLID WASTE DISPOSAL

Solid waste disposal is defined as the final placement of refuse that is not salvaged or recycled. The treatment and disposal of solid waste vary from one country to another and depend on various factors, such as waste type, composition, infrastructure, land availability, labor, economic aspects, recycling strategy, public awareness, and environmental impact. The objectives of waste disposal are to remove

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

the solid waste from the community as soon as possible, reduce its quantity, stabilize it, and maintain the cleanliness. Landfilling is currently the only technology employed for solid waste disposal in Malaysia, and the majority of landfill sites are open dumping areas, which cause severe environmental and social risks (Manaf et al., 2009; Yunus & Kadir, 2003). The current volume of generated waste continues to increase because of the growing population and rapid development. Moreover, only less than 5% of waste is recycled. The rapid development and industrialization of Malaysia necessitate an efficient waste management plan (Fauziah et al., 2004). Despite the numerous advantages of landfilling, the resulting highly polluted leachate has been a cause of significant concern, particularly because landfilling is the most common technique of solid waste disposal (Ghafari et al., 2005). MSW disposal requires handling waste in a manner that does not cause problems to society or to the environment. Furthermore, solid waste can be processed to recover several components that can be used for useful purposes (Weiner and Matthews, 2003).

MSW disposal methods include open dumping, sanitary landfilling, composting, incineration, grinding and discharge to sewer, compaction, milling, hog feeding, dumping and burial at sea, reduction, and anaerobic digestion (Davis and Cornwell, 2008).

Landfilling

General Overview

A landfill is like a big rubbish bin (JICA, 2005). In the last few decades, the disposal of waste to land has become the most favored means of waste management (Chong et al., 2005). Open landfill sites are the most popular solid waste disposal method in Southeast Asian countries which is primarily due to their ability to deal with high quantities of solid waste generated each day (Ngoc & Schnitzer, 2009). Further, landfilling provides economical MSW disposal and it is also suitable for the type of wastes which constitute higher percentage of organic matter. However, landfills in many places in ASEAN are classically unsanitary open disposal sites without a leachate management system. Figure 3 illustrates the waste treatment methods used in ASEAN.

Robinson and Maris (1983) reported that the landfill is one of the most sustainable forms of solid waste disposal because adverse environmental effects and other risks and inconveniences are minimized, thereby allowing waste to decompose under controlled conditions until it eventually transforms into relatively inert and stabilized material. In fact there are no combinations of waste management practices that do not require landfilling.

Among other management alternatives, landfilling is the only management technique that is both necessary and sufficient. Several wastes are basically not recyclable and they finally reach a point where their intrinsic value is dissipated completely. Recycling also generates residuals that require ultimate disposal in a landfill (Messineo & Panno, 2008).

The challenge is to ensure that all operating landfills are properly designed and monitored after their closure. Currently, operating landfills do not continue to take hazardous wastes. In addition, they do not receive bulk liquids. They have gas control systems, liners, leachate collection and extensive groundwater monitoring systems (Theisen, 2002)

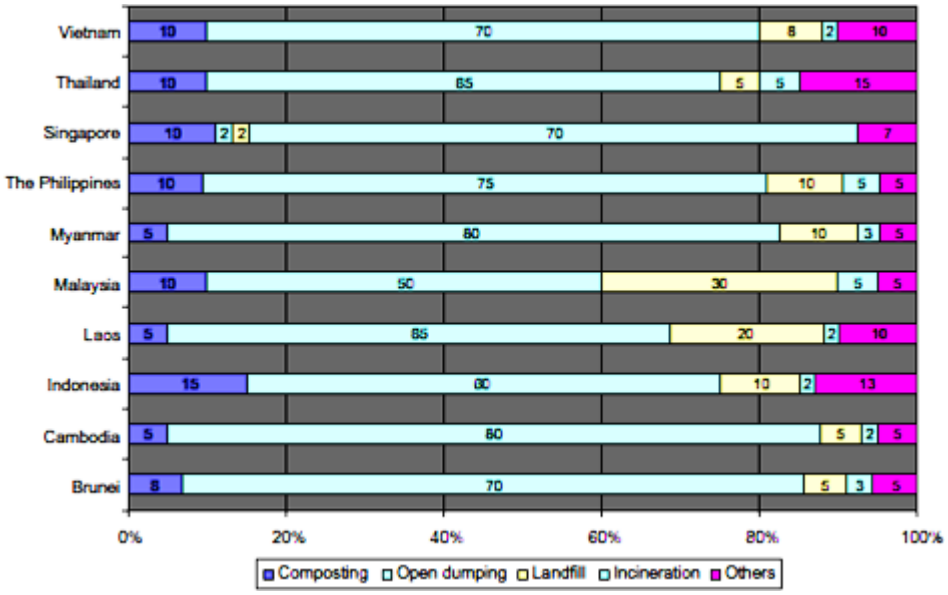
Figure 3. Solid waste treatment methods in ASEAN (%) (Ngoc and Schnitzer, 2009)



Landfilling Design, Operation and Challenges

Landfill Siting

Land selection for construction of landfill is one of the main problems of MSW landfilling because of the difficulty in locating the suitable site and in obtaining administrative clearance and public consensus. Public will generally oppose to the decision for the landfill situated near their neighbourhood. This is because they are driven by the fear of unknown and the distrust of the government in securing the safety of the landfill (Tammemagi, 1999). Thus, it is important to find a site which is technically suitable and at the same time safeguarding the interest of the community especially in relation to the health issue and compensation that they should be received.

Landfill Design

A proper designed landfill should incorporate different features according to sound engineering principles and environmental codes of practice (i.e (1) base liner and leachate collection system, (2) daily soil covering, (3) final top liner, (4) diversion of surface runoff system, (5) gas emission control system (6) and proper access roads to the site) in order to prevent and to minimize any negative environmental impacts during the waste degradation process. The materials of choice in landfill construction are limited and no more, so then the regulations requiring them for liner use for consideration. The biggest challenges of base liner system are to contain the waste so that the waste doesn't cause problems in the outside environment, particularly groundwater. The composite base liner consists of an upper geomembrane liner and a lower compacted soil. However, the lifespan of the landfill liner is yet to be sure and there is a high probability that the leachate could form and leach through the artificial liner as the liner deteriorates along time and the interaction with the chemical components in the landfill cell (Allen 2001).

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Allen et al., (2001) suggested that the landfill should be situated at land with natural hydrogeological characteristics which can contain and naturally attenuate contaminants to acceptable level instead of trying to contain the contaminants within the landfill by relying on artificial liners.

Landfill and Environmental Impacts

Disposal of waste in the landfill can cause serious environmental problems if the landfills are not properly designed and constructed. During the waste degradation process, the temperature within the landfill will increase. And with the high percentage of methane, this will cause fire hazard. Other environmental threats that posed by dumpsites and landfills including stench, water pollution, air pollution and potential health hazards.

Leachate Generation and Effect on Water Resources

One of the most significant disadvantages of landfill disposal methods is the generation of highly polluted liquid (i.e., landfill leachate). Landfill leachate is the liquid that seeps through solid waste in a landfill (Christensen et al., 2001). The amount of leachate produced depends on the amount of water that percolates through the landfill cell and mixes with waste. The more water content in the waste, the more leachate will be produced. This leachate will leach through the landfill either vertically or laterally. Numerous factors affect the quality and quantity of leachate, including seasonal weather variation, landfilling technique, waste type and composition, and landfill structure (Mohajeri, 2010; El-Fadel et al., 2002). Unfortunately, landfill leachate is rapidly generated in tropical countries, such as Malaysia, because rainfall generally exceeds the evaporation rate during the rainy season (Lema et al., 1988). Researchers have yet to determine an effective solution to this problem. The technology that can be used may differ according to the type of leachate produced. Unless returned to the environment in a carefully controlled manner, landfill leachate is a polluting liquid that may bring harmful effects on groundwater and surface water around a landfill site. The sequential migration of leachate away from landfills and its release into the environment pose serious environmental risks that threaten public health and safety (Read et al., 2001).

To protect groundwater from contamination, an impermeable liner system should be placed inside the landfill, and prober collection and drainage systems should be designed to allow rainfall to run off. EU waste management and legislation introduced this containment strategy to keep the pollutant and inert waste within the landfill (Allen, 2001). The belief is that the lining system can completely contain the leachate produced during the waste degradation process, thus preventing the pollution of water sources. However, Dr. Montague explained that landfill liners cannot hold leachate and toxic materials within the landfill site forever. The durability of the artificial liner system is still unknown, and waste degradation may take decades or even centuries to achieve its inert state; thus, leachate leakage problems have a high probability of occurring (Allen, 2001). On the basis of laboratory experiments, researchers determined that volatile organic chemicals, such as toluene and xylene, can eat through synthetic liners and leave the landfill unable to hold the leachate within it (Breen, 1990). Hence, the durability of the lining system is not guaranteed in the long term. Leachate and toxic materials may percolate and leach through the liners, thus causing ground water pollution. Modern sanitary landfills only postpone these effects to future generations. Thus, many environmental specialists have sought to develop efficient treatment methods for large quantities of polluted leachate.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Gas Emission

When MSW is disposed of in a landfill, naturally occurring Microorganisms (bacteria) degrade the waste. The amount of water in and the temperature of the MSW control the rate of degradation. This process turns the organic portion of the waste into methane (a primary constituent of natural gas) and carbon dioxide in about equal proportions. Additionally, some organic compounds may be released directly into the gas from products contained in the waste, such as household cleaning materials. The non-methane organic compounds (NMOC) in the gas amount to less than one percent of the total gas created by waste degradation. Gas generated can threaten human health and the environment if it migrates off site or is not collected and destroyed. Landfill odors often prompt complaints from community members. People may also have concerns about health effects associated with these odors and other emissions coming from the landfill. Typical constituents found in MSW landfill gas is given in Table 4.

Landfill Operation and Maintenance

A safe design of landfill is barely enough to ensure the safety of the public and the environment protection; it requires a well-managed operation which should include the following: (1) the waste that is entering to landfill should be identified by Landfill operators to prevent hazardous waste from being delivered and co-disposed with other municipal solid waste at the landfill. They should be authorized to reject any waste until it is identified to be safe and acceptable at the landfill site, (2) daily cover should be used at the end of each working day operation or in a more frequent interim to control disease, vectors from breeding, scavenging activities by rodents, seagulls, crows, odors and windblown littering, (3) Run-on control to prevent water from outside the landfill from entering the landfill cell because the additional water will increase the leachate production, and runoff control to prevent the escape of contaminants from the landfill area, (4) protective equipment should be provided and safety operation should be implemented to the site workers in order to minimize the risks of operators and workers. Most of the existing solid waste landfill sites in developing countries are practicing either open dumping or unsanitary landfilling. Some are located at the upstream of water intakes or at sensitive groundwater catchment area. Most of these sites are simply dumping grounds without any environmental protection. This practice is very

Table 4. Typical constituents found in MSW landfill gas (Tchobanoglous et al., 1993)

Component	Percent (Dry Volume Basis)
Methane	45-60
Carbon dioxide	40-60
Nitrogen	2-5
Oxygen	0.1-1.0
Sulfides, disulfides, mercaptans, ect.	0-1.0
Ammonia	0.1-1.0
Hydrogen	0-0.2
Carbon monoxide	0-0.2
Trace constituents	0.01-0.6

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

unsustainable and creates a lot of problems such as fires due to landfill gases, rodents, bad odours and leachate pollution. Proper sanitary landfill concepts and the usage of intermediate treatments such as incineration, pyrolysis, and recycles are not actively practiced to effectively remove the wastes in many countries. This is mostly due to technological and financial constraints.

CATEGORY OF MUNICIPAL LANDFILL SOLID WASTE

Landfill sites are generally classified into five: anaerobic, aerobic, anaerobic sanitary, improved anaerobic sanitary, and semi-aerobic. The use of these different landfills is generally based on environmental concerns and economic factors.

A. **In an Anaerobic Landfill:** Solid wastes are decomposed by a conventional municipal method (Matsufuji, 1990). However, this type of landfill poses many major environmental and health concerns because it produces toxic leachate. Hudgins and Harper (1999) reported that anaerobic landfills contain high concentrations of organic compounds and pathogens. The waste mass also slowly degrades, posing long-term risks (Figure 4a).
B. **In an Anaerobic Sanitary Landfill:** Solid waste is sandwiched by soil. The conditions of solid waste here are the same as in anaerobic landfills (Figure 4b).
C. **In an Improved Anaerobic Landfill:** the leachate collection system is installed at the bottom of the site. Other features are the same as in an anaerobic sanitary landfill. The conditions are still anaerobic, but moisture content is much lower than that in anaerobic sanitary landfills (Figure 4c).
D. **Semi-Aerobic Landfills:** Are designed with an underlying piping system that allows air to flow inside and outside the solid waste. This design enlarges the aerobic zone inside the landfill, creates active aerobic consortia, and increases the rate of waste decomposition (Figure 4d).

Technology used in aerobic landfills has been evaluated over the last few years. The aerobic landfill system adds air and re-circulates leachate to maintain air humidity and to provide nutrients to microorganisms in order to reduce methane gas, volatile organic compounds, and odor emissions and thereby eliminate site leachate treatment. The aerobic landfill process enhances the biodegradation of waste and speeds up the stabilization of the landfill (Figure 5e).

SEMI-AEROBIC LANDFILL (FUKUOKA METHOD)

This type of landfill was first tested at the Shin-Kamata landfill in Fukuoka, Japan in 1975 (Chong et al., 2005). The Fukuoka method is specially designed for temperate climate and has been adopted in Japan and in tropical countries, such as Malaysia, Indonesia, China, Sri Lanka, and Iran, since the 1980s. A schematic diagram of semi-aerobic (Fukuoka) landfills is shown in Figure 5. The mechanism of the semi-aerobic landfill system allows oxygen flows into the waste mass through leachate collection pipes by passive ventilation to accelerate aerobic microbial decomposition in the waste. One of the main advantages of this landfill system is that discharged leachate and gas are continuously used in the leachate collection and gas ventilation system, thereby improving leachate quality.

PRINCIPLES OF DECOMPOSITION OF SOLID WASTE

A complex series of reactions occurs at the landfill when wastes are buried: physical, chemical, and biological decomposition reactions. Decomposition progress rates of solid waste largely depend on waste characteristics. Physical decomposition occurs during the operational management of solid waste landfill and includes segregation, mechanical size, and volume reduction. Chemical decomposition involves combustion, pyrolysis, and gasification. Biological decomposition includes aerobic and anaerobic degradation. Biodegradation generates highly contaminated hazardous leachate and gases (Matsufuji, 2007).

Biodegradation increases BOD levels in leachate and reduces the pH level, and then gasification generates gas from organic acids, thereby reducing BOD levels and increasing pH (Matsufuji, 2007). Decomposition in landfills is divided into five phases: initial adjustment (Phase I), transition (Phase II), acidification (Phase III), methane fermentation (Phase IV), and maturation (Phase V) (Tchobanoglous, 1993).

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Phase I: Initial Adjustment Phase

During this phase, aerobic conditions occur where organic biodegradable materials undergo microbial decomposition facilitated by air trapped within the landfill. Leachate generated from this phase is characterized by entrained particulate matter and small amounts of organic substances from aerobic degradation (McBean et al., 1995).

Phase II: Transition Phase

In this phase, biological decomposition of waste occurs. Transformation from aerobic to anaerobic environment occurs as the oxygen in waste cell decreases with more carbon dioxide being produced.

During the initial aerobic phase, oxygen present in landfill is rapidly consumed; resulting in the production of CO_2 and the leachate temperatures can be increased. The aerobic phase in a landfill lasts only a few days because oxygen is not replenished once the waste is covered and the pH in this early stage becomes neutral. When the condition turns anaerobic, the hydrolytic, fermentative, and acetogenic bacteria becomes dominant, resulting in an accumulation of carboxylic acids. Consequently, chemical oxygen demand (COD) and pH in the leachate are reduced by the end of this phase as more volatile organic acids and CO_2 are produced (Kjelsen et al., 2002).

Phase III: Acid Phase

This phase is also known as the acetogenic phase and is governed by acidogenic bacteria (acid formers). In this phase, oxygen in the landfill is consumed by aerobic bacteria. Development of organic acids and dissolved CO_2 reduces leachate pH to 5 or lower (Salem et al., 2008). Therefore, the heavy metals become soluble, and essential nutrients are removed from the leachate because of the decreasing pH. Ammonium and metal concentrations also rise, and complex molecules are degraded.

Phase IV: Methane Fermentation Phase

In this phase, methanogen conditions are established after several months or years, and leachate becomes neutral or slightly alkaline. Methanogenic bacteria consume acids and produce methane and carbon dioxide. Under stabilized methanogenic conditions, landfill gas is composed of approximately 55% to 60% methane and 40% to 45% carbon dioxide, with trace amounts of other gases (He et al., 2004). The pH in this phase increases to neutral values of 7 or 8.

Phase V: Maturation Phase

In this phase, nutrients and substrates become limited, and biological decomposition is less active. Aerobic conditions may return after conversion of biodegradable waste to carbon dioxide and methane gas. Landfill gas is depleted, and then the leachate stabilizes. Leachate often contains humic and fulvic acids, which are difficult to biodegrade. The slow degradation of these resistant organic materials may continue with the production of humic-like substances.

9.	C / N ratio	8:1	11:1	8:1	10:1	7.5:1	12:1

Table 5 and 6 summarize the physical and chemical parameters of a composite sample for municipal solid waste in India. Bulk density is a measure of the weight per unit volume of a substance (kg /m^3). Materials with a high bulk density typically have very few air spaces with most of the fine pores filled with water. These conditions allow bacteria to grow in the absence of oxygen led to producing methane and other foul smelling gases. Mixing manures with low bulk density improves air exchange minimizing the need for artificial aeration. In the various samples used, the bulk density ranges from 219.6 to 275.1 kg m^3. Since these values are not high, so that the condition for the bacterial growth is prevented.

- **Water Holding Capacity:** Is the amount of water held into pores after gravitation loss for a specified time. This test is assessed to find the utilization of compost for growing media. This reveals that the amount of water held in pores increases with days of composting.
- **Moisture Content:** Is an important parameter for waste composting. Composting material with moisture content between 30% and 100% will be under aerobic condition. In practical aerobic composting, however, high moisture content must be avoided because water displaces air from the interstices between the particles causing anaerobic conditions. However, too low moisture content deprives organisms of water needed for their metabolism and inhibits their activity. Moisture content for satisfactory aerobic composting varies with material used.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

- **Calcium Content:** Has strong influence on ion absorption by soil particle and on the availability of other elements. Calcium is important in the formation of plant cell walls and in the layers between the cells is called middle lamella.
- **Magnesium:** Is closely related to calcium and is absorbed in the soil as anion. It involves in energy conversion and phosphorous metabolism. The percentages of calcium and magnesium for the various samples studied have been observed to increase as the time of composting increased. This shows that the composted material obtained when used for growing plants will have the capability to supply other elements for the solid and the ion absorption by soil particle will be enhanced (Mendoza.and Jamora 2008) . The composted material also helps in energy transfer and phosphorous metabolism.

Other elements such as nitrogen, phosphorous, sodium and potassium are playing a significant role if used in the form of fertilizer. Since composting finally leads to organic manure, it is worthwhile in estimating these elements in the composted material obtained after a period of 30 and 60 days. In the various samples of the solid wastes that have been studied, it is observed that as the days of decomposition increased, there is an increase in the percentage of nitrogen, phosphorous, sodium and potassium.

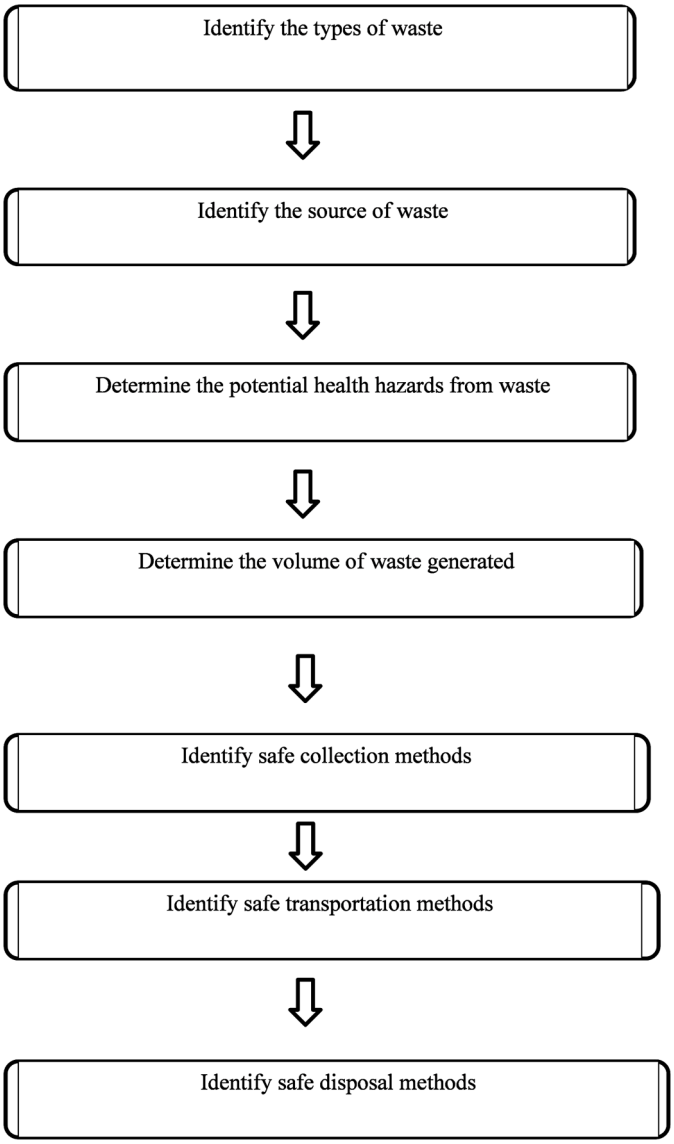
- **C/N Ratio:** Is an important parameter to determine the extent of composting and degree of compost maturity. The C/N ratio below 20 is considered suitable for compost maturity. The C/N ratio is used as an index for maturity of organic wastes. C/N ratio less than 20 indicates an advanced degree of organic matter stabilization and reflects a satisfactory degree of maturity of organic wastes (Janakiram & Sridevi 2010).
- **The Electrical Conductivity:** In matured aerobic compost increased as the days progressed which may be due to high microbial activity and mineralization, so that the soluble salt content is high.
- **pH:** Generally gives and approximate index of compost maturation. Manure composts tend to have near neutral pH values, while composts under maturation tend to be more acidic. Averagely, mature composts have pH between 6 and 8 and the composts prepared have pH in this range indicating maturity of the compost.

Municipal Solid Waste Management

MSW management is considered a public service, providing citizens with a scheme of disposing of their waste in an economically and environmentally friendly method (Beigl et al, 2008). It is one of the main concerns in most cities of the developing countries due to rapid modernization and urbanization that consequently lead to increased rate of MSW production and disposal (Zhang et al., 2010; Manaf et al., 2009). Additionally, Al-Khatib et al. (2010) stated that rapidly growing population, quick economic growth and improved community living standards have resulted in increased generation rate of MSW, the management of which is a great challenge for concerned authorities. MSW management is a significant feature of environmental hygiene in addition to planning, administration, organization, financial and legal aspects of different activities associated with generation, collection, transportation, and disposal processes (Figure 6). In other words, MSW management in an environmentally friendly way shall adopt principles of aesthetics, economy, conservation and energy (Pattnaik and Reddy, 2010; Hui et al., 2006). In order to establish an effective management of municipal solid waste, the following steps should be used (Figure 6).

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 6. Initial steps for solid waste management



Integrated MSW Management and Waste Management Hierarchy

MSW management is strongly required in order to deal with the huge daily amounts of solid waste. Solid waste management involves the overall management of activities associated with waste such as generation, storage, collection, transportation, processing, reuse, recycling and disposal (Hamer, 2003; Khatib & Al-Khateeb, 2009). Normally, an integrated waste management approach is used to cover all these activities. Several types of solid waste management systems have been implemented in different countries. Most of the countries including Malaysia employ landfill as the most common method of MSW management. On the other hand some countries have adopted different waste management schemes such as incineration. In Japan, incineration is the most common method of MSW management (Beychok, 1987).

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Tchobanoglous et al. (1993) recognized integrated solid waste management as the selection and application of appropriate techniques, technologies and management programs to achieve specific waste management objectives. Solid waste management hierarchy classifies waste management strategies according to their desirability. As shown in Figure 8, the most common methods used for the management of MSW are waste prevention, minimization, reuse, recycle, energy recovery and landfill disposal.

Sustainable waste management simply means managing waste by prioritizing as per the waste hierarchy (Butt et al., 2008). A proper waste source separation is expected to improve the overall recycling process. The waste hierarchy prioritizes prevention and source reduction of waste followed by reuse, recycling and the optimization of ultimate disposal.

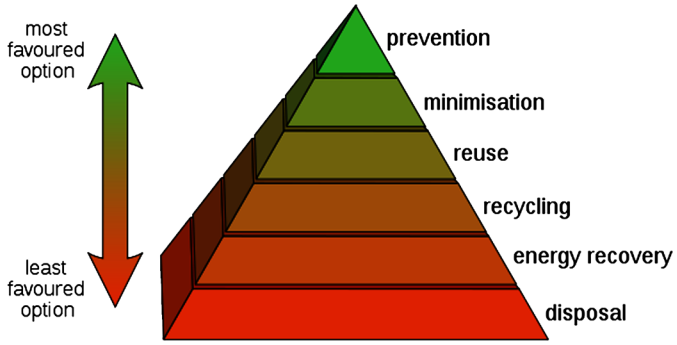
Waste Reduction and Minimization

MSW problems should be solved from various angles by using an integrated system with a combination of different techniques. The combination of methods should be complementing and not competing with one another. Furthermore, a solid waste management system should be tailored to suit local, regional, and national conditions (USEPA, 1988; Rylander, 1998). Therefore, regardless of the combination of methods being adopted, the following priorities should be followed (Figure 8):

1. Waste prevention
2. Waste reduction and reuse
3. Waste recycle and recovery
4. Final disposal

The first and most effective component of the waste hierarchy is reducing the waste produced. Waste minimization is defined as a process of elimination that involves reducing the amount of waste produced in society (US Environmental Protection Agency, 2012). The most environmentally resourceful, economically efficient, and cost-effective way to manage waste is to try to determine a suitable and applicable action to reduce waste in the first site of generation. Waste minimization should be considered a primary focus for most waste management strategies. Proper waste management can require a significant amount of time and resources; therefore, understanding the benefits of waste minimization is important, as well as how it can be implemented in all sectors of the economy, in an effective, safe, and sustainable manner (Davidson, 2011).

Figure 7. Solid waste management hierarchy (UNDP, 2008)



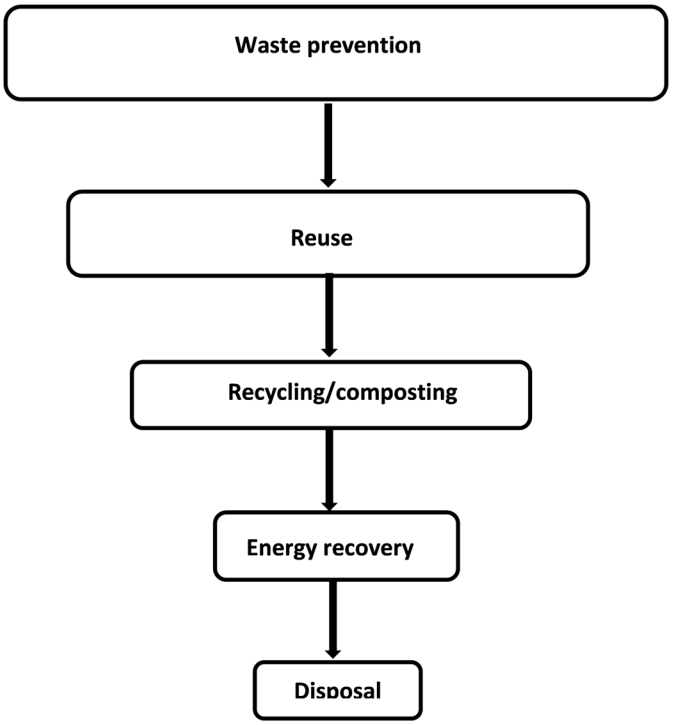
EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Waste prevention means to reduce the amount of waste produced. Reuse means to use products and materials again for the same or different purpose. Recycling and composting seeks to recover resources from waste. Energy recovery involves recovering value by producing energy from waste. Disposal means waste should be disposed of only if none of the aforementioned methods offers an appropriate solution. Waste minimization involves efforts to minimize resource and energy use during manufacture. For the same commercial output, the less materials used corresponds to less waste produced. Waste minimization typically requires knowledge of the production process, cradle-to-grave analysis (the tracking of materials from their extraction to their return to earth), and detailed knowledge of waste composition. The zero waste concept has been recently introduced to confront waste problems (Zaman, 2014). The zero waste concept is being developed and implemented in various sectors, including waste management and treatment, mining, manufacturing, and urban development. This concept has been adopted by decision makers and professionals in solid waste management because it stimulates sustainable production and consumption, optimum recycling, and resource recovery. On the basis of critical review, zero waste programs are applied in many countries without any holistic zero waste strategy.

Reduction and Reuse

Waste reduction should be the top priority in the solid waste management hierarchy because this method reduces the amount and toxicity of waste before entering the municipal waste stream (Franklin Associates, 1999). Source reduction can be implemented in several ways, as shown in Table 7.

Figure 8. Waste minimization hierarchy holistic zero waste strategy



EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 7. Some ways for waste reduction

Redesign	The producers should redesign the products and packages in order to reduce the quantity of materials and the toxicity of the materials used and lengthening the products life to delay for disposal
Reduce material used	Consumers should change their consumption behaviour to reduce wastegenerated such as buying in large quantity or in refillable package in order to reduce the packaging. Removing from commercial mailing list could also significantly reduce the paper waste.
Reuse of product and packages	Examples of reuse including using refillable containers, washable plates, glass instead of using disposable products. Durable goods such as furniture and appliances can be resold or donated to the needy family.

Source reduction is a prevention technique to reduce waste generation. The success of source reduction is significantly dependent on the attitude of producers and consumers, which involves legislation, social perception, and education, among others. Along with an increasing living standard, Malaysians are developing the "use and throw" consumption behavior, wherein disposable products are increasingly being consumed. This consumption pattern should be inverted to reduce waste from entering the waste stream. Furthermore, emphasis should be placed on producers because preventing waste from being generated must begin with the product and production process (Rylander, 1998). In Malaysia, source reduction has yet to be recognized as a major part of solid waste management. Thus, encouraging people to reuse products is imperative in the recycling program.

CONCLUSION

A sustainable waste management system requires full compliance to the waste management hierarchy in overall management systems, either in developed or developing countries. The waste reduction and minimization aspects are important factors for the successful management of MSW. As landfilling is widely accepted as a suitable method of solid municipal waste disposal worldwide, the implementation of a fully engineered semi-aerobic sanitary landfill is suggested in developing countries to achieve the goal of sustainable development.

Source reduction is rather a prevention technique to reduce the waste from being generated. The success of source reduction is very much depended on the attitude of producers and consumers which involves legislation, social perception, education and so on. Along with the increasing living standard, Malaysians are developing the "use and throw" consumption behaviour where there are more and more disposable products being consumed. This consumption pattern should be inverted in order to reduce the waste from entering the waste stream. On the other hand, emphasis should be placed on producers because preventing waste from being generated must begin with the product and the production process (Rylander, 1998). In Malaysia, there is yet any emphasis on source reduction as a major part of the solid waste management. It is imperial in the recycling program to encourage people to reuse products.

Sustainable waste management system requires full compliance to the waste management hierarchy in the overall management systems, either in developed or developing countries. Waste reduction and minimization aspect is an important key factor for successful management of MSW. As landfilling is widely accepted as a suitable method of solid municipal waste disposal worldwide, Implementation of a fully engineered semi-aerobic sanitary landfill is suggested in developing countries towards achieving the goal for sustainable development.

Chapter 2
The Role of Waste Management in the Green Economy: An Empirical Analysis of Economic Data of the Business

Massimo Saita
University of Milano Bicocca, Italy

Maria Vittoria Franceschelli
University of Milano Bicocca, Italy

ABSTRACT

Green economy has become highly relevant over the last years. We are currently experiencing pollution issue and environmental decay that had its origin, however, in the previous centuries. The development of industrial economy inevitably entails the production of waste, in such a quantity that the environment is incapable of assimilating and transforming it naturally. Therefore, it is believed that one of the main green economy sectors is the waste retrieval and recycling, that means waste management. In the existing literature, this sector has not been deeply analyzed from a viewpoint of performance business analysis. Although a European legislation exists, every country manages this business by itself. After a historical introduction, this study, using the regression model, analyses the variables that influence the Italian business of waste retrieval and recycling, in the process establishing which of them has a deeper impact on performance.

INTRODUCTION

Environment and Human Beings: A Historical Background

Animal and vegetable organisms carry out their lives in the biosphere, i.e. in the environment surrounding them. Such physical and biological components have neither been designed not built by man.

No doubt, the environment undergoes an ongoing evolution, and accordingly changes as years elapse by virtue of nature itself. Not only that. The activities engaged in by man have altered the terrestrial biosphere; thereby have occasioned changes in soil, air and water. Such transformations may result in environmental decay.

The natural environment changes by the action of endogenous or exogenous agents. These agents modify the earth demolishing a part and constituting another, to thereby maintain a balance.

Classical literature describes Germany as entirely covered by forests (Tacitus in *Germania)* and Egypt and Mauritania as the granaries of the Empire. In the first case, human settlements of Germanic tribes expanded the vital space by creating glades to locate the settlements and develop agriculture. In the second one natural events transform it in desert.

Human activity has often transformed the landscape through destructive actions, which have irreversibly compromised the environmental balance. At the beginning of agricultural activity that the human species started causing deep changes to the territory. Man has exploited the environment for the sake of his personal sustentation. Over time, this exploitation increased ever more, because it was related to the country development. The trend began to abuse the available resources, as if they were at no cost (which was, after all, the case from the perspective of sheer economic cost). The Earth was offering resources to man, and men were using them.

Through the cultural development, spread awareness that such resources were not "free of charge". One of the first environmental protection laws dated back to 1769, when it was decreed that forests on the island of Mauritius should be safeguarded. As Grove (1996) stated, the most important and innovative aspect of French's environmental protection in Mauritius, was the acknowledgment of a link between deforestation and local climatic changes. Deforestation, after all, is the work of man, implemented in order to set aside the soil for a different use than the preservation of forests, generally by using the soil first for agricultural purposes and then for industrial ones. Consciousness was thus undergoing a change. The development of industrial economy was deemed by many scientists to represent "a threat to mankind's survival". Well-known, among others, is Wilson's (1858) study on the drying up of the earth and the atmosphere, in which his concern surfaced: changes in the atmosphere are slowly drawing close to the state in which it will be impossible for man to live on the Earth. *This paper can be said to mark the onset of a truly international environmental debate in which processes operating at a global scale were being considered* (Grove, 1995, p. 159).

This realization burst forth in the 70s of the XX century. So a new branch of economic discipline, viz. "environmental economy", was born for the sake of picking up the interactions between environment and development, by setting a limit on the constant growth of production and on the use of resources, and by implementing the environment's ability, to receive the only product unable to transform itself, save across millennia: waste.

Environmental economy may be defined as the study of the regulation of polluting activities and the assessment of environmental beauties. Famous is the exemplification of the economy-environment relationship by the economist Kenneth Boulding (1966). He used the "metaphor of the space shuttle": the economy experienced up to this moment was compared to a cowboy who saw the far west as a «frontier» capable of being continuously shifted by acquiring new lands, and thus new resources to exploit. The economy, instead, should be considered as an astronaut aboard a space shuttle, who can solely enjoy a limited kit of resources, which he must try to save and recycle as much as possible.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

In this period, there was no way of severing the link between environment and economy. Politics began to adapt to these new ideas and realizations. Companies began to adapt to the policies and the new legislative provisions, until they arrived at a system where health and environmental integrity acquired an ever-increasing relevance.

Pollution

The term "environmental pollution" means the change in the biosphere composition caused by pollutants and emitted from many human activities. This change has a negative connotation; in fact, it interferes with the growth rate of the species and causes damage both to human health and territory.

The effect of the different agents depend on their own characteristics and on the quantity released.

There are different types of pollution categorized according to the polluted site. For each site the causes, sources and the effects are different. They are: air pollution that changes the composition of air; water pollution that changes the composition of the water; soil pollution that changes the composition of the territory; noise pollution that changes the sound in a given environment; electromagnetic pollution that alters the natural values of the electromagnetic field.

Pollution is a direct result of industrial development. Human activities, which are promoted for the economic development, produce most of the contaminants. The economic processes (mining, processing or manufacturing and consumption), generate necessarily waste that will inevitably come back to nature. This involves a biological change, damaging animals, plants, and then the ecosystem, i.e. a contamination that is defined pollution (Turner et al., 1993, p. 16). It has a direct effect on the economy. One of the first researcher in this field was Pigou (1920), who introduced the concept of "externalities": pollution causes external costs that result in a gap between private costs and social costs.

Sustainable Development and Waste

In order to fulfil human's needs, it is necessary to obtain goods and services. Their fulfilment is strictly linked to economic development, and in order to obtain goods and services, the use of energy is required. Yet its use inevitably entails repercussions on the environmental balance, such as "negative externalities".

Already Malthus (1798) had concerned himself with the limits, which he had termed absolute that existed in the relationship between population and economic resources.

The fact that the availability of resources was limited, gave rise the problem of a sustainable development; in other words, the tendency is to promote social-economic growth that might be sustained over time both by the natural environment and by society.

The best-known definition is the one given in the *Brundtland Report* 1987 (WECD): *the "Green Development"* (Adams, 2001) is *development that meets the needs of the present without compromising the ability of future generations to meet their own needs (Brundtland, 1987)*[1]. Companies simultaneously consider their financial, social, and environmental performance (Marshall & Brown, 2003, p.101), keeping services and quality of natural resources.

Inevitably, economy is linked also to natural resources: renewable and nonrenewable. Gray and Hotelling were the firsts who studied the relationship between economy and non-renewable resources.

By resorting to the manufacturing industry as a case study, they identify an optimal rate of exploitation of resources, so that the current extracting activity does not affect the future extraction quantity.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

In order to achieve that, they identify a value, and thus a cost of utilizing the non-renewable resource, which includes extraction and user cost (Gray, 1914). Nevertheless, user cost should increase over time based on the discount (Hotelling, 1931).

Two types of approach to sustainable development have been classified in accordance with the hypothetical replaceability scenario between natural capital and artificial (man-made) capital (Pippo, 2011): can be achieved the same level of well-being by replacing the natural capital with the artificial (man-made) one?

The "Strong substitutability current", believes that the artificial capital is not able to produce the same well-being given by natural capital, i.e. there is a very weak and limited compensation level. You need to preserve the natural capital because is irreplaceable by human activities. The risk of damaging environmental resources irreversibly must be minimized. According to this approach the economic growth should be slowed down or even stop in order to preserve the environmental capital integrity.

Instead, according to the "weak sustainability current", there is an almost perfect substitution between the two types of capital (environmental and human), since the satisfaction derived from human can easily equal or exceed that received by the natural capital. This approach believes in the possibility of decoupling between environmental growth and degradation. Technological progress allows more efficient use of resources and the reduction of human activities.

The objective of sustainable development is therefore to achieve simultaneously both socio economic growth and environmental care. Emerge the three pillars of the concept sustainability: economy, environment, society (Williamson, Lynch-Wood, & Ramsay, 2006). The link among these tree aspect is deeply developed in literature. Lounsbury et al. (2003) have found that industries are shaped by social structures of meanings and resources. Lounsbury et al., have explained that the waste management is strongly interconnected with the political, social, and cultural situation. The both social movement and political practices transform the extant socio-economic practices. Given this background the authors believe that a complete analysis of the Green Economy should include both environmental aspects (in this case the waste management), and economic aspects (in this case an analysis of a green business) through the study of economic performance using indicators such as EBITDA.

WASTE

Maybe one of the most relevant issue is to identify waste. The problem may seem trivial, but it is not. Economic operations such as produce, research and develop, create inevitably the existence of products or waste products. While there have always been, during the last two decades of the 1900s waste has started to be a great issue for States and policy. As a consequence of that, it was formed ad hoc legislation on waste management.

To define uniquely waste, here is used the legislative definition that is found in the Basel Convention: *Waste are substances or objects which are disposed of or are intended to be disposed of or are required to be disposed of by the provisions of national law*[2].

At European level, the previously mentioned legislation is possibly the first and most exhaustive legislation in the waste field. The Basel Convention was signed in 1989 and came into force on 5 May 1992. It was born out of the need to contain the production of a wide range of waste categories and the possibility of handling and disposing of it as close to the place of production as possible, with a view to reducing the environmental risk associated with handling activities and combating transport towards developing Countries, a then frequent phenomenon (Marzetti, 2001).

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

The Basel Convention made a change in the environmental situation, now unsustainable, that many developing countries or "economies of the transaction" were living. In fact, many large industries were using these countries for disposal of waste, as easy way, less "controlled" and certainly cheaper. In doing so, however, it is threatened not only the environment but also human health. Therefore, with the Convention of 1989 it was decided to establish a genuine system of checks in respect of both imports and exports, both disposal of hazardous and non-hazardous.

The Italian legislation, in article 184 of Legislative Decree No. 205/2010, regulates the classification of waste categories, which are differentiated according to their origin into urban and special waste, and according to their dangerous characteristics into dangerous and non-dangerous waste.

The function of waste classification is the prerogative of the producer (or holder), who bears the obligation and thus the responsibility to assess it carefully for purposes of allocating the CER code.

Such classification is important because indicates the type of waste involved and distinguishes between "waste" and "non-waste" (i.e. "end of waste"). **R**etrieval activity, as regulated by Legislative Decree 152/2006 in article 181, is the reuse, recycling and the other forms of recovery. The result is a departure[3] from the regulations in the field of waste of substances or objects in question.

Directive 2008/98/CE: Waste Management

Article 4 has a great relevance. It establishes a waste hierarchy as a priority order in waste prevention and management legislation and policy[4].

The hierarchical order, as established by the Directive is:

1. Prevention;
2. Preparing for re-use;
3. Recycling;
4. Other recovery, e.g. energy recovery;
5. Disposal.

Member States shall take measures to encourage the options that deliver the best overall environmental outcome. However, they must ensure that waste management does not jeopardize human health and does not affect the environment. When they are subjected to a salvage operation, they stop to be regarded as waste and therefore they are no longer subject to this law.

The Directive lays down measures to protect the environment and human health by preventing or reducing the adverse impacts of the generation and management of waste and by reducing overall impacts of resource use and improving the efficiency of such use[5]

The said hierarchy sums up whatever has been asserted so far, namely, that all the activities pertaining to waste management are of equal environmental impact. Nay, the legislator, in his intent to promote an ecologically rational management of those substances or objects which must be necessarily disposed of, wanted to specify the fact that certain activities have a lesser impact on environment and health, and that they should be favoured over the others.

The legislation does not promote "the removal of existing waste", but first the prevention, and only subordinately, the waste management through the reuse or processing of waste, to cause the least possible.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

When it is not possible, it will be necessary to dispose waste in precisely demarcated places, equipped in conformity to the law. In this work, it is studied the economic performance of a green business: the waste business. Particularly retrieval and recycling business.

RECYCLING AND WASTE MANAGEMENT

The recycling process could be implemented in a very broad range of sectors and fields, through infinite methodologies and motivations. Accordingly, it becomes hard to find in the literature, a unique definition of waste recycling, without focusing on any specific sector or any specific type of recycling.

It is believed that, even in this instance, the broadest definition of recycling may be drawn from the legislation in force, Directive 2008/98/CE of the European Parliament and of the Council:

'Recycling' means any recovery operation by which waste materials are reprocessed into products, materials or substances whether for the original or other purposes. It includes the reprocessing of organic material but does not include energy recovery and the reprocessing into materials that are to be used as fuels or for backfilling operations[6].

Therefore, the very same European directive identifies the recycling activity as one of the main paths for a sustainable waste management.

As the authors were pointing out, the said specific activity is strictly interconnected with many sectors and thus with several subjects, such as health care, public administration, local legislation, education etc. Suffice it to think of the repercussions which inappropriately managed waste causes to the health of living beings and to the proper functioning of civilization.

An efficient waste retrieval system, in fact, must involve both the citizens and the companies. In other words, is necessary to pay heed both to the phase "at source", i.e. where the waste is produced, and the "end-of-pipe" phase, i.e. where the waste is managed. In such a system, efficiency is accordingly determined both by producers and by consumers. As regards the former, they may contribute from different viewpoints: by devising a "sustainable product", they may facilitate both a lesser waste of resources at the time of transforming the input into finished product and an easier retrieval of the utilized products. The consumers may instead contribute by efficiently managing the products capable of being retrieved (for instance through waste separation). Uncertainty concerning the quality of recycled materials and the incapacity of laying down a «common language» of dialogue between buyers and sellers may not only engender problems caused by asymmetrical information but also, more generally, give rise to significant transaction costs (D'Amato, 2008, p. 436).

Other research studied the "organizational citizenship behaviour", defined by Organ as *individual behavior that is discretionary, not directly or explicitly recognized by the formal reward system, and that in the aggregate promotes the effective functioning of the organization*'' (1988, p. 4). These researches suggest that such ''organizational citizenship behaviors for the environment'' are a distinct and important aspect of organizational behavior and there is a strong relation between citizenship behaviors and environmental performance (Organ, 1988; Boiral 2009; LePine and Erez 2002; Podsakoff et al. 2000; Boiral and Paille 2012; Daily et al. 2009).

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

For example, in this field it has been carried out a research that presented a *case study of recycling at a large University, that does not have a formal organizational structure to address sustainability concerns*, and they *found that recycling behavior was influenced in important ways by the university context and by processes designed to promote recycling* (Weaver et al., 2015, p.427).

Companies have used recycling as a sustainable strategy. Many studies analyze the effects and reasons for the implementation of environmental strategies. It has been shown that more and more companies implement environmental strategies as a key success factors (Maas et al., 2014; Siegel, 2009; Aragon-Correa & Sharma, 2003; Sharma & Vredenburg, 1998; Gouldson, 2004; Ambec & Lanoie, 2008; Anderson & Anderson, 2009; Al-Najjar & Anfimiadou, 2012).

To the best of our knowledge, little attention has been devoted on recycling retrieval as core business and not only as an environmental strategy implemented to gain competitive advantage.

Having the aim to study the performance of the waste business, it seems that this study is not broadly connected to the research on environmental performance. It is significant, however, that some studies using environmental performance as variable, the percentage of total waste that is treated, recycled or recovered as a percentage of total waste generated (Dobler et al., 2014, p. 8)

The Italian Context

Already in the past years, studies on environmental issues have been conducted in our jurisprudential doctrine (A.A. V.V., 1998; Catturi, 1990; Ferrara, 1998; Matacena, 1984; Miolo Vitali, 1978).

Within the Italian background, researches have been carried out in the green economy field. More specifically, studies have been undertaken on social reporting (Campedelli, 2005; Secchi, 2006) as well as on the more specific environmental report (Noci, 2000), on Corporate Social Responsibility (Masini, 1970; Fiori et al., 2007), and on voluntary environmental disclosure (Quagli & Teodori, 2005; Andrei & Pesci 2009; Garzella et al., 2011).

To the best of our knowledge, neither at an Italian level nor at the level of other nations, have specific studies been conducted on the retrieval/recycling business.

This research has deliberately focused on a single country, given that business is undoubtedly influenced by national politics and culture. It is moreover undoubted, based on the different current episodes that a link exists between the said sector and mafia, at the Italian level as well as at the level of other countries.

Prior to developing the linear regression model, we deem it useful to provide some information of a general character about the Italian recycling business.

The Foundation for sustainable development (2014) has elaborated, based on the CONAI[7] data, a table setting out the amount of recycling of packages. As evinced by the following table, results have improved. This is no doubt due both to a higher "environmental consciousness" and to a better waste management.

REGRESSION ANALYSIS ON WASTE BUSINESS

Development of Hypotheses

Given the scant literature in the field of business analysis of retrieval and recycling companies, are used some variables utilized in the analyses of other businesses. The independent variables analyzed are deemed to be of a strategic nature. Regard was paid to two macro-categories: "where" and "what" determinants.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

"Where" Determinants:

Localization

Waste is a European and world problem.

The Italian situation presents some peculiarities. In Italy, waste is mostly managed at regional level. For the purposes of this research, it is believed that the two macro areas distinction is sufficiently significant: the northern area and the central-southern area. This distinction is made because frequently, in the current news, come across several instances of mafia-like waste management and the legal or illegal trade in the same, mainly in the Centre-South area. Moreover, some reports by Italian companies (Amsa and Gruppo A2A, for instance) set out extremely positive data relate to northern Italy. As a consequence, the authors consider the retrieval and recycling companies performing in a different way, depending on their area: better in the north of Italy than the Centre-South, where companies have to manage higher waste levels and are obliged to interface with illegal organizations.

This work studies, first and foremost, the distribution of these companies in the North and Centre-South areas, in order to examine their performance level, in accordance with the following distribution:

- What is meant by north are the companies situated in the following regions: Emilia Romagna; Friuli Venezia Giulia; Liguria; Lombardia, Piemonte; trentino alto Adige, Valle d'Aosta e Veneto.
- What is meant by center are the companies situated in the following regions: Lazio; Marche; Toscana e Umbria.
- What is meant by south (and islands) are the companies situated in the following regions: Abruzzo; Basilicata; Calabria; Campania; Molise; Puglia; Sardegna e Sicilia.

The authors want to study, therefore, the relationship between the localization of retrieval and recycling companies and performance.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

H1: There is a positive relation between localization in the North area and the performance level of Italian retrieval and recycling companies.

"What" Determinants

Company Size

Another relationship that is studied in literature is the relationship between company size and performance. The number of employees is a variable frequently used to indicate company size. European Union considers this parameter, together with the total balance sheet, liabilities and the net turnover, in order to assess the company size. Even recently, Directive 2013/34/UE of the European Parliament and Council, dated 26 June 2013, has stipulated that, in order to fall within one of the three defined categories, the company must have *exceed the limits of at least two of the three following criteria (article 3):*

Based on previous literature, there is a positive relationship between profitability and company size. Many authors (Alexander 1949; Stekler, 1964; Hall and Weiss, 1967; Scherer, 1973; Ravenscraft & Scherer, 1987; Fiegenbaum & Karnani, 1991; Helfat et al., 2007; Jonsson, 2007 Bayyurt, 2007; Dogan, 2013) theoretically supported this link. Prior research confirms the existence of a positive relation.

H2: There is a positive relationship between the size of a retrieval and recycling company and performance.

Shareholders

A peculiarity of the recycling business, which is deemed as a "sustainable business", is that it is thoroughly interconnected with many different sectors. In fact, the environment care is interconnected with many different fields, healthcare, politics and business.

Regarding human health, the number of people who need medical attention and therapeutic treatment because of pollution is increasing, and it is going to continue to grow. This of course strains the whole system and increases the financial burden of health care providers, the state, and ultimately the individual. An "environmental culture" has been growing in many ways: by educating children at school, originating new university classes, new jobs specialized on environmental care, pollution prevention, green economy etc...

There is a patent link with the "public sector" and the extent to which it might be interested in a waste management system. Consequently, in order to conduct a deep analysis of this business, it indispensable to study the equity participation by public Authorities, State and Government and if exist a relationship

Table 2. Directive 2013/34/UE

	Micro Undertakings	Small Undertakings	Medium Undertakings	Large Undertakings
Balance sheet total (euro)	≤ 350.000	4.000.000 ≤	≤ 20.000.000	> 20.000.000
Net turnover (euro)	≤ 700.000	≤ 8.000.000	≤ 40.000.000	> 40.000.000
Average number of employees	≤ 10	≤ 50	≤ 250	> 250

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

between this type of participation and the performance by retrieval/recycling companies. It is believed that, given the strong link between this business and various public sectors, the State is interested in intervening in the recycling business with a view to rendering it more efficient.

H3: There is a positive relation between participation by a public company in retrieval/recycling companies and performance.

Ageing

Undoubtedly, the recycling sector has been lively for a while. However, a substantial growth is being experienced by all the green economy sectors. No doubt, an increasingly greater number of companies have emerged in the recycling sector, by virtue also of the new legislative enactments, which enjoin a retrieval of waste. For this research the authors have considered only the companies which have drawn up the 2014 financial statement. Among the sample, the oldest company dates back to 1932, and it is a family business. From the 50s to the end of the 80s, have been founded 79 companies that are still active. 111 companies have been established in the 90s and the remaining 234 companies have come into being during the last 15 years.

These statistics evince that the business is certainly growing and that it is gaining considerable importance. Moreover, the specific legislation in the field of managing the retrieval and recycling of waste has become ever stricter, while technologies are more state-of-the-art.

Given that it is a very modern sector, the authors believe that, the most recent companies may attain a higher level of efficiency. In fact, they possess state-of-the-art equipment and technologies and, having been born in an age where the problem of the environment and in particular that of waste management, they are more capable of confronting the current situation.

H4: There is a positive relation between the age of retrieval/recycling companies and performance.

Presentation of the Sample

Using Aida database, 811 Italian companies have been identified (the main economic activity of which consists in the retrieval and preparation for recycling of solid urban, industrial and biomass waste). More specifically, this activity comprises the following:

- Crushing, cleaning and sorting of glass;
- Crushing, cleaning and sorting of other kinds of waste, such as demolition waste (rubble), in order to obtain secondary raw materials;
- Transformation of cooking oils and fats into secondary raw materials;
- Transformation of other types of waste relating to food, drinks, tobacco and residual substances in secondary raw materials.

Aida is a database produced by Bureau Van Dijk Electronic Publishing, which groups together financial, personal data and commercial information on Italian joint-stock companies.

In order to contextualize the selected sample, it is necessary to set out some general characteristics.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

The total number of employees amounts to 8.263 units that means an average of ten employees per company.

Out of n.811, n.425 companies, i.e. 52.4%, have lodged their financial statements in 2014.

In this sector, only three companies out of 811 are registered under the Company Registry's special section as innovative Start-ups. They draw up financial statements in abbreviated form. In 2014, one of these start-ups has not lodged its financial statement. The other two, instead, have recorded negative results at EBITDA level. This obviously entails a negative net income, a loss for the financial year, and negative profitability ratios (ROE and ROI). These data indicate that the analysed sector has no special interest in developing along this new company characteristic.

As for the economic performance of the sector, we may observe that 124 companies record a negative ROE (i.e. 29.18%), with a ROE in excess of 3% (that is, a level indicating a par condition) as regards 235 companies, i.e. 55.29%. These initial remarks point to a rather positive business result, especially if we contextualize it within the current period of crisis.

Among the 811 companies, it was our intention to focus the research on those companies that had lodged their financial statements in 2014, in order to make them comparable in accordance with the latest available data. We excluded, instead, those companies that did not record the other variables analysed by us, such as the region of the registered office or the year of foundation.

Our sample, therefore, analyses 386 companies, i.e. 48% of total companies in the business, a sample felt to be undoubtedly representative.

Variables and the Model

Dependent Variable

Because the aim of this empirical analysis is to study the economic performance of a "green business", we have used **EBITDA** as performance indicator. It is believed that this data might highlight income based on the characteristic management (Saita, 2015), thereby excluding interest, taxes, depreciation and amortization.

No account was taken of sales, inasmuch as these companies may deal with extremely different types of waste. The company dealing with food waste, of course, will have a lower turnover than another company managing the same amount in ferrous waste or companies from which, for instance, one might extract substances with a high monetary value (such as copper, zinc, etc.).

Likewise, no regard was paid, as a business performance indicator, to the Net Income. As we deem it better not to consider some components, such as taxes and amortizations, that might impact differently depending on the type of company involved (possibly one with public shareholding) or on the localization of the same in a region, possibly one governed by a Special Act.

EBITDA it is a good variable for cash earnings. Depreciation and amortization are non-cash expenses. So, EBITDA is a good way to know how much cash a company is generating – cash that can be used to pay dividends or reinvest in the company EBITDA is the preferred metric. Furthermore, EBITDA mitigates the distortions to operating income caused by arbitrary asset depreciation schedules (Becker-Blease, et al., 2010).

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Independent Variables

Localization

As previously explained, Italy is divided into 20 regions. Account has been taken of the region where the registered office is situated rather than the operational headquarters, given that this data was not always available. Having classified every region based on the area, the companies analysed in this database are equally apportioned between the two areas, as set out in the following table.

The area variable has been turned into a dummy variable, by assigning a value of 1 to companies in the northern area, and a value of 0 to those having their registered offices in the central-southern area.

The central-southern region with the largest number of retrieval and recycling companies is Campania (54); the northern region is instead Lombardy with 89 companies.

Company Size

The company size has been studied by paying regard to the number of employees. This choice has been made for two main reasons: the existing literature and the characteristics of the recycling business.

The number of employees is a parameter widely used as a size indicator in the literature as well (Cavusgil & Nevin, 1981; Bilkey & Tesar, 1997; Burton & Schlegelmilch, 1987; Kaynak & Kothari 1984; Mugler & Miesenbock, 1986; Bonaccorsi, 1992; Cavusgil & Naor, 1987; Holzmuller & Kasper, 1991). The existence of a relationship between size and profitability has been proven in multiple sectors, such as the hotel one (Israeli 2002; Pine & Phillips 2005; Claver-Cortés et al. 2006; Ruggero & d'Angella 2011; Santoro, 2015).

The retrieval and recycling companies are considered as a service companies. In this kind of companies, the number of employees is seen as the most significant size parameter (Saita, 2012, p. 23)

Moreover, the analysed companies deal with different kinds of waste. It is thus inevitable that those which handle urban waste, for instance, will boast a mostly lower turnover or profit, and not just negligibly so, than other companies that deal with other types of waste, such as industrial waste. The number of employees is accordingly deemed to be a fair index of company size in this sector.

In the analysed sample, most are micro-companies, which thing is absolutely in line with the Italian structure (Saita, 2015, p. 21).

Table 3. Localization variable

	Independent Variable	No. of Companies	% Companies Across Whole of Italy
Where - localization	**Area**		
	North	192	49,74%
	Centre - South	194	50,26%
	Total for Italy	386	100%

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 4. Company size variable

	Independent Variable		N. Companies	% Companies in Italy
where	**Company Size**			
	Micro	x<10	257	66.67%
	Small	10<x<50	114	29,45%
	Medium	50<x<250	13	3,36%
	Large	x>250	2	0,52%
	Total Italy		386	100%

Shareholding

In the sample, the shareholders of more than half of the companies consist in physical persons or families. This data, too, is in line with the Italian business structure. Other reference shareholders are represented by "industrial companies", which hold shares in more than 34% of the sample businesses. Relatively few, instead, are the companies in which holdings are in the hands of "public authorities, the State or Government" (Public shareholding), nearly 2%. In order to study the relationship between public shareholding and performance level, the variable has been turned into a Dummy, by assigning a value of 1 to all the companies in which shareholding is in the hands of a public authority (including as a minority shareholder), and and a value of 0 to companies where shares are not held by pubic bodies, the State or Government.

Ageing

For the sake of a comprehensive business analysis, it is important to study the seniorities operating there.

As indicated by the previously mentioned data, the business of retrieval and recycling companies mostly consist in companies born in the 2000s. No doubt, the know how acquired over time is an important element, but in this specific business it is believed that to be in the forefront when it comes to systems and structure is a highly relevant factor.

In the literature, the age variable has often been paid heed to when assessing a business (Campa and Kedia, 2002; Villalonga, 2004; Radipere and Dhliwayo, 2014).

Other Controls

Other variables have been taken into account:

1. Total asset
2. Equity
3. Current asset
4. Sales
5. ROE (Return on equity)
6. Net income

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

These variables are deemed to be of great significance when conducting a business analysis. Just to give an example, among the selected control variables, total assets and sales are (besides the number of employees) the other two standards adopted by the European Union to measure company size. By contrast, is sufficiently independent from performance and is an index of stability. Current assets is an index of solvency, and points therefore to the capacity of duly meeting one's obligations. In order to avoid problems of multi-collinearity, the current asset, total asset, equity and sales variables have been clustered together in the Stability variable, as we are going to specify hereunder. In other words, a variable called "Stability", which groups together total asset, current asset, equity and sales variables, has been created.

As we may discern in the under-mentioned table, among the variables there are no problems of correlation, save to a slight degree between size and the variable by us established, i.e. stability. This correlation, however, is not particularly high, and the variables forming part of the Stability variable prove essential to the effectiveness of the model, indicated by the Rsquare.

As proven by the earlier literature, multi-collinearity has been studied through two tests: the Variance Inflation Factor (VIF) and the Condition Index. It should be noted that, apart from the "stability" variable, the maximum value of the VIF is less than 3, i.e. the threshold suggested by Hair et al. (2005). The variable reaches a value of 3, and is thus deemed thoroughly acceptable by the literature (Myers, 1990).

Model and Results

The gathered data relate to the year 2014.

The independent variables refer to the previously described what and where sizes.

Table 5. Pearson correlation table

ROE %	2,2318	35,42813	386
Net income €	12513,42	987663,072	386

The model utilized for the analysis of these variables is a model of multiple linear regression:

$$yi = \beta 0 + \beta 1X1i + \beta 2X2i + \cdots \beta nXni + \varepsilon i$$

Where

- *Yi* = Dependent variable, i.e. the performance of Italian retrieval and recycling companies;
- *X1…Xn* = Independent variables;
- *β1… βn* = Regression coefficients;
- $\mathcal{E}$ = Stochastic error.

Empirical Results

For purposes of this research, after having studied the correlation between independent and control variables of the model, and after having detected some rather high correlations between total assets, current assets, equity and sales, the "Stability" variable was created through the "mean" operation in order to avoid problems of multi-collinearity. In conclusion, therefore, the model takes into account the relationship between the dependent performance variable, by resorting to EBITDA (Earnings Before Interest, Taxes, Depreciation and Amortization) as performance indicator, and the independent variables:

- *Company size,* by utilizing as indicator the number of employees;
- *Area,* by utilizing as indicator the region of the registered office;
- *Shareholding,* by distinguishing whether or not, among shareholders, there are public Authorities, the State or Government;
- *Ageing* of companies, by paying regard to the year of their foundation;
- *Stability,* which takes into account the total asset, current asset, equity and sales;
- *Net income,* i.e. the result for the 2014 financial year;
- *ROE,* i.e. the return on equity.

If we analyse the correlations more specifically, the Beta columns indicate the sign of the relationship between the dependent variable and the independent variables. We may observe how size and seniority

a. Dependent Variable: EBITDA €								

are negatively linked to performance. This entails that the more recent the company, the worse is the performance result, and also that the bigger the company, the worse is its performance. Conversely, the higher the total assets, current assets, equity, sales, net income and return on equity (ROE), the better will be the company performance.

It is nevertheless important to observe that not all the variables have significant causal relationships with performance, in particular those variables that show p-value > 0.05. The variables indicating the type of shareholder, the age and the percentage ROE do not explain the performance variation. Despite that, the model is altogether thoroughly valid, as will be elucidated by the Table hereunder.

Among the other variables, instead, size, stability and net income have a higher impact on the level of company performance, given that they show a value of Sign. < 0,000. The where variable, too, proves to have an impact on performance.

By virtue of what has been asserted, the H3 and H4 hypotheses are refuted, in that the type of shareholder found in the companies and the age thereof do not impact at all on performance. The H1 hypothesis is accepted, whereas hypothesis H2 evinces the fact that size negatively impacts on the company performance.

In order to assess the effectiveness of the model, we should bear in mind the value of the RSquare. In the model implemented by us, the RSquare equals .831, which represents a pretty satisfactory value, hence the model of the aforesaid seven variables proves to be significant and accordingly capable of explaining the 83% performance variance in the waste sector.

Analysis of Results

As shown by the model summary, the totality of utilized variables proves to be especially significant when trying to explain the performance trend of companies active in this waste business. That is further confirmed by the value 2 of the Durbin-Watson statistic indicating the absence of self-correlation in regression.

Relationships Between the Independent Variables

If we embark on an in-depth analysis of the relationships between control variables and independent ones (by breaking up the stability variable into the four variables it consists of), we will note that *current asset* is the item with a stronger correlation with control variables: net income, sales, total asset, equity and company size variable as well. This data is quite easy to deduce, in that current assets is an index of solvency, and thus of stability as well. As confirmed by the Pearson Correlation, as current asset increase the total activities, sales, equity and number of employees all increase. These data may be explained on the basis that companies with available liquidity generally have a wide turnover (hence large Sales), but at the same time need also to provide guarantees to their own customers and creditors (equity).

More singular is instead the significant and negative relationship (-0.66) with the fiscal year result. This may be explained if one pays regard to the items making up current assets in the Italian budget. Current assets consists of inventories, receivables, and financial assets other than fixed assets and cash. If, accordingly, some of these items, such as receivables and inventories, increase, there will be a simultaneous increase in financial need. Since, in fact, companies are small in size and with scant capital, they have to resort to market financing (we should not forget, moreover, that these companies have a limited self-financing capacity), save in the case of exceptions arising from the leverage (where investments are obviously made only until profitability exceeds the investment cost). The same explanation holds true for the negative relationship between the net profit and the stability variables. After all, if we analyse the correlation between net income and four variables grouped together under Stability, we may discern a negative link with each one of them.

The age of the companies, by contrast, is not specifically linked to any variable (the Pearson Correlation always shows values not exceeding 0.185). This indicates the fact that the year of foundation of the company does not impact on such fundamental budgetary variables as equity and net income or even on the company size.

The number of employees, hence the company **size** as well, besides showing a positive link with current assets and turnover, discloses a positive link (weak and yet existing) with the type of shareholder. We may infer from it that public shareholding in recycling/retrieval companies mostly occurs in medium- to large-size companies. That fact is confirmed by the data retrieved by the database, which indicate that 50% of companies with shares held by public authorities, State and Government, fall under the “medium- to large-size” category, which in turn represents only 3.63% of the total companies of the sample. This means that public bodies, State and Government hold shares especially in medium- to large-size companies.

Relationships between the Dependent Variable and the Independent Ones

Once the significant relationships have been clarified, we will now proceed to analyse the hypotheses that have not been accepted by virtue of the statistical results, given the lack of any correlation. The performance proves to be correlated neither with the company's seniority nor with the presence of public shareholders.

As far as the first relationship is concerned, different explanations might be put forward. Despite being a new sector, it does not means that companies established on a more recent date should record a higher level of performance. The new companies, in fact, must locate themselves in the most favourable areas, acquire sufficient know how to offer a good service, invest in state-of-the-art structures and in marketing operations, and thus establish a new customer base. Less recent companies must instead face problems of modernization and implementation of new structures and operations. On the other hand, however, they already boast good market shares and experience in the sector. Accordingly, a relationship between the company's seniority and its performance cannot be established, since the factors impact on the two variables in a radically different manner. Earlier, we had also discussed the presence of innovative start-ups in the Italian retrieval and recycling sector. Given the very negligible presence (3 companies out of 811) and the invariably negative result, account being taken of both EBITDA and the net income, we might assert that these innovative companies do not find in the Italian recycling and retrieval business a good sector wherein to operate and make profits.

The second unconfirmed hypothesis concerns the positive relationship between performance and the presence of public authorities, State and Government in the shareholding structures of Italian retrieval and recycling companies. The subject has been actually studied to an ample extent in other works as well as in various disciplines. In this sector, too, it is not possible to assert a better performance level in either public or private companies. This study indicates that performance is independent of the type of shareholding. This is an extremely significant element. It has in fact been explained that this business, and thus a sustainable waste management, is strictly linked to a Country's level of civilization and health care. The authors hold the view that a public presence in most of the sector companies might serve as an incentive to improve the performance level and standardize the sectorial management towards a more efficient and sustainable economy. Studies tackling economics often contend that, in Italy, public intervention, understood as public authorities, State and Government, most of the times does not entail efficient results. In the retrieval and recycling sector, however, it is believed, due to the abovementioned reasons, that the State has a specific interest in intervening in an efficient and constant fashion.

CONCLUSION

An analysis was conducted on a representative sample of the Italian retrieval and recycling sector, a sector of undoubtedly high relevance and importance within the green economy context. The analysed companies' record positive results altogether.

The companies are equally distributed between the Centre-South and Northern areas; the size thereof is in line with the Italian structure, and most of them have been set up during the last 15 years. We may notice that the most significant variables to explain the company performance are obviously represented by net profit and stability. Among the initially postulated hypotheses, the existence of a link between performance and size has been confirmed. The zero level of significance indicates in fact that the com-

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

pany size impacts on performance. The Beta value, however, indicates that this link is negative, hence as company size increases the performance level decreases. This data may be explained by the fact that the difficulty in organizing large-size companies and the inability to exploit economies of scale created thanks to the company's size expansion do not only entail the fact that an improvement in the performance level cannot be attained, but also an actual worsening thereof.

The authors may accept the second hypothesis, and thus the fact that performance is better in companies having their registered offices in Northern Italy. The economic growth gaps between the two areas are well known (Daniele and Malanina, 2007). This data, too, is in line with the Italian situation, which generally records better performances in the northernmost Italian region.

Limitation

The study suffers from a few limitations: 1) the analysis has been conducted by analysing solely the Italian retrieval and recycling companies which have lodged their financial statements in the last year; 2) reliance was placed exclusively on results from one year, the 2014 financial year; 3) The current market crisis, which has been already going on for several years, has undoubtedly impacted on company performances in general, hence those of the analysed companies as well; 4) exclusive reliance was placed on the data available from the Aida database; 5) since any reference to other studies in the recycling sector was lacking, studies from different sectors were taken into account.

ABSTRACT

Worldwide there is an increasing industrialization leads to increased disposal of uncontrolled waste products into the environment which made the environment more pollute and creates hazards. Industrial wastewater is having a major role in the environmental pollution. The major physical, chemical and biological products of the wastewater are solid content, organic matter, in-organic compounds, detergents, soap, cleaning products, metals, gases, volatile compounds, numerous pathogenic microorganisms, nutrients and toxic compounds. Untreated wastewater can cause various environment pollutions problems such as eutrophication or oxygen depletion in the environment. Hence a effective wastewater treatment process and its management is necessary to reduce the contaminants in the permissible levels in the treated waste streams. The final outcome of an effective wastewater treatment and its management is to ensure and provide an appropriate environment protection to the living things and public human beings in the world.

INTRODUCTION

Wastewater is a combination of water and water-carried wastes originating from homes, commercial, industrial facilities and from various institutions. Untreated wastewater generally contains more than 99% of water, but the remainder contains high levels of organic material, small amounts of inorganic ions, numerous pathogenic microorganisms, nutrients and toxic compounds leads to environmental pollution and health hazards.

Wastewater treatment is becomes a critical one due to its water resources, disposal costs, regulations which reduces the wastewater contaminant levels in the disposal waste water streams. The critical goal of waste water treatment and its management is to protect the environment, public health and at last the socio-economic concerns (Tchobanoglous & Burton 1991).

Hence, waste water must be treated suitably to meet the required standard before it is getting disposed to protect the environment from the pollution and prevent the health hazards of the human beings.

Choosing an appropriate waste water treatment technology is depends upon the nature of the contents in the waste water.

Selecting a suitable waste water treatment process is depends upon:

- How clean the final water effluent from our plant must be.
- The quantities and nature of the influent water we need to treat.
- The physical and chemical properties of the pollutants we need to remove or render to neutral in the effluent water.
- The physical, chemical and thermodynamic properties of the solid wastes generated from treating water. (Cheremisinff, 2002)

Treatment of Wastewater

Generally wastewater treatment is carried out in four stages. They are:

1. Preliminary treatment
2. Primary treatment
3. Secondary treatment
4. Tertiary treatment (Bozkurt et al., 2015; Kalbar et al., 2012; Garrido et al., 2011; Al-Rekabi et al., 2007)

VARIOUS TREATMENT PROCEDURES

Preliminary Treatment

Solids and oil with grease are combined to form sludge. Preliminary treatment is the first process which makes the effluent suitable for further process by reducing the non-favourable wastewater characteristics like large solids and rags, abrasive grit, odours and in certain cases, unacceptably high peak hydraulic or organic loadings.

Preliminary treatment processes consist of screening/filtration as physical unit operation which removes the coarse suspended matter and flotation for the removal of oil and grease. Other preliminary treatment operations are comminution, removal of greases and oils, flow equalization, equalization and neutralization of acid wastes and alkaline wastes.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

1. Screening

The screening of is one of the old technique used to remove the solids, gross pollutants from the waste water through the use of a porous medium by downstream equipment process. The porous shape may be of any shape, but in general circular or rectangular shape is used. In screening process various larger suspended and floating materials such as fibres, paper, rags, string substances and other materials are removed, before entering into the primary settling tanks.

Conventional screening process is carried in two stages. In first stage coarse screens such as metal bars or heavy wires spaced 25 to 50 mm apart is used in the waste water flow channel to remove the coarse/denser materials. Bar screens consist of vertical or inclined steel bars distributed equally across a channel through which wastewater flows.

In the second stage 0.8 to 6.0 mm fine screen size opening is used to remove the finer particles. Fine screens consist of various types of screen media, including slotted perforated plates, wire mesh, woven wire cloth and wedge-shaped wire.

The accumulated solid waste materials are frequently removed by screening process to avoid the clogging/choking of the screen filters. Various screen categories with its size of openings and its applications in preliminary treatment process are given in ***Table 1*** (Davis, 2013; Waste-water treatment technologies: A general review. United Nation, NY, 2003).

2. Comminution

Comminutors are used to pulverize large floating material into small one in the waste flow, where the screening technique is impractical. Generally comminutors are installed between the grit chamber and the primary settling tanks to remove the pulverized materials, which reduces odours, flies and unsightliness.

Table 1. Different screening technique in wastewater treatment

Screen Category	Size of Openings (mm)	Application	Types of Screens
Coarse Screen	≥ 6	Remove large solids, rags, and debris.	Manually cleaned bar screens/trash racks Mechanically cleaned bar screens/trash racks Chain or cable driven with front or back cleaning Reciprocating rake screens Catenary screens Continuous self-cleaning screens
Fine Screen	1.5-6	Reduce suspended solids to primary treatment levels	Rotary-drum screens Rotary-drum screens with outward or inward flow Rotary-vertical-disk screens Inclined revolving disc screens Travelling water screens Endless band screen Vibrating screens
Very fine screen	0.2-5	Reduce suspended solids to primary treatment levels	---
Micro fine screen	0.001-0.3	Upgrade secondary effluent to tertiary standards	---

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Two types of comminutors are used in the comminution process, such as Rotating cutter comminutor and Oscillating cutter comminutor (Waste-water treatment technologies: A general review. United Nation, NY, 2003).

3. Removal of Greases and Oils

In primary treatment the water is left to stand so that oil and grease can form an insoluble layer on the surface of the water. Grease traps can be removed from the surface of the water, whereas gravity or simple skimming methods can also be used to remove the grease and oil (Abd El-Gawad, 2014).

4. Flow Equalization

Flow equalization is a technique used to improve the effectiveness of secondary and advanced wastewater treatment processes by leveling out operation parameters such as flow, pollutant levels and temperature to achieve constant flow to minimizing the downstream effects during the treatment process.

There are four type of flow equalization processes are available.

1. Alternating flow diversion
2. Intermittent flow diversion
3. Completely mixed, combined flow
4. Completely mixed, mixed flow

In waste water treatment process flow equalization can be applied in various locations in the treatment plants. The locations are

- Near the head end of the treatment works
- Prior to discharge into a water body
- Prior to advanced waste treatment operations

5. Equalisation

Different properties of waste materials may be produced and discharged into the waste water stream at different intervals in an industry, hence waste water might having different characteristic properties from time to time. So, uniform treatment can't be possible to treat the waste water, unless the waste water has uniform properties. The receiving or initial treatment tanks of a facility often serve as equalization tanks. To attain the uniform properties wastes need to equalize in waste treatment facilities by holding waste streams in a tank for a certain time period to attain uniform properties which provides easier to the treatment. Introducing uniform waste stream to the treatment system controls the treatment operations resulting to produce more predictable and uniform treatment results. Operation parameters of waste water treatment processes are to improve its effectiveness which is based on the equalization technique, a leveling out operation by checking the flow, pH, BOD and pollutant levels. During equalisation process solids present in the waste will settle along with heavy metals. The size, shape and its dimension of equalisation tanks vary depends upon the quantity of waste and mode of discharge of the waste materials. The equalisation tank should have a capacity to hold the volume of waste produced up to the completion

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

of a cycle of operations. Usually equalization tanks are equipped with agitators or aerators for mixing are preferred to prevent the settling of suspended solids to the bottom of the tank and to provide uniform effluent for the effective treatment. The agitators are normally placed at the centre line of the length of the tank spaced equidistantly, whereas aeration prevents settling of solids at the bottom of the tank. Systematic diagram of equalization tank is shown in ***Figure 1***.

Uniform effluent can be obtained by proper mixing in the equalization tank by:

1. Appropriate distribution and baffling
2. Mechanical agitation
3. Aeration

6. Neutralisation of Acid Wastes and Alkaline Wastes

Wastewater might have a wide range of pH depends upon the type of waste added into the waste water stream. Neutralization is required in the untreated waste waters to eliminate either high or low pH values prior to such as biological treatment. Generally chemical treatment process such as chemical precipitation is utilized along with the neutralization to adjust the pH of the waste water. Various chemical precipitating agents includes lime, sodium hydroxide (caustic), soda ash, sodium sulfide, and ferrous sulfate. Neutralization is performed by adding acids such as sulfuric acid or hydrochloric acid, to reduce pH, and alkalies, such as sodium hydroxides, to raise pH values. Neutralization may be performed in a holding tank, rapid mix tank, or an equalization tank to control the pH of the discharge between 6 and 9 (Waste-water treatment technologies: A general review. United Nation, NY, 2003; Cheremisinff, 1995; Spellman, 2004; Wastewater treatment technologies; Sincero, & Sincero, 2003; Drinan, & Whiting, 2001; Subramanyam, 2005). Systematic neutralization tank is shown in *Figure 2*.

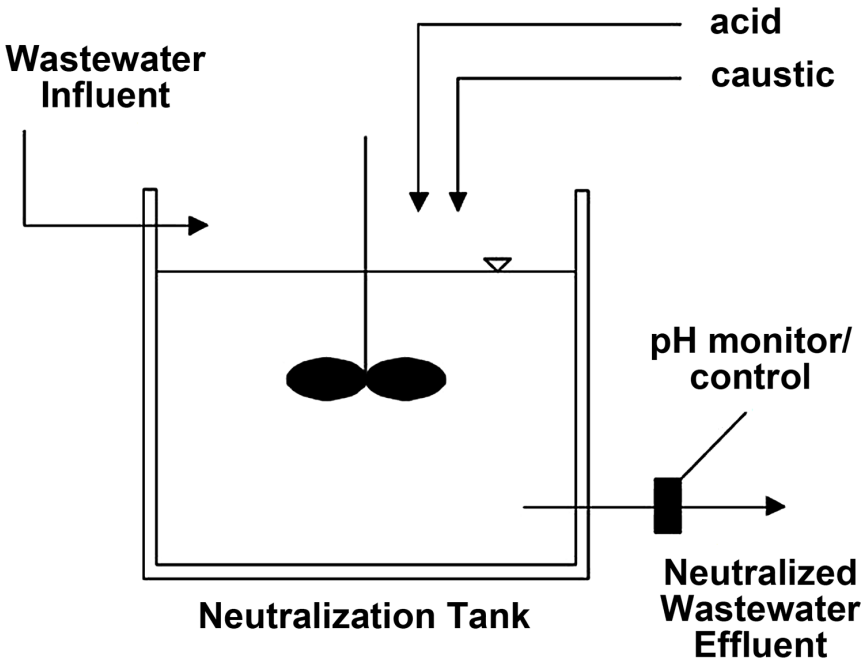
Figure 2. Systematic diagram of Neutralization tank



PRIMARY TREATMENT

Primary treatment acts as a precursor for secondary treatment which makes the effluent suitable for further downstream biological treatment by separating the solids as sludge. In primary treatment solids are removed as sludge by the physical operations such as screening and sedimentation, but doesn't remove or degrade the dissolved organic matter. Some circumstance depends upon the nature of the effluent pre-aeration or mechanical flocculation with chemical additions can be used to enhance primary treatment.

1. Sedimentation

Sedimentation is one of the unit operation in wastewater treatment involves settling of solid particles based on gravitational force in a suspended mixture. In this way the gritty particles, particulate and biological substances in the sludge, and chemical precipitates are removed. Sedimentation takes place in a settling tank, also referred to as a clarifier. There are three main designs, namely, horizontal flow, solids contact and inclined surface (Sperling, 2007).

2. Flocculation/Coagulation

Flocculation is a process of stirring or agitation of chemically-treated water to induce coagulation. Both flocculation and coagulation process are interchangeable one. In general "coagulation" is the reduction of the net electrical repulsive forces at particle surfaces by addition of coagulating chemicals, whereas "flocculation" is the agglomeration of the destabilized particles by chemical joining and bridging.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Flocculation usually consists of a rapid mix tank which enhances the sedimentation or filtration treatment processes results increased settling rates. Coagulating agents are added in the waste water to initiate the coagulation. Once coagulation over, the coagulated wastewater flows into a flocculation basin where slow mixing of the waste occurs, which allows the flocs to absorb and entrap the particles and other suspended materials to agglomerate into heavier, more settleable/filterable solids by bring them down.

Generally three types of chemicals are used in the coagulation/flocculation treatment processes. They are inorganic electrolytes, natural organic polymers and synthetic polyelectrolytes.

Commonly employed coagulating agents in the waste water treatment process are:

1. Alum (Aluminium sulphate)
2. Ferric sulphate
3. Chlorinated copper
4. Ferric chloride

Among these, alum is the most popular coagulant used in the wastewater treatment (Waste-water treatment technologies: A general review. United Nation, NY, 2003; Wastewater treatment technologies; O'Melia, 1972; Amirthanrajah, & Mills, 1982; Davis, 2013).

3. Flotation

Flotation is a unit operation used to remove solid or liquid particles from a liquid phase by introducing a fine gas, usually air bubbles. The gas bubbles either adhere to the liquid or are trapped in the particle structure of the suspended solids, raising the buoyant force of the combined particle and gas bubbles.

Flotation is the process of introducing fine bubbles into the tank to encourage suspended particles to rise to the surface of the tank. When gas bubbles are introduced into the wastewater, gas bubbles either adhere to the liquid or are trapped in the particle structure of the suspended solids, thereby reducing their specific gravity and causing them to float. Flotation process is used to remove the suspended solids and oil and grease from oily wastewater by reducing the sedimentation times of suspended particles; which have a specific gravity closer to that of water (solids particles which has the specific gravity slightly greater than water whereas the oil/grease particles have specific gravity slightly less than water. Various components of a flotation process include a centrifugal pump, a retention tank, an air compressor, and a flotation tank. When the air introduced into fine bubbles, the bubbles are trapped inside the liquids or solids to form sludge flocs, which raises the buoyant force of the combined particle and gas bubbles and then floating them to the surface. The float is continuously swept from the tank surface. Flotation is mainly used to remove suspended matter and to concentrate biological sludge. Various flotation methods utilized in the waste water treatment process are dissolved air-flotation, air-flotation, vacuum flotation and chemical additives.

The mechanism involved in the formation of sludge flocs includes:

1. Attachment of the bubbles on the particle surface
2. Collision between a bubble and a particle
3. Agglomeration of individual particles or a floc structure as the bubbles rise

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

4. Absorption of the bubbles into a floc structure as it forms (Waste-water treatment technologies: A general review. United Nation, NY, 2003; Wastewater treatment technologies; Spellman, 2010 & 2001; Qasim, 1999)

SECONDARY TREATMENT

Secondary treatment acts as a precursor for tertiary treatment which makes the processes are used to convert the finely divided and dissolved organic matter in wastewater into flocculent settle able organic and inorganic solids by chemical decomposition catalyzed by microorganisms. The untreated and escaped soluble, colloidal organics and suspended solids from the primary treatment are further treated in secondary treatment to reduce the Biological oxygen demand (BOD) and chemical oxygen demand (COD) through biological process.

In the secondary treatment process, micro-organisms, particularly bacteria, convert the colloidal and dissolved carbonaceous organic matter largely converted to 'biogas', a mixture of CH_4 and CO_2. Secondary treatment process operation involves trickling filtration, activated sludge process, oxidation ditch and oxidation ponds.

1. Activated Sludge Process

The activated sludge process is an aerobic biological treatment process employs suspended-growth aerobic microorganisms to biodegrade organic contaminants. This activated sludge process is one of the most valuable biological processes to treat the industrial wastes. A suspension of aerobic microorganism is utilized by mechanical mixing or turbulence induced in an aeration basin by diffused aerators in the waste water to mix the contents. In this process, industrial waste or sewage is continuously exposed and subjected to biological degradation. A series of biochemical reactions takes place in the aeration basins, which degrades the organic matters and generate new biomass. Microbial mass of bacteria, fungi, protozoa, rotifers and nematodes are used in the activated sludge process. They include carbon oxidizers, nitrogen oxidisers, floc formers but primarily gram-negative in strain. The nature of organic matter in the waste is the determining factor to identify exact type and species of bacteria or other microorganisms in the slimes.

Microorganisms oxidize the soluble and suspended organic materials into carbon dioxide and water using the available supplied oxygen. Oxygen is an important one to oxidize the organic materials. For effective oxidation atleast a residual of 0.5mg/l of oxygen should be present at all times which can be supplied either by mechanical or diffused aeration systems.

The amount of Oxygen requirements are based on the amount required for biodegradation of organic matter and for endogenous respiration of the microorganisms. The turbid effluents due to the growth of filamentious bacteria than the other required bacteria and protozoa when anaerobic conditions developed due the reduced supply of oxygen. The retarding of floc compaction and settling is observed in filamentous bacterial growth.

After the specific time duration, the treated mixture is passed to a settling tank, where the microorganisms are separated from the treated water. A portion of the settled sludge is recycled to the aeration basin to maintain a required concentration of microorganisms in the process. The remaining settled solids is collected as waste and discorded. For effective oxidation process the microorganisms should

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

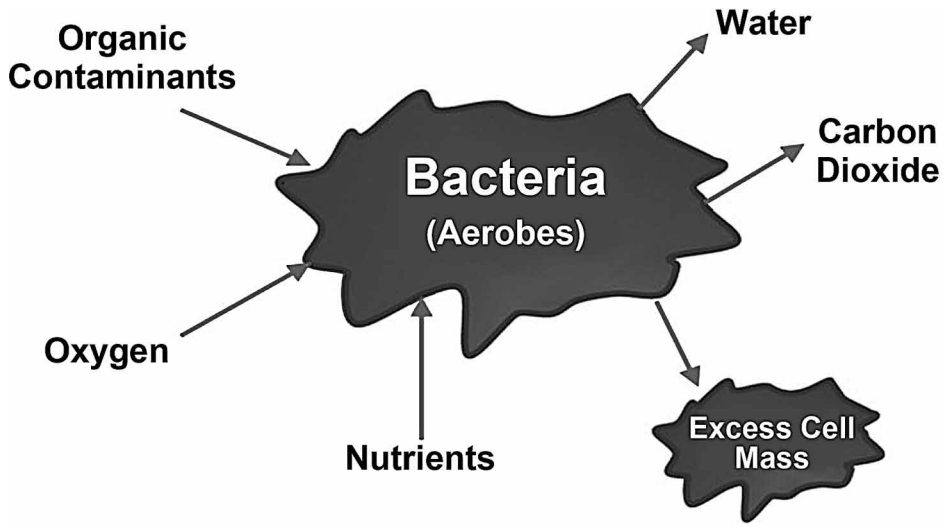
supply with adequate nutrient (nitrogen and phosphors) levels must be available to the biomass. Lack of these nutrients can impair biological activity and result in reduced removal efficiencies. Nitrogen and phosphorus are supplied by the addition of either urea or mono ammonium or diammonium hydrogen phosphate. Other than nitrogen and phosphorous various nutrient elements such as potassium, calcium, magnesium are usually present in the waste. Inorganic substances such as iron, molybdenum and cobalt are also required in trace quantities. Temperature, pH and oxidation-reduction potential are the other factors having important role in the activated sludge process. The optimum pH range for the activated sludge process is between 6.5 and 9.0; if the pH value is below 6.5 fungi will compete with the bacteria. Hence, for effective oxidation of the organic matters by bacteria, pH measurement must be made at regular intervals in the aeration tank.

Various operating variable have a role on the effectiveness of the activated sludge process, such as organic loading, sludge retention time, hydraulic or aeration detention time, oxygen requirements levels in the aeration tanks, Regulation of the amount of returning activated sludge and Control of the waste activated sludge. Role of bacteria in the activated sludge process is shown in *Figure 3.*

2. Aerated Lagoons

Aerated lagoons are large holding tanks used to oxidize the dissolved organics by mechanical aeration by surface, turbine or diffused aeration technique. Generally floating aerator technique is used to supply the required quantity of oxygen and mixing power. Aerated lagoons, the internal surface is lined with cement or butyl rubber or polythene used. In this process the waste materials are treated for 2 to 6 days depends upon the contaminant present in the effluent. During this time duration, around 90% of biological oxygen demand is removed by oxidation of organic matter and to form a denser flocculent sludge. This flocculent sludge is removed in a settling basin before final effluent discharge. After complete process, bacteria might be present in the final effluent, hence further biological purification is required.

Figure 3. Role of bacteria in the Activated Sludge process



EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

3. Trickling Filtration

Trickling filtration is an aerobic fixed-film biological treatment process for the removal of organic matters from the wastewater. In this process consists of a structure of highly packed with inert permeable such as rock, wood, or plastic. The treated wastewater is spread/sprinkled over the upper surface of the medium by moving sprinklers using either a fixed spray nozzle system or a rotating distribution system. The inert medium develops a biological slime layer, that absorbs and biodegrades organic pollutants by percolation. Air flows through the filter by convection, thereby providing the oxygen needed to maintain aerobic conditions. The microbial slimes formed on the bottom of the bed oxidize the wastewater. The thickness of the slime layer increases due to microbial growth. During this process, a gelatinous film of the microbial growth is formed on the whole surface of the bed which absorbs the dissolved and colloidal organic matter and degrades the organic matters. In trickling filtration process, organic concentration, temperature of the waste, size of the bed stone, microbial surface area, depth of the filter, retention time and oxygen transfer are having the important role in the removal of organic matters. The microbial layer formed at the bottom of the bed is very sensitive to temperature, and the metabolic activities are directly proportional to the temperature of the waste passing through the filter. A flow diagram of trickling filter is shown in *Figure 4*.

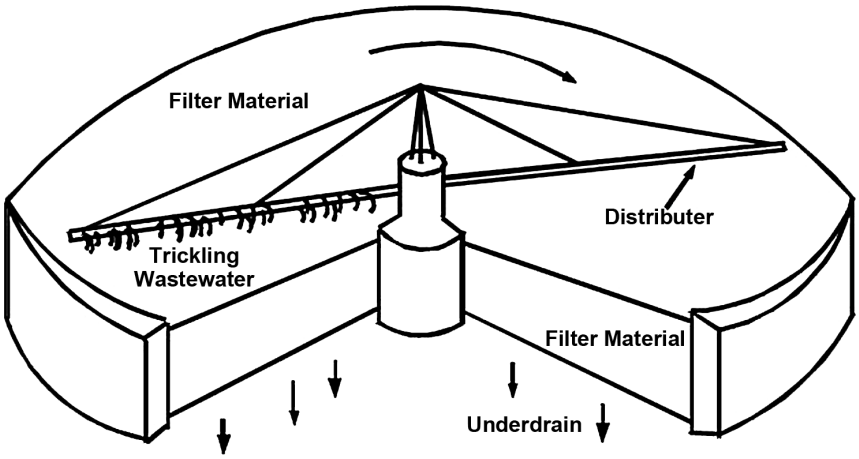
Trickling filters are classified depending upon the organic loading. They are:

Low-rate: In this the filters has a media bed depth of 1.5 to 3 meters
High-rate: In this the filters may have a bed depth from 1 to 9 meters.

4. Oxidation Ditch

Oxidation Ditch is a modified Activated Sludge process, which consists of a ring- or oval-shaped channel and is equipped with mechanical aeration devices. In this aeration is done by using an aeration system and mixing done by using brush rotors placed across a race-track-shaped basin. Filtered waste-water enters the ditch at one end, is aerated by rotors and circulates. Oxidation ditches normally operate in prolonged aeration mode with longer detention and solids retention time are provided.

Figure 4. Flow diagram of Trickling filter



EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

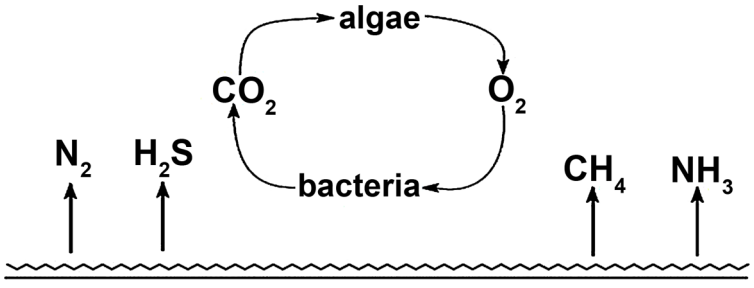
5. Oxidation Ponds

The liquid is treated by bacteria which break down the organic matter remaining in solution and then it is sent to oxidation ponds. Oxidation pond treatment is a very economical secondary treatment process. The effluent entering the ponds is a mixture of primary and secondary treated effluent. Oxidation pond is a large shallow pond in which wastes are added at one end where heterotrophic bacteria continue the breakdown of the organics in which the required oxygen is supplied by the algae for its metabolism. The composition of the effluent is varies during the year. In summer generally primary treated effluent, whereas in winter more secondary treated effluent is used. The carbon dioxide that is released by bacteria will be utilized by algae for the photosynthesis reaction. High penetrative photosynthesis of algae, powerful mixing and natural aeration are needed in effective treatment of wastes. These aerobic and anaerobic processes enable the purification of waste water.

Solids present in the waste are getting settled at the bottom of the pond. In this oxygen bond solid layer acts as anaerobic phase whereas the top liquid layer acts as aerobic phase. In the pond, algae use solar energy to produce oxygen from carbon dioxide and water, and bacteria use oxygen to break down the remaining organics to simple molecules such as carbon dioxide and ammonia.

The rate of purification is depends upon the amount of the algae present in the pond due to the release of more amount of oxygen released by the algae. The growth of algae is enhanced by the nutrients present in the waste. After the treatment the effluent is removed at another end. During this process maximum amount of BOD is reduced and no longer is BOD treatment required for the effluent. If there is any lacking of oxygen in the pond, the anaerobic conditions is created in the ponds leads to breakdown of waste and produce foul odour in the pond (Technology Transfer Manual of Industrial Wastewater Treatment, Overseas Environmental Cooperation Center, Japan, March 2003; Biological wastewater treatment; Boari, et al., 1997; Wastewater treatment technology and application in Industrial facilities; Hoffmann, 1998; Wang, et al., 2009; Melin, et al., 2006; Henze, et al., 2008; Van Haandel, & Van der Lubbe, 2012; Kalbar, et al., 2012; Sewage treatment; Verbyla, & Mihelcic, 2015; Mara, & Johnson, 2007; Muga, & Mihelcic, 2008'; Mahajan, 2007). The chemical reaction taken place in oxidation ponds is shown in *Figure 5*.

Figure 5. Chemical reaction of Oxidation Ponds



EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

TERTIARY TREATMENT

Tertiary treatment is the final treatment process in the waste water treatment to remove significant amounts of nitrogen, phosphorus, heavy metals, biodegradable organics, bacteria and viruses for further. This treatment process is also to remove the dissolved inorganic solids, bacteria and traces of organics. Removal of bacteria especially of faecal origin is achieved by keeping the effluents from secondary biological treatment units in maturation ponds for specified periods. If the final effluent still contains enough bacteria, then it is chlorinated. The tertiary treatment process operation involves chemical coagulation, flocculation and sedimentation, followed by filtration and activated carbon. Ion exchange and reverse osmosis for specific ion removal or for dissolved solids reduction are less frequently used. Inorganic dissolved solids are removed by the following methods.

1. Evaporation

It is a process utilized only when the recovered solids or concentrations solutions are reused. This process is specifically useful for the concentration of radioactive waste and other wastes of smaller volume. In this process waste effluent is evaporated by boiling and vaporising the water phase. The degree of evaporation is greatly dependent upon climatic conditions. This process is generally available only to those facilities located in arid regions (Waste-water treatment technologies: A general review. United Nation, NY, 2003; Wastewater treatment technologies; Evaporation - A Wastewater Treatment Alternative).

2. Reverse Osmosis

Reverse osmosis (RO) is a process for separating dissolved solids and metals from water, and it is useful only when the solute molecules are same size as the solvent molecule. Osmosis is the process of diffusion of a solvent (such as water) across a semi-permeable membrane from lower concentrated solution into higher concentrated solution. Whereas in the reverse osmosis process, pressure is applied which is greater than the normal osmotic pressure is applied in the higher concentration region to force the purified water pass through the membrane and into the lesser concentrated solution through permeation. The effluent liquid waste containing dissolved solids is passed over the surface of a semi permeable membrane and at a pressure, which leaves the concentrated liquor on the surface of the semi permeable members. In RO the low molecular-weight solutes such as salts, surfactants do not pass through the membrane, which are called as concentrate. These concentrates are recirculate through the membrane until the flow of permeate drops.

Various factors such as dissolved solids concentration and temperature of the feed stream, the applied pressure, and the type of membrane selected having the important role in the separation of solids in RO. Selectivity for water over ions, permeation rate and durability are the other factors need to be considered while selecting the semi-permeable membrane in the RO. Generally Cellulose acetate and polyamide-hydrazide membranes are used for the effective separation (Matsuura, 1993; Cruver, & Nusbaum, 1974; Xiao, et al., 2014).

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

3. Membrane Separation

Various membrane separation processes such as reverse osmosis, ultrafiltration, dialysis, piezodialysis and electrodialysis are used; whereas dialysis and piezodialysis techniques are not having any significant role in the waste water treatment. In the dialysis technique separation of solutes from the solution is based on the difference in the rates of diffusion. In electrodialysis gradient electrical potential is used as driving force and an ion exchange membrane as discriminating barrier. Electrodialysis technique is used to remove the ionic constituent in the wastewater treatment process (Davis, 2013; Water Environment Federation, 2005).

4. Chemical Precipitation

Chemical precipitation technique is used to remove metal compounds from wastewater by forming a chemical precipitation of soluble metallic ions into insoluble form as precipitated product. Coagulation/ flocculation processes are used in conjunction with chemical precipitation to enhance the removal of suspended and colloidal materials by forming an agglomeration and convent into more readily settle able flocs and removed by liquid filtration or by clarification technique.

Commonly the metal ions are present as hydroxides, sulfides or carbonate forms. Commonly most of the heavy metals are precipitated as hydroxide at elevated pH. Chemical precipitation process taken place in two steps.

1. Addition of chemical precipitating agents: Precipitating agents are added into the wastewater and mixed by means of mechanical mixture to induce the formation of insoluble metal precipitants.
2. Filtration or clarification: The metal precipitates are removed from the wastewater through filtration or clarification technique. If clarification technique is used, a flocculent is sometimes added to aid the settling process. The degree of clarification in the separation of the precipitates is depends on the quantity of chemicals used.

Various chemicals are used as precipitants, but selection of suitable precipitants is based on performance, reliability and cost. Commonly used precipitants in the wastewater treatment are lime, sodium hydroxide (caustic), soda ash, sodium sulfide, and ferrous sulfate. Lime is the cheapest and effective precipitating agent. Chemicals such as sulfuric acid and phosphoric acid are used for the pH adjustment, whereas polyelectrolytes are used as flocculation aids in the wastewater treatment. Various factors such as chemical interactions, temperature, pH, solubility of waste contaminants, and mixing effects have an important in the formation of chemical precipitation.

There are two type of precipitation technique such as Hydroxide precipitation and sulfide precipitation are used in wastewater treatment process, often combination technique is used to remove the optimal metal.

Hydroxide precipitation: This technique is used to remove the metals like antimony, arsenic, chromium, copper, lead, mercury, nickel and zinc.

Sulfide precipitation: This technique is used to remove the metals like lead, copper, silver, cadmium, zinc, mercury, nickel, thallium, arsenic, antimony and vanadium (Waste-water treatment technologies: A general review. United Nation, NY, 2003; Wastewater treatment technologies; Davis, 2013).

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

5. Ion Exchange

It is general technique used to remove the heavy metals from the low–concentration waste streams, such as electroplating wastewater, is ion exchange. This process is used only when the metal contaminants and exchanged salts are recovered and reused. In this technique, the waste water stream is passed through a bed of resin (cationic or anionic or mixed) containing ionic charge on its surface; which are used for exchange of same charge of ions in the wastewater. Selection of ion exchange technique in waste water treatment is dependent upon the contaminant to be removed and for water softening. Often, individual resin beds containing different resins are arranged in series, in specific treatment purpose mixed bed system is used. Generally polystyrene copolymerized with divinylbenzene resin is used for the treatment.

Ion exchange process is taken place in four steps.

1. **Treatment:** Wastewater is passed through the resin bed and ions are exchanged until pollutant breakthrough occurs.
2. **Backwash:** Backwash the bed to remove the suspended solids on the surface.
3. **Regeneration:** The resin bed is treated with higher concentrated acidic or alkaline solution to charge the resin originally present in the resin bed.
4. **Rinsing:** The resin bed is rinsed to remove the residual regeneration solution present in the surface of the resin (Gregory & Dhond, 1972).

ANALYTICAL TECHNIQUES

After the tertiary treatment wastewater can have different elements. The amount of elements such as phosphorous, nitrogen, dissolved oxygen, nitrite, nitrate, sulphide, might be present in the treated wastewater, and it's needed to be quantified. Various analytical techniques are available to detect the residuals in the treated waste water. The chosen analytical technique should be very specific to determine the residual present in the treated waste water even in very low levels to ensure the effluent purity and provide the assistance to the other stages for the treatment process.

Various instruments are used in the determination of residues in the treated waste water. They are:

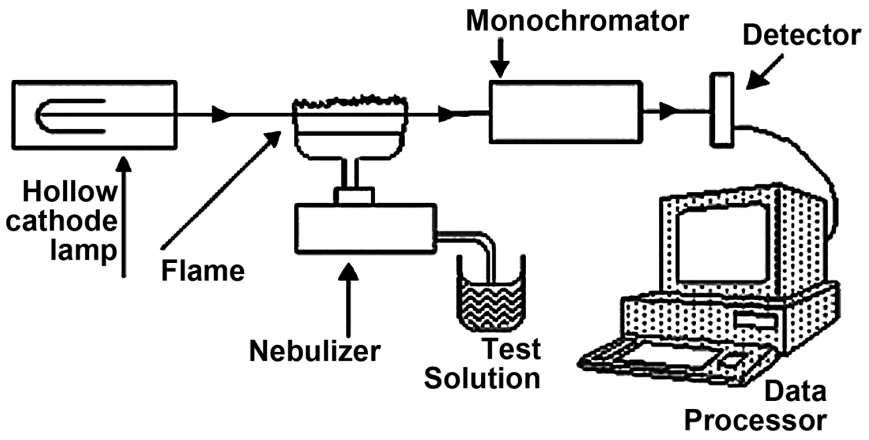
1. Atomic absorption spectroscopy (AA)
2. Gas Chromatography (GC)
3. Inductively coupled plasma (ICP)

Atomic Absorption Spectroscopy (AAS)

AAS is used principally for the quantitative determination of metal elements in aqueous and solid samples. AAS deals with the absorption of specific wavelength of radiation by neutral atoms in the ground state. In the Atomic absorption spectroscopy, solution of metallic salt sample is atomising to form fine droplets. Due to thermal energy the solvent in the droplet evaporates leaving fine residues, which are converted into neutral atoms. These neutral atoms absorbs the light passing through the atoms present in the vapour stage and measure the amount of light absorbed by the atoms. The amount of light absorbed depending on the amount of element present in the vapour. Various lamps are used which are depends upon

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 6. Schematic diagram of Atomic Absorption Spectroscopy



the element to be determined in the treated waste water. This technique is used for detecting cadmium, chromium, copper, lead, silver and zinc (Willard, et al., 1989). Schematic diagram of Atomic absorption spectroscopy is shown in *Figure 6*.

Gas Chromatography

Gas Chromatography consists of Gas solid chromatography (GSC) and Gas liquid chromatography (GLC). In GSC the principle of separation is adsorption, whereas in GLC the principle of separation is partition. In GLC, gas is used as mobile phase and liquid which is coated onto a solid support is used as stationary phase. In GLC, sample is converted into vapour and mixed with gaseous mobile phase. The components are separated based on their partition coefficient. The component which is less soluble in the stationary phase, travels faster and eluted out first and the components which is having more soluble will be eluted later (Willard, et al., 1989). Schematic diagram of Gas chromatography is shown in *Figure 7*.

Inductively Coupled Plasma (ICP)

ICP is one of the commonly used instruments for the determination of various metal elements such as arsenic, cadmium, chromium, copper, lead, silver and zinc. In this technique the sample is atomized and injected in a chamber packed with argon plasma, to convert the sample solution into an aerosol and pass into central channel to vaporize the sample. The vaporized sample liberates the atoms, due to collision excitation, atoms are promoted to higher energy excited states. The excited atomic and ionic excited species return to the ground state with the light emission of a photon, this photons have a characteristic energies that can be measured. The total number of the proton is directed proportional to the concentration of the element present in the sample. The intensity of the emission band is compared with the previously measured intensities of the known concentration of the elements, by interpolation in the calibration curve we can able to measure the concentration of the given sample. Thus the wavelength of the photons from the element has a characteristic emission band which can be used to identify the elements in the treated waste water (Hou, & Jones, 2000; Stefansson, et al., 2007). Schematic diagram of inductively coupled plasma is shown in ***Figure 8***.

Figure 7. Schematic diagram of Gas Chromatography

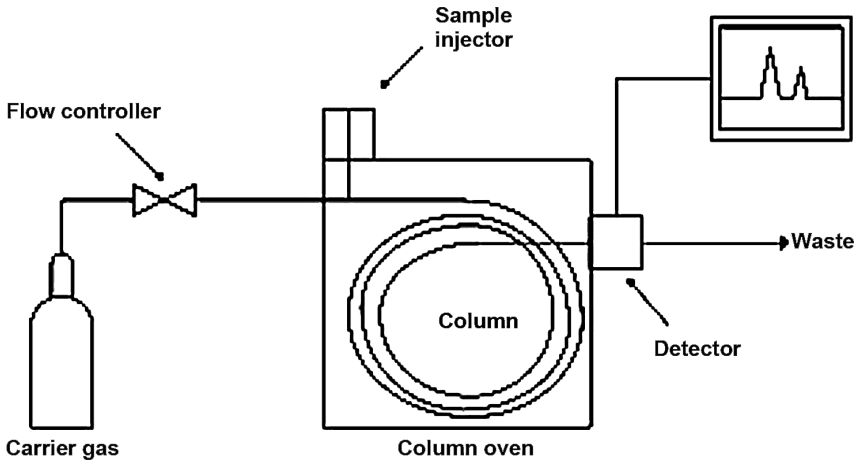

Figure 8. Systematic diagram of inductively coupled plasma

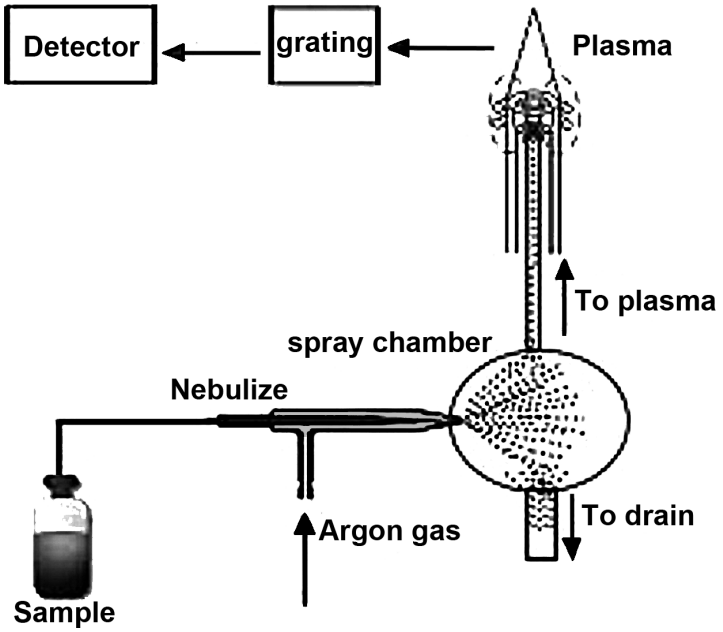

Total Phosphorous

Normally phosphorous is occurs in the fifth oxidation level. In wastewater phosphorous is present as phosphates, whereas the phosphorous atom combined with four oxygen atoms (PO_4^{-3}). Phosphorous is the limiting nutrient for the plant growth. Generally phosphates are originate from various sources such as cleaning solutions, fertilizers and biological wastes. If concentration of phosphate in high level persists, algae and other aquatic life will grow by decreasing the amount of dissolved oxygen by increasing the decay of organic matter.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

The amount of phosphorous in the treated wastewater can be determined by colorimetric method. The determination of phosphorous is done in three steps:

1. Oxidise the phosphate into orthophosphate using the mixture of sulphuric acid and nitric acid.
2. Formation of yellow complex by the reaction between the orthophosate with ammonium molybdate and potassium antimonyl tartrate in presence of acid.
3. Reduction of yellow complex with ascorbic acid to molybedenum blue.

The intensity of the blue colour is directed proportional to the concentration of the element present in the sample. The concentration of the phosphorous as phosphate present in the treated waste water can be determined from the standard curve.

Total Organic Nitrogen

In surface and ground water various concentrations of Organic nitrogen is present from free amino acids and ammonia. Presence of ammonia in the waste water is an indication of sanitary pollution. Ammonia is readily oxidized by bacteria and converts into nitrite and nitrate. Nitrogen present in the treated wastewater can be determined by heating the sample in acid using copper sulphate as catalyst. The reaction is continued until the complete conversion of nitrogen into NH4 + ions and then converted into ammonia by treating with a base. The amount of ammonia can be determined by using an autoanalyser with colorimetric detection.

Dissolved Oxygen

Oxygen enters into the water by diffusion from the atmosphere and dissolved oxygen is a vital one for various aquatic living things. The solubility of the oxygen in the water is directly proportional to the partial pressure in the gas phase, to salt concentration and temperature. The amount of dissolved oxygen in the water is affected by various factors such as temperature, flow (velocity of water flowing in a stream), presence of aquatic plants, altitude and dissolved or suspended solids. The amount of dissolved oxygen in the treated waste water can be determined by:

1. Oxygen selective electrode method
2. Redox reaction

Nitrite (NO_2)

Biological breakdown of organic nitrogen (oxidation of ammonia or reduction of nitrate) produces nitrites as an intermediate product in the water. Amount of nitrite in the wastewater is an indicative of the pollution. Amount of nitrite in the treated wastewater can be determined by reacting the nitrite with sulphanilamide to form diazonium compound (Griess-Ilosvay's method). This diazonium compound is reacts with N-(1-napthyl)ethylenediamine to form a colored azo dye, which can be measured spectrophotometrically.

Nitrates

Nitrates are produced as end product in the water when biological breakdown of organic nitrogen occurs. When water shows presence of excess amount of nitrates, it indicates the poor quality of water. The quantity of nitrite present in the sample illustrates the amount of nitrate present in the treated wastewater. By measure the difference of nitrite present on successful treatment gives the quantity of nitrate present in treated waste water.

Hydrogen Sulfide

Sulfide as hydrogen sulphide which inhibits the aerobic respiration, muscle contractions, including breathing, and promotes excess breakdown of glucose. Hydrogen sulfide level in the treated wastewater increases when sulfate-reducing bacteria grow up in the anaerobic sludge of a pond. The amount of sulphide present in the treated wastewater can be determined by reacting the H_2S and N,N-dimethyl-*p*-phenylene diamine to form methylene blue (a strongly coloured complex) in the presence of $FeCl_{3.}$

Total Solids

Total solids include both the suspended and dissolved solids in the wastewater. These solids have an important role in the conductivity and turbidity of the sample. The amount of the total solid present in the treated wastewater can be measured by place a specific quantity of the sample in a previously weighed dish in a drying oven at the temperature between 103°C and 105°C to evaporate the water. The dish is weighed frequently until get the constant weight, the difference between the initial and final weight of the dish gives the total weight of the solid present in the sample.

pH

pH is defined as the negative logarithm of the hydrogen ion concentration. The pH value indicates the amount of hydrogen ion present in the sample and to categorise the sample into acidic, basic or neutral of the treated wastewater. pH of the treated wastewater can be measured by using an ion-sensitive electrode known as a glass electrode.

Alkalinity

The alkalinity of the sample is mainly due to bicarbonate, carbonate and hydroxide ions in the water, which increases the pH of the water above 4.5. Alkalinity of the sample indicates the buffering capacity of water and its ability to resist a change in pH. Alkalinity is differs from pH, and it can be measured by simple acid-base titration (amount of acid required to neutralize the sample) using a suitable color indicator.

Five Day Biological Oxygen Demand (BOD5)

Biological Oxygen Demand measures the amount of oxygen utilized by organisms in the biochemical oxidation of organic matter in a wastewater sample in a specified time (usually 5 days), and at a specified temperature. BOD measurements are used as a measure of the organic strength of the water.

BOD of the sample can be determined by diluting the sample to get concentration of 2 mgL^{-1} O_2 (approximately) and incubating the sample in a sterile condition at the temperature of $20 \pm 1°C$ for five days (allyl thiourea is added to the incubating material to prevent the oxidation of these compounds); measure the dissolved oxygen content which gives the BOD value.

Chemical Oxygen Demand (COD)

Chemical Oxygen Demand measures the total quantity of oxidisable materials (organic and inorganic matters) present in the sample. COD of the sample can be determined by oxidation reaction (using strong oxidant like potassium dichromate). The amount of oxidant utilized for the oxidation of the sample gives the value of COD (Janben, https://www.ecn.nl/docs/society/horizontal/hor16_nutrient.pdf; Elser, et al., 2007; Lapa, et al., 2000; Park, & Noguera, 2004; Posadas, et al., 2015; Barker, et al., 1999; Ma, et al., 2001; Interpreting Results From Additional Water Tests; Water quality parameters).

STANDARDS AND GUIDELINES

Globally various standards for the treated wastewater has been developed to ensure it's physical and chemical quality. Each country they have a standards for the treated wastewater, whereas the limits of the elements are reviewed and updated to meet the global needs for the protection of ambient waters.

Various regulatory agencies mandate the control of water pollution. They also establish secondary treatment standards, the agency which controls are United States Environmental Protection Agency (USEPA) and National Pollutant Discharge Elimination System (NPDES). Table 2 shows limitations in secondary waste water treatment plants and European Community Environmental Directive Requirements (EC EDR) for discharges from urban waste water treatment (United States Environmental Protection Agency, 2007; Eaton, & Franson, 2005). Various organizations of wastewater treatment standards are given in *Table 2*.

Table 2. NPDES and EC EDR for Discharges from Wastewater Treatment Plants

Parameter	NPDES			EC EDR WD	
	30-Day Average Concentration	7-Day Average Concentration	Percentage of Removal	Concentration (mg/L)	Percentage of Removal
BOD	30mg/L	45mg/L	85	25	70-90
TSS	30mg/L	45mg/L	85	35-60	70-90
pH	6-9	--	--	--	--
COD	--	--	--	125	75
Total Nitrogen	--	--	--	10-15	70-80
Total Phosphorous	--	--	--	12	80

CONCLUSION

The effluent from the various industries contains various matters such as organic material, numerous pathogenic microorganisms, nutrients and toxic compounds which leads to environmental pollution and hazards of health community of various living things. An optimized wastewater treatment process and plant design needs to be developed to support the effective treatment process. The critical role of the wastewater treatment process is to ensure that the effluent leaves the treatment plant should meet the limitation of the environmental standard.

Hence, the treated effluent must ensure the safety, efficacy, quality of the treated wastewater and regulatory requirements to protect the public health from the various effluent environmental pollutions.

Chapter 4
The Fundamentals of Water and Natural Waters

Benjamin Cuker
Hampton University, USA

George Bugyi
Pennsylvania State University, USA

ABSTRACT

This chapter provides information on the fundamental concepts needed to understand water and water pollution, enabling better comprehension of the subsequent material. Examining the molecular structure of water provides context for understanding its most important properties. The reader explores the various types of natural waters and learns how they are tied together in the global water cycle. An examination of the contents of natural waters reveals the presence of dissolved solids, liquids and gases and the intimate relationship between these substances and the community of life that dwells in aquatic systems. The chapter introduces basic concepts of the chemistry of water and discusses the action and distribution of pollutants. Readers also learn about the basic interaction between various pollutants and the aquatic food chain.

INTRODUCTION

This book is about the complex relationship between people, water and health. It will explore how the health of humans is intimately tied to the health of natural water systems. The first chapter will prepare the reader for a fuller understanding of the topics covered in the rest of the book. The objective of this chapter is to examine the fundamental properties of water beginning with molecules and finishing with the ocean. Life, water, and the atmosphere of Earth function together in a highly interdependent way. One cannot understand one single component without having some appreciation for the entire system. So this chapter is organized in a holistic way, with topics often blending together in order to give a fuller understanding.

BACKGROUND

When viewed from a spacecraft, the Earth appears as a shining blue and white orb. The blue light is reflected from the water of the ocean and the white light from the condensed water vapor of the clouds. Water is the dominant and defining feature of our planet. Not surprisingly, water is also one of the defining features of life.

The Earth formed some 4.5 billion years ago. The ocean appeared about 1 billion years later (Stanley, 2009). From that primordial sea evolved the first forms of life about a half a billion years later. So for most of its existence Earth has been wet and alive. Water shaped the forms of life that evolved in the sea and eventually invaded the land. And as life developed it reshaped the nature of the ocean and atmosphere above. About three billion years ago the process of photosynthesis developed in certain bacteria and algae. This new type of metabolism used energy from sunlight to fuel these early plant-like creatures. To access the energy in sunlight, photosynthesis splits water molecules resulting in the release of free oxygen as a waste product. That oxygen changed the chemistry of the sea and the air. The splitting of water also produces high-energy electrons and protons that are used in photosynthesis to do the work of

Figure 1. View of Earth from space taken by Apollo astronauts on December 7, 1972.

the cell, including building sugars from atmospheric carbon dioxide (Garrison, 2001). Algae use sugars made in photosynthesis as the basis to create a huge variety of organic compounds. Those organic molecules fuel the rest of the ocean food chain, and a portion of them is buried in the ocean sediments. Over time those buried organic molecules transform into petroleum and natural gas that now fuel much of our economy. Indeed, it is the burning of millions of years' worth of fossil fuels over the last two centuries that is once again changing the atmosphere and the global climate (Miller & Spoolman, 2014).

THE STRUCTURE OF WATER AND ITS CHEMESTRY

Water is a wondrous substance. Its special structure gives rise to a variety of important properties the reader will need to understand in order to appreciate subsequent chapters. Water is a molecule made up of two different kinds of atoms, oxygen and hydrogen. Mostly water appears as H_2O, one larger oxygen molecule sharing electrons with two smaller hydrogen atoms. The sharing of electrons by the oxygen and hydrogen atoms results in what are called covalent bonds (Becker & Wentworth, 1973).

The oxygen molecule contains in its nucleus eight protons and eight neutrons. By comparison hydrogen atoms are much smaller, each containing only one proton and one neutron in its nucleus. The eight positively charged protons in the oxygen nucleus attract the negatively charged electrons away from the single protons of the hydrogen nuclei. Oxygen is said to be more electronegative than hydrogen due to its superior attractiveness for electrons. As such, the electrons from the hydrogen atoms in the molecule spend most of the time near the oxygen end of the structure. This makes the oxygen end carry a charge of -2, and each hydrogen on the other end carry a charge of +1. The overall charge of each water molecule is neutral, with -2 on the oxygen end and +2 on the hydrogen end. This distribution of charge makes the water molecule polar meaning that is it has a negative and a positive end (Armstrong, 1983).

That water is a polar molecule leads to its numerous special properties. First, the polarity causes water molecules to arrange themselves in a particular way. The negatively charged oxygen end of one molecule will be attracted to the positively charged hydrogen sections of an adjacent water molecule. Since it has a charge of -2, each oxygen end attracts two different +1 hydrogen ends. The resulting arrangement is a liquid crystal in which each water molecule is bonded with four other water molecules. The attraction between the positive H ends of one molecule and the negative O end of another results in what is called a hydrogen bond. Unlike the strong covalent bonds that hold a single water molecule together, the hydrogen bonds formed between different water molecules are rather weak. Yet, there are so many of these weak hydrogen bonds, four times the number of water molecules in a container, that they become very important (Armstrong, 1983).

The numerous hydrogen bonds of water hold together the molecules with surprisingly great strength. One can see this by laying a straight pin on its side on the surface of water in a cup. It remains on top of the water supported by the surface tension created by hydrogen bonds joining the water molecules cradling the pin. A gentle push on the pin is sufficient to break those H-bonds long enough for the pin to quickly sink.

The temperature of the water determines the distance between each water molecule. If heated, the energy imparted to the water will cause the hydrogen bonds to expand and as such makes the water expand, the same number of molecules now occupying a greater volume. The warmed water becomes less dense. Conversely, cooler water is denser than warmer water, but only down to the temperature of 4° C. As water cools further the liquid crystal again expands. At 0° C and with the removal of some more heat, the water turns to low-density ice and it floats on the surface (Wetzel, 1983).

The global warming of recent decades means increasingly warmer ocean waters. The warmed seawater expands, submerging low-lying coastal lands. Expanding ocean waters coupled with drainage from melting glaciers leads to raising sea levels that endanger coastal communities.

The formation of coastal dead zones is an important hazard to the environment and human wellbeing. Those dead zones form in the summer when the warmed surface waters float on the cooler deep waters. This creates stratification, with little mixing of the two layers. As such, life forms in the isolated deeper waters use up the available oxygen, creating the dead zone conditions (Diaz & Rosenberg, 2008). The reader can see why understanding a bit about H-bonds and temperature is important to fathom the workings of natural waters.

The expansion and contraction of hydrogen bonds takes a lot of energy. As such, a surprising amount of energy is exchanged when water either warms or cools and so much so that scientists use water as the defining substance for the concept of specific heat. The specific heat of a substance is defined as the amount of energy it takes to increase or decrease the temperature of 1 gram (g) of that substance 1°C (Centigrade, this is calculated at 25°C, at sea level). For example it would take 10 calories to increase the temperature of one gram of water 10°C. Water has a very high specific heat compared to most other substances (Becker & Wentworth, 1973). It is 1 cal/g for water compared to 0.19 cal/g for quartz sand (Engineering Tool Box, 2015). Thus it takes about 5 times the amount of heat to warm a gram of water 1° C as it does to warm a gram of sand. This explains why the range of temperatures for natural waters is about -2 ° C to 38 ° C (Levinton, 2014), and for deserts like the Gobi in Asia, from -55 °C to 40 °C (Weather Online, 2015). The high specific heat of water also explains in part why humans (who are 60% water by mass) are able to maintain a near constant temperature. One can thank the power of H-bonds for the coolness of the ocean breeze on a hot day, and as will be seen below, for the ability of humans to cool themselves.

Figure 4. The molecular arrangement of liquid water is shown on the left, and that of ice on the right. Note that there is more space between the molecules of ice than liquid water. This makes the ice less dense then liquid water and is why ice floats on the surface of lakes or a polar ocean sea.

While it takes a lot of energy to warm a gram of water, it takes much more to transform it from liquid to gas. When a gram of water is at 100° C it takes 540 calories to evaporate that water to a gas. This is called the heat of vaporization. All that energy is required to completely break the hydrogen bonds between the water molecules. Once the added heat breaks those bonds, the individual water molecules float away as a gas. When humans become too warm they perspire. The sweat evaporates from the skin surface, using heat from the body. Since it requires so much energy to evaporate water, sweating is a powerful way for humans to cool themselves. Evaporation is also a key feature of the global water cycle and central to determining the climate on Earth as will be explained later.

When water is at 0° C it will turn into ice with the removal of 80 calories of heat per gram. Adding back that same amount of heat would melt the ice to liquid water. This is called the heat of fusion. Melting ice does take a lot of heat, but only about 1/7 the amount of heat needed to evaporate the same mass of water.

Recall that water molecules are polar with negatively and positively charged ends. Polar solutions like water will dissolve other polar molecules. For examples of other polar molecules just look to what is commonly dissolved in natural waters. The list includes ions (such as Ca++, Mg++, Na+, K+, HCO_3^-, Co_3^{--}, SO_4^{--}, Cl^-), and gases (O_2, N_2, CO_2) (Garrison, 2001).

Non-polar substances do not dissolve well in water. They have molecular shapes that produce even distribution of charge, rendering them non-polar. This includes most hydrocarbons, molecules assembled from, carbon and hydrogen. Lipids (oils, fats and waxes) are hydrocarbons modified with the addition of oxygen into carbohydrates, and also are non-polar (Armstrong, 1983).

Water is the universal solvent because it will dissolve all polar substances, and to some degree many non-polar molecules. While water certainly is polar the actual matrix of water molecules is dynamic and permits localized charge environments that dissolve some non-polar molecules. Take benzene, for example. It is a naturally occurring hydrocarbon found in petroleum, products of combustion, and various manufactured chemicals. At standard conditions of 25 C° in fresh water, it has a solubility of 1.8 grams/liter. Recall that there are 1,000 grams of water in a liter, so at most a liter of fresh water would be 0.18% contaminated by benzene. That is still 36 times the safe limit for drinking set by the United States Environmental Protection Agency (USEPA a, 2015). So although many toxins are of low solubility in water, not much is needed to produce dangerous effects for humans and wildlife.

Another important point about non-polar toxins in water is the way they interact with the food chain. In the chapter entitled Industrial and Agricultural Sources and Pathways of Aquatic Pollution and the chapter entitled Health Professions Can Protect Water Quality: Tools for Educators, Advocates and Practitioners, the reader will learn more about the action of certain chemicals used as fire-retardants. These chemicals have low solubility in water, but enough to interact with bacteria, protozoans, worms, fishes and other living organisms. The non-polar contaminant tends to accumulate in the lipids of living cells, as it is much more soluble there then in the surrounding water. Since many cells have no way to destroy or excrete the toxins they accumulate, the contaminants are moved up the food chain with every meal. The worm that eats contaminated bacteria will tend to accumulate almost the entire toxic load from its diet. The fish that eats that worm will do the same. The animals at the top of the food chain will have the highest levels of toxins as a consequence of this process of biological magnification. Consequently humans that eat predatory fishes such as tuna get elevated loads of mercury and other toxins in their diets.

Some of the contaminants are polar and easily dissolve in water. In the chapter entitled Cyanobacteria Toxins in Water Sources and their Impacts on Human Health discusses the role of excess nutrient ions from agriculture in promoting the overgrowth of Cyanobacteria, also known as blue-green algae in

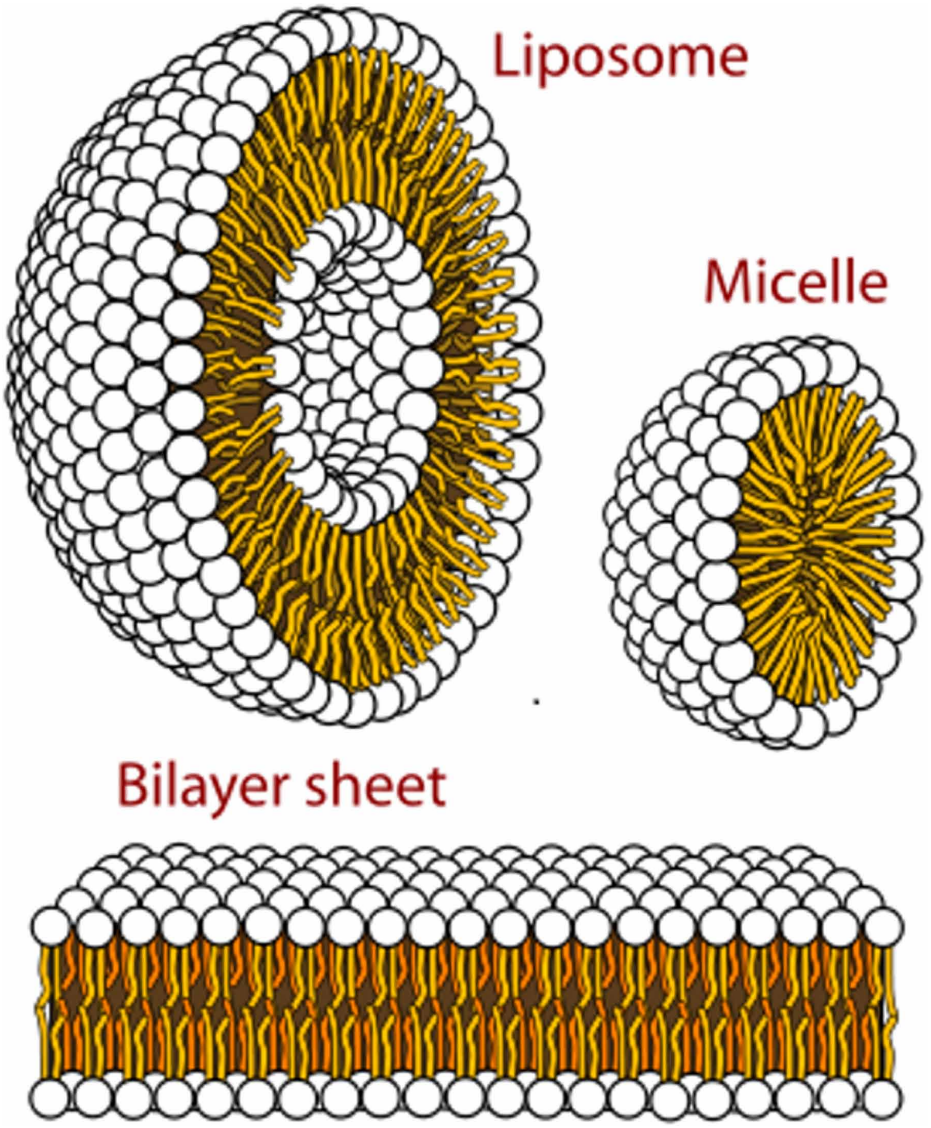
Figure 5. Example of amphipathic molecules forming a micelle. Non-polar substances like grease can dissolve in the centers of micelles, allowing the grease to remain in the water rather than floating to the surface.
http://commons.wikimedia.org/wiki/File:Micelle_scheme-en.svgby SuperManu



contaminated waters. Although many contaminants are non-polar and don't easily dissolve in lakes or the ocean, they may still have devastating effects on natural waters. Generally non-polar contaminants form associations with other molecules that are polar on one end and non-polar on the other. Such amphipathic molecules form tiny spheres (micelles) in water, with the polar heads facing out and the non-polar tails facing in. The non-polar contaminants like pesticides and petroleum dissolve in the non-polar environment inside the micelles. This is how soap is used to wash non-polar grease from cooking pans (Armstrong, 1983).

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Non-polar pollutants like the pesticide DDT never appear in high concentration in water itself, but often accumulate in the non-polar environments within living cells, or on the non-polar surfaces of bits of plastic floating in the sea. A more detailed discussion on pesticides in general and DDT specifically is provided in the chapter on industrial and agricultural pollution.

Revisit the structure of water molecules, H_2O, with H and O atoms sharing electrons. Pure water is a weak acid. That is some of the water molecules disassociate to form ions of OH^- and H^+. For a strong acid, such as sulfuric acid (H_2SO_4,) there is a much higher rate of disassociation than for water.

Water is a weak acid because its disassociation leads to an imbalance of OH^- and H^+ ions, with more H^+ than OH^- in the solution. For a base, the imbalance is the other way, with more OH^- than H^+. The measure of acidity is called pH. Neutral pH is 7. That is when the concentrations of OH^- and H^+ ions are equal. Pure water has a pH of about 6.1. The pH of natural waters ranges from about 3.5 in acid bog lakes to as high as 10 in soda (sodium carbonate) rich watersheds (Wetzel, 1981; Lampert & Sommer 1997). The entire acid-base scale goes from zero, most acidic, to fourteen, most alkaline, or base (Becker & Wentworth, 1973).

The pH scale is deceptive. A drop in pH from 7 to 5 is actually a 100-fold increase in H^+ ions. This is because pH is based upon the $^-$log of the H^+ concentration. Every pH unit represents a 10-fold change in acidity.

Adding or subtracting H^+ or OH^- ions to water will change its pH. However natural waters contain various amounts of dissolved salts that can absorb some of the excess ions. These are called buffers. The buffer salts disassociate and recombine with the extra H^+ or HO^- ions. Calcium carbonate ($CaCO_3$) and magnesium carbonate ($MgCO_3$) are important buffers in natural waters. When in high concentrations these buffers maintain constant pH levels in natural waters. But many inland lakes occur in areas with low concentrations of those buffers. Consequently those lakes are very susceptible to the acids contained in rain and snow. This acid precipitation is produced from the sulfuric and nitric acids in the smoke from burning fossil fuels. The emissions from burning coal with high sulfur content are a major source of acid precipitation. The Clean Air Act of 1990 authorized a system of cap-and–trade in the U.S. to restrict acid-causing pollutants from coal burning power plants. This very successful program pioneered the system of cap-and-trade where companies have to either reduce their emissions or pay for other companies to reduce theirs (Miller & Spoolman, 2015).

Oceanographers once considered the ocean a very well buffered system and paid little attention to pH, which typically remained around 8.2 in surface waters. However, the extensive burning of fossil fuels that commenced during the industrial revolution increased the CO_2 concentration in the atmosphere by 43% as of 2015. While the added CO_2 is well known as a greenhouse gas that causes global warming, it

Figure 6. Equation showing disassociation of water.

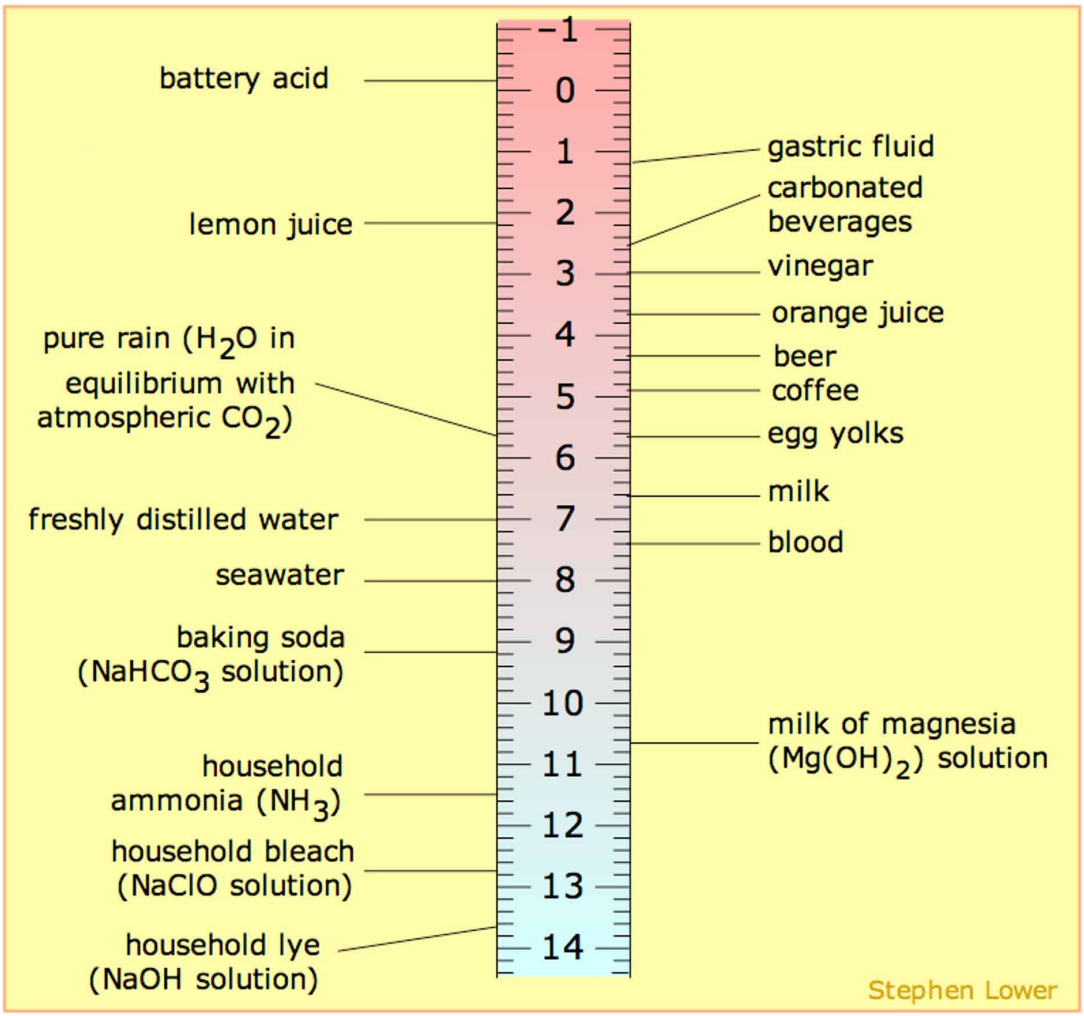
Figure 7. The pH scale with example liquids
http://chemwiki.ucdavis.edu/@api/deki/files/8232/639px-PH_scale.png?revision=1 by Stephen Lower



is also acidifying the ocean. A growing amount of the CO_2 in the atmosphere is dissolving in the ocean, creating carbonic acid. Consequently average ocean pH levels have dropped from 8.2 to 8.1. This might not seem like much but recall that the pH scale is logarithmic, meaning that acidity has increased by 30% since the beginning of the Industrial Revolution. More alarming is that acidity will increase by 150% by the end of the 21st Century if fossil fuel consumption continues as the same rate (National Oceanic and Atmospheric Administration [NOAA], 2015].

Extremes in pH are directly dangerous to life in water as the high concentrations of ions react with molecules of life on the cell membranes. Yet even seemingly minor changes in pH can be detrimental to life. For example, the acid precipitation mentioned above acidified lakes in New England during the 1970's. Consequently the charge state of aluminum ions (Al) changed, and the Al^{+++} ions proved toxic to fishes in those poorly buffered lakes (Lampert & Sommer, 1997). There is evidence that the 0.1 unit acidification of the ocean is also harming corals, oysters, and other sea life that uses $CaCO_3$ as part of body structure (NOAA, 2015).

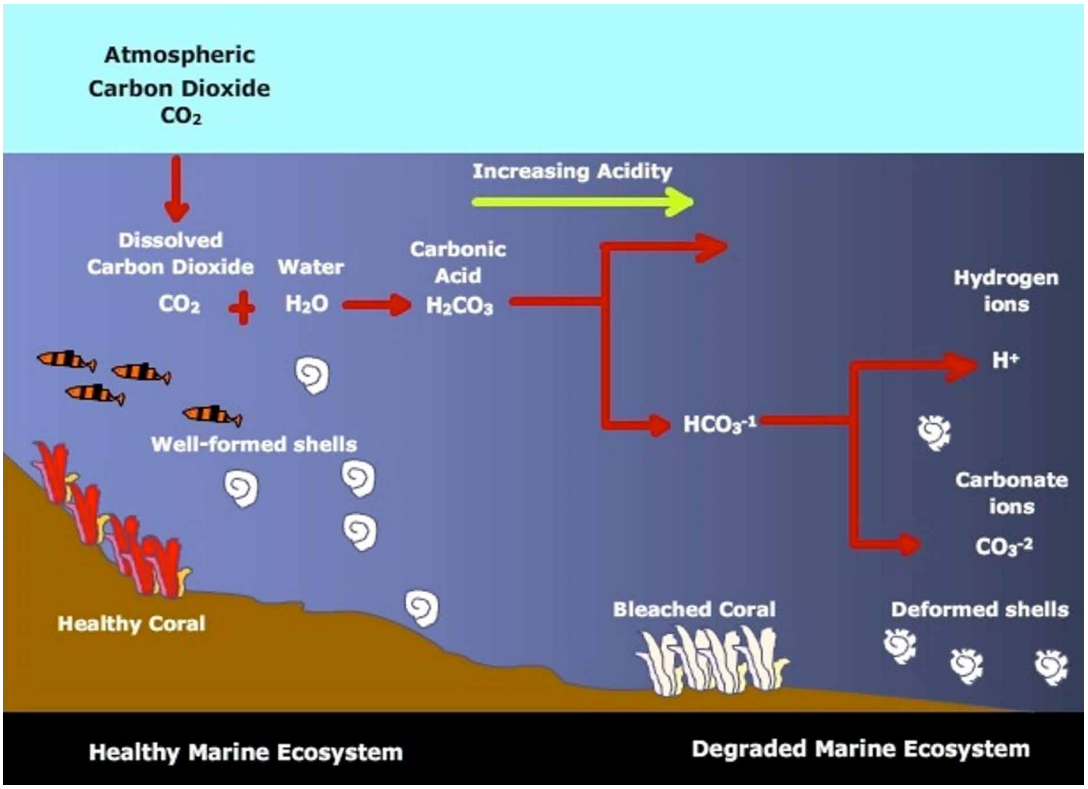
Figure 8. The impact of elevated atmospheric CO2 levels on the global ocean ecosystem
https://theotherco2problem.files.wordpress.com/2009/11/ocean-chemistry.gif



Restricting the range of pH variations is also important in the human body. Bicarbonate and carbonic acid buffer pH changes in blood. The phosphate buffer system regulates pH in cells (Armstrong, 1983).

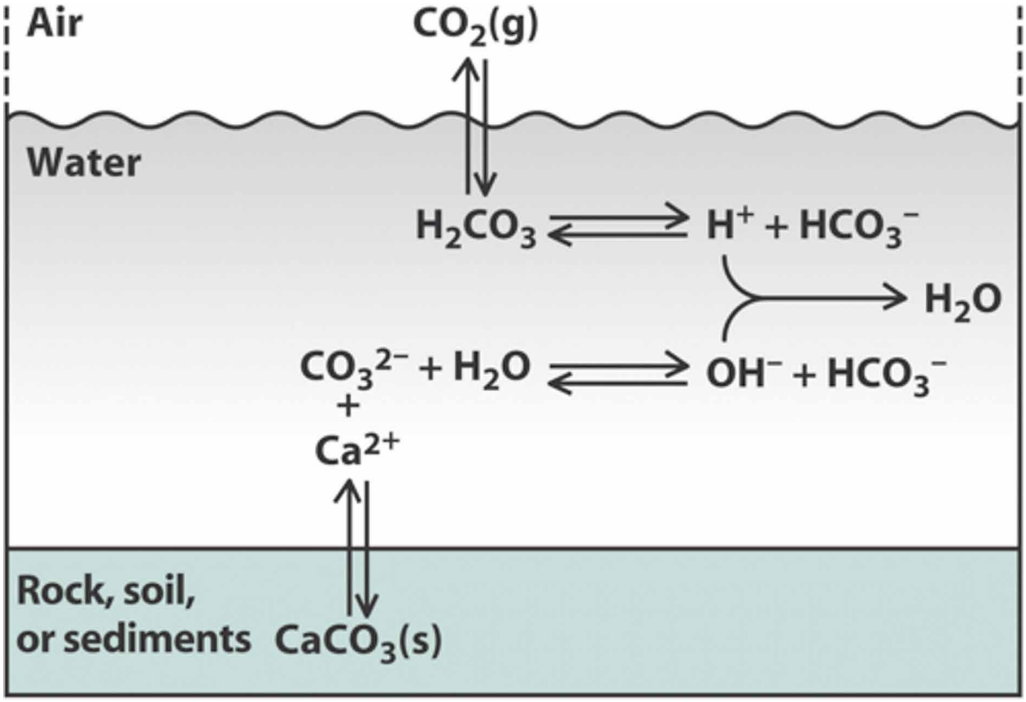
Carbon dioxide (CO_2) in the air is in equilibrium with natural waters. Since CO_2 is increasing in the atmosphere there is net movement into bodies of water. The dissolved CO_2 reacts with water to produce carbonic acid (H_2CO_3), which is in equilibrium with bicarbonate (HCO^{3-} and H^+). Carbonate ($CO3^{2-}$) reacts with water to also form carbonic acid. Carbonate also reacts with calcium ions ($Ca^{2+)}$ to form calcium carbonate ($CaCO_3$). All of the reactions are reversible. When extra acid (H^+) or base (OH^-) is added to the water, the reactions maintain the pH by incorporating those ions. As such this system serves to buffer natural waters from changes in pH. Too much acid or base exceeds the buffering capacity of the water and the pH will change, as is now occurring in the ocean due to excess CO^2.

KINDS OF NATURAL WATERS AND HOW THEY ARE AFFECTED BY HUMANITY

Consider a system of classification for natural waters. Streams, brooks and springs drain the land that surrounds them called, the watershed. These small running-waters flow together to form larger rivers. Estuaries occur along the margins of the ocean where rivers empty into the sea.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 9. The carbonate buffer system in natural waters



Estuaries

Estuaries are semi-enclosed basins where the freshwater from the river mixes with the saltwater from the sea. These are very important ecosystems, LC feature very productive food chains that support extensive fishing activity.

Lakes, Ponds and Reservoirs

Unlike rivers and streams, lakes, ponds and reservoirs contain relatively still waters. As such there is much less mixing than in flowing water systems. This sets up conditions that may lead to a lack of oxygen in bottom waters or build-up of contaminants due to lack of dilution (Levinton, 2014). Note that reservoirs are artificial lakes created by damming rivers.

The Ocean

The ocean is the largest of all bodies of water. It contains 97% off all the water on Earth. The ocean is much more than a gigantic salty lake. The action of tides, wind, freezing water and evaporation all combine to keep ocean waters in motion. This motion is seen in currents that may move faster than a person can run (Levinton, 2014; National Aeronautics and Space Administration [NASA a], 2015). While ocean currents can sweep away oil spills and dumped trash from a particular shore, know that the contaminants going away from one area means their transport to another place. In Chapter Two the reader will learn about the role that plastics play in environmental problems.

Glaciers and Sea Ice

In addition to the familiar types of waters given above, there are other important kinds. Glaciers are massive blocks of ice on land that formed from frozen precipitation. Naturally glaciers occur where it is cold, at high altitude (mountains) and at high latitude (the Arctic and Antarctic). Over geological time Earth's climate cycles through periods of warming and cooling. The last great period of cooling reached its peak about 15,000 years ago. At that time a sheet of ice over 1 km thick covered much of Canada, the northern states of the US, and northern Europe. As a consequence of so much water being stored in ice, the sea level was 100 m lower during that period (Stanley, 2009). Currently Earth is in a period of rapid warming, accelerating the melting of remnant glaciers. The rapid heating is driven by human production of greenhouse gases (GHGs) mentioned in the chapter entitled Nurses, Health Care and Environmental Pollution and Solutions. The greenhouse gases produced by health care are referred to as part of the cycle of harm that must be broken to protect water and health. Some 70% of Earth's freshwater is stored in glaciers. Mountain top glaciers are important sources of melt-water, filling streams and rivers that flow into otherwise dry areas. The flow of Ganges River in India depends on the seasonal melting of glaciers in the Himalayas. This flow is threatened as the glaciers continue to shrink with the warming climate (Shiva, 2002).

Sea ice forms in the Polar Regions during the long cold winters. The persistent low seasonal temperatures cause the surface waters of the ocean to freeze. The salts dissolved in the freezing seawater are excluded from the forming ice crystals. This creates a layer of cold and salty brine below the sea ice that sinks due to its high density. This annual cycle of freezing produces a current of cold salty water that is essential to the natural circulation of the sea. The system of ocean circulation takes about 1,000 years to make the circuit around the Earth and along the way redistributes heat around the globe. The system also circulates nutrients for the ocean food chain and oxygen.

As with glaciers, global climate change is reducing the rate of sea ice formation, and its persistence during the summer. This threatens the patterns of ocean circulation. For the first time in recorded history the sea ice covering the Arctic Ocean now undergoes extensive melting (USEPA b, 2015). This summer-time loss of reflective white ice means that the newly exposed waters of the Arctic Ocean are further warmed by the penetration and absorption of sunlight, exasperating the effects of global warming. Additionally, changes in the ocean circulation system will render some regions significantly cooler and others much warmer. New England, England and northern Europe may lose much of the heat presently transported by the Gulf Stream (Rahmstorf et al., 2015). Thus the result of overall global warming will actually decrease annual average temperatures in some places (Levinton, 2014; NASA b, 2015).

Groundwater and Aquifers

Much of the world's freshwater occurs underground. That portion found near the surface is referred to as groundwater. Rain and melt-water percolates through the soil to recharge groundwater. Groundwaters may reappear in downslope springs that feed streams. Groundwater may also drain into porous geological formations called aquifers. Humans drill wells to gain access to groundwater and aquifers. In many regions of the world the rate of withdrawal of water from wells far exceeds the rate of recharge. Wells must be drilled deeper as the water table and aquifer levels decline. Eventually many over-drawn wells

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

run dry. The loss of undergroundwater has several consequences. Communities lose their source of drinking water. Sometimes the overlying land subsides or sinkholes develop. In coastal areas salt water from the adjacent ocean seeps in the aquifers rendering them useless as source of freshwater (Shiva, 2002).

The so-called Green Revolution in India clearly illustrates the unstainability of unrestricted use of groundwater. In the 1960' and 1970's Western scientists working with the government of India introduced high-yield strains of wheat and other crops to the agricultural system. While these new varieties produced more food per unit area, they demanded much more water and fertilizers. The subsequent overuse of water drained aquifers, leaving once fertile lands useless for agriculture. This displaced the farmers, driving them to overcrowded cities. The ancient system of agriculture that once sustained vibrant communities over millennia were thus lost to a seemingly good idea that ultimately proved otherwise. Presently there is a movement in India to return to the time-tested practices of the past that worked harmoniously with the natural availability of water (Shiva, 2002).

Groundwater and aquifers are susceptible to contamination from industrial and agricultural pollutants. The heavy use of chemical fertilizers and toxic pesticides characterizes contemporary industrial agriculture. These pollutants seep into groundwater and aquifers. Many rural communities can no longer use well water for drinking as the groundwater contains excessive levels of nitrates that came from over application of artificial fertilizers (Powers & Schepers, 1989). Nitrates in groundwater increase rates of infant mortality (Johnson & Kross, 1990).

The recent expansion of oil and gas production in the US and other parts of the world is driven by the process called fracking or hydraulic fracturing. This involves injecting in wells a toxic mixture of chemicals under high pressure. The pressurized fluid shatters the layer of shale rock, allowing the escape of natural gas and petroleum. The fracking fluid that returns to the surface is gotten rid of by reinjection into other wells. This process often contaminates groundwater (Myers, 2012).

It is nearly impossible to remove pollutants from contaminated groundwater and aquifers. A section of river polluted by a toxic spill will usually recover quickly as the flowing water flushes away the contaminants. Since flow is very slow or non-existent for underground waters, there is no natural mechanism to remove persistent contaminates.

The Atmosphere

There is one more pool often neglected when thinking about natural waters, yet it is the most dynamic part of the water cycle that ties together all of the rest. It is the atmosphere. Earth's atmosphere consists of 78% nitrogen gas (N_2), 21% free oxygen (O_2), and whole host of other gasses that despite their concentrations play major roles in the functioning of the environment. The list includes carbon dioxide, water vapor, methane, oxides of nitrogen and sulfur, and so forth (Miller & Spoolman, 2015).

First consider the role water and the atmosphere plays in determining Earth's climate. The moon and Earth are about the same average distance from the sun, yet the average temperature of the moon is only -5 C^o. That for the earth is about 15 C^o. The difference is due to the greenhouse effect of earth's atmosphere and the ability of the ocean to absorb and redistribute heat from sunlight. The mass of the Earth is 81 times that of the moon. So the earth has sufficient gravity to keep gases from floating away, allowing for the formation of an atmosphere. The less massive moon lacks a significant atmosphere as gasses simply float away. Lacking a significant atmosphere and an ocean, the moon can't retain as much heat as the Earth.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Sunlight consists mostly of short wave radiation, primarily visible light and invisible ultraviolet radiation. This short wave radiation easily penetrates Earth's atmosphere. Only about half is reflected away. The rest is absorbed by the atmosphere or by surface features (land, forest, ocean, etc.). When absorbed the shortwave radiation is changed to long-wave radiation (also known as infrared radiation or simply heat). While earth's atmosphere is fairly transparent to shortwave radiation, it blocks some of the longer wave radiation from bouncing back to space.

Consider a closed automobile sitting in the sunshine on a cold day. The temperature in the car might be 30° C above that of the outside air. The glass windows allow the shortwave radiation to enter but block much of the longer wave radiation from leaving. This is what the greenhouse gasses (GHGs) do in the atmosphere. They let in sunlight and reduce the back-radiation of heat. Two of the most important GHC's are water vapor and carbon dioxide (Miller & Spoolman, 2015).

The amount of water vapor in the atmosphere is dependent on a host of parameters including temperature and pressure. As such concentrations vary from 0.01% for cold dry regions to 4.24% in warm tropical air masses. Overall, water vapor is responsible for 60% of the greenhouse effect, followed by carbon dioxide (26%), ozone (8%), methane (4.4%) nitrous oxide (1.5%) and others (0.1%) (Climate Data Information [CDI], 2015).

Despite the leading role of water vapor, most discussion on GHCs centers on CO_2. In a broad sense humans do influence the water vapor concentrations of the atmosphere. Deforestation, irrigation and other human endeavors alter concentrations of water vapor. But these pale in the face of how humans have increased concentrations of CO_2 in the atmosphere.

At the beginning of the industrial revolution CO_2 concentrations were about 280 ppm (parts per million). In 2015 concentrations reached 400 ppm or 0.04% of the atmosphere. While seemingly tiny by percentage, CO_2 is very effective in trapping long-wave radiation. The increased CO_2 and to a lesser extent the other GHGs are responsible for Earth's average temperature increasing about 1 C° over the last 250 years. Projections for the future have the earth's temperature raising another 3 – 6 C° by 2100 (Miller & Spoolman, 2015). The increased temperature will disrupt the climate with increasing frequency and intensity of droughts, floods, and storms. The chapter entitled Nurses, Health Care and Environmental Pollution and Solutions will discuss the human health consequences of these climate change related events. This all traces to the burning of fossil fuels; first coal, than natural gas and oil. Over 100's of millions of years photosynthesis had taken CO_2 from the atmosphere and fossilization of plants has stored much of that in the ground. Almost overnight in a geological sense, the mining and burning of fossil fuels has returned much of that CO_2 to the atmosphere. This has created a new geological period of rapid warming and climate change.

THE WATER CYCLE

The ocean, rivers, lakes, estuaries, groundwater, glaciers, sea ice, water vapor and clouds are all linked together by the water cycle. This cycle is powered by solar radiation. Indeed, about 25% of the sun's energy falling on Earth goes to evaporating water, which is the beginning of the cycle (NASA b, 2015).

Some 75% of the Earth surface is covered by water. The bulk of that water is stored in the ocean (96.5%) and is salty. The remaining 3.5% is in freshwater. About half of the freshwater is frozen (1.7% is found in ice caps, glaciers and snow). An equal amount (1.7%) is in lakes, rivers, streams, soil and groundwater (United States Geological Services [USGS a], 2015). So only 1.2% of the world's freshwater

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

is available as surface water (lakes, ponds, rivers and streams). Water vapor and clouds constitute only a tiny fraction of Earth's water, 0.001%. Yet atmospheric water is a dynamic pool tying the rest of the hydrologic cycle together.

Solar radiation drives the evaporation of water from the sea, land and plants. The water vapor produced in this process is cleaned of any salts or contaminants. It is just molecules of water floating in the atmosphere. The atmosphere can hold only so much water at any given time or place. Warmer air and higher pressure accommodates more water vapor. Yet as air masses circulate they cool and experience lower pressures. This causes the air to exceed levels of saturation, and the vapor condenses to form clouds or fog. Further cooling causes the clouds of water droplets to coalesce to form precipitation in the form of rain, snow, sleet and hail. In some climates clouds and fog encounter the ground and plants, forming dew, which is another form of precipitation.

Note that once water condenses into droplets, it then includes dust particles and atmospheric gases. This is how rain and snow becomes contaminated with atmospheric pollutants resulting in acid precipitation and the like.

While the ocean contains the vast bulk of water on earth, most of it stays there a very long time, about 3,200 years. In contrast a liter of water in the atmosphere will stay there only about 9 days. So there is a constant supply of freshwater coming from the atmosphere. This is critical to humans and all terrestrial life, as creatures of the land require access to freshwater. While most (80%) of the freshwater precipitation falls directly to the sea, the rest nourishes the land. Some is stored in ice, aquifers, soil,

Figure 13. The global water cycle

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

living tissue, lakes, rivers and streams. Evaporation and precipitation adds to or subtracts from these compartments. The pull of gravity draws flowing waters to the sea (University Corporation for Atmospheric Research [UCAR], 2015).

Global climate change is altering the water cycle. This is evident from the disappearing glaciers mentioned above. The once frozen water mostly flows into the sea. This along with thermal expansion of the warming ocean accounting for an average rise in sea level of about 13.9 inches (30.9 cm) between 1900 and 2015. Rising sea levels cause massive destruction and migration of populations from low-lying coastal areas and islands. Some projections of sea level rise are as high as an additional 39 inches (1 m) by 2100 (Levinton, 2014).

The general global warming also increases the rate of evaporation and the ability of the atmosphere to hold water vapor. Since water vapor is a powerful GHG, this is an example of a destabilizing positive-feedback system. The warmer Earth gets, the more water vapor will be in the atmosphere to inhibit back-radiation. Consequently Earth will continue to warm at an even faster rate. As noted above, sea-ice in the Arctic Ocean is now much reduced. This enables new offshore drilling for oil. As that new Arctic oil goes to the market its use will further increase the emission of CO_2 and consequently global warming.

THE CONSTITUENTS OF NATURAL WATERS

Knowing about the basic chemistry of pure water is important but tells only a small part of the story of the composition and functioning of natural waters. Scientists and mangers differentiate natural waters by what they contain other than water. Sea water typically has about 34 grams of salts dissolved in a liter of water. Oceanographers use the measure of PPT (parts per thousand), so salinity of seawater is about 34 PPT. Most inland waters are considered freshwater, as they contain small levels of dissolved solids (<0.5 ppt). The salinity of the sea is primarily due to the following ions: Cl^-, Na^+, $SO4^{--}$, Mg^{++}, $HCO3^-$, Ca^{++}, K^+ (Garrison, 2001).

Humans require freshwater for drinking and the irrigation of agricultural plants. Drinking saltwater causes; vomiting, diarrhea, and dehydration. Irrigation of crops with salty water will cause the plants to dehydrate and wither. In very dry regions irrigation often results in salt build-up in soils. As the irrigation water evaporates it leaves behind the small amount of salt it contained. Over time the accumulation of salt renders the soil useless for continued agriculture (Shiva, 2002).

