Library of Congress Cataloging-in-Publication Data

Names: Information Resources Management Association, editor.
Title: Data analytics in medicine : concepts, methodologies, tools, and applications / Information Resources Management Association, editor.
Description: Hershey, PA : Medical Information Science Reference, [2020] | Includes bibliographical references and index. | Summary: “”This book examines practical applications of healthcare analytics for improved patient care, resource allocation, and medical performance, as well as for diagnosing, predicting, and identifying at-risk populations”-- Provided by publisher.
Identifiers: LCCN 2019027003 (print) | LCCN 2019027004 (ebook) | ISBN 9781799812043 (h/c) | ISBN 9781799812050 (eISBN)
Subjects: MESH: Medical Informatics Applications | Data Science--methods | Big Data | Data Mining
Classification: LCC R855.3 (print) | LCC R855.3 (ebook) | NLM W 26.5 | DDC 610.285--dc23
LC record available at https://lccn.loc.gov/2019027003
LC ebook record available at https://lccn.loc.gov/2019027004

Gaivéo, José / *Polytechnic Institute of Setubal, Portugal* 1683
Galli, Brian J. / *Long Island University – Post, USA* 1467
Garza, Roberto / *Escuela de Ingenieria y Tecnologias de Informacion, Mexico* 614
Gewald, Corinna / *Neu-Ulm University of Applied Sciences, Germany* 1720
Gewald, Heiko / *Neu-Ulm University of Applied Sciences, Germany* 1720
Ghosh, Poulami / *Jadavpur University, India* 833
Giokas, Kostas / *National Technical University of Athens, Greece* 2033
Girdhar, Anup / *Sedulity Groups, India* 1485
Girish, Amoolya / *M. S. Ramaiah Institute of Technology, India* 1328
Gomes, Jorge / *Universidade de Lisboa, Portugal* 2018
Gómez, Lorena G / *Escuela de Ingenieria y Tecnologias de Informacion, Mexico* 614
Gonzalez, Rafael A. / *Pontificia Universidad Javeriana, Colombia* 325
Good, Alice / *University of Portsmouth, UK* 879
Gürsel, Güney / *Command post of Gendarme Logistics, School ol of Technical and Auxiliary Forces, Turkey* 50
Gyaase, Patrick Ohemeng / *Catholic University College of Ghana, Ghana* 117
Hahn, Michael E. / *University of Oregon, USA* 762
Hallberg, Josef / *Luleå University of Technology, Sweden* 1599
Hassanien, Aboul Ella / *Cairo University, Egypt* 565
Haueisen, Jens / *Technical University Ilmenau, Germany* 249
Helm, Emmanuel / *University of Applied Sciences Upper Austria, Austria* 424
Hertzberg, Libi / *Tel Aviv University, Israel & Weizmann Institute of Science, Israel* 580
Hirche, Johannes / *Luleå University of Technology, Sweden* 1599
Hung, Che-Lun / *Providence University, Taiwan* 629
Idrish, Sherina / *North South University, Bangladesh* 1632
Iqbal, Mehree / *North South University, Bangladesh* 1632
Issa, Mohamed / *Zagazig University, Egypt* 565
Jácome, Cristina / *University of Aveiro, Portugal* 815
Jeong, Hyeon-Cheol / *Sahmyook University, Korea* 1674
Jeyanathan, Josephine / *Kalasalingam University, India* 1328
Jiang, Furen / *Changchun University, China* 1006
Joseph, Rhoda / *Penn State University, USA* 1364
Joshi, Deepak / *Indian Institute of Technology (IIT) Delhi, India* 762
Kamal, Md Sarwar / *East West University, Bangladesh* 1168
Kamalashree, N. / *Sri Jayachamarajendra College of Engineering, India* 410
Kannot, Yaman M. Khalid / *Arab Academy for Science, Egypt* 1814
Karakitsos, Petros / *National and Kapodistrian University of Athens, Greece* 1921
Kartsidis, Panagiotis Emmanouil / *Aristotle University of Thessaloniki, Greece* 1963
Katehakis, Dimitrios G. / *Institute of Computer Science (ICS), Greece* 1450
Kelder, Jo-Anne / *University of Tasmania, Tasmania* 1537
Kesari, Anupama / *Sri Jayachamarajendra College of Engineering, India* 410