The estuaries mentioned above are places where freshwater and saltwater mix. These coastal features contain waters of intermediate salinity, called brackish water. Many marine animals rely on these brackish water environments to complete their life cycles. Juvenile fishes, and crabs thrive in estuaries. Estuaries typically attract extensive human habitation. Agriculture, industry and urban environments produce contaminants that often pollute estuaries. This threatens the health of the plant and animal residents of the estuaries as well as the human populations that consume seafood from contaminated systems (Levinton, 2014).

Natural waters contain dissolved gases. Surface waters in direct contact with the atmosphere contain the same gasses as that in air; including nitrogen (N_2), Oxygen (O_2) and (CO_2). Of these, oxygen is most critical to sustaining higher forms of marine and aquatic life.

Oxygen is necessary for the process of aerobic respiration. This is the metabolic sequence that cells use to release energy from sugars and other organic molecules. Oxygen removes the low-energy electrons at the terminus of the electron transport chain. Without oxygen this chain stops, and so does the production of ATP (Adenosine Triphosphate). ATP powers most of the processes in cells (Armstrong, 1983). Depriving a human of oxygen for just a few minutes proves fatal, illustrating the importance of this process. Oxygen is just as important for fishes and other forms of multicellular life in natural waters. Water in equilibrium with the atmosphere contains from 7-14 mg of oxygen per liter (mg/l) depending on temperature and concentrations of dissolved salts. Oxygen concentrations below 3 mg/l tend to exclude animal life. The amount of gas that can dissolve in water decreases with increasing salinity and temperature. So cold freshwater lakes will contain more oxygen than warm tropical seas (Garrison, 2001).

Oxygen gets into natural waters two ways. Winds promote mixing of surface waters with the atmosphere, speeding the diffusion of oxygen from the air to the water (Garrison, 2001). The other way oxygen enters natural waters is by the process of photosynthesis (Levinton, 2014). Green plants and algae use the energy of sunlight to split water. This supplies the plants and algae with high-energy electrons to power the metabolism of the plant with ATP. Most of that ATP powers the conversion of carbon dioxide into sugars, proteins and fats. Oxygen is released as a waste product of photosynthesis. This waste product of photosynthesis proves necessary for animal life.

Shallow waters generally have sufficient oxygen supplies from mixing with the atmosphere and photosynthesis. Since photosynthesis requires sunlight it is restricted to the top 100 m or so of lakes and the ocean (Levinton, 2014; Wetzel, 1983). This is due to the absorption and scattering of light by

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

the water molecules and substances dissolved and suspended in the water. Consequently deeper water relies on the mixing down of surface waters to sustain a supply of oxygen. During the warm months of the year, temperate lakes and ocean waters are stratified by temperature. That is the warm surface waters float atop the cooler deeper waters, forming two distinct layers separated by a thermocline (region of rapid temperature drop). The difference in density prevents the warmer upper and the cooler lower layers from mixing. This becomes a problem in places where the bottom waters are subjected to overloading with decaying organic matter. The microbial digestion of the excess organic matter uses up the supply of available oxygen in those deeper waters. This creates a so-called dead zone, excluding higher forms of life (Levinton, 2014).

There are two ways excess organic matter gets into the deep water. First, the process of photosynthesis occurring in surface waters forms organic matter. This happens in all natural waters, and is the basis for the food chains in those systems. The photosynthesizing algae and rooted aquatic plants use the sun's energy to convert carbon dioxide into organic matter. The floating algae are called phytoplankton. Tiny animals comprising the zooplankton consume them. Small fishes and various other animals consume the zooplankton. Larger fishes, birds, and aquatic mammals may be the next step in the food chain.

In most cases the growth rates of the phytoplankton are controlled by the supply of certain essential nutrients; phosphorus, nitrogen, iron and silica. The addition of excess nutrients (usually phosphorous in freshwaters and nitrogen in seawater) promotes the overabundance of algae. This is called an algal bloom. Most of the phytoplankton of an algal bloom escapes consumption by zooplankton and instead sinks into the deeper water as it ages. Bacteria and other microorganisms consume the dead algae as it sinks and accumulates in the sediments on the floor of the lake or sea. The bacteria will deplete the oxygen as they consume the remains of the algae (Levinton, 2014).

Some lakes naturally occur in watersheds that supply high loads of nutrients and display regular algal blooms and the accompanying loss of oxygen in bottom waters. These lakes are called eutrophic. Lakes that have low rates of natural inputs of nutrients, and thus don't experience algal blooms or depletion of oxygen from the bottom waters are called oligotrophic (Wetzel, 1983).

Nutrient pollution from agriculture and sewage convert once oligotrophic lakes and coastal areas to eutrophic systems. This process is called cultural eutrophication. The extent of cultural eutrophication and the resulting dead-zones grew dramatically during the last half of the 20th Century. Changing agricultural practices, patterns of habitation and overall population size, drives cultural eutrophication. Agriculture based upon inputs of artificial fertilizers, pesticides and fossil fuels creates sever water pollution that feeds algal blooms. This type of industrial agriculture also reduces the need for human labor, driving rural populations to urban areas. The nutrient rich urine and feces created by residents of urban areas is not making its way back to fertilize cropland. But instead it is dumped into rivers and coastal areas, causing algal blooms and dead zones (Shiva, 2001; Diez & Rosenberg, 2008).

Sewage is the second way excess organic matter enters natural waters. Humans absorb only a fraction of the organic mater, which they consume in their diets. As such they produce organic-rich feces. Modern wastewater treatment plants remove most of that organic matter, but such infrastructure is missing in most of the developing world. As such, organic matter from feces fuels the oxygen-consuming bacteria in many coastal areas, contributing to formation of dead zones. The inadequate or missing facilities and potential solutions are discussed in the chapter entitled On-Site Sanitation System for Low-Income Countries. Related discussion on constructed wetlands will be found in the chapter entitled Constructed Wetlands: Description and Benefits of an Eco-Tech Water Treatment System. Both of these chapters are noted to contain suitable material for use in developing countries as does the chapter entitled Access to Safe Drinking Water.

LIFE IN WATER

Natural waters team with life. On average even the cleanest ml of water from an ocean or lake will have one million bacterial cells (Levinton, 2014) and ten million viruses (Breitbart, 2012). Life is built upon a complex framework of organic molecules, carbon based structures of sugars, lipids, amino acids and nucleic acids. Surprisingly, for any square meter of ocean or lake, there is more mass in dissolved organic molecules then there is in the rest of the food chain. This supply of dissolved organic molecules comes from decomposition of dead cells or excretion from living cells. The bacteria feast on this pool of organic matter, feeding protozoans that in turn feed higher forms of life. This food chain is called the microbial-loop.

While very important to the ecology of natural waters, the microbial-loop food chain is much less familiar than the traditional food chain based upon photosynthesis. In the sea and lakes tiny green cells called algae do the process of photosynthesis. They are harvested by microscopic animals, which intern feed somewhat larger animals, then small fishes, larger fishes, mammals and birds.

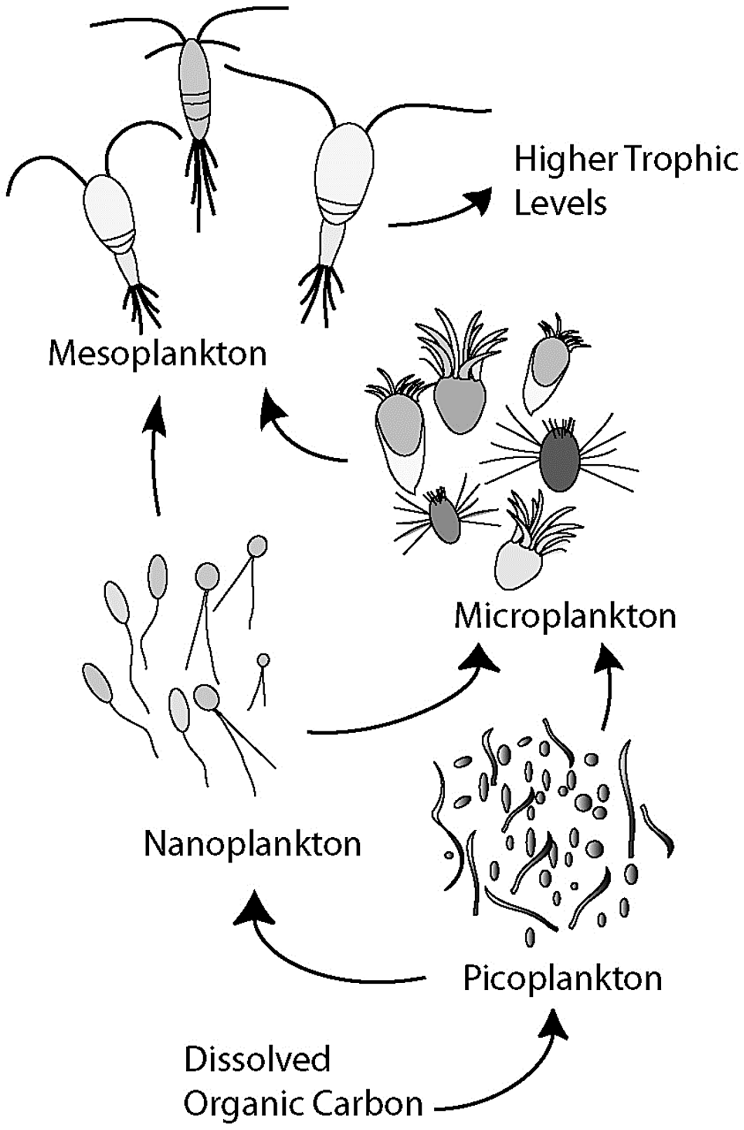
Figure 16. The microbial loop. Bacteria harvest dissolved and particulate organic carbon making that source of energy available to higher levels of the food chain.
http://www.google.com/url?sa=i&source=imgres&cd=&cad=rja&uact=8&ved=0CAwQjRwwAA&url=http%3A%2F%2Fcommons.wikimedia.org%2Fwiki%2FFile%3AMicrobial_Loop.jpg&ei=7vhlVcW9Oo6KyASOiYHABg&psig=AFQjCNEF9Sos3XqbSynf_P1SxrxxueU8Vg&ust=1432832623066480 by Umarina



It is convenient to classify aquatic life into different categories. Tiny plants and animals that float or swim are called plankton. Phytoplankton are plant- like and photosynthetic, zooplankton are tiny animals that eat the phytoplankton and bacteria plankton. Some plankton are quite large, like jelly fish but still classified as plankton as they are weak swimmers. Nekton refers to the stronger swimmers, such as fishes, squid, turtles and whales. Benthic animals and plants live on the seafloor or attached to structures. Think of flatfishes oysters, clams and worms.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

The life cycles of many aquatic creatures includes membership in different categories. Almost all sea creatures have gametes or larvae that are distributed in the plankton. Some settle to the bottom to join the benthos and others grow into strong swimmers of the nekton. There are important exceptions. Marine mammals and some sharks give live birth to competent swimmers. In freshwater, planktonic phases of benthic animas are rare. The Asian zebra mussel and quahog mussel are two freshwater benthic forms with planktonic larvae, which has led to their status as damaging invasive species in the Great Lakes and elsewhere in the US (USGS b, 2015).

Life in natural waters is mostly fueled by photosynthesis. Yet in special habitats ranging from marsh sediments to deep-ocean vents, inorganic compounds form the basis of the food chain. Energy rich compounds such as H_2S (hydrogen sulfide) and CH_4 (methane) fuel chemosynthetic bacteria. Before the evolution of photosynthesis such chemicals fed the primordial food chains of Earth. Today chemosynthesis is locally important but contributes little to the energy economy of the living Earth (Levinton, 2014).

Since photosynthesis is so important to the aquatic food chain, it is not surprising that the availability of light is essential to understanding life in salt and fresh waters. Typically photosynthesis is restricted to the top 100 m or less of the water column. Deeper than that, heterotrophy (eating and decomposition) prevails. Note that the average depth of the world's ocean is 3,800 m. So significant illumination and photosynthesis is restricted to the top 2.6% of the water column. Most of the ocean is deep, dark, cold (3^o C), and dependent on the sinking or swimming of life from above (Garrison, 2001).

POLLUTION

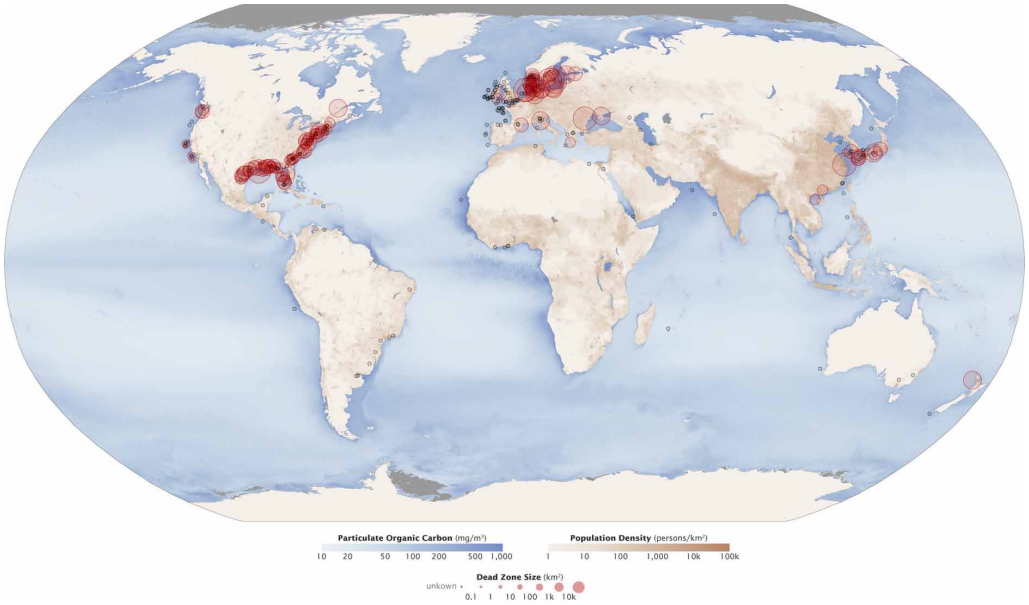
Much of this book is about water pollution. One way to look at pollution is to consider it a misplaced resource. The extra nutrients (N and P) that cause eutrophication in lakes and coastal waters are important fertilizers for crops that are misplaced by runoff from land into waters. Carbon dioxide is essential for photosynthesis, but its overproduction from burning fossil fuels is acidifying the sea and warming the planet. Plastics used to make water bottles, bags, cigarette lighters, and thousands of other manufactured goods are finding their way to the sea where they kill marine creatures and poison food chains. Almost every water pollutant from antibiotics to petroleum is made from useful resources that are allowed or encouraged to be disposed of in our natural waters. The reader will learn more about pharmaceuticals in waterways in the chapter entitled A Review of Emerging Contaminates in Water and the chapter entitled Pharmaceuticals and Personal Care Products as Emerging Water Contaminants.

Scientists classify water pollutants by their source. Point sources of pollutants were the first to be tackled by the landmark laws of the 1970's and 1980's. These are mostly pollutants traced to pipes draining from industrial processes. Coming from single points those pollutants were relatively easy to measure and regulate. For example, it was easy to determine how much phosphate was being produced from a wastewater treatment plant simply by sampling what was coming out of the effluent pipe. A sinking oil tanker or leaking underwater oil well are other examples of point sources of pollution. Both point source and non-point source pollution is discussed further in the chapter entitled Floodplain Infrastructure and the Toxic Tide. Also the chapter Industrial and Agricultural Sources and Pathways of Aquatic Pollution, deals with the same issues of pollution sources.

Non-point source pollutants emanate from large portions of the landscape and are more difficult to trace to their sources. Much of the mercury pollution in the sea comes from the burning of coal in power plants. At the time of emission this is clearly a point source of pollution. Yet the mercury gets into the

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 17. Distribution of coastal dead zones around the world.
http://upload.wikimedia.org/wikipedia/commons/c/c7/Aquatic_Dead_Zones.jpg by Robert Simmon & Jesse Allen, NASA Earth Observatory



sea by being released from the atmosphere, and functions more like a non-point source pollutant. Much of the carbon dioxide pollution released from land comes from automobiles that are widely distributed over the landscape; hence they are non-point source polluters.

Pollutants work in various ways to diminish the health of waterways and people. The ensuing chapters will discuss these pollutants as well as other ways humans interact with the watery environment. Chapter Five: Impacts of Artisanal and Small Scale Gold Mining on Water Quality in Mozambique and Zimbabwe will have a lengthy discussion of the health hazards of gold mining related mercury in water.

SOLUTIONS/RECOMMENDATIONS AND FUTURE RESEARCH DIRECTIONS

The entire upcoming book with deal not just with the problems related to water quality, but also suggest some solutions. Future research directions will also be discussed in other chapters. The purpose of this chapter was to present the fundamental properties of water and to point forward to other chapter's contents.

CONCLUSION

In the end it is hoped that the reader will understand the links between human health and the health of our natural waters. Further it is hoped that the reader will feel informed, empowered and motivated to educate others on the subjects of vital importance to future generations. The three chapters that lead off the second section of the book specifically deal with educational theory and practice to facilitate envi-

KEY TERMS AND DEFINITIONS

Acid: A molecule that adds hydrogen ions to a solution, causing a drop in pH.

Amphipathic Molecule: These structures have a polar head and a non-polar tail. Such molecules form the bi-layer structure of cell membranes.

Aquifer: A geological formation containing water in the free spaces between the rocks, gravel, sand or other mineral deposits. Wells are drilled into aquifers to obtain that water.

Estuary: A semi-enclosed basin formed where rivers join the sea. The water in estuaries is a mix of salt and freshwater.

Eutrophic: A term applied to waters that contain high levels of nutrients. Such waters appear green from the abundance of phytoplankton. In deeper eutrophic waters there is often very little oxygen as it is used-up by the decaying phytoplankton that sinks from above.

Fossil Fuels: This refers primarily to coal, oil, natural gas, and peat that were formed from the once living tissues of organisms now long dead. Burning fossil fuels results in excess carbon dioxide in the atmosphere and ocean, and often other types of pollution such as those containing sulfur or nitrogen.

Green House Gases: (GHC's). These are gases such as carbon dioxide, water vapor and methane that are transparent to sunlight, but block much of the heat created by the sunlight being intercepted by the atmosphere, land and water. These gases result in the increased retention of heat by the earth.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Green Revolution: A term applied to the adoption of western-style agriculture in India and other parts of the developing world in the 1960's and 1970's. It was built around using higher yielding varieties of crops to produce more food per area of cultivation. It requires extensive use of water and fertilizer well beyond the traditional agricultural system it replaced.

Groundwater: This refers to the water held in soil and deeper layers below the Earth's surface. The term is often used interchangeably with the word aquifer. However, some will use groundwater to refer to shallower deposits and aquifer to refer to deeper and longer-term storage. To wit, the process of transpiration by plants transports water from groundwater to the atmosphere, but does not directly effect deeper aquifers.

Heat of Fusion: The amount of thermal energy released from one gram of a substances when it changes state from a liquid to a solid. The same amount of heat is added back to the solid to cause it to melt or return to a liquid.

Heat of Vaporization.: The amount of thermal energy needed to cause a liquid to change state to form a gas. The same amount of heat is released from the gas when condenses to form the liquid state.

Hydrocarbon.: A molecule containing only carbon and hydrogen, such as what forms fossil fuels.

Industrial Revolution: The period between about 1760 and 1840 when the economies and social structures of the western world changed in response to a rapid rise in manufacturing and the adoption of new technologies. Coal fueled much of the industrial revolution, leaving a legacy of reliance on fossil fuels.

Micelles.: Spherical formations of amphipathic molecules in which the heads all out and the tails all face in, or vice versa. For micelles in water, the polar heads face out and the tails face in. This allows non-polar substances found in the water to migrate into the centers of these spheres.

Microbial-Loop: This refers to the aquatic food chain linking dissolved organic matter to bacteria, protozoans, and larger zooplankton.

Oligotrophic: A term applied to natural waters that contain relatively few plant nutrients, such as phosphorus and nitrogen. Such waters appear clear as they can support only low phytoplankton populations.

pH Buffers: These are weak acids that disassociate in response to the addition of a strong acid or strong base. In doing so the buffer maintains a nearly constant pH for the solution. However, excessive additions of acids or bases will consume the buffering capacity, and the solution will change in pH. Buffers maintain pH balance human cells, the blood stream and in natural waters.

Phytoplankton: Tiny plant-like organisms that float in the water and that obtain most of their energy from sunlight using photosynthesis. Some of these cells can also use dissolved organic carbon for fuel.

Polar Molecule.: A molecule that has one end with an effective positive charge and the other end with an effective negative charge. It is not an ion, but the distribution of protons and electrons are such to create the effective charge distribution.

Salinity: A measure of how much salt is dissolved in water. Different authors use different systems for units. Earlier texts use PPT (Parts Per Thousand). Others moved to PSU (Practical Salinity Units), and more recently some authors abandon the unit all together and simply report a number. So 35 PPT is equivalent to 35 PSU or simply a salinity of 35.

Thermocline: This refers to the rapid change in temperature with increasing depth that occurs in bodies of water consisting of a warmer surface layer floating over a cooler deeper layer. For example the surface water of a lake might be 25^{o} C in the summer and the bottom water only 4o C. The rapid drop in temperature between the two layers constitutes the thermocline.

Thermohaline Circulation: This refers to the pattern of water movement in the ocean driven by differences in density. Water density is controlled by both temperature and salinity. Thermo refers to

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

temperature and haline refers to saltiness. Colder and saltier water is denser than warmer and fresher water. So cold salty water sinks, driving this type of ocean current.

Specific Heat.: The amount of thermal energy used to raise the temperature of one gram of a substance one degree Centigrade at standard conditions of 25^{o} C and one atmosphere of pressure. The same amount of heat is released from that substance when it drops one degree.

Water Pollution: The contamination of aquatic systems by substances that change the character and functionality of those systems. The pollution may be the addition of excessive amounts of substances that are normally found in the water, such as excessive plant nutrients like nitrogen and phosphorus. Or the pollution maybe an exotic substance such as a pesticide or industrial compound.

Zooplankton.: Tiny animals that float or swim in the water and rely upon phytoplankton for food.

ABSTRACT

This chapter gives an overview on the main technologies for nutrient removal from industrial wastewater by focusing on principles and operational parameters of real applications. A plethora of technologies can achieve the nutrients removal from wastewater depending mainly on their concentration and forms; however, biological nitrification and denitrification and chemical precipitation are the most common processes used today to remove nitrogen and phosphorus, respectively. Stripping, adsorption and membrane based processes for nutrients recovery can be economically viable only when nitrogen concentration is higher than 1.5-2 gN/L. On the other hand, phosphorus recovery should always be pursued and struvite crystalization is the most common option that should be evaluated together with biological phosphorus accumulation in sludge or plants for the following post-processing and valorization.

INTRODUCTION

Nitrogen and phosphorus are essential elements of life, however, the continuous release of excess nitrogen and phosphorus into the environment during naturally occurring processes (e.g. weathering, leaching, erosion) and anthropogenic activities (e.g. surface run-off from agricultural and livestock activities, wastewater treatment plants, etc.), which may lead to eutrophication (i.e. algae bloom and oxygen depletion in aqueous systems) in natural water systems. The eutrophication problem is expected to increase due to the increasing population, agricultural intensification and industrialization. Nevertheless, eutrophication can be reversed by reducing the nutrients load to water bodies. One such solution is to decrease the load of nutrients discharged from wastewater treatment plants. Thus, efficient and reliable nutrients removal and/or recovery technologies are required. Nitrogen and phosphorus removal/recovery from wastewater can be achieved by biological or physical-chemical processes. The selection of nutrients removal/recovery technologies is determined by the nitrogen and phosphorus concentrations, and consequently the cost-effectiveness of the process. The nutrients removal/recovery technologies can be classified into three concentrations ranges (Mulder, 2003):

- Diluted wastewater with phosphorus concentration <40 mg P/L and ammonium concentration <0.1 g N/L. In this nutrients concentration range, biological nutrients removal is the preferable process based on cost-effectiveness. In addition, chemical phosphorus precipitation can be an option for phosphorus removal from diluted wastewater.
- Concentrated wastewater with phosphorus concentration >60 mg P/L and ammonium concentration in the range 0.1-5 g N/L. Chemical phosphorus precipitation processes are identified as interesting alternatives for the simultaneous recovery of phosphorus and nitrogen as an agricultural fertilizer (struvite) or phosphorus recovery as a raw material for the phosphorus industry (calcium phosphates). For nitrogen, biological treatment processes are also to be preferred.
- Concentrated wastewater with ammonium concentration >5 g N/L. In this range, the physical-chemical process for ammonium removal can be technically and economically feasible (e.g. ammonia stripping, selective ion exchange and breakpoint chlorination).

Thus, this chapter summarizes the methods and technologies commonly used for nitrogen and phosphorus removal/recovery from wastewater. While the processes for nutrients removal, such as biological nutrients removal or chemical phosphorus precipitation from diluted wastewater, have been widely adopted in nutrient removal plants, strategies for its recovery are still being studied. One such technology is the phosphorus recovery by struvite crystallization from wastewater streams with high phosphorus concentration. Moreover, ammonium removal from concentrated wastewater by ammonia stripping can be used because of its simple operation and high efficiency.

NITROGEN AND PHOSPHORUS IN INDUSTRIAL WASTEWATER

The characteristics of industrial wastewater vary essentially with the type of industry and the type of industrial process used (Table 1). Agro-industrial effluents, like piggery effluents or fishery discharges, slaughterhouses and meat processing, food processing, frequently combine high concentration both in

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 1. Industrial wastewater composition in terms of nitrogen and phosphorous content (mg/L)

Type of Wastewater	Total Nitrogen	Total Phosphorus
Slaughterhouse poultry	10-190 (NH_4^+-N)	-
Distillery	1200 (NH_4^+-N)	-
Brewery	25-35 (TKN)	20-30
Vegetable processing	-	1-30
Seafood processing	25-405	5-95
Dairy product	60-310	1-40
Personal care and pharmaceutical products	15-130	3-30
Meat processing	90-700 (TKN)	12-120

TKN: Total Kjeldahl Nitrogen
(Wun-Jern, 2006)

ammonium, phosphorus and organic matter. For many industrial wastewaters, especially in chemical and petrochemical industry, reduction of effluent total nitrogen is difficult because of batch production operations and the refractory nature of many complex organic nitrogen compounds in process chemicals.

REMOVAL VS RECOVERY: FEASIBILITY AND SUSTAINABILITY

There are different technologies for nutrients recovery from nitrogenous industrial wastewater. Besides the solid/liquid separation technologies are often involved to separate the organic and mineral forms of nitrogen, there are two main groups of technologies aiming the removal and recovery of nitrogen, respectively:

- Physical-chemical processes which separate ammonia and concentrate it in other flows, either solid, liquid or gaseous, that can be further processed to recover ammonium salts;
- Biological processes which convert ammonia into nitrogen gas that returns to the atmosphere.

Although the nutrients recovery always appears the desirable option, its sustainability for removal or recovery at large-scale applications should be evaluated as well, both from the technical, environmental, administrative/regulatory, and finally, economic aspects. However, the latter is closely linked to the market for recovered materials and the ability to compete with traditional chemical fertilizers. Maurer et al. (2003) compared the energy consumption of different technologies for N recovery from source separated urine and calculated that:

1. N recovery by air stripping followed by acid condensation and $(NH_4)_2SO_4$ production needs 90 MJ/kg N;
2. Biological removal with nitrification/denitrification with methanol as substrate needs 109 MJ/kg N;
3. Biological removal with the completely autotrophic process (partial nitritation + anaerobic ammonia oxidation) needs only 19 MJ/kg N;

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

4. The Haber-Bosch process to produce ammonia from N_2 needs 45 MJ/kg N.
5. It follows that the combination of the conventional biological removal process with the Haber-Bosch process (154 MJ/kg N) results less convenient than the N recovery with air stripping (90 MJ/kgN), but completely autotrophic processes plus the Haber-Bosch process could be more energetically convenient (64 MJ/kg N).

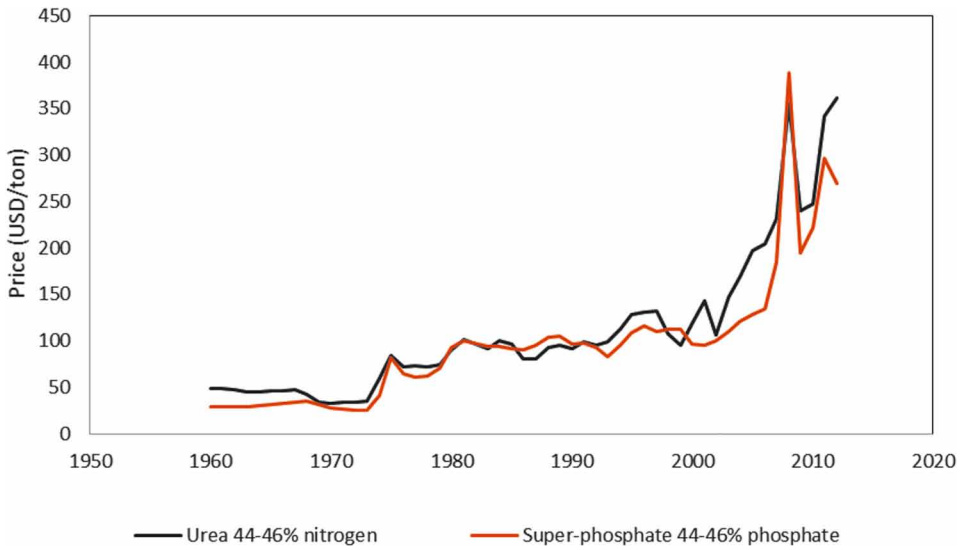
The conventional technologies for the removal of phosphorus from wastewater are chemical phosphate precipitation by adding metal salts or biological phosphorus removal processes. However, in these technologies, the phosphorus is not recovered as a sustainable product, but rather like a waste sludge that needs to be treated or disposed of in landfills. An important requisite for phosphorus recovery technologies is generating a final product with high quality, high purity and free from pollutants. Thus, the aim of phosphorus recovery technologies must be to obtain a product that has a potential to be used as fertilizer or as raw material for phosphorus industry. Thus, the technologies of nutrients recovery should not only be technically feasible, but they should also be cost-effective. The economic viability is, therefore, crucial to decide on the implementation of a nutrients recovery technology.

Market and Opportunities of Recovered Nutrients

During the last decades, the steadily growing global demand for grain crops has generated higher crop prices and higher needs of fertilizers (N and P based) with the consequent rise in the prices (Figure 1). The consumption of fertilizer in 2011 was estimated at 176.8 million tonnes. With a successive growth of 1.9 percent per year, it is expected to reach 194.1 million tonnes by the end of 2016 (FAO, 2012).

Nitrogen is recovered from concentrated industrial wastewater often as ammonium sulfate which has potential applications as fertilizer. Ammonium sulfate account for about 4.7% of the world nitrogen fertilizer market (www.ihs.com, Chemical Economics Handbook Ammonium Sulfate). There are no

Figure 1. Price for urea and super-phosphate procurement during the years from 1960-2013
Source: USDA, 2013



EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

serious environmental concerns involved with the use of ammonium sulfate as a fertilizer material. The global ammonium sulfate market size was estimated at USD 2.86 billion in 2014, and the forecast is for a further increase in the next seven years (Grand View Research, 2016). Although the total nitrogen fertilizer market grew substantially between 1987 and 2013 and it is expected further growth for 2018, the bulk of the world demand for nitrogen fertilizer is being filled by urea, another solid fertilizer material with a higher nitrogen content.

Struvite is considered as a potentially marketable phosphorus product from wastewater streams. Some potential applications of struvite are: secondary phosphate ore (as raw material), source of phosphate in other industrial processes or slow-release fertilizer (Schuiling & Andrade, 1999). The possible use of struvite as a raw material is associated with the production of elementary phosphorus or P-based fertilizer. Another use could be as a raw material in magnesium phosphate cement of building materials (p.e. fire resistant board material).

The most promising use of struvite is as a slow release fertilizer. Struvite can have low rates of leach and, thus, to slowly release nutrients (El Diwani, Rafie, Ibiari, & El-Aila, 2007; Le Corre, Valsami-Jones, Hobbs, & Parsons, 2005; de-Bashan & Bashan, 2004). The fertilizer properties of struvite have been studied by numerous researches. These studies are in agreement that the struvite is an excellent fertilizer for crops, ornamentals, vegetables, flower boards, turf grass, tree seedlings and garden grass (Rahman, Liu, Kwag, & Ra, 2011; Uysal, Yilmazel, & Demirer, 2010; González-Ponce & García López, 2007).

FUNDAMENTALS

Biological Nutrient Removal: Principles

Biological Nitrogen Removal

Biological nitrogen removal in activated sludge (AS) systems is based on two main separated but complementary processes called nitrification and denitrification (Figure 2).

Nitrification

Nitrification in AS systems is defined as the biological oxidation of the ammonium present in wastewater to its most oxidized form (nitrate). In AS systems, this process is performed by two different nitrifying bacteria communities, and thus, nitrification is considered as a two-step process. Ammonia Oxidizing Bacteria (AOB) firstly oxidize ammonium to nitrite (nitritation, Equation 1) and Nitrite Oxidizing Bacteria (NOB) perform the nitrate formation (nitratation, Equation 2). The nitrification process has the following stoichiometric equations (Wiesmann, 1994):

$$NH_4^+ + \frac{3}{2} O_2 \rightarrow NO_2^- + H_2O + 2H^+ \textit{ AOB (Nitrosonomas spp., Nitrosospira spp.,...)} \quad (1)$$

$$NO_2 + \frac{1}{2} O_2 \rightarrow NO_3 \textit{ NOB (Nitrobacter spp., Nitrospira spp.,...)} \quad (2)$$

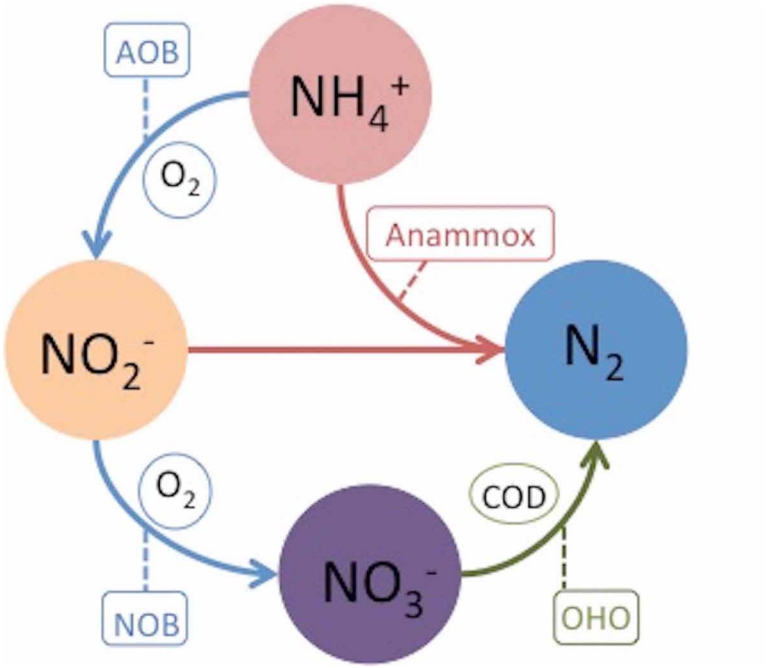
(Adapted from Tayà, 2013)
Source: Tayà, 2013



If the synthesis of new bacteria is considered (assuming that the empirical formulation of bacterial cells is $C_5H_7NO_2$), the above equations are modified as follows (Haug & McCarty, 1972):

$$55\ NH_4^+ + 76\ O_2 + 5\ CO_2 \rightarrow 54\ NO_2^- + 52\ H_2O + 109\ H^+ + C_5H_7NO_2 \quad \textit{Nitritation} \tag{3}$$

$$400NO_2^- + 195O_2 + 2H_2O + NH_4^+ + 5CO_2 \rightarrow 400NO_3^- + H^+ + C_5H_7NO_2 \quad \textit{Nitratation} \tag{4}$$

It is important to take into account the affectations or inhibitions in the nitrification process. Temperature, pH (Metcalf & Eddy, 2003), free ammonia (FA) and free nitrous acid (FNA) concentration (Anthonisen, Loehr, Prakasam & Srinath, 1976; Kim, Lee, & Kellet, 2006; Torà, Lafuente, Baeza & Carrera, 2010) or the lack of inorganic carbon presence (Wett & Rauch, 2003; Guisasola, Petzet, Baeza, Carrera, & Lafuente, 2007; Torà *et al*., 2010; Ganigué, Volcke, Puig, Balaguer & Colprim 2012) are one of the most deeply studied parameter that could affect this process.

Current knowledge on nitrification process has attributed to the nitritation step the majority of nitrous oxide (N_2O) and nitric oxide (NO) emissions detected in WWTP (Kim, Mishurov & Kiely 2010; Wunderlin, Mohn, Joss, Emmenegger & Siegrist 2012). Among them, N_2O has received increasing attention due to the detrimental effects that it can cause as greenhouse gases (GHG) and as a toxic to living organisms (Guerrero, 2014).

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Denitrification

The following step inside de nitrogen removal is the denitrification. Denitrification is the reduction of nitrate to nitrogen gas (N_2), which is removed from the system achieving the wastewater nitrogen removal. This process is composed of different steps (Equation 5) starting with nitrate reduction to nitrite, followed by nitrite reduction to nitric oxide and nitrous oxide and finally to nitrogen gas (Gujer, Henze, Takahashi & van Loosdrecht 1999).

$$NO_3^- \rightarrow NO_2^- \rightarrow NO \rightarrow N_2O \rightarrow N_2 \tag{5}$$

The stoichiometry of total denitrification to N_2 when using ethanol as carbon source is showed in Equation 6 (Wiesmann, 1994):

$$12NO_3^- + 5C_2H_5OH^- \rightarrow 6N_2 + 10CO_2 + 9H_2O + 12OH^- \tag{6}$$

The synthesis of new bacteria follows the stoichiometry presented in equation 7 (Liu, Qin & Yang, 2007):

$$97NO_3^- + 50C_2H_5OH \rightarrow 46N_2 + 75CO_2 + 84H_2O + 97OH^- + 5C_5H_7NO_2 \tag{7}$$

Conventional denitrification in AS (i.e. heterotrophic denitrification) is mainly conducted by one microbial population called ordinary heterotrophic organisms (OHO). Under anoxic conditions, where the electron acceptor is nitrite or nitrate, OHO can use them for organic matter (organic electron donor) oxidation to CO_2 and H_2O. Although the amount of organic carbon present in urban wastewaters is commonly enough for total nitrogen denitrification, some industrial influents have low COD/N ratios limiting this process. Among other possible solutions, a biodegradable external carbon source can be used for these cases. As an example, in the north of Europe the addition of methanol is a widespread practice to enhance the denitrification capacity of urban WWTP (Purtschert, Siegrist & Gujer, 1996), however treating industrial wastewater an external carbon source has to be added to complete the denitrification and therefore the BNR.

For some years, it is being studied the denitrification process as a contributor of N_2O and NO emissions because they are intermediate compounds of nitrate or nitrite reduction to nitrogen gas (Equation 5). Although low emissions are related to denitrification in comparison with nitrification for normal WWTP operation, some specific conditions have been focused as possible factors to favour N_2O and NO accumulation under anoxic conditions. Carbon source limitations, low pH or high nitrite concentrations are some examples (Thörn & Sörenson, 1996; Itokawa, Hanaki, & Matsuo, 2007). At present, there is still a lack of studies about understanding the influence of environmental factors and operational configurations on N_2O and NO emissions, being then current hot research topics (Guerrero, 2014).

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Advanced Nitrogen Removal Processes

Novel advanced N removal processes have been developed in the recent years mainly focused on reducing organic carbon necessities for denitrification step. Most of them are based on nitrification and denitrification via nitrite pathway (i.e. shortcut biological N removal). This process has the following stoichiometry (Henze, van Loosdrecht, Ekama, & Brdjanovic, 2008):

$$NH_4^+ + {}^{3}\!/\!_{2}\, O_2 \rightarrow NO_2 + H_2O + 2H^+ \textit{ Nitritation (AOB)} \quad (8)$$

$$8\ NO_2^- + 3\ CH_3COOH \rightarrow\ 4\ N_2\ + 6\ CO_2 + 2\ H_2O\ + 8OH^-\ \textit{Denitritation (OHO)} \quad (9)$$

The first step consists in a partial nitrification where ammonium is oxidized to nitrite (nitritation) but not to nitrate. Consequently, total NOB washout is mandatory to ensure nitratation suppression. Several methods have been proposed so far for selecting AOB against NOB, which are based on decreasing growth rate of the NOB over AOB under some specific operational conditions.

For complete biological N removal through nitrite, a second step for nitrite reduction, autotrophically or heterotrophically, has to be included. Comparing with conventional nitrification/denitrification process, the combination of partial nitritation (Equation 8) and heterotrophic denitritation (Equations 9) has some advantages since it results in a decrease of 25% in oxygen requirements, around 30-40% less of carbon source requirements for denitrification step and a reduction of 40% in biomass production (Turk & Mavinic, 1987; Van Hulle et al., 2010). In addition, the anoxic volume can be reduced because denitrification rates from nitrite are around 1.5-2 times faster than denitrification from nitrate (Peng & Zhu, 2006; Aslan & Dahab, 2008).

Regarding autotrophic denitrification, the anaerobic ammonium oxidation (anammox) is the most innovative nitrogen removal process. Under anoxic conditions, anammox microorganisms oxidize ammonium to nitrogen gas by using nitrite as an electron acceptor. Hence, differently to heterotrophic denitritation, for anammox process only 50% of the ammonium entering the system has to be previously oxidized to nitrite. As can be observed in anammox stoichiometry (Equation 10) no carbon source is needed during this process, and around a 10% of the nitrogen treated is converted to nitrate (Strous, Heijnen, Kuenen & Jetten, 1998).

$$NH_4^+ + 1.32NO_2^- + 0.0066HCO_3^- + 0.13H^+ \rightarrow 1.02N_2 + 0.26NO_3^- + 2.03H_2O + 0.0066CH_2O_{0.5}N_{0.15} \quad (10)$$

This process presents different advantages (Liu et al., 2008):

1. Overall energy savings around 40-50% related to low oxygen requirements,
2. There is no need for carbon source supply and
3. The amount of sludge produced is lower due to low biomass substrate yield of anammox bacteria.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

On the contrary, the slow growth rate of such microorganisms, the inhibitory effect of oxygen presence and the complexity to find a proper inoculum enriched in anammox results in long-term start-up periods. In spite of this, several treatment processes that combine nitritation and anammox have been already developed: SHARON/Anammox (two reactors system; Hwang, Min, Choi & Yun, 2005), CANON (complete autotrophic N removal over nitrite; Vázquez-Padin et al., 2009), OLAND (oxygen-limited autotrophic nitrification and denitrification; Vlaeminck et al., 2010) or NAS (floc-based partial nitritation and anammox process; Desloover et al., 2011).

Some other autotrophic denitrification processes have also been studied during last decade not based on anammox bacteria. In these cases, autotrophic denitrification is carried out by using hydrogen (H_2) as electron donor (Lee & Rittman, 2002; Rezania, Oleszkiewicz & Cicek, 2007) or sulfur compounds such as H_2S, S, $S_2O_3^{-2}$ or SO_3^{-2} (Batchelor & Lawrence, 1978; Sierra-Alvarez et al., 2007; Fajardo, Mosquera-Corral, Campos & Méndez 2012; Mora, Lopez, Gamisans & Gabriel 2014). As also occurred with anammox microorganism, the organic carbon source is neither needed during denitrification. This process presents the same advantages as anammox systems over heterotrophic denitrification. However, the high alkalinity required during the process and the sulfate production due to the oxidation of sulfur compounds constitute the main drawbacks.

Biological Phosphorus Removal: Enhanced Biological Phosphorus Removal (EBPR) Process

EBPR aims at removing and recovering phosphorus using biological processes and thus, without the addition of chemicals, which increases the costs and produces a chemical undesired sludge. This process is based on the enrichment of activated sludge with polyphosphate accumulating organisms (PAO) under alternating anaerobic/aerobic or anaerobic/anoxic conditions. Under anaerobic conditions, PAO can uptake organic substrates (preferably volatile fatty acids, VFA) and store them as a polyhydroxyalkanoates (PHA). This storage requires energy provided by hydrolysis of poly-phosphates (poly-P) resulting in P-release into solution. The reduction power is provided mainly by the catabolism of stored glycogen. The release of phosphate produced under anaerobic conditions is compensated by its aerobic P-uptake. In the aerobic stage, PHA is used as a carbon and energy sources for growth, and the replenishment of internal glycogen and poly-P pools (Mino, van Loosdrecht & Heijnen, 1998). A schematic representation of the PAO metabolism most widely accepted is presented in Figure 3.

The two most common VFA present in municipal wastewater are acetate and propionate. The metabolism of acetate and propionate by PAO has been amply studied (Oehmen, Zeng, Yuan & Keller., 2005; Pijuan, 2004; Hood & Randall, 2001; Lemos, Serafim, Santos, Reis & Santos, 2003; Lu, Oehmen, Virdis & Yuan, 2006; Chen, Randall & McCue 2004; Thomas, Wright, Blackall, Urbain & Keller, 2003). Depending on the carbon source used, PHA polymers are produced with a different composition. Pijuan et al. (2009) studied the effect of carbon sources on the type and quantity of PHA synthesis obtained with different EBPR microbial communities enriched with acetate or propionate. It was shown that the same carbon source produced different PHA composition in each community. The PHA composition was also strongly influenced by the carbon source. Acetate produced PHB-PHV copolymer with a much higher amount of PHB (70%), propionate produced PHV (53%) or PH2MV (49%) copolymer, while other non-identified PHA monomers were also detected with butyrate (Tayà, 2013).

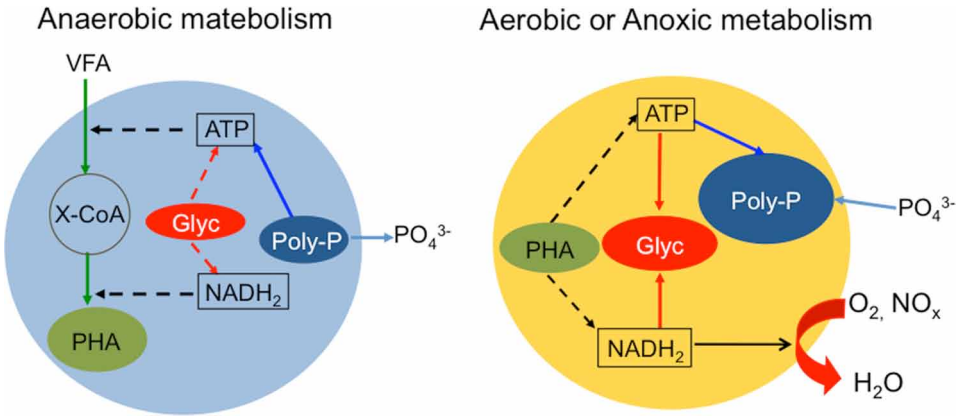
Figure 3. Schematic representation of PAO metabolism
(Tayà, 2013)
Source: Tayà, 2013



Through microbial techniques, *Acinetobacter* was first proposed to be the primary organism responsible for P removal in EBPR (Fuhs & Chen, 1975), and was long believed to be the sole PAO present in EBPR plants. However, the use of fluorescence *in situ* hybridization (FISH), 16S rRNA-based clone libraries or denaturing gradient gel electrophoresis (DGGE), showed that a high diversity of phylogenetic groups are present in lab- and full-scale EBPR sludge (Seviour, Mino & Onuki, 2003; Hesselmann, Werlen, Hahn, van der Meer & Zehnder 1999; Crocetti et al., 2000; Liu et al., 2001; Ngunyen, Le, Hansen, Nielsen, & Nielsen 2011).

However, one of the large known failures on EBPR systems is the presence of other microorganisms able to survive under anaerobic/aerobic conditions and compete with PAO for donor electron (carbon source). These microorganisms are able to uptake the carbon source under anaerobic conditions without any P activity (Cech & Hartman, 1990, 1993; Crocetti, Banfield, Keller, Bond & Blackall, 2002; Liu, Mino, Nakamura, & Matsuo, 1994; Nielsen, et al., 1999; Satoh, Mino & Matsuo, 1994; Wong, Tan, Ng, & Liu, 2004). The term GAO (glycogen accumulating organisms) was proposed by Mino, Liu, Kurisu, & Matsuo, (1995), and is defined as the phenotype of organisms that store glycogen aerobically and consume it anaerobically as their primary source of energy for taking up carbon sources and storing them as PHA. These microbial competitions in the EBPR systems is influenced by several factors, such as the carbon source, pH, temperature and aeration (Filipe, Daigger, & Grady, 2001; Brdjanovic et al.,1998a,b; Oehmen, Zeng, Yuan & Keller, 2005; Oehmen, Saunders, Vives, Yuan, & Keller, 2006a: Oehmen et al., 2006b; Lopez-Vazquez et al., 2008; 2009; Lu, Oehmen, Virdis, & Yuan, 2006).

Main Schemes Applied for Conventional and Advanced BNR for Industrial WWTP

Treatment of wastewater by means of biological processes has been widely implemented for classical urban and industrial wastewater. Moreover, there are many biological nutrient removal systems to deal with nutrient removal such as: Phoredox (A/O) (Figure 4), A^2/O (Figure 5), Five-stage Bardenpho (Figure 6), UCT (University of Cape Town) (Figure 7), modified UCT (Figure 8) and VIP (Virginia Initiative Plant) (Figure 9) (Metcalf & Eddy, 2003).

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 4 describes the A/O process, which is a patented version of Phoredox by *Air Products and Chemicals, Inc*. The main difference is the use of multiple-staged anaerobic and aerobic reactors. This process is used for combined carbon oxidation and phosphorus removal. In this process there is no nitrification, and the anaerobic retention time is 30 min to 1 h to provide the selective conditions for the biological phosphorus removal (Tayá, 2013).

A^2/O process (Figure 5) is patented by *Air Products and Chemicals, Inc*. It is a modified A/O process to provide an anoxic zone for denitrification. The operation is relatively simple compared to other processes. With this process it is achieved simultaneous nitrogen and phosphorus removal. In the anoxic zone there is a low oxygen concentration, but nitrite and nitrate can be used as an electron acceptor from the recycle of the aerobic zone. However, it requires high COD/P ratios.

On the other hand, Barnard (1975) first achieved phosphorus removal in a mainstream process later called Bardenpho process. Figure 6 shows a 5-stage Bardenpho process, which provides anaerobic, anoxic, aerobic stages for phosphorus, nitrogen and carbon removal. A second anoxic stage is provided

Figure 4. Phoredox or A/O process

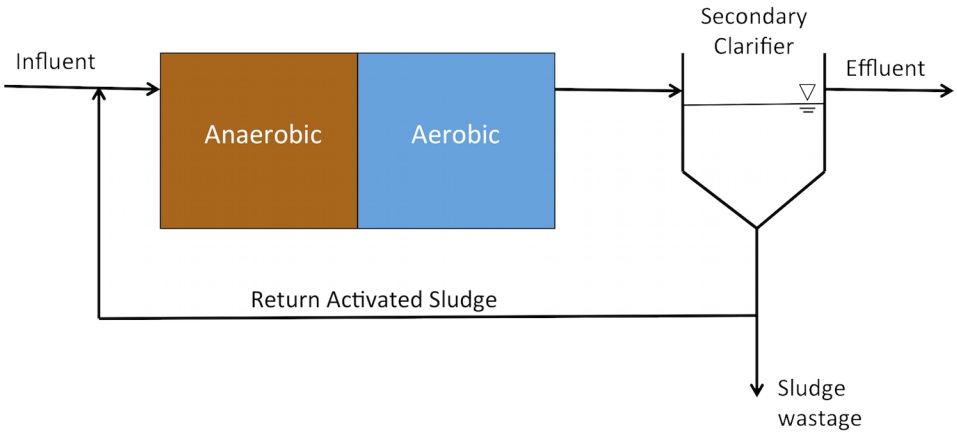


Figure 5. A2/O process

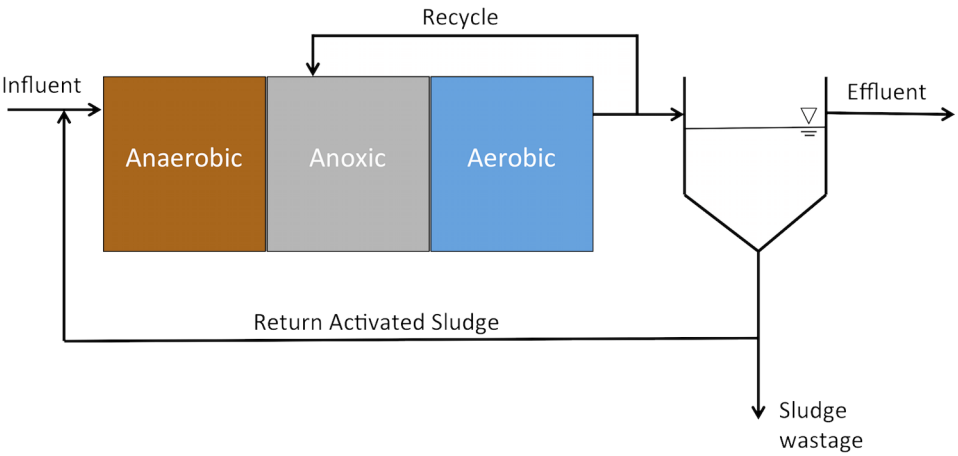

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

for additional denitrification using nitrate produced in the aerobic stage as the electron acceptor and the endogenous organic carbon as the electron donor. The final aerobic stage is used to strip residual nitrogen gas from solution to prevent rising problems and to minimize the P-release in the final clarifier (Metcalf & Eddy, 2003).

The UCT process (Figure 7) was developed at the University of Cape Town and is similar to the A^2/O process. There are two differences:

1. The return activated sludge is recycled to the anoxic reactor instead of the anaerobic stage, and
2. There is an additional recycle from the anoxic phase to the anaerobic phase. This configuration decreases the amount of nitrate recycled to the anaerobic reactor, increasing the organic matter availability for EBPR.

The modified UCT process (Figure 8) splits the anoxic zone into two stages. The nitrate rich recycle from the aerobic zone is recycled to the head of the second anoxic stage. The nitrate contained in the return activated sludge is recycled to the first anoxic stage where it is denitrified. Next, the denitrified

Figure 6. Modified Bardenpho (5-stage) process

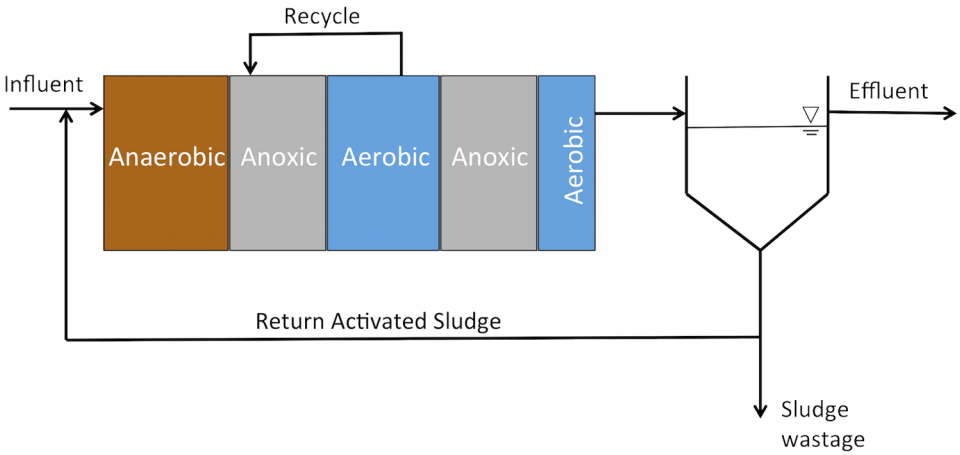

Figure 7. University of Cape Town (UCT) process

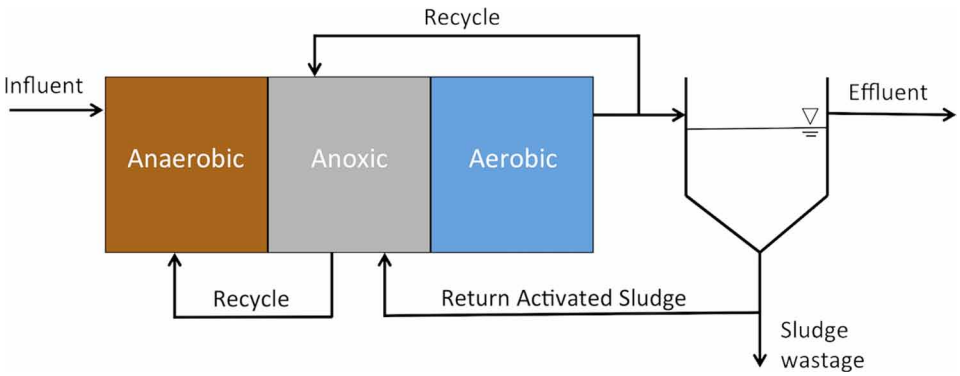

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

returned activated sludge is recycled from the end of the first anoxic stage to the head of the anaerobic stage and mixed with the incoming wastewater

The VIP process (Figure 9) (from Virginia Initiative Plant in Norfolk, US) is similar to A^2/O and UCT processes except for the methods used for recycling. The return of activated sludge is discharged to the inlet of the anoxic zone along with nitrified recycle from the aerobic zone. The mixed liquor from the anoxic zone is returned to the head end of the anaerobic zone. The organic matter in the process influent is stabilized through anaerobic mechanisms in the anaerobic zone, which reduces the oxygen requirements of the process (Metcalf & Eddy, 2003).

The Sequencing Batch Reactor (SBR) (Figure 10) is a single tank where the biological processes and settler occur under distinguished temporal sequence. The SBR is often applied for the treatment of both domestic and industrial wastewater because allowed high removal of the pollutant and flexibility of the operations. The principle of the SBR is the operation in cycles which involves the same pattern of phases, which typically are: 1) Filling; 2) Batch reaction wise (aerobic and/or anoxic and/or anaerobic); 3) Settling; 4) Discharging; 5) Idle. For continuous-flow applications, at least two SBR tanks must be provided so that one tank receives flow while other completes the treatment cycle (Metcalf & Eddy, 2003).

Nitrogen Stripping, Adsorption, and Vacuum Distillation, Processes: Principles

Stripping of Ammonia

Ammonia removal from high nitrogenous wastewaters can be accomplished by air or steam stripping. Ammonia stripping is a well-known application to concentrate nitrogen in concentrated wastewater treatment (e.g. landfill leachate, supernatants of anaerobic digestion processes, specific flows of the petrochemical industry), while very few applications in sewage treatment are reported in the literature (Capodaglio, Hlavínek, & Raboni, 2015).

The stripping of ammonia requires a high pH (around 10 to 12), which is usually achieved by addition of base in significant amounts:

$$NH_4^+ + NaOH \rightarrow NH_3 + H_2O + Na^+ \quad (11)$$

$$NH_4^+ + Ca(OH)_2 + HCO_3^- \rightarrow NH_3 + CaCO_3 + 2H_2O \quad (12)$$

The equilibrium is governed by pH and temperature, according to the Equation 13 describing the reaction's ionization constant (K_{eq}).

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

$$K_{eq} = \frac{[NH_4^+][OH^-]}{[NH_3]} = 1.8 \cdot 10^{-5} \text{ at } 25\ ^\circ\text{C} \tag{13}$$

The stripping factor (S) describes the balance between gas and water at the upper end of the stripping column (Morales et al., 2013). The minimum required amount of air (Q_{Air}) in relation to the supernatant (Q_{Liquid}) is in accordance with Equation (14) (Siegrist, Laureni, & Udert, 2013) to be at least $1/H_{NH3}$ where H_{NH3} is the NH_3 Henry's constant.

$$S = \frac{Q_{AIR}}{Q_{LIQ}} \geq \frac{1}{H_{NH_3}} \tag{14}$$

There are two ways to strip the ammonia out the water (Figure 11):

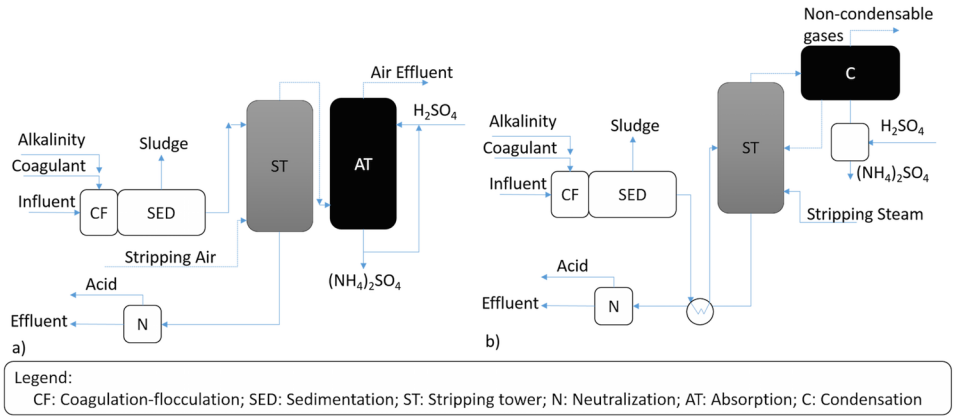
a. Air stripping: air is bubbled through the wastewater and takes up the gaseous ammonia. This gas has to be washed out in a second reactor under acidic conditions.

$$2NH_3 + H_2SO_4 \rightarrow (NH_4)_2SO_4 \tag{15}$$

b. Steam stripping: steam is blown through the water and after condensation a concentrated ammonia solution is produced.

This process requires 2.4 kg/kg N calcium oxide for increasing the pH above 9 and 7.0 kg sulphuric acid each kg of ammonia nitrogen absorbed (Purtschert, Siegrist, & Gujer, 1996). The electricity requirement for the aeration is an estimated 26.3 MJ/kg N and the following energy data are used for the calculations (Patyk & Reinhard, 1997).

Figure 11. Typical flow diagrams of the stripping processes with air (a) and steam (b)
(Adapted from: Raboni, Torretta, Viotti, & Urbini, 2013)
Source: Adapted from Raboni et al., 2013



EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

The stripping process is not applicable for wastewater of low strength. Certain wastewater, like from manure, from the production of PU-foams or digester supernatant in municipal WWTP, can be treated economically.

Air stripping is often used in the treatment of municipal solid waste (MSW), landfill leachate (or groundwater polluted by the same leachate). An example of the process is represented in Figure 12. The system consists of: 1) coagulation-flocculation at pH > 11; 2) water heating at 38°C and ammonia air stripping; 3) ammonia recovery by absorption with a sulfuric acid solution.

Raboni et al. (2013) obtained a reduction of ammonia from 199 mg/L (as N) down to 22.5 mg/L (as N). The plant showed severe scaling issues, with an increase in weight of the single filling components (Pall rings) up to seven times their original weight. The progressive scaling produced an 18% loss of ammonia removal efficiency, caused by the reduction of both the packing interfacial surface and the air/water ratio due to head loss increase. Periodical (every six months) chemical washing of the stripping towers with a 30% HCl solution was carried out to avoid scaling build-up. Closed-loop air recirculation allowed the water temperature inside the column to be maintained in the range of 25-38°C, even during winter, but caused a gradual decrease in the solution's pH within the tower. This was due to the acidic characteristics of the stripping air coming from the ammonia absorption tower. Subsequent experiences proved the actual possibility of achieving high ammonia removal efficiencies (greater than 95%) by operating the stripping towers at 38°C with liquid rates below 4.5 $m^3/(m^2 \cdot h)$ and air/water ratios above 1500 Nm^3/m^3 (Viotti & Gavasci, 2015).

Vacuum Distillation

In the case of highly concentrated streams vacuum distillation is a viable solution for ammonia recovery (EPA, 2013).

Vacuum flash distillation processes (Figure 13) have been applied to ammonia recovery from centrate of manure digested sludge, using as a heat source the biogas generated by the anaerobic digestion (Orentlicher, Brown, & Hall, 2009). The ammonia can be removed from approximately 1000 mg

Figure 12. Diagram of a physical-chemical process for leachate treatment, with wastewater pre-heating and a closed-loop air stripping process

NH_3–N/L to less than 100 mg NH_3–N/L operating at a pH value of 9.5 and a temperature of 60°C under vacuum (Orentlichter et al., 2009). Other combinations of temperature and pH achieve similar high free ammonia fractions, allowing an effective stripping process. The resulting ammonia-rich distillate is a marketable product or it can be converted into an ammonium sulfate solution. If desired, such a solution can be further concentrated, using multiple vacuum distillation stages.

Adsorption

Zeolites and other mineral like clay or tuff have ion exchange properties and are used to adsorb ammonium when is present at low concentration. A common approach is to pump wastewater through columns packed with zeolite. Ammonia concentrations of 25 to 50 mg NH_4-N/L can be lowered to levels around 1 mg NH_4-N/L (zeolites: Booker, Priestley, & Fraser, 1996; Nishimura, Somiya, Tsuno, & Iwabu, 1996; Nguyen & Tanner, 1998; Komarowski & You, 1997; Cooney, Booker, Shallcross, & Stevens, 1999; Lahav & Green, 2000; tuff: Ibrahim, 2001; clay: Gisvold, Odegaard, & Follesdal, 2000).

Buday (1994) used cation exchange resins to reuse ammonia from wastewater of an ammonium nitrate fertiliser plant. The exhausted resins were regenerated with nitric acid, gaining an ammonium nitrate solution that is recycled into the fertiliser production. Chen et al. (1999) successfully tested the use of different cellulose acetate fibres for the adsorption and recovery of proteins. Kioussis et al. (2000) developed polymer hydrogels that remove nitrate, nitrite and phosphate from aquaculture wastewater. They claim to achieve following qualities: 10 mg N/L for nitrate and 0.08 mg N/L for nitrite. Gel regeneration is accomplished by flushing 1 M sodium hydroxide solution.

Chemical Phosphorus Precipitation and Crystallization: Principles

Chemical Phosphorus Precipitation Processes

The chemical phosphorus precipitation by addition of metal salts is widely used due to its simple operation and implementation. However, the disadvantages of chemical precipitation are high sludge production and costs of chemicals. The sludge produced during chemical phosphorus precipitation cannot be applied to agriculture lands because it has a low bioavailability (Morse, Brett, Guy, & Lester, 1998). Chemical phosphorus precipitation process is widely used to remove phosphorus from diluted wastewater streams. Generally, chemical phosphorus precipitation process is based on the addition of metal salts to wastewater, producing an insoluble metal phosphate precipitate. This precipitate is separated from the liquid phase using conventional separation technologies such as sludge filters or centrifuges. The phosphate precipitation efficiency by metal salts addition is highly dependent on the solids separation process. Even though phosphorus removal by adding metal salts is usually used, it is not appealing for recovering phosphorus because the obtained precipitates are difficult to manage, and so they are often disposed to landfills. This is because the aluminium in aluminium phosphates may be toxic to many plants and some soil organisms. Meanwhile, phosphorus in iron phosphates is usually considered to be unavailable for plants, therefore reducing its suitability for replacing phosphate fertilisers (Rittman, Mayer, Westerhoff, & Edwards, 2011). Iron phosphates are no significant industrial outlets for recovered ion phosphates because its recycle is very expensive at present. Regardless, phosphorus in aluminium phosphates can be used as raw material for phosphorus production by using the electrothermal process of Thermphos (Schipper et al., 2001).

The most important parameter for the chemical phosphate precipitation process is the dose of metal salts added. The amount of metal salts used influences the performance and the economy of the precipitation process. The metal ions should be added in excess relative to phosphate concentration to achieve a low concentration of phosphate in the effluent (Rybicki, 1997). The amount of metal salt added cannot be determined only by the concentration of phosphate, and it should be determined for each case. It also depends on the wastewater characteristics, operational pH, method of chemical addition, flocculation method, chemical addition feeding point(s) and time after chemical addition, and it is usually determined by on-site testing (EPA, 2010). It is possible to calculate only an approximate dose of metal salts for removing phosphorus. Several side reactions can take place alongside the precipitation of phosphate during the phosphate removal process. The EPA Design Manual (1987) recommends a 20% excess of aluminium ions to reduce phosphate by around 80%, while the 100% excess is suggested to obtain a phosphate removal of 95%.

Phosphorus Crystallization Processes

Phosphorus crystallization processes can be considered separately than phosphorus precipitation by adding metal salts because the chemistry involved in both technologies is quite different. Like in phosphorus precipitation processes, phosphorus crystallization allows transferring soluble phosphorus from wastewater to solid phase. However, phosphorus crystallization process is only used for removing phosphorus from wastewater but also generates a final product that has a potential to be used as fertilizer or as raw material for phosphorus industry.

Calcium Phosphate Precipitation

Phosphorus can be recovered from wastewater by crystallization processes either using lime to produce calcium phosphates, or adding magnesium salts to produce magnesium ammonium phosphate (struvite). Calcium phosphates are less valuable than struvite as a multiple source of nutrient and fertilizer. However, calcium phosphate can be recovered and recycled into phosphate and fertilizer industries. Calcium phosphate is a suitable form of recovered phosphorus because they are similar to phosphate rocks. Different calcium phosphate species may precipitate from wastewater. The nature of calcium phosphate is influenced by the wastewater characteristics and the operating pH. Hydroxyapatite ($Ca_5(PO_4)_3OH$) is thermodynamically the most stable calcium phosphate species, but hydroxyapatite does not precipitate readily. Amorphous calcium phosphate ($Ca_3(PO_4)_2 \cdot n\ H_2O$), dicalcium phosphate dihydrate or brushite ($CaHPO_4 \cdot 2\ H_2O$), dicalcium phosphate anhydrous or monenite ($CaHPO_4$) and octacalcium phosphate ($Ca_8H_2(PO_4)_6 \cdot 5\ H_2O$) can be precursors of hydroxyapatite, depending on the operational conditions.

As mentioned above, lime is usually used to recover phosphorus from wastewater. This calcium compound can be added either as quicklime (CaO) or hydrated lime ($Ca(OH)_2$). Lime is an effective phosphate removal agent, but it produces large volumes of sludge. This chemical has been widely used to remove phosphorus from wastewater, but its use has been declining due large amounts of lime are required to obtain low levels of phosphorus (Metcalf & Eddy, 2007; EPA, 1987). Thus, phosphorus recovery by adding lime can produce large volumes and high chemicals costs.

Usually, the dose of lime added to the precipitation system is higher than the amount required to remove phosphate from wastewater. Lime reacts with phosphate to form insoluble precipitates of calcium phosphates, and it can also react with the alkalinity of wastewater to produce calcium carbonates (EPA, 2010). The operating pH must be fixed at high values to obtain a high phosphate removal efficiency (i.e. pH values higher than 10), and the amount of lime added must be approximately 1.5 times the total alkalinity (expressed as mg $CaCO_3$/L) (Rybicki, 1997). Thus, the amount of produced precipitates will be influenced by the level of bicarbonate alkalinity in wastewater.

Struvite Crystallization

The crystallization of struvite is one of the most recommended technologies to phosphorus recovery from concentrated phosphorus wastewater, such as effluents from anaerobic digesters or sludge dewatering process (Desmidt et al., 2015). The reason is that the crystallization of struvite is not only used for recovering phosphorus from wastewater but also generates a product with a commercial value as a fertilizer.

Struvite is a magnesium ammonium phosphate salt ($MgNH_4PO_4 \cdot 6H_2O$) that usually crystallizes in a reversible reaction and produces crystals with a Mg^{2+}:NH_4^+:PO_4^{3-} molar ratio of 1:1:1. Struvite can be used as a slow release fertilizer, either directly or after processing by fertilizer industry (El Diwani et al., 2007; de-Bashan & Bashan, 2004). The formation of struvite is conditioned by a combination of factors, including the presence of seed crystals, thermodynamics and mass transfer between solid and liquid phases, and reaction kinetics. At the same time, these factors are influenced by several physical-chemical parameters such as pH, the chemical composition of the wastewater, mixing energy and temperature (Doyle & Parsons, 2002). The most important parameters that must be controlled are: pH, temperature and presence of other ions.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

The pH is one of the key factors in struvite crystallization process. Theoretically, there should be a direct relation between the efficiency of phosphorus recovery as struvite and pH. This is because the ionic equilibriums involved in the struvite crystallization are very pH dependent, which in turn could affect the struvite formation (Andrade & Schuiling, 2001). A slight variation in the pH can significantly affect the crystallization of struvite because it varies the distribution of the struvite constituents, affecting their availability for struvite formation. The pH range in which struvite may crystallize is between 7.0 and 11.5, but the suitable pH range is from 7.5 to 9.0 (Rahman et al., 2014). The solubility of struvite is also conditioned by the pH of the solution. It is highly soluble at acidic pH and highly insoluble at alkaline pH (Doyle & Parsons, 2002).

Temperature also influences the struvite crystallization process, struvite characteristics and its thermal stability. Temperature affects the struvite solubility in a way that its solubility increases with the temperature increase, and thus the formation of struvite is more difficult to occur at high temperatures (Le Corre, Valsami-Jones, Hobbs, & Parsons, 2009). So, struvite solubility product is inversely proportional to the variation of temperature (Ben Moussa, Tlili, Batis, & Ben Amor, 2011; Aage, Andersen, Blom, & Jense, 1997).

The presence of other ions in solution, also known as foreign ions, affects the performance of struvite crystallization process because these foreign ions can interfere with struvite crystallization by competing for magnesium and phosphate to form other precipitates species. So, the efficiency of struvite crystallization is affected by the presence of foreign ions, such as calcium and/or carbonate, and also the formation of calcium and/or carbonates precipitates affects the purity of the produced struvite. In this regard, the struvite crystallization is more affected by the presence of calcium at low phosphate concentrations (<40 mg $PO_4^{3-} \cdot L^{-1}$) (Desmidt et al., 2013). Crutchik & Garrido (2011) indicated that a high ammonium concentration could be highly beneficial to the reaction of struvite crystallization, so to obtain a relatively pure solid phase in terms of struvite purity. Thus, it could be possible to obtain a high purity regarding struvite, instead of precipitates of calcium phosphates in high ammonium wastewater.

Moreover, the economic viability of struvite crystallization is highly influenced by the availability of magnesium in the raw wastewater, the cost of alkali used or the cost magnesium source used. This is because wastewater usually contains a low amount of magnesium compared with phosphate and nitrogen and it is necessary to supply a magnesium source to promote the crystallization of struvite. In the literature, the use of high grade magnesium sources, such as $MgCl_2$, $MgSO_4$, MgO or $Mg(OH)_2$, has been reported (Rahaman et al., 2014; Hutnik et al., 2013; Jaffer, Clark, Pearce, & Parsons, 2002; Nelson, Mikkelsen, & Hesterberg, 2003). Nevertheless, the utilization of these high grade and expensive magnesium sources can lead to high operating costs compromising the viability of the process. In this sense, the use of low cost magnesium sources, such as industrial grade MgO or $Mg(OH)_2$, seawater or bittern, can significantly reduce the cost of struvite crystallization. MgO and $Mg(OH)_2$ can be used in a dual function, as magnesium and alkali sources. Unlike for NaOH, the use of MgO and $Mg(OH)_2$ does not produce drastic pH changes. Meanwhile, seawater, brine and bittern can be added to promote struvite crystallization for those urban or industrial WWTP located near the seashore (Liu, Giannis, Zhang, Chang, & Wang, 2013; Señoráns, Barros, García, & Garrido, 2011; Lee, Weon, Lee, & Koopman, 2003; Matsumiya, Yamasita, & Nawamura, 2000).

FULL SCALE APPLICATIONS

Biological Nutrients Removal by SBR from Industry

The SBR system has demonstrated high removal efficiency, and thus, it is an optimal process for the treatment of nitrogenous industrial wastewater, such as landfill, textile effluent, tannery, meat product processing, toxic and slaughterhouse wastewaters, because of its simplicity in operation and economic aspects. Table 2 shows the typical application of SBR with various kinds of wastewaters. Among them, the leachate showed a very low BOD_5/COD ratio, a high concentration of COD, NH_3-N, heavy metals, and other toxic compounds which decrease the activity of the biomass and the treatment capacity of the SBR as a consequence (Uygur & Kargi, 2004). Typically, the treatment of leachate for nutrients removal using the SBR is reported in the literature (Guo, Abbas, Chen, Liu, & Chen, 2010; Spagni, & Marsili-Libelli, 2009; Klimiuk & Kulikowska,2006). Although leachate may have a very low BOD_5/COD ratio (0.09 to 0.3), with the addition of an external carbon source high nutrients removal efficiency can be achieved.

The variability in the operating conditions of the SBR is mainly related to the type of the wastewater fed and the quality of the final effluent. Table 3 reports the operating conditions for the treatment applied to leachate.

Table 2. Type of industrial wastewater treated using Sequencing Batch Reactor

Type of Wastewater	Pollutants/Removal	Removal	Reference
Landfill leachate	COD	<83	Timur & Ozturk (1999)

Nitrogen Recovery from Industry and Agrowaste

Nitrogen and Phosphorus Recovery from Anaerobic Effluent in Glattbrugg, Switzerland

A full-scale stripping reactor including a CO_2 pre-stripper was located in the Kloten/Opfikon Wastewater Treatment Plant (60,000 population equivalent, Glattbrugg, Switzerland). It was the first of these reactors installed in Switzerland (Böhler & Liebi, 2012a). The ammonia stripping process was set in operation for the first time in fall 2010. Some of the characteristics of the stripping reactor were summarized in Table 4, while the scheme of the overall process is shown in Figure 14. The stripping columns (ST) use special UV-stabilized Fluorpolymere packing with a honeycomb shape (CF 12F, Hewitech GmbH & Co, Ochtrup, Germany). This material has 12 mm of channel opening, a specific surface of 300 m^2/m^3 and a cross-flow channel structure. The ammonium rich stream is fed to the top of the CO_2-pre stripper where the air is fluxed in counter flow. The CO_2 stripping increases the pH of the liquid due to the displacement of carbonic acid system equilibrium (Cohen & Kirchmann, 2004).

Table 4. Dimensions and operational condition of the stripping system

Parameter	Value	Units
Column height (CO_2 and Ammonia)	10	M
Packing bed height	6	M
Diameter	0.98	M
Liquid inflow	5-12	m^3/h
Air flow to ammonia stripper	1000-6250	Nm^3/h
Gas flow to the CO_2 stripper	50-200	Nm^3/h
Average NH_4-N concentration inlet	1000	mg/L
Average NH_4-N concentration effluent	30	mg/L
Maximum removal rate	99	%

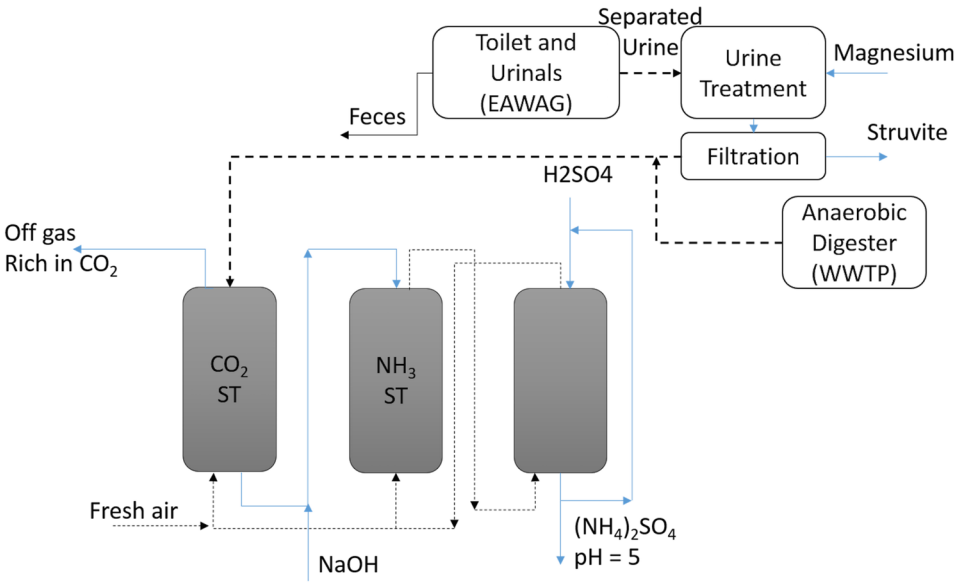
Figure 14. Flow-chart of the co-treatment of sludge liquid and treated urine
(Adapted from: Morales, Boehler, Buettner, Liebi, & Siegrist, 2013)
Source: Adapted from Morales et al., 2013



To avoid a CO_2 accumulation in the column the CO_2 rich gas was discharged after this unit, and fresh air was provided. The pH of the liquid in the ammonia stripper was increased using sodium hydroxide up to a fixed value to favor the equilibrium displacement towards the NH_3, as showed in Equation (16):

$$NH_4^+ + OH^- \leftrightarrow NH_{3(aq)} + H_2O \quad (16)$$

This liquid was fed by the top of the stripper reactor, where the ammonia solved in the liquid phase is stripped to the gas phase. The flow rate of the urine maintained up to around 5.1 m^3/h, while the operation Q_{Air}/Q_{liq} ratio used in the air stripping unit was in the range of 700–750 Nm^3/m^3 at 60 °C, because higher air to liquid ratios resulted in higher electricity consumption (Böhler, Büttner, Morales, Liebi, Schachtler, & Siegrist, 2012b). Then, the ammonia rich gas was washed in the sorber unit using a sulfuric acid solution (H_2SO_4 at 32% solution, 1.16 kg/L, Thommen-Furler AG, Büren, Switzerland) and ammonia sulfate was recovered (Equation 15) obtaining a final density solution of 1.2 kg/L.

Acid cleaning of the stripping reactor is executed daily using hydrochloric acid at pH 0–2 (HCl at 35%, Thommen-Furler AG, Büren, Switzerland) with an automated pH control. Each kg of N removed need at least 3.5 kg of H_2SO_4 and will produce 4.7 kg of $(NH_4)_2SO_4$. In a cost study for a full-scale stripping plant with a CO_2 pre-stripper, the estimated costs for treatment were around 3–4.5 €/kg N recovered (Zuleeg et al., 2012).

Cold Stripping and Water Recovery from Liquid Manure in Remedello (Brescia, Italy)

The N-Free® plants is a patented process installed in the North of Italy, which is considered a Nitrate Vulnerable Zone by the Nitrate Directive (91/676/EEC).

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

The N-Free® process (Fiolini e Savani s.r.l., Brescia, Italy) is characterized by a series of physical/chemical treatments which allow separation and concentration of the liquid fraction of the digestate and a final stripping for the production of ammonium sulfate (Figure 15). The N-Free® unit operated in batch mode and treated up to 100 m^3/day of raw anaerobic digestate (about 14 m^3 each batch cycle). The overall process scheme is composed by the following steps:

1. Rough solid/liquid separation achieved by a screw press (SC) separator (Doda, Mantova-Italy).
2. Conditioning (with polyamide flocculant) of the liquid fraction from the screw press and effective solid/liquid separation by decanter centrifuge (DC) (MAMMOTH 570/3, Pieralisi, Jesi-Italy).
3. Ultrafiltration (UF) of the liquid effluent from the decatenter by a 40 kDa grafted polyacrylonitrile membranes (PAN) (Orelis, France), operating at 3.5 to 4.5 bar of exercise pressure.
4. Treating of the UF permeate in a two-stage reverse osmosis unit (Dow, USA).
5. Refining in zeolites bed of the final reverse osmosis permeate before the final discharge in the water body.
6. Cold stripping of the reverse osmosis (RO) concentrate by air blowing recirculation and through addition of 15-18 kg/m^3 sludge of lime which allows pH raising up to 12-12.5. At these conditions, the equilibrium NH_4/NH_3 is completely shifted to NH_3 which is easily stripped as gaseous ammonia by the controlled air flow. Air plus ammonia is then scrubbed with sulfuric acid producing liquid ammonium sulfate (8% on a wet weight basis as N).

Finally, the cold stripping resulted in RO ammonia reduction of 78% from the anaerobic digestate, a significant reduction of the exportable volumes, leading a more sustainable livestock farming.

Electrical consumptions and use of reagents during the operation led to a total cost of 2 €/m^3 of digestate, while up to 4.2 €/m^3 considering personnel cost for assistant and depreciation charge. However, the income could be related to the savings regarding less transportation volume required (about 1 €/m^3 of digestate) and incomes related with ammonium sulfate trade (about 0.5 €m^3 of ammonia sulfate at 6-8% as N).

Chemical Phosphorus Precipitation from Industry

The DHV Crystalactor© was developed by DHV Consulting Engineers (The Netherlands) to remove calcium from drinking water. Later, this technology was used to remove other compounds, such as phosphate, from wastewater streams. This technology utilizes a cylindrical fluidized bed reactor to recover phosphorus by phosphate precipitation in which sand is used as seed material. Phosphorus can be recovered either by calcium phosphate precipitation or by struvite crystallization, which takes place over these sand grains (Giesen, 1999; Eggers, Dirkzwager, & Van der Honing, 1991). For calcium phosphates precipitation, $Ca(OH)_2$ solution is added to the precipitation system and the dosage is controlled by the measurement of operational pH. Efficient calcium phosphate crystallization requires an operational pH around 9. Most of phosphate recovery technologies are based on the same crystallization chemistry of the DHV Crystalactor© technology, but with some variation (e.g. in seeding materials).

Struvite Recovery from Industry

The full-scale facilities of struvite crystallization have the potential to produce a commercial product, which could be used in combination with fertilizers from mined phosphate. Struvite can be produced using different crystallization technologies. The technology chosen will likely be a determining factor in the quality of the produced struvite. The particle size of struvite may vary with the operating conditions and reactor configuration used. According to particle size, struvite can be divided into two categories: fine crystals and pellets. In order to obtain a product suitable for application to agricultural lands, struvite pellets must be produced. Struvite pellets are much easier to handle and to transport than fine crystals. Thus, the quality product determines the user-friendliness of struvite, and consequently it can influence the cost-effectiveness of struvite crystallization process. Up to date, the main technologies to recover phosphate by struvite crystallization at full-scale are DHV Crystalactor©, Unitika Phosnix© process, Ostara PEARL© process, Phospaq™ process, NuReSys© process and Multiform Harvest™ (Table 5). Currently, several full-scale facilities based on the aforementioned technologies have been developed in Europe. These facilities tend to be concentrated in certain countries: Belgium, The Netherlands, Germany and United Kingdom, and the struvite crystallization technologies implemented in these countries are: Ostara PEARL©, NuReSys© and Phospaq™.

The first applications of struvite crystallization at full-scale were implemented in Japan. The Unitika Phosnix© process is based on the struvite crystallization in a fluidized bed reactor (FBR), in which the crystallization of struvite is promoted by adding sodium hydroxide and magnesium hydroxide as alkali and magnesium sources, respectively. Additionally, struvite seed crystals are added to facilitate the phosphorus recovery by struvite crystallization (Ueno & Fuji, 2001). Another technology developed is the Ostara PEARL© process, which is based on the phosphorus crystallization using a two-phase fluidized bed reactor. This system is composed by a column comprising some sections. The diameter of the column increases stepwise between the sections. This technology uses magnesium chloride when required, and sodium hydroxide as magnesium and alkali sources to facilitate the struvite crystallization (Koch, Mavinic, Yonemitsu, & Britton, 2009). Like in the Unitika Phosnix© process, Ostara PEARL© process uses recycled struvite as seed material. The Phospaq™ process recovers phosphorus by struvite crystallization in a continuous stirred tank reactor (CSTR) aerated. In this technology struvite crystallization is facilitated by the increase of pH via stripping of carbon dioxide (CO_2) and the addition of magnesium oxide as magnesium source (Abma, Driessen, Haarhuis, & van Loosdrecht, 2010). This

technology removes biological degradable chemical oxygen demand (COD), phosphate and ammonium in the same reactor. Aeration provides optimal conditions for struvite crystallization and the oxygen for the biological conversion of COD. The NuReSys© process is based on two CSTRs: a stripping reactor and a stirred crystallization reactor, in which magnesium chloride and sodium hydroxide are added to promote struvite crystallization (Moerman, Carballa, Vandekerckhove, Derycked, & Verstraete, 2009). Finally, Multiform Harvest™ uses a cone-shaped fluidize-bed crystallizer for struvite crystallization. Sodium hydroxide and magnesium chloride are added to produce struvite crystals from a stream with high concentrations of nitrogen and phosphorous (Bowers & Westerman, 2005).

CONCLUSION

This chapter presents and discusses the main options for nutrient management in industrial wastewater treatment, including the parameters to optimize the processes and the different technology readiness levels. Phosphorus recovery should always be pursued in order to recycle a critical raw material. Struvite recovery is a robust technology which optimization is mainly related to the reactor configuration and magnesium source. However, other possible technologies for P recovery, including enhanced biological P removal or novel ion exchange resins should be promoted especially for low concentrated streams. On the other hand, nitrogen recovery should be evaluated case by case on the basis of its economic and environmental sustainability. Ammonia stripping and recovery as ammonium sulfate is the most traditional and reliable system, but it could be limited by the legislation restriction. If the biological process can be applied, nitrogen deammonification and its recovery via Haber-Bosh process are energetically favorable. In the case of biological processes, the via-nitrite pathway represents an advance over conventional activated sludge systems, and the best carbon source may enable the optimization of denitritation with the concurrent anoxic phosphorus uptake.

KEY TERMS AND DEFINITIONS

Aerobic Process: Biological process in which, microorganisms depend on oxygen for their metabolic activities.

Anaerobic Process: Biological process that occur in the absence of any form of oxygen available for metabolic activities of microorganisms.

Anoxic Process: Biological process, that occur in the absence of molecular gaseous oxygen, but other forms of oxygen can be present and they are used for metabolic activities of microorganisms.

Biodegradable: A substance that can be broken down by biological processes (e.g. by bacteria, fungi, and other microorganisms) under aerobic, anoxic and/or anaerobic conditions.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Biological Nutrient Removal (BNR) Processes: An adapted process of the conventional activated sludge process where anaerobic and anoxic zones are included to biological reactor to create the conditions in which microorganisms are able to remove carbon, nitrogen and phosphorus.

Chemical Precipitation: A chemical reaction, in which two or more compounds react to form a precipitate, resulting in the formation of a separable solid substance from a solution.

Nutrient: Any element that is essential for the growth of animals, plants and humans. Usually nitrogen and phosphorus in wastewater streams.

Nutrient Recovery: Recovery of nutrients from wastewater streams through physico-chemical processes (e.g. precipitation) or other biological technologies.

Struvite: A magnesium ammonium phosphate salt ($MgNH_4PO_4 \bullet 6H_2O$) that usually precipitates from wastewater with high concentrations of phosphorus. This precipitate is a crystalline substance that may be used in agriculture as slow release fertilizer.

Chapter 6
Introduction of Environmental Materials

Takaomi Kobayashi
Nagaoka University of Technology, Japan

ABSTRACT

Advances in environmental materials are described especially concerning about utilization of natural source and their waste, for example biomass and their re-uses. They strongly support development to sustainable society. So, these classify and demonstrate environmental technologies, which strongly contribute to overcome pollution environment for the purpose of sustainable society. In view point of green chemistry and the related technologies to representative biomasses and inorganic wastes are applying for advanced functional materials. Since biomass and inorganic wastes are very interesting candidates for regenerated materials, it is very meaningful to understand and attention to environmentally and friendly materials and technologies. This is because that an increasing environmental concerns to sustainability.

INTRODUCTION

Chemistry brings comfort in modern life. For example, clothing is made with a synthetic fiber, and dye of various clothing is a product of the chemical industry. Computers have each outside of home electric appliances made with plastic and metal. These are mostly made from oil and a mineral through many chemical steps. So, chemistry greatly contributes to securing of richness of the human and supports to construct the high civilization. On the other hand, pollution of air, water and soil increases as industry becomes active. The pollution has influenced human health and been injured. However, many developed countries including Japan have overcome the pollution now, and the global environment has been improved by green technologies. However, the problem of the global environment was gradually actualized. Resources and the acceleration of the energy consumption lead to anxiety of earth resources. Furthermore, the consumption of a large quantity of fossil fuel causes the sharp increases of carbon dioxide and soot particles such as particle pollution (PM2.5) in atmosphere (Liu, Hsu, Lee, Ye, Zheng, Liu, Li, & Cui, 2015). When the growth of the human reaches the limit by the resources drying up and environmental aggravation, the report “The limit grow” of 1972, in particular, Club of Rome, sounds an alarm bell

(Meadows, Meadows, Randers, & Behrens,1972). Therefore, this has reviewed the development of the economy that the earth is infinite. This also comments that to keep world balance is important. In addition, the toxic substance has an influence on the people and gives uneasiness in the society. For sustainable development, the planethood has various actions and global environment improvement has been directed to deeply consider it, for example, by United Nations Environment Programme (UNEP) (UNEP, 2014) In late 2014 world climate change was already affecting many contents in global warming. This gives strong impact to food security and therefore, emphasizes the chemistry and the related technology with the global community. It is desirable to develop the consideration for environment conservation, since green chemistry can solve problems in energy, a material, an environmental pollution to pull sustained society. In other words, because the green chemistry strongly relates to eco-friendly manufacturing, the harmony with environment and the process adapted to technical development leads to development of clean technology (Williams, 2001; Andrews, Brecombe, Jikel, & Brianreid, 2004). Recently, therefore, attention has been increasingly devoted to bio-based environmentally and friendly materials because of increasing environmental concerns related to sustainability.

BACKGROUND

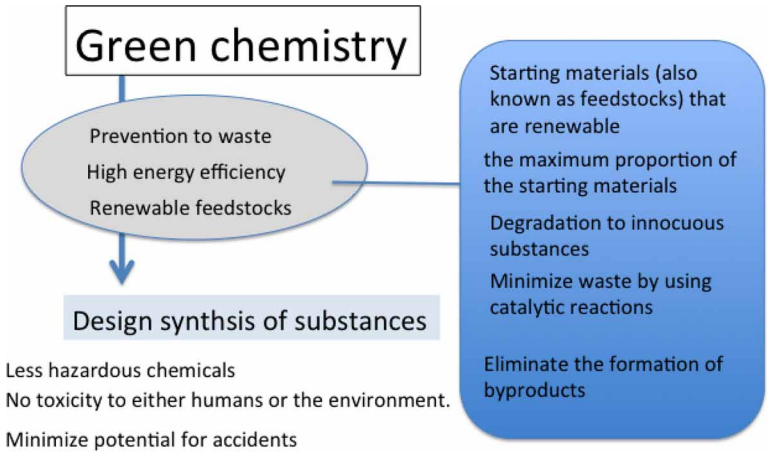
As already mentioned, people should recognize a limit of the growth of the global environment. The coexistence of global environmental conservation and the industrial activation becomes extremely important. This is because that, as one of example, the danger signals such as the frequent abnormal weather strongly suggest an importance in sustainable society. From such a background, the practice of the concept called “green” becomes required in a chemical technique and materials development for the sustainable society. In the minimum waste and the recycling, people should bring highly efficient environmental symbiosis in energy technology, reuse of the biomass waste and the switch to a re-used material and to the remediation technology, which is applied to the earth pollution for the conservation of our environment. Therefore, the substantial use is urgent in this century. In this chapter, an action to the sustainable society and green chemistry is introduced in the points of view of the green technology using about biomass and waste re-utilization for environment materials.

Green Chemistry for Sustainably Renewable Sources

Sustainable means operating with a long-term mindset that includes responsibly maximizing our use of renewable resources. So one of the goal of sustainability is for renewable resource management (Rosenberg, Fogarty, Sissenwine, Beddington, & Shepherd, 1993). To provide both positive examples of sustainable resource use and lessons for future improvements in materials, a renewable resource is mainly an organic natural resource and can replenish to overcome usage and consumption. In such a background, United States Environmental Protection Agency (EPA) proposed green chemistry in 1994. In green chemistry, people design chemical products and processes for reduction or elimination of the use or generation of hazardous substances. Now, green chemistry strongly relates with the product life cycle by approaching its design, manufacture, use, and ultimate disposal. So it is also known as sustainable chemistry. The rapid development of new chemical technologies and the vast number of new chemical products in the last decades turned the attention of environmentalists to remedial actions for the negative impacts. Two decades after the implementation of EPA, the Pollution Prevention Act (1990) was created

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. Green chemistry



to enforce eco-friendly strategies. The EPA defines green chemistry as following principles (Figure 1) (EPA,1990); Prevention of pollution at the molecular level, application to all areas of chemistry, not a single discipline of chemistry, innovation of scientific solutions to real-world environmental problems, results in source reduction because it prevents the generation of pollution, reduction of the negative impacts of chemical products for better reflection on human health and the environment, sometimes elimination of hazard from existing products and processes, designs of chemical products and processes to reduce their intrinsic hazards.

What is different point in green chemistry and general remediation process unlike cleaning up pollution? The remediation processes involve treating waste streams or cleanup of environmental spills and other releases. So remediation mainly relates to removal process for hazardous materials from the environment. Green chemistry, on the other hand, keeps the hazardous materials out of the environment for purpose of clean up environmental contaminants. Here, this needs technology to remove pollutant. The green chemistry technology also includes remediation technology, but also relates to non-disposable technology. This contains that processes prevent waste, high energy efficiency and effective uses of renewable feedstocks and then can produce less hazardous chemicals with no toxicity to either humans or the environment. Also this minimizes potential for accidents with explosions, fires, and releases chemicals to the environment or less byproducts in the reaction. In addition these processes should have that the final product contains the maximum proportion of the renewable starting materials. To degrade after use to innocuous substances and to minimize waste in reaction, catalytic reactions without stoichiometric reagents are preferred for the prevention of chemical accumulation in the environment. Green chemistry may change all these negative impacts and through design, innovation and green processes to restore the planet's sustainable development.

To implement sustainable practices, green chemistry technologies can modify their practices in ways that provide better and cleaner tomorrow. The technology aims to be innovative to restore, protect and ensure the sustainability of water resources and also identifies the renewable energy potential of current and formerly contaminated lands. The next bre1akout to a solution of environmental problems is beneficial to improve environmental protection and human health.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

ENVIRONMENTAL MATERIALS IN SUSTAINABILITY

In such situation, now, materials science and technology intersects with the fields of environmental science and sustainability in green chemistry ways. Environmental materials are related with challenging a serious environmental problem such as an energy problem and the water pollution in a various materials technology. Both developing new materials and conducting basic science research to pollution and hazardous chemicals are included as environmental prevention technologies (Table 1). To date, most sustainability or green technologies have attempted to quantify sustainable materials and focused primarily on energy, material, and water conservation. The sustainable materials also cover lower regeneration cost and energy and long term uses for environmentally friendly materials.

Table 1. Prevention technologies for earth environment

Classification	Development Theme	Specific Examples	Materials & Technologies
Energy	Liquid fuel	Biofuel Biodiesel	Alcohol fermentation Vegetable oil Fats Peterorium
		Bioalchol	Methanol Ethanol Buthanol
	Gaseous fuel	Hydrogen	Photocatalysis Electro-decomposition of water
		Methane	Fermentation
	Solid fuel	Biomass	Tree Bagasse Coal
		Batteries Fuel cell	Electricity Hydrogen Methane Alchole
Regeneration of biomass and mine resources	Biomass	Biopolymer	Polysaccharide Protein Nucleic acid Natural rubber
		Bioplastics	Polyglycolic acid Polylactic acid
	Mine	Heavy metals	Cadmium Lead, Zinc
		Ash	Geopolymer
Environmental remediation technology	Air	Filter Adsorbents	Gas adsorbents
	Water	Chemical precipitation,	Precipitation induced by the addition of an alkali, sulfide, coagulant, or other reagent.
		Chemical stabilization	Using phosphate for treatment of solid mining wastes and reducing divalent heavy metals.
		Electrocoagulation	Technologies using an electrical current that coagulates organic constituents and suspended solids in water.
		Biochemical reactors	Microorganisms to transform contaminants in the treated water to another chemical and to increase pH; Sulfate reduction to sulfide and bicarbonate and heavy metal precipitation in high pH.
		Pressure-driven membrane separation	Thin barrier that permits selective mass transport of solutes and solvents across the barrier; Reverse osmosis, ultrafiltration and microfiltration.
		Ion exchange	Interchange or exchange of ions between a solid media and water containing ion; Various resins and peat or zeolites.
	Soil	Biosolids	Using organic phosphate to eliminate heavy metals
		Bioremediation	Controlling biological processes to reduce the contaminants of concern to target levels of heavy metals or fuel oils.
		Soil chemical oxidation	Treatment of chemical oxidation to reduction of contaminants.
		Thermal desorption	Heating certain contaminants to reduce their concentrations

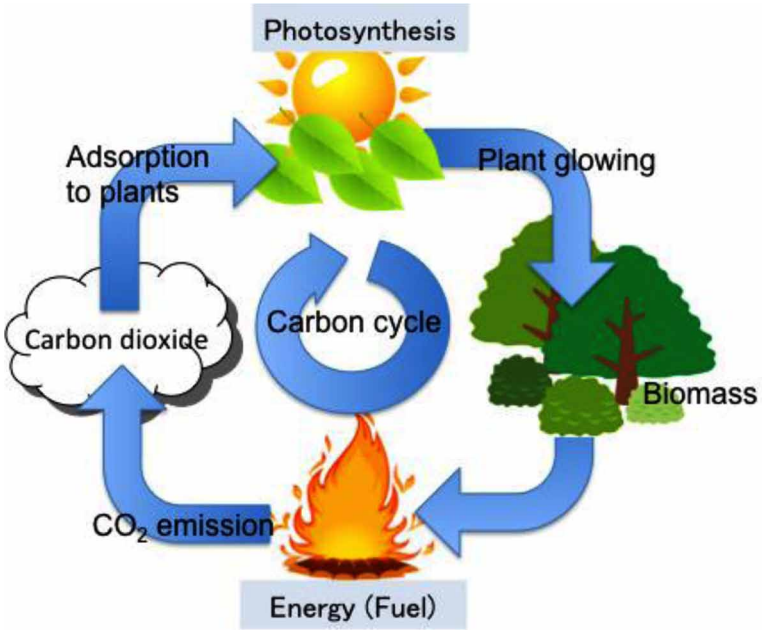
EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

There is a way of thinking called the carbon neutral. This is based on the biomass being generated by photosynthesis with CO_2 as raw materials. So, there is an idea that the atmospheric CO_2 is not to increase even if biomass is used to burn fuel derived from biomass. This is expressed for the Carbon neutral; the CO_2 income = the expenditure zero in the atmosphere, as seen in Figure 2 for carbon cycle of biomass. However, the problem is not easy. The biomass fuel uses fossil fuel from seeding into crops cultivation, crop work, fermentation, manufacturing process with the chemical processing. Therefore, when additional injection of fossil fuel is performed and then the amount of energy is more than that of the last fuel, the process cannot be said as carbon neutral. However, although the burned carbon is returned to the atmosphere as CO_2, these processes have happened for plants on earth as the carbon cycle.

The representative trial is biofuel. The production of the biofuel is provided by converting biomass to fuel and the biofuel is available as a substitute of gasoline and the diesel. Generally, the bioethanol is made more by the fermentation of the saccharide (Bajiai, 2013; Goldemberg, 2007; Yaman, 2004; Chavez-Guerrero,& Hinojosa, 2010). The alcohol fermentation is processed, for example, by yeast to the sugarcane bagasse containing saccharide. Through this, mono-saccharides is able to be converted into ethanol and carbon dioxide; $C_6H_{12}O_6 \rightarrow 2C_2H_5OH + CO_2$

On the other hand, oils and fats are the matters synthesized with the long chain fatty acid of 2-3 molecules to form ester combination of three values glycerin. The oils and fats are used generally by edible oil or butter. The oil and fat itself has high viscosity and is not suitable for an internal combustion engine, but, it becomes the fuel of the diesel engine with ester glyceride of mono-substitute of long chain molecules or the methanol ester. Therefore, the organic matter provided with exchange reaction of methanol with rapeseed oil or used edible oil is used for biodiesel fuel, which has low enough viscosity to allow proper atomization of the fuel. These biofuels have a characteristic not to include sulfur. However, the fossil fuel includes sulfur derived from creatures like an amino acid such as methionine and cysteine

Figure 2. Carbon cycle scheme of biomass



EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

constituting protein. When the fuel is burned, sulfur of the fuel becomes the sulphur dioxide, SO_2. The SO_2 released in the atmosphere finally becomes the sulfuric acid and causes acid rain in earth environment. Therefore, the biofuel without the problem attracted attention from the side of the environmental conservation. After oil crisis of the 1970s, Brazil was considered to have the world's first sustainable biofuels economy. As the biofuel industry leader, ethanol fuel program is based on the most efficient agricultural technology in this country (Hofsetz & Silva, 2012), especially for sugarcane cultivation. Its sugarcane ethanol is the most successful alternative fuel. Since 1976 the government made it mandatory to blend anhydrous ethanol with gasoline, fluctuating is between 10% to 22%. Also, alternative fuels are known to including biodiesel, bioalcohol (methanol, ethanol, and butanol), chemically stored electricity (batteries and fuel cells), hydrogen, non-fossil methane, non-fossil natural gas, vegetable oil, and other biomass sources.

In addition to the biofuel, another representative group is biopolymer and bio-plastic (Pilla, 2011). Actually, there are various kinds of nature macromolecules in the natural world. A representative macromolecule is polysaccharide, protein and nucleic acid (Kalia, 2011). For instance, glucose forms α-1,4 bond of the starch which is kind of polysaccharides. Starch is divided into amylose and amylopectin by the structure. These are soluble in warm water and are decomposed by an enzyme in the body. Also, glucose performs α-1,4 bond of cellulose and the chief ingredient constitutes the cell wall of the plant (Brett & Waldron,1990). The polymeric chains interact with hydrogen bond and form fibrous fibers. Cellulose is relatively rigid and insoluble in water. The human cannot digest cellulose due to the absence of hydrolysis enzyme in our body. Furthermore, natural rubber (NR) is the candidate in gum tree growing in the tropics and 1,4-isoprene, $CH_2=C(CH_3)CH=CH_2$, polymerizes, as NR hardens the sap of the tree. Latex is existed as water dispersed organic component in the sap. This is a material composed primarily of cis-polyisoprene $[(C_5H_8)n]$. After the latex is refined and dried, the aggregated product is NR which has elasticity property and has been used for a tire, elastic string and ball. Protein is polymer condensed between the carboxylic acid and amino groups in amino acid molecule. The amide linkage to form here is called peptide bond in particular and belongs to polypeptide;-C(=O)- N(H)-. The peptide structure of protein molecules forms hydrogen bonding in the same molecules nearby relatively peptide and takes spiral structure (α helix) (Figure 3). Also, hydrogen bonding between the molecules next to each other can take plane structure (β sheet). The former spiral structure body is fully elastic and the latter plane structure can give superior mechanical strength.

On the other hand, there is biomass plastic based on idea of the carbon neutral. The representative plastic is polyester-based material of polyglycolic acid or polylactic acid. These have already came to be industrialized and are plastics made from creature resources (biomass) made from corn or sugarcane with much content of starch and the sugar mainly. A definition of these materials is to include a polymer derived from the organic resources which can reproduce as raw material and provided by synthesizing it chemically or biologically. In other words, the renewable resources of corn and sugarcane are used for raw materials of the plastic. Therefore, there is not influence for a rise in density of the atmospheric greenhouse gas and is less cause of the global warming, even if it returns to carbon dioxide by combustion after use. For these carbon neutral materials, following future is found; Even if burn and discard it, the income and expenditure of carbon dioxide is zero, When it burns up, heat of combustion is low, but no dioxin occurs. As seen in Figure 4, polylactic acid shows hydrolysis to lactic acid and then biodegradates to H_2O and CO_2 (Steavens, 2002; Ebnesajjsd, 2013). Litter is a problem with a very negative social and environmental impact. As an environmentally-friendly solution, one way to tackle this problem is to use biodegradable plastics.

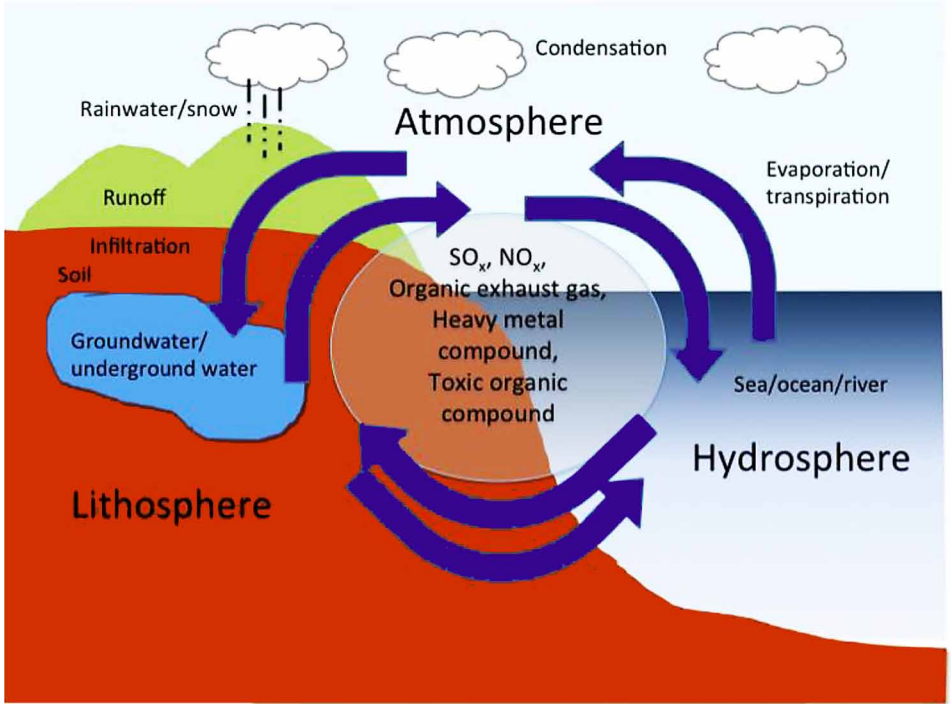
Environmental Green Technology

Environmental technologies, which have been developed in pollutant decontamination for the earth, incorporates environmental materials. The contribution of environmental materials to quality of the water purification and the detection of the pollutant is in particular large. The water is a resource circulating universally because of supporting our ecosystem. Therefore, it has deep relation to environment, industry and life. As shown in Figure 5, the water circulates in various forms through earth environment, as the evaporation, condensation, raining or snowing, running off, infiltration and flowing occur in the natural world. Chemicals (SO_x, NO_x, organic exhaust gas, heavy metal compound, and toxic organic compound) are carried through the medium of water and fixed to the soil and hydrosphere. In the water cycle, the

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 5. Water cycle with contaminants through hydrosphere-lithosphere-atmosphere



animals, fishes and plants adsorb and immobilize the chemicals in their body. Furthermore, heavy metal may dissolve by acid rain. In addition, the acid rain acidifies a river and wetlands, affects the habitation of the creature and causes deterioration of the cultural heritage. In the present when industry developed, it becomes the problem source of water pollution such as organic matter or the heavy metal.

Therefore, recovery process for decontamination to their pollutant is needed by introduction of functional adsorbents. For example, after the Great East Japan Earthquake and Tsunami damaged the Fukushima Daiichi Nuclear Power Plant during and after March 11, 2011, long-term radiation contamination ensued, presenting severe difficulties to human life and the local environment (Morino, Ohara, Watanabe, Hayashi, & Nishizawa, 2013). The neighboring inhabitants within a radius of 30km are evacuated forcibly in now when 5 years pass for the accident. It is felt uneasy about that diffusion of the radiocesium through the medium of the water from the soil and the forest polluted by emission. Figure 6 shows adsorption materials that adsorb radiocesium efficiently are developed to prevent this in Tomioka town between 2013 and 2014 (Kobayashi, Ohshiro, Nakamoto & Uchida, 2016). The porous composite fibers showed decontamination to low-level Cs in the flowing river, preventing its flow further downstream by the diffusion of radioactive Cs through water contaminant in natural environments.

ENVIRONMENTAL MATERIALS IN SUSTAINABILITY

Agro-Industrial Biomass Wastes and Biopolymers

As many global issues start to influent our daily life, people begin to focus attention to renewable resources mainly included in agricultural production. In recent years, there have been many studies on the effective utilization of agro-industrial residues including sugarcane bagasse, cassava bagasse, rice husk, wheat straw and coconut fiber, etc (Pandey, Soccol, Nigam, & Soccol, 2000; Ashori & Nourbakhsh, 2010). It is currently used mainly as an biofuel for power and heat generation (Goldemberg, 2007;Yaman, 2004; Jorapur, & Rajvanshi, 1997) and in the manufacture of pulp for paper. However, eco-profile studies measure the re-generation of the waste bagasse and other inputs require to make a product obtained from the extraction process or harvesting of raw plant materials for eco-friendly, recyclable, advanced materials, especially for cellulose. The natural plant polymer, cellulose, originated from bagasse wastes is utilized for the regeneration process to cellulose (Kobayashi, 2015; Tovar-Carrillo, Tagaya, & Kobayashi, 2013). The cellulose fibrous fibers are sustainable materials in plants and have numerous functional possibilities, as expected to be developed into a broad range of applications, especially with the demand for environmentally friendly and biocompatible products.

Among them, sugarcane bagasse is generated as a biomass fibrous residue in extraction process of sugar juice from the sugarcane (Chandel, daSilva, Carvalho, & Singh, 2012). The sugarcane was produced about 1.69×10^3 million tons in the world in 2010 and generally 280 kg of humid bagasse is generated from 1 ton of sugarcane. Therefore, this is one of the largest cellulosic agro-industrial by-products. At the present time, the most of sugarcane bagasse is used as manure, feedstock and fuel of the boiler in the sugar industry (Hofsetz, & Silva, 2012). Several attempts for potentially renewable and sustainable have been made to utilize sugarcane bagasse as a low material. These contain ethanol production by hydrolysis and fermentation, synthesis of cellulose derivatives (Jorapur, & Rajvanshi, 1997) and also are converted to functional materials (Nakasone, & Kobayashi, 2016; Saucedo-luna, Castro-Montoya, Campos-Garcia, & Rico, 2010; Nakasone, Ikematsu, & Kobayashi, 2016). Also, agave tequilana weber azul, which is an economically important plant cultivated in central Mexico for the production of tequila (Goldemberg, 2007;Yaman 2004) and the bagasse is a byproduct material consisting of the cellulose tissue of the blue agave after extraction of the sap. More than 800,000 tons of agave bagasse has been

Figure 7. Pictures in Mexico, Guanajuato, for the production of tequila and agave bagasse. The agave pinier (left)is steamed (middle) and bagasse (right) is obtained after extraction process of sugar juice

disposed as a waste product per year (Figure 7). The disposal becomes similar problem and gives attention with regard to its regeneration. It is well known that cellulose is the most abundant natural polymer consisting of β-glucose in the nature and forms about half to one-third of plant tissues (Reid,1997). The cellulose and its derivatives have attracted many researchers due to their unique properties such as low toxicity, biocompatibility and biodegradability (Kobayashi, 2015; Kobayashi, Tovar-Carrillo & Tagaya, 2015). Several research studies have been performed to offer an alternative use for their bagasse waste, but, until now, none has offered us a final solution, due to the necessity for development of new technologies to solve this problem.

Mine Wastes for Environmental Materials

Mine reuse often brings economic, environmental, and social benefits to our communities. It also may serve as a catalyst for expediting environmental risk reduction, as EPA recognizes (EPA,1990). The economical matter strongly relates with industry and the environmental one with pollution decontaminant. For example, Interstate technology & regulatory council in USA repots that heavy metal impacts in the world, primary including cadmium, lead, and zinc (ITRC, 2010; Broadbent, 1998). The specific criteria for the reuse are for lead (15 μg/L) and cadmium (5 μg/L) in potential drinking water sources by the National Primary Drinking water standards and freshwater chronic National Recommended Water Quality Criterion for zinc of 120 μg/L. The re-uses and reprocessing technologies are effective for remediation of solid mining wastes. Also, there is attractive technology to turning mining waste into beneficial products. This can decrease human and ecological exposure to contaminated materials. The toxic heavy metal contamination, for example, can be remediated by one or more of the technologies. Their remediation technologies generally refer to chemical precipitation, chemical stabilization, electrocoagulation, biochemical reactors, pressure-driven membrane separation, permeable reactive barrier. Among them, efficient removal and recovery of toxic heavy metals from industrial wastewater is a major challenge (Gaballah & Kilbertus,1998; Saeed, Akhter, & Iqbal, 2005). Furthermore, reutilization of solid wastes of coal combustion ashes is reported (White & Stegemann, 2001; Chindaprasirt, 2009) and reused to adsorbents of gaseous waste (Suchiai, Shizaka, Nakamura, Ueno, & Hattori,1996) and heavy metals (Sekhar & Chakravarthy, 2001) and also to glass ceramic (Strad, 1986) and concreat materials (Onutai, Sirithan, Thavorniti, & Kobayashi, 2015). Geopolymers are also sustainable materials, which can be prepared from mine and ash (Davidovits, 2011), as mentioned below.

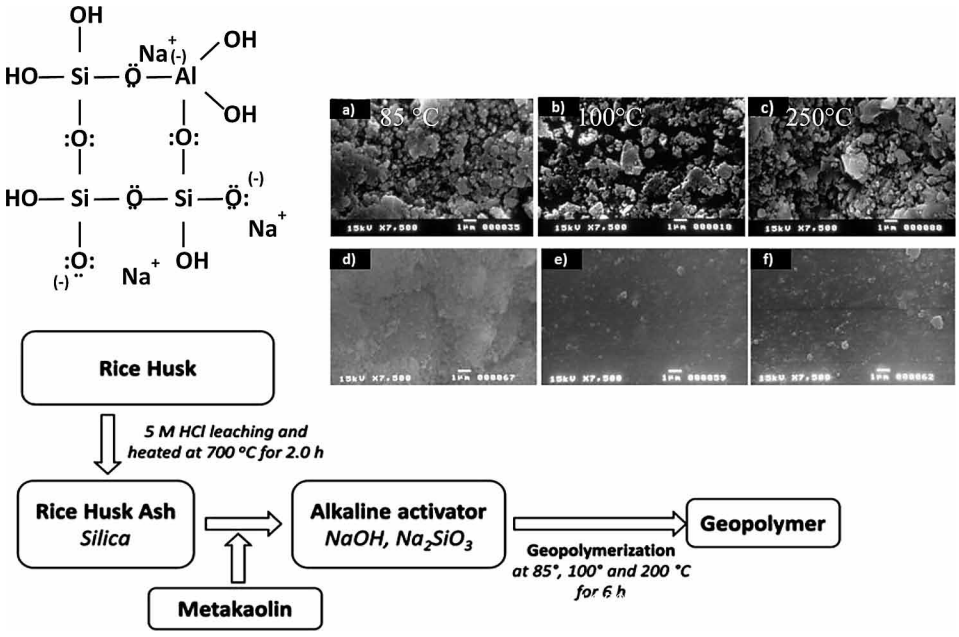
EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

For example, the presence of the toxic metals generated by mineral processing in industries causes a major hazard to the water environment (Matis, Zouboulis, & Lazaridis,1998). Thus, serious regulations are required to establish in many countries to remove effectively the toxic metal ions from the waste waters prior to discharge into natural environment. So, the adsorption techniques present excellent qualities for treating industrial waste waters containing metal ions, when solid adsorbents are employed for recovery of metal ions as lead, copper, cadmium, nickel and zinc (Brauckmann, 1990: Cheng, Lee, Ko, Ueng, & Yang, 2012: Lopez, Sugita, & Kobayashi, 2014). Geopolymers are alkali activated aluminosilicates, consisting of a solid reactive component that contains SiO_2 and Al_2O_3 (Komnitsas & Zaharaki, 2007; Ahmaruzzaman, 2010). By using rice husk, fly ashes, active clays, pozzolanas and slags, decontamination of heavy metal ions were reported as geopolymer adsorbents (Li, Wang, & Zhu, 2006).

GREEN TECHNOLOGIES LEADING FOR SUSTAINABLE SOCIETY

Scientific and technological change brought the human a great benefit until now. By various kinds of harmful chemical substances released abundantly to environment, the various issue of environmental pollution is taking place. To raise the possibility that humanity can continue soundly and to succeed a global environment in a future generation, conservation technologies are necessary. It is essential to purify and have maintenance of environments of air, water and soil. To this end, green technology can prevent the diffusion circulation of the pollutant, causing the environmental damage. The goal is the global environment construction, where people can live under sustainable energy society. Also, the cyclically used technology conserves resources of the earth. The green technique can prevent the cycle.

Figure 8. Protocol of geopolymerization synthesis with rice husk and metakaolin
Source: Lopez, Sugita, Tagaya, & Kobayashi, 2014



EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

As seen in Figure 5 diffusion circulation of the pollutants, SOx, NOx, hazardous organic chemicals and heavy metal ion takes part in the environmental purification especially in the developed country. The green technology has the following evaluation guidelines:

1. Technology to reduce consumption resources and energy,
2. To produce energy,
3. To make use of unused resources in,
4. To reduce environmental load,
5. To make quality of life and
6. To make economic competitiveness.

The critical technology of the materials enables energy saving. New energy, resource saving recycling, and living environment risk reduction is summarized in Table 2. These technical examples are followed; biodegradable polymers as an environmental ecad chemistry product, a compact detergent as a life-related article, a energy saving chemical products, a quickness diagnosis technology with a small size sensor, the high-performance material in eco-tire, health and medical care with the field of diagnosis. Among others, carbon fibers made of polyacrylonitrile is mainstream and are light weight and high strength in the rainforced materials. These are used for a aeroplane, a car, a golf club, engineering works, construction materials or an inquiry material widely.

Table 2. Lists of critical technologies of the field of materials

Classification	Development Theme	Specific Examples
Energy saving	High strength, lightweight resin composite materials	CFRP, carbon / cellulose nano fiber
	Polyolefin having super heat-resistant, and high strength	Post-metallocene catalysts
	Metal substitute super lightweight materials by the organic inorganic hybrid material	Metal-replaced boad
	Materials having a low friction surface and lubrication	Carbon materials, surface coating, nanolubrication materials
	semiconductor for light source materials	Next-generation LED, organic electroluminescence, inorganic EL
	Heat train conversion materials for the low temperature waste	Peltier element, polymer materials, organic no plane based materials
	high-performance decicant air conditioning by high temperature adsorbent materials	Energy saving de-humidification air conditioner

Table 2. Continued

Classification	Development Theme	Specific Examples
New energy	Polymer actuator	Micromachine, sensor for the biomaterial
	Super high accumulation of electricity type rechargeable battery materials	Original cathode active substance, carbon electrode, electrolyte, separator (film)
	New battery materials including the lithium substitute	Lightweight small batteries
	Organic radical battery, redox polymer materials	Thin and light devices
	Electrolyte for the high accumulation of electricity	High performance ionic liquid
	High accumulation of electricity energy materials for the movement / fixation power supply	New solid electrolyte, electrolyte membrane, ionic liquid
	New materials for the fuel cell	Pt substitute electrode, fluorine substitute film, CO reduction catalyst, H_2 production device
	Dye sensitization type solar battery materials	Titania dye sensitization type, plastic board type
	Thin film silicon type solar battery materials	Amorphous; crystalline
	Organic semiconduction type solar battery materials	P-type semiconductor polymer, n type fullerene
	High performance organic semiconductor materials	Fullerene type new materials
Resource saving recycling	Substitute materials for the fluorine-based functional chemicals	Refrigerant, blowing agent, jet agent, insulating material, glass for the semiconductor / liquid crystal
	Substitute materials of the laminated film, easy recycling materials	Single-like layer film
	Easy recycling and decomposable adheisive, self-detachment material	Non-epoxy adheisives
	Rare metal, noble metal substitute materials	Ni,Co,Mo,W,Li,In, rare earth elements, Ta, platinum group, boron
	Non-organic solvent-based lithography and patterning technology	Liquid hardening resin nano imprint methods
Life environment risk reduction	Halogen, phosphorus free new incombustible materials	Nanoparticles composite, carbonization layer formation, high density filler composites
	Complete water-based paints	De-VOC (volatile organic compounds)
	Non-VOC component building materials for the residence environment	Material-related industry for building and the residence materials
	Non-VOC component adhesive, ink	Public welfare, assembling processing-related industry
	Safe insect killing, insect repellent, mold agent-proof, sanitization	Photocatalyst, nanocatalytic model antibiotics
	Security deodorization, deodorant materials	Nanocatalytic model deodorant, nanopore type deodorant
	Easy biodegradability surfactant	Natural sourced soap and detergent
	Future model cosmetics materials using a nanotechnique and an interface technique	Anti-aging function, safety
	High functional foods wrapping materials	Materials for detection of cold insulation, oxidization prevention, dehydration, humidity retention, shading and, abnormality
	Self-repairing materials	Organic-inorganic hybrid, plastic
	Insulation materials for sound, heat and electromagnetic wave	New glass, new building materials, insulation paint

CONCLUSION

This chapter accounts environmental materials in the point of view of green chemistry and technology. Sustainability in eco-friendly materials and the related technologies for biomass resource is described especially for biomass fuel, biomass waste and inorganic waste. Also, trials of pollution problems in earth are reviewed in this chapter. As prevention techniques applied, it is described that green technology is suitable for the future sustainable society.

KEY TERMS AND DEFINITIONS

Biomass: In general, this means plant as the source of supply of the alternative energy. In this chapter, supply to alternative energy and material source of plants.

Biofuel: Fuels derived from biomass; any matter derived from plants or animals.

Biopolymer: Polymers produced by living organisms.

Carbon Neutral: Achievement of a product, service or event being equal to zero, as net greenhouse gas emissions of an organization to earth.

Environmental Material: Materials applied to a serious environmental problem such as an energy problem and the water pollution in a various materials technology.

Geopolymer: Typically inorganic ceramic materials having non-crystalline amorphous networks of silico-oxide (-Si-O-Si-O-), silico-aluminate (-Si-O-Al-O-), ferro-silico-aluminate (-Fe-O-Si-O-Al-O-) and alumino-phosphate (-Al-O-P-O-) by geopolymerization.

Green Chemistry: Chemistry related science to solve problems in energy, a material, an environmental pollution and for development of sustained society.

Green Technology: Technology for clean and sustainable communities.

Remediation: The following technologies, isolation, immobilization, toxicity reduction, separation and extraction remediate contaminant level in soil, water and air.

Sustainable Society: Ensuring the health and vitality of human life and culture and of nature's capital, for present and future generations.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Toxic Heavy Metal: Heavy metals, particularly cadmium, mercury, lead and arsenic has potential toxicity, especially in environmental contexts. Additionally, the major public concern of other examples includes manganese, chromium, cobalt, nickel, copper, zinc, selenium, silver, antimony and thallium.

Water Cycle: Hydrological cycle occurs continuously in the movement of water in earth through atmosphere, hydrosphere and lithosphere. When water moves, it goes through different phases of liquid, ice and vapor phases.

Chapter 7
Introduction to Leachate Treatment

Amin Mojiri
Shanghai Jiao Tong University, China

Siti Fatihah Binti Ramli
Universiti Sains Malaysia, Malaysia

Wan Izatul Saadiah Binti Wan Kamar
Universiti Sains Malaysia, Malaysia

ABSTRACT

Leachate is created while water penetrates through the waste in a landfill, carrying some forms of pollutants. The goal of this chapter is the introduction to leachate treatment. Biological, physical, and chemical treatments of leachate are the most common methods. The biological techniques in leachate treatment are studied. The physical-chemical ways for landfill leachate treatment like chemical precipitation, chemical oxidation, coagulation–flocculation, membrane filtration, ion exchange, adsorption and electrochemical treatment are studied. The landfill leachate properties, technical applicability and constraints, effluent discharge alternatives, cost-effectiveness, regulatory requirements and environmental impact are important factors for selection of the most suitable treatment technique for landfill leachate treatment.

INTRODUCTION

The rapid growth in volume and forms of solid and hazardous wastes as a result of continuous economic development, industrialization, and urbanization is an increasing problem faced by domestic and local governments in ensuring an efficient and sustainable waste management (Mojiri, 2014). Municipal Solid Waste (MSW) has continued to be a major problem in many nations of the world. MSW has gradually become a threat to the environment of developing countries as they progressively move towards industrialization. MSW has become one of the most serious environmental challenges facing many cities in the country (Oloruntade et al., 2013). MSW management is an important aspect of urban planning and development.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

In 2006, the estimated total volume of MSW generated internationally reached 2.02 billion tons, indicating a 7% annual rise since 2003. Between 2007 and 2011, the rise in universal generation of urban waste was estimated at 37.3%, equivalent to an increase of approximately 8% per year (UNEP, 2009).

In most countries, sanitary landfills are a common means of solid waste disposal. Although this method has numerous benefits, one of its drawbacks is leachate production, which must be managed properly. Without proper treatment, landfill leachate greatly increases water pollution as it can penetrate through soil and subsoil. Therefore, the levels of hazardous components in leachate should comply with discharge standards before releasing into landfills to avoid pollution of water sources and to prevent acute and chronic toxicity (Aziz et al., 2011sa). Leachate is created when water penetrates into landfill waste, carrying with it certain forms of pollutants, such as ammoniacal nitrogen (NH_3–N), chemical oxygen demand (COD), color, biological oxygen demand (BOD_5), suspended solids, and metals. Leachate composition depends on deposited waste, landfill age, site hydrology, landfill operation, and landfill type. High concentrations of suspended solids, BOD_5, COD, NH_3–N, and metals are usually present in leachate (Foul et al., 2009). Landfill leachate treatment methods depend on leachate composition, landfill age, and site hydrology, among other factors. The main applicable methods of landfill leachate treatment contain physical/chemical and biological treatment methods. Typically, combinations of physical, chemical, and biological techniques are applied for landfill leachate treatment because of the difficulty in obtaining satisfactory treatment efficiencies by a single method (Aziz, 2011).

BIOLOGICAL TREATMENT

Biological treatments include aerobic treatments, anaerobic treatments, and phytoremedation.

Aerobic Treatment

The word "aerobic" refers to the characteristic of being in the presence of air, which usually implies being in the presence of oxygen. Thus, aerobic treatment methods are performed in the presence of air and utilize microorganisms called "aerobes," which utilize molecular/free oxygen to assimilate organic impurities; that is, aerobes convert these impurities into carbon dioxide, water, and biomass (Mittal, 2011).

Membrane Bioreactor (MBR)

The MBR technique is the combination of activated sludge sewage treatment and microfiltration (MF) or ultrafiltration (UF) membranes, with pore sizes ranging typically from 10 nm to 0.5 μm. In a conventional activated sludge treatment plant, the membrane filtration process replaces the final clarifier step treatment achieved solely by gravity, whereas the activated sludge bioreactor is kept separated from the UF treatment. In addition, the membrane disinfects by eliminating bacteria and viruses as well as by producing high-quality, suspended solid (SS)-free effluent (Battilani et al., 2010). The benefits of MBR include better control of biological activity, effluent that is free of bacteria and pathogens, smaller plant size, and higher organic loading rates (OLR) (Cicek, 2003; Johir et al., 2011). Advantages and disadvantages of the MBR are presented in Table 1.

Table 1. Advantages and disadvantages of MBR

Advantages	Disadvantages
Better effluent quality	Typically higher capital
Smaller space requirements	Operating costs
Ease of automation	Energy costs

Activated Sludge System

Biological wastewater treatment hastens waste disintegration. Activated sludge is supplemented to wastewater, and the combination of treatment process is aerated and agitated. After a certain period, the activated sludge is allowed to settle by sedimentation and is disposed of or reused by returning it to the aeration tank.

The ability to perform wastewater treatment in the mosteconomical technique is advantageous for a community. The activated sludge method applies microorganisms to feed on organic pollutants in wastewater, producing a high-quality effluent that results in reasonable operating and maintenance costs. The basic principle behind all activated sludge processes is that as microorganisms grow, they form particles that clump together. These particles, known as floc, are allowed to settle to the bottom of the tank, leaving a relatively clear liquid free of organic material. Screened wastewater is blended with various amounts of recycled liquid, including a high proportion of organisms taken from a secondary clarifying tank, becoming a product called mixed liquor. This mixture is stirred and injected with large quantities of air to provide oxygen and keep solids in suspension. Afterward, mixed liquor flows to a clarifier, in which the liquor is allowed to settle. A portion of the bacteria is eliminated as the liquor settles, and the partially cleaned water flows on for further treatment (Pipeline, 2013).

The activated sludge method is extensively applied worldwide for the treatment of domestic and industrial wastewaters in situations where high effluent is necessary and space is limited. However, the activated sludge system is more heavily mechanized than other systems, involving a more sophisticated operation. Another disadvantage is the consumption of electrical energy for aeration (Sperling, 2007). Figure 1 shows the main units in the biological stage of the activated sludge system.

Activated sludge methods come in several forms, such as conventional plug flow activated sludge process, extended aeration activated sludge method (i.e., extended aeration), contact stabilization, step-feed, complete mix, and sequencing batch reactors (SBRs). Advantages and disadvantages of the activated sludge system are presented in Table 2.

Table 2. Advantages and disadvantages of activated sludge System

Advantages	Disadvantages
Efficient removal of BOD, COD and nutrients	Larger volume, high aeration costs
Flexibility and numerous modifications	Associated with biomass instabilities like sludge bulking

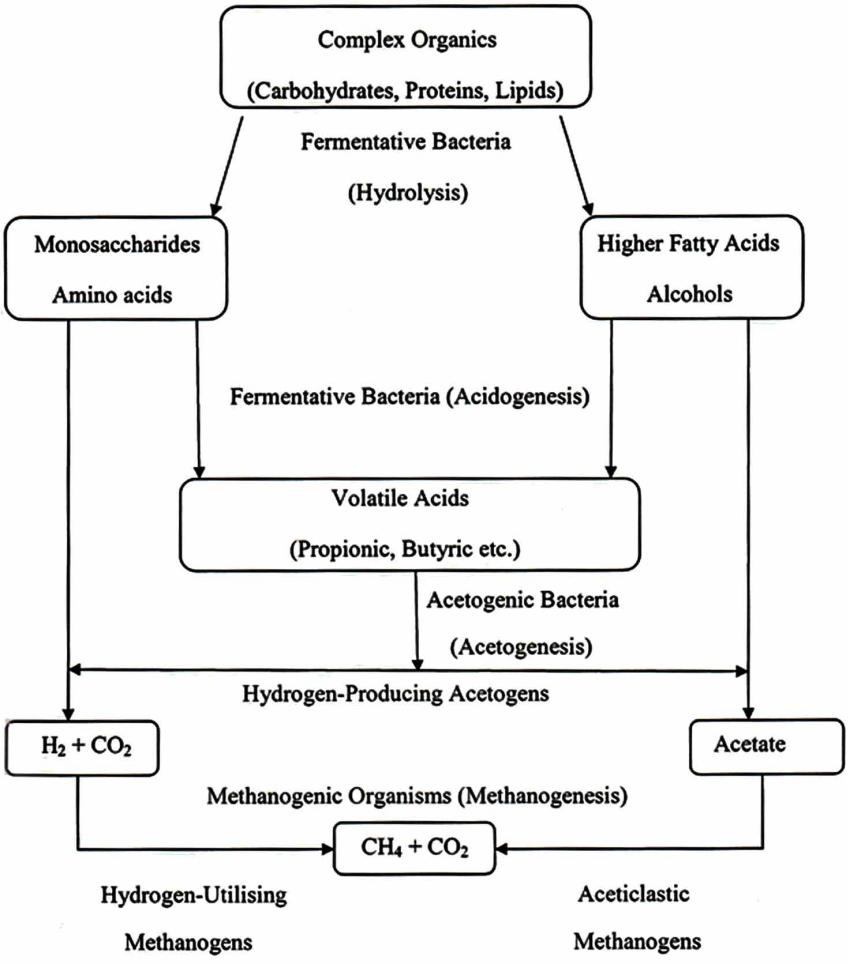
Figure 1. Representation of the main units in the biological stage of the activated sludge system
(Source: Sperling, 2007)



Conventional Plug Flow Activated Sludge Method

In the conventional plug flow activated sludge (Figure 2), the influent and the returned activated sludge enter at the head of the aeration tank and travel through the tank at a constant rate. The sludge age is commonly less than 15 days, and the optimal age is usually between 3 and 10 days (Water/Wastewater Distance Learning, 2014).

Extended Aeration Activated Sludge Process (Extended Aeration)

The extended aeration uses conventional plug flow patterns. However, aeration tanks are large and allow 15 hours of hydraulic retention times (HRT). The sludge age is normally greater than 15 days, and the optimum age is between 15 and 30 days. As such, the effluent is thoroughly treated, and less waste-activated sludge is produced. The oxidation ditch (Figure 3) is a variation of the extended aeration process (Water/Wastewater Distance Learning, 2014).

Contact Stabilization

This type of activated sludge process has several properties:

1. Microorganisms employ organics in the contact tank.
2. Fresh wastewater flows into the contact tank where it is aerated and blended with bacteria.
3. Soluble materials pass through bacterial cell walls, whereas insoluble materials stick to the outside of the cells.
4. Solids settle out later and are ejected from the tank or returned to a stabilization tank.
5. Microbes digest organics in the stabilization tank and are then recycled back to the contact tank as the organics are consumed.
6. Retention time is minimized; thus, the size of the contact tank can be decreased.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

7. The volume requirements for the stabilization tank are also smaller because the basin receives only concentrated return sludge. Moreover, no raw wastewater enters the tank.
8. Normally, primary clarification is not conducted before the wastewater goes into the contact tank because of the rapid uptake of soluble and insoluble food (Dohse and Heywood, 1999).

Step-Feed

In the step-feed method, the primary effluent is added at two or more points along the aeration tank length (Figure 4). This configuration allows for better control in handling shock loads and lowers the amount of mixed-liquor SSs to the secondary clarifiers. This configuration spreads out the organic load and evens out the rate of oxygen uptake throughout the basin length (Water/Wastewater Distance Learning, 2014).

Complete Mix

Complete mix method is currently the most commonly used approach in leachate treatment. In this method, the concentration of volatile-SSs and oxygen demand are the same throughout the tank because the wastewater is completely mixed with bacteria and oxygen (Dohse and Heywood, 1999).

Sequencing Batch Reactor

An SBR is a comprehensive mix-activated sludge method without a secondary clarifier. A number of different sequences are completed within the aeration basin. Aeration and clarification are also accomplished in one tank (Alkhaddar et al., 2005). Research on SBRs started in the 1970s, along with the development of other discontinuous processes. One of the benefits of these batch systems is that they can be merged for numerous variations of contaminant concentrations (Liermann, 2009). In the literature, different methods of biological treatment were used for the treatment of wastewater and leachate. SBR is a type of biological treatment that is different from activated sludge plants. Specifically, SBRs band all treatment phases and processes into a single basin, whereas conventional methods rely on different tanks. The treatment phases of SBR are fill, react, settle, draw, and idle. In many investigations, SBR was used to treat domestic, urban, dairy, industrial, synthetic, and slaughterhouse wastewaters and landfill leachate, as shown in Table 3 (Aziz et al., 2011c). Figure 5 shows the phases of SBRs.

Table 3. Treatment of different types of wastewaters by using the SBR process

No.	Type	Contaminants	Removal (%)
1	Landfill leachate	COD	75
		Ammonium	44
		Phosphate	44
2	Landfill leachate	COD	<83
3	Municipal wastewater	Biochemical oxygen demand	98
		Total SS	90
		Ammonia	89
4	Dairy wastewater	COD	80.2
		Total solids	63.4
		Volatile solids	66.3
		Total nitrogen	38.3
5	Textile effluent	Total organic carbon	66
		Color	94
6	Wool dyeing effluents	COD	79 to 91
		Biochemical oxygen demand	91 to 99
7	Slaughter house wastewater	COD	96
		Total nitrogen	96
		Total phosphorus	99
8	Abattoir effluent	Nitrogen	85.5
		Phosphorus	90
9	Tannery wastewater	COD	80 to 82
		Ammonia	83 to 89
10	Synthetic wastewater	Biochemical oxygen demand	97.7
		COD	94.9
		Total nitrogen	71.4
		Total phosphorus	55.9

(Source: Aziz et al., 2011c)

Advantages and Disadvantages of SBR

The main advantages of the SBR process are as follows:

1. Simple construction,
2. Flexible plant setup,
3. Flow through plants require regular-shaped sites,
4. Fewer channels and pipe work,
5. Easily scalable, and
6. Can be adapted to nitrification and denitrification.

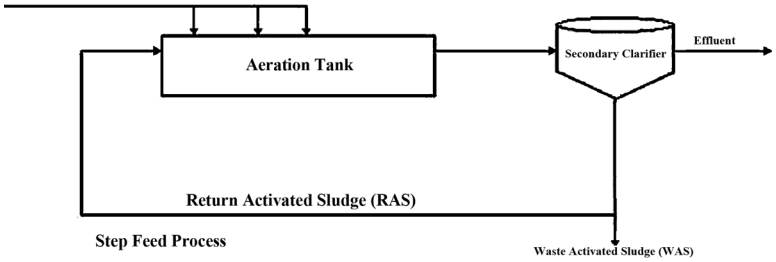
Figure 5. Phases of normal SBR
(Source: Mahvi, 2008)



The main difficulties of the SBR methods are as follows (Mace and Alvarez, 2002; USEPA, 1999):

1. A higher level of sophistication is required compared with conventional systems for timing units and controls, especially for larger structures;
2. A higher level of preservation is achieved compared with conventional systems associated with more sophisticated controls, automated switches, and automated valves required;
3. Floating or settled sludge is potentially discharged during the draw or decant phase with certain SBR configurations;
4. Equalization is potentially required after SBR, depending on the downstream processes; and
5. Batch feeding from storage or bioselectors is required to control bulking.

Additional Information on SBR

Janczukowicz et al. (2001) investigated the settling properties of activated sludge from an SBR, and their results showed good settling properties of the sludge. Low sludge volume index (SVI) (30 mL/g to 60 mL/g SS) caused severe and rapid sedimentation, which shortened the settling phase to less than 1 hour. Moreover, low SVI prevented the sludge from bulking. High dissolved oxygen concentrations in the aeration tank during the reacting phase resulted in minimal sludge biomass growth, which is vital in terms of sludge dumping at a wastewater treatment plant.

Mahvi et al. (2005) investigated the feasibility of continuous flow SBR in synthetic wastewater treatment. The results showed that the removal efficiencies achieved by the system were 97.7%, 94.9%, 85.4%, 71.4%, and 55.9% for BOD_5, COD, TKN, total N, and total P, respectively.

In many investigations, the SBR has been applied in the treatment of leachate with low BOD_5/COD ratios ranging from 0.09 to 0.37. The capability of SBR in leachate treatment was lower than that for municipal and industrial wastes because of the low biodegradability ratio and high concentration of heavy metals, COD, NH_3–N, and other compounds in landfill leachate. In the reported studies, the adsorption method improved the SBR process and increased the elimination efficiencies of organic matter, heavy metals, NH_3–N, and other pollutants. Aziz et al. (2011b) investigated landfill leachate treatment by powdered activated carbon SBR (PAC-SBR) method and optimization by response surface methodology. This result indicated that PAC-SBR showed superior performance in terms of removal efficiencies compared with the SBR Anaerobic Treatment.

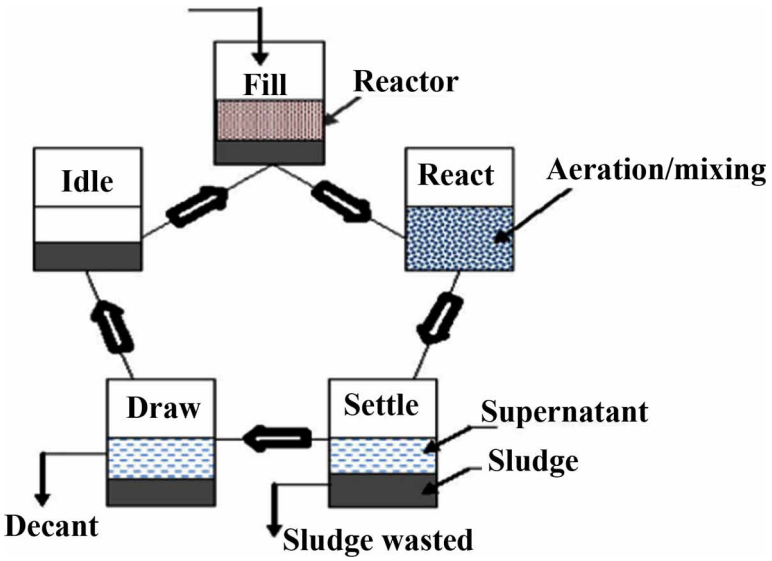
EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

This part describes several anaerobic methods, such as anaerobic hybrid reactors and other anaerobic bioreactors. Anaerobic treatment is a sustainable wastewater treatment system for developing countries and is already gaining acceptance as a simple and cost-effective technology for the treatment of a variety of wastewaters (Alptekin, 2008). Anaerobic digestion (AD) is a biological process that occurs when bacteria breaks down organic matter in environments with minimal or no oxygen. AD is an efficiently controlled and enclosed version of the anaerobic breakdown of organic waste in a landfill that releases methane (Friends of the Earth, 2007). Figure 6 shows the metabolic pathways and microbial groups involved in AD.

Upflow Anaerobic Sludge Blanket

The upflow anaerobic sludge blanket (UASB) reactor was established in the Netherlands in the early 1970s (Lettinga et al., 1980). Originally proposed by Lettinga, this reactor was one of the earliest systems in which the development of a granular biomass was observed. Excellent sludge retention is ensured in this reactor system as a result of the excellent settling characteristics of this granular biomass and the presence of a specially designed three-phase (biogas, water, and biomass) separator device in the upper part of the UASB reactor. The major disadvantage of the UASB process is the relatively long start-up period, although this occurs merely in cases where proper seed sludge is not available in sufficient quantities. A significant washout of sludge generally manifests during the initial phase of the start-up process of a UASB reactor inoculated with flocculent seed sludge. Therefore, the first reactor start-up would highly benefit from skilled operation (Mai, 2006).

Figure 6. Metabolic pathways and microbial groups involved in AD
(Source: Lettina et al., 1996; Hampannavar, 2010)



EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Upflow Anaerobic Filter

Anaerobic filters have been used successfully for the treatment of dilute wastewater with COD removal efficiencies between 60% and 80%, depending on the HRT used (Alptekin, 2008). The upflow anaerobic filter (UAF) maintains the biomass immobilized over a fixed support, thereby retaining high cellular retention times even when operating at low HRT. The UAF also tolerates low and variable OLR and pH. These features enable a reduction in the dimensions of the reactor.

Anaerobic Hybrid Reactor

The anaerobic hybrid reactor (AHR) combines the sludge blanket in the lower portion and the filter in the upper part; the AHR has been reported to enhance the advantages of the UASB and upflow filter while minimizing their limitations (Kumar et al., 2007). The AHR is a combination of the UASB reactor and an anaerobic filter. A layer of biomass carrier is placed in the upper part of the AHR instead of the gas–liquid–solid phase separator. This layer separates the bubbles of the biogas from the biomass and functions as a support material for biomass growth. In addition, the layer has a notable efficiency as a SS separator (Hutnan et al., 1999).

Phytoremediation

The use of plants for the remediation of polluted soils and waters has gained acceptance in the past two decades as a cost-effective and non-invasive method (Mojiri et al., 2013). Phytoremediation is a new approach that offers more ecological benefits and a cost-efficient alternative. Although this method is less expensive than other techniques, it requires technical strategy and expert project designers with field experience to choose the proper species and cultivars for specific metals and regions. Phytoremediation presents many advantages compared with other remediation techniques; for instance, phytoremediation can be performed with minimal environmental disturbance (Mojiri, 2012 & 2011a). The most vital factor in implementing phytoremediation is the selection of a suitable plant. A list of potentially beneficial plants for remediation must be prepared first to select the most appropriate plant (Kutty et al., 2009). Several investigations on wastewater treatment by phytoremediation can be found in literature (Mojiri et al., 2013; Mojiri et al., 2012; Khider et al., 2012).

PHYSICAL/CHEMICAL TREATMENT

Reduction of floating material, colloidal particles, color, and toxic compounds using flotation, coagulation/flocculation, adsorption, chemical oxidation, and air stripping are considered physical and chemical processes. Physical/chemical treatments for the landfill leachate are employed in addition to the treatment line (pretreatment or last purification) or treatment of a specific contaminant (e.g., stripping for ammonia) (Renou et al., 2008).

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Chemical Precipitation

Chemical precipitation is employed as pretreatment to eliminate high-strength ammonium nitrogen in leachate treatment (Renou et al., 2008). Given its efficiency, simplicity, and low cost, chemical precipitation has been used to remove non-biodegradable organic combinations, NH_3–N, and heavy metals from landfill leachate. During chemical precipitation, dissolved ions in the solution are converted to an insoluble solid phase via chemical reactions. The removal of ammoniacal–nitrogen from anaerobically pre-treated leachate was studied using struvite (magnesium ammonium phosphate) precipitation in the Odayeri landfill (Turkey). Using this method, ammonia was converted into a nitrogen fertilizer, such as urea. Approximately 50% COD and 90% NH_3–N, with an initial COD concentration of 4,024 mg/L and NH3–N concentration of 2,240 mg/L, were removed (Kurniawan et al., 2006). Table 4 shows advantages and disadvantages of this method.

Chemical Oxidation

Chemical oxidation processes have been developed at different sites over the past few years. A mixture of oxidation agents, such as ozone or hydrogen peroxide and ultraviolet (UV) light, is applied. This mixture displays high oxidation rates for leachate COD. The method involves a mixing chamber, which is used to combine the influent leachate and oxidation agent. This mixture then goes into a chamber with UV lamps. Flows are recirculated to increase the elimination rates of leachate manifold. Mixing gaseous ozone and water is more difficult than mixing hydrogen peroxide and water.

Inorganic compounds may also be oxidized during chemical oxidation. A biological pretreatment, e.g., nitrification/denitrification, should be considered to prevent the expensive oxidation of easily biodegradable components. During chemical oxidation, not all organics are oxidized to carbon dioxide and water. Some organics are only partly oxidized, often to biodegradable intermediates. These so-called "new" biodegradable organics should be reduced by biological treatment. A fixed film reactor may be an option for the reduction of these relatively low concentrations of organics. Feeding the effluent of the chemical oxidation plant back to the influent of the biological reactor may also be considered (Stegmann et al., 2005). Table 5 shows advantages and disadvantages of this method.

Fenton Treatment

The Fenton process has been widely studied in recent years, and analyses indicate that the Fenton method is one of the most cost-effective alternatives among potential physicochemical technologies for leachate treatment (Deng, 2007). Fenton oxidation is one of the advanced oxidation processes with high efficiency

Table 4. Advantages and disadvantages of chemical precipitation

Advantages	Disadvantages
Chemical precipitation is a well-established technology with ready availability of equipment and many chemicals	Chemical precipitation may require working with corrosive chemicals, increasing operator safety concerns.
Some treatment chemicals, especially lime, are very inexpensive.	Large amounts of chemicals may need to be transported to the treatment location

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 5. Advantages and disadvantages of chemical oxidation

Advantages	Disadvantages
Contaminant mass can be destroyed in-situ	Potentially higher initial and overall costs relative to other source area solutions
Rapid destruction/degradation of contaminants (measurable reductions in weeks or months)	Contamination in low permeability soils may not be readily contacted and destroyed by chemical oxidants.
Reduced operation and monitoring costs.	Dissolved contaminant concentrations may rebound weeks or months following chemical oxidation treatment.

and low capital costs. Fenton oxidation involves a mixture of H_2O_2 and ferrous salts, which can generate aggressive hydroxyl radicals at ambient temperatures. The generated radicals are able to oxidize an extensive range of chemicals in aquatic medium, theoretically, all organic compounds containing hydrogen (R–H). The Fenton procedure can effectively achieve not only good oxidation of organics, but also their removal because of coagulation in the presence of ferrous salts (Gotvajn et al., 2011).

Coagulation–Flocculation or Flocculation–Precipitation

Table 6 shows that coagulation–flocculation has been used to remove non-biodegradable organic compounds and heavy metals from landfill leachate. The coagulation process destabilizes colloidal particles through the addition of a coagulant. Coagulation is usually followed by flocculation of the unstable particles into bulky floccules so that they can settle more easily and increase the particle size. This method facilitates the removal of SS and colloid particles from a solution. The general approach for this method involves pH adjustment and the addition of ferric/alum salts as coagulant to overcome the repulsive forces between the particles (Kurniawan et al., 2006).

Table 6. Removal of recalcitrant compounds using coagulation-flocculation (Source: Kurniawan et al., 2006)

Membrane Filtration

A membrane is a material that creates a thin barrier that can selectively resist the movement of different constituents of a fluid, thereby affecting the separation of the constituents (Visvanathan et al., 2000). Usually, a thin layer of material with high surface porosity and a narrow pore size affects the physical structure of the membrane. Different membrane filtration techniques, namely, microfiltration(MF), ultrafiltration(UF), nanofiltration(NF), and reverse osmosis(RO), are employed in landfill leachate treatment.

Microfiltration

MF with pore sizes of 0.05 μm to 10 μm is used to capture microbial cells, small particles, and large colloidal particles. Based on landfill leachate treatment, this method is unsuitable to be used by itself. MF is used as a pretreatment process with other membrane processes (i.e., UF, NF, or RO) or in combination with 10 chemical treatment processes to remove suspended matter and colloids. Piatkiewicz et al. (2001) used this method in the prefiltration stage and obtained COD removal rates of 25% to 35%.

Ultrafiltration

UF is a selective method that utilizes pressures of up to 10 bar. This technique efficiently removes suspended matter either by direct filtration or with biological treatment to replace the sedimentation unit. UF is significantly dependent on the material that constitutes the membrane. Syzdek and Ahlert (1984) proposed that this process might prove useful as a pretreatment method for RO. UF eliminates the larger molecular weight components of leachate that tend to foul RO membranes (Bohdziewicz et al., 2001; Rautenbach et al., 1997). A COD removal rate of 50% was obtained by using UF alone (Bohdziewicz et al., 2001). Tabet et al. (2002) reported that UF membranes have been successfully used in full-scale MBR plants by combining bioreactors and membrane technology. High level of landfill leachate treatment have also been obtained using this method.

Nanofiltration

NF has been used to remove recalcitrant organic compounds and heavy metals from landfill leachate because of its unique properties. NF also has the ability to remove particles with molecular weights greater than 300 Da and inorganic substances through electrostatic interactions between ions and membranes. The significance of this membrane lies in its surface charges, which permit charged solutes smaller than the membrane pores to be rejected, along with larger neutral solutes and salts. Table 7 shows that NF is also effective in removing heavy metals because of the negatively charged groups on the membrane. The application of NF enables material dissolved in water to be separated into monovalent and divalent ions (Kurniawan et al., 2006).

Reverse Osmosis

RO is one of the developments in leachate treatment over the past decade. However, in contrast to biological treatment, RO separates leachate into two streams: a barely contaminated permeate stream and

a highly contaminated concentrate stream. Biological pretreatment may be necessary when leachate from the acetic phase is treated. Ammonium separation is often insufficient during RO. Reduction of ammonia concentrations in permeate may be improved through a two- or multiple-step RO. In various cases, ammonium is eliminated through a prestripping process or through a biological nitrification and denitrification steps. However, a disadvantage of RO is the production of liquid concentrate that is approximately 20% of the leachate. The method of back passing the concentrate into the landfill is a suggestion of researchers and may not be the best option (Stegmann et al., 2005). In contrast to RO, NF has a looser membrane structure, thus enabling higher fluxes and lower operating pressure for lecheate treatment (Kurniawan et al., 2006).

Electrochemical Treatment

In recent years, electrochemical methods have been used to treat organic materials with high toxicity and low biological degradability. Electrochemical methods, such as electrocoagulation, electrooxidation, and electro-photooxidation, have been frequently used to treat wastewaters from textile, tannery, and oil industries. Treatment of landfill leachate by electrochemical methods is another important research area. Electrooxidation was specifically examined in most of the studies in this field (Deng, 2007).

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Electrooxidation

In recent years, the electrochemical oxidation process has shown promise in wastewater treatment mainly because of its effectiveness and ease in operation. This process has significant efficacy in destroying refractory pollutants, such as cyanide, EDTA, and aniline, as well as for color removal (Chiang et al., 1995).

Ion Exchange

Ion exchange is a reversible interchange of ions between solid and fluid phases without changing the structure of the solid. This treatment can effectively eliminate traces of metal impurities to meet the increasingly strict discharge standards in developed countries. The leachate should be subjected to biological treatment prior to ion exchange (Kurniawan et al., 2006).

Solid ion exchange particles can be classified as natural inorganic particles (e.g., zeolites) and synthetic organic resins developed from high-molecular-weight polyelectrolytes (Bashir et al., 2010). Development of ion exchange resins and characterization of naturally occurring ion exchange materials have demonstrated that ion-exchange technique has numerous possible applications in water and wastewater treatment (Wang & Peng, 2010).

The ion-exchange technique offers many benefits, including the ability to handle shock loadings and the ability to operate under a wide range of temperatures. Some of the most popular and widely available natural ion exchangers are zeolites, which consist of an aluminosilicate molecular structure with weak cationic bonding sites. Natural zeolites have been avoided in high purity processes, or where consistency is vital, because of their irregularities and impurities. Zeolites are hydrated aluminosilicates comprising silica and aluminum tetrahedra that are mutually bound by chemical covalent bonds with common oxygen atoms (Mojiri, 2011b). Table 8 shows advantages and disadvantages of ion exchange.

Adsorption

Among all techniques, adsorption is the most widely used in the removal of recalcitrant organic compounds from landfill leachate. In this process, a substance is transferred from the liquid phase to the surface of a solid and then bound by physical and/or chemical interactions (Kurniawan et al., 2006). Regardless of the initial organic matter concentration, adsorption of contaminants onto activated carbon in columns or in powder form results in better reduction in COD levels than that in the chemical methods. However, adsorption requires frequent regeneration of columns or an equivalently high consumption of PAC. Along with biological treatment, adsorption by activated carbon has been used for the effective treatment of landfill leachate. Non-biodegradable organics, inert COD, and color may be reduced to acceptable levels for biologically treated landfill leachate (Renou et al., 2008).

Table 8. Advantages and disadvantages of ion exchange

Advantages	Disadvantages
An advantage of the ion exchange treatment process is that it does not change the pH or alkalinity of the water.	First is the increase of total dissolved solids (TDS) in the treated water due to the release of sodium
Excellent process reliability, process stability, and chemical safety	Second is the cost of disposing of the regeneration cycle's salt brine.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Adsorption technique is an efficient and a promising straightforward approach in wastewater treatment processes (Foo & Hameed, 2009). This technique is employed as a phase of integrated chemical–physical–biological method for leachate treatment or performed simultaneously with a biological process. The most commonly applied adsorbent is granular-activated carbon (GAC) or PAC (Mojiri, 2011b).

Adsorption using GAC or PAC has been widely used in the removal of organic and inorganic contaminants from polluted wastewater because of its inherent physical properties, large surface area, microporous structure, high adsorption capacity, and surface reactivity (Kurniawan et al., 2006).

Rodriguez et al. (2004) studied the efficiency of PAC and different resins in reducing non-biodegradable organic matter from landfill leachate. Activated carbon presented the highest adsorption capacity, with 85% COD decrease and a residual COD of 200 mg/L (Renou et al., 2008).

CONCLUSION

The main landfill leachate treatment methods are the physical, chemical, and biological methods. Each method has benefits and disadvantages based on the purpose of the research. Landfill leachate properties, technical applicability and constraints, effluent discharge alternatives, cost-effectiveness, regulatory requirements, and environmental impact are important factors in selecting the most suitable treatment technique for landfill leachate treatment. Physical/chemical treatments such as chemical precipitation, chemical oxidation, coagulation–flocculation, membrane filtration, ion exchange, adsorption, and electrochemical treatments were described in this manuscript. Physical/chemical treatments for landfill leachate are used in addition to pretreatment or final purification to treat a specific pollutant. Physical/chemical methods have been mostly used to remove metals from leachate. Biological methods, such as aerobic and anaerobic methods, were also discussed in this chapter. These methods have been used to reduce contaminations, such as COD, BOD, ammonia, color, and metals, from leachate.

Chapter 8
A Review of Emerging Contaminants in Water:
Classification, Sources, and Potential Risks

Alexandros I. Stefanakis
University of Brighton, UK

Julie A. Becker
University of the Sciences, USA

ABSTRACT

Contaminants of emerging concern or, simply, emerging contaminants represent a newly discovered group of chemicals present in surface and groundwater. It was only the improvements in analytical instrumentation that allowed for the detection of these contaminants even at trace levels. The continuous detection of new chemicals with time raises questions concerning their source pathways, their fate, transport, transformations and impact on aquatic environments. The scope of this chapter is to present an overview of the contaminants classified as "emerging", their sources and introduction pathways to the environment and the related risks to human health and aquatic life.

INTRODUCTION

Current practice and experience dictates that investments in detection, prevention, control and elimination strategies of environmental pollution by chemical pollutants will continue to rise. However, given the huge number of pollutants occurring in the environment due to the combined effects of both natural processes and human activities, it seems that the range of currently regulated chemical pollutants represents only a small fraction of the total chemical pollution. To this, the gradual detection and identification of new emerging pollutants further increases the long list of chemical pollutants. It is then unavoidable that national and international lists of regulated chemicals will ignore the majority of other chemicals occurrence based on the assumption that the chemicals considered by the regulatory processes are the most significant and that they possess the greatest risk to the environment, human

health and the economy. However, questions will still remain concerning the right (or not) selection of the most dangerous chemical pollutants. Additionally, developments of the last 10-15 years imply that there is a large chemical universe still unidentified that will be possibly determined in the near future.

Contaminants of emerging concern or emerging contaminants (ECs) represent relatively newly discovered groups of unregulated contaminants which occur in surface and groundwater, such as pharmaceuticals and personal care compounds, and generally include compounds used in everyday life and various industrial additives. Most of these pollutants were previously (e.g., 15-20 years ago) unknown or simply unrecognized or unidentified and have recently emerged as contaminants associated with potential environmental risks. Their fate in water/wastewater treatment plants, in engineered systems and generally in the environment still remains relatively unknown. At the same time, potential impact and risks to human health, wildlife, aquatic life and ecosystems is another important topic of great interest which needs further investigation. These pollutants are usually bioactive and bioaccumulative and can have a widespread occurrence and persistence. The vast majority of ECs is currently not regulated which means that a continuous monitoring and reporting of their possible presence in water supplies and effluent discharges is required. Today, it is clear that an integrated research and approach to these contaminant groups should be multidisciplinary, involving disciplines such as chemistry, biology and engineering.

Background

ECs are not necessarily newly created chemicals. It could be stated that term refers to three general categories. The first category includes compounds which are recently introduced into the environment (e.g., industrial additives). The second category consists of compounds that might have been present in the environment in the past for many years, but it is only during the last years that their presence was detected and their significance started to attract interest (e.g., pharmaceuticals). The third category includes compounds that are known for a longer time but their potential negative impact on humans and the environment was only recently realized (e.g., hormones). The main problem with ECs is that available data for most of these contaminants are scarce and relatively limited and respective detecting methods and instrumentation either do not yet exist or are at the early development stage. This is why only with the gradual progress in analytical detecting and measuring techniques became possible the detection of these micro-contaminants in the environment. In other words, for many ECs it is not yet clarified the level of risk they represent for the environment and human health, while the techniques to monitor them and the effective technologies to further mitigate contamination are still in development. Only advances in analytical chemistry and instrumentation, as well as in engineering, made it possible to identify ECs in the environment. Analytical capabilities have significantly improved during the last two decades from parts per thousand to parts per trillion (ppt) or even parts per quadrillion (ppq) in some cases, which allowed for the detection and investigation of these contaminants in environmental samples.

The goal of this chapter is to present an overview of these newly discovered contaminant groups, mainly of the organic chemicals detected in surface and groundwaters. The chapter includes their classification, sources and related environmental and human risks, along with a brief analysis of the current legislative status in Europe.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

CLASSIFICATION OF EMERGING CONTAMINANTS

ECs include a large variety of natural and synthetic chemical compounds which are considered as potential hazards, although sufficient knowledge for all the various ECs is still not available. ECs include compounds such as pharmaceuticals, personal care products (PCPs), Endocrine Disrupting Chemicals (EDCs), steroids, hormones, surfactants and surfactant metabolites, flame retardants, pesticides, industrial additives, nanomaterials and gasoline additives. Table 1 presents a general overview of the various contaminant groups that are considered as emerging.

Pharmaceuticals and PCPs are typical examples of emerging contaminants present in surface water for a long time now but whose presence was only recently identified. As Table 1 shows, the term "ECs" is rather extended and includes a large variety of chemical contaminants, which sometimes could be confusing concerning the different categorization of chemical pollutants (Daughton, 2005). Thus, chemical pollution could also be categorized in the following groups based on different properties:

- CMR: carcinogenic, mutagenic, toxic to reproduction,
- EDCs (toxic contaminants)

Table 1. List of major emerging contaminant groups.

Emerging Contaminant groups	Examples
Pharmaceuticals	
Human antibiotics and veterinary	Trimethoprim, erytromycine, amoxicillin, lincomycin, sulfamethaxozole, chloramphenicol
Analgesics, anti-inflammatory drugs	Ibuprofene, diclofenac, paracetamol, codein, acetaminophen, acetylsalicilyc acid, fenoprofen
Psychiatric drugs	Diazepam, carbamazepine, primidone, salbutamol
β-blockers	Metoprolol, propanolol, timolol, atenolol, sotalol
Lipid regulators	Bezafibrate, clofibric acid, fenofibric acid, etofibrate, gemfibrozil
X-ray contrasts	Iopromide, iopamidol, diatrizoate
Personal care products (PCPs)	
Fragrances	Nitro, polycyclic and macrocyclic musks, phthalates
Sun-screen agents	Benzophenone, methylbenzylidene camphor
Insect repellents	N,N-diethyltoluamide
Endocrine Disrupting Chemicals (EDCs)	Octylphenols, nonylphenols, Di(2-ethylhexyl)phthalate (DEHP)
Hormones and steroids	Estradiol, estrone, estriol, diethylstilbestrol (DES)
Perfluoronated compounds	Perfluorotoctane sulfonates (PFOs), perfluoroctanoic acid (PFOA)
Surfactants and surfactant metabolites	Alkylphenol ethoxylates, 4-nonylphnol, 4-octylphenol, alkylphenol carboxylates
Flame retardants	Polybrominated diphenyl ethers (PBDEs): polybromonated biphenyls (PBBs) – polybromonated dibenzo-*p*-dioxins (PBDDs) – polybromonated dibenzofurans (PBDFs), Tetrabromo bisphenol A, C10-C13 chloroalkanes, Tris (2-chloroethyl)phosphate, Hexabromocyclododecanes (HBCDs)
Industrial additives and agents	Chelating agents (EDTA), aromatic sulfonates
Gasoline additives	Dialkyl ethers, Methyl-t-butyl ether (MTBE)
Antiseptics	Triclosan, chlorophene

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

- PBT: persistent, bioaccumulative, toxic,
- vPvB: very persistent, very bioaccumulative,
- POP: persistent organic pollutant (based on their environmental properties)
- PPCPs: pharmaceuticals and personal care products (based on their usage)
- Priority pollutants (regulated)
- Xenobiotics, exotics (foreign vs endogenous pollutants)
- Toxicants, toxins, toxics (based on the overall toxicity)
- HPV: high production volume chemicals

Most of these substances exist in the environment and persist to a greater extent, not only in industrialized regions but even in remote areas. Table 2 contains examples of common contaminants and their main properties. Some pollutants are conservative and do not degrade in the environment (e.g., heavy metals). Persistent organic pollutants (e.g., DDT, EDTA, perfluorinated compounds) are degradable but at a very slow rate, as many pharmaceuticals too (e.g., carbamazepine, sulfamethoxazole). Polar persistent water-soluble chemicals can easily infiltrate into waters (Schwarzenbach et al., 2006). It should be noted that although some contaminants are not persistent in the environment and they can be transformed/removed through natural processes, their continuous introduction from various sources (e.g., wastewater treatment plant outflows) prolongs and maintains their presence in waters and the possible negative impacts on the aquatic life (Vera-Candioti, García, Galera, & Goicoechea, 2008). In an interesting study, Loos et al. (2009) analyzed samples from 100 rivers in 27 different European countries for 35 compounds, including pharmaceuticals, pesticides, PFOs, PFOA, benzotriazoles, hormones, triclosan and EDCs. The most frequently detected compounds and at the highest concentrations were benzotriazole, ceaffeine, carbamazepine, tolyltriazole and nonyl-phenoxy acetic acid (NPE1C). It is also interesting that among the monitored rivers, only 10% could be classified as "very clean" in terms of chemical pollution.

Pharmaceuticals and Personal Care Products (PPCPs)

These substances are natural or man-made chemicals used in prescription medicines and veterinary drugs. To better understand their potential level of presence in the environment, we should consider the annual global mean consumption of pharmaceuticals of 15 g per capita, which rises up to 50-150 g in developed countries (Zhang, Geiβen, & Gal, 2008). Nowadays, more than 3,000 known pharmaceutical compounds are produced (Davis, 2008). Of course, consumption rates vary from country to country according to national legislation and prescription lists. Latest developments in analytical techniques and improvements in analytical instrumentation allowed for the detection of these substances at trace levels. The transformation products of these substances can also be persistent in the environment (Fent, Weston, & Caminada, 2006).

Table 3 presents examples of different analytical techniques used to detect various pharmaceutical compounds in the water cycle (surface water, groundwater, treated wastewater, drinking water). Advanced technologies such as gas chromatography with mass spectrometry (GC-MS) or tandem mass spectrometry (GC-MS/MS) and liquid chromatography with mass spectrometry (LC-MS) or tandem mass spectrometry (LC-MS/MS) can detect pharmaceuticals in water at very low concentrations (down to ng/L). For more polar and water soluble substances LC-MS/MS is more appropriate, while for more volatile substances

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 2. Examples of common emerging contaminants and their properties.

Contaminant	Source/origin	Persistence and Bioaccumulation	Occurrence in the environment
Nonylphenol	Degradation of non-ionic surfactants	Medium persistent, bioaccumulative	Soil, sediment, sludge, water
Bisphenol A	Plastics and epoxy resins	Not bioaccumulative	Surface water, groundwater
Veterinary medicine	Use in aquaculture, release from animals at pasture	Persistent, bioaccumulative	Water, soil, sediment
Phthalates	Plastics	Low to medium persistent, atmospheric deposition	Water, sediment, sludge
PBDE	Flame retardant	Persistent/highly bioaccumulative, atmospheric deposition	Soil, sediment, sludge
Nanomaterials	Use of nanopesticides in agriculture, release of nanomedicnes in livestock, waste landfill disposal	Persistent, nioaccumulative	Surface water, soil, sludge
C_{10}-C_{13} chloroalkanes	Flame retardant	Persistent, bioaccumulative	Surface water
Sulphonamides	Human and veterinary drugs	Slightly-very persistent	Groundwater
Tetracyclines	Human and veterinary drugs	Moderately-very persistent	Groundwater, soil, sludge
Steroid sex hormones	Contraceptives	Moderately persistent	Water, sediment, sludge
MTBE	Gasoline additive	Persistent, not bioaccumulative, ubiquitous in the atmosphere	Groundwater

GC-MS/MS is better (Fatta, Nikolaou, Achilleos, & Meriç, 2007). It should be noticed that currently there is no standardized protocol for the sampling and determination of pharmaceutical compounds in water to provide proven comparability and quality of the obtained data.

Pharmaceuticals and their related metabolites are subjected to natural transformation/removal processes in the environment (e.g., dilution, degradation, sorption), based on their hydrophobicity, biodegradability and the environmental conditions, which explains their presence at trace levels in water sources and drinking water. Pharmaceuticals can be classified based on their purpose and biological activity to antibiotics, analgesics, anti-neoplastics, disinfectants, anti-flammatory compounds, X-ray contrast media etc. Another classification can be made based on the mode of action, e.g., anti-metabolites, alkylating agents, etc. Due to the large variety of compounds, pharmaceuticals have varying biological and physicochemical characteristics. Typical concentrations of these compounds vary within the range of microgram per litre (μg/L) down to nanogram per litre (ng/L), which explains why they are also called as micro-pollutants. Pharmaceutical compounds (as most of chemicals) are subjected to various biotic and abiotic processes which might change their structure, once introduced into the environment. Human and animal metabolism activities also result in structural changes of many pharmaceuticals caused by biological and non-biological transformations (processes initiated by human enzymes, fungi, bacteria as well as processes including oxidation, hydrolysis and photolysis; Kümmerer, 2009), which are the production processes of pharmaceutical metabolites.

Table 3. Analytical methods and instrumentation used for the detection of pharmaceutical substances in water and wastewater (Fatta et al., 2007).

GC-MS or GC-MS/MS without derivatization	**GC-MS or GC-MS/MS after derivatization**	**LC-MS or LC-MS/MS**		
Aspirin	Aspirin	17α-Ethinylestradiol	Hydrochlorothiazide	Penicillin G
Codeine	Etofibrate	7β-Estradiol	Iopamidol	Penicillin V
Cyclophosphamide	Etofyllinclofibrat	Acetyl-sulfamethoxazole	Lofepramine	Pindolol
Galaxolide	Flurbiprofen	Amidotrizoic acid	Metronidazole	Piroxicam
Pentoxyfylline	Ketoprofen	Aminopyrine	Ofloxacin	Ranitidine
Tonalide	Nadolol	Amoxycillin	Enalapril	Ronidazole
Triclosan	Tolfenamic acid	Anhydro-erythromycin	Furazolidone	Spiramycin
		Atenolol	Ifosfamide	Sulfacetamide
		Betaxolol	Ketorolac	Sulfadiazine
		Bisoprolol	Methicillin	Sulfadimethoxine
		Chloramphenicol	Nafcillin	Sulfadimidine
		Chlortetracycline	Erythromycin	Sulfaguanidine
		Ciprofloxacin	Furosemide	Sulfamethazine
		Clarithromycin	Iomeprol	Sulfapyridine
		Clenbuterol	Lincomycin	Sulfasalazine
		Cloxacillin	Methotrexate	Sulfathiazine
		Cyclophosphamide	Norfloxacin	Tamoxifen
		Dapsone	Oleandomycin	Terbutaline
		Demethyl diazepam	Simvastatin	Tetracycline
		Dextropropoxyphene	Sotalol	Tilmicosin
		Dicloxacillin	Omeprazole	Trimethoprim
		Doxycycline	Oxacillin	Tylosin
		Estrone	Oxytetracycline	Virginiamyci
	Bezafibrate, Clofibrate, Diclofenac, Fenofibrate, Fenoprofen, Gemfibrozil, Indomethacine, Iopromide, Mefenamic acid, Metoprolol, Naproxen, Propranolol, Propyphenazone, Roxithromycin, Salbutamol, Sulfamethoxazole			
Carbamazepine, Diazepam, Ibuprofen, Paracetamol, Phenazone				

Personal care products (PCPs) detected in waters include:

- DEET – N,N-diethyl-meta-toluamide, which is the most frequently used active ingredient in insect repellents,
- Parabens – alkyl esters of p-hydroxybenzoic acid, which are used for decades as bacteriostatic and fungistatic agents in cosmetics, drugs and foods,
- Triclosan, a bacteriocide and antifungal agent used in household products (e.g., toothpaste, soap),
- Polycyclic musks, such as tonalide and galaxolide which are used as fragnances in washing and cleaning agents and PCPs,

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

- UV filters/sunscreen, including benzophenones and methoxycinnamates,
- Caffeine and nicotine: substances connected with the modern lifestyle and way of living.

Pharmaceuticals and PCPs are the more frequently detected groups of ECs in surface and groundwater (Lapworth, Baran, Stuart, & Ward, 2012). Among them, common substances in groundwater are anti-inflammatory drugs (ibuprofen, ketoprofen, diclofenac), three antibiotics (triclosan, sulfamethoxazole, lincomycin and partially erythromycin), five analgesics (paracetamol, ibuprofen, phenazone, propyphenazone and salicyclic acid), one anti-epileptic (carbamazepine), one barbiturate (primidone), a commonly used insecticide (DEET), an X-ray contrast agent (iopamidol) and clofibric acid (a metabolite of the lipid regulator clofibrate).

Caffeine and nicotine are probably the two most commonly detected lifestyle compounds in water produced by human activities (Loos et al., 2010). Sulfamethoxazole, ibuprofen, carbamazepine and caffeine are more frequently detected in Europe than in the USA (Lapworth et al., 2012). Other common compounds are fragrances (e.g., galaxolide and tonalide) and non-steroidal pharmaceuticals such as ibuprofen, paracetamol, naproxen, diclofenac, clofibric acid and fluoxetine (Caliman & Gavirilescu, 2009). It should be mentioned that this group of pharmaceuticals also contains drugs used for non-medical applications, ie., cocaine, heroin, cannabinoids (marijuana, hashish) and amphetamine-like stimulants (Castiglioni, Zuccato, Chiabrando, Fanelli, & Bagnati, 2008). These compounds have not been studied extensively and little is known concerning their presence in the environment. Veterinary drugs group includes medicines used exclusively for veterinary purposes. Examples of these drugs are sulfamethazine, which is often detected in groundwaters in Europe and in the USA, as well as monensin and tylosin (Lapworth et al., 2012).

Hormones and Steroids

This category of ECs includes natural endogenous steroids, such as sex hormones (androgens such as androstenedione and testosterone, oestrogens such as oestrone, oestriol and progesterone), phytoestrogens, faecal indicators and plant sterols, which are excreted from the human body. Synthetic androgens include oxandrolone, nandrolone and synthetic oestrogens (xenoestrogens) such as diethylstilbestrol, which are used as contraceptives. Natural and synthetic steroids and hormones occur in wastewater influents and effluents as free active steroids. Most of these compounds are considered as EDCs. Estrone, E2, NP and bisphenol A are the four most frequently detected compounds in groundwaters (Lapworth et al., 2012).

Perfluorochemicals (PFCs)

Perfluorochemicals are anthropogenic chemical compounds used for the manufacturing of products resistant to oil, grease, heat, water and stains. PFCs surfactants are bioaccumulative, persistent, toxic, and ubiquitous contaminants (Nguyen, Reinhard, & Karina, 2011). Their basic chemical bond (C-F) is one of the strongest chemical bonds. These compounds have been detected in many environmental samples including surface waters, groundwater, drinking water, wastewater and sediments. Their impact on human health and ecotoxicological effects are not yet well known, although they are suspected as EDCs (Clarke & Smith, 2011). The most common substances in the environment are perfluoroalkyl sulphonates (PFASs) (e.g., perfluorooctane sulphonate – PFOS) and perfluoroalkyl carboxylates (PFACs) (e.g., perfluorooctanoic acid – PFOA), both synthetic chemicals. It is reported that effluent concentrations of

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

PFOA and PFOS were higher than influent ones in wastewater treatment plants, which indicates possible degradation of other fluorinated organic compounds into PFOA and PFOS during the treatment processes (Clarke & Smith, 2011).

Nanomaterials

Nanomaterials are materials with a structure designed at the nanoscale or sub-microscale (1-100 nm) with high strength, low permeability, thermal stability and high conductivity. Their chemical composition varies and may include nanotubes, metal oxanes, nanosliver, TiO_2 nanoparticles, nanogold and quantum dots. Engineered nanomaterials are used in PCPs, e.g., in cosmetics for sun protection and in hip replacement materials (Colvin, 2003). Although nanotechnology could bring significant societal benefits, there is a certain risk associated with the release of nanoparticles to the environment and questions arise concerning their possible effects on human health. These materials have relatively large active surface and high chemical reactivity and biological activity which means that they can enter the body and the cells easier than other larger particles. However, related information about their potential toxicity or the damages they can cause is still limited (Wiesner et al., 2009).

Flame Retardants

These compounds are used in plastics, textiles and furnishing foam in order to reduce their flammability by interfering with polymer combustion. They can be halogenated or brominated compounds. Polybrominated diphenyl ethers (PBDEs) flame retardants are bioaccumulative and are considered as EDCs (Rahman, Langford, Scrimshaw, & Lester, 2001). PBDEs have been used in plastics, textiles, electronic circuitry among other materials.

Pesticides

Pesticides are often detected in groundwater at trace concentrations for many years now. They can be synthetic chemicals or natural compounds. They are used in agriculture to control weeds, pests and diseases in crops. Over the last years, compounds such as atrazine which were considered to pose a high risk to the environment are no longer in use, although the compounds used to replace them (e.g., diuron) could also have a negative impact. Currently, pesticides of special interest are metaldehyde which in some cases has been detected above the EU drinking water limit for pesticides (Environmental Agency, 2010).

Industrial Compounds

This group includes substances used in industrial processes and production, especially in the chemical industry. Two known EDCs, bisphenol A and the metabolite NP, the fire retardant (tri(2-chloroethyl) phosphate) and the musk galaxolide are among the most frequently detected substances, especially in groundwaters (Lapworth et al., 2012). Nonylphenol and bisphenol A present the highest detection frequency in Europe (11% and 39.6%, respectively) compared to the USA in wastewater influents and effluents and in sewage sludge, with higher values occurring in Austria for both compounds. It is reported that wastewater treatment processes achieve high removal rates of bisphenol A (up to 99%) through biodegradation (Clarke & Smith, 2011). Polychlorinated alkanes (PCAs) are industrial chemicals detected

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

in treated wastewater effluents at trace levels, as well as in sewage sludge. However, little is known concerning their impact on human health and the environment. MTBE (methyl tertiary-butyl ether) and BTEX compounds (benzene, toluene, ethylbenzene, m-, o-, and p-xylene) are frequently detected in groundwater (van Afferden et al., 2011; Stefanakis et al., 2013). They are considered as posing potential risks for human health and drinking water contamination and MTBE is classified as a potential carcinogen.

SOURCES OF EMERGING CONTAMINANTS

Currently, the role, the importance and the related contribution of the various sources to the occurrence and transport of ECs in the environment are under investigation and many related projects are running to determine the concentrations and fate of various ECs. Most of the available information in the literature has to do with the so-called priority pollutants such as pesticides, heavy metals and other regulated priority organic pollutants, thus, respective information for emerging contaminants is relatively limited, although information about some pharmaceuticals and other ECs was published during the last 10 years. ECs can be found in water in relatively low concentrations (ng/L to μg/L). This means that the detection of ECs could be challenging in practice, given that analytical measurements are still time consuming, expensive and require the use of sophisticated advanced equipment. However, currently available techniques such as liquid chromatography and mass spectrometry allow the detection and study of many ECs in the environment, mainly in surface waters and treated wastewaters

ECs have been detected in both surface and groundwaters. Their concentrations in surface waters is usually lower than those measured directly at the outflow of wastewater and sewage treatment plants, due to dilution and natural attenuation processes (biodegradation, photolysis, volatilization, sorption) or combination of all of them (Gurr & Reinhard, 2006; Pal, Gin, Lin, & Reinhard, 2010). Local and regional usage frequency and dosage of pharmaceuticals and PCPs, as well as the effectiveness of wastewater treatment plants affects the concentration level that reaches the surface water body. Range and concentrations of ECs measured in surface waters are usually higher than respective ones in groundwaters, since surface waters are the direct receiver of effluents from wastewater treatment plants and the residence times occurring in surface waters are shorter than in groundwaters (Barnes et al., 2008). Generally, current knowledge and data show that the levels of ECs concentrations in groundwater are low enough so that their presence would not have any toxic or other harmful effects on the environment, due to natural attenuation processes and dilution mechanism. However, it should be noted that increased concentrations could be found in groundwater if the aquifer is close to pollution sources. It is reported that the most frequently substances detected in groundwater are carbamazepine, sulfamethoxazole, ibuprofen, caffeine, diclofenac and bisphenol A (Lapworth et al., 2012).

The presence, distribution and fate of the various ECs in the environment and the aquatic ecosystems are affected by many factors. The source type controls the exposure levels and the properties of the substance. Physicochemical characteristics including water solubility, polarity, volatility etc., as also environmental parameters such as temperature, pH, organic matter content, precipitation and altitude-latitude among others, also play an important role in the transport and transformation of ECs. These properties are crucial since they define the life time of an EC in the environment. ECs can be soluble in water, which means that they can be introduced in the aquatic environment through run-off. Polarity expresses the tendency of a chemical compounds to be in the organic or aqueous phase, thus, compounds with high octanol-water partition coefficient (K_{ow}) tend to bioaccumulate in organisms.

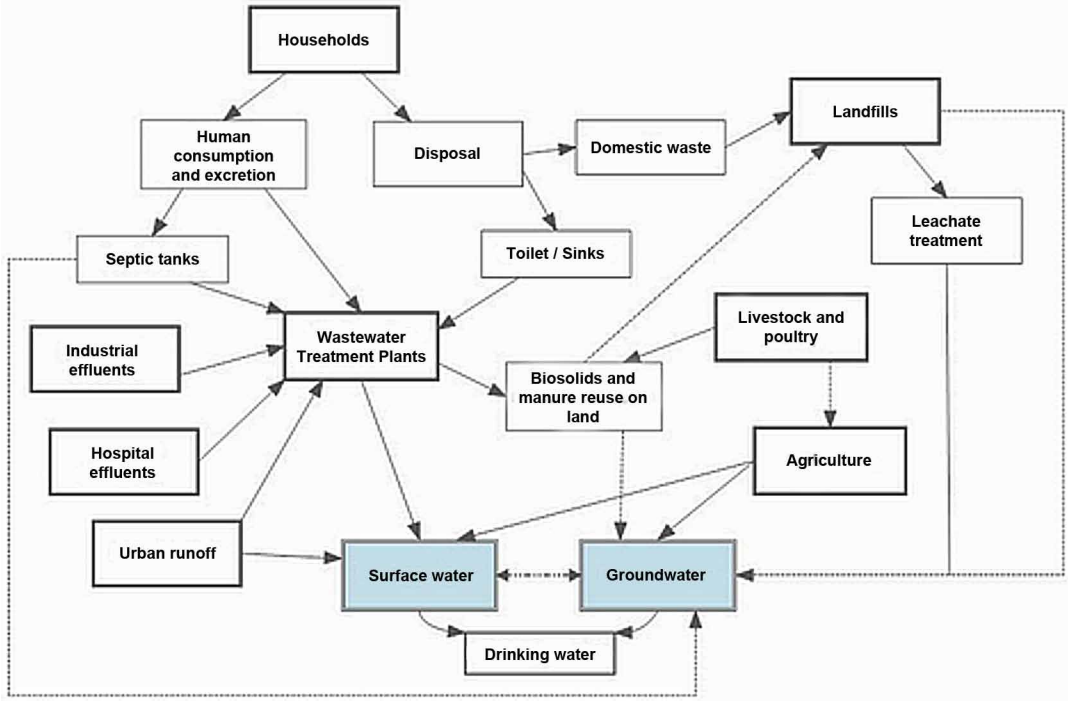
Figure 1. Sources and pathways of emerging contaminants in the environment.



Point Sources

ECs sources vary in both number and nature. They can be classified into point-sources and diffuse pollution sources (Lapworth et al., 2012). Figure 1 presents schematically the various point and non-point sources of ECs.

Point sources include excretion in human and animal urine and feces, flushing of unused drugs, household uses and bathing. The major pollution point source is treated municipal and industrial wastewater at the outflow of wastewater treatment plants in urban, industrial as also in agricultural areas (Glassmeyer et al., 2005; Pal et al., 2010; Lapwoth et al., 2012). Due to their high solubility, low volatility and – for many of them – low degradability, ECs can pass through the different treatment processes. Conventional biological wastewater treatment plants (e.g., activated sludge systems) and combined sewage-stormwater overflows treatment facilities have been proved to provide inadequate level of treatment for most of these contaminants, which means that ECs are still present – at low concentrations – in the effluent of these treatment facilities (Asano, Burton, Leverenz, Tsuchihashi, & Tchobanoglous, 2007; Stefanakis et al., 2014). Many parameters of ECs including their treatability in wastewater treatment plants, their persistence or their mobility are defined by their chemical properties (Clarke & Smith, 2011). Other ECs point sources are industrial facilities such as manufacturing factories, food processing plants, mining activities and landfill sites. Related data such as mass balance, flow levels and fate in the environment for most of the ECs are still limited. Generally, ECs sources could be summarized as follows (Kümmerer, 2009; Pal et al., 2010):

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

- *Wastewater and sewage treatment plants*: residual concentrations containing hormones and drugs
- *Drug manufacturing industries*: industrial wastes containing residual drug concentrations and stormwater runoff carrying powdered drugs
- *Hospitals*: waste discharge and expired drugs
- *Livestock farms*: drugs and hormones injection to poultry and cattle
- *Aquaculture:* hormones used to feed fish and antibiotics added to food and water
- *Household outflows:* effluents containing used and expired drugs

Households are considered as important point sources of many ECs, especially of pharmaceuticals and PCPs (e.g., natural hormones, synthetic steroids). Expired or unused drugs in Europe are usually disposed via household solid waste or are flushed down in the toilet (Vollmer, 2010; Khan, 2012); for example, it is estimated that more than 30% of the pharmaceuticals sold in Germany and 25% in Austria are disposed this way (Kümmerer, 2008; 2009). Same results were also obtained in the UK and in the USA (Bound & Voulvoulis, 2005; Glassmeyer et al., 2009). In the UK, the disposal of unused and expired pharmaceuticals with household waste or through the sink/toilet was the dominant disposal route, while in the USA more than half of patients participated in a study flushed them in the toilet. Table 4 presents common pharmaceutical compounds found in wastewater in the UK, mainly originated from household effluents. These facts clearly show that introduction of ECs through households should be taken into account. In Europe, the EU Directive 2004/27 (European Commission, 2004) mentions that all EU member States should ensure the installation of appropriate collection systems for unused or expired pharmaceutical products, although household disposal routes are not yet illegal in Europe. Disposal of pharmaceuticals with household waste usually results in the occurrence of these compounds in leachates produced in landfill sites and, thus, contaminate groundwater if no treatment takes place.

Artificial recharge for maintaining and increase groundwater levels is considered as an effective strategy to counterbalance water losses through intensive abstraction of groundwater. However, recharge with treated wastewater (of both domestic and industrial origin) or urban and stormwater runoff poses the risk of re-introducing to the environment various chemical contaminants that might be still present in these waters (Díaz-Cruz & Barceló, 2008). Thus, this strategy may have adverse impact on the groundwater

Table 4. Excretions rates of unmetabolized active pharmaceutical compounds (DWI, 2007).

Compound	Pharmaceutical group	Parent compound excreted (%)
Atenolol	β-blocker	90
Amoxycillin	antibiotic	60
Bezafibrate	lipid regulator	50
Cetirizine	antihistamine	50
Felbamate	antiepileptic	40-50
Erythromycin	antibiotic	25
Diclofenac	anti-inflammatory	15
Ibuprofen	analgesic	10
Clofibric acid	active metabolite	6
Carbamazepine	antiepileptic	3

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

quality and followingly on human health, since groundwater is often used as drinking water source. Furthermore, excess drinking water is also often used for recharge purposes. In this case and given that drinking water is usually pre-treated to reach drinking water standards, disinfection products such as trihalomethanes (THMs) and haloacetic acids which are formed during chlorination process can also reach surface and groundwater. It has been proved that some pharmaceuticals and other organic chemicals present in treated wastewater effluents such as carbamazepine, sulfamethoxazole, benzophenone, 5-methyl-1H-benzotriazole, N,N-diethyltoluamide, tributylphosphate, tri(2-chloroethyl)phosphate and cholesterol, can reach the aquifer when used for recharge (Cordy et al., 2004).

The same risk also exists even then surface waters are used for recharge purposes (Díaz-Cruz & Barceló, 2008). A study in Berlin, Germany showed that pharmaceuticals such as carbamazepine, primidone, bezafibrate, indomethacine, diclofenac and propyphenazone, and two drug metabolites (clofibric acid and 1-acetyl-1-methyl-2-dimethyloxamoyl-2-phenylhydrazide (AMDOPH)), were detected in water from recharging ponds and wells, while six of them were found to be persistent in a water recharge plant of the lake Tegel (Heberer & Adam, 2004; Heberer, Verstraeten, Meyer, Mechlinski, & Reddersen, 2011).

Hospital wastewater outflows are another source of ECs including residual concentrations of typical prescription medicines as well as pharmaceutical substances, X-ray contrast media, which represent the main fraction of the adsorbable organic iodine in waters, solvents and disinfectants (Ternes & Hirsch, 2000; Verlicchi, Galletti, Petrovic, & Barceló, 2010). Hospital wastewater contains higher concentrations of pharmaceutical compounds than municipal wastewater, but the volumetric flow of this wastewater source is far smaller. X-ray contrast agent was detected in extracted raw water from local wells in lake Tegel in Berlin, Germany where artificial recharge of the aquifer takes place (Grünheid, Amy, & Jekel, 2005). Some substances present in hospital wastewater (e.g., iopromide, iopamidol, diatrizoate) are very persistent in the aquatic environment and have also been detected in groundwater (Ternes & Hirsch, 2000; Sacher, Lange, Brauch, & Blankenhorn, 2001; Schulz, Loffler, Wagner, & Ternes, 2008).

Landfill sites are also important sources of ECs (e.g., polychlorinated compounds), specifically of those found in groundwater. Contamination of local aquifers in landfill sites is known for many years now due to parameters such as false choice of the location or bad design, although today the vast majority of landfills in western countries do not raise such issues. However, such problems still occur in many countries. For example, groundwater contamination with pharmaceutical substances in landfill areas has been detected in Croatia (Ahel, Mikac, Cosovic, Prohic, & Soukup, 1998) and in Denmark (Holm, Rügge, Bjerg, & Christensen, 1995), as well in the USA (Buszka et al., 2009).

Swine farms and livestock farms represent point sources for estrogenic compounds in the environment. It is reported that the effluent of a treatment plant for swine and dairy wastewater contains estrogens (e.g., E1, E2, oestrone, testosterone, androstenedione) at levels higher than the respective ones in municipal wastewater treatment plants (Kolodziej, Harter, & Sedlak, 2004; Furuichi et al., 2006). Concentrated animal feeding operations (CAFOs) also produce contaminants such as veterinary antibiotics due to waste production and waste storage in lagoons or waste land application, which poses the risk of leakage to the groundwater (Bradford, Segal, Zheng, Wang, & Hutchins, 2008; Bartelt-Hunt, Snow, Damon-Powell, & Miesbach, 2010).

Although often disregarded, water contamination from onsite wastewater disposal systems – mainly septic tanks – also takes place, especially in areas where the groundwater level is high enough. Septic tanks are widely used which makes it difficult to monitor and estimate the actual contamination risk posed from these point sources (Pal et al., 2010). A Canadian study reported that pharmaceutical substances (i.e., gemfibrozil, ibuprofen and naproxen) were detected in samples taken from septic tanks

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

at elevated concentrations (Carrara et al., 2008). This means that leakage from septic tanks may result in groundwater contamination with ECs. PCPs concentrations have also been related with septic tanks leakage (Swartz et al., 2006). However, sampling close to the sources (i.e., households) could partially explain the relatively high concentrations, while the general low leakage volumes of septic tanks probably do not produce high loads of ECs.

Non-Point Sources

Diffuse pollution sources of ECs are more difficult to be identified since they can be extended over large geographical areas, which means that the actual definition of the exact sources is difficult (Lapworth et al., 2012). This category includes sources such as stormwater runoff, terrestrial runoff from roads, urban areas, highways and agricultural land. Compared to point-sources, diffuse sources usually discharge to the environment lighter loads of pollutants (Lapworth et al., 2012).

The use of pesticides in agriculture is considered as the major contamination source. For example, pesticides (two metabolites of DDT) and herbicides (bentazone and mecocrop), as well as flame retardant compounds (tris(2-chloroethyl)-phosphate and tris(2-chloroisopropyl)-9-phosphate) were detected in Lakes Tegel and Wannsee in Berlin, Germany, whose water were used for artificial recharge of the local aquifer (Heberer et al., 2004). Agricultural activities also account for various ECs including veterinary medicines, hormones, natural toxins and transformation products of synthetic chemical substances which are used in agriculture.

Chemical contaminants can stick to sludge particles in the activated sludge system. Since a portion of the daily sludge production in wastewater treatment plants is removed at a daily basis and it is often reused in many areas as a fertilizer in agricultural land, ECs can be re-introduced this way to the environment. When biosolids from wastewater treatment plants are used for land application, ECs in biosolids can potentially reach and contaminate groundwater (Topp et al., 2008; Clarke & Smith, 2011). Two halogenated hydrocarbons (polychlorinated alkanes and perflurochemicals) are reported as potential important groundwater contaminants due to biosolids application to soils and surface runoff (Clarke & Smith, 2011).

Impacts of Emerging Contaminants Presence in the Environment

The development of analytical instrumentation for the detection of ECs in surface and groundwater allowed for the improvement of ECs measurement and assessment in the environment. It has been shown that surface and groundwater are contaminated with a large variety of ECs often at significant concentrations which could potentially represent major environmental risks. Despite the advances in water and wastewater treatment processes and methods, complete elimination of ECs does not take place in water/wastewater treatment facilities, thus, ECs concentrations are still reaching the water bodies (Kümmerer, 2009; Houtman, 2010).

Chronic effects of certain ECs have been studied in the past, e.g., short-term effects of pharmaceuticals on anthropods, but the concentrations tested were usually higher enough that the typical ones found in environmental samples. Thus, in order to obtain more realistic results, concentrations closer to the ones measured in the environment are today more often used. In such tests the species used and their respective sensitivity is also important. For most of the ECs, related risk assessment and ecotoxicological effects are not precisely identified due to the lack of data, although during the last 10 years the investigation of

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

the ecotoxicological effects of ECs was significantly increased. As already mentioned, until today only 8 pharmaceutical compounds are under review for their characterization as possible priority substances or priority hazardous substances; a number very small compared to the total number of pharmaceutical compounds or other contaminant groups under review process. The EU has published guidelines for the environmental risk assessment (ERA) of human medicinal products, which is required by all manufacturing companies during the medicine production (EMA, 2006; 2013). ERA in Europe includes three phases: initial screening (estimation of the exposure levels for a trigger value of 0.01 μg/L), fate evaluation of the medicinal product and potential effects on the aquatic environment and refinements and extended risk assessment.

A web-based database has been created which summarizes ecotoxicological data of the most common ECs (Molander, Agerstrand, & Ruden, 2009). A preliminary risk assessment database for the most common pharmaceuticals and related risks to the environment is also reported in the literature (Cooper, Siewicki, & Phillips, 2008). Physicochemical and toxicological data, as well as the level and extent of environmental transport, fate and aquatic toxicity were used to identify potential risks. This study showed that drugs from the central nervous system, cardiovascular and anti-infective classes possess the highest risk to the environment. Anti-infectives are the most toxic compounds, thus, respective risks from these substances are on top. However, there are still uncertainties concerning the long-term impact of ECs on human health, aquatic and terrestrial wildlife and ecosystems, especially for long-term exposure even at low concentrations (Li, Zhu, Ng, & Tan, 2014). Furthermore, most of respective scientific studies focus on certain groups such as antibiotics, hormones or antineoplastics, but other groups such as antiulcerants and non-prescribed drugs also possess potential negative impact on the environment.

It is known that some ECs can have biological effects on ecosystems and aquatic life. The aquatic toxicity of four different ECs groups (antibiotics, antineoplastics, cardiovascular drugs and sex hormones such as estrogens and androgens) has been evaluated and it was found that daphnids fish and algae were susceptible to these pharmaceutical compounds, while antibiotics and sex hormones were reported as the most dangerous substances for human health and aquatic life (Sanderson, Brain, Johnson, Wilson, & Solomon, 2004). Aquatic organisms can be more sensitive than humans to the presence of ECs in water, since many chemical contaminants can interfere with the normal function of the endocrine system of many aquatic and terrestrial organisms. This interference can have negative impacts on the wellbeing of the organisms including reduced fertility, reproductive dysfunction and population decline (Falconer, Chapman, Moore, & Ranmuthugala, 2006).

It is believed that the presence of ECs in the environment poses a risk mainly for the natural water bodies and the respective ecosystems and aquatic life rather than for human health. Aquatic organisms can be more sensitive than humans to the presence of ECs in water, since many chemical contaminants can interfere with the normal function of the endocrine system of many aquatic and terrestrial organisms. Some pharmaceuticals, PCPs, domestic and industrial cleaning agents, fire-retardants and pesticides are considered as EDCs. Pharmaceuticals such as sex hormones, veterinary growth hormones and antibiotics and glucocorticoids are known for their endocrine disrupting properties, although tests for more pharmaceutical compounds are still ongoing to identify other substances with these properties. EDCs can interfere with the "*synthesis, secretion, transport, binding, action or elimination of natural hormones in the body that are responsible for the maintenance of homeostasis, reproduction, development and/or behavior*" (USEPA, 1998). According to the Endocrine Society, EDCs are "*exogenous chemicals or mixture of chemicals that interfere with any aspect of hormone action*" (Zoeller et al., 2012). However,

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

EDCs may have impact on humans as well, with suspected effects being malformations of newborn infants, abnormal and/or low sperm counts, disorder of the thyroid functions and possible breast-testicular or prostate cancer.

Antibiotics presence in treated wastewater effluents and, generally, in aquatic environments may enhance the resistance among microorganisms and can have a significant impact on the microbial ecosystems. They can interfere with the microbial community structure and affect this way the microbial populations and the ecological function of the aquatic ecosystem (Baquero, Martínez, & Cantón, 2008). It is reported that the presence of ECs in the environment could enhance the bacterial antibiotic resistance due to the continuous antibiotics release to waters (Guardabassi, Petersen, Olsen, & Dalsgaard, 1998). Antibiotic resistant bacteria and antibiotic resistant genes are often detected in wastewater, even at higher concentrations than in surface water, which means that wastewater treatment facilities contribute to the dissemination of these antibiotic resistant bacteria (Bouki, Venieri, & Diamadopoulos, 2013). Bacterial organisms of different origin (e.g., human or animal) in water can be mixed and develop resistance through the exchange of genes and different genetic platforms (Baquero et al., 2008). Antibiotic resistant bacteria such as enterococci, *Klebsiella pneumonia* and *Pseudomonas* spp, represent potential threat for human and animal health and can create problems in infection control. Studies have shown that even pathogenic bacteria such as *Aeromonas* and *Pseudomonas* spp can develop resistance to one or more antibiotics (Blasco, Esteve, & Alcaide, 2008). Incidents such as clinical infections, diseases and even death have been associated with resistant bacteria (Bouki et al., 2013). For example, few years ago where was an outbreak in Europe, mainly in Germany, of bloody diarrhea and haemolytic uraemic syndrome (HUS) due to the multi-resistant enterohaemorrhagic *E. coli* (EHEC), which resulted in the infection of thousands of people (877 HUS case with 32 deaths and 3,043 cases of EHEC with 16 deaths) (Rubino, Cappuccinelli,& Kelvin, 2011).

The presence of pharmaceuticals and PCPs in drinking water appears to be a crucial issue. Contamination of water supplies (surface water bodies and groundwater) is directly connected with the drinking water quality. It is not yet clearly and unanimously accepted that these compounds represent a risk for human health. Typical pharmaceuticals concentrations detected in drinking water are usually lower than 0.05 μg/L, lower enough than the lowest therapeutic doses. Thus, exposure levels to individual compounds in drinking water are not considered as a direct threat to human health and there are not regulated guidelines for these compounds (WHO, 2011), although there is an increasing concern due to the continuous and unlimited exposure to pharmaceuticals. However, regular monitoring of pharmaceuticals should not be neglected, especially in regions where local conditions may imply possible higher concentrations in local waters. Although pharmaceuticals, PCPs and EDCs are widespread substances, their concentrations in drinking waters (usually at the level of ng/L) might not be of significant risk for human health (Snyder, 2008; Kümmerer, 2009). On the other hand, potential environmental effects of pharmaceutical metabolites are not known (Hernando, Rodríguez, Vaquero, Fernández-Alba, & García, 2011). However, given that the exact fate of these numerous compounds in water and during water treatment processes are not yet known in detail and that the existence of new chemicals is continuously reported, precaution measures should not be neglected. In addition, possible interactions and respective combined effects of multi-component mixtures of ECs in the environment should be further investigated, since combined presence might have different effects than the presence of single compounds. It is practically impossible to estimate and evaluate the risk for each one of the thousands of chemical compounds and medicines that have been detected in waters, thus, the focus should be given to those substances that are known for their harmful effects. This is why risk management and risk assessment studies are of high importance.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Current European Legislation

The main issue with emerging contaminants is that the majority of them still remain unregulated. It is only during the last years that steps forward were taken for the regulation of these substances in national and international legislation. The Water Framework Directive (WFD) published in 2000 (European Commission, 2000) is the main European Water Policy Instrument for the protection of European waters and aims at achieving good surface water chemical status. This Directive includes strategies and measures for the mitigation of pollution caused by chemical compounds listed as priority substances. The Decision 2455/2001 (European Commission, 2001) presents the first list of priority substances which were considered as the most dangerous for the aquatic environment. The Directive on Environmental Quality Standards 2008/105 (known as the Priority Substances Directive; European Commission, 2008) set the quality standards for 33 priority substances and 8 other pollutants that are persistent, bioaccumulative and toxic.

However, gradual realization of the new compounds that are detected in waters resulted first in the review of the above mentioned list in 2012 and then in a proposal for the addition of 15 new compounds to this priority list (European Commission, 2012), while for the first time three pharmaceutical compounds (from oral contraceptives to hormone medications) were included among the regulated substances in EU countries: the endocrine disruptors 17 alpha-ethinylestradiol (EE2), 17 beta-estradiol (E2) and diclofenac, which are used in the drug manufacturing, were regulated as potential hazards for humans and fish reproduction. Current and continuous pressure towards the regulation of more toxic chemicals and substances is expected to result in the regulation of additional chemicals in the near future. Other proposed substances to be included in the regulated list are:

- Aclonifen, bifenox, cypermethrin, dicofol, heptachlor and quinoxyfen, which are used for crop and plant protection,
- Cybutryne, dichlorvos and terbutryn, which are used for coastings and surface protection,
- Perfluorooctane sulfonic acid (PFOS) and hexabromocyclododecane (HBCDD), which are chemicals used in the industry,
- Dioxin and dioxin-like PCBs, which were used in the past in electronic equipment and now are produced from combustion.

EU is willing to adopt stricter environmental standards for newly-identified compounds by 2018. Each member state is required to submit a monitoring and measuring program to the European Commission, in order to achieve a good chemical status of the surface water by 2012 for the currently known substances and by 2027 for newly-identified substances. Given that the risk levels related with ECs are varying from growing risk (for recognized substances) to future/unidentified risk (for new chemicals-drugs), the need for additional monitoring programs is necessary. The WFD priority list of the 33 substances aims at exactly that point.

The significance of these pollutants surely is today better understood than it used to be 10-15 years ago. It is not accidental that the EU launched last year a new program on emerging water contaminants aiming at the development and improvement of regulatory issues concerning water quality and use and the promotion of research towards the data collection and future implementations of new directives for water pollution prevention. It is reported that in the EU the number of registered chemicals exceeds 100,000 and 30-70,000 of them are used on a daily basis (EINECS, European Inventory of Exist-

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

ing Chemical Substances; URL1; Loos et al., 2009). The new European Regulation on Registration, Evaluation, Authorization and Restriction of Chemicals (REACH; REACH, 2006), which is in force since 2007, aims at providing a deeper understanding of the chemical pollution in Europe by making the industry responsible for the assessment and management of risks related with chemicals through the implementation of environmental risk assessments (URL2). The REACH regulation dictates that compounds associated with serious and irreversible health impacts (e.g., carcinogenicity, mutagenicity and reproductive health effects) should be categorized as Substances of Very High Concern (SVHC), subjected to formal authorization and high levels of control. The required criteria for assignment as SVHC include considerations of severity of adverse health effects, their reversibility, the latent period between exposure and the manifestation of adverse effects, the impact on life quality and the ability to identify a safe exposure level. Also, the societal cost of the anticipated adverse health effects is taken into consideration. It should be noted that pharmaceuticals release to the environment from manufacturing industries is already regulated in the United States and is not considered as a major contributor to the environmental pollution in this country (Bell et al., 2011).

A specific environmental assessment system for pharmaceutical substances was developed in Sweden by the Environmental Department of the Stockholm County Council in 2003. By 2005, the classification included an environmental risk assessment carried out by the Swedish Association of the Pharmaceutical Industry. According to the Swedish model, the pharmaceuticals are classified based on their inherent capacity to affect the environment (environmental hazard) and on the toxicity risk to the aquatic (environmental risk). This classification is used in considering the environmental impact of the pharmaceuticals on the so called Wise List, a list of recommended pharmaceuticals for common diseases in Stockholm County Council, issued by the Drug and Therapeutics Committee.

Increasing focus is gradually given on the endocrine disrupting compounds (EDCs), a group which includes a wide range of emerging contaminants. Since November 2011, a special group (Endocrine Disrupters Expert Advisory Group) of the European Commission deals with the scientific aspects and the identification of EDCs, in order to support and provide information to the European Commission concerning the criteria adoption for EDCs identification and assessment for any future regulatory framework (Munn & Goumenou, 2013). The EU introduced a priority list of chemicals, under the frame of the EU-Strategy for Endocrine Disrupters, which includes 564 chemicals suspected for endocrine disrupting activity. Out of them, 147 compounds are likely to be persistent in the environment and of these, 66 chemicals have a proven endocrine disrupting activity, including 60 chemicals that considered likely to be exposed to humans. Further 52 chemicals were recently identified as potential EDCs and added to the list.

FUTURE RESEARCH DIRECTIONS

It is anticipated that new chemicals will continue to be identified. Future research should focus on the identification of those chemicals that will pose the greatest threat for humans and ecosystems and limit the potential risks. The new scientific targets should then be the identification of new contaminants and their potentially new sources and pathways and the continuous development of the detection techniques and analytical instrumentation down to trace levels. Additionally, drinking water and wastewater treatment processes should further be improved and – if necessary – re-designed in order to effectively remove as many as possible ECs.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

It is reported that compounds such as diazapem, diclofenac, estradiol, fluoxetine and others have not been detected in the effluents from drinking water plants, due to the effective treatment with ozonation, activated carbon filters or membranes, while UV and chlorination were not of the same performance (Snyder, 2008). Advanced water/wastewater treatment processes such as the above mentioned are used to further treat the water effluents, eliminate (as far as possible) the concentration levels reaching surface and groundwater and reduce the related environmental risk. Many technologies have been tested and applied, however there are still many limitations (Kümmerer, 2009). The treatment efficiency of the various methods and technologies varies significantly, given that the treatment depends on the physicochemical characteristics of the compounds (e.g., hydrophobicity), as well as on operation parameters such as temperature, hydraulic retention time and solids retention time. A good example of the complexity in the removal efficiency of ECs is pharmaceutical substances. Most of them are hydrophobic, thus, they tend to cluster and sludge sorption processes may not be very effective. Although most of advanced treatment processes (i.e., oxidation, ozonation, membrane filtration) are very effective in the removal of specific compounds, the main limitation is that none of the available technologies is effective for the removal of mixture of ECs, i.e, most of the technologies are composition/compound-dependent (Schriks, Heringa, van der Kooi, de Voogt, & van Wezel, 2010). Furthermore, it is known whether these technologies will be effective for the future compounds to be identified.

Current fundamental knowledge over the anthropogenic release of ECs to the environment, their possible (bio) transformations and the potential threat they represent to human health and the ecosystems is still incomplete. Although progress in analytical instrumentation allowed for the detection of numerous ECs in surface and groundwater and the identification of the various sources, human and ecotoxicological effects of the emerging environmental contamination remains a challenge. Quantification of exposure levels is difficult due to the insufficient understanding of the natural attenuation processes of ECs once introduced into the environment. Current available data are scarce and do not allow for global conclusions. Effects of long-term exposure and respective impacts of single or even multiple ECs on aquatic life cannot be safely evaluated, while the extrapolation of toxicological data obtained at higher concentrations than the ones occurring in nature does not provide the necessary credentials. In a few words, current knowledge concerning the fate of most of the ECs in the environment does not allow for the prediction of concentrations, exposure levels and effects. Thus, regulation of these compounds is practically difficult since there are not yet recommended limit values. Field studies as well as lab studies are needed in order to deepen our understanding of ECs fate and transformation pathways. Moreover, since the performance of wastewater treatment plants in resistant bacteria removal is still not reliable, further investigations should be carried out to give answer to many uncertainties which still exist, e.g., it is not known which bacteria are subjected to possible mutations and for which antibiotics.

An important parameter which should be further investigated is the potential effects caused by long-term exposure to some compounds. For example, although available risk assessments indicate that trace level concentrations of pharmaceuticals in drinking water do not represent a significant risk for humans, it is not known if this is also valid for long-term exposure even to these low concentrations, as well as the combined impact due to exposure to mixtures of pharmaceuticals. Of course, the necessary prerequisite for all these actions and measures is that there will be extended monitoring programs, which means increased costs for infrastructure and human resources, as well as the development of standardized sampling and analysis protocols which are up to day not available.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

These indicate that there is the need for the development of prediction models for the description of the fate, transport and transformations of ECs in the environment. Further implementation of ecotoxicological studies, toxicity tests and related risk assessment is needed for the development of more reliable databases. Data from these studies are necessary to be listed in databases which will allow the correlation of ECs occurrence in the environment, their concentrations and their effects and the identification of those compounds with the highest risks and the greater threat for the ecosystems. Such data will also assist in the determination of multiple sources. It is also crucial that respective studies will cover larger geographical areas to include regions such as African and South America countries, given that currently most of the available data are derived from Central Europe and North America.

CONCLUSION

Emerging contaminants are widely present and distributed in the aquatic environment. They include different groups of contaminants such as pharmaceuticals, personal care products and fragrances, industrial additives, pesticides, nanomaterials, flame retardants and surfactants, as well as their metabolites and hormones. Many of these compounds are not effectively removed in wastewater treatment plants and residual concentrations are reaching surface and groundwaters. Some ECs are known for their toxic effects and their endocrine disrupting activity. Most commonly ECs detected in Europe are carbamazepine, caffeine, bisphenol A, ibuprofen, triclosan, galaxolide, iopamidol, DEET, phthalates, phenyl ethoxylates, and sulfamethoxazole, among others. There is a variety of point and non-point sources which continuously introduce ECs into the environment.

Current knowledge over the numerous ECs, their environmental fate and their possible effects on human health and the aquatic life is relatively limited and scarce and demands a deeper understanding of their properties and their distribution and transformations in water. Although research conducted during the last 10 years gave a better insight into the risks associated with many ECs such as pharmaceuticals, there are still knowledge gaps concerning the effects of long-term exposure, especially for mixtures of chemical compounds. Future scientific targets should be the identification of new emerging chemicals, the implementation of lab and field studies along with model development to determine their occurrence, fate and behavior in the environment and development of integrated strategies in order to reduce their environmental input. Since there are thousands of ECs present in water, it is practically very difficult, economic infeasible and environmentally unsustainable to implement programs for the detection, risk assessment and removal of all of these substances. The goal is to distinguish the most significant compounds, in terms of related risk for human health and aquatic life, and focus on them, which is the optimal way of using available resources. According to WHO (2011), the key principle in water safety plans is to take into account the whole life cycle approach of the compounds, i.e., their production, consumption/usage and disposal routes.

KEY TERMS AND DEFINITIONS

Bioaccumulative: Accumulation of a contaminant by an organism at a rate which exceeds the respective extraction rate of the contaminant from the organism.

C-F: Chemical bond of carbon and fluoride.

DDT: Dichlorodiphenyltrichloroethane, a known insecticide.

DEET: N,N-Diethyl-meta-toluamide or diethyltoluamide, common ingredient used in insect repellents.

EDTA: Ethylenediaminetetraacetic acid, used in the industry (e.g., to dissolve limescale) and in medicine and cosmetic industry.

Polarity: Chemical term, which describes the status of electrons sharing between bonding atoms.

Solubility: The property of a liquid (or solid or gaseous) chemical substance (i.e., contaminant) to dissolve in a liquid, solid or gaseous solvent to form a homogeneous solution.

Volatility: The tendency of a substance (i.e., contaminant) to vaporize.

UV: Ultra-violet radiation.

Chapter 9
Integrated Leachate Treatment Technology

Zawawi Daud
Universiti Tun Hussein Onn Malaysia, Malaysia

Halizah Awang
Universiti Tun Hussein Onn Malaysia, Malaysia

ABSTRACT

In this chapter, the performance of combined treatment of municipal landfill leachate is reviewed. Although individual physico-chemical treatments are suitable for the removal of heavy metals and hydrolyzation of some organic compounds, a combination of two physico-chemical treatments or physico-chemical and biological is required for optimum treatment of stabilized landfill leachate. A combination of two physico-chemical treatments can give optimum results in removal of recalcitrant organic compounds from stabilized leachate, as reflected by a significant decrease of the COD values after treatment. On the other hand, a combination of physico-chemical and biological treatments is required to achieve effective removal of NH3-N and COD with a substantial amount of biodegradable organic matter. In many cases, physico-chemical treatments are suitable for pre-treatment of stabilized leachate. The objective of this paper is to highlight various types of integrated leachate treatments as it has been difficult to get optimum efficiency from single approached treatment.

INTRODUCTION

Over the past 20 years (1983-2005), numerous research studies have been carried out worldwide in the treatment of stabilized leachate using various types of individual and/or combined physico-chemical and/or combined physico-chemical and biological technologies (Kurniawan et al., 2006). Due to the high ratio of COD/BOD, ammonia nitrogen (NH_3-N) and heavy metals in leachate, there are major difficulties presence in treating leachate. Most of the methods used for landfill leachate treatment include coagulation/flocculation, adsorption, membrane filter, sedimentation, air stripping (Marttinen et al., 2002; Bohdziewics et al., 2001; Trebouet et al., 2001). A combination of physical/chemical and biological methods is

almost necessary for the efficient treatment of heavily polluted leachate (Rautenbach & Mellis, 1994). The selection of the most suitable treatment technique for leachate depends on the characteristics of landfill leachate, technical applicability and constraints, effluent discharge alternatives, cost effectiveness, regulatory requirement and environmental impact (Kurniawan et al., 2006).

Biological techniques can be effective in simultaneous removal of organic carbon and nitrogen for biodegradable (BOD5/COD) ratio > 0.3) landfill leachate. Biological treatment is commonly used for the elimination of the high concentration of BOD and COD due to its simple, reliable and cost effective (Uygur & Kargi, 2004). The application of biological process alone, for example, cannot eliminate the refractory organics and residue. Therefore, additional treatment is often required (Izzet et al., 2003). Biological treatment is mostly the first stage in a combination with additional chemical/physical process. Methods used for biological leachate treatments are mainly aerobic, anaerobic and anoxic processes which are used in combination (Im et al., 2001).The ammonia nitrogen is identified as a major toxicant to microorganisms in the landfill leachate treatment. Therefore, pre-treatment prior to biological treatment is required to reduce high concentrations of NH_3-N (Daekeun et al., 2007). Pressure driven membrane filtration methods have been used along with biological treatment of landfill leachate (Bohdziewics et al., 2001). Prior to biological treatment, ozone pre-treatment should be employed in order to improve COD removal.

The physical/chemical techniques have been used widely for post treatment of biologically pre-treated leachate (Izzet et al., 2003). Physico-chemical treatments can act as a refining step for the stabilized effluent of biologically treated leachate. The use of combined coagulation/flocculation with other processes such as reverse osmosis (Izzet et al., 2003), photo-oxidation process and biological treatment (Kargi & Pamukoglu, 2003a) gave satisfactory results. After an aerobic pre-treatment, ion exchange normally achieves an excellent metal removal from effluents. Prior to ion exchange, appropriate pre-treatment system such as the removal of suspended solids from leachate is required (Kurniawan et al, 2006). Combination of anaerobic-aerobic and rotating biological contactor (RBC) systems in treating leachate improved the removal of organic matter (Park et al., 2001).

PHYSICAL AND CHEMICAL TREATMENTS

Physical and chemical processes include reduction of suspended solids, colloidal particles, floating material, color, and toxic compounds (Renou et al., 2008). Chemical and physical methods, such as chemical oxidation, adsorption, chemical precipitation, coagulation-flocculation, sedimentation/flotation and air stripping were applied successfully for the treatment of landfill leachate (Gandhimathi et al., 2013; Kurniawan et al., 2009; Papastavrou et al., 2009). The combination of the above process reduces the drawbacks of each single process. (Gandhimathi et al., 2013; Zazouli et al., 2012; Papastavrou et al., 2009).

Kilic et al., (2007) conducted a research on leachate treatment collected from Bursa landfill. In this study, the first alternative, pre-treatment with lime + ammonia stripping + neutralization were operated. This alternative achieved 19% COD removal. The second alternative included chemical coagulation + ammonia stripping + granular activated carbon (GAC) adsorption, achieved to produce an effluent COD of 160 mg/L, which complied with the Turkish discharge standard. Consequently, the second alternative was determined to be appropriate according to discharge standard. The following pre-treatment with lime, co-treatment with municipal waste water is appropriate for lower treatment costs.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

A study on the treatment of stabilized leachate was carried out by Zamora et al. (2000) by comparing coagulation – flocculation to the Fenton oxidation ($Fe(II)/H_2O_2$) process in combination with GAC adsorption. In the study, it was found that Fenton oxidation precursory treatment enhanced the adsorption by of GAC for COD removal (443 mg/g of GAC) at pH 4.0, in contrast to application of coagulation-flocculation only (193 mg/g of GAC) at pH 5.7. This may be because of the change of carbon compounds by oxidation to smaller particles than the original compounds, and as a result, the particles were capable of traversing the micropores of GAC. Rivas et al. 2004 also performed a study on the combination of coagulation-flocculation and Fenton oxidation process in treating leachate. The merit of utilizing this combined procedure was to clear the colloidal particles present in the leachate. The result showed that about 90% of COD were removed at an initial concentration of 7400 mg/L and pH 8.5 by using 0.8 g/L of $FeCl_3$.

Gunes et al., (2014), combined coagulation-flocculation and adsorption to treat stabilized landfill leachate. Ferric chloride and aluminium sulphate employed as a coagulant and granular activated carbon (GAC) and waste metal hydroxide (WMH) utilized as an adsorbent. The result indicated that the ideal working pH for the coagulants was at 9.5. The dosage was optimum at 2.4 g/L for both aluminum sulphate and ferric chloride. And of the two coagulants, $FeCI_3$ demonstrated the higher COD removal efficiency (40%) and exhibiting small seasonal variability according to ideal conditions. The adsorption experiment also showed that the ideal dosage for GAC was 18 g/L and WMH was 13 g/L, at the contact time of 12 h. At the optimum conditions of coagulation/flocculation/GAC adsorption and coagulation/flocculation/WMH adsorption, the COD removal efficiencies were 56-63% and 45-48%, respectively. –Besides that, color removal efficiencies were 77-91% and 81-92%, respectively.

Gandhimathi *et al.,* (2013) combined coagulation and adsorption processes for leachate collected from municipal solid waste open dumping site. Coagulation process was examined by using alum and ferric chloride. A low cost adsorbent, fly ash was used for adsorption studies. Coagulation studies were carried out for fresh and stabilized leachate. Adsorption studies have been conducted for alum pre-treated stabilized leachate. The effect of coagulant dose, adsorbent dose, pH and contact time were carried out. The effective optimum coagulant dosages were 0.6 g/L and 0.7 g/L for alum and ferric chloride respectively, for stabilized leachate and incase of fresh leachate 0.8 g/L and 0.6 g/L for alum and ferric chloride, respectively. For the alum pretreated stabilized leachate, the maximum COD removal is 28% using fly ash adsorbent with equilibrium time of 210 min and optimum dose of 6 g/L. Overall COD removal efficiency of 82% was obtained by coagulation using alum and adsorption using fly ash for stabilized leachate. The results obtained showed that combined coagulation and adsorption process can be used effectively for stabilized leachate treatment.

Li et al., (2010) conducted the combined process of coagulation/ flocculation and powder activated carbon (PAC) adsorption treatment method for stabilized landfill leachate. In coagulation/flocculation experiments, coagulants including aluminum sulphate ($Al_2(SO_4)_3$), ferric chloride ($FeCl_3$), polyaluminium chloride (PACl), and polyferric sulphate (PFS) were utilized to study the ideal conditions for the removal of COD, SS and turbidity by jar tests. The ideal working pH for the coagulants was 5.5 to 6.0, which affirmed charge counterbalance as the main method of coagulation/flocculation process. The dosages were determined as 0.6 gAl^{3+}/L for $Al_2(SO_4)_3$ and PACl, 0.6 g Fe^{3+}/L for $FeCl_3$ and 0.3 g Fe^{3+}/L for PFS, respectively. From the result of the coagulants, PFS had shown the highest COD removal efficiency (70%), suspended solids removal efficiency (93%), turbidity removal efficiency (97%), toxicity reduction (74%) and also the least sludge volume (32 mL). The adsorption experiments found that the

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

dosage of PAC as 10 g/L and the contact time as 90 min at optimum condition. The removal efficiencies achieved of COD, Pb, Fe and toxicity of the stabilized landfill leachate were 86%, 97.6%, 99.7% and 78%, respectively using the combined coagulation/flocculation and adsorption process.

Motling et al., (2014) combined physico-chemical of coagulation-flocculation and carbon adsorption process an efficient treatment method for MSW landfill leachate. An investigation was taken to examine the phenol and organic load (COD) removal from diluted real life landfill leachate sample using some common coagulants followed by batch adsorption study. Coagulants including aluminum sulphate [$Al_2(SO_4)_3$], ferrous sulphate ($FeSO_4$), and polyaluminium chloride (PAC) were employed for determining their optimum experimental conditions for the removal of COD, SS and phenol along with the interference of pH. The optimum range of pH for the COD removal was found to be 6.0-7.0. The optimum dosages were determined as 1.5 g/L for Al_2 $(SO_4)3$, 2g/L for both PACL and $FeSO_4$. Alum exhibited highest COD removal efficiency (72%) among the all other coagulants tested in the present study. Removal of suspended solids was observed as 92% by using Alum. In the adsorption experiments, the optimum dose was found to be 0.4 g/L by using commercial grade activated carbon and the equilibrium time was observed as 3hr. The combined coagulation-flocculation and adsorption process observed that phenol and COD removal were found to be 97% and 92%,respectively, under optimum condition.

Zamora et al., (2000) compares two pre-treatments by coagulation-flocculation process (CF) and the Fenton oxidation Method (FE) of the activated carbon adsorption process (AC) to optimize the removal of the organic compounds in landfill leachates. The content of organic compounds was measured in terms of three global parameters: colour, chemical oxygen demand (COD) and dissolved organic carbon (DOC). The result obtained in discontinuous reactor conditions showed an increase in colour removal from 1.5 to 2.0 times and a decrease of COD between 0.3 to 0.5 times for the FE-AC treatment, in relation to the CF-AC treatment. On the other hand, the data obtained in continuous reactor conditions (packed columns) showed that the column fed with leachate CF exhibited operation times 1.3 times longer and a better physiochemical quality in the filtrate (COD and colour) than the one fed with the FE leachate. Nevertheless, the adsorption capacities in the colour removal column of COD and DOC were higher for the FE leachate.

Yilmaz *et al.,* (2010) carried out a study using combined system of coagulation-flocculation and air stripping for the treatment of leachate from landfill in the Konya Municipal area. The organic content and color removal were examined by using different chemical coagulants (Alum, $FeCl_3$, $FeSO_4$) and the pH were adjusted with lime, NaOH and H_2SO_4. Ammonia stripping and the efficiency of its removal was investigated. For effluent organic matter content removal, the highest removal efficiency achieved was 44% by using 9 g/L alum at pH 11 adjusted using lime, and efficiency of 45% by using 15 g/L $FeCl_3$ at pH 3. Moreover, color removal in the coagulation experimentations indicated that the highest efficiency of color removal could be obtained when pH was adjusted using lime. The coagulant concentration of 1 g/L yielded similar removal efficiencies as the concentration was increased. The optimum flow rate in ammonia stripping was 1 L/min at an optimum aeration time of 8 hours.

Kurniawan and Lo (2009) carried out a study on the treatment of raw leachate from the NENT landfill (Hong Kong) using hydrogen peroxide (H_2O_2) to investigate the treatment performances of H_2O_2 oxidation alone and its combination with granular activated carbon (GAC) adsorption. From an initial COD concentration of 8000 mg/L and NH_3-N of 2595 mg/L, the integrated treatment process had achieved substantially a higher removal (COD: 82%; NH_3-N: 59%) compared to the use of H_2O_2 oxidation alone (COD: 33%; NH_3-N: 4.9%) and GAC adsorption alone (COD: 58%) under optimized experimental conditions. Further improvement in the removal of refractory compounds was enhanced by the addition of a Fe (II) dose at 1.8 g/L by the integrated treatment from 82% to 89%.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

In another study by Mariam and Nghiem (2010) performed an experimental investigation on a combined electrocoagulation – nanofiltration (EC-NF) for the treatment leachate from Whytes Gully landfill in Wollongong, Australia. It was reported that at the optimum dosage of $Al_2(SO_4)_3$, TOC and turbidity removals by the chemical coagulation process achieved 10% and 65%, respectively. In the combined process TOC and turbidity removals, were approximately 92% and 99%, respectively. The results indicated that an EC – NF hybrid system can be a promising candidate for landfill leachate treatment, particularly for small and decentralized landfills, where simplicity and robustness are required.

The study by Trebouet et al (2001) examined the treatment of stabilized leachate from the Saint- Nazaire landfill (France) using a combination of NF (Nanofiltration) and coagulation. MPT-31 membrane with high negative charge was employed for leachate having COD and NH_3–N initial concentrations of 2150 and 790 mg/L, respectively. The maximum removal was found to be 80 and 21%. However, by employing MPT-20 that has a low negative charge, a lower removal of COD (74%) and NH_3–N (12%) was achieved at the same conditions. The difference of treatment performance between the two membranes might be attributed to the electrostatic effects that affect the repulsion between the negatively charged membrane surface and humic-type compounds. Treatment of landfill leachate using a combination of ozonation and GAC adsorption column was carried out (Fettig et al., 1996). With an initial concentration of 205 mg/L, about 40% COD was removed when 6mg of ozone/mg of dissolved organic carbon (DOC) was applied. Biodegradation inside the activated carbon beds was suggested to be the major mechanism for the removal of organic compounds from ozonated leachate.

Stabilized leachate from the Badazos landfill (Spain) was treated by integrating ozone and GAC adsorption (Oh et al., 2004). Approximate 90% COD removal was accomplished with an initial concentration of 4970 mg/L. Using adsorption after the ozonation step allowed the formation of smaller molecules during ozonation, which are more suitable for adsorption than the big molecules present in the leachate. In addition, adsorption is capable of removing the remaining organic compounds and metal species in the leachate.

The treatment of stabilized leachate from the Berg landfill (Germany) was explored using a combination of NF (nanofiltration) and GAC adsorption/ozonation (Rautenbach and Mellis, 1994). Due to its high rejection rate for organic compounds and high permeate flux, Desal 5K was selected as the NF membrane. An approximate 99% COD removal with an initial concentration of 4000 mg/L was achieved. HCl was used for pH adjustment in order to avoid CaSO4 scaling and for cost reasons. Dong et al., (2014) used filtration techniques in a forward osmosis (FO) membrane system used to post-treat the effluent of a membrane bioreactor (MBR) fed with landfill leachate (LFL). In short-term tests, it was observed that the water flux with the membrane active layer facing the draw solution (AL-DS mode) was lower than that with the membrane active layer facing the feed solution (AL-FS mode) for LFL treatment.

Mathematical models could well simulate the flux evolution of AL-FS mode while the flux of AL-DS deviated from the modeling curve, suggesting that fouling could be rapidly developed within 1 h filtration for AL-DS mode. During long-term filtration, about 98.6% of COD, 96.6% of TP, and 76.9% of ammonium was removed by FO system. A decrease of water flux was also observed with an increase in operation time. Confocal laser scanning microscopy and Fourier transform infrared spectroscopy confirmed the existence of polysaccharides and proteins in the fouling layer. Inorganic fouling was mainly caused by Ca, Na, Mg, K, Si, Fe and Al. It was also found that the effect of cake enhanced concentration polarization played an important role during long-term operation. About 88.9% of the permeate flux was recovered after hydraulic cleaning while it reached 98.9% of the initial flux after chemical cleaning, indicating that chemical cleaning was needed to eliminate irreversible fouling and to recover membrane permeability during long-term operation.

BIOLOGICAL AND CHEMICAL TREATMENTS

Batarseh (2006) conducted a study on non-biodegradable organic removal of landfill leachate by chemical oxidation combined with biological treatment. In this study, an oxidation removal efficiency of 75% was used. This oxidation removal efficiency was determined from Fenton's reagent optimization experiments performed on matured leachate samples. The recommended oxidation conditions were pH range of 3-5 and a 1.0 g H_2O_2 per gram chemical oxygen demand (COD) dosage with a molar ratio of 0.4 Fe_2 to H_2O_2 and reaction time of 15 minutes. The biological removal efficiency is related to the aerobic biological degradation of treated leachate. The BOD as carbon/dissolved organic carbon (BOD/DOC) was increased from almost zero to 0.15 after oxidation of similar leachate samples, indicating 15% of organic carbon remained after Fenton's reagent is aerobically biodegradable.

Combined treatment of Fenton's oxidation and activated sludge (AS) was performed by Kurniawan et al., (2010). In this study, almost complete removal of COD and NH_3-N was reported for combined reversed osmosis (RO) and UASB with initial COD concentration of 35 000 mg/L and NH_3-N concentration of 16000 mg/L. While integrated Fenton's oxidation and AS (activated sludge) could achieve about 98 and 99% of COD and NH_3-N, respectively, with both initial COD and NH_3-N concentrations of 7000 mg/L. Hybrid treatment of wet oxidation and activated sludge in treating leachate was reported by Avezzu, (1992). In this study, leachate samples were taken from few landfills, namely Brescia, Veneto, Fossalta which located in Italy and Mechernich in Germany. The results showed the removal efficiency of COD were 50, 26, 27, 38%, respectively after undergone those treatments with the initial COD concentration ranging from 3100 – 19 400 mg/L.

Asha and Latha, (2013), conducted a study on mature landfill leachate treatment from Vilappilsala, India. In this study, Fenton process is applied as chemical pre-treatment prior to anaerobic process. After Fenton pre-treatment, the removal of COD, BOD, turbidity, nitrate, sulphate and TSS were 92.1%, 83.5%, 94.2%, 18.8%, 11.0% and 96.6%, respectively. At optimum parameters; pH 3, reaction time of 30 min, H_2O_2/COD ratio 3, H_2O_2/Fe^{2+} ratio 15 and 3 g/L sludge recycling, the biodegradability (BOD5/COD) enhanced from 0.3 to 0.65 while acute toxicity (96 hr LC_{50}) reduced to 6.3%. Fenton's treated leachate after undergone post treatment anaerobically at HRT 13 days, pH 7, COD, BOD, turbidity, nitrate, sulphate and TSS removal was 90.3%, 98.2%, 28.3%, 69.9%, 40% and 78.2%, respectively and toxicity reduced by 22%.

In 2000, Sheng and Chih, reported an investigation of the treatment of an aged landfill leachate by the combination of chemical and biological process. The electro-Fenton method assisted by chemical coagulation was employed for the treatment. The result revealed it to be highly efficient in removing large amounts of refractory organic and inorganic compounds in the leachate. The findings also showed that at an optimum pH 5 yielded better COD and color removal of more than 50%. And at PAC/polymer ratio 100: 1, the amount of PAC required to effect a maximum COD removal was found to increase linearly with the initial leachate COD concentration and a slope of 0.184 mg/L PAC per mg/L of initial leachate COD concentration. It was observed that the electro-Fenton oxidation employed was able to greatly enhance the COD removal of leachate effluent from chemical coagulation. At an optimum pH 4,the oxidation process rendered the leachate effluent totally colorless. It was also observed that at an optimum H2O2 dosage of 750 mg/L yielded a very good COD, color, NH3-N and phosphorus removal in less than 30 minutes.

Research on combined UV/Fenton and sequencing batch biological reactor (SBR) treatment of a semi-aerobic landfill leachate was investigated by Gan et al., 2013. In this study, Fenton pre-treatment of the leachate was optimized by the response surface methodology (RSM). UV/Fenton pre-treatment of

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

the leachate was performed under the optimum operating conditions of the Fenton pre-treatment (H_2O_2/COD molar ratio 2.25, H_2O_2/Fe^{2+} molar ratio 10.0 and reaction/irradiation time 1.5 h). The characteristics of the UV/Fenton pre-treated leachate were: COD 390 mg/L, sCOD 330 mg/L, BOD5 136 mg/L, BOD5/COD ratio 0.35, NH_3-N 112 mg/L, TKN 157 mg/L, NO_3--N 6.8 mg/L and colour 99 Pt-Co Unit. SBR treatment of the UV/Fenton pre-treated leachate resulted in COD, BOD_5 and NH_3-N removal of 78%, 81% and 88%, respectively. The final effluent characteristics were: COD 92 mg/L, sCOD 71 mg/L, BOD5 26 mg/L, NH3-N 7 mg/L, NO_3--N 27 mg/L, TKN 13 mg/L and TSS 38 mg/L. The effluent met the Malaysian discharge standard (B) – COD 100 mg/L, BOD_5 50 mg/L and TSS 100 mg/L. Combined UV/Fenton and SBR is an effective treatment for mature leachate from semi-aerobic landfill.

A laboratory scale investigation was conducted by Claudio et al., 2006 aimed at evaluating the effectiveness of mature municipal landfill leachate treatment by a biological stage, carried out in a periodic biofilter with granular biomass (SBBGR), followed by a chemical oxidation step, performed using ozone or Fenton, for further COD removal. The results show that the biological treatment was able to remove roughly 80% of COD in leachate at an organic loading approximately equal to 1.1 kgCOD/m^3/ day). Ammonia removal efficiency was very low (lower than 20%) because of the presence of high salinity and inhibitory compounds. When the leachate was pre-treated in order to reduce considerably the ammonia content, it was found to be possible to reach organic loadings as high as 4.5 kgCOD/m^3/day with a decrease in COD removal of only 10%. The biological treatment was characterised by a negligible sludge production. Ozone and Fenton reagent were used to reduce the remaining COD content presumably made up of recalcitrant compounds. The treatment with ozone was able to remove only 33% of residual COD whereas using Fenton reagent an 85% removal efficiency of COD was achieved.

Rivas et al., (2004) conducted a study on combined sequential coagulation-flocculation and Fenton oxidation processes. The purpose of performing this combined process is to remove the colloidal particles in the leachate. In this study, it was found that about 90% of COD removal was achieved with an initial concentration of 7400 mg/L at pH 8.5 by using 0.8 g/L of $FeCl_3$. The transformation of recalcitrant organic compounds from stabilized leachate using a coagulation – ozonation coupling was investigated by Monje-Raminez et al., 2004. The use of iron (III) sulphate as the coagulant during pre-treatment was found effective. Combined treatment with ozonation was able to reduce 78% COD with an initial concentration of 5000 mg/L.

A pilot-scale study of the application of a combined solar photo –fenton and biological oxidation process for the treatment of landfill leachate was also conducted (Silva et al., 2013; Vilar et al., 2011). They reported that the solar fenton was more efficient as compared to the subsequent biological oxidation process in the leachate treatment. The overall combined treatments were able to remove 86% DOC of which 55% was through solar photo fenton process. The result suggests that the combination of the two treatments improved the efficiency of the treatment as compared to a single process.

PHYSICAL AND BIOLOGICAL TREATMENTS

Biological treatment is the most common practice for leachate treatment. Biological systems can be divided in anaerobic and aerobic treatment processes which include anaerobic filter, anaerobic sludge bed reactor (UASB), aerated lagoons, activated sludge plants, rotating biological contactors (RBC), trickling filter, sequential batch plant and co-treatment with sewage (Stegmann et al.,2005) and well known physical treatment for leachate treatment is air stripping, adsorption and membrane filtrations (Kılıç et

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

al., 2007). A combination of two treatments is more efficient and effective than individual treatment due to the fact that a two-step treatment has the ability to synergize the advantages of individual treatments, while overcoming their respective limitations (Kurniawan et al.,2005).

Mojiri (2014) researched on adding a new adsorbent (powdered ZELIAC; PZ) to the SBR technique as another alternative for landfill leachate and domestic wastewater treatment. ZELIAC adsorbent was prepared from zeolite, activated carbon, limestone, rice husk ash, and Portland cement composite. Two reactors were used comprising of Normal SBR and PZ (powdered Zeliac) augmented SBR process. At optimal operating conditions for the SBR reactor was reported at an aeration rate of 4.49 L/min, contact time of 12.05 h and leachate to wastewater ratio 20%, which resulted to about 55.83%, 45.92%, 98.27%, and 33.56% rates of removal for COD, NH3-N, and phenols, respectively. The optimum experimental conditions for the PZ-SBR reactor happened at an aeration rate of 1.6 L/min, contact time of 15.43 h and leachate to wastewater ratio of 20%, which resulted to 82.04%, 71.56%, 98.27%, and 61.98% rates of removal for COD, NH3- N, and phenols, respectively. The results indicated that the PZ-SBR showed higher performance in removing certain pollutants compared with normal SBR.

Other research about SBR treatment showed by Aziz et al., (2011); which in this study, landfill leachate was treated by using two types of the SBR, namely non-powdered activated carbon and powdered activated carbon (PAC-SBR) were used. Throughout this study, removal efficiencies of chemical oxygen demand (COD), colour, ammoniacal nitrogen (NH3-N), total dissolved salts (TDS), and sludge volume index (SVI) were monitored and based on the results, the PAC-SBR displayed superior performance in terms of removal efficiencies when compared to SBR. At the optimum conditions of aeration rate of 1 L/min and contact time of 5.5 h the PAC-SBR achieved 64.1%, 71.2%, 81.4%, and 1.33% removal of COD, colour, NH3-N, and TDS, respectively.The SVI value of PAC-SBR was 122.2 mL/g at optimum conditions.

Lim et al., (2010) also studies on supplemented an adsorbent in SBR treatment using powdered activated carbon (PAC) and also ethylenediamine-modified rice husk (MRH). The objective of this study is to evaluate the performance of MRH compared to PAC as supplemented SBR in the removal of COD and nitrogen from a combined landfill leachate and domestic wastewater. The SBRs were operated with the Fill, React, Settle, Draw and Idle periods in the ratio of 2:12:2:1:7 for a process duration of 24 h. The efficiency of the reactors was assessed by monitoring the effluent quality as well as the adsorption of COD, ammonia nitrogen (AN), nitrite nitrogen and nitrate nitrogen during the Reaction time of an operating cycle at different mixing proportions of the wastewater. The results demonstrated that the equivalent performance of the MRH and PAC augmented SBRs in terms of the performance and degree of COD and ammoniacal nitrogen removal was accomplished at a lower loading rate of MRH in comparison to that of PAC. The better performance of the MRH-supplemented SBR was attributed to be due to the existence of attached-growth biomass which to a smaller extent constrained by toxic components in leachate than suspended-growth biomass. Overall, MRH shows a promising potential for being utilized as an alternative adsorbent to PAC in leachate treatment.

In leachate treatment, because of the high chemical oxygen demand (COD), ammonia nitrogen content and presence of toxic compounds such as heavy metals, direct biological treatment of landfill leachate results in less removal efficiency. Thus, in order to improve the biodegradability of the leachate, coagulation/flocculation and air stripping of ammonia was used as pre-treatment. Kargi and Pamukoglu (2003a); carried out a study on the pre-treated leachate that was treated biologically using an aeration tank operated in fed-batch by adding adsorbent. The experiment was conducted by comparing results of tests in the absence and presence of powdered activated carbon (PAC) respectively as an adsorbent.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

The result showed that PAC addition, improved COD removal significantly, especially at concentrations above 0.5 g/L. However, improvements in COD removals were marginal for PAC concentrations above 2 g/L. And about 86% COD removal was achieved with 2 g/L PAC added with biological treatment, whereas, COD removals by the only biological oxidation process or only PAC adsorption were about 74 and 38%, respectively at the end of 30 h of fed-batch operation. The authors reported that adsorbent concentrations were varied between 0 and 5 g/L. The percentage of COD and ammonium-N removals had increased with increasing adsorbent concentrations. Percentage of COD removals with PAC addition was significantly higher than those obtained when used with the zeolite. However, zeolite was more effective than the PAC in ammonium-N removal from the leachate. Nearly 87% and 77% COD removals were accomplished with PAC and zeolite concentrations of 2 g/L, respectively. Ammonium-N removals were 30% and 40% with PAC and zeolite concentrations of 5 g/L, respectively at the end of 30 h of fed-batch process.

In another study, Tsilogeorgis et al.,(2008) carried out an alternative leachate treatment process by using bench-scale membrane sequencing batch reactor (MSBR) on a stabilized landfill leachate which was obtained from the solid waste landfill of Thessaloniki (North Greece). The MSBR was set up with a hollow fiber ultrafiltration membrane with a working volume of 5L at a non-steady state flow. The mean concentration of the influent leachate was 2456 mg/L COD, 375 mg/L total nitrogen (TN) and 8.2 mg/L PO_4-P. The hydraulic retention time (HRT) was set at a constant state for 10 days for a majority of the assays, in contrast the solids retention time (SRT) was basically limitless. Low COD removal was observed (40% to 60%). The low MSBR efficiency of COD removal was associated to the high SRT. However, the ammonia nitrogen concentration was negligible, moreover, TN removal performance was considerable during the various stages of the MSBR operation, attaining up to a peak value of 88%. Finally, it was observed that MSBR was economically a cost effective process of landfill leachate treatment producing effluent of desirable properties.

Horan et al., (1997) investigated the performance of the Envirex granular activated carbon biological fluidized bed (GAC-BFB) process to treat landfill leachate containing organic material with typical COD values in the range 800 to 2700 mg/l with high concentrations of ammonia in the range 220 to 800 mg/L. Prior to the treatment, lime was added to the leachate to raise the pH to 9.0 and also to reduce any heavy metal impurities. Two identical pilot plants GAC-BFB's were used in series in order to achieve the removal of both organic and ammoniacal nitrogen within the same process.The pH within the reactors were maintained between 6.5 to 7.5. During the early stages of operation, loading rate of 1.56 kg ammonia-N/m3 d was employed. The reactors were able to remove 70% of the ammonia. 60% of COD and achieved a complete removal of BOD. After achieving optimal reactor operating system, it proved to be possible to achieve greater than 90% removal of ammonia at a loading rate of 0.71 kg N/m d; however the COD efficiency remained constant. In order to compare the ammonia removal efficiency of the GAC-BFB system. Two conventional activated sludge reactors were operated in parallel at hydraulic retention times of 24 and 36 hours (equivalent to ammonia loadings of 0.72 and 0.48 kg ammonia-N/m^3 d) and with a sludge age of 20 days. These reactors were not able to nitrify and although a BOD removal of 90% was achieved the COD removal efficiency was very low at 20%. Thus, the GAC-BFB system offers a highly effective option for the biological removal of ammonia from high ammonia leachates with the additional advantage of a good fraction of COD removal.

PHYSICAL, CHEMICAL, AND BIOLOGICAL TREATMENTS

Mavros et al., (2008) mineralize a leachate from Olive Pomace sequential alum coagulation, activated-carbon adsorption and electrochemical oxidation process are used. The effect of coagulant and adsorbent concentration on treatment efficiency was assessed in the range 0.1–50mM Al^{3+} and 2.5–50 g/L activated-carbon and optimal conditions were established. Coagulation at 7.5mM Al^{3+} resulted in substantial solids and color removal (i.e. 80% and 93%, respectively). This was accompanied by only 30% chemical oxygen demand (COD) reduction (initial COD was about 3500 mg/L). The latter increased to 80% though when coagulation was coupled with adsorption at 25 g/L activated carbon. Electrochemical oxidation of the original effluent for 360 min led to 63% and 82% COD reduction at 10 and 20A current intensity, respectively. When this process was tested as a polishing stage following coagulation and adsorption, overall COD removal reached values of 92% and 97%, respectively. The final effluent was also colorless and solids free. However, the treated effluent still exhibited ecotoxicity possibly due to the formation of ecotoxic oxidation products.

The treatment efficiency of stabilized leachate from the Gramacho landfill (Brazil) by combining coagulation-flocculation and ozonation followed by ammonium stripping for 96 h was evaluated (Silva et al., 2004). This combination was found to be effective for complete removal of NH_3–N with an initial concentration of 800 mg/L. When 3 mg/L of ozone was employed, ozonation was able to achieve 48% COD removal with an initial concentration of 3460 mg/L. Marttinen et al., 2002 suggested nanofiltration and air stripping process for the treatment of low strength municipal landfill leachates to remove of organic matter, ammonia, and toxicity from low strength leachates (NH_4-N 74–220 mg/l, chemical oxygen demand (COD) 190– 920 mg O_2/l, EC50 ¼ 2–17% for Raphidocelis subcapitata. Ozonation was studied as well, but with the emphasis on enhancing biodegradability of leachates. Nanofiltration at 25° C was capable to remove 52–66% of COD and 27–50% of ammonia, the latter indicating that ammonia may in part have been present as ammonium salt complexes. Air stripping (24 h at pH 11) resulted in 89% and 64% ammonia removal at 20ºC and 6ºC, respectively, the stripping rate remaining below 10 mg N/l h. COD removals of 4–21% were obtained in stripping. Ozonation at 20ºC increased the concentration of rapidly biodegradable COD (RBCOD).

A combination of two physical and biological treatments is also efficient as reported by Wang, G., et al.(2014). In this study, anoxic/aerobic granular active carbon is used to assist membrane bioreactors (A/O-GAC-MBR) integrated with nanofiltration (NF)–reverse osmosis (RO) in leachate treatment of the Taizhou Municipal Landfill plant. The result showed excellent and stable removal efficiency with an average above 80% of chemical oxygen demand (COD) and ammonia-nitrogen (NH_3-N). It was noticed that the amount of high-valence metal ions were removed more than low-valence ones. The addition of GAC not only improved the removal of hazardous organic pollutants and heavy metals, but also enhanced the bioflocculation and particle size of flocs, which greatly alleviated membrane fouling. NF and RO membranes were then used for advanced treatment of MBR effluents. NF membrane exhibited excellent color removal rate of 93.75% compared to 41.82% of A/O-MBR. With the advantage of NF pretreatment, RO membrane held a steady and higher flux as well as salt rejection than other cases reported. The final permeate from RO was proved to exceed related qualification for reutilization and can easily be recycled in the industry.

Zhang et al., (2013) studied treatment of stabilized leachate from Zhoushan, Zhejiang (China) using Fenton - submerged membrane bioreactor- reverse osmosis system. In the process, the Fenton oxidation was designed to deliver more samples for the aerobic SMBR treatment under an ideal condition.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

The fenton reactor was loaded with 15 L of leachate sample, and the treated leachate were utilized as influent for the Aerobic submerged membrane bioreactor (SMBR) to increase the removal of organic matters and ammonium. SMBR with a working volume of 40 L were utilized for treatment. A self-made polyvinylidene fluoride (PVDF) hollow fiber module was immersed in the bioreactor. Fenton effluent was stored in the tank and constantly pumped into the bioreactors. The air was supplied consistently to bio- reactor at the steady rate (0.1-0.15 m^3/h) to provide dissolved oxygen and decrease membrane fouling. The MBR effluent was pumped into the Reverse osmosis (RO) modules. The filtration unit comprised of three stacks of plate-frame membrane modules, which was set in the serial arrangement with effective filtrating zone of 66 cm^2. The concentrate was then combined with secondary effluent and returned back to the feed tank. The specimens from the effluent and the concentrate were both collected simultaneously as operation continuous. The result produced high quality effluent with COD less than 15 mg/L and Ammonia-nitrogen less than 8 mg/L and membrane fouling was reduced.

In a study carried out by Wu et al., (2011) on the treatment of landfill leachate using a combination system that comprise of sequence batch reactor (SBR), coagulation, fenton oxidation and biological aerated filtration (BAF) in series. The leachate was treated by a combined plant utilizing a consecutive batch reactor (SBR) as the initial stage, poly-ferric sulfate (PFS) coagulation and a Fenton system as secondary treatment and biological aerated filter (BAF) as the tertiary treatment (Li et al., 2009; Hasar et al., 2009; Wang et al., 2009; Renou et al., 2008). Biological treatment in SBR reactor was operated at normal atmospheric temperature. The supernatant from the SBR was collected and combined together with coagulant PFS without pH alteration in a flocculation basin where coagulation and sedimentation were performed. At that stage, the PFS-treated leachate was further treated by the Fenton system through four stages: oxidation, balance, flocculation, and sedimentation. Supernatant from the Fenton treatment was collected and pumped into the BAF for last treatment. The air was introduced into the reactors from the base.The system was found to achieve removal of COD (98%), BOD (99.1%), NH_4-N (99.3%), TP (99.3%), SS (91.8%), Turbidity (99.2%) and Color (99.6%).

Another study of the treatment of stabilized leachate was conducted by Chemlal et al., (2014), applying a combination of advanced oxidation using photocatalytic reactor with UV- lamp for continuous irradiation of a coated adsorbent media to treat stabilised leachate of Oued smar landfill in Algeria. The photocatalysis analyses were carried out in batch. The photocatalytic reactor comprises of a 3 L capacity tank steel chasis menu, a slanted glass plate is coated with the photocatalytic media (TiO2, silica and zeolite) on which runs a thin layer of leachate to be treated with a cover under which are added three UV-C lamps which ensures constant irradiation of the media. The irradiated leachate obtained was then treated with aerated bioreactor. The leachate even distribution over the catalyst entire surface is provided by a distribution valves. The sample agitation is made with a helical stirrer and the leachate is aerated through by a vacuum apparatus. The biological treatment comprised of the establishment of three bioreactors inoculated with different inoculums ; raw leachate, soil extract from the Oued Smar landfill and lastly the activated sludge. The treatment had reduced the initial BOD5 value by 90% and the initial COD by 87%.

A combination of nanofiltration and microfiltration-PAC hybrid process application after treatment with a Jet-loop membrane bioreactor for the treatment of landfill leachate was explored by Ince et al., (2010) in Turkey. It was found that the nanofiltration (NF) unit alone put after the Jet loop membrane bioreactor to further treat the effluent was not adequate to reduce the COD concentration to desired levels (700 mg COD/L), but the combination of hybrid (MF-PAC) to treat the effluent was able to reduce the COD from the Jet loop membrane to desired levels. The hybrid treatment with application of 8g PAC/L

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

was efficient in COD removal yielding lower values than the allowed discharge limit (700mg COD/L). It was also observed that an increase in PAC, the amount of pollutants adsorbed increased yielding an efficiency of 0.169g COD/g PAC. Moreover, it was suggested that the reason for this increased yielding an efficiency was because the Jet-loop effluent does not contain suspended solids. This result suggests that the hybrid treatment process is more effective than a single process.

In the Changshengqiao landfill (China), the treatment of leachate from the stabilized landfill using a combination of air stripping, Fenton, SBR and coagulation process was investigated by Guo et al.,(2010). In the combined successive treatment test run, the landfill leachate was initially applied to the air stripping for pretreatment to withdraw ammonia. The effluent from that unit was then oxidized in the Fenton reactor to remove bio-refractory compounds. At that point, the effluent from the Fenton treatment was combined with sewage wastewater at a ratio of 1:3 and transfered to the SBR unit to improve the removal of organic matter. Eventually, the effluent was transfered to the chemical coagulation reaction to remove suspended solids. The intergrated treatment was run under the ideal conditions for all the processes. COD, BOD5, and NH_3-N of the effluents were measured toward the end of each one process. The general effectiveness of the intergrated treatment was analyzed. It was reported that the integrated system achieved an outstanding performance in the overall removal of COD (93.3%) and NH_3-N (98.3%).

The treatment of leachate from the Herbin landfill (China) was explored by Bu et al., (2010) using a combination of sequence batch reactor (SBR)+aeration corrosive cell-fenton (ACF)+ granular activated carbon (GAC) adsorption in series. With a volume of 10 L, the SBR reactor was operated one cycle every day at room temperature. considering the resistance of aerobic micro-organism inside SBR, tap water was diluted with the leachate 9 times. The SBR was run persistently after acclimation of 1.5 months. The effluent of the SBR was pumped into the ACF reactor. The columnar Plexiglas ACF reactor had a volume of 0.6 L. To accomplish corrosive cell response, the ACF section was loaded with a mixture of iron scraps (350 g) and GAC (100 g) based on the ideal dosage test, bringing about a mass ratio of iron scraps and GAC of 3.5:1. Initially, the iron scraps were activated with 1% hydrochloric acid (V/V) to clear the iron rust thereafter cleansed with distilled water. The SBR effluent was pumped into the ACF reactor with an upflow rate of 6.7ml/min. The effluent of ACF would be pumped into the GAC segment. The columnar Plexiglas GAC adsorption reactor had a powerful volume of 0.28 L. Commercial GAC of 1 mm x 3 mm was filled into the reactor at a dose of 0.9 g/L as the adsorbent. The ACF effluent was pumped into the GAC section at an upflow rate of 9.3 ml/min. It was reported that the removal efficiencies of COD, BOD_5 and DOC were 97.2%, 99.1% and 98.7%, respectively. And also in the final effluent Fulvic-like compounds were effectively removed.

The treatment of stabilized leachate from the Chang shankou landfill (China) using a combination of agitation,coagulation, SBR and filtration was evaluated by Abood *et al*., (2014). Work was carried out by observing a combined successive treatment test run. The landfill leachate was initially fed to an agitation process to deplete ammonia. The effluent from that unit was treated by the coagulation–flocculation process applying PFS as a coagulant to reduce the concentration of organic matter and to alter the BOD /COD ratio. At that point, the effluent was combined with the sewage wastewater at a varying proportion and supplied to the SBR unit to improve the removal of organic matter. Eventually, filtration using a layer of carbon and sand as a viable medium was utilized as a refining procedure to meet effluent release standard. The combined treatment was run under the ideal conditions for each single process. COD, BOD_5, SS, TOC and NH_3 -N of the effluents were measured at the end of each process. The final effluent concentration of COD, BOD_5,SS, NH_3-N and TOC at the end were 72.4mg/L, 22.8mg/L,

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

24.2mg/L, 18.4mg/L and 50.8mg/L, respectively, which were below the permissible discharge standard (COD ≤100mg/L, BOD_5 ≤ 30mg/L, SS ≤ 30mg/L and NH_3-N ≤ 25mg/L). This was reported as an outstanding treatment performance with an overall removal of COD (97.4%) and NH_3-N (99.2%).

CONCLUSION

As a conclusion, a combination treatment proves to be more efficient and effective than individual treatment. This could be due to the fact that two or three-step treatment has the ability to achieve the advantages of individual treatments as well as subduing their unit process limitations. A combined treatment is indeed capable of improving the effluent quality and minimizing the residue at a lower treatment cost than an individual treatment.

Chapter 10
Structure Development for Effective Medical Waste and Hazardous Waste Management System

Nilgün Cılız
Boğaziçi University, Turkey

Hacer Yıldırım
Boğaziçi University, Turkey

Şila Temizel
Boğaziçi University, Turkey

ABSTRACT

Management of medical and hazardous wastes is a serious problem especially for developing countries. People are not aware of possible threats and/or they are afraid of the cost of application. Rapid population growth leads municipalities towards proper solid waste management applications. In this study, data were collected from the Turkish Statistical Institute and a general framework was drawn for medical and hazardous waste amounts and disposal methods. Starting from this point of view, the authors analyzed both the Regulation on Control of Hazardous Waste and the Regulation on Control of Medical Waste applied in Turkey. Taking into account all of these factors, this chapter is intended to develop the medical and hazardous waste management system economically and environmentally including waste generation, collection, transportation, disposal and treatment activities. Additionally, it investigates the reasons for lack of proper application of the regulations in light of the statistical data.

INTRODUCTION

Handling of medical and hazardous waste has been a serious problem for countries all over the world. Economically developing countries are facing the waste management issue more than developed countries. An effective waste management system necessitates special operations, which have to be subjected to wastes in order to prevent damages for both environment and human health. National policy, training of employee and increased public awareness are the fundamentals of medical and hazardous waste management system.

Unless the collection and disposal of medical waste are applied separately, transmission of diseases will be unavoidable. Additionally this situation causes some problems including economic and environmental issues. Therefore, to increase the quality of life, medical waste management system should be applied and shed light on the service manner in terms of technical, social, economic and environmental areas.

Likewise, both hazardous wastes; which affect environment, human health and other living organisms negatively in physical, chemical and/or biological ways; and hazardous waste management system are very important matters for developing societies to deal with. As a result, for the protection of the environment and sustainable development, integrated medical and hazardous waste management system should be developed and applied depending upon related regulations.

As a part of this study, related regulations, application requirements, sources of medical and hazardous waste, classification of waste, responsibilities of waste generators, municipalities and ministries are subjected. Moreover, all stages will be examined separately, starting from the generation to the disposal of waste. Within this context, the following topics will be referred: collection of medical and hazardous waste in a separate way, processes to reduce the amount of waste, temporary storage, transport and methods for disposal.

BACKGROUND

Definition of Medical Waste

The medical waste definition covers the waste that is produced by medical facilities, research units and laboratories. In addition, there are small and distributed sources of medical waste, for example household medical waste which can be expressed as dialysis waste, insulin syringe or hypodermic needles etc. (Tchobanoglous et al, 1993).

According to WHO (2011) around 75% to 80% of waste produced by medical activities are considered as nonhazardous wastes. These are called as “general medical waste” which is produced by administrative activities of medical facilities, and must be processed as household wastes.

Classification of Medical Waste Generated from Healthcare Organizations

Medical waste producers are classified related to the size of the waste that they produce; as small, medium and large. Some examples for these producers can be found in the following table: (Regulation on Control of Medical Waste, 2005) (see Table 1).

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 1. Examples of medical waste producers

Size of Waste	Healthcare Organization
Large amount of waste producers	• University Hospitals • Hospitals (for general purposes) • Maternity Hospitals • Military Hospitals
Medium amount of waste producers	• Dispensary, medical centers • Outpatient care centers • Morgue, autopsy centers • Search and experiment centers which are working with animals • Nursing homes • Medical and biomedical laboratories • Animal Hospitals • Blood banks and transfer centers • Emergency rooms • Dialysis centers • Rehabilitation centers • Biotechnology laboratories and institutes • Medical research centers
Small amount of waste producers	• Consulting rooms • Dental health clinics • Veterinaries • Acupuncture centers • Tattoo and piercing activities • Physiotherapy centers • Medical treatment and nursing done at home • Pharmacies • Zoo • Ambulances

Infected Waste

Contagious waste may contain pathogens such as bacteria, viruses, parasite and fungus; and this situation may cause some diseases. This contains the following classes;

- Infectious samples and cultures that are formed in laboratories,
- The materials and equipment that are used for pestiferous patients,
- The waste of quarantined patients (urine, excrement, perspiration, clothes of contagious patients etc.),
- The waste of patients who use kidney machine and have infectious disease (dialysis equipment, tubes, filters single use stuff, laboratory clothes etc.),
- Animals which have infectious diseases in laboratories,
- All stuff that are contaminated with patients who have infectious diseases (both human and animal) (Veeken, 2000).

Pathogenic Waste

Pathogenic waste consists of tissue, organ, parts of human body, fetus, carcass, blood and secretion. Moreover, both human and animal body parts are called anatomic waste and existed in this class. However, this category includes healthy body parts, which may be accepted as sub class of infectious wastes.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Sharp Objects

This group consists of materials that can cause several injuries. Syringe needles, hypodermic needles, lancet and razor blade, knifes, vaccine sets, saws, broken glasses and nails are the most common examples for sharp objects produced in healthcare organizations.

Pharmaceutical Waste

This group consists of medicines that are expired, spilled and contaminated in some ways. In addition, discarded materials such as bottles, boxes, gloves, masks, connection tubes, hoses, pharmaceutical vials are accepted in this group.

Genotoxic Waste

Genotoxic wastes are high degree toxic materials and may contain teratogenic, mutagenic or carcinogenic characteristics. These materials can cause serious security problems in hospitals and they need to be handled very carefully. Genotoxic wastes may contain cytotoxic medicines, chemicals such as benzene and radioactive materials. Cytostatic medicines and materials have the characteristic of killing and/or stopping the production of significant cells, for this reason they are used to kill cancer cells. Most common genotoxic materials are shown in Table 2 (Veeken, 2000).

Chemical Waste

The chemical wastes are produced during medical operations may be both hazardous or not. The wastes can be classified as hazardous if they have the following properties:

- Toxic
- Corrosive (for ex: acids with pH < 2 or bases with pOH > 12)
- Flammable
- Reactive (explosive, sensitive to any impact)
- Gene poisonous (cytostatic medicines)

Formaldehyde, photographic chemicals, solvent containing wastes, heavy metal containing wastes are highly toxic and sub classes of hazardous waste (Veeken, 2000).

Table 2. Genotoxic materials

Class	Genotoxic Materials
Carcinogenic	• Chemicals: benzene • Cytotoxic and other kinds of medicine: Azathioprine, chiorambucil, chiornaphazine, ciciosporin, cyclophosphamide, melphalan, semustine, tamoxifen, thiotepa, treosuifan • Radioactive materials
Possible carcinogenic	• Cytotoxic and other medicines: Azacitidine, bleomycin, carmustine, chioramphenicol, chiorozotocin, cisplatin, dacarbazine, daunorubicin, dihydroxymethyifuratrizine (for example Panfuran S is not allowed to use any more), doxorubicine, lomustine, methyithiouracil, metronidazoie, mito – mycin, nafenopin, niridazoie, oxazepam, phenacetin, phenobarbital, phenitoin, procarbazin hydrochioride, progesterone, sarcolysin, streptozocin, trichlormethine

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

High Pressure Containers

These containers are inert and not potentially dangerous, but if they contact with fire or punctured, they may explode. This class should be treated very carefully to avoid inconvenient circumstances.

Radioactive Waste

Radioactive wastes are contaminated by radionucleotides that include solid, liquid and gas materials. Radioactive wastes can be classified as following (Veeken, 2000):

- Radionucleotides which are out of usage,
- Wastes that are contaminated after treatment (for ex: towels, glass materials, syringes, tubes etc.),
- Wastes which are produced during transportation,
- Wastes contaminated by radioactive materials,
- Wastes that are produced during treatment with radionucleotides,
- Liquid wastes, for ex: remaining liquids from cleaning the medical devices,
- The gases are released during treatments.

Responsibilities Related to Medical Waste

In Turkey, Regulation on Control of Medical Waste (2005) regulates how to collect waste separately, to store temporarily, to transport and to dispose the waste. This regulation gives the responsibilities to municipalities and/or authorized institutions for application of required steps.

According to this directive, the responsibilities and duties of waste generators, municipalities and ministries are given below:

Waste Generators

Health institutions are obliged to prepare and implement the waste management plan, which includes collection, transport and temporary storage of wastes. In addition, the plan must include actions to be taken in case of accident. Additionally they are obliged to:

- Reduce the waste at source,
- Separate and collect medical, household and packaging wastes at their source,
- Use proper bags and containers (as defined by related regulations) for sharp materials,
- Transport wastes by licensed vehicles,
- Build up a place as temporary storage or provide containers,
- Teach and train personnel about waste management periodically,
- Collect data of produced waste and report the data to governorship annually, to archive the documents.

Municipalities

Municipalities are obliged to:

- Make plans and directives to collect and dispose the medical waste,

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

- Train people about the directives,
- Collect and transport the medical waste to disposal areas,
- Get related licenses and build/operate sterilization facilities,
- Get license for transporting vehicles,
- Give license for temporary waste collection areas,
- Teach personnel about medical waste management periodically,
- Provide appropriate clothes for personnel who is working in medical waste management,
- Collect data of produced waste and report the data to governorship annually and archive the documents.

Ministries

Ministries are obliged to:

- Coordinate and operate the regulative sanctions in the scope of management system,
- Control and audit the processes from production to disposal, periodically,
- Ensure the coordination with national and international corporations about application of updated technological approaches, as part of management system,
- Give license to medical waste disposal and sterilization plants.

Definition of Hazardous Waste

In US legislation, hazardous waste is described as ''Leftover products that contain corrosive, toxic, ignitable, or reactive ingredients'' (USEPA, 2005). In Europe this term is defined as "such wastes that could potentially increase the hazardous properties of municipal solid waste when landfilled, incinerated or composted" (Inglezakis et al., 2014). Lastly, UK National Household Hazardous Waste Forum provided an explanation for hazardous waste as "any discarded material, which is difficult to dispose of, or which puts human health or the environment at risk because of its chemical or biological nature" (NHHWF, 2008).

In Turkey, there are serious problems related to separation, disposal and recycling activities of hazardous wastes. According to official records come from industrial facilities, around 938.498 tons of hazardous waste is produced. However, the estimated waste production is about 1.3 million tons per year (Ministry of Environment and Urbanization, 2014). Examples for hazardous wastes can be as following (Dogru, 2012):

- Packages that are contaminated by hazardous materials (paint, chemical, oil tins and barrels) and marked with warning symbols,
- Waste oil (oil and grease, emulsion and solutions),
- Oily machine tools,
- Hazardous material leaped clothes and gloves,
- Expired batteries, organic solvents,
- Fluorescent lambs, ink and toner cartridge,
- Pesticides,
- Asbestos containing materials,

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

- Filter dusts,
- Cyanide containing hardeners,
- Oil contaminated cables.

There are additional regulations in European Union, which are related to hazardous wastes and its management system. The directive covers the methods reducing the hazardous waste, recycling and disposal activities. In Turkey, our legislation (Regulation on Control of Hazardous Waste, 2005) is compatible with European Union related directives, which are:

- Waste Framework Directive (75/442/EEC)
- Hazardous Waste Directive (91/689/EC)
- Revised European Waste Catalogue (EWC/2002)
- Landfill Directive (1999/31/EC)
- Waste Incineration Directive (2000/76/EC)

However, there were some differences between Regulation on Control of Hazardous Waste and EU directives related to the coding systems. In 2008, Regulation on Control of Hazardous Waste revised and became fully compatible with EU Waste Catalog (2000/532/EC Directive).

Classification of Hazardous Waste

Defining hazardous waste is very complex application, since there are many factors that contribute to waste's nature; it depends on the individuals view (Wentz, 1989). The waste that generated mainly from the economic and industrial activities and harmful for human health (toxic, carcinogen, flammable, explosive and infectious) are accepted as hazardous waste. For instance, batteries, paints, lubricants and some chemicals are in this group.

Classification of hazardous waste is expressed in Regulation on Control of Hazardous Waste as following:

Q1: Production and consumption waste that is not defined below.
Q2: Nonstandard products.
Q3: Expired products.
Q4: Modulated, spilled and/or contaminated materials because of misusage.
Q5: Contaminated materials (e.g. cleaning activities, packaging waste, containers etc.).
Q6: Obsolete materials (e.g. dead batteries, catalyzers etc.).
Q7: Materials that show bad performance (e.g. contaminated acid, contaminated solvent, dead surface salts etc.).
Q8: Industrial waste (e.g. slag, clinker, sediments etc.).
Q9: Cleaning and filtering waste (e.g. cleaning muds, filter dusts, used filters etc.).
Q10: Machine/surface treatment waste (e.g. turning machine waste, milling waste etc.).
Q11: Waste produced from raw material production and cultivation (e.g. petroleum and mineral mining etc.).
Q12: Defiled materials (e.g. PCB contaminated oil).
Q13: Prohibited materials and products.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Q14: Obsolete products by producers (e.g. agricultural, household, office, commerce and marketing activity waste).
Q15: Waste produced from land improvement and reclamation activities.
Q16: Materials that are not expressed above.

Properties of Hazardous Waste

Hazardous waste is the material that has harmful effects on human health and their environment. Hazardous materials' properties, which can be found in Regulation on Control of Hazardous Waste, are given below:

H1 – Explosive: Materials those are flammable; more sensitive to shocks and friction than dinitrobenzene; reacting and releasing gas under certain conditions.
H2 – Oxidizing: Materials that exhibit highly exothermic reactions when in contact with other substances, particularly flammable ones.
H3 A – Highly Flammable:

- Liquid substances those having a flash point below 21°C (including extremely flammable liquids),
- Substances which may become hot and catch fire in contact with air at ambient temperature without any application of energy,
- Solid substances which may readily catch fire after brief contact with a source of ignition and which continue to burn or be consumed after removal of the source of ignition,
- Gaseous substances which are flammable in air at normal pressure,
- Substances, which, in contact with water or damp air, evolve highly flammable gases in dangerous quantities.

H3 B – Flammable: Liquid substances and preparations having a flash point equal to or greater than 21°C and less than or equal to 55°C.
H4 – Irritant: Non-corrosive materials, which, through immediate, prolonged or repeated contact with the skin or mucous membrane, can cause inflammation.
H5 – Harmful: Substances which, if they are inhaled or ingested or if they penetrate the skin, may involve limited health risks.
H6 – Toxic: Materials which, if they are inhaled or ingested or if they penetrate the skin, may involve serious, acute or chronic health risks and even death.
H7 – Carcinogenic: Substances and preparations which, if they are inhaled or ingested or if they penetrate the skin, may induce cancer or increase its incidence.
H8 – Corrosive: Materials that may destroy living tissue on contact.
H9 – Infectious: Materials containing viable microorganisms or their toxins that are known to cause disease in living organisms.
H10 – Teratogenic: Materials which, if they are inhaled or ingested or if they penetrate the skin, may induce non-hereditary congenital malformations or increase their incidence.
H11 – Mutagenic: Substances which, if they are inhaled or ingested or if they penetrate the skin, may induce hereditary genetic defects or increase their incidence.
H12: Substances and preparations that release toxic or very toxic gases in contact with water, air or an acid.
H13: Waste capable by any means, after disposal, of yielding another substance.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

H14 – Ecotoxic: Waste which presents or may present immediate or delayed risks for one or more sectors of the environment.

Responsibilities Related to Hazardous Waste

In Turkey, Regulation on Control of Hazardous Waste regulates how to collect waste separately, to store temporarily, to transport and to dispose the waste. This regulation gives the responsibilities to municipalities and/or authorized institutions for application of required steps.

According to this directive, the responsibilities and duties of waste generators and ministries are given below:

Waste Generators

Waste generators are obliged to:

- Take precautions to reduce the amount of waste,
- Make appropriate waste management plan to reduce the harmful effects of the waste to environment and living organisms. In addition, they are obliged to get permission from governorship for temporary storage,
- Record the waste and package/label them as indicated in international standards,
- Manage documentations including waste declarations for prior year and send them to governorship,
- Apply procedures for disposal and storage and fill the international forms if these applications take place out of the plant,
- Monitor international standards for transportation,
- Contribute to expenses for setting up disposal facilities,
- Preserve hazardous waste in durable, impermeable and safe containers, which are in accordance with international standards and located far from production area but in that facility,
- Label that containers with international hazardous waste symbol, amount of waste inside and the storage date,
- Locate waste to ensure safe storage and prevent occurring chemical reactions,
- Take precautions for health and safety issues of the personnel,
- Document accident reports to governorship and contribute to expenses for rearrangement of that area in a month at the latest,
- Leave a personnel in charge for temporary storage and give him/her personal information to governorship (this situation is just for facilities that are producing one tone of hazardous waste in a month),
- Prove that waste disposal completed successfully.

Ministries

Ministries are obliged to:

- Indicate programs and policies to apply waste management system efficiently,
- Coordinate/audit application of regulations and report them to governorship,
- Prepare waste management plan and inform people,

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

- Carry out international works on transportation of the waste,
- Audit the disposal facilities and apply necessary sanctions,
- Control and audit closed disposal facilities for 20 years,
- Indicate principles of emergency plans for facilities,
- Coordinate the usage of environmentally friendly technologies and waste management systems.

WASTE MANAGEMENT

Medical Waste Management

The total amount of waste generated by health-care activities, about 80% is general waste comparable to domestic waste. The remaining 20% is considered hazardous material that may be infectious, toxic or radioactive. Lack of awareness, inadequate training, absence of waste management and disposal systems, insufficient financial and human resources and the low priority given to the topic are the most common problems connected with medical waste. Still, many countries do not have appropriate regulations; if they have, they do not enforce them effectively (Prus et al., 1999; WHO, 2011).

Integrated medical waste management is a system in which reduction, minimization, collection by degradation, temporary storage, transportation and disposal mechanisms are examined separately for household, medical and hazardous wastes. In this system, following up the control periods for these wastes are implemented with the light of the legal obligations. Typical flowchart of medical waste management is shown in Figure 1 (Esmen et al., 2013).

To minimize the risks posed by medical wastes to the environment, medical wastes must be treated with the most appropriate technologies. Medical waste handling methods, e.g. packaging, depend largely upon the disposal method or location of the disposal facility, and the existence of state and local regulations.

Separation of Medical Wastes

Firstly, medical wastes are separated whether they are hazardous or not. Then the second separation is carried out for recoverable medical wastes; which are glass, paper, plastic etc.; and these wastes contribute to economy by recovery. On the other hand, thermometers, manometers, mercury containing wastes, dental polyclinic wastes containing metallic mercury and silver (which is used while printing x-ray films) can be recovered. Except those, recovery is not a preferable option for medical wastes.

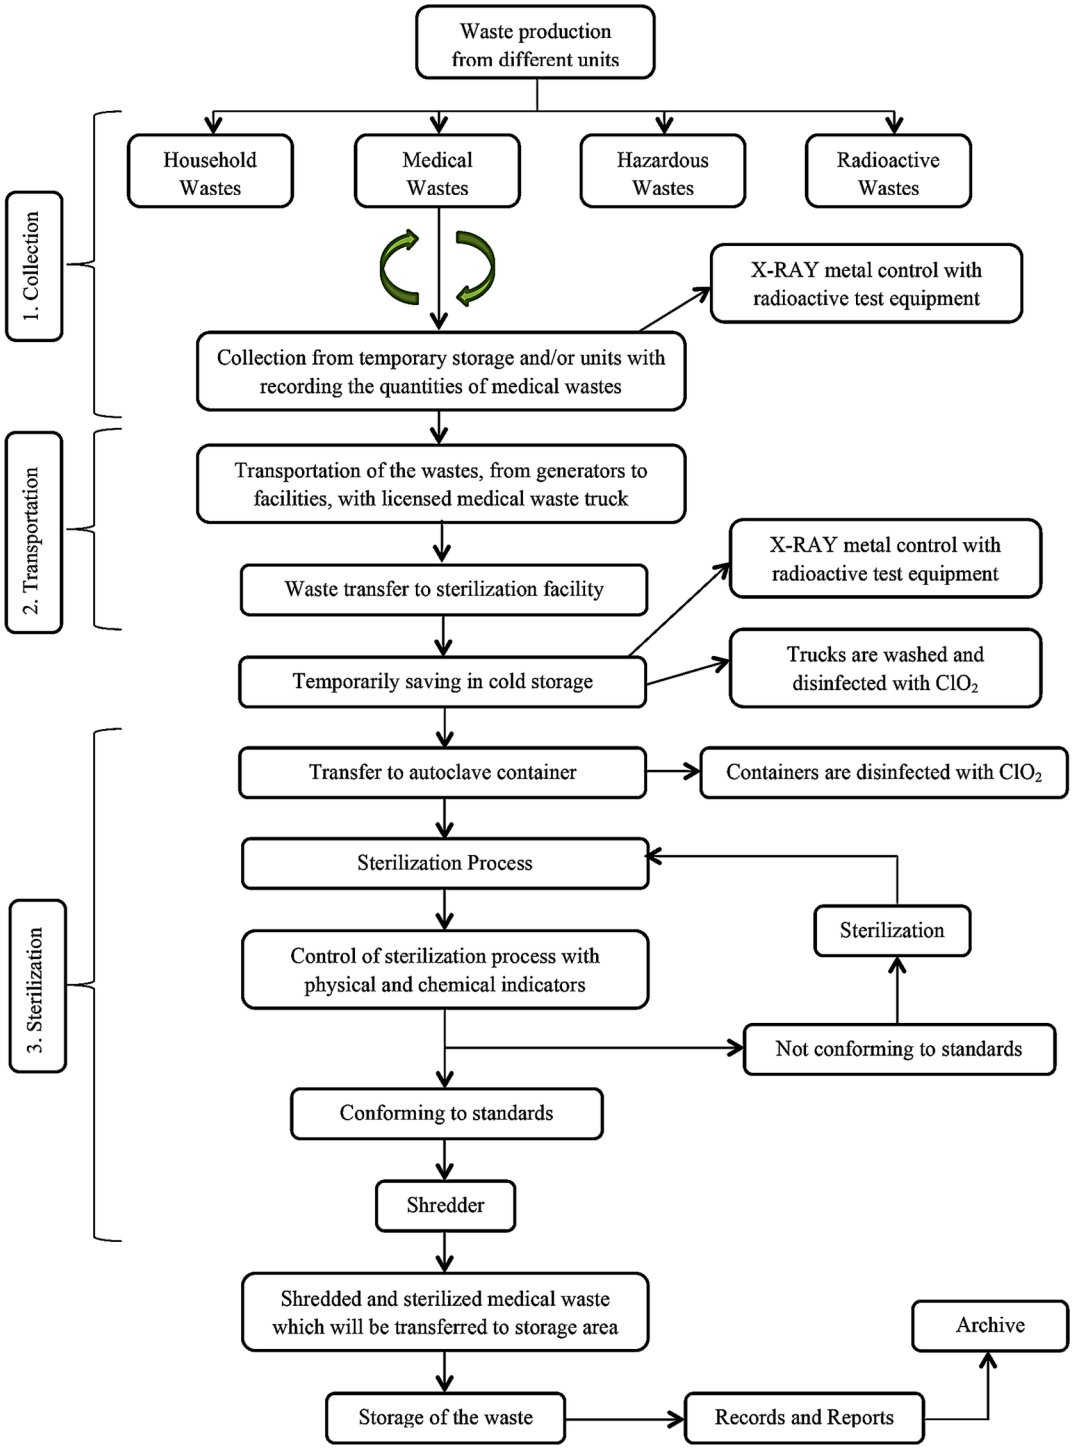
Clinical wastes including infectious waste, pathological waste, syringe, needle etc. should be collected separately to prevent contamination. This situation results greater gain on medical waste management system. Moreover, expired medicines are directed to pharmaceutical warehouses, waste chemical solvents are separated if they are hazardous or not. Nonhazardous wastes must be separated from hazardous wastes immediately, after that hazardous ones are directed to authorized companies to disposal (Veeken, 2000).

Reduction in the Quantity of Waste

In the light of "polluter pays" principle, waste generators should pay money related to their wastes' amount and type. This approach emphasizes the concept of reduction. To reduce the amount of waste following policies could be applied: lowering the amount of waste produced, using materials repeat-

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. Typical flowchart of medical waste management
(Esmen et al., 2003).



EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

edly, applying an adequate management and control, separating the wastes, implementing management and control measurements and storing of pharmaceuticals and chemicals. Making changes in the raw materials during production phase, both disposal costs and risks are reduced. These changes can be like using less hazardous chemicals, applying integrated reduction technologies, preferring electronic devices instead of mercurial instruments etc. (Tutar, 2004).

"Polluter pays" principle supports the idea for reduction of waste. This causes decrease both in the cost for disposal and in the amount of waste. In this concept, to implement all of these steps, education of the personnel is required for each workplace.

Collection of Medical Wastes

Wastes from health-care activities are collected separately depending upon their types (such as packaging materials, medical, hazardous or radioactive waste). Although there is an important point, which indicates that these wastes should not be contaminated before separation. Regulation requires generators to segregate sharps, and fluids, from other regulated medical waste to the extent practicable if the waste is intended for off-site transport and disposal. For instance; in Medical Waste Control Regulation, it is mentioned that there are four types of bags, which are special for medical wastes:

- For household medical wastes, black plastic bags are used,
- For packaging wastes, blue plastic bags are used,
- For infectious wastes, red plastic bags (which has to have an universal symbol showing that waste is biohazard /infectious waste) are used,
- For sharp objects, yellow plastic containers are used.

Figure 2. Universal logo for clinical waste
(Regulation on Control of Medical Waste, 2005).

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Regulation requires generators to label packages containing untreated regulated medical waste with the words "infectious waste" or "medical waste" or with the universal biohazard symbol (see Figure 2). Each layer of packaging or container used to meet the packaging requirements must be labeled.

The outer surface of all regulated medical waste containers that are used to meet the packaging requirements must be marked to identify the generator, if the waste is transported off-site. The outermost surface of the container must also identify the transporter and the date of shipment. The markings must be water resistant and required to help identify those persons responsible when waste that has been mismanaged or improperly disposed is found.

The packaging requirements are designed to protect people from exposure to regulated medical waste. Prior to off-site transport, medical waste must be packaged in rigid and leak-resistant containers that are impervious to moisture, sufficiently strong to prevent tearing or bursting under normal handling, and sealed to prevent leakage during shipment. Reusable containers are permissible; in many cases, containers that can be loaded on pallets and mechanically moved can be used, as long as the containers are not subjected to undue stress or compaction during transport, loading and unloading (EPA, 1991).

Temporary Storage

Medical waste that is transported off-site for disposal may be stored in indoor or outdoor storage areas. The location and capacity of a storage area depends on the quantity of medical waste generated, the frequency of pick-ups, urban/rural location, and whether on site or off-site disposal will occur.

Before transporting to disposal area, wastes can be stored in those places or containers for up to 72 hours between October-April and up to 48 hours between May-September. If there is a cooling system and the temperature is between 3 – 8^{o}C, storage time can be extended up to one week.

Properties of temporary storage area, which are explained in Regulation on Control of Medical Waste, are given below:

- It must be closed, and access must be restricted to authorized persons only,
- It must have two divisions, one is for medical wastes, the other one is for household wastes,
- It must be separate from any food store,
- It must be covered and sheltered from the sun,
- The flooring must be impermeable with good drainage,
- It must be easy to clean,
- It must be protected from rodents, birds and other animals,
- There must be easy access for on-site and off-site means of transport,
- It must be well aired and well lit,
- It must be compartmented (so that the various types of waste can be sorted),
- There must be wash basins nearby,
- The entrance must be marked with a sign,
- The doors must be clean and have universal logo for biohazard /infectious waste.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Transport to Disposal Area

Trucks are the most common type of vehicle used to pick up and transport medical waste. Small vehicles similar to vans are used to pick up small quantities of medical waste from individual practitioners. Dump trucks are sometimes used in rural areas. Flatbed trucks are also used when the waste is stored in large containers, which can be removed from the facility for transport to a disposal facility.

Methods for Disposal

Most medical waste that is not incinerated, and ash from incineration, is disposed in landfills. While infectious medical waste is often treated prior to landfilling, depending on state and local regulations, several types of generators dispose of small quantities of untreated medical waste directly in landfills. Generally, disposal methods are chemical disinfection, sterilization, microwave, landfilling, microwave radiation and incineration (Prus et al., 1999). In this chapter sterilization and incineration, most common methods used in Turkey, will be explained briefly.

Sterilization

This method is also known as autoclaving, which ensures elimination (around 99,99%) or killing all forms of microbial life, including transmissible agents; by physical, chemical, mechanical methods or irradiation (Regulation on Control of Medical Waste, 2005). Sterilization system consists of the following units: feeding system, sterilization unit, fractionation unit, boiler and software system to integrate all units. The sterilization steps can be explained respectively:

1. Transportation of medical waste from cold storage room to autoclave container,
2. Transportation of autoclave container to autoclave system,
3. Autoclaving, in which vacuum pumping and sterilization occur,
4. Boiling,
5. Electronic control system, in which all the data are followed and saved,
6. Transportation of treated waste to grinder,
7. Shredding, where wastes' volume is decreased,
8. Transportation of treated waste to the last container for waiting,
9. Loading treated waste for transportation to storage area
10. Handling

Some advantages and disadvantages of sterilization and factors affecting the effectiveness of this process are discussed as follows (U.S. EPA, 1991):

- **Advantages:** The equipment used in this method is simple to operate, has automatic processes and needs low cost. Additionally, it is safe and because of being closed system contamination does not occur. The method is capable of decontaminating most medical waste classes, reduces the volume and reproduces some plastics. Moreover, this method is easy to test and environmentally friendly.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

- **Disadvantages:** This process does not reduce the mass of material that must be disposed, produces odor, release VOCs and toxic emissions to air. In addition, a potential safety hazard exists because of the hot surfaces in the autoclave.
- **Factors Affecting Effectiveness:** Three important factors in sterilization processes are temperature, pressure, and exposure time. Together with these parameters, the size and material of the load, autoclave bag, and waste's configuration also affect the efficiency.

Incineration

Incineration is a process in which wastes are burned under controlled conditions to oxidize the carbon and hydrogen present in the waste. This method can be used to treat many types of waste; materials which cannot be incinerated remain as residue. In Turkey, because of being the most secure method, incineration is used generally. However, this method is expensive that's why sterilization is used an alternative disposal technology. As discussed below, incineration has some disadvantages as it releases air emissions containing several pollutants. In Turkey, there is a regulation to control the stack gas emissions, and incineration plant has to have the special certificate to operate the plant. Incineration is conducted by İSTAÇ in Istanbul and it consists of the following units: waste receiving unit, vibrating conveyor system, rotary kiln, secondary combustion chamber, filtration system and activated carbon dosing system (İSTAÇ, 2014).

In 2004 (the latest data available on Turkish Statistical Institute), 61502 tons/year medical waste was generated and 8224 tons/year was incinerated. The rest of the waste was buried, discharged to lakes/sea, landfilled and/or transferred to other municipalities' dumps. In addition, a data was collected in 2010, indicating the amount of incinerated medical waste as 17287 tons/year.

Some advantages and disadvantages of incineration and factors affecting the effectiveness of this process are discussed as follows (U.S. EPA, 1991):

- **Advantages:** This method can destroy any material containing organic carbon, also pathogens that found in medical waste. Additionally, reduces the volume and mass of material that must be disposed of by 80-90%. The heat from incineration can be recovered and used to generate stream, which can be used directly or can be used to generate electricity. This helps to reduce the operating cost and makes the process environmentally friendly.
- **Disadvantages:** Main disadvantage of this process is air emissions, which contain several pollutants. It produces ash that contains leached metals, dioxins and furans. Moreover, incinerators are complex, difficult to test, and require experienced personnel. In the same manner, medical waste incinerator's waste is considered as hazardous waste.
- **Factors Affecting Effectiveness:** Firstly, incineration temperature affects the effectiveness, for instance high temperatures increase the destruction of organics. Secondly, the residence time of the solid materials in the incineration is important; the longer time the more complete destruction. Thirdly, the mixing of the waste with the combustion of high temperature air is another parameter. Additionally, the characteristics of the waste can influence incinerator temperature and residence time. As an example; waste material, which contains plastics and paper, has high heat content and will burn quickly and produce high temperatures.

Table 3. Disposal methods and amounts of medical waste (TurkStat)

Disposal Method	Amount (Tons/Year)		Data Year
	Hazardous Medical Waste	Non-Hazardous Medical Waste	
Landfilling	32.471	13.883	2010
Incineration	17.287	-	
Composting	13	-	
Landfilling	37.195	2.688	2008
Incineration	14.801	-	
Composting	15	-	
Landfilling	5.989	20.559	2006
Incineration	6.474	-	
Composting	17	-	
Landfilling	13.497	-	2005
Incineration	10.408	-	
Composting	-	-	
Landfilling	12.557		2004
Incineration	8.224		
Landfilling	14.042		2003
Incineration	8.541		
Landfilling	14.468		2002
Incineration	7.045		
Landfilling	12.948		2001
Incineration	7.410		

Following table describes the general frame for medical waste and their disposal method statistics in Turkey (see Table 3).

From the graphed data, it is obvious that the most preferred option for disposal of medical wastes is landfilling in Turkey. After landfilling, incineration and composting comes, respectively (see Figure 3).

Hazardous Waste Management

Hazardous waste is considered as dangerous or potentially harmful to human health and/or the environment. They consist of liquids, solids, gases, or sludge and can be disposed of commercial products, like cleaning fluids or pesticides, or the by-products of manufacturing processes.

Resource Conservation and Recovery Act (RCRA) legislation in the United States has been defined hazardous waste as a combination of solid wastes, which because of its quantity, concentration, or physical, chemical, or infectious characteristics may cause an increase in mortality and/or (ir)reversible illness or pose a potential hazard to human health or the environment when improperly managed (Wentz, 1989).

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 3. Disposal methods and amounts of medical waste

	2010	2008	2006	2005	2004	2003	2002	2001
Composting	13	15	17	0	0	0	0	0
Incineration	17,287	14,801	6,474	10,408	8,224	8,541	7,045	7,410
Landfilling	46,354	39,883	26,548	13,497	12,557	14,042	14,468	12,948

Integrated hazardous waste management is a system in which reduction, minimization, collection, declaration, packaging and labelling, temporary storage, recovery, transportation and disposal mechanisms are examined separately hazardous wastes. In this system, following up the control periods for these wastes are implemented with the light of regulations.

Separation of Hazardous Wastes

The characteristics must be identified by physical, chemical and biological properties of the waste and the properties should be measured by standardized testing methods. Hazardous waste generated from industries has to be collected and stored separately in accordance with special waste codes (characteristics), which are specified in Regulation on Control of Hazardous Waste (2005). Defining hazardous waste is a difficult process; there are many factors that contribute to the nature of the waste. For instance, the unsafe handling and transportation of waste can result in their becoming hazardous, toxic, flammable or reactive. But if the hazards and characterization of the waste have been determined and they have been collected separately, the risks go away (Charles et al., 1989).

Reduction in the Quantity of Waste

The best approach to avoid the waste is source reduction, which is considered the most preferred option in waste management hierarchy. The EPA waste minimization program offered a hierarchy for approaches to hazardous waste reduction or minimization. These are: waste reduction, waste separation and concentration, waste exchange, energy/material recovery, incineration/treatment and secure land disposal, respectively (Blackman, 2001). Waste reduction, which can both save money and protect environment, should be applied. This includes techniques to separate toxic, hazardous and recoverable wastes from the total waste stream. These are used to increase recoverability, reduce the volume and costs and increase management options. The companies, those have implemented this approach effectively, see it

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

as a way to improve their profits and competitions among others. In this case, hazardous waste requires special precautions for transportation, recovery and disposal activities. This situation increases the cost and makes generators to budget for these applications. Source reduction makes these costs decrease and helps elimination of the potential threats (Dogru, B., 2012).

Packaging and Labelling

As mentioned in the Regulation on Control of Hazardous Waste, waste generators should apply packaging and labeling of hazardous waste. Each waste has its own storage tank, for instance for liquid waste it should be carried with impermeable barrels; for solid/dust waste it should be impermeable bag (size depends on the volume of the waste) etc. After packaging, the bags or barrels should be labeled. These labels must include the waste name, waste code, physical characteristic and hazardousness of the waste. Additionally, there are DOT labels for hazardous materials packages that are used to warn people about the effects of the hazardous waste (US. Department of Transportation).

Temporary Storage

Temporary storage indicates the process, which is implemented before interim storage, recovery, recycle or disposal applications. This process is applied by the waste generator and takes place in the facility or any appropriate area out of the facility. The most important point is that, the area whether in or out of the facility, has to be safely protected (Wang et al., 2007).

The accumulation or storage area of hazardous waste must meet some conditions, which are indicated in each country's related regulation. In Turkey, as indicated in the Regulation on Control of Hazardous Waste, these conditions are:

- Facility can store its waste without permission, if the waste amount is 6000 kg for six months, (1000 kg/month each),
- Personnel should be trained and governorship must be informed about his/her communication details,
- The area must be closed, and access must be restricted to authorized persons only,
- The area must be steady, impermeable, safe and convenient to international standards for storage,
- There should be absorbent materials to ensure the protection; drainage channel to collect the leakage, if any,
- Safety precautions must be taken for all emergency cases, such as fire,
- Waste must be labelled, all necessary information should be written on the labels, put in the containers and closed.

Subjects (updates/differences) related to the design of the storage area are determined by an advice issued by the Ministry (Regulation on Control of Hazardous Waste, 2005).

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Transport to Disposal Area

All hazardous waste must be transported in special containers that are labeled with the information about the name of the waste, type of hazard, generator's name and address and "hazardous waste" expression. Licensed transporters' and treatment, storage and disposal facilities' information can be found in municipalities.

Vehicles must have special license for transportation of hazardous waste, and must contain some documents (types: A, B, C, D and E, each for different purposes) to record the process. For example; domestic and international transportation papers should be filled and kept by transporter, also sent to the municipality (Regulation on Control of Hazardous Waste, 2005).

To investigate the waste stream effectively; to prevent the inappropriate waste handling, recovery and disposal; to detect inadequate waste declaration of producers and deficient reporting applications and to interfere the emergency situations, there is a system called MoTAT (Mobil Tehlikeli Atik Takip Sistemi) in Turkey, which is established by the Ministry of Environment and Urbanization in 2012. This is an online system that helps to record all necessary information for hazardous waste generators and transporters.

Recovery

Through various physical and/or chemical treatments, waste is converted into a secondary raw material for different processes. Recovering wastes can contribute a cost effective management alternative. This approach helps to eliminate waste disposal costs, reduce raw material costs and provide income from marketing of the waste. Recovery of wastes is an expansive practice in many processes, for example; in chemical manufacturing the technique is using spent electrolyte from one division as raw material to another; or in printed circuit boards the technique is recovering copper and tin or lead from process wastewater using an electrolytic recovery system (Librizzi; 1999).

Recovery activities that are applied in Turkey, are mentioned in the Regulation on Control of Hazardous Waste as follows (see Table 4).

Table 4. Recovery activities of hazardous waste (Regulation on Control of Hazardous Waste, 2005)

R1	Use as a fuel
R2	Solvent recovery
R3	Organic substance recovery
R4	Metal recovery
R5	Inorganic substance recovery
R6	Acid – base reproduction
R7	Recovery of used parts to reduce pollution
R8	Catalyzer recovery
R9	Oil recovery
R10	Land spreading
R11	Reuse for wastes produced between steps R1 and R10
R12	Recovery for wastes produced between steps R1 and R11
R13	Stocking wastes until processing

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

These activities can be done both on-site and off-site. In most cases, the most appropriate place for recovering process is the facility, where waste is generated. Although, they may be recovered at an off-site facility when the equipment is not available on-site, generated waste amount is less or the recovered material cannot be reused (Wang, 2007).

Physical and Chemical Pretreatment

Wastes are processed to some physical and chemical pretreatment applications (i.e. material handling, physical-chemical fining, liquid separation, solidification/sterilization, refuse-derived fuel and sludge drying) to ensure recycling, landfilling or reducing the harmful effect on the environment (Saltabas et al., 2012). After the pretreatment processes, if the wastes become inert and free of hazard, then they can be stored at regular storage areas. This application should be documented by authority and should be applied within the scope of related regulations (Regulation on Control of Hazardous Waste, 2005).

Methods for Disposal

Characterizing a waste to determine the proper cost-effective treatment requires both a description of the waste composition and a definition of hazardous or nonhazardous streams. The selection of the process mainly depends on the chemical composition of the waste.

When disposed improperly, hazardous wastes can contaminate air, soil and groundwater and also increase the risk of human disease and environmental contamination. A large quantity of any hazardous waste can only be properly transported or disposed of by certified environmental professionals. Small quantity of hazardous waste can be handled by generator. Most common methods for disposal are deep well injection, incineration and landfilling, which are mentioned in this chapter as follows.

Deep Well Injection

Deep well injection is a technique, which is applied by pumping liquid hazardous waste through steel pipes into wells, clearances or evaporites. High pressures are applied to force the liquid into the pores, where it will be permanently stored. Applicants should prepare a feasibility study and present it to ministry before using deep well injection. There are some concerns about this method, which are mainly groundwater and aquifer contamination and geological damage. Criteria for deep well injection are determined by ministry and take part in related regulations (Regulation on Control of Hazardous Waste, 2005).

Incineration

Generally, hazardous wastes consist of carbon, hydrogen and oxygen; also they may contain halogens, sulfur, nitrogen and heavy metals in small quantities. If the waste molecules can be reduced to carbon dioxide, water and some additional inorganic substances, this means they can become non-hazardous materials. Because of this reason, incineration is the most preferred option in hazardous waste management. This technology reduced the need for landfills, and related problems like landfill leakage, releasing hazardous materials into environment (Wentz, 1989).

Incineration is the controlled high temperature oxidation of organic compounds to produce carbon dioxide and water. This method requires control of the kinetics of chemical reactions, and represents a combustion process applied to destruct hazardous substances. In Turkey, incineration facilities are

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

designed according to related regulations. For this case, in addition to the Regulation on Control of Hazardous Waste, there is one more regulation called Regulation on Control of Industrial Air Pollution. In which, extreme values are mentioned for gas outlet.

Some advantages and disadvantages of incineration are discussed as follows (Wentz, 1989):

- **Advantages:** This method is an advantageous technology for management of hazardous wastes that have high heat-release potential. Waste can be either liquid or solid, the bulkier the materials to be incinerated, the grater the reduction in volume of wastes. Incineration ensures reduction of harmful effects like carcinogen, mutagen and teratogen; additionally prevents disease transmission and adverse effects on other processes. Further, it reduces leachable wastes from landfills and eliminates long term odors caused from landfills. Another advantage of this method is the potential energy recovery of the heat released and recovery of valuable products by recycling, reusing or marketing.
- **Disadvantages:** Main disadvantage is its investment costs; not only initial investment, but also operating costs are higher than many other technologies. In addition, it requires highly trained operators, because the control of this technology is a complex application and the equipment requires high maintenance. In order to provide compliance, qualified supervisory is needed. This method has various impacts on human health and the environment. The emission of odors, particulate matter, and some gaseous substances should be controlled within the scope of regulations. Wastewater and runoff storm water can be affected by the formation of air pollutants, such as hydrogen chloride, sulfur dioxide, carbon monoxide, heavy metals and other ash particulate matters. Both waters must be effectively managed to ensure safety.

Landfilling

Landfills are sites where non-liquid hazardous waste is deposited and covered. This method is designed to minimize the releasing of hazardous waste into environment. If the precautions are enough to protect environment and characterization of the waste is suitable for landfilling, this method can be applied. If limit values are not feasible, physical, chemical and biological treatment must be applied before operation. The limit values are mentioned in related regulations, for this case in the Regulation on Control of Hazardous Waste.

Following table describes the general frame for hazardous waste and their disposal method statistics in Turkey (see Table 5).

From the graphed data, it is obvious that the most preferred option for disposal of hazardous wastes is landfilling in Turkey (see Figure 4).

SOLUTIONS AND RECOMMENDATIONS

The waste management strategies applied by developed countries cannot be translated directly to developing countries. Reasons behind this are lack of resources, legislation, personnel and lower public awareness (Curi, 1993). In most developing countries, medical and hazardous wastes are not considered as an important concept, and because of the absence of proper applications, problems become more serious.

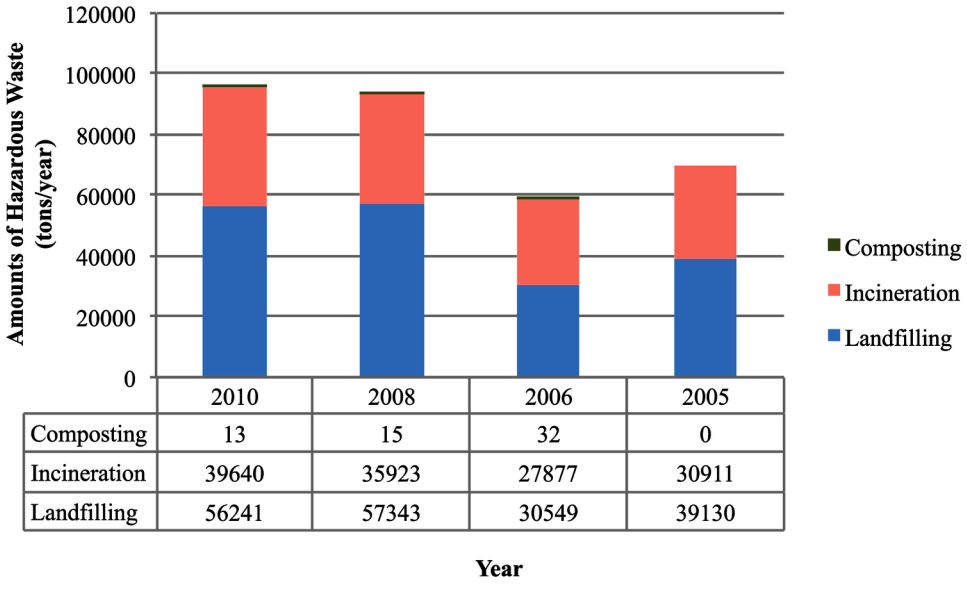
Figure 4. Disposal methods and amounts of hazardous waste



In Turkey, there are insufficiencies while applying regulations. Application ratio of legislations is low, also collection of data is not implemented regularly; as a consequence, environmental related problems are extensive. Tables 6 and 7 show the reasons for the lack of application of related regulations.

It is obvious that the most dominant factor behind the lack of application is economic issues. Other reasons are lack of personnel, technical issues, lack of instruments and lack of information, respectively. Municipalities are responsible for this situation; they have to budget for environmental issues, train personnel and apply all stages mentioned in regulations. Awareness programs on handling of wastes and management of personnel can prevent adverse effects.

Year	Number of Municipalities	Reasons for Lack of Application					
		Lack of Information	Economic Issues	Lack of Personnel	Technical Issues	Lack of Instruments	Other
2008	3225	341	1.520	996	898	674	97
2006	3225	341	1.507	917	860	598	102

Education of the general population should be increased about waste sorting, recycling, disposing and composting of the waste. For sustainable development and protection of both environment and public health, there should be a system that is applied effectively.

CONCLUSION

There is a growing demand on safe and clean environment. On the other hand, increasing demand on industrial capacity causes increase in waste amounts. Minimization and prevention of wastes is more effective and long-term approaches than to operate treatment plants. Additionally they have short-term benefits such as relief of some disposal problems. For instance, in manufacturing and production of goods, usage of hazardous materials should be lessened. This will ensure prevention of waste and have positive effect in dealing with it. Although, waste minimization, prevention and recycling are not well practiced in Turkey, which results in large amounts of medical waste that is disposed in different ways. If medical and hazardous waste are not handled and disposed separate from domestic wastes, transmission of diseases may occur and this situation has adverse effects on both public health and environment. Efforts have to be made for improving both hazardous and medical waste management technologies. In addition, there are many methods for disposal of medical and hazardous wastes. In Turkey, incineration is the most applied method for both waste groups, which ensures destruction of toxic organic substances and avoidance of risks resulting from improper disposal.

KEY TERMS AND DEFINITIONS

Public Health: A science and practice for protecting the health of a community. Possible applications can be mentioned as health education, control of diseases and monitoring environmental related problems.

Refuse-Derived Fuel: A fuel produced by dehydration of solid wastes with special technologies. Combustible materials are preferable (i.e. plastics or biodegradable wastes) to ensure high quality refuse-derived fuels.

Risk Assessment: Managers need to think about the factors that might cause harm to people and need to take some special steps to prevent them. This concept is risk assessment and to ensure health and safety of the business, risk assessment should be applied.

Solid Waste Management Hierarchy: A concept developed by United States Environmental Production Agency, which ensures ranking of all methods applied to the solid waste. The hierarchy consists of five steps, they can be sorted from most preferred to less as follows: source reduction and reuse, recycling or composting, energy recovery and treatment and disposal.

Waste Management: An approach that consists of all stages to process waste such as generation, prevention, characterization, transport, storage, treatment, handling, reuse etc.

This research was previously published in the Handbook of Research on Waste Management Techniques for Sustainability edited by Ulas Akkucuk; pages 303-327, copyright year 2016 by Information Science Reference (an imprint of IGI Global).

Chapter 11
Design and Operation of Semi-Aerobic Landfill

Mohd Suffian Yusoff
Universiti Sains Malaysia, Malaysia

Mohd Faiz Muaz Ahmad Zamri
Universiti Sains Malaysia, Malaysia

ABSTRACT

Landfilling is broadly recognized as a proper waste disposal method. Although ranked at the bottom of sustainable waste management hierarchy, final waste disposal technologies like sanitary landfill remain crucial for development country due to increasing waste generation. Since landfill is a permanent disposal site that could cause serious environmental pollution, a proper planning and development of landfill are important in avoiding problems in the future. In this chapter the general principles of landfill design and operation is given at the beginning. Then the following discussions were focusing on the design and operation of semi-aerobic landfill. The revision for design and operation of semi-aerobic landfill working phase were reported separately. Finally the summary of the discussion were given at the end of this chapter.

INTRODUCTION

Solid waste management is a systematic practice of waste generation storage, collection, transport, treatment and disposal (Agamuthu, 2010). Sanitary landfill is one of the important methods for solid waste disposal in waste management system. Even though there are more advance disposal methods have been developed, the sanitary landfill remains as an ideal method for developing country (Idris & Hassan, 2004). The sanitary landfill is a final disposal method that treats and restores the organic portions of the waste to the nature which emphasizing the technical aspects like siting, design, operation and long-term environmental addeddment (Hans & Ramke 2001).

Table 1. Landfill classification system based on decomposition process employed

Landfill Type	Characteristics
Anaerobic landfill	Solid wastes are filled in dug area of plane field or valley. Waste is commingled with water in anaerobic condition.
Anaerobic sanitary landfill covered daily	Solid waste is covered in a sandwich shape. Condition in solid waste is same as anaerobic landfill.
Improved anaerobic sanitary landfill	Leachate collection system is installed at the bottom of the landfill site. Others are the same as anaerobic sanitary landfill. The conditions are still anaerobic but the moisture content is much less than anaerobic sanitary landfill.
Semi-aerobic landfill with natural ventilation and leachate collection facilities	Leachate collection duct is bigger than the one of improved sanitary landfill. The opening of the duct is surrounded by air and the duct is covered with small crushed stones. Moisture content in solid waste is low. Oxygen is supplied to the solid waste from leachate collection duct.
Aerobic landfill with forced aeration	The leachate collection pipe and air supply pipes are attached. Air is forced to enter the solid waste causing it becomes more aerobic than semi-aerobic landfill.

Unlike open dumpsite, the sanitary landfill is designed to deal with leachate, landfill gas and odor management. The collected wastes are handled at a disposal facility that is designed and operated at a constraint of public health and environment protection. The primary purpose of landfill site is to implement final disposal of the waste with minimum environmental impact. Besides, the sanitary landfill system can be classified based on decomposition process employed. Table 1 describes the characteristics of the landfill types.

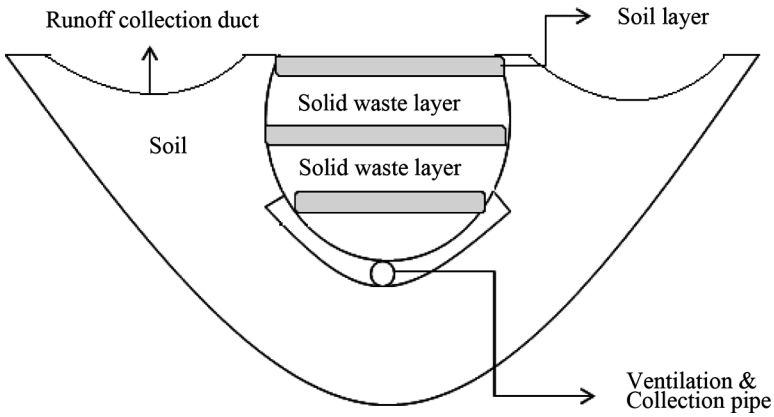
Among others sanitary landfill syste,m the semi-aerobic landfill is the most desirable landfill design (MHLG, 2004). It is also referred to as "passive aeration" by the United Nations (UN) and was approved as a new Clean Development Mechanism (CDM) (Tashiro, 2011). Initiated by Prof. Masataka Hanashima of Fukuoka University, pilot semi-aerobic landfill was first tested in 1975 at Shin-Kamata Landfill in Fukuoka, Japan (Chong & Hassan, 2005). Interestingly, the semi aerobic landfill is largely implemented in the eastern part of Asia (Zhang et al., 2013; Sangjae et al., 2014). This is most probably due to the leachate and waste stabilization via passive aeration without using any type of mechanical equipment (Toshishiko et al., 2015). Figure 1 shows the schematic diagram of semi aerobic landfill. In semi-aerobic landfill system, oxygen flows into the waste mass through the leachate collection pipes by passive ventilation to accelerate an aerobic microbial decomposition in the waste body. It hastens waste stabilization and improves leachate water quality (Theng & Mohd, 2005).

Meanwhile, leachate and gas are continuously discharged using leachate collection and gas venting system. Semi-aerobic landfill is claimed to be a simple environmentally and economically sound technology. The advantages of semi-aerobic landfill are listed down as follows:

A. It purifies leachate significantly by increasing waste decomposition rate.
B. It contributes towards global warming mitigation by reducing methane gas emission substantially.
C. The risk of gas explosion and fire hazard is reduced by releasing the gas from ventilation pipes.
D. It converts open dumps into sanitary landfills in an easier way.
E. Earlier landfill rehabilitation is expected through enhanced stabilization.
F. It is cost-effective due to the high degree of freedom in construction material selection and utilization of less intensive leachate treatment system.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. The schematic diagram of semi aerobic landfill



G. It is easy to construct, operate and maintain. Self-purifying capacity is used to stabilize waste body and only requires commonly used machinery and equipment.

The effectiveness of the sanitary landfill site is based on disposal performance in fulfilling the actual need of the region (Peter et al., 2000). In planning the sanitary landfill, it is necessary to determine and establish the master design and operational plan for landfill. Landfilling process includes a series of activity which begin from delivery of solid waste into the landfill site until the maintenance and control of the landfill. Semi-aerobic landfill design requires particular planning by considering the actual site conditions like precipitation rate, ambient temperature, soil foundation and rainwater flow area (Matsufuji, 2007). Therefore, in this chapter, the revision for the design and operation of semi-aerobic landfill working phase are reported.

LANDFILL DESIGN

The design process is an important phase in the development of sanitary landfill.The design of sanitary landfill generally refers to the lifetime and the capacity of desired landfill. Besides, the requirement and the standards of the landfill design are dependent on the landfill classifications. In this section the main principles of design process description and explanation for semi-aerobic are discussed.

DESIGN CONSIDERATION

Design Objective

Generally, landfills are constructed on a phased basis. The initial step of landfill development is landfill design process. The main objective of landfill design is to provide effective control measures to prevent and minimize the negative effects on the environment (Peter et al., 2000). The pollution of surface water, groundwater, soil and air, as well as the resulting risks to human health were among the potential

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

negative effect of landfilling waste (MHLG, 2004). The engineering criteria and design concept of sanitary landfill are depending on the ground conditions, the geology and hydrogeology of the site, the potential environmental impacts and the location of the landfill (Peter et al., 2000). Therefore, ground investigations for a landfill planning should provide sufficient information to enable the formulation of a site specific design.

Besides that, the function of landfill design is to provide safety and storing capability of the waste within its environment boundary (MHLG, 2004). The minimal standard function of landfill design should provide retaining function, waste control function and treatment function (MHLG, 2004). Each of the landfill design planning should be kept in workable conditions throughout the operational period, closure and post closure use period. Other than that, the landfill design is used to evaluate the suitability of selected landfill location. Ideally, at the closed landfill site, the continuous monitoring must be carried out before any redevelopment being proposed. The design of monitoring continuity provides future environmental effects and their conditions. Thus, it is necessary to design landfill system which fulfilling the design objective.

Design Requirement

The design requirement for landfill site is necessary to ensure a systematic and consistent approach. The designer should follow the actual practice of design aspects in planning a landfill site. The design requirements are listed as follows:

A. **Waste Characteristic and Lifetime:** Waste characteristic will dictate the control measure needed for the landfill lifetime. The nature and quantities of waste will change the landfill facility conditions and considerations (Menard et al., 2004). The failure of waste type consideration may result in the reduction of disposal capacity and environmental problems. This corresponds to the policy of implementing adequate solid waste treatment from the landfill lifetime (Peter et al., 2000).
B. **Water Measure:** The water control measure is required for the reduction of leachate generation (Peter et al., 2000). It will minimize the amount of water entering to landfill through precipitation, surface water and groundwater. In addition, the water control design is important for the water collection and treatment process before allowing it to be discharged.
C. **Soil and Water Protection System:** The protection system for the landfill soil and water will prevent hazardous chemicals from contaminating groundwater and surface water. A liner system must be designed based on the waste material. Clay and composite liner are applicable for organic waste while other type of waste must meet the prescribed permeability and thickness requirements of the liner (Michael & Tanya, 2002). Thus, the designer must be able to model the effects of any hazardous matter migration through the liner and into the groundwater.
D. **Leachate Management:** The landfill leachate management must be consisted with the collection, storage and treatment systems. These system facilities are to ensure efficiency of the system to keep the accumulation of the leachate at the minimal level (MHLG, 2004). This system must be designed based on the specific waste to be disposed, climate and the volume of leachate to be collected.
E. **Gas Control:** The landfill designer should provide the collection system for the accumulated and migrated landfill gas either for utilization or disposal. The common types of collection system to control the migration of landfill gas are flaring and venting systems.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

F. **Environment Nuisance:** Environmental nuisance such as noise, odors, dust, litter, birds, vermin and fires may arise during the construction, operation, or closure of the landfill. The landfill designer should provide a control system to minimise the environmental nuisance (Peter et al., 2000).

G. **Landfill Stability:** The landfill stability covers the conditions of the landfill slope, the systems components (liner, cover material, leachate collection system and etc.), the waste mass and the capping system (Peter et al., 2000). The landfill designer should provide the landfill stability system to avoid land sliding or any stability failure (MHLG, 2004). In addition, the retaining facilities design is necessary for the landfill stability.

H. **Site Development:** The landfill design must consist with the site development and site infrastructural requirements. Site accommodation, weighbridge, waste inspection area, wheel wash, site services and security facilities are necessary during landfill operation and restoration (Peter et al., 2000; MHLG, 2004).

I. **Landfill Monitoring:** The landfill monitoring process is the collection and comparison of information to the permit and determining compliance (Peter et al., 2000). Permit and engineering drawings, field measurements, sampling requirements for surface water and groundwater monitoring, gas testing, and waste volume data are the data categories that needed in the landfill design (Michael & Tanya, 2002).

J. **Facility Cost:** The landfill design should include the facility cost planning. Predevelopment cost, site preparation and construction cost, operating cost, site closure cost, post closure and maintenance care cost are the cost categories that needed in the landfill design (Michael & Tanya, 2002). The budget estimation for the facility at the design stage is necessary in order to ensure sufficient funds for the landfill development.