Table of Contents

Preface xxvii

Volume I

Section 1
Fundamental Concepts and Theories

Chapter 1
A Guideline to Use Activity Theory for Collaborative Healthcare Information Systems Design 1
Carolin Durst, University of Bremen, Germany
Nilmini Wickramasinghe, Epworth HealthCare, Australia & Deakin University, Australia
Jana Riechert, University of Erlangen-Nuremberg, Germany

Chapter 2
A Review of Type 1 Diabetes (T1D): To Assist Patients' and Carers' Understanding of This Condition 13
Eileen O'Donnell, Technological University Dublin, Ireland
Liam O'Donnell, Technological University Dublin, Ireland

Chapter 3
For Better Healthcare Mining Health Data 50
Güney Gürsel, Command post of Gendarme Logistics, School ol of Technical and Auxiliary Forces, Turkey

Chapter 4
Population Health Management and the Science of Individuality 74
Anastasius Moumtzoglou, Hellenic Society for Quality and Safety in Healthcare, Greece, & P. & A. Kyriakou Children's Hospital, Greece
Abraham Pouliakis, National and Kapodistrian University of Athens, Greece

Section 2
Development and Design Methodologies

Chapter 5
A Yes/No Answer Generator Based on Sentiment-Word Scores in Biomedical Question Answering 103
Mourad Sarrouti, Sidi Mohammed Ben Abdellah University, Morocco
Said Ouatik El Alaoui, Sidi Mohammed Ben Abdellah University, Morocco

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Chapter 6
Towards an Integrated Electronic Medical Records System for Quality Healthcare in Ghana: An Exploratory Factor Analysis 117
Patrick Ohemeng Gyaase, Catholic University College of Ghana, Ghana
Richard Darko-Lartey, Catholic University College of Ghana, Ghana
Harrison William, Catholic University College of Ghana, Ghana
Foster Borkloe, Catholic University College of Ghana, Ghana

Chapter 7
SOA Governance in Healthcare: Beyond Early Ideas to a Structured Framework 133
Konstantinos Koumaditis, University of Piraeus, Greece, & Aarhus University, Denmark
Marinos Themistocleous, University of Piraeus, Greece & University of Coimbra, Portugal

Chapter 8
KIIPF - An Integrated Inter-Operable Knowledge Management Process Framework for Healthcare: Implementation in Pakistani Healthcare Industry 150
Mohamad Fauzan Noordin, International Islamic University, Malaysia
Arfan Arshad, International Islamic University, Malaysia & Jazan University, Kingdom of Saudi Arabia
Roslina Othman, International Islamic University, Malaysia

Chapter 9
Semantic Health Mediation and Access Control Manager for Interoperability Among Healthcare Systems 169
Abdullah Alamri, University of Jeddah, Saudi Arabia

Chapter 10
A Conceptual Framework for an Extension Access Control Models in Saudi Arabia Healthcare Systems 182
Amin Shaqrah, Taibah University, Saudi Arabia
Talal Noor, Taibah University, Saudi Arabia

Chapter 11
Strategies of Virtual Screening in Medicinal Chemistry 194
Giovanna Ilaria Passeri, Molecular Discovery Ltd., UK
Daniela Trisciuzzi, Università degli Studi di Bari "Aldo Moro", Italy
Domenico Alberga, Università degli Studi di Bari "Aldo Moro", Italy
Lydia Siragusa, Molecular Discovery Ltd., UK
Francesco Leonetti, Università degli Studi di Bari "Aldo Moro", Italy
Giuseppe F. Mangiatordi, Università degli Studi di Bari "Aldo Moro", Italy
Orazio Nicolotti, University of Bari, Italy

Chapter 12
Relationships between Models of Genetic Regulatory Networks with Emphasis on Discrete State Stochastic Models 226
Randip Pal, Texas Tech University, USA