K. **Post Closure Care:** The landfill closure steps must accomplish the final certification of landfill report (MHLG, 2004). The post closure care design of landfill is used to monitor the physical layout and the material component of the landfill surrounding. The corrective action for redevelopment plan of the landfill will be taken based on the monitoring report.

L. **Risk Assessment:** The risk assessment design is used to develop control methods and procedures that minimize the harm to employees, the public and the environmental surrounding (Peter et al., 2000). This risk assessment is designed based on the proposed development plan of the landfill.

LANDFILL DESIGN STANDARD

The design of landfill is bonded with a standard compliance regulated by environmental authorized bodies (Michael & Tanya, 2002). The standard provides the outline of technical requirement and approval process for each category of landfill. The design approval must be followed by submission of the application with engineering drawing for each performance specifications (e.g. leachate control system). In fulfilling each requirement, the specific guidelines are provided on different aspect of the landfill design. The guidelines manual is used to assist the general process of landfill design and to provide the updated relevant information. It is necessary for every landfill design to keep the records of the process systematically. The quality control procedures of the landfill design should be used to ensure the design and development process is carried out satisfactorily (Peter et al., 2000).

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

SEMI-AEROBIC LANDFILL DESIGNCONSIDERATIONS.

The main consideration of semi-aerobic landfill design is given to the facility specification. The considerations includes the construction cost, maintenance control, leachate discharge pipe opening, leachate collection discharge capacity and material, cross section of leachate collection discharge capacity, protection and perforated areas in leachate collection discharge pipe, protection and installation of gas venting pipe and feasibility of leachate circulation. The detail explanations for each design consideration are given as follow:

A. **Construction Cost and Maintenance Control Capability:** The design of semi aerobic landfill is aiming to reduce the construction cost as low as possible (Matsufuji, 2007). This cost effective landfill constructions are performed using various materials that can be obtained easily. Bamboo, tires and waste barrel are among accessible materials which can be used as facility component for leachate collection pipe, discharge pipe and gas venting pipes protection material (Matsufuji, 2007). Even though, the constructions are using such types of materials, the importance of maintaining health hygiene is not left behind. The construction cost design must be ensured to provide suitable final disposal site with cost effective results. Besides that, the availability of local competent person must be provided prior to the landfill construction. These competent personnel are required to provide maintenance control during the configuration of landfill construction.

B. **Leachate Discharge Pipe Opening:** The design consideration for leachate removal prefers a simple system of maintenance control. The discharge pipe opening is used to supply air into landfill layer and remove the excess of water quickly from the landfill. This discharge pipe opening must always be opened to the atmosphere to maintain the aerobic state of the landfill (Matsufuji, 2007). Figure 2 shows the comparison of leachate discharge pipe opening flow. The natural flow is a cost effective construction method and more efficient compared to the out site and in site pit pump method which increases the operation expenses.

C. **Cross Section of Leachate Collection Discharge Pipe:** The cross section design for leachate collection discharge pipe must be able to supply smooth air flow into the landfill area. Depending on the topography of the landfill area, the cross section design of the discharge pipe can be arranged into different line patterns (e.g. ladder pattern, herring bone pattern). However, the pipe diameter of the main leachate collection discharge pipe is recommended to be small at least 450 mm with spacing range from 20 to 30 m (MHLG, 2004; Matsufuji, 2007).

D. **Leachate Collection Discharge Pipe and Covering Material:** The design of covering material for leachate collection discharge pipe is necessary to avoid the leachate retaining in the landfill (Kim et al., 2009). In order to prevent clogging of the discharge pipe, the thickness of the cover material should be more than 50 cm from the ground level. The width of the cover material must be 3 times more than the diameter of the pipe; this is to ensure the functionality of the collection discharge pipe. Therefore an improved structure of the covering material should be designed in ensuring the air streaming in leachate collection discharge pipes is open for allowing aerobic decomposition.

E. **Protection and Perforated Areas in Leachate Collection Discharge Pipe:** The protection and perforated areas in leachate collection discharge pipe are implemented by using protective layer of buffer blanket, sand and soil cover. This is to ensure a proper streaming of leachate collection and air flow through the landfill. In order to ensure the discharge pipe streaming are smooth, the base should be fixed and built up by packing material around the pipe.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

F. **Installation and Protection of Gas Venting Pipe:** The function of the gas venting system is mainly to remove the gas generated within the landfill layers into the atmosphere. The proper design of gas venting facility would support the management of landfill site upon the completion. Therefore, the overall structure, position, size etc. should be considered. The installation design of gas venting system must be equipped with the protection of the venting facility. In the flat landfill site, the spacing for each venting pipe is 20 m to 40 m (MHLG, 2004). However, for landfill with high waste level, the installation of horizontal pipe at every 15 m of waste layer is recommended (Matsufuji, 2007).

LANDFILL OPERATION

The landfill operation is a continuous process after designing and constructing the sanitary landfill plan. The landfill operation describes the operation and maintenance facilities of the specific design elements. In this section, the consideration of semi aerobic landfill operation is discussed.

Landfill Operation Consideration

The landfill operation consideration is important to ensure that the related design and constructed facilities are activated. The operations of the landfill should follow the considered aspects in operating the landfill site. The details of the operation consideration are listed as follows:

A. **Landfilling Process and Waste Handling:** The process of landfilling begins with solid waste delivery into the landfill site. The process followed by spreading, mixing, and covering the waste using final soil (Hans & Ramke, 2001). In this process, the suitable method must be selected based on the specification of the landfill site as well as the volume of waste generated daily. Among the available methods were area method, trench method and depression method. However, there are also other appropriate methods for each series of landfilling activities. Cell construction, dumping, spreading and compaction of the waste landfilling process has each specified method (Hans & Ramke, 2001). Therefore, consideration should be taken in handling the landfilling process. Besides that, the type of waste admitted and landfill equipment used for disposal must be classified into different categories (MHLG, 2004). Although the waste is generally commercial waste, there is also hazardous waste that formed by industrial sector. Thus, the list of waste admitted for disposal must be included as an operational manual of the landfilling process.

B. **Safety Measures:** The landfill operation is involved with many kinds of potential risks. The heavy equipment of processing, transportation hazards, foreign materials in the raw material, noise, dust and fire are among the potential risks that might be occurred in landfill operation (Michael & Tanya, 2002; MHLG, 2004). The accidents cases during the landfill operation could give negative effect to the workers morale and productivity. Therefore, the operational safety system shall be considered in minimizing and preventing the potential risk. The descriptions of the safety measures, security and working activity at the landfill site are necessary for the landfill operational safety. Besides that, permit approval should be provided for every working process in the landfill operation. This permit is used as an identification system for the landfill operation. Furthermore, every work conducted in the landfill must be registered based on the category of facilities, personal involved, processing and type of management.

C. **Monitoring and Maintenance:** The monitoring and maintenance system of the landfill operation are necessary in prolong the lifetime of the landfill. This operational consideration comprises of meteorological data, leachate, gas emissions, ground water and surface water monitoring (MHLG, 2004). The monitoring of the meteorological data is used for the water balance of the landfill site. This monitoring calculation is based on humidity and temperature condition. Besides that, the monitoring of leachate collection is used for the quality and quantity measures. The quality and quantity of the leachate provides the indication of the necessary treatment method (Kashif et al., 2012). Other than that, the gas emissions analysis calculates the potential of gas utilization. The gas emissions monitoring is important to avoid potential of explosion or fire. Plus, the surface and

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

the ground water monitoring provide the analysis of the contaminants in the water. This monitoring presents the influence of waste disposal to the ground water. However, the monitoring work must represent all of the landfill area involved.

D. **Supplemental Operation Facilities:** The supplemental facilities can be used to improve the landfill operation efficiency. This supplemental facility is mainly used to enhance the control and management system of the landfill site. However, the addition of the facilities is basically depending on the size and the condition of the landfill. The related supplemental facilities are listed as follows (MHLG, 2004):
   1. Proper access road for transportation
   2. Littering preventer facilities
   3. Fire station facilities
   4. Bunds and retaining walls
   5. Temporary water ponds facilities to prevent overflow of rain water and flood.

OPERATION OF SEMI-AEROBIC LANDFILL

The operation of semi aerobic landfill is mainly concerned on maintaining the aerobic conditions of the landfill. Therefore, the focus of landfill operation is to maintain the collection discharge pipe of leachate and gas venting system. The details for other semi aerobic landfill operation basic items and specifications are listed in Table 2.

Table 2. Basic items and specifications of semi aerobic landfill operation. (Theng et al., 2005)

No.	Item	Specifications
1	Leachate collection and re-circulation facilities Gravels	Estimation of 2063 m3 (2800 tonnes) for both main pipes and branch pipes
2	Leachate collection pipes (Main)	400 m length · 1 pipe (600 mm diameter)
3	Leachate collection pipes (Branch)	150 m length · 30 pipes (450 mm diameter)
4	Leachate circulation pipes and pump	Estimation of whole re-circulation system
5	Collection pond (excavation work)	3 ponds of 15,400 m^3
6	Surface water interception drainage	Drains: 0.6 m deep
7	Drainage installation (with piping system)	Standard concrete drainage with 0.6 m depth, 1600 m length
8	Gas venting pipes	Concrete pipes of 375 mm in diameter · 45 pipes · 16 m length
9	Leachate treatment Facility Aerators	3 units at each primary and secondary pond
10	Monitoring wells Boreholes and wells constructions	2 at upstream, 2 in the middle and 3 at the downstream
11	Primary retention ditch	3 m depth and 2 m width for about 1600 m length
12	Secondary retention ditch	3 m depth and 2 m width for about 1700 m length

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

A. **Maintaining Leachate Collection and Discharge Pipes:** The maintenance of the leachate collection discharge pipes is important for keeping aerobic disposal condition in the landfill operation. This maintenance work is to ensure smooth air flow circulation through discharge pipe. The malfunction of the discharge pipe is mainly due to the small size and non-soluble waste material that clogged inside the pipe. Besides that,the small layer of landfill thickness promotes the damage of discharge pipe by the movement of vehicles in the site. Therefore, the application of filter and easily flow waste material must replace the bulky and rough waste material along the discharge pipe leachate collection area. Besides that, the first layer of landfill thickness should be protected with steel plate (thickness> 20 mm) at least 1 m from the discharge pipe to disperse the load stress from the transport vehicle (Matsufuji, 2007). Furthermore, the leachate water level should be controlled to ensure the discharge pipe is open to the atmosphere all the time.

B. **Maintaining Gas Venting Facility:** In semi aerobic landfill operation, the gas venting system is installed vertically within 20 m distance from each other. This vertical gas venting pipe diameter must be 10 cm and covered with 1 m of filter diameter. In order to maintain the aerobic disposal condition, the rising of gas venting facility must be in meandering manner. Figure 3 shows the rising of gas venting pipe in a meandering manner. This configuration enables sufficient time for air and rainwater flow to promote oxygen supply. Practically, the thickness of each waste layer must be 3 m apart from each layer. As shown in Figure 3, the gas venting pipe rising configuration must be installed inclined with the stone filling in each of the waste layer. The connection of the gas venting pipe must be arranged in the center within the waste and stone layer. The direction of the gas venting pipe must different from the previous direction. This step should be repeated up to the specified height of the waste layer. This configuration is used to introduce the air to the waste layer. The air could accelerate the stabilization of landfill sites, improve leachate quality and avoid the anaerobic decomposition (Ishigaki et al., 2011). Nevertheless, the maintenance and prevention step must be taken to avoid the gas venting pipe from broken or collapse due to the load of transport vehicle and landfill material during the operation. The gas venting pipe must be protected with independent construction type which is 50 cm higher than the waste layer (Matsufuji, 2007). Other than that, the installation of temporary steel frame around the pipe could prevent the damage of gas venting pipe during the operation. Furthermore, the steel frame installation enables efficient rising operation of the gas venting pipe in the future.

C. **Maintaining the Aerobic Area and Waste Layer:** The selection of covering soil for waste layer is important during the landfill operation. The less permeability of covering layer can stop the air transmission within the waste layer. Besides that, the leachate that is generated through waste decomposition may retain within the waste layer and form a barrier. In order to avoid this condition, the high permeability covering soil such as gravel and sandy soil are desirable (Brogaard et al., 2013). Other than that, the installation of additional leachate collection discharge pipe may remove the retaining leachate within the waste layer. Therefore, for the mountain area of disposal site (20 m of landfill high), the reliable installation of leachate collection and gas venting system is highly desirable. The width of each waste layer is necessary to be at least 1 m directly above the leachate collection discharge pipe. The vertical layer of gas venting pipe must be filled with crushed rock layer which is on the bottom up through the final layer. This configuration enables more collection of leachate as well as promotes good transmission of air within the waste layer.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

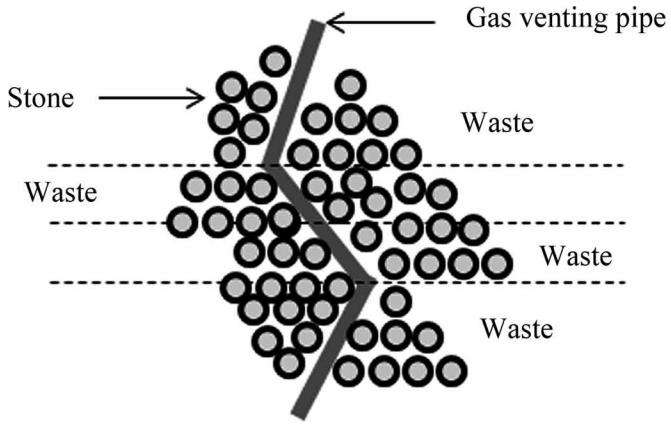
D. **Environmental Monitoring:** In order to ensure the development of aerobic area within the waste layer, the monitoring of leachate and gas generation is necessary (Qi et al., 2013). In semi aerobic landfill, the organic waste is decomposed by aerobic microorganism through solubilization and gasifaction process. Through the decomposition process, solubilize organic substances is converted to solubilize gas of carbon dioxide (CO_2) (Matsufuji, 2007). This process reduced the biological oxygen demand (BOD) value and increased the pH of the leachate. Besides that, the nitrate and sulfate ions are generated through the decomposition process (Matsufuji, 2007). In contrary, the decomposition of anaerobic process produced the accumulation of methane (CH_4), ammonia (NH_3) and hydrogen (H_2 sulfate (SO_4) gases. In fact, the CH_4/ CO_2 ratio for anaerobic landfills and semi-aerobic landfills were reported to be 1.9 and 0.8 (Yang et al., 2012). Therefore, the monitoring of the leachate and gas effluent enables the evaluation of aerobic landfill condition. Other than that, it is used to ensure the quality of the discharged effluent is complied with the environmental standard.

CONCLUSION

The sanitary landfill is an important disposal method in the solid waste management. The development of sanitary landfill enables the utilization of filled land for othernew development. However, the landfill-requires proper planning, design and operation of the sanitary landfill. In this subchapter, the design and operation of the semi aerobic landfill has been discussed. The important factors of design and operation for semi aerobic landfill were elaborated. The main consideration of semi-aerobic landfill design and operation must be given to the facility specification.

In conclusion, the effectiveness of semi aerobic strategy could only be achieved through maintaining the aerobic disposal condition. This condition is mainly depending on the leachate collection system and the gas venting system. The leachate collection discharge pipe and gas venting pipe is specifically used to allow proper air circulation in the landfill. Thus, the design and the operational of semi aerobic landfill are to ensure the acceleration of aerobic microbial decomposition in the waste body. Although

Figure 3. The rising of gas venting pipe in a meandering manner



EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

the semi aerobic landfill is a convenient, cost effective and reliable implemented system, it requires a full attention of monitoring and maintenance work to be applicable. As a result, the proper design and operation strategy could efficiently promote the practice of the sustainable environment.

Chapter 12
Items of Consideration in the Design of a Malaysian Landfill

Mohamad Razip Selamat
Universiti Sains Malaysia, Malaysia

Hamidi Abdul Aziz
Universiti Sains Malaysia, Malaysia

ABSTRACT

The rate of waste generation in Malaysia continues to rise and this trend has created a pressure on landfills to perform in terms of capacity and quality. This scenario is not unique to the country alone but probably shared by many in the developing world. On one hand newly designed projects are initiated while on the other the old ones are still operating as open dumps. As in most cases with municipalities, a new site is not readily available for the new initiative, thus the existing facility has to accommodate both the newly designed landfill and the existing dump. In most cases also, due to lack of space and economical reasons, the two facilities have to eventually connect with each other and form a single facility. Thus this chapter is not only about designing a new provision but also about amalgamating the new one with the old one. In the design, the new one would require items such as leachate collection and treatment facilities while the old one would necessitate proper cover and drainage.

INTRODUCTION

Solid Waste in Malaysia

Municipal solid waste (MSW) has been defined as to include garbage, refuse, and any unwanted solid material arising from human activities. Disposal of MSW continues to be a major environmental challenge in developing countries including Malaysia.

The rate of waste generation in this country continues to rise each year mainly because of the general and domestic development. The increase has been in line with population and economic growth. In 1998, the yearly waste generated was 6 million tons (0.5-0.8 kg per capita per day). In 2005 however,

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

it has increased to 7.43 million tons (Agamuthu, 2006). By the year 2020, the quantity of solid waste generation per year is expected to top 30 million tons (Manaf et al., 2009). Such a tremendous increase is primarily due to the rapid urbanization, increase in population, improvement of per capita income, and changes in consumption patterns (Umar 2009).

Food waste, categorized as organic waste is an important constituent of the solid waste for its unique degradation properties. It represents 32% of the waste composition in Malaysia (Ridhuan, 1995). Typically, an MSW sent to landfill is comprised of food, garden refuse, paper products, plastics, rubber, textiles, woods, and ashes.

Use of Landfills

A landfill allows disposal of large quantities of MSW at an economical cost. Thus MSW disposal by land-filling continues to be the most commonly used method worldwide. In Malaysia, MSW has been disposed off in landfills though some of these facilities have not been properly presented and were simply of open dump category.

The continued used of landfill disposal method is commonly due to convenience. For as long as the adverse environmental effects is tolerated, or mitigated, the use of landfills will eventually transform all waste into relatively inert and stabilized materials (Robinson & Maris, 1983; Williams, 2005). Basically, there are no combinations of waste management practices that do not require landfills. Even in incineration process, there will be waste eventually to be disposed off in a landfill.

The foremost challenge in running a landfill is in ensuring that all operating facilities are designed properly and are monitored not only during operation but also after closure.

Landfill Closure

Designing a sufficient final cover is crucial in ensuring a proper landfill closure (Bagchi, 2004). The final cover is as significant as the liner system that is placed at the base of a landfill early in the preparation. However, the final cover becomes even more important when a liner system has not been used for the base which is common for many of the open dumps that are currently operating in the country. In the Malaysian practice, an open dump is normally closed by having simply about 1 m thick of laterite soil laid over the entire dump area.

Principally, a final cover is applied when a landfill reaches maximum volume capacity in order to minimize rainfall infiltration, reduce leachate generation, and avoid possible environmental contamination. Elshorbagy and Mohamed (2000) define that the covering system of a landfill should involve partial or complete isolation of waste materials from the surrounding environment. Many would agree that the main aim of having a landfill final cover is to decrease or eliminate transport of liquids through the waste. In general, a good landfill final cover should effectively eliminate the generation of landfill leachate as typical landfill leachate contains a large amount of poisonous pollutants that can cause a severe hazard to the surrounding ecosystem (Aziz et al., 2010 (a&b); Bashir et al., 2010).

Generally, the criteria for a sound landfill closure focus on the establishment of a low cost maintenance cover system and on the minimization of infiltration from precipitation. Some of the technical issues that must be addressed by a landfill designer are the changes that will take place with the surface cover barriers such as settlement and damage. A landfill cover simply must be durable in the long term (Murphy & Garwell, 1998). The final cover system should have at least 450 mm of suitable soil for protection

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

against infiltration and another at least 150 mm, also of suitable soil, for protection against erosion. The infiltrating protecting layer must have a hydraulic conductivity of less than or equal to any bottom liner or natural sub-soils in order to avoid the 'bathtub' effect. This protection layer against infiltration may have a hydraulic conductivity not greater than $1x10^{-7}$ m/s regardless of the permeability of underlying liners or natural subsoil – with the earlier stated condition applies. If a synthetic membrane is used for the bottom liner, there must also be a synthetic membrane in the top cover. In other words, the top final cover must be designed to have a permeability less than or equal to the permeability of the bottom liner, which both must fulfil the requirement of having a permeability of not greater than $1x10^{-7}$ m/s.

The Geosynthetic Clay Liner (GCL) and the HDPE Geomembrane have often been quoted for use in landfills. The GCL normally has the bentonite layer sandwiched by a reinforcement fabric-mesh on the bottom side and a non-woven fabric-filter on the upper side. The main asset of a GCL is the self-sealing capability in case of puncture or rupture due to the expansive nature of bentonite, provided there is moisture in the vicinity. The HDPE geomembrane is often quoted to have a thickness of 25 mil (0.65 mm) or 40 mil (1.0 mm). HDPE membrane provide an absolute non-penetrable barrier but only when puncture-free or tear-free.

Leachate Management

Leachate management is another important aspect to be considered in designing and running a landfill. Two options or rather, concepts, need to be considered for landfill leachate management i.e., either entombment or recirculation. Entombing is a total infiltration protection method in the design, construction, and maintenance. The entombed solid waste will eventually remain in a state of mummification unless the cover system is breached and moisture enters. Leachate from an entombed landfill may still be pumped out through wells or escape through the base. The latter process may cause pollution to the surrounding water body and therefore undesired.

The recirculation concept, on the other hand, may result in the rapid physical, chemical, and biological stabilization of the waste. In a recirculation system, leachate collected from the waste is reintroduced by spreading over the temporary or daily cover of the landfill. A moisture balance within the landfill accelerates the stabilization process of the waste. Recirculation needs a sound leachate collection system and an efficient leachate injection or spreading system. This approach has the advantage that after stabilization, the facility may be provided with a final cover and thus does not require further maintenance. A more important advantage is that the decomposed and stabilized waste may be removed and used like compost, the plastics and metals recycled, and the site used again (Daniel et al., 1991).

The strategy in Leachate management should take into consideration the age of the landfill. A young landfill, say up to 5 years old, would have higher carbonaceous pollutant concentrations than those of an older landfill, say between 10 and 15 years old (Lee et al., 2010). The BOD, COD, and DOC of the new landfill would have readings in the thousands of mg/l while the same readings of the old landfill would be in the hundreds. The young landfill would also have the metal contaminants higher in concentration in comparison to those of the older landfill.

Landfill Failures

The literature has reported many landfill failures after closures that are attributed to insufficient surface barriers. Even in arid regions, over time, buried waste is vulnerable to transport via rainwater percola-

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

tion, gas diffusion, erosion, and intrusion by plant roots, burrowing animals, and humans (Daniel, 1994). The popular design practices have erroneously assumed that surface barrier technology is always well developed and will work as expected, without proper protective or safety measures.

Landfill settlement is one of several ways a cover may fail by. A large post-closure settlement can occur after waste disposal in a landfill. Landfill settlement is generally due to both mechanical compression and biological decomposition of solid waste (Liu et al., 2006). The settlement generally extends over a long period of time which may prolong a landfill lifespan but may also lead to surface retention or stagnation, development of cracks, and failure of the cover system including the tearing of cover geomembrane (Ling et al., 1998).

Understanding the long term settlement pattern is essential in the work of landfill design and rehabilitation. The damage to landfill facilities such as with pipes for facilitating landfill gas escape and drainage of leachate can be avoided if settlement is better predicted. For these reasons, data on compressibility of different types of fresh wastes have been collected and analyzed through a number of researches carried out at Universiti Sains Malaysia. Certain consolidation characteristics have been described and became part of a new knowledge in predicting landfill settlement. Eventually, the settlement will also affect efficiency in leachate collection and recirculation.

Need for Proper Landfills and Management

The running and management of a solid waste disposal facility in the form of a proper sanitary landfill is clearly needed not only during operation but also after closure. A proper planning and design in the early stages will help in having a good operation during the many years a landfill receives waste.

Consequently, a properly run landfill will be easier to close whenever the time comes. A good closure will then facilitate an easier monitoring. All of these processes, when taken together, are part and parcel of an appropriate design of a sustainable landfill facility without which the country where such provision is located cannot be qualified as modern or advanced. In trying to achieve the Vision 2020, Malaysia cannot afford to have a solid waste disposal facility that isn't sanitary or sustainable. Thus the development of proper sanitary landfills throughout the country is a basic necessity. The proper design of a landfill would consider every possible avenue leading to a successful facility. The designers must not only content with local codes for reference but should also refer to international sources. Guidelines have been continually updated throughout the world even from as recent as 2014 and 2015 (EPA Victoria, 2014, NSW EPA, 2015).

Submission of Plans

The Malaysian Department of Solid Wate Mangement (Jabatan Pengurusan Sisa Pepejal Negara or JPSPN) evaluates submitted plans and provides suggestions and comments for the appointed consultants to proceed with design works. Meetings between teams of designers or consultants and officers of the department normally take place in department headquarters in Putrajaya, Malaysia on agreed dates. Many countries around the world have similar departments overseeing activities related with landfill facilities.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Arrangement of this Chapter

This chapter provides a quick picture to landfill designers particularly those practicing in the Malaysian scenario about aspects that are relevant in their work. A landfill planned for a municipality in the country would be most likely located in an already operating facility although of a lesser quality or presentation. This situation is not only happening here but probably in many other countries especially the developing ones. Section 2 describes some common aspects of a landfill that requires address in a planning, Section 3 discusses design, Section 4 elaborates the liner system, Section 5 deals with leachate collection, Section 6 with gas venting, Section 7 with cover material, and Section 8 with infrastructure. Section 9 closes the chapter by covering various miscellaneous aspects. The examples quoted in this chapter have not all come from a specific site, but from various places in the country and also from abroad. Nevertheless, special attention has been paid to the practices prevailing in the Northern Region of Peninsular Malaysia.

ASPECTS OF A PROJECT

The following aspects of a project are normally considered in the design of a landfill in Malaysia. In most circumstances, a site would have an area run in an open dump manner while another area is being considered for a more proper procedure.

Location

The description of a landfill location normally includes distances to the nearest town, major highway, and JKR roadway. The distance of the access road leading to the site is described to the nearest metre. Maps and figures are almost necessity.

Site Description

Site description normally includes lot number, mukim name, town, and state. The current ownership would be identified. Most likely, an existing open dump would belong to the municipality however an additional area could be an existing private property. The approximate location of the site is normally identified over a Google Maps.

Within the facility, the existing activity and the areas affected are normally described in detail. The areas of each sector are identified including their status – gazetted or not. Certain sector probably has been in operation for some time and it is important to mention this.

The general terrain is normally described as either undulating or flat, and the presence of any stream and depression is also included. Main streams are named and the presence of any bridge crossing is identified. In the case of an existing open dump, the pollution level of the streams is described and colour photos of the water are provided. Polluted streams are normally compared to the unpolluted ones of the same area. Figure 1 shows a presentation of an unpolluted stream while Figure 2 shows a presentation of a polluted one.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. A view of an unpolluted stream

Figure 2. A view of a polluted stream

An Account of the Existing Open Dump

The same site could have an operating open dump in one of its sectors while another is being considered for an upgraded facility. The site of a future landfill cell may just be within metres to an existing open dump. Such is at least the normal case with Malaysian scenario. Thus the circumstances of the open dump are normally described when discussing aspects of the new project. In such case, the existing dumping activities are described in detail. The account would include areas covered and every significant structures of the vicinity, such as transmission lines and telecommunication towers.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

A waste received by a facility is normally identified by the municipality it originates from. The types of waste are most likely domestic, but could be industrial or inert (such as construction waste). The amounts coming from various localities are normally described in ton per day. But a visit to the receiving office at the site could reveal figures that are more real though only estimates, such as:

1. The number of incoming trucks per day from specific collecting municipality or contractor and the tonnage and volume of each.
2. There are also trucks belonging to small enterprises and these could be identified by their number of trips per day and their tonnage and volumes.
3. The final amount of disposal per day for each entity would then be determined tonnage and volume.

Charge per trip could also be recorded for trucks of various categories. For example, the current charge per trip for a 6 ton truck coming into a Malaysian landfill is about RM30 while for a 3 ton truck about RM15. Finally, the daily collection could be determined. This amount can be verified by enquiring the personnel manning the site. A discrepancy could simply be due to inconsistency in calculation or accounting but can be confusing. In such case, an explanation may become necessary. The following Table 1 is an example of presenting waste amounts entering a facility. The tonnage per day can be converted to volume per day by dividing tonnage by density. The density of compacted waste is about 0.5 to 0.6 ton per cubic meter depending on the effort given. A simple experiment can be carried out in the field to determine the actual densities for a particular facility.

The condition of access road leading to the facility requires description and probably a photo too. The number of bulldozers in operation could also be noticed together with the specific type. The front loader bulldozer with chain crawler type seems popular with landfills in many countries. Man-scavengers encamped at landfills are common occurrence in Malaysian facilities – this aspect is normally described by the number of people involved.

A Statement of the Objective

A statement of the objective is the title describing the intention of a project – normally put on letterheads, notice boards, banners, and other significant places. The overall and main objective of a landfill project when an existing dump is involved is normally to design, construct, complete, test, and certify the upgraded overall facility. In Malay, which is the language a statement of the objective is normally put, this is to 'Merekabentuk, membina, menyiapkan, menguji terima, dan mentauliahkan Projek Menaik taraf

Table 1. Table of incoming wastes

	Municipality	Amount of waste (tons/day)
1	Municipality A	300
2	Municipality B	
3	Municipality C	20
4	Municipality D	155
	Total	Approximately 475 tons/day

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Tapak Pelupusan Sisa Pepejal'. The aim of a specific phase of the project however could be to provide a conceptual design, to provide a detail design, or to review a design. A further explanation normally follows a statement of the objective.

A statement of the objective is normally explained or expanded in longer phrases in related documents. The example of an explanation to a statement of the objective is given as follows. 'The existing dumping operation in Sector A of the landfill is at Level 1 category which is as open dump. The intended operation level of the new project is either at Level 3 or Level 4 in accordance with definitions stated in the 'Technical Guideline for Sanitary Landfill, Design and Operation' of the Department of Local Government, Ministry of Housing and Local Government (2006). The consultant is responsible to identify which level of operation is appropriate for the upcoming site or which will finally come into existence in the new facility.'

The explanation could also include some amount of detail estimates such as given in the following phrases. 'The consultant is required to design a sanitary landfill with an operating life of 5 years and with a daily rate of 500 tons. By assuming the waste at site to be normally compacted to 450 kg/m^3, the total volume of the waste in 5 years will be about 900000 tons. The expected height of the new landfill will be about 25 m. Therefore, the area required for the cell will be about 10 ha, including areas for leachate treatment plants and other amenities.'

Solid waste is not homogeneous and also subject to the variation in the compaction, thus the specific weight is usually expressed in a range of values. Typical values are assumed in calculations. Different figures for final volume and final height will change with the assumed density of compacted waste, and vice versa. The typical specific weights are tabulated in the following Table 2.

Consideration for Amenities and Other Aspects

A landfill designer will also be required to decide which of the amenities at site require upgrading or if any of these items to be provided anew. Among the facilities which require consideration are as follows:

1. Paved access roads going into the facility, appropriate for the purpose of operating a sanitary landfill facility.
2. Unpaved roads within the site, appropriate for the operation (gravel roads, concrete slabs, etc.)
3. All signs within the area including for directions and security.
4. Leachate treatment facility which will either be a 'Leachate Treatment Plant', or 'Leachate Recirculation System', or a combination of both, whichever is appropriate for the facility. The selected method must be from the type which can be easily maintained, cost effective, and able to improve the quality of leachate to the standard acceptable for discharge into a common stream.
5. Perimeter drain of concrete type to cater for storm surface runoff and prevent it from entering waste disposal area.

Table 2. Typical specific weight of landfill waste

Type of Waste	Range (kg/m^3)	Typical (kg/m^3)
Normally compacted	362 - 498	450
Well compacted	590 - 742	600

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

6. A leachate collection system which may consist of leachate collection pipes and leachate collection ponds.
7. Underlying liner system which will consist of clay or GCL, HDPE or GCL, drainage layer, geotextile, and gravel layer.
8. Gas collection system.
9. Wells for monitoring underground water.
10. Weigh bridge and control booth
11. Site cabin with basic amenities.
12. Power and piped water supplies.
13. Concrete wash basin – for washing outgoing trucks.
14. Perimeter fence – PVC coated chain link type, 1.5 m high, and stainless steel gate.
15. Guard house – cabin type with basic amenities.
16. A facility for recycling at site in the form of a shed or open shade together with a conveyor system (if needed).
17. Cells for construction waste.

The designer is also normally required to provide the following:

1. An assessment of the technical, cost, and environmental aspects of the project.
2. Design proposal for the landfill, the preparation of tender document for construction works/activities, and tender selection.
3. Detail design of landfill including related facilities which are cost effective, appropriate for the site and purpose, and easy to maintain.
4. Approvals from related agencies

Nevertheless, the actual aims of a planning and scope of work of a designer for specific projects are normally defined and they differ from one project to another. In most cases, a specialist is required to provide a conceptual design; an assessment of the existing amenities at site which can be retained, or are required anew; disposal manual; and costs for construction, maintenance, and operation.

CONCEPTUAL DESIGN ASPECTS

A conceptual design consists of objective, literature review, capacity analysis, landfill concept, proposed layout, and note on the existing practice at site which is normally open dumping.

Objective

A conceptual design report could be preliminary, interim, or final, submitted by the designer in fulfilment of the requirements of Terms of References. The main objective of a conceptual report is to illustrate the designer's approach in carrying out the task. The Malaysian Department of Solid Wate Mangement (Jabatan Pengurusan Sisa Pepejal Negara or JPSPN) evaluates submitted plans of various stages in the process prior to the final approval. The topographic survey is almost a mandatory aspect of each submission as it conveys the objective of the design in a single graphical presentation.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Literature Review

Information on the various types of landfill can be conveniently found in the literature. Basically, they are classified by the decomposition process – anaerobic, aerobic, and semi-aerobic. The difference between these can be sought conveniently in the literature. When fully implemented with facilities and features, a normal landfill for Malaysian scenario would come under the category of semi-aerobic, although with lesser aeration that would otherwise be required for a landfill of such category. An anaerobic landfill is one that does not allow air to circulate within the waste; a semi-aerobic landfill is one that partially allows air circulation; and an aerobic one is one that allows maximum air contact with the waste and leachate.

Landfill Capacity

The designer is normally required to design a sanitary landfill with an operating life of the number of years and with a daily rate of tonnage as required by the owner. The total waste volume will be generated by assuming the waste at site to be normally compacted to about 450 kg/m^3, which is about the average density of a normally compacted waste. However, there are the normally assumed yearly increases of 1.3% for population growth and 2% for industrial growth. A simple calculation would yield the estimated amount of waste for the number of years given. Landfill cells would then be appointed to cater for the figures. The designer must also keep in mind that that at least an area must be reserved for stockpile of cover material, which is normally coming from the excavation of the cells. Otherwise, this material has to be imported from somewhere else. An estimation exercise of a landfill volume based on accumulated mass is given in Table 3. The table also relates area of landfill to final height. In this case, 12 hectares of land will be required to cater for waste disposal for the given number of years, with only one cell appointed.

The same area can also be divided into 3 proposed cells. The three given cells have areas shown in the following Table 4, which together may amount to an area slightly different from the first assumption. The capacities of cells are also given in the table.

Land Filling Options

During operation, certain cells might have been covered while operating the other. Such scenario is given conceptually in Figure 3; however, this is just an example. In this case the landfill consists of three cells namely Advanced Cell 1, Advanced Cell 2, and Final Cell which is positioned over the fully covered Advanced Cell 1 and Advanced Cell 2.

Table 3. An estimation exercise of a landfill volume

	Cell No.	Area (ha)	Mass to cater (ton)	Volume to cater (m^3)	Thickness of waste or final height (m)
1	Just 1 cell	12 ha approx	992,800	2,206,222 waste + 330,933 daily cover + 551,555 liner components = 3,088,710 m^3	25

Note: Assuming unit weight of 450 kg/m^3 (for normally compacted waste)

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 4. An estimation exercise of areas of various cells in a landfill

	Cell No.	Area (ha)	Mass to cater (ton)	Volume to cater (m^3)	Thickness of waste (m)
1	1	4.95	398,089	884,643	25
2	2	3.64	292,283	649,518	25
3	3	4.04	324,490	721,089	25
Total		12.63	1,014,862	2,255,250	25

Note: Assumed unit weight is 450 kg/m^3 (normal compaction)

Figure 3. Progress in a landfill consisting of 3 cells

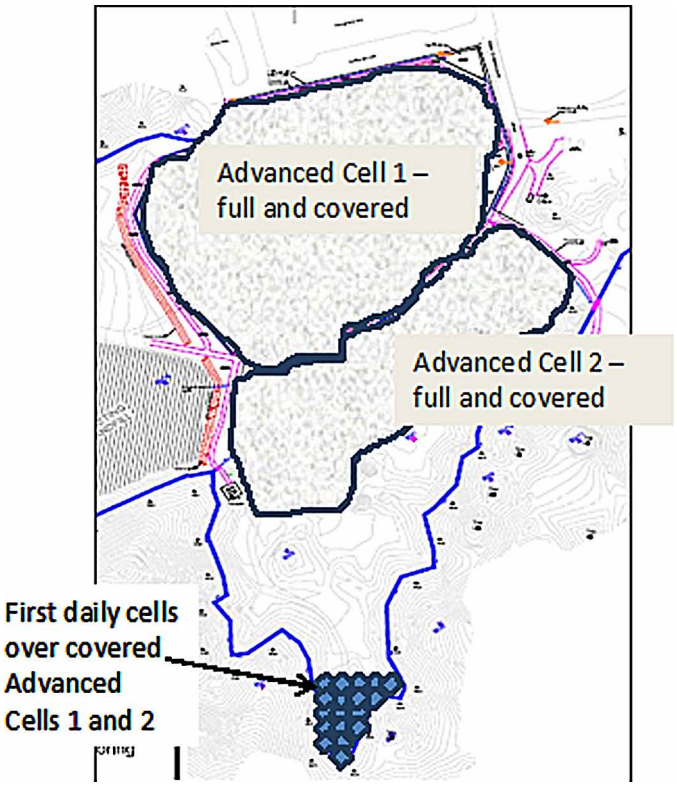

Figure 4 is another representation of a landfill arrangement which indicates presence of 3 cells - Cell 1, Cell 2, and Cell 3. Note that Cell 2 is located over closed Cell 1 and Cell 3. The disposal procedure in this case can be either by Option A or Option B. In Option A, Cell 1 is separated from Cell 3 in order to provide space for stockpiling of cover material. While operating Cell 1 for example, cover soil dug up from developing Cell 1 can be located over Cell 3. The procedure could mean that the two cells would be created not at once but at different times. Option B would be to develop 2 cells – Cell 1 and Cell 3 - at once and as one cell, but in such case, a large flat area elsewhere will be needed for stockpiling the cover material. Depending on space availability, one option may be more preferred than another.

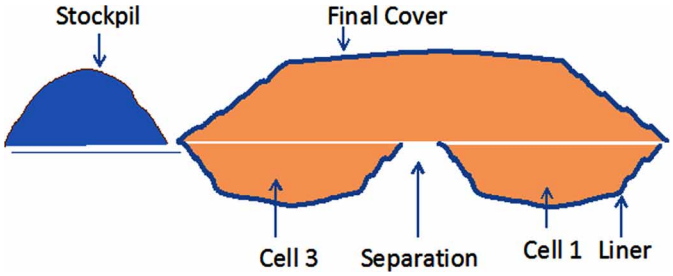
EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 4. A landfill with 3 cells



Berms and batter faces will define the walls of a landfill. Diversion channels will be constructed to divert storm water out of the landfill area. Leachate channels will lead to leachate holding pond and on to leachate treatment plant. The cells may be 100% lined with impermeable membrane – HDPE membrane or Geosynthetic Clay Liner (GCL). The access road into the landfill will not cut through the lining but over ramps to be built over the lining. Leachate collection system will be featured by an assembly of pipes with mains running along the central depressions on the bed. A landfill can be small and technical, or large and old style.

Most Malaysian facilities, when closed, would fall under the category of anaerobic landfill. The semi-aerobic status is next in the improvement ladder and something that is desirable. Given the specific circumstances, some facilities may qualify for the semi-aerobic type. In a semi-aerobic landfill, leachate is discharged as soon as it is collected to reduce the seepage. Fresh air is brought in through the same pipes that carry the leachate to enhance waste stabilisation, improve leachate quality, and reduce the cost of final treatment of leachate. Gas is released through gas ventilation pipes to reduce gas pressure and the likelihood of gas explosion. This type of landfill is cost effective as the initial investment and the maintenance expenditure is lower than that of the aerobic type. For the Malaysian scenario, the semi-aerobic conditions can probably be achieved by having oversized leachate pipes.

Providing a Proposed Layout of Landfill

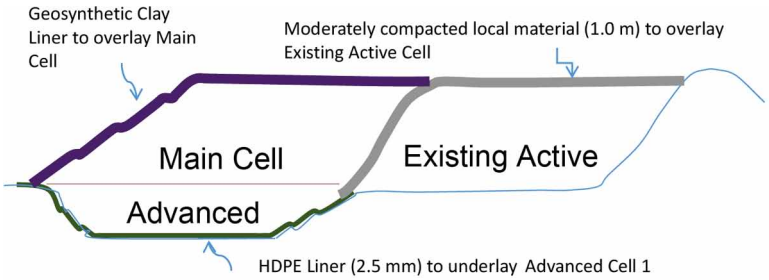
Providing a proposed layout of a landfill requires a good comprehensive understanding of the parameters surrounding the facility. The first decision would be with external surrounding perimeter. In case of undulating terrain, the immediate results of having borders would be the slopes which will be designed according to standards of the civil construction industry in the country.

Berms will be about 2 m to 3 m wide and batter faces will have slopes of 1:1.0, 1:1.5, or 1:2.0 depending on other factors but mainly soil properties. Factor of Safety against sliding failure will be checked and it must be at least 1.5. Berm drains will function as either storm drains or leachate drains depending on the stage of operation.

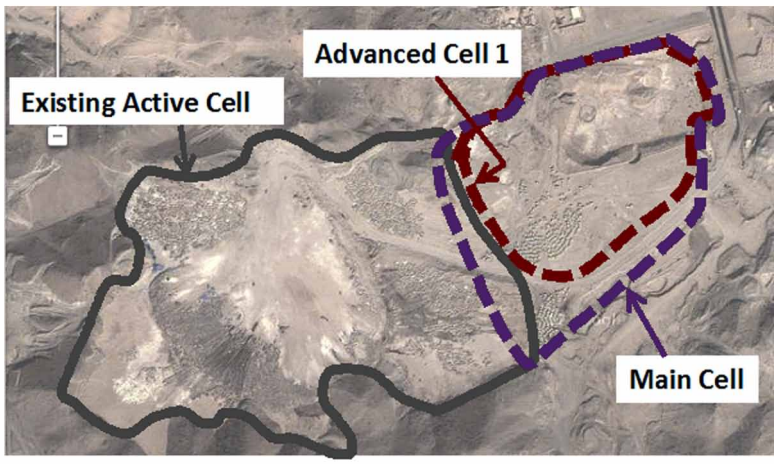
An example of the proposed initial layout of a project together with a final cross section is given in Figure 5. However, this particular one is not Malaysian. In this case an ample space has been provided for leachate treatment plant and other facilities which can be upgraded, downgraded, or modified from the drawing as the process of the design progressing.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 5. A proposed initial layout of a project (a) Cross Section and (b) An aerial view over a Google Maps



(a)



(b)

Among the features that can be incorporated into the drawing are:
Existing paved access road going into the facility – originating from main road and ending at disposal areas.

1. Guard house which will be located just inside the entrance or just across the second bridge.
2. Power sub-station.
3. Weigh bridge.
4. Wash through.
5. Workshop.
6. Parking space for trucks (lorry).
7. Truck washing facilities.
8. Leachate holding pond.
9. Leachate Treatment Plant (LTP).
10. Proposed landfill cell.
11. Stockpile of daily (intermediate) cover material.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

12. Perimeter storm diversion drain.
13. Retention pond

In this case, the lnadfill consists of 3 cells: Existing Active Cell which is a currently running open dump, Advanced Cell 1, and Main Cell – the latter cells being the ones to be properly designed. Advanced Cell 1 will be generally excavated down to about 12 meter below the existing ground level and will be filled up to 13 m or slightly above the existing ground level. When full, the main cell on top of it will begin operation. Meanwhile, the Existing Active Cell will continue to operate until a certain convenient stage when it will be closed.

Another example is given in Figure 6. In this case, Cell 1 and Cell 3 are prepared together in the beginning with a separation embankment built in between. When the two adjacent cells are full and closed, operation of the overlying cell would commence.

A Description of the Existing Open Dump

The existing open dump in a landfill facility would require a descriptive assessment. If the dump is ready for closing, a closure design can be appointed – an example of such design in simple terms is given in Figure 7.

A covered dumpsite would probably contribute to leachate generation as much as the open dump would. The issues will be addressed in the new design. The basics will however go as the following:

1. As the covered dumpsite of the old open dump does not have proper underlining, the cover will be strengthened in terms of capability to resist infiltration. This cover may involve a layer of compacted laterite soil, 1 m thick, as commonly practiced in the Malaysian scenario. The designer will provide specifications for the closure which will address the issues of surface runoff, leachate production and treatment, and gas control.

Figure 6. An example of conceptual cross section of a landfill

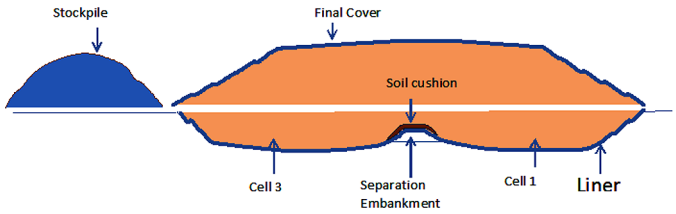


Figure 7. A probable future cross section running through the existing dump

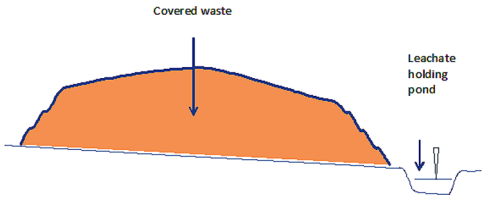

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

2. Once the new cells of the landfill are ready to receive waste, dumping will cease at the existing open dumpsite. The open dump site will be tidied and topped up with final cover. Some waste may be transported to the new cell.
3. Leachate originated from the closed dump may be treated together with leachate of the new cell. Leachate from these sites will be arrested via interception drains and wells. In the best possible manner, leachate from the dump will be channelled via drains, pipes, and intermediate collection pond, to the appointed leachate treatment plant. The location of the new leachate treatment plant should be just below the new cell or cells.
4. Perimeter storm diversion drains will be constructed around the closed dump areas.

The Sorting or Recycling Facility

The sorting or recycling facility provides an area where recyclable materials are sorted for recycling. Once waste deposited over the sorting platform, the waste will be lesser in density, at about 300 kg/m cu or about 3 m cu per ton. A truck with 6 ton waste will have a volume of about 18 m cu. when its content is deposited over the sorting platform. Thus the sorting platform should be at least capable of handling about 250 m sq. of waste spread. The content of two trucks will amount to about 0.15 m (about 6 inches) thick if spread evenly over the entire area of the platform. Of course, not all incoming trucks will head to the sorting building upon entering the facility. Some will go directly to the landfill. Thus the sorting building will only cater part of the waste.

LINER SYSTEM

Literature Review

A liner system refers to the whole components of a liner, not just the geomembrane. A landfill liner, or composite landfill liners, is intended to be a low permeable barrier, which is laid down under landfill sites. The liner retards migration of leachate, and its toxic constituents. Landfills generally require a layer of compacted clay with a minimum required thickness and a maximum allowable permeability, overlaid by a high-density polyethylene geomembrane. Chipped or waste tires are also used to support and insulate the liner.

The primary forms of mechanical degradation associated with geomembranes result from insufficient tensile strength, tear resistance, impact resistance, puncture resistance, and susceptibility to environmental stress cracking (ESC). In selecting liner material, these properties are examined for their suitability in the project.

Landfills are designed with cells that are lined to prevent groundwater contamination. Normally, for a municipal facility, the liner consists of a two foot layer of low permeability, re-compacted clay soil. Over this layer, high-density polyethelene (HDPE) secondary plastic liner is installed to cover the entire bottom and sides of the landfill cell. This plastic liner, which is chemical resistant to corrosion and damage, is then welded together and tested to ensure a continuous seal in accordance with regulatory requirement.

A blanket of geotextile fabric, composed of synthetic, felt-like fibers, is laid above the primary liner system, along with a geonet made of mesh-like plastic. Together, these prevent fine clay particles from clogging the leachate collection layer and promote removal of leachate from the liner surface.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Liner facility is installed to prevent pollution of public water bodies or groundwater by leachate discharge from the landfill site when installed at the base of waste body. When installed on top or side of waste body, it prevents the increase of leachate volume caused by inflow of surrounding ground water into the landfill site.

The structures and types of liner facility used shall conform to the topographical and geological conditions of the landfill site, soil conditions, ground water conditions, as well as the location of leachate collection facility. The thickness of a base liner facility shall be determined in accordance with its classification, quality of materials, construction standard, subterranean condition, joint method, corrosion and durability. The general thickness of liner facility is given in Table 4. The use these various geosynthetics for the project are sometimes kept optional due to cost implication. Simply speaking, the landfill liner may consist of one, two, three, or even more layers of geosynthetics depending of various factors. The decision of using either one out of the many choices will best be made after carrying out a site investigation for the selected site.

The situation with the foundation will affect the cost of geosynthetics. A soft foundation may be subject to settlement and therefore must be treated first. A sound foundation of sandy material should be ready for laying geosynthetics with reduced cost. Obviously, the surface landscape will affect the overall work effort.

A network of leachate collection pipes will be assembled on top of the impermeable base liner. Drainage aggregates will be spread throughout the area and topped with a filtration geotextile where waste will rest upon.

Normally, the provision will be made to install horizontal as well as vertical liners at appropriate locations and appropriate use. Horizontal liners will form the base of landfill cells while vertical liners will be used underneath waste (or leachate) retaining dam and in location where it is intended to protect leachate side migration.

The thicknesses and other specifications of geomembranes are conveniently available in the literature.

LEACHATE COLLECTION AND TREATMENT

Literature Review

Leachate is collected at the base of a landfill via a network of collection pipes to collect leachate generated from the landfill site and channelling it to a pre-determined facility for treatment before discharging it to the environment.

The treatment of leachate can be through one of the followings:

1. A combination of bio-treatment and physio-chemical.
2. A combination of recirculation, bio-treatment, and physio-chemical.
3. A combination of recirculation and natural attenuation.
4. A combination of recirculation, natural attenuation, and physio-chemical treatment.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Leachate Collection Facility

The collection facility is aimed to collect and channel the leachate generated from the landfilled waste layers to the leachate treatment facility. The leachate volume generated in a landfill should be kept minimized and removed immediately to the leachate treatment facility, so that there will be no trapped leachate in the landfill site. This is to ensure the water pressure acting on the liner facility and waste retaining facility is minimized. This also serves to supply air into the landfilled waste layers through the collection pipes for the semi aerobic sanitary landfill. The general conceptual layout plans for a leachate collection facility are shown in Figure 8.

Components of a Leachate Treatment Facility

Leachate Treatment System

A leachate treatment system may consist of a combination of recirculation, natural attenuation and physio-chemical treatment. When there is ample space available, the wet land treatment will be a good option. The concept of such treatment is shown in Figure 9. A leachate treatment process can be divided into several sub-processes involving various structures such as leachate collection sump, grease grit chamber, aeration lagoon, sedimentation tank and natural filtration before the leachate final discharged.

A relatively new leachate treatment procedure has been recently proposed for the landfill practice in Malaysia, namely the electro-flocculation, which will require a plant to be set up in the area designated for leachate treatment plant. The details of the procedure are partly given in Figure 10.

By this method, the leachate will be first stored in the influent raw water storage tank and then pumped into the treatment water tank for further adjustment. Chemical treatment is carried out in order to adjust the load characteristics at specific feed rate for 24 h/day. Coagulant will be dosed in automatically by mean of dosing pumps to coagulate the unsettleable solids in the leachate. In this process some non-

Figure 8. Conceptual layout plan for a leachate collection facility

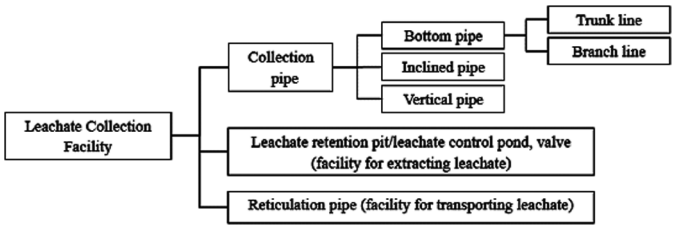

Figure 9. A conceptual leachate treatment facility

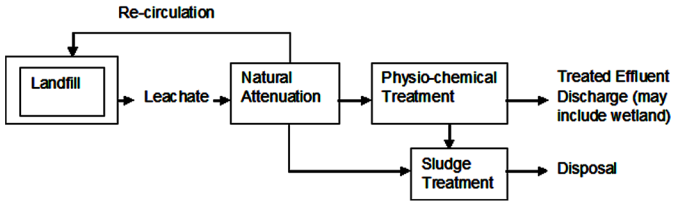
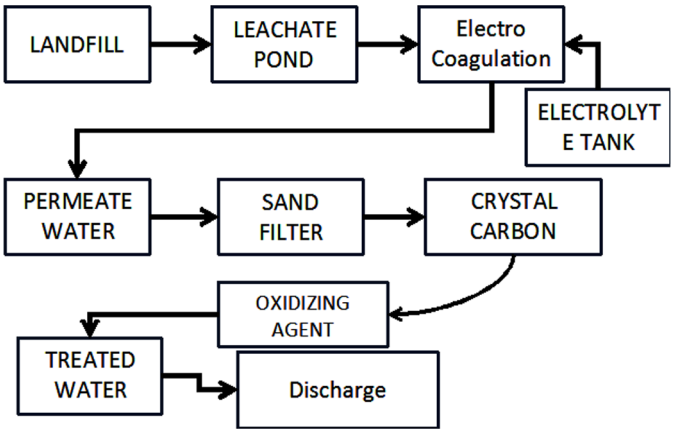


EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 10. An electro-flocculation process in leachate treatment



biodegradable components that are present in the lechate will also be reduced. Thereafter the solid will be allowed to floc and settled in the tank. After the flocculation process, the flocculated water is fed into a micro filtration system to remove most of the settled solids. The filter media for the filtration system will be about 200 microns. Particles sizes larger than this will be remove this way. The partially clear liquid with lower solid content and smaller particles will be fed into the electro-coagulation processor.

In the electro-coagulation process, the electrical current is introduced into water via parallel plates constructed of metals that are selected to optimize the removal process. The electro-coagulation process moves the electrons through the water between positive and negative plates. Sufficient residence time in the chamber is designed for the system so that the electric current destabilizes, dissolves, and alters the charge on the surface of the suspended matter. The removal of particles by electro-coagulation process is enhanced by the surface reaction, so the surface area of the electrodes within the chamber is designed based on the removal capacity by square cm per litre per minute. The electro-coagulation process does the following:-

- Removes heavy metals as oxides
- Removes suspended and colloidal solids
- Breaks oil emulsions in water.
- Removes fats, oil, and grease
- Removes complex organics
- Destroys and removes bacteria, viruses, and cysts
- Reduces Sludge Volume
- Uses no chemicals
- Addresses contaminant problems
- Processes Waste Streams with up to 5% solids.
- Harvests Proteins, Oils, and Metals

A thick layer of sludge comprising of oils, grease, solids, and other contaminants that was previously present in the leachate will float to the top and form sludge at the surface. These floatable matters will be scraped and removed continuously using a scraper. The collected sludge will be transferred into the

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

sludge holding tank. The solids in the holding tank will separated from the filtrate using a plate and frame filter press. The permeated water of the dewatering system will be returned into the water tank for further treatment. The almost dry solid will allow drying of the sludge bed.

The clarified water coming out of the electro-coagulation unit is finally filtered using another filtration system in order to remove particles less than 20 microns. The filtered water then goes into the treatment water tank before being fed into the Activated Carbon Filter. This filter in turn removes more impurities such as total dissolved solids (TDS), turbidity, heavy metals and many dissolved organics. The process will also remove chlorine content. The treated water will be suitable for use as chemical solution, boiler feed, general wash water, and fire hydrant. The treated water may not be good enough for drinking or human consumption unless further treated.

Collection Sump

Landfill leachate in a landfill is normally diverted into a collection sump. Before entering the collection sump, the leachate in normally filtered from solid waste by Mechanical trash screen and fine trash screen. A level sensor may be installed in the sump in order to aid pumping and monitoring operation. Other data such as Temperatures, Biochemical Oxygen Demand (BOD), Chemical Oxygen Demand (COD) and ammonia content can be collected by using suitable sensors. The collection pump is normally equipped with pump of submersible type. The collected leachate can be pumped into grease grit chamber for grease and grit separation.

Grease Grit Chamber

Grease grit chamber functions to separate grease from leachate. Grease trap is normally shall be equipped with sensor to identify trapped grease level. With increasing amount of grease in the trap, additive can be dosed in. Grease free leachate may then be diverted to the aeration lagoon.

Aeration Lagoon

Aerators of floating surface type may be employed. This instrument transfers air into the leachate helping biological oxidation reaction. It also mixes and promotes contacts between air and leachate for the biological reaction to take place. Besides natural air, oxygen can be injected into the aeration lagoon to enhance the reaction. To maintain an optimum pH of the leachate, sodium hydroxide as a chemical catalyst can be dosed in accordingly and the resulting pH monitored. From the aeration lagoon, leachate with lower BOD can be diverted to the sedimentation tank.

Sedimentation Tank

The sedimentation tank may be equipped with air pipe with air transferred in using blowers. Here, polyelectrolytic and flocculant solution can be added in to treat the COD materials producing sludge that sinks at the bottom of the sedimentation tanks. A scrapper can be employed to remove the sludge. The sedimentation tank can be equipped with sensors that detect leachate content. From the sedimentation tank, before the final discharge, the treated effluent can be further treated by natural method.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Red Bed System

Natural filter of red bed can be employed. Underneath the ground, filtered, treated leachate (clear water) can be collected via culvert before being discharged to the drains. Here, the clear water can be monitored just to ensure it meets the discharge requirements.

GAS VENTING SYSTEM

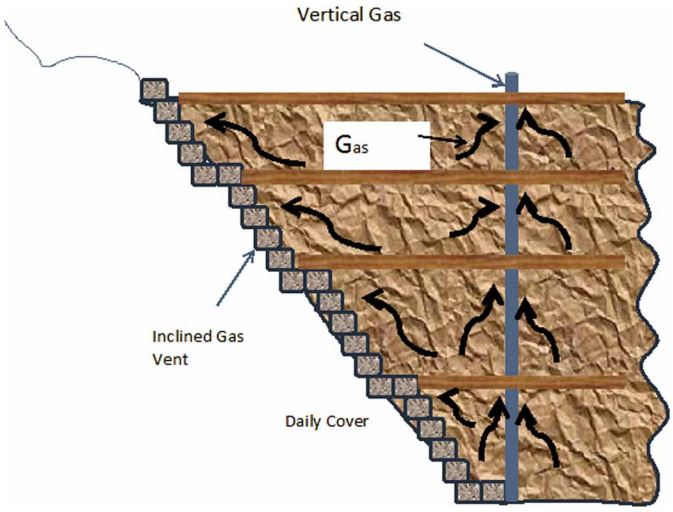
Literature Review

The main function of a gas venting system is to release gases generated from the landfill layers as soon as possible in order to prevent the adverse impacts caused by the gases. The gases are generated by the decomposition of organic materials in the landfill sites, which may cause fire disasters or affect the surrounding environment and human health.

Components of Gas Venting System

Gas venting system may be designed with no impediments to the activities on the landfill site. The main components of a gas vent system are normally not much more than perforated PVC pipes and simple gabions. The gas can be collected and burned, but it can also be released to atmosphere. A cross sectional view of a landfill with gas vents in place is shown in Figure 11. The vertical gas vents normally have intervals of between 30 m and 40 m. The vertical gas vents will be made of perforated PVC pipes while the inclined gas vents will be gabions arranged in place.

Figure 11. Inclined gas vent and vertical gas vent



EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

COVER MATERIAL

Literature Review

A cover minimizes infiltration from precipitation, and hence minimizes leachate generation. A cover develops a cap that is not more permeable than the bottom liner system. It promotes drainage from the surface with minimal erosion. It accommodates settlements and subsidence. The operation should be with minimum maintenance.

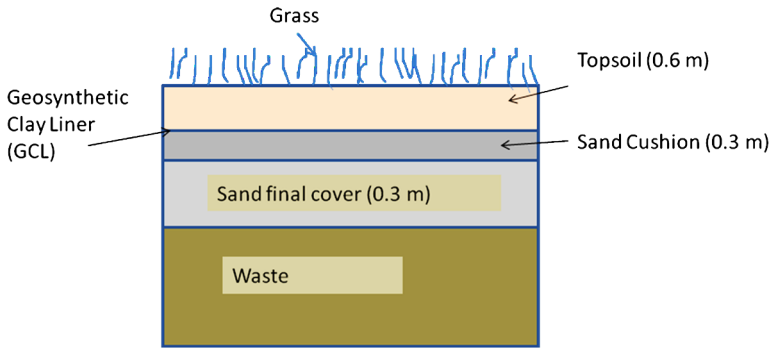
Daily Cover

Daily cover for the Malaysian scenario is normally laterite soils amounting to about 150 mm in thickness. Soils excavated during site preparation can be put aside in stockpiles and be used as daily cover.

Final Cover

Final cover in Malaysia is normally and mainly laterite soils amounting to about 1 m in thickness if used alone. An ideal cover layer however should consist of many more components such as shown in Figure 12. The vegetation cover is needed to minimize erosion and bring about naturalization process. Top slopes between 3% and 5% are recommended to avoid pooling and erosion. A surface drainage system must accommodate runoff to avoid rills and gullies. To avoid clogging, a separation filter is recommended between the drainage layer and the vegetative support layer. The 0.5 mm (minimum thickness) geomembrane (also called liner) must be protected by a bedding of sand free of stone or sharp objects 15 cm above and below the barrier unless the clay below and the drainage layer serves as bedding. The final cover may not have all the components of an ideal landfill.

Figure 12. A proposed final cover profile of a landfill



EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

INFRASTRUCTURE

Access Road

To ensure proper management and operation of a new sanitary landfill, additional facilities may be established at the site such as access road, site office, and weighbridge, amongst others. These can be new facilities to the existing dump, and are generally related with control and operations of the proposed landfill. The rest of proposed infrastructures have been mentioned in earlier sections.

In case of an existing dump, an access road may already exist connecting the lot to a federal (JKR) road. This access road is normally in good enough condition with existing premix surface and probably bridges. Figure 13 is an example of an access road suiting the above description. The access road probably has own reserve, except here and there where it strays into private lands – this will have to be addressed. The road probably is littered with rubbish. If the existing road is deemed safe and capable of providing nominal flow of traffic for the purpose of running the facility, it may only require minimum improvement. Nevertheless, the aspects must be addressed in the designer's report.

Proposed Roads

New roads for a proposed landfill could come from two categories:

1. Access road i.e., road connecting entrance from a federal carriageway and landfill.
2. Internal service road i.e., roads within landfill site.

Figure 13. An access road leading to a dump site

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Recommendations could involve the followings:

1. Widening or upgrading the access road. A new upgraded road should come with drainage facilities.
2. Stretches that have intruded into private lands should be addressed such as by acquiring the lands or straightened or redesigned in order to correct the situation.
3. Adequate road furniture should be provided.
4. An internal service road shall cross an overhead power lines perpendicularly (at 90 degree) to the ground footprint of the lines.
5. Wash trough will prevent outgoing trucks from dirtying access road.

Weigh Bridge and Control Booth

Weighbridge is a basic requirement of a landfill. It is used as base for recording the quantity of incoming wastes to the landfill. Normally, at least two (2) unit of weighbridges are needed – one for entry and another for the exit. The weighbridge should come with control booth to house the staffs doing the recording and inspection. The weighbridges will be positioned at strategic locations where the vehicles pass through when entering and leaving the landfill site.

Site Cabin with Basic Amenities

A site office is required to facilitate day to day activities such as supervision, inspection, and weighing of the incoming vehicles. The site office will also serve as centre for overall land filling activities such as the management of cover soils; and operation, maintenance, and monitoring of leachate treatment facility. A good site office facility will enable an easier control of the entire landfill operations. The facility shall be equipped with utilities such as water supply and electricity, and complete with communication systems. Other facilities such as worker's rest room, locker room, showers, toilet, weighing room, and store are also required.

Truck Washing Facilities and Wash Trough

A truck washing facility is normally provided for washing trucks after every waste disposing activity. To prevent collection vehicles from carrying dirt onto the public road, the vehicle wash through should be installed at where an unpaved road meets paved one.

Underground Monitoring Station (Well)

The monitoring of groundwater in areas surrounding the landfill site shall be carried out for the following reasons:

- To check the quality of the groundwater to ensure that the liner system of the landfill site are functioning well without any leakage.
- To detect pollution at the earliest possible time so that immediate remediation works can be carried out in order to minimize adverse impacts to the groundwater and the surrounding environment.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

A monitoring well shall be constructed to capture water directly below the subterranean level. In addition, the groundwater monitoring station shall be constructed downstream of the landfill site where a pollutant dispersion is at its fastest rate. This will allow a comparison of groundwater quality between the upstream and the downstream. The monitoring well shall be at least 100mm in diameter. Further aspects of a good monitoring well are widely available in the literature.

Mechanical and Electrical Facilities

The mechanical and electrical facilities may include the followings:

1. Generator
2. Electrical systems
3. Firefighting system
4. Communication system
5. External electrical system/street lighting and compound lighting
6. Security lighting
7. External telephone
8. Aerator and mechanical system for Leachate Treatment Plant
9. Air conditioning and mechanical ventilations
10. Lightning protection system

Other Infrastructures

Other infrastructure may include the followings:

1. Workshop
2. Perimeter fence and drain
3. Guard house
4. Sign boards
5. Ramps over waste dams

MISCELLANEOUS

Bore Holes and Monitoring Wells

The positions for site investigation (SI) may be decided based on site situation but the main aim is these should represent the whole landfill area. A number of SI points should be drilled by wash boring method while additional points can be carried out by piezocone and/or macintosh method. Each cell should at least have one SI point located within. The penetration positions should be evenly distributed throughout the landfill area, more or less.

A borehole drilled for SI may be converted into a functioning monitoring well and if so it should be finished as one. It is preferable to locate a monitoring well either near a river, next to plantation ground, or on low ground in order to capture the out flowing ground water.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Excavation and Construction of Cells

An excavation is almost always expected in the preparation of a new landfill cell. The depth of excavation will be normally limited to about 1 or 2 m above water table. The bottom of a cell should not breach the ground water table in order to avoid possible contamination.

Excavation on higher ground would result in having slopes bordering the new facility. A cut slope should be finished with batter faces having either 1:1, 1:1.5, or 1:2.0 gradient, which ever that would result in acceptable Factor of Safeties (FOS). These FOS against sliding should all be at least 1.5. Berms should each be about 2 to 3 m width. The vertical distance between two berms should be 5 to 6 m maximum. The final excavation design however could be affected by actual findings from site investigation or laboratory tests on soil samples.

The positioning of cells should allow for space for stockpiling of cover material. Excavated material may be stockpiled in another cell that is already closed or not yet operating. While operating an active cell, the cover soil dug up from developing it can be located over another cell not yet dug or already covered. While operating Cell 1 for example, cover soil dug up from developing Cell 1 may be stockpiled over Cell 2 and Cell 3. In other words, if there were three cells in a landfill, these may be developed not at once but at different times. It is also possible to develop all cells at once, but in such case, a large flat area elsewhere will be needed for storing the cover material.

Cell Bund and Leachate Dam

The higher ground of an area designated for a cell may get excavated more so than the lower ground. The lower ground is more likely to get encircled with bunds to prevent it from inundations. In case of a leachate spill, simple dams may be appointed to confine it before channelling to the collection pond.

Cell for Inert (Construction and Agricultural) Waste

An area of the landfill may be designated for inert waste. This area will not require an underlying protection because the waste will have no contaminating consequence. Inert waste shall not be mixed with municipal waste because the cost of disposal per volume of the latter is more costly than of the former. Also, the volume above an inert cell should not become another cell of municipal waste because leachate will then be produced and the downward migration would contaminate the underlying cell which has no liner. Also, agricultural waste should be separated from construction waste as the latter is more likely used as recycled construction material than the former. An agricultural waste would turn into compost after a certain period of time and can be used in farms and planting grounds.

Disposal Activity near Power Pylon and underneath Power Transmission Line

All activities related with landfill operation shall not breach the 30 m clearance distance from any power pylon. An internal service road inside a landfill shall cross at 90 degree or perpendicular to the ground print of any power transmission line. A vertical clearance of at least 10 m should be allowed between a permanent landfill structure to the power transmission line running above it. On either side of a transmission line, no structure shall be allowed to remain within 25 m distance to it.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Wash Trough

Wash trough will prevent outgoing trucks from dirtying access road. It normally uses water from a detention pond of surface runoff.

Leachate Treatment Plant (LTP) and Leachate Holding Pond (LHP)

The leachate treatment plant (LTP) will occupy a certain amount of acreage and this can be located economically underneath a power transmission line if such exists in a facility. A leachate holding pond (LHP) too may economically located in an area underneath a power transmission line.

Closure

Multiple cells will merge into one during closure. A cover geomembrane can be designed to embrace the whole landfill area. For the final cover, a sufficient amount of top soil topping and installation of drainage system will ensure a good protection against rain infiltration possibility. A service road too can run over it provided there is a sufficient thickness of embankment to protect the membrane from puncture by passing vehicles.

Chapter 13
An Approach to Sustainable Watershed Management:
Case Studies on Enhancing Sustainability with Challenges of Water in Western Maharashtra

Sneha Kumari
Symbiosis International University, India

Yogesh Patil
Symbiosis International University, India

Prakash Rao
Symbiosis International University, India

ABSTRACT

Western Maharashtra consists of drought prone villages, which around seventy years ago were facing drastic challenges regarding water requirements. People living in such areas started to migrate from these villages in need of food and water. The chapter focuses on few case studies of drought prone areas of Western Maharashtra which made a move towards sustainability and has created an excellent model of watershed projects. Several practices like ban on cutting trees, terrace farming, contour bunding, drip irrigation, sprinkle irrigation, introduction of cooking stoves, rotational grazing, efficient water distribution and change in cultivation of agricultural crops according to the climate were followed which led the village to become a model for Aadarsh Gaon (An Ideal Village). The author has used secondary data from previous research work and critically analyses the case studies on water management in drought prone areas of Western Maharashtra which managed to become a model for sustainable use of water.

INTRODUCTION

The State of Maharashtra is located in the Western parts of India and is classified into five regions namely, Konkan, Desh (Pune region), Vidharba, Khandesh and Marathwada. Along the Arabian Sea the state has a coastline of 720 km. Maharashtra is home to renowned historical monuments, caves, temples, festivals and a bustling lifestyle. Moreover, it is housed by large number of educational institutions, industries and service sector organizations and 45% of total population in the state lives in urban area. As the second most populous state, Maharashtra is one of the most developed states of India and plays a key role in the overall economic development of country as major educational and financial institutions are located in this state. The current population of Maharashtra is 121 million people accounting for over 9.29% of the total population of India.

With time large population has been shifted towards urban areas, while rural areas have undergone limited shifts in their boundaries. Cities like Thane, Mumbai, Raigarh, Ratnagiri and Sindhudurg are separated by the Western Ghats which receive heavy rains (>1000 mm) whereas the rain-shadow region towards the east of the Western Ghats suffers from low rainfall. Furthermore, far Eastern regions of Maharashtra again receive a good rainfall. Western region comprises of Nashik, Satara, Sangli, Kolhapur, Solapur, Ahmednagar, Aurangabad and Pune which has comparatively low rainfall than other district of Pune since they lie in the rain shadow region of the Western Ghats. The rain shadow regions receive an average rainfall of 500-600 mm. The state has a pleasant climate throughout its season with rainfall exceeding to 6000 mm in Western Ghats to 500 mm in the rain-shadow regions. The state has been surrounded by Krishna, Godavari, Tapi, Narmada and Konkan River providing water for the need. About 50% of the Maharashtra region lies in the drought prone area of Deccan plateau (nidm.gov.in/pdf/dp/Maharashtra.pdf). In the past few years it has been noticed that the Western region of the state is facing severe water scarcity problems. Most of the water supply in this region is happening through water tankers. Water being the life is essential at every step of day-to-day activity and therefore must be sustained for a better living.

This chapter focuses on the key approach towards watershed management, a topic of great concern in present era of climate change. Watershed management is an approach towards life of the earth since excess water flow leads to soil erosion, floods and other natural calamities which ultimately destroy the resources of living and scarcity of water again concludes to drought (Dixon & Easter, 1991). Western Maharashtra consists of drought prone villages which around seventy years ago was facing drastic challenges regarding water requirements. People living in such areas started to migrate from these villages in need of food and water (Foster et al., 2009). Then a commerce student Mr. Popatrao Pawar took an initiative to become Sarpanch (Head) of the Hiware Bazar village and tried to change the history of the village. Several practices like ban on cutting trees, terrace farming, contour bunding, drip irrigation, sprinkle irrigation, introduction of cooking stoves, rotational grazing, efficient water distribution and change in cultivation of agricultural crops according to the climate were followed which led the village to become a model for Aadarsh Gaon (Phand & Arya, 2007). Mr. Anna Hazare thirty years ago also took an initiative to achieve watershed resources by implementation of Programs through public participation in Ralegan Siddhi village of Parner (Sharma, 2006).

The authors in the present chapter have used secondary data from previous research work and critically analyses the case studies on water management in drought prone areas of Western Maharashtra which managed to become a model for sustainable use of water. The objective of the chapter is to focus on case studies in the drought prone areas which managed to survive efficiently with a successful water management and to discuss measures for a sustainable watershed management with reference to Maharashtra.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

GROUNDWATER MANAGEMENT IN WESTERN MAHARASHTRA

Groundwater is defined as the water available in the aquifer below the ground at the zone of saturation which can be dug through machines and water extracted as bore well, tube well or by other means. The groundwater table is abundant in Eastern part of the country than in the Western part. The Western region has limited water leading to depletion of water resources.

NABARD has been utilizing the finance for developing wells in the rural areas. The increasing tariffs on water can make a sustainable use of water for irrigation by the use of diesel and electric wells (Moench & Kumar, 1995). This electricity tariff will lead to increase the efficient utilization of groundwater and use of electricity (Kumar & Singh, 2001). With time due to variation in the climate, the groundwater level has gone down due to less rainfall and the unhealthy use of water.

L.A Bill No. XLII 2009 has been introduced to ensure the sustainable water management in Western Maharashtra and established state groundwater authority and district groundwater authority to protect drinking water resources and managing the groundwater exploitation within the districts of Maharashtra. This has led to forward a law for managing the demand and supply of water for various purposes at different sectors. This act is commonly called as the Maharashtra Groundwater Development and Management enacted in the year 2009. This act focuses on valuable terms required for sustainable management of water as described in Table 1.

It is the responsibility of the state authority to check the polluters in the ground water both in the rural as well as in the urban areas and make it safe for drinking purpose for the population. The State Authority and the State Government ensures the implementation of integrated watershed development and management. It is the responsibility of the State Authority to charge water for the highly water intensive crops grown by the farmers. This practice has been made to ensure the sustainable management of water. Training Programs have been held by the state authority to ensure awareness in the rural areas of Maharashtra regarding integrated water management. The Program discusses on the best practices for the implementation of watershed management. Watershed Water Resource Committee supplies ground

Table 1. Valuable terms used in sustainable management of water

Rainwater harvesting	This is the essential part for water management which cannot be ignored. The rain water must be stored or collected instead of being wasted. This water can be conserved for future purposes.
Aquifer	This refers to a structure for storing saturated water underground.
Area of influence	Refers to the area beneath the ground which is modified for pumping purpose.
Artificial water recharge to groundwater	refers to the water being available due to the natural climatic conditions
Deep well	This is the groundwater dug deep in the soil covering twenty- five strata of the soil and includes bore well, tube well and even sixty meter deep.
District watershed management committee	Enrolled under section18 for the better management of groundwater in the districts.
Drinking water purpose	This was included in the bill for assessing the demand and supply of drinking water for the human population of the state.
Groundwater surveys and development agencies	Under the water supply and sanitation measures the survey is made underground in Maharashtra and the developing agencies manages the water supply in the state.
Integrated watershed development and management	is the key for the sustainable management of water in the state

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

water for the highly water intensive crops with terms and conditions. The District Authority shall take the responsibility to preserve the drinking water from the groundwater. At times of water scarcity in the areas, the District Authority regulates the extraction of water from any well and manages to supply water within the area of one kilometer of the public drinking water source. The inspection of wells is carried out and the water is tested in terms of quality and any contamination.

The State Authority has a watershed water review committee who is responsible for water management in the villages of Maharashtra affected by water scarcity. The Watershed Water Resource Committee comprises of a chairman of the Panchayat Samiti, one representative from the water supply and sanitation measure, one from the water use association, elected members of the Panchayat Samiti, block development officer and member of village and water committee. It is mandatory that one-third of the members of the water resource committee must be women. The Watershed Water Resource Committee allocates the water budget of every area and on the basis of availability of water all the year around, the cropping pattern of that particular area is decided. The groundwater and developing agency carry out the hydro-geological study of a particular area for the management of water.

The Maharashtra Groundwater Act 1993 has been enacted to protect the drinking water for the rural population and also to regulate the exploitation of groundwater. The Government of Maharashtra has enacted a new law under Groundwater Act to ensure the sustainable supply of groundwater, protecting drinking water, conservation of groundwater resources and provide beneficiary schemes in rural as well as urban areas to support the ground water protection. The bill also provides the following proposals as mentioned in Table 2.

Table 2. Clauses of the bill proposed in 2009 for enhancing sustainable water management

Clause	Sub-clause	Objectives
1		The state Government has been assigned with the power to bring out the act of watershed resource development.
2		Such authorities must be specified by the state Government which can provide water from the public drinking water resources.
3		The state groundwater authority must exercise the power on discharge of water to different sectors. The state authority must be assisted by the groundwater surveys and development agencies, one expert from the field of groundwater and one women representing the user of groundwater.
4	1	An official gazette must be notified in the area
5		The area where the groundwater has improved must be denotified by the state authority.
6	3,5	The state Government is assigned with the power to restore the groundwater quality with the minimum water standards and it's preservation for drinking purpose.
7		Registration of the owners of the wells in the notified as well as non-notified areas of the state must be ensured by the state authority.
8	1, 3, 5, 4	Permission should be granted to any person by the state authority for digging well in the area for drinking purpose. The use of existing deep wells is ensured and permissions should be obtained by the district authority for the users of groundwater.
9	3,6,7, 8,10	District watershed management committee should look after the efficient implementation of integrated watershed management plan. The state Government shall issue the guidelines for disincentives the use of water for water intensive crops. The State Government must prescribe the efficient manner for rain water harvesting by the top roof method in urban areas. Incentives shall be provided to the water resource committee by the state Government.

continues on following page

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 2. Continued

Clause	Sub-clause	Objectives
10	1, 3	The state Government must give directions regarding the cropping plan in a particular area based on its water requirement. In case for the cultivation of water intensive crops, the farmers may approach to the water resource committee for discharge of groundwater.
12		Compulsory registration must be done by the rig owners and other operators in consultation with the groundwater survey and developing agency.
14		The state authority can direct special order to water resource committee or the village groundwater surveys and developing agency for sustainable management of water
16		The state Government can assign responsibility of the state watershed management council to the state water council
18	1, 2, 3	The state Government can constitute a district committee called as district watershed management committee as per need. The members of the district watershed management committee can be appointed by the state Government. The decisions carried out by the district watershed committee shall be then implemented by the district authority.
19		For artificial recharge of water Integrated watershed management plan should be prepared by the district watershed committee.
20		Power has been assigned to the district authority for public drinking water source.
21		The district authority shall see the influence of the area under public drinking water source.
22		The excess discharge of water can be prohibited by the district authority from any well for a particular period of time. The state Government also holds the power to prohibit the discharge of water from a well for a particular period of time.
23		The extraction of groundwater can be regulated by the district authority in the village
25		The district authority shall declare any area as water scarcity area for a specific period of time
26		The district authority can place an order to extract water from any well in case of water scarcity.
27		The state Government looks after the method of payment charged by the district authority.
28	1	The state Government is assigned with the power to look after the manner in which a person sinks a well and the preservation of the soil
29	1, 5, 6	The state Government shall look after the work of the water resource committee as per required. The terms of the official members of the watershed water resource committee are assigned by the state Government
30	1, 4, 5	The state Government has the power to look after the manner in which the watershed water resource committee prepares the groundwater plan, which is notified by the district authority. The cropping pattern will be then decided on the basis of the water budget by the watershed water resource committee with consultation to the state Government.
32	1, 4	The state Government has the power to give permission for the artificial recharge of water.
33		The watershed water resource committee shall promote the participation of people for sustainable and equitable management of water.
34		The watershed water resource committee implements plans in coordination with Panchayat.
35		The watershed water resource committee can regulate or prohibit the mining of sand under the recommendation of district authority.
36	2	The service charge and fees shall be collected by the watershed water resource committee for the use of groundwater
37		It is mandatory for the watershed water resource committee to submit its report to the Gram Sabha
39		The state Government prescribes the time for the water budget to be prepared for the watershed water resource committee.
40		Rules are made for the account statement submitted annually.

continues on following page

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 2. Continued

Clause	Sub-clause	Objectives
43		The groundwater surveys and developing agencies shall assist the watershed water resource committee for watershed preparation.
45	1	The state Government shall prescribe the rules for the hydrogeological studies carried out by the groundwater surveys and developing agencies.
46	1	The state Government has the power to look after the manner in which the Panchayat and other local bodies looks after the maintenance of the water bodies and the water budget. The artificial water recharge structure is also taken care of.
47		The state Government shall look after each and every rule and the manner in which it is followed for a sustainable water management.
56	1, 2	An appeal can be made to the state Government with fees for going against the orders of the district authority.
58		Difficulties must be removed in following such rules for the ground watershed management

CASE STUDIES ON ENHANCING SUSTAINABILITY OF WATER IN WESTERN MAHARASHTRA

Maharashtra occupies a total area of 3,07,713 square kilometers with an average annual rainfall of 1433 mm. Majority of the area of the state lies in the Deccan belts. The rocks of different areas are confined with different characteristics which divides the area into unconsolidated, consolidated and semi-consolidated.

Wadgaon

This is a village which is suffering from water scarcity. Roof top rainwater harvesting was found as the best measure for conserving water in this village. This has been implemented in most of the areas of the village and the measure was also supported by the Panchayat of the village by constructing several water storing structures in the local nullah.

Watershed Warud Taluka in Amravati

Due to water scarcity the groundwater has declined to a very lower level in this village. This led to the construction of three percolation tanks at Manikpur, Benoda and Bhindi and ten cement plugs or nullah bunds at Alora, Benoda, Mamdapur, Malkhed, Temburkhed, Loni, Sendurjanaghat. Five underground water storage tanks were also constructed for conserving water.

Watershed at Yuvraj Taluka in Jalgaon

The Yuvraj taluka has a declining groundwater by one meter every year due to cultivation of banana. For sustaining water in the region a total of three percolation tanks were constructed at Ichkeda, Haripura and Dongaon. Injection well, recharges shift, dug wells and nullah's were constructed in the village to fulfil the water requirement of the village.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Watershed at Yaval Tehsil of Jalgaon

Percolation tanks and recharge shifts have been constructed at Borkheda, Wadri, Sangvi and Dongarda to allocate water in twenty-eight villages of Jalgaon district. The storage capacities of these tanks were found to be seventy-one to ninety-eight thousand cubic meters and a catchment area of 0.425 to 4.273 sq.km each and a submergence area of 12.35 to 42 thousand sq.m.

Warud at Amravati

Roof top rain water harvesting was initiated as a project in the village by the Panchayat samiti. Roof top area of 500 sq.m was used for rain water harvesting. This water has been used for storage of water in the ground well. The ground water well level showed a substantial increase in its level due to roof top rain water harvesting. The water stored from the rain water harvesting was an essential measure for storing water at times of need and a major portion of the water stored was used to increase the level of groundwater.

RALEGAN SIDDHI

Ralegan Siddhi is a small village of Parner taluka of Ahmednagar District, Maharashtra. The village was once under the hands of poverty followed by the scarcity of water and limited agricultural growth. The village was very badly shattered due to climate change and unsustainable management of water. Agricultural crops were badly ruined and farmers faced few bad days.

Figure 1. Scenario of Ralegan Siddhi village in 1975

Figure 2. Hind Swaraj Trust run by Mr. Anna Hazare

THE NEW BEGINNING FOR CHANGE IN RALEGAN SIDDHI

It was Mr. Anna Hazare who made the first step to bring out a change in the village some thirty years ago. With consistent and committed efforts of Mr. Anna Hazare, the village came out to be named as the first ideal village of Maharashtra. Mr. Anna Hazare made a successful implementation of sustainable practices in the village.

Prohibition on grazing of agricultural crops, cutting of trees, consumption of alcohol, shramdan and regeneration of water resources were some of the practices for the development of the village. In the present scenario availability of water resources in the village for irrigation in agriculture land has been found to be the luxurious asset for the village. Phand & Arya (2007) made a detailed study on the developing trends of Ralegan Siddhi before and after sustaining practices and came to a conclusion that the village has twelve hundred acres of land out of seventeen hundred which are under irrigation. This has led to increase in the agricultural yield and ultimately this has led to increase the number of livestock animals. In 2007, it was found that dairy sector in the village contributes to Rs. one crore per annum (USD 1,50,212/- pa). Practices of this nature have made the village full-fledged with drinking water, school facilities, roads, medical hospitals and sanitation thereby making it sustainable. Further the model of Ralegan Siddhi village was taken as the Aadarsh Gaon Yojana for other villages. This model focused on practices for making water safe for drinking and was taken as Aadarsh Gram Yojana in about three hundred villages across Maharashtra.

The implementation became famous and was based on five principles namely shramdan, ban on cutting of trees, ban on grazing, ban on consumption of alcohol and introduction of family planning as one of the sustainable practice. With shramdan, forty thousand contour trenches were built for conserving water and increasing the groundwater table. Along with contour trenches several trees were planted around. The trees like neem (*Azadirachta indica*), babul (*Acacia nilotica*), kashid (*Cassia siamea*) and shisam (*Dalbergia sissoo*) were given preference.

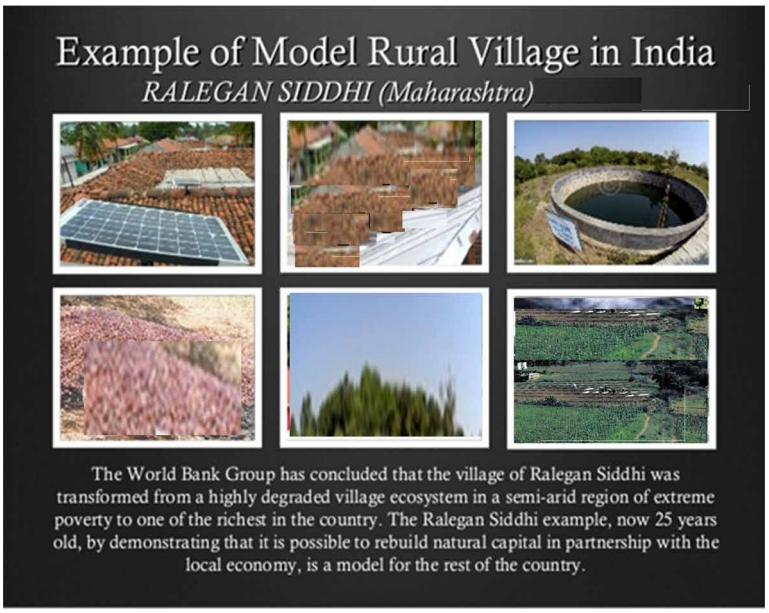
Figure 3. Ralegan Siddhi as an example of Model Rural Village



HIWARE BAZAAR

Hiware Bazaar is one of the village located in Ahmednagar District which has been suffering from drought conditions. During British rule, Hiware Bazaar village was full of joy and peace since it was surrounded by the hills therefore it had a pleasant weather during rainy seasons which resulted into wells and groundwater table to be filled with water all the year around.

This promoted agricultural crops with good yield and the farmers of the village chose agriculture as their main occupation for living and trading their crops in Mumbai. With time the things did not remained

Figure 4. Drought conditions in Hiware Bazaar

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

the same and with the growing population trees were cut down for wood and agricultural land were shifted towards construction of houses. With the decrease in the number of trees the soil left barren with excess of erosion and maximum water being wasted into the floods. This resulted into wash down of the fertile soils into rain and the village drowned down to adverse conditions. In 1972, things did not remain the same and the wells were left dry with the groundwater table went significantly down. Shortage of potable water led the people to lead a miserable life. People began shifting away from the village and the farmers' crop lands converted into deserted ones. Losing the means of their life farmers got addicted to alcohol and few committed suicide. By 1973, things got even worse with 80% people being addicted to alcohol and agricultural land turned into desert. With no means of survival Government officers were scared of being posted in the village, therefore only blacklisted candidates were posted there as a punishment. By the year 1988, the village was ruined in terms of economic, social and environmental aspects. The teachers in the school rushed away from the village and the schools were locked in waiting for the good teachers to return. This resulted into adverse education system in the village. Therefore it was found that not only elders but children also suffered from the scarcity of water in the village.

NEW BEGINNING IN THE WESTERN REGION

Hiware Bazaar Village

As discussed in the background it is clear that the village wanted a change for the need of water as their survival. The young generations saw some ray of hope for sustaining the village and requested Mr. Popatrao Pawar for becoming the sarpanch (Head) of the village in the election. By 1990 Popatrao Pawar was elected as the sarpanch on a condition that villagers must not quarrel among themselves. Pawar called out Gram Sabha for hearing the needs of the villagers and found out that the basic needs of the farmers in the village was water for drinking and agricultural purpose which had resulted an adverse impact on their health and environment.

Figure 5. Popatrao Pawar transformed the village from drought to a sustainable one

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

The need for water in the village was given prime importance with other needs. To begin with Mr Pawar planted tamarind saplings which were destroyed by the villagers because it was not considered relevant for them. This promoted the sarpanch to educate people as his first step for the betterment of the village and also for sustaining water. The schools were painted with playground and education was started as an initial step in the village. The primary school led to high schools where teaching was made by the youngsters without charging any fee from them. The next step was to generate availability of water in the village. The villagers requested the forest department for initiating afforestation in their village but the overgrazing practice made by the villagers had made the farm barren. Therefore, their request was not taken by the forest department. In 1993, the villagers went to Ralegaon Siddhi and Aadgaon in Kolhapur to understand the water management practices implemented there. This visit taught them measures to fight with scarcity of water in the drought regions. In 1993, with the support of forest department around seventy hectare of village forests was regenerated and sustainable practices were made to conserve water. Contour trenches around the hills were found to be the most important measure for saving water from wastage and also for maintaining the fertility of the soil. Contour trenches in Government land led to plantation of about 45000 trees. Plantation of trees was carried out on hills which helped to conserve water. Pits were dug to store water and grazing was prohibited. The practice of cooking food in chulhas was also banned and a shift towards LPG (Liquified Petroleum Gas) was made in order to save the trees and avoid cutting down of wood. In 1994, a NGO called 'Yashwant Krishi Ram Va Panlot Vikas Sanstha' was established consisting of eleven members who planted local trees and limited the plantation of Eucalyptus and Subabul which consume a lot of water from the soil. In order to review the initial steps taken and continue for further development, the villagers felt that it was necessary to have a social audit body at place in the village. This led to audit in the village and by 1994 the transparency and accountability were regarded as the key for the village development. In 1994, twelve agencies were implemented under employment guarantee scheme for addressing water scarcity problems. Hence then Hiware Bazaar was selected as the Aadarsh Gaon Yojana by the Government of Maharashtra (Sakhuja, 2008). The Aadarsh Gaon Yojana was based on prohibition of grazing, cutting down trees consumption of alcohol and promotion of family planning and labors (Sangameswaran, 2006). Following were the main five principles which made Hiware Bazaar as the Aadarsh (Ideal) village.

1. **Ban on Tree Cutting:** Cutting down of trees for wood as fuel or fodder was strictly prohibited in the village. This led to the promotion of long lasting trees and thereby replacing the conventional chulhas with LPG.
2. **Restrictions on Grazing:** Grazing was also restricted as it resulted into tremendous soil erosion and wastage of water. As a remedy for the farmers having animals rotational grazing was thought to be a better means.
3. **Family Planning:** According to Malthusian Theory of Population it was found to control the growing population to meet the need for food. This practice had a limitation that family planning was not made a part of the health concern.
4. **Ban on Consumption of Alcohol:** The basic purpose of this step was to save the people from the evil effects of alcohol and also to minimize the gap between their debt and consumption. People addicted to alcohol were provided bank loans for purchasing animals in order to run their life.
5. **Shramdam:** This was a common practice which led to promotion of agricultural practices and water conservation measures for the village.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Several water harvesting structures and wells have been constructed in the village for storing water in times of need. The production of grass also increased from 100 to 6000 tons by the year 2004, which resulted to increase the livestock animals with the farmers and this resulted in increase in the milk supply (Singh, 2010).

Implication of Water Rules in the Village

Water rules were made for the distribution and use of water. The rules for distribution of water were bifurcated into two, one being for people who get access to water and another for the distribution of water. Water is supplied to lands as per the ownership and groundwater is accessed through private wells.

Impact of Watershed Management in the Village

The main effect of watershed management is an increase in the groundwater table and the percentage people being benefitted from the water also increased tremendously. This also led to increase in employment since the practices involved a great number of labours. Drinking water was supplied to every households and this resulted into good health of people. During drought situation water was available both for domestic as well as agriculture purposes.

Phand & Arya (2007) conducted a research study on Hiware Bazaar village of Ahmednagar District to find out the impact of Aadarsh Gaon Yojana in the villages and also the status of the village before and after the implementation of Aadarsh Gaon. The Aadarsh Gaon Yojana was implemented on 15 August, 1994. From the research conducted it had been found that the total village area remained the same before and after. The total area for plantation of trees had increased with good storage structures, nullah bunding, increasing number of wells and contour trenches. The cropping pattern grown in the agricultural land was also found to change as per the availability of water in the area throughout the season. With increase in the number of animals the total production of milk also increased. The areas having no schools were found to be led by two or more schools.

As regards to adaptation of sustainable measures in Hiware Bazaar for sustaining water, the contour bunding was practiced in the area of 414 hectare, cement nullah bunding in an area of 4 hectare and nullah bunding in an area of 51 hectare. The two measures helped in assuring conservation of soil and water for future needs. Afforestation was also considered as an important aspect for enhancing sustainability in the village in an area of 404 hectares. Tree plantation was made along road side covering a length of six kilometers. Storage as well as earthen structures was constructed in an area of 9 sq.km for conservation of water

SUSTAINABLE WATERSHED MANAGEMENT

A sustainable water use is defined as the use of water beneficial for all the users without reducing the need for other users being human beings, animals and also natural resources (Gleick, 1998). The demand for water is not just limited for fulfilling the need of water but also the wants of people for water in future. Variation in the stock and flow of water that changes the availability of water at proper time and space and variations in the demand for water use disturbs the sustainability of watershed management. The disturbance in sustainability of water is mainly caused due to increasing human population and chang-

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

ing technologies. The first and foremost task to be done for sustaining water is to control the above two problems. Since the increasing human population requires enough water for meeting their needs and the technologies which is changing every now and then decreases the amount of water required for the social benefit. The sustainability of water can be managed by controlling the disturbances created by the four parameters namely, water requirement for human being, water requirement for environment, maintenance of water quality standards and the renewable water resources maintenance (Gleick, 1998). Maharashtra is the first state in India to take an initiative for sustaining water and prepared a state disaster management plan giving importance to water requirement in the state. It is also the first to regulate water resource authority for regulating water requirements and its availability.

Balawadi and Tandulwadi: These are the drought prone villages which faces problems for water availability for the agro based industries and plantation of sugarcane crops which requires a lot of water. Baliraja Memorial dam was constructed in South-Western Maharashtra which allocated water to the villages for meeting the farmer's irrigation needs as well as the household domestic needs of the villagers. The dam changed the living style of the village and addressed the water issues in the village.

AN APPROACH TO SUSTAINABLE WATERSHED MANAGEMENT

Das (2006) reported in his research different approaches and Programs for sustainable management of water. In the present era with the upcoming challenges of water, the availability of water for the fast growing population of the country is a matter of deep concern. In many parts of the rural areas availability of safe water is a major problem while few areas are facing scarcity of water. With this thought it has become very essential to take some initiatives for sustaining water for different uses. Various centrally sponsored schemes have been working for accelerating water in the rural areas by the implementation of minimum water tax for conserving water. During 1981-91, United Nations International Drinking Water Supply took an initiative step for sustaining water and concluded that drinking water must be paid or charged by the user in order to give it a value. Government also took an initiative step for making water available to the rural areas and came out with Sector Reform Program. The Sector Reform Program Swajaldhara comprised of four basic elements namely, demand for water, accountability, contribution of people and community participation (Das, 2006). The Constitution 73rd and 74th amendments act in the year 1992 focused on drinking water supply, water management and sanitation measures in rural areas from the Panchayats and Nagarpalikas (Corporation). The drinking water supply in rural areas are managed by the Ministry of Rural Development; Ministry of Water Resources at the central level; Public Health Engineering Department at the state level; Zilla Parishad, executive engineer from public health engineering department and district rural development agencies at the district level; and taluka Panchayat, gram Panchayat and village water and sanitation centre at the block level. The five year plan of Indian Govt. has brought different policies and Programs to come over from the issues of water scarcity. The problems of rural water are managed by the respective bodies as mentioned above in the state, central, district and block level. In 1950, constitution of India was set up and first national water supply was started in 1954. Then in the year 1956-1972, public health engineering department was set up at the state level to look after the rural water supply in towns and villages. Rural water schemes were sanctioned by financial terms in 1968 followed by the accelerated rural water supply Program in 1972 for handling the problems of the village related to rural water supply. In 1974, the Programs related to minimum need of water supply were introduced in states. The accelerated rural water supply Program

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

identified the problems of the village for supply of drinking water throughout the year with a sustainable management of water in 1977. National Drinking Water Mission was initiated in the year 1986 for the application of conservation measures for sustaining supply of water. Ultimately the National Water Policy evolved in the year 1987 to look after the planning of different water resources and supply of drinking water in India. In 1991, the National Drinking Water Mission was renamed as Rajiv Gandhi National Drinking Water Mission. This Mission put forward standards for the supply of drinking water to the rural population. The year 1996-1999 began with audit of water resources with World Bank and other agencies. All the developments led to Swajaldhara Program in the year 2002 and the national water policy was revised by the National Development Council.

Several Government agencies, World Bank, German Development Bank and other non-Government organizations are indulged in the implementation of an efficient water supply in Maharashtra. The effort started with the dug well era from1960 to 1970, which provided several dug wells with power pumps. The year 1971-1985 led to the bore well era where bore well technologies came into existence leading to several hand pumps and power pumps. Rural piped water supply era arrived from the year 1985 to 1997 which led to increase in the number of piped water supply scheme in the rural areas. Several water projects were handled in this era. The year 1997 to 2000 began with the Master plan era which led to expenses for different water supply schemes. Since the year 2000 the policy reform era was evolved for delivering water in the rural areas and providing several sanitation measures in the rural area (Das, 2006). This made Maharashtra to be the first state known for launching Program for allocating water resources and sanitation services. The Government of Maharashtra has implemented several Programs for conserving groundwater. Shivkalin pani sathawan yojana is one such Program started by the Government of Maharashtra for storing rain water, rainwater harvesting, construction of tanks for water storage and other measures which can sustain water. A large number of Programs and schemes have been developed by Government of Maharashtra for conserving water.

The Government has also implemented two programs namely the Sant Gadge Baba Gram Swachatha Abhiyan and the Total Sanitation Campaign (TSC) based on the sanitation measures. The Government has focused the hygiene and sustainable practices for clean rural area.

CHALLENGES OF WATER IN WESTERN MAHARASHTRA

In rural areas of Maharashtra, water has been suffering with several challenges. The major issue of concern is about the water industry to work efficiently meeting the demand of water. It has been found that the groundwater has been over wasted for the private productive use and must be controlled. The first challenge faced by the Maharashtra sector for the availability of water is the technologies which interfere with the sustainable water management (Das, 2006). In 2002 the state Government of Maharashtra took an initiative to address the water resources in rural areas of thirty three districts of Maharashtra. After testing of water it was found that the water in such districts was contaminated. The districts like Jalgaon, Buldana, Akola, Washim, Wardha, Nagpur, Bhandara, Chandrapur, Yavatmal, Parbhani, Jalna, Nashik, Bid, Latur, Ratnagiri, Sangli, Sindhudurg and Solapur are facing problems regarding groundwater quantity as well as quality. The water table has been found to decline (increase in vadose zone) in the districts of Akola, Beed, Bhandra, Buldana, Chandrapur, Gadchiroli, Gondia, Hingoli, Jalgaon, Jalna, Kolhapur, Latur, Nagpur, Nashik, Nandurbur, Thane, Sindhudurg, Sangli, Solhapur, Satara, Ratnagiri,

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Parbani, Osmanabad, Yavatmal, Wardha and Washim with problems in taluka. The TDS, fluoride and nitrate content in water is high causing severe problems (Scott et al., 2005).

Eastern districts of Maharashtra are facing problem of high presence of iron in water while the ground water in Akola, Amravati and Buldhana are facing problems of salinity. One third of the area under Maharashtra lies in the rain shadow region mainly from the Western part of Maharashtra and Marathwada. The problem arises when such regions lying in the rain shadow regions cultivate high water intensity crops. Most of the rain shadow regions of Maharashtra consist of porous rocks which drains water quickly (Das, 2006). Government has led to Programs for increasing water supply for rural areas. Many wells have been dug to overcome water scarcity problems in Maharashtra. The limitation to such a program is that majority of the wells dug by the Government scheme are left dry in the summers with few of them aquifer polluted due to deposition of debris. Most of the problem arises due to lack of appropriate information about the status of water in the area or there is delay in the implementation of rural water scheme. In most of the rural areas people are resistant to take up the Programs or policies implemented by the Government easily (Das, 2006).

Farmers are very sensitive to water prices. The lowest water use efficiency is that point when farmers continue to apply irrigation till the net marginal productivity becomes equal to zero. The price shifts in the market results in the shifts in the selling price of water. The farmers generally do not go for water markets because the demand and supply do not match among themselves and the returns obtained from the crops are higher than the selling price of water. The farmers have to pay for the water on hourly basis and pay a percentage of their crop yield as a charge for water. The well owners charge water on the basis of the opportunity cost for excess water supply for irrigation. If water is charged on volumetric basis then the farmers would generally shift towards the cropping pattern which gives higher yield return from per unit of water consumed. This results into a limitation that supply of water for agriculture has been found to be limited so water is charged at a higher price for agriculture. The table given below reflects the status of availability of water in different districts of Maharashtra:

INITIATIVES TAKEN BY THE STATE MAHARASHTRA REGARDING MANAGEMENT OF SUSTAINABLE WATER REQUIREMENT

Maharashtra state is the first to carry out an initiative for sustaining water requirement in the state and is the first to prepare a state disaster management plan. The state has undertaken several managing plans regarding a sustainable use of water which are given in the table below (Table 3).

CONCLUSION

The Maharashtra state has several challenges regarding availability of water due to the structural location of the regions since the area has been classified into Eastern and Western Maharashtra. It has been found that there are few regions in the state which are drought prone while few of them are affected by floods, cyclones and earthquakes. Some regions receive adequate rainfall where as in few region rainfall is very limited. Diverse climatic conditions are seen in Maharashtra due to its location thereby affecting the availability of water in few regions. Inspite of the above challenges the state has been able to overcome the challenges of water scarcity by adapting sustainable practices in the state for enhanc-

Table 4. Managing plans undertaken by the State of Maharashtra for sustaining water

Sr. No.	Managing Plans	Characteristics
1	State Disaster Managing plan	Maharashtra is the first to prepare a state disaster management plan. The plan addresses the risks due to floods, cyclones, accidents and other disasters in the state. Such issues are undertaken by the state to solve the problem. The water disaster is also undertaken in the plan for the proper management.
2	District Disaster Managing Plan	The districts facing problems of disasters are undertaken in the plan by the Government of Maharashtra. These problems include earthquakes, floods, cyclones, industrial disasters and accidents which must not be ignored.
3	Disaster Management plan	The center for disaster management was set up in the month of august in 1996 with an objective to develop plans for preparing the state from any disaster like earthquakes, floods, cyclones for a sustainable water management.
4	District disaster management plan	The district disaster management plan has been developed to analyze the occurrence of disasters in the district and improve the preparation for overcoming the challenges of the disaster.
5	District Disaster Management committee	The district disaster management committee analyses the occurrence of disasters reviewing the threats in order to improve the fulfilment of the demand for water in the state.
6	Maharashtra state disaster management authority	Under section 14 of the disaster management act 2005 Maharashtra state disaster management authority came into existence in 24th May, 2006 involving chief minister, deputy chief minister, ministers, official members and the chief secretary.
7	State emergency operation center	The emergency operation center tackles the hazardous events which can lead to emergency situation.
8	Maharashtra water resource regulatory authority	It has been evolved with an objective to regulate water resources within the state and analyze the issues regarding use of water.
9	State executive committee	This committee was developed with chief secretary, additional chief secretary, member secretary and other secretary.
10	Hydrological projects	It was developed in the year 1996 in Nashik with an objective to improve hydrological data and assess the availability of water.
11	Dam safety organization	It evolved in 1980 in Nashik for the inspection of large dams.
12	Government department soil conservation	It was organized by Marathwada Sheti Sahayak Mandal in Adgaon at Aurangabad
13	Government department soil conservation and soil forestry	It was organized by local organization under Mr. Anna Hazare at Ralegan Siddhi in Ahmednagar
14	Aadarsh gaon yojna	It was organized by Yashwant agriculture and watershed development at Hiware bazar in Ahmednagar
15	Indo-German watershed Program	This Program was organized at Vijju Bhulgaon in Ahmednagar
16	Indo-German watershed Program	It was organized by SEWA at ambewadi in Beed
17	N.G.O	Organized by Manavlok at Bhavthan in Beed
18	N.G.O	Organized by Afarm at Damoli in Beed
19	Drought prone area Program	Organized by Sarwodaya welfare at nandgaon khadeshwar in Amravati
20	Drought prone area Program	Organized by Sarwodaya welfare at Nandgaon Khadeshwar in Amravati
21	Drought prone area Program	Organized by Chandrapuri maharaj shikshan prasarak at Pimpalgaon in Amravati
22	Drought prone area Program	Organized by Prabhodankar Thakre at Dharani Chikaldhara in Amravati
23	Drought prone area Program	Organized by Mahila Utkashtha at Hirangimangulpur in Wasim
24	Drought prone area Program	Organized by Shriram Sukhshainik at Sanglud in Akola

Watershed Development in Maharashtra: Present Scenario and Issues for Restructuring the Program. ö Technical Report. Pune: SOPPECOM.

http://cgwb.gov.in/documents/case-studies-rwh-ar-may2011.pdf

drapur, Yavatmal, Parbhani, Jalna, Nashik, Bid, Latur, Ratnagiri, Sangli, Sindhudurg and Solapur are facing problems regarding groundwater quantity as well as quality. Western part of Maharashtra has been affected by several measures of water scarcity. There have been several sustainable measures being adopted by the people of the villages of the Western Maharashtra which has made their living easier by allocating water for irrigation as well as household domestic needs. Not only the people of the villages even the Panchayat samiti and central Government has supported several schemes for sustaining water management in the Western part of the state. There has been a great participation of the central groundwater board regarding the sustainability of water in the eighth, ninth, tenth and eleventh five year plan. With instant application of the sustainable practices it has been found that several villages located in the Western part of the state are doing great work for enhancing water availability through storage of water in earthen structures as well as through rain water harvesting. Several other measures like afforestation, terrace farming, contour bunding, tree plantation along road side and limitations to grazing of animals have led to conservation of water as well as the soil. Villages like Ralegan Sidhdhi, Hiware Bazaar, Wadur, Yaval, Yuvraj and Wadgaon have come up with sustainable practices for allocation of water for future needs. Villages like Ralegan Siddhi and Hiware Bazaar which once had severe water problems are now called as the Aadarsh Gaon (Ideal Village) and are the true symbols for sustainable water management in a drought prone area. The Maharashtra Government has also come up with several schemes which have supported the sustainability of water. Several initiatives have been taken by the

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Maharashtra Government for overcoming the challenges in availability of water in the Western regions of the state. Supportive mechanisms has been followed to encourage agriculture in the Western areas and to control floods by the construction of bunds and dams which otherwise may have destroyed the villages and also will lead to soil erosion making the soil infertile for agriculture. Thus, in the current era of climate change, sustainable water management practices at the local level is the need of the hour to resolve the problems at state and national level.

Chapter 14
Characteristics of Chitosan Nanoparticles for Water and Wastewater Treatment:
Chitosan for Water Treatment

Cayla Cook
Mississippi State University, USA

Veera Gnaneswar Gude
Mississippi State University, USA

ABSTRACT

Chitosan is a naturally occurring biopolymer originating from several microbial species as well as crustacean species, such as shrimp and lobster. Chitosan has excellent physical and chemical properties that allow its use in various environmental applications especially in water treatment. It is a biodegradable polymer, and it is inexpensive providing an environmentally friendly and economic option for water and wastewater treatment. Chitosan offers a myriad of applications through chemical coagulation and flocculation, antimicrobial properties, adsorption capabilities, and nanofiltration and can provide a sustainable route for water and wastewater treatment. This book chapter elaborates the recent developments in chitosan applications in water and wastewater treatment.

INTRODUCTION

Water---an innate right---is somehow squandered even in the 21st century. Approximately 10,000 people die as a result of inadequate water supply and related third-world issues every day (UNwater, 2015). Currently, civilizations are growing at twice the rate of the availability of water resources, and it is projected that up to 1.8 billion people will experience absolute water scarcity by 2025 (UNwater, 2015). The importance of economical, clean water cannot be overstated in a society facing environmental issues such as pollution of water resources, droughts, and increasingly dwindling freshwater availability.

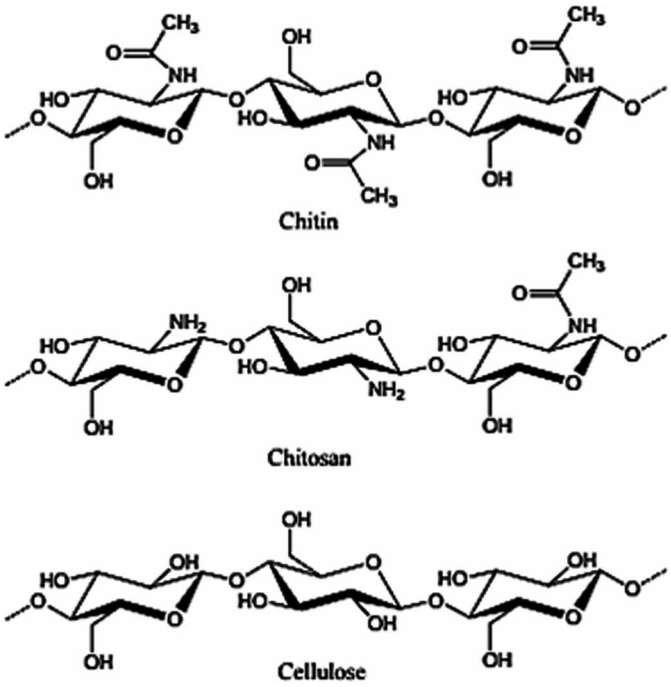
Fortunately, modern day science might have the answer in a naturally occurring polymer: chitosan. Chitosan is simply derived by the deacetylation of shellfish exoskeletons. Chitin can also be found in fungi, cell walls, and yeast. Although small, this nanoparticle continues to substantially impact water treatment through its idealistic properties, diverse applications, and economical potential. These diverse applications of chitosan include coagulation and flocculation for water and wastewater treatment, antimicrobial properties, adsorption capabilities of dyes and heavy metals, and desalination through nanofiltration. Many physical and biological properties of chitosan produce a linear polysaccharide ideal for water and wastewater treatment applications.

CHITOSAN PROPERTIES AND PREPARATION

Chitin, as shown in Figure 1, is the acetylated precursor to chitosan. The removal of these acetyl functional groups allows for higher solubility due to the increase in positive charge. Due to its deacetylation, chitosan is considered a pseudo-natural biopolymer which is predominantly characterized by its degree of deacetylation (DD) and molecular weight (MW). Considering that these two properties are directly proportional, the degree of solubility can be seen as inversely proportionate to the MW and directly proportionate to the DD. The degree of deacetylation is a molar percentage which differentiates chitin from chitosan at precisely 50% mol. This 50% DD allows for solubility in acidic aqueous solutions.

Acetylated Chitosan, or Chitin, is known to exist in two allomorphs, α and β. The more abundant α Chitin is found within traditional yeast, fungi, shrimp, crab, krill, lobster, and crawfish. The less abundant β Chitin is found within the protein in squid pens and is not an industrial source. Beyond knowledge of

Figure 1. Chitin, chitosan, cellulose (Alvarenga, 2011)



EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

the biopolymer's source, differentiation can be determined through Nuclear Magnetic Resonance (NMR) spectroscopy and infrared in conjunction with X-ray diffraction (Younes & Rinaudo, 2015). Moreover, whereas α Chitin contains two antiparallel molecules per unit cell, β Chitin contains merely one. β Chitin is more reactive; however, both α and β allomorphs remain insoluble.

Chitosan's solubility can also be affected by the distribution of acetyl compounds as well as ionic concentration. Chitosan's cationic property enables it to strongly adsorb negatively charged toxins. This positive charge can be modified by pH, while chitosan acts with inverse efficacy to its pH for coagulation and flocculation. This capability of changing solubility and cationic charge through pH causes both desirable and undesirable aspects considering that the extent of coagulation and flocculation can also be manipulated to repel particles and prevent agglomeration.

Chitosan Preparation

Chitosan can be prepared through both enzymatic and chemical routes. Chemical route is much more common due to production rates and greater economic viability. Preparation begins with extraction from one of its various sources (Figure 2); however, raw chitin is primarily acquired from the cuticles of shellfish. Both chemical and biological extraction suffice with chemical being the predominant methodology. The extraction process begins with grinding and washing of raw materials followed by deproteinization. Deproteinization essentially depolymerizes the biopolymer while removing any protein which is the primary cause of allergic reactions to shellfish. Reagents used for deproteinization include sodium hydroxide (NaOH), sodium bicarbonate ($NaHCO_3$), sodium carbonate (Na_2CO_3), potassium hydroxide (KOH), potassium carbonate (K_2CO_3), and several others. As shown in Table 1, there are multiple concentrations, temperatures, and durations used for NaOH, the most common deproteinization solvent. These variations include 0.125 M to 2.5 M concentration, 25°C to 100°C, and one half hour to overnight soaking in the solution.

Following deproteinization, demineralization removes calcium carbonate as well as other minerals. Although hydrochloric acid (HCl) solution is generally used, nitric acid (HNO_3), sulfuric acid (H_2SO_4), and others will also achieve demineralization. Similar to deproteinization, demineralization's solvent and extent vary with raw materials. Generally two to three hours will suffice; however, much longer incubation times can be used. As the incubation time increases, the potential for degradation of the polymer increases as well. Additionally, the greater the temperature of the process, the more quickly and effectively the solvent will penetrate the chitin matrix. Moreover, the demineralization process may directly affect the physicochemical properties through "high temperatures, longer incubations, high acid concentrations, and granulometry" resulting in potentially undesirable structural changes (Younes & Rinaudo, 2015).

Following deproteinization and demineralization, the chitin must be extracted and dried with acetone. In order to convert the chitin to chitosan, the material must then be deacetylated. This is one of the most important processes in the preparation of chitosan due to its effect on the biopolymer's properties through acetyl group distribution, MW, and viscosity. These properties can be affected by temperature and incubation period. Although this chemical process is performed either heterogeneously or homogeneously, a hot, heterogeneous NaOH solution is most common. In contrast, a homogeneous reaction process would require 12-24 hours of pre-swollen chitin in an alkali solution. The alkali solutions used for either heterogeneous or homogeneous reactions must penetrate the amorphous region and typically leave some crystalline structures intact. These solutions will yield a maximum DD of 75-85%.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

These methodologies for preparation directly affect the simple physicochemical properties of the chitosan produced. The differential characteristics enable diverse applications through many physical forms such as chitosan powder, dehydrated chitosan flakes, crystalline chitosan, chitosan nanoparticles, and even chitosan as a modification to pre-existing surfaces. Chitosan surface engineering has proven to be an incredibly complex category, ranging from chitosan biosorbents to chitosan acting as an active layer for nanofiltration surfaces. These various physical forms allow for maximum efficacy of the biopolymer for any desired application.

CHITOSAN CHARACTERIZATION

Certain methodologies for characterization of chitosan can ensure a thorough deacetylation and transformation from chitin to chitosan. Determination of the DD is a high priority. Methods such as H-NMR Spectroscopy, Titration, and Infrared spectroscopy are primary means of characterization and determination of DD.

Fourier Transform Infrared Spectroscopy

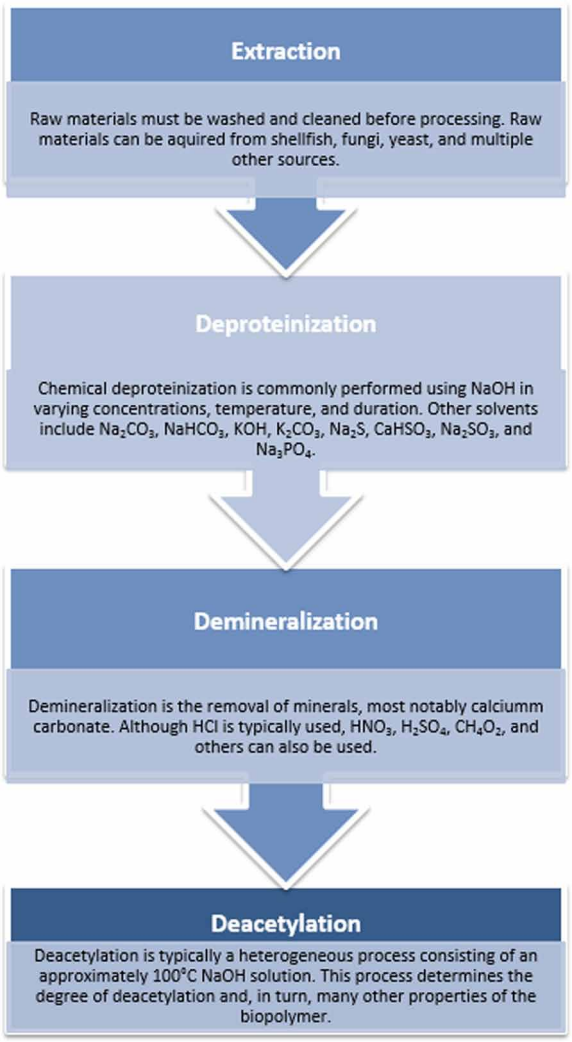
Infrared Spectroscopy (IR) provided below determines the organic functional groups present within the chitosan produced by Czechowska-Biskup et al. (2012). It should be understood that as the acetyl functional group is removed, the number of IR bands decreases to show the loss of the presence of amides. As shown in Figure 3, bands referencing hydroxyl, carbon, carboxyl, and amide bonds are all present. In order to determine the DD, multiple equations can be utilized. However, due to the inexact numerical nature of an FTIR, the calculations themselves are only estimations. For this particular sample, the DD was determined to be 77.84 $\pm$2.36, 66.11 $\pm$ 2.36, -12.5 $\pm$ 23.30, and 74.60 $\pm$3.60 through the use of FTIR. More importantly, the bands become less pronounced upon increased DD.

Zeta Potential

Zeta potential is a significant characterization of chitosan nanoparticles not only for the calculation of Degree of Deacetylation but also due to properties dependent upon surface charge interactions, i.e. antimicrobial, adsorption, and coagulation. The greater the positive charge of the chitosan nanoparticles,

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. Generalized Chitosan Preparation Process



the greater will be the antimicrobial properties exhibited by modifying the permeability of the cellular membrane. in addition, a higher zeta potential present in the nanoparticle can further attract and coagulate toxins within a solution. Research by Qi et al. (2004) determines a range from 30.8 to 68.9 milliVolts (mV) present in nanoparticles purchased from Chitosan Company of Pan'an. The mean charge is shown to be at 51 mV and the DD was determined to be 85%. The DD directly affects zeta potential by removal of negatively charged acetyl groups while the MW is also important due to the quantity per monomer. In further studies focusing on cationic-anionic ratios, an average zeta potential of 28.0 ±0.6, 28.8 ±0.7, 30.3 ±0.4, 31.4 ±0.5, and 32.4 ± 11.1 mV with increasing particle size was determined, respectively (Abbas, 2010).

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

GENERAL APPLICATIONS OF CHITOSAN

Being one of the most abundant biopolymers in the world, chitosan's slew of functionalities and properties only add to the vast applications and uses spanning fields from biomedicine to paper finishing. Within the biomedical field, chitosan is being considered for controlled drug release due to its swelling in acidic medium, antacid properties, and prevention of stomach irritation. In ophthalmology, chitosan is being researched for contact lens use due to several properties including "optical clarity, mechanical stability, sufficient optical correction, gas permeability, particularly towards oxygen, wettability, and immunological compatibility" (Kumar, 2000). Chitosan is an ideal polymer for the use in cosmetics and hair care products. More importantly, it also has a spectrum of uses within water treatment and wastewater treatment systems such as coagulation and flocculation, antimicrobial properties and uses as a biosorbent material to remove dyes, metal ions, and salt. Within the coagulation and flocculation functionality alone, many pollutants and suspended particles have successfully been removed and separated including algae, oil-in-water emulsions, brackish water, and lead and chromium wastewater.

Nontoxic and Allergen Considerations

In addition to desirable physicochemical properties for water and wastewater treatment, chitosan is surprisingly nontoxic to those with shellfish allergies and can be used as an antihistamine. Despite its shellfish origins, it remains non-toxic to those with shellfish allergies when applied externally. In 2011, a study was conducted to consider if HemCon, a chitosan bandage mandated for soldiers which stops bleeding, would cause adverse reactions from patients with shellfish allergies. The study concluded that 100% of the patients with predispositions to shellfish allergies were unaffected by the chitosan powder applied externally to wounds. However, this was contradicted when a very small percentage of the public reported delayed onset contact dermatitis to a chitosan cream. Although for some, shellfish increases allergic responses, chitosan could potentially decrease anaphylaxis responses for those with peanut allergies. Currently being tested on mice, this treatment has a 47% efficacy (Bae et. al., 2013). Its antihistamine properties have also resulted in a patent granted in 2011 for topical application.

WATER TREATMENT APPLICATIONS

Due to the interrelated concepts of water treatment and wastewater treatment, coagulation and flocculation are present for both processes as well as for antimicrobial purposes. The following sections will not only discuss studies in which chitosan is used for chemical coagulation and flocculation or antibacterial purposes, but also the mechanisms through which it achieves the goal.

Coagulation and Flocculation in Water Treatment

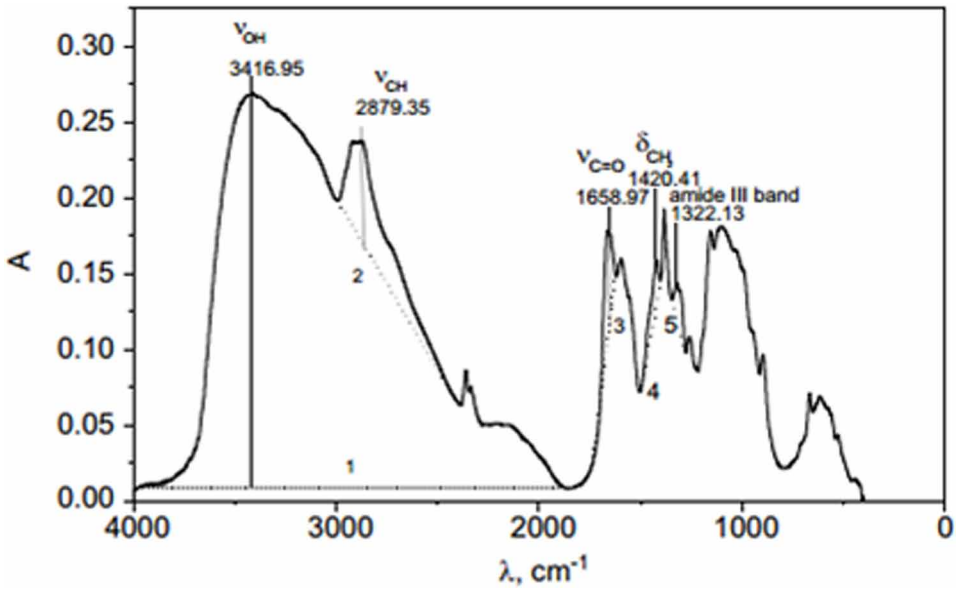
Among many other preferential processes, chemical coagulation is widely used due to its efficient removal of toxins. This coagulation is due to a chemical's cationic charge which attracts and conglomerates negatively charged toxins. Traditionally, aluminum sulfate, "alum", is used for this process; however, mass mildly toxic chemical addition and sludge generation is a downfall of this option. Considering this, chitosan is a viable option due to biocompatibility which allows degradation of sludge by microorganisms

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

resulting in less landfill usage. As a result, the use of chitosan for many bioeffluents has been explored including food waste, oil-in-water emulsions, effluents containing dyes, lead and chromium wastewater, partially purified sewage, and algal waters. It has been observed that increased MW results in greater coagulation; however, the relationship is nonlinear. Moreover, a greater DD at equivalent MW further optimizes coagulation. This somewhat necessitates a balancing act between MW and DD seeing as an increased DD decreases MW. A greater MW creates greater removal of NTUs and suspended solids (SS) with a reduction in biochemical oxygen demand (BOD) and chemical oxygen demand (COD). Contrastingly, a greater DD which decreases MW results in increased removal of inorganic nutrients and organic compounds. All in all, the DD and MW of chitosan should be tailored to specific applications and purpose. The mechanism of chitosan coagulation-flocculation is shown in Figure 4.

Due to lack of degradation of alum sludge as well as the slight toxicity of alum itself, more biocompatible options such as chitosan must be explored. Recent research has compared traditional alum with high velocity mixing versus proposed chitosan with ultrasound-enhanced flocculation (Fast et al. 2014). Chitosan for coagulation and flocculation creates flocs less vulnerable to shearing although less likely to flocculate again after shearing has occurred while traditional alum is highly vulnerable to shear but can easily agglomerate once more (Fast et. al, 2014). Moreover, the pHs of turbid waters are not a deterrent to alum's treatment efficiency; whereas chitosan only remains soluble in acidic pH solutions. Another significant advantage to the use of chitosan is the much lower dosage necessary to remove turbidity; this, in turn, reduces exposure to consumers compared to alum usage. Ultimately, a 1.5 mL dosage of chitosan using ultrasound was the most effective at removing turbidity (Fast et al. 2014). Further research conducted by Fast & Gude utilized a much wider range of NTU and dosage. Results expressed increased efficiency of chitosan with increased turbidity (2015). Furthermore, the longer the

Figure 3. Chitosan Fourier transform infrared spectroscopy (Czechowska-Biskup, R., Jarosińska, D., Rokita, B., Ulański, P., & Rosiak, J. M., 2012)



EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

sedimentation time, the lower the final turbidity. In conclusion, optimal conditions were indicated at 40 NTUs and 30 minutes flocculation time which produced an optimal 94% removal efficiency which rivals conventional alum at 99%.

Although fresh surface water resources emphasize the removal of algal blooms, salt water constitutes 96.5% of Earth's water with approximately 1% of the global population reliant upon desalination resources (Desalination, n.d.). Future global outlook by the United Nations foresees a massive increase to 14% by 2025 as stated by Christopher Glausson, publisher of Global Water Intelligence. One of many issues desalination industries face is the quality of received saltwater due to high turbidity. Research on chitosan in alkaline medium was conducted in order to determine efficiency as compared to alum at a dosage range from 0-370 mg/L and pH 2-11(Altaher, 2012). Results showed a 97.5% removal of NTUs using significantly less dosage and in turn less toxicity and exposure than alum. The optimum removal efficiency was found at pH 8.1 and 18 mg/L.

Beyond types of water and wastewater which chitosan effectively coagulates, multiple apparatus for which have been studied due to an increase in household water treatment and on-site water treatment interests. In an attempt to address ceramic water filtrations (CWF) lack of virus removal mechanisms, chitosan was tested for *Escherichia coli* K011 and coliphage MS2 contamination with CWF apparatus (Abebe, Chen, & Sobsey, 2016). CWF traditionally uses silver nanoparticles which produce uncertain results. Chitosan hydrochloride, chitosan acetate, and chitosan lactate were tested with 30 minute coagulation, flocculation, and sedimentation. The resulting waters were filtered by gravity flow and sampled. The mean reductions were 4.7 and 7.5 $\log_{10}$ for *Escherichia coli* and 2.8 to 4.5 $\log_{10}$ for MS2. Resulting turbidity present meets both US EPA standards (<1 NTU) and World Health Organization (WHO) guidance. Furthermore, the treated water met viral and bacterial reduction health targets.

Although chitosan is an effective biocoagulant for many water sources, including pre-treated sea water, various types of monomers can be co-grafted onto chitosan to provide further specific functionalization and utilization. Non-ionic co-polymerizations include acrylamide, N-vinyl formamide, and N,N-dimethyl acrylamide. Cationic monomers include (2-Methacryloyloxyethyl) trimethyl ammonium chloride, 3-(Acrylamide) propyl trimethylammonium bromide, N-binyl-2-pyrrolidone, and diallyl dimethyl ammonium chloride. Lastly, anionic grafts include with methacrylic acid and 2-Acrylamidoglycolic acid. However, the most established and commonly grafted nonionic polymer is acrylamide. Overall, the most common chitosan graft would be positively charged copolymerization due to increased efficacy of charge neutralization during coagulation and flocculation (Yang et. al., 2016).

Antimicrobial Properties

One cornerstone property of chitosan is antimicrobial and antifungal abilities. These abilities within a nanoparticle vastly increase possible functionality. It is considered effective in drug delivery schema such as vaccines, insulin adsorption, and even wound treatment as shown in Figure 5 (Qi et al. 2004).

In another study, chitosan nanoparticles are applied to *E. coli*, *S. choleraesuis*, *S. typhimurium*, and *S. aureus* bacteria to determine antibacterial activity. Considering copper nanoparticles also exhibit antibacterial and antimicrobial abilities, copper-loaded chitosan nanoparticles were prepared through ionic gelation. These samples were then left at 121°C with the bacteria at varying concentrations. Minimum Inhibitory Concentration (MIC), or the lowest concentration which causes absorption of the

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

bacteria, was tested as well was Minimum Bactericidal Concentration (MBC). MBC is defined as the lowest concentration of the antibacterial solution which eradicates 99.9% bacteria. The results of this study are shown below.

Although chitosan effectively eradicates 1-$\log_{10}$ bacteria of each strain tested, it is less effective than the copper-loaded chitosan alternative. Due to chitosan's sensitivity to pH, the test was only used in a highly acidic solution of pH 6.5.

Two mechanisms that facilitate antimicrobial properties are exhibited by the biopolymer. The initial mechanism is believed to create an impermeable layer surrounding the cell which prevents necessary transport from the cell. This effect on microbial cells is only present in slightly acidic solutions and has the potential to be reversed in different solvents. Secondly, the chitosan prevents the synthesis of RNA and protein by invading the cell's nucleus. For the latter effect, DD must be increased to increase electrostatic interaction with the negatively charged microbe. For the former, MW must increase in order to permeate the cell membrane.

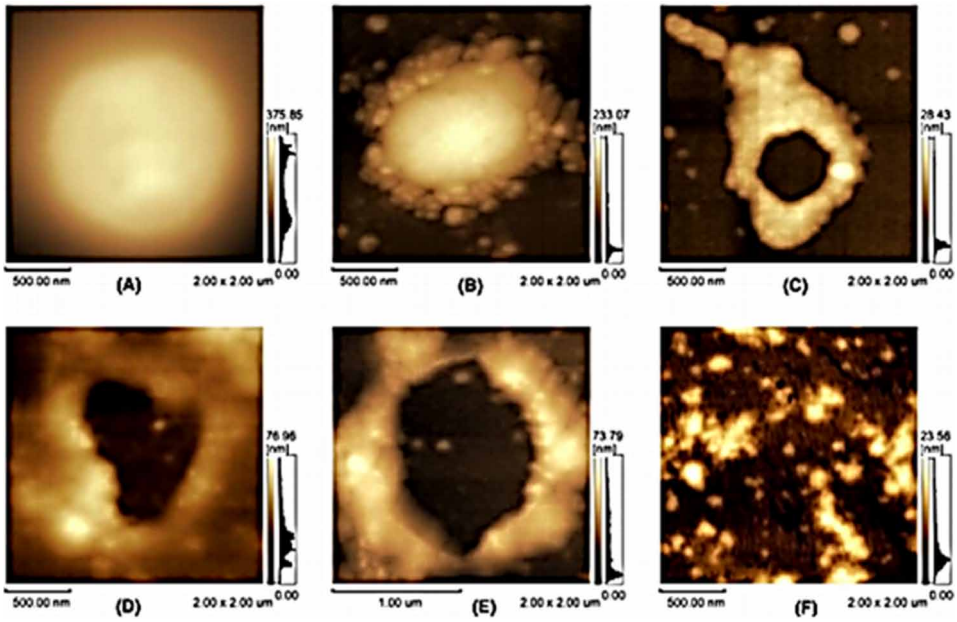
Figure 5.



WASTEWATER TREATMENT

In contrast to water treatment, wastewater treatment generally converts unusable water into an environmentally safe effluent by reducing the BOD (biochemical oxygen demand), COD (chemical oxygen demand), and SS (suspended solids). By reducing the SS, the BOD and COD can be lowered as well. These are extremely important parameters to wastewater considering potential ecological catastrophes caused by high BOD levels. Due to this concept, coagulation and flocculation are two of the most important processes for water treatment as well as wastewater treatment.

Coagulation and Flocculation in Wastewater Treatment

As previously mentioned, the importance of the coagulation and flocculation step in water and wastewater treatment cannot be overemphasized. What makes chitosan a great potential industrial and municipal coagulation and flocculation agent is not merely its effectiveness, but also its nontoxic nature and the plethora of effluents which are successfully treated with a much lower concentration than is necessary with alum. This process is primarily due to multiple flocculation mechanisms including simple charge neutralization, charge patching, bridging, and sweeping. Simple charge neutralization is inherently the neutralization of positive and negative charges present within the cationic biopolymer and anionic toxin or effluent. Charge patching creates flocs of biopolymer and effluent with the overall particle's charge. Bridging allows larger flocs created by adsorption onto the biopolymer and other primary flocs. Lastly, sweeping allows the entrapment of particles within a net-like structure of biopolymer. These flocculation mechanisms have been tested in food waste, seafood and fish processing wastes, brewery wastewater, surimi wash water, bentonite suspension, organic suspensions, kaolinite, bacterial suspensions, particulate and dissolved contaminants, effluents containing humic substances, effluents containing dyes, pulp

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

and paper mill wastewater, oily wastewater, oil-in-water emulsions, agriculture wastewater, effluents containing metal ions, effluents containing phenol derivatives, partially purified sewage, brackish water, lead and chromium wastewater, poultry waste, coal mine wastewater, algal waters, egg industry effluent, grey wastewater, sugar industry effluent, and even pre-treated sweater as shown in Table 3.

One of many effluents successfully treated with chitosan is grey wastewater. Grey wastewater is present within approximately 75% of resident wastewaters and is considered a cleaner effluent of bath tubs, sinks, laundry appliances, and schools. Despite the nonreactive nature of this effluent, it still poses tenable threats to ecosystems and must be treated effectively. Batch testing was used with varying agitation speed, pH, chitosan dose, and settling time were used. As predicted, pH efficiencies increased with increasing pH to 4. The maximum efficiency settling time was determined at 15 minutes due to shear stress and compaction of flocs. Upon optimization, NTU, BOD, and COD were determined to be 96%, 91%, and 73% reduced (Thirugnanasambandham et. al, 2013).

With superior removal and reduction efficiencies of many types of effluent, the natural question is to consider what chitosan cannot effectively treat. In "Influence of Effluent Type on the Performance of Chitosan as a Coagulant", authors Ritha Pambi and Paul Musonge considered that within the scope of food processing plants. Chitosan with a 75% DD was purchased through Sigma-Aldrich and dissolved in 20 mL of 0.1 M hydrochloric acid. Sugar Processing effluent, Milk Processing Effluent, and Brewery processing effluent were all tested with jar-test apparatus and rapid mixing for 3 minutes at 100 rpm. The COD removal for sugar, milk, and brewery effluents were 11%, 54%, and 50% respectively. The Total Suspended Solids (TSS) were much more significant at 98%, 95%, and 95%. Significant factors which influenced the removal efficiencies include dissolved solids (TDS), initial TSS, and a pH value maximum of 9. The dissolved solids (TDS) were notably higher in the milk effluent. Moreover, the optimal pH value varied with effluent type. It can be concluded from this study that chitosan's coagulation and flocculation efficiency is dependent upon the effluent type and TDS.

Biosorption Properties

Beyond antimicrobial and coagulation-flocculation applications, chitosan and magnetic nanoparticles grafted with chitosan have proven effective at adsorption of Cobalt II, Copper II, Zinc II, and cation or anionic dyes. This adsorption ability is due to amino groups as well as hydroxyl groups. These amino groups are positively charged and attract dyes electrostatically. A wide range of adsorption studies was summarized in Table 4 which includes various types of chitosan and adsorbates.

Dye Adsorption

Due to the inert properties and low concentrations of dyes, they are difficult to be removed effectively and economically. Many other methods are currently being employed; however, they remain ineffective and expensive alternatives. These methods include adsorption, coagulation and flocculation, reverse osmosis, and others. Common chitosan composites that are used to remove dyes are chitosan/montmorillonite composites, chitosan/polyurethane composites, chitosan/activated clay composites, chitosan/bentonite composites, chitosan/oil palm ash composites, and chitosan/kaolin/γ-Fe_2O_3 composites. Each composite type, naturally, has different adsorption properties. For example, a chitosan/montmorillonite composite has an increasing adsorption capacity with respect to the molar ratio of chitosan and the composite, but

Table 3. Bioeffluents successfully treated with chitosan

Effluent	Purpose	Experimental Details	Results	Reference
Food waste	Coagulation of high fat and protein milk waste	Chitosan-treated sludge is considered for feed supplement of cleaning in place wastewater.	25 mg/L at pH 7.0 yielded optimum efficiency showing that the material could be recycled at no extra cost.	(Chi & Cheng, 2006)
Seafood and fish processing wastes	Crawfish shell chitin tested for pigment extraction of seafood processing streams	150 mg/L Chitosan at pH 6.0 (commercial and synthetic)	97% SS removal and 83% tubidity removal. 150 mg/L at pH 6 resulted in 45% reduction in COD.	(Hong & Meyers, 1989)
Brewery wastewater	Coagulation of wheat dregs in wastewater	120 mg/L in 4.5 pH for optimal removal efficiency; increasing pH decreased turbidity	Maximum removal efficiency was observed at ~85% with a pH of 4.5, pH 7 at ~65%, and pH 8 at ~65%.	(Cheng, Chi, Yu, & Lee, 2005)
Surimi washes water	Protein adsorption and turbidity reduction of surimi wash water	20, 40, and 100 mg/L chitosan-alginate complexes were tested; 100 mg/L for maximum protein removal; 20 mg/L for maximum turbidity removal	Maximum 86% removal of protein, Minimum 73.1%; Maximum 95.7% turbidity removal, minimum 85.5%	(Wibowo, Velazquez, Savant, & Torres, 2007)
Bentonite suspensions	Chitosan coagulation with bentonite suspensions using varying degree of deacetylation (DD), MW, viscosity, and polydispersity	Tap water (TW)–deionized water comparison at varying pH and concentration; maximum efficiency at 0.10 mg/L in TW pH 7.0	The efficiency of coagulation was observed with both TW and DW at pH 5 or 7. With concentration 0.02 mg/L and lower, less than 10 NTU was observed.	Roussy, Cooren, Dempsey, & Guibal, 2005)
Organic suspensions	Varying DD and MW tested using coagulation/ flocculation	Mushroom powder TW mixes were tested for pH 5, 7, and 9	DD was shown to have little effective on coagulation.	(Roussy, Vooren, & Guibal, 2005)
Kaolinite	Chitosan flocculation of kaolinite particles	Distilled water with TW was tested with highly refined kaolinite powder	A maximum turbidity removal was observed as ~85% with a 0.75 mg/L dosage.	(Divakaran & Pillai, 2004)
Bacterial suspensions	To determine antibacterial properties in sterile water	Maleic acid sodium grafted onto hydroxypropyl chitosan was tested using cut plug method and viable cell counting	All concentrations tested yielded maximum 99.90% at removal of *S. aureus* and *E. coli*	(Xie, Xu, Wang, & Liu, 2002)
Particulate and Dissolved Contaminants	Determine removal efficiency of bentonite suspensions, organic suspension, anionic dye solutions, and humic acid solutions	Both sorption and coagulation/ flocculation were effective at removal of dyes; charge destabilization effectively coagulated humic acid and kaolin	Multiple coagulation mechanisms were determined for (a) bentonite, (b) organic suspensions, (c) anionic dye solutions, and (d) humic acid solutions which were charge destabilization for a, b, and d. However, sorption was observed for c.	(Guibal, Vooren, Dempsey, & Roussy, 2006)
Effluents containing humic substances	Chitosan hydrochloride (CH) and glutamate (CG) were tested for flocculation in dissolved humic solutions	CH and CG solutions were prepared using air-dry chitosan flakes and tested for color removal	CH yielded maximum effectiveness of >95%	(Bratskaya, Schwarz, & Chervonetsky, 2004)
Effluents containing dyes	Dye removal at differential pH and concentrations	Chitosan samples were ground and dissolved in acetic acid; agitated aqueous solutions of 2% acetic acid, 98% deionized water were incubated overnight. Experiments were done using Jar-Test apparatus at room temperature.	100% efficiency was observed for multiple dye concentrations and chitosan concentrations at pH 3	(Guibal & Roussy, 2007)
Pulp and paper mill wastewater	Coagulation/flocculation of post-bleaching effluent of the paper industry	Coagulation then photo catalysis determined properties such as biodegradability and through absorbance	100% reduction in absorbance for chromophores at 500 nm	(Rodrigues et. al., 2008)

Table 3. Continued

Effluent	Purpose	Experimental Details	Results	Reference
Oily wastewater	Adsorption of oily wastewater was tested with differential concentrations, sedimentation times, and pH values	Palm oil mill effluent was tested using Jar-Test equipment at ~2000 mg/L of residue	~97-99% removal of residue was obtained at 0.5 g/L of chitosan powder, 15 minute contact time, 5.0 pH, and 30 minute sedimentation time	(Ahmad, Sumathi, & Hameed, 2004)
Oil-in-water emulsions	Flocculation of oil-in-water emulsions was tested with differential pH as well as SDS-stabilized emulsion and surfactant-free emulsion	0.05% diesel oil emulsions with an average droplet diameter of 200 nm were mixed with chitosan using ultrasonic treatment	Removal efficiencies decreased with increasing pH possibly due to chitosan's low solubility; complete phase separation was achieved at pH values greater than 7.5 through SDS-stabilized schema	(Bratskaya, Avramenka, Schwarz, & Phillippova, 2006)
Aquaculture wastewater	Aquaculture wastewaters were tested for turbidity, SS, chemical oxygen demand, ammonia, and phosphates after being treated with varying deacetylation degree, pH, and concentrations of chitosan	Chitosan leaves beneficial bacteria while removing *Edwardsiella itctaluri*	Optimal removal efficacies were 90% turbidity, 61% SS, 69.7% COD, 89.2% NH_3, and 95.6% PO_4^{3-}.	(Chung, 2006)
Effluent containing metal ions	Adsorption of heavy metals Hg(II), Fe(II), Ni(II), Pb(II), Cu(II), and Zn(II) were tested at pH 5, 6, and 7	0.1 g of chitosan mixes were added to 50 mL of wastewater; these samples were left in room temperature for 3 hours followed by a 5 min centrifuging process	Chelation capacities for each heavy metal were 94.1% Fe(II) at pH 5, 22.9% Mn(II) at pH 7, 26.3% Co(II) at pH 7, 62.8% Ni(II) at pH 7, 64.9% Cu(II) at pH 7, 50.3% Zn(II) at pH 7, 15.6% As(II) at pH 5, 19.9% Mo(II) at pH 7, 39.1% Cd(II) at pH 7, 97.5% Hg(II) at pH 7, and 91.0% at pH 7 for Pb(II). Most of these maximums were with a 91.3% DD.	(Gamage & Shahidi, 2007)
Effluent containing phenol derivatives	Chitosan was tested alongside tyrosinase and two synthetic polymers polycondensate and polyethlenemine	Industrial wastewater removal involving a color change from clear to dark brown was tested using tyrosinase and different polymers.	Synthethic polymers were observed to be more effective due to lack of coagulation but precipitation of phenol and aromatic amines. However, all cationic polymer coagulants produced a precipitation. Retention of immobilization and storage stability were 80%.	(Wada, Ichikawa, & Tatsumi, 1995)
Partially purified sewage	Chitosan flocculation composites were compared with traditional flocculation solutions	Raw sewage waters were added to differential dosages and stirred for 10 minutes then transferred to separating funnels and settled for 30 minutes	Chitosan composites were shown to optimize COD by 1.8-23.7%, SS by 50%, and Al^{3+} by 61.2-85.5%.	(Zeng, Wu, & Kennedy, 2007)
Brackish water	Differential pH of 4-9 with a varying SS was tested on flocculation and settling time of river silt.	Turbidity was tested using Jar-Test apparatus with a 0.1 M HCl or $NaCO_3$. Solutions were stirred for 30 minutes and allowed a 30-minute settling time.	Maximum flocculation occurred at a pH of 7.0 while SS vs. NTU relationship was linear. 90% removal efficiency was observed.	(Divakaran & Pillai, 2002)
Lead and chromium wastewater	Comparing chitosan to aluminum sulfate for removal of metal salts and *Daphnia magna* with differential pH in actual conditions and humic acid spiked surface water.	Jar Test apparatus with 1 L high alkalinity water tested from 0.5-10 mg/L chitosan solutions. 1 g/L chlorine solution was added with a 24-hour contact time.	Increased toxicity of *Dapnia magna* was effectively 0% immobilization in some conditions.	(Rizzo, Gennaro, Gallo, & Belgiomo, 2008)

Table 3. Continued

Effluent	Purpose	Experimental Details	Results	Reference
Poultry waste	Chitosan combined with dissolved air flotation were tested at multiple poultry effluent sites for SS and COD.	Poultry processing wastes were coagulated with chitosan and dissolved air flotation at sites such as the chiller and scalder	Composite SS effluents were reduced by 74-94% at different sites; COD of effluents were reduced by up to 82%.	(Bough, Shewfelt, & Salter, 1975)
Coal mine wastewater	Chitosan grafted N-vinyl formamide were tested with varying concentration of N-vinyl formamide, bromate ions, and chitosan.	Experimental setup involved a 1 L beaker of 1% weight coal with stirring apparatus for 15 minutes and 30 minute settling time.	Chitosan had little effect on NTU reduction; however, approximately 10% was the maximum for both coking and non-coking coal.	(Mishra, Tripathy, Srivatstava, Mishra, & Behari, 2008)
Algal waters	Chitosan with ultrasound flocculation was compared with aluminum sulfate rapid mix flocculation of algal turbid waters.	Batch testing with 25 kHz ultrasonic frequencies followed by 50 rpm rapid mix for 20 min at a range of 10 to 40 NTUs.	Turbidity removal efficiencies of chitosan ranged from 84.1%-90.5% for rapid mix and 84%-97% for ultrasound.	(Fast & Gude, 2015)
Egg industry effluent	Differential COD concentration, adsorbent dose, pH, and settling time were tested.	Batch studies performed from 0.7-1.3g/L of wastewater in 100 mL of wastewater with 2-7 pH range. The supernatant was then centrifuged and filtered. A three-level, four-factor Box-Behnken design (BBD) studied each variable.	Optimal pH 4 1.1g/L chitosan with a 40 min settling time was determined. Maximum reductions were 94%, 88%, and 83% for turbidity, COD, and BOD respectively.	(Thirugnansambandham, Sivakumar, & Prakash, 2014)
Grey wastewater	Differential COD concentration, adsorbent dose, pH, and settling time were tested.	Batch studies were carried out using 1-3 min agitation time, 2.5-5.5 pH, 0.3-0.5 g/L chitosan, and 10-20 min settling time. The supernatant was centrifuged and filtered following settling time.	Optimal reduction efficiencies for turbidity, BOD, and COD were 96%, 91%, and 73% respectively.	(Thirugnanasambandham, Sivakumar, Prakash, & Kandasamy, 2014)
Sugar Industry Effluent	Resin effluent and final effluents were tested of a sugar refinery using chitosan for coagulation.	Both effluents were tested at varying pH using chitosan powder with aqueous hydrochloric acid. Sodium hydroxide was used to adjust pH.	Final effluent turbidity reduction was more successful than resin effluent yielding 97% suspended solids, 61% color, and 35% COD removal efficiencies versus 68% suspended solids, 30% color, and 15% COD.	(Pambi & Musonge, 2015)
Pre-treated Seawater	The pre-treated sweater was tested using chitosan coagulation at the differential dosage, initial pH, solvents, and compared to metal coagulants.	Jar test apparatus was performed on Red Sew waters as well as distilled water. Turbidities were 50 NTU in order to duplicate natural rainwater induced turbidity. The samples were flash-mixed for 5 min and flocculated at 50 rpm for 30 min with a 30 min settling time. Lastly, a multiple layer filtration column was used consisting of dry sand, glass wool, and gravel.	Removal efficiencies ranged from 95.8% to 97.6% within a 6 mg/L to 60 mg/L dosage. Tests also showed that chitosan performs better in a hydrochloric acid solvent.	(Altaher, 2012)

this property plateaus at a 1:1 ratio. It is also noted that chitosan/montmorillonite composites closely follow a Langmuir isotherm (Wang & Wang, 2007). In contrast, a chitosan/polyurethane composite acts as a matrix due to the high surface area which immobilizes dyes similarly to granular activated carbon. Moreover, chitosan/activated clay was shown to have the highest adsorption capacity when used with the reactive dye RR222. Chitosan/activated clay yielded an absorbance of 1912 mg/g compared to an average of 342 mg/g average adsorption for the other composites.

Table 4. Adsorbent properties of chitosan and chitosan composites (Kamble et. al, 2007) (Bhatnagar & Sillanpää, 2009)

Adsorbent	Adsorbate	Adsorption capacity (mg/g)	Reference
Dye Adsorbent			
Chitosan/montmorillonite	Congo Red	53.42	(Guzman, Saucedo, Navarro, Revilla, & Guibal, 2002)
Chitosan/polyurethane	Acid Violet 48	30	(Guibal, Milot & Roussy, 1999)
Chitosan/activated clay	Methylene blue	330	(Guibal, Milot & Tobin, 1998)
Chitosan-activated Clay	Reactive dye RRR22	1912	(Moret & Rubio, 2003)
Chitosan/bentonite	Tartrazine	294.1	(Dambies, Roze, & Guibal, 2000)
Chitosan/bentonite	Malachite Green	435	(Chen & Chung, 2006)
Chitosan/palm oil	Reactive blue 19	909.1	
Chitosan flakes	Reactive red 222	293	(Gupta, Chauhan & Sankaramakrishnan, 2009)
Chitosan beads	Reactive red 222	1103	(Adyun & Aksoy, 2009)
Chitosan-ECH	Reactive red 289	1802-1840 (g/kg)	(Schmul, Krieg & Keizer, 2001)
Chitin	Reactive yellow 2	28	(Hasan et. al, 2003)
Chitin	Reactive black 5	65	(Boddu, Abburi, Talbott, & Smith, 2003)
Chitin	synthetic reactive dye wastewater	133-167	(Spinelli, Laranjeira & Favere, 2004)
Chitin modified by sodium hypochlorite	synthetic reactive dye wastewater	59-124	(Rojas, Silva, Flores, Rodriguez, Ly, & Maldonado, 2005)
Quarternary chitosan salt	Reactive orange 16	1060	(Geng, Jin, & Qi, 2009)
Chitosan	Remazol black 13	91.47-130	(Yan, Haijia & Tianwei, 2007)
Powdered cross-linked chitosan grafted with acrylic acid	Remacryl Red TGL	204.2-510.7	(Kim, Benedetti & Boulegue, 2004)
Chitosan beads	Malachite green	74.83-93.55	(Niu & Volesky, 2003)
Chitosan-g-poly(acrylic acid)montmorillonite	Methylene blue	1859	(Ngah & Liang, 1999)
Chitosan-based adsorbent	Basic blue 3	166.5	(Arrascue, Garcia, Horna, & Guibal, 2003)
Disulfonate derivates of chitosan	Basic blue 9	121.9	(Lasko & Hurst, 1999)
Chitosan	Acid green 25	645.1	(Zou, Liu & Liu, 2009)
Chitosan	Acid orange 10	922.9	(Metwally, Elkholy, Salem, & Elsabee, 2009)
Chitosan	Acid orange 12	973.3	(Wang, Liu, Wang, Xie, & Deng, 2009)
Chitosan	Acid red 18	693.2	(Juang, Tseng, Wu & Lin, 1996)
Chitosan	Congo red	93	(Juang, Tseng, Wu & Lee, 1997)
Poly(methylmetacrylate) grafted chitosan	Procion Yellow mx	250	(Annadurai & Krishnan, 1997)
Poly(methylmetacrylate) grafted chitosan	Remazol Brilliant Violet	357	(Annadurai, Chellapandian & Krishnan, 1997)
Poly(methylmetacrylate) grafted chitosan	Reactive Blue H5G	178	(Wu, Tseng & Juang, 2000)
Cross-linked chitosan beads	Metanil yellow	1334	(Wu, Tseng & Juang, 2001)
Cross-linked chitosan beads	Reactive blue 15	722	(Chiou & Li, 2002)
Chitosan grafted with amide groups	Remazol Yellow Gelb 3RS	1211	(Choi & Li, 2003)

Note. Adapted from "Applications of chitin-and chitosan-derivatives for the detoxification of water and wastewater-a short review" by Bhatnaga, & Sillanpää, 2009 Advances in Colloid and Interface Science 152(1), p. 26-38.

Heavy Metal Adsorption

Toxicity of heavy metal ions released daily by industry has not yet accumulated to become a public health concern; however, a long-term risk is present both for the environment and society. Similarly to dye adsorption, chitosan produces the best adsorption as a composite. A few examples of heavy metal adsorption composites are chitosan/ceramic alumina, chitosan/perlite, chitosan/magnetite, chitosan/cotton, chitosan/sand, chitosan/cellulose, and chitosan/montmorillonite. Chitosan composites are much less sensitive to acidic environments than chitosan alone. Magnetite composites, in particular, attract heavy metals magnetically using nanoparticles such as iron oxide and maghemite. These magnetic nanoparticles are not only lower toxicity but can also be produced cheaply. Furthermore, they have been effectively used for removal of Pb(II) through ultrasound enhanced agitation.

Desalination

Foam biosorbents consisting of hemicellulose grafted with diethylene triamine pentaacetic acid (DTPA) and cross-linked with chitosan successfully removed ~0.3 g of salt per gram of biosorbent (Ayoub et al, 2013). The absorption properties of this solution can be attributed to the swelling of the biosorbent and also the effect salinity has upon the polyelectrolyte complexes. As the concentration of NaOH in the solution increases, the gel swells in response. This same biosorbent material was also used for uptake of heavy metals; however, a much different absorption mechanism took place.

A more popular surface modification for desalting and salt rejection purposes employs chitosan for nanofiltration. Nanofiltration is used as a pretreatment for desalination through reverse osmosis in decreasing the pressure necessary. The primary mechanism for rejection of the salt solutions is due to ion valency. Due to the interaction between electrolytes and the nanofiltration surface, different feed solutions produced a range of removal efficiencies varying from 12.7% to 92.8% (Ming, Chen, & Gao, 2005). Many recent studies have been conducted to better understand and assess chitosan's nanofiltration properties through further surface engineering and membrane modification. In studies conducted by Wang et. al, an O-(Carboxymethyl)chitosan nanofiltration membrane was functionalized with graphene oxide to optimize desalination. After characterization and testing, the membranes exhibited better rejection capabilities than "pristine membranes and the commercial [nanofiltration] membranes". These were seen to definitively enhance desalination capabilities of the media (2015). Furthermore, Shenvi, Rashid, Ismail, Kassim, and Isloor synthesized a composite chitosan-poly(1,4-phnylene ether sulfone) (PPEES/CH) membrane which was then crosslinked by glutaraldehyde. Following characterization and water flux studies, the salt rejection was shown as a positive correlation with glutaraldehyde concentration of up to 34% and 53% for NaCL and $MgSO_4$ while simultaneously decreasing flux (2012). In another study, sulfated chitosan was cross-linked with polysulfone ultrafiltration membrane and epichlorohydrin which exhibited salt rejections of 90.8% for Na_2SO_4 and 32.5% for NaCL solutions. Another example of chitosan as an active layer for nanofiltration is exhibited by Zhou, Gao, Li, and Gao (2013) through a composite nanofiltration membrane from O-carboxymethyl chitosan an epoxy chloroprpone with a polyacrylonitrile supporting layer. Optimal concentrations were determined through studying salt rejection and permeation flux. The optimal membrane exhibited 94.36% Na_2SO_4 removal.

ENVIRONMENTAL IMPACT OF CHITOSAN IN WATER TREATMENT

Studies have been done on chitosan to determine potential toxicity after coagulation and flocculation of different surface waters. While some high turbidity levels with an excessive dosage of chitosan can create chitosan flocculation, the appropriate dosage naturally would not increase the NTUs. In addition, higher pH values generally cause a decrease in efficiencies which can sometimes be seen as drastic. Although chitosan's purpose is to decrease toxicity, some studies have shown increased toxicity compared to alum and ferric acid or NOM removal and *Dapnia magna* toxicity removal of humic acid spiked samples (Rizzo et. al., 2008). However, all coagulants decreased the toxicity in unspiked samples. Moreover, chlorination increased toxicity with chitosan being more toxic than traditional coagulants. Thus, surface water type is highly important to determine if chitosan could potentially increase toxicity.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Of course, it must be considered that the lower toxic material in some cases is not always so in others. For example with chitosan use in the well treatment fluid, replacement of phenols and formaldehyde absolutely decrease toxicity to the consumer (Eoff & Reddy, 2004). Moreover, potential cationic polyelectrolytes could possibly contribute to toxicity leading to an increased use in bioflocculants.

COST OF WATER TREATMENT

Many studies show that chitosan can be a less toxic, more economical option compared to traditional coagulants. Chitosan was proven to be more economical than aluminum sulfate and polyaluminum chloride when used as a coagulant for palm oil mill effluent and residue oil (Ahmad, Sumathi, & Hameed, 2006). For the most effective, least toxic alternatives, composites may provide optimal results. Polyaluminum chloride and silicate chitosan composite effectively enhanced COD, SS, and Al^{3+} by 1.8-23.7%, 50%, and 61-85.5% respectively. It also reduced costs by 7-34% (Zeng, Wu, & Kennedy, 2007). Furthermore, chitosan proved an efficient and cost-effective adsorbent for dozens of dyes such as AB25, AB40, AB62, AB113, AB193, AR73, RR24, RY2, RB74, and RY18 in alkali solution (Shen et. al., 2011). It has long been seen as a cost-effective alternative to activated carbon (Gupta & Imran, 2004). Beyond cost-efficiency for water treatment properties, its coagulation capabilities can allow further profitability for companies through recycling materials such as milk and poultry industry effluents (Chi & Cheng, 2006).

SUMMARY

Chitosan and its derivatives provide numerous opportunities for potentially sustainable water and wastewater treatment. Presently, the EPA has approved chitosan for use of point-of-use coagulation of bacteria among other uses with an aim at developing countries as a sustainable and economical alternative. Future research could include cost-benefit analysis as well as the implementation of successful antimicrobial, coagulation and flocculation, and adsorption functionality. Considering the environmental and social need for more drinking water alternatives, cost efficiency for biosorbent capabilities of salts should also be further studied and combined with other leading desalination initiatives such as microbial desalination cells. Environmental and aquatic toxicity of chitosan should be evaluated in detail as well.

ACKNOWLEDGMENT

This work was supported by the research grants from USEPA-P3 program and USGS-MWRRI research program. This work was also supported by the Department of Civil and Environmental Engineering (CEE), the Bagley College of Engineering (BCoE), and the Office of Research and Economic Development (ORED) at Mississippi State University.

Chapter 15
Life Cycle Costing on Waste Management

Sami Gören
Umm Al-Qura University, Saudi Arabia

ABSTRACT

Sustainability is the essential key point in every aspect of our life. It cannot be successful when it is limited to some certain issues in daily life. It is a revolutionary step for continuous development without any impact to the nature that should be adapted to the economy, manufacturing, urbanization, industrialization, etc. Increasing population and increasing wealth causes increase in the necessities of the human being. If it is considered as inevitable to give many bad impacts to the environment, this type of perspective is more dangerous and harmful to the environment and society than giving unconscious damages. This point of view might make these impacts to be accepted as legal, and this is what should be strongly discarded. There should be a new concept which enlarged our sphere of concern to include the entire physical environment including animals, plants, and landforms.

INTRODUCTION

There should be a new concept which enlarged our sphere of concern to include the entire physical environment including animals, plants, and landforms. Assuming responsibility for other individuals, society, whole environment (plants, animals, soil, water, atmosphere, etc.) should be the main idea in sustainable development and manufacturing. An ethic, of course, cannot prevent the alteration, management, and use of these 'resources,' but it does affirm their right to continued existence, and, at least in spots, their continued existence in a natural state.

This chapter will focus on the necessity of sustainability for the future of humanity by highlighting the environmentally friendly manufacturing technologies by explaining the methodology of life cycle assessment and costing to choose the correct production and marketing techniques.

Manufacturing and technology make life easier, more comfortable and more accessible. The production is inevitable for that reason; the production systems and processes should be more logical and gentler to the human and nature. Uncontrolled increase in human population with exponential growth is one

of the essential problems. As the world is facing with limited resources in the limited regions and the necessities are also increasing not only because of the population increment but also because of growing demand for the welfare & wealth, the technological development should be long-running status not to exploit all the resources from today. Sustainability should be the environmental objective for everyone and especially for the major decision makers. Renewable and nonrenewable resources should be applied to the sustainable global economy with the balance of nature approach. Finite resources cannot support an exponential increase of people forever.

Related to the increasing population and industrial activities; the convergence of three entities of 'resources, needs and wastes' is the crisis. Crisis is inevitable with;

1. Absence of moral direction in treatment of natural resources,
2. Inability for social institutions to adjust to reduce environmental stress,
3. Abiding faith in technology.

It will be impossible to supply resources and a high-quality environment in the next century for the entire world's population. Besides that; overpopulation, urbanization, industrialization trigger the size of the crisis. Increased awareness, changes in political, social and technological systems can only be the solution for this problem. The main motto is hidden in the maximum benefits with the minimum of disturbance to the natural environment. Regardless of personal profits, it is important to achieve a sustainable global economy with an integrated approach by;

- Changing the bulky, useless technologies that disturb the nature and resources (A resource utilization plan for nonrenewable resources that does not damage the global environment, and provides for future generations),
- Adopting new environmentally friendly manufacturing technologies (A utilization plan or renewable resources such as water, forests, grasslands, fisheries that don't deplete the resource or destroy the ecosystem),
- Completely restructuring energy programs (An energy policy is needed that does not pollute, and cause climatic change),
- Developing an effective population control strategy (Populations of humans and other organisms must live in harmony with natural support systems such as air, water, and land),
- Instituting economic planning, financial aid and tax incentives (careful management and wise use of the planet and its resources),
- Instituting social, legal, political, and educational changes with a goal to maintain environmental quality (A legal, social, and political system dedicated to sustainability and a socially just global economy).

Earth is the only suitable habitat we have, and the resources are limited. Some resources are renewable, but many others are not renewable. For this reason, there is a huge necessity for large-scale recycling of many materials. The recycling can be achieved only by an integrated waste management. In fact, some economists have the idea of 'finding resources is less problematic than finding ways to use existing ones and technology and ingenuity will overcome lack of resources', however it is a great fact that resources

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

are finite, so this type of reasoning is fallacious because the population increase with a finite resource base cannot be sustained, and it is not cheap and easy to rehabilitate the damaged environment. You need not only the money for rehabilitation but also extremely long time.

The key to sustainable development is effective environment management. Inputs and outputs should be balanced with no disturbance of the natural equilibrium of earth systems. Wastes are causing a tremendous impact on the environment as they pollute the nature but also the limited resources come to nothing easily if they are not used again. Integrated waste management including recycling or gaining the raw materials again is very relevant in that sense and will save the earth's resources.

Environmental resources should be sustained; waste management is one of the leading factors for sustainability that will supply the quality of human environment. The issues related with the sustainable development should be discussed in this chapter, because the present is the key to the future.

WASTE MANAGEMENT

Protecting public health and the environment becomes the crucial problem, due to the increasing population around the world. Increasing population and wealth also means, increasing garbage which is technically described as "solid waste" or only as "waste." Semisolid food wastes and municipal sludge may also be included in solid waste. Liquid wastes such as lavatory and bathroom wastes are termed as "grey-water" or "waste water," which should also be handled and removed from the public life through sewer system (Goren, 2015).

Waste management is directly related to the amount and the content of the waste. Each attempt for collecting, transporting and treating the waste has a direct and indirect influence on the environment and depending upon this; it has a significant effect on human health. Any waste itself and all the operations to get rid of the waste have environmental scope such as emission to land, emission to water and emission to air and also have effect on the economy. The use of energy, occupational health and safety issues, noise, vibration, heat, and odor are also the biggest problems that the community should have to face. In the past 20 years, the sheer numbers of humans and their increasing demand for material goods have done the following:

- Lead to severe degradation of the natural environment that supplies our renewable resources such as food, wood, and water,
- Lead to rapid exhaustion of non-renewable resources,
- Placed humans in competition with other species for necessary resources such as space, food, and water,
- Forced people to live in areas of significant natural hazards.

The '4 R' system, consisting of Reduction, Reuse, Recycling, and Recovery is the core step for an integrated waste management system that supports the sustainable development. Reduction of waste is imperative in case of toxic wastes.

All the waste treatment processes have not only effect on life quality but also have a significant impact on the economy by having an influence on the workload and work capacity for that community.

The effect of this cycle can be estimated by the help of "LIFE CYCLE ANALYSIS" also known as "LIFE CYCLE ASSESMENT" or shortly named as "LCA."

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

LCA has a great relationship with the "Process Chain Analysis," by enabling to analyze the entire life cycle of the products or services concerning their environmental impacts and to display these analyses in a transparent way (Goren, 2015).

It is a necessity especially in this century, to choose the correct manufacturing and marketing techniques, in order not to cause environmental impact. This process depends on identifying and documenting all the costs related to the production which is known as "LIFE CYCLE COSTING (LCC)" (Australian National Audit Office, 2001). This is not related only to the manufacturing duration of a product but also directly linked to transporting, advertising, launching and even connected with the whole lifetime of that product. It is inevitable to mention; life cycle also involves the management and treatment costs of that product after finishing its life as a product. Future costs are nonignorable facts about a product or a process; usually, they are much more than the expenses of manufacturing and ownership period. For this reason, it is also paramount to estimate the future costs correctly.

1. Functioning
2. Expenditures
3. Maintenance
4. Repairment
5. Recycle or disposal

The cost of the waste management system has a direct and indirect effect on the inhabitants (Reich, 2005). The immediate effect is related to the budget used for collection, transportation, and disposal; however, the indirect effect is much more important as it has an effect through emissions. The emissions have short term and long term effect. Cost Benefit Analysis (CBA) can be employed for evaluating the economical methods for waste management. CBA's main idea is to cover all positive and negative impacts of a policy or project in monetary terms (Reich, 2005). Long term health effects should be the most important factor for CBA, which is usually neglected for short term budgets. Economic analyses are used for different scenarios for waste management. These scenarios can be presented including all the methods by changing the rate of that process, compared to the total system. However, this evaluation should start by integrating the analysis of economic and environmental aspects of waste management which have mostly opposite effect.

Municipal solid waste -more commonly known as trash or garbage- consists of everyday items such as food wastes, product packaging, garden wastes, durable & nondurable goods like furniture, clothing, containers and miscellaneous inorganic wastes. This is regularly generated from peoples' homes, but it also comes from commercial, institutional and some industrial sources (Goren, 2011). To understand what types of wastes are generated, "waste characterization process" is applied to the wastes. This will help to estimate what will come across during the waste management which is very important in the sense of treatment costs. The cost is directly correlated with the technology that is chosen. However, it is also related to dealing with normal situation or an unexpected situation. Each community may have different types of wastes according to their lifestyles, culture, tradition and social activities. Each region, even in the same city may have different characteristics. Not only the region but also the seasons can show diversity in the content of the waste. For that reason, the characterization processes should be done every season for each and every single community. This helps to control the waste, by understanding the content and the varieties.

EVERYTHING AFFECTS EVERYTHING ELSE

In the sense of environment friendly technologies; all the attempts should be in favor to human health. Environmental health directly means of human health. Without human comfort and human health, anything has no meaning. There may be a common misconception that natural resources are plenty around the world. In fact, we have many but they are not limitless, and the "regenerate" power of nature is limited. Also, the "regenerate" speed is very slow. For that reason, there should be a "balance" between consuming (polluting) and preserving (protecting). Consuming less can be a solution to this large-scale problem; but because of the increasing population and growing needs, this cannot be effectively accomplished. This should be performed by the manufacturing processes which is well-planned by the life cycle analysis by taking into account of the lifetime, consumption rate and life cycle cost of the product. This type of manufacturing and consuming is a part of sustainable development. This means of using the resources for today, not for tomorrow. The development should not use "tomorrow's resources." Tomorrow's resources will be necessary for the future and should be utilized by the generations to come.

Waste is everywhere because the human being is everywhere. It is normal to have waste if there is a human activity anywhere. The type of the waste depends on the kind of the activity, such as domestic or industrial. Whatever the type; increasing amount of wastes requires, not only recycling and reuse but also the technologies with "zero-waste." These types of technologies are called as "green technologies" that produce less waste or zero-waste. This is a necessity not only for the environment but also for the economic issues. This type of green technologies may allow increasing the manufacturing benefits by gaining maximum benefit from the manufacturing and marketing process. Whenever the correct feasibility is performed, this new type of manufacturing technologies can generate good business opportunities. The dilemma of protecting the environment and gaining money will be fade out by the help of this type of planning by correct life cycle costing. This is a process of having interaction with technical, economical and social disciplines.

The environmental problems, which we are facing today, are diversified due to the context and the generation. Likewise, the diversity of the source, the factors affecting the environmental problems are also diverging. These are, mainly, intense industrialization, irregular urbanization and the lack of infrastructure. There are also some specific reasons based on the regions. Domestic wastes increase in the amount and complexity as a result of rising standards of living. Industrial wastes are the main sources of pollution and threat to public health. However, domestic wastes can also be as dangerous as the industrial wastes because of the many chemical materials used in daily life and also due to the formation of new by-products by decomposition of organic wastes. If the wastes are not treated properly, they cause soil pollution and water pollution for surface, sub-surface & underground water. Furthermore, the landfill gas occurred at the dump sites, cause air pollution, contribution to global warming and even in some cases they may cause explosions.

The removal and elimination of the wastes are not only related to public health but also related to the economy. The recyclables cause lost in the economy by not being used as a resource. The production from raw material also causes loss of energy. The main problem for not a good waste management is mainly from the economic concern and also from the lack of the needed technical background about pollution and basic waste management information.

To solve the environmental pollution caused by the wastes, only one approach is not enough. All the possible and feasible techniques and technologies should be used to form an integral, efficient management. This active management is called as integrated waste treatment. It should start from preventing the

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

generation of the waste; every individual should do his/her best to reduce the waste he/she is producing daily by cooking less and do not waste food, by using durable containers, by reusing some materials for other purposes, etc. Of course, this is not limited to an individual. The most significant breakthrough should come from the industry. They should review and renew their technology to produce less waste, less polluted water, less air pollution, less energy while manufacturing, servicing, transporting and marketing. During all kinds of industrial activities, there should be less consumption and the environment should be less affected.

The second most important step for integrated waste management is source reduction by separating the wastes according to their types. Especially the package wastes should not be mixed with organic wastes. This will help to decrease the amount of costly treated, troublesome wastes. Moreover, may cause an income from the package wastes which are completely recyclables. It's a fact that; package wastes are not 'garbage'. They are a good input for further production with less energy and cost. If the paper becomes wet by the organic wastes, those papers will have no more economic value. The main earning is from nature by using less resource. This point is important than ever, in the sense of both environment and economics.

In the economic approach of waste management, usually, there are two methods (Massarutto, de Carli, & Graffi, 2011). The first one is focusing on only one type of technology such as incineration, etc. and does the comparative assessment of technologies for example; incineration vs. composting, anaerobic digestion vs. landfilling, as if they are the alternatives to each other.

This kind of comparison is useful for evaluating the range of application of each technical solution but unsatisfactory for assessing the management system as a whole since no single technology can address the 100% of waste flows and all of them generate residues that should be treated in some other points of the system (Massarutto, de Carli, & Graffi, 2011).

The second economic approach is related to the integrated management scenarios. The models are used for the materials balance, considering the bulk of waste flows generated and following them through the management system, with the aim of optimizing the choice of decision makers (Pires, Martinho & Chang, 2011). The analyses are executed by over simplifying the cost of different techniques with a primary approach to average costs remaining constant. However, the costs for collection depend on the parameters like daily collected amount, the method of collection, the frequency of emptying the containers, whether it is a curbside collection or source separation method. The unit-cost for collection also depends on the target of 10% or 90% of the total amount of each recyclable material. In this case, the quality of the collection is also important. The different types of materials should be completely separated from each other to have high income from the recycling activity; however, this generates higher sorting costs. On the other hand, if the paper or cardboard package wastes become wet, they lose their economic value as should be. The savings from the less landfilling amount might be calculated correctly; however, it is difficult to calculate a social cost for source separation with this type of approaches.

The method that was put into practice by life cycle analyses, all the above uncertainties disappear by the concept of "from cradle to grave" through adopting to waste management. The market value of the materials could be considered as a practical indicator of when something begins and ends to be a waste (Cleary, 2009). The "cradle" should be the moment when a certain good acquires negative value like disposing something to the garbage. The "grave" could be the moment when some materials return to the productive system with a positive value, like using it as a raw material in any manufacturing process (Cleary, 2009).

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

International Standard Organization has explained this type of life cycle assessment in ISO 14040 as follows; "The heightened awareness of the importance of environmental protection, and the possible impacts associated with products) manufactured and consumed, has increased the interest in the development of methods to comprehend better and reduce these impacts. One of the techniques being developed for this purpose is Life Cycle Assessment (LCA)" (Porter, 1992).

In this standard, the principles and framework for conducting and reporting LCA studies are also described. The method for assessment is explained as follows;

"LCA is a technique for assessing the environmental aspects and potential impacts associated with a product, by

- Compiling an inventory of relevant inputs and outputs of a product system;
- Evaluating the potential environmental impacts associated with those inputs and outputs;
- Interpreting the results of the inventory analysis and impact assessment phases about the objectives of the study.

LCA studies the environmental aspects and potential impacts throughout a product's life (i.e. cradle to grave) from raw material acquisition through production, use, and disposal. The general categories of environmental impacts needing consideration include resource use, human health, and ecological consequences (Cleary, 2009).

In this standard, the "cradle" is taken as the raw material, and the disposal is named as "grave." This type of approach seems as opposite to the previous idea for cradle & grave. However, they become identical in the sense of transformation to air and water emissions.

While this general rule is conceptually clear, applying it in concrete is not straightforward; in order to decide whether to incorporate a certain cost in the analysis or not, we previously need to clarify the perspective of the analysis: whether private or social, and in the latter case whether referred to the optimization of a particular local management system or having an holistic vision. For example, materials collected for recycling often have a positive market value only because the set of incentives provided by extended producer responsibility enable industry-funded compliance schemes to pay the price to collectors; yet these systems have to bear further costs after collection, even if these will not be paid in the waste bill, but rather through the market price of goods incorporating charges levied by compliance schemes. In other cases, benefits may be overrated because waste-derived outputs (such as energy) receive an extra above the market price (for example, incentives to non-fossil energy sources paid by many EU governments, revenues from so-called ''green certificates''). Other prices may be distorted by taxation (e.g. landfill) or market power of operators (ISO 14040: 2006).

The basic stages of conducting an LCA are as follows;

1. The definition of goals and scopes (study model which defines the methodological framework which all other LCA phases must comply with)
2. Inventory analysis (Inventory of all the inputs and outputs related to the product system)
3. Impact assessment (Assessment of the potential impacts associated with these inputs and outputs)
4. Interpretation of the inventory data and impact assessment results related to the goal and scope of the study.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

According to the International Standard Organization, some phases of the LCA technique, such as impact assessment, are still in relative infancy. Considerable work remains to be done, and practical experience gained to further develop the level of LCA practice. Therefore, it is important that the results of LCA should be interpreted and applied appropriately. In this step, the most important point is to understand that what we are trying to learn. Otherwise, the entire attempt becomes meaningless.

GOAL AND SCOPE DEFINITION

Within the standard, ISO 14041 covers Environmental management - Life cycle assessment - Goal and scope definition and life cycle inventory analysis. The standard series continues with ISO 14042 by covering life cycle impact assessment while ISO 14043 covers life cycle interpretation.

As with other assessments, the first step involves clarifying the purpose and extent of the LCA. This entails formally determining the functional unit, impacts of interest, and system boundary—elements from the "First Choice".

While LCA "light" approaches have been described above, a "full" LCA includes actual primary environmental impact data gathered once the product's full lifecycle has been determined. Such detailed LCAs take, on average, three months and cost $10,000-$60,000 (Reich, 2005), and are only possible to complete once the product is in use and has gone through all stages of its life cycle. This increased accuracy is worth it for benchmarking or external reporting (such as green marketing) purposes.

LIFE CYCLE INVENTORY ANALYSIS (LCI)

The next phase entails creating a list of all of the components of the products life cycle that fall within the defined system boundary. It has three major steps:

1. **Construct a process flowchart that shows the following:**
    a. Raw materials
    b. Manufacturing processes
    c. Transports
    d. Marketing
    e. Users
    f. Waste management
2. **Collect data for:**
    a. Material inputs
    b. Products and by-products
    c. Solid waste, air and water emissions
3. **Calculate the amounts of each in relation to the functional unit:** Essentially, this is the process flow diagram with detailed mass and energy values. The resulting Life Cycle Inventory (LCI) provides a breakdown of all of the energy and materials involved in a product's system at a level of detail that provides a basis for evaluation.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

IMPACT ASSESMENT

Once a detailed LCI is created, environmental impacts can be ascribed to its parts, and if desired to the whole system. There are four steps to the Life Cycle Impact Assessment (LCIA) process, the first two of which are considered mandatory, while the last two are optional (Massarutto, de Carli & Graffi, 2011).

Classification

Classification involves assigning specific environmental impacts to each impact categories (component) of the LCI. It is here where decisions made during the scope and goal phase about what environmental impact categories are of interest come into play.

Characterization

Once the impact categories have been identified, conversion factors – known as characterization or equivalency factors – use formulas to convert the LCI results into directly comparable impact indicators.

Normalization (*Optional*)

In this step, a basis is provided for comparing different types of environmental impact categories. Some practitioners choose to normalize the impact assessment by scaling the data by a reference factor, such as the region's per capita environmental burden. This helps to clarify the relative impact of a substance in a given context. For instance, if global warming contributions are already high in the context in which the product is being assessed, a reference factor would normalize whatever the product's global warming contributions are to clarify its relative impacts.

Weighting (Optional)

The process of weighting is assigning a weighting factor to each impact category depending on the relative importance. It is related to the energy consumption of manufacturing and the quantity of the product. This will help to calculate the equivalence of carbon footprint.

INTERPRETATION

Although listed fourth, life cycle interpretation occurs throughout the whole LCA. It involves the ongoing process of clarifying, quantifying, checking, and evaluating the information used by, and resulting from, the life cycle inventory (LCI) and impact assessment (LCIA) phases. The standard that covers the LCA process, ISO 14044, gives two main objectives:

1. Analyze results, reach conclusions, explain limitations, and provide recommendations based on the findings of the preceding phases of the LCA, and to report the results of the life cycle interpretation in a transparent manner.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

2. Provide a readily understandable, complete, and consistent presentation of the results of an LCA study, following the goal and scope of the study.

To achieve these objectives, the ISO standard states that interpretation should cover at least three major elements of the following.

1. Identification of the significant issues based on the LCI and LCIA. Which life cycle stages or components stand out as major contributors to overall impact? What are the anomalies?
2. Evaluation which considers completeness, sensitivity, and consistency checks. Is all the information needed for interpretation present in the LCI and LCIA? How reliable is the information related to any identified significant issues? How much do changes in such factors influence the overall results? Are all of the assumptions, data, characterization factors, etc. that were used in the assessment consistent internally and with the overall goal and scope of the LCA?
3. Conclusions, recommendations, and reporting. As discussed in later sections of this guide, a great deal of an LCA's value depends on how its results are communicated to people involved in making relevant decisions, whether other designers, engineers, management, marketers, or other parts of the supply chain.

CONCLUSION

It is very important to note that no matter how carefully assembled, analyzed, assessed, and measured; LCAs are never the "real" answer. They require interpretation, which is turn requires transparency and judgment. The data sources, assumptions, and all other relevant information need to be transparent to decision makers so that they can understand the full context of the results of the life cycle inventory assessment. Deciding among design options is not as easy as just comparing LCIA numbers, whether single- or multi-factor, weighted or not. LCIA results can be a source of insights, but do not stand alone in guiding product development choices. Engineers will need to take them in the context of the other attributes they are trying to optimize, including cost, manufacturability, performance, and so on. Besides, there are myriad other factors guiding product development decisions not covered by LCAs, including social impacts and acceptance, pricing, political agendas, and regulations.

The major stages in an LCA study raw material acquisition, materials manufacture, production, use/reuse/maintenance, and waste management (Curran, 2006). This way is the only scientific method to analyze the environmental impacts of production.

Adding life cycle assessment to the decision-making process provides an understanding of the human health and environmental impacts that traditionally is not considered when selecting a product or process. This valuable information provides a way to account for the full effects of decisions, especially those that occur outside of the site that are directly influenced by the selection of a product or process.

Remember, LCA is a tool to inform decision-makers better and should be included with other decision criteria, such as cost and performance, to make a sensible decision.

Chapter 16
A Decision Support System for Sustainable Waste Collection

Mattias Strand
University of Skövde, Sweden

Anna Syberfeldt
University of Skövde, Sweden

André Geertsen
University of Skövde, Sweden

ABSTRACT

This paper presents a decision support system (DSS) for making the waste collection process more sustainable. Currently, waste collection schedules and routes are created manually in most waste management organizations. This is both very time consuming and likely to result in poor solutions, as the task is extremely difficult due to the large number of bins combined with the many parameters to be considered simultaneously. With a sophisticated DSS, it becomes possible to address the complexities of optimal waste collection and improve sustainability—not least from the environmental perspective. The DSS proposed here is designed to be used on the operational level in the waste management organization and supports daily operations and activities. System evaluation indicates that it can reduce truck operating time by approximately 25%, corresponding to a saving of approximately 21,300 kg of carbon dioxide and 187 kg of nitrogen oxides per year and truck.

INTRODUCTION

An important part of our welfare concerns ensuring properly functioning and environmentally sound waste management in both cities and rural areas. This is becoming increasingly important with the use of new raw materials and steady yearly increases in the total amount of waste. Over the past decade, the amount of household waste in Sweden has increased by 15 percent and in 2015 more than 4.3 million tonnes of household waste were generated – approximately 460 kilograms per person (Swedish Waste Management Association, 2016). One consequence of the increasing amount of waste is an increased

number of waste collection trucks, which release greenhouse gas (GHG) emissions that contribute to climate change and cause health problems for people in urban areas. From the environmental and health perspectives, there is a strong need to optimize the procedures of planning and executing waste collection routes. From the societal and civic perspectives, there are also reasons to consider the economic aspects of household waste collection, as it is financed by taxes and/or fees.

This paper presents a decision support system (DSS) for improving the waste collection process and optimizing it from a sustainability perspective. The main focus is on the environmental aspect, as waste collection is associated with large GHG emissions from garbage trucks, each of which consumes an average of approximately 30,000 liters of diesel per year. We propose a DSS that helps the waste management organization optimize its truck operations and increase their efficiency, making them more environmentally sustainable. The DSS is designed to be used on the operational level in the waste management organization and supports the daily operations and activities. Note that, although various waste collection systems have been proposed in the literature (see, e.g., Giribone et al., 2002; Abeliotis et al., 2009; Caballini et al., 2010; Revetria et al., 2011; Chang and Lin, 2013), as far as the authors are aware, none of these focuses on a complete DSS for operational use with an explicit focus on optimization from a sustainability perspective.

Waste collection schedules and routes are currently created manually in most waste management organizations. Manually planning truck operations is very difficult due to the large number of bins combined with the many parameters to be considered simultaneously. Parameters include driver working hours and breaks, truck capacity (in terms of both weight and volume), and time windows at offload facilities. Even greater difficulties are created by the temporal constraints that must be considered, meaning that some bins preferably should, or should not, be emptied at certain times (e.g., bins at daycare centers should be avoided when children are outside playing). Furthermore, the problem of route optimization is a highly complex mathematical problem: finding the shortest route between a number of points (in this case represented by bins) is classified as an "NP-hard" problem in its simplest form. This means that the time it takes to solve the problem grows exponentially with the problem size, i.e., number of nodes. Finding the optimal route is possible, but might take a very long time because all possible routes must be evaluated to find the best one. Even for small-sized problems of this sort, a huge number of possible routes must be considered; for example, in a problem with only 15 nodes to visit, there are 6,227,020,800 possible routes.

The high complexity of efficiently optimizing the waste collection process, in combination with the obvious need to reduce emissions from garbage trucks, has motivated this study and the development of a DSS for sustainable waste collection. The next section describes the research method used in the study. In Section 3, the conceptual modeling of the waste collection problem used as a basis of the DSS is presented. Sections 4 and 5, respectively, present the optimization algorithms and simulation used in obtaining sustainable solutions. The DSS is presented in Section 6, followed by an evaluation of the system in Section 7. Finally, conclusions from the study are presented in Section 8.

RESEARCH METHOD

The research method chosen for this work may be characterized as an action case method (Vidgen & Braa, 1997). The action case study can be described as a hybrid between interpretative case studies and interventional action research (Vidgen & Braa, 1997). The action case method aims to balance the po-

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

tential contradiction for the researcher in being both the observer of a particular case and simultaneously interfering with the process by contributing knowledge and ideas as part of bringing the process forward. This balance can also affect the generality of the results. The action case method has been criticized (Baskerville & Wood-Harper, 1996), and to alleviate some of these criticisms, an iterative approach has been applied. The iterative approach is inspired by Susman's (1983) generic model, which comprises the following five cyclic activities guiding the process: diagnosing, action planning, action taking, evaluation, and specifying learning. Here, it is also worth mentioning that although the activities are sequentially connected, some parallelism normally occurs, especially in relation to the specifying learning activity.

The action case study, which started in 2010 and is still ongoing, has been conducted at a waste management company. The company is responsible for collecting household waste in nine municipalities in western Sweden from a total of approximately 134,000 bins. Each bin is emptied once or several times during a 14-day period according to a predefined schedule. The company has 50 employees and an annual turnover of EUR 8.5 million. Currently, 25 trucks are needed to collect the waste and most of them are fueled with diesel. During the study, and following Creswell's (2009) advice, a lot of empirical material has been collected from various sources. Thirty-five interviews were conducted with transportation planners and garbage truck drivers, as well as with managers in several positions. In addition, observations, document analysis, internal company as well as external system analysis, and DSS prototyping have contributed material used in developing and analyzing the DSS and in related processes.

PROBLEM MODELING

In the study, we approach the overall waste collection problem as a pickup and delivery problem, while the lower-level optimization problem of finding the best possible route linking a number of selected bins is approached as a traveling salesman problem (TSP). The basics of these two problems are explained in the next two subsections.

Pickup and Delivery Problem

The general pickup and delivery problem (GPDP) concerns creating routes for carrying out a number of transportation requests using a fleet of vehicles (Savelsbergh & Sol, 1995). Each vehicle has a given maximum capacity, starting point, and endpoint. A transport request defines the quantity of goods to be transported and the locations where the goods are to be picked up and delivered. Each request is fulfilled by a single vehicle without intermediate transshipment.

The pickup and delivery problem (PDP) is a specialized version of GPDP in which all vehicles start and stop at a central depot (Montané & Galvão, 2002). Furthermore, for each transport request, only one location is defined for pickup and delivery, respectively. Another common problem is the vehicle routing problem (VRP), which is identical to PDP except that either all pickup or all delivery locations are located at the depot (Tan et al., 2006). An example of a VRP problem is shown in Figure 1. This problem illustrates a realistic situation in which there are multiple vehicles with different capacities serving multiple locations with heterogeneous time windows, priorities and load to be picked-up.

Based on GPDP, PDP, and VRP, further specialized problems can be defined and divided into two categories: static and dynamic. A problem is static if all transport requests are known when the routes are constructed (Savelsbergh & Sol, 1995). In a situation in which transport requests may be added

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. Example of VRP problem (adopted from OptaPlanner.org)

while running routes, meaning that routes have to be changed on the fly, the problem is instead dynamic. Besides static and dynamic problems, it is also meaningful to distinguish between problems involving one and several operating vehicles, i.e., single- and multi-vehicle problems. Furthermore, problems can also be categorized according to whether or not they involve time constraints. For example, vehicles are often only available during the drivers' working hours or, if people are being transported, pickups must be performed at specific times. Such restrictions are called time windows.

The above problems have several possible optimization objectives (Savelsbergh & Sol, 1995). Some common examples are minimizing the total time for the route, minimizing the distance driven, or meeting the time windows as closely as possible. A problem may be either a single-objective problem, i.e., involving only one aspect to be optimized, or a multi-objective problem, i.e., involving several, often conflicting, aspects to be optimized simultaneously. Various solution techniques are used depending whether the problem is a single- or multi-objective one.

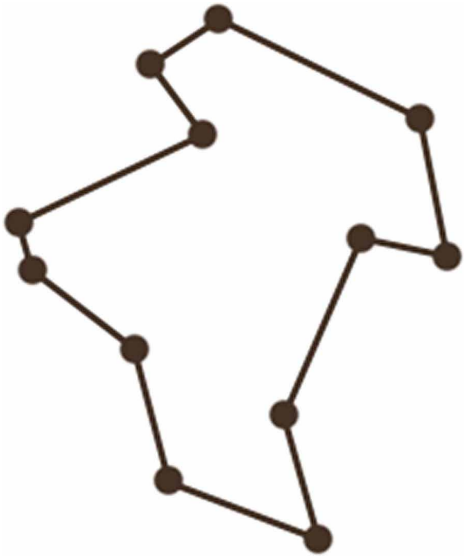
In this paper, we model the problem of waste collection as a static multi-vehicle pickup and delivery problem with time windows and multiple optimization objectives. The lower-level optimization problem of finding the best possible route between bins that have been allocated to a truck is modeled as the TSP, as described in the next subsection.

Traveling Salesman Problem

The traveling salesman problem (TSP) is an optimization problem belonging to the NP-complete class of combinatorial problems (Russell & Norvig, 2003). The definition of the problem is that, given a finite graph, the goal is to find the shortest Hamiltonian circuit. A Hamiltonian circuit is a path in a graph that visits each node exactly once except the start node, which is also the end node. A graph is

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. An optimal Hamiltonian circuit in a graph consisting of 12 nodes



a structured set of nodes and edges, where edges connect the nodes. Figure 2 illustrates a Hamiltonian circuit. As TSP is NP complete, and finding the optimal circuit entails calculating every possible circuit in the graph, the complexity of the problem grows exponentially with the number of nodes in the graph (Gen & Chen, 2000).

TSP is one of the most studied problems in combinatorial optimization due to its simple definition and field of applications (Applegate et al., 2006). A typical example application of TSP is in the industrial manufacturing of circuit boards. When manufacturing circuit boards, holes are usually drilled or stamped through the board in a specific pattern. The mean time of drilling or stamping is constant and cannot be altered by improving the manufacturing process. The time spent moving the drill or stamping cylinder can, however, be improved by optimizing the order in which the holes are processed, thus optimizing the distance traveled by the drill or stamping cylinder. Using the same concept, TSP can be also applied to problems related to finding the shortest possible path through a number of geo-locations, as in the case of waste collection.

The next section describes the software algorithms used in solving the optimization problem on the technical level.

DEVELOPMENT OF THE OPTIMIZATION ALGORITHM

Due to the general complexity of PDPs and TSPs, optimization techniques that are not guaranteed to find the optimal solution, but a sufficiently good one in a short time, are often used rather than exact methods (Zbigniew & Fogel, 2000). Evolutionary algorithms are a class of such inexact optimization techniques that can be used to approach these problems (Jozefowiez et al., 2008), and such a technique is used in this study.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Evolutionary Algorithms

Evolutionary algorithms are essentially based on Darwin's theory of the "survival of the fittest" (Darwin, 1859). According to this theory, in a population of individuals (i.e., solutions), those having the most desirable characteristics will obtain the best opportunities to mate and carry on their genes. In this way, Darwin argued, genes promoting fitness will propagate through generations and the population will increase in fitness over time. In this study, a solution represents the fleet of vehicles and provides a set of routes each specifying what bins should be visited each day, in what order and by what trucks.

In evolving a population of solutions, evolutionary algorithms apply biologically inspired operations for selection, crossover, and mutation (Pham & Karaboga, 2000). The operators are applied in a loop, an iteration of the loop being called a generation. The following pseudo code presents the basic steps of this evolutionary process:

Step 1: Initialize population
Step 2: Evaluate the fitness of solutions in the population
repeat
Step 3: Select solutions to reproduce
Step 4: Form a new generation of population through crossover and mutation
Step 5: Evaluate the new solutions
until terminating condition

The solutions in the initial population are usually generated randomly (step 1). The solutions in the population are evaluated and assigned fitness values, representing a quantification of their optimality (step 2). In each generation, a proportion of the solutions in the population is selected from which to breed offspring for the next generation of the population (step 3). Solutions are selected based on their fitness and those having a high fitness typically have a higher probability of being selected, but to prevent premature convergence, it is common for a small proportion of solutions with worse fitness also to be selected. From the solutions selected, new solutions are created to form the next generation of the population (step 4). To create each new solution, two parent solutions are chosen and, through mating (called crossover), an offspring is produced (see Figure 3).

Occasionally, the new solution can undergo a small mutation to maintain high diversity in the population and avoid local minima. A mutation usually involves changing an arbitrary part of a solution with a certain probability, in this case changing the order in which two collection sites are visited, as shown in Figure 4.

When the new population is formed, the solutions are evaluated and the average fitness will have generally increased (step 5). After evolving populations for some time, near-optimal collections of routes have been found. The process of evolving generations continues until a user-defined termination criterion has been fulfilled, for example, that the best solutions in the last n generations have not changed or that a certain time has elapsed.

Two fitness values (optimization objectives) are considered in the optimization, as specified by the waste management organization: 1) minimal carbon dioxide emissions and 2) minimal violations of temporal constraints. These two objectives conflict with each other, as considering temporal constraints negatively affects the driving distance. The difficulty with conflicting optimization objectives is that there is usually no single optimal solution with respect to both objectives. Instead of a single optimum,

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 3. Example of a crossover

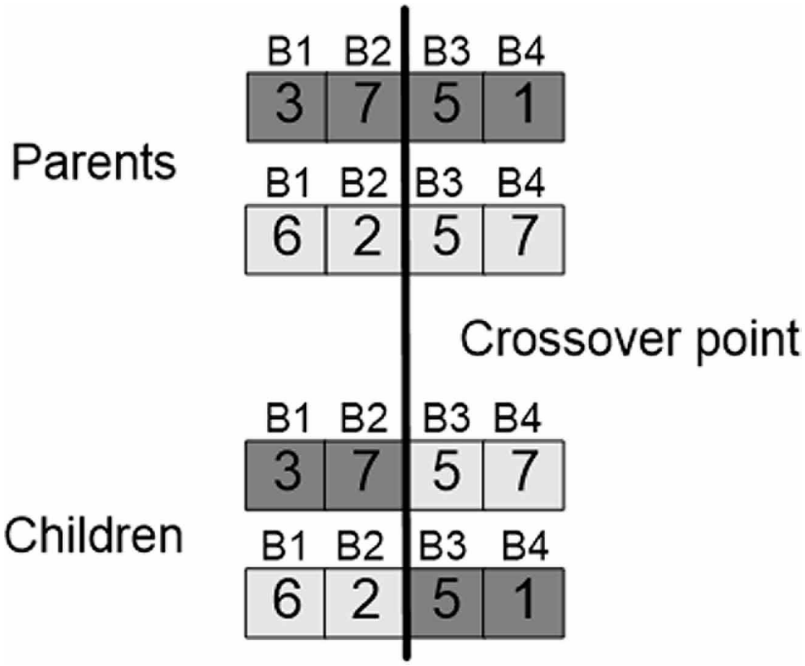


Figure 4. Example of a mutation

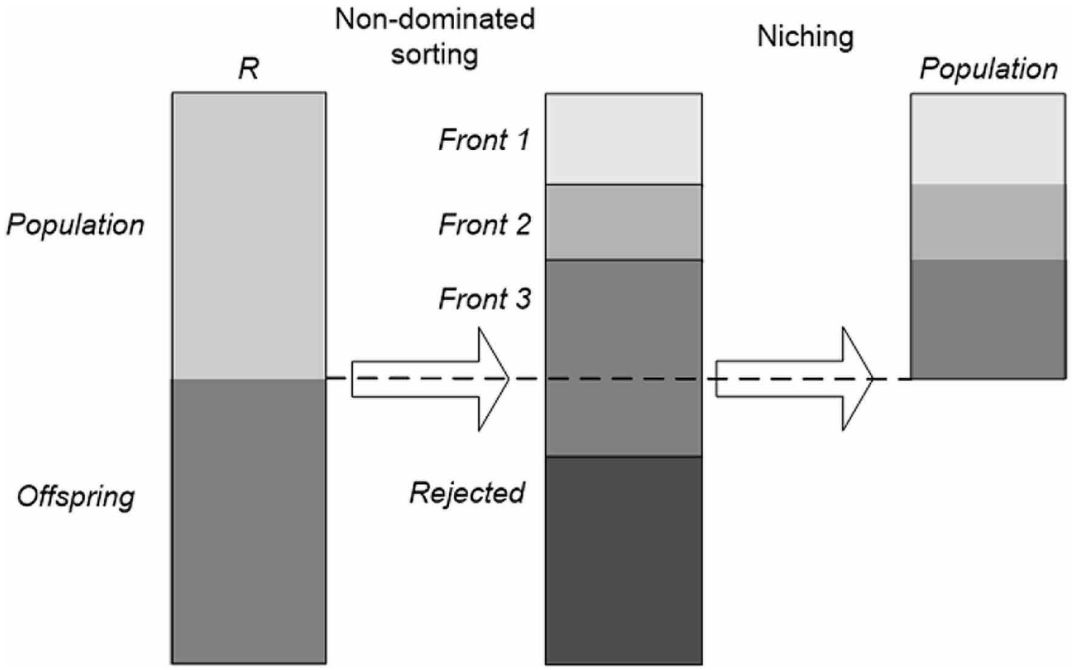
there is a set of optimal tradeoffs between the conflicting objectives, called Pareto-optimal solutions (Deb, 2004). To manage multiple objectives, specific optimization algorithms have been suggested. Instead of seeking only a single optimum, these algorithms maintain a set of Pareto-optimal solutions. One of the most efficient algorithms for Pareto optimization is the elitist non-dominated sorting genetic algorithm (NSGA-II) (Deb et al., 2000). Due to the algorithm's proven efficiency, this is the optimization algorithm selected for the study.

NSGA-II is basically an evolutionary algorithm extended with features for handling multiple tradeoff solutions. To deal with conflicting objectives, NSGA-II selects solutions for the next generation of the population based on Pareto ranks: rank 1 includes the Pareto-optimal solutions in the complete population, and rank 2 the Pareto-optimal solutions identified when temporarily discarding all solutions of rank 1, and so on. More specifically, solutions for the next generation are selected from set *R*, which is the union of the parent and offspring populations (both of size *N*). Pareto-based sorting (also called

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 5. Selection procedure of NSGA-II



non-dominated sorting) is applied to *R* and the next generation of the population is formed by selecting solutions from one Pareto front at a time. The selection starts with solutions in the best Pareto front, then continues with solutions in the second-best front, and so on, until *N* solutions have been selected. If there are more solutions in the last front than there are remaining to be selected, niching is applied to determine which solutions should be chosen. All the remaining solutions are discarded. The selection procedure is illustrated in Figure 5 (adapted from Deb, 2004) and the pseudo code is presented below:

```
Initialize Population
Generate N random solutions and insert into Population
for (i = 1 to MaxGenerations) do
Generate ChildPopulation of size N
Select Parents from Population
Create Children from Parents
Mutate Children
Combine Population and ChildPopulations into CurrentPopulation with size