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Chapter 13
Integral Equation Formulations and Related Numerical Solution Methods in Some Biomedical Applications of Electromagnetic Fields: Transcranial Magnetic Stimulation (TMS), Nerve Fiber Stimulation 249
Dragan Poljak, University of Split, Croatia
Mario Cvetković, University of Split, Croatia
Vicko Dorić, University of Split, Croatia
Ivana Zulim, University of Split, Croatia
Zoran Đogaš, University of Split, Croatia
Maja Rogić Vidaković, University of Split, Croatia
Jens Haueisen, Technical University Ilmenau, Germany
Khalil El Khamlichi Drissi, Blaise Pascal University, France

Chapter 14
Efficient Algorithm for Answering Fuzzy Medical Requests in Pervasive Healthcare Information Systems 268
Wissem Labbadi, University of Tunis, Tunisia
Jalel Akaichi, King Khalid University, Saudi Arabia

Chapter 15
Development of Portable Medical Electronic Device for Infant Cry Recognition: A Primitive Experimental Study 288
Natarajan Sriraam, M. S. Ramaiah Institute of Technology, India
S. Tejaswini, M. S. Ramaiah Institute of Technology, India
Ankita Arun Chavan, M. S. Ramaiah Institute of Technology, India

Chapter 16
Efficient String Matching Algorithm for Searching Large DNA and Binary Texts 298
Abdulrakeeb M. Al-Ssulami, King Saud University, Saudi Arabia
Hassan Mathkour, King Saud University, Saudi Arabia
Mohammed Amer Arafah, King Saud University, Saudi Arabia

Chapter 17
Concept Attribute Labeling and Context-Aware Named Entity Recognition in Electronic Health Records 325
Alexandra Pomares-Quimbaya, Pontificia Universidad Javeriana, Colombia
Rafael A. Gonzalez, Pontificia Universidad Javeriana, Colombia
Oscar Mauricio Muñoz Velandia, Pontificia Universidad Javeriana, Colombia
Angel Alberto Garcia Peña, Pontificia Universidad Javeriana, Colombia
Julián Camilo Daza Rodríguez, Pontificia Universidad Javeriana, Colombia
Alejandro Sierra Múnera, Pontificia Universidad Javeriana, Colombia
Cyril Labbé, University Grenoble Alpes, France

Chapter 18
Knowledge Management Process-Oriented Strategy for Healthcare Organizations 340
Nurhidayah Bahar, UCSI University, Malaysia
Shamshul Bahri, University of Malaya, Malaysia

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Chapter 19
Use-Case Driven Approach for a Pragmatic Implementation of Interoperability in eHealth 357
Karima Bourquard, IHE – Europe, France
Alexander Berler, IHE – Europe, Belgium

Chapter 20
Agent-Based Modelling in Multicellular Systems Biology 369
Sara Montagna, Università di Bologna, Italy
Andrea Omicini, Università di Bologna, Italy

Chapter 21
The Role of Artificial Intelligence in Clinical Decision Support Systems and a Classification Framework 390
Steven Walczak, University of South Florida, USA

Chapter 22
Predictive Modeling of Surgical Site Infections Using Sparse Laboratory Data 410
Prabhu RV Shankar, University of California Davis, USA
Anupama Kesari, Sri Jayachamarajendra College of Engineering, India
Priya Shalini, Sri Jayachamarajendra College of Engineering, India
N. Kamalashree, Sri Jayachamarajendra College of Engineering, India
Charan Bharadwaj, Sri Jayachamarajendra College of Engineering, India
Nitika Raj, Sri Jayachamarajendra College of Engineering, India
Sowrabha Srinivas, Sri Jayachamarajendra College of Engineering, India
Manu Shivakumar, State University of New York at Buffalo, USA
Anand Raj Ulle, Sri Jayachamarajendra College of Engineering, India
Nagabhushana N. Tagadur, Sri Jayachamarajendra College of Engineering, India

Chapter 23
Towards Semantic Interoperability in Health Data Management Facilitating Process Mining 424
Barbara Traxler, University of Applied Sciences Upper Austria, Austria
Emmanuel Helm, University of Applied Sciences Upper Austria, Austria
Oliver Krauss, University of Applied Sciences Upper Austria, Austria
Andreas Schuler, University of Applied Sciences Upper Austria, Austria
Josef Kueng, Johannes Kepler University Linz, Austria

Chapter 24
A Secure Robust and Privacy Enhanced Mobile Healthcare Framework 437
Hisham M. Alsaghier, Majmaah University, Kingdom of Saudi Arabia
Shaik Shakeel Ahamad, Majmaah University, Kingdom of Saudi Arabia

Chapter 25
An Intelligent Multi-Objective Framework of Pervasive Information Computing 456
Basant Tiwari, Hawassa University, Ethiopia
Vivek Tiwari, IIIT-NR, India

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Section 3
Tools and Technologies

Chapter 26
Detecting Human Diseases Relatedness: A Spreading Activation Approach Over Ontologies 471
Said Fathalla, Bonn University, Germany & Alexandria University, Egypt

Chapter 27
An Artificial Neural Network Classification of Prescription Nonadherence 487
Steven Walczak, University of South Florida, USA
Senanu R. Okuboyejo, Covenant University, Nigeria

Volume II

Chapter 28
Applying CI in Biology through PSO 502
Rojalina Priyadarshini, C. V. Raman College of Engineering, India
Nilamadhab Dash, C. V. Raman College of Engineering, India
Brojo Kishore Mishra, C. V. Raman College of Engineering, India
Rachita Misra, C. V. Raman College of Engineering, India

Chapter 29
Semantic Reconciliation of Electronic Health Records Using Semantic Web Technologies 528
Karim El Guemhioui, University of Quebec in Outaouais, Canada
Steven A. Demurjian, University of Connecticut, USA

Chapter 30
Principles and Analysis of Biological Networks: Biological Pathways and Network Motifs 551
Manika Sehgal, Institute of Microbial Technology, India
TirathaRaj Singh, Jaypee University of Information Technology, India

Chapter 31
Multiple Sequence Alignment Optimization Using Meta-Heuristic Techniques 565
Mohamed Issa, Zagazig University, Egypt
Aboul Ella Hassanien, Cairo University, Egypt

Chapter 32
GEView (Gene Expression View) Tool for Intuitive and High Accessible Visualization of Expression Data for Non-Programmer Biologists 580
Libi Hertzberg, Tel Aviv University, Israel & Weizmann Institute of Science, Israel
Assif Yitzhaky, Weizmann Institute of Science, Israel
Metsada Pasmanik-Chor, Tel Aviv University, Israel

Chapter 33
An Affordable Hybrid Cloud Based Cluster for Secure Health Informatics Research 593
Basit Qureshi, Prince Sultan University, Saudi Arabia

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Chapter 34
EEMI - An Electronic Health Record for Pediatricians: Adoption Barriers, Services and Use in Mexico 614
Juan C. Lavariega, Escuela de Ingenieria y Tecnologias de Informacion, Mexico
Roberto Garza, Escuela de Ingenieria y Tecnologias de Informacion, Mexico
Lorena G Gómez, Escuela de Ingenieria y Tecnologias de Informacion, Mexico
Victor J. Lara-Diaz, Escuela de Ingenieria y Tecnologias de Informacion, Mexico
Manuel J. Silva-Cavazos, Escuela de Ingenieria y Tecnologias de Informacion, Mexico

Chapter 35
Constructing a Bioinformatics Platform with Web and Mobile Services Based on NVIDIA Jetson TK1 629
Chun-Yuan Lin, Chang Gung University, Taiwan
Jin Ye, Chang Gung University, Taiwan
Che-Lun Hung, Providence University, Taiwan
Chung-Hung Wang, Chang Gung University, Taiwan
Min Su, Beijing University of Technology, China
Jianjun Tan, Beijing University of Technology, China

Chapter 36
Genetic Diagnosis of Cancer by Evolutionary Fuzzy-Rough based Neural-Network Ensemble 645
Sujata Dash, North Orissa University, India
Bichitrananda Patra, KMBB College of Engineering and Technology, India

Chapter 37
Wired and Wireless Distributed e-Home Healthcare System 663
Booma Devi Sekar, University of Macau, Macau
JiaLi Ma, University of Macau, Macau
MingChui Dong, University of Macau, Macau

Chapter 38
Hybrid Ensemble Learning Methods for Classification of Microarray Data: RotBagg Ensemble Based Classification 707
Sujata Dash, North Orissa University, India