```
until N solutions found and determine crowding distance between
points on each front
end for
Present results
```

To evaluate the fitness of solutions, the algorithm uses a simulation model that represents the real-world bin collection. This model is described in the next subsection.

DEVELOPMENT OF THE SIMULATION MODEL

To simulate a waste collection procedure, a discrete-event simulation model was constructed. A discrete-event model was used instead of a traditional analytical (mathematical) representation of the problem because analytical methods require simplifications, as these methods do not provide means for modeling complex behavior (Al-Nory & Brodsky, 2008). Furthermore, the concepts of event order and timing are usually not explicit in analytical models, making it difficult to achieve a correct representation of the real-world system (Al-Nory & Brodsky, 2008). For a complex problem like that considered here, discrete-event simulation is a powerful alternative to analytical methods and provides better means for incorporating complex relationships using easier methodologies and tools than does mathematical programming (Law, 2007).

Discrete-Event Simulation Model

A simulation model essentially consists of a set of system states and transitions between these states, which correspond to elements and event sequences in the real system (Banks, 1998). The execution of an event-driven simulation model is controlled by the time points of the scheduled events. After an initialization phase in which the simulation clock is reset and the state variables, statistical variables, and event list are initiated, the simulation cycle, i.e., the simulation main loop, is started (Law & Kelton, 2000). In each iteration, the type of the next event in the event list is determined (i.e., the event with the first start time). Subsequently, the simulation clock is advanced to the start time for this event and a routine for handling the current event type is run. An event routine first updates the state variables and then the statistical variables; finally, future events are generated and added to the event list. The last thing that happens in the simulation cycle is testing whether the condition for when the simulation is considered completed has been satisfied. If it is not, a new simulation cycle is run. If the condition is met, the simulation is terminated, and output parameters are calculated and reported.

Data for the simulation model used in the study were collected for two months in cooperation with the waste management company. Validation of the simulation model indicates that it represents reality very well, with an average deviation from reality of only 7%.

The next subsection describes how the simulation model and the evolutionary optimization algorithm have been integrated in a simulation-based optimization procedure.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Simulation-Based Optimization

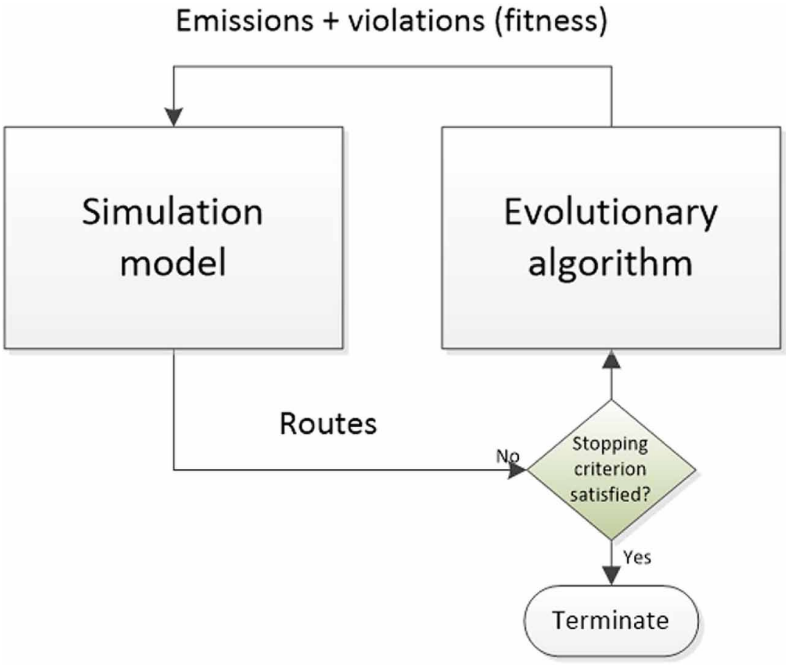
Simulation-based optimization is an iterative process (see Figure 6): the evolutionary algorithm generates a solution (in this case, a set of routes) and feeds it to the simulation model, which computes the fitness (in this case, carbon dioxide emissions and violations of temporal constraints). Based on the evaluation feedback obtained from the simulation model, the optimization algorithm generates a new set of parameter values and the generation–evaluation process continues until a user-defined stopping criterion is satisfied (April et al., 2004). Such a criterion may, for example, be that a certain amount of time has passed or that specific objective values have been achieved (Boesel et al., 2001).

The next section describes how the simulation-based optimization is integrated in a DSS for improved waste collection from a sustainability perspective.

DEVELOPMENT OF THE DECISION SUPPORT SYSTEM

The DSS was designed in close collaboration with the Swedish waste management company AÖS to ensure the system's real-world usability. An iterative prototyping approach was used in which the system was gradually developed based on feedback from domain experts (i.e., its future users). From a conceptual perspective, the system consists of three parts: (a) the back-end, (b) the driver's front-end, and (c) the transportation planner's front-end. All parts share a software infrastructure and use the same database for accessing information to ensure that all users can always access complete and consistent data. The common software infrastructure handles basic data such as information about customers, trucks, facilities, routes, users, etc. It also provides services to view and manipulate data.

Figure 6. Simulation–optimization process



EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

DSS Back-End

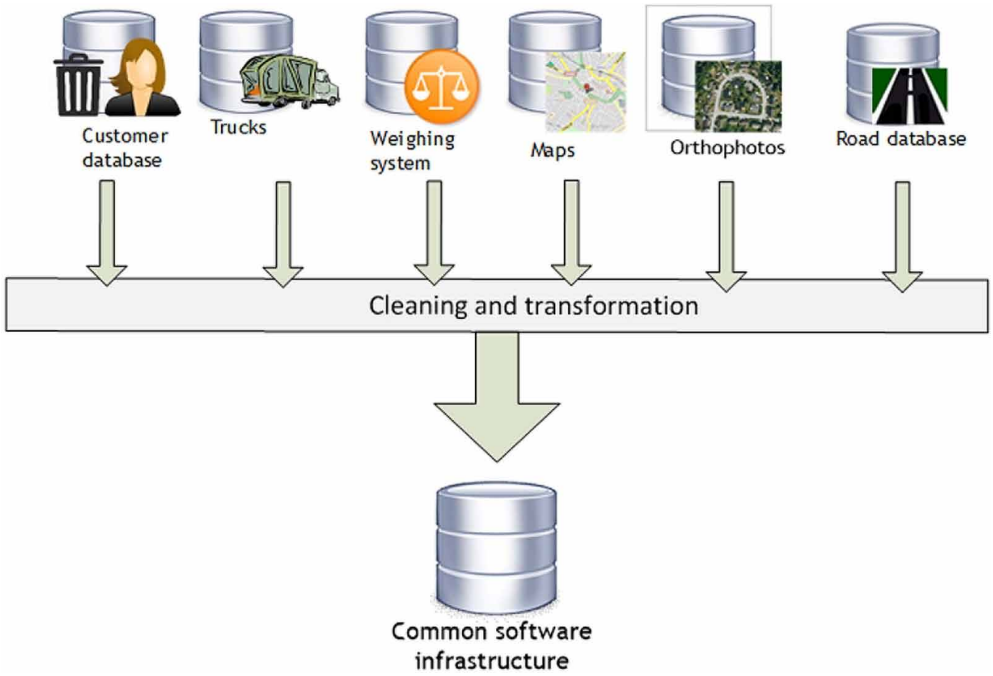
To provide complete, dynamic, and updated information to the users, the DSS programmatically integrates various data sources (Figure 7). These include map services, orthophotos (similar to satellite photos), road data, vehicle tracking systems, weighing systems, and customer databases. The various data sources are both on-line and off-line in nature and data synchronization occurs either regularly based on a synchronization schedule or on-demand as follows:

- **Maps and Orthophotos:** Synchronized on-demand when needed (e.g., when new buildings or roads appear in the community), approximately twice per year;
- **Road Data:** Synchronized on-demand when the Swedish Transport Administration releases major updates;
- **Vehicle Tracking:** Automatically synchronized every second;
- **Weighing Data:** Automatically synchronized as soon as a vehicle unloads at a recycling facility;
- **Customer Databases:** Automatically synchronized every 15 minutes.

Transportation Planner's Front-End

The transportation planner's front-end includes all the functionality needed to plan, optimize, and operate the waste collection process. An early decision in the development process was to make the system web-based so it would be accessible from anywhere with an Internet connection, and not only from a specific computer with specific software installed. An important part of the transportation planner's front-end

Figure 7. DSS back-end



EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

is the display of dynamic information and the opportunity to constantly monitor what is happening in real time. To facilitate this, current status information is the first thing viewed when the user logs into the system (see Figure 8). The status view shows, for example, the location of each truck, how much of each collection route has been completed, and the locations where problems have arisen.

The system also shows all routes for all trucks on the current day, as well as past and future routes. All routes are generated using the previously described simulation-based optimization system. An example of a route of one truck is shown in Figure 9. Each blue/purple dot on the map indicates a bin to be visited, which are also shown in an ordered list on the left.

On the current day, the route of an individual truck can also be monitored and manipulated in real time. Figure 10 shows a route currently being traversed by a vehicle. A green dot (and its corresponding row in the list to the left) indicates that the bin has been emptied without any problem. A red dot indicates that the bin could not be emptied and more information about the reason for this is given if the user clicks on the dot. Blue dots are bins that have not yet been visited. The position of the truck in relation to the bins is also shown on the map and updated in real time, making it possible to monitor the progress of the route in detail.

Several times per day, customers call the transportation planner to say that their bins have been overfilled and must be emptied immediately, although the bin is not part of any route on that day. To help the transportation planner handle suddenly arising requests and ensure that they add as little extra environmental load as possible, the DSS includes a real-time optimization function. This function checks where all the trucks are located, their current loads, their planned routes for the rest of the day, and their current progress in relation to what is left of the workday. Based on this information, the real-time optimization function automatically assigns the request to the truck that is optimal in terms of minimal emissions. The request is immediately communicated to the driver's front-end, which is described in the next subsection.

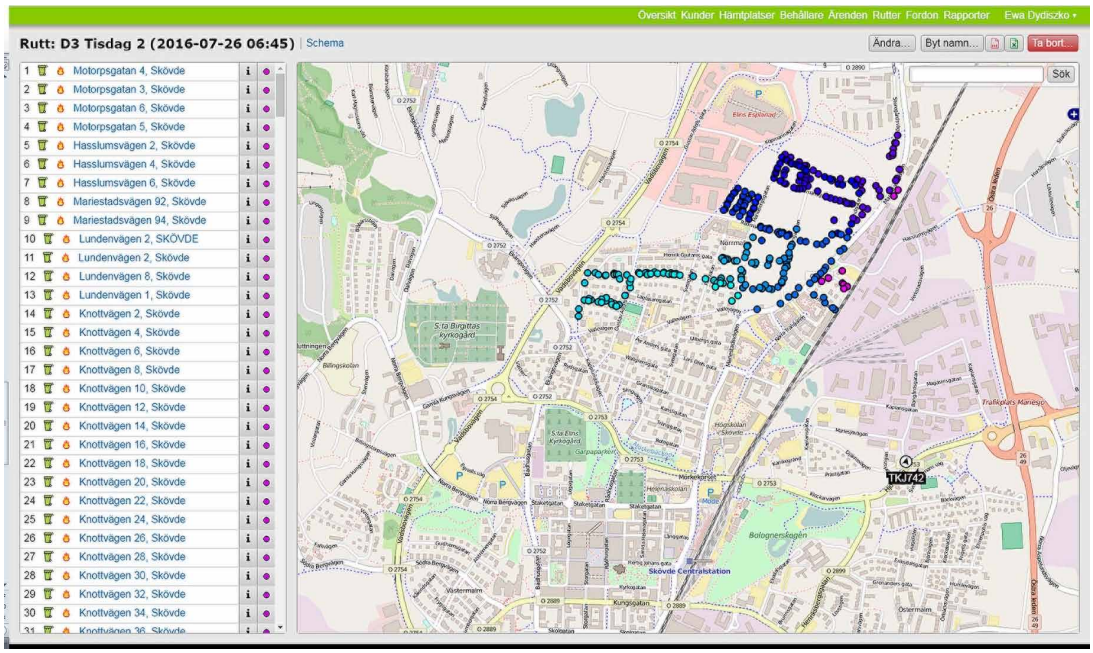

Figure 10. Overview of a route currently being executed

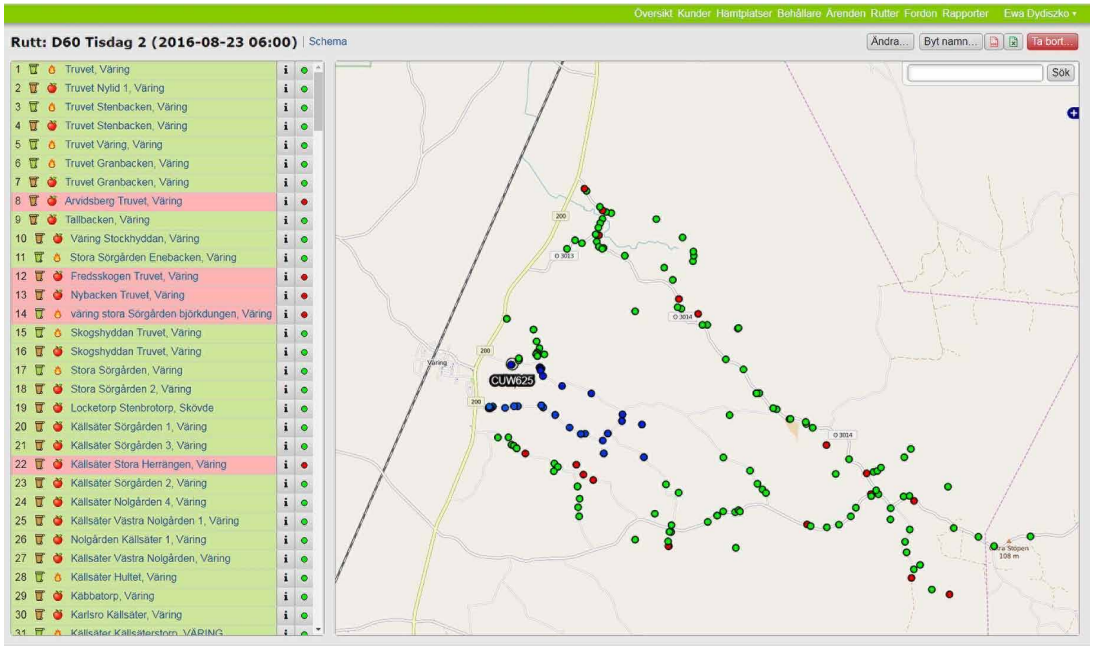


EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Driver's Front-End

The driver's front-end is Android based and accessed through a 10" tablet available in the truck. The front-end has been designed in close collaboration with drivers, starting with a "blank slate" and successfully adding functionality according to driver requirements. The front-end shows what bins to visit during the day, in what order, and the current status of each bin—similar to the transportation planner's front-end shown in Figure 11. Through the tablet, the driver can also report when a bin has been emptied and also various problems encountered when traversing the route. Problems might, for example, be related to parked cars blocking bins, traffic accidents, or hidden bins. A screenshot of the driver's front-end is shown in Figure 11.

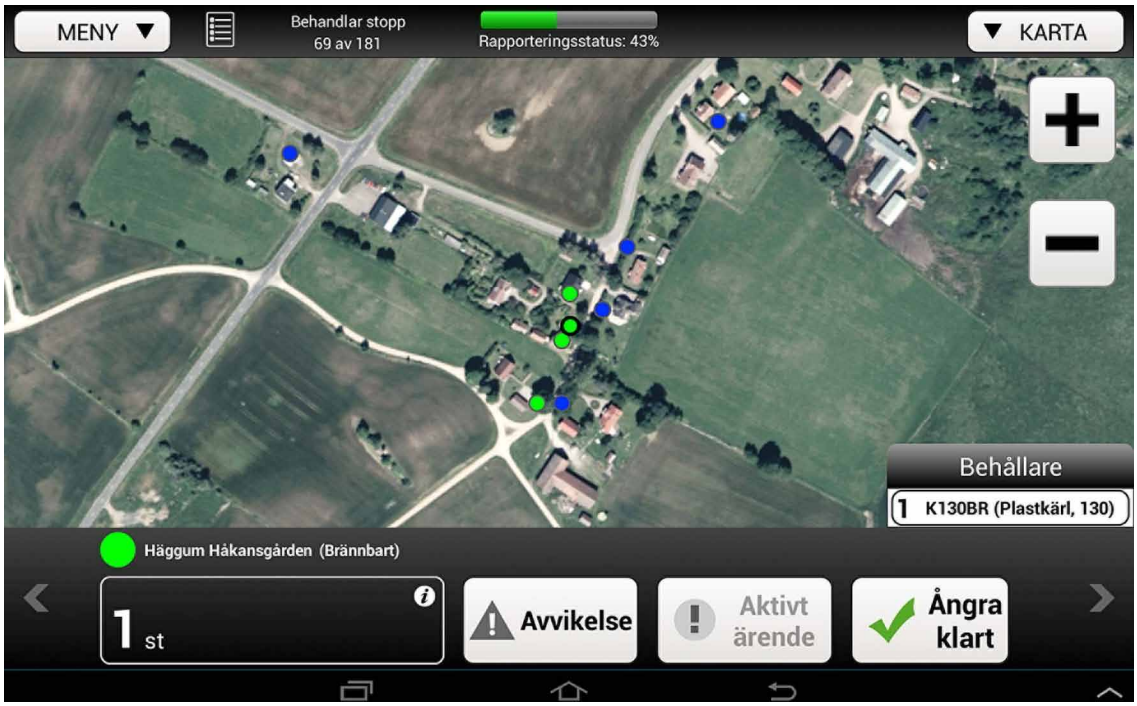
The truck is equipped with a communication unit that provides access to the mobile network, allowing the vehicle to communicate with the base system in real time. This enables direct communication between the driver and the transportation planner, who can instantly send information to each other.

The next section evaluates the sustainability gains made using the described DSS.

EVALUATING THE DSS FROM A SUSTAINABILITY PERSPECTIVE

To assess the sustainability gains made using the DSS, a case study was conducted. For the case study, we selected one of the nine municipalities served by AÖS, which includes approximately 17,000 unique bins spread over an area of approximately 40 × 50 km. For the reader to grasp the problem, the geographical locations of the bins are plotted on maps shown in Figure 12 and Figure 13 (the latter zooms in on part of

Figure 11. Driver's front-end



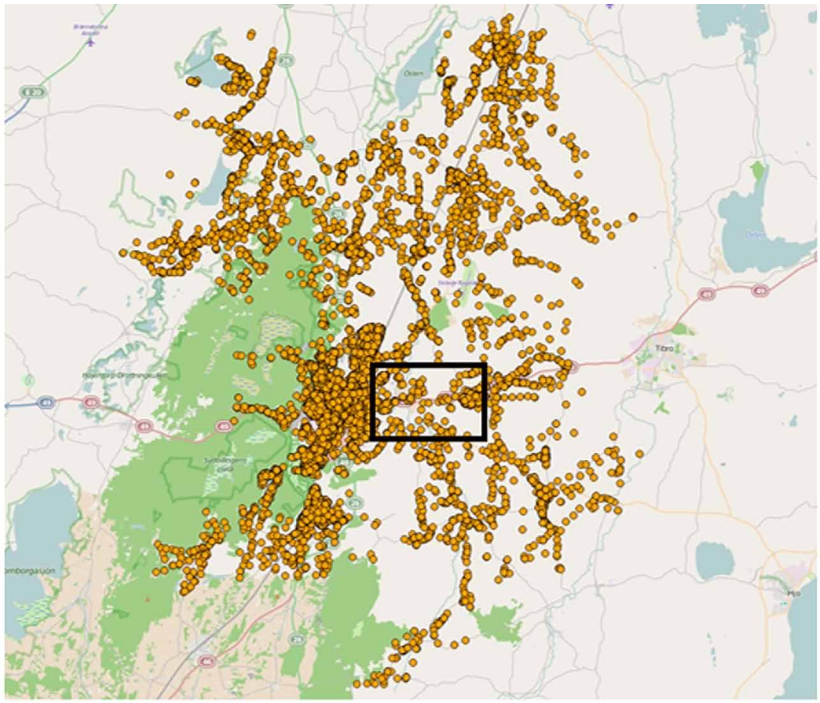
EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

the former). Three trucks are available for emptying the selected bins, and each of them empties on average approximately 550 bins per day. This means that a unique route should be created for each truck and each workday during a 14-day period (excluding Saturdays and Sundays). If successful, the optimization will reduce the driving distance and possibly also free one or several trucks for one or several days, which would save a great deal in terms of both the emissions and costs associated with the collection process.

Each truck has a limited capacity in terms of both weight and volume, and when this capacity is reached must be emptied. Emptying is done either at a recycling center (for compostables and corrugated cardboard) or at a heating plant (for combustible waste). Because different kinds of waste must be deposited in different places, different types of waste cannot be mixed in the truck. All these constraints are fed into the simulation-based optimization process and labeled mandatory, meaning that a route that violates any of the constraints is considered invalid and of no value.

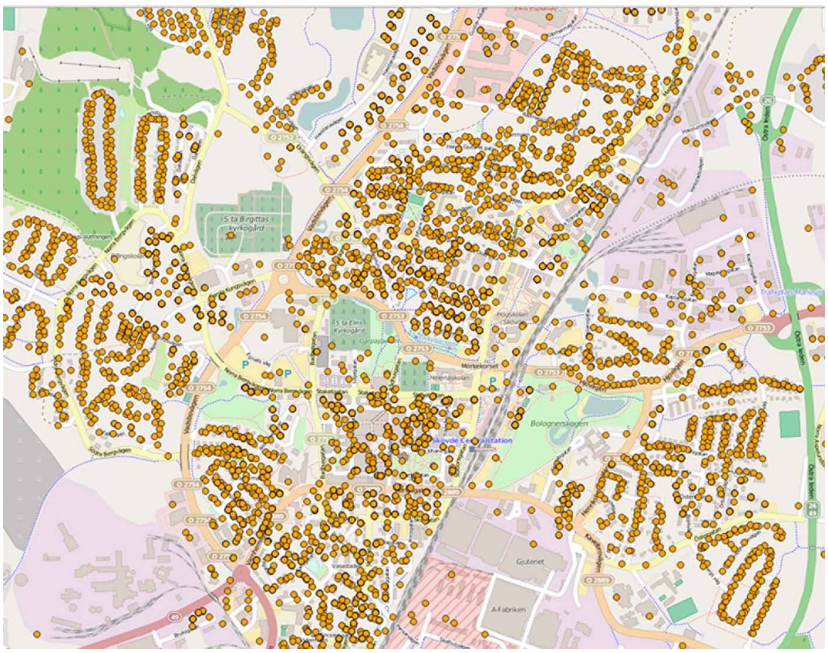
The routes resulting from the most successful optimization runs were presented to domain experts in the waste management organization, who carefully studied and evaluated them. The domain experts estimated that the optimized routes would reduce the operating times of the trucks by approximately 25% compared with the operating times for the routes created manually by the transportation planner. The operating time of a truck denotes the time its engine is running (either in motion or stationary) and corresponds directly to the amount of emissions from the truck. As mentioned in the Introduction, a garbage truck consumes on average approximately 30,000 liters of diesel per year, corresponding to approximately 85,200 kg of carbon dioxide and 747 kg of nitrogen oxides. A 25% reduction in emissions therefore means that 21,300 kg of carbon dioxide and 187 kg of nitrogen oxides per truck and year can be saved using the DSS, which is a substantial environmental saving.

Figure 12. Garbage bins included in the optimization



EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 13. Zoomed-in view of the area corresponding to the black square in Figure 5



Considering the economic aspect of sustainability, a 25% reduction in the operating time of the trucks also represents substantial economic savings, not least related to staffing. The trucks are operated by one or two drivers and, because labor costs are very high in Sweden, as in most industrialized countries, reduced staffing needs correspond to substantial financial savings. Furthermore, less driving also means that considerable money can be saved on fuel.

Considering the social aspect of sustainability, this is improved mostly through the real-time optimization function in the DSS. This function can improve customer service, ensuring that all urgent customer requests are handled promptly. Reduced waste collection costs also mean that the associated fee could be reduced for citizens.

CONCLUSION

This paper presents a decision support system (DSS) for improving the waste collection process from a sustainability perspective. Currently, waste collection schedules and routes are created manually in most waste management organizations. This is both very time consuming and likely to result in poor solutions, as the task is extremely difficult due to the large number of bins combined with the many parameters to be considered simultaneously. With a sophisticated DSS, it becomes possible to address the complexities of optimal waste collection and improve sustainability—not least from the environmental perspective.

In the proposed DSS, the overall waste collection problem is approached as a pickup and delivery problem (PDP), while the lower-level optimization problem of finding the best possible route linking a number of selected bins is approached as a traveling salesman problem (TSP). To solve the problem, i.e., find optimal solutions, a multi-objective evolutionary algorithm is implemented. The evolutionary

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

algorithm uses a discrete-event simulation model to evaluate and assess the feasibility of various solutions. This model closely mimics the real waste collection process and can be used for testing various scenarios.

The proposed DSS was designed to be used on the operational level in waste management organizations, where it supports daily operations and activities. From a conceptual perspective, the system consists of three parts: (a) the back-end, (b) the driver's front-end, and (c) the transportation planner's front-end. All parts share a software infrastructure and use the same database for accessing information to ensure that all users can always access complete and consistent data. To ensure the real-world usability of the DSS, it was designed and evaluated in collaboration with the Swedish waste management company AÖS.

To assess the sustainability gains made using the DSS, a case study was conducted examining one of the municipalities served by AÖS, which includes approximately 17,000 households. An optimization was run in the case study and domain experts estimated that the truck operating time would be reduced by approximately 25% compared with the operating times for the routes created manually. For an average garbage truck, using the proposed DSS would prevent the release of approximately 21,300 kg of carbon dioxide and 187 kg of nitrogen oxides per year. There are also considerable cost savings, not least related to staffing and fuel costs. Besides the environmental and economic improvements, the system would also provide improved customer service and the opportunity to handle urgent customer requests efficiently.

From a broader perspective, the potential sustainability gains with a DSS like the one proposed here are enormous. In Sweden, approximately 2000 garbage trucks serve households, in Europe approximately 90,000, and in the rest of the western world approximately 400,000. Although a 25% improvement might not be reached in all waste management organizations, even a small improvement means a huge reduction in carbon dioxide emissions if the DSS were broadly adopted. For example, assuming an average improvement as low as 5%, over two billion kg of carbon dioxide emissions would be prevented every year. It should also be noted that the numbers of trucks mentioned include only trucks serving households; the total number of garbage trucks is much larger if we also include trucks serving industries and recycling facilities.

To large extent, the results of the study are generic and can be applied in other domains as well. Many examples of pickup and delivery problems are encountered in everyday life, such as parcel, dial-a-ride, and postal services. The underlying simulation and optimization approach implemented in the DSS is generic and can be applied to essentially any PDP. The technical infrastructure of the system is also generic and can be reduced for other applications. The front-ends, however, need to be tailored to each specific application domain, although many concepts can certainly be reused.

Future work will concentrate on the possibility of incorporating additional data sources in the back-end of the DSS to improve system efficiency. With more information available, it will be possible to improve the optimization results and it might also be possible to realize real-time optimizations with a one-to-one mapping to the real world. Both internal company and external public data sources will be considered for inclusion.

Chapter 17
SCOR Model and the Green Supply Chain

Ulas Akkucuk
Bogazici University, Turkey

ABSTRACT

Supply chain management (SCM) is a continually evolving field, relying on breaking down internal and external organizational barriers to gain efficiencies, improve customer support and increase flexibility, thereby resulting in lower costs and increased market share. An emerging area in supply chain practice is green SCM, which integrates environmental management with traditional SCM. Green supply chain management is seen as an important step companies need to take on the road to sustainable practices. SCOR Model (Supply Chain Operations Reference) has been developed by the Supply Chain Council (SCC now merged with APICS) in order to guide companies applying SCM principles. The GreenSCOR model was also developed as an integrated green SCM tool that allows companies to manage their supply chain's environmental impacts, resulting in more efficient operations which have minimal impact on the environment. This chapter will talk about how SCM principles can be modified to reduce the adverse effects of company operations on the environment, especially using the GreenSCOR model.

INTRODUCTION

Supply chain management (abbreviated as SCM) is a continually developing field, relying on breaking down internal and external organizational barriers to gain efficiencies, improve customer support and increase flexibility, thereby resulting in lower costs and increased market share. An emerging area in supply chain practice is green supply chain management, which incorporates environmental management with traditional supply chain management. Green supply chain management is seen as an important stride companies need to take on the road to sustainable practices. SCOR Model (Supply Chain Operations Reference) has been developed by the Supply Chain Council (SCC is now merged with APICS) in order to guide companies applying SCM principles. The GreenSCOR model was also developed as an integrated green supply chain management tool that allows companies to manage their supply chain's

environmental impacts, resulting in more efficient operations which have minimal impact on the environment. This chapter will talk about how SCM principles can be modified to reduce the adverse effects of company operations on the environment, especially using the GreenSCOR model.

Supply chain management involves all facilities, functions, and activities associated with flow and transformation of goods and services from raw materials to customer, as well as the associated information flows (Russel & Taylor, 2008). SCM can be regarded as an integrated group of processes to "source," "make," and "deliver" products. Namely SCM deals with the corporate functions of procurement, production and distribution. SCM can be applied in service industries (hospitals, fast food, supermarkets, retail), petroleum industries, chemicals industries (continuous processes), textile industries (ready to wear clothing) and many others. The specific SCM applications are influenced by type of process (continuous, batch, project, mass production), number of stock keeping units (SKU's) and government regulations among other factors.

Sustainable supply chains are becoming more important as firms focus on the resource consequences of the operations that they carry out. The three P's of sustainability can be listed as People, Profits and Planet. These concepts can easily be applied to supply chain operations as well. As the world population is increasing the waste generated also increases. The growing waste problem can be reduced by applying the principles of 4R many of which are related to the operations of the supply chain:

- **Reduce:** For example, designing concentrated detergent that uses less packaging,
- **Reuse:** Using reusable packaging,
- **Recycle:** Packages used in transportation can be recycled and turned into new packages,
- **Recover:** Energy can be gained from waste.

Creating a sustainable supply chain can start with the design of the products. Products can be designed in such as way so as to consume less materials, result in less transportation costs and be easily disassembled so that parts can be used for remanufacture or refurbishing. As an example, polyester fabric 100% recyclable, polar fleece may be made by recycled soda bottles, also the new BMW i30 interior is made from recycled materials. Firms can generally follow these principles for design for the environment or DFE:

- Use fewer materials.
- Use recycled materials or recovered components.
- Don't assume that natural materials are always better.
- Don't forget energy consumption.
- Extend the useful life of the product.
- Involve the entire supply chain so they share the responsibility in terms of the environmental impact.
- Change designs, some consumers' solutions may require services rather than products, an example could be using laundry services rather than selling washing machines.

We can see Walmart as an example of applying the above principles. Package reduction in certain toy lines reduced transportation costs by $2.4 M/year which is equivalent to 3800 trees and 1 billion barrels of oil. Stores use solar panels, windmills, and skylight thereby reducing the power consumption. Spoiled food is composted and resold as fertilizer using a 0% waste policy. Stores sell power saving light bulbs such as Compact Fluorescent (CFL) or LED lights.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Recycling can be defined as the process to change (waste) materials into new products to prevent waste of potentially useful materials, reduce the consumption of fresh raw materials, reduce energy usage, reduce air pollution (from incineration) and water pollution (from landfilling) by reducing the need for "conventional" waste disposal, and lower greenhouse gas emissions as compared to plastic production. The following materials and more can be recycled (EPA, 2015):

- **Iron:** Ferrous Metals include iron and iron-containing metal scrap. Ferrous metal is handled in the same manner as non-ferrous metal, but generally has lower market value.
- **Steel:** Tin-Coated Steel Containers Includes cans used for food packaging (i.e., canned foods). Some local recyclers might require cans to be cleaned and crushed with labels removed. Bimetal Containers: A typical example includes tin-plated steel cans with aluminum "pop top" (e.g., peanut cans). These containers can be separated from aluminum cans by using a magnet. Many recyclers accept bimetal containers with tin-coated cans.
- **Copper:** Non-Ferrous Metals include most types of scrap metal which do not contain iron (such as copper and brass). This scrap can be a relatively valuable commodity, depending on quantity. It is often recycled through scrap metal dealers, although some general recyclers will handle it with other materials.
- **Aluminum:** Included in this category are aluminum beverage cans, as well as clean aluminum scrap and aluminum foil. Currently, aluminum is a highly valued material for recycling.
- Lead.
- **Batteries:** Lead-acid batteries are used in automobiles, back-up lighting systems, lawn mowers, and computers. Lead-acid batteries contain lead, a toxic metal and sulfuric acid. Many US states prohibit disposal of lead-acid batteries in municipal solid waste, and many require either retailers, wholesalers, or distributors to take back batteries. Currently, about 90 percent of lead-acid batteries used in automobiles are recycled. Household batteries come in a variety of types including alkaline, carbon-zinc, mercuric-oxide, silver-oxide, zinc-air, and nickel-cadmium. Currently, only button catteries containing mercury and silver or nickel-cadmium batteries can be recycled, often at net cost.
- **Paper:** High-Grade Paper is usually generated in office environments and can earn recycling revenues when present in sufficient quantity. Types of high-grade paper include:
    - Computer paper (also known as Computer Print Out or CPO). Can be all white or have a white main fiber with bright green or blue bars.
    - White ledger. Most white office paper, including white computer paper, copy machine paper, letterhead, white notebook paper, and white envelopes. Common contaminants include glossy paper, wax-coated paper, latex adhesive labels, envelopes with plastic windows, and carbon paper.
    - **Tab Cards:** Usually manila-colored computer cards; may be other colors but must be separated by color to be valuable as a high-grade paper.
    - **Other Papers:** These papers are less valuable than high-grade paper in terms of recycling, although they still can be cost effective to recycle in many cases. Examples of other types of paper include:
        - **Colored Ledger:** Most non-white office paper, including carbonless paper, file folders, tablet paper, colored envelopes, and yellow legal paper.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

    - **Corrugated Cardboard:** Also known as Old Corrugated Cardboard or OCC. Includes unbleached, unwaxed paper with a ruffled (corrugated) inner liner. It usually does not include linerboard or pressboard, such as cereal boxes and shoe boxes. For most business, cardboard is a cost-effective material to recycle.
    - **Newspaper:** Also known as Old News Print or ONP. It is most valued when separated from other paper types, but can be recycled as mixed waste paper.
    - **Miscellaneous Waste Paper:** Encompasses most types of clean and dry paper which do not fall into the categories mentioned above, including glossy papers, magazines, catalogs, telephone books, cards, laser-printed white ledger, windowed envelopes, paper with adhesive labels, paper bags, wrapping papers, packing paper, sticky-backed notes, and glossy advertising paper. This mixed paper has limited value in existing markets.
    - **Mixed Waste Paper:** Paper that is unsegregated by color, quantity, or grade (e.g., combination of white ledger, newsprint, colored paper, envelopes without windows, computer paper, glossy paper, etc.) Mixed paper generally sells below the price of the least valuable paper in the mix.
- **Plastics:** There are 7 types of plastics that are identified by a Society of Plastics Industry (SPI) code number ranging from 1 to 7. These numbers are usually found on the bottom of plastic containers inside a three-arrow recycling symbol. A description of each kind of plastic is presented below.
    - **PET (SPI = 1):** Polyethylene terephthalate (PET) is the most readily recyclable material at this time. It includes 1- and 2- liter clear soda bottles, as well as some bottles containing liquor, liquid cleaners, detergents, and antacids.
    - **HDPE (SPI = 2):** High-Density Polyethylene (HDPE) is currently recyclable in some areas. This class includes milk, juice, and water jugs, base cups for some plastic soda bottles, as well as bottles for laundry detergent, fabric softener, lotion, motor oil, and antifreeze.
    - **PVC (SPI = 3):** Polyvinyl Chloride (PVC, also referred to simply as "vinyl") includes bottles for cooking oil, salad dressing, floor polish, mouthwash, and liquor, as well as "blister packs" used for batteries and other hardware and toys.
    - **LDPE (SPI = 4):** Low-Density Polyethylene (LDPE) includes grocery bags, bread bags, trash bags, and a variety of other film products. LDPE is currently being recycled by some of the major retail chains.
    - **Polypropylene (SPI = 5):** Polypropylene includes a wide variety of packaging such as yogurt containers, shampoo bottles, and margarine tubs. Also cereal box liners, rope and strapping, combs, and battery cases.
    - **Polystyrene (SPI = 6):** Polystyrene includes Styrofoam coffee cups, food trays, and "clamshell" packaging, as well as some yogurt tubs, clear carry-out containers, and plastic cutlery. Foam applications are sometimes called EPA, or Expanded Polystyrene. Some recycling of polystyrene is taking place, but is limited by it low weight-to-volume ration and its value as a commodity.
    - **Other (SPI = 7):** Can refer to application which use some of the above six resins in combination or to the collection of the individual resins as mixed plastic (e.g., camera film can include several types of plastic resins). Technology exists to make useful items such as plastic "lumber" out of mixed plastic resins, but generally the materials are more useful and valuable is separated into the generic resin types described above.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

- Rubber.
- Engine oils.
- Other oils.
- Textiles.
- Tires.
- Concrete.
- X-ray films.
- Electronics.
- **Organic Waste:** There are several types of organic waste commonly recycled.
    - **Compostables:** Usually, compostable materials include food scraps and yard trimmings. Paper that cannot be recycled also can be composted.
    - **Food Scraps:** Includes grease-free organic scraps from restaurants, cafeterias, motels, and other places producing food waste. It is technically possible to compost food waste in a manner similar to yard trimmings, although additional problems with rodents and other scavengers need to be addressed. Some sates allow farmers to sterilize food waste and use it as animal feed.
    - **Yard Trimmings:** Includes landscaping debris, grass clippings, branches, and leaves. There are large-scale facilities which compost yard trimmings, producing a product that can be used for mulch, potting soil, landfill cover, and soil amendment. Also, composting can be performed directly on site or in backyards.
- **Glass:** Recycling can involve Color-separated glass. This includes all container glass that is separated into clear, green, and brown. When this glass is broken or crushed for recycling, it is called "flint," "green," and "amber" cullet, respectively. Also Mixed Color recycling can take place. This is the same as color-separated glass except clear, green, and brown glasses are mixed together. It generally has very limited market value.

To give an example of textiles or apparel, factory waste can be made into yarn or fiber, can be combined with other raw materials and made into paper, can be used as insulation material, can be burned, made into banknotes, glue and other useful products. In apparel and textile industries, "Green Marketing" efforts also force companies into using recycling as a competitive marketing tool. In effect these campaigns promote the habit of recycling among customers and promote an environmentally friendly image and help boost sales. Intimissimi as part of a global campaign started a recycling/recollection program. Similar promotional materials (adapted to culture of course) were used in different countries. With 800 stores in US and Canada American Eagles Outfitters company started a recycling and recollection effort. Boxes named "I:CO" were placed in stores and consumers were given credit for donating their clothes. Clothes are sorted into 350 different categories.

All of these activities involve the firm having a good reverse logistics infrastructure. Reverse logistics can be defined as the operations related to the reuse of products and materials. It is the process of planning, implementing, and controlling the efficient, cost effective flow of raw materials, in-process inventory, finished goods and related information from the point of consumption to the point of origin for the purpose of recapturing value or proper disposal. More precisely, reverse logistics is the process of moving goods from their typical final destination for the purpose of capturing value, or proper disposal. Remanufacturing and refurbishing activities also may be included in the definition of reverse logistics. Examples of reverse logistics can be found in:

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

- Water bottles.
- Netflix (DVD movies).
- Previously mentioned textile examples.
- Soda bottles.
- Electronics (EU mandates a certain fraction be recollected by the companies).

Some concerns reverse logistics mainly deals with would be whether or not to use reusable packaging, having a returns management (RM) system, and administering the returns management systems (maybe blacklisting consumers who return too much). Also what to do with the reverse logistics flow is another problem, several options may be donating to charity, auction, selling via outlet, remanufacture, refurbish, or send to landfill. Some terminology in reverse logistics could be summarized as follows:

- **A Channel:** Primary channel of sales.
- **B Channel:** Secondary channel for goods that have been through a reverse flow.
- **Centralized Return Center (CRC):** Facility where returns are processed.
- **Design for Disassembly (DFD):** Designing a product so it can be easily disassembled.
- **Returnable Tote:** Packaging that can be reused.

SUPPLY CHAIN COUNCIL (SCC) AND APICS

The Supply Chain Council, otherwise known as SCC, originated as Supply Chain Council, Inc. The SCC was organized in 1996 by Pittiglio Rabin Todd & McGrath (PRTM) and AMR Research, and initially included 69 voluntary member companies. SCC now has closer to 1,000 corporate members world-wide and has established international chapters in North America, Europe, Greater China, Japan, Australia/New Zealand, South East Asia, Brazil and Southern Africa. Development of additional chapters in India and South America are underway. SCC membership consists primarily practitioners representing a broad cross section of industries, including manufacturers, services, distributors, and retailers. In April 2014, it was announced that the Supply-Chain Council would merge with APICS. This merger was completed on 5 August 2014 (APICS-SCC, 2015; APICS, 2015).

SCC is an independent, non-profit global association. Formed in 1996 to create and evolve a standard industry process reference model of the supply chain for the benefit of helping companies rapidly and dramatically improve supply chain operations. SCC has established the supply chain world's most widely accepted framework – the SCOR process reference model – for evaluating and comparing supply chain activities and their performance. It can be used to describe supply chains that are very simple or very complex using a common set of definitions and enabling a common understanding. It lets companies quickly determine and compare the performance of supply chain and related operations within their company or against other companies. SCC continually advances its tools and educates members about how companies are capitalizing on those tools. With membership open to all interested organizations. In August 2014 SCC merged with APICS – American Production and Inventory Control Society.

APICS Supply Chain Council (APICS SCC) is the world's largest nonprofit supply chain organization that advances supply chains through research, benchmarking, and publications. Business leaders, academia and global enterprises gain valuable insights, information and actionable data through APICS SCC's wide supply chain network, frameworks and resources. APICS SCC maintains the Supply Chain

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Operations Reference (SCOR®) model, the supply chain management community's most broadly accepted framework for evaluating and comparing supply chain activities and performance. APICS SCC, was formed through the 2014 merger between APICS and the Supply Chain Council. APICS is the leading professional association for supply chain and operations management and the leading provider of research, education and certification programs that elevate end-to-end supply chain excellence, innovation and resilience. The APICS Certified in Production and Inventory Management (CPIM), APICS Certified Supply Chain Professional (CSCP) and APICS SCOR-P certifications are viewed as the industry standard.

SUPPLY CHAIN OPERATIONS REFERENCE (SCOR)

The SCC or APICS-SCC maintains the SCOR standard which is a supply chain process reference model containing over 200 process elements, 550 metrics, and 500 best practices including risk and environmental management. Organized around the five primary management processes of Plan, Source, Make, Deliver and Return. SCOR was developed by the industry for use as an industry open standard. Any interested organization can participate in its continual development.

SCOR model has business categories including:

- **Plan:** Processes associated with planning, scheduling, and coordinating supply chain activities.
- **Source:** Processes associated with procuring material, physically receiving material, and storing raw materials.
- **Make:** Processes associated with transforming raw material into a finished product. In defense maintenance, repair, and overhaul operations, the Make category is used to model maintenance activities.
- **Deliver:** Processes associated with storing, packaging, and delivering finished products to the customer.
- **Return:** Processes associated with delivering and receiving material from a customer to a supplier, commonly called reverse logistics.
- Enable.

Based on these processes the SCOR model defines metrics at five levels, starting from strategic level all the way to transaction level. SCOR metric can be grouped as internal facing or customer facing. In terms of level 1 strategic metrics we can talk about reliability, responsiveness and agility related metrics. Internal facing metrics are grouped into cost and asset related metrics. Some examples are given below:

- **Reliability:** The ability to deliver, on-time, complete, in the right condition, packaging and documentation to the right customer, an example is perfect order fulfillment rate.
- **Responsiveness:** The speed at which products and services are provided, for example order fulfilment cycle time.
- **Agility (Flexibility):** The ability to change (the supply-chain) in order to support changing (market) conditions, for example upside and downside supply chain adaptability metrics.
- **Cost:** The cost associated with operating the supply chain, for example Cost of Goods Sold (COGS) and supply chain management cost.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

- **Assets:** The effectiveness in managing assets in support of demand satisfaction, for example cash to cash cycle time, return on supply chain fixed assets, return on working capital.

The SCOR processes are defined in increasing levels of details beginning with a description of the overall process. The processes are further separated into process elements, tasks, and activities. Each basic supply chain is a ``chain'' of source, make, and deliver execution process elements. Each interaction of two execution processes (source-make-deliver) is a defined as a ``link'' in the supply chain. Planning sits on top of these links and manages them all. The SCOR model contains three levels of process details. Level I is the top level that handles process types, these are strategic decisions. Level II is the configuration level and deals with process categories, mainly dealing with tactical level problems. Level III is process element level and is the lowest level in the scope of the SCOR model, mainly operational day to day tasks. By providing a complete set of supply chain performance metrics, industry best practices, and enabling systems' functionality, the SCOR model allows companies to perform very thorough fact based analyses of all aspects of their current supply chain (Huang, Sheoran & Wang, 2004). Table 1 provides a list of SCOR process categories.

GREEN SUPPLY CHAIN AND SCOR

The field of Supply Chain Management evolved over the years. Initially the focus was on improving collaboration between the departments, now the focus is on increasing collaboration and information

Table 1. SCOR process categories (Huang et al., 2004)

Code	Explanation
P0	• Plan infrastructure
P1	• Plan Supply Chain
P2	• Plan Source
P3	• Plan Make
P4	• Plan Deliver
S0	• Source Infrastructure
S1	• Source Stocked Products
S2	• Source Make-To-Order Products
S3	• Source Engineer-To-Order Products
M0	• Make Infrastructure
M1	• Make-To-Stock
M2	• Make-To-Order
M3	• Engineer-To-Order
D0	• Deliver Infrastructure
D1	• Deliver Stocked Products
D2	• Deliver Make-To-Order Products
D3	• Deliver Engineer-To-Order Products

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

sharing between trading partners such as suppliers or retailers. Efficiency gains are made possible by the channel partners acting towards a common goal rather than trying to maximize their own profits. To help managers achieve these efficiencies the SCOR model was developed by the Supply Chain Council (now merged with APICS). The SCOR model offers metrics and best practices for each function of the Supply Chain. The managers responsible for the supply chain can use these metrics to continuously monitor their performance and identify areas for process improvements.

Likewise the concept of environmental management has evolved from the 1960s to the 1990s. Initially the focus was simply on building treatment plants and minimizing pollution resulting from factory operations. Now the focus is on minimizing pollution upstream in the supply chain, at the sources, suppliers, transportation and other components. Concepts such as design for environment, and life cycle analysis have evolved from this pollution prevention attitude.

Finally the goal of promoting a holistic approach to minimizing waste and harm to the environment in the supply chain resulted in the green supply chain and the green SCOR model. The Green SCOR modifies the original SCOR model to consider the environmental aspects as well. Table 2 provides the environmental impacts of the five SCOR processes.

SCOR metrics are aligned with five specific supply chain performance attributes defined by the model. Because SCOR was developed as a supply chain model, these attributes do not directly address environmental concerns. To effectively develop environmentally oriented metrics, the performance attributes should be linked to environmental impacts. Several options were investigated for managing the placement of environmental metrics, including creating a sixth attribute, Environmental Impact, which would have its own definition. In a report prepared by the Logistics Management Institute (LMI, 2003) it was stated "we wanted to avoid changing any of the fundamentals of SCOR, however, and needed to avoid creating an attribute that would be too easy to dismiss when performing analysis, thus negating the purpose of our efforts." As a compromise, parallel environmental definitions were established to use as a framework for developing environmental metrics. Table 3 (taken from LMI, 2003) shows the SCOR

Table 2. SCOR Process environmental impacts (LMI, 2003)

SCOR Process	Potential Impact
Plan	• Plan to minimize energy consumption and hazardous material usage. • Plan the handling and storage of hazardous materials. • Plan for the disposal of ordinary and hazardous waste. • Plan compliance of all supply chain activities.
Source	• Select suppliers with positive environmental records. • Select materials with environmentally friendly content. • Specify packaging requirements. • Specify delivery requirements to minimize transportation and handling requirements.
Make	• Schedule production to minimize energy consumption. • Manage waste generated during the Make process. • Manage emissions (air and water) from the Make process.
Deliver	• Minimize use of packaging materials. • Schedule shipments to minimize fuel consumption.
Return	• Schedule transportation and aggregate shipments to minimize fuel consumption; prepare returns to prevent spills of hazardous materials (oils, fuels, etc.) from damaged products.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 3. SCOR performance attribute environment linkage (Taken from LMI, 2003)

Performance Attribute	SCOR Definition	Environmental Definition
Reliability	The performance of the supply chain in delivering: the correct product, to the correct place, at the correct time, in the correct condition and packaging, in the correct quantity, with the correct documentation, to the correct customer.	The ability to deliver the correct product reduces waste from product discards; reduces air emissions and fuel use from extra transportation for returned products. Proper documentation enables all players of the supply chain to keep better track of hazardous materials or toxins that are embedded in certain products; thus allowing them to arrange for proper storage, handling, and disposal.
Responsiveness	The velocity at which a supply chain provides products to the customer.	The environmental impacts that affect the speed of material movement, including regulatory or pollution control steps within a process.
Flexibility	The agility of a supply chain in responding to marketplace changes to gain or maintain competitive advantage.	The degree to which a firm can meet the environmental demands of its customers. This pertains to the products, their production, transportation and recyclability, etc.
Costs	The costs associated with operating the supply chain.	The costs of environmental compliance and cleanup as well as energy costs.
Asset Management Efficiency	The effectiveness of an organization in managing assets to support demand satisfaction. This includes the management of all assets: fixed and working capital.	Managing assets in a manner that reduces environmental impacts and reduces internal costs.

performance attribute definitions with their corresponding environmental definitions. The environmental definitions assist only as a guide to assist the development of metrics. They ensure the metrics for each process element are consistent; they are not endorsed for addition to the SCOR model itself.

There might be some obstacles to implementing a green supply chain in some industries, as explained by Luthra et al. (2011) "Market Competition and Uncertainty; Lack of Implementing Green Practices; Cost Implications; Unawareness of Customers and Supplier Reluctance to Change Towards GSCM have been identified as dependent variables. Lack of Government Support Systems; Lack of Top Management Commitment and Lack of IT Implementation have been identified as the driver variables. Resistance to Technology Advancement Adoption; Lack of Organization Encouragement and Poor Quality of Human Resources have been identified as the linkage variables. No barrier has been identified as autonomous variable. Market Competition and Uncertainty; Lack of Implementing Green Practices; Cost Implications; Unawareness of Customers have been identified as top level barriers and Lack of Government Support Systems as most important bottom level barrier. Removal of these barriers will be helpful in implementing GSCM in Indian automobile industry."

As it is well know some forms choose to use third party companies for running their logistics operations. 3PL logistics has grown in importance as firms like to focus on their core skills. Logistics industry itself contributes heavily to greenhouse gasses. Considerable efforts are under way in order to green the industry. Vural (2015) provides the following examples presented in Table 4 at three levels of greening for the logistics industry.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 4. Examples for greening strategies of logistics service providers (taken from Vural, 2015)

	Tactical Greening	Quasi-Strategic Greening	Strategic Greening
Targeting	Participating ecological and industrial fairs to catch environmentally conscious logistics customers	Adoption of an environmental management system (EMS) for industrial customers that set this as supplier selection criteria.	Launching a new service line that offers a seamless logistics solution with lowered carbon emission impact.
Green Design	Changing the existing truck fleet with new generation trucks with low emission motors.	Transforming the delivery process into a consolidated system in order to avoid empty haulage through extensive use of information technology	Conducting a life cycle analysis for logistics services provided by the company and developing solutions for the environmentally harmful processes within them
Green Positioning	Giving an interview to a sector periodical to emphasize the green aspects of its transportation services	Communicating the number of trees that a logistics service provider plants for every unit of carbon emission that its services produce	Integrating corporate environmental objectives with values, vision and mission statements and communicating them with the stakeholders
Green Pricing	Reducing the cost of packaging through designing backhaul transport for reusable containers	Offering incentives for customers who prefer a slower but less harmful transportation solution such as intermodal transport	Initiating carbon trade with customers who save carbon emission units at one logistics service they purchase for future use in other logistics services they will buy
Greening Logistics	Changing the raw material for pallets into recyclable plastics from wood	Reducing the number of warehouses and consolidating the inventory at larger stock points	Converting all of the offices located in different parts of the world into green offices
Marketing Waste	Reducing carbon emission waste by using environmentally friendlier transportation modes such as rail and sea	Collecting and selling old truck tires to recycling organizations	Establishing a reverse logistics branch as a separate business unit and providing services through reverse channels
Green Promotion	Sending tree plantation certificates as gifts to industrial customers that exceed a specific transportation volume with the company	Issuing annual environmental performance reports via the website and other frequently followed channels	Launching a CSR campaign with a non-profit organization like Greenpeace to share a percentage of logistics service sales with the elimination of adverse environmental impacts of logistics industry accidents
Green Alliances	Cooperating with a university in order to minimize its energy usage in one of its warehouses	Making an agreement with an accreditation company in order to transform all its warehouses into green buildings	Joining green logistics associations or research groups in order to foster new solutions and innovation for environmental problems

CONCLUSION

It is getting more and more important for firms to realize that the resources the earth can provide us are limited and that production and distribution operations consuming large amounts of resources are responsible for air, land and sea pollution and global warming. One way that companies can reduce their negative impact on the environment is through the application of green supply chain and Green SCOR model. Companies are under extreme competitive pressures in order to act in an environmentally responsible way. Greening their supply chains is gaining fast ground as an alternative to achieve this purpose (Sarkis, 2006).

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Firms are generally held accountable for the labor practices and environmental impact of their suppliers as well (Bacallan, 2000). Companies may have nothing to do with the practices of their suppliers and legally they may not be challenged, however the public opinion will change against them dramatically. Controlling all parts of the supply chain upstream and downstream may prove to be a valuable technique in terms of reducing such negative backlash.

Manufacturers are increasingly recycling and remanufacturing their post-consumer products due to higher levels of public awareness, strict legislation and extended producer responsibility (McGovern & Gupta, 2011). There are also economic incentives for reusing parts or subassemblies instead of throwing them away. Recycling can be seen as a method to extract the useful content from used or nonfunctioning products. Remanufacturing is a method to bring some used parts to like-new condition. Product recovery tries to use recycling and remanufacturing in order to minimize the amount of waste sent to landfills. Disassembly systems are designed in order to extract these parts as efficiently as possible from the used parts. Issues such as modular design and identification pf parts by color codes makes the disassembly process easier and these issues need to be considered in the design of the products.

We should also talk about the long term impact of green laws passed in some western countries including the European Union. The EU has been heavily focused on the development and adoption of green laws intended to reduce or eliminate adverse environmental impact of companies (Blumberg, 2005). The initial focus was in Germany and in Northern European countries such as Norway and Denmark where environmental impact is an important issue. Much of the focus was concentrated on waste materials and recycling, but in the recent years focus has shifted to disposal of products and technology. The essence of the new laws was that the Original Equipment Manufacturer (otherwise known as OEM) would take the final responsibility for the disposal of that product. Laws could hold the OEM responsible for any physical or economics damage resulting from the improper disposal of that technology.

Waste of electrical and electronic equipment (WEEE) such as computers, TV-sets, fridges and cell phones is one the fastest growing waste streams in the EU, with some 9 million tons generated in 2005, and expected to grow to more than 12 million tons by 2020. WEEE is a complex mixture of materials and components that because of their hazardous content, and if not properly managed, can cause major environmental and health problems. Moreover, the production of modern electronics requires the use of scarce and expensive resources (e.g. around 10% of total gold worldwide is used for their production). To improve the environmental management of WEEE and to contribute to a circular economy and enhance resource efficiency the improvement of collection, treatment and recycling of electronics at the end of their life is essential. To address these problems two pieces of legislation have been put in place: The Directive on waste electrical and electronic equipment (WEEE Directive) and the Directive on the restriction of the use of certain hazardous substances in electrical and electronic equipment (RoHS Directive). The first WEEE Directive (Directive 2002/96/EC) entered into force in February 2003. The Directive provided for the creation of collection schemes where consumers return their WEEE free of charge. These schemes aim to increase the recycling of WEEE and/or re-use. In December 2008, the European Commission proposed to revise the Directive in order to tackle the fast increasing waste stream. The new WEEE Directive 2012/19/EU entered into force on 13 August 2012 and became effective on 14 February 2014 (EC, 2015).

Taking into consideration all of the important developments concerning green manufacturing, green marketing and a generally increased level of green consciousness it is evident that firms will receive payoffs for implementing green practices in their supply chains. The SCOR model turns out to be a useful tool that environmentally conscious firms can implement to make their supply chain greener. The most

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

important reason for this is that the SCOR model provides a common supply-chain framework, standard terminology, common metrics with associated benchmarks, and best practices. The model can be used for evaluating, positioning, and implementing supply-chain application software. This paper argued that the SCOR model should consider the green supply chain and discussed issues related to the use of SCOR performance metrics for greening the supply chain. It is intended to serve as a facilitator for SCC and APICS to further enhance the Green-SCOR model and eventually make it an industry standard for environmentally conscious companies.

KEY TERMS AND DEFINITIONS

APICS: Acronym for the American Production and Inventory Control Society, APICS is the premier professional association for supply chain and operations management and the leading provider of research, education and certification programs that elevate supply chain excellence, innovation and resilience.

DFE: Acronym for Design for Environment, DFE-design for environment-involves designing products from recycled materials, using components that can be recycled, designing a product easier to repair than discard, and minimize unnecessary packaging.

EPR: Acronym for Extended Producer Responsibility, EPR-extended producer responsibility- producers are responsible for their products even after their useful life.

Green SCOR: An extension of the SCOR model to cover environmental areas and sustainability issues for the logistics and production related areas.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

LCA: Life Cycle Analysis is a technique to assess the environmental aspects and potential impacts associated with a product, process, or service, by (1) Compiling an inventory of relevant energy and material inputs and environmental releases, (2) Evaluating the potential environmental impacts associated with identified inputs and releases, (3) Interpreting the results to help you make a more informed decision.

LCEA: Life cycle energy analysis is an approach in which all energy inputs to a product are accounted for, not only direct energy inputs during manufacture, but also all energy inputs needed to produce components, materials and services needed for the manufacturing process.

Recycling: Series of activities by which discarded materials are collected, sorted, processed and used in the production of new products.

Refurbishing: To renovate and recondition a used product to a certain level, perhaps not as high as in remanufacturing.

Remanufacturing: To disassemble a used product completely and inspect all modules and parts. Worn out parts are replaced to bring the quality standard of final product to like-new condition.

SCC: Acronym for the Supply Chain Council now merged with APICS.

SCM: Acronym for Supply Chain Management, Supply chain management involves all facilities, functions, and activities associated with flow and transformation of goods and services from raw materials to customer, as well as the associated information flows.

SCOR: Acronym for Supply Chain Operations Reference, a set of guidelines providing metrics and best practices for supply chain functions of procurement, production, delivery, and return.

Sustainable Operations: Performance measures and continuous improvement are the components necessary to translate sustainable corporate strategy into sustainable operations, using an integrated quality, environmental and safety management system. Sustainable operations entail total quality management, sustainability, environmental stewardship and process safety.

Chapter 18
Participation Framework to Sustainability:
The Undercurrents in Bottled-Water Production and Consumption

Taksina Chai-Ittipornwong
Muban Chombueng Rajabhat University, Thailand

ABSTRACT

The topic of bottled water is particularly timely since water crisis and waste plastics are shifting from one of problem-framing to what is much more concerned to climate agenda. As plastics are everywhere to make life possible for a faster and convenient pace of society, bottled water has become one of the most disposable products to be consumed and disposed of, on a regular basis, both at and away from home. These eventually translate to consumer wastes causing a profound impact to the environment. The more bottles mean more greenhouse gases from production, transportation, waste bottles management, including fresh water supply. These adverse impacts are compounding a framework to justify as to how producer and consumer apply, individually and within the whole product life cycle, to sustainable consumption and production practice (SCP).

INTRODUCTION

The world has been pushing the planet away from sustainability. Humanities are shaped their lives on materially intensive economies and consumerist lifestyle regardless of living in a finite world. Many disposable products are developed to make life possible for a faster and convenient pace of society. Bottled water has become one of the most common plastic products to be consumed and disposed of, on a regular basis, both at and away from home. These bottles eventually translate to consumer wastes (Amano & Ness, 2004; Chamornmarn, 2008; Huber, 2010). Water and plastics are two major materials of bottled water. More bottles mean more greenhouse gases from production, transportation and waste

management, including continued risk of ecological vulnerability and water conflict with commercializing a public resource. Without greater understanding of how to produce and how to consume bottled water in sustainable ways, it may even worsen the most disagreeable impacts to the planet and future livelihoods.

Thailand was ranked near the top in bottled-water consumption in Southeast Asia and is among the top 9 consumers globally (Rodwan, 2010) In global context, bottled water has been the top end-used application of Polyethylene terephthalate (PET) plastic since its introduction into beverage packaging (Willett, 2003) According to the survey during 2008-2010, bottled-water business in Thailand maintains annual growth by 15 percent in total volume terms, with the consumption of 40,000 tons of PET plastic and 2.4 billion liters of water (Chamornmarn, 2008; Euromonitor International, 2010; Ratthanin, 2010).

The bottles can constitute various pollutions to air, water and soil quality as carbon substance is the key element of PET resin formulation. Increasingly, the ways to capture surface water supplies and underground sources are compounding the problem of water inadequacy into environmental degradation. Precisely, this chapter deals with an evidence-based case of sustainable consumption and production (SCP) implementation for PET-bottled water. Consumers' environmental awareness is evaluated whereas an input-output approach to bottling system is included to address the role of bottlers in an SCP. The undercurrents of bottled-water production and consumption are therefore closely examined for filling the gaps between socio-economic development and environmental protection.

The presumption is that if enough bottlers implement sustainable production whereas more and more consumers are aware of sustainable consumption, they can drive change towards a sustainable consumption and production of PET-bottled water. The guiding research questions are as to

1. Whether the bottled-water businesses and the consumers perform the SCP for PET-bottled water?
2. How the practice is? and
3. What the differences are in terms of resource efficiency and impact reduction?
4. How is an LCM approach contributed to the SCP success?
5. What is the most practice for bottling drinking water done in Thailand?
6. What are the environmental and health consequences occurred from PET bottles?
7. Is there any different impact compared between virgin and recycled bottles?

BACKGROUND

Sustainable Consumption and Production

In 2002, all the nations facing the climate crisis agreed not only to develop a 10-year framework of the SCP programs (the Marrakech Process)[1], but also had the SCP addressed as a prerequisite for sustainable development. The vision of sustainability was first referred to in *Our Common Future* in Bruntland Report defining sustainable development as a pathway to meet the present needs without compromising the ability of future generations to meet their own needs (Elliott, 2006).When environment lost capacity to continuously support the overexploitation placed upon it, a stronger and sensitive linkage between sustainability and socio-economic growth is truly required (Akenji & Bengtsson, 2009). Hence, sustainable practices in resource efficiency from less material consumption and less pollution have been universally addressed to handle the consequences of economic globalization and bring about sustainable development (Jones, Hillier, & Comfort, 2014).

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Definitions of SCP have been internationally discussed in many respects. SCP is linked to the adoption of sustainable lifestyle to meet the increasing demand for goods and services of both present and next generations, while improving the level of emissions and energy used or released over a product lifecycle (Giljum, Burger, Hinterberger, Lutter, & Bruckner, 2011). SCP implies the ways that humanities who live in a finite world protect the planet away from sustainability (United Nations Department of Economic and Social Affairs [UNDESA], 2010). SCP becomes an effective framework for improving resource efficiency and impact reduction occurred from the production and consumption of products and services (Cellura, Longo, & Mistretta, 2011). As such, SCP is not only essential for decoupling socio-economic growth from environmental degradation, but is also behind the success of sustainable development (Economic and Social Commission for Asia and the Pacific [ESCAP], 2011; United Nations Environment Programme [UNEP], 2015).

Many empirical studies exhibit the outcomes of SCP approach. The interaction analysis of consumption and production in China revealed that consumer's demand for energy-intensive product was the driving force of pollutant emissions (Liu, Wang, Yang, & Shi, 2010). It was substantial to apply the SCP framework for identifying energy and environmental impacts from household consumption (Cellura, Longo, & Mistretta, 2011; Zhao, 2009). An SCP offered better solution for impact management and sustainability objectives (Tukker, 2008). Resource efficiency and pollutant emission reduction were the basis of energy sustainability under the SCP domain (Sampattakul, 2010).

In completing the SCP of products and services, the roles are shared among four parties: producer (business), consumer, government and other stakeholders like retail and distributer (ESCAP, 2011). Businesses and consumers can apply individually and within the entire product life cycle for a reach of SCP (Hoff et al., 2014; Parent, Cucuzzella, & Reveret, 2013). The contributions involve responsible industrial development from supply side as well as an individual change to sustainable lifestyle in demand side (Brodhag, 2010; Raskin, Electris, & Rosen, 2010). State entity is a regulator to deliver a top-down policy to the concerns, facilitate the treatments and enforce the law and regulation. The other three elements those from supply and demand sides stand for bottom-up participation. Businesses can respond to the SCP of PET-bottled water at the early stage of product design, during bottling processes, product distribution, or even extend to the end of the useful life of product (Akenji & Bengtsson, 2009). Consumers can adopt the SCP through the patterns of use and waste handling.

A trade-off between resource efficiency and impact reduction targets is referred to in every step of SCP implementation because the valuation of resource efficiency is actually linked to a reduction of environmental impacts. Thus, the approach to impact prevention and reduction is often discussed as a component of resource consumption practice.

1. **Resource Efficiency:** On an everyday basis, natural resources are extracted and transformed to provide goods and services for supporting all social and economic activities. When people use fewer resources and generate fewer emissions, they minimize natural resource consumption as well as maximize its all benefits (Niccolucci et al., 2011; Prakash, Yogesh, Viraja, & Shilpa, 2015). Resource efficiency could be expressed in accordance with the domestic environment and import materials and goods. Consumption efficiency is based on a reduction of resource intensity, material and product flexibility, utilization of all resource benefits and applying saving technology (ESCAP, 2011). The adoption also deals with possibilities of reuse, recycling and recovery approaches, reduced risk to resource scarcity, lower environmental cost on less wastes and pollution generation and lower prices for materials and products (Liu et al., 2010; Pogutz & Micale, 2011).

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Eventually, resource efficiency can deliver the rebound effects not only to increase a demand for the goods and a growth in resource consumption, but also contradict efforts to save resources for greater efficiency.

2. **Impact Reduction:** Treatment on impact reduction implies the ways of utilizing resources and processes to eliminate pollutants and wastes generation both at the source and within the use (Vasami, 2010). Environmental and human health impacts are caused by both natural events and human activities those involving with procedures in producing and consuming goods and services. Reducing environmental impact profile includes the attempts to conserve finite resources and prevent natural resource depletion together with decreasing possibilities of greenhouse gases emission, pollutants and wastes generation (Brodhag, 2010; Veshagh & Obagun, 2007). Additional is energy used or released over the life cycle of goods and services. Potential impacts could decrease if businesses prioritize clean technologies in producing goods and services, whereas societies are aware of the precedent consumerist-lifestyle (Raskin et al., 2010; Termpittayapaisith, 2011).

PET-Bottled Water

1. **Life Cycle Management:** On a linear basis, a product is developed, produced, distributed, consumed and disposed. A product life cycle management (LCM) is very close to a reduction of carbon and ecological footprints by minimizing socio-economic burdens as well as maximizing environmental value and sustainability (Power, 2009). When LCM is reconciled with products and services, a set of activities and processes is applied to the whole product life cycle for improving impact reduction, environmental protection and sustainability (Ramani et al., 2010). LCM helps in improving the impact profile generated from every interaction with environment, directly or indirectly, both at present and in future (Harris, 2011; Hertwich, 2005; Kuczenski & Geyer, 2010).

LCM can be diversified to three perspectives: a cradle to gate, a cradle to grave, and a cradle to cradle (DuPont, 2011; Gironi & Piemonte, 2010) A cradle-to-gate LCM involves with the stages of material acquisition and manufacture as belonging to inputs and outputs from production operation in factory only. A cradle-to-grave LCM, which is an extension of the cradle-to-gate boundary, includes contributions to the retail, the use and the end of the useful life of the product. When businesses possess a partnership with customers and suppliers, the LCM is implemented from a cradle of product to a grave by thinking about sustainable processes to access sources of raw materials, to deliver materials and products and to foster environmentally-friendly practices for the end-of-useful life management. Towards a cradle-to-cradle LCM, the involvement with all stages in a product life cycle is required so that all wastes are sustainably discharged and recovered for starting a new product life cycle.

In identifying potential impacts from PET-bottled water, the LCM begins with an initial stage of material extraction (plastics and water) to material processing (productions of PET bottles and water disinfection), product manufacture (bottling system), distribution (retail of bottled water), use and reuse (bottled water consumption) and end-of-useful life management (waste bottles management) (Nestlé Waters North America, 2010). A profile of impact inventory relates to certain amount of finite resource, a series of transformations and releasing emissions of diverse natures from landfill, burning, incineration, recycling and recovery used for handling the wastes (Hauschild, Jeswiet, & Alting, 2005; Huber, 2010; Song & Hyun, 1999; Takahashi, 2010).

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

In view of many researchers, toxic substances, such as antimony, aldehydes and carcinogenic chemicals, are reasoned to health consequences caused by improper use and multiuse (Schmid, Kohler, Meierhofer, Luzi, & Wegelin, 2008; Shotyk & Krachler, 2007; Westerhoff, Prapaipong, Shock, & Hillaireau, 2008). The cause relates to direct contact between mouth and bottle after leaving it in sunlight exposure at longer time because time is dominant factor to the organic substances leaching out from PET bottle (Mutsuga et al., 2006). Logistics and transportation in distribution management are also the inclusive factors to reach efficient use of fuel energy and carbon dioxide emission reduction in the LCM of PET-bottled water (Amano & Ness, 2004; Coelho, Castro, & Gobbo, 2010; Foolmuan & Ramjeeawan, 2012; Huber, 2010; Takahashi, 2010)

a. Life cycle inventory of PET bottles. Basically, PET resin is a thermoplastic condensed between ethylene glycol with terephthalic acid forming long chains of repeating units of carbon, oxygen and hydrogen. When producing PET bottles, the resins are melted and polymerized till feasible for a pre-form injection in latter conjunction with a blow molding process. The processes consume both materials and energy while emitting much of chemical substance, including dust and debris of pollutions and acetaldehyde from the polymer degradation (Foolmuan & Ramjeeawan, 2012). Much of the fossil fuel used in the PET bottle derives from feedstock energy, which is truly bound within the product (Zhang & Kimura, 2007).

Referring to ISO 14040[2] and 14044[3], life cycle inventory (LCI) deals with the interpretation of impact categories. It means LCI implies all input-output unit processes quantified along with a product system so that environmental impact profile can appear in classification and characterization (Gironi & Piemonte, 2010). Hence, LCI refers to a compilation and quantification of input-output data against the environmental profile of a product. For examples, the impact category of global warming represents the inventory item of carbon dioxide (CO_2) while cadmium (Cd) and lead (Pb) inventories stand for the impact category of eco-toxicity and human toxicity when exposed to toxic substances.

As with the data in many researches, the LCI of PET bottles increased to the highest level when 100 percent of used bottles went to landfill (Takahashi, 2010) The waste bottles approximated 14 percent of post-used bottles were recycled (Huber, 2010) The balances ended up in landfills, lakes and streams leading to many impact consequences. PET bottles could be recycled in multiple times and into a variety of end products (Hurd, 2000) The production processes and transportation of PET polymerization and PET bottles generated higher impact on global warming than did the categories of nonrenewable energy, acidification and eutrophication (Gironi & Piemonte, 2010).

b. Recycled PET. Among all plastics types, PET resin is defined as the most recyclable plastic corresponding to the symbol of number 1 in the loop of chasing arrows. In early 1978, PET bottle was first recycled into a fiber product (Willett, 2003). It is evident that recycled-PET plastic is possibly used as 100 percent virgin material for new applications as the scraps from PET bottles could recapture resin properties for a second life either in bottles or new applications (Coelho et al., 2010; Shen, Nieuwlaar, Worrell, & Patel,2011; Vakili & Fard, 2010). In case of bottle to bottle application, the outcomes are based on the efficient use and cost effectiveness, except environmental profile (Amano & Ness, 2004; Vasami, 2010).

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

LCI of recycled PET can be changed towards many conditioning factors those including recycling rates, recycling system, sorting process, modes and distances for transport of the wastes (Vakili & Fard, 2010). Recycled PET could be optimized within three recycling trips. The multiple-recycling trips (the useful number of lives of the material) also influenced on the LCIs of both fuel energy and electricity used for processing operation and greenhouse gases emissions (Gleick & Cooley, 2009; Song & Hyun, 1999). However, there was no difference of CO_2 released from producing 10,000 units of 12-ounce PET bottle compared between virgin PET and a mix of recycled resin (Franklin Associates Ltd [FAL], 2010a, 2010b). It was revealed that the recycled resin alternated better consequences than the reuse, in terms of cheaper recycled cost and easier recycling process (Gironi & Piemonte, 2010)

c. Recycling system. Recycled PET is actually processed by two methods: mechanical recycling and chemical recycling (Hurd, 2000; Ida, 2006). Mechanical recycling is defined for material recycling, whereas chemical recycling serves feedstock recycling. Both methods have a typical processing sequence beginning with a collection and transporting, sorting and separation, and reprocessing.

In mechanical system, PET plastics are crushed and grinded into small flake for further contaminants separation. The flakes are washed and dried before feeding into an extruder where they are heated to melting state and converting into recycled PET manufacturing.

Feedstock recycling, which waste PET is chemically recycled, refers to a de-polymerization process, in which plastic polymer is broken down into the constituents-monomers. There are three main methods in PET chemical recycling: glycol for glycolysis, methanol for methanolysis, and water for hydrolysis (Vakili & Fard, 2010). In identifying the best device, the results of desired products yield and environmental impact profile are first accounted. Particularly, the category of global warming is the major impact from chemical recycling because the inventory of CO_2 derives from fuel-related emissions, not process emissions (Hurd, 2000; Vasami, 2010).

Mechanical recycling is best to recover the waste bottles for textile and yarn applications whereas the bottle application is limited to chemical recycling. A standardized procedure also influences to have waste PET recycled effectively. Development of recycling technology for waste bottles is still continued in demand to be reconciled with the growing market of PET-bottled water.

2. **Bottling System:** Upon a basis of bottling processes, the inputs of plastics and water resources are required, including utilities of electricity and fuel energy, while delivering the outcomes of bottled water and the impacts. The bottling system featured in Figure 1 displays the used resources and the outcomes against the input-output approach to PET-bottled water. Bottling system of drinking water in PET container is technically classified as the open-loop and the closed-loop processes. The difference is that the close loop begins with producing PET stretch-blow-molding bottles from PET pre-forms while the open loop sets the production of PET bottle apart.

Towards the closed-loop process, production lines of bottles manufacture and filling stage are automatically connected together. In filler room, the closed loop begins with using PET pre-forms appearing in tube-formed objects as intermediate materials to produce the formed-bottles. Then, the bottles fed by electronically-automatic system are moved forward to dust detection and elimination with an infrared light scanner and a high speed blower before filling. The infrared light is also equipped to limit

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

the volume of filled water in every bottle prior capping and labeling stages. The closures and labels are generally sourced from plastic molders, instead of the bottler's own production. Label application is an intermediate step following capping stage in the closed-loop process.

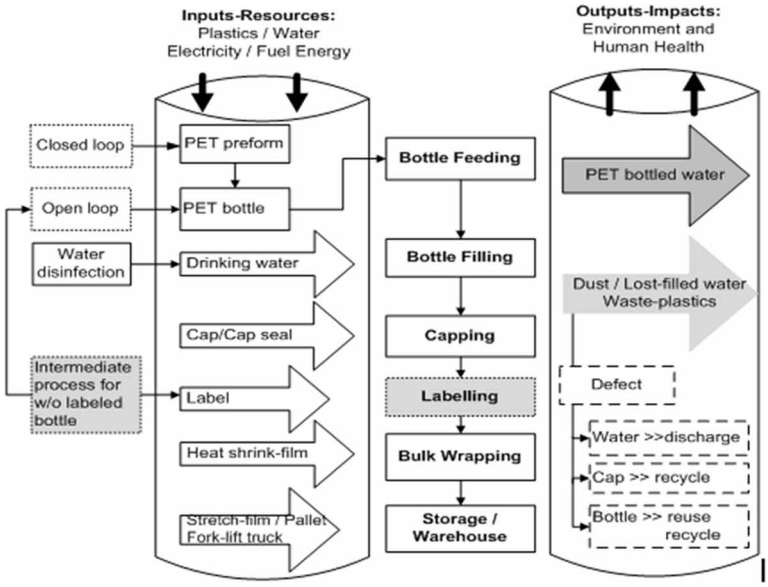
The open loop is a semi-manually-conventional process, in which returnable bottles are possibly refilled. The loop initially proceeds with a feeding of the formed-bottles, which are usually hand fed onto a conveyor to be filled with drinking water passing through orifice at a continual rate of flow. As would be true, the open loop produces the lost-filled water approximates 30 percent compared to the close loop. On the other, the bottlers investing in the open-loop process can both exclude PET bottles production from bottled-water business, or separate filling and capping stages (filler room) from labeling and bundle packaging. In case that closure wrapper is specially required, the open loop enables a separate operation of cap-sealing. It means the open loop allows the bottle to be labeled either before or after filling step. The water is also shared for cleaning the inside of the bottles before filling.

ENVIRONMENTAL AWARENESS

Environmental impacts and human health risk would decrease when societies are aware of the precedent consumerist-lifestyle for daily pleasure. Humanities generally behave to satisfy the opportunity to consume and the sense of fulfillment and satisfaction upon the experience of social life. Consumer behavior is therefore mediated through the consumption and production practices those certainly covering emissions, energy and water use, and waste produced.

When unsustainable consumption and production pattern stands out in public realm, environmental awareness becomes a stronger and sensitive device to sustain the planet. A consumption and production pattern exhibits the degree to which the market economy has shaped the surroundings and eventually

Figure 1. Bottling system of PET-bottled water on the input-output approach
Source: Author, doi:10.4028/www.scientific.net/AMR.807-809.2897



EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

the way of living (Shobeiri, 2005). In contemporary society, humanities are induced in adjusting their lifestyle towards low-carbon pattern by consuming reduced material and less energy of functional utility. This is due to the fact that consumption activities are demanding nature's resources and producing greenhouse gases at a faster rate than nature regenerated and reabsorbed (Liu et al., 2010; Sze, 2010)

Consumer behavior is not simply about the act of purchase but is rather a thoroughly cultural phenomenon that serves to legitimate capitalism on an everyday basis (Poonuchaphai, 2010) . The social experiences eventually constrain a wider recognition of sustainable lifestyle. When asked to rank what was most important to Thai people aged 13-18, playing LINE application in smart phone came first. Saving environment employed the lowest interest (Suwajittanont & Chai-ittipornwong, 2011). A sense of responsibility to care, protect and enhance environmental quality can be concerted to people if more and more environmental issues are documented through mass media, with the eco-journalism basis those relevant to verifying, informing, educating and giving a warning to news receivers. (Kaweeya, 2006).

Humanities are actually shaped their lives on social action with various factors, including the external influences of norms and values as everyone wants to be inside the mainstream behavior (Berger & Corbin, 1992) Level of environmental awareness can interpret as to how people view themselves on social agenda. The more people have education and information, the more they could account for environmental protection and a change in behavioral perception (Larijani, 2010). Environmental awareness can be expressed in the manners of environmental prevention and protection on waste and pollutant emissions, coupled with the increasing efficiency in resource consumption (Harris, 2011; Peattie, 2010). A new kind of consumers' relationship with the public realm could be constructed if environmental protection and management are truly converged with economic and humanistic values those within bio-geophysics, way of thinking and social interaction in a social system (Flor, 2004).

In psychological view, the stages of covert and overt activities and experiences, which individuals engage in their behavioral patterns, are conceptualized for an interplayed set of thought and action (Peacocke, 2006). A conceptual form of human behavior is actually linked between perception and action. Person's actions are expressed with the intention to environmental protection can represent an individually-environmental behavior linked between areas of action and the readiness to act (Brodhag, 2010). Thus, the gap between bodily action and mental action belongs to the interplay of awareness and action against consumption behavior.

In business scale, the institutional attributes to environmental issues deal with a corporate social responsibility expressed in the formats of policy, plan, project and activity. The responsibilities determine the level of environmental awareness consistent with reducing unnecessary resource depletion and sustaining resource benefits together with creating social value along a product LCM (Power, 2009; Schultz, W., Nolan, J.M., Cialdini, R.B., Goldstein, N.J., & Griskevicius, V., 2007). When businesses are conscious to reducing environmental disruption and integrating environmental care into a corporate vision, a product value chain is simultaneously reconciled with business sustainability (Po gutz & Micale, 2011; Raskin et al., 2010).

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

MAIN FOCUS OF THE CHAPTER

Potential Impacts from PET Bottles

Within characteristics of food container, PET bottle is considered a safe, healthy and convenient packaged food product as much as a more sustainable container, in terms of CO_2 emissions and energy consumption, compared to aluminum can and glass bottle (Feron, Jetten, De Kruijf, & Van Den Berg, 1994; Lehmann, Vilaplana, Strömberg, Suliman, & Rodriguez, 2005). In this section, the author set an assessment against a content ratio of resin quality for greater understanding of the impact variation from PET bottles. A tested scenario was simply arranged to three parameters: virgin PET resin, half-by-half between virgin and recycled resin, and 100 percent recycled PET resin, with functional unit of one kilogram of 500-milliliter bottle. As it was an additional part in this chapter, the parameters of virgin resin and recycled PET were based on the literature LCIs from the SimaPro 7.1 software supported by the National Metal and Materials Technology Center in Thailand. These data were computed to support the half-by-half parameter (a mix ratio of virgin-PET resin and recycled PET by 50 percent for each). Three potential impacts were focused on the categories of global warming potential (GWP), eco-toxicity and human toxicity. GWP was expressed as kg CO_2 eq. inventory (kilogram of CO_2 equivalent), while contamination of para-dichlorobenzene (1,4-DB) substance in fresh water aquatic, marine aquatic and terrestrial ecologies were translated to inventory data of both eco-toxicity and human toxicity.

As drawn in Table 1, producing PET bottles with the virgin PET delivered better result in impact reduction of every category whereas the recycled PET valued for finite resource efficiency. The highest amount of GWP (2.8108 kg CO_2 eq.) came from the recycled PET, while the mix ratio was highly sensible for the impact categories of eco-toxicity (675.5046 kg 1,4-DB eq.) and human-toxicity (0.9852 kg 1,4-DB eq.). Towards the eco-toxicity result, the marine aquatic resource was much more vulnerable than did the fresh water aquatic and terrestrial ecologies, in all parameters. It was obvious with regard to the test that PET bottles from 100 percent of virgin resin exhibited better environmental profile. Nevertheless, the discrepancy in the parameters is possibly due to quantities and types of input resources; material and utilities used upon the recycling methods. Either are selection of assigned functional unit and the coverage on PET recycling method. Sources of CO_2 emission those including process energy, transportation and non-process emissions during material management can also differ the impact profile of recycled PET. The chemical recycling requires a lot of energy in spite that there is no energy possibly recovered by landfill. The impact category of GWP between the energy use in landfill operation and the recycling system are different. That's why waste-PET bottles are mostly valuable for recycling to new applications of textiles, sheeting for vacuum packaging, office stationery and detergent bottles, instead of bottle to bottle in drinkable water application. However, LCI data varies within five percent is not considered significantly different (FAL, 2010a).

Role of Bottlers in SCP

As could be expected, bottled-water manufacturing is one of the fastest-growing businesses in Thailand. The business value approximates USD 300 million has the growth rate maintained by 15 percent since 2007. Among 6,000 bottlers throughout nation, 65 percent of the market is captured by four leading brands consisting of two local entities; Crystal and Singha, and two international brands; Namthip and Purelife. The remaining 35 percent are shared by the bottlers regarded as small and medium enterprises (SMEs) that partly own their brands and also provide bottling service as an original equipment manufacturer (OEM).

Table 1. A test scenario of potential impacts from PET bottles based on content ratio of resin quality set for three parameters: virgin PET resin, half-by-half between virgin and recycled resin, and recycled PET

Parameters (% of Quality Resin)	Impact Sensitivity (Functional Unit:1 kg of 500 ml-PET BOTTLES)					
	GWP ($KgCO_2$ eq.)	Eco-toxicity (Kg 1,4-DB eq.)				Human-toxicity (Kg 1,4-DB eq.)
		Fresh water aquatic	Marine aquatic	Terrestrial	Total	
Virgin PET	0.0494	0.0014	11.5351	0.0003	11.5368	0.0088
Virgin + Recycled 50:50 (%)	2.7364	0.0962	675.3979	0.0105	675.5046	0.9852
Recycled PET	2.8108	0.0033	544.8582	0.0022	544.8637	0.9210

PET-bottled water has widely dominated Thai consumers, and caused the decline in returnable glass bottles and the opaque bottles made of high density polyethylene polymer (HDPE bottles). The SME bottlers are most likely to produce a 500-milliliter-water weighted bottle. Either are the individual cups by 150 milliliter, or smaller bottle sizes of 330-350 milliliter. The larger pack sizes of 1000-1500 milliliter serve the highest sale volume of leading brands.

It is interesting that varieties of sustainability framework are particularly addressed for bottled-water businesses in Thailand. The measures to say exclude the FDA registration and good manufacturing practice (GMP) certification as they are mandatory bottled-water manufacture. Global quality certifications, such as ISO (International Standards Organization) 9001 for quality management system, ISO 14000 for environmental management, ISO 22000 for food safety and ISO 26000 for social responsibility, are accounted by all leading brands and some SME brands.

1. Resource efficiency:
    a. Plastics. In PET-bottled water business, efficiency in plastics consumption mostly begins with a lighter-weight bottle. A bottle with thinner wall, shorter neck (from 18 to 12 millimeter) and narrow cap (from 32 to 28 millimeter) is primary designed for reducing PET plastic consumption. PET-bottled water can employ a sustainable design or design for environment from the initial stage of development of bottle to bottling process and logistic operation. In drinking water business, the design in bottle shape and bottle body together with bottling process really compromise with the efficiency in reducing waste-in-process plastics, which can be caused by several threats, such as bottle-mold quality, uneven thickness, deviations in the spiral neck, bottle clarity, leakage and off-centered bottoms.

As results, the efficient use of plastics material is initiated from bottle-mold preparation. The design in bottle neck is also advantageous for common cap of all bottle shapes and size. Included is increasing toughness of bottle bottom for better stiffness, which is beneficiary for multi-layer stacking and storage of bundle packaging normally holding twelve bottles. The design for multi-layer stacking can helps in decreasing trip of distribution that affects reduced fuel energy consumption and distribution cost.

Among the SMEs, a device of bottle-shape harmonization across brands is another efficiency to enhance sustainability in plastic resource consumption. The leading brands do the contrary. The varieties of bottle shape and sizes, which are not valued by the SMEs, are used among the leading brands to manage

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

consumer perception to brand identity and satisfy the requirement at all aspects. Neither leading nor SME brands own the accessory production of closures, films, labels and bulk-wrapper though some SMEs experience in plastic molding. Selection of bottling process also affects the success of SCP implementation for PET-bottled water. The open loop is generally worthwhile for the brands familiar with plastic injection and blow-molding production. They can utilize their knowledge and skills to establish a cross-sector business regarding plastics injection and blow-molding and bottled-water manufacturing service.

Additionally, the most lighter-weight bottle approximates 12-13 grams for reduced plastics consumption by 30 percent and easier squeezing after use for reduced space of landfill volume. This green bottle is neither attractive nor feasible for the bottlers, except a leading brand. Due to the thinnest wall and the slightest bottle bottom, these special bottles require additional investment in nitrogen feeding connected to the bottling system. The process deals with an installation of gas feeding system and nitrogen gas reserve in a tank those requiring a more safety operation.

Recovering waste-PET bottles to new applications is less taken. The interest in advancing the recycling technology is quite low, too. A huge demand for PET-bottle scraps can distort the bottlers' interest in renewable PET technology. Thus, waste PET is less frequently recycled among Thai bottlers, with remarking on the relevant laws and regulations prohibiting use of recycled plastics for food packaging. As waste plastics are a major concern in the bottling system, amounting to 2.0 percent of all materials, the limitation of waste-in-process bottles is arranged at 0.2-0.3 percent. These wastes are sorted and sold to recycling agents since these flakes are mostly required for export market in China and India. Indeed, there is no difference between the leading brands and the SME bottlers in handling waste plastics from bottling system. The wastes are directly turned to money, instead of renewal approach.

b. Water a rapid growth of bottled water business is truly related to depletion of surface-water supplies and groundwater sources. The leading brands in Thai market mainly use underground water to produce bottled water while the SMEs bottle tap water. Efficiency in water resource is not the major concern among Thai bottlers because of the low cost of water acquisition. Nevertheless, tap water is the option providing insurance against shortages, as does a reserve of underground water that should supply the companies for approximately five years.

The open loop processes 65 -70 percent drinkable water ends up in the bottle. The rest is wasted. The lost-filled water can be reused for chilling the process before drainage, however, it cannot be recirculated to clean empty bottles or bottled and sold. The bottlers using the open loop should be aware of the substantial waste of drinkable water, which can reach 30-35 percent, which can be reduced through the close loop.

The other sensible point of water efficiency in bottling system is that the water is both a final product and a cleaning product. The open loop consumes drinking water for cleaning the inside of the bottles while the close loop processes with a high-speed blower. The discharged water is treated as clean is not appropriate for filling bottles under food-contact regulations. The closed-loop process, which seems newly for Thai-based bottling manufacturing, is equipped for all the leading brands. The SMEs, including every branch of leading brands, are common to the open loop. However, it would be inconceivable for thousands of the SMEs to switch to a closed-loop system.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

2. Impact Reduction:
    a. Plastics. The amount of PET plastics used in bottled-water businesses in Thailand is quite interesting. The SME bottlers consume PET plastic amounting to 120 tons per month, while the leading brands approximate 400 tons, excluding the peak period in the hot season (when consumption reaches 500 tons per month). It is evident that reduced use of plastics and reduced defects are major concerns to the bottlers. Except for a multi-plant policy taken by all leading brands, a truck-loaded management is accounted by the manufacturers who prefer the efficiency in reduced energy consumption and unit cost reduction to impact reduction from uses of electricity and fuel energies.

Most bottlers assert that the bottling system generates no CO_2 emissions to the air, water and soil. In case of PET pre-form blow-molding in the filler room, the closed-loop process is equipped with a cleaner technology because it enables use of electrometers and infrared device for debris and dust elimination, instead of emitting to the air. For the open loop, the bottles are supplied by PET-bottle manufacturing. The outsource supply becomes an excuse by the bottlers that no emission is generated in the open-loop bottling system.

Based on LCM perspective, the attempts to impact reduction direct to a cradle-to-grave module. The cap-seal wrapper is modified to every bottle to ensure a primary use in health concern. Additional is the communicated information via the bottle label about sustainable use for environmental protection from the waste bottles. However, recycling the post-used bottles for new purposes is slightly accounted, either encouraging the consumers or by the bottlers themselves. A legal constraint on using recycled material for food packaging, enforced by the Food and Drug Administration (Thailand) is addressed for a low literacy in recycling technology in bottled-water businesses. Precisely, reduced use of plastics and reduced defects in bottling system that are the major concerns to the bottlers can be converged with the corporate contribution to environmental prevention and protection.

    b. Water. Bottled-water business requires a shift to the SCP. In Thailand, most bottling plants are located in the provinces along the Chao Phraya River and its tributaries that can cause the profound impact on ecological system. The water is mostly extracted from underground water or artesian wells, with a fee paid per cubic meter to the office of municipal affairs or to the Ministry of Natural Resources and Environment at USD 0.40 per cubic meter for the right to capture the water. The water of any quality discharged from factories in the provinces near the Chao Phraya River and its tributaries must legally undergo filtration before drainage. Increasingly, PET-bottled-water manufacturing is simply established for the SMEs because they bottle tap water, with a normal filtration.
    c. According to unsustainable water resource management spread over the country for many years, the surface water supplies are currently limited as well as groundwater sources are highly vulnerable to depletion. The belief that the discharged drinking water is neither hazardous nor wastewater is not considered justified by those aware of the water crisis.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Consumer Behavior of SCP

Consumer behavior towards the SCP of PET-bottled water is evaluated by the strength of agreement to avoid the manners, which are known to be damaging to the environment. The analysis contains comparative statements about the contributions to improving greater efficiency in consuming PET-bottled water and decreasing the impact from the post-used bottles.

In most cases, Thai consumers moderately perform the SCP, with more emphasis on the resource efficiency rather than the impact reduction. In their opinion, PET-bottled water is purified, clean and safe for drinking. Increasing use of tap water is totally declined due to negative perception of the impurity. Meanwhile, the refrigerated water from coin-machine and freezer services, which is tap water, is considered appropriate for drinking due to a filtration in chilling step. The convenience in use of PET-bottled water, either in or away from home, becomes the normal practice in working days and during shopping and travelling.

The idea of zoning gas station and shopping mall is most credited for improving waste bottles management. A forbidden use in the offices is totally declined, so does the enactment of the Polluter Pays Principle (PPP) when asked to treat them as the SCP behavior. It is interesting that business sector is expected by nearly all consumers to take the leading role in the SCP development by incorporating environmental-awareness rising to product campaigns. Two histograms as shown in Figure 2 and 3 present consumers' performances in between resource efficiency and impact reduction for bottled water, respectively.

1. **Resource Efficiency:** Drinking up a whole bottle of water is considered best effective to resource efficiency target; otherwise, consumers tend to choose a smaller pack size of 330-350 milliliter that fits to demand, so does taking the leftover for further use. Consumers also like to optimize all product benefits and minimize resources used with the reuse. Additional are preparing personal flask when away from home and avoiding the use of bottled water for coffee, tea and cooking. Selling post-used bottles to junk shop is the preferable way for handling the wastes bottles, rather than recycling approach. According to consumers' feedback, a change to tap water is neither performed nor considered valuable for increasing efficiency in bottled-water consumption.
2. **Impact Reduction:** Thai consumers are willing to accompany the post-used bottle until finding a litterbin but hesitate to recycle the waste bottles for decreasing impact generation. In their opinion, changing to ordering glass bottles helps in decreasing the impacts from PET-bottled water as little as choosing refillable jug when eating out. Consumers prefer using personal flask for sake of decreasing the volume of waste bottles

In most cases, the post-used bottle are sorted for recycle bin rather than disposed in the environment inappropriately. Additional addressed is that the inadequacy of recycle bin for plastics waste, compared to consumers' need, becomes a significant burden to sort out the waste bottles. Among the concerns to waste-PET bottles, a large number of door-to-door collectors represent the key role of junk dealer in the logistic flow of recycling waste bottles.

In view of health concerns, most consumers do not avoid using the bottle that has been opened and exposed to direct sunlight contact. Nor is the reuse without proper cleaning that can cause the health risk. On the other, performing a mouth-to-bottle, without a straw or pouring into a glass is least considered related to health risk. Notwithstanding, PET refillable bottles could be safely reused, if the bottles derive from the good manufacturing procedures and the appropriate cleaning prior refilling. In brief, the

Figure 2. Consumer behavior of resource efficiency in consuming PET-bottled water and disposing of the post-used bottles to fulfill the SCP

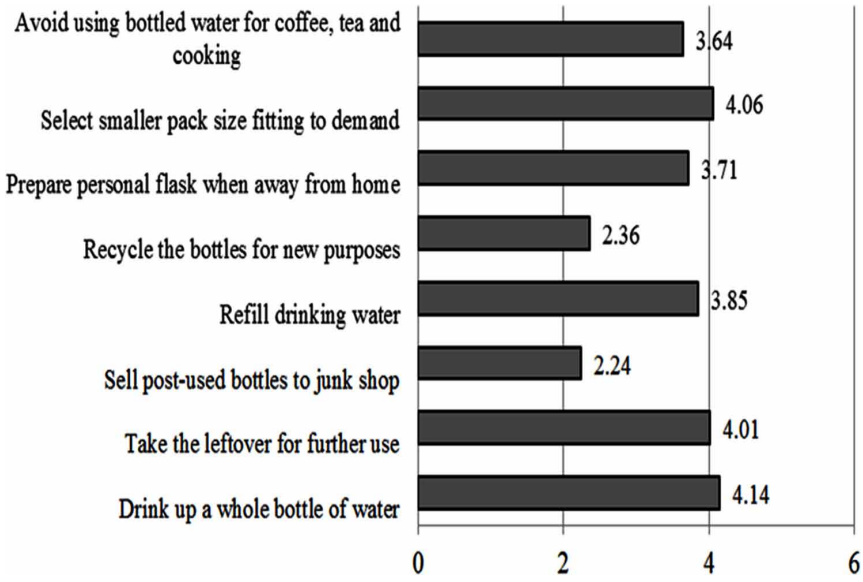

Figure 3. Consumer behavior of impact reduction in consuming PET-bottled water and disposing of the post-used bottles to fulfill the SCP

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

consumption pattern of PET-bottled drinking water is somewhat away from impact reduction implication due to the speeding up of lifestyles together with increasingly disposable products for consumerism.

SOLUTIONS AND RECOMMENDATIONS

The conflict agenda of water resource; agriculture and fishery sectors against industries, habitants against businesses, and within the community, is heavily increasing, nationwide. Towards the undercurrents in the LCM of bottled water, a paradigm shift to the holistic view and sustainable actions is truly required so as to bring the implementable solutions to and from all concerns. As a production and consumption pattern is actually related to sustainability objectives, the increasing demand for bottled water shows what social gains for better living is what the world has lost. We must accept that without environmental awareness, the SCP will not advance the larger development in industry practice and consumer behavior. This is important to the SCP implementation, which several variables are associated, which public participation and regulatory policies have not been fully developed.

Under the leadership of the government, its role remains an option to foster a consumption and production pattern away from or toward sustainability. The tasks shall be responded by many governmental entities like the Department of Industrial Works, the Department of Industrial Promotion, the Department of Environmental Quality Promotion, the Department of Health, the Department of Mineral Resources and the Metropolitan, or Provincial, Waterworks Authority. Business would go beyond a product value chain to sustainability objectives in order to reach a viable solution that helps in reducing environmental disruption and compromising economic and social value at the same time. These concerns can be fixed by a removal of unsustainable goods and service from the market. The eco-tax or a refund fee shall be rewarded to those who produce and consume sustainable products and services or eco-products. If putting harm to environmental quality, the polluter could be charged a fee towards funding environmental rehabilitation, and finally edited out of the market – Polluter Pay Principle (PPP). Any related governmental entities could put a driving force to the SCP by either shaping the business practice to influence consumer behavior, or formulating solution taken by each stakeholder. In such case, they should separately set minimum recycling standards and indicate material combinations with recycled PET for the new packaging those covering nonfood-contact products.

Environmental themes in advertising and marketing processes should be employed for raising awareness of sustainable practices. Both business and consumers should be alert to the duties and responsibilities when there is no legislation, nor strict enforcement of disposing of waste bottles. Technological knowledge about recovery of waste-to-energy device should be widely disseminated to communities. Coupled with marketing-based instruments, public policies that support cleaner technologies for a value chain of bottled water could be established. The waterworks authority shall also be due on the establishment of tap-water supply throughout nation. There has to be a thematic agenda inspiring people for the quality of tap water that is appropriate for drinking. The consideration shall also direct to the role of recycling agents and retailers in responsibility for the logistics of waste bottles. These should be well organized in order to prevent the reverse channel from inappropriate approach at landfills and dumping areas.

Finally, environmental education has to be driven so that a positive change in production and consumption pattern of products and services like PET-bottled water can translate to larger sustainability gains. This is concurrent to the agreements across the globe adopted from the 2015 Paris Climate Conference

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

(COP21) that sustainable lifestyle in the SCP approach is an important role in addressing climate change (United Nations Framework Convention on Climate Change [UNFCCC], 2015).

FUTURE RESEARCH DIRECTIONS

The content in this chapter is by no means exhaustive, but enables a potential for the methods and data-sets of sustainability framework. More extension could be observed in new areas of study and possible pathways that are branched in various directions. The approaches to soft drinks, energy drinks and health drinks could be developed to identify the differences of causes, effects and solutions on the SCP target themselves. There should be opportunities for future studies about the SCP approach that provide greater interdisciplinary expectations, especially externality cost analysis and a power of eco-journalism to public participation in SCP development. In addition, the improvement of assessment on a linkage between globalization and sustainability from a multi-disciplinary perspective could be set for reframing current public awareness of mitigation and adaptation manners towards climate agenda.

CONCLUSION

PET bottles are potential to the impact categories of global warming, eco-toxicity and human toxicity, especially waste-bottles management that causes a profound impact to the planet. The SCP of PET-bottled water is accounted by the businesses and consumers, with emphasis on efficiency in water and plastics resource use. Contributions to impact prevention and reduction are the contrary. The advance in plastics recycling technology is required, so does consumer behavior in recycling waste bottles. Due to the most practice in bottling the water by open-loop system, the LCM of PET-bottled water can be direct and indirect burden to sustainability target in water resource management, both at present and in future. In general, particular information about demand and supply of fresh water resource varies geographically and culturally. The undercurrents of bottled water are in evidence when the production and consumption pattern are radically addressed through the bottling system and consumer behavior towards the level of environmental awareness. A rapid growth of bottled-water business in Thailand that are captured by many thousands bottlers becomes the interplay of social, economic and environmental development. The concerns are in need to reconsider the impact on water supply, use and management. Businesses and consumer are challenging for greater efficiency in water resource consumption and the improvement of plastics recycling. Shortly, this chapter is particularly timely as water resource and waste plastics are shifting from one of environmental issues to what those are much more concerned to sustainability success.

KEY TERMS AND DEFINITIONS

Bottled Water: A disposable product that serves one-way usage and appears in the form of PET bottle with the filled water for drinking.

Bottling System: An input-output approach for filling drinking water in the bottle. The system consumes the input of several resources, such as plastic bottles, purified and disinfected water together with electricity and fuel energy in order to deliver the output of bottled water and environmental impact profile.

Bottom-up Participation: Role of business and consumer in environmental protection and prevention from the interactive processes between production and consumption.

PET Bottles: A plastic container appears in bottle body which is made of polyethylene terephthalate polymer.

Sustainability in Bottled Water Production and Consumption: An integration of sustainable consumption and production approach into the whole product life cycle of bottled water.

Sustainable Consumption and Production Pattern: The ways of producing and consuming products and services with environmental awareness of improving efficiency in resource consumption and reducing potential impact generation.

Undercurrents of Bottled Water: Environmental impact profile occurs from PET-bottled water directly and indirectly, both at present and in future, in many categories, such as global warming, ecotoxicity and human-toxicity.

ENDNOTES

1. The Marrakech Process is a global process driven by the United Nations Environmental Programme (UNEP, 2015) and the United Nations Department of Economic and Social Affairs (UN DESA) to support the elaboration of a 10-Year Framework of Programs (10YFP) on SCP according to Johannesburg Plan of Action in the World Summit on Sustainable Development (WSSD).
2. ISO 14040 (2006) is the leading standard to describe the principles and framework for life cycle assessment (LCA) that can be followed by the steps of environmental management - life cycle assessment - principles and framework.
3. ISO 14044 (2006) is the international standard to specify requirements and provide guidelines for life cycle assessment (LCA), with the following steps; environmental management - life cycle assessment - requirements and guidelines.
4. SimaPro 7.1 is the software developed by PRé Consultants as the tool for a product life cycle assessment through the phase of LCI. The software provides several literature-based inventory data covering the compilation and quantification of inputs and outputs for a given product system throughout its life cycle, plus various impact assessment methods, e.g. Eco-indicator, CML (Center of Environmental Science of Leiden University). The software and the literature LCIs used in this chapter are supported by the National Metal and Materials Technology Center (Thailand) for academic purpose only.
5. GWP is the abbreviation of global warming potentials. Due to the International Panel on Climate Change (IPCC), CO_2 emission is normalized as an equivalent weight of carbon dioxide for the relationship between greenhouse gases (GHGs) emission and the 100-year time horizon Global Warming Potentials (GWP).

This research was previously published in Reconsidering the Impact of Climate Change on Global Water Supply, Use, and Management edited by Prakash Rao and Yogesh Patil; pages 272-293, copyright year 2017 by Information Science Reference (an imprint of IGI Global).

Chapter 19
Water Quality Impacts of Abattoir Activities in Southern Africa

Never Mujere
University of Zimbabwe, Zimbabwe

ABSTRACT

The meat processing produces solid, liquid and gaseous wastes from stockyards, abattoirs and packing plants contain blood, fats, protein, gut contents, heavy metals, antibodies, hormones and other substances. Solid and liquid wastes can lead to an impairment or disruption of water eco-functionality and a preponderance of disease-causing organisms. In developing nations, many abattoirs dispose of their waste directly into streams or rivers and also use water from the same source to wash slaughtered meat. Most solid, liquid and gaseous wastes are released into the immediate environs of the abattoir. This chapter is a literature review of the impact of untreated slaughterhouse wastewater on water quality in selected areas of Southern Africa. The review shows that abattoir activities significantly reduced the physical, chemical and microbiological quality of water bodies. Although an improvement of the water quality was observed downstream, this was a result of self-purification and dilution effects.

INTRODUCTION

The killing of cattle, sheep, pigs, goats, poultry and other equine animals to supply meat for human consumption is a common practice in Southern Africa. Abattoir waste contains high levels of organic matter due to presence of manure, blood, fats, grease, hair, grit or sediments and undigested feeds. Blood and fats contribute mostly to organic load; blood is also a major contributor of nitrogen content in the effluent. It can also contain high level of salts, phosphate, nitrates, trace or heavy metals, bacteria, viruses and other microorganisms (Muhirwa et al., 2010; Kosamu, Mawenda & Mapoma, 2011). Abattoir effluent affects water, land or air quality if proper disposal practices are not followed. Improper waste disposal reduces oxygen in water, thereby endangering aquatic life. It can lead to animal diseases being transmitted to

humans through contact with animal faeces. Pollution of the environment in the vicinity of the abattoir as well as reduced quality of health of residents in the local area result in elevation of excessive coughing, typhoid fever, diarrhoea, and malaria and muscle pains (Benker-Coker & Ojior, 1995). Noise pollution is also associated with abattoir activities (WHO, 2011). Respiratory and mucous membrane effects are common in areas close to intensive swine operation (Itodo, Awulu & Harrison, 1999). Thus, surface and ground water quality in vicinity of the abattoirs can be adversely affected by effluents.

BACKGROUND

Meat processing, slaughtering and processing remain critical in ensuring that consumers receive a hygienically safe product. Production processes for meat products have been shown to have a significant impact on the environment, accounting for between 15% and 24% of greenhouse gas emissions (Mittal, 2006). Abattoirs are an important industry in Africa's domestic meat supply and export industry, as well as employment opportunities to many communities. Abattoir effluent is known to degrade the quality of receiving water bodies. Waste from abattoirs changes the microbiological and physico-chemical water quality parameters such as pH, temperature, electrical conductivity, salinity, turbidity, total dissolved solids (TDS), total suspended solids (TSS), dissolved oxygen (DO) and coliforms (GDARD, 2009). The effluent characteristics of the abattoir are nutrients and biologically active constituents which pose a considerable challenge for water resources management particularly the delivery of essential water, sanitation services and environmental protection. Nitrates are very high in the abattoir wastewater especially at the evisceration and slaughter step where the urine and undigested stomach content concentrated in nitrate was mixed in wastewater streams (Mittal, 2004). This is because wastewater streams for these processes consist of mixed intestinal contents and blood with a high content of nitrates. This chapter focuses on the environmental effects of meat processing in general. In particular, it highlights how meat processing contributes to changes in water quality.

Water Quality

Water quality describes the physical, chemical, biological and aesthetic properties of water which determine its fitness for a variety of uses and for protecting the health and integrity of aquatic ecosystems. The quality of any body of surface or ground water is a function of either or both natural influences and human activities. Levels of water quality are assessed in terms of: physical characteristics e.g. color, temperature, taste, turbidity, hardness and smell or odor which are determined by senses of touch, sight, smell and taste; chemical characteristics such as conductivity, dissolved salts and oxygen demand; and biological e.g. amount of micro-organisms present such as bacteria, protozoa and algae parameters (WHO, 2011).The definition of water quality takes into account the fact that even when water is polluted say with sewage, depending on the level of the contaminant, it can be used for other purposes such as agriculture.

Environmental Pollutants from Abattoirs

An abattoir is loosely defined as any registered facility that is responsible for the conversion of animals to meat via a slaughtering process. This includes livestock, poultry and special classes of animals, e.g. crocodiles and game (GDARD, 2009). The slaughtering process remains critical in ensuring that consumers receive a hygienically safe product.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Effluent Salinity

Skin preservation by dry salting is a common procedure at small abattoirs that are remote from tanning operations and often export their hides and skins for tanning. After salting, often in converted cement truck mixers, the hides are hung to dry for a minimum of 5 days. During this period, the salt draws the moisture out of the hide, together with the protein-filled fluids contained in the attached flesh. The effluent from drying sheds is therefore highly saline and has a very high biochemical oxygen demand (BOD). It also contains high levels of fluoride, since the salt used contains up to 1 percent sodium fluoride as a bactericide.

Wastewater

Wastewater produced in animal slaughter areas typically has a high BOD. It is also very saline and has high levels of nutrients, suspended solids and bacterial contamination.

Solid Waste

Sources of solid wastes generated at abattoirs include: manure generated in animal holding areas; slaughterhouse and processing areas; sludge generated in waste treatment ponds; and unwanted carcasses, hide or skins, paper, cardboard, plastics, feathers and pieces, and unwanted carcasses and carcass parts (Mittal, 2004).

Odors

Potential sources of odors in abattoir operations include stale materials and fugitive emissions from cookers. Odors in animal holding pens are produced by manure and urine. Abattoirs odors come from solid wastes such as paunch contents and blood residues. Anaerobic waste treatment ponds may produce gases such as methane, ammonia and hydrogen sulphide, which give rise to objectionable odors (GDARD, 2009). Odor control may be a significant issue, particularly when the abattoir is located near residential areas or in a hot environment.

Dust

Potential sources of dust emissions at an abattoir are: paddocks, sale-yards and holding pens; and materials burned at an abattoir (GDARD, 2009).

Greenhouse Gases

Animals produce methane gas (a greenhouse gas) during the process of digestion which is released to the atmosphere during processes such as defecation. Little can be done to prevent or reduce the amount of methane produced. However, by varying the food types and quality, methane generation may be reduced. Chlorofluorohydrocarbons (CFCs) may be used in refrigeration and freezer plants. These are ozone depleting gases and their production and use are subject to national and international regulation

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

(McLaughlin & Mineau, 1995). Ozone depleting gases used in refrigeration units should be replaced in existing abattoirs and new abattoirs must install refrigeration units that do not utilize such substances (Quinn & McFarlane, 1989).

Noise

In abattoirs noise can be generated by several sources, including: animals, especially when in concentrated groups; processing activities within the slaughterhouse; plant machinery; and plant and service vehicles (Muhirwa et al., 2010).

EFFECTS OF ABATTOIRS ON WATER QUALITY

The people and environment in Southern Africa are highly vulnerable to pollution from abattoirs. Availability of safe water in the region is worsened by poor sanitation and improper disposal of animal waste. The majority of the people living along and down river courses depend on untreated stream water supply for domestic purposes and sometimes for drinking. While rivers and streams serve as major sources of reliable domestic water supply, most abattoirs are located close to such water sources. Nevertheless, abattoirs discharge untreated wastewater into water bodies because they normally face difficulties in meeting costs of treating wastes such as fats, oils, greases and suspended solids (Chukwu, 2008). Thus, there are high chances of people drinking unclean water contaminated with bacteria or pathogens that could impact on public health. The following are case studies findings on the physico-chemical and microbiological impacts of abattoir activities on water quality in selected countries. Table 1 shows findings of a study conducted to assess the water quality of abattoirs in Ghana.

Generally the influent met the recommended standard for treated water quality except for fecal and total coliform counts of 36 and 84 CFU, respectively, instead of 0 CFU recommended by the World Health Organization (WHO, 2011). The effluent was highly polluted and did not meet the set standards for effluent discharges into the environment. Its extremely high levels of BOD (3300 mg/L) and low dissolved oxygen (0 mg/L) are strong indications of high organic pollution in the effluent. Effluent fecal coliforms level of 450,000/100 ml and total coliforms of 550,000/100 ml were recorded. Excessive turbidity, or cloudiness, in drinking water is aesthetically unappealing, and may also represent a health concern. Turbidity can provide food and shelter for pathogens. If not removed, turbidity can promote

Table 1. Effects of Tamale abattoirs on water quality in Ghana

Parameter	Influent	Effluent	WHO Standard
DO (mg/l)	4.6	0	5
BOD (mg/l)	2.2	3,300	20
TSS (mg/l)	4	2,567	30
Turbidity (NTU)	4.8	>1,000	5
Fecal coliforms (CFU/100 ml)	36	450,000	0
Total coliforms (CFU/100 ml)	84	550,000	0

(Weobong & Adinyira, 2011, p. 388).

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

regrowth of pathogens in the distribution system, leading to waterborne disease outbreaks, which have caused significant cases of gastroenteritis throughout the United States and the world. Although turbidity is not a direct indicator of health risk, numerous studies show a strong relationship between removal of turbidity and removal of protozoa. Residents of the community where the abattoir is located complained about bad odor, pollution of their water source (dam) from the effluents and the outbreak of maggots, flies and diseases such as malaria, typhoid, dysentery and diarrhea (Weobong & Adinyira, 2011).

Table 2 shows the results of a study conducted in Malawi and Nigeria. The first sampling point was located 10 m upstream with respect to abattoir discharge point. It served as reference point. A second sampling point was located at abattoir effluent discharge point. The third sampling point located 10 m downstream from effluent discharge. The physico-chemical parameters tested were: pH, biochemical oxygen demand (BOD), dissolved oxygen (DO), suspended solids (SS) and electrical conductivity (EC).

From Table 2, it is clear that at a point upstream, the BOD value was 257.3 mg/l, and the concentration went higher to 612.3 mg/l at discharge point. This was because of the effluent discharged by the abattoir on the stream at this point and therefore not completely mixed. At the sampling point downstream, the mean value of BOD was reduced to 487.0 mg/l. This can partially be attributed to dilution due to mixing and partially as a result of settling along the stream course and dilution.

Because oxygen from the atmosphere is dissolved in the water, (Verheignjen, Weiersna, Hulshoff & de Wit, 1996). It is one of the most significant tests for measuring the quality of water. The standard for sustaining aquatic life is stipulated to be 5 mg/l. Concentration below 2 mg/l adversely affects aquatic and biological life hence lead to death of fish. The low DO concentration at discharge point was be due to high organic load as shown by BOD and suspended solid values (Table 2).

The concentration of suspended solids show the highest value of 477.3 mg/l at discharge point hence exceeded the WHO (2011) recommended maximum limit of 30 mg/l. This was due to lack of proper sedimentation facility to separate the solid waste from liquid waste before the effluent is discharged. High

Table 2. Effects of meat processing on water quality on Mchesa stream in Malawi and Ogbogoro stream in Nigeria

Parameter	Upstream	Discharge Point	Downstream	WHO Standards
BOD (mg/l)	257.3	612.3	487	20
COD (mg/l)	42.87	42.08	42.57	1000
DO (mg/l)	3.8	1.8	2.4	5
SS (mg/l)	286.0	477.3	272.0	30
EC	99.3	128.3	177.7	400
pH	7.4	7.7	7.5	6.5-9.5
Total alkalinity (mg/l)	2.55	2.37	2.25	NA
Nitrate (mg/l)	0.39	0.83	0.62	10
Phosphate (mg/l)	0.05	0.07	0.06	NA
Turbidity (NTU)	0.46	0.77	0.56	5
Odor	Odorless	Offensive	Offensive	Inoffensive

(Kosamu et al., 2011).

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

concentrations of suspended solids can also cause problems to aquatic life such as by reducing water clarity and clogging fish gills (GDARD, 2009). The changes downstream can be attributed partially to dilution and partially to settling.

Electrical conductivity (EC) is used to indicate the dissolved solids in water because the concentration of ionic species determines the conduction of current in an electrolyte. The high values of electrical conductivity downstream therefore suggest that has a considerable loading of dissolved salts (WHO, 2011).

The mean values of pH obtained ranged from 7.4 to 7.7. These pH values were normal to unpolluted freshwater. Water having a pH range of 6.5 -8.5 will generally support a good number of aquatic species. Thus, the values obtained were also within the recommended ranges (6.5-9.5) as stipulated by WHO (2011).

Table 3 shows findings of a study conducted to determine the bacteriological characteristics of abattoir effluents from 6 abattoirs discharged into water bodies in Nigeria. The concentrations of total coliform (TC), fecal coliform (FC), F. streptococcus, and E. coli were determined from upstream water servicing the abattoir and water bodies receiving abattoir effluents downstream. Total coliform bacteria concentration in the abattoir wastewater discharged exceeded the recommended limit for the discharge of effluents into water bodies.

The receiving water bodies were used for drinking, bathing, washing, watering of animals, watering of crops, and other domestic purpose downstream. Total coliforms and fecal coliforms or E. coli are generally not harmful themselves. While total coliforms are common in the environment, fecal coliforms or E. coli are usually associated with sewage or animal wastes. The presence of these bacteria in drinking water is a result of a problem with water treatment or the pipes which distribute the water, and indicates that the water may be contaminated with organisms that can cause disease. Symptoms may include diarrhea, cramps, nausea, and possibly jaundice, and any associated headaches and fatigue (Benker-Coker & Ojior, 1995).

F. Streptococci are common bacteria that live in the human body, including the nose, skin, and genital tract. These bacteria can damage, and destroy red blood cells. Drinking water which meets the WHO standard is usually not associated with a health risk from disease-causing bacteria and is considered safe.

Twelve wells were sampled and assessed of their physico-chemical and bacteriological parameters in Nigeria (Adeyemo, Ayodeji & Aiki-Raji, 2002). Four wells were sited within the ground of the Bodija abattoir, four were about 50 m – 80 m upstream of the abattoir and four were 500 m – 100 m downstream of the abattoir in a residential area (Table 4).

Table 3. Mean wasterwater values of bacteriological characteristics upstream and downstream of Kuje, Gwagwalada, Kubwa, Deidei, Karu abattoirs in Nigeria

Parameter	Upstream Station	Downstream Station	Discharge Limit into Surface Water
TC ($x10^2$)	38	6100	4.0
FC ($x10^2$)	2.5	230	0
F. streptococcus ($x10^2$)	3.3	7	120
E. coli ($x10^2$)	2.7	24	0

(Chukwu, Adeoye & Chidiebere, 2011, p. 104; Agwa, Sito & Ogugbue, 2013, p. 882).

Total dissolved solids	950.00	2,100.05	750.00	500-1500
Total hardness (mg/l)	133.25	371.25	151.00	100-500
Total chloride (mg/l)	134.75	312.05	94.85	250
Clarity	Clear	Clear	Clear	Clear
Odor	Odorless	Odorless	Odorless	Odorless
Taste	Tasteless	Tasteless	Tasteless	Tasteless

(Adeyemo et al., 2002, p. 52).

From Table 4 it is clear that most parameters at discharge points and downstream stations met the WHO standards. However, microbiological, total solids, manganese, lead and total chloride were outside the recommended limits.

Total dissolved solids in water supplies originate from natural sources, sewage, urban and agricultural runoff, and industrial wastewater. Salts used for treating animal hide can also contribute to the TDS loading of water supplies. Ingestion of TDS in drinking water appears to be associated with various health effects such as incidence of cancer, coronary heart disease and arteriosclerotic heart disease.

Manganese occurs naturally in air, soils, surface water and groundwater sources. However, human activities are also responsible for much of the manganese contamination in water in some areas. Manganese is an essential nutrient for the proper functioning of humans and animals, as it is required for the functioning of many cellular enzymes. Although manganese is an essential nutrient at low doses, chronic exposure to high doses may be harmful. The health effects from over-exposure of manganese are dependent on the route of exposure, the chemical form, the age at exposure, and an individual's nutritional status. The nervous system is the primary target organ with neurological effects generally observed (WHO, 2011).

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Chlorine is generally found only in industrial settings. It enters the body breathed in with contaminated air or when consumed with contaminated food or water. It does not remain in the body, due to its reactivity. Most direct releases of chlorine to the environment are to air and to surface water. Exposure to chlorine effect on human health depends on the amount of chlorine that is present, the length and frequency of exposure. Breathing small amounts of chlorine for short periods of time adversely affects the human respiratory system. Effects differ from coughing and chest pain, to water retention in the lungs. Chlorine irritates the skin, the eyes, and the respiratory system. These effects are not likely to occur at levels of chlorine that are normally found in the environment.

Lead is a useful and common metal but can be a very dangerous poison, particularly for children, when it is accidentally inhaled or ingested. In children, lead is most damaging when they are six years and younger. High levels of lead are life threatening and can cause seizures, unconsciousness, and death. Even at low levels, lead can be harmful and be associated with learning disabilities resulting in a decreased intelligence, attention deficit disorder, behavior issues, nervous system damage, speech and language impairment, decreased muscle growth, decreased bone growth and kidney damage. High levels of lead in adults can cause increased chance of illness during pregnancy, harm to a fetus, including brain damage or death, fertility problems in both men and women, high blood pressure, digestive issues, nerve disorders, memory and concentration problems and muscle and joint pain (WHO, 2011).

Thus, the discharge of abattoir waste negatively imparts on the chemical and microbiological quality of the stream especially at discharge points and downstream stations. The spatial distribution of the physico-chemical parameters along the stream showed relatively higher values at the effluent discharge point with increased attenuation in the levels of the parameters downstream indicating the capacity of the stream for self-purification. Nevertheless, the organoleptic assessment showed that the samples from all the wells were clear, without odor and taste. It is vital to have adequate treatment of waste before discharge and waste management practices that ensure waste reduction, re-use and recycling, should be encouraged by environmental regulatory bodies in order to protect the water resources from negative impacts of abattoir wastes. Therefore, the discharge of untreated abattoir waste into rivers and streams can have adverse environmental consequences on water quality (Agwa et al., 2013).

CONCLUSION

While the slaughtering of animals results in meat supply and useful by-products like leather and skin, livestock waste spills can introduce enteric pathogens and excess nutrients into surface waters and can also contaminate ground waters. These leachates consist largely of solids, microbial organisms and in special situations chemicals and shallow wells like hand-dug wells are more dangerously polluted. Abattoir operations produce a characteristic highly organic waste with relatively high levels of suspended solid, liquid and fat. The solid waste includes condemned meat, undigested ingesta, bones, horns, hairs and aborted fetuses. The liquid waste is usually composed of dissolved solids, blood, gut contents, urine and water. As population grows and urbanization increases, more water is required and greater demand is made on ground and surface sources and an even greater amount of organic and inorganic wastes are speared back into water sources so that less potable water becomes available. Water is regarded as being polluted when it is unfit for its intended use.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

In developing countries abattoirs are known to pollute the environment either directly or indirectly from their various processes. Wastewater from an abattoir is a particularly concentrated source of oxygen consuming waste. In most countries, abattoir operations are generally unregulated. Moreover, abattoirs are usually located near water bodies in order to gain unhampered access to water for processing. Abattoirs generally use large quantity of water for washing meat and cleaning process areas. The disposal of effluent into rivers and streams is a common practice.

This study has shown that the operations of abattoirs have some negative impacts on water quality in Southern Africa. The water used by the abattoir for its operations (influent) is generally of good physical, chemical and microbiological quality. If proper abattoir management practices are not followed, animal waste can be washed into unprotected water bodies. Abattoirs however pose the following contamination risks to water resources:

- Nutrients from animal manure and process wastewater leading to eutrophication in wetlands and waterways, and toxic concentrations of nitrogen compounds;
- Depletion of oxygen levels in surface waters due to the breakdown of organic matter;
- Pathogens such as salmonella bacteria from any diseased stock held at the site;
- Increased salinity derived from waste stabilization pond effluent evaporation;
- Increased turbidity due to solids transfer to waterways and wetlands; and
- Alkalinity and surfactants derived from equipment cleaning.

Even though there are a number of state of the art abattoirs around the world, waste management practices in such facilities remain incompetent in resolving the environmental and human contamination risks and impacts. In the context of Southern Africa, emergency response and remediation are not always readily available to address contamination and pollution considerations, which renders humans and the environment more vulnerable and mean the risk of environmental and human adverse impact is potentially more serious.

Based on current knowledge, no South African abattoirs operate on a closed water circuit, as in general, it is prohibitively costly to treat waste water to a water quality standard fit for recycling and/or re-use. Thus, most abattoirs discharge (after appropriate pre-treatment) to municipal sewers.

Many of these small abattoirs relied on denaturing as a sole option for the disposal of condemned products and blood. With the increase in slaughtering and structural changes to these abattoirs over the past ten years, by-product treatment, in any form, was not included as a prerequisite.

Discharge costs due to the high organic loads in the untreated abattoir waste water are relatively high. Abattoirs normally also have difficulty in meeting municipal by- law quality standards for fats, oils, greases and suspended solids. A degree of on-site pre-treatment is thus necessary. However, to minimize waste volumes, water conservation and optimum water housekeeping are essential. In addition to good abattoir housekeeping, abattoir waste management should be progressively implemented commencing with low-cost, low-technology practices and thereafter progressing to more sophisticated technologies.

Therefore, the importance of adopting appropriate abattoir wastewater treatment measures to prevent the chances of contaminating water bodies and ground water is recommended. Determination of specific pathogenic microorganisms in abattoir wastewater and their health impacts is also recommended. It is therefore instructive to treat the abattoir wastes appropriately and properly dispose them to avert environmental disasters. Furthermore, legislation on abattoir operations and management can reduce the negative impacts and enhance sustainability in the industry.

KEY TERMS AND DEFINITIONS

Abattoir: An abattoir or slaughterhouse is a place where animals are slaughtered for meat.

Dissolved Oxygen: The measure of the degree of pollution by organic matter, the destruction of organic substance as well as self-purification of the water bodies.

PH: Refers to hydrogen ion concentration, and is the indicator of acidity or alkalinity of water. It is a measure of the effective concentration (activity) of hydrogen ions in water.

Pollution: The change in the physical, chemical, radiological or biological quality of the resource (air, land or water) caused by people or due to human activities that is liable to cause hazards to human health, harm to ecological systems, damage to structures or amenity and is injurious to existing, intended or potential uses of the resource.

Water Quality: Describes the physical, chemical, biological and aesthetic properties of water, which determine its fitness for a variety of uses and for protecting the health and integrity of aquatic ecosystems. Water quality is the degree of usefulness of water for a particular purpose. It is a measure of the amount and types of substances contained in water with respect to what it is intended to be used for.

Chapter 20
Green Manufacturing: The Need of the Hour for Developing Nations – A Case Study

Saurabh Sen
Sunbeam College for Women, India

Ruchi Sen
Sunbeam College for Women, India

ABSTRACT

The manufacturing sector has greater responsibility for conducting and operating its business. The primary objective of every unit is to maximize profits. The manufacturing sector is the key driver of energy consumption and if an automobile consumes high fuel or if the resources are under-utilized, it is definitely the fault of the manufacturer. If we seriously need a solution to these problems, we need to change the way we design, manufacture, and sell the products. The manufacturing sector must use energy and resources efficiently. 'Green Manufacturing' or sustainable industrial activity is the need of the hour and the Government of India requires the manufacturing sector to play a bigger role in the country's economy. This paper focuses on the initiative taken by the industries to make the environment eco-friendly. The paper further will emphasize upon a case study of Hero MotoCop.

MEANING AND IMPORTANCE OF 'GREEN'

The term Green here refers to the ecological sustainability and encompasses elements like energy usage, efficiency and waste management and recycling. Green initiative aims to minimize the impact of human activities on the environment.

There are various factors which call for concerns for Green. They are:

1. **Rising emissions:** Greenhouse gas emissions have been increased rapidly in the recent past and are continuously accelerating. It is revealed by the scientists that it will increase by double by 2050. This means that there would be an exceptional negative change in the global eco-system, sea-level, crop production and relative activities.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

2. **Fast depletion of scarce natural resources:** With growing population, the need for industrialization will increase and also the consumption of natural resources will rise. This will result in the imbalance between the demand and supply of products, rise in the price of goods and services. This problem could be solved by optimal utilization of natural resources and their alternate uses.
3. **Growing waste generation and pollution:** Rapid industrialization and urbanization has led to increase in industrial waste and chemical compositions. This results in environment pollution which can be dangerous to health of human beings.
4. **Growing Technological waste:** Another problem which is encountered by the nation is e-waste. With growing demand of technologies and gadgets, the problem of e-waste has emerged which again is a major source of environment pollution.

The above factors have persuaded the manufacturers to adopt Green manufacturing. A number of companies have started adopting Green initiatives as an integral part of their operations. These initiatives are driven by five factors:

- Rising energy and input costs
- Growing consumer pull for Green products
- Increasing regulatory pressures as policy makers introduce new and stricter environmental and waste management laws.
- Technological advances which open up new attractive business opportunities
- The need to enhance competitive differentiation, particularly for first movers or those who are able to break the compromise between short–term higher costs and numerous benefits (example: brand premium, new customer segments). (Bhattacharya, Jain & Choudhary 2011)

Why Green Manufacturing?

The manufacturing companies produce goods which are not eco-friendly. So, they should focus on three major areas:

1. **Green energy:** Green energy basically includes the renewable energy sources like biomass, wind, solar, CNG etc. The manufacturing units should use these green energy sources to produce goods which are not only eco-friendly but also benefits the society as a whole.
2. **Green products:** Green products are the products which can be recycled, low in carbon, organic and are natural. These products are gaining popularity but are little costly. However, if the consumers demand these products and if these products are marketed well, the cost of developing these products will gradually decrease.
3. **Green processes in business operations:** The third and the last area on which the manufacturing units should focus is the business operations. This includes the use of appropriate technology which may increase the efficiency and decrease the cost.

Green Manufacturing: The Need of the Hour for Developing Nations

Green manufacturing has the potential to achieve sustainable development and eradicate poverty on an unprecedented scale. A green manufacturing economy substitute‘s clean energy and low carbon tech-

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

nologies for fossil fuels, which addresses climate change, creates jobs, and reduces import dependencies. Adopting new technologies promote energy, resource efficiency and provide growth opportunities in new directions. If a developing economy moves towards green manufacturing, it will require the initiatives of leaders, civil society and leading businesses. It will require a sustained effort on the part of policy makers and their constituents to rethink and redefine traditional measures of wealth, prosperity and wellbeing. A developing economy can however, develop better opportunities for the people by adopting the concept of 'Green'. It can be self-reliant and thus can minimize its dependency on other countries for importing goods. Not only this, the countries can develop their quality 'green' goods and play the role of exporters. Thus, a developing economy need to move ahead and think in a different way to promote green manufacturing so as to preserve the environment, maximize their profits, play active role as exporters and provide better living to its citizens.

India's Green Challenge

The rapid industrial, economic and demographic growth in India has resulted in high Greenhouse gas (GHG) emissions, rising demand of scarce resources and has generated wastes particularly in urban areas. Today, India is the fourth–largest economy and the fifth–largest GHG emitter in the world. During the 18 year period between 1990 and 2008, India's CO2 emissions increased more than 150 percent, placing it just behind China. Rapid urbanization and industrialization generate massive amounts of waste. For example, India generates close to 4 million tonnes of hazardous waste from industrial and biomedical sources. Apart from hazardous industrial waste and effluents which cause water and land pollution, e–waste is also becoming a major area of concern for India. Estimates suggest that only 3 percent of e–waste makes it to authorized recycling facilities, with the rest either going into landfills or being processed at informal recycling yards. (Digalwar Abhijeet, Tagalpallewar Ashok & Sunnapwar Vivek, (2013). The Indian e–waste market is expected to nearly double from 450 KT per annum currently to about 800 KT per annum by 2020.

Green Business: An Integral Part

Green business is an important strategy to build a green brand that customers can trust. Though, developing such a brand is not an easy task and requires an integrated promotion campaign which consistently communicates the company's Green positioning and policies. Standard setting and labeling can be powerful tools used by companies to build the credibility as well as to help consumers make informed decisions. A survey conducted by CII-Ascon for the April-June quarter (2014) indicates positive growth in important sectors like consumer durables including the vehicle industry and white goods industry, which recorded a growth of 5-10 percent, leading to improvement in the overall industry growth. The CII-Ascon survey found that sub-sectors such as tablets, LEDs and LCDs, smartphones have achieved phenomenal growth of over 20 percent. The passenger car segment also for the first time in last two years has grown between 5 and 10 percent. Thus, it can be interpreted that, if, the companies adopt green business, it will benefit not only the business but the entire eco-system.

The success of companies adopting Green depends on the economic assessment which includes two basic elements, costs and profits. The companies then select their quantitative and qualitative Green initiatives- price strategy, cost strategy, employee recruitment strategy etc.

Making Sense of Green: Hero MotoCorp

Environmental sustainability lies at the core of manufacturing practices of Hero MotoCorp and the company have been continuously introducing new steps in this regards. The company has proactively restricted the use of mercury and cadmium in painting and rubber compounding processes. All plastic parts come in a moulded form, which facilitates easy recyclability at the end of a vehicle's life cycle at the Hero MotoCorp. The company also installed a waste heat recovery system to utilize waste heat from its gas generator. This enables to save 4,000 Standard Cubic Metre (SCM) of natural gas and thereby, prevent 2,600 tonnes of CO2 emissions. The company also installed a vapour absorption machine, which enables to reduce 400 TR (340 KW) of electrical energy, thereby saving 524 tonnes of CO2 emissions annually. It also recycled paint sludge from its paint processes, which is 5-10 percent of the total volumes of paint sludge generated.

The products of the company once used to rely on asbestos based parts. However, they have now been replaced with non-asbestos based parts, which include brake liners, gaskets and other assembly parts. Similarly, lead was replaced by lead-free materials. Hazardous chemicals like hexavalent chromium were substituted in the plating process. The Green Vendor Development Programme is a landmark initiative that disseminates and embeds green practices among suppliers of the Hero MotoCorp. Around 130 suppliers are part of the Green Vendor Development Programme.

The Green Vendor Development Programme of Hero MotoCorp is the supply chain initiative drive taken to extend the corporate environment responsibility down the supply chain. As the production at Hero MotoCorp is increasing, the manufacturing activities at the vendor's are also increasing in the same proportion. This gives rise to the load on the environment. In order to improve the vendor environmental performance, Hero MotoCorp has developed exclusive vendor development program, which is a collaborative effort between the Hero MotoCorp Environmental group and the materials department, in order to influence the vendors to adopt pre-specified environmental requirements and undertake environmental initiatives.

In addition to the above steps taken, the concept of Hybrid Scooters was also unveiled in the 2012 Auto Expo in Delhi by the Hero MotoCorp. The concept of Series Hybrid is fuel productive and eco-friendly. The Hybrid Scooter launched by HeroCorp runs primarily on battery in urban conditions and will use range extender gasoline engine for long runs.

There are other areas in which the company is taking initiative to make the environment eco-friendly.

1. **Green Roof:** Hero's green roof, covering about 45000 sq meters, helps to conserve energy by moderating the temperature on the roof and within surrounding areas. The green roof can restore aesthetic and ecological value of open urban spaces. It addition to this, it protects conventional roofing systems by doubling the service life of the underlying waterproof membrane.
2. **Sewage Treatment Plant:** Hero ensures that sewage is biologically treated to attain efficacy. This treatment plant is designed to accommodate up to 6 hours of holding and ensuring effluent is 100% treated and recycled into soft water that is used in cooling towers.
3. **Effluent Treatment Plant:** To prevent water pollution, Hero has also invested in an Effluent Treatment Plant which is capable of treating waste water that contains degreasing chemicals, acidic/alkaline nature, plating waste, heavy metals and waste oil that is generated out of processes. The output parameter is maintained strictly with norms to ensure that 100% treated water is recycled back into the process while the sludge is safely disposed of at a secured landfill.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

4. **Waste Food Recycling:** Hero ensures hygienic disposal of municipal waste through its organic waste converter, which in turn generates manure. This waste goes through 15 minutes of treatment and is then homogenized and odor free.
5. **Paint Conservation:** Along with preventing water pollution, Hero MotorCorp does its very best to prevent releasing pollutants in the air as well. On an annual average, the company recycles about 120 tons of paint sludge and additives and turns it into paint primer. It also has a Solvent Recovery Machine that helps to prevent 59 Kl of volatile organic compounds from getting released into the air on a yearly basis, thus ensuring cleaner air.
6. **Energy Conservation:** In January 2011, Hero initiated the Heat Recovery from Incineration project which has helped to save 1,258 tons of Co2 emissions and 16, 22, 400 units per annum. This process includes the recovery of waste heat from the incinerator through heat recovery coil. The waste heat is used for heating process water in engine component washing.

In October 2011, Hero introduced its Solar Power Project – 100 KW which has helped to save 1, 56, 000 units per annum, 121 tons of Co2 emissions and 37.96 tons on furnace oil. This is done through the solar energy that is captured by the photovoltaic cells during the day. This electrical energy is then connected to the main grid, to ensure optimum energy conservation.

In June 2012, Hero replaced its 400 ton air conditioner with a VAM chiller to reduce Co2 production and energy consumption. This machine produces chilled water by using heat from power generator sets or through heat sources such as oil, gas, hot water and steam.

Apart from these, Hero MotorCorp has also initiated other energy saving processes like:

- Substituting furnace oil with natural gas
- Replacing aluminum alloy fans by FRP fans of cooling towers
- Replacing copper ballast with electronic ballast in all lighting tasks
- Introducing power saving circuits in all machine panels of engine plants
- Installing power correction panels for loads running on state electricity for cost saving.

7. **Oil Conservation:** Hero MotorCorp has also initiated oil conservation through the installation of Chip Wringer which is capable of recovering neat cutting oil from chips that are generated from m/c operation. This has led to oil recovery of about 56 liters/ day per plant. The company also uses on line hydraulic oil filtration system on presses which has helped in saving 1200 liters/ year.
8. **Water Conservation:** Perhaps one of the biggest initiatives taken by Hero has worked consistently hard in conserving water through Water Management, Rain Water Harvesting and ETP Recycling Plant.
9. **Water Management:** Hero provides training and awareness on how to develop water balance. It also includes reducing water consumption at the source and recycling it back to process applications and other beneficial applications like cooling towers and irrigation after treatment. Water management also entails recharging rain water and regular monitoring to sustain savings.
10. **Rain Water Harvesting:** Hero has also introduced a rain water harvesting scheme that includes the collection and de-silting of rain water. The company has a catchment area in plants that measures about 2, 60, 000 square meters and has a potential recharge of about 1, 32, 600 cubic meters of rain water annually.
11. **ETP Recycling Plant:** This plant introduced by Hero has a capacity of recycling approximately 1400 Kld of treated effluent daily. It uses the modern technology of reverse osmosis and ultra

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

filtration for purifying water. The recycled water is then supplied to the paint shop with desired parameters or used as Soft water/ DM as required.

12. **Green Supply Chain:** To complete the process of sustainable development, Hero MotorCorp has also included the company's supply chain in its green processes. It has put together a "Green Dealer Development Program" at the front end and a "Green Vendor Development Program" for the backend of the supply chain. Through these programs Hero makes it partners aware of the importance of caring for the environment. Dealers and vendors are also encouraged to manage their material resources, energy resources, industrial wastes, pollution and other effluents on the basis of a number of pre-determined parameters. Hero MotorCorp supports its partners in the Green Supply Chain venture by
    - Developing required competencies
    - Sharing knowledge
    - Providing technical support

Through its Green Supply Chain, Hero MotorCorp aims at generating sufficient momentum in the industry and looks forward to the day when the entire automotive industry runs on a seamless green chain.

CONCLUDING REMARKS

Green manufacturing is the core to manufacturing companies' competitive strategies. Though, the transformation journey to Green manufacturing has just started, yet the destination is far to reach. There are few early adopters like Hero MotoCorp to green manufacturing, yet other industries, manufacturers and the developing economies needs to develop comprehensive plans to address three basic areas — Green energy, Green products and Green processes. Hero MotoCorp has adopted numerous means and strategies to maintain and make the economy eco-friendly, but still it has to go a long way to make the economy a 'green' economy. The Government of these economies also has to play an effective role in this transformation with both stronger incentives on one hand and regulatory mechanisms on the other. Also, the industry associations can bring different stakeholders together and support the roll-out of a communication strategy. Thus, the chance for success is enormous for both manufacturing companies and the developing countries, what is required are the zeal to adopt 'Green Manufacturing'.

KEY TERMS AND DEFINITIONS

Eco-Friendly: It is referring to goods and services, laws, guidelines and policies that impose reduced, minimal, or no harm upon ecosystems or the environment.

Environment: The sum of all surroundings of a living organism, including natural forces and other living things, which provide conditions for development and growth as well danger and damage.

Green Manufacturing: It is a process of reducing pollution and waste by minimizing natural resource use, recycling and reusing what was considered waste, and reducing emissions by the industries.

Manufacturing Sector: Collection of industries engaged in chemical, mechanical, or otherwise or physical transformation of materials, substances, or components into consumer or industrial goods.

Chapter 21
Applications of Nanomaterials for Water Treatment:
A Future Avenue

Anupreet Kaur
Punjabi University, Patiala, India

ABSTRACT

Development of new technologies, progressive urbanization, increasing consumerism and industrial boom in developing countries has led to elevated pollution of the environment. The spectrum of pollutants produced and released to the environment has increased in the last few decades including the agricultural, industrial, pharmaceutical and plastic industries. In the developed and underdeveloped countries where environmental pollution goes on increasing day by day, the concern of mankind to the threat of humanity increases which comes from anthropogenic degradation of the environment. An analytical chemist is always in search of cheaper, quicker, more sensitive, more reliable, precise methods of analysis. To achieve such a goal many properties of the materials are studied. Nanotechnology meets many of the conditions mentioned above and is very economic. So, analytical nanotechnology is an important tool for preconcentration and separation of pollutants at low levels.

INTRODUCTION

Rapid urbanization and industrialization of human civilization leads to the discharge of several hazardous contaminants and pollutants into aquatic streams, these effluents contains toxic wastes such as metals, organic impurities, etc., which directly produces a detrimental impact on the biotic resources (Mara 2003; Moore et al. 2003). The unmanageable discharge of pollutants and contaminants due to their severe toxicity and more carcinogenic nature as comparable to other water contaminants, metal ions can cause brutal health troubles for aquatic fauna as well as flora but it also troubles human health through the prevailing ecological food chain (Hutton et al. 2007). Thus, the instantaneous removal of these toxic pollutants from wastewater is a noticeable issue in the aerobic and aquatic world.

The severity of pure drinking water scarcity has to be looked at from two aspects: First, quantity of available water and second, the quality of drinking water. With the rapid development of industries, such as batteries, metal plating facilities, mining operations, fertilizers industries, tanneries, and pesticides (Lvovich 1979).

As nanotechnology continues to proceed steadily, the primary focus of the research agenda has progressively advanced from the fundamental discovery and characterizations to look into the opportunities of presenting nanotechnology and the resultant nanomaterials as the major key to address the challenges of improving global sustainability, particularly in a wide spectrum of pivotal areas involving energy and environment (Seckler et al. 2003).

The properties of nanotechnology innovations are overpowering. Nanoscience and nanotechnology inspired images of "science fiction" with the word invoking visions of technologies wonders such as atoms and molecules joining to create materials with extraordinary physical and chemical properties which can mimic all of the things developed by nature in millions of years. This great deal of optimism and global enthusiasm about"small" encourages developing a lot of nanosensors which are used for detection of various pollutants. Nanotechnology is the creation and utilization of materials and devices at the levels of atoms, molecules, clusters supramolecular structures and exploitation of their unique properties at the nanoscale. It has introduced these novel Nanomaterials including Nanoparticles into our environment. Environmental protection, water pollution, food safety and human health are major issues which need to be addressed as soon as possible. Nanotechnology endeavored to provide" smatter" materials used in environmental sensing and remediation of water pollution problem as well as protecting human health from various toxic materials. The advent of nanotechnology has given immeasurable opportunities to purify water even at ionic state. The various nanostructures materials have been fabricated with features such as high aspect ratio, reactivity, and tunable pore volume, electrostatic, hydrophilic and hydrophobic interactions which are useful in adsorption, catalysis, sensing, and optoelectronics. Nanotechnology, which literally refers to the manipulations of materials and processes that are engineered to the molecular scale of 1–100 nm, is an emerging field that poses immense ability to hierarchically construct materials from the bottom up approach to significantly improve the performance as well as add new functionality to the existing products. The evolutions and advancements explored in this field have urged seawater desalination progress as a more economical and sustainable option (Shannon et al. 2008). In this context, the paradigm shift made by the new approaches and technological innovation based on the new frontier in enabling nanoscience and nanotechnology, although not one size fits all, has advocated the progress of maintaining the sustainability in terms of reduced membrane materials, chemical and energy usage that eventually leads to minimized sources of environmental issues (Cloete 2010). Nanomaterials are the drivers of the nanotechnology revolution and a key bottleneck to the applications of nanotechnology to solve this world water crisis. Nanomaterials have a number of key physicochemical properties that make them particularly attractive as separation media for water purification. On a mass basis, they have much large surface areas than bulk particles. Nanomaterials can also be functionalized with various chemical groups to increase their affinity toward a given compound. They can also serve as high capacity/ selectivity and recyclable legends for toxic metal ions, radionuclides, organic and inorganic solutes/ anions in aqueous solutions. Nanomaterials also provide unprecedented opportunities to develop more efficient water-purification catalysts due to their large surface areas and their size and shape-dependent optical, electronic and catalytic properties.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Water pollutants have huge impacts on the entire living systems including terrestrial, aquatic, and aerial flora and fauna. In addition to conventional priority, and newly emerging micro/nano-pollutants, increasing global warming and consequent climate changes are posing major threats to the freshwater availability. Global warming and climate change are constantly increasing the salinity level of both land and sea water, dwindling the availability of existing fresh water for household, agriculture and industry. This has made it urgent to invent an appropriate water treatment technology that not only removes macro-, micro- and nano-pollutants but also desalinates water to a significant extension. Continuing population growth and urbanization as well as rapid industrialization are constantly putting pressure on global water demand and resulting in an alarming scenario where accessible freshwater supply is no longer matching the patterns of these developments. Desalination has long served as a feasible option to provide safe drinking water in many deserted areas, coastal regions or remote locations (Crittenden et al. 2005). Water, being a universal solvent dissolves all kinds of contaminants like metal ions, inorganic anions, organic dyes, pesticides and insecticides, radioactive elements, *etc.* Therefore, great challenges lie in the removal of contaminants from drinking water at ultra-trace levels at an affordable cost.A common problem in developing countries in drinking water that is contaminated with bacteria and viruses, which are the main cause of water-borane diseases (Patzke et al. 2002). Due to change in climatic conditions, growing pollution, water will become an even scarer, especially in developing countries. Moreover, in these countries, available water is often unsafe to drink. The interesting facts are shown in Table 1.

This chapter mainly concerned with providing a review of the interests of scientists and researchers in the application of nanomaterials in the improvement of water treatment, and application of nanotech in water treatments has several advantages than the traditional water treatments and this review also identifying the grand challenges and directions for future avenues in the field of Nanotechnology applications in water treatment.

2. NANOPARTICLES IN WATER TREATMENT

Nanoparticles have two key properties that make them particularly attractive as sorbents. First, on a mass basis, they have much larger surface areas than bulk particles. Second, they can also be functionalized with various chemical groups to increase their affinity towards target compounds.

Table 1. The interesting facts are shown in Table 1

Figures	Facts
3.4 millions	In developing countries people dies from water-related diseases every year
63 millions	In developing countries like Bangladesh, India and Nepal people suffers from arsenic pollution
6Km	Women's from Asia and Asian continent walk to fetch water
80%	Water-related deaths in children between age 0-14 years
40%	Water-related deaths are due to diarrhoea

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

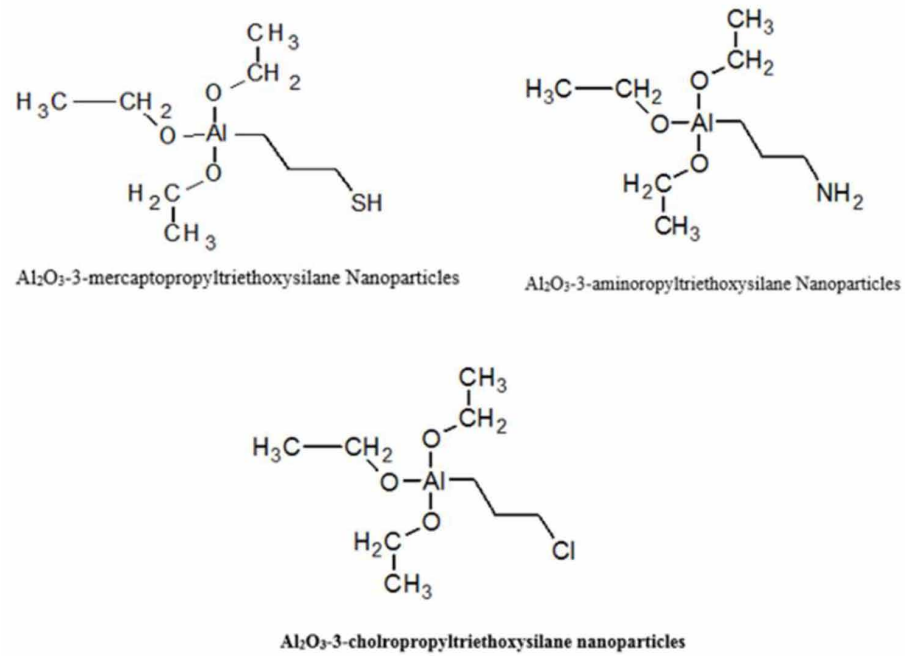
Applications of nanoparticles as adsorbents for high efficient removal of heavy metal ions from wastewater must satisfy the following criterions:

1. The nanosorbents themselves should be nontoxic
2. The sorbents must show relatively high sorption capacities and selectivity even to the low
3. The concentration of pollutants.
4. The adsorbed pollutant could be removed from the surface of the nanoadsorbent easily,
5. The sorbents could be infinitely recycled
6. The process should be reversible so that we can get our adsorbent back; the Nanoparticles
7. Studied in the removal of heavy metal ions from wastewater should show high adsorption
8. Capacity.

2.1 Alumina Nanoparticles for Water Remediation

Alumina is a traditional adsorbent for pollutants and Nanoparticles of alumina is anticipated to be more active than alumina in bulk state. Nanosized Al_2O_3 can be prepared by sol-gel method and has been employed as solid phase extraction materials for separation/ preconcentration of trace pollutants. Physical /Chemical modification of Al_2O_3 with various functional groups containing some donors atoms such as nitrogen, oxygen, and phosphorus have improved their separation/preconcentration toward emerging trace pollutants. Chitosan-grafted polyacrylamide nano-alumina Nanoparticles had been applied for the removal of arsenic from drinking water. Sorption of As(V) on aluminosilicate treated with iron nanocomposites and also alumina-silica nanocomposites had been applied for the adsorption of cadmium, lead from waste water (Medina et al. 2010). Figure 1 shows the structures of some alumina samples.

Figure 1. The structures of some alumina samples



EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

2.2 Silica Nanoparticles for Water Remediation

Silica nanoparticles is a promising material as a solid phase extractant because of its large surface area, high adsorption capacity, low-temperature modification, less degree of unsaturation and low electrophilicity (Kaur et al. 2009). The sequence of reactivity is expressed as follows:

$Zr(OR)_4$, $Al(OR)_4$> $Ti(OR)_4$> $Sn(OR)_4$>> $Si(OR)_4$

Some pollutants are poorly adsorbed on nanoparticles. To overcome this problem, physical or chemical modification of the surface of these nanoparticles with certain functional groups containing some donor atoms such as oxygen, nitrogen, sulfur and phosphorus are necessary. The most often used method is to load a kind of specific chelating reagent by the physical or chemical procedure. The formal method is simple but the loaded reagent is prone to leaking out from the sorbent, while the chemically bonded material is more stable and can be used repeatedly. The modification of nanometer sized materials is usually required in order to prevent a conglomeration of particles and to improve its consistency in relation to other materials. Also, the modification of nanometer-sized material can improve the selectivity of nanometer–sized materials toward pollutants. Selectivity of suitable specific functional groups towards metal ions depends on certain factors such as (1) size of the modifiers (2) activity of loaded group and also (3) on the basis of the concept of hard-soft acids and bases. Chemisorption of nanoparticles provides immobility, mechanical stability, and water insolubility, thereby increases the efficiency, sensitivity and selectivity.

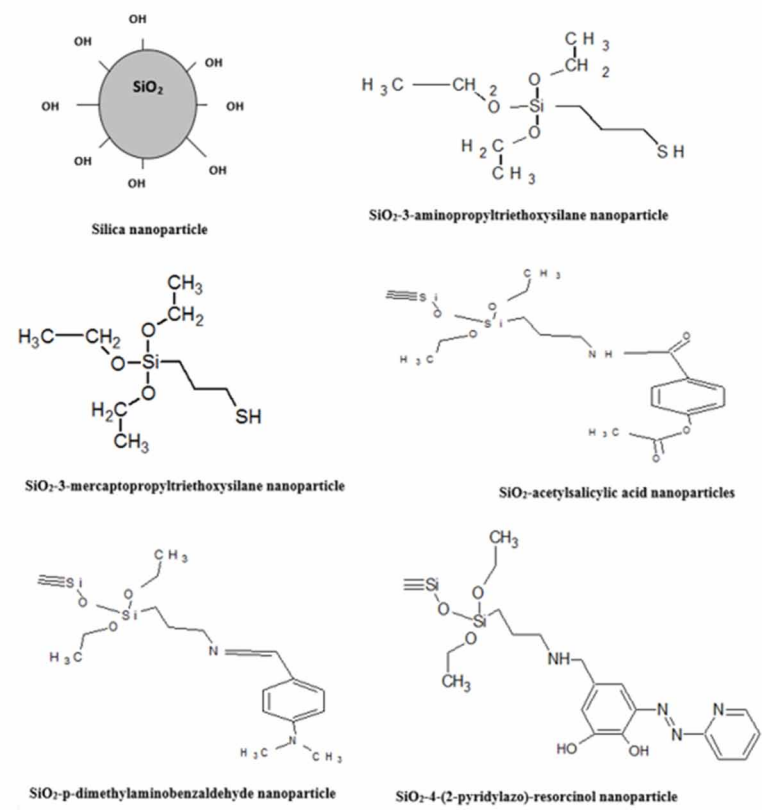
Chemical modification is a process that leads to change in chemical characteristics of the surface of nanoparticles. By the modification, the adsorption properties are significantly affected. Chemisorption of chelating molecules on nanoparticle surface provides immobility, mechanical stability, and water insolubility, thereby increases the efficiency, sensitivity and selectivity of nanoparticles for the analytical application. Chemical modification of nanoparticles by silylation procedure using different silylating agents such as 3-aminopropyltriethoxysilane, 3-chloropropyltriethoxysilane and 3-mercaptopropyltriethoxysilane provides immobility, mechanical stability and water insolubility, Figure 2. 1-(2-pydriylazo)-2-naphthol-modified SiO_2 nanoparticles have been used for the preconcentration of some toxic heavy metal ions such as Cd(II),Zn(II), Mn(II), Ni(II), Sb(III), Pb(II) and also ferbam pesticides from various samples (Kaur and Gupta 2010). Resacetophenone-modified silica nanoparticles have also been used for the preconcentration of Pb(II) and Cd(II) from water samples.

2.3 Titania Nanoparticles for Water Remediation

Tiny particles of titanium dioxide are found as key ingredients in wall paints, sunscreens, and toothpaste; they act as reflectors of light or as abrasives. However, with decreasing particle size and a corresponding change in their surface-to-volume ratio, their properties change so that crystalline titanium dioxide nanoparticles acquire catalytic ability; activated by the UV component in sunlight, they break down toxins or catalyze other relevant reactions. Titanium oxide photocatalysts have been widely studied for solar energy conversion and environmental applications in the past several decades because of their high chemical stability, good photoactivity, relatively low cost and nontoxicity. However, the photocatalytic capability of TiO2 is limited to only ultraviolet light; to overcome this problem both chemical and physical modifi cation approaches were developed to extend the absorption band-edge of TiO2 into

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. Chemical modification of silica nanoparticles with various silanes and ligands



visible region. In the photocatalytic oxidation process, organic pollutants are destroyed in the presence of semiconductor photocatalysts, an energetic light source, and an oxidizing agent such as oxygen or air. Only photons with energies greater than the bandgap energy (ΔE) can result in the excitation of the valence band (VB) electrons which then promote the possible reactions. The absorption of photons with energy lower than ΔE or longer wavelength usually causes energy dissipation in the form of heat.

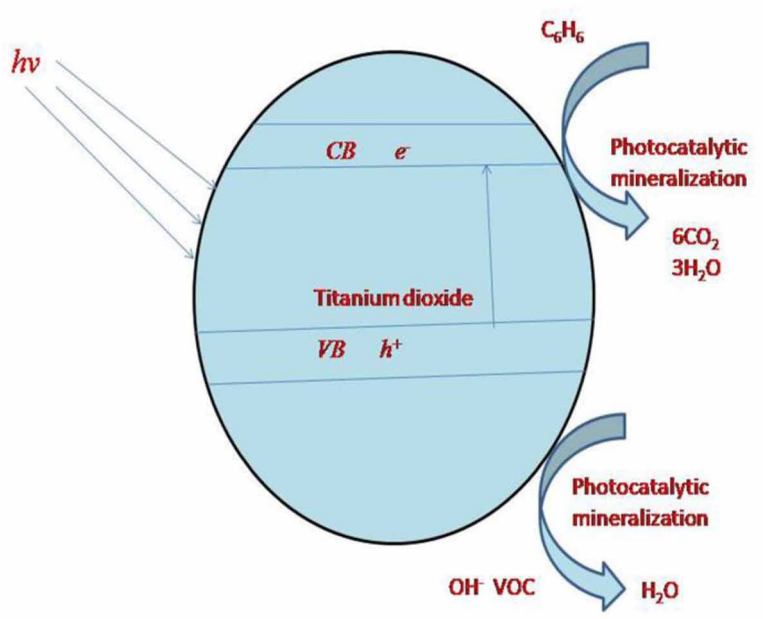
TiO_2 nanoparticles have emerged as promising photocatalysts for water purification, Figure 3. The removal of total organic carbon from waters contaminated with organic wastes was greatly enhanced by the addition of TiO_2 nanoparticles in the presence of ultraviolet light. It was successfully used to degrade organic compounds (e.g. chlorinated alkanes and benzenes, dioxins, furans) pentacholorophenol and aromatic chlorinated compounds had been photo-catalytically studied using titania Nanoparticles (Mills Hoffmann 1993). Separation and microcolumn preconcentration of traces of rare earth elements on nanoscale TiO_2 and their determination in geological samples (Jardim et al. 1997).

2.5 Nanoscale Zero-Valent Metals

Iron is one of the most abundant elements on earth. Elemental iron has been used as an ideal candidate for remediation because it is inexpensive, abundant easy to prepare and apply to a variety of systems, and devoid of any known toxicity induced by its usage. The concept of using metals, such as iron, as remediation agents are based on reduction–oxidation or "redox" reactions, in which a neutral electron

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 3. Photocatalytic studies by titania nanoparticles



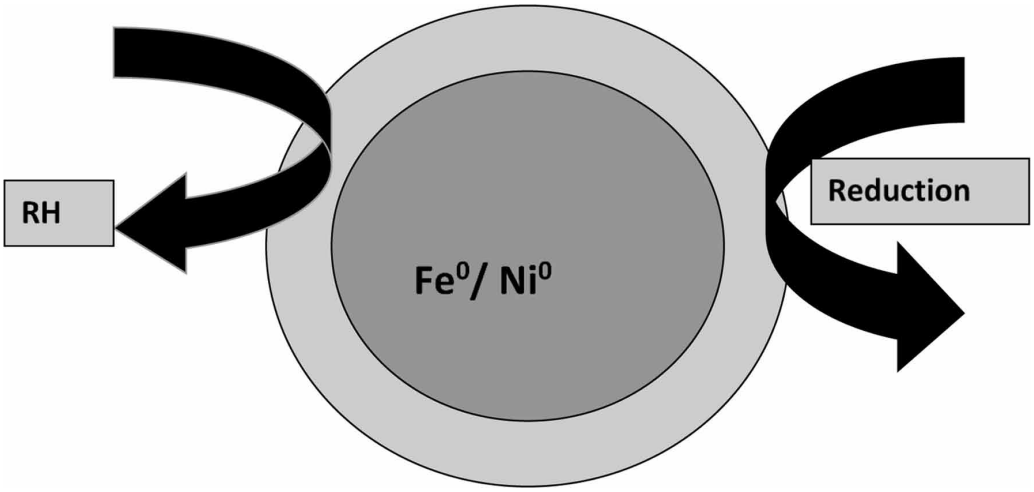
donor (a metal) chemically reduces an electron acceptor (a contaminant). Nanoscale iron particles have surface areas significantly greater than larger-sized powders or granular iron, which leads to enhanced reactivity for the redox process. As a result, iron nanoparticles have been extensively investigated for the decomposition of halogenated hydrocarbons to benign hydrocarbons and the remediation of many other contaminants including anions and heavy metals. Zero-valent iron nanoparticles are highly reactive and react rapidly with surrounding media in the subsurface (Zhang Elliot, 2006). A significant loss of reactivity can occur before the particles are able to reach the target contaminant. In addition, zero-valent iron nanoparticles tend to flocculate when added to water, resulting in a reduction in the effective surface area of the metal. Therefore, the effectiveness of a remediation depends on the accessibility of the contaminants to the nanoparticles; and the maximum efficiency of remediation will be achieved only if the metal nanoparticles can effectively migrate without oxidation to the contaminant or the water/contaminant interface. To overcome such difficulties, a commonly used strategy is to incorporate iron nanoparticles within support materials, such as polymers, porous carbon, and polyelectrolytes. Dissolved As(III) had been removed by iron Nanoparticles-embedded macrporous composites. Amine-functionalized Nanoparticles used for the rapid capture and removal of bacterial pathogens. Nanoscale zero-valent iron and bimetallic particles for a contaminated site for water remediation. Zerovalent iron Nanoparticles were applied for reductive decholrination of octacholorodibenzo-p-dioxin. Bentonite supported Fe/Pd Nanoparticles for the dechlorination of p-cholorophenol and also for PCB (Zhao et al. 2011), Figure 4.

3.Other Materials for Nanoremediation

Graphene is the allotrope of carbon. Especially, graphene–metal oxide composites have attracted extensive attention for their potential applications in environmental and energy-related areas. In this brief

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 4. Dechlorination by Zerovalent iron Nanoparticles



review, we will summarize recent achievements of effective strategies for synthesizing high-quality graphene–metal oxide composites and their photocatalytic applications. Photo-catalytically degradation of volatile aromatic pollutant had done by TiO_2-graphene nanocomposites. Removal of Pb(II) ions from aqueous solutions on few-layered graphene oxide nanosheets (Zhao et al. 2011). Preconcentration of U(VI) ions on few-layered graphene oxide nanosheets from aqueous solutions. Folding/aggregation of graphene oxide and its application in Cu^{2+} removal. Adsorptive remediation of environmental pollutants using novel graphene-based Nanomaterials.Graphene-based PANI nanocomposites have also been used as sensing platforms due to their good electrocatalytic activity, high specific surface area, excellent reliability, and low-cost properties. These composites are successfully used for DNA, 4-aminophenol, dopamine, artesunate, hydrogen peroxide and hydrazine detection, as well as hydrogen (H_2), methane (CH_4) and ammonia (NH_3) gas sensing.

Innovative sensors with high sensitivity and selectivity, and fast response are in great need, and also we know the fast response is in great need. Biosensors and affinity sensor devices have been shown to have the ability to provide rapid, cost-effective, specific and reliable quantitative and qualitative analysis. To date, the developments in nanomaterials and biosensor fabrications technology are moving rapidly with new and novel nano biorecognition materials being developed which can be applied as the sensing receptors for mycotoxins analysis. Biosensors, as tools have proofed to be able to provide rapid, sensitive, robust and cost effective quantitative methods for on-site testing. Developing biosensor devices for different mycotoxins are attracting much research interest in recent years with a range of devices are being developed and reported in the scientific literature. However, with the advent of nanotechnology and its impact on developing ultrasensitive devices, mycotoxins analysis is benefiting also from the advances taking place in applying nanomaterials in sensors development (Saini and Kaur, 2012).

It was established that gold supported on various metal oxides is a useful candidate for alkenes hydrogenation. A few interesting revelations arose from this research. Thiol–modified gold-coated polystyrene particles had been used for adsorption of aromatic compounds. Dansyl-norvaline stereospecfic recognition had been done by albumin gold nanoparticles. Gold nanoparticles were also employed for an immunoassay for the detection of aflatoxin B1 (AFB1) in foods (Liu et al. 2003).

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Recently, MOFs, obtained by linking metal cations (or cationic metal clusters) with organic linkers, have attracted significant interest in the last years mainly due to the advantage of showing a large variety of structural types and chemical compositions, high surface area and permanent nanoscale porosity (Abhijith and Thakur 2012). MOFs have been widely studied as materials for catalysis gas storage and separation sensing and drug delivery and, more recently, the analytical applications of MOFs have emerged (Sumida et al. 2011). In this field, MOFs have shown to be promising materials as sorbents for sample preparation as chromatographic stationary phases, as well as for the development of improved detection systems and sensors. However, MOFs crystalline powders generally possess a random crystal size and shape, which makes troublesome their direct application and have led to engineer hybrid materials containing them, such as through supports, magnetic beads, beads coated with a MOF shell, or MOF crystals entrapped porous monolith. Porous materials are defined as solids containing empty voids which can host other molecules. The fundamental features of these materials are their porosity, the ratio between total occupied and empty space, the (average) size of the pores and the surface area (Meek et al. 2011). Typical surface area values for the porous materials applied in technological processes range between 2,000 and 8,000 $m^2\ g^{-1}$. The most important applications of such materials are the storage of small molecules and filtering .The metal organic frameworks are defined as a nanocomposite material which can be consisted of either inorganic or organic materials. MOFs have shown high potential in gas storage, separation, chemical sensing, drug delivery, and heterogeneous catalysis applications. In general, the flexible and highly porous structure of MOFs allows guest species such as metal ions to diffuse into their bulk structure. The shape and size of the pores lead to selectivity over the guests that may be adsorbed. These features make MOFs an ideal sorbent in solid phase extraction of heavy metals. However, there is little information about MOFs as an adsorbent.

Nanomaterials are well known to possess excellent electrical, optical, thermal, catalytic properties and strong mechanical strength, which offer great opportunities to construct nanomaterials-based sensors or devices for monitoring environmental contaminations in air, water, and soil. Various nanomaterials, such as carbon nanotubes, gold nanoparticles, silicon nanowires and quantum dots, have been extensively explored in detecting and measuring toxic metal ions, toxic gasses, pesticides, and hazardous industrial chemicals with high sensitivity, selectivity, and simplicity.

CNTs and graphene have been extensively studied for nanodevices or nanosensors (Bagheri et al. 2012). CNTs and graphene ideal candidates for environmental pollution detection, such as heavy metal ions (Hg^{2+}, Pb^{2+}, As^{3+}, Ag^{+}), organophosphate pesticides,toxic gasses,industrial wastewater. Kim *et al.* constructed a selective, sensitive, and fast single-walled carbon nanotube (SWCNT)- based field effect transistor nanosensor for Hg^{2+} ion detection (Kim et al. 2009; Zhang et al. 2010).

Metallic nanoparticles, especially gold nanoparticles (AuNPs) and silver nanoparticles (AgNPs) have received much attention due to their potential applications in chemical and biological sensors, medical diagnostics and therapeutics and biological imaging (Rosi et al. 2006). AuNPs or AgNPs exhibit high extinction coefficients and strong size- and distance-dependent optical properties, and are considered as a new class of reporters and have been applied in colorimetric sensing (Lee et al. 2007). Mirkin's group developed a series of colorimetric sensors based on the color of the AuNPs or AgNPs from the red to blue, which allow in situ, real-time qualitative or semiquantitative detection without complicated analytical instruments (Mirkin et al. 1997). On this basis, Lu et al. developed colorimetric sensors for environmental monitoring, such as heavy metal ions ($Pb^{2+,}$ $Hg^{2+),}$ radioactive metal detection ($UO_2^{\ 2+}$) (Liu and Lu, 2003).

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Chen et al. synthesized b-cyclodextrin (CD)-functionalized silver nanoparticles as probes for highly robust, quantitative, sensitive, and observable by the naked eye colorimetric detection of different isomers of aromatic compounds (Chen et al. 2010). He *et al.* developed an oligo-T-based gold nanoprobe for rapid and portable detection of mercury with the help of a power-free poly(dimethylsiloxane) (PDMS) microfluidic device (He et al. 2008).

Silicon-based nanomaterials are an important type of nanomaterial, which has been extensively studied due to their with single-molecule sensitivity. Therefore, metallic nanoparticles are also excellent candidate substrates for environmental monitoring by surface-enhanced Raman scattering techniques, such as phenol, pesticides, TNT and heavy metal ions.

Dasary *et al.* 2009, used a cysteine modified AuNPs-based miniaturized, inexpensive, ultrasensitive SERS probe for highly sensitive and selective screening of 2,4,6-trinitrotoluene (TNT) from aqueous solution, which can induce aplastic anemia and abnormal liver functions.

Other nanomaterials also have been used for environmental monitoring, such as Fe_3O_4, SiO_2, ZrO_2 *etc*. For example, Zuo et al. 2009, used a nanocomplex made of MWNTs and magnetic nanoparticles (MNPs, Fe3O4) for highly efficient catalytic oxidation of phenols and their removal from wastewater.

More importantly, several portable nanomaterials-based devices have been designed in this direction. The unique chemical and physical properties of nanomaterials provide a versatile toolbox for developing various detection techniques with high sensitivity, specificity, speed, simplicity and cost-effectiveness for environmental monitoring. However, there is still an urgent need to further improve the sensitivity, and probably more importantly, the operation convenience from a practical point of view. The possibility for mass production is also a critical point for widespread application of nanomaterials-based sensors. In this regard, the design simplicity and compatibility with industry standards should be considered. Overall, we expect that the exploration of new nanomaterials and/or elaborate nanostructures will become an innovative source for developing sensors for environmental monitoring, and such sensors may eventually find widespread applications with the efforts from both academics and industry.

CONCLUSION

Decontamination is the reduction or removal of chemical and biological agents by means of physical, chemical neutralization or detoxication techniques. Nanotechnology revolution will play an essential role in solving the problem of rising demands of clean water and decreasing of the available supplies of fresh water. Nanomaterials have a number of physicochemical properties that make them particularly attractive as separation media for water purification.Nanotechnology has shown huge potential in areas as diverse as drug development, water decontamination, information and communication technologies, and the production of stronger, lighter materials and human health care. Water and air are two vital components of life on earth; the existence of life on earth is made possible largely because of their importance to metabolic processes within the body. Clean and fresh water and air are essential for the existence of life. The recent development of nanotechnology has raised the possibility of environmental decontamination through several nanomaterials, processes, and tools. This chapter summarizes the expertise of various approaches of decontamination for the successful realization of remediation in the environment.

Chapter 22
Determination of Rate of Medical Waste Generation Using RVM, MARS and MPMR

J. Jagan
VIT University, India

VIT University, India

Barnali Dixon
University of South Florida St. Petersburg, USA

ABSTRACT

The prediction of medical waste generation is an important task in hospital waste management. This article uses Relevance Vector Machine (RVM), Multivariate Adaptive Regression Spline (MARS) and Minimax Probability Machine Regression (MPMR) for prediction of rate of medical waste generation. Type of hospital, Capacity and Bed Occupancy has been used as inputs of RVM, MARS and MPMR. RVM is a probabilistic bayesian learning framework. MARS builds flexible model by using piecewise linear regressions. MPMR maximizes the minimum probability that future predicted outputs of the regression model will be within some bound of the true regression function. MARS, RVM and MPMR have been used as regression techniques. The results show that the developed RVM, MPMR and MARS give excellent models for determination of rate of medical waste generation.

INTRODUCTION

All over the world, wastes are generally interpreted as industrial or domestic. However, one kind of waste, on the rise, is bio-medical waste, disposed by hospitals. The number of hospitals is on the rise but these hospitals carry their share of potentially harmful baggage, that is, bio-medical wastes. These wastes, which can be municipal, pathological, sharps, etc, pose several threats such as environmental

pollution, unfavourable smell. If they serve as breeding grounds for rodents, insects, they aid in affecting human and animal health by spreading diseases like typhoid, cholera, hepatitis and AIDS due to reuse of contaminated syringes, etc. The best possible method to tackle this is efficient and effective waste management. Unfortunately, collection, transport and disposal of waste have no proper strategy or planning behind its implementation. It urgently needs to that needs to be regulated by definitive rules (Askariana et al., 2004). Thus, the data that is needed primarily is the rate of waste generation. This depends upon several factors such as (i) number of bed/patient available at the hospital; (ii) type of specialization (type and range of care); and (iii) number, kind, and size of departments (Award et al., 2004). The objective of this paper is to predict the rate based on these factors as it will directly assist in planning an efficient waste management strategy. Artificial Neural Network (ANN) and Multiple Linear Regression (MLR) have been used for this purpose (Jahandideh et al., 2009). But they have shortcomings such as the low accuracy of MLR and the black box approach, over fitting issues, lack of generalization capability and slow convergence rate of ANN (Park & Rilett, 1999; Kecman, 2001).

This article adopts Relevance Vector Machine (RVM), Minimax Probability Machine Regression (MPMR) and Multivariate Adaptive Regression Spline (MARS) for determination of rate of medical waste generation. This article adopts the database collected from the work of Jahandideh et al., (2009). The dataset contains information about type of hospital, Capacity(C), Bed Occupancy (B_0) and Waste generation rates (kg/day) (w_t). RVM is based on Bayesian Estimation Theory. The distinctive advantage is that it gives rise to sparse regressors without affecting the performance (Tipping, 2000). RVM typically uses very less basis functions and it has proven its accuracy (Tipping, 2001). It has been used to solve different problems in engineering (Wang et al., 2012; Hsu et al., 2013; Cui et al., 2014). In MPMR, prediction is done while ensuring that the maximum probability of error is minimized (Lanckriet et al., 2002). This method has a plus point over ANN as control on future prediction data is possible (Lanckriet et al., 2002). MPMR has been used to solve different engineering problems (Sun et al., 2009; Yang et al., 2010; Zhou et al., 2013). GPR is a generic supervised learning method used to solve regression problems. This is developed based on Gaussian Processes. This is done by modelling the random processes as Gaussian processes. This method is versatile, practical, allows for generalization, and can specify very flexible non-linear regression too. This has been implemented for solving different problems in engineering (Heyns et al., 2012; Verrelst et al., 2013; Sun et al., 2014). A comparative study has been presented between the developed MARS, MPMR and RVM models.

DETAILS OF MARS

MARS uses basis functions to model the complex relationship between input(x) and output(y). The expression of MARS model is given below.

$$y = a_0 + \sum_{m=1}^{M} a_m B_m(x) \tag{1}$$

where a_0 is coefficient, $B_m(x)$ is basis function, a_m is coefficient of $B_m(x)$ and M is the number of basis functions. In this study, $x=[C, B_0, x_3, x_4, x_5, x_6]$ and $y=[w_t]$. Table 1 shows the value x_3, x_4, x_5 and x_6 for the different hospitals.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 1. Input variables for different types of hospital (Jahandideh et al., 2009)

Type of Hospital	x_3	x_4	x_5	x_6
Private	1	0	0	0
Governmental	0	1	0	0
Educational	0	0	1	0
Non-educational, but university-related hospital	0	0	0	1

MARS adopts two-sided truncated power functions as basis function. The expression of two-sided truncated power function given below:

$$b_q^-\left(x-t\right)=\left[-\left(x-t\right)\right]_+^q=\begin{cases}\left(t-x\right)^q & \text{if } x>t\\ 0 & \text{otherwise}\end{cases} \tag{2}$$

$$b_q^+\left(x-t\right)=\left[+\left(x-t\right)\right]_+^q=\begin{cases}\left(x-t\right)^q & \text{if } x>t\\ 0 & \text{otherwise}\end{cases} \tag{3}$$

where q is power, t is the knot location and $b_q^-\left(x-t\right)$ and $b_q^+\left(x-t\right)$ are the spline functions.

A two-step procedure is used to develop the MARS model. In 1st step, basis functions are added to define equation (1). This step is called forward step. Overfitting can occur due to large number of basis functions. In 2nd step, basis functions are deleted based on Generalised Cross-Validation (GCV) (Craven & Wahba, 1979). This step is called backward step. The value of GCV is determined from the following equation.

$$GCV=\frac{\frac{1}{N}\sum_{i=1}^{N}\left[y_i-f(x_1)\right]^2}{\left[1-\frac{C\left(B\right)}{N}\right]^2} \tag{4}$$

where N is the number of data and C(B) is a complexity penalty that increases with the number of BF in the model and which is defined as:

$$C(B)=(B+1)+dB \tag{5}$$

where d is a penalty for each basis function (BF) included into the model.

In MARS, Analysis of Variance (ANOVA) is possible (Friedman, 1990). The expression of ANOVA for the MARS is given below:

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

$$f(x) = \beta_0 + \sum_{B=1} f_i(x_i) + \sum_{B=2} f_{ij}(x_i, x_j) + \sum_{B=3} f_{ijk}(x_i, x_j, x_k) + \ldots \quad (6)$$

$\sum_{B=1} f_i x_i$ is over all basis functions that involve only a single variable.
$\sum_{B=2} f_{ij}(x_i, x_j)$ is over all basis functions that involve exactly two variables.
$\sum_{B=3} f_{ijk}(x_i, x_j, x_k)$ represents (if present) the contributions from three variable interactions and so on.

The total datasets have been divided into the following two groups:

- **Training Dataset:** This is used to develop the MARS. In this article, 35 datasets out of 50 have been adopted as training dataset.
- **Testing Dataset:** This is used to verify the developed MARS. This article uses the remaining 15 datasets as testing dataset.

The datasets are scaled between 0 and 1. The programming of MARS has been done by using MATLAB.

DETAILS OF RVM

RVM is a sparse Bayesian approach. In RVM, Gaussian prior is introduced on each parameter. RVM uses the following equation for prediction of output(y).

$$y = \Phi w + \varepsilon \quad (7)$$

where w is weight vector, $\Phi=[\varphi(x_1),\ldots,\varphi(x_N)]^T$ is design matrix, ε is noise and it follows mean-zero Gaussian distribution with variance σ2. The expression of $\phi(x_n)$ is given below:

$$\varphi(x_n) = \left[K(x_n, x_1), K(x_n, x_2), \ldots, K(x_n, x_M)\right] \quad (8)$$

where $K(x_n,x_i)$ is a kernel function.

The likelihood of the training dataset is given below:

$$p\left(y \mid w, \sigma^2\right) = \left(2\pi\sigma^2\right)^{-N/2} \exp\left\{-\frac{1}{2\sigma^2}\left\|y - \Phi w\right\|^2\right\} \quad (9)$$

The value of w and σ^2 has been determined by maximizing the above expression (9). To avoid over-fitting, w is set as a zero-mean Gaussian prior distribution with variance α-1:

$$p\left(w/\alpha\right) = \prod_{i=0}^{n} \mathrm{N}\left(w_i/0, \alpha_i^{-1}\right) = \prod_{i=0}^{n} \frac{\alpha_i}{\sqrt{2\pi}} \exp\left(-\frac{\left(w_i\alpha_i\right)^2}{2\pi}\right) \quad (10)$$

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

where $\alpha=[\alpha_1,\alpha_2,\ldots,\alpha_n]$.

The posterior distribution of weight is given below:

$$p\left(w/y,\alpha,\sigma^2\right)=\left(2\pi\right)^{-(n+1)/2}\left|\sum\right|^{-1/2}\exp\left[-\frac{1}{2}\left(w-\mu\right)'\Sigma^{-1}\left(w-\mu\right)\right] \tag{11}$$

where μ is mean and $\sum$ is variance.

The marginal likelihood is given below:

$$\begin{aligned} &p\left(y/\alpha,\sigma^2\right)= \\ &\int p\left(y/w,\sigma^2\right)p\left(w/\alpha\right)dw=\left(2\pi\right)^{\frac{-n}{2}}\left|\sigma^2 I+\Phi A^{-1}\Phi'\right|^{\frac{-1}{1}}\times\exp\left[-\frac{1}{2}y'\left(\sigma^2 I+\Phi A^{-1}\Phi'\right)^{-1}y\right] \end{aligned} \tag{12}$$

Hyperparameter estimation is typically carried out with an iterative formula such as a gradient ascent on the objective function (Tipping, 2000). Predictions for a new data are then made according to integration of the weights to obtain the marginal likelihood for the hyperparameters.

RVM adopts the same training dataset, testing dataset, inputs, output and normalization technique as used by the MARS model. Radial basis function has been adopted as kernel function. The expression of radial basis functions is given below:

$$K\left(x_k,x\right)=\exp\left\{-\frac{\left(x_k-x\right)^T\left(x_k-x\right)}{2\sigma^2}\right\} \tag{13}$$

where σ is the width of radial basis function.

The program of RVM has been done by using MATLAB.

DETAILS OF MPMR

MPMR is developed by using kernel formulation on Minimax Probability Machine Classification (MPMC) (Lanckriet et al., 2002).

In MPMR, the relation between input(x) and output(y) is given below:

$$y=\sum_{i=1}^{N}\beta_i K(x_i,x)+b \tag{14}$$

where N is number of datasets, $K(x_i,x)$ is kernel function, βi and b are outputs the MPMR.

The datasets are divided into two classes (u_i and v_i).

$$u_i=(y_i+\varepsilon,\ x_{i1},\ x_{i2},\ \ldots,\ x_{in}) \tag{15}$$

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

$$v_i = (y_i\text{-}\varepsilon, x_{i1}, x_{i2}, \ldots, x_{in}) \quad (16)$$

The classification between these two classes is regression surface.

MPMR adopts the same training datasets, testing dataset, inputs, output normalization technique, and kernel function as used by the RVM model. The program of MPMR has been constructed by using MATLAB.

RESULTS AND DISCUSSION

For MARS, ten basis functions have been added in forward step. In backward step, three basis functions have been deleted. So, the final MARS model contains seven basis functions. The expression of final MARS model is given below (by putting $y=w_t$, $a_0=0.047$ and $M=7$ in equation 1):

$$w_t = 0.047 + \sum_{m=1}^{7} a_m B_m(x) \quad (17)$$

Table 2 shows the details of a_m and $B_m(x)$.

The performance of training and testing datasets has been determined by using the above equation (Sun et al., 2014). Coefficient of Correlation(R) has been adopted to assess the performance of MPMR model. For a good model, the value of R should be close to one. The performance of training and testing datasets has been depicted in figure 1 and 2 respectively.

It is observed in figures 1 and 2 that the value of R is close to one for training as well as testing datasets. Therefore, the developed MARS proves his capability for prediction of wt. ANOVA decomposition has been done on the developed MARS. Table 3 shows the result of ANOVA decomposition.

The value of GCV is maximum C and B_0. So, C and B_0 have maximum effect on the predicted w_t. For developing RVM, the design value of σ has been determined by trial and error approach. The developed RVM gives best performance at σ=0.7. The performance of training and testing dataset has been illustrated in figure 1 and 2 respectively. It is clear from figures 1 and 2 that the value of R is close 1. The developed RVM presents the following equation for prediction of w_t.

Table 2. Details of $B_m(x)$ and a_m

$B_m(x)$	Equation	a_m
$B_1(x)$	max(0, C - 0.132)	-0.036
$B_2(x)$	$B_1(x)$max(0, B - 0.347)	4.109
$B_3(x)$	max(0, 0.038 – C)	-2.188
$B_4(x)$	max(0, C – 0.038) max(0, x_6 – 0)	0.231
$B_5(x)$	max(0, 0.277 – B)	-0.176
$B_6(x)$	max(0, 0.132 – C) max(0, 1 – x_6)	0.5
$B_7(x)$	max(0, 0.038 – C)	1.57

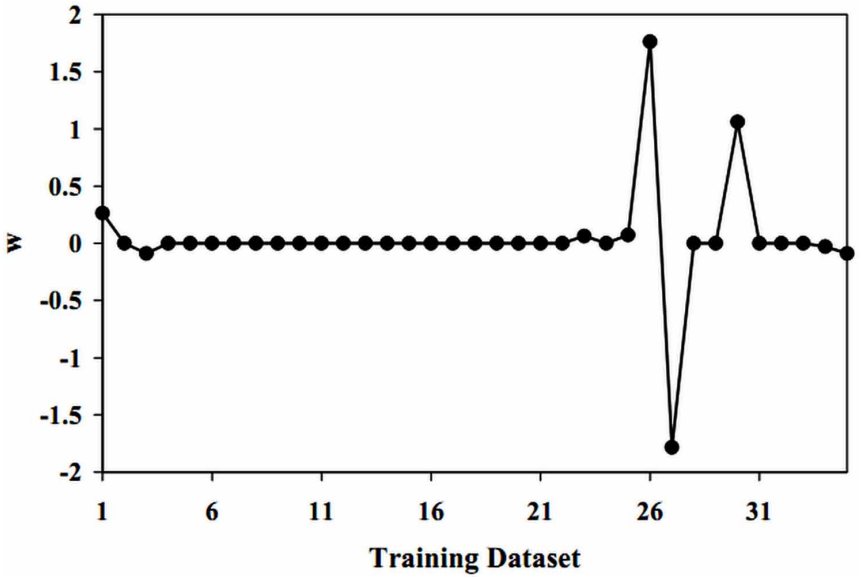
$$w_t = \sum_{i=1}^{35} w_i \exp\left[\frac{-(x_i - x)(x_i - x)^T}{0.98}\right] \tag{18}$$

where the value of w has been given in figure 3.

This article adopts trial and error approach for determination of design values of ε and σ for developing the MPMR model. The developed MPMR gives best performance at ε=0.009 and σ=0.8. Figures 1 and 2 illustrate the performance of training and testing respectively. As shown in figures 1 and 2 that the value of R is close to one for the MPMR model. The performance of MPMR, MARS and RVM is comparable. MARS uses basis function for final prediction. However, RVM and MPMR adopt kernel function for developing model. There is a control over future prediction in the MPMR model. Whereas, the developed RVM and MARS have no control over future prediction. There are some statistical parameters mean (μ), and standard deviation (σ), other than the coefficient of correlation value, which have been used to justify the performance of the prediction techniques. The ratio of the predicted capacity (C_p) to the measured capacity (C_a) is the important parameter in evaluating the developed models (Farsakh & Titi, 2004; Das & Basudhar, 2006). The mean (μ), and standard deviation (σ) values of C_p/C_a explains the precision and accuracy of the developed predictive models.

From the above table 4, it was clearly depicted that the developed models mean and standard deviation values are nearby 1 and 0. Hence we can justify that the developed model performs well. Also with other distribution techniques have been adopted to determine the performance of the predictive techniques. The cumulative distribution values and probability density values of C_p/C_a have been determined and it's been plotted. The following figures will clearly project the performances of the developed models (see Figures 4, 5, and 6).

Figure 3. Values of w for the RVM model

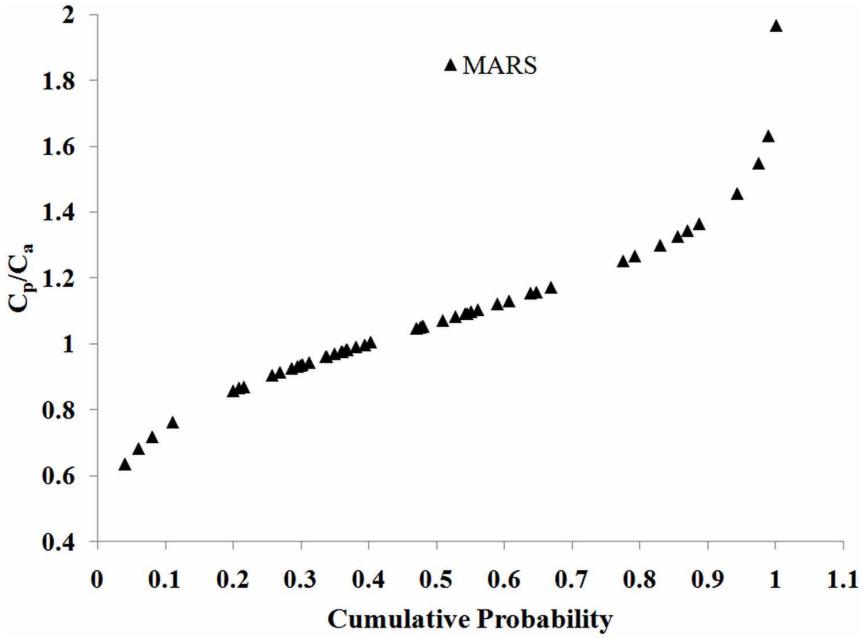


EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 4. Statistical criteria for the developed models

	MPMR	RVM	MARS
Mean (μ)	1.0371	1.0536	1.0648
Standard Deviation (σ)	0.176	0.3169	0.247

Figure 4. Cumulative probability plots of C_p/C_a for MARS model



These figures show that the maximum values have been lie on and nearby 1. These also refer the performance of the developed models. The following figure depicts the normal distributions of the developed models (see Figure 7, 8 and 9).

These figures exposed that the maximum values are closely packed on and nearby the peak 1. This also can be justified for the performance of the developed models.

In this chapter, the capacity of beds has been determined by using various techniques like MARS, RVM and MPMR. Different statistical criteria like Root Mean Square Error (RMSE), Mean Absolute Error (MAE), Coefficient of Efficiency (E), Root mean square error to observation's standard deviation ratio (RSR), Normalized Mean Biased Error (NMBE) and Performance Index (ρ) have been used to compare the developed model. The above mentioned statistical criteria have been determined by using the following equations.

$$RMSE = \sqrt{\frac{\sum_{i=1}^{n}\left(h_i - t_t\right)^2}{n}} \tag{19}$$

Table 5. Statistical criteria's for the developed models

	MPMR		RVM		MARS	
	Training	**Testing**	**Training**	**Testing**	**Training**	**Testing**
RMSE	10.02467	5.03506	16.37498	11.92397	13.28719	14.80699
MAE	5.94222	2.33106	11.69365	7.56408	9.61780	9.93414
E	0.98946	0.98753	0.97188	0.93005	0.98149	0.89213
RSR	0.00105	0.00248	-45.60998	0.00587	0.00139	0.06754
NMBE (%)	0.84955	-0.00623	-0.46869	-3.26163	0.90300	-1.77127
ρ	0.06563	0.28911	0.10769	0.29308	0.08717	0.29609

where h_i and t_i are the actual and predicted values for the i^{th} output, $\bar{h}_i$ and $\bar{t}_i$ are the average of the measured and predicted outputs, n is the total number of data and p is the number of predictor variables.

By using the above equations the values have been determined and it is tabulated in the following table 5.

CONCLUSION

This chapter examines the capability of MARS, MPMR and RVM for prediction of rate of medical waste generation based on type of hospital, capacity and bed occupancy. The developed MARS, MPMR and RVM give encouraging performance. The developed equations can be used practically. The result of ANOVA decomposition shows that C and B0 have maximum impact on the predicted w_t. The developed RVM only produces sparse solution. This article gives robust models based on MARS, RVM and MPMR for prediction of rate of medical waste generation.

KEY TERMS AND DEFINITIONS

Artificial Neural Network: Artificial Neural Network is a structure framed with densely interconnected with artificial neurons that performs the parallel computations for data processing and knowledge representations.

Medical Waste: Medical waste is all waste materials generated at health care facilities, such as hospitals, clinics, physician's offices, dental practices, blood banks, and veterinary hospitals/clinics, as well as medical research facilities and laboratories.

Minimax Probability Machine Regression: It is the method used for maximizing the minimum probability of future predictions being within some bound of the true regression function.

Multivariate Adaptive Regression Spline: MARS is a nonparametric regression modeling technique based on split and conquer approach in which the training dataset are segregated into separate piecewise linear segments (splines) of differing gradients.

Prediction: The action of forecasting or estimating something is called as prediction.

Relevance Vector Machine: Relevance Vector Machine (RVM) uses Bayesian inference to get the solutions for classification and regression problems. It has same functional form of SVM, but provides the probabilistic classification.

Chapter 23
Decision Insights for Shipbreaking using Environmental Impact Assessment:
Review and Perspectives

Joshin John
Indian Institute of Management, India

Rajiv Kumar Srivastava
Indian Institute of Management, India

ABSTRACT

This article describes how the shipbreaking industry has been under the microscope, more often in recent years, with scrutiny from governments, international agencies and environmental activists, on issues pertaining to sustainability in general and environmental impact in particular. Several cases of vessels-to-be-dismantled, by and large in yards located in South Asia, have been discussed in literature, with concerns on the modus operandi of dismantling end-of-life ships, and the mode of disposal of hazardous residual wastes. In this article, the authors review extant methodologies, and examine the decision alternatives available to shipbreakers, recyclers and waste material handlers to minimize damage to the environment. Impact assessment results using Open-LCA has been presented to demonstrate the relative impact loadings on various environmental parameters, from the path functions adopted. The results of the environmental impact assessment provide decision insights on various alternatives that may be appropriated in order to mitigate environmental damage. The article concludes with discussion, perspectives and future research directions to improve decision making for sustainable shipbreaking.

1. INTRODUCTION

Shipbreaking is the process of dismantling a vessel, generally after its service period, for disposal, recycling or recovery of its structural components (Demaria, 2010; Patel et al., 2012). Over the last few decades, shipbreaking has grown into a multibillion dollar industry primarily located in India, Bangladesh, China, Pakistan and Turkey (Neşer et al., 2008; Sawyer, 2001). The industry is a major feeder of raw materials to the steel and construction industries (Sujauddin et al., 2015; Singh & Kaushik, 2002) in these countries and has flourished, thanks to the abundant labor resources available for shipbreaking at relatively cheaper rates (Rousmaniere & Raj, 2007). The regulatory framework (Bhattacharjee, 2009; Puthucherril, 2010; Alam & Faruque, 2014) and geographical advantages (Sibilia, 2015; Chang et al., 2010) have also contributed towards the growth of the shipbreaking industry in these locations. However, there has been increasing concern on the sustainability (Kusumaningdyah et al., 2013; Khan et al., 2012) of shipbreaking industry, particularly in view of the practices (Dodds, 2007; Hossain & Islam, 2006) that were prevalent in yards located in the subcontinent, comprising of the nation states of India, Bangladesh and Pakistan. This article examines the sustainability issues associated with shipbreaking activity, and draws insights to mitigate environmental impact using Life Cycle Assessment tool.

The desiderata of sustainable development envisioned by Brundtland Commission (1985) has been widely acknowledged and conceptualized as the sustainability pillars of (a) Economic Benefit, (b) Environmental Protection, and (c) Social Justice. The post-Brundtland world (Sneddon et al., 2006) has evolved on the tenets of sustainability and branched into field-specific discourses such as in operations (Kliendorfer et al., 2005; Gimenez et al., 2012; Tang & Zhou, 2012), manufacturing (Jayal et al., 2010; Garetti & Taisch, 2012) and supply chain management (Seuring & Müller, 2008; Carter & Rogers, 2008; Carter & Easton, 2011; Pagell & Wu, 2009; Gold et al., 2010). Over the years, there have been several research studies on environmental and social impact due to shipbreaking activities, capturing both qualitative and quantitative aspects. Considerable research in the past has been fixated on the environmental issues (Reddy et al., 2003, 2004a, 2004b, 2005a, 2005b; Hossain & Islam, 2006; Hossain et al., 2010; Asolekar, 2006, 2012) due to ship scrap wastes, while some researchers (Anderson, 2001; Deshpande et al., 2012; Neşer et al., 2008) have focused on worker safety aspects and human impact due to shipbreaking. Case studies of vessels-to-be-dismantled such as the French Aircraft Carrier 'Le Clemenceau' (Thomas, 2007) and Cruise liner 'Blue Lady' (Pelsy, 2008) have been deliberated in literature. Some researchers (Mikelis, 2008; Knapp et al., 2008) have undertaken statistical and econometric analyses of shipbreaking industry whereas others (Carvalho et al., 2011) have demonstrated methodologies for environmental impact modeling. However, we observe a lacuna in literature on insights to determine cause-effect relations on environmental impact parameters during shipbreaking, recycling and disposal. These insights would be useful to mitigate specific and measurable environmental impacts based on standard parameters.

The motivation for this study stems from the need to address and contain issues (Smith, 2003) related to environmental impact due to shipbreaking and waste disposal post-dismantling that affects the local population and their livelihoods in the form of health problems, resource degradation, lower agricultural produce and deterioration in fishing catchment areas (Abdullah et al., 2013; Pasha et al., 2012) among others. Shama (2005) had proposed the use of Life Cycle Assessment to determine the environmental performance of ships, and since then, several studies (Kameyama et al., 2005; Zuin et al., 2009; Tincelin et al., 2010; Chatzinikolaou & Ventikos, 2013) have been conducted along those lines. However, the employment of this technique is constrained in practice by the necessary inventory control documentation

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

required. With the adoption of Hong Kong Convention (Nassar & Moursy, 2016) and book keeping of the Inventory of Hazardous Materials (IHM) on board in the form of 'Green Passport', we demonstrate in this research the decision insights available to mitigate environmental impact post-dismantling.