Chapter 39
Fall Detection Depth-Based Using Tilt Angle and Shape Deformation 726
Fairouz Merrouche, University of Science and Technology USTHB, Algeria
Nadia Baha, University of Science and Technology USTHB, Algeria

Chapter 40
Energy Efficient Particle Optimized Compressed ECG Data over Zigbee Environment 743
Dilip Kumar, SLIET, India
Rajeev Kumar, DAVIET, India
Tony Singla, DAVIET, India

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Chapter 41
Electromyogram and Inertial Sensor Signal Processing in Locomotion and Transition Classification 762
Deepak Joshi, Indian Institute of Technology (IIT) Delhi, India
Michael E. Hahn, University of Oregon, USA

Chapter 42
A Hybrid Kernel Extreme Learning Machine and Improved Cat Swarm Optimization for Microarray Medical Data Classification 779
S. Chakravarty, Orissa Engineering College, India
R. Bisoi, Siksha 'O' Anusandhan University, India
P. K. Dash, Siksha 'O' Anusandhan University, India

Chapter 43
Integrated Approach for Automatic Crackle Detection Based on Fractal Dimension and Box Filtering 815
Cátia Pinho, University of Aveiro, Portugal
Ana Oliveira, University of Aveiro, Portugal
Cristina Jácome, University of Aveiro, Portugal
João Manuel Rodrigues, University of Aveiro, Portugal
Alda Marques, University of Aveiro, Portugal

Chapter 44
Electromyography-Based Functional Electrical Stimulation (FES) in Rehabilitation 833
Poulami Ghosh, Jadavpur University, India
Ankita Mazumder, Jadavpur University, India
Anwesha Banerjee, Jadavpur University, India
D.N. Tibarewala, Jadavpur University, India

Chapter 45
A Novel Delay-Based GFSK Demodulator in 65 nm CMOS for Low Power Biomedical Applications 852
Meng Fu, University of Melbourne, Australia
Stan Skafidas, University of Melbourne, Australia
Iven Mareels, University of Melbourne, Australia

Chapter 46
Step Towards Interoperability in Nursing Practice 865
Daniela Oliveira, University of Minho, Portugal
Júlio Duarte, University of Minho, Portugal
António Abelha, University of Minho, Portugal
José Machado, University of Minho, Portugal

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Chapter 47
An Analysis of Factors Affecting Postnatal Depression Intervention Adherence 879
Omobolanle Omisade, University of Portsmouth, UK
Alice Good, University of Portsmouth, UK
Tineke Fitch, University of Portsmouth, UK
Jim Briggs, University of Portsmouth, UK

Chapter 48
Modelling and Simulating Complex Systems in Biology: Introducing NetBioDyn – A Pedagogical and Intuitive Agent-Based Software..... 898
Pascal Ballet, Université de Bretagne Occidentale, France
Jérémy Rivière, Université de Bretagne Occidentale, France
Alain Pothet, Académie de Créteil, France
Michaël Theron, Université de Bretagne Occidentale, France
Karine Pichavant, Université de Bretagne Occidentale, France
Frank Abautret, Collège Max Jacob, France
Alexandra Fronville, Université de Bretagne Occidentale, France
Vincent Rodin, Université de Bretagne Occidentale, France

Chapter 49
Analysis of Electrocardiogram Data Compression Techniques: A MATLAB-Based Approach 930
Anukul Pandey, Dr. B. R. Ambedkar National Institute of Technology, India
Barjinder Singh Saini, Dr. B. R. Ambedkar National Institute of Technology, India
Butta Singh, Guru Nanak Dev University Regional Campus, India
Neetu Sood, Dr. B. R. Ambedkar National Institute of Technology, India

Chapter 50
A Study on Lifetime Enhancement and Reliability in Wearable Wireless Body Area Networks 971
Saranya Vasanthamani, Sri Krishna College of Engineering and Technology, India

Section 4
Utilization and Applications

Chapter 51
Pluralistic Tendencies in Healing Abantu Illness in the Contemporary South Africa 986
Kholekile Hazel Ngqila, Walter Sisulu University, South Africa

Chapter 52
Kinect-Based Limb Rehabilitation Methods 1006
Yongji Yang, Changchun University, China
Zhiguo Xiao, Changchun University, China
Furen Jiang, Changchun University, China

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Volume III

Chapter 53
Knowledge Acquisition Through Ontologies from Medical Natural Language Texts 1023
José Medina-Moreira, University of Guayaquil, Ecuador
Katty Lagos-Ortiz, University of Guayaquil, Ecuador
Harry Luna-Aveiga, University of Guayaquil, Ecuador
Oscar Apolinario-Arzube, University of Guayaquil, Ecuador
María del Pilar Salas-Zárate, University of Murcia, Spain
Rafael Valencia-García, University of Murcia, Spain

Chapter 54
Utilizing Combined Claims and Clinical Datasets for Research Among Potential Cases of Rare Diseases..... 1038
Kevin J. Bennett, University of South Carolina, USA
Joshua Mann, University of Mississippi Medical Center, USA
Lijing Ouyang, Centers for Disease Control & Prevention, USA

Chapter 55
PAGeneRN: Parallel Architecture for Gene Regulatory Network 1052
Dina Elsayad, Ain Shams University, Egypt
A. Ali, Ain Shams University, Egypt
Howida A. Shedeed, Ain Shams University, Egypt
Mohamed F. Tolba, Ain Shams University, Egypt

Chapter 56
Research Perspectives on Functional Micro and Nano Scale Coatings: New Advances in Nanocomposite Coatings for Severe Applications..... 1076
Jaime Andrés Pérez Taborda, Universidad Tecnológica de Pereira, Colombia & Instituto de Microelectrónica de Madrid-CSIC, Colombia
Elvis O. López, Centro Brasileiro de Pesquisas Físicas, Brazil

Chapter 57
Optimal Intervention Methods for Markovian Gene Regulatory Networks 1110
Mohammadmahdi Rezaei Yousefi, The Ohio State University, USA

Chapter 58
Human-Data Interaction in Healthcare 1148
Federico Cabitza, Università degli Studi di Milano-Bicocca, Italy
Angela Locoro, Università degli Studi di Milano-Bicocca, Italy

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Chapter 59
An Optimized Graph-Based Metagenomic Gene Classification Approach: Metagenomic Gene Analysis 1168
Md Sarwar Kamal, East West University, Bangladesh
Mohammad Ibrahim Khan, Chittagong University of Engineering and Technology, Bangladesh
Kaushik Dev, Chittagong University of Engineering and Technology, Bangladesh
Linkon Chowdhury, Chittagong University of Engineering and Technology, Bangladesh
Nilanjan Dey, Techno India College of Technology, India

Chapter 60
Healthy 3.0: Healthcare Digital Dimensions 1193
Maria Teresa Borges Tiago, University of Azores, Portugal
Flávio Tiago, UAC, Portugal
Francisco Emanuel Batista Amaral, University of Azores, Portugal
Sandra Silva, Unidade de Saúde de Ilha de S. Miguel Azores, Portugal

Chapter 61
Informed Consent in Healthcare: A Study Case of Genetic Services 1222
Bo Yu, George Mason University, USA
Duminda Wijesekera, George Mason University, USA
Paulo Costa, George Mason University, USA

Chapter 62
Towards User Authentication Requirements for Mobile Computing 1254
Yaira K. Rivera Sánchez, University of Connecticut, USA
Steven A. Demurjian, University of Connecticut, USA

Chapter 63
Perceptions of Play: Using Play-Doh to Enhance the Student Experience in Bioscience Higher Education 1283
Gemma Lace-Costigan, University of Salford, UK

Chapter 64
Pre-Implementation Case Studies Evaluating Workflow and Informatics Challenges in Private Primary Care Clinics for Electronic Medical Record Implementation 1297
Calvin Or, The University of Hong Kong, China

Chapter 65
Extraction of Protein Sequence Motif Information using Bio-Inspired Computing 1306
Gowri Rajasekaran, Periyar University, India
Rathipriya R, Periyar University, India