2. SHIPBREAKING SCENARIO

The shipbreaking business got an impetus post the Lehmann crisis (Ahn et al., 2011), with global ship-scrap tonnage volumes swelling up to decade high levels (MEPC, 2012). This trigger that boosted the shipbreaking activity was understandable, given the concerns about the world economy slipping into a recessionary phase, plunging spot rates and declining shipping indices such as Baltic Dry Index (Gemen & Smith, 2012), HARPEX (Balliauw, 2015) and BDTI (Kavussanos & Dimitrakopoulos, 2011). Foreseeing excess supply of ships and lackluster business for the next couple of years, several ship owners took their ships to the shores, for scrapping well ahead of its service life; sometimes cutting into as much as a third of the vessel's intended design life. A majority of these vessels found their graveyards along the beaches of South Asia, principally in Bangladesh, India, Pakistan, and to a lesser extent in China (Mikelis, 2013). The location of the major shipbreaking yards and their salient characteristics are depicted in Figure 1 and Table 1 respectively. The data for ship demolition gross tonnage over the years was collated from a combination of registers such as Clarkson Research, Lloyd's IHS Fairplay and BIMCO bulletins, and trends of ship demolition market from 1980-2011 are represented in Figure 2. More recent trends of country-wise ship demolition from 2011-2015 is presented in Figure 3.

It may be noted that the type of vessels demolished and the method of shipbreaking varies at different locations. For example, a great majority of the large vessels such as bulkers, general cargo vessels, oil tankers, chemical tankers, gas tankers and large passenger vessels run up on the intertidal zones of Alang, Gadani and Chittagong where beaching method is practiced (Lloyd's Register, 2011). The beaching method in open mudflat areas is a source of severe coastal pollution, combined with dangerous working conditions for the workers (NGO Shipbreaking Platform, 2016), although more profitable for the ship owners, and cash-buyers, who often recourse to re-register waste laden end-of-life vessels with flags of convenience, to circumvent stringent norms. Vessels that are dismantled in controlled conditions such as in dry-docks at locations in Western Europe, United States and to some extent in China, represent

Table 1. Salient Characteristics of Shipbreaking Facilities around the world

Shipbreaking Facility (Location)	Shipbreaking Method and Unique Characteristics	Business Practices and Areas of Concern
Bangladesh	Beaching method is practiced for shipbreaking over the 15 km long intertidal mudflats in Sitakund region along the coastline just outside the major port city of Chittagong in Bangladesh. Dismantling happens in open beaches using winches and cutting equipment, predominantly in leased government owned land with little regulation.	Dangerous working condition due to lack of proper Personal Protection Equipment (PPE) for workers, medical facilities, low pay, long working hours, exploitation of underage or child laborers. No strict law enforcement, hazardous waste dumping and absence of downstream waste management facilities are major points of concern.
India	Alang-Sosiya Ship Recycling Yard, 50 km away from the port city of Bhavnagar (Gujarat) was the largest shipbreaking facility in the world particularly during the last decade, employing the beaching technique. Of the 170 shipbreaking plots leased-out, about 50 are active and 4 are compliant with IMO's Hong Kong Convention [certified by Class NK], with cemented secondary cutting zones, installed drainage systems & improved hazardous waste storage facilities.	Environmental concerns related to continued operations in unprotected tidal waters at some shipbreaking plots at Alang. No proper disposal site for some end components of disassembled ship such as PCBs, re-sale of asbestos containing materials in second hand market, inadequate environmental impact assessment regarding pollution by toxic paints, slag, debris, oil spill etc. at the intertidal zone, and air pollution due to release of toxic fumes.
Pakistan	Beaching is practiced at Gadani, in Balochistan Province, about 50 km west of Pakistan's largest port city of Karachi. There are about 40 companies operating in 130 shipbreaking plots. Shipbreaking is labor intensive with large migrant workforce from the North-Western Frontier Province of Khyber Pakhtunkhwa. The yards operate directly on the beach without any impermeable and drained working sites to protect land & sea from pollution.	Shipbreaking is unregulated and there is no proper legal regime in place. The hazardous working conditions came to light recently with the campaigns of international and local NGOs to provide better working conditions and environmental protection. The shipbreaking sites at Gadani do not have any hazardous waste management system, resulting in wastes, asbestos & chemicals being dumped at site.
China	Shipbreaking in China is mainly done at 3 locations: Dalian in the north, and Xinhui & Zhoushan in the south. The quay-side method of breaking the vessel from the superstructure to the keel using cranes is practiced in some locations; slipways & dry-docking is also being practiced in China. Beaching is banned in China with efforts to upgrade & modernize facilities for environmental protection as per IMO's Hong Kong Convention.	China subsidizes demolition of Chinese flagged vessels retaining domestic end-of-life vessels for its own dismantling industries. Banning beaching, facility upgrade and compliance with Hong Kong Convention has made China preferred destination for European Owners. Concerns include absence of independent trade unions, minimal protective gear for workers, lack of fully safe asbestos removal & hazardous waste tracking downstream.
Turkey	Shipbreaking is practiced at Aliaga in Turkey using the Landing Method, wherein the bow of the vessel is grounded on the shore while the stern is afloat, and cut blocks lifted up stepwise using cranes and moved to a controlled working area for further disassembly. Aliaga is 50 km north of Izmir on the Aegean coast, and shipbreaking activity is carried out mostly by migrant workers from Tokat and Sivas area in Eastern Turkey.	Although shipbreaking yards in Turkey are in better standing than their South Asian counterparts, the working conditions and environmental standards lag OECD criteria. In recent years, Turkish yards have opened doors to cooperate with European governments, research experts & consultants to dismantle obsolete naval vessels; concerns still persist on downstream management of heavy metals, paints and PCBs.
Rest of the World	Shipbreaking facilities such as dry-docks & slipways are available in OECD countries such as USA, UK, Belgium, Denmark, South Korea and Sweden. Dismantling at these locations are done under controlled and safe environment, nonetheless not viable at large scale due to high cost factor.	Small and medium size commercial vessels and naval ships are dismantled in these locations in North America & Western Europe. The quality of service is generally considered high in OECD countries, with proper worker safety and downstream waste management systems in place.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

only a minority of the global shipbreaking activity (UNCTAD, 2015). The European Regulation on Ship Recycling (European Parliament, 2013), which entered into force in 2013, requires all ships (not only EU-flagged vessels) entering EU ports to have an Inventory of Hazardous Material (IHM) on board, enabling tracking vessels of European origin, and effectively prohibiting and preventing trans-boundary movement of hazardous wastes including end-of-life ships. The regulation also mandates EU flagged vessels to be dismantled only at locations in the European Commission approved list of global recycling facilities.

Turkey and China are two other notable shipbreaking locations. The landing method is generally practiced at Aliaga, Turkey, which accounts for less than 5 per cent of the global shipbreaking. China, has maintained its foothold at about one-fifth of the global shipbreaking, and is attracting new customers using a combination of policies, domestic subsidies and investments in modern, environment friendly, ship dismantling & recycling facilities. The method of ship dismantling in China include slip-way, dry-docking and quay side method.

3. METHODOLOGY

In this research, we use life cycle assessment (LCA) method to study the environmental impact during ship dismantling and subsequent waste treatment. It may be noted that the total impact of the vessel during its lifecycle will be dependent on the original design and components of the vessel, its operation and maintenance during service, and method of shipbreaking and waste treatment adopted. In this study, we will be focusing on the final phase post-decommissioning of the vessel, i.e. the impact due to breaking, disposal or recycling of the vessel.

The environmental impact due to method of decommissioning, and the consequent effects can be assessed by using an appropriate LCA tool. In this study, we adopt CML 2001 impact assessment criteria developed by the Centre of Environmental Science, Leiden University, which has been applied in similar contexts (Shen et al., 2010; El-Houjeiri et al., 2013) to assess the impact of end-of-life products. The analysis is performed using Open-LCA 1.3.0, an open-source software for Impact Assessment created by GreenDelta. The inventory of materials is sourced from the 'Green Passport' of the vessel (ship or boat), and the requisite path functions representing the material treatment processes post decommissioning is coded using the *Ecoinvent* database inbuilt in the software. Based on the LCA model, the effects observed from analysis results is interpreted. Further, the effects on multiple parameters such as acidification potential, climate change, eutrophication potential, freshwater aquatic eco-toxicity, freshwater sediment eco-toxicity, human toxicity, ionizing radiation, land use competition, photochemical oxidation, marine aquatic eco-toxicity, marine sediment eco-toxicity, stratospheric ozone depletion, terrestrial eco-toxicity etc. are deliberated. In conclusion, using LCA, we consider and evaluate the alternatives for mitigating the environmental impact on specified standard criteria, and in effect alleviate the carbon footprint associated with the shipbreaking and recycling processes.

4. CASE ILLUSTRATION

This section illustrates a case of applying LCA tool to model and assess the environmental impacts from breaking a vessel. There have been few case studies (Thomas, 2007; Pelsy, 2008) in the past illustrat-

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

ing the visible impacts of shipbreaking, such as decrease in agricultural produce, reduction in fishing catchment in the region, and occupational diseases affecting workers involved in shipbreaking activity. However, the latent effects of shipbreaking which are explicit only in medium or long term can be significant, as exemplified in this case.

The case is of a Ro-Ro Lo-Lo (Roll on / Roll off & Lift on/ Lift off) Semi-Submersible Heavy Lift Container Carrier Vessel. The vessel is over 20 years old and is lined up for decommissioning and subsequent disassembly. The location of last port of call is Alang, Gujarat (India), one of the largest shipbreaking and recycling yards in the world. In order to ascertain the impact, the system, material and energy inflows and outflows from the system boundaries are to be defined. The boundaries of our system, in this context is defined as the region in Bhavnagar, Gujarat, within 100 km radius of Alang-Sosiya yard wherein there is maximum concentrated impact due to the shipbreaking activity. The material and energy flows are collated from the vessel data (effectively, the *Green Passport*), inclusive of inventory of all structural, piping, outfit, and other components. This serves as the input data to the LCA model, the major part of which is mass-component, with a minor component representing energy transactions. The inventory of material is sourced from 52 functional group categories of the vessel with subcategories, the total of which amounts to 6700 Tonne of lightship with over ten thousand parts at component level.

It must be critically noted that the model inflows may include traces, heavy elements such as zinc, cobalt, chromium, traces of asbestos etc. that may be part of the vessel in small quantities but can cause significant impact on certain impact categories. The mass-energy factors such as transport fuel burnt, routing and logistical distances covered, amount of heavy fuel, plastic wastes, landfill disposal quantity, amount of incinerated wastes etc. also need to be represented in the model. In this case, we compare 2 product systems representing decision alternatives: (a) Ship Recycling where over 90% of the vessel is recycled, and (b) Ship Scrapping where over 50% of the vessel components are disposed, and not reused. The 5-step LCA model preparation for each of the product systems is enumerated below:

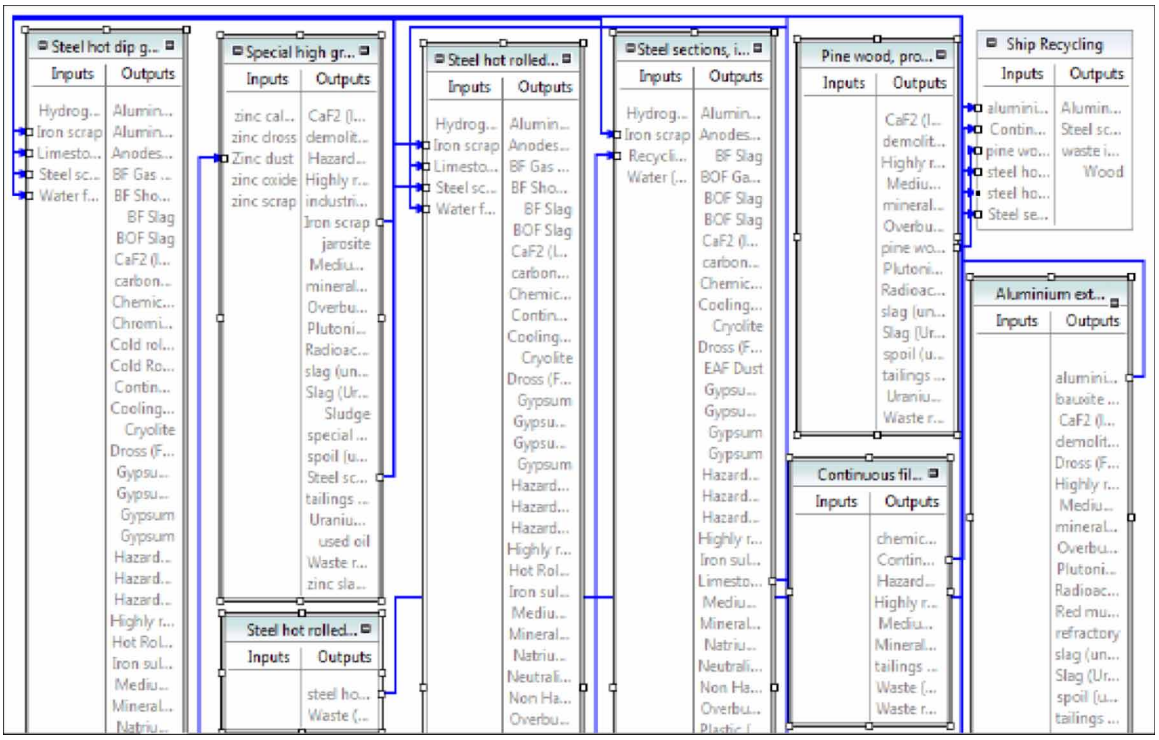
1. Defining boundary condition for product system
2. Defining flows: Material & Energy Movement in/out of the system
3. Defining Processes: Combination of flow relations within the system
4. Defining Product Systems: Combination of 2 or more Processes
5. Inputting Specific Data relating to Product Systems

The processes within alternative product systems defined, namely ‘ship recycling’ and ‘ship scrapping’ could be inherently different. This is because, despite the basic flows such as steel smelting and transport being similar in alternative product systems, the process paths and distribution may vary. For example, in ship recycling more than 90% ideally is recycled and fed back into the steel rolling and reusage; unlike in ship scrapping wherein sometimes about 50% of the material may be disposed away in landfills. The processes within a product system is therefore defined by the path it ensues, and hence to be defined by the system modeler to be as close to reality. The complexity of the processes varies according to the flows within the systems and the inter-linkages between them. Figure 4 show part of the processes within the ‘Ship Recycling’ product system. Note that there are sub-processes as well, some of which may be defined within the open source database.

The data is inputted from the *Green Passport* of the vessel to model the ‘Ship Recycling’ and ‘Ship Scrapping’ Product Systems. Note that in this case, 50-60% of the decommissioned vessel was retrieved for reuse during Ship Scrapping’. About 40-50% of outfit and structural & paneling material such as glass-

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 4. Processes defined by paths in a product system (ship recycling)



wool /filament was disposed during disassembly, in addition to heavy elements that otherwise seep into the environment during the disassembly process. In contrast, for the 'Ship Recycling' Product System, over 90% of the materials enter the closed-loop of the supply chain and are remanufactured, recycled or reused. Figures 5 & 6 depict representative summaries of Data input/output for Ship Recycling & Ship Scrapping Product Systems respectively. The product systems are analyzed based on CML 2001 criteria. The parameters for impact comparison based on the two product systems are listed in Table 2 with their definitions.

5. RESULTS

In this section, we describe the results of LCA analysis of the two product systems, namely, 'Ship Scrapping' & Ship Recycling'. For the purpose of comparative representation of results we present the relative impact of 2 product systems, in addition to absolute impact of ship scrapping product system, which the LCA analysis demonstrates to cause higher environmental impact. Figure 7 depicts the comparative analysis of impact due to steel. Note that steel is the principal category of the vessel by weight including significant of structural components such as hot rolled steel plates, steel piping and outfit components.

It may be observed from Figure 7 that there is significant difference in impact based on post treatment of steel, based on recycling or scrapping methods; photochemical oxidation causing the highest impact in recycling but considerably lesser than the alternative of scrapping. Steel being major component of ships, accounting for over 80% weight of small-to-medium sized ships and as much as 95% for very

Table 2. Impact parameters for product systems analysis based on CML 2001 criteria

Parameter	Description
Acidification Potential	It is an important environmental indicator that denotes the acidic latency of the atmosphere due to aggregating acid air emissions. It is expressed in SO_2 equivalents.
Climate Change	It refers to any significant change in the measures of climate lasting for an extended period of time. It includes major changes in temperature, precipitation, or wind patterns, among other effects.
Eutrophication Potential	It is defined as the potential of nutrients to cause over-fertilization of water and soil which in turn can result in increased growth of biomass.
Freshwater Aquatic Eco-Toxicity	It refers to the impact on fresh water ecosystems, as a result of emissions of toxic substances to air, water and soil. Eco-Toxicity Potential (FAETP) is calculated with USES-LCA, describing fate, exposure and effects of toxic substances. Characterization factors are expressed as 1, 4-dichlorobenzene equivalents/ kg emission. This indicator applies at global/ continental/ regional and local scale.
Freshwater Sediment Eco-Toxicity	It is the impact on the sediments of freshwater or increase in the amount of toxic substances such as heavy metals (cadmium, for example) on freshwater sediments over a period of time.
Human Toxicity	It is the degree to which a chemical substance elicits a deleterious or adverse effect upon the biological system of human exposed to the substance over a designated time period. The human toxicity potential (HTP) reflects the potential harm of a unit of chemical released into the environment.
Ionizing Radiation	It is the radiation with enough energy so that during an interaction with an atom, it can remove tightly bound electrons from the orbit of an atom, causing the atom to become charged or ionized. Only the high frequency portion of the electromagnetic spectrum which includes X rays and gamma rays is ionizing.
Land use competition	It refers to the conflict over multiple forms of use for land resources especially over agricultural use. A comparison on this parameter for different product/eco-systems shows the amount of land lost from one system to another, particularly regarding agricultural usage.
Marine Aquatic Ecotoxicology	It refers to the impact of toxic substances emitted to marine aquatic ecosystems. The characterization factor involved is the potential of marine aquatic toxicity of each substance emitted to the air, water or/and soil. The unit of this factor is kg of 1, 4- DB equivalents per kg of emission.
Marine Sediments Eco-Toxicity	It refers to the accumulation of a variety of contaminants that demonstrate toxicity. Toxicity identification evaluation (TIE) methods provide tools for identifying the toxic chemicals causing sediment toxicity like arsenic and chromium.
Photochemical Oxidation	Photochemical oxidation (also known as summer smog) is the reaction of a chemical change in a substance which causes it to lose electrons which is initiated by light. An example of photochemical smog which is when hydrocarbons and NOx react under the influence of UV light.
Depletion of Abiotic Resources	This refers to the depletion of abiotic substances (any fundamental chemical element or compound in the environment like hydrogen, oxygen, carbon etc.) due to processes within a product system.
Stratospheric Ozone Depletion	The growing emissions of synthetic chlorofluorocarbon molecules cause a significant diminution in the ozone in stratosphere, resulting more solar ultraviolet-B radiation (290–320 nm wavelengths) reaching the surface, causing drastically severe problems such as the 'Antarctic ozone hole'. Stratospheric Ozone Depletion is primarily due to reactions of atomic Cl and Cl-O, the product of its reaction with ozone.
Terrestrial Eco-Toxicity	It is a parametric index in the subfield of ecotoxicology which is used to evaluate and quantify the effects of toxic substances on the diversity and function in soil-based plants and animals. The test measures the relevant parameters and meets environmental requirements, and also reveals toxic responses given variation in environmental conditions such as pH, solubility, exposure time, antagonism, and synergy.

large crude carriers (VLCC) and ultra large crude carriers (ULCC), is a component category that merits careful treatment to contain environmental impact. In recycling, although most of metallic components such as aluminium and other heavy elements are recovered, there is some impact due to disposal in shipbreaking vicinity or landfill occurs during scrapping particularly during beaching. Table 3, 4 and 5 presents the impact results of example case considered, emanating from to aluminium, glass fiber and plastic waste disposal respectively, in ship scrapping product system.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

It may be noted that in the ship-scrapping product system, most of the solid-material waste are considered to be disposed in landfill, whereas liquid wastes such as bilge oil are incinerated. For bio-degradable components such as wood, which has a sizeable quantity of almost 25 Tonne as part of the vessel considered in the case, which is mainly used for paneling and framing, the relative impact is not substantial vis-à-vis landfill or incineration methods. This is opposed to the relative impacts for other materials such as oil, glass fiber and plastic wastes for which there is significant difference in impact based on the post-process method of material treatment during shipbreaking. From Table 4, it may be observed that disposal of glass fiber contributes to the effect on impact parameters such as climate change, human toxicity, marine aquatic and sediment eco-toxicity; whereas Table 5 explains effect of plastic waste disposal on most of the 14 impact categories except Ionizing Radiation, Land Use and Stratospheric Ozone Depletion.

In order to view the big picture, and ascertain the total impact contribution from a holistic standpoint with regards to this case, we list the top 2 contributors for each of the 14 CML 2001 impact parameters. This is represented in Table 6, which shows that the principal impact causality is due to steel sections and glass fiber, and therefore, primarily the need to recycle them as opposed to disposal to mitigate the damage to environment. Glass fiber is the chief contributor for 7 listed parameters; climate change, fresh water eco-toxicities, depletion of abiotic resources etc. to name the significant few. Container Ocean Transport is a major contributor to acidification potential and photochemical oxidation. We can infer from the LCA results that at a generic level ship recycling product system causes lesser impact than ship scrapping eco-system. At a practical level, from LCA results, we can ascertain the contributors of significant impact on CML 2001 parameters and adopt material treatment methods post vessel-disassembly to mitigate environmental impact.

Table 6. Major contributors to overall impact

Parameter	1st Major Contributor	%	2nd Major Contributor	%
Acidification Potential	Container Ocean Transport	63.73	Hot Rolled Steel Section	27.72
Climate Change	Glass Fibre	71.94	Hot Rolled Steel Section	15.61
Eutrophication Potential	Hot Rolled Steel Section	42.21	Glass Fibre	24.22

6. DISCUSSION, LIMITATIONS, MANAGERIAL IMPLICATIONS & FUTURE RESEARCH DIRECTIONS

The LCA methodology is a useful tool in analyzing the environmental impact based on specific parameters as discussed in the case article in the previous sections. To conduct LCA is a difficult challenge since the accuracy of the results depends on the quality of inputs vis-à-vis material and energy inflows and outflows across the system boundaries, the nuances in path functions adopted, interpretation of relative impacts etc. However, the mandating of the *Green Passport* for new vessels by IMO, with inventory of all components on board to be maintained since the vessel construction, has been beneficial for industry analysts and researchers to obtain data, which was earlier often not archived as a set, untraceable, and difficult to obtain from behind proprietary veils of vessel design data. It is now possible to conduct LCA of vessel much more easily given the record tracking that is enabled by maintenance of *Green Passport*. LCA also reveals specific cause-effect relationships, pin-pointing the root cause of higher values on certain impact categories that may be otherwise be counterintuitive. For example, recent research (Rahman et al., 2016) in the context of ship recycling in Bangladesh showed that certain impacts on parameters such as Human Toxicity may be more due to usage of certain cutting torches, fuel or gas during the shipbreaking process, than from the material release from the ship as widely believed. This emphasizes the need to allocate appropriate path functions in the LCA design in well-defined stages of dismantling processes, lest the objective to accurately identify causes of impact be lost in translation.

While acknowledging the progress made possible in conducting LCA for end-of-life-ships using *Green Passport*, there are limitations for the current studies. Future research should focus on bridging these gaps and filling some of the following specific lacunas. Firstly, the process of LCA is still a research-intensive process. To the best of our knowledge, there are no Decision Support Systems (DSS) for managers to practically employ LCA philosophies in ship recycling at a detailed level in work-related contexts. Data used to be an issue, but now and in future, handy managerial tools and software needs to be developed to incorporate LCA techniques into standard operating procedures of ship-recycling industry, much along the lines of an Engineer's Handbook for quick reference and application. In recent years, researchers (Hiremath et al., 2015, 2016) have developed emission factors classified based on 'ship type' and their inherent composition. Such efforts are a first towards understanding impacts from different types of ships such as general cargo ships, bulk carriers, container ships, oil tankers, chemical takers, reefer vessels, passenger vessel etc. However, more progress towards development of managerial tools is vital to integrate these contextual ship impact information directories, for practical decision-making.

Second, we draw the reader's attention towards use of inventory suites and databases. Several tools used for LCA are based on *Ecoinvent* database. Although, at the moment, this database serves not only as a useful tool but vital for conducting LCA analyses, it is important to note that it has been developed based on European contexts (Weidema, 2013), processes and ecosystems. For shipbreaking ecosystems largely based out of South Asia (India, Bangladesh and Pakistan) and China, the results drawn from information databases not reflective of local ecosystems need to be taken with a pinch of salt. Having said that, these databases are currently the best options available, but future research must focus on developing geography specific inventory suites and databases that reflect the true conditions accurately.

Third, the choice of impact assessment method (Bach & Finkbeiner; 2017) used for industry and context specific studies such as ship recycling merits serious deliberation. There are several methods that are extensively used in environmental impact assessment studies, such as CML 2001, IMPACT 2002+, IPCC 2013 100a etc., with varying criteria and impact assessment parameters. In this regard, it is

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

important to note the accuracy and contextual relevance of results drawn in selecting and applying these tools (Kounina et al., 2013; Wathern, 2013; Kelly et al., 2013). From our review of assessment tools and observation of results in the context of ship recycling, it is inferred that some techniques fail to capture pertinent impact categories, parameters, and elemental processes involved vis-à-vis other methods. The objectives of the assessment, including but not limited to understanding of issues, disciplines, processes and stakeholders involved, scales of measurement and their comparisons, are points to be considered while selecting the method.

Fourth, we draw the readers' attention on the relatively lesser progress made in development and usage of SIA (Social Impact Assessment) method, an important pillar in the realm sustainable management (Hildebrandt & Sandham, 2014). Future research must focus on developing and integrating social indicators such as worker safety, training, job satisfaction, corruption, medical facilities etc., particularly in the community-driven ship recycling industries to develop a holistic sustainability framework.

Fifth, the mandate of Green Passport introduced through instruments envisaged by IMO creates a mechanism for identifying, tracking and documenting vessel details at firm level, industry level and port state (government) level. There are several benefits emanating out of the concept of Green Passport. In the short term, it delineates vessels, builders and scrappers that comply with the requirements, and works akin to a social security number for tracking real-time health status of the vessel. In the medium term, the Green Passport will aid in closing the supply chain loop of materials (Broadbent, 2016), tracking raw, processed or finished inventory that enters or leaves the system, and to enforce norms for implementing baseline environmental standards. In future, ship designers, naval architects and operators equipped with information on vessel's environmental impact throughout its life cycle are empowered to think along the lines to Design-for-Recycling (Sivaprasad & Nandakumar, 2013), an extension from the concept of Design-for-Manufacture (Kuo et al., 2001), encompassing considerations of the extended supply chain, and moving in the direction of broader sustainability targets.

In conclusion, through this research we may decisively infer that recycling of steel is superior with marked advantages than disposal of steel during scrapping. Recycled steel may substitute use of virgin steel for good, reducing the carbon footprint and contributing towards lesser impact on a multitude of environmental indicators. LCA also helps practitioners understand and use better options among disposal alternatives, and internalize procedures to be adopted for mitigating environmental impact. It also enables vessel designers, manufacturers and regulators to identify components associated with higher impact on important environmental parameters and substitute them with alternative materials, in order to minimize the carbon footprint during the vessel's lifecycle.

ACKNOWLEDGMENT

The author(s) would like to thank the *Gujarat Maritime Board* for facilitating the field visits, industry experts who contributed to this study by providing valuable insights, shipyards & shipping companies for assistance with Green Passport documentation & data related to onboard inventory. We thank *FPM Office*, *Indian Institute of Management Lucknow* for the financial assistance provided for conducting this research. Special thanks to the anonymous reviewers for their valuable feedback to enrich this study.

ABSTRACT

The development of cost-effective, efficient and stable materials helps to provide the affordable solutions to get safe and fresh water to increasing population with health guidelines of emerging contaminants. Nanomaterials (NMs)-based techniques involve the design, synthesis, manipulation, characterization and exploitation of materials for adsorption and separation of target species from the contaminated and waste water. NMs show better adsorption capacity and catalytic for number chemical species and microbes because of their small size and large surface area that favors the purification and treatment of waste or contaminated environmental water. Here, we present the chemical properties, adsorption/removal mechanism and applications of advanced NMs such as magnetic nanoparticles (MNPs), carbon nanotubes (CNTs), graphene and graphene oxide (GO), titanium oxide (TiO_2), silica (SiO_2), silver (Ag), gold (Au) NPs and zeolites in effective and efficient removal of toxic metal ions, organic and inorganic chemical substances and disease-causing microbes from contaminated and wastewater.

1. INTRODUCTION

Water is a most important resource for vitality for life on earth and sustaining human life. The major civilizations of the world originated nearby the water reservoirs or river due to the ample supply of water and fertile land. Water is a universal solvent that dissolves most of the organic and inorganic substances to meet the requirement of the life. Providing clean and safe water is a necessity and it is also challenging attempt to sustain the same level (LVovich 1979; Postel et al., 1996; World Health Organization 2013). About, millions of people die every year because of contaminated drinking water incorporated with water borne microorganism, toxic chemical substances and thousands of children die due to the water-related problems and diseases. At present, more than billions of people in the world lack to access the safe drinking water and a couple of decades the supply of safe water would suppose to be reduced one-third of the present scenario (Hutton et al., 2007; Mara 2003; Ashbolt 2004; Moore et al., 2003). The limited supply of fresh water to the increasing populations throughout the world is due to the drastic exploitation of water resources for domestic, industry and irrigation purposes in many parts of the world. The increased disposal of industrial, domestic and agricultural and mining wastages into surface and ground water bodies cause the contamination of several inorganic, organic and microbes (Ritter et al., 2002; Fawell et al., 2003). The inorganic species such as arsenic (As), mercury (Hg), cadmium (Cd), lead (Pb), chromium (Cr) and selenium (Se), etc.; organic substances such as pesticides, dyes and phenolic compounds etc.; and microbes such as bacteria and viruses could cause contamination of water (Cao et al., 2014; Yu et al., 2014; Walcarius et al., 2010). Today, the providing of safe and clean water to the fast-growing world population is on the high challenge and needs the plan to sustain the life for future generations.

There are several technologies have been developed for the removal of toxic chemical substances from environmental water samples, including chemical oxidation or reduction (Kohler et al., 2006; Theepharaksapan et al., 2011), chemical precipitation, coagulation or flocculation (Kim et al., 2002; RubI et al., 2009), UV or chlorination (Zhang et al., 2015), ozone treatment (Xiao et al., 2015), adsorption (Kojima et al., 2002), biological treatment (Rosal et al., 2010), reverse osmosis (Jian et al., 1999), membrane filtration (Amin et al., 2014) and ion exchange system (Velizarov et al., 2001). The use of conventional chemical oxidation or reduction through the activated sludge or carbon process unable to remove complex materials comprises of pharmaceuticals, surfactants, dyes various industrial additives. Activated sludge and biological trickling filters come under the biological treatment systems are also not efficient in removing the wide range of chemical substances and remain soluble in the effluent (Urase et al., 2005). Coagulation and flocculation process showed an ineffective in removing the variety of pharmaceutical drugs in different investigations (Vieno et al., 2006). The purification of water by chlorination is implemented to prevent the growth of bacteria and pathogens; however, this treatment causes the undesirable tastes and odors with different by-products (Becher, 1999). Ozone and UV treatment are used to stop the growth of microbes but these techniques are found to very expensive (Adams et al., 2002). Purification of water through the membrane filtration such as microfiltration, ultrafiltration, nano-filtration and reverse osmosis are found most effective and efficient techniques. All these filtration techniques are pressure driven process and removal of contaminants are dependent on the pore size of a semi-permeable membrane which is found specific for the removal specific particulates from water. Microfiltration, ultrafiltration, nano-filtration and reverse osmosis are cost-effective because these techniques require a more energy for the removal of contaminants (Walha et al., 2007; Saleh et al., 2016; Saleh et al., 2012).

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

There is the need for the sustainable development of cost-effective, eco-friendly and stable materials that meets the challenges of providing the fresh water to the increasing world population. Nanotechnology has established an effective way for the removal of harmful toxic chemical substances and microbes from the wastewater or contaminated water (Bottero et al., 2006). In recent years, there have been increasing activities in design and development of nanomaterials (NMs) for versatile applications. It is still a challenging task to synthesize a novel NMs with unique physical, chemical and electrical properties suitable for biochemical probes, sensors, separating and pre-concentrating probes (Obare et al., 2004). NMs can be synthesized using various methods such as chemical, electrochemical, γ-radiation, photochemical, laser ablation, etc. NMs of these substances exhibit an excellent adsorption capacity and photochemical activity because of their high surface to volume ratio and unusual electronic properties (Rickerby et al., 2007). Currently, there are many NMs such as magnetic nanoparticles (MNPs), carbon nanotubes (CNTs), titanium oxide (TiO_2), mesoporous silica (SiO_2), graphene, zeolite, silver (Ag), gold (Au) and other oxide NPs are used for removing the toxic metal ions, organic substances and disease-causing microbes from waste and contaminated water.

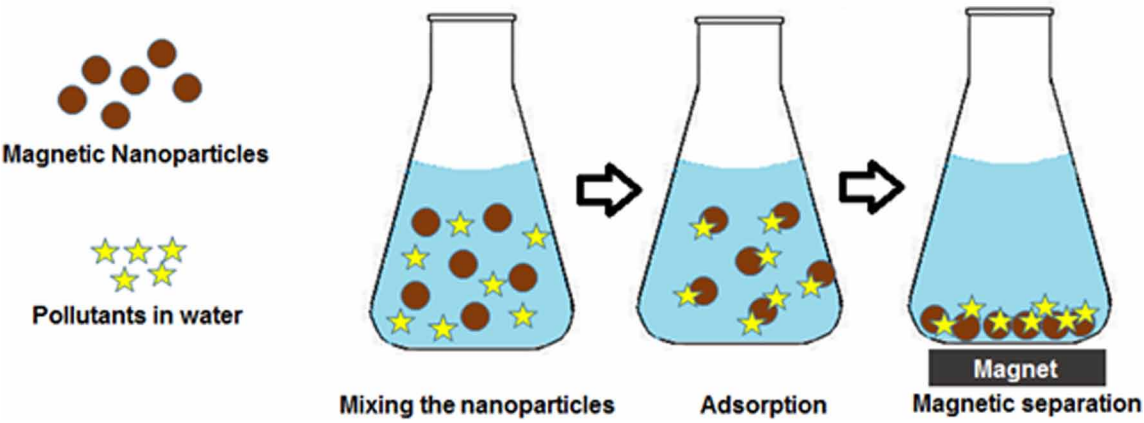
2. ADVANCE OF NMS FOR REMOVAL OF CHEMICAL SUBSTANCES AND MICROBES FROM CONTAMINATED AND WASTE WATER

2.1. Magnetic Nanoparticles (MNPs)

Magnetic nanoparticles (MNPs) have many unique properties such as supra magnetic, high coactivity and high magnetic susceptibility that make them extraordinary for distinct function. There are various types of MNPs such as hematite (α-Fe_2O_3), maghemite (γ- Fe_2O_3), magnetite (Fe_3O_4) and wustite (FeO) used for variety applications. Among these Fe_3O_4 MNPs exhibit the most fascinating properties because the presence of non-equivalent iron such as Fe(II) and Fe(III) in the crystal structure (Yantasee et al., 2007; Domingo et al., 1994). The co-precipitation method is used for the synthesis of Fe_3O_4 MNPs in basic condition (Mascolo et al., 2013). MNPs have been used in medicinal applications, catalysis and now specifically used for water purification (Yallapu et al., 2011; Rossi et al., 2014; Ambashta et al., 2010). MNPs act as an efficient adsorbent with ionic exchange capacity for removal of heavy metals and organic substances assisted with magnetic separation property. The magnetic and surface properties of MNPs allow it for the selective adsorption of ions, molecules, macromolecules, cells, colloidal substances from sample solution. The zero-valent of MNPs make it for specific removal of metallic species such as Hg(II), As(III), Cd(II), Se(III), Cr(VI) and Pb(II) from drinking water and wastewater to show its potential for environmental applications (Ambashta et al., 2010; Xu et al., 2012; Singh et al., 2011). The oxidation of zero-valent iron produces ferrous iron to magnetite in presence of water and oxygen. The adsorption of different pollutants on the MNPs from water sample is demonstrated with Figure 1. The adsorption capacity of organic, inorganic and microbes on the surface of MNPs depends on the electrostatic force, van der Waals force and chemical binding. The adsorption and removal of contaminants from water sample is also dependent upon redox conditions and pH (Tang et al., 2013). Many carbonaceous NMs such as graphene, graphene oxide, CNTs, etc., are attached with MNPs for better adsorption and separation for the removal of contaminants (Yang et al., 2012).

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. MNPs used for the separation of pollutants present in water by chemical adsorption and further removal of MNPs by magnetic separation



2.2. Carbon Nanotubes

Carbon nanotubes (CNTs) are fascinating a new material and have wide range of applications such as reinforcing materials in composites, chemical sensors and catalysts due to their large surface areas, hollow and layered structures and remarkable electrical conductivities (Peng et al., 2014; Saleh et al., 2011; Saleh et al., 2010). CNTs can act as potential solid phase separating probes for removal of metal ions, organic and organometallic compounds from variety of samples. CNTs can be divided into single-walled carbon nanotubes (SWCNT) and multi-walled carbon nanotubes (MWCNT) according to the carbon atom layers in the wall of the nanotubes (Izakmehri et al., 2015; Tawabini et al., 2010). Recently, there is more increase in the applications of CNTs by surface modifications or making the composite materials with NPs. The carboxyl groups or hydroxyl groups can be introduced into CNTs by the treatment with H_2SO_4 and HNO_3. The presence of oxygenated functional groups or other modification helps in binding with a positive species. The removal of dyes using CNTs can be explained with hydrophobic interaction, π-π stacking interaction, covalent and electrostatic interactions. The high π electron density of sp^2 carbons on sidewalls of CNTs provides it high hydrophobic property. The π-π stacking interaction takes place between the bulk π system of CNTs and the C-C or benzene rings (Ai et al., 2011). This is very much similar to the interactions in graphene oxides. Also, the hydrogen bonds formations take place between the functional groups present on the surface of CNTs and the dyes. However, the heavy metals mainly get adsorbed by electrostatic interactions.

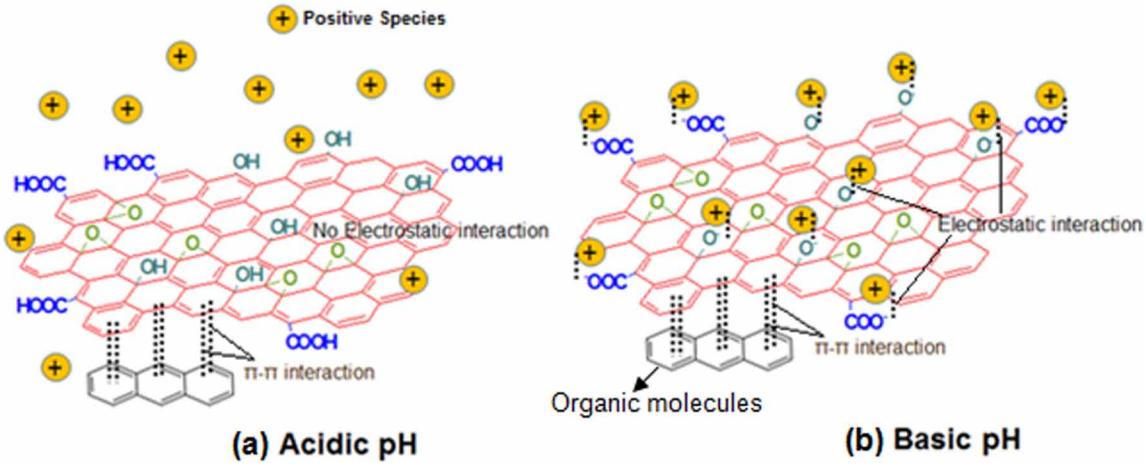
2.3. Graphene and Graphene Oxide

Graphene is a two-dimensional sp^2 carbon network with a honeycomb structure in the form of sheets with only one atomic thickness. It is supposed to be next-generation NMs that could be applied for nano-electronics, nano-composites, nano-sensors and nano-devices due to its high electron mobility, high thermal conductivity and mechanical strength. In addition, it has a high specific surface area of 2,630 m^2g^{-1}. Therefore, this superiority allows graphene to be used as a novel adsorbent for the removal of different types of pollutant from water (Liu et al., 2012). The graphite is used as a starting material for

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

preparation of graphene in the presence of $NaNO_3$, H_2SO_4 and $KMnO_4$. The whole solution is stirred for 30 min followed by the addition of 30% H_2O_2 in warm water (Saleh et al., 2010). Graphene oxide (GO) is prepared from graphene by modification with different functional groups such as epoxy (C–O–C), hydroxyl (OH) and carboxyl (COOH) capping groups on the surface (Mkhoyan et al., 2009). Graphene and GO have shown many versatile applications in nanoelectronics (Westervelt, 2008), sensors (Ang et al., 2008), and structural composite materials (Liang et al., 2009). The large number of functional groups on GO makes it a smart material for removal of metal ions, biomolecules or cationic substances from sample solution through the electrostatic and coordination interactions. In solution phase, GO can act as a cation exchange resin because of the ionizable carboxyl groups, which allows surface complexation with metal ions or positively charged organic molecules (Dreyer et al., 2010; Zhang et al., 2010). Figure 2 demonstrates the π-π interaction between the sp^2 hybridized GO sheet and the organic molecules responsible for the interaction and separation of organic compounds (Ji et al., 2013). In addition, the removal of positive ions (metal ions) using GO is increased in basic pH due to the base abstracts the protons of the acidic group and hydroxyl groups present on the surface of GO. These take part in attraction with the positive ions and the GO resin by electrostatic interaction. Although the adsorption occurs due to the π-π interactions have no effect on the change of pH of sample solution. Yang and coworkers reported the use of as a GO separating probe for removal of Cu (II) from sample solution considering the electrostatic attraction between the GO and Cu (II) ions as driving force for the separation (Yang et al., 2010). Fan et al. gave a simple route for the fabrication of a magnetic beta-cyclodextrin/GO nanocomposite for fast removal of Cr (IV) from water. This material could be a good candidate for efficient separation of Cr (VI) from wastewater and also useful for purification of polluted water (Fan et al., 2012). There are several reports are available for separation of toxic metal ions, organic substances and microbe from water samples. The graphene/GO NPs composite material exhibits an efficient candidate for removal of heavy metals and organic substances in short period of time with good recovery percentage (Cao et al., 2014; Yang et al., 2010; Fan et al., 2012; Teymourian et al., 2013; Sun et al., 2014; Zhu et al., 2012; Sivashankar et al., 2014). Graphite can be also directly used for the removal of organic pollutant and desalination of water with 55% removal of efficiency (Zhou et al., 2015).

Figure 2. Schematic design showing the electrostatic interaction between GO and target positive chemical species from water and also π–π stacking in organic molecules in (a) acidic medium (b) basic medium



EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

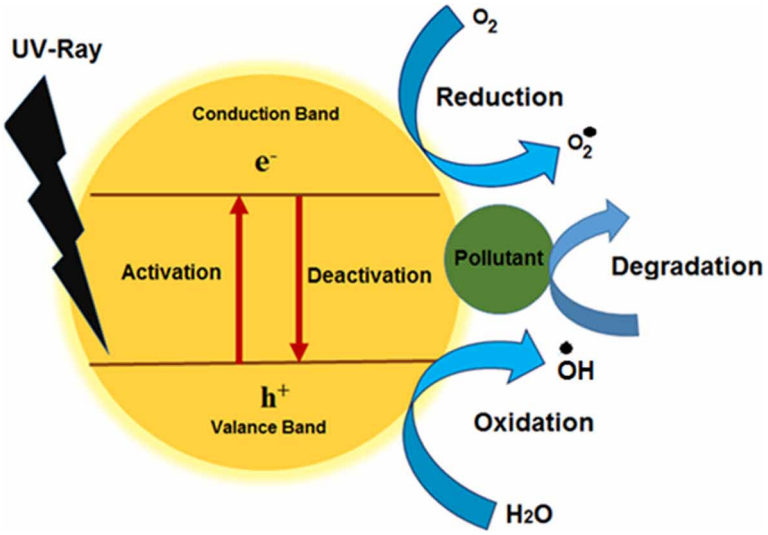
2.4. Titanium Oxide Nanoparticles

The surface properties of titanium oxide (TiO_2) NPs are better than that of bulk TiO_2, though it has been used for years in industries and water treatment and purification of water. TiO_2 NPs have better photo-catalytic, adsorption capacity and anti-microbial properties that have been used for removal of toxic substances and microbes from a water sample. The photo-catalytic activity of the TiO_2 NPs causes the removal of pollutants from waste water through the generation of reactive hydroxyl radicals upon the irradiation with UV light (Gupta et al., 2012; Saleh et al., 2011; Daels et al., 2015). Gupta et al. demonstrated the photo-catalytic activity of TiO_2NPs for the degradation of contaminates (Gupta et al., 2012). The interaction of TiO_2 NPs with a photon of light having a comparable band gap of energy results in the separation of conduction and valence bands given in Figure 3. These photo-catalytic reactions involved oxidation and reduction reactions by the photo generated electrons and holes. The hydroxyl radical is a strong oxidizing agent for the organic matters presents on the surface of TiO_2 which further undergo the degradation. This property of TiO_2 makes it an excellent catalytic material for the removal of toxic chemical substances from the environment by gaining solar light as an energy source (Mahlambi et al., 2015). Nabi et al. demonstrated the use of TiO_2 and iron doped-TiO_2 NPs for removal of As(III) and As(V) and iron-doped TiO_2 NPs are found to be better material for the removal of arsenic from contaminated water (Nabi et al., 2009).

2.5. Mesoporous Silica Nanoparticles

Silica (SiO_2) NPs have a high surface area with a number of pore sizes that make them highly reactive and useful for making effective adsorbents in water and wastewater treatment. The mesoporous SiO_2 NPs such as MCM-41 and SBA-15 having a uniform pore, high pore volume, surface area, high adsorption capacity with high hydrothermal and chemical stability (Adjdir et al., 2015; Gandhi et al., 2012). The mesoporous SiO_2 NPs is mainly functionalized with NPs or organic compounds with suitable functional

Figure 3. Mechanism for the photo-catalysis of organic pollutants on the surface TiO_2 NMs



EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

groups for better removal of pollutants from water. The amino-functionalized SiO_2 NPs showed an excellent capacity to separate a wide variety of harmful metal ions from water samples through the complexation between the amine group and metal ions. In addition, the regeneration of amino-functionalized adsorbents is found to be easy by proton displacement of the metal ion in acid washing. Chung et al. demonstrated the separation of Pb (II) and Cu(II) using multi-amine grafted mesoporous SiO_2 with MNPs (Chung et al., 2012). MNPs/SiO_2core-shell NPs can be easily dispersed in aqueous solutions due to the hydrophilic nature. In acidic condition, the presence of hydroxyl or silanol groups can be used for attachment and chemical modification to remove the target chemical species from the sample (Emadi et al., 2013). In addition, silica can be grafted with a variety of functional groups, leading to considerable enhancement of their surface properties. Fellenz et al. reported the synthesis and characterization of MNPs embedded with mesoporous MCM-41 (Fellenz et al., 2006). Jing-po et al. accounted the removal and detection of Hg(II) using core-shell structured nanocomposite of SiO_2 NPs (Jing-po et al., 2015).

2.6. Silver and Gold Nanoparticles

Silver nanoparticles (AgNPs) and gold nanoparticles (AuNPs) have received considerable attention for their potential application in catalysis, biological, medicine, pharmaceutical and environmental as adsorbents and disinfectants (Sondi et al., 2004; Agnihotri et al., 2014; Sumesh et al., 2011). The synthesis of these NPs was done by wet chemical methods using a reducing agent and stabilized with certain bulky groups to provide a stability in aqueous solution and also responsible for the interaction with target chemical substances for the separation from contaminated water samples. The colloidal AgNPs have been used as a disinfectant in hospitals and medical centers which are approved by the U.S. Environmental Protection Agency (U.S. EPA, 1993). This is also exploited as a supporting agent for several materials to prevent the microbial formation on the most of the surfaces. AgNPs have good potential antibacterial activities (U.S. EPA, 1993; Gunawan et al., 2011). AgNPs can penetrate into the bacterial membrane of *Escherichia coli* and other gram-negative bacteria. The bactericidal activity of NPs was found to increase with decreasing the size of NPs and also depends on particles shape (Sondi et al., 2004; Agnihotri et al., 2014; Sumesh et al., 2011; Gunawan et al., 2011; Shrivastava et al., 2007). In addition, the inhibition of nitrification in activated sewage sludge is also observed by AgNPs than by the equivalent amount of Ag (mgL^{-1}) as Ag(I) ion (Kaegi et al., 2011). Abbasi et al. reported the synthesis of AgNPs through a greener approach with a garlic extract as stabilizing and reducing agents. The synthesized NPs have demonstrated for the removal of phenanthrene, pyrene and anthracene with 85% removal capacity (Abbasi et al., 2014). Karimi et al. presented the use of activated carbon capped with AgNPs for the removal of methyl orange from water sample (Karimi et al., 2012).

AuNPs is also used as a scavenger for removal of mercury ions from polluted waters in the presence of sodium borohydride. The NPs capped with citrate ions act as a reducing agent to catalyze the Hg(II). The removal of mercury ions from waste water sample is means of amalgamation by mounting onto the colloidal NPs, which are then removed from the AuNPs solution (Ojea-Jimenez et al., 2012). Lee at al. showed the use of nano-composite film of AuNPs/BSA-decorated agarose gel membrane for removal of Hg(II) and Pb(II) from waste water (Lee at al. 2012). Ayati et al. exploited the use of AuNP/TiO_2 NPs for photo-catalytic oxidation of various toxic organic pollutants such as azo dyes and phenols under solar, visible and UV irradiation. The loading amount and particle size of AuNPs are the most important parameters to show the better catalytic activity of AuNP/TiO_2 (Ayati et al., 2014).

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

2.7. Zeolites

Zeolites are named after two Greek words "zein" and "lithos" which mean "boiling stone" which was first used by a Swedish geologist, in 1756. Zeolites are micro-porous minerals which may be natural or synthetic. They are hydrated aluminosilicates having a general composition of $Al_xSi_yO_{2(x+y)}$ and are insoluble in water (Diale et al., 2011). The structure of zeolites is three-dimensional, micro porous, crystalline solids being used for water treatment because of their ion exchange properties and thermal stability. In addition, the surface modifications and pore size of zeolites make them attractive candidates for a variety of applications (Liu et al., 2013; Rahamani et al., 2006). They act as base exchangers in the removal of metal ions from contaminated water (Hui et al., 2005; Mehdizadeh et al., 2014; Dong et al; 2015).

3. REMOVAL OF INORGANIC CHEMICAL SUBSTANCES FROM WATER USING NMS

Trace metals are essential constituents of our body that are needed for proper physiological and chemical process. However, the excess intake of metals through the drinking water are harmful to humans including Hg, Pb, As, Cr, Se, and Cd. Chronic exposure to these toxic metals can have serious health consequences. Humans are exposed to metals through inhalation of air pollutants, consumption of contaminated drinking water, exposure to contaminated soils or industrial waste, or consumption of contaminated foods. Natural sources such as weathering, erosion of rocks or soils and volcanic emissions also contribute the metal pollution. There are serious effects of exposure of metals on human health including reduced growth, cancer, damage to nervous system and extreme cases death. Therefore, the removal of these toxic metals is important to prevent the entry of these chemical substances into the different compartments of the environment.

3.1. Removal of Arsenic

As is a toxic element with metalloid properties and it exists in soil, water, plants. Arsenic exists in both organic and inorganic compounds in the oxidation states, shown as –3, 0, +3 and +5. The compounds of As have wide application in agriculture as pesticides and semiconductors, transistors, metal adhesives, explosives and pharmaceutical products in various industries (Patel et al., 2005; WHO, 1999; Furst et al., 1983). In term of toxicity, As(III) is more toxic than As(V). The tolerance limit of arsenic is 10 μgL^{-1}. Hyper pigmentation, depigmentation, keratosis, peripheral vascular disorders are the most commonly reported symptoms of chronic exposures of arsenic (Bissen et al., 2000; Chen et al., 1995). Therefore, the separation of arsenic from contaminated water is required to provide the clean water to the world increasing the population.

Recently, there are several NMs have been reported for the removal of As(III) and As(V) from contaminated and waste water. For As removal, NMs exhibited a better response compared to existing conventional technologies. The different NMs are used for separation of As(III) and As(V) from contaminated water, given in Table 1. Martinson et al. synthesized CuO NPs of the surface area of 85 m^2g^{-1} with a diameter of 12–18 nm and employed as an adsorbent for removal of As(III) and As(V) from ground water in the pH range of 6-10. The maximum adsorption capacity of As(III) and As(V) is 26.9

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

mgg^{-1} for and 22.6 mg/g, respectively (Martinson et al., 2009). Shipley et al. demonstrated the adsorption efficiency of As using MNPs at different NPs concentration, pH, ionic strength, and temperature (Shipley et al. 2009). Jegadeesan et al. synthesized nano-sized amorphous and crystalline TiO_2 and used for specific separation of As (III) and As(V) due to its size and crystalline property of NPs (Jegadeesan et al., 2010). Thanh et al. prepared a nano-composite of γ-Fe_2O_3 and α-MnO_2 through a ball-milled process and illustrated for removal of As(V) from water (Thanh et al., 2011). The adsorption of As(V) on the NMs was dependent on the pH of the sample using pseudo-second-order kinetic model. Selvakumar et al. synthesized a carbonized yeast cells on AgNPs for the removal of As(V) using yeast strain *Saccharomyces cerevisiae* (Selvakumar et al., 2011). Savina et al. synthesized nanocomposite gels of α-Fe_2O_3 and Fe_3O_4 NPs of pore size up to 100 µm through the polymerization. These nanocomposite materials showed an excellent capability for the removal of 3 mg of As(III) from sample solution (Savina et al., 2011). Similarly, nano p(4-vinylpyridine)-based hydrogels (Sahiner et al., 2011)[106], bi-metal doped nano multifunctional polymeric adsorbents (Kumar et al., 2011), nano-alumina dispersed in chitosan-grafted polyacrylamide (Saha et al., 2012), polysaccharide stabilized Fe-Mn oxide NPs (An et al., 2012) and mesoporous γ-Al_2O_3 NPs demonstrated for efficient removal of different species of As from water (Patra et al., 2012).

Table 1. Different NMs for removal of arsenic at specific particle size, surface area, pH, Adsorption capacity

NMs	Particle Size	Surface area (m^2g^{-1})	pH	Adsorption capacity (mgg^{-1})	Arsenic	Ref.
CuO	12-18 nm	85	–	26.9	As(III)	Martinson et al. 2009
Fe_3O_4	20 nm	60	8	–	As(III)+As(V)	Shipley et al. 2009
Nanocrystalline TiO_2		98	4.8	38.4	As(III)+As(V)	Jegadeesan et al., 2010
Perlite/γ-Fe_2O_3	14.9 µm	27.7	7.1	-	As(V)	Thanh, et al. 2011
Silver/yeast cells	19 nm	–	–	0.975	As(V)	Selvakumar et al., 2011
α-Fe_2O_3–Fe_3O_4–polymer	2 nm	50	–	2.7	As(III)	Savina et al., 2011
P(4-VP)-HCl NPs	20 nm	–	–	31.75	As(V)	Sahiner et al., 2011
Al-doped phenolic bead	0.80 µm	330	–	20	As(V)	Kumar et al., 2011
Al_2O_3 polymer bead	–	–	–	6.56	As(V)	Saha et al., 2012
CMC-Fe-Mn NPs	0.35 µm	~6	–	338	As(III)+As(V)	An et al., 2012
γ-Al_2O_3	3–6 nm	–	–	–	As(III)+As(V)	Patra et al., 2012

3.2. Removal of Chromium

Cr is a transition metal with oxidation states of III and VI, where Cr(VI) is more toxic than Cr (III) due to its high solubility and mobility in biological systems. Cr(III) is an important element needed for proper functions of biological process in human (Agency for Toxic Substances and Disease Registry (ATSDR), 1993; Kotas et al., 2000; Nriagu et al., 1988). The main sources of Cr contamination are through industries like chrome plating, electroplating, pigment fabrication, water-cooling towers and sanitary landfill leaching (Sharma, 2003). The chronic exposure of Cr(VI) causes the chronic ulcer and damage of lining of nose, throat, lungs as well as the gastrointestinal tract (Basu et al., 1983). Thus, the separation of chromium from contaminated water is needed to assure the good public health.

For this, different NMs are showed effective results for the removal of chromium from contaminated water. Xiao et al. used a greener approach for the synthesis of FeNPs for highly effective removal of Cr(VI) from the water. They used fifteen plants extract for the plant-mediated synthesis of FeNPs and then used for removal of Cr(VI) (Xiao et al. 2016). Zhong et al. exploited the use of TiO_2 nanotubes (NTs) coupled with CuNPs for efficient photoelectron-catalytic removal of Cr(VI) (Zhong et al., 2016). Niu et al. reported the application MNPs for the removal Cr(VI) (20 mgL^{-1}) with 100% removal efficiency (Niu et al., 2005). Zhu et al. prepared magnetic graphene nano-composite through a thermal decomposition process to remove Cr(VI) ions from water. The synthesized NMs had double shell-structure where iron oxide as inner shell and amorphous Si-S-O compound as an outer shell. It showed the fast removal of Cr(VI) in few minutes (Zhu et al., 2012).

3.3. Removal of Mercury

Hg is a toxic persistent pollutant that affects the nervous system. There are three main species of mercury such as Hg(II), methyl mercury (MeHg) and dimethylmercury (Me_2Hg). MeHg is found to be more poisonous since it readily undergoes bio-magnifications in the food chain as well as it is found to be water soluble (US Environmental Protection Agency). Mercury has a wide range of industrial applications such as the production of batteries, cathode tubes, medical laboratory chemicals and electronic production of mercury vapor lamps and household cleaners, etc. There are several harmful effects of mercury such as cancer, damages the stomach and large intestine, brain and kidneys, lung and increase blood pressure and heart rate (Stern et al., 2001). Hence, the potential materials are needed for the effective removal of these toxic substances from contaminated water.

For this, Shen et al. synthesized Cys-Fe_3O_4 MNPs functionalized with cysteine using Fe (II) as a precursor by oxidation–precipitation method at room temperature. The MNPs were used for removal of Hg(II) from the water. It showed a fast removal with 95% removal efficiency (Shen et al., 2014). Parham et al. demonstrated the application of MNPs capped with 2-mercaptobenzothiazole as an efficient adsorbent. MNPs showed very high adsorption ability than non-magnetic NMs. It shows fast, simple and effective for treatment of Hg polluted water (Parham et al. 2012). Girginova et al. employed silica coated MNPs for removal of Hg(II) from water with 74% removal capacity (Girginova et al., 2011). Sumesh et al. synthesized mercaptosuccinic acid capped AgNPs supported on activated alumina for the removal of mercuric ions from contaminated water at room temperature (Sumesh et al., 2011).

3.4. Removal of Cadmium

Cd is one of the most toxic metal presents in the form of Cd(II). It enters the environment through mining, smelting, oil and coal combustion. Gastrointestinal absorption of Cd(II) from food or water is the principal source of internally deposited Cd(II) in the human body. The excess intake of Cd(II) through the contaminated water may result in the damage of respiratory system, causing bronchial and pulmonary irritation (Seiler et al., 1988; Forstner et al., 1981). So, the separation of Cd(II) from contaminated water is highly demanded.

For this, Gupta et al. prepared Fe_3O_4 MNPs by aco-precipitation method using agricultural waste for the removal of cadmium ions (Gupta et al., 2012). Vukovic et al. prepared ethylene-diamine modified MWCNTs via chemical modification. The biocompatibility of the material is found to be goad and showed no cytotoxic effect (Vukovic et al., 2010). Skubal et al. synthesized colloids of anatase TiO_2 NPs through the controlled hydrolysis of $TiCl_4$ and surface modification with the bidented thiolactic acid. These nanocolloidsshowed10% removal of cadmium ions from water without undergoing reduction or modification in aerobic condition; however, the removal is increased up to 40% in anoxic condition without undergoing reduction or modification of the metal ion as before (Skubal et al., 2002).

3.5. Removal of Lead

Pb is a highly toxic metal and its compound is found in a variety of commercial products and industrial materials, including paints, storage batteries, insecticides, and ceramics. Presently, the important source of Pb in our environment is anthropogenic activities such as the burning of fossil fuels, mining, and various manufacturing processes. Pb may cause irreversible neurological damage as well as renal diseases, cardiovascular effects, reproductive toxicity, damage the kidney and brain when it is taken in large excess through the contaminated drinking water (Qi et al., 2004; WHO, 1989; Patel et al., 2006). As consequences, smart materials are needed to get rid of the Pb present in contaminated water sample.

Masoumi et al. used rice husk and poly methylmethacrylate-co-maleic anhydride for the removal of Pb(II) ions from water. The system can undergo adsorption and desorption in few cycles of removal process (Masoumi et al., 2016). Mostafa et al. exploited the use of $CoMo(CO_3^{2-})$ NMs for spontaneous and endothermic removal of Pb(II) ions (Mostafa et al., 2016). Awual et al. developed a ligand-based conjugate adsorbent for simultaneous removal and detection of Pb(II) from water samples. The organic ligand 4-dodecyl-6-[{4-(hexyloxy) phenyl}diazenyl] benzene-1,3-diol is immobilized onto mesoporous silica by a direct immobilization approach for removal detection and of lead. The detection of Pb(II) ion is based on charge transfer (π–π transition) transduction mechanism (Awual et al. 2014). Zhang et al. synthesized monodispersed and spherical $Fe_3O_4@SiO_2–NH_2$ core–shell NMs with uniform core-shell structure. The high loading of amino moieties on MNPs helped the material for easy removal of Pb(II) from water (Zhang et al., 2013).

3.6. Removal of Selenium

Se is present in the environment in the form of selenide, selenate, or selenite. A maximum acceptable concentration of Se in drinking water is 0.01 mgL^{-1} (U.S. Environmental Protection Agency, 1980). Se is an important element present in several enzymes needed for the proper function of thyroid gland. The excess intake of inorganic and organic Se through the contaminated drinking water may result in the

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

symptoms such as fatigue, hair loss, and white blotchy nails (Schamberger et al., 1984; Merian, 1984). Hence, the appropriate elimination of this toxic chemical species is required with specific material to get the clean water.

Awual et al. described the use of organic–inorganic based novel composite adsorbent for removal and detection of Se(IV) from contaminated water and showed adsorption capacity of 111.12 mgg^{-1} of Se(IV) is demonstrated. The presence of diverse competing ions did not affect the separation of Se(IV) (Awual et al., 2015). Loyo et al. demonstrated adsorption capacity of SeO_3^{2-} on the surface of Fe_3O_4 and Fe/Fe_3C NPs. The Fe/Fe_3C NPs showed a better adsorption efficiency than Fe_3O_4 NPs for the removal of Se(IV) from the water samples (Loyo et al. 2008). Gonzalez et al. described $MnFe_2O_4$ NMs for separation of Se from aqueous solutions at pH 6.0 for 5 min of reaction time (Gonzalez et al., 2010).

4. REMOVAL OF ORGANIC CHEMICAL SUBSTANCES FROM CONTAMINATED AND WASTE WATER USING NMS

The disposal of large amounts of domestic, agricultural and industrial waste contains potentially toxic organic chemical substances such as pesticides, phenols, polyaromatic hydrocarbons, and dyes, etc. These toxic substances when entering into drinking water or foods through contamination may cause mutagenic and carcinogenic effects on humans. Recently, NMs are being great attention to using as potential adsorbents to remove toxic and harmful organic substances from contaminated and wastewater.

4.1. Removal of Pesticides

The pesticide is an organic chemical substance used to kill, repel or control certain forms of unwanted weeds or pest in agriculture to prevent the damage of crops. They include insecticides, herbicides, and fungicides. However, both soils and water sources can become contaminated with excess use of these compounds. The acute exposure to these pesticides can disrupt the normal physiological functions of human and cause neurobehavioral disorders, reproductive abnormalities leukemia, malignant lymphoma, nausea, vomiting, hyperventilation and weakness (Hayes et al., 1991; Smith et al., 2002; Corsini et al, 2008). Hence, the removal of the pesticides from drinking water with respect to human health is important concerns.

More recently, Gkementzoglou et al. synthesized a highly specific molecularly imprinted polymer NPs and used for removal of atrazine pesticide from water (Gkementzoglou et al., 2016). Liu et al. prepared graphene-coated silica NPs by mixing GO with acid-treated silica in the presence of hydrazine hydrate. The strong π-bonding network of the benzene rings and interaction of the composite with the electron-donating abilities of the S, P, and N atoms helped in explaining the adsorption and removal mechanism of pesticides from water (Liu et al., 2013). Wu et al. synthesized a graphene-based magnetic nano-composite and used it as an effective adsorbent for the pre-concentration of carbamate pesticides (metolcarb, carbofuran, pirimicarb, isoprocarb and diethofencarb) from environmental water (Wu et al., 2011). Gao et al. utilized a novel nano-structured polyaniline-ionic liquid (i.e. 1-butyl-3-methylimidazolium hexafluorophosphate) composite film coated on steel wire through the electrochemical deposition and used it for the removal of pesticides such as hexachlorocyolohexane, dichlorodiphenyl dichloroethylene, dichlorodiphenyl dichloroethane, dichlorodiphenyl trichloroethane from water samples (Gao et al., 2011).

4.2. Removal of Dyes

Dyes are another class of an organic chemical substance that widely used in many industries such as textile, cosmetics, plastics, leather, paper, plastics for coloring their products. The effluents from various industries are a major source for the disposal of dyes into the environment. Now, thousands of dyes are annually used for coloring the variety of the materials. The discharge of dyes after their use through the industrial waste results in the contamination of groundwater and drinking water supplies that may produce health risks. Dyes give undesirable color to the water and reduce the sunlight penetration and their degradation products being toxic or even mutagenic, carcinogenic (Lin, 1993; Perez-Urquiza, 2000). Therefore, a novel material is highly demanded to eliminate the dyes present in waste water or contaminated water.

Recently, Singh et al. demonstrated the photo-catalytic properties of semiconductor NPs for oxidation and degradation of dyes assisted with UV light (Singh et al., 2013). Patra et al. synthesized polysaccharide (agar)-based adsorbent through the modification of monometallic and bimetallic NPs (Fe, Cu, Pd, Fe/Cu and Fe/Pd) to remove cationic dyes such as methylene blue and rhodamine B. The NPs showed a 90% adsorption capacity for removal of dyes (Patra et al., 2016). Dadfarnia et al. used iron-basedmetal-organic framework loaded on Fe_3O_4 for the removal of methyl red (Dadfarnia et al. 2015). Singla et al. used a novel boron nitride NMs which showed a very high surface area and high adsorption capacity for brilliant green and methyl orange from water samples (Singla et al., 2015). Gautam et al. synthesized a novel bimetallic Fe-Zn NPs via a co-precipitation method and applied it for the removal of a carcinogenic dye such as malachite green and congo red from water samples (Gautam et al., 2015).

4.3. Removal of Phenol and Phenolic Compounds

Phenols and phenolic compounds are highly toxic to the human health at low concentrations. The major sources of these compounds are oil industry, municipal waste and coke plant effluents (Kolthoff et al., 1971; Kuriacose et al., 1987). In chlorinated water, phenol reacts with chlorine to form chlorophenol which can cause toxic effects on human or animals if the contaminated water is taken. The excess intake of phenol and phenolic compounds through the contaminated water may cause protein denaturation and paralysis of the central nervous system and also damages the kidney, liver, and pancreas (Knop et al., 1985). Thus, it is recommended to remove the phenol and phenolic compounds from waste water before entering the water stream.

For this, Mani et al. reported carbon-doped anatase TiO_2 NPs with high surface area employed for the removal of phenol from water under the simulated solar light (Mani et al., 2015). Yang, et al. demonstrated the separation of phenols through the H-bonding interactions between the target molecule and CNTs followed by π-electron polarizability play important roles on the adsorption of phenols from environmental water (Yang, et al., 2008).]. Zuo et al. presented the catalytic oxidation and removal of phenols from waste water using MWCNTs and MNPs in the presence of H_2O_2 (Zuo et al., 2009). Yao et al. reported the combined effect of cobalt oxide (Co_3O_4) and reduced GO NPs for the catalytic performance for the decomposition of phenol. The combined effect of both the NPs showed a better catalytic activity than individual NPs (Yao et al., 2012). Asmaly et al. presented the Fe_3O_4 MNPs impregnated with carbon fibers for the removal of phenol from water using Langmuir and Freundlich model (Asmaly et al., 2015).

5. REMOVAL OF BACTERIA AND VIRUS FROM CONTAMINATED WASTE WATER USING MNS

Bacteria and virus are microscopic organisms present in contaminated and waste water that may cause water borne diseases. Thus, there is a need of novel technology for effective removal and inactivation of waterborne microbial pathogens from water bodies. For this, Zarpelon et al. prepared a thin film of AgNPs crosslinked with glutaraldehyde as a new material to act as a bactericidal agent for the treatment of industrial wastewater. The material showed a good inhibitory effect against *Escherichia coli* and also decreased the growth of coliform in water (Zarpelon et al., 2016). Jin et al. presented the use of Fe_3O_4 NPs modified with cetyltrimethylammoniumbromide [Fe_3O_4-CTAB] NPs as a bactericidal material in a water sample. The prepared Fe_3O_4-CTAB NPs are found to be good in capturing both Gram-negative *Escherichia coli* and Gram-positive *Bacillus subtilis* from water (Jin et al., 2015). Motshekga et al. developed a novel silver–zinc oxide bentonite chitosan nano-composite for complete inactivation of bacteria from water in short period of time (Motshekga et al. 2015). Zhan et al. prepared an amine-functionalized magnetic (Fe_3O_4–SiO_2–NH_2 NPs) and used for the removal of both pathogenic bacteria and viruses from water. The amine-modified NPs showed an excellent response in capturing a wide range of pathogens including bacteriophage, virus *(Poliovirus-1), S. aureus, E. coli, P. aeruginosa, Salmonella and B. Subtilis* (Zhan et al., 2014). Radzig et al. demonstrated the antibacterial action of AgNP on Gram-negative bacteria such as planktonic cells and biofilms. AgNPs stabilized with casein peptides strongly inhibit the biofilms formation and prevent the growth of various bacteria in water (Radzig et al., 2013). Ma et al. fabricated a novel nanofibrous microfiltration membrane system with nanofibers and employed for the effective removal of bacteria and viruses from contaminated water. Behra et al. exploited the use of porous polyethylene glycol microparticles functionalized with sugar ligands for capturing the specific bacteria from the water. Its selective and specific binding capacity is used for the separation of different strains of *Escherichia Coli*.

6. CONCLUSION

The uses of different NMs such as magnetic, carbon nanotubes, graphene/graphene oxide, titanium oxide, silica, silver, gold NPs are elaborately demonstrated for the removal of toxic metal ions, organic substances and disease-causing microbes from contaminated and waste water. The surface area and the functional groups attached to the NMs play an important role the removal of contaminates which depends on the pH, concentration of NMs and contact time of the sample. The electrostatic, π-π interaction and vander wall forces etc. are the main forces responsible for the separation of target chemical substances from water. The use of NMs is found easy, rapid and eco-friendly for selective and efficient removal of contaminants from water. These NMs are very stable and produce less amount of waste generation compared to another traditional method for removal of contaminants. In addition, these described methods are rapid and energy saving for adsorption of target environmental pollutants from contaminated and waste water.

Chapter 25
Constructed Wetlands: Description and Benefits of an Eco-Tech Water Treatment System

Alexandros I. Stefanakis
University of Brighton, UK

ABSTRACT

Constructed Wetlands are an alternative, promising technology for water/wastewater treatment and pollution mitigation. They belong to the wider category of natural treatment systems. The main principle is to exploit natural materials (gravel, sand, plants) and naturally occurring processes under controlled conditions for treatment purposes. Constructed Wetlands have been characterized as an environmentally friendly, sustainable technology which provides multiple economic, ecological, technical and societal benefits. It is a rising technology which can be effectively used for domestic, municipal and industrial wastewater treatment, as also for sludge dewatering and drying. This chapter presents an overview of this eco-technology; its different types, main design considerations and various advantages over conventional treatment methods.

INTRODUCTION

The use of natural processes is not something new in waste/wastewater processes. Practically, most known technologies and techniques are based on these processes, such as sedimentation, filtration, biological activity etc, and are often constructed with complex and energy-consuming mechanical equipment. The difference that separates natural treatment systems from conventional ones is that only natural components are used for the treatment. Naturally occurring processes are utilized under a controlled environment, without the input of external energy source, unless perhaps for pump operation. Among the various natural treatment systems such as facultative and oxidation ponds, Constructed Wetlands (CWs) appear as one of the most promising eco-tech treatment methods, which have been attracting increasing worldwide interest. Their excellent treatment performance, coupled with an environmentally friendly character and reduced overall costs are gradually placing Constructed Wetlands in the forefront

of the scientific and marketing interest. This chapter discusses the multiple environmental, economic and technical advantages of these treatment systems and includes a brief description of their design and the wide range of their applications. These characteristics aim at presenting current research progress on sustainability issues in innovative wastewater treatment systems.

Background

Wetlands are considered today as natural systems with great ecological significance which provide habitat for numerous species and support their life. Natural Wetlands includes various benefits such as groundwater aquifer enrichment, control of flood incidents, absorption of carbon dioxide, heat storage and release, sediment trapping and other (Stefanakis, Akratos & Tsihrintzis, 2014). Their values can be translated in ecological, social, cultural and economic units (De Grot, Stuip, Finlayson, & Davidson, 2006). It was gradually realized that natural wetlands had always been capable of providing water purification and improving water quality, at least up until the point where industrial contamination had become so intensive. This observation initiated the investigation of re-assessing existing wetland purification potential. Natural wetlands have been utilized as disposal sites for secondary or tertiary wastewater effluents for many years, even some thousands years ago. Sewerage collection systems were constructed in the Zakros and Knossos Palaces during the Minoan era in the Greek Island of Crete, where nearby torrents and wetlands were used as disposal sites (Angelakis, Koutsoyiannis, & Tchobanoglous, 2005; Stefanakis et al., 2014). In modern times, the transition from Natural to Constructed Wetlands (CWs) was based on the potential exploitation of naturally occurring processes in a controlled environment for beneficial human and environmental usage and the healthy perpetuation of the natural environment. In this context, man-made Constructed Wetlands are designed to mimic and, thus, enhance the functions and operations of natural wetlands. While Constructed Wetlands generally offer the same functions and values as natural wetlands do, they also may appear as a more ecologically endowed system. Studies have shown that Constructed Wetlands possess a higher value in terms of flood and stormwater control, water quality improvement and biodiversity restoration (Ghermandi, Van den Bergh, Brander, De Groot, & Nunes, 2010). This may be because they are more easily integrated into the built infrastructure by urban planners, engineers, and landscape architects.

Today, the term "Constructed Wetlands" (also known as ""Treatment Wetlands" or "Reed Beds") refers to engineered systems which are designed to exploit under controlled conditions the processes that occur in nature (Stefanakis et al., 2014). Constructed Wetlands belong to the wider category of natural treatment systems which primarily rely on natural processes and/or natural components for wastewater treatment, where intensive use of external energy input can be avoided. Natural treatment systems are mainly classified into terrestrial, aquatic and wetland systems. Aquatic systems include stabilization or oxidation ponds and terrestrial systems slow rate systems and soil aquifer treatment (Stefanakis et al., 2014). Constructed Wetlands are in the middle of these two categories. The technology of Constructed Wetlands began with laboratory experiments in the Max Planck Institute in Germany in the 1950s. The first system in Europe was constructed in the 1960s and in the USA in the 1970s-1980s. Despite these early experiments and attempts, until the end of the 1980s Constructed Wetlands technology was not widely tested or utilized. Failure incidents of some of the first systems due to inadequate design, indicating lack of experience, and competition from conventional treatment methods in use for more than 80 years, were considered as the main initial obstacles for this limited expansion. However, over the last 20

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

years the interest for alternative treatment methods has increased and the Constructed Wetlands technology has experienced a tremendous increase in both research and applications, due to the simultaneous increase of environmental awareness and sensitivity. Stefanakis et al. (2014) reported that the number of published scientific papers on Constructed Wetlands during the decade 2000-2010 has more than doubled, compared to the previous decade (1990-2000).

Constructed Wetlands represent one of the most interesting and attractive developments in environmental/ecological engineering. The philosophy behind this type of wastewater system is based on the decentralized approach in contrast to what had been regarded as the centralized approach of conventional biological treatment methods which dominate the wastewater market. This new approach also introduces new parameters and views in wastewater treatment, such as sustainability and overall environmental impact. The following section of this chapter presents an overview of constructed wetland classification, technology and description of its principal characteristics, with a focus on its advantages and benefits and its various wastewater treatment applications.

CONSTRUCTED WETLANDS TECHNOLOGY

Classification

Constructed Wetlands can be classified according to their functions and aims in three main application areas (Knight, 1997; Stefanakis et al., 2014):

- **Habitat creation:** these systems are designed to provide a revitalized wildlife habitat and to enhance the pre-existing ecological benefits of the technology such as attracting animals such as birds and creating a green area, while addressing the water/wastewater treatment and mitigation. In this category, four different types of CWs exist: ponds, marshes, swamps and ephemeral wetlands.
- **Flood control:** these systems operate as runoff receivers during flood incidents and increase the storm water storage capacity in urban areas.
- **Wastewater treatment:** systems designed and operated to receive and treat wastewater of different origin.

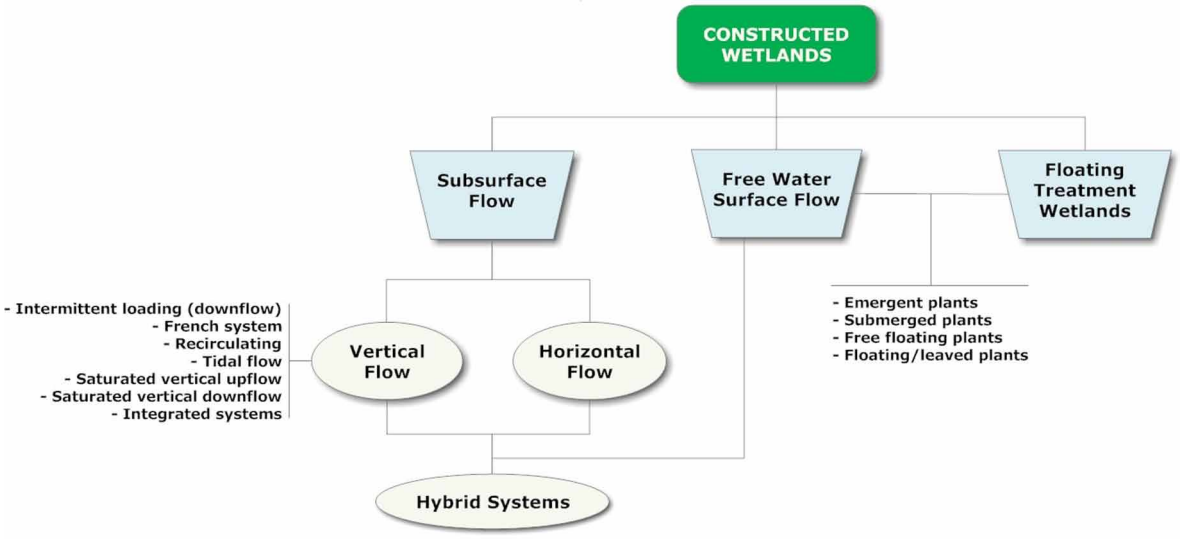
Another widely used classification of CW systems is based on the main characteristics of the system such as the direction of the water flow and the type of vegetation used, as it is depicted in Fig. 1. Thus, based on the flow path across the CW system, there are two general types (Kadlec & Wallace, 2009; Stefanakis et al., 2014):

A. Free water surface constructed wetlands (FWS CWs) and
B. Subsurface flow constructed wetlands (SF CWs).

A further classification of SF CWs can be made depending on the flow path direction; horizontal (HSF CWs) or vertical (VFCWs).

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. Classification of Constructed Wetlands.



The type of vegetation used in CWs is one of the major characteristics of the system. Thus, based on the vegetation type, CWs can be also classified as (a) emergent macrophyte wetlands, (b) submerged macrophyte wetlands and (c) floating treatment wetlands (FTWs) (Vymazal, 2007; Stefanakis et al., 2014). CWs with rooted emergent macrophytes are the most widely used.

Free Water Surface Constructed Wetlands (FWS CWs)

This type of CWs is widely used in North America, almost exclusively for wastewater treatment applications (Kadlec & Wallace, 2009). They are shallow basins or channels containing a soil layer (30-40 cm thick), in which the macrophytes are planted. Most common plants species used are common reeds (*Phragmites australis*), cattails (*Typha* spp), bulrush (*Scirpus* spp) and herbs (*Juncus* spp) (Vymazal, 2013; Stefanakis et al., 2014). The bottom of the basin (as in all CW systems) is covered by a geo-textile/geo-membrane or clay material in order to prevent wastewater leakage to the groundwater. Above the soil layer there is a water column (20-40 cm deep or deeper) which is exposed to the atmosphere and the solar radiation (Vymazal, 2013). Appropriate water level control at the outlet of the system regulates the depth of the water column; usually there is flexibility in the depth adjustment. The water flows through the plant stems and comes into contact with the top layer of the soil and the plant parts, which allows for the pollutant removal through various physical, biological and chemical processes. FWS CWs tend to attract mosquitos, especially when the water remains almost stagnant. This system performs well for suspended solids (SS) and biochemical oxygen demand (BOD_5) removal. Removal of nitrogen (N) and pathogens is satisfying, but phosphorus (P) removal is usually limited (Vymazal, 2007; Kadlec & Wallace, 2009; Kotti, Gikas, & Tsihrintzis, 2010; Stefanakis et al., 2014). FWS CWs have been applied for the treatment of primary and secondary municipal effluents, storm water and highway runoff and agricultural wastewater (Vymazal, 2013; Stefanakis et al., 2014). This type of CWs has higher area demands when compared with other types for the same wastewater characteristics (origin, flow). Since these systems have an open water surface they tend to resemble natural wetlands at a greater level.

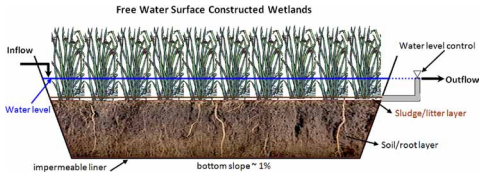
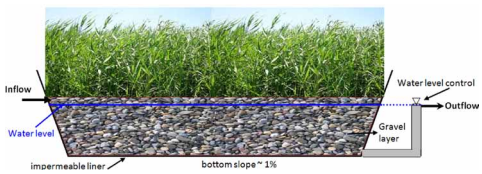
Figure 2. Schematic Representation of Free Water Surface Constructed Wetlands.



Horizontal Subsurface Flow Constructed Wetlands (HSF CWs)

HSF CWs are more widely used in Europe than in the USA (Stefanakis & Tsihrintzis, 2009a). These systems are basins containing gravel material, usually planted with common reeds (*Phragmites australis*) or other species such as *Typha* (e.g., latifolia, angustifolia) and *Scirpus* (e.g., lacustris, californicus) (Vymazal, 2011). The substrate used is rocks of different origin and composition. Unlike FWS CWs, in this CW type there is no water surface exposed to the atmosphere; the water level is kept 5-10 cm below the gravel layer surface and water flows through the pores of the substrate media and comes into contact with the media grains, the plant roots and the attached biofilm (Stefanakis et al., 2014). Thus, respective health risks due to possible human contact with the wastewater and mosquito issues are limited in this CW type (Kadlec & Wallace, 2009). The substrate layer thickness varies from 30 to 80 cm (Akratos & Tsihrintzis, 2007; Kadlec & Wallace, 2009). The bottom of the bed is usually covered with an impermeable geo-membrane and has a slight slope (1-3%) to allow the water flow. As for FWS CWs, the uniform distribution of the wastewater across the wetland width at the inflow point is a key parameter for the proper function of the system (Akratos & Tsihrintzis, 2007), while step-feeding of the wastewater along the wetland length has been found to enhance the system performance (Stefanakis, Akratos, & Tsihrintzis, 2011a). HSF CWs have the advantage of lower area demands compared to FWS CWs, although capital costs might be higher (Kadlec & Wallace, 2009; Stefanakis et al., 2014). This CW type has been proved to be very effective in the treatment of municipal wastewater, removing SS and organic matter (BOD_5) at high rates, although nutrient removal (nitrogen, phosphorus) is usually lower (Akratos & Tsihrintzis, 2007; Vymazal, 2007; Kadlec & Wallace, 2009; Stefanakis et al., 2014). Various modifications of the system design have been proposed in order to improve the performance such as effluent recirculation (Stefanakis & Tsihrintzis, 2009a), wastewater step-feeding (Stefanakis et al., 2011a), water level raising (Stefanakis & Tsihrintzis, 2009a) and effluent treatment with zeolite gravity filters (Stefanakis, Akratos, Gikas, & Tsihrintzis, 2009a). HSF CWs have been also applied for the treatment of industrial wastewater, e.g., mine drainage, dairy, swine, olive mills, landfill leachate, cork effluent, contaminated groundwater, hydrocarbons etc. (Vymazal, 2009; Santos et al., 2012; Stefanakis et al., 2013).

Figure 3. Schematic representation of Horizontal Subsurface Flow Constructed Wetlands.



EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Vertical Flow Constructed Wetlands (VFCWs)

Until recently, this type of CWs was the least developed and applied. At the early stages of CW technology, FWS and HSF CWs were the dominant types, mainly due to higher overall costs for VFCWs construction and operation. However, the interest in VFCWs was gradually increased with time; especially when the higher oxygen transfer capacity of this CW type was realized compared to the horizontal flow beds. Thus, over the last 15 years research on VFCW systems was substantially intensified. Today, there are various modifications of VF systems which are either already applied or under investigation. VFCWs are mainly used in Europe, and especially in Denmark, Austria, Germany, France, and the United Kingdom (Kadlec & Wallace, 2009; Stefanakis et al., 2014). The most common setup is a basin containing several layers of gravels and sand with increasing gradation from top to the bottom (Stefanakis & Tsihrintzis, 2009b; 2012a; Stefanakis et al., 2014). The total thickness of the substrate varies from 30 to 180 cm (Stefanakis et al., 2014). Usually, the top layer of the bed is a sand layer. Plants are established in the top gravel layer or in the sand layer (if any). As for the other CW types, common reeds (*Phragmites australis*) and cattails (*Typha latifolia*) are the two most widely used plant species. The bottom of the bed is covered by a geo-membrane/geo-textile material and has a slight slop of 1-2%. VFCWs also contain perforated vertical aeration tubes which are connected at the bottom of the bed with the drainage collection pipeline system. These aeration tubes allow for the better aeration of the deeper parts of the bed (Stefanakis & Tsihrintzis, 2012a). The wastewater is applied in batches on top of the bed and drains vertically by gravity, while it should be uniformly distributed across the entire surface of the bed (Stefanakis & Tsihrintzis, 2012a; Stefanakis et al., 2014). VFCWs have smaller surface area demands compared to HSF and FWS CWs. Due to the better aeration capability, VFCWs are very effective in organic matter (BOD_5) and ammonia nitrogen removal, usually more effective than HSF CWs (Vymazal, 2007; Kadlec & Wallace, 2009; Stefanakis et al., 2014). Phosphorus removal remains limited and alternative modifications have been proposed for performance improvement, e.g., an additional stage with gravity filters containing bauxite, zeolite or other material for effluent treatment (Brix & Arias, 2005; Stefanakis & Tsihrintzis, 2012b). Their overall effectiveness enabled the use of this CW type for the treatment of wastewater with different origin, e.g., domestic, municipal, industrial, agro-industrial and landfill leachate (Stefanakis et al., 2014).

Figure 4. Schematic representation of Vertical Flow Constructed Wetlands.

Floating Treatment Wetlands (FTWs)

This type is the latest version of CW technology, combining both a traditional CW system and a pond (Van de Moortel, Meers, Pauw, & Tack, 2010). These systems consist of a floating element (usually made of a plastic material) on which the plants are established; thus, it could be stated that these systems optically look like floating islands. As in the other CW types, the plants develop a deep and dense root system within the underlying water column (Tanner & Headley, 2011; Stefanakis et al., 2014). Since the combined system of the porous plastic basis and the plants floats on the water surface, the system is not affected by fluctuations of the water level. FTWs have been used for water purification in rivers, channels, lakes etc., as also for stormwater, domestic and municipal wastewater treatment (Van de Moortel et al., 2010; Stefanakis et al., 2014).

Sludge Treatment Wetlands (STWs)

These systems represent a special and very promising application of CW technology, for the treatment and management of excess sludge that is produced in conventional wastewater treatment plants. STWs appear as alternative systems to mechanical dewatering methods such as centrifuges or filter presses. They resemble vertical flow constructed wetlands (Fig. 4) in the design and construction, but they are modified systems for wastewater sludge dewatering and drying (Stefanakis & Tsihrintzis, 2012c; Stefanakis et al., 2014). As the vertical flow systems, STWs are rectangular or trapezoidal excavated basins filled with substrate materials planted with reeds (Nielsen, 2003). Usually the basin contains 1-2 gravel layers and on top a sand layer (Nielsen, 2005), although there have been systems designed without a top sand layer (Stefanakis et al., 2009b; Stefanakis & Tsihrintzis, 2012c). The total thickness of the porous media layers varies between 30-70 cm (Stefanakis et al., 2014). Sludge is applied on top of the bed in feeding cycles: a typical feeding scheme is 2-10 days of sludge feeding followed by 1-3 weeks of resting (Nielsen, 2003; Stefanakis et al., 2009b; Stefanakis and Tsihrintzis, 2012c). The bottom of the beds can be either constructed with concrete or excavated and covered with a liner, typically with a material of low-permeability as for the other CW types (i.e., HDPE geo-membrane covered in both sides with geotextile or clay) (Stefanakis et al., 2014). The bottom layer also contains a network of perforated plastic pipes for the collection of the drained water that flows vertically through the bed body. This bottom pipe network is connected with the atmosphere with vertical perforated plastic aeration pipes which are extended above the top layer and are open on their top end. STWs achieve high rates of sludge dewatering (volume reduction up to 96%; Stefanakis & Tsihrintzis, 2012c; Stefanakis et al., 2014), through evapotranspiration and draining processes (Stefanakis & Tsihrintzis, 2011).

Design Considerations of Constructed Wetland Facilities

CW beds are generally considered as easy to build and operate; however, the proper design of a CW facility is not as easy as it seems. Since it is a relatively new technology, there are not unanimously accepted guidelines or a widely applied setup. System design tends to differ not only from country to country but also among designers and experts/engineers. Personal experience is usually a key parameter. However, there are general rules and some basic design considerations which are used during the design process, including meteorological, topographical and operational parameters such as (Stefanakis et al., 2014):

- Climatic conditions of the area where the system will be installed,
- Topographical information in order to choose the most appropriate installation site,
- Geological structure of the area,
- Availability of the necessary land,
- Current and future wastewater flow and volumes,
- Any legal limits that apply in the area for the effluent quality – desired treatment performance
- Possibilities/desire for effluent reuse options,
- A nearby water body-effluent receiver,
- Total costs.

As it is obvious, most of these general parameters are common prior the implementation of any treatment technology. There are three main design parameters for constructed wetland systems which should be taken into account: (a) unit area demand (m^2/pe), (b) organic and hydraulic loading and (c) oxygen transfer capacity (Stefanakis et al., 2014). The unit area demand expresses the surface area demand (m^2) per person equivalent (pe). This parameter is generally accepted and serves as a good indication of the overall land area demands. Apparently, this parameter is affected by the climatic conditions. However, it is common than even for the same region different values are proposed based on the individual experience. Generally, VFCWs have lower area demands (1-2 m^2/pe) than HSF CWS (5-10 m^2/pe) (Stefanakis et al., 2014). Organic (e.g., g BOD_5 or COD/m^2/yr) and hydraulic (m^3/m^2/d or m/d) loads are also used and give a good idea of the system load. These parameters are very helpful in the determination of the optimum loading which will cause no operational problems. Finally, the oxygen transfer capacity (OTC) provides important information concerning the oxidation potential of the system, especially for organic matter decomposition and ammonia nitrogen nitrification.

Another important parameter which is mostly applied in horizontal CWs (either surface or subsurface) is the hydraulic retention time (HRT), which is described as the ratio of volume (m^3) to flow rate (m^3/d). Its value is crucial since it defines the available time for direct contact of the wastewater and the wetland elements (porous media grains, plant roots, biofilm) and, thus, the extent of the various removal/transformation processes. The selection of an appropriate HRT is directly related to the system surface area (and so to the unit area demand) and performance. Currently, there are many published studies and results from pilot and full-scale installations. For example, typical HRT in HSF CWs varies between 5-20 days, depending on the climatic conditions, the level of treatment etc. Dimensions of horizontal beds are also important; usually HSF and FWS CWs have a rectangular plan view with a varying width to length ratio of 1:3-5. Longer length than width is preferred in order to ensure plug flow hydraulics.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Generally, designing and sizing a wetland bed varies from simple "rule of thumb" to more complex models. The plug-flow first order k (known as the kC* model) is often used, as also Monod-type equations (Kadlec & Wallace, 2009). A simple equation which is often used for the calculation of the required surface area for BOD_5 removal is the following:

$$A = \frac{Q\ [\ln(C_o / C_e)]}{K_T\ d\ n} \quad (1)$$

where, A = the surface area of the bed (m^2), d = the saturated depth of the bed (m), n = the substrate porosity (decimal fraction), K_T = the first-order areal rate constant (m/d), Q = the average daily flow rate (m^3/d), C_o the mean influent BOD_5 concentration (mg/L) and C_e the required effluent BOD_5 concentration (mg/L). For example, for a bed depth of 0.6 m at 10°C, K gets the value 5.2. K values depend on the biodegradability of the wastewater. Usually, BOD_5 is used as the main target parameter, but other pollutants such as suspended solids (SS), ammonia nitrogen and total phosphorus have also been used. The parameters used for the evaluation of CWs performance are the same pollutant indicators as for every wastewater treatment technology, such as organic matter (BOD_5 and COD), nitrogen compounds (total nitrogen, ammonia nitrogen, nitrate, nitrite), phosphorus (total phosphorus, ortho-phosphate), coliform bacteria (*E. coli*, feacal coliforms) and heavy metals. Physical characteristics (e.g., dissolved oxygen, electrical conductivity, pH etc) are also used to describe CWs operating conditions.

In Sludge Treatment Wetlands, the design is based on the quality of the raw sludge and the local climatic conditions, as well as on the annual sludge production of the wastewater treatment plant (Stefanakis et al., 2014). As for other CW types, the design and dimensioning of STWs follows mostly empirical observations and personal experience of the designer. Again, there are no commonly accepted guidelines and the design varies from country to country. The basic design parameter is the sludge loading rate (SLR; kg dm/m^2/yr), which expresses the annual dry mass (dm/yr) or dry solids (ds/yr) that will be applied to the bed per surface unit (m^2). It is directly related to the climate of the installation area. For example, proposed SLR for Denmark is 60 kg dm/m^2/yr for activated sludge and 50 kg dm/m^2/yr for sludge with higher fat content (Nielsen, 2003). Higher SLRs have been proposed for the Mediterranean basin: up to 90 kg dm/m^2/yr in Greece (Stefanakis & Tsihrintzis, 2012c), as also 45 kg dm/m^2/yr in Italy (Bianchi et al., 2011) and 55-110 kg dm/m^2/yr in Spain (Uggetti et al., 2009; Uggetti, Ferrer, Molist, & Garcıa, 2011). Stefanakis et al. (2014) presented an overview of SLRs applied in various countries around the world. The operational life time of STWs can last up to 30 years and more and it is divided in 2-3 phases of 8-12 years, based on the applied SLR. After the completion of each phase, the bed is left to rest for some period (a few months up to 1 year), then the accumulated sludge residual is removed and a new feeding cycle begins (Nielsen, 2003; Stefanakis & Tsihrintzis, 2012c; Stefanakis et al., 2014).

Two important design features of CW facilities are the plant species and the substrate media. The most common emergent plant species used are common reeds (*Phragmites australis*) and cattails (*Typha latifolia*) and also *Scirpus* spp, due to their wide presence in most parts of the world. However, other locally available species may also be used, for example in tropical regions bamboo has been tested in CW systems. Generally, the selected species should be well adapted to the local climatic conditions, tolerant against the various pollutants and with uptake capabilities of certain constituents such as nitrogen. It should be noted that indigenous species are always preferred for use in CWs and not exotic ones, to avoid ecological risks such as invasion of the new species and/or diseases (Stefanakis et al., 2014).

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

The selection of an appropriate substrate media is also important for the CW system and, as plants, is connected with the system performance. The grain size should be carefully selected, especially for subsurface systems, since clogging problems due to low porosity and high hydraulic loads might occur and affect the system efficiency. An ideal substrate would also have the capacity of removing some constituents from wastewater by various processes (e.g., ion exchange, adsorption, precipitation). The substrate layer is also where the plants are established, thus, it supports plant growth and enhances system stability, provides filtration effects and together with the plants supports the various transformation/removal processes (Vymazal, 2007; Stefanakis et al., 2014). Media used in CW systems include natural materials (e.g., minerals, rocks and soils), synthetic materials (e.g., synthetic zeolites, activated carbon) and industrial by-products (e.g., slags, blast furnace) (Stefanakis et al., 2014).

Facility Layout

A full-scale CW facility comprises of several treatment stages. The first treatment stage is usually the pre-treatment stage. In this stage, large material (e.g., papers, leaves, plastics etc.) and coarse particles are firstly removed using mechanical equipment (e.g., screens and bars), along with a portion of the SS and organic matter. Most common pre-treatment methods are septic or Imhoff tanks and primary sedimentation tanks, although anaerobic digesters and stabilization ponds have also been used (Stefanakis et al., 2014). This pre-treatment stage is very important in CW facilities, since a good performance limits the clogging potential of the following CW beds. In case of industrial or agricultural wastewater, pre-treatment can be more complex and intensive due to the heavier loads of these wastewater types.

Different CW types can be combined in the second and third (or even fourth if necessary) treatment stages of a full-scale facility, usually HSF CWS and VFCWs (Stefanakis et al., 2014). These combined systems are also known as *hybrid CW systems*. The concept is to exploit the specific treatment advantages of each type in one facility and reach higher treatment efficiencies. For example, low nitrification capacity of HSF CWs (due to limited OTC) is counterbalanced by VFCWs (good nitrification capacity, high OTC). Additionally, HSF CWs can be used to provide denitrification of the nitrified effluent from VFCWs. The most common combination is a two-stage system of a first VFCW bed followed by a HSF CW. Stefanakis et al. (2014) presented several possible combinations of CW types in hybrid systems that have been tested, e.g., VF-HSF, HSF-VF, HSF-VF-HSF, VF-HSF-HSF, VF-HSF-FWS.

The two-stage VFCW system gains increasingly interest since it has been proved very effective. VFCWs operate with parallel beds in each treatment stage. The presence of parallel VFCWs beds is necessary to ensure the continuous operation of the facility, since VFCWs usually operate with intermittent wastewater application (2-4 days of feeding followed by 2-8 days of resting) (Stefanakis & Tsihrintzis, 2012a; Stefanakis et al., 2014). The number of parallel beds in the third treatment stage is lower, since the pollution load is respectively lower due to the prior treatment in the second-stage CW beds. A modification of the two-stage VFCW system has been developed in France, also known as the French system (Molle, Liénard, Boutin, Merlin, & Iwema, 2005; Stefanakis & Tsihrintzis, 2012a). This setup includes two stages of VFCWs but no pre-treatment stage (only screens are used). The wastewater is applied directly on the surface of the first-stage VFCW bed. The key here is that the first-stage beds contain only coarser material (no sand), in order to avoid clogging and gradually accumulate sludge on the surface. The advantage of the French system is that it may have lower costs since no pre-treatment is applied.

A final post-treatment stage is not a basic element in the design of CW facilities but it is often applied when stringent effluent quality criteria have to be met, especially concerning pathogenic micro-

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

organisms. Of course, the goal is not to produce a final effluent appropriate for use as potable water, but to further improve the effluent quality and reach higher sanitation levels, in order to minimize or even eliminate the environmental impact. This final stage could include disinfection methods such as chlorination, ozonation or UV radiation. Maturation ponds or a final FWS CW system have also been used as a final treatment stage. A post-treatment stage could also improve the overall system efficiency, e.g., in phosphorus removal.

Facilities of Sludge Treatment Wetlands are similar to those of VFCWs. A STW facility consists of several beds which are alternately loaded with sludge. The presence of several beds allows for the application of feeding and resting periods in the beds and provides flexibility in the loading cycles applied which may vary during winter and summer months (Stefanakis et al., 2014). The number of beds in a STW facility depends on the sludge production of the wastewater treatment plant, the chosen SLR, the cycles of feeding/resting periods and the climatic conditions. For example, Uggetti et al. (2009) used 3 beds, Stefanakis & Tsihrintzis (2012c) 4 beds and Nielsen (2003) 18 beds, which correspond to 400 and 123,000 pe served, respectively.

Advantages of Constructed Wetlands Technology

As an alternative, ecological treatment technology, CWs provide a series of multiple significant advantages compared to conventional treatment methods such as activated sludge systems. Conventional treatment systems are in use for more than 100 years now, serving a different approach of wastewater treatment than CWs. The approach of conventional treatment systems consists in the construction of large, centralized facilities and respectively extended sewer networks for the collection and transport of wastewater. It is not difficult to understand that big end-of-the-pipe centralized plants and the accompanied sewer network represent high required investments. These facilities are also expensive in their operation and maintenance. Of course, this type of facilities appears as the only solution to provide wastewater treatment for large cities, capitals, and other populated urban areas. For these cases, high investment costs are considered as reasonable and unavoidable. However, the question is whether this approach of centralized treatment systems is even applicable in smaller cities, communities and rural areas. Over the last years, an alternative approach of wastewater treatment has risen; the decentralized approach.

Although there have been in the past huge investments in infrastructure for centralized plants, gradual population increase was not accompanied by respective increase in budgets to meet the needs for new wastewater treatment facilities. Insufficient funding was even more realized due to the aging of existing infrastructure, which means that additional investments are needed not only for new installations but also for the refurbishment and technological upgrade of existing facilities. This means that new, innovative and cost-effective methods are more welcome than in the past and the approach of decentralized treatment becomes gradually more attractive. CWs belong exact to this category and serve this philosophy. They are point-of-use treatment systems which can deliver effluents of the desired quality. They can be installed in many areas and regions with reduced overall costs. However, the CW technology should not be viewed as a direct and total competitor of conventional treatment systems. A complete replacement of centralized facilities with CW systems is practically infeasible, since the required land area would be very high; a demand which cannot be met in large densely populated urban areas. But CW systems appear as an ideal solution for small and medium communities, small cities, villages, single households or block of flats and generally rural, mountainous and remote areas, where sewer network does not exist

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 1. Main characteristics of conventional treatment systems (CTS) and Constructed Wetlands (CWs) (Stefanakis et al., 2014).

	Conventional Treatment Systems	Constructed Wetlands
Infrastructure	Many and complex mechanical parts	No mechanical parts (maybe only pumps)
Investment	High construction costs	Usually lower construction costs than CTS (especially if there is available land)
Operational costs	High	Very low to zero
Land area demand	Low	High demand (e.g., 2-10 m^2/pe)
Application scale	Small - medium	Medium - large
Performance	Continuous effluent of high quality	Similar with CTS, small fluctuations may appear with temperature variations
Raw materials	Use of non-renewable materials during construction (concrete, steel, etc.) and operation (electrical power, chemicals)	Almost exclusive use of renewable sources (solar, wind, etc.) - "ecological" character
Energy consumption	High	Low
Greenhouse Gas Emissions	High	Very low
Operation	Need for daily monitoring Useful lifetime up to 25-30 years	Need for periodical check only (e.g., on a monthly basis) – autonomous operation, Prolonged lifetime (>30 years)
Staff during operation	Demand for specialized personnel	No specialized personnel needed
Maintenance	High maintenance needs and costs - regular damages due to large/complex mechanical equipment	Low maintenance cost (only small mechanical parts – pumps)
Odors	Large open air tanks, odor production	Small problems only in free water surface systems
Insects	Usually no significant problems	Small problems only in free water surface systems
Response to flow variations	Higher/shock inflow rates negatively affect the performance	Robust to high flow variations
Robustness to toxic substances	Toxic pollutants may lead to system breakdown	Robust to some toxic constituents
By-products	Large daily volumes of sludge production, which needs handling and management on a daily basis	Zero production of by-products
Appearance	Unattractive, "industrial appearance"	Aesthetically accepted, green view

and the construction of a conventional treatment plant is economically unfeasible. For these areas, CW technology provides many technical, economic and ecological benefits, which are summarized in Table 1.

CWs are in general easy to build, simple to operate and provide treatment robust to flow fluctuations and pollutant concentrations. They appear as an ideal solution especially for small communities and settlements and for onsite treatment, where current requirements and needs for effective wastewater treatment are high. CWs facilities can satisfy general effluent discharge limits (e.g., BOD_5 < 30 mg/L, COD < 100 mg/L, total nitrogen < 15 mg/L), while effluents of even higher quality can also be achieved (Kadlec & Wallace, 2009; Stefanakis et al., 2014).

Although conventional treatment systems provide effective wastewater treatment for many decades now, they have certain disadvantages. Typical facilities of this type have an industrial appearance and are unattractive, thus, they are usually installed away from residential areas. Centralized plants include

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

large and complex mechanical equipment such as ventilators for aeration, pumps etc., while extensive use of non-renewable materials (concrete, steel) takes place for the construction of the various basins, tanks and equipment. This means that construction of such facilities can be expensive and non-environmentally friendly, despite the fact that the aim is environmental-oriented (wastewater treatment). On the other hand, CW facilities do not include mechanical parts. The only mechanical equipment is pumps to transfer the water from one stage to the other, which - however - can be avoided with a proper design and exploitation of the topography of the installation area. Moreover, conventional treatment plants are energy-intensive systems and they require a large energy input for their operation. Facilities having many complex mechanical parts and equipment may also require high maintenance demands. This means that operational costs of such facilities are also high. On the contrary, minimum operational costs probably represent the main advantage of CW facilities. In CWs, the energy input needed is very small, usually only for the pumps that may exist in the facility. Energy requirements for the treatment processes are covered by renewable energy sources used by plants (solar, wind energy). At the same time, maintenance needs are also low, since the operation of a CW facility is practically autonomous; at the stage of full operation, a typical maintenance scheme applied is one visit at the site on a monthly basis. There may also be far less need for specialized personnel to run the CW facility, contrary to conventional plants where specialized staff is necessary. Global experience from many countries and professionals has shown that operational costs of CW facilities can be up to 90% lower compared to conventional plants. Moreover, CWs operate without the need for the addition of any chemical substances, which is not the case in conventional treatment plants.

Additionally, the treatment in CWs does not generate any by-product. Produced sludge is accumulated within the system. On the other hand, in conventional treatment plants large amounts of excess sludge are produced on a daily basis. This excess sludge needs to be managed, dewatered and stabilized in order to be further exploited. Although the sludge volume represents only a small portion (1-3%) of the total treated volume, its management and handling can reach up to 50% of the total facility costs (Stefanakis et al., 2014). It is then realized the significant advantage of CWs of no by-product production. To be accurate, though, it should be noted that occasional sludge removal (e.g., 2-3 times/years) should take place if there is a pre-treatment stage (e.g., sedimentation or Imhoff tank), but this cost is by far lower than the sludge production and handling cost in conventional systems. The only product that could potentially be viewed as by-product in CW facilities is the plant biomass. Usually, the produced plant biomass is harvested and collected once annually. However, this biomass can be exploited as biofuel for energy production or for compost production. Additionally, in most CW systems problems with mosquito and odor production are very low, especially in systems with subsurface flow, which is not the case in conventional treatment facilities where the open wastewater tanks for settling and/or aeration attracts mosquitos and insects and produce odors.

Disadvantages of Constructed Wetlands

Despite the various advantages of this technology, CWs have also some downsides which should be taken into account. The major one is that CWs require a larger land area compared to a conventional treatment facility. Although continuous research managed to reduce the total footprint of CW facilities and optimize their design (e.g., the use vertical flow systems and lately of aerated systems), area demands are still higher (e.g., 3-10 times) for CWs than for conventional systems (Stefanakis et al., 2014). Furthermore, false design could also result in odor problems and the appearance of a water surface in

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

subsurface systems. However, it should be noted that if properly designed and constructed, CWs generally do not create odor issues.

Since the wetland technology still remains relatively new, the CW system is often viewed using the "black box" approach and simple regression equations are used for the design (Button, Nivala, Weber, Aubron, & Müller, 2014). On the other hand, it is known that most of the pollutant removal mechanisms are based on microbial processes (Faulwetter et al., 2009), which means that a better understanding of the fundamental processes taking place inside the system is necessary, in order to provide an optimum design and performance (Stefanakis et al., 2014). Thus, the design of CWs is still largely based on empirical data and professional experience. This also explains the fact that there are not yet widely accepted design guidelines for CW systems. Additionally, optimum performance is usually reached after one or two years of operation, when the plants are fully developed, while there might be some seasonal variations in the overall efficiency.

It should be noted that all the above mentioned drawbacks are currently under investigation by the scientific community. Intensified research over the last 10-15 years has managed to abate most of these issues and further improvements are anticipated in the future.

Sustainable Character of Constructed Wetlands

Based on the above, it is obvious that CW systems possess various and multiple characteristics which attach to this treatment technology an ecological character. They are often characterized as sustainable systems. Low energy consumption and use of natural materials (gravel, soil, sand and plants) are the two main treatment parameters in CWs. One of the largest projects using the wetland technology is the Everglades restoration project, where CWs were used to remove nutrients from agricultural runoff entering the Everglades (Guardo et al., 1995). This project is the largest restoration project in the USA for stormwater treatment and presented in the most emphatic way the sustainable dynamic and treatment capacity of CWs. Similar projects of sustainable design using the wetland technology have been developed for the removal of nonpoint-source pesticide pollution in river catchments (Schulz & Peall, 2001) and diffuse pollution at the catchment scale (Harrington, O'Donovan, & McGrath, 2013), the protection of coastal zone from human activities and pollution in China (Zuo, Wan, Qin, Du, & Wang, 2004), stream restoration (Wang, Gao, Guo, Li, & Zhang, 2012; Palmer, Filoso, & Fanelli, 2014), among others.

However, in order to characterize a technology as "green" there are specific factors which should be met such as effective treatment, robustness, no by-products, recycle/reuse of materials, minimum energy consumption – use of renewable energy sources, minimum/no use of chemicals and minimum environmental nuisance (Brix, 1999). The sustainable character of a treatment system is defined by its economic viability, technical feasibility, environmental protection and social acceptance (SunSanA, 2008). Additionally, it should close the flow cycle of materials, i.e., provide the option for safe reuse of the treated effluents. The approach of sustainable sanitation systems integrates aspects such as public health and hygiene, protection of the environment and natural resources, technological and operational parameters, financial parameters and socio-cultural aspects (SunSanA, 2008; Langergraber, 2013).

Health aspects are of crucial importance since they would determine the level of exposure risk to pathogenic microorganisms and other hazardous compounds. CW systems have been found to be effective in pathogens elimination (Kadlec & Wallace, 2009; Stefanakis et al., 2014). In VFCWs reported elimination rates reach up to 3 logs (i.e., 99.99%) (Stefanakis et al., 2014), while in FWS CWs respectively high rates are reported due to direct UV radiation and disinfection (Kadlec & Wallace, 2009).

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

The level of environmental protection and natural resources preservation in CW systems is also high. Effective treatment and high removal efficiencies significantly decrease the pollution load that reaches the final receivers (surface and ground water bodies), thus, limiting the risk for ecosystem and aquatic life degradation. Moreover, the construction of CW systems takes place with natural materials (gravel/sand, plants) which are locally available worldwide and minimum use of synthetic or non-renewable materials takes place. This means that the production and provision of raw materials for CWs construction does not include significant energy-consuming and pollution generating processes. The minimum energy consumption in CW facilities also saves natural resources and minimizes pollution generation, especially when the energy source is non-renewable (e.g., fossil fuels). These environmental benefits can be translated to low levels of greenhouse gas emissions (CO_2, CH_4 and N_2O) (Langergraber, 2013; Stefanakis et al., 2014).

Quantification of these gas emissions for various wastewater treatment methods during both construction and operation phases is important for the estimation of the ecological impact and the global warming potential. Studies report that CW systems have a slightly lower environmental impact during the construction phase compared to other conventional methods (e.g., activated sludge, trickling filters), but a much lower impact for the operation phase (Georges, Thornton, & Sadler, 2009). Life cycle analysis studies on CW systems and comparison with alternative scenarios of using conventional treatment methods have also shown that the global warming potential of CWs is lower in terms of CO_2 emissions (Stefanakis et al., 2014). It is also interesting that in CW systems the major portion of the environmental impact occurs during the construction phase than the operation phase (Dixon, Simon, & Burkitt, 2003; Machado et al., 2007), while in conventional treatment plants the environmental impact of the operational phase is higher than the impact of the construction phase (Dixon et al., 2003; Ortiz, Raluy, Serra, & Uche, 2007; Renou, Thomas, Aoustin, & Pons, 2008; Stefanakis et al., 2014). Among the various CW types, FWS systems produce the lowest CO_2 emissions, VFCWs the lowest CH_4 emissions, while N_2O emissions are reported to be comparable in all CW types (Mander et al., 2014). It should be noted that hybrid CW systems, where different CW types are combined, achieve higher removal efficiencies and minimum greenhouse gas emissions at the same time. The ecological character of CWs is also enhanced by the fact that they promote biodiversity, they provide habitat for various wetland organisms, water savings and multiple hydrological functions (Langergraber, 2013).

Similar results are reported for sludge dewatering in Sludge Treatment Wetlands (Stefanakis et al., 2014). The comparison with conventional centralized facilities such as centrifuges, including all parameters of sludge management (transport, construction, raw materials, energy consumption), has shown that STWs have the lower environmental impact (Uggetti et al., 2011). As for CWs for wastewater treatment, the main impact occurs during the construction phase due to the raw materials used, while respective impact for the operational phase is minimum. If the basin for the CW is simply excavated or recycled concrete is used, when the impact of the construction phase can be reduced. Centrifuges have the highest environmental impact, since their operation requires a high energy input. The contribution of STWs to global warming is negligible. It is reported that the overall environmental impact of Sludge Treatment Wetlands is 500 times lower when compared with centrifugation technique and 2000 times lower compared to sludge transport to a centralized facility (Stefanakis et al., 2014). Moreover, studies have shown that the final sludge product after treatment in STWs (biosolids) is a well stabilized and non-phytotoxic valuable material which is safe for reuse and recycle, e.g., as fertilizer in agriculture (Stefanakis et al., 2011b; Uggetti et al., 2011; Stefanakis & Tsihrintzis, 2012d)

CW systems are in general easy to build and simple in the design and operation (Kadlec & Wallace, 2009). This facilitates the efficient installation of CW facilities, especially in remote areas. Proper design and construction of a CW system allow it to perform in an effective and reliable manner. Problems such as bed clogging, water runoff from the surface or limited plant development may be caused by inadequate design or construction (Stefanakis et al., 2014). Typical problems such as pump/valve failure may occur in CW systems as in conventional plants (Langergraber, 2013). Increased maintenance time and more advanced skills may be required only in case of more complex CW modifications such as aerated beds.

The economic aspect is also an important factor in order to characterize a treatment method as sustainable. The major costs during the construction phase of CWs are, in general, for the earthworks (excavation and fill of the basin), the filter media to be used as substrates, the plants and the bottom liner (e.g., geomembrane/geotextile) (Kadlec & Wallace, 2009; Stefanakis et al., 2014). Most of items are usually locally available, which can decrease transportation costs, especially for short distances. The liner and mechanological equipment (e.g., pumps) may represent a high portion of the costs if they are to be purchased or imported. Labor costs also vary from country to country. Generally, construction costs of CW facilities are comparable or slightly lower with those of conventional treatment plants (Langergraber, 2013; Stefanakis et al., 2014). For small-scale applications (e.g., up to 1,000 pe) CWs offer an economic advantage in terms of investment but as the population served increases, the investment costs become comparable mainly due to the higher land requirements. However, the main economic benefit of CWs are the significantly reduced costs for operation and maintenance due to lower energy consumption and technical equipment used (Brix, 1999; Dixon et al., 2003; Langergraber, 2013; Stefanakis et al., 2014).

The social aspect of CWs as treatment systems is increasingly enhanced. The green, aesthetical appearance of CW facilities compared to the conventional treatment plants (Fig. 6) makes them more acceptable by the society. Many enterprises (e.g., industries, municipal-private companies) choose the CW technology for the treatment of wastewater produced in their premises as a mean to enhance their green profile and incorporate the CW installation to their corporate social responsibility plan.

Providing Clean Water for Better Health

Being a wastewater treatment technology, the main goal of Constructed Wetland systems is to purify wastewater and provide a final effluent of high quality. Degradation of the natural environment and ecosystems is a result of the various human activities and the respective production and uncontrolled discharge of wastewaters to surface- and groundwater. Wastewater treatment is today an absolutely necessary process not only to protect the natural environment and the habitat, but also to protect human health. Water pollution is an existent threat to human health, since surface water bodies (e.g., rivers, lakes) as well as groundwater and aquifers are used as potable water supplies. Therefore, it is crucial that wastewater generated by the various and multiple human activities is treated and purified prior the final discharge, in order to reduce and eliminate the pollutant load. Under this frame, eco-friendly systems such as Constructed Wetlands play a significant role. Their ability to provide wastewater treatment and sanitation in a sustainable way adds credits to their role in the protection of the ecosystems and human health. The further exploitation of the treatment potential of the Constructed Wetland technology will bring additional benefits for the society, since it will contribute to the issues of human health protection and natural environment conservation without causing an additional environmental impact.

FUTURE RESEARCH DIRECTIONS

The CW technology is a relatively new technology, although first attempts were made almost 50 years ago. Actual interest and increasing research and applications mainly occurred only during the last 20 years and have been intensified over the last decade. This means that design optimization and basic understanding of the fundamental processes are still under investigation. Currently, there are not widely accepted design guidelines, although some general parameters and assumptions are used by the majority of researchers and engineers. Thus, the challenges in the field of CW technology are to further improve the design of the system and optimize their performance. Design optimization is crucial since it may allow for the decrease of the required surface area or footprint of the wastewater treatment facility. Furthermore, future studies under varying climatic conditions will assist in the development of design guidelines for extended regions. Additionally, the use of CWs for the treatment of more complex water sources such as industrial wastewater is another field of great interest. While it is has been proven that domestic and municipal wastewater can be effectively treated in CWs, recent applications for various industrial wastewater, such as tanneries, textile mills, landfill leachates, olive oil mills etc., reveal the great potential of the CW technology. Also, the development of reliable modeling tools for the performance prediction and design improvement of CWs will be a major step forward. Finally, it is realized that the various economic and environmental benefits of CW technology make them appropriate systems for water sanitation in developing countries, a topic which is expected to be further developed in the near future.

CONCLUSION

The technology of natural treatment systems and especially of Constructed Wetlands is appearing today as one of the most attractive alternative technologies for wastewater treatment and sludge dewatering. These treatment systems provide multiple economic, environmental, technical and societal benefits over the conventional treatment methods such as activated sludge. Following the decentralized approach, the technology of Constructed Wetlands is particularly appropriate in areas where the implementation of a conventional treatment method is economically infeasible, such as in small-medium settlements and communities, rural, mountainous and remote regions and for onsite treatment for single households or block of flats. Especially for small-scale applications (i.e., up to 1,000 pe), Constructed Wetlands possess significantly lower investment costs. Their main economic advantage comes from their operation phase due to the minimum energy requirements and the low needs for maintenance and personnel. Constructed Wetland systems have been proved to provide very effective treatment of domestic and municipal wastewater. Their overall effectiveness enables their application for various industrial and agro-industrial wastewaters with very promising results. As natural treatment technology, Constructed Wetlands can be characterized as sustainable systems, fulfilling sustainability criteria such as effective sanitation, contribution to public health and hygiene aspects, environmental protection, protection of natural resources, simple, reliable and robust operation and social acceptance. The potential of this treatment technology is today widely recognized and further future expansion of the technology is anticipated in both developed and developing countries.

KEY TERMS AND DEFINITIONS

BOD: Biochemical Oxygen Demand. An organic pollution indicator which expresses the part of organic pollution which can be removed biologically (using microorganisms).

COD: Chemical Oxygen Demand. An organic pollution indicator which expresses the total organic pollution which can be removed by using a strong oxidant agent.

CH_4: Chemical formula of methane. Atmospheric methane represents one of the greenhouse gases.

N_2O: Chemical formula of nitrous oxide. It is a greenhouse gas and an air pollutant.

Facultative Pond: A pond type of natural systems where wastewater is treated biologically under low oxygen conditions. The wastewater remains in this open-air pond for a prolonged period and then is transferred to the next treatment stages.

HDPE: High-density polyethylene, a material made from petroleum. It is used in the production of geomembranes that cover the bottom of tanks, constructed wetlands etc to prevent leaching of liquids to the groundwater.

Imhoff Tank: A V-shaped tank used as primary treatment for wastewater. Its design aims at the removal of solids and the separation from the liquid wastewater, as also the accumulation of sludge at the bottom.

Landfill Leachate: The liquid which percolates from landfill sites and which contains several contaminants, sometimes toxic chemicals.

Log: Logarithm, the mathematical operation that is the inverse of exponentiation. It is used to express the bacteria removal during wastewater treatment. Thus, 1log removal mean 90% kill of bacteria, 2log 99%, 3log 99.9%, 4log 99.99% etc.

Macrophytes: Aquatic plants that grow in water (or near water sources). Can be emergent, submergent or floating.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

OTC: Oxygen Transfer Capacity. An indicator of the oxygen amount that can be transferred to wastewater with different treatment technologies.

Oxidation Pond: A pond type of natural systems for wastewater treatment. They are large, shallow basins where wastewater is treated through natural processes such as bacterial activity, sunlight and algae. Mechanical aeration can also be used to increase the levels of oxygen required for the treatment processes.

Plug Flow: A flow type of a fluid inside a pipe, where it is assumed that the fluid has a constant velocity across the cross-section of the pipe and no back mixing takes place.

Zeolite Gravity Filter: Filters containing a natural rock (zeolite) which operate with gravity (i.e., the use of pumps is avoided). These filters are used in wastewater treatment to remove pollutants mainly through filtration and other processes.

Chapter 26
Systems Based on Physical-Chemical Processes:
Nutrient Recovery for Cycle Closure

ABSTRACT

High strength waste streams, namely rejected water from a wastewater treatment plant, livestock slurry, and agro-food wastewater, are characterized by its high organic matter and nutrient content which favours processes aiming to recover energy and nutrients, instead of removing them. In this regard physical-chemical processes are suitable technologies to attain these objectives. Among others, stripping coupled with absorption, struvite precipitation, membrane separation, and vacuum evaporation, are all physical-chemical processes aiming to concentrate nutrients in a stream that can later be reused as fertilizer. In this chapter the main physical-chemical processes will be defined and described in terms of the objective of each process technique, their theoretical fundamentals, environmental effects (air, water and soil emissions, resource depletion), technical indicators (efficiencies, energy consumption, etc.), and by-product characteristics.

INTRODUCTION

An increasing food demand and the sharpening of agricultural detrimental effects on the environment raise urgent technological challenges. The inadequate nutrient supply, mainly nitrogen (N) and phosphorous (P), that characterizes agricultural practices in most developing countries, lead to soil quality depletion, water bodies and atmosphere pollution (Vitousek et al., 2009; Galloway et al., 2003).

On the other side, up to about 2-3% of the global energy consumption is ascribed to energy intensive fertilizer production processes (EU-BAT, 2006), with nitrogen fertilizers accounting for about 70% of it (Ramírez and Worrel, 2006). Almost all nitrogen fertilizers are synthesized from ammonia and around 80% of the world production capacity, estimated to be 109 Tg in 2003, is used for this purpose (EU-BAT, 2006). Direct energy requirements for the production of one Mg (tonne) of ammonia are between 40-45 GJ (Ahlgren et al., 2008) with an average cost of 100$ (Erisman et al., 2008). Moreover, fossil fuel use, mainly natural gas, is reported to represent 70-90% of these costs, thus exposing fertilizers and, indirectly, food sectors to international energy price fluctuations and instabilities (EIA, 2009).

Phosphorous, in its turn, is a mining resource with a very limited predicted lifetime; it is said that within the next 100 years it will be completed depleted (Zhang et al., 2015). This fact makes P a geo-strategic resource for most countries. Moreover, P recovery technologies and the subsequent marketing of phosphorous-rich solid products could have important positive environmental implications, as a replacement of inorganic-based P in the fertilizer industry would generate a global warming potential offset via reductions in climate emissions from P mining and production.

Management and technological solutions leading to an increase in nutrient use, and recycling efficiencies within agro-ecosystems, are receiving a renewed interest for their significant potential contribution in reducing fertilizer inputs and nutrient losses. Nevertheless, a development towards bio-base and circular economies is dependent on a more cost-effective nutrient recycling technologies from waste streams.

In this sense, both the quality and marketability of those end and by-products are relevant issues which could contribute to this economic balance. By-products from processing wastewater technologies (namely struvite, ammonia water, concentrates, etc.) are relatively new on the market, and legislations applicable to them are not always clear. Some products are not yet included and market operators are in doubt about their classification and requirements. Furthermore, due to associated logistic challenges, they have a considerably lower market price, even if also linked to market prices for mineral fertilisers (Foged et al., 2011). Besides this, end users are not always sure about the fertilization characteristics and harmlessness of these products; in this sense a lot of information is still missing.

In this chapter the main physical-chemical processes (Table 1) will be defined and described in terms of objectives of the technique, theoretical fundamentals, environmental effects (air, water and soil emissions, resources depletion, etc.), technical indicators (efficiencies, energy consumptions, etc.), side stream and by-products characteristics and destiny/use, etc. A detailed scheme of each technology and specificities for each waste stream application will also be presented.

MECHANICAL SEPARATION TECHNOLOGIES

Mechanical separation can be an effective technique to remove solids from a (semi) liquid stream obtaining a liquid fraction containing soluble components such as mineral nitrogen (N), potassium (K) and other ions, and a solid nutrient-rich fraction containing the majority of the organic matter, including a significant proportion of phosphorus (P) (Jorgensen and Stoumann, 2009). Decanting by gravity or natural settling is usually used to easily obtain these two fractions. However, the long times and large spaces required, makes this technology not always feasible. A quicker separation can be obtained using mechanical separators which are able to reach, at the same time, high removal efficiencies and a thick stream with high dry matter and most of the nutrients.

Table 1. Main physicochemical process technologies to recover nutrients from wastewater

Physical base technologies	• Mechanical separation technologies	• Sieves • Screw pressing • Filter belt • Decanter centrifuge
	• Membrane filtration	• Nanofiltration • Ultrafiltration • Reverse osmosis • Other emerging technologies
	• Evaporation and Drying	
Chemical base technologies	• MAP (struvite) precipitation	
Physical-Chemical base technologies	• Electrocoagulation	
	• Stripping and Absorption	

Theoretical Fundamentals and Process Description

During the separation process, the distribution of nutrients between the two phases varies widely reflecting the solubility of the different compounds. For example, organic nitrogen is concentrated in the solid phase, while ammonia nitrogen remains at a similar concentration in the liquid phase. Phosphorous compounds, in their turn, are largely removed into the solid fraction, though pH can have a large effect.

Separation efficiencies of these mechanical separators may vary widely, due to the difference in the efficiency of each separator, and because separation efficiencies are affected by the variable physicochemical composition of the streams (Moller et al., 2002)

Most separation processes are either set up to produce concentrated sludge or clarified effluents but rarely both in a single stage operation. Ensuring a clear supernatant is often at the expense of a diluted thick phase; conversely, achieving a concentrate filter cake compromises the clarification process. If both are required, then a multistage process is needed (Burton and Turner, 2003).

The performance of a separation process is often quoted as the simple ratio of the mass of a given component in the solid or concentrated phase divided by the presence of that same component in the feed stream (Equation 1). However, it should be considered that any separation process is also a method of dividing a stream. In this regard, if the apparent removal of a given component is of 25%, but the concentrate stream represents 25% of the original volume, this equates to a non-effective separation (Burton, 2007). Martinez et al. (1995) aiming to incorporate this issue, defined efficiency in more meaningful terms (Equation 2);

$$\eta = (S \times X_s / X_f \times F) \times 100 \quad (1)$$

$$\eta = S/F(X_s/X_f - 1) \times 100 \quad (2)$$

Where η is efficiency, S is the concentrate solid stream (m^3/h), F is the feed stream (m^3/h), X_s is the concentration of a given component in S (kg/m^3), and X_f is the concentration of the same component in F (kg/m^3).

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Similarly, Moller et al. (2000) proposed a reduced separation efficiency index; where an index value of 0 indicates that the nutrients are distributed equally between the solid fraction and the liquid fraction, and a value of 1 indicates that all the nutrients are concentrated in the solid fraction.

However, the simple ratio of the mass balance is the efficiency index most commonly used.

Usual Applications, Equipments, and Environmental Aspects

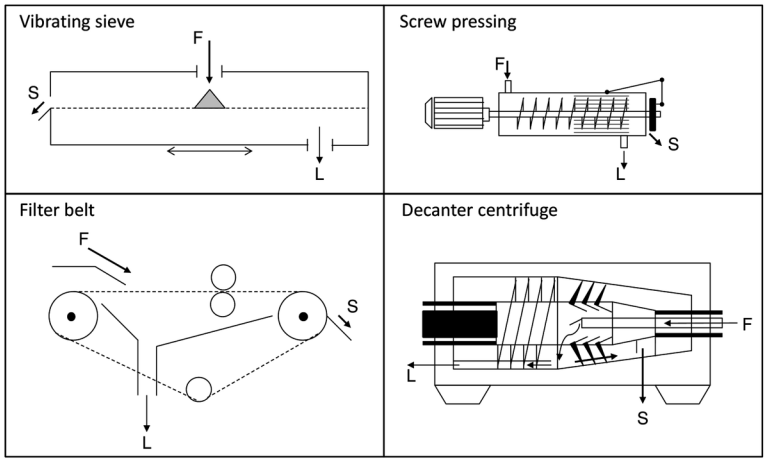
Mechanical separators are usually applied for the processing of streams with high un-dissolved solid content, namely livestock manure, sewage sludge whether raw or digested, agro-food wastewater, etc., and it is almost always a necessary first step if a further recovery technology is to be later applied.

The total solid content of a liquid stream is divided, in general terms, between those solids dissolved and those present as suspended matter. Beyond this, a useful division of the suspended matter can be made to outline the performance of the main groups of separating equipment available (Figure 1). The selection of one or another depends not only on the composition of the feed but on the final aim of the required processing technology (e.g. maximize nutrient recovery in the dry solid fraction, obtaining a liquid fraction without suspended solids, etc.).

There are different mechanical separators, the more common ones are described below (Flotats et al., 2011):

- **Sieves:** It consists of a screen of a specific pore size which allows solid particles smaller in size than the openings to pass through. The liquid flows through the screen and is drained off. There is a compromise between sieve size, separation performance, and risk of clogging. Sieve separators may be static or vibrant. Indeed, sieve clogging is one of the most common problems of static screens. Such risk is diminished in vibrant sieves due to vibration. If the flow is too high, a large amount of water can remain in the solid fraction.

Figure 1. Common mechanical separator equipments (F: feed, L: Liquid phase, S: Solid phase) (Adapted from Moller et al., 2000, Burton and Turner, 2003)



EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

- **Screw Pressing:** This is a process consisting in the application of pressure in order to separate the suspended and dissolved solids contained in a (semi) liquid, by filtration. The material to be separated enters into a cylindrical 0.5-1 mm screen by means of a screw. The liquid passes through the screen and is collected in a container surrounding the screen. At the end of the axle, the dry matter-rich fraction is pressed against a plate. The filter cake is compressed during pressure filtration, ensuring that the screw press produces a solid fraction with high dry matter content.
- **Filter Belt:** The filter belt separator also applies pressure to achieve separation. In this case the band filter is constantly turning on rollers to keep the material moving and to increase pressure on the material, whereby the liquid part will pass through the filter. The filter cake is continuously removed as the belt rotates, so that the loading and solid-fraction unloading areas are being constantly cleaned and changed over.
- **Decanter Centrifuge:** In decanter centrifuges, a centrifugal force is generated to cause the separation of solids from the liquid. There are two types of decanter centrifuges: vertical and horizontal. A horizontal decanter centrifuge uses a closed cylinder with a continuous turning motion (3000-4000 rpm). The centrifugal force separates solids and liquids at the wall, into an inner layer with a high dry matter concentration and an outer layer consisting of a liquid containing a suspension of colloids, organic components and salts. The solid and liquid phases are transported to either end of the centrifuge rotating the entire centrifuge at high speed and simultaneously rotating the conveyor at a speed slightly differing from the speed of the bowl (outer conical shell) (Flotats et al., 2011). The vertical decanter is designed and built primarily for high-temperature and/or pressurized operation. The vertical orientation lends itself to better and more reliable pressurization, with only one end to be provided with rotational seals. The amount of engineering required for pressurization and sealing makes the vertical decanters more expensive than the non-pressurised and open horizontal decanter. The availability of inexpensive vertical decanters is very limited, such that in some circumstances one has to select horizontal model even though a vertical one might have been preferred (Records and Sutherland, 2001).

Regarding possible environmental issues, some systems involve a high exposition of slurry to atmosphere, and thus, entail a risk of gaseous emissions in the form of volatile organic compounds (VOC) and/or NH_3, and odour problems. Nevertheless, this technology cannot be considered to have large environmental impacts.

Nutrient Recovery by Mechanical Separation Technologies

As mentioned, nutrient recovery efficiency in the thick fraction is dependent on the characteristics of the equipment, the composition of the liquid stream and the use of additives such as coagulant-flocculants or polyelectrolytes. The separation efficiency for removal of dry matter and phosphorus (P) is ranked as follows: centrifugation> sedimentation> non-pressurized filtration> pressurized filtration. In general, total separation of N and NH_4^+ follows the same pattern, but separation efficiencies are lower than for dry matter and P (Hjorth, et al., 2009).

In Table 2, a summary of the efficiencies of the different devices applied on livestock slurry is shown.

As can be observed, the range of efficiencies is quite wide, corresponding to a great variability in composition of this kind of streams and the adjustment of the different equipment.

Table 2. Efficiency of different mechanical separators with livestock manure (adapted from Campos et al. 2004)

	Efficiency (%)[1]			
Mechanical Separator	**Dry Matter**	**COD**	**Nitrogen**	**Phosphorus**
Static sieve	0-40	0-40	0-10	0-10
Vibrant sieve	0-40	0-50	0-10	0-30
Filter belt	10-60	30-60	10-40	20-80
Screw pressing	20-60	30-60	10-40	30-80
Decanter centrifuge	20-60	30-60	10-40	40-80

[1]% of the component removed from the feed stream

By-Products Characteristics and Economics Aspects

The characteristics of solid and liquid fractions resulting from mechanical separators mainly depend on the separation technique and it can be assumed as well, that the availability of nutrients for the plants can be also affected (Fangueiro et al., 2015). Furthermore, the inclusion of a previous process (e.g. anaerobic digestion or acidification) will also have a great influence over nutrient speciation, removal efficiencies and the characteristics of the two streams obtained (Moller, et al., 2000; Fangueiro et al., 2009).

The two fractions obtained with different organic matter, nutrient and ion composition should be further processed and/or used as fertilizers if an appropriate management is applied. The liquid phase is usually processed to further recover nutrients or remove them, e.g. reject water from sludge dehydrating is usually returned to the head of the WWTP; on the contrary, the liquid fraction of livestock manure is often used directly as fertilizer. The solid fraction can be used directly as fertilizer; but before usage, it is preferable to stabilize the organic matter, for example by means of composting.

Investment and operational costs of these technologies vary a lot depending on the equipment and the use of additives or not. Investment costs range between 10.000 € for sieves and 150.000 € for a decanter centrifuge. Operational costs are most influenced by the use of additives. In this case, it moves between 1.5 €/t and 3 €/t when using polyelectrolyte additives (Flotats et al., 2011).

MEMBRANE FILTRATION

Membrane technology is a physical process for the separation of material mixtures in which a membrane acts as a filter, and the separated substances are neither thermally nor chemically nor biologically modified. This technology has grown in recent years due to growing concerns about water quality and pollution trends in relation to more complex global challenges such as rapid urbanization, increasing water demands in the domestic and industrial sectors, and problems associated with surplus nutrients in areas with high livestock density. In the last case, it could be partly solved by the use of membrane technology to concentrate manure nutrients in small volumes that could be exported as fertilizers to other agricultural regions. Membrane filtration offers concrete benefits in the production processes, such as the significant reduction in equipment size, efficiency boosting, energy savings, capital costs reduction, environmental impacts minimization, safety increase, and remote control and automation usage.

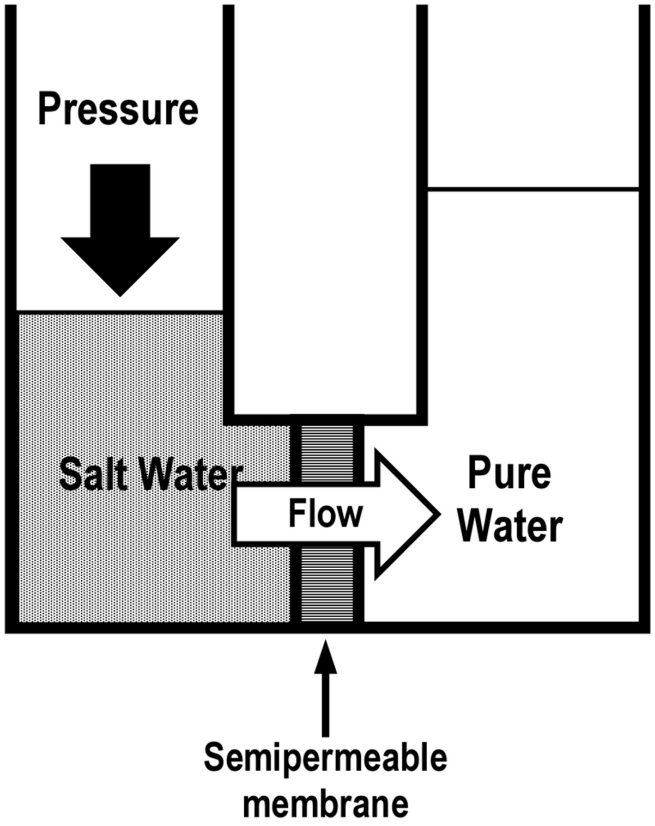
EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Theoretical Fundamentals and Process Description

Membranes are typically classified depending on their pore size, applied pressure, molecular weight cut-off, and permeability (Table 3). The commonly accepted classification in the field of water and wastewater treatment includes microfiltration (MF), ultrafiltration (UF), nanofiltration (NF), and reverse osmosis (RO). Depending on wastewater composition and characteristics, as well as operational requirements, different materials are used for membranes. Membrane materials can be organic (e.g. cellulose or polymer membranes) or inorganic (e.g. ceramic or metal membranes). Compared to organic membranes, the advantages of inorganic ones are a high resistance against heat and chemicals with, correspondingly, a high regeneration capacity, as well as a long service life. Disadvantages are, above all, the higher investment due to the membrane material, and more expensive module constructions (Sadr and Saroj, 2015). Figure 2 shows a schematic diagram of the reverse osmosis process.

From a structural point of view, they can be symmetric (isotropic) or asymmetric (anisotropic). Symmetric membranes have a uniform composition and structure throughout; such membranes can be either porous or dense. Asymmetric membranes, on the other hand, consist of a number of layers, each with different structure and permeability properties. A typical asymmetric membrane has a relatively dense thin surface layer supported on an open, much thicker, microporous substrate. The surface layer performs the separation and is the principal flow barrier through the membrane. The open support layer

Figure 2. Schematic diagram of the reverse osmosis process



EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

provides mechanical strength. Inorganic membranes can be either isotropic or anisotropic (Pinnekamp and Friedrich, 2006). The most important property of membranes is their ability to control the permeation rate of different species based on two main models (Table 3):

1. The solution-diffusion model, in which permeants dissolve in the membrane material and then diffuse through the membrane down a concentration gradient. The permeants are separated because of the differences in solubility of the materials in the membrane and the differences in the rates at which the materials diffuse through the membrane (NF, RO); and
2. The pore-flow model, in which permeants are transported by a pressure-driven convective flow through tiny pores. Separation occurs because one of the permeants is excluded (filtered) from some of the pores in the membrane, through which other permeants move on (MF, UF) (Baker, 2004).

Coarser membranes are associated with MF and the most selective membranes are associated with RO processes. Generally, suspended solids (including large microorganisms like protozoa and bacteria) are easily separated by MF whereas UF is used to remove particles down to size of around 20 nm. Moreover, NF is able to retain smaller organics and multivalent ions and RO is capable to remove all dissolved species (Table 3).

Often, membrane technologies are employed in a combination of physical, chemical, and biological processes, resulting in an efficient process configuration for a particular scenario of wastewater or waste treatment. For example, MBR technology combines activated sludge processes, or an anaerobic biodegradation process with MF, UF or RO.

Table 3. Membrane processes classification and operational conditions

Model	Membrane Process	Pore Size (μm)	Size of the Particles, Colloids, or Molecules to be Separated	Driving Force (Pressure Difference, Bar)	Application
Pore-flow	Microfiltration	0.1-5	Solids > 0.1 μm	0.1-3	Separation of solid matter from suspensions
Pore-flow	Ultrafiltration	0.005-0.1	200,000 – 20,000 D*	0.5-10	Separation of macromolecules or colloids, disinfection
Solution-diffusion	Nanofiltration	0.001-0.01	20,000 – 200 D*	2-40	Separation of dissolved organic molecules and polyvalent inorganic ions
Solution-diffusion	Reverse Osmosis	0.0001-0.001	< 200 D*	5-70 In special cases up to 120 bar	Separation of organic molecules and all of ions

*Dalton, numerically equivalent to the molecular weight in g/mol
(Modified from Pinnekamp and Friedrich, 2006)

Usual Applications and Environmental Aspects

Although membrane technology was initially used almost exclusively for the desalination of sea and brackish water in arid zones, it has been tested and lately also applied for the separation of valuable materials from small water volumes and other waste streams: in biotechnology, in pharmaceutical and chemistry industries, in the metal-working industry, in the food and beverage industry, and in high strength wastewater such as livestock slurries. Specific applications of membrane processes for wastewater treatment are summarized in Table 4.

Due to its small footprint, flexible design and automated operation, membranes are a suitable option in developing countries for decentralized wastewater treatment and the extraction of valuable resources such as nutrients and energy.

Nutrient Recovery by Membrane Processes

High-rejection membrane processes such as NF and RO have demonstrated huge potential in wastewater nutrient recovery. RO has been applied for urine concentration in a source-separation toilet system, achieving a concentration factor of five and high concentrations of ammonium, phosphate and potassium (Maurer et al., 2006). NF separation also exhibited a medium to high rejection of a range of nutrients, such as urea (Pronk et al., 2006), ammonium, phosphate and potassium (Niewersch et al., 2014, Schütte et al., 2015). Häyrynen et al. (2009) studied the concentration of ammonium and nitrate in mine water by RO and NF membrane processes achieving retentions up to 96% for nitrate and 91% for ammonium. Retention of ammonium by NF membrane was 56.2% in this case.

Table 4. Membrane processes application in municipal and industrial wastewater treatments

Membrane	Municipal Wastewater Treatment	Industrial Wastewater Treatment
Micro and ultrafiltration	• Separation of activated sludge and water • Disinfection • Pre-treatment prior to a reverse osmosis plant • Phosphate removal after precipitation	• Waste water recycling and reuse as process water for different purposes • Treatment of landfill leachate combined with a biological stage • Recovery of water-based paint from spray booth effluents by concentration • E.g. in the metal-working industry: - Prolongation of the service life of electro-dipcoat bathes - Concentration of water-oil emulsions - Recycling of degreasing baths
Nanofiltration	• For further treatment after biological methods for wastewater reuse (few cases)	• Relief of ions exchangers downstream reverse osmosis units • Removal of color in the wastewater of the textile and the pulp and paper industry • Demineralization of wastewater containing surfactants
Reverse Osmosis	• For further treatment after biological methods for wastewater reuse (few cases)	• Concentration of drainage water from mines containing $CaSO_4$ • Dewatering of flushing water from photo laboratories for silver recovery • Treatment of waste water from textiles dyeing (cotton and polyester dyeing) • Concentration of cellulose washing water • Recovery of phosphoric acid • Treatment of wastewater from bleacheries • Treatment of landfill leachate • Treatment of livestock slurries

(Modified from Pinnekamp and Friedrich, 2006)

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

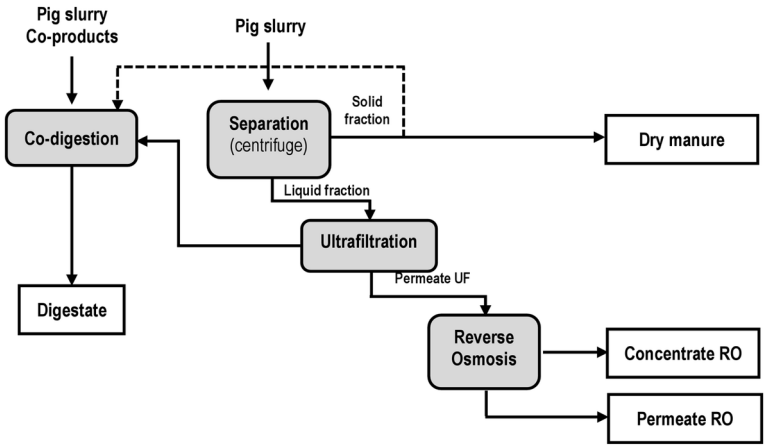
For manure nutrient recovery, ammonia and potassium retention requires NF or RO, which have demonstrated a very good performance, whereas MF and UF membranes basically act as very efficient solid-liquid separators that can isolate nutrients associated with particles such as phosphorus (Masse et al., 2007). Konieczny et al. (2011) recovered water from pig slurry utilizing an integrated system consisting of centrifugation followed by a two-step UF followed by NF. However, the amount of ammonium in the produced water was too high, resulting in regenerated water suitable for irrigation. Guo and Jin (2014) investigated anaerobically digested cattle manure treatments with RO pre-treated by UF. It was observed that ammonia was rejected with a rate of 77.1% at the first pass and only 54.2% at the second pass, most probably due to the pH increase in the RO feed. However, the concentration of NH_4^+ in the final permeate was around 63 mg/L from the initial 836 mg/L. Rejection of other species such as K, Na and Cl was observed to be as high as 90%. Beyond laboratory experiences, RO has been applied in several pilot experiences at manure treatment plants to separate the liquid manure fraction into water that can be discharged and a concentrated salt solution, the so-called mineral concentrate (Velthof, 2011).

Fouling of the membranes by deposition of salts and the growth of microorganisms is one of the main problems when using reverse osmosis of the liquid fraction of slurry. Fouling of NF and RO membranes impairs membrane performance and shortens the membrane lifetime, thereby restraining productivity in nutrient recovery. Therefore, in reverse osmosis solids and organic matter should be previously removed as much as possible from the liquid fraction. This includes techniques such as UF, dissolved air flotation, low pressure membrane filtration and using cloth or paper filters, resulting in process flowcharts as the one showed in Figure 3. Thus, although the use of reverse osmosis for nutrient concentration and manure treatment is technically feasible with the proper pre-treatment, the steep maintenance and operation cost is the main hindrance to the application of this technology in the livestock manure sector.

By-Products Characteristics and Economics Aspects

The typology and characteristics of end and by-products obtained in a processing plant including a membrane process depends on the process flowchart but, in general, there are three effluents: solid fraction, concentrate and permeate.

Figure 3. Treatment scheme of a manure treatment plant located in The Netherlands
(Modified from Velthof, 2011)



EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

The composition of the solid fraction is largely dependent on the separation technique, which leads to differences in the moisture content and, thus, to differences in nutrient contents of the solid fraction. This fraction contains most of the suspended solids, the organic matter and phosphorous. The levels of ammonium and potassium are largely determined by the levels of these nutrients in the untreated slurry. The composition of concentrates presents large differences depending on the processing plant, but in general, it can be said that they have a high content of N and K and low concentrations of P, as compared with the untreated slurry. The low content of organics could be classified as a mineral fertilizer. Finally, the permeate characteristics enable its direct discharge.

Based on the study carried out by Velthof (2011), the economic viability of plants treating animal slurry and other high strength streams with reverse osmosis heavily depends on the kind of slurry separator, mineral fertilizer prices, the price received from the providers of slurry, the prices of end products and of competitive products from slurry and fertilizers.

For example, the cost of the reverse osmosis installation unit is on average 7 to 8 € per ton of slurry treated. This applies to a lifespan of 10 years. The variability of the end products (low or high water content, much or little solid fraction) significantly affects profitability. Other factors affecting profitability are the further treatment of the solid fraction and the digestion of slurry. When the price paid by the providers of slurry is around 15 € per ton, or higher, plants are profitable. As a general practice in Europe, the costs of transport to the plant, weighing and sampling of the slurry are paid by the slurry supplier.

Emerging Technologies for Nutrient Recovery by Membrane-Based Processes

Forward osmosis, membrane distillation and electrodialysis are three emerging membrane-based processes considered suitable to overcome the challenges in nutrient recovery, which could potentially represent a paradigm shift in nutrient management:

Forward Osmosis (FO)

FO is a membrane operation developed from a natural process occurring in plants and human bodies. In FO, a semipermeable membrane is placed between two solutions of different concentrations: a concentrated draw solution and a more diluted feed solution. The driving force of the process is the chemical potential difference across the membrane which forces the water to flow from the low to high concentrated compartment, i.e. instead of hydraulic pressure; FO employs an osmotic pressure difference to drive the permeation of water across the membrane. In comparison with pressure-driven RO membrane filtration, FO has demonstrated a lower fouling propensity and a higher fouling reversibility (Blandin et al., 2016); also, a high rejection of phosphate and ammonium from activated sludge and wastewater by FO membranes has been reported (Huang et al., 2015; Xie et al., 2016). Moreover, FO has the potential to concentrate phosphate, ammonium, and magnesium in the source solution to facilitate struvite recovery due to the lack of hydraulic pressure and the occurrence of a reverse draw solute flux. These unique mass transfer properties of FO impel nutrient recovery from various waste streams such as urine, sewage, and sludge (Xie et al., 2016). Figure 4 shows a schematic diagram of the forward osmosis process.

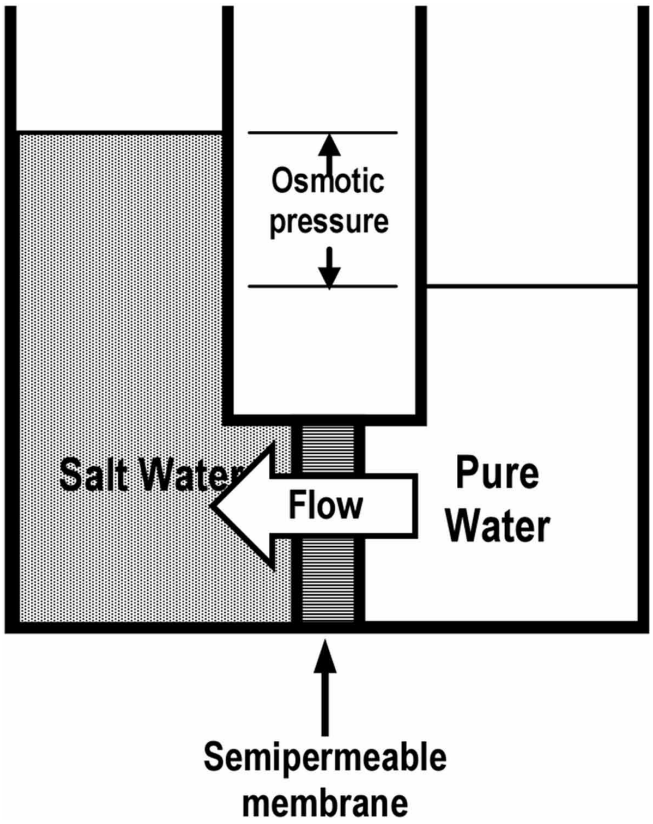
EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Membrane Distillation (MD)

MD using gas-permeable membranes (GPM) is another prominent technique, which is not yet completely commercialized. Its transport mechanism is based on the volatility and vapour pressure of the compounds to be separated. These components can be concentrated either in the feed stream or the permeate streams. For example, non-volatile inorganic nutrient ions, such as potassium and phosphate, can be concentrated in the feed stream to facilitate subsequent nutrient precipitation (Quist-Jensen et al., 2015). Ammonia recovery can be another important application of a GPM process in wastewater nutrient recovery. Dissolved ammonia (NH_3) can cross through the micro-porous hydrophobic membrane and concentrate in an absorption solution on the other side of the membrane. The membrane is submerged in the liquid and the NH_3 is removed from the liquid before it escapes into the air; NH_3 permeates through the hydrophobic membrane reaching the acidic solution located on the other side of the membrane. Once in the acidic solution, NH_3 combines with free protons to form non-volatile NH_4^+ ions that are converted into a valuable ammonium salt fertilizer $(NH_4)_2SO_4$, (Garcia-González and Vanotti, 2015). These MD processes achieved more than 96% in ammonia recovery in the form of aqueous solution.

MD offers a number of advantages over alternative pressure-driven processes such as reverse osmosis. As the process is driven by temperature gradients, low-grade waste heat can be used, and expensive high-pressure pumps are not required. Membrane fluxes are comparable to reverse osmosis fluxes, so

Figure 4. Schematic diagram of the forward osmosis process



EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

membrane areas are not excessive. Finally, the process is still effective with slightly reduced fluxes even with very concentrated solutions. This is an advantage over reverse osmosis, in which the feed solution osmotic pressure places a practical limit on the concentration of a salt in the feed solution to be processed (Baker, 2004).

Besides, gas-permeable membrane processes can be combined with other treatment technologies such as anaerobic digestion to improve their performance. The inhibition of methanogens by high NH_3 concentrations in manure severely inhibits the production of biogas. Hence, the use of gas-permeable membranes to recover NH_3 without damaging the carbonaceous material will improve the process.

One of the most innovative applications of gas-permeable membranes is its use coupled to bio-electrochemical systems (BES) with the objective of recovering ammonia from the anolyte without using energy-intensive stripping of the catholyte. NH_4^+ migration across a cation exchange membrane to maintain the charge balance, leads to a pH increase in the catholyte (pH >10) (Sotres et al., 2014), whence NH_3 can be recovered in an acidic solution using a hydrophobic membrane (Cheng et al., 2013).

Electrodialysis (ED)

ED is an electro-membrane process, in which ions are transported through ion exchange membranes from one solution to another under the influence of a potential gradient. The electrical charges on the ions allow them to be driven through the membranes. Charging a voltage between two end electrodes generates the potential field required. As the ion exchange membrane has the ability to selectively transport ions with a positive or negative charge and to reject ions of the opposite charge, the useful concentration, removal or separation of electrolytes can be achieved. Therefore, it is possible that the excess nitrogen and phosphorus, which are found as ions in nutrient-rich streams such as swine liquid fraction, can be removed by this technique (Fukumoto and Haga, 2004). The ion separation is attained by ion-exchange membranes that include cation-selective, anion-selective, and bipolar membranes.

The mechanism of an ED process provides a selective tool for wastewater nutrient recovery. ED processes selectively partition phosphate from nutrient-rich streams containing various ions as a concentrated phosphate solution, achieving a concentration factor of up to 7. Similar selective phosphate enrichments by ED processes were also observed in urine nutrient recovery, resulting in a purified phosphate concentrate (Pronk et al., 2006). Phosphate selectivity in an ED process can be further enhanced by either adjusting the feed stream to the alkaline pH range or increasing current density. Better performance was expected based on the ED separation mechanism, where multivalent phosphate migrates more slowly than monovalent ions under the current field (Xie et al., 2016).

EVAPORATION AND DRYING

The aim of evaporation and drying is to vaporize (applying heat) most of the water from a solution obtaining a concentrate that contains a desired product (in this case nutrients and organic matter). Apart from obtaining a concentrate with a lower water content and higher nutrient concentration than the original solution, another objective should be to obtain a purified condensate (water) that could be later reused (Bonmatí et al., 2003).

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Theoretical Fundamentals and Process Description

Evaporation could be performed at atmospheric pressure or under vacuum conditions. Vacuum evaporation is more common as the lower temperature for the process and the closed vessel used allow for a better emission control and an expected less energy consumption. When the pressure inside the evaporator unit is reduced below the vapour pressure of the liquid, the liquid evaporates and the consequent concentration of the treated substrate occurs; evaporated water, then, is condensed by cooling and collected in the condensate tank (Figure 5a) (Chiumenti et al., 2013).

One limitation of evaporators is that they only work with fluids. Grüter *et al*. (1990) defined three different zones of sludge consistency in a dryer: a wet zone where the sludge is free-flowing, a sticky zone where the sludge is pasty, and a granular zone where the sludge is crumbly. This constitutes a limit to the final concentration: slurry cannot be converted into a completely dry product. The limit is about 20–25% TS, depending on the corrosion and viscosity of the concentrate. Prior removal of suspended solids is also necessary. Should this not be done, concentration would be limited as the particles form a matrix and the concentrate ceases to be a flowing liquid (Have and Chiappini, 1993). A further drying process is necessary to increase the dry matter concentration.

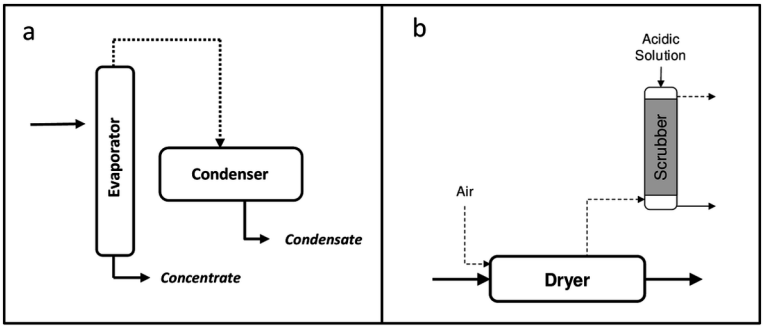
Drying works under the same principle, but in this case, the inflow is the solid fraction of a centrifuged slurry/sludge or the concentrate of an evaporation process. Most of the water (>85%) is removed applying heat, the concentrate reaching dry matter values >90%. In order to avoid the sludge sticky zone, dryers work in the granular zone (>60-65% of TS) where the concentrate is crumbly.

The dried product is often pelletized to increase its added value as fertilizer, pushing it through the holes of a matrix of the desired shape/size. Compression and temperature, as well as the composition of the raw material are the major factors affecting the process.

General Applications and Environmental Aspects

This technology is mainly implemented in the field of the treatment of residuals from industrial production, in some cases with the aim of recovering chemicals, like, for example, in the galvanic industry. Vacuum evaporation has been applied for years also for the treatment of landfill leachate. In the agro-industry sector, this technology has been tested on the dairy industry, for the recovery of proteins from serum, in the olive oil industry, for the treatment of wastewater from mills and olive husks. Other tests

Figure 5. Schematic diagram of the vacuum evaporation process (a) and drying process (b) (adapted from Flotats et al., 2011)



EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

have been performed on residues from the production of wood pulp and paper (Chiumenti et al., 2013). Regarding livestock manures, evaporation has been applied for processing pig slurry and the digestate from the co-digestion of biogas plants (Flotats et al., 2009). Although this process is applied usually at a large scale, there are some proposals for implanting it at a farm scale (Levasseur, 2004).

The increase in temperature causes the emission of several volatile compounds that can be present in the slurry leading to serious atmospheric pollution. Vacuum evaporation minimizes this effect since it occurs in closed systems, at lower temperature, and the exhausted gases can be easily treated. Considering its effects on air, water and soils, the process theoretically does not show air emissions, since the evaporated flow is recovered as a condensate. Thus, theoretically, this is a '0 gas emissions' process, including odours.

Adversely, drying is not usually operated in vacuum conditions and hence, all gaseous emissions from the dryer must be recovered (by filtration or scrubbing) to avoid ammonia (NH_3), organic volatiles (VOC) and odour emissions (Figure 5b).

Nutrient Recovery by Evaporation

To ensure the recovery of nitrogen in the concentrate flow steam, and guarantee its absence in the recovered condensates, the ammonia (NH_3)-ammonium (NH_4^+) equilibrium must be modified, by means of pH control (usually adding a strong acid). If pH inside the evaporator is maintained under pH 5.5 it is guaranteed that ammonium will be recovered in the concentrate. Adversely, at this pH values, other volatile organics such as volatile fatty acids (VFA) are present in its un-ionized form (volatile) and can be easily transferred to the condensate, with manifest implications (organic contamination) in the condensate and post-treatment requirements.

Theoretical studies performed by Marks *et al*. (1994) showed that at pH=4, 1% of ammonia and 75% of acetic acid are transferred to the condensate and that, at pH=10, 93% of ammonia and 1% of acetic acid are transferred. This demonstrated that if a liquid has a high ammonia nitrogen and VFA content, it is not possible to prevent the volatilization of both components by adjusting its pH to a given value. A two-stage evaporation process or a previous treatment is necessary to achieve this. Furthermore, the non-ionized volatile organic compounds (VOCs) cannot be fixed by modifying pH. A previous treatment (i.e. stripping or anaerobic digestion) to remove VOCs is necessary in order to prevent their emissions during evaporation (Bonmatí, 2001).

For pH regulation, sulphuric acid or other strong acid should be added (Bonmatí et al., 2003). The acid consumption will depend on the slurry alkalinity. Reagents do not need to be reagent-grade. Consequently, in some applications H_2SO_4 sub-products of low purity have been used.

As it has been mentioned, the processed stream requires a previous acidification step to avoid ammonia emissions. The use of a strong acid has different implications:

- The choice of constructive materials (resistance to high temperature and low pH) which requires high quality materials (e.g. stainless steel).
- Risk of accidents and the requirement of Health and Safety training courses for the workers.
- Introduction of S forms (if acidification is performed with H_2SO_4) which could later appear (at low concentrations) in the condensates.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

By-Products Characteristics and Economics Aspects

Two by-products are obtained in this process, the concentrate and the condensate. If the process is operated correctly, the concentrate will contain most of the nutrients. Phosphorous and potassium will remain in the concentrate, and, as mentioned, if pH is set below 5.5 the majority of nitrogen will also be found in the concentrate. Likewise, if heavy metals are present in the raw manure, they will be found in the concentrate stream and, depending of their concentration, could compromise the use of the concentrate as a fertilizer.

On the other hand, condensates may be free of nutrients but can contain remarkable amounts of organic matter, as the low pH process will favour the volatilization of VOC which will later be transferred to the condensate. A previous process to remove VOC, such as stripping or anaerobic digestion, is a possible way to obtain a cleaner condensate (Bonmatí and Flotats, 2003).

In terms of energy consumption, 21 kWh/m^3 of electric energy and between 107 and 353 kWh/m^3 of heat have been obtained in a pilot experience at a farm scale unit treating 0.5 m^3/hour (Flotats et al., 2011). On the other hand, the increasing number of evaporation steps could significantly decrease energy consumption. For this reason a full scale evaporation system usually consists in at least two steps. Energy consumption in single-effect evaporators is very high and makes up for most of the cost of the evaporation system. Each evaporation step added reduces the energy consumption by 33%; although investment costs increase.

However, with clearly different evaporator designs, the process could be attractive for slurries/manures with high dry matter content, especially over 30% (e.g. poultry) due to the smaller volume of water to be removed and the higher yields of dry product (Burton and Turner, 2003). In this regard, the use of the residual energy from a CHP engine or other processes could be a way to make this process feasible.

MAGNESIUM AMMONIUM PHOSPHATE (STRUVITE) PRECIPITATION

Typically, P in wastewater is removed biologically, using P- accumulating bacteria, or chemically, through precipitation by adding metal salts. Chemical precipitation introduces high costs and yields a large amount of chemical sludge to dispose of. Another option to recover nutrients is to create the physical-chemical conditions in the bulk solution (pH, ion strength, etc.) to favour the formation of different salts with low solubility products, and its subsequent precipitation to recover them. Among others, magnesium ammonium phosphate (MAP), usually called struvite, is the most common salt enabling the recovery of phosphorous and nitrogen from wastewaters.

Theoretical Fundamentals of Map Formation

Struvite is a white crystalline substance composed of nitrogen (ammonia, NH_4^+), phosphorus (phosphate, PO_4^{3-}) and magnesium (Mg^{2+}) in equimolar relation ($MgNH_4PO_4 \cdot 6H_2O$), also called MAP (Magnesium Ammonium Phosphate), which is considered as a slow releasing and valuable fertilizer, as it is sparingly soluble under neutral and alkaline conditions but readily soluble in acid (Yetilmezsoy & Sapci-Zengin, 2009).

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Struvite precipitation is produced in alkaline conditions when the concentration of Mg^{2+}, NH_4^+ and PO_4^{3-} exceeds the solubility product, according to the following reaction (3):

$$Mg^{2+} + NH_4^+ + H_2PO_4^- + 6\,H_2O \rightarrow MgNH_4PO_4 \cdot 6\,H_2O + 2H^+ \quad (3)$$

Struvite crystal development occurs in two chemical phases: nucleation and crystal growth. In the nucleation phase, ions are arranged in the characteristic pattern of a crystalline solid, forming foundation sites for deposition of crystallizing particles which then grow into detectable crystals (Ohlinger et al., 1999).

A combination of physical and chemical parameters controls the complex mechanism of struvite precipitation. One of the main factors is pH, as it changes the concentration of free ions available for reaction. When pH increases, Mg^{2+} and NH_4^+ concentrations decrease, as the first one complexes with hydroxides, and the second one increases its volatilization in the form of ammonia (NH_3). On the other hand, PO_4^{3-} concentrations increase as the pH increases. pH is also involved in controlling struvite solubility, being minimal with pH values between 9 and 10.7 (Doyle and Parsons, 2002). So, pH is usually increased to favour struvite precipitation, generally using NaOH or $Mg(OH)_2$. Alternatively, CO_2 stripping can be used to reduce the use of alkali (Cerrillo et al., 2015) for, when CO_2 is liberated from solution, the change in carbonate speciation leads to a pH increase.

The molar ratio of N, Mg, and P can limit the precipitation process if one of the components is lacking in the wastewater, as can be the case of magnesium in wastewaters from anthropogenic, livestock or municipal leachate, where it may be necessary to be added in order to optimize the struvite crystallization process. Low contents of soluble phosphate in the wastewater may require a prior solubilization process and, in some cases, the solids content of the influent can slow down the struvite precipitation process (Tao et al., 2016).

The reactor design (agitation and sedimentation properties) influences the size of the obtained crystals and the easiness to recover them, as fine struvite crystals are difficult to settle or separate. The size of the aggregates influence notably in the economic value of the product. The typical struvite precipitation reactor consists in a mixed crystallization reactor with two zones. The lower zone is the reaction zone, and the upper section is the sedimentation zone, which prevents the formed particles to leave the reactor (Figure 6). The reactor could also include an aeration system to favour CO_2 stripping and pH increase, and prevent mechanical mixing (Cerrillo et al., 2015). The process temperature needs to be taken into account as it influences the solubility of the salts: low or ambient temperatures are preferable as maximum solubility of struvite is attained at 50 ºC (Doyle and Parsons, 2002).

Finally, the ionic strength of competitive cations, such as Ca^{2+} and Na^+ that can form other salts, especially with phosphates, as newberyite ($MgHPO_4 \cdot 3H_2O$), bobierrite ($Mg_3(PO_4)_2 \cdot 8H_2O$) or hydroxiapatite ($Ca_5(PO_4)_3OH$) can hinder struvite obtainment (Cerrillo et al., 2015). Even depending on the relative concentrations of Ca^{2+} and Na^+, struvite formation may be inhibited (Doyle & Parsons, 2002; Moerman et al., 2009).

The analysis of the thermodynamics equilibrium and kinetics reaction can help to predict and explain the formation of struvite in different conditions (Crutchik and Garrido, 2016). However, industrial wastewater can be a complex matrix containing various compounds which might interfere with struvite precipitation, its quality as a fertiliser, and the length and shape of the crystals, as impurities block active growth sites by adsorption to crystal surfaces and inhibit crystal growth (Le Corre et al., 2009), leading to

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

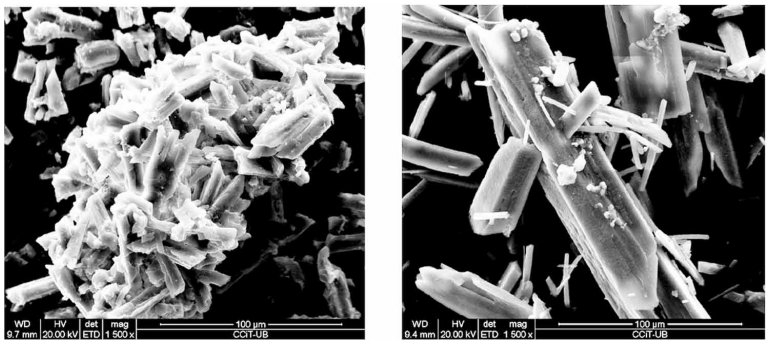
Figure 6. Lab scale struvite precipitation reactor (left), and pilot plant at SAT Sant Mer Biogas Plant (Vilademuls, Girona) (right)

a possible necessary detailed study for each wastewater. As an example, Figure 7 shows struvite crystals obtained with the liquid fraction of pig slurry and the crystals formed with synthetic water applying the same operational conditions.

Usual Applications and Environmental Aspects

Struvite precipitation technology has been studied and applied to different wastewaters, as food industry wastewater (Moerman et al., 2009), dairy manure (Uludag-Demirer et al., 2008), poultry manure (Yetilmezsoy and Sapci-Zengin, 2009), digested pig and cow slurry (Huang et al., 2011; Cerrillo et al., 2015) or even human urine (Liu et al., 2013). Most of these studies show that high amounts of NH_4^+ and PO_4^{3-} can be removed when adding the limiting reactive to wastewater (usually Mg^{2+} and PO_4^{3-}), and working at an optimal pH. Reported NH_4^+ and PO_4^{3-} recovery efficiencies vary depending on the substrate and the operational conditions, but are usually above 95% (Kataki et al., 2016).

Figure 7. Stuvite crystals obtained from pig slurry (left), and synthetic wastewater (right) (Bonmatí, A. ©)



EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Apart from the benefits obtained when recovering P and N from wastewater, some environmental issues can be attributed to these systems if they are not operated correctly. Highly mixed reactors, or those equipped with air flow systems, can induce the removal of NH_3 from the solution, as the relatively high operational pH and agitation creates a removal pathway for dissolved ammonia to volatilize from the solution. Moreover, the air flow dilutes the concentration of the gas-phase NH_3 equilibrium and increases the driving force for dissolving NH_3 to separate the gaseous phase (Yetilmezsoy and Sapci-Zengin, 2009).

By-Products Characteristics and Economics Aspects

The positive value of struvite obtained from calf manure (Schuiling & Andrade, 1999), municipal wastewater (González-Ponce et al., 2009) or anaerobically digested pig slurry (Cerrillo et al., 2015), among others, has already been demonstrated. The advantages of struvite as a solid fertilizer relative to the direct land application of manure as a liquid fertilizer include ease of application, low transportation costs, reduced bulk storage, and the avoidance of odour and pathogen contamination issues (Tao et al., 2016). Moreover, struvite recovered from wastewater reduces the necessity of using chemical fertilizers obtained from phosphate rocks, a non-renewable geological reserve. Struvite dissolves slowly in the environment to release nutrients at a rate suitable for crop uptake. Its low solubility prevents struvite from contributing to typical fertilization problems such as crop burn and generation of nutrient-rich runoff (Nkoa, 2014).

Struvite production costs have been established between 4 and 15 \$/kg $N\text{-}NH_4^+$, depending on the ammonia concentration in the influent (Türker & Çelen, 2007). As the economic feasibility of struvite is heavily influenced by reagent costs, several low cost magnesium sources as by-products of industrial processes, such as magnesite pyrolysate (Huang et al., 2011), or other magnesium rich renewable sources such as sea water and brine (Liu et al., 2013), have been proposed to replace high grade magnesium. The investment for the precipitation reactor can be of around 0.12 €/$m^3_{REACTOR}$, according to Jaffer et al. (2002).

There are few crystallization plants at full scale, as there is still a lack of knowledge of struvite properties as a fertilizer by end users; and its quality, market value, difficulties in the crystallization process, pH control and reagent costs may be a hindrance to widespread struvite precipitation technology. However, some commercial full scale systems are already in the market, for example: PEARL, NuReSys, PHOSPAQ, AirPrex, etc. Commercial struvite recovery units handling municipal wastewater sludge are in operation in countries like Japan, Canada, England, USA, Australia, Sweden, The Netherlands and Italy (Kataki et al., 2016). Struvite sale price has been reported to be approximately 198-1885 \$/t in Australia and Japan (Le Corre et al., 2009), mainly depending on its purity.

ELECTROCOAGULATION

The objective of electro coagulation (EC) is to destabilize suspended, emulsified or dissolved particles within an aqueous media, by applying an electric current. Electricity destabilizes those particles favouring the aggregation of colloidal particles just like chemical reagents do in a conventional coagulation-flocculation process.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Theoretical Fundamentals and Process Description

EC is an electrolytic process that has been already used for the treatment of various liquid wastes and consisting of dissolution of sacrificial anodes (iron or aluminium) upon application of a current between two electrodes. This provokes the dissolution of the electrode to yield metal ions (Fe^{2+}, Fe^{3+} or Al^{3+}) at the anode, which are involved in the neutralization of the negative charges on the colloids of the effluent. The cathodic reaction involves the formation of hydrogen gas and hydroxide ions which favour the formation of flocks; these flocks are then easily separated by decantation or filtration, depending on their density.

EC offers some advantages over chemical dosing: it has simple equipment requirements and can be readily automated; it reduces the chemical cost using cheaper materials; gas bubbling provides for a gentle mixing which promotes coagulation and helps form bigger flocks; and gas bubbling carries some particles up to the surface of the liquid in a kind of flotation, which may then be easily separated. The main disadvantages of this method are lack of a systematic approach to EC reactor design and operation, the need to replace electrodes at regular intervals, high electricity costs and anode passivation (Shalaby et al., 2014; Lin et al., 2015).

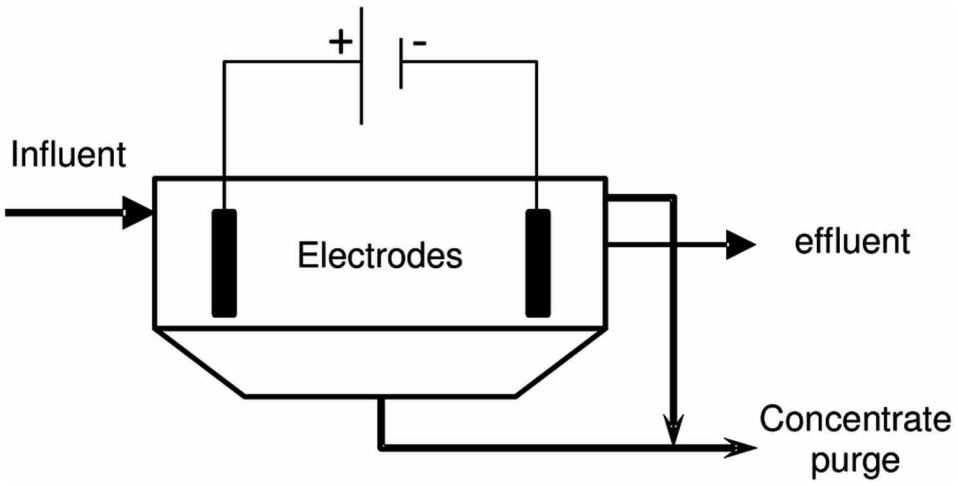
The EC process occurs in three steps. In the first step, a coagulant is formed due to anode oxidation. In the second step, pollutants are destabilized. In the last step, destabilized matters are aggregated. The most common electrode materials for electrocoagulation are aluminium and iron. These are cheap, readily available, and have proven to be effective (Gharibi et al., 2010).

If the effluent has a high enough electrical conductivity, the electrochemical process can generate an electrical field and/or produce a field 'in situ' by sacrificial electrodes, without adding additional ionic species The process alters the surface charge of the effluent and enhances P and solids settling.

When aluminium is used as electrode material, the reactions are as follows:

$$\text{Cathode: } 3H_2O + 3e^- \rightarrow 3/2\ H_{2(g)} + 3OH^- \tag{4}$$

Figure 8. Scheme of an electrocoagulation reactor



EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Anode: $Al \rightarrow \ Al^{3+} + 3e^{-}$ (5)

Solution: $Al^{3+}\left(aq\right) \ + 3H_2O \rightarrow Al\left(OH\right)_3 + \ 3H^{+}\left(aq\right)$ (6)

When iron is used as electrode material, the reactions are:

Cathode: $3H_2O \ + \ 3e^{-} \rightarrow \ 3 / 2 \ H_{2(g)} + \ 3OH^{-}$ (7)

Anode: $4Fe\left(s\right) \ \rightarrow \ 4Fe^{2+}{}_{(aq)} + \ 8e^{-}$ (8)

Solution (with dissolved O_2): $4Fe^{2+}{}_{(aq)} + \ 10H_2O_{(l)} + \ O_{2(g)} \rightarrow \ 4Fe\left(OH\right)_3 + \ 8H^{+}{}_{(aq)}$ (9)

Overall reaction: $4Fe_{(s)} + \ 10 \ H_2O_{(l)} + \ O_{2(g)} \rightarrow \ Fe\left(OH\right)_{3(s)} + \ 4H_{2(g)}$ (10)

The release of hydroxyls and metal ions, and the formation of metal hydroxides cause the precipitation of different dissolved ions. As an example, phosphates precipitation reactions are as follows.

$\mathrm{H_3PO_4} + \ 3\mathrm{OH^{-}} \rightarrow 3\mathrm{H_2O} \ + \ \mathrm{PO_4}^{3-}$ (11)

$\mathrm{Al^{3+}} + \ \mathrm{PO_4}^{3-} \rightarrow \mathrm{AlPO_4}$ (12)

$\mathrm{Al} \ + \ \mathrm{H_3PO_4} \rightarrow \mathrm{AlPO_4} + \ 3 / 2\mathrm{H_2}$ (13)

In the solution, H_3PO_4 is neutralized by the hydroxyl ions released at the cathode (Equation 11). So, for pH lower than 6.5, aluminium phosphate is formed before aluminium hydroxide; consequently, the PO_4^{3-} ions obtained react with Al^{3+} ions produced at the anode (Equation 5). This results in the precipitation of aluminium phosphate (Equation 11). The overall reaction is best summarized by Equation 13 (Tchamango et al., 2010).

Usual Applications and Environmental Aspects

EC has been a promising technology aiming to destabilize and remove fine particles from water and wastewaters since the beginning of the 20th century. Presently, it is considered as a prospectively competitive technology for the removal of pollutants from supply water, urban wastewater, and also for the treatment of industrial effluents such as those generated in the agro-food industry, metalworking and textile industries (Lacasa et al., 2013). EC has been successfully used to remove different kinds of pollutants such as solids, nitrogen, organic compounds, heavy metals, dyes, hardness, chemical oxygen

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

demand (COD), and important anions such as nitrate, fluoride and phosphate (Shalaby et al., 2014). Furthermore, it has demonstrated its superior performance in treating effluents containing suspended solids, oil and grease, and other similar substances (Zhao et al., 2010). Thus, EC is also effective at removing phosphorus and solids from digestates without any chemical addition.

Regarding its environmental side effects, the performance of some systems entails a high exposition of manure/slurry to atmosphere (high stirred systems), and thus, risk of gaseous emissions (COV) and odour problems could arise. Also during flotation (aeration) a high proportion of ammonia can be discharged into the air. It is therefore necessary to treat or collect the exhaust air coming from the flotation equipment.

Nutrient Recovery by Electrocoagulation

As mentioned, EC has proven to be a good option, in terms of efficiency, for the removal of several components such as total solids, COD, N and P. Tchamango et al. (2010) obtained N and P removals of 81% and 89%, respectively. Zhao et al. (2010) achieved P removals between 70-90%, whereas Lekuona (2004) reported higher P (>99%) but lower N (>60%) removals with electrocoagulation combined with a band filter, as can be seen in Table 5. The efficiency of the electrocoagulation process depends on many operational parameters such as the initial pH, initial pollutant concentration, temperature, nature of electrolyte and current density (Shalaby et al., 2014).

Besides, EC has been also successfully applied for removing nitrate NO_3^- from different liquid streams such as wastewater, groundwater (Lacasa et al., 2011), surface water (Koparal et al., 2002) and drinking water (Vasudevan et al., 2010), among others.

By-Products, Characteristics, and Economics Aspects

Settled solids resulting from EC have high nitrogen contents, phosphorus and other minerals, which can be used as fertilizer. Although the solids separated from the EC unit still contains considerable amount of water, they can be dried in the open air or by waste heat from the electric generator which is generally set up near the anaerobic digester. However, if the original influent contained heavy metals or other pollutants, they will end up in this solid fraction and its usefulness as a fertilizer could be compromised.

In terms of energy consumption, 20-22 kW·h per m^3 of pig slurry liquid fraction with about 1.1-1.3% TS has been reported (Lekuona, 2004). Additionally, EC represents an improvement in separation efficiency compared to other techniques (by electric supply) but sacrifice electrodes, consisting in iron plats, should be regularly replaced due to the release of Fe^{2+} in the slurry.

Table 5. Efficiency of EC for various components

	Concentration in Slurry (mg/l)	Concentration in Effluent (mg/l)	Removal (%)
Total Suspended Solids (TSS)	20,000-30,000	100-200	>99
Chemical Oxygen Demand (COD)	25,000-35,000	1,500-2,500	>90
Total N	2,000-3,000	600-800	>60
Total P	200-350	<2	>99

(Lekuona, 2004)

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

As commented before, simple equipment is required for EC and it can be readily automated. Moreover, EC reduces chemical costs using cheaper materials. Therefore, the cost investment for this technology is mainly related to the cost of electrodes. The chemical and electrical costs come to 20¢$/m^3 and 6¢$/m^3, respectively (Zhao et al., 2010) when settling is used as dewatering strategy and a sacrificial electrode as chemical input.

AMMONIA AIR STRIPPING AND ABSORPTION

Ammonia air stripping is a physical-chemical process aiming to transfer volatile ammonia (strongly dependent on pH and temperature) from a liquid phase to a gas phase by means of liquid-gas (air or steam) intimate contact (usually in counter current), and its subsequent recovery in an acidic solution as ammonium salt, or by condensation. The process is usually performed in columns with packing material to favour the contact between liquid and gas (Frear et al., 2011).

Theoretical Fundamentals and Process Description

The amount of ammonia that can be stripped from a liquid waste or absorbed in the acidic solution is, to a great extent, dependent on two thermodynamic equilibria:

- Ammonia dissociation equilibrium in the liquid: $NH_{3\,(l)} \leftrightarrow NH_{3\,(g)}$
- And, ammonia gas/liquid equilibrium: $NH_4^+ \leftrightarrow NH_3 + H^+$

In the case of a diluted ammonia solution, Henry's Law can be applied to represent the equilibrium between phases (Equation 14).

$$y = \frac{K_H}{P} \cdot x \tag{14}$$

Where: y is the concentration of ammonia in the gas (molar fraction), x is the ammonia concentration in the liquid (molar fraction), P is the total pressure in the system (bar) and K_H is Henry's constant (bar).

Like all equilibrium constants, Henry's constant is strongly influenced by temperature. The temperature dependency of K_H can be expressed according to Dasgupta and Dong (1986). Ammonia equilibrium in aqueous solution is pH and temperature dependant (Equation 15).

$$[NH_3] = \frac{[NH_3 + NH_4^+]}{1 + \frac{[H^+]}{K_a}} = \frac{[NH_3 + NH_4^+]}{1 + 10^{pK_a - pH}} \tag{15}$$

Where: $[NH_3]$ is the free-ammonia concentration, $[NH_3 + NH_4^+]$ is the total ammonia concentration, $[H^+]$ is the hydrogen ion concentration, and pK_a is the acid ionisation constant for ammonia which can be expressed as function of temperature (T) by the following Equation (16) obtained by polynomial regression of data from Lide (1993); the higher the pH and temperature, the higher the free ammonia fraction.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

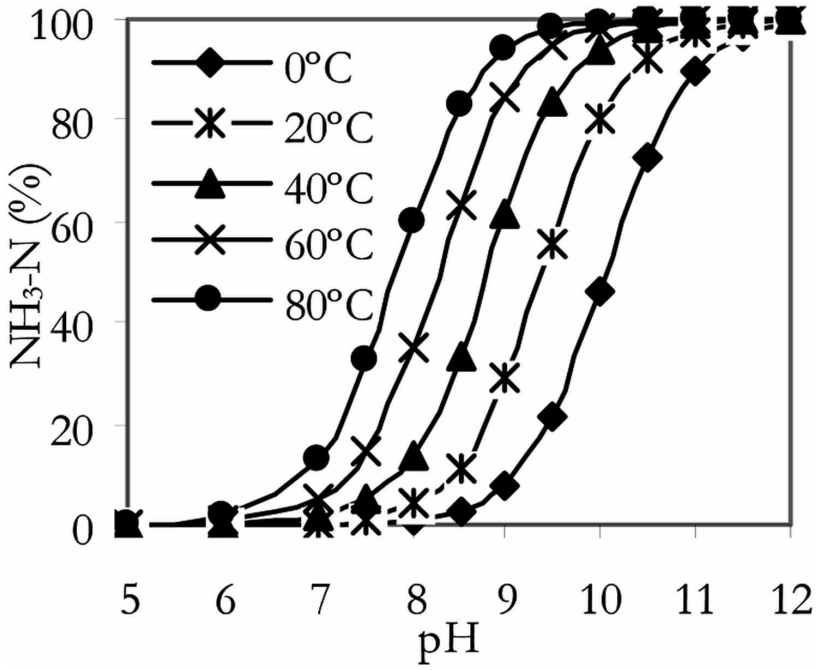
$$pK_a = 4{\cdot}10^{-8}\cdot T^3 + 9{\cdot}10^{-5}\cdot T^2 - 0.0356 \cdot T + 10.072 \quad (16)$$

As seen in Figure 9, if ammonia air stripping is performed at room temperature, a high pH is required to move the ammonia equilibrium towards free ammonia. However, with an increase in temperature a lower pH is required. pH is usually set between 9 and 10 by means of base addition or previous CO_2 stripping. On the other hand, ammonia absorption is clearly favoured when operating at pH values below 5, with almost no temperature effect.

Figure 10 shows a schematic diagram of the stripping-absorption technology. The process is usually performed in vertical columns where the liquid phase (ammonia riche stream) is introduced in the upper part while the gaseous phase enters in counter current from the bottom. To enhance liquid/gas contact the columns are usually filled with packing material (specifically shaped pieces of inert material). Stripped ammonia is recovered either by absorption in a second column, with a counter current acid solution, or by vapour condensation, obtaining NH_4OH or ammonia salts.

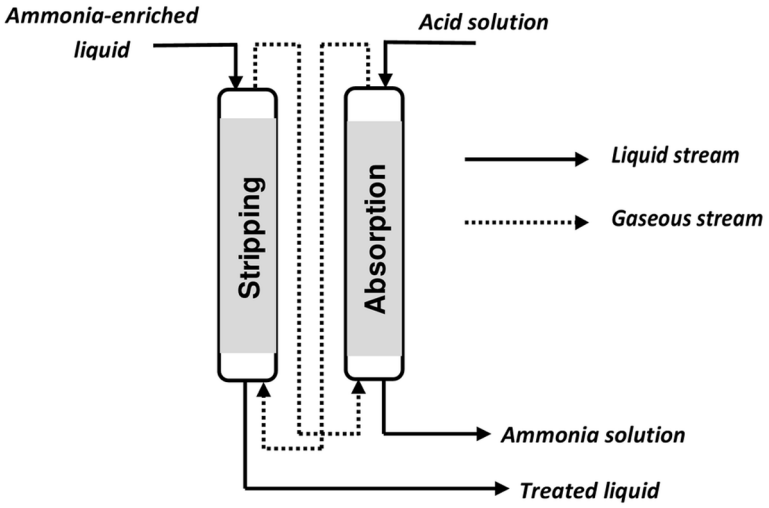
Up to 95% of ammonia reduction can be achieved under optimal conditions and almost complete ammonia recovery by absorption in acid solutions is possible with only a little acid stoichiometric excess (1.1:2 H_2SO_4:NH_3). With respect to the reagents used, NaOH, $Ca(OH)_2$ or other bases are added to increase pH (if CO_2 stripping is not enough), whereas H_2SO_4, HNO_3 or H_3PO_4 solutions are commonly used to absorb the NH_3 from the gas phase.

Figure 9. Free ammonia fraction as a function of pH at different temperature levels (data from Perry, 1992)



EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 10. Schematic diagram of the stripping-absorption process



Usual Applications and Environmental Aspects

Ammonia stripping has already been successfully applied in anaerobic digestion (AD) supernatants from municipal wastewater treatment plants, landfill leachate, and industrial wastewater at a commercial scale. In the livestock sector, the process has been applied, both as pre- and post-treatment for anaerobic digestion, to pig slurries, cattle and fermented chicken manures, with a wide range of reported removal efficiencies. The use of digested slurry showed clear advantages compared with raw slurry, achieving efficiencies above 90% even without pH adjustment (Bonmatí & Flotats, 2003, Laureni et al., 2013, Jiang et al., 2014). However, not many cases can be found when it comes to farm-based AD systems. In the Lombardy Region (Italy), there are some facilities that have been implemented as part of a treatment chain mainly as post-treatment of the anaerobic digestion supernatant (Moscatelli & Fabbri, 2008) (Figure 11).

Figure 11. Ammonia stripping plant located in an agricultural biogas plant in Brescia, Italy - CRPA, 2015

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Nutrient Recovery by Stripping-Absorption

The removal efficiency of a stripping process depends on a number of operational parameters. As mentioned, the main parameters are pH and temperature, as they have a direct effect over ammonia speciation (NH_4^+/NH_3), but other parameters such as the characteristics of the inflow stream should be also taken into account. In this regard, a distinct relationship between the inflow characteristics and removal efficiency has not yet been clearly established, but the content of organic matter is likely to be the most relevant parameter (Laureni et al., 2013).

Slurries with an initial low organic matter ($< 10\ g_{COD}\ L^{-1}$) content led to higher N removal efficiencies ($> 90\%$) when stripping was performed at 50 ºC and pH was not modified. In contrast, nitrogen removal efficiency was limited to about 50% when organic matter concentrations were high, above 27 $g_{COD}\ L^{-1}$ (Laureni et al., 2013). Similarly, Bonmatí and Flotats (2003) compared fresh and digested pig slurries in terms of stripping efficiencies at high temperature (80 ºC). The authors reported higher N removals with anaerobically digested slurry (90%) than with the fresh substrate (63%). This behaviour could be explained by the capacity of the organic matter present to bind cations (e.g. NH_4^+) with the consequent reduction of the strippable ammonia available (Laureni et al., 2013).

The combination of ammonia stripping with anaerobic digestion processes presents other advantages besides diminishing the organic matter content. The biological process itself increases the ammonia content; part of the organic nitrogen is hydrolyzed to ammonia; and it slightly increases pH reducing alkali requirements. Furthermore, as stripping is usually performed at high temperatures, the biogas produced during anaerobic digestion can partially or totally provide for the necessary heat for stripping at high temperature.

By-Products Characteristics and Economic Aspects

Stripping/absorption processes resulted in a liquid ammonia solution or solid ammonia salts, produced after a crystallization process. Both, products could be used directly as fertilizers or sold for other industrial applications (WWT of paper industry). However, the products recovered should have a marketable quality, in terms of nutrient concentration and organic matter contamination.

Organic matter contamination of the recovered ammonium solution, in terms of TOC and VOC concentration, strongly depends on the initial organic matter content of the treated slurry and, to some extent, on the operational pH. The higher the organic matter content, the higher the contamination; and oppositely, the higher the pH, the lower the contamination (Laureni et al., 2013).

Investment costs could be set between 0.25 and 0.5 M€ for treating 10-15 m^3/h, and operational costs amount to 0.66€/m^3 for NaOH and 0.21 €/m^3 for H_2SO_4 as well as 2.5-4.5 €/kg of stripped nitrogen (only for the stripping column). At least an equivalent range of values should be considered for the absorption step (Flotats et al., 2011). The by-product obtained (ammonia salts) can be used as raw material for the production of liquid fertilizers. An ammonium-sulfate solution with low organic contamination and a nitrogen concentration of 6% w/w, can be sold at a price of about 0.35 € kg^{-1} N (Laureni et al., 2012).

CONCLUSION

In the current juncture of increasing raw materials and energy sources scarcity, organic waste (e.g. livestock manure and other industrial wastewaters) arises as an attractive resource which, if processed properly, can yield renewable energy and be a source of added-value products (e.g. nutrient fertilizers) while, in turn, reducing the environmental impacts associated to its management.

The development and implementation of cost effective processing technologies aiming to recover valuable products as nutrients, is crucial to redirect the development towards a circular economy. In this chapter, the main process technologies already in operation, as well as the new technological developments have been reviewed, showing that these technologies are ready but have different hindering issues which should be overcome before it can spread worldwide. Operational costs, the quality of the recovered products and the need to open the market for this kind of products are the main limiting factors. Nevertheless, these recovering technologies present good potential to be widely implemented in a near future.

ABSTRACT

Constructed Wetlands (CWs) are low-cost and sustainable systems for wastewater treatment. Traditionally they have been used for urban and domestic wastewater treatment, but in the last two decades, the applications for industrial wastewater treatment increased due to the evolution of the technology and the extended research on the field. Nowadays, CWs have been applied to the treatment of different kind of wastewaters as such as refinery and petrochemical industry effluents, food industry effluents including abattoir, dairy, meat, fruit and vegetables processing industries, distillery and winery effluents, pulp and paper, textile, tannery, aquaculture, steel and mixed industrial effluents. In this chapter, the authors present the main types of CWs, explain how they work and the expected performances, and describe the principal applications of CWs for industrial wastewater treatment with particular attention to suspended solids, organic matter and nutrient removal. A review of these applications as well as some case studies will be discussed.

INTRODUCTION

In this chapter, the authors refer to the use of constructed wetlands (CWs) for industrial wastewater treatment and their efficiency for nutrient removal. CWs are engineered systems that have been designed and constructed to utilize the natural processes involving wetland vegetation, soils, and their associated microbial assemblages to achieve wastewater treatment (Vymazal, 2014). "Modern treatment wetlands are man-made systems that have been designed to emphasize specific characteristics of wetland ecosystems for improved treatment capacity" (Kadlec & Wallace, 2009). "Besides treatment wetlands", constructed and engineered wetlands can cover a broad range of objectives such as improving biodiversity and environmental conditions related to, wildlife use, irrigation of agriculture lands, improving river water quality, or riverine restoration. Some misleading names have been given to the technology including green filters, biofilters and even sand filters or artificial wetlands. As CWs have evolved with time and applications, other terms like engineered wetlands have appeared that might include the use of devices that upgrade the performance using energy input.

CWs are low-cost and ecofriendly technologies, that take advantage of natural processes to remove pollutants from the water, generally avoiding the use of chemical products and the input of high amounts of external energy. On the other hand, CWs may require a large surface, which is its major drawback. As a result; they are included in the group of extensive technologies for wastewater treatment.

The first research into CWs for wastewater treatment took place in Germany, in the 1950s (e.g., Seidel, 1961), with special focus on phenols removal. From the beginning, the first applications of CWs dealt with urban wastewater, but in the last two or three decades, they have been applied for industrial and agricultural wastewater, as well as stormwater runoff and the treatment of landfill leachates (Vymazal 2011a).

CONSTRUCTED WETLANDS: HOW DO THEY WORK?

Pollutant removal in natural wetlands takes place due to the combination of physical, chemical and microbial processes. The processes involved in pollutant removal are sedimentation, sorption, precipitation, evapotranspiration, volatilization, photodegradation, diffusion, plant uptake, and microbial degradation (for instance, nitrification, denitrification, sulphate reduction, carbon metabolization, etc.) among others.

Types of Constructed Wetlands

There are several types of CWs, depending on the hydrology, the type of macrophytic growth and the direction of the flow inside the wetland. As a result, if the hydrology is considered, the principal types of CWs are surface flow (or free water systems) or subsurface flow systems (Figure 1). According to the macrophytic growth, there are emergent, submerged, free-floating and floating leaves. Finally, the direction of flow inside the CW can be vertical, horizontal or mixed flow.

The most widespread CWs are the surface flow systems (FWS), the horizontal subsurface flow systems (HSSF) and the vertical subsurface flow systems (VF). For improving the performance and the removal of pollutants and nutrients, a combination of these systems can be used, known as hybrid systems. The hybrid systems can combine several features in only one or in several sequential steps.

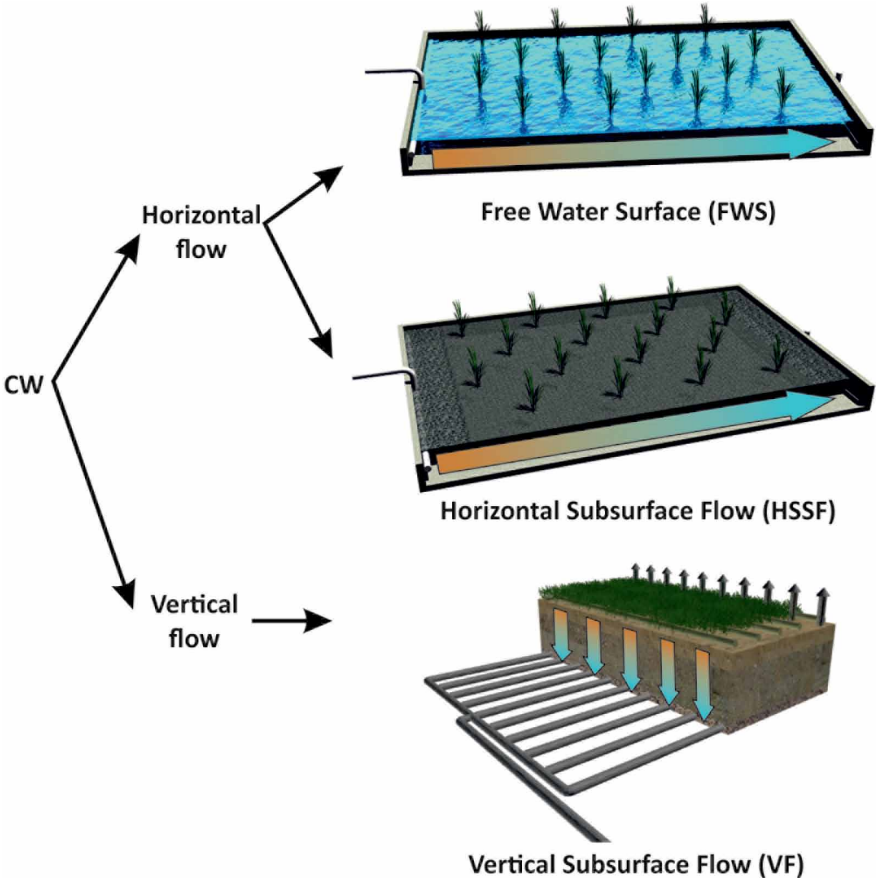
Figure 1. Schematic representation of types of CWs, depending on the flow regime



Free Water Surface Systems (FWS)

The FWS system CWs are shallow beds (often from 20 to 40 cm), planted with aquatic vegetation. The pollutants are removed as wastewater goes exposed to the atmosphere through the planted beds, due to several processes including sedimentation, oxidation, reduction, precipitation, sorption and biological degradation.

This type of FWS is often used for tertiary treatment, to polish effluents from a previous physical-chemical or biological wastewater treatment. The FWS systems have several characteristics:

- Simple to operate and low-cost systems.
- Low removal rates.
- Demand large surface requirements (up to 20 m^2/PE^1).
- Risk of odors forming (if they receive untreated sewage directly) and freezing in winter.
- Can host vectors.

Horizontal Subsurface Flow Systems (HSSF)

HSSF systems are cells filled with media (from 30 to 60 cm deep) in which aquatic vegetation is planted (Figure 1). This kind of wetland is saturated, and the water column is not exposed to the atmosphere, usually remaining about 5 to 10 cm under the surface of the bed and therefore avoiding fouling odors and the proliferation of vectors.

Water is distributed in the inlet zone by perforated pipes or Thompson channels. The inlet of the wetland is filled with coarse gravel (30-100 mm size), to improve influent distribution and delay the possible clogging in the inlet zones. The bed media is generally gravel (5-20 mm size), where the biofilm develops and at the same time, the media serves as a support for the vegetation. At the outlet zone and the bottom of the bed, a collection pipe is placed to evacuate the treated waters. The pipe is also embedded with coarse gravel to facilitate the effluent collection. After the bed, there must be an outlet sump where a pipe is connected to the collection pipe and can regulate the water level in the wetland by a swivel joint or a flexible pipe.

In a HSSF wastewater goes through the wetland and the media in a horizontal path, coming into contact with aerobic, anoxic and anaerobic zones. The oxygen from the air is transported through the stems and leafs of the vegetation to the rhizosphere, where an aerobic-anoxic microcosm is present (Brix & Schierup, 1990). Normally, the amount of oxygen in HSSF CW treating typical wastewaters is not enough to degrade all the organic matter via aerobic processes much less to allow high dissolved oxygen concentration into the wetland. Therefore the processes responsible for the degradation are mainly anoxic-anaerobic. Some characteristics of this system are the following:

- High resistance to freezing conditions.
- Less surface area needed than FWS (5 m^2/PE).
- Higher removal rates than FWS, although this is dependent on operational conditions.
- Risk of clogging problems in the inlet zone.

Vertical Flow Systems (VF)

The subsurface VF systems are cells filled with coarse sand or fine gravel, usually from 60 to 100 cm deep, and planted with aquatic vegetation (Figure 1). Most VF systems are unsaturated and fed sequentially in short pulses and then a drainage period takes place. The wastewater is loaded homogeneously onto the surface of the wetland, trickles vertically through the filter media and is collected at the bottom by drainage pipes. Additionally, passive aeration pipes from to the drainage pipes to the atmosphere to improve the oxygen transfer to the bed. Due to aeration pipes, pulse loadings and drained periods, the oxygen transfer can reach much higher values, if compared to HSSF or FWS systems. VF CWs have aerobic conditions and therefore higher organic removal rates as well as the capacity to nitrify.

The wastewater distribution system of VF CWs consists of a manifold of pipes installed on the surface of the bed. The media filling the bed can be either by one layer or even several sand layers. At the top and the bottom of the bed, a layer of about 20 cm of coarse gravel is placed to facilitate the distribution and evacuation of the waters.

Some other characteristics of VF CWs are the following:

- Less surface area needed (2-3 m^2/PE).

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

- No clogging problems (if well designed and operated).
- Demands a good influent distribution system.

A modification of VF is commonly called "the French system" or French reed beds (FRB). It is basically a 2-step CW but with some differences, mainly the stratification of the substrate layers and the distribution system. It can treat wastewater directly, without primary treatment. In the FRB the 1-step VF demands parallel beds that are loaded sequentially and used as primary treatment and the bed retains suspended solids as well as other particulate pollutants. As times goes by and after loading, a layer of stabilized sludge accumulates on top of the wetland. After 8 to 10 years, the sludge layer is removed and can be further composted or applied directly to land as fertilizer. After the first step and according to the effluent needs the vertical bed can be followed by a new set of vertical flow beds or a horizontal flow bed.

The recirculation of treated effluents back to the pumping well or to the sedimentation tank improves the overall system performance and enhances the removal of nitrogen. The recirculation of treated water dilutes and makes the water loaded onto the filter more homogeneous. Additionally, the recirculation of treated water helps maintain the presence of water during vacation periods ensuring the survival of the plants and bacteria/biofilm. The optimal recirculation rate is circa 100%, i.e. the recirculation of half of the effluent back to the pumping well (Arias *et al*, 2011).

Tidal Flow Constructed Wetlands

Other type of CWs developed during last decade are the tidal-flow constructed wetlands (TFCWs), which have enhanced the organic matter and ammonia removal by overcoming the lack of oxygen in conventional CWs (Sun *et al*., 2005; Wu *et al*., 2011). However, the total nitrogen removal efficiency in TFCWs is not ideal because of the high oxygen content that limits the denitrification processes (Ju *et al*., 2014; Cui *et al*., 2012).

The "tidal flow" principle includes four operational procedures (fill, contact, drain and rest) that constitute the main difference with conventional CWs (Sun *et al*., 2006).

Engineered Wetlands

As reviewed by Wu *et al*. (2014), different operation strategies and innovative designs can be used in order to intensify the performance of CW systems. These strategies include recirculation, aeration, tidal operation, flow direction reciprocation, earthworm integration, short-term fluctuations in the water table, step-feeding, circular-flow corridor wetlands, towery hybrid CWs, baffled subsurface CWs for the intensifications of the performance.

Aerated wetlands are subsurface flow wetlands, both horizontal and vertical flow, but with artificial aeration implemented in the bed where the air is pumped into the wetland by means of compressors. Forced bed aeration (FBA®) wetlands were patented in USA by Scott Wallace and are gaining ground and are being used more due to their versatility and better capacity to treat industrial waters. Aerated wetlands testing different regimes of aeration "on" and "off", nitrification or denitrification processes can be enhanced.

Pretreatments for CWs

The most frequently used pretreatments for CWs treating domestic wastewater and, frequently used for treating industrial wastewater, are septic tanks (ST) and Inhoff tanks (IT). Often, these primary treatment technologies are not efficient enough for removing suspended solids, and can promote clogging in CWs, especially when high organic loads are applied. The use of anaerobic digesters and CWs is gaining importance in latest years for treating different industrial wastewaters. Both systems are low-cost, robust and effective in wastewater treatment. According to Álvarez *et al*., (2008) an average and 95 percentile TSS concentrations of anaerobic treated wastewater were below 60 and 100 mg/L, respectively, for all configurations reported suggesting that anaerobic treatments might be an option when using CWs.

Removal of Pollutants in CWs

Solids are removed in CWs mainly by physical processes such as sedimentation and filtration. The removal of solids takes place in the inlet zone of HSSF (1/3 or 1/4 of the total length) and in the surface of VF CWs. These processes are favored by the low velocity of the water and the sieving in the interstitial spaces of the granular media inside the CWs.

Organic removal processes are complex and vary, with the interaction of several physical, chemical and biotic mechanisms involved. Particulate organic matter is retained like solids, as described before, and hydrolyzed in simple substrates that can be assimilated by heterotrophic, anaerobic and facultative bacteria. Aerobic degradation of organic matter takes place close to the water surface and the rhizosphere, while facultative and aerobic degradation occurs in the bottom of HSSF and FWS systems. The rest of the bed is dominated by anaerobic organisms and as such anaerobic processes are responsible for further transformations.

Pathogens are removed by complex processes, including filtration, sorption, died off due to environmental conditions and predation.

Under aerobic conditions, heavy metals (HM) retention and accumulation in wetland substrate is mainly due to the formation of metal hydroxides (i.e. Fe and Mn hydroxides; Singer & Stumm, 1970). Under anoxic or anaerobic conditions, precipitation of metal sulphides is the main process contributing to the removal of HMs in CWs. In anaerobic conditions, sulphate reduction leads to the formation of hydrogen sulphide and most HMs react with sulphide to form highly insoluble precipitates (Stumm & Morgan 1981).

Removal of Nutrients in Constructed Wetlands

The most important mechanism to remove nitrogen from wastewater in CWs is nitrification-denitrification process. The process begins with nitrogen from organic compounds like proteins, transformed both in aerobic and anoxic conditions into ammonia, (ammonification). Nitrification consists on the oxidation of ammonia into nitrite and nitrate by autotrophic bacteria. This process occurs in aerobic conditions. Denitrification is the conversion of nitrate to dinitrogen gas (N_2) by heterotrophic bacteria. This process needs organic matter and anoxic conditions.

Recently, the presence of anaerobic ammonium oxidation (anammox) processes has been described in CWs as another path to remove nitrogen (Saeed and Sun, 2012b). Anammox is a reaction that oxidizes ammonium to dinitrogen gas using nitrite as the electron acceptor under anoxic conditions. When

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

partial nitritation (NH_4^+ to NO_2^-) and anammox is combined, only about one half of ammonium needs to be oxidized to nitrite first, then anammox bacteria use the remaining ammonium as electron donors for autotrophic denitrification of the nitrite produced (van der Star *et al*., 2007; Kartal *et al*., 2010). Anammox process consumes 60% less oxygen than nitrification-denitrification cycle and no organic carbon source is required (He *et al*., 2012).

Other processes involved in nitrogen removal are plant uptake, volatilization, dissimilatory nitrate reduction, and biomass assimilation. The latest process takes place through incorporation of NH_4^+ in the heterotrophic biomass to fulfil nutrient requirements. In stationary systems like CWs, biomass accumulation could lead to clogging problems, so biomass assimilation is not expected to be an important process in CWs for removal of nitrogen.

The presence of phosphorus in wastewater is mainly in the forms organic phosphorus, orthophosphate, and polyphosphate. Soluble reactive phosphorus is taken by plants and transformed to biomass, in the form of vegetal tissues and/or organisms. Sorption by sediments, sand or gravel media is the most important phosphorus removal process in CWs. Precipitates and co-precipitates of Al, Fe and Ca occur under certain circumstances mainly depended on pH, but can be redissolved under altered conditions (Kadlec & Wallace, 2009).

Nitrogen Removal in CWs

If organic matter concentration (carbon source) is sufficient, denitrification might be an important process to remove nitrogen in FWS systems. Unvegetated open water does not promote denitrification, resulting in rate constants about one third of those for vegetated systems (Arheimer & Wittgren, 1994). Smith *et al.* (2000) have shown nitrate removal proportional to the number of shoots in a *Schoenoplectus* spp. planted wetland. These considerations lead to the conclusion that fully vegetated marshes with either emergent or submergent communities are the preferred option for denitrification.

Since HSSF CWs are saturated reactors they have limited nitrification capacity, on the contrary the conditions are best for denitrification processes and therefore total nitrogen removal is effective only if a previous nitrifying system is implemented. However, low loaded HSSF systems can remove influent total nitrogen because near all the nitrified ammonia is effectively removed (nitrification-denitrification), or by the existence of other removal mechanisms.

In VF CWs, ammonia oxidation to nitrate is highly dependent on the organic and nitrogen surface loads and on the VF operation regime, mainly the pulse frequency and volume as well as the duration of drained periods. If well designed and operated, VF systems can reach more than 90% of nitrification, both for urban and industrial wastewater. With aerobic conditions, total nitrogen removal in VF systems is poor or null, due to very limited denitrification rates. Partial recirculation of VF effluent to previous septic tanks or anaerobic reactors can enhance total nitrogen removal (Brix & Arias, 2005; Torrijos *et al*., 2015).

In TFCWs ammonium cations (NH_4^+) are first adsorbed on matrix, pores, and surfaces when wetland cells are flooded. Second, as wetland cells drain, matrix pores are immediately filled with air and the absorbed ammonia is nitrified by bacteria. Finally, in the next flood cycle, nitrate (NO_3^-) and nitrite (NO_2^-) desorb into bulk water, where they are denitrified into atmospheric nitrogen (Austin, 2006; Chang *et al*., 2014). Therefore, the flooded time of TFCWs plays a key role in forming effective anoxic conditions that are favorable for reducing oxidized nitrogen and to improve total nitrogen removal (Li *et al*, 2015b).

The Role of Plants in Constructed Wetlands

Nutrient transformation and sequestration in low-loaded systems, organic matter production and plant uptake of nutrients, as well as root-zone oxygen and organic carbon release systems have been identified as key factors (Brix, 1997; Tanner, 2001; Vymazal, 2011b). According to Tanner (2001), wetland plants promote the enhancement of nutrient removal, mainly by favoring transformations to gaseous forms and sequestration in accumulating organic matter. Recent studies reported that nitrogen removal is usually better for planted systems (Hijosa-Valsero *et al*., 2012; Pedescoll *et al*., 2013a; Webb *et al*., 2013; Huang *et al*., 2013; Seeger *et al*., 2013; Lv *et al*.,2013; Chen *et al*., 2014).

Carballeira *et al*. (2016) reported a linear correlation between ammonia nitrogen removal rate (g N/m^2·d) and biomass production (g volatile solids VS/m^2·d) in HSSF CWs treating domestic wastewater. According to that correlation, biomass production explains 91% of additional nitrogen removal in planted systems. Unplanted CW removed 0.34 g NH_3/m^2·d while planted systems removed an additional 13.4% per each g VS/m^2·d of above-ground biomass produced or the equivalent 36.6% additional per each kg VS/m^2 year.

The contribution of plants, in terms of nitrogen removal has been reported within the range 0.5-40.0% of the total nitrogen removal (Drizo *et al*., 1997; Shamir *et al*., 2001; Healy and Cawley, 2002; Meers *et al*., 2008; Kantawanichkul *et al*., 2009; Bialowiec *et al*., 2011, Saeed and Sun, 2012b). Chen *et al*., (2014) reported that N mass balance showed that denitrification, sedimentation burial and plant uptake respectively contributed 54%-94%, 1%-46% and 7.5%-14.3% to the N removal in CWs, mainly stored in aboveground biomass. Zheng *et al*., (2015) reported that plants harvesting in the first year improved nutrients removal by plant uptake (41.9 g N/m^2 and 3.7 g P/m^2 versus 37.3 g N/m^2 and 3.2 g P/m^2) as well as in the substrate layer (216.9 g N/m^2 and 8.0 g P/m^2 versus 191.0 g N/m^2 and 5.7 g P/m^2) during the second year.

Phosphorus Removal in CWs

In FWS, phosphorus is removed, due to three processes in wetlands: sorption, utilization to build a larger biomass compartment and storage as newly created, refractory residuals (burial). Sorption and biomass storage have a limited phosphorus retention capacity. Moreover, there are secondary processes like particulate settling that can rapidly remove high amounts of phosphorus from runoff water with a high level of suspended sediments (Kadlec & Wallace, 2009).

Similar phosphorus removal processes take place in subsurface flow CWs (HSSF and VF), biomass accumulation, sorption in the gravel media and sediment accretion. Sorption mechanisms are limited to the gravel media capacity, which can be high, but only when considered in a short term. In this sense, latest research in new materials with higher phosphorus sorption capacity has been done.

Like in HSSF systems, phosphorus removal in VF systems takes place mainly by sorption in the filter media. VF systems are designed principally to remove organic matter, solids and ammonia. As a result, phosphorus loading rate is bigger than the capacity of plants to accumulate phosphorus as vegetal biomass.

The biological removal of phosphorus by microorganisms in tidal flow CWs has never been considered as a significant factor in CW design. However, results from Li *et al*. (2015a) suggest that the cycling of phosphorus in CWs might depend significantly on the type of operations employed. Nevertheless, further investigations on the detailed mechanism of phosphorus removal are needed before any concrete conclusion can be made regarding phosphorus removal efficiency in tidal flow CWs.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Influence of Filter Media of CWs on Phosphorus Removal

A review of different filter media used for phosphorus removal was elaborated by Vohla *et al*. (2011). These researchers reported that the most commonly used materials are described as natural materials, industrial byproducts and man-made products. Most of the studied materials had a pH >7 and high Ca (CaO) content. Several industrial byproducts achieved the highest P removal capacity, including some furnace slags (up to 420 g P/kg), followed by natural materials (maximum 40 g P/kg for heated opoka) and man-made filter media (maximum 12 g P/kg for Filtralite-P®). Some important factors such as saturation time, availability at a local level, the content of heavy metals, and the reuse of the saturated filter media as a fertilizer should be taken into consideration regarding the applicability of filter materials.

Moreover, a good hydraulic conductivity and the chemical composition of the adsorption media are key factors for CW design. Since phosphorus is removed via sorption and precipitation, Ca, Fe and Al content of the filter media is important for P removal. Even if a medium with high P binding capacity has been selected, it may be saturated after a few years (Arias *et al*., 2001). An easy, practical and sustainable solution might be to install a separate well filled with replaceable high binding P capacity media after the treatment for P removal (Brix *et al*., 2001).

Recovery of Nutrients in Constructed Wetlands

Recovery of nutrients by CWs is generally not very effective, comparing with other wastewater treatment systems and will depend on the type of CW and the water quality. For example, harvesting of plants for uptaken nutrient recovery might be interesting, but it is only feasible for large surface areas. Another example for carbon and nutrient recovery can be sludge treatment wetlands (STW).

STW is a type of VF, and were developed to treat sludge produced as a result of activated sludge wastewater treatment. The required specific surface area can be roughly assumed as 0.25 to 0.50 m^2/PE (Kainz, 2006). These systems consist of several parallel beds filled with three or more layers with a bottom gravel drainage layer, an intermediate layer with coarse material and a soil/sand layer for favoring the vegetation establishment (commonly reeds, *Phragmites australis*). In STWs homogenized sludge is pumped intermittently and sequentially to the different beds by alternating dosing regimens and allowing resting periods for the different beds. The resting periods will depend on the design conditions, but the intervals between loadings must be sufficient to allow the drainage of trapped water from the sludge. As sludge is accumulated and built up, the rhizomes will develop in the sludge and penetrate, increasing dewatering by evapotranspiration process.

After the sludge storage capacity of the bed is filled, the sludge from the STW is stable. This process reaches a final product with a dry solid content higher than 25%, and is suitable for direct reuse. As an example, the sludge produced in the Helsinge STW after 10 years of operation resulted in total phosphorus content of 30-35 g/kg dry solids and total nitrogen content of 20-25 g/kg dry solids (Nielsen, 2015).

Nutrients concentration in biosolids depends on the wastewater composition and treatment, and on subsequent sludge management. Nitrogen comes from biomass present in the sludge and form wastewater residues. In a study carried out by Uggetti *et al*., (2012), total Kjeldahl nitrogen (TKN) values in biosolids ranged from 0.03 to 0.25% TKN/TS (TS total solids), being significantly lower than in activated sludge (Andreoli *et al*., 2007). TKN values were significantly higher (2.30-2.53% TKN/TS) in compost of sewage sludge (Ruggieri *et al*., 2008; Sanchez *et al*., 2010). Uggetti *et al*., (2012) reported a certain nitrogen reduction in STW, due to sludge mineralization, ammonification and plant uptake.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

The main sources of phosphorus in sludge are biomass formed during wastewater treatment, residues and phosphate-containing detergents and soaps. Uggetti *et al*., (2012) reported a decrease in total phosphorus values from the influent (2.7-3.0% TP/TS) to treated sludge (0.07-0.39% TP/TS), probably due to phosphate immobilization in microbial cells (Elvira *et al*., 1996).

STATE OF THE ART OF CONSTRUCTED WETLANDS TREATING INDUSTRIAL EFFLUENTS

Industrial Applications of Constructed Wetlands

CWs were initially used for treating domestic wastewater. But in the last two decades, industrial wastewater has been treated with hybrid CWs, both surface and subsurface flow. CWs started treating industrial effluents like petrochemical, dairy, meat processing, abattoir, and pulp and paper factory effluents. Brewery, tannery and olive mills wastewaters have been recently added to CWs applications. So, CWs can be applied to several and different kinds of industrial wastewaters, including acid mine wastewater with low organic matter content and landfill leachate. Vymazal (2013) reported industrial wastewater treatment with hybrid CWs systems with influent concentrations up to 10,000-24,000 mg COD/L and up to 496 mg NH_4^+/L. But there are not general rules to select the most suitable type of CW for a certain industrial wastewater or even urban wastewater. Every single case must be studied particularly due to several conditions: type of wastewater, land availability, the amount of flow and pollutant load, outlet discharge limits, etc. Some recommendations to be taken into account could be:

- Good pretreatments like anaerobic digesters (UASB, HUSB) to remove solids and avoid or at least delay clogging of media. A degreaser is necessary if wastewater contains huge grease concentration.
- If the industrial wastewater has a low volume to be treated and land availability, the simplest type of CW like HSSF can be a suitable solution.
- If high surface loading rate needs to be applied, VF or aerated wetlands are recommended.
- For the removal of nutrients, hybrid systems including VF and HSSF are specially indicated.

In this section, the authors will revise a few of the industrial effluents treated by CWs.

As shown in Table 1, the efficiencies can vary extensively, depending on the wastewater characteristics and the system design features and operational conditions. Regarding environmental conditions, CWs can work in extreme weather conditions ranging from the coldest temperatures to tropical conditions.

It seems hard that natural systems like CWs can work treating industrial wastewater, for instance, refinery, pulp and paper, tannery or textile effluents, where hardly biodegradable compounds are present. In wastewater with a high BOD/COD ratio, CWs can perform well as a secondary or tertiary treatment, with good pretreatments that can reduce the organic loads. For these types of wastewaters, the conventional primary treatment and activated sludge or SBR reactors as secondary treatment are the most common used systems. The variety of different industrial wastewater treated by CWs is high, and the latest research in the field is increasing this range of possibilities. The evolution of CWs has been enormous, from the simple FWS to the intensified systems. The treatment technology of CWs has evolved into a reliable technology which is nowadays successfully used for many types of industrial effluents (Vymazal, 2014).

CWs for Dairy Parlor Wastewater Treatment

CWs have gained a place in dairy parlor and wastewater treatment from different farm activities. Table 2 summarizes main results for some applications.

Three cases are shown in this section. Newman *et al*. (2000) designed a FWS of 400 m^2 for dairy parlor wastewater treatment from a farm with 100 milk cows. Real BOD_5 concentration was much higher (2683 mg/L) than expected and the treatment was not sufficient due to effluent values of 692 mg/l with a 74% BOD_5 removal. After this experience, an estimation of pollutant loadings when designing the systems is not recommended by those authors.

Mantovi *et al*. (2003) described a two-stage HSSF system in series to treat a mixture of domestic and dairy parlor effluent, previously treated in an Inhoff tank and a well with plastic filter for the removal of sedimentable suspended solids. Removal efficiency was satisfactory, with values of more than 90% in organic matter (TSS, COD and BOD), 48.5% of TKN and 60.6% of TP.

The 16-years of expertise of van Oirschot (2015) treating dairy wastewater is described in this section. In rural areas from the Netherlands and Belgium the main sources of wastewater discharged into fresh water are untreated widespread domestic and dairy farms wastewater. Several projects were developed, testing different additions to the substrate for their efficiency in the removal of phosphorus. The ratio BOD/COD in wastewater coming from milking parlors, seems to be greater than domestic wastewater, and low N-values due to the presence of milk. Results of nitrogen and phosphorus removal of 13 CWs treating dairy farms were 84.2%, 78.7%, 47.9% and 72.3% for TKN, NH_4^+, TN and TP, respectively.

These results from van Oirschot (2015) show a high removal of organic matter and organic nitrogen, as well as a significant reduction of total phosphorus. Denitrification occurs to about 50%, good if considering that is single-stage VF being used. This denitrification rate is higher than the same CW treating domestic wastewater, due to the relatively high C/N ratio of the dairy wastewater. In VF systems, it seems that the lack of carbon in the lower anaerobic parts of the wetland is the main cause for the low denitrification rate. The total P concentrations of 6 CWs at dairy farms with $CaCO_3$ and iron additions in the substrate ranged from 8.8 to 29.1 mg P/L and 0.14 to 8.8 mg P/L in the inlet and the outlet respectively.

Cheese Production Wastewater

Gorra *et al*., (2014) reported the performance of a HSSF from a medium-sized cheese factory which processes 8 ± 4 m^3 of milk. The local climate conditions were a mean air temperature of 12ºC and mean total precipitation of 430 mm. The system consists of a pretreatment by means of sedimentation tank (45 m^3) and a HSSF CW of 200 m^2 of total area and planted with common reed (*Phragmites australis*). The CW is divided into five sections, each one filled with a different material: (1) gravel from metamorphosed limestone, (2) ground ceramic wastes, (3) by-products from magnetite extraction, (4) zeolitite and (5) a horizon of a Dystrict Endoskeletic (Siltic) Cambisol. The input average flow was 10 ± 2 m^3/d, with a maximum during spring of $12 \pm 1 m^3$/d and a minimum of $8 \pm 2 m^3$/d during summer. Different volumes of influent treated have influenced the retention time, which for such reason varied from 15 to 5 days (average value about 7 days). Average SLRs were 40 (BOD_5), 10 (TN) and 0.5 (TP) g/m^2·d, while maximum SLR reached approximately 100 (BOD_5) and 25 (TN) g/m^2·d. The average mass removal was 55%, 55%, 59% and 58% for TN, organic N, NH_4^+ and TP, respectively.

[a]IT: Inhoff tank, ISF: Intermittent sand filter .[b]Domestic effluent means a dilution of dairy parlor effluent in this case, reducing 70% concentration. Effluent from holding room is separated to the slurry tank, not contributing to reported concentration. Pretreatment, IT (40 PE), includes a filter and reaches removal rates of 64% TSS, 48% COD and 35% BOD in the original mixed effluent.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Most of the influent nitrogen was in the form of organic N (>85%), while ammonium and nitrate were around 8-14% and 2-4% respectively. The average removal of biochemical oxygen demand (BOD_5) was higher than 90%.

The treated effluent had a final quality that would allow the use for direct irrigation in agriculture.

Tannery Wastewater

CWs have been used for secondary or tertiary treatment for the treatment of tannery wastewater as a cost-effective and environmentally friendly technology. Calheiros *et al*., (2014) reviewed the tannery sector in Portugal and the performance of CWs for treating this wastewater. Depending on the kind of treatment, tannery wastewater has different BOD/COD ratios, ranging from 0.23 and 0.66 for water that had primary treatment, and from 0.1 to 0.65 for water after secondary treatment. As shown by the ratio, these waters are not easy biodegradable, if compared to domestic wastewater or even with most industrial wastewater. When considering CW as part of a treatment system an efficient pretreatment and the primary treatment and precious treatments are of upmost importance before the wastewater is conducted to the CW (Calheiros *et al*. 2007). The reported treatments for tannery wastewater CWs are conventional primary treatments and an activated sludge as a secondary treatment.

Regarding the construction and establishment costs CWs correspond to circa 10–20% of the conventional secondary biological treatment and the running costs account for approximately 10% (Daniels, 2007), although it may vary according to the country where the system is implemented. Dias *et al*., (2006) reported that in the Portuguese scenario the capital costs, with pretreatment included, are equivalent to a conventional treatment, however, concerning the operation and maintenance cost the same authors state they are at least 6–20 times lower.

Efficiencies of CWs treating tannery wastewater in Portugal ranged from 2.3 to 160 g COD/m^2·d and 0.6 to 61 g BOD/m^2·d removed.

Focusing on the phosphorus and nitrogen removal in tannery wastewater, Kadlec *et al*. 2000 reported that the performance is lower when compared to the organics removal, although in some way expected for this type of systems. For instance, Calheiros *et al*. (2008), reported that for an inlet of 0.21–0.43 mg P/L the outlet was 0.18–0.35 mg P/L and for an inlet of 63–87 mg NH_3/L the outlet was 40–56 mg NH_3/L. Removal of PO_4 reaching 61% (inlet 15 ± 7 mg/L, hydraulic retention time (HRT) of 12.5 d) has been reported for the treatment of tannery wastewater by CW in Bangladesh (Saeed *et al*. 2012a). High removal of NH_4^+ (99%) from tannery effluents has been reported by Kucuk *et al*. (2003) for an inlet of 20 mg/L at a HRT of 7 days.

Greenhouse Gas Emissions (GHG) in CWs

Greenhouse gases namely CO_2, CH_4 and N_2O are emitted from both natural and constructed wetlands. During the mineralization of organic matter, CO_2 production is desirable but, on the other hand, CH_4 and N_2O emissions must be avoided due to their high greenhouse effect potential (they have a global warming potential of 34 and 298 relative to CO_2 over a 100 year time horizon (Myhre *et al*., 2013).

HSSF CWs have the bottom as the principal anaerobic environment, and the zone close to the water surface and the rhizosphere as aerobic zones. Both organic and hydraulic loading rates are key operational variables that can influence the importance of anaerobic and aerobic roles, together with water level as a design variable. As a result, these factors determine the influence on methane generation and emission (Pedescoll *et al*., 2011).

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Methane emission rates from CWs treating different types of wastewaters can vary from -208 to 36,792 mg $CH_4/m^2 \cdot d$ (Pei-Dong *et al*., 2002; Wang *et al*., 2008) but more usual range is from 0 to 2000 mg $CH_4/m^2 \cdot d$. Some important factor affecting the measured gas emissions are the position on the length of the wetland in the direction of flow, and the season of the year (Tanner *et al*., 1997; Mander *et al*., 2003; Johansson *et al*., 2004; de la Varga *et al*., 2015).

According to the literature review reported by Mander *et al*., (2014), CO_2 emissions are significantly lower in FWS than in HSSF CWs, with average values of 2208 and 4440 mg $CO_2/m^2 \cdot d$, respectively. Additionally, in VF systems, methane emissions were significantly lower than in HSSF and FWS (average values of 97, 178 and 142 mg CH_4 $m^2 \cdot d$, respectively). For N_2O emissions, no significant differences were found for several types of CWs (average values for FWS, VF and HSSF of 2.2, 2.9 and 3.1 mg $N_2O/m^2 \cdot d$, respectively). As a conclusion, Mander *et al*., (2014) reported that hybrid systems (VF, HSSF and/or FWS) perform better for treating wastewater and reducing direct greenhouse gas emissions. The emissions are affected by the loading, the operation mode as well as the local climatic conditions.

The emission factor for methane might be defined as the ratio of carbon emitted as methane to the total organic carbon influent to the CW (CH_4/TOC_{in}). Mander *et al*., (2014) reported that the greatest emission factor for methane was found for FWS (average of 16.9%), followed by HSSF (4.5%) and VF (1.2%). These researchers reported that significant differences of emission factor for N_2O (percentage ratio of N_2O emitted to influent total nitrogen TN) were found for HSSF (0.79%), FWS (0.13%) and VF (0.023%). Moreover, according to Mander *et al*., (2014), a significant correlation between the influent rate of total organic carbon (TOC) and the methane emission rate and between the influent rate or total nitrogen (TN) and N_2O emission rate for all types of studied CWs was found as well.

Data about gas emissions from CW treating industrial effluents is still scarce. Tanner *et al*., (1997) found an average methane emission rate of 225 mg $CH_4/m^2 \cdot d$ (standard deviation SD of 28-482) in a HSSF treating dairy wastewater, with a surface loading rate from 2.5 to 4.2 g $BOD/m^2 \cdot d$. Maltais-Landry *et al*., (2009) reported an average methane emission rate of 20 to 120 mg $CH_4/m^2 \cdot d$ in an aerated HSSF pilot plant treating fish factory effluent. De la Varga *et al*. (2013b) reported methane emissions ranging from 143 to 1899 mg $CH_4/m^2.d$ for HSSF system treating winery wastewater while carbon dioxide emissions in this system ranged from 1783 to 6137 mg $CO_2/m^2 \cdot d$.

Economics of CWs

CWs include mainly two types of costs: capital costs (construction, engineering and indirect costs) and operation and maintenance (O&M) costs. The main difference between FWS and subsurface flow system is the amount of gravel media which affects the construction costs. Although it is not possible to stablish universal cost guidelines, every system shares a similar set of construction components. Kadlec and Wallace, (2009) reported some equations for calculating costs of FWS and HSSF systems depending on surface needed or flow rate. As an example, for a 1 ha FWS system, total costs would be $480,000 (for 2006 USD), which means $48/m^2$.

Area:

FWS: $C=194A^{0.690}$ $R^2=0.79$ $0.03<A<10{,}000$

HSSF: $C=652A^{0.704}$ $R^2=0.75$ $0.005<A<20$

HSSF: $C=561A^{0.498}$ $R^2=0.76$ $0.5<Q<10{,}000$

where:

A= wetland area, ha

C=cost, 2006 dollars in thousands

Q=flow rate, m^3/d in thousands

DiMuro *et al*., (2014) reported a study in which a comparison of economic and environmental costs of a constructed wetland vs. a sequential batch reactor (SBR) was assessed. The selected industry was the wastewater treatment facility of a large industrial complex containing several manufacturing units involved in the production of plastic resins and other organic chemicals. Wastewater and storm water captured in containment areas are routed through the wastewater treatment system. The input variables for the design of both systems were flow rate ($6.9 \cdot 10^6$ m^3/year), total organic carbon (TOC, 500 mg/L), COD (1500 mg/L), BOD_5 (875 mg/L) and TSS (918 kg/d). The financial results indicated that the total net present value savings calculated for implementing the CW instead of the SBR reactor was $282 million over the project's lifetime (30 years). The Life Cycle Assessment (LCA) demonstrated that the lower energy and material inputs to the CW resulted in lower potential impacts for fossil fuel use, acidification, smog formation, and ozone depletion and likely lead to lower potential impacts for global warming and marine eutrophication.

CASE STUDIES

Winery Wastewater Treatment

Winery wastewater is generated by the various processes and operations carried out in wine production, and wastewater comes mainly from the water used to wash equipment and bottles and from the cooling processes.

Winery wastewaters contain COD concentrations ranging from 500 to 45000 mg/L and total suspended solids (TSS) from 12 to 7300 mg/L, while BOD_5 is about 0.4-0.9 of the COD value (Shepher *et al*., 2001; Petruccioli *et al*., 2002; Masi *et al*., 2002; Mosteo *et al*., 2008). The concentrations of nitrogen and phosphorus compounds in winery wastewater are usually low and the pH varies from 3.5 to 7 (Serrano *et al*., 2009).

Conventional biological treatment systems do not effectively treat wastewater generated by wineries (Petruccioli *et al*., 2002; Mosteo *et al*., 2006), as wastewater from these facilities are highly concentrated in terms of COD and show highly variable flows and loadings, both daily and seasonally. CWs have also been considered as a means to treat this wastewater (Masi *et al*., 2014). Wetlands remove efficiently

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

organic matter, excess nutrients and other pollutants. CWs are robust and can assimilate large and highly variable flows and organic loadings and neutralise low pH.

As a complement and to ensure the best performance, anaerobic pretreatment such as hydrolytic upflow sludge bed (HUSB) digesters are recommended. HUSB is an intensive, efficient and low-cost technology for domestic wastewater and industrial wastewaters (Álvarez *et al*., 2008) that can also be applied to the pretreatment of winery wastewater (de la Varga *et al*., 2013a).

Winery Wastewater Treatment in Hybrid CW System in Spain

In this section the authors summarize the results obtained on a full-scale hybrid CW with an anaerobic digester as primary treatment, followed by CW which combined VF and HSSF units for treating winery and a touristic and restaurant wastewater component (which provided higher nutrients concentration than a normal winery). (Serrano *et al*., 2011; de la Varga *et al*., 2013b). The wastewater was previously pretreated in an HUSB digester (de la Varga *et al*., 2013a). The system installed showed an average removal efficiency of 76, 26 and 21% of TSS, COD and BOD respectively. The anaerobic digester mainly initiated the ammonification of organic nitrogen compounds and the acidification of organic matter.

Description of the Plant

The full-scale plant was designed to treat the wastewater coming from a winery with a production capacity of 315000 L of white wine. The touristic and restaurant component increased nutrient concentration of wastewater.

The constructed-wetland system consisted of a HUSB anaerobic digester 6 m^3 in volume, a VF CW 50 m^2 in area and three HSSF CW at 100 m^2 each. The water depth for HSSF1 was 0.3 m, while the depth for HSSF2 and HSSF3 was 0.6 m, respectively. CWs were planted with three to four units/m^2 of *Phragmites australis* (VF) and *Juncus effusus* (HF) and started up on April 14th 2008.

CW Performance and Efficiency

Average influent temperature was 20.2±4.5 ºC, while effluent temperature was in general 3 ºC lower (17.2±4.6 ºC in average, ranging from 12 to 28 ºC). Average influent pH was 6.41±0.95, while effluent pH was 6.7±0.5 (ranging from 5.4 to 7.4), and then the wastewater increased pH in 0.5 units passing through the HSSF wetlands.

The average surface loading rate (SLR) to the VF ranged from 43 to 466 g COD/m^2d and from 22 to 296 g BOD_5/m^2d, while COD removal ranged from 29% to 70% and BOD_5 removal from 36% to 68%. Thus the VF unit reached high surface removal rates of up to 153 g COD/m^2d and 107 g BOD_5/m^2/d.

Influent TSS levels to HSSF were generally low as they had been efficiently removed in the preceding steps of the plant (mainly in the HUSB reactor). Therefore, SLR of suspended solids remained low (ranging from 0.5 to 5 g TSS/m^2·d) and solids have been efficiently removed in HSSF units, which reached TSS effluent concentrations below 44 mg/L (17 mg/L on average) and TSS removal efficiencies of about 74%.

Influent COD and BOD_5 were highly variable, ranging from 50 to 4000 mg COD/L and from 12 to 2400 mg BOD_5/L (n=68). Higher influent concentrations and flows were registered for vintage phases of years 2008 and 2009, respectively. This led to highly variable SLR to the HSSF units, ranging from

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

4-85 g TCOD/m^2·d and from 2 to 49 g BOD_5/m^2·d. TCOD and BOD_5 removals were generally between 60 and 80% but clearly decreased when the influent concentration or the SLR applied increased.

Regarding nutrient removal, variable concentrations of nitrogen and phosphorus compounds were present in the influent, due to touristic and restaurant component of the wastewater. Influent TKN of VF CW was between 19 and 109 mg N/L (average of 52.9 mg N/L) and the VF effluent ranged from 11 to 63 mg N/L (average of 26 mg N/L). Ammonium concentration ranged from 1 to 101 mg NH_3/L in the VF influent (average of 28 mg NH_3/L) and from 0.6 to 76 mg N/L (average of 19 mg NH_3/L) in the VF effluent with an average removal of 32% (made on average values). This relatively low nitrification might be due to high organic load in the VF CW which primary consumed the oxygen present and subsequently reducing nitrification. Phosphate in the VF influent ranged from 0.28 to 5 mg P/L (average of 2.3 mg P/L) and from 0.9 to 6.3 mg P/L (average of 2.4 mg P/L) in the VF effluent. HSSF effluent concentrations of TKN, ammonia and phosphate ranged from 12 to 52 mg N/L (average of 25.2 mg N/L), from 2 to 52 mg (average of 12.5 mg N/L) and from 0.3 to 6 (average of 1.9 mg P/L), respectively. Removal of nitrogen compounds and phosphate in HSSF units was reduced, ranging from 6 to 29% on average. Limited data indicates that polyphenols removal averaged 39% in HSSF units.

The full-scale hybrid CW system successfully treated winery wastewater. Surface removal rates up 41 g COD/m^2·d, 25 gBOD_5/m^2·d and 4.4 g TSS/m^2·d were reached by the overall (VF + HF) system. Overall percentage removals ranged from 54% to 93% of COD, 45% to 95% of BOD_5 and 75% to 94% of TSS. The overall system also removed up to 1.4 gTKN/m^2·d (52%), 0.7 gNH_3/m^2·d and 0.04 g PO_4^{3-}/m^2·d (17%).

Upgrading of a CW System for Winery Effluents in Italy

The Cecchi system in Italy (Masi *et al*., 2002; 2014) consisted of an Inhoff tank, a single stage of HSSF of 480 m^2 and a FWS of 850 m^2. Due to growing production of the winery, the treated flow increased from 35 m^3/d to 70 m^3/d. An upgrading of the treatment plant was developed in 2009, with a French reed bed (FRB), followed by four parallel HSSF, with the existing FWS and optional sand filter before discharge into fresh water (Gena River). Results from a 3 years period show a COD reduction of up to 96% even at peak loads while COD average removal efficiency was 75%. For the HSSF unit, average removal was 87%.

Further Considerations about CW Design Criteria for Winery Wastewater Treatment

Hybrid systems of CWs can themselves treat winery wastewater, as well as a complement to other systems like sequential batch reactors (SBR) or activated sludge. For small wineries producing less than 100.000 L wine/year, a septic tank +HSSF CW with more than 5 days of HRT during peak flow period can ensure a proper treatment for fresh water discharge or for irrigation purposes (Masi *et al*., 2014).

A good pretreatment or primary treatment to decrease the solids and the organic particulate matter is important. For small wineries, a septic tank could be enough if a sort of resting period of 10 months with lower organic and hydraulic loads takes place. For bigger wineries, this first stage (SBR, FRB, etc.) should remove 40-50% of pollutants from the raw wastewater.

Some of the wineries have additional nutrients in the wastewater, like black waters from employees, small households or restaurants. No supplementation of nutrients has been necessary, as well as neutralization of low pH. If we do so, performance of CWs might be increased, and this is a good point for future research.

HIGHWET Project for Food Processing Industry

The research project "Performance and validation of HIGH-rate constructed WETlands" (HIGHWET), under the European call FP7-SME-2013-1, was developed during years 2013 to 2015. There were two pilot plants, one located in Spain to treat domestic wastewater, and the other "real" plant was implemented in Denmark, to treat the discharges generated from a food production factory, a house inhabited by the factory owners and a small dairy factory.

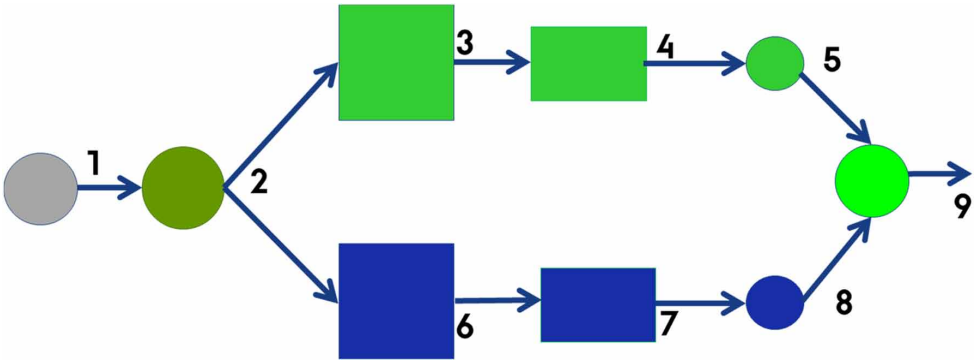
The final design includes a combination of the anaerobic treatment HUSB reactor, aerated *CWs* and conventional CWs. In addition, the system was fitted with reactive media to improve phosphorus removal in order to achieve discharge limits.

Figure 2 presents the layout and the different units of the treatment plant. During the project, inflow was limited to 1000 L/d to control the process. After a pumping well, water is conducted to the primary treatment, which is a HUSB reactor. Then, the system is split in two treatment trains. The first one (aerated train) is composed by an aerated VF, an aerated HSSF and a phosphorus removal well, filled with tobermorite. The second train (conventional train) has a conventional VF, an aerated HSSF and a second phosphorus removal well, with polonite. Both VF beds have an area of 16 m^2 while the HSSF beds are of 3 m^3 followed by wells of 1 m^3. The aeration systems installed in the beds supply air to the beds using individual blowers that provide atmospheric air to increase the oxygen availability and improved the aerobic depletion processes of pollutants. The aeration time to each wetland cell can be regulated depending on the operation planned. The aerated train treated 80% of the total flow, and conventional train treated 20% of the total flow.

Operation of the Plant

During the plant operation, pollutant loadings, aeration times and hydraulic loadings by recirculation of VF effluent to the pumping well after the HUSB reactor were changed to determine the capacity of the plant. In this sense, five campaigns were carried out under different operational conditions. As the

Figure 2. Sampling points along the treatment trains 1) inlet; 2) after the HUSB, 3) after the aerated VF; 4) after the aerated HF bed; 5) after the P removal filtered filled with tobermorite 6) after the non-aerated bed 7) after the aerated bed 8) after the P removal filter filled with Polonite 9) final effluent



EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

wastewater produced at the site did not reach the projected organic and nutrient loadings, a system with a prepared solution was installed to increase the pollutant and hydraulic loads. The loading solution was prepared using a blend of pig manure, molasses, starch, urea and fertilizer.

After plant start-up (campaigns 1 and 2), several monitoring campaigns with high nutrient loadings were carried out (campaigns 3, 4 and 5). During campaigns 3 and 4, aeration schemes were changed in order to increase the total nitrogen removal, and during campaign 5, recirculation (increasing to around 80% the hydraulic load to each bed) from the VF effluent to the well after the HUSB was implemented. Following, the efficiency reached during campaign 3 is presented (Table 3). Similar results were obtained for campaigns 4 and 5.

The third campaign took place in May when temperatures increased and the local weather was mild. The vegetation growth was better in the aerated beds, due to higher water flow that allowed major nutrient availability. On the other hand, plant growth in the passively aerated beds was poor. The water temperature did not change too much, compared to the winter temperatures, due to low temperatures at night. As expected, anaerobic conditions were prevalent before and after the HUSB digester. After this primary treatment, dissolved oxygen was close to saturation generally, except in aerated beds when aeration regime was decreased to improve denitrification.

Total suspended solids were efficiently removed, with a concentration in the final effluent below 3 mg/L. A high COD percentage was removed at the HUSB reactor, and further COD removal was high in both VF beds which reached similar effluent concentrations. Along the system, biological oxygen demand (BOD_5) was removed to very low concentrations.

During the third campaign, the HUSB reactor removed around 20% of NH_4^+, so NO_3^- was denitrified effectively in this stage. After the HUSB reactor and in both treatment trains, N-removal was effective producing nitrified effluent with a NH_4^+ concentration below 1 mg/L. The results show that the NH_4^+ nitrified in the aerated VF bed is also denitrified during the shut-off time after the oxygen supply. The conventional VF bed does not show the same denitrification rates as the aerated bed and the effluent from the bed has a NO_3^- concentration of 40 mg/L. Even though NO_3^- seems high in the outlet, concentration in

Table 3. Pollutant concentrations at the different sampling points during campaign 3. Concentrations are presented in average. BDL: Below detection limit

Sampling point	TSS (mg/L)	COD (mg/L)	BOD_5 (mg/L)	NH_4^+ (mg/L)	TN (mg/L)	TP (mg/L)
Inlet	117	5268	4167	250	382	25.1
After HUSB	25.2	2055	1383	197	201	18.2
Aerated train						
After aerated VF	22.6	211	44	5.2	11	5.2
After aerated HSSF	33.6	156	6	0.12	9	4.0
After tobermorite	33.8	156	6	0.14	11	2.2
Conventional train						
After VF	86.5	174	3	0.10	42	2.9
After aerated HSSF	101.7	82	2	BDL	40	1.2
After polonite	102.7	61	2	0.7	45	0.5

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

the inlet was much higher and denitrification was considerable in the passive VF. Total nitrogen followed the same dynamics as the nitrogen species. Phosphorus removal was effective in both tested materials, but the P concentration in the effluent after tobermorite material was higher than the Danish limits.

In all campaigns, the percentage of total nitrogen removal was higher than 80%. The HUSB reactor removed between 30% and 40%, corresponding to NO_3^- denitrified. The aerated VF bed performance of total nitrogen removal was better for periods with discontinuous aeration compared to continuous aeration, as well as with recirculation of nitrified VF effluent. The non-aerated VF nitrified quite well, and removed total nitrogen as well, which means that some parts of the bed have good denitrifying environmental conditions.

CONCLUSION

Constructed wetlands are engineered systems that have been designed to utilize natural processes involving wetland vegetation, soils, and their associated microbial assemblages to assist in treating wastewater. In CWs, removal of pollutants takes place due to physical, chemical and microbial processes including, among others, sedimentation, sorption, precipitation, evapotranspiration, volatilization, photodegradation, diffusion, plant uptake, and microbial degradation (i.e. nitrification, denitrification, sulphate reduction, carbon metabolization, etc.). The most used types of CWs are the FWS, the HSSF and the VF. For improving the performance and the removal of pollutants and nutrients, a combination of these systems, the hybrid systems, may be used. CWs are also used to recover nutrients from the macrophyte biomass and particularly from sludge in the sludge treatment wetlands. Nowadays, CWs have been applied to the treatment of different kind of wastewaters as such as refinery and petrochemical industry effluents, food industry effluents including abattoir, dairy, meat, fruit and vegetables processing industries, distillery and winery effluents, pulp and paper, textile, tannery, aquaculture, steel and mixed industrial effluents.

The reached efficiencies can vary depending on the wastewater characteristics and the system design features and operational conditions.

Regarding environmental conditions, CWs can work in extreme weather conditions ranging from the coldest one to tropical conditions. TSS, COD and BOD_5 are potentially removed in any kind of CWs if proper design and loading rates are provided.

On the other hand, nitrogen removal requires the combination of adequate oxic and anoxic/anaerobic conditions which can be provided by hybrid systems and other intensified systems involving water recirculation or artificial aeration.

Phosphorus removal requires extensive application of CWs (large footprint) or specific filtering substrates to absorb phosphorus compounds.

As reviewed, CWs are particularly suitable for the treatment of dairy parlour wastewater, cheese production wastewater and other food industry wastewater, as well as for tannery and winery wastewater.

KEY TERMS AND DEFINITIONS

Hydraulic Loading Rate (HLR): Amount of influent wastewater per unit of wetland surface. It is often expressed as mm/d, which means $L/m^2 \cdot d$, or cm/d.

Hydrolytic Up-Flow Sludge Blanket Reactor (HUSB): Up-flow anaerobic reactor in which only hydrolysis and sedimentation of particulate organic matter and solids are aimed, avoiding methanogenic reactions.

Surface Loading Rate (SLR): Amount of a certain pollutant applied to a wastewater treatment system per surface and time units.

Surface Removal Rate (SRR): Amount of a certain pollutant removed in a wastewater treatment system per surface and time units.

Chapter 28
Economic Instruments for Sustainable Environmental Management

Günay Kocasoy
Bogazici University, Turkey

ABSTRACT

Environmental pollution has been continuously threatening the world. In the combat with environmental pollution problems, waste management authorities, in compliance with the "User Pays Principle-USP", apply the "Polluter Pays Principle-3Ps" to the waste generators. Thus the resource users and the waste generators will be paying a fee for the resources and services they are using. They can be summarized as water fee, wastewater discharge fee, effluent permit fee, air emission fees, solid waste disposal fee, landfill tax, and hazardous waste tax and product charge, Advance Disposal Fee (ADF), Ozone-Depleting Chemicals (ODC), government product charge and road user fees. The main purpose of charging a fee is to encourage the users and the polluters to reduce the amount of pollutants they are generating and disposing into the environment. These fees can also be named as "a pollution charge fee", "user charge fee" or "product charge fee". This chapter outlines the many existing waste fee models.

INTRODUCTION

Environmental pollution has reached to such a high level which causes global disasters that threaten the public health and natural resources. The natural resources such as water, minerals and fuel are not limitless. Extraction of virgin materials and usage of these amenities carelessly will eventually end up as waste in the form of disposals/emissions to land, air and water (European Commission, 2011a; Söderholm, 2011). Throughout the world the waste amounts are growing, and so is the sensitivity and concern about how to deal with them and the corresponding environmental problems (Bruvoll, 1998). According to the research studies conducted, global municipal solid waste amounts will increase at an annual rate of 2.4 per cent through the year 2019 (Beede & Blom, 1995). The waste management au-

thorities have been having difficulties both in handling and financing the environmental protection and clean-up activities lately. On the other hand waste management is also important for achieving several other environmental quality objectives including "reduced climate impact" and "a non-toxic environment". Waste management in many countries has undergone significant changes during the last decades (Finnveden, et.al., 2013; Broome, 1992).

In the combat with the generated environmental pollution problems, several policy instruments such as "Polluter Pays Principle-3Ps" in compliance with the "User Pays Principle-USP" can be effective and possible to implement. Thus people will be paying a fee for the services they are using. This fee can also be named as "a pollution charge fee", "user charge fee" or "product charge fee". Although all of these terminologies are used interchangeably, they have subtle differences in their meanings. A pollution charge fee is a fee based on the quantity of pollutants that are disposed into the environment. A user charge fee is a fee paid for using natural resources or for the collection and/or disposal of pollutants (European Commission, 2011b). A product charge fee is a fee imposed on products that are having negative impacts on environment. While "tax" is used for the revenue rising instruments, "fee" and "charge" are the applications used to offset costs to the government. Those charges and fees collected are retained to be used to supplement the budget allocated for the protection of environment and management of wastes (ISWA, 2011; Kocasoy, 2014).

Most environmental taxes are designed to fund environmental protection activities. The economic rationale behind them is that those who generate and cause environmental pollution should bear the costs of both damages to the environment and the administrative costs incurred. To be economically efficient, environmental taxes should include both of these costs. The fee should cover all the costs of the collection, treatment and final disposal of wastes as well as the costs of the administrative work and the operation of the waste management, treatment and disposal facilities. The most important issue in the design and the application of the waste fee model is the "fairness"

ENVIRONMENTAL FEES-TAXES

In the following sections various environmental fees and fee models will be discussed. After the discussion of some of the environmental fees such as water fees, wastewater discharge fees, air emission fees, permit fees, air toxics and ozone-depleting chemicals emission fees, solid waste disposal fees and landfill fees, criteria in the design of the solid waste disposal fees and the different fee models will be explained in detail.

Water Fees

Water fees are classified as user fees for groundwater, surface water or drinking water supplied by waterworks and as fees for direct or indirect water discharges. The idea behind the water user fees is that water is not a free unlimited resource but rather a scarce commodity that should be priced to avoid inefficient use and environmental pollution. The water fees are designed to raise budget to recover costs of providing service rather than the allocation of the scarce resource among competing needs (Bruvoll, 1998; Smith, et al., 2011).

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Direct Water Discharge Fees

The rationale for discharge fees is being in compliance with the Polluter Pays Principle. While discharge fees in some countries varied according to discharge volume and toxicity, at some others fees are charged according to discharge volume alone. The criteria used by different countries in setting fees include the purpose of the water use, the characteristics of the receiving water, and the type of the facility releasing the discharge. (Toj, 2008).

Indirect Water Discharge Fees

Households and businesses that discharge their wastewater into Publicly Owned Treatment Works (POTWs) are subject to indirect discharge fee. Fees for Publicly Owned Treatment Works (POTWs) are sometimes based on the size of the population that is connected to the local sewage system. Most of the time, the water and wastewater utilities that service households or businesses are one and the same. Then a single invoice includes both water use fee and discharge fee. In most cases water used is measured but wastewater discharged is not. They are assumed to be equal in volume to water usage, consumption. Some discharge fees for large businesses are based not only on water use but also on discharge toxicity. This is an incentive for the businesses to reduce the volume and the toxicity of their discharges.

The effect of the water user fee on the reduction of water usage and consequently polluting potential depends largely on the elasticity of the demand for water, that is whether demand is responsive to changes in price or not. If the demand is inelastic, an increase in user fees will not affect consumption behavior in a significant way. If demand is elastic, however, consumption behavior is going to be changed by raising the water usage fee. Although water demand is often assumed to be inelastic, research studies conducted indicated that household water demand is inelastic in winter but elastic in summer. The researches also showed that water demand by industrial and agricultural users is sensitive to price changes (Piotr & Malecki, 2010).

To promote water conservation, there are suggestions about the use of rate schedules that impose higher rates per certain cubic meter after the consumption of certain volume of water.

Effluent Permit Fee Structures

The primary purpose of effluent fees is to discourage high volume of wastewater discharges to prevent receiving water media pollution. Then the second purpose is to raise revenue for the administrative costs of the effluent permit program. Most of the time fees are based on easily measured parameters that are related to discharge characteristics. At most of the cases fee structures have broad classes for discharge volume or toxicity level, or both. Since these structures impose the same fee within a set volume or toxicity bracket, polluters have no incentive to limit discharges unless they can move from a lower fee bracket to a higher one.

At some countries the annual permit fee is determined by a worksheet that assigns points on basis of several factors such as flow volume and type; pollutants released; heat load; potential public health threat; facility complexity and the designation of a facility as major or minor depending upon how many people it employs. The points are multiplied by a rate factor of certain dollars per point for municipal facilities and higher amount of dollars per point for industrial facilities to determine total annual fees (Speck, 2006).

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

At some other countries annual fees are based on the threat to water quality and the complexity of the permit. The characteristics are classified at three categories as categories I, II, and III for the level of threat to water quality; and as categories a, b, and c for the complexity of the permit. Permit holders with an I-a rating (the greatest threat to water quality and the most complex permits) pay the highest fees and III-c permit holders pay the lowest fees annually. Some countries also charge Bay Protection and Toxic Clean-up fees to dragging operations, boat construction and repair facilities and beach replenishment activities in addition to the annual permit fee. The highest Bay Protection Fee is charged to the I-a permit holders while the lowest fee is charged to the III-c permit holders (Ocean Conservancy, 2007; Moore et.al, 2001).

The effluent fee system in which the most harmful pollutants are taxed at the highest rate per unit volume has potential incentive for the polluters to reduce both the quantity and the toxicity of pollutant releases (Nordic Council of Ministers, 2006).

Air Emission Fees

Countries use emission fees as an air quality management tool. Most of them impose fees for issuing air emission permits. Some of them also charge fees on Volatile Organic Carbon (VOC) emissions.

The authorities impose permit fees to recover the administrative costs. They charge a fee of certain dollars/Euro per unit weight of emissions of air toxics. The rate increases as the pollutant amount moves to a higher bracket. Each level of pollutants has different rates. Some countries base their fees not only on the pollutant level, but also on the pollutant's potential harm to the environment. Facilities that exceed their allowable emission levels must pay excess emission fees. The excess emission fees for the pollutants such as Sulphur oxides (SOx), nitrogen oxides (Nox), Volatile Organic Carbons (VOCs) and particulate matter are about the same as the regular fees while emission fees for carbon monoxide, asbestos, cadmium, hexavalent chromium, chlorinated dioxins, 1.3 butadiene and lead is approximately twice as high (European Commission, 2011a; Söderholm, 2009).

Solid Waste Disposal Fees

Variable rate programs are used for the design of the solid waste disposal fees. Application of the solid waste management fee is a relatively new trend for the household wastes. The primary purpose of these fees such as the household waste collection fees/taxes, landfill fees/taxes, and hazardous waste disposal fees/taxes is to discourage waste generation and encourage recycling. Unfortunately, they also are incentives for the disposal of waste illegally or to transport waste to other locations where disposal is cheaper (Pires, et. al., 2011).

According to Fischer and his colleges (2012) there is some variation regarding the waste types covered by the landfill tax, but this variation is not very large between countries. Tax is charged on construction and inert wastes; residues, hazardous waste and biodegradable waste. In some countries the tax only covers non-hazardous waste (European Commission, 2011b).

The landfill tax level varies between countries. Different tax levels have been depending on the waste type. Inert waste types, residues from incineration of waste or construction waste generally have a lower tax level than mixed municipal waste. Also most countries operate with only a limited numbers of tax levels (1-3), while some countries have more differentiated tax system. Increased taxation levels have a considerable economic incentive for diverting waste away from landfills to other treatment forms (Mayers, 2011).

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

The main aim of the tax is to reduce the amount of waste that is landfilled, and to make the environmentally friendly handling of waste more attractive. Several tax rates are charged to reach the aim and as the tax rate increases, the diversion of waste from landfill increases (Kinnaman, 2010).

Hazardous Waste Tax

Taxes charged to hazardous waste have different rates based on the final removal method. Some countries charge higher tax rates for landfilling than for incineration. In some other countries, taxes per ton vary according to the type of waste. All the taxes are based on the tonnage of the hazardous waste to be treated. Removal fees vary by quantity removed with rates fixed within a given range of tons per year.

There are two fees applied to raise revenue and to encourage waste minimization. The fee of the tonnage of hazardous waste sent to landfills is lower than the incineration. Although this leads to the decline in the tonnage sent to the landfilling, it is difficult, however, to determine to what extent this decline is due to the fees, because there are many other factors that influence the generation and disposal practices. According to a research conducted, due to the differences in the disposal type, the amount of waste incinerated rose, but it did not increase as much as the amount of waste sent to landfills declined. Also according to another research about the impact of the landfill and incineration taxes on the generation of four types of chlorinated solvent wastes from metal cleaning industry, the quantity of the hazardous wastes sent to landfills or incinerators was very sensitive to the tax. The other outcome of the research was that taxes encouraged generators to choose incineration or other treatment options rather than landfilling as their waste management method. However, the estimated impact of these taxes was minor because the fees were low in comparison to the total costs of waste management (Watkins, et al., 2013).

The social cost of hazardous waste generation should also be reflected at these taxes in order to maximize the efficiency of the taxes. This cost depends on the factors, such as the type of waste, method of disposal, geographic location which are difficult to assess and incorporate into the fee structures. Beside these, if taxes are too high, illegal dumping will be encouraged and it will cause enough environmental damage to offset the increased efficiency achieved by fees (Mayers, 2011).

Product Charges

Product charges are imposed on either a product or some characteristic of that product whose disposal causes environmental pollution. These are charges on chemicals, fuels, transportation and transport equipment. Fees charged to the products are a kind of advance disposal fee of the product for its proper disposal after the completion of its useful life. Therefore they have minimum effect on incentives for the reduction of the products.

Another mechanism is the take-back responsibility of the manufacturer who is responsible for the proper disposal of the wastes. This is called as the "extended producer responsibility" (Monomaivibool & Vassanadumrongdee, 2011; Watkins, et al., 2013).

Ozone-Depleting Chemicals

After the 1987 Montreal Protocol on Substances that Deplete the Ozone Layer the production of ozone-depleting chemicals (ODCs) such as chlorofluorocarbons (CFCs) is taxed. The magnitude of the tax is determined by multiplying a base rate per unit weight of ozone-depleting chemicals produced or imported

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

by an ozone depletion factor that is set by the Montreal Protocol. The ozone depletion factors indicate each chemical's damage to the ozone layer and vary according to the type of chemical. For example, methyl chloroform has a factor of 0.1, whereas Halon-1301 has a factor of 10.0, which means that methyl chloroform is less harmful to the ozone layer than the Halon-1301. The producers and importers of these chemicals as well as the products that contain these chemicals are responsible for paying these taxes.

Unlike most product charges, ODC tax has a significant incentive impact on the reduction of the ODCs consumption. They are either substituted or recovered for reuse (Mayers, 2011).

Government Product Charges

Some governments have imposed charges on some products such as beverage containers, refrigerators, furniture, tires, fertilizers, motor oil, pesticides and solvents. These charges are in the form of advance disposal fees (ADFs). Some governments also impose litter tax on the sale of some products which are commonly found in litter (Beck, 2007; Carlozo, 2008). Many governments impose severance taxes on the removal of minerals from the ground.

Another product charge is the tax imposed on the tires. Because of the lack of substitutes for tire, the incentive effect of tire charges on the buyers of tires is minimal. On the other hand, the system encourages the proper disposal of tires. Governments use the tire fee revenues to subsidize recycling of tires as well as the development of markets for end uses of used tires, such as rubberized surfaces, noise barriers, blasting mats, and rubberized asphalt pavement and for the clean-up of tire disposal sites.

Litigation has been pursued against manufacturers of products that damage the environment. In fact, entire communities have filed class action lawsuits to sue polluters, and these cases are typically based on two tort theories: negligence and nuisance. (Novotny, et.al, 2009).

There are also some governments charging fees for "hard-to-dispose materials "such as antifreezes and lubricating oils (Watkins, 2013).

Advance Disposal Fee (ADF)

Concern about toxic waste resulting from some technology products such as computers, telephones, and televisions, has given rise to the implementation of a legislation which is a consumer funded Advanced Recycling Fee (ARF). It is obtained at the point of purchasing the products. These fees are intended to pay for the costs of recycling the item and the cost of disposing any non-recyclable material properly. The fees, compared to the cost of the products, are minimal (Thompson, 2002; Hogg, 2012).

Some countries also imposed a low tax to a variety of containers. Containers made of plastic, plastic-coated paper, and glass that had average recycling rates of at least 50%; and glass, plastic, aluminum and steel containers having respectively 35%, 25% and 50% recycled content are exempt from this tax (Edjemo & Söderholm, 2008).

Although low ADF tax imposed on "white goods," such as refrigerators and freezers does not have a significant incentive effect, it generates revenues to manage the disposal of white goods.

Another aspect of the ADF is the option for the companies to work with other firms in the same sector to raise recycling rates, to increase the recycled content of packaging to obtain exemptions (Nicolli, et.al, 2012; Nakatani, et.al, 2010).

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Road User Fees

Tolls, which are the most common type of road user fees, are mostly unrelated to environmental protection. They are generally used for the road construction and maintenance.

However, the tolls designed according to the heavily usage of the road and the tolls varying according to the time of the day help the coverage of social costs of traffic congestion. One of these costs is the increased emissions per kilometer travelled. Congestion pricing is an important environmental management tool. The economic gains from congestion pricing can be more effective than any other traffic management tool. (Florida Department of Revenue, 2015).

Toll fees designed according to the time of the day should be announced in advance, so motorists can plan their trips accordingly. Drivers, by using windshield-mounted transponders, can pay toll-lane use without stopping at toll booths. Some countries exempt the vehicles having three or more occupants, public transportation vehicles, zero-emission vehicles, and vehicles with a disabled-person license plate paying the tolls.

SOLID WASTE FEE DESIGN

Waste management authorities at many countries are charging solid waste collection fee based on the volume or weight generated by the household. EPA is also encouraging variable rates. Variable rate programs are applied in different forms such as prepaid garbage bags required for collection, or collection fees that are based on the number of containers, the size of containers, or both of these characteristics. Some other communities have weight-based systems. Most popular ones are mixed programs that combine a fixed rate programs which entitles households to allow the collection of a pre-specified amount of waste and then incremental rates for amounts in excess of the maximum amount covered by the flat rate These programs are relatively easy and inexpensive to implement and they have the potential to reduce illegal dumping (Dahlén & Lagerkvist, 2010; Kocasoy, 2015).

Collection systems that require periodic billing are likely to be more expensive to administer than bag systems. On the other hand, the disadvantage of the bag system is the torn of the bags if they are handled improperly or opened by animals.

Charging waste fee has many constraints. People in some countries are not ready to pay for the waste they are generating and for the related services they are using. There are different models of waste management fees. Each of them has advantages and disadvantages. There is not a single model which can be accepted as “fair” by everybody.

There are many issues, which differ from region to region, to be considered in choosing the fee model. The issues to be considered in the development of a “fair-suitable fee model” are as follows:

- Fairness,
- Independence of fee-models and the collection system,
- Fixed and variable costs to be covered,
- Social effects,
- Administrative costs,
- Behavior / attitude of the residents and
- Influence of the waste authority (Hauer et.al, 2011; Ljunggren, 2011).

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

General Requirements

There are many requirements to be met in developing waste fee. Some of them are legal requirements while the others are economic, financial and social aspects. The general requirement/request is the "fairness". Although there is not a single model that can meet all these requirements completely, the model developed and applied should be practical, suitable and appropriate for the region. General requirements of waste management fee models can be summarized as follows:

- The User Pays Principle should be applied,
- The fee should be based on the system's policy such as dispose or recycle,
- Each model should encourage people to generate less waste,
- Each waste generating facility should be within the public waste collection region,
- Some commercial and institutional waste generators prefer to take the responsibility of collection and disposal of the wastes themselves - "self-disposers",
- It should be simple, so that it can be applied very easily. It should be transparent and reduce both the regulation and the administration requirements,
- The fee should cover both the collection and disposal costs, there should be no differentiation between them,
- Fee should be collected either monthly or yearly,
- Differentiation between the "household waste" and the "commercial waste" should be made according to the waste composition and/or the amount of the waste (Hauer, et.al, 2011; Tyskeng, 2012).

Interrelation between the Collection System and the Fee Model

The waste fee model applied should be in compliance with the type of the waste collection system. The waste fee should be based on the measurable quantity such as weight or the volume of the waste of the identifiable generator. The generator cannot be identified if the waste is collected from the containers placed at the curb-side.

If the waste is determined according to the data which changes very often such as the floor space, number of the residents using the same single house or the value of the premise, the data should be updated periodically which causes the increase of the administration cost. Therefore the waste fee should be based on the data which do not change frequently and can be understood clearly by the public. If the collection system applied based on the collection of the containers of single premises, the fee can be based on either the volume of the containers or the number of emptying the containers during the collection period.

Specifications of the Different Fee Models

It is not possible to apply a fee model which will satisfy all people in the community. (Ohio EPA, 2015). There are many requests from different stakeholders which cannot be met by a single fee model. Some of the issues of the applied fee models are explained in the following sections.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Fairness

The fairness of the fee model applied is very important for the acceptance of the public. It should be kept in mind that every fee model has some kind of unfairness for some stakeholders. Decision makers should be careful not to have the waste fee based on the data that is difficult and costly to obtain. For example, measurement of the weight or the volume of the waste of every single premise is much more costly and requires more effort than the measurement of the mass of the waste of the whole city by just weighing the collection / transportation vehicles at the disposal site. Also identification of the quantity of the waste disposed by the different residents of the multi-storage buildings using a single container requires additional effort. The easiest method is the application of the waste fee based on the volume of the waste container multiplied by the number of emptying. For the multi-story buildings, the administration of the property-building can break down the cost based on the floor space or the number of the residents in the premise which can be decided and accepted by the owners (Kocasoy, 2014).

Distance of the Settlement Structures to Collection Points

Another issue of fairness is the distance of the source of the waste generation to the disposal site. The collection cost of the wastes from the houses at open fields is much higher than the ones which are very close to the treatment/disposal areas of the wastes. This reality does not justify charging higher waste fee to those premises at the open field. The fairness of this issue is debatable.

Premises Which Are Used Only for Part of the Year

Another common issue is the application of waste fee for the houses (holiday premises) which are occupied only for part of the year. The waste fee of these houses should be calculated based on the periods/ months that are used. Authorities should assure that no service is given at the months that the buildings are claimed to be empty.

Generated Waste Quantities/Volumes

Waste fee, determined according to the amount / volume of the waste generated, can be applied only if each premise has its own waste container and if there is no collection bins at public places. Thus the quantity of the waste generated / collected can be decided by the size of the container and the frequency of emptying the container. The actual weight / volume of the waste in the container is not considered in this method. Additional measurements should be made to determine the actual amount of waste in the containers which makes the waste collection more expensive.

Waste quantity has effects only on the variable costs which is just a small part of the waste management costs. The fixed costs such as the costs of the collection vehicle, the salary of the driver and the waste collection staff and the fuel used do not depend on the waste quantity such as if the container is full or only 50 percent full. If the waste fee is determined according to the measured weight or volume of the waste generated at a premise, additional administrative costs will occur (Dahlén & Lagerkvist, 2010).

Comparison of the Different Fee Models

The comparison of the advantages and disadvantages of the different models of the fee application are as follows:

1. Fee Model Based on Waste Quantity:
    a. It is the application of the "User Pays Principle". People pay according to the amount of the waste they are generating. It is a fair system.
    b. Disadvantage of this system is that people tend to avoid paying by using public or neighbors' bins or by illegal dumping.
    c. Each premise has to have its own waste container which should be used only by the inhabitants of the house.
    d. Size of the container of the premise and the frequency of the emptying of it should be known.
2. Average (Flat-Rate) Fee:
    a. No incentive for reducing the waste generation as well as for illegal dumping.
    b. The User Pays Principle is not applied.
    c. It is easy to administer if the waste fee is the part of another fee- such as water fee- of the premise.
    d. It is easy to administer if the fee is fixed by known data such as the area of the building, rate of the building and number of the inhabitants living at the premise, etc.
    e. It is more difficult if such a data is not available or if it changes frequently such as the number of residents.

Affordability

Costs of the waste collection and disposal is much more lower than the costs of other public services, such as water supply, waste water treatment and discharge, transport, telecommunication, etc. This is true for all countries of different economic levels. People generally are not willing to pay for the cost of services of collection, transportation and disposal of solid wastes although the fee is lower than the costs of other services. It is irrespective of the level of economic development of the society. It is not the matter of "non-affordability". It is very easy to dispose waste "illegally" without paying any fee which most of the time is not possible for the other services such as the electricity or telephone, etc. (Söderholm, 2010).

Social Effects

The social situation should be also considered when the fairness of the waste fee applied is discussed. The social factors such as families with low income, houses used by a single person, families with many children, and families with newly born babies using disposable diapers etc. should be considered from the point of view of fairness. All of the groups have excuses to pay reduced waste fee; but it is recommended not to make any differentiations at the waste management fee for certain groups or legal entities. If it is necessary to support a special group, this support should be given by other methods, not by reducing the fees.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Administrative Costs

Each fee model discussed needs some data on which the waste fee is based. It is preferred to have a simple fee model which has low administrative costs. Data, such as number of the people in a resident, which changes very often is both difficult to monitor and to manage and also costly. Therefore it is preferred to base the waste fee on data, such as the size/area of the premise, living space which is stable and easy to obtain and has low cost. The minimum data required are the names and addresses of the owners as well as the person who is responsible for the payment of the waste fee of the premise. For more sophisticated fee models, more additional data should be collected and kept up-to- date which will cause extra costs.

Fixed and Variable Costs

Fixed costs are the costs occurred irrespective of the amount of the waste disposed into the waste containers. The main portion of the waste management budget is spent for the fixed costs which cover the collection costs, administrative costs, collection of recyclable goods and costs for public relations. The variable costs include just a small part of the collection cost and the treatment cost of the collected waste. The variable costs are much less than the fixed costs. As the cost of the waste treatment becomes less, the ratio of the fixed costs to the variable costs increases. This indicates that quantity of the waste has a limited effect on the waste management costs. In some waste fee models, fixed and variable costs are charged separately

Citizens' Behavior and Steering Effect

The possible steering effects should be taken into consideration in the design of the waste management fee. It is known that people have the tendency to avoid paying a fee or try to pay a lower fee when they have opportunities to do so (Söderholm, 2010).

Waste fee also should cover the costs of the collection and the administration of the recyclable and hazardous wastes. No extra fee should be charged for them.

There is always a tendency of using the containers allocated for recyclable wastes for the municipal solid wastes. If the same attitude continues in spite of warnings, these containers should be replaced with the municipal solid waste containers and the waste fee should be raised. Thus, the people in that district will start to use these recyclable containers properly.

So the steering effect can be summarized as;

- The fee model should have financial incentive for the reduction of the waste generation,
- The fee should cover the collection of the bulky, recyclable and hazardous wastes.

Influence of the Competent Authority in the Development of the Municipal Waste Management

There should be a single organization within the municipality or the region as an authority for the management of the solid waste in the region. The organization should have the responsibility of all issues related to the solid waste management such as collection system, public awareness, waste treatment, identification / definition of the wastes to be collected separately and recycling methods. This organization should also be responsible for setting the waste fee (Pires, et.al, 2011).

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Another issue is the identification of the responsible authority for the collection of the waste fee. There is a debate about the collection of the waste fee by the private or the public organizations.

Handling the Commercial Wastes of the Companies

In some countries commercial waste generators do not require the services offered by the municipalities, such as collection of bulky or hazardous wastes, taking collection bins from the premises, collection of bio-wastes and special wastes as electronic equipment etc. (Francesc, 2011; Monomaivibool & Vassanadumrongdee, 2011). Thus, the waste fee charged to the commercial waste generators will be less than the fee tariff of the private households. The waste fee for the commercial waste generators will be calculated according to the services given to them. Since the municipality is collecting wastes over a large area with close distances between collection points, the price offered by the municipalities will be lower than the fee offered by private companies specialized on only commercial waste collection. Thus a cost–efficiency can be realized by the municipalities by combining the wastes generated at residential and commercial premises. Thus, the municipalities have a kind of contribution to the fixed costs from the commercial premises which in turn cause the reduction of the average costs (Pires, et al., 2011).

DESIGN OF THE WASTE FEE

In the design of the waste tariff, the authority should take many issues into consideration. Among these, the most important one is the simplicity and the fairness of the selected models. The steps of designing the tariff for the waste fee can be summarized as follows:

- **Simplicity**: The fee model decided should be simple and it should be explained to people very easily.
- **Fairness**: The tariff should be fair to everybody. It should reflect the "User Pays Principle" so the waste generator can believe in the fairness of the applied tariff, but it should be kept in mind that there is not an ultimate fairness.
- **Additional Costs**: Weighing the contents of every waste container causes additional costs. This system should not be incorporated into the waste fee.
- **Fee Collection:** Collection of waste management fee should be considered independently from the "waste collection". Waste collection can be accomplished by a private sector, but the fee collection should be conducted by the public authority.
- **One Waste Management Fee:** Recyclable, hazardous, bulky wastes should be separately collected, but no extra separate fee should be charged for them. All the services conducted should be financed by one fee.
- **Household and Commercial Waste Fee:** Different services are given to households and commercial areas, therefore different waste fees should be applied to them.
- **Affordability:** The fee should be adjusted in such a way that people can afford it. But also it should be kept in mind that people's reluctance to pay the fee should not be confused with the affordability of the people.
- **Stopping the Service:** Stopping the collection of waste is not a solution, but it causes the illegal dumping of the wastes.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

- **Collection of Fee:** It is easier to collect the waste fee together with the fee of other services. Most of the time the waste fee is collected together with the electricity or water bill (ISWA & Abrelpe, 2012).

Who Should Collect the Waste Fee?

There is always a debate going on about the identification of the authority for the collection of the waste fee. The municipality and the private companies are the alternatives for the fee collection. According to the experiences in the past, it is suggested that the municipalities should collect the waste fee.

The disadvantages of the collection of the fee by the private organizations can be summarized as follows:

- Payment losses are higher when the waste fee is collected by the private organizations.
- The fee collected by the private organizations does not include the separated collection of the recyclable, hazardous, bulky wastes and the cleaning of the streets from littering as well as the public relation activities.
- It is also difficult for waste generator to have a waste management contract. It is not possible for each waste generator to have an affordable contract with the private sector.
- People can easily dispose waste "illegally" without paying fee. This is not so easy for the other services such as telephone, electricity, etc.
- The private organizations always have the tendency to stop the service to the people who do not make the due payments regularly. This causes the dumping of wastes illegally and the municipality has to interfere and remove these wastes.
- When the private organization has difficulty in collecting the waste fee, they concentrate their services on the commercial premises and the region in which there is no problem in the collection of the waste fee.
- Public sector such as municipality will have no influence on the waste management method.
- Administrative work of the municipality is not recognized and acknowledged by the public.
- More legislation will be necessary to reach the target.

The advantages of the collection of waste management fee by the regional authority have the following advantages:

- There will be fewer defaults of fee payments,
- Municipality has to finance the other public services such as cleaning the streets,
- Municipality will be sure that waste from each facility is collected,
- Municipality applies the same waste fee to all premises, even for those at remote areas,
- A uniform waste management system in the region is accomplished.

So, as a result it is more reasonable and effective to have the public authority such as the municipality to decide and collect the waste fee.

FUTURE RESEARCH DIRECTIONS

The following topics can be investigated to minimize the use of natural resources, virgin materials and waste generation and encourage the recycling of wastes for the protection of the both natural resources and environment.

- Comparing the impact of the application of different types of fees at different social groups.
- Impact of recycling in the diversion of waste from the landfill. Comparing the amount of waste recycled with the amount of waste diverted from the landfill.
- Comparing the effect of recycling and the effect of application waste fee in the waste minimization at different social groups. Which is more effective?

CONCLUSION

The natural resources have been diminishing very fast by the careless usage of them. These natural resources are not limitless and they are becoming more scare because of the emissions and discharges of pollutant. The authorities apply fee for the services of supplying natural resources and treatment and discharge/disposal of wastes. Thus the Polluter Pays Principle is applied. The aim of the fee application is to minimize the waste generation. The fee model should be designed and the fee should be collected by the waste authorities. There are many fee models and many criteria to be considered in the design of the waste fee. The most important criterion in the designing of the waste fee is fairness, but it is not easy to satisfy everybody about the fairness of the model. It is also suggested to apply to a fee model based on the data which can be obtained easily and not change very often. The fee based on the weight/volume and the pollutant load of the waste generated encourages the people to generate less waste.

KEY TERMS AND DEFINITIONS

Air Emission Fee: Fees imposed for the air emission permit.

Environmental Tax: Revenue rising instruments which are designed to fund environmental protection activities.

Government Charges: Charges imposed by governments on some products such as beverage containers, refrigerators, furniture, tires, fertilizers, motor oil, pesticides and solvents.

Ozone-Depleting Chemicals: Chemicals damaging the ozone layer.

Pollution Charge Fee: Fee based on the quantity of pollutants that are discharged into the environment.

Product Charge: Fee imposed on products that are believed to have harmful effects on environment.

Solid Waste Management Fee: Fee charged for the collection, disposal of municipal solid wastes.

User Charge: Fee paid in exchange for the use of natural resources or for the collection and/ or disposal of pollutants.

This research was previously published in the Handbook of Research on Waste Management Techniques for Sustainability edited by Ulas Akkucuk; pages 192-211, copyright year 2016 by Information Science Reference (an imprint of IGI Global).

ABSTRACT

Water is the most valuable natural resource for all living things and the ecosystem. The quality of groundwater is changed due to change in ecosystem, industrialisation, and urbanisation, etc. In the study, 60 samples were taken and analysed for various physio-chemical parameters. The sampling locations were located using global positioning system (GPS) and were taken for two consecutive years for two different seasons, monsoon (Nov-Dec) and post-monsoon (Jan-Mar). In 2016-2017 and 2017-2018 pH, EC, and TDS were obtained in the field. Hardness and Chloride are determined using titration method. Nitrate and Sulphate were determined using Spectrophotometer. Machine learning techniques were used to train the data set and to predict the unknown values. The dominant elements of groundwater are as follows: Ca2, Mg2 for cation and Cl-, SO_4^2, NO_{3-} for anions. The regression value for the training data set was found to be 0.90596, and for the entire network, it was found to be 0.81729. The best performance was observed as 0.0022605 at epoch 223.

1. INTRODUCTION

It is found that nearly one-third of the Global population is using groundwater for their drinking purpose. Groundwater is the main sources of water supply for local purposes in urban areas as same as in the rural areas in India. Tripathi et al. (2012) had studied that groundwater is an essential natural resource. Be conditioned on its utilization; it can be a renewable and non-renewable or a non-renewable facility. Talabi and Tijani (2013)convey that groundwater studies are an important issue in water quality research because which will directly affect the people due to pollution in various places. Due to pollution, there will be various kinds of disease like typhoid fever, paratyphoid fever, dysenteries, infectious hepatitis, schistosomiasis, Asiatic cholera, back pain, pneumonia, and nasal congestion will attack us severely. Ben et al. (2014)found that water is an important essential need in all humans' life for drinking and all another domestic purpose. In current scenario, up to a considerable extent, it is found that the life and majority of our financial action depend on population. The intemperate requirement on water facility by improving a population of the most developing district like Tirupur aggravate by the collision of environment change results in the drying up of exterior water and exhaustion of groundwater. Selvakumar et al. (2017) evaluated that it is one of the major need features in groundwater studies. The hydrochemical study divulges excellence of water that is a match for drinking, agriculture and industrial needs. Chemical research forms the basis of the explanation of the quality of water in connection to source, geology, use, and climate. Water being a fantastic solvent, it is mainly to know the geochemistry of dissolved voters and methods of announcing analytical facts. Mogaddam (2011) described that in huge groundwater basins, urbanization had created a developing demand for drinking water; while long histories of agricultural bustle have remain aquifers potentially at suffering from NO_3^-.Fehdi and Rouabhia (2014) analyzed that groundwater is one of the controlled aquifers. It is underground water soaked stratum formation that can cultivate a usable amount of water to a well. Aquifers are again classified into two: confined aquifer and unconfined aquifer. If the zone of saturation is overlapped between two impermeable layers, then it is termed as confined aquifer, and when impermeable strata are absent just above the saturated zone, it is termed as an unconfined aquifer.

Gampson et al. (2014) extended that for the purpose of healthy living safe drinking of water is essential in all human life. Groundwater is a selected source of water for human needs. Gnanachandrasamy et al. (2015) studied the groundwater has become the main source for domestic purposes, industrial and irrigation sectors of various countries. Millions of pumps by hand and profound bore wells have been released throughout India since 1970 to provide pure water than the water influenced by microbes. More or less, this water has some dissolved chemical constituents that are not acceptable by humans for drinking as it may cause bad taste and diseases also.

Malhotra et al. (2014) extended the hydrochemical computation of deep bore ground systems are more or less based on the presence of a high amount of files depending upon groundwater chemistry. Gampson et al. (2014)conveyed that various multivariate statistical proficiencies are widely applied to compute water standard through data reduction, types, and relationship. Although multivariate statistical techniques like principal elements analysis, discriminate analysis, cluster analysis and factor analysis are widely used to determine surface water and groundwater standard, to our knowledge, however, there have been limited attempts to demonstrate surface water standard parameters to incorporate into common linear mixed models to evaluating low and high flow hydrology and physicochemical surface water standard. Bharathi et al. (2017) investigated that a huge majority of groundwater standard issues are caused by contamination and over-exploitation. Mostly water standard issues are various to detect

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

and hard to analyze. The solutions are commonly much branded, time-consuming is not always in effect. An altering picture is beginning to issue in many parts of our nation. Groundwater pollution is as such different to detect, since the problem may be not shown below the surface and also monitoring may be expensive, time-consuming and somewhat hit-or-miss by nature.

The primary objectives are to quantify groundwater sources, evaluate groundwater sources have changed over time, and provided tools need to forecast system response to future anthropogenic and environmental stress.

2. STUDY AREA

The area for this study is located at 11.10°N 77.33°E situated in the bank of the river, and total study area spreads over 5186.42 sq.km. The study was carried out in some bore wells from different areas in Tirupur district. The population density of Tirupur is 2479052. Tirupur district is an industrial district plays a vital role in agricultural also. The total area of cultivation is around 2,28,556 hectares. The climate in this study area is mostly tropical in nature, with temperature ranging from 22^0C to 35^0C throughout the year. Study area receives monsoon from June to August, which receives showers with reduced temperatures. Months of September to January will be post monsoon period of the study area which experiences moderate to cool climate with the peak temperature of 29^0C which can go down up to 20^0C; the Summer season will be from March to May during which the temperature shoots up to 35^0C with a hot and dry climate. The region is covered by red soil (50%), black soil (46.4%), and other soil (3.6%). Ordinary well and surface water are found to be major sources of irrigation compared to canal irrigation with water table available at a depth of 7m to 25m.

2.1. Sampling Procedure

Bore water samples from deep bore wells, and sampling of hand pumps was chosen based on the industrial unit along with several usage conventions. In brief, the 60 water samples from bore wells were collected randomly in polyethylene bottles for each season based on the prelude field survey done in several locations of Tirupur. Initially pumping was done for 10 minutes, and the water samples were taken for testing purposes. They were examined in the laboratories to find major ions by applying standard test methods. After 24 hours of collection, analysis of samples was carried out. Each parameter was found based on the standard test procedures while pH & EC were taken by using pH meter and EC meter, respectively. Total hardness and calcium hardness were calculated by EDTA titration method. Iron, Chromium, nitrate was calculated by the calorimeter. Silver Nitrate was used to find Chloride in titration method. Total solids (TS) and Total dissolved solids (TDS) were also computed. The tests were shown in Figure 1 & Figure 2.

The groundwater samples are analyzed by different parameters using the standards American Public Health Association. The test pH, EC and TDS are obtained by using pH meter, EC meter and TDS meter respectively. Water bath method is used to measure TSS. A titrimetric method is used for measuring Chloride, Total hardness, Calcium hardness and Magnesium hardness. Sulphate, Iron and Chromium are determined using Calorimeter. A spectrophotometer is used for determination of Nitrate.

3. METHODOLOGY

3.1. Machine Learning

Machine learning is one of the most developing techniques which is expected to evolve in very near times. The soul of Artificial Intelligence lies in the utilization of machine learning depending on the inputs and outputs given to build functional relationships among data. Machine learning tools are used in various fields like weather forecasting, public health, communication systems, smart systems and many. The spirit of machine learning lies in applying various techniques like statistical approach, probabilistic approach and optimization techniques which help in finding the regularity of the training data set and to construct the linear relationship interdependent and noisy parameters. This makes things easy to make decisions which are difficult by traditional statistical approaches. Machine learning flowchart was shown in Figure 3.

Ni-Bin Chang et al. (2017) discussed that within the field of investigation, machine learning is a technique which can be used effectively to solve complex problems. In business terms, it is also called a prescient examination. Reasonable machine learning is tough knowing the fact that identifying the design or pattern is very hard and regularly sufficient data may not be accessible. Thus these machine learning programs are neglected to deliver.

3.2. Descriptive Statistics

Descriptive statistics Together with simple graphics analysis, they form the basis of virtually every quantitative analysis of data. The central tendency of a distribution is an estimate of the centre of a distribution of values. Measures of a central tendency include the mean, median and mode while measures of variability include the standard deviation (variation), the minimum and maximum values of the variables, kurtosis, and skewness.

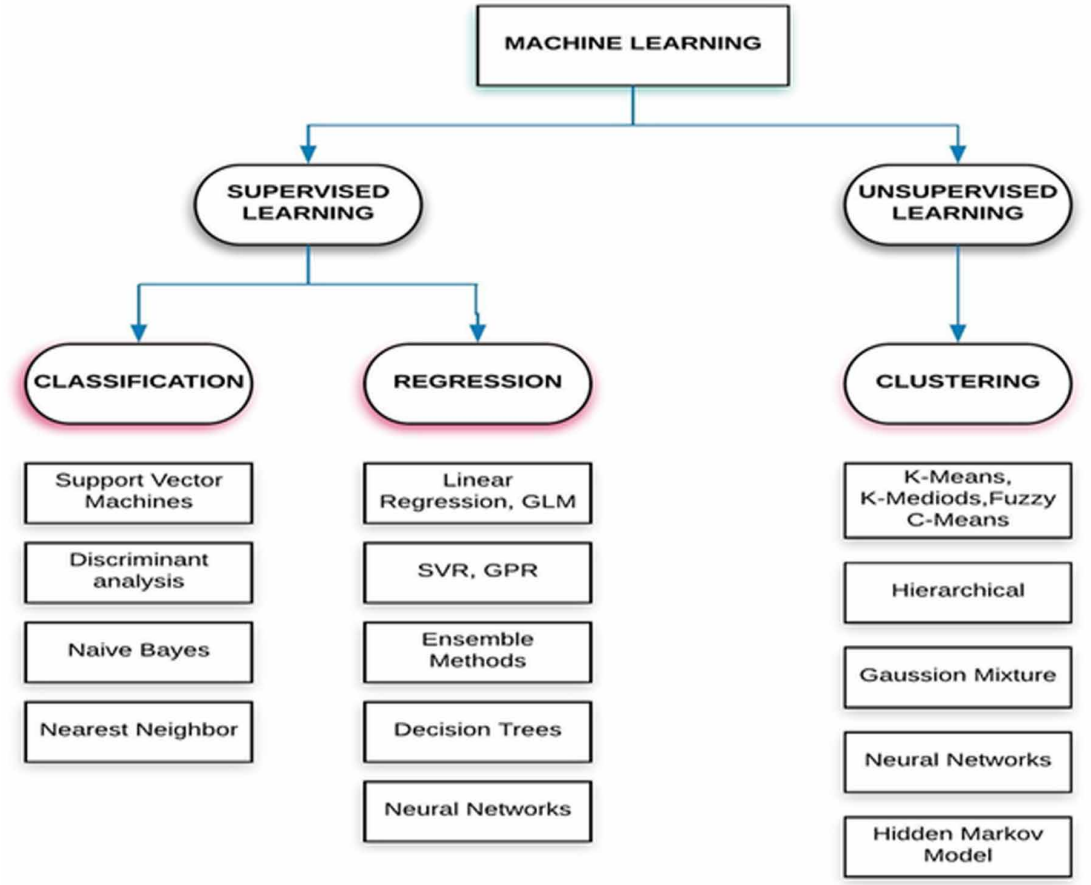
EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. Laboratory test for hardness, chloride and iron

A mean is the simple mathematical average of a set of two or more members. The median is a simple measure of central tendency. The model is the number that occurs most often in a set of numbers. A measure of the range of values in a set of numbers. Standard deviation is a statistic used as a measure of the dispersion variation in a distribution, equal to the square root of the arithmetic mean of the squares of the deviations from the arithmetic mean. The standard deviation is a numerical value used to indicate how widely individuals in a group vary. If individual observations vary greatly from the group mean, the standard deviation is big and vice versa. A standard error is the standard deviation of the sampling

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 3. Machine learning flow chart



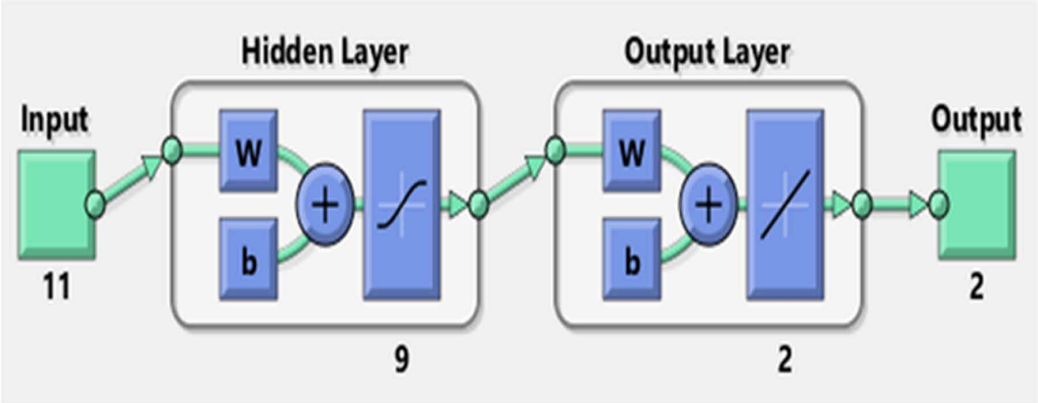
distribution of the statistic. The standard error is a statistical term that measures the accuracy with which a sample represents a population. In statistics, a sample means deviates from the actual means of a population. Skewness is asymmetry in a statistical distribution, in which the curve appears distorted or skewed either to the left or to the right. Skewness can be quantified to define the extent to which a distribution differs from a normal distribution. This situation is also called negative skewness. The variance is defined as, the average of the squared differences from the mean. In arithmetic, the range of a set of data is the difference between the largest and smallest values.

3.2. Neural Network Analysis

Artificial neural networks (ANNs) are the computing systems of Artificial Intelligence, which are truly inspired by biological neural networks which are similar to human brains. ANN works mainly depending on neurons in connections which are called artificial neurons. Each neuron will transfer the information from one node to another node. The architecture of ANN consists of three layers: input layer, hidden layer and output layer. The neurons in the hidden layer receive the data from the input layer to process and then it sends to the output layer. Figure 4 represents the architecture of a neural network opted for present work.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 4. Matlab input and output circuit diagram



In general ANN applications, the signal at any connection is a real number, and the output is calculated by activation functions in hidden layers. The connection between artificial neurons is assigned with weights that adjust accordingly as the training process proceeds. Weight plays a vital role in increasing or decreasing the signal's strength at any connection. Artificial neurons will set a threshold number such that it passes the signal to the further neuron only when the aggregate value crosses the threshold number. Regression plot and best performance obtained were shown in Figure 5.

Initial normalization is very necessary and it mainly depends upon transfer function's operating range (1 to 0 or -1 to 1 or any other) in the neural network. The training efficiency can be increased if certain measures are taken on the inputs and outputs. Sometimes scaling of inputs and outputs prior to training will give better results, as they will fall within a particular range. Premnmx is a function which can be used to scale the information in a range -1 to 1. This scaled output values can be converted back into original targets by using a function named postmnmx. If training the data is done after using premnmx, then for every new input, preprocessing by using tramnmx function is mandatory with minimum and maximums which were obtained from the training dataset.

4. RESULTS AND DISCUSSIONS

Total of 60 groundwater samples was collected in the year 2016-2017 and 2017-2018 and referred for different parameter during monsoon seasons and Post- monsoon seasons respectively. In this analysis, two years data is attached and referred to the quality of water. Groundwater samples were collected using the standard procedure from deep bore wells settled at various area of the district during seasonal variation. Through the analysis, it is base that pH values are slightly acidic and basic for some samples rating from 4 to 9. For monsoon analysis in 2016, the 27 samples crossed the permissible limits, and in 2018, minimum samples are affected. In post-monsoon period in 2016-2017 for 27 samples, it is less than the permissible limits, and in present year one sample crossed the permissible limits. EC values range from 0 to 1.300 /cm. TDS and TSS value ranges from 0mg/l to 1200 mg/l in 2016 -2017 and 0 mg/l to 1600mg/l in present year for monsoon period. In post-monsoon season the value ranges from 0 mg/l to 1700 mg/l and 0mg/l to 1500 mg/l for different samples. There are no samples which crossed

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

the permissible limits.36 samples are less than acceptable limits. Hardness in groundwater is established to be more and it exceeds the permissible limit in different samples. Geographical International System (GIS) is enforced to visualize the place of bore water standard in the study zone. Table 1 & Table 2 gives the statistics of water quality parameters for monsoon and post-monsoon respectively. The analysis was done for all the quality parameters, and it was shown in Figure 5.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

The dominant elements of groundwater are as follows: Ca_2, Mg_2 for cation and Cl^-, SO_4^{2}, NO_{3-} for anions. Deep bore well water is found to be good quality for drinking and agriculture purpose with less alkalinity and changing to high chromium hazard. Chloride value is limit in the post-monsoon and monsoon seasons. In 2016 – 2017 for monsoon the values are 0 to 900 which is under the permissible limits used for drinking and irrigation purposes and in post monsoon season the samples are under the limits. In 2017 to 2018 for monsoon and post-monsoon only 4 samples crossed the permissible limits and few samples under the acceptable limits. Values in Nitrate is about 90% of samples lies below the permissible limits, and only 10% of samples lies above the permissible limits. Comparing with the Sulphate, the values lies between the limits. Where the sulphate was below guidelines value for monsoon season and exceeded 45% for post monsoon and Nitrate exceeds about 5% in post monsoon compare to monsoon. And in monsoon Nitrate is good and lies between the permissible limits.

ANN technique has been applied to the data of investigations. The data was divided into 70% for training, 15% for validation and 15% for testing the network. Levenberg Marquardt algorithm was used for training. The regression value for the training data set was found to be 0.90596,and for the entire network, it was found to be 0.81729. The best performance was observed as 0.0022605 at epoch 223. The error histogram is obtained. The entire analysis using ANN was shown in Figure 6.

Figure 6. Best training performance graph

5. RECOMMENDATIONS AND CONCLUSIONS

We concluded that this is our prime work to allow for a healthy environment and clean water for our future generation and let us provide our upcoming generation with a neat and clean environment. ANN was employed to train and develop the models for water quality. Regression value for the complete data was found to be 0.81729, and the best performance was observed at epoch 223. The calculated regression is very near to 1, indicating the high accuracy of the model. It is recommended that the water in this zone good and suitable for irrigation purposes and drinking purposes.

Chapter 30
The Contribution of ICTs to Sustainable Urbanization and Health in Urban Areas in Cameroon

ABSTRACT

The uncontrolled urbanization in African cities with inadequate access to urban domestic waste, housing and sanitation management services (DWHSMS) generates landscapes that become places of the spread of many pathologies leading to many public health problems. The city of Yaoundé (Cameroon) is not an exception in this situation which exposes an urban population to the most recurrent diseases. The situation become more complex in the fact that, the performance of the policies and the actions undertaken implied in developing countries, is not known in a precisely. The information sources are dispersed, old and not coordinated. ICT can, at the service of the great causes like the sustainable urbanization and/or environmental health, constitute the irreplaceable ones and essential decision-making tools. For this purpose, integrated and interoperable YUSIIP platform has proposed and deployed. The objective of this article is to present this Domestic platform and to show its contribution in (DWHSMS).

1. INTRODUCTION

Bad Domestic Waste, Housing, Sanitation Management Services (DWHSMS), and the absence of the application of law on the matter presents enormous consequences on health, the environment and the individuals living environment, particularly in the African cities, notably the town of Yaoundé, capital of

Cameroon, concerned with our research tasks (Wéthé et al., 2002). The population of the city increases each year by 6% on average since 2001. This population growth appears by the increase in the domestic waste production, the proliferation of the shantytowns and the weakening safety systems, hygiene and sanitation. Each one of these factors can largely improve or degrade health in urban area and the city environment (economic and social situation, security and food quality, service of sanitary emergencies management, urban governance, etc.). According to the cases, they can also involve the proliferation of several fatal diseases as well as imbalances in ecosystems (Manegabe et al., 2017). The consequences of the dysfunction of their management systems on living environment and the natural ecosystem gain more and more in importance. They challenge all the actors implied to make suitable decisions and the proper authorities to make management of these factors the priority of their action.

Since about ten years, initiatives of the public authorities, private and public organizations, regional and local authorities and universities (Ngnikam et al., 2002; Fonkou et al., 2002) are being multiplied in Cameroon faced with the environmental degradation and urban area health. The informal sector, NGOs and associations joined the movement which aims at:

- **Domestic waste management:** The treatment and the valorization of domestic waste play a key role in the fight against the environmental pollution and the conservation of natural resources (Aloueimine et al., 2006);
- **The housing management:** The spontaneous and precarious shantytowns very populated cover more than 70% of urban space where the lack of basic services such water and the cleaning constitutes a vector of propagation of many pathologies which are posing multiple public health problems (the complication of paludism, respiratory infections acute, infections of the digestive system, etc.), as well as the environmental factors exposure to the health risks (Sy et al., 2011);
- **The sanitation management:** This management falls on the municipalities which must build and manage the autonomous drainage systems, main sources of diffuse pollution, not easily controllable (Wéthé et al., 2002), etc.

However, these initiatives of the public authorities, municipalities, private and public organizations, and NGOs and associations implied, faced with the degradation of the socio-sanitary and environmental conditions, encounter some problems related, on the one hand, on the organizational level, with the accelerated urbanization, the impoverishment of an important frank of the population, with a deficit in means and an insufficient dialogue between the various speakers, on the other hand, on the technical plan, public information on the influential factors on urban health and the academic research results, are very scattered and not always reliable, heterogeneous and difficult of access. The various methodological approaches and the development models of these systems were often unaware of the transverse dimension of the various processes, being limited to the computerization of some functions of the factors (Bagayoko et al., 2010). The risks related to these factors could wellness avoided if the data and knowledge were available (Ayissi & Moskolai, 2017). The lack of data exposes the population and the environment to the proliferation of several fatal diseases, the contamination by the pathogen and chemical substances (Corcoran et al., 2010). Moreover, urban area health would not be truly assured as a long time as the population will be kept out of urban waste management and. This population will continue to throw heterogeneous waste in the streets, drains, waterways, etc., and related risks to this waste could involve a delay on the economic plan through high mortality and morbidity rates which would be followed in the cities (UN- DESA, 2014).

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

It's to contribute to the general problems of urban data control for a sustainable urbanization that we started, since 2002, research on the integration and interoperability mechanisms of the heterogeneous and incomplete information systems for decision-making in urban area in Cameroon. The setup of a Distributed Data warehouse (DDW), urban memory in Yaoundé, which is pressed on the technology of the data warehouses, Services Oriented Architectures (SOA), the urbanization of the information systems and Master Data Management (MDM) through the design and the development of Yaoundé Urban Systems Integrated and Interoperability Platform (in abbreviated form YUSIIP). The effectiveness of this mixed approach and the results of the capitalization of knowledge on urban environment through a unifying platform of multi-source data YUSIIP, from the point of view of the decision-making aid as regards management and the urban planning are already convincing (Ayissi & Moskolai, 2017; Kouamou al., 2008). The aim of this paper is to show the contribution of the DDW of YUSIIP in the problem of Domestic Waste, Housing and Sanitation Management Services (DWHSMS) in the particular case of Yaoundé town, the political Capital of the Republic of Cameroon. The multiple and varied health risks related to domestic waste, housing and sanitation management services in urban areas could be avoided if the data of different factors enumerated above would be available.

In the rest of this article, a state of the art relative on integration techniques of information systems and urban waste management systems is proposed in section 2, section 3 presents the general architecture of the YUSIIP platform. Then, in Section 4 a model of production of urban indicators is proposed, section 5 presents the results and discussions and finally a general conclusion and perspectives to finish the paper.

2. INTEGRATION OF INFORMATION SYSTEMS AND THE WASTE MANAGEMENT SYSTEMS

2.1. Integration Systems, Data Warehouse, Enterprise Architecture, Multi-Source Information Systems and the Master Data Management

The needs for urban stakeholders in the processes management of sustainable urbanization are varied (environment management, demography management, transport management, living environment management, etc.). They relate at the same time to the data, the figures which they seek to understand and the realization of the statistics and other exploitable relevant information, within the framework of decision-making, which it's operational nature, occasional or strategic. To solve these problems, several approaches are proposed that it's the integration of information systems, Enterprise Architecture, the construction of multi-source information systems and Master Data Management (MDM).

Integration is operation which consists of assembling the various parts of a system and to ensure their compatibility as well as the efficient operation of the complete system. The concept of integration can apply to various levels or objects: at the organizational unit level, processes, computer applications, software base and material. On the computer applications level which relates to the problems of the DWHSMS particularly (Reix, et al., 2016) one distinguishes two possible approaches to the problem. The priory integration which is matching to systems thought at the beginning of the construction of a single integrated information system or Management Information System (MIS), recovering the whole functional fields and various levels of piloting. The posterior integration which consists in arranging the relations between conceived systems in an independent way, to constitute a "unified" system or meta-system.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Compared to a posterior integration, the recent solutions concern:

- EAI (Enterprise Application Integration) which consist of replacing the multiple links (footbridges) between applications by the construction of a platform centralized exchange ensuring the communication and the exchanges between these applications by diffusion messages (Avignon, Joguet, & Pezziardi, 2000);
- DW (Data warehouse) which are systems managing the data resulting from various applications and ensuring they are making up in accordance with common formats. These systems are especially used in the field of Decision Support Systems;
- The ERP (Enterprise Resource Planning) which are integrated information systems composed of modules, conceived in a coherent way and sharing a common database. The ERP are standardized, but adaptable systems which correspond to a logic of brutal urbanization, standard big bang consisting of replacing "small islands disparate and badly built" (old applications) by harmonized units, carefully connected to each other (modules). The harmonization concerns not only on the definition of the data, but also, in a major way, to a new design of the processes management. It's a unified and coherent information system making it possible to manage the various fields of the undertaking, and whose realization can combine several approaches (EAI, DDW, etc.);
- YUSIIP Project (Kouamou, Eteme, & Pettang, 2008) which the ambition is to contribute to the reach of the objectives for a sustainable urbanization in Cameroon implements the approach Data warehouse and identifies all the principal data which need urban managers and decision makers. First of all, the idea is to create an ideal model of data of which must lay out these urban stakeholders. It has been elaborated based on the principal processes suitable for environment management, demography, living environmental; such processes of Domestic waste, Housing, Sanitation and the pollution management Services, etc. This model is according to Bolognigni (2002) which allows the integration of data of the various information systems.

For the approach Enterprise Architecture "the metaphor of the city has been largely used in the field of information systems because of the similarity of the starting problems: How to remake, modernize? How to benefit from advanced technologies, without wiping the slate clean of the past, within limits of controlled costs while maintaining the life of the city during works? "(Longépé, 2003). It proposes to pass from a system existing to a new solution, the target system, by successive evolution (by definition of projects). It's a question of ensuring the evolution of the system for answering the evolution of requirements while improving its coherence and its effectiveness. In the framework of YUSIIP project, the setup objective of an operational platform starting from existing YUSIIP prototype is reached. Technological choices for the implementation of its architecture has been operated. Application architecture of the prototype has been described, by showing the various levels: the application zones (great functional units), the application quarter, the application block (programs, modules), then to guide the evolution of a situation where each block thus defined, according to the degree of accuracy (zone, quarter, block) corresponds to a unit within which data and treatments are strongly connected and having a coupling or weak connection with the other blocks. What constitutes "land use plan" or the YUSIIP guiding diagram and which organizes the platform while specifying: - the mission of each application, each block; - the regrouping of the blocks in coherent units; - the perimeter booked with the future applications to build; - the rules which the originators for the realization of the future applications must comply with. The urbanization of information systems thus seems a permanent concern aiming improving coherence of

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

cuttings in applications, at increasing the effectiveness and the efficiency of the information system and, to limit the effects of technological proliferation. Thus, the urbanization and the integration of information systems pursue the same goal and seen two different moments from the same process of consistency and piloting of evolution of the information system (Reix, et al., 2016).

The construction of Multi-Source Information Systems (MSIS) addresses the problems: "how to optimize the city by the data and the uses?". Indeed, the urban planners and managers are working for several years to control the organization of territory, to improve coherence of interventions of many local and external actors (ministries, private and public organizations, Regional and Local Authorities, NGO and development assistance organizations, etc.), to ensure the well-being of populations and to coordinate development projects, made difficult because of multiplication of planning (Repetti & Prélaz-Droux, 2003). The recourse to communication and information technologies does not make it possible yet to completely apprehend the complexity of the processes of urban management and to improve the effectiveness of territorial management (computers, data bases, computer applications, ISDMA, GIS, SIRS, observatories, etc.) (Pettang et al., 1997; Prélaz-Droux & Musy, 1994). These monolithic tools are disparate and under exploited because of difficulties of insertion in institutional organizations, as well as the weak taking control by the stakeholders of urban management who are independent and have each one own destiny. With the optimization objectives of the city by the urban data (reuse, shares, co-production, publications, analyzes great volumes of data), of generations of a common strategic vision of the city which directly influences the actions of the actor's management and the co-operation with various partners, the urban reflection was then extended to the analysis of the management processes and the decision, with a partnership approach of Co-construction, as the technic resulting from company management.

The implementation of the platform YUSIIP identified two major challenges: firstly, SOA and the development of generic services do not solve the problems of surface heterogeneity and secondly the lack of a common data model for the data warehouse does not allow the normalization of the structure of semantic data models. Heterogeneity remains for the two cases, at the data level. (Ayissi, & Moskolai, 2017) propose to associate the approach of Master Data Management (MDM) by the setup of data repositories which will be coupled with the data warehouse, thus constituting a Distributed Data Warehouse (DDW). MDM is focusing on the rationalization management of data shared within an organization or between several organizations while managing in a unified and transverse way of heterogeneous data and dispersed in several not synchronized application systems.

2.2. Waste Management Systems

According to BRUNET Roger, waste is an "inevitable product of human activity, whose treatment is expensive and difficult, although it is useful (...)". Jean GOUHIER retorts that: "the study of waste makes it possible to understand the way in which people live and discharge their vital functions (consumption, food, health) and cultural (leisure, various activities), or professional. It's not divination: by studying dust bins, one can establish trends of behavior, based on the typologies carried out on the basis of content analysis of dust bins carried out over several years". In the literature, there does not exist a single definition. Researchers and professionals mobilize themselves and organize themselves more and more to take part directly in the management of the city and this since the economic transfers, policies and social which knew the urban companies in particular, in Africa at the beginning of the Nineties. Several works testify some.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

In their work, Morrissey and Browne (2004) examined the types of model systems currently used in the field of municipal waste management and highlighted some important gaps in these models. Based on their analyses, most of the municipal waste models identified in the literature are decision support models and seem to fit the objectives of this work. These models are mainly divided into three categories: those based on cost-benefit analysis, those based on life-cycle assessment and those based on multicriteria decision-making. Much of their work has focused on examining the models used to support decision-making in the area of waste management in an urban setting and highlighting some of the important gaps in these models.

In order to assess these systems on the point of view of sustainability, it's important to be based on reliable and relevant indicators. (Rigamonti et al., 2016) proposes thus the definition of a set of indicators for evaluation of the environmental and economic sustainability of the integrated management systems of domestic waste. The challenge consists to define simple but understanding indicators which can also be calculated by the administrators and the local managers of the waste management system and not only by the scientists or the experts.

In the literature, many studies have also concerned the behavioral study of recipients of waste management systems. The objective of the work of (Guerrero et al., 2013) was to determine the action and behavior of the recipients who play an important role in the waste management process and to analyze the influencing factors on the system. a period of more than thirty years. This study was conducted in urban areas in 22 developing countries on four continents. To evaluate the recipients, the authors used a combination of methods. Other works such as those of (Shekdar, 2009) have also worked on the subject and have identified the main stakeholders (people or organizations) who may be interested in waste management.

The heterogeneity of the cities and the recipients lead to requirements for the ICT systems deployed in waste management to collaborate, while being able to work autonomously, autonomous and resilient way. Moreover, it requires systems able to integrate the existing infrastructures and ICT. (Soto, et al., 2016) proposes a platform of intelligent city which should be an integration platform able to adapt to the regulations and policies of the cities which quickly change.

The result of these many research works and project that the problems related to the interoperability and the integration of urban waste management systems in the developing countries is not largely dealt. However, to have reliable and relevant indicators for strategic decision-making, it's important to federate the urban data in order to make them single. YUSIIP brings a solution to this problem.

3. GENERAL AND FUNCTIONAL ARCHITECTURES OF YUSIIP

In this section, general architecture and YUSIIP operations are presented and described. The general architecture of YUSIIP listed in the Figure 1 (a) shows that YUSIIP are a Multi-source Information System (MSIS), a platform of information exchanges between various organizations implied in urban management and a support of decision-making aid.

The YUSIIP platform is based primarily on a SOA (Services Oriented Architecture) architecture that promotes the use of standards in data exchange between heterogeneous information systems. It thus contributes to the development of an integrated system giving access generically to data coming from the different actors of urban management (individuals, organizations, municipalities, etc.). SOA streamlines service management, supports the division and distribution of consolidated data between heterogeneous

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

applications via Data Services. Data from urban actors provides factual data or the characteristics of their data in the form of web services through (WSDL / XML / UDDI) complying with specific standard formats (1-thirds). These data formats ensure interoperability for the exchange of information between data providers and consumers (data users). Web services (2-tiers) that query the platform through its central repository (3-tiers). The YUSIIP platform implements a computer-aided software engineering (CASE) which builds the interactive system of decision-making aid (ISDMA), the data warehouse, and the relevant urban indicators progressively. Principle contributions within the choice of the CASE relates to the technical sides such as processes ETL ("Extract – Transform – Load"), OLAP technology (One Line Analytical Processing), the production of data bases of the concepts and the interfaces of visualization brute or incorporated data.

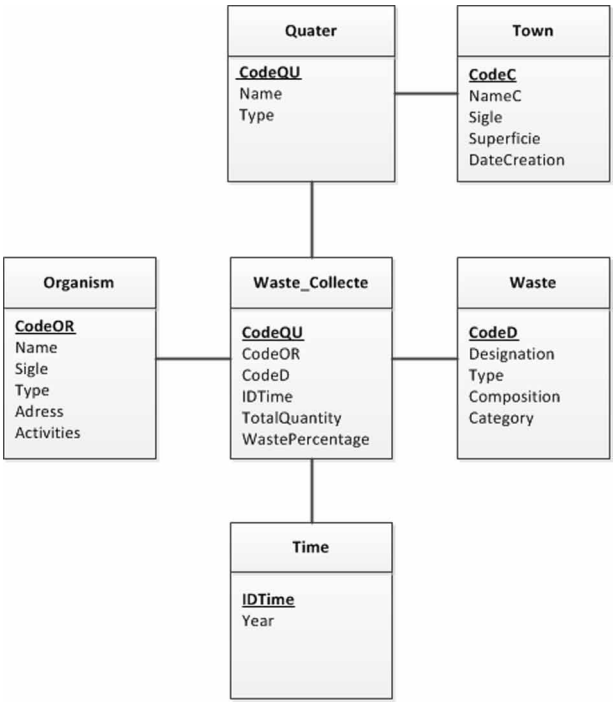
A data warehouse beginning from several disparate and heterogeneous data sources, which makes it possible to memorize perennially urban information and to refer to the sources existing data in order to facilitate their access and their reuse. According to (Inmon, 1994), data warehouse can be defined as "a collection of oriented subject data, integrated, not birds and historized, organized for the support of a process of decision-making aid". For decision-making applications that use heterogeneous data from a variety of sources, data warehouses are an interesting solution. Two storage spaces are distinguished: the data warehouse and the data smarts. The warehouse is perceived as a homogenous centralized storage space gathering useful data for analysis and decision-making, extracted from sources and able to be the subject of historical data. Smart is an extract from the warehouse, where the data is specifically prepared to facilitate their analysis and exploitation by users (decision-makers or managers). In order to provide an effective means for urban managers in their process of analyzing urban waste, housing and sanitation data, data from multiple and heterogeneous sources are integrated into a data warehouse.

To collect the needs of users of the YUSIIP platform, two main approaches have been proposed in this study:

1. The first approach concerns source-oriented collection. It is limited to identifying the needs of the data warehouse from all available data at the level of urban managers such as CIPRE, which since 1996 had been the statistical data on the direct recycling and recycling of plastic waste in Yaoundé. These data mainly concern statistics on: the amount of waste recovered, the geographical location of waste deposits, income, etc. For the management and production of these statistical data, CIPRE uses traditional calculation software (spreadsheets). Other urban managers also feed the data warehouse, such as HYSACAM, which specializes in the collection of household waste and dry and inert materials (glasses, metals, plastics, etc.). LAU undertakes studies and research on slums and sanitation, the INS (National Institute of Statistics) which produces general survey data on the living environment (information about neighborhoods, waste management, garbage cans, evacuations, etc.);
2. The second approach is a needs-driven collection that identifies the needs of users and stakeholders. Data are analyzed according to the relevance of user demand. These data come from information provided by urban managers such as CIPRE, HYSACAM, LAU and INS as well as the documents provided. The conceptual model for intelligent data retrieval in the warehouse in relation to the DWHSMS is shown in Figure 2. The model is composed of six tables: a "Waste Collect" and a set of tables (Organization, Waste, Quarter, City, and Time) connected by foreign keys. The Waste collection table contains information or measures relating to the description of the regular collection of solid waste, such as "Total quantity" and "Percentage of waste."

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. Conceptual model of data smart relating to urban waste



Our work has helped develop a solution for data management for the benefit of urban stakeholders to improve the quality of life in cities. Following the proposed Entities-Relations modeling (Figure 2), the multidimensional model consists of several tables, a "Waste Collect" and a set of size tables (Organism, Waste, Neighborhood, City, Time) each containing a primary key, and a set of entities. These size tables are interconnected by foreign keys. This type of dimension is particularly important for building a data warehouse based on a set of inter-linked data stores. For example, the Waste Collection table contains information or measures related to the description of regular solid waste collection, such as "Total Quantity" and "Percentage of Waste". It also contains information about the types of waste, the time, and code of the organization in charge of its management. Indeed, these conformal dimensions (multiplicity of foreign keys) have the same meaning in all the tables of facts with which they are related. Thus, these dimensions will ensure the consistency of all data warehouse by building a kind of link between data stores. This set of interrelated data is sometimes called decision bus. The above approach is a warehouse building approach for non-complex attribute data.

To provide semantic consistency of the data exchanged with the data warehouse solution, an integration of a Master Data Management (MDM) module has been proposed. This solution also makes it possible to set up a data repository as well as an adapted organization that will make it possible to manage the data in a transversal manner with the various sources of applications professions (Trigaux, 2009). The MDM solution centralizes data in a reference frame and propagates it between applications deployed within a single information system. It is therefore possible to apply a strategy for sharing information. The MDM integration provides the YUSIIP platform a better user interface (HIM) for data administration and all related governance functions: versioning, rights management, querying, validation, approval process up to date and interfaces with the integration data middleware. It is also an ideal solution considered as

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

a repository of storage (Ayissi & Moskolai, 2017) and is complementary to the other two approaches (SOA, DW). MDM will enrich the data warehouse of a new layer by providing a unified, personalized and secure data retrieval environment in a meaningful way. In relation to the DW approach, MDM also focuses on unifying models and tools within the information system. To build a truly distributed data warehouse that takes heterogeneous data into account, SOA needs MDM to structure, standardize, and consolidate data from different sources. Similarly, MDM needs SOA to share and distribute consolidated data across heterogeneous applications. A sequencing of the various activities and functionalities of the YUSIIP platform for strategic management and decision making has also been presented in Figure 1(b).

Figure 1 (b) describes the operation of YUSIIP platform as it follows: (A) Various Equipment of connection (PDA, Smartphone, computers, etc.), (B) Average of network Internet connection, (C) Interfaces Web services which the users are reaching, (D) Waiter in which YUSIIP platforms are lodging, (E) Organizations being able to be in the private sector, public or even individuals, (F) Directory of Web services, (1) Once the Web service implemented, the provider service must publish the service in the register. This publication is done through the WSDL and the attribution of a UUID (Universal Unique ID) which makes it possible to identify each service in a single way, (2) When a user reaches the platform, it reaches the interface and a request is sent to the Web server where YUSIIP is lodging, (3) The research of the Web service will be done in our UUID register within the framework of a private register, (4) If it happens that the required service is not being present in our deprived directory then he will be researched in the public directories, service corresponding to the formulated request, (5) The answer (result) of the formulated request is returned to the Web server. This answer can be positive or negative; if it's positive, it will send the characteristics necessary to the use of the found services corresponding to request (details on the supplier, type of connection, address of the service, etc.), if it's negative then the service is not found and end of the process one passes directly to (8). (6) The Web server will thus establish a connection with the service in question. (7) If the service is available the exchange of messages (based on XML) can then start. (8) The answer is thus transmitted to the interface of the user.

4. SUGGESTION FOR A MODEL OF INDICATORS PRODUCTION

In this section, the data models (warehouse, stores) are supplemented by a necessary modeling of the treatments for the calculation of the indicators. In general, evaluation based on indicator systems extends to all domains (economy, urban development, etc.) by considering the recommendations of sustainable development. Indicators are used to show, measure or appreciate a given phenomenon. In the DWHSMS case, Figure 3 presents the model of production of the relevant indicators starting from urban phenomenon to appreciate.

The proposed model is articulated around several major axes namely: themes or subjects (examples: urban management, economic and social governance, environmental governance, etc.), factors or fields (examples: urban waste, housing, sanitation, pollution, etc.), problems relating to each field, observation variable ones and descriptive cards of relevant indicators. Its application to the DWHSMS (urban waste case) has structured information into a dashboard of indicators and statistics to understand certain areas and underlying issues. This availability of data makes it possible to solve existing problems and to anticipate others. The dashboard allows for the collection of generally dispersed data, providing a global view and better management of urban data.

5. RESULTS AND DISCUSSIONS

YUSIIP project contributes to building an overall vision of management and city planning in Yaoundé via the installation of a multi-source information system, making it possible to produce knowledge at the same time global (consolidated) and detailed. In this section, the YUSIIP contributions to the DWHSMS are presented and hold an overall discussion on the study of YUSIIP.

5.1. Contribution of YUSIIP Data Warehouse to the DWHSMS

The need for DWHSMS, sanitation, pollution, waste waters and the waterways is dictated by the sanitary and environmental imperatives in urban area. From this prospect, the exploitation of the YUSIIP Data Warehouse presents a real issue. According to the United Nations criteria for Sustainable Development Goals (SDGs), information on household waste management, housing and sanitation or the environment would contribute to the production of statistics, indicators that would make it possible to evaluate the city.

In other to help urban managers in decision-making to improve the quality of life in the urban area, some statistics and indicators of decision support are produced by the YUSIIP platform:

- **Urban Waste:** YUSIIP allows the data collect the characterization of domestic waste in the Yaoundé City and ensures the provision of this data for information and decision-making aid purpose;
- **Production of waste:** Waste is continuously generated, in increasing quantity with the development of lifestyles. They are heterogeneous and their quantitative composition varies according to

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

space (city, quarter, household) and from time (year, month, week, day, and season/climate). For example, in Yaoundé (Cameroon), in 2005, the quantity of produced waste per habitant and per day was 0.85 Kg/hab/day. The average production of domestic waste was 0.6 Kg/hab/day in dry season whereas it was 0.98 Kg/hab/day in rain season. The production of waste also varies according to the living standard and the migration of the population (for example the tourist period). The geographical, climatic, economic and demographic factors are determining in the quantification of the generated waste in a city. Table of Figure 4 gives the evolution of quantity of collected waste to Yaoundé since 1996. Knowledge of the waste quantity produced in a given area is essential for the planning of a management system in order to envisage at the best dimension of the collect, installations of treatment and the storage center of waste (Aina et al., 2012). Moreover, the knowledge of quantity of produced waste could make it possible to predict the adequate strategies for a sustainable management of waste and environmental protection in urban area;

- **Physical Composition of waste:** Domestic waste constitutes a heterogeneous mixture of materials having very different chemical and physical properties. Table of Figure 5 gives the physical composition of waste in Yaoundé urban area.

The knowledge of this composition is essential because it makes it possible to determine the management mode of waste and to possibly promote the creation of the treatment and valorization channels. As indicated, the treatment and the valorization of domestic waste play a key role in the fight against pollution of the environment, the conservation of natural resources and energy saving. They can also slow down the global change of climate, caused by the emissions of greenhouse gases, which are responsible for the progressive warming of ground and which involves a global imbalance of natural ecosystems.

- **Chemical and Biological Composition of Waste:** Chemical and biological characterization of waste can contribute to highlighting the existence of harmful effects of pollutants recorded on human health and the environment of untreated waste, especially in urban area. The studies of WHO-Habitat (2010), Rajaganapathy et al. (2011) show for example that cadmium and lead are

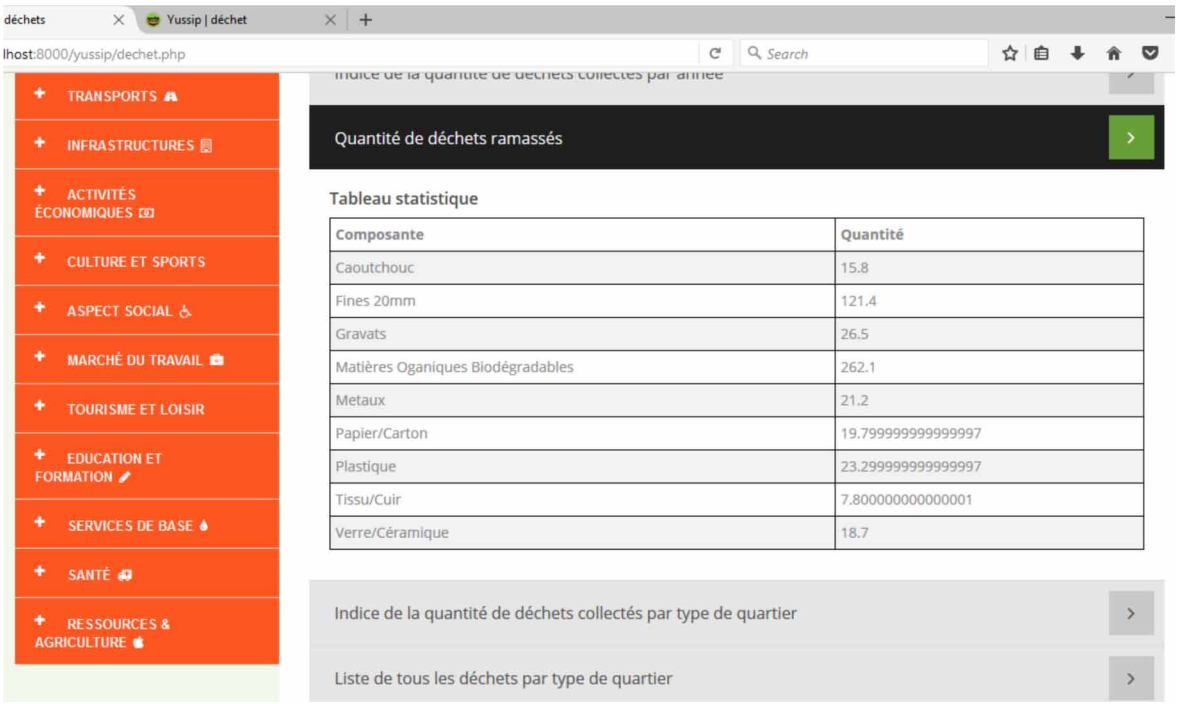
Figure 5. The physical composition of waste in Yaoundé urban area



carcinogenic substances, the manganese excess causes the cirrhosis of the liver, zinc is phytotoxic and is suspected of being carcinogenic for the man. In addition, in a Cameroonian society where the self-medication phenomenon is strongly widespread, the antibiotics used by the population against the bacterial infections, constitute another category of pollutants available in domestic waste. Indeed, these chemical substances are not absorbed in the host organism. Most of them turn over in the environment through the urine and the fecal matter (Czekalski et al., 2014; Samanta et al., 2012). The presence of these antimicrobials in the environment could lead to the dissemination of resistant bacteria in the ecosystems and would pose enormous problems on the man and the biodiversity in the cities.

5.2. Providing Data, Results of Studies on DWHSMS, a Real Issue

Domestic waste, planned and shantytowns, sanitation, waterways, groundwater, waste waters, etc., the studies in these fields are multiplied and it data collect is much developed. However, the data banks as well as the treatments and analysis results relating to it carried out by the researchers are not known from proper authorities. They also are not put at the disposal of managers, other researchers, expert trade or populations. YUSIIP can contribute to curing the lack of legibility and information pedagogy which can lay out the DWHSMS researchers. It collects, cleans and crosses supplements the existing data thanks to its CASE (computer-aided software engineering) set up. The data thus developed are diffused in the form of tables or of interactive cards, which gives accurate information about each Regional and Local Authorities (RLA) and by types of quarters (Figure 6).

Public education on the socio-sanitary and environmental risks on the DWHSMS in urban area:

- To conduct public awareness campaigns in keeping with waste and environment management. Thus the population which lives in the insalubrity and pollution of its environment would then be protected from pollutants coming from domestic waste;
- To educate populations on the dangers which waste would represent on health and environment.

5.3. Discussions

YUSIIP Project implements a strategy of the setting up of an efficient model of information systems oriented towards the decision-making aid and with the diagnostic, in order to promote a sustainable urbanization in Yaoundé (Cameroon). The platform can contribute to the piloting of management and urban planning in Yaoundé, i.e., to better concentrate efforts and resources towards the relevant urban problems thanks to reliable indicators; to contribute to the elaboration of the urban development models and the implementation of an information system adapted to the city is one of the objectives of our research project. This contribution aims to:

- Improve the processes of the factors influencing the urban development;
- Set up the means of improvement of the practices of urban development;
- Have indicators of piloting management and urban planning;
- Introduce the tools of the approach quality;
- Integrate the individuals and the populations into the process of the city management.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Being particularly the DWHSMS, YUSIIP platform can contribute so that proper authorities in charge of domestic waste, housing and sanitation make to these factors, the priority of their action. Data control and knowledge goes:

- To contribute to controlling the urban waste management, without which there will be more loss in human lives, imbalances in the economy and the ecosystems, poverty and the delay in the development of Yaoundé compared with others of the same size cities;
- To contribute to the awareness of populations on the dangers which would present for example urban waste in health and environment. This awareness must pass obligatorily by the availability of data and knowledge on these influential factors in urban health, which constitute the required passage for sustainable management of urban areas.

However, YUSIIP data are still incomplete and the various cases of studies are not carried out in a systematic way. The task which consists in making available the produced data by the whole stakeholders, public and private organizations, social networks, connected objects imply that YUSIIP is integrated in a project of the city.

5.4. Prospects for Master Data Management

With technological advanced, and the view of computerization "proprietary", methodological approaches and models of different systems have often ignored the transverse dimension of urban processes. Today, with the need for interoperability of different systems for information exchange, enterprise architecture solutions alone have found their limits. Therefore, an enrichment of these solutions with the implementation of Service Oriented Architecture (SOA) and Reference Data Management (MDM) contributed to the integration of heterogeneous and sparse data. It is in this sense that the perspectives of the YUSIIP project to develop the data referential relate to:

- Produce continuously data which the availability will not be anachronistic any more in the absence of method and adapted means;
- Produce continuously data and reliable statistics.

6. CONCLUSION

African cities in general and those of Cameroon in particular face a waste management problem due on the one hand to the high population density in urban areas and on the other hand to the development of spontaneously inhabited neighborhoods. This situation is at the origin of the development of diseases such as cholera, malaria, typhoid, asthma, etc., which emanate from the pollution of the environment by waste of various kinds. It is therefore becoming important for cities and decentralized local authorities to take an interest in controlling urbanization and all that goes with it, in order to ensure the well-being of populations. Thus, this control of urbanization will integrate good waste management. However, the lack of DWHSMS data on the level of knowledge of the population of African cities, urban waste and its composition (physical, chemical, microbiological, etc.) expose the population and the environment to the proliferation of several deadly diseases, contamination by the pathogen and chemical substances.

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

The multiple and varied risks associated with urban waste, in particular household waste in urban areas, could be avoided if the data listed above were available. Our previous work, which focused on the study of mechanisms for the integration and interoperability of heterogeneous and multi-source information systems, in a context of African cities, particularly Cameroonian cities, marked by a lack of resources (financial, personal, technical), insufficient dialogue between the various actors and scattered and not always reliable information, enabled the YUSIIP to be implemented. These results call for an integrated approach to sustainable organization, urban health, environment and poverty in urban development policies. The basic functions of the YUSIIP are to produce global knowledge about the city, to make available the data produced by all actors, public and private organizations, social networks, connected objects. In the case of DWHSMS, the YUSIIP's distributed data warehouse produces information on urban waste management, housing, sanitation and indicators, which would reduce the social, health and environmental risks of these factors. The distributed data warehouse could provide a basis for public education in urban waste management and environmental protection. The characterization of urban waste can help authorities to make waste management a priority for their action and to remove the dangers that waste would pose to health and the urban environment. In terms of DWHSMS research, our work is an opening for the implementation of an integrated and participatory waste management plan in Yaoundé. As a perspective we count:

- Intensify the collection of information on household waste, housing and sanitation through the promotion and/or strengthening of public-private-civil society partnerships for the enhancement of databases and the refreshing of the YUSIIP data warehouse;
- Integrate data on the behavior, practices and attitudes of the population of Yaoundé regarding household waste;
- Transform YUSIIP into a true open platform and services (OpenPaas) and application on DWHSMS management.

All this will help to reinvent the way urbanization is thought and urban waste is managed by national authorities, the city and local communities.

Chapter 31
Advanced Nanomaterials for Water Engineering and Treatment:
Nano-Metal Oxides and Their Nanocomposites

Rabia Nazir
Pakistan Council of Scientific and Industrial Research Laboratories Complex, Pakistan

ABSTRACT

Loading of water with multifarious pollutants has dwindled the availability of quality fresh water and put questions on reliability and efficacy of conventional water treatment technologies. Also the quest for developing robust and cost-effective methods with minimum impact on environment had driven the focus of researchers and technologists on new technological developments. Nanotechnology – better referred as Aqua-nanotechnology in this regard provides scientists a new dimension to deal this big problem with small particles having application in 1) water treatment, 2) remediation, and 3) pollution prevention. This chapter will focus on fabrication and use of advance nanomaterials categorized as nanoadsorbents and nanoatalysts for these three main areas. A range of materials exploited in this regard are single and mixed metal oxides and their composites with polymer, clay, carbon based materials etc. while keeping focus on technological developments taken place over the period in regard with treating water and waste water.

INTRODUCTION

The importance of clean and safe water cannot be negated but a famous quote by Jacques Cousteau portrays the true reality about today's world approach that *We forget that the water cycle and the life cycle are one*. As per a report published by World Business Council for Sustainable Development (WBCSD) (Fry, 2005), there is a considerable increase in water consumption with an increase in the industrial

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

revolution. All this development has no doubt made human life easy but on other hand has raised serious concerns over the sustainability of clean water as it caused limited share accounting for only 11% of water available for domestic consumption. Water pollution scenario is creating hype in the world and with its cross-border perspective water pollution is not an issue to be addressed and solved by some countries independently but it requires a consolidated approach to mitigate the pollution jinni. According to United Nations World Water Development report 2014, with depleting world water reservoirs and an anticipated rise of 55% in global water demand by 2050; an appreciable number of people are expected to have no access to clean water and improved sanitation (WWDR, 2014). With the development of new materials, chemicals, and technologies, the pollution scenario is getting worse. Also, the application of stringent laws and requirement of reduced levels of minimum contamination levels have put a question mark on the effectiveness of simple biological processes and conventional water treatment technologies (Zhou et al., 2002). Therefore, with the advent of technological innovations, there is a need to revolutionize methods for water treatment and remediation.

With its growing realm, Nanotechnology provides scientists a new dimension to deal with the ever rising problem of clean water availability (Bora et al., 2014; Qu et al., 2013). Also, the quest for developing robust new methods at lower cost, less energy, minimum use of chemicals and least impact on the environment, had driven the focus of environmentalist, water technologists, and engineers on nanotechnology revolution for rejuvenating the polluted fresh water reservoirs by implication of new materials and technologies. Already, the technology had put in a dramatic impact on water quality research and with its broad and diverse range of applications it offers various opportunities and challenges to further stimulate positively in this area of water engineering and treatment.

BACKGROUND

Access to safe and adequate water is the right of every individual living in this world but still 0.8 billion people according to WHO do not have access to quality drinking water and further 2.5 billion people lack access to improved sanitation. The industrial revolution in addition to bestowing us with amenities of life had also resulted in the production of diverse nature of new chemicals and materials which degradation is becoming a serious concern. Hence, loading of water with these diverse nature of pollutants including disinfectants and their byproducts, inorganic and organic chemicals, radionuclides and even resistant strains of microbes has not only limited the fresh water availability but has greatly impacted the water quality. All this resulted in inadequate drinking water, sanitation, and hygiene, which are estimated to cause more than 0.8 million diarrheal disease deaths per year and contribute substantially to several other diseases. Loading of the above-mentioned diverse range of pollutants and emerging of new contaminants also requires new treatment technologies to address the provision of safe water – the search lead to utilization of nanotechnology for water cleanup and remediation.

AQUA-NANOTECHNOLOGY

"Aqua-nanotechnology" has now been recognized as a branch of nanotechnology that deals with the application of nanomaterials for 1) water treatment, 2) remediation and 3) pollution prevention (Tratnyek et al., 2006). Nanotechnology-enabled treatment of water and wastewater provides the much needed

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

technological revolution desired to facilitate the removal of a large range of contaminants in an easy, timely and affordable manner with much-improved treatment efficiency (Qu et al., 2013). This chapter addresses the development and implication of nanomaterials like metal and mixed metal oxides, polymer composites, clay composites, carbon-based composites etc. that ameliorated the water quality by promoting sustainable water management.

1. Nano Metal Oxides:

A variety of nano metal oxides (NMO) and their composites have been developed to treat water and wastewater for the removal of inorganic, organic and microbial impurities. Among these, titanium oxide, iron oxides, aluminum oxide, and zinc oxide are commonly used ones (Hua et al., 2012; Zhan et al., 2014).

Different synthetic approaches have been used to synthesize these NMO, among which co-precipitation, sol-gel and hydrothermal techniques (Rao, C. N. et al., 2006) have gained attraction because of their ease and low cost. These NMOs have been able to remove multiple contaminants simultaneously ranging from heavy metals and anions to dyes, pesticides, and microbes but in majority of cases their role as adsorbents is manipulated owing to their economic feasibility and ease of modification to enhance their selectivity and adsorption potential as well as considering (Bora et al., 2014).

Titanium dioxide, TiO_2, in anatase phase, had long been recognized as a material of choice for decontamination of water because of its structure and surface properties (Kumar et al., 2014) in addition to being low cost (Ghasemzadeh et al., 2014). Various heavy metals (Pb, Cu, Ni, Cd, Hg etc.) have been removed using TiO_2 showed adsorption capacities in the range of 7 to 166 mg/g mostly obeying pseudo-second order kinetics and Langmuir adsorption model (Ghasemi et al., 2012; Jin et al., 2015; Liang et al., 2000). The adsorption process was observed to be endothermic supported by pH in the range of 5-8 irrespective of the type of metal adsorbed (Ghasemi et al., 2012; Rashidi et al., 2010). At this pH electrostatic attraction between negatively charged TiO_2 NP and positively charged metal ions dominated promoting surface complexation reactions that support metal uptake (Jin et al., 2015). The adsorption process was dependent on crystalline phase both in the case of anions (F^{1-}) and cations (Pb^{2+}) uptake; pure anatase NPs are found more effective (Suriyaraj et al., 2014). Further, the removal efficacy was found to be independent of coexisting ions normally present in water i.e. Na; K, Ca, Mg; Al; Zn, Fe at tolerance levels of 5000; 2000; 1000 and 500 mg/L, respectively (Liang et al., 2000). The photocatalytic potential of these NMOs was exploited for removal/degradation of organic pollutants like dyes etc. (Farooq et al., 2009) and in some cases ensures complete mineralization of organic pollutants. The photocatalytic activity of TiO_2 was initiated by illumination, thereby transferring an electron to conduction band with the generation of a hole in valance band (Ba-Abbad et al., 2012) as shown in Figure 1a depicting the general photocatalysis mechanism. Because of its photocatalytic nature (Gautam et al., 2016; Hua et al., 2012) TiO_2 is found equally effective in degrading microbes and organic pollutant but the process is usually assisted by H_2O_2 or/and UV light (Ba-Abbad et al., 2012; Gautam et al., 2016) to activate TiO_2 to release photo-generated charges that then initiates the degradation (Gautam et al., 2016). This portrays major disadvantage of TiO_2 for its applicability in industrial settings (Abou-Gamra et al., 2015). In this regard few efforts were done to modify the TiO_2 structure to make it visible light responsive (VLR) by undergoing incorporation of other metals (Kaur, T. et al., 2016; Rauf et al., 2011), metal oxides (Wang, X. et al., 2006), metal salts (Hu, C. et al., 2006), non-metals (Long et al., 2011) or a combination of these (Wang, X. et al., 2006). This process led to the introduction of new states in the band gap of TiO_2

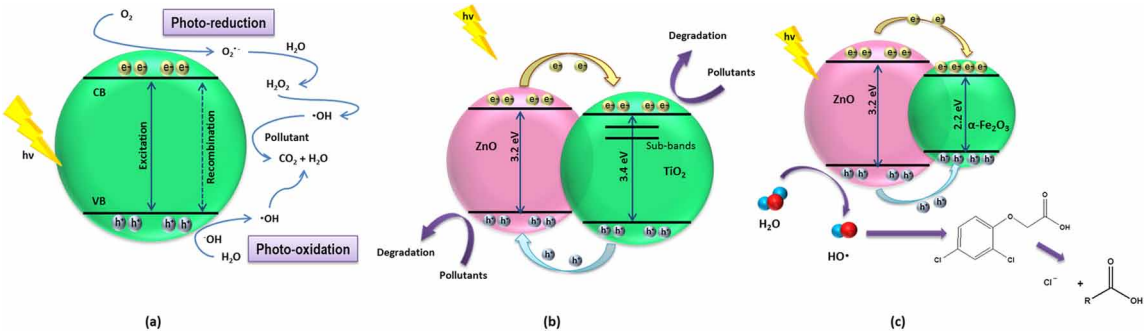
EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

resulting in overlapping of these states which consequently improve visible light absorption properties and charge transfer (Long et al., 2011). Enhanced adsorption capacities and degradation rates were observed for these VLR-TiO_2 nanomaterials (Kaur, T. et al., 2016).

Alumina, Al_2O_3, is another famous material used for water purification purpose as adsorbent because of its amphoteric nature (Szekeres et al., 1998). Enhanced toxicity of alumina and its mixed oxides nanoparticles as compared to their bulk counterparts was reported for algal as well as bacterial strains (Jiang, W. et al., 2009; Sadiq et al., 2011). The activity is affected by the size of NPs as indicated by the studies carried out on gram-negative bacteria i.e. *Pseudomonas* and *Enterobacter* (Riaz et al., 2016). The interaction of alumina NPs with bacterial strain led to changes in cell wall morphology causing cell deactivation and death of the organism (Jiang, W. et al., 2009). In addition to that alumina NPs underwent several other mechanisms that were proposed for the antimicrobial potential of metal oxide nanoparticles in general which are highlighted in Figure 2 (Dizaj et al., 2014). Nano-alumina is also used for scavenging of metals but with low adsorption capacities (Zhan et al., 2014). Efforts were put in to enhance the uptake of metal ions by undergoing modification (Li, J. et al., 2008) but results are not much encouraging except in some cases e.g. Cu^{2+} (167 mg/g) (Mahdavi et al., 2015; Stietiya et al., 2014). On another hand, high adsorption capacities were noticed in the case of dyes on unmodified nano Al_2O_3 (Zhan et al., 2014) while that of pesticides are determined by their nature and availability of positive sites on the adsorbent surface (Clausen et al., 2001).

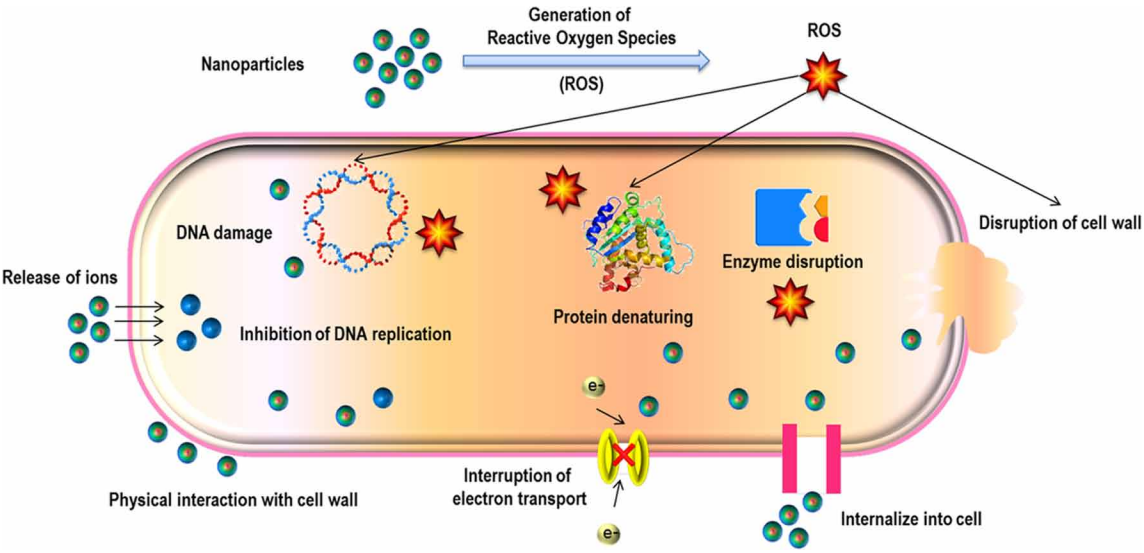
Zinc oxide, ZnO, antimicrobial properties of its nanoparticles were exploited against various gram-positive and negative bacterial and fungal strains (Dobrucka et al., 2016; He et al., 2011; Yousef et al., 2012) and found to have highest toxicity when compared with their bulk counterparts (Yousef et al., 2012; Zhang, L. et al., 2007) and other metal oxides (Azam et al., 2012; Jiang, W. et al., 2009). The mode of action proposed is typical as for other NPs based on the release of metal ions, electrostatic interactions, generation of reactive oxygen species (ROS) and the collapse of the bacterial membrane as portrayed in Figure 2 (Dizaj et al., 2014). Antibacterial activity was affected by synthetic approach (Sirelkhatim et al., 2015) as well as water chemistry and showed an inverse dependence on particle size as it directly impacts the release of Zn^{2+} ions (Li et al., 2011; Zhang, L. et al., 2007). Some studies have also marked NP's concentration as a more dominating factor towards antimicrobial activity than the particle size. Moreover, stabilizing agents can augment the activity by directly affecting agglomeration, but no direct impact on the type of stabilizing agents was observed (Zhang, L. et al., 2007).

Figure 1. Photocatalytic degradation mechanism of pollutants on a) MONP b) ZnO-TiO_2 nanocomposite c) ZnO-α-Fe_2O_3 Nanocomposite for degradation of 2,4-D (Chen, J. et al., 2016; Homaeigohar et al., 2014; Lee et al., 2016; Maya-Treviño et al., 2014; Umar et al., 2013)



EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. Different mechanisms responsible for antimicrobial activity of metal oxide nanoparticles (Dizaj et al., 2014)



ZnO system has the advantage of being not UV-assisted (Dobrucka et al., 2016) however use of it can enhance the photocatalytic potential to a considerable extent (Sirelkhatim et al., 2015). High degradation/ removal rates for various dyes (Zhan et al., 2014), pesticides (Khan, S. et al., 2015), organometallics (Olushola et al., 2014), pharmaceutical compounds (Han et al., 2012) and other organic aliphatic and aromatic contaminants (Anju et al., 2012; Shinde et al., 2011) were noticed both in absence and presence of irradiation on treatment with ZnO NP/ thin films/ nanowires/ nanoneedles. The reaction displayed dependence on calcination temperature, irradiation time, pH and ZnO dosage (Hayat et al., 2011), defects formation (Meng et al., 2015), particle size and structure/morphology (Wang, H. et al., 2007; Yang, J. L. et al., 2004). Correspondingly, photocatalytic degradation efficiency of anions like CN^- (Bagabas et al., 2013) and PO_4^{3-} (Elkady et al., 2016) was greatly impacted by the morphology of ZnO. In case of metal adsorption, overall low adsorption capacities were observed for Ni^{2+}, Pb^{2+} and As^{5+} (Mahdavi et al., 2012; Venkatesham et al., 2013; Zhan et al., 2014) while for Cd^{2+}, Cu^{2+}, Zn^{2+} and Hg^{2+} higher removal rates were noticed (Mahdavi et al., 2012; Rafiq et al., 2014; Sheela et al., 2012) which were even greater than the ones shown by iron and copper oxides (Mahdavi et al., 2012) but lower than that of MgO (Rafiq et al., 2014). For Nobel metals, three times improved removal efficacy was observed for nano ZnO as compared to nano TiO_2 (Park et al., 2003).

Oxides of iron, magnetite (Fe_3O_4), maghemite (γ- Fe_2O_3), hematite (α-Fe_2O_3) and goethite (α-FeOOH) because of their low toxicity, unique magnetic properties and biocompatible nature have always remained the material of choice for water treatment (Teja et al., 2009; Xu, P. et al., 2012). Rapid fluoride adsorption had been assisted by nano γ-Fe_2O_3 but with low adsorption capacity (Jayarathna et al., 2015). The use of mixed iron oxides helped in increasing the uptake capacity but system took much longer time to achieve equilibrium (Mohapatra et al., 2011). Chemical and electrostatic interactions together with ligand exchange reactions between an anion and OH^- or water on adsorbent surface played their role in the removal of anions (Mohapatra et al., 2011). The uptake as a general protocol depends on upon the initial pH, adsorbent dose, temperature and initial adsorbate concentration and presence of co-ions like

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

SO_4^{2-} and Cl^{-1} (Mohapatra et al., 2011; Nalbandian et al., 2016). In the case of α-Fe_2O_3 nanofiber, indirect independence of CrO_4^{2-} removal was observed on the diameter of nanofiber which was attributed to change in the surface area solely because of physical nature of adsorption (Nalbandian et al., 2016). In the case of heavy metals, fast removal of on nano γ-Fe_2O_3 was facilitated by the presence of reactive sites on surface hence enabling the system to reach equilibrium in short time (Hu, J. et al., 2006). Contrarily, nano-Fe_3O_4 took a longer time to achieve equilibrium (Giraldo et al., 2013; Mahdavi et al., 2012) probably due to differences in surface area and particle size. Introducing functionalization to Fe_3O_4 had greatly reduced the time to achieve equilibrium and with better adsorption capacity that increased with increase in the concentration of functionalizing moiety (Huang et al., 2009). The uptake efficacy though dependent on cation nature, pH, temperature etc. (Giraldo et al., 2013) but dramatic change in adsorption were observed with change in particle size (Xiao et al., 2015) surface sites, porosity and ionic strength (Giraldo et al., 2013). In contrary to previous studies Cheng *et.al.* showed no effect of a change in ionic strength on adsorption of Arsenic (Cheng et al., 2016). Studies on the effect of competing ions like HCO_3^{1-}, SO_4^{-2}, F^{1-}, Cl^{1-} and NO_3^{1-} indicated no effect on adsorption while HPO_4^{2-} and SiO_3^{2-} impacted to somewhat extent (Cheng et al., 2016). Similar studies performed pointed out that the effect of coexisting ions (i.e. sulphate, phosphate, nitrate, silicate) on removal efficacy vary with change in pH (Tuutijärvi et al., 2012).

The surface adsorption of IONP was more effective and rapid for hydroxyl containing dyes like bromocresol green than the ones that don't have OH group e.g. methyl red (Saha et al., 2011). Complete and fast removal of such dyes was achieved by use of hematite hollow nanofibers (Gao, Q. et al., 2015) and γ-Fe_2O_3 owing to chemisorption (Khan, M. et al., 2016). Simply changing the pH to alkaline media effectively desorbed these IONP ensuring their reuse (Saha et al., 2011). In the case of phenol, the mineralization efficacy depended on the generation of OH radicles and presence of other organic pollutants which suppressed the degradation process (Wang, W. et al., 2013). The process can be speeded up by use of UV irradiation and controlling its irradiation time and laser energy (Bardajee et al., 2013; Gondal et al., 2009).

IONP have proved themselves as effective antimicrobial agents as well against different microbial strains (Ismail et al., 2015). They operate in similar way as other NMO (Figure 2) i.e. on basis on reactive oxygen species generated that later interact with DNA and protein of bacteria leading to damage of cell (Tran et al., 2010) but the activity level achieved by Fe_2O_3 was less than ZnO and CuO NPs (Azam et al., 2012). Gram negative bacteria were more resistant to IONP than gram positive owing to differences in the cell wall, cell physiology and degree of contact (Azam et al., 2012). Positively and negatively charged surface modified Fe_3O_4 NP depicted dissimilar response to bacterial toxicity since different surface charges interacted with the bacterial cell differently; order of toxicity observed was positively charged > bare Fe_3O_4 > negatively charged. Moreover, surface properties of NMO are more decisive in determining antimicrobial activity than the properties of the core itself (Javanbakht et al., 2016).

Nano-Mixed metal oxides (NMMO) of iron, aluminum, titanium and zinc have also been exploited for water treatment. Several methods have been used for their synthesis which includes sol-gel, co-precipitation, wet chemical synthesis, microemulsion etc. Unique properties resulted from the combination of these materials (Kapoor et al., 2004). Among these, photocatalytic activity is one of the most exploited property in water treatment. This in the case of NMMOs helps in reducing electron-hole pair recombination which portrays the major disadvantage of NMO. In addition to that such combinations promote the generation of OH● and ROS thereby enhancing the photocatalysis process. A model system of ZnO-TiO_2 and ZnO-α-Fe_2O_3 is presented in Figure 1 b and c. which are produced by a combination of

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

two NMOs (Chen, J. et al., 2016; Homaeigohar et al., 2014; Lee et al., 2016; Maya-Treviño et al., 2014). The introduction of ZnO into TiO_2 promoted sub-bands production along with generation of defects resulting in a decrease in energy gap and better response to UV illumination (Chen, J. et al., 2016). Hence, owing to these attributes much higher and faster dye degradation was achieved by these NMMO systems when compared to pure NMO. Various combinations used in this aspect are ZnO/TiO_2, γ-Fe_2O_3/SiO_2, Al_2O_3/TiO_2, ZnO/Fe_2O_3, WO_3/TiO_2, ZnO/Fe_3O_4, ZnO/SnO_2, CeO_2/TiO_2, SnO_2/TiO_2, ZrO_2/TiO_2 CuO/ZnO etc. Factors like the type of dopant, doped or molar concentration, irradiation time, precipitation agent during synthesis, sintering temperature, crystallite size, pollutant type, counter ions etc. determined the degradation efficacy in these cases. The change in molar concentration considerably affected the band gap, phase change, purity, morphology, crystallite size (Cun et al., 2002; Hameed et al., 2009; Wang, J. et al., 2009). In the case of mixed metal oxides of IONP presence of competitive ions like heavy metals considerably altered the uptake of dyes depending upon radii and charge they carry. In addition to that low concentrations of humic acid promoted adsorption process because of enhancement in the available surface area but in excess amounts they obstructed the adsorption process by blocking the passage of adsorbate (Chen, D. et al., 2016).

Defluoridation achieved by use of MgO/γ-Al_2O_3 was higher than $/\gamma$-Al_2O_3 and was slightly affected by the presence of counter-ions (Nazari et al., 2015) while in the case of Al_2O_3/Fe_3O_4 NMMO, the presence of other ions had no impact on removal efficacy (Chai et al., 2013). The electrostatic interactions which demarked the main role in adsorption process were affected by the presence of competing ions in order phosphate > carbonate >> sulphate > nitrate > chloride (Azari et al., 2015). TiO_2 doped IONP when used as an adsorbent, the equilibrium was achieved within 5 min for As^{3+} uptake even in dark while for As^{5+} UV illumination was required to remove it from the water. As^{3+} adsorption was predicted to take place by oxidation to As^{5+} which then adsorbed on to the NMMO surface (Yu, L. et al., 2013).

Triple metal combinations were also evaluated by many researchers in the search for having effective and efficient photocatalysts, adsorbents and antimicrobial agents with promising results (Motlagh et al., 2015).

2. Polymer Composites

Metal matrix polymer nanocomposites are usually synthesized by two main techniques

1. *In situ* synthesis, and
2. Direct compounding (Zhang, Q. et al., 2013; Zhao et al., 2011).

Incorporation of these MONP into polymer matrix have not only increased the surface area, reactivity and mechanical strength but also inherent in them the unique combination of properties of both inorganic nanoparticles and organic polymer matrix making them fit for meeting the water treatment process requirements i.e. antifouling, photocatalytic, flux enhancement, hydrophilicity etc. (Baghbanzadeh et al., 2016; Jeon et al., 2010; Zhang, Q. et al., 2013). Further, it facilitates to overcome separation issues of NP (Zhao et al., 2011). Many inorganic materials have been used as inorganic fillers to prepare these polymeric hybrids e.g. metal NP (Palza, 2015), MONP (Baghbanzadeh et al., 2016), metal carbonates (Rong et al., 2006) etc. but here in this chapter the scope will just focus on the ones prepared using MONP.

The addition of metal oxides advocated hydrophilic character of the polymeric material thereby promoting antifouling properties. Moreover, modifications using magnetic or superparamagnetic MONP

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

ensured easy separation and recovery of the adsorbent by application of low-gradient magnetic field (Qu et al., 2013). Highest and fastest recovery achieved in the case of core-shell magnetic nanorods based polymer composites was ~ 25s (Venkateswarlu et al., 2015). Optimization of nano Fe_3O_4 in Polyethersulfone (PES) - nano Fe_3O_4 membrane facilitated in achieving desirable pore size, roughness, porosity, contact angle, water flux and rejection capacity. Using high weight % of IONP put a negative impact on water flux by suppressing microvoids growth and enhancing film skin thickness; the best results were achieved for 10 and 15 wt.% doping (Alam et al., 2013). Likewise, doping of Al_2O_3 into PES, having application as membrane bioreactors, led to decrease in de-ionized water permeation with an increase in polymer ratio while the opposite effect was observed with the rise in NP concentration (Maximous et al., 2009). Correspondingly, varying the amount of SiO_2 NP (30 nm) in PES potentially impacted water flux, hydrophilicity and antifouling abilities of the membrane and hence this can be tailored to achieve desirable properties (Shen et al., 2011).

Magnetic capturing of Cu^{2+} was achieved by controlled coating of polyethylenimine (PEI) onto Fe_3O_4 NP. Increase in PEI coated amount enhanced the uptake which was facilitated by the presence of amino nitrogens in the structure of PEI; this enabled manipulating the adsorbents' colloidal properties to achieve maximum adsorption even at ultra-trace levels of free Cu^{2+} ions selectively (Goon et al., 2010). Contrary to this, uptake capacity increased (341.43 – 489.12 mg/g) with decrease in PVA content (4.55 – 1.43%) in case of PVA/ SiO_2 NC fibers modified by mercapto groups with maximum adsorption reaching to 504.89 mg/g in just 40 min. Higher affinity for Pb^{2+} was detected in hybrid polymers prepared by unmodified or amino functionalized Fe_3O_4 NP and nanorods followed by other metals like Cd^{2+}, Zn^{2+}, Ni^{2+}, Hg^{2+} and As^{3+} (Badruddoza et al., 2013; Ge et al., 2012; Venkateswarlu et al., 2015). Contrarily, better uptake was achieved in the case of Fe_3O_4 NP/carboxymethyl-β-cyclodextrin; attributed to the presence of –COOH and –OH functional groups in adsorbent (Badruddoza et al., 2013). Uptake was slightly affected by the presence of monovalent ions but in the case of divalent strong competition was observed (Ge et al., 2012). Additionally, increase in ionic strength can cause decreases in ions removal (Badruddoza et al., 2013). Ion exchange properties of Fe_3O_4/polypyrrole core-shell NC were exploited for Cr^{6+} that replaced doped Cl^- with chromate ions (Bhaumik et al., 2011). On another hand, Pb^{2+} uptake was expedited by improving porosity and surface roughness of Polyethersulfone /hydrous manganese dioxide (PES/HMO) NC membranes achieved by increasing HMO:PES ratio (Gohari et al., 2013). Type of MONO doped, particle distribution with respect to depth, the amount of doping and dopant to polymer ratio considerably affects the behavior and properties of the composite membranes (Maximous, N. et al., 2010). Desorption of metals like Pb^{2+}, Cd^{2+}, Ni^{2+} and Cu^{2+} from polymer composites was attained through Na_2-EDTA, HNO_3, H_3PO_4 and HCl solutions depending on the polymer system, metal adsorbed and leaching agent nature (Badruddoza et al., 2013; Gohari et al., 2013; Venkateswarlu et al., 2015). Relating these polymer composite systems with activated carbon showed comparable removal efficiencies for Pb^{2+}, little less for Cr^{3+} and much lower for Cd^{2+} (Maximous, N. N. et al., 2010).

High fluoride adsorption capacities were also reported within 60 and 120 min for the magnetically modified polyacrylonitrile and polyaniline hybrids, respectively. Desorption studies performed indicated irreversible nature of adsorption process in former case 85% desorption was achieved for polyaniline NC at pH 12 (Jokar et al., 2014; Nouri et al., 2014). Dye adsorption on to Fe_2O_3/Polyacrylonitrile NC occurred as a result of electrostatic attraction between positively charged IONO and negatively charged dye molecule. The uptake capacity depended on the synthetic approach used with maximum adsorption achieved for the hydrothermally grown nanoparticles i.e. 50.08 mg/g (Patel et al., 2016). Mixed metal

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

oxide polymer (Fe_3O_4/Cu_2O/PANI) NC with different morphologies i.e. flower-like, microsphere with ordered nanosheet and porous dandelion were synthesized by altering aniline/Cu^{2+} ratio and used for dyes and oil adsorption. The high uptake capacity was achieved due to porous structure and in the case of dyes combined effects of electrostatic interactions, coordination of dyes anionic group with metal ions and van der Waals forces. The prepared materials were selective for anionic dyes as cationic dyes face repulsive interactions between positively charged dyes groups and metal ions (Cao, J. et al., 2014). Complete mineralization of phenol was attained under visible light by optimizing the aniline/TiO_2 concentration during *in situ* synthesis of TiO_2-PANI NC. The photocatalyst maintained the activity till 5 recycles and performed much better than neat TiO_2 (Li, X. et al., 2008).

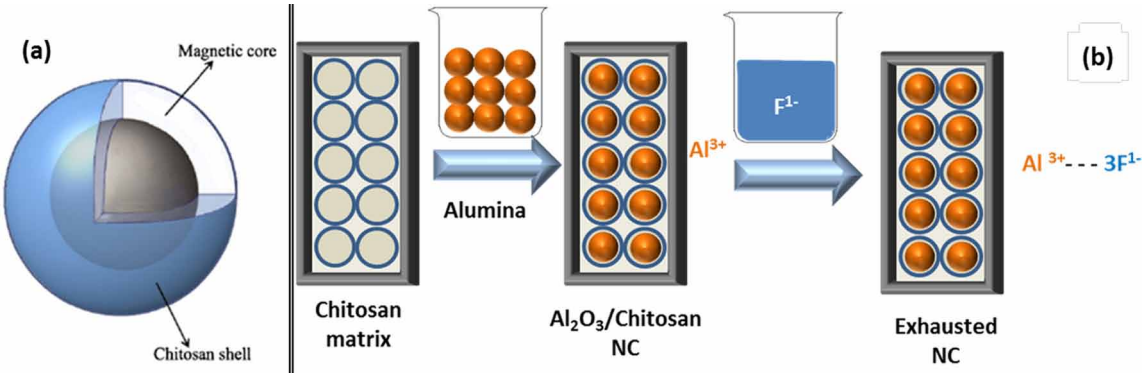
3. Chitosan and Clay Based Nanocomposites

Chitosan is a natural low-cost polymer having excellent chelation properties and easy modification protocols making it suitable for water purification purposes (Ngah et al., 2011; Reddy et al., 2013). The presence of amine groups facilities adsorption of cations, anions or polar molecules by chelation, electrostatic interactions, dipole interactions, van der Waals forces etc. (Rangel-Mendez et al., 2010). Certain disadvantages of these biopolymers i.e. agglomeration, denaturing, separation inefficiency and inadequacy to be used in packed columns limit their applications. Provision of support or modification helps in overcoming these disadvantages but lowers the uptake potential and intraparticle diffusion of these bio-composites (Ngah et al., 2011; Rangel-Mendez et al., 2010; Tanhaei et al., 2015; Zhang, J. et al., 2011).

Using IONP as additives in Chitosan NC enhances chemical stability and provide ion selectivity (Tanhaei et al., 2015). The usual procedure of making these NC is to grow a layer of chitosan on NP making core-shell structure (Figure 3a (Reddy et al., 2013)) that not only prevents agglomeration of chitosan but also increase number of free amino groups (Fan et al., 2011; Zhang, J. et al., 2011). In other studies, hydrogen bonding of MONP with these amino groups and availability of free O-H with partial positive charge was suggested (Shrifian-Esfahni et al., 2015). In the case of Arsenic removal, these magnetically active chitosan materials showed higher selectivity for As^{5+} than As^{5+} but the process was highly pH dependent (Wang, J. et al., 2014). Beads prepared by dispersing of FeOOH NP in chitosan chelates with arsenic either by forming a covalent bond with amine group or iron (Hasan et al., 2014) as contrary to Fe_3O_4/chitosan NC where –OH group on adsorbent surface interacted with arsenic (Wang, J. et al., 2014). Besides, NC of chitosan with single metal dopant e.g. Al_2O_3 (Gandhi et al., 2010), TiO_2 (Miller et al., 2010), CuO (Elwakeel et al., 2015) or with mixed metal oxides like Al_2O_3- TiO_2 (Yamani et al., 2012), Fe-Mn binary oxide (Qi et al., 2015) had been used for heavy metal removal. On comparative account, the bimetallic NC had better adsorption potential than the pure systems (Yamani et al., 2012). The presence of counter ions presents in water impacted differently on the metal uptake. For example As^{5+} uptake was hindered by HPO_4^{2-}, HCO_3^{1-} and SiO_3^{2-} ; not affected by SO_4^{2-} and enhanced by Ca^{2+} and Mg^{2+} ions (Qi et al., 2015) while that of Cr^{6+} was reduced by presence of all the co-ions employed in the experiment i.e. NaCl, Na_2SO_4, $NaNO_3$, $CaSO_4$ and $MgSO_4$ (Gandhi et al., 2010). Effective separation was achieved in the case of these NC but employing ultrasound radiation ensured much faster separation (Liu, X. et al., 2008). These nanocomposites offered the advantage of reuse owing to reversible nature of metal and magnetic chitosan NC interaction hence, the simple weak acid treatment made these adsorbent workable up to 6 cycles (Fan et al., 2011).

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 3. a) Magnetic core chitosan shell (Reddy et al., 2013) b) Mechanism of F^{-1} adsorption on Al_2O_3/ Chitosan NC (- - - shows electrostatic adsorption and complexation) (Viswanathan et al., 2010)



Fluoride removal onto Al_2O_3/chitosan composite was directed by 1) electrostatic attraction between Al^{3+} and F^{1-} and 2) complexation of F^{1-} with positively charged surface as shown in Figure 3b (Viswanathan et al., 2010). However, dyes adsorption on to MONP/chitosan was suggested to be chemisorption in which amino groups on the surface of chitosan NC bind to negatively charged groups of dyes (Salehi et al., 2010; Zhang, J. et al., 2011). Magnetic chitosan NC promoted dye removal as well through spontaneous and endo- or exo-thermic process obeying Langmuir adsorption model and pseudo-second-order kinetic model (Cao, C. et al., 2014; Fan, Zhang, Li, et al., 2012; Fan, Zhang, Luo, et al., 2012; Reddy et al., 2013). The selectivity for a specific dye uptake can be enhanced by using the molecular imprinting technique (Fan, Zhang, Li, et al., 2012). Synergistic effects of mixed metal oxides and chitosan were also exploited to achieve better removal percentage of acidic dyes (Jiang, H. et al., 2013; Zhu, H. et al., 2012). Higher uptake i.e. 216 mg/ g was achieved for Remazol Red 198 in 60min at room temperature by using O-carboxymethylchitosan-N-lauryl doped with γ-Fe_2O_3 NP (Demarchi et al., 2015). Faster (< 20min) and even higher removal were achieved for methyl orange by using Fe_3O_4/Al_2O_3/chitosan and γ-Fe_2O_3/chitosan NC i.e. 416 mg/g and 779 mg/g (Obeid et al., 2013; Tanhaei et al., 2015). Factors like chitosan amount, MONP wt. %, solidifying solutions type and concentration, UV light, adsorbent structure, dye nature etc. affected the degradation efficacy of the chitosan NC (Haldorai et al., 2013; Li, Q. et al., 2008; Zubieta et al., 2008). In the case of dyes as well co-ions present in the water and wastewater like Cl^{1-}, SO_4^{2-} and HCO_3^{1-} affected uptake capacity negatively (Salehi et al., 2010). Concurrently, multifunctional nature of these hybrid materials had been investigated for simultaneous uptake of heavy metal, bactericidal activities and photocatalytic properties and results obtained were encouraging (Haldorai et al., 2013, 2014; Zhang, X. et al., 2011). Also, studies carried out on actual wastewater samples showed effective cleanup by the MONP and chitosan NC (Zhang, X. et al., 2011).

Even better results are obtained by introduction of layer by layer system (i.e. TiO_2/ chitosan supported on glass) that achieved 32 times faster decolourisation rate as compared to single layer system (TiO_2) owing to collective role played by multiple effects of photocatalysis, adsorption in sub-layers and charge-transfer process (Nawi et al., 2012). The rate of degradation strongly depends on the TiO_2 content and number of layers as increase in these parameters led to increasing in film thickness, mobility, and diffusion of dye molecules, penetration of light source and growth in crystallite size of TiO_2 (Nawi et al., 2012; Zainal et al., 2009).

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

Antimicrobial applications of chitosan against many fungal, bacterial and viral strains are well researched. This broad-spectrum nature, higher bacteriostatic and bactericidal activities and lower toxicity to mammalian cells make it a material of choice. The mode of action is based on interaction with the cell membrane and chelating action (Rabea et al., 2003). With the incorporation of NP, the bactericidal effects of NC are amplified owing to multifarious mechanisms that hamper bacterial growth and promote cell inactivation (Haldorai et al., 2013; Shrifian-Esfahni et al., 2015). The viable bacterial count results showed 99% and 93% *E. coli* inactivation by CuO and MgO impregnated chitosan, respectively as compared to 7% for pristine chitosan (Haldorai et al., 2013, 2014). Likewise, Lower MIC values were observed in the case of susperparamagnetic IONP/chitosan NC *vs* superparamagnetic IONP i.e. 40 µg/mL compared to 70 µg/mL for *P. aeruginosa* and 45 µg/mL compared to 90 µg/mL for *E. coli* respectively (Shrifian-Esfahni et al., 2015).

Clays, another natural source, are hydrous aluminosilicates that act as a natural scavenger of pollutants (Bhattacharyya et al., 2008). Modifications of clays either through intecalation, acid activation, functionalization, incorporation of dopants, the formation of hybrid structures etc. had been practiced for improving their properties (Bhattacharyya et al., 2008). Montmorillonite, bentonite, kaolinite, sepionite, halloysite and zeolite are the common clay minerals that have been used as fillers for preparing NC materials (Motshekga et al., 2013). Dispersing MONP into the clay structure reduce agglomeration and settles the particles on the surface or inside the pores of clay thereby enhancing surface area (Yuan et al., 2009).

Antimicrobial potential of clays is enhanced by harnessing them with the MONP ones making these hybrid materials extremely useful. Comparative account of undoped and doped bentonite against *E. coli* and *E. faecalis* showed that pristine bentonite had no effect on the bacterial growth; ZnO-bentonite showed inhibition zone in the range of 5-9mm and Ag/ZnO-bentonite (6-11mm) had activity comparable to Ag/bentonite (8-11mm) (Motshekga et al., 2013).

Different clays like bentonite, sepiolite, montmorillonite were doped with Fe_3O_4 and utilized for adsorption of heavy metals. 15.3 mg of Cr^{6+} /g of Fe_3O_4/monmarillonite was removed owing to the electrostatic interaction that led to its reduction to Cr^{3+}; the adsorption depended on upon the synthetic approach used to prepare adsorbent (Yuan et al., 2009). Much higher uptake of Cr^{6+} (161.29mg/g) was achieved on $MgFe_2O_4$ /bentonite composite and with easy regeneration using 0.1N NaOH (Kaur, M., Singh, et al., 2015). On another hand, Fe_3O_4 impregnation in bentonite resulted in low uptake capacity (18.76 mg/g) for Co^{2+} (Hashemian et al., 2015). Higher uptakes for As^{3+} i.e. 50.35 mg/g were observed when sepiolite was used instead with good effectiveness on real ground water samples as well. The fast adsorption of As^{3+} into NC was facilitated by the highly porous structure of clay that promoted easy access to iron oxide to result in As(III) – Fe(III) complexes and partial oxidation of As^{3+} to As^{5+} as outlined in Figure 4. The presence of F^{-1} and PO_4^{3-} as counter-ions impact the removal of As (III) to some extent because of competition posed by the similarity in structure and dissolution constants (Tian et al., 2015). Quick uptake of heavy metals (i.e. 2 min) was achieved using Fe_3O_4/talc NC leading to adsorption capacities in order of Pb^{2+} (74.62 mg/g) > Ni^{2+} (33.33 mg/g) > Cu^{2+} (21.05 mg/g) as calculated using Langmuir model (Kalantari et al., 2014).

MONP were supported on different aluminosilicate for evaluating their catalytic degradation pattern towards organic contaminants (Khatamian 2012). In general, the supports provided better degradation potential compared to unsupported ones by augmenting the radicle attack on organic moiety. Moreover, changing its size to nanoscale further enhanced the degradation rate. The type of support also impacted considerably as it not only determines the morphology of NC but also facilitates the binding of adsorbate to its surface.

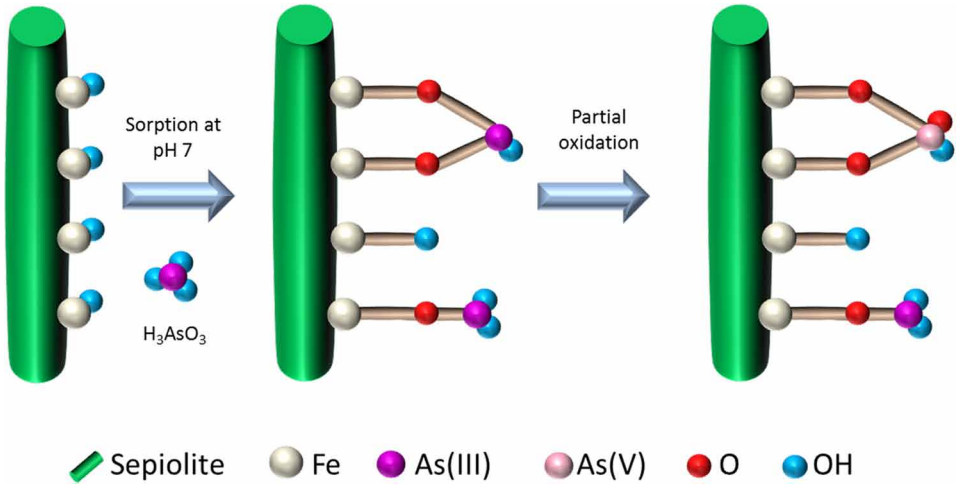
Figure 4. Proposed mechanism of As^{3+} adsorption on Fe_3O_4/ sepiolite nanofibers (Tian et al., 2015)



Among the three type of supports i.e. HZSM-5, clinoptilolite and zeolite HY, the best results were obtained with HZMS-5 because it promoted finely dispersed structure, enhanced hydrophobicity, high adsorption capacity, and delocalization of electrons generated . Reduction in pore size and surface area of support was observed with incorporation of ZnO NP in nanoclinoptilolite or HZSM-5 (Khatamian et al. 2012) while the opposite behavior was observed when Fe_2O_3 NP was doped in montmorillonite (Hristodor et al., 2011) probably due to the differences in synthetic approach used. Also, increase in MONP loading reduced the rate of degradation owing to aggregate formation and surface masking led to a reduction in active sites or due to $OH^{\cdot}$ trapping). Changing the type and concentration of electron scavenging agents e.g. H_2O_2 and $KBrO_3$ influenced degradation rates by controlling $OH^{\cdot}$ availability and electron - hole combination (Hristodor et al., 2011). Incorporating metal ions like Fe^{3+}, Ni^{2+}, La^{2+}, Y^{3+} etc. into TiO_2/Zeolite NC had also played their role in reducing the electron – hole recombination and introducing defects in MONP crystal structure thereby enhancing catalytic degradation rate even higher than the undoped TiO_2/ZSM-5 NC (Khatamian et al., 2012). Further investigation into the mechanism of degradation points out that the pore size of zeolites is usually less than 1nm while the size of organic molecules e.g. dyes is greater than that hence adsorption into the porous structure is not probable just surface interactions of MONP or zeolite play their role in adsorbing these molecules. The size of these molecules sterically hinders adsorption of more molecules on NC surface, therefore, the researchers claim that dye degradation does not take place on the surface of NC directly rather due to $OH^{\cdot}$ generated on the surface of catalyst and holes as well (Wang, C.-C. et al., 2008). Further insight into the adsorption potential of these NC led to important findings i.e. Fe_3O_4 NC with bentonite had a really high affinity (1600 mg/g) for methylene blue which is 2 to 3 times higher than the normal bentonite (Hashem, 2012).

4. Carbon-Based Composite

Graphene (GR), Graphene oxide (GO) and reduced graphene oxide (rGO) are known to be a good adsorbent and used in many water treatment studies (Cohen-Tanugi et al., 2012; Gao, W. et al., 2011; Kemp et al., 2013). Modification of GR or GO were carried out to exploit its properties for water remediation by using metal oxides (Upadhyay et al., 2014). Such incorporation not only averts the possibility of

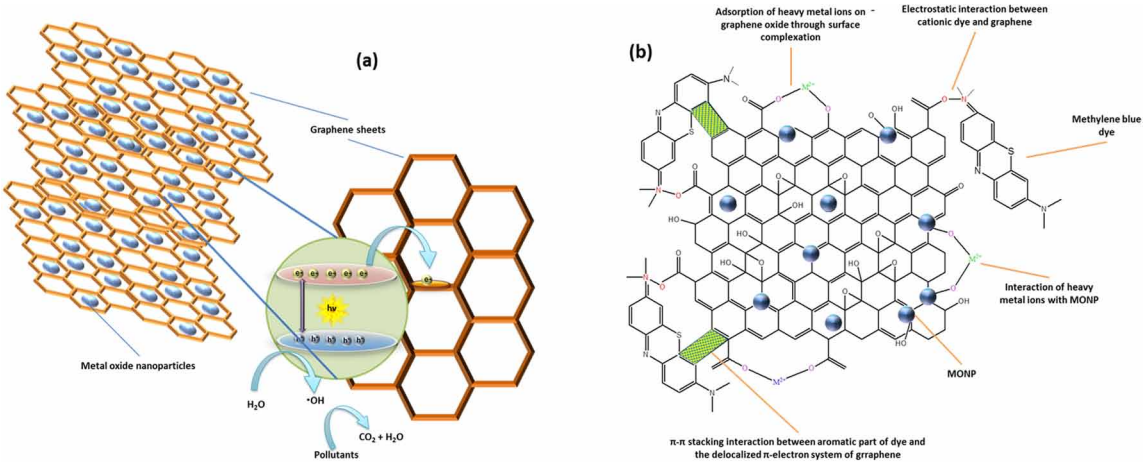
Figure 5. Metal oxide-graphene composites a) Photocatalytic activity based on percolation mechanism showing electron transfer from metal oxide's conduction band to graphene b) various interactions operative in adsorption of pollutants i.e. heavy metal ions and dye molecules (Upadhyay et al., 2014)



electron-hole recombination and metal leaching but also promotes pollutants' removal by π-π stacking. The arrangement also favors the appearance of new valence bands by promoting hybridization. Therefore, owing to these properties the photocatalytic activity and adsorption of this graphene-based MONP composites have been investigated and exploited for enhanced removal of organic moieties and heavy metals. Figure 5 gives an insight into photocatalytic mechanism operating in these composites and various mechanisms leading to adsorption of pollutants from water (Upadhyay et al., 2014).

TiO_2 doped GO NC membranes were found 100% effective in filtering dye molecules at low concentrations (Xu, C. et al., 2013). Much improved uptake capacity (83.26 mg/g) was achieved by using sheets of reduced GO (rGO) with TiO_2 incorporation which was even higher than its nanotubes (75.36 mg/g), pure sheets of GR (48.73mg/g) and tubular titanate (36.51mg/g) (Nguyen-Phan et al., 2012). Use of $ZnTiO_3$ in modifying rGO resulted in improved methylene blue degradation when assisted with visible light irradiation in comparison to $ZnTiO_3$. The adsorption occurred as a result of π- the π interaction between dye and GO that manipulated with structural changes of the composite, for this reason, less uptake was noticed in the case of the cubic structure as compared to hexagonal one (Gayathri et al., 2015). Fe_3O_4/GO magnetically active material had been exploited as a multipurpose water purification material that achieved 97% dye degradation, 77.67% bacterial cell lysis and 69 mg/g Pb (II) adsorption capacity that remains viable up to 5 cycles (Santhosh et al., 2014). The NC was also effective in removal of both anionic (33.66 mg/g) and cationic dyes (13 – 173 mg/g) (Ai et al., 2011; Meral et al., 2014; Sun et al., 2011; Yao et al., 2012), p-chloroaniline (43.86 mg/g) and aniline (375.94 mg/g). Simultaneous removal of Cd^{2+}, methylene blue, and orange G was carried out by using Fe_3O_4-GO leading to reduction in adsorption capacity from 91.92, 64.23, 20.85 to 59.69, 58.08, 20.48 mg/g, respectively as the matrix changed from ultrapure water to tap water owing to presence of interfering ions (Deng et al., 2013).

Fe_3O_4/GO exhibited better adsorption properties for the metals under study at all the pH values following the order Pb(II) > Cu(II) > Cd(II) when compared with MWCNT and powdered activated carbon (AC). Experiments also suggested a decrease in each metal uptake in the multi-component system as compared to the single component system though overall metal adsorption capacity was enhanced in the

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

former case (Hur et al., 2015). Yoon *et.al.* advocated that conversion of GO to rGO was a facile step as a comparison of $As^{3+/5+}$ adsorption on to Fe_3O_4 NP modified GO and rGO displayed a compatible affinity with both the composite materials. Insight into adsorption mechanism suggested that electrostatic interaction played important role in binding As^{5+} to the adsorbent while surface complexation governed As^{3+} attachment (Yoon et al., 2016). Modification of GO with mixed metal oxide NP (Fe_3O_4 and MnO_2) was tried for sorption of $As^{3+/5+}$ but led to the removal of only 14.04 and 12.22 mg/g, respectively (Luo, X. et al., 2012). Metal adsorption on Fe_3O_4/GO NC depends on the nature of ions and level of affinity with Fe to form an inner or outer shell complex (Tayyebi et al., 2015). In case of double core GR structures containing iron core, Fe_2O_3 inner shell and outer shell of Si-S-O compound the adsorption mechanism was due to synergetic effects of surface complexation and single layer adsorption which is different from the pure GR in which only the later phenomenon plays its role (Zhu, J. et al., 2011). The dispersion of mesoporous Fe_2O_3/TiO_2 nanoparticles on reduced GO helped in enhancing the number of active sites ensuring attainment of equilibrium in 15 min and 99.5 mg As^{5+} and 77.7 mg As^{3+} uptake per gram of adsorbent at neutral pH while maintaining the same sorption up to 4 cycles. The order of interfering anions in this case follows: phosphate > sulphate > nitrate > chloride > fluoride (Babu et al., 2016).

In the case of nanocomposites doping with MONP gained attention and showed considerably high activity as compared to the pristine MONP or Graphene-based compounds (Cao et al., 2013). Diverse nature of bacterial strains was used as a model to determine the effect of these NC using TiO_2, ZnO, and Fe_3O_4 as dopants (Bykkam et al., 2015; Dědková et al., 2015; Upadhyay et al., 2014; Wang, Y.-W. et al., 2014). The usual mechanism responsible for the antimicrobial activity was through the generation of ROS and release of anions (Chang et al., 2015; Wang, Y.-W. et al., 2014). GO role was proposed as the main agent that either proliferates in bacterial cells or caused slicing off a cell resulting in oozing of cell contents (Upadhyay et al., 2014). Factors like weight % of MONP, ROS amount produced, time of irradiation, the viability of microorganisms and production of extracellular protein by microorganisms impacts the antimicrobial potential of these nanocomposites. Among these, the first four are related to each other as Wt.% and time of irradiation directly affects the ROS generation which should be more than the bacterial colonies growth so that bacteria do not have ample time to divide themselves. As far as protein generation is concerned, it is expected to block MONP active sites by adhering onto their surface hence causing a decrease in their activity (Dědková et al., 2015). In addition to that activity was also affected by changing the loading of GR as the excess of it can also hamper the availability of MONP active sites (Cao et al., 2013). Further, the presence of anions e.g. HCO_3^{1-} and HPO_4^{2-} considerably hampered the activity by capturing the holes, reacting with OH●, blocking the active sites of MONP surface by adsorbing on its surface and absorption of exciting light. The same impact but with less intensity was observed for SO_4^{2-} and NO_3^{1-} ions. The presence of Cl^{1-} ions on contrary either had no impact on the activity or assisted the antimicrobial activity by propagating formation of Cl●, a disinfectant. The cations i.e. Na^{1+} and K^{1+} occurrence did not influence on the viable count of bacteria (Chang et al., 2015).

Carbon nanotubes (CNT), single walled (SWCNT) and double walled (MWCNT), properties have been exploited for the water purification with and without modifications (Ong et al., 2010; Rao, G. P. et al., 2007; Upadhyayula et al., 2009). The potential of MWCNT for dye adsorption in absence and presence of light irradiation was accessed by using methyl orange as test contaminant. MWNT synthesized by chemical vapor deposition showed better adsorption capacity (35.4–64.7 mg/g) as compared to the commercial one (25 mg/g) (Yan et al., 2011; Yao et al., 2011). Structural modification of CNT by MONP doping complements the degradation potential of NC (Ahmad et al., 2014; Behnam et al., 2013). Removal efficacy rose in order CNT < MO < MO/CNT and irradiated > non-irradiated systems

EBSCOhost - printed on 2/14/2023 11:45 AM via . All use subject to https://www.ebsco.com/terms-of-use

together with noticeable change in light absorption properties (Ahmad et al., 2014; Saleh et al., 2012) that facilitated enhanced photocatalytic, sonocatalytic and sonophotocatalytic activity as compared to the single component systems (Ahmad et al., 2014). Such systems also accelerated the degradation of contaminant (e.g. diazinone) to less toxic product (i.e. 2-isopropyl-6-methyl-4-pyrimidinol) (Behnam et al., 2013). Varying the amount of either CNT or the dopant directly influenced the uptake potential of NC. Gain in CNT loading from 1-20 wt. % led to increasing in surface area from 49.6 -135.5m^2/g facilitating boost in COD reduction from initial value of 627 to 43 mg/L (Ahmad et al., 2014). The process was governed by slip-induce surface diffusion that assists electron trapping and photon absorption (Nguyen et al., 2016). Also, synergistic effects, enhanced by the homogeneity of the composite, promoted effective charge transfer that impacted the degradation or adsorption potential (Miranda et al., 2014).

Higher uptake potential of modified CNT was also noticed in the case of heavy metals adsorption. Independent studies carried out on NMO/ CNT exhibited improved removal % for metal ions when compared with CNT, charcoal and pure NPs (Chen et al., 2009; Gupta et al., 2011). The studies indicated dependence on agitation time and pH in case of batch studies while on bed thickness subject to column studies (Gupta et al., 2011). The composites were selectively adsorbed Pb^{2+} in mixed systems irrespective of dopant used (Gupta et al., 2011; Peng, Luan, Di, et al., 2005). Ca^{2+} and Mg^{2+} always present in water significantly enhanced the As^{5+} adsorption from 10 to 81.9 and 78.8 mg/g on to CeO_2-CNT owing to the formation of ternary surface complex reaction (Peng, Luan, Ding, et al., 2005). Cd^{2+} removal was aided with MnO_2 doped o-MWCNT (acid oxidized) prepared at different pH and compared with unmodified MWCNT and o-MWCNT; the order followed was MnO_2/o-MWCNT (pH5) > MnO_2/o-MWCNT (pH3) > MnO_2/o-MWCNT (pH7) > o-MWCNT > MnO_2/o-MWCNT (pH1) > raw MWCNT. The reason was attributed to 1) increase in surface roughness with pH, 2) enhancement in uniformity and thinness of MnO_2 layer deposited with an increase in pH and 3) increase in MnO_2 loading with pH that hinders available area for adsorption (Luo, C. et al., 2013). The introduction of 20-30 nm thick diamine functionalized SiO_2 homogeneous layer onto MWCNT was able to remove Pb(II) > Cu(II) > Zn(II) > Ni(II) in larger amounts as compared to SiO_2@MWCNT, o-MWCNT and MWCNT. The intraparticle diffusion model predicts the adsorption process to occur in three stages i.e. adsorption onto the exterior surface of NC, adsorption into the interior surface of pores and diffusion resistance leading to attainment of equilibrium (Yang, W. et al., 2013). Antibacterial activity of TiO_2/CNT thin films (5-30nm) depended on CNT:TiO_2 and annealing temperature that altered the photocatalytic performance owing to indirect impact on the formation of carbonaceous bonds between the CNT and MO (Akhavan et al., 2010)

Carbon encapsulated magnetic nanoparticles (CEMNPs) has emerged as a new class of nano adsorbent consisting of metallic cores completely covered in carbon coatings that are 1-5 nm thick (Pyrzyńska et al., 2010). The magnetic core helps in easy separation and carbon shell ensures effective adsorption (Zhang, D. et al., 2010). Comparative account of these CEMNPs with activated carbon and CNT promoted better uptake of Cu^{2+} and Cd^{2+} i.e. 30-60% *vs.* < 20% owing to differences in surface charge densities of these materials (Pyrzyńska et al., 2010). It was also determined that limiting step in CNMEPs is film diffusion in contrast to intraparticle diffusion (Bystrzejewski et al., 2011). The adsorption capacities reported for these nanoparticles for Cu^{2+}, $Cd^{2+,}$ and Co^{2+} fall in the range of 1.23 – 3.21 mg/g (Bystrzejewski et al., 2009; Pyrzyńska et al., 2010) while for Cr^{6+} it is 0.63 mg/g (Zhang, D. et al., 2010). These NP effectively decontaminated water by adsorbing phenols, phthalates, sulfonamides, tetracyclines and quinolones antibiotics based on hydrogen bonding, π-π and hydrophobic interactions. The adsorption phenomena and uptake of certain compounds were affected by the amount of oxygen-containing species and surface graphitized carbon which can be varied by changing the temperature during synthesis of CNMEP (Niu et al., 2011).

NP impregnated activated charcoal (AC) helps is solving water treatment issues by enhancing the properties of activated charcoal. Incorporation of magnetic nanoparticles assisted in the fast and easy separation of adsorbate making them useful for water purification applications (Fayazi et al., 2015). The addition of these enhanced the basicity as well as adsorption potential of modified charcoal in comparison to pure one. Utilization of these NC in micro-filter membrane system led to 85.3, 80 and 79.6% removal of dissolved organic compounds, turbidity and UV_{254}, respectively, in addition to longer removal operation when compared with other micro-filter systems (Kim et al., 2013). Clustering of $MgFe_2O_4$ into AC structure formed 40-50 nm sized nanocomposite that effectively adsorbed Cr^{6+} through the spontaneous and exothermic process leading to increasing in q_e from 500 (NC) to 333 mg/g (unmodified charcoal) at room temperature. NaOH treatment helped in 80% desorption but with 5% reduction in removal efficiency (Kaur, M., Kaur, et al., 2015). Dyes removal efficacy varies by changing the amount of loading of MONP into AC. The reason can be attributed to resulting differences in particle sizes, surface morphology, and photocatalytic effects. Experiments had also shown a considerable decrease in degradation percentage for the same adsorbent or photocatalyst by changing the systems' exposure mode from UV light to fluorescent lamp (Hu et al., 2011). The efficiency of ZnO/AC NC system for dye adsorption depended on the size of charcoal particles, irradiation time, H_2O_2 amount (Yu, X. et al., 2015) and sonication time (Jamshidi et al., 2016).

In addition to these, there is various nanomaterial i.e. hybrid nanomaterials are used for the water treatment and purification. In this regard NMO-clay-polymer composites, NMO-polymer-CNT, NMO-Chitosan-Graphene oxide, NMO-chitosan-activated carbon etc. have been exploited and some of them proved to have good qualities needed for water purification purposes (Jeon et al., 2010; Larraza et al., 2012; Liu, L. F. et al., 2010; Ray et al., 2015).

CONCLUSION

The water pollution scenario arising from the flow of omnifarious contaminants led to evolution and need of aqua-nanotechnology that through its broad spectrum approach gives rise to various possibilities to solve this problem. In this regard metal oxide nanomaterials had gained attention but owing to their agglomeration and separation issues led researchers and technologist to opt for their nanocomposites. These include composites with carbon-based materials (carbon nanotubes, graphene etc.), natural and synthetic polymers, clays (including zeolite). Efforts were put into synthesizing the materials with high adsorption capacities, photocatalytic potential and recyclable, in essence, to make the water purification procedure fast, cost-effective and environmentally friendly. Among this variety of nanomaterials, the choice of best nanomaterial to be used always depends on the nature and concentration of a contaminant to be removed and matrix composition which needs to be treated in addition to cost involvement. The magnetic clay based composites offer advantages including the combination of materials available owing to its natural source and magnetic nature that makes the material cost effective. In addition, it offers easy separation and multifunctional nature that enables adsorption of heavy metals, decontamination from microbial impurities and photocatalytic degradation of organic pollutants hence offering a single solution to this wide scoped water pollution problem.