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Chapter 66
Classification of Breast Thermograms Using Statistical Moments and Entropy Features with Probabilistic Neural Networks 1328
Natarajan Sriraam, M. S. Ramaiah Institute of Technology, India
Leema Murali, M. S. Ramaiah Institute of Technology, India
Amoolya Girish, M. S. Ramaiah Institute of Technology, India
Manjunath Sirur, M. S. Ramaiah Institute of Technology, India
Sushmitha Srinivas, M. S. Ramaiah Institute of Technology, India
Prabha Ravi, M. S. Ramaiah Institute of Technology, India
B. Venkataraman, Indira Gandhi Centre for Atomic Research, India
M. Menaka, Indira Gandhi Centre for Atomic Research, India
A. Shenbagavalli, National Engineering College, India
Josephine Jeyanathan, Kalasalingam University, India

Chapter 67
HIPAA Security and Privacy Rules Auditing in Extreme Programming Environments 1341
Mahmood Alsaadi, Princess Sumaya University for Technology, Jordan
Malik Qasaimeh, Princess Sumaya University for Technology, Jordan
Sara Tedmori, Princess Sumaya University for Technology, Jordan
Khaled Almakadmeh, Hashemite University, Jordan

Chapter 68
The Cloud Gets Personal: Perspectives on Cloud Computing for Personalized Medicine 1364
Rhoda Joseph, Penn State University, USA
Patrick Brown, Thermo Scientific NanoDrop Products, USA

Chapter 69
Analysis of Healthcare Workflows in Accordance with Access Control Policies 1378
Sandeep Lakaraju, Dakota State University, USA
Dianxiang Xu, Boise State University, USA
Yong Wang, Dakota State University, USA

Chapter 70
Big Data and IoT-Allied Challenges Associated With Healthcare Applications in Smart and Automated Systems 1401
Mamata Rath, C.V. Raman College of Engineering, India

Section 5
Organizational and Social Implications

Chapter 71
Shared Electronic Health Records as Innovation: An Australian Case 1416
Troy Pullen, Queensland State Archives, Australia
Latif Al-Hakim, University of South Australia, Australia

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Chapter 72
Electronic Medical Record Implementation Challenges for the National Health System in Greece 1450
Dimitrios G. Katehakis, Institute of Computer Science (ICS), Greece

Chapter 73
Ethics of Electronic Health Record Systems 1467
Brian J. Galli, Long Island University – Post, USA

Chapter 74
Hierarchy Similarity Analyser-An Approach to Securely Share Electronic Health Records 1485
Shalini Bhartiya, IITM, India
Deepti Mehrotra, Amity University, India
Anup Girdhar, Sedulity Groups, India

Chapter 75
Patient Data De-Identification: A Conditional Random-Field-Based Supervised Approach 1502
Shweta Yadav, Indian Institute of Technology Patna, India
Asif Ekbal, Indian Institute of Technology Patna, India
Sriparna Saha, Indian Institute of Technology Patna, India
Parth S Pathak, ezDI, LLC, India
Pushpak Bhattacharyya, Indian Institute of Technology Patna, India

Chapter 76
Mobile Application for Patients' Waiting Time Control and Management of Diagnostic Imaging Examinations 1522
Dimitrios Zarakovitis, University of Peloponnese, Greece
Dimitrios Tsoromokos, University of Peloponnese, Greece
Nikolaos Tsaloukidis, University of Peloponnese, Greece
Athina Lazakidou, University of Peloponnese, Greece

Volume IV

Chapter 77
Ensuring Privacy of Participants Recruited via Social Media: An Australian Retrospective Visualisation and Roadmap 1537
Chandana Unnithan, Torrens University Australia, Australia
Paula M Swatman, Swinburne University, Australia
Jo-Anne Kelder, University of Tasmania, Tasmania

Chapter 78
Implications of Molecular Docking Assay for Bioremediation 1556
Zarrin Basharat, Fatima Jinnah Women University, Pakistan
Monazza Bibi, Fatima Jinnah Women University, Pakistan
Azra Yasmin, Fatima Jinnah Women University, Pakistan

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Chapter 79
The Performance of Educational Institutions Through the Electronic Records Management Systems: Factors Influencing Electronic Records Management System Adoption 1578
Muaadh Mukred, National University of Malaysia (UKM), Malaysia
Zawiyah M. Yusof, National University of Malaysia (UKM), Malaysia

Chapter 80
Online Social Exergames for Seniors: A Pillar of Gamification for Clinical Practice..... 1599
Stathis Th. Konstantinidis, NORUT, Norway
Ellen Brox, NORUT, Norway
Per Egil Kummervold, NORUT, Norway
Josef Hallberg, Luleå University of Technology, Sweden
Gunn Evertsen, NORUT, Norway
Johannes Hirche, Luleå University of Technology, Sweden

Chapter 81
Exploring the Role of Service Quality and Knowledge for Mobile Health Services 1632
Nabila Nisha, North South University, Bangladesh
Mehree Iqbal, North South University, Bangladesh
Afrin Rifat, North South University, Bangladesh
Sherina Idrish, North South University, Bangladesh

Chapter 82
Effect of Power and Phase Synchronization in Multi-Trial Speech Imagery..... 1654
Sandhya Chengaiyan, SSN College of Engineering, India
Divya Balathayil, SSN College of Engineering, India
Kavitha Anandan, SSN College of Engineering, India
Christy Bobby Thomas, M.S.Ramaiah University of Applied Sciences, India

Chapter 83
Nursing Students' Perception of Medical Information Protection in Hospitals..... 1674
Hyeon-Cheol Jeong, Sahmyook University, Korea

Chapter 84
Information Security Standards in Healthcare Activities 1683
José Gaivéo, Polytechnic Institute of Setubal, Portugal

Chapter 85
The Politics of Establishing ICT Governance for Large-Scale Healthcare Information Infrastructures 1704
Gro-Hilde Ulriksen, University Hospital North Norway, Norway
Rune Pedersen, University Hospital North Norway, Norway
Gunnar Ellingsen, Arctic University of Norway, Norway

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Chapter 86
Inhibitors of Physicians' Use of Mandatory Hospital Information Systems (HIS) 1720
Heiko Gewald, Neu-Ulm University of Applied Sciences, Germany
Corinna Gewald, Neu-Ulm University of Applied Sciences, Germany

Chapter 87
Using Key Performance Indicators to Reduce Perceived Perioperative Complexity and Improve Patient Workflow 1738
Jim Ryan, Auburn University at Montgomery, USA
Barbara Doster, University of Alabama, USA
Sandra Daily, Duke Medical Center, USA
Carmen Lewis, Troy University, USA

Chapter 88
Building Intelligent Systems for Paying Healthcare Providers and Using Social Media to Detect Fraudulent Claims 1758
Jack S. Cook, The College at Brockport, USA
M. Pamela Neely, The College at Brockport, USA

Chapter 89
Forensic Investigation of Digital Crimes in Healthcare Applications 1781
Nourhene Ellouze, University of Carthage, Tunisia
Slim Rekhis, University of Carthage, Tunisia
Noureddine Boudriga, University of Carthage, Tunisia

Section 6
Critical Issues and Challenges

Chapter 90
Bidirectional Spreading Activation Method for Finding Human Diseases Relatedness Using Well-Formed Disease Ontology 1814
Said Fathalla, University of Bonn, Germany & Alexandria University, Egypt
Yaman M. Khalid Kannot, Arab Academy for Science, Egypt

Chapter 91
An Investigation Into the Efficacy of Deep Learning Tools for Big Data Analysis in Health Care 1826
Rojalina Priyadarshini, KIIT University, India
Rabindra K. Barik, KIIT University, India
Chhabi Panigrahi, University of Rajastan, India
Harishchandra Dubey, The University of Texas at Dallas, USA
Brojo Kishore Mishra, C. V. Raman College of Engineering, India

Chapter 92
Real Time Analysis Based on Intelligent Applications of Big Data and IoT in Smart Health Care Systems 1839
Mamata Rath, C.V. Raman College of Engineering, India

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Chapter 93
The Impact of Healthcare Information Technology on Patient Outcomes 1858
Edward T. Chen, University of Massachusetts Lowell, USA

Section 7
Emerging Trends

Chapter 94
Role of Bioinformatics in Nanotechnology: An Initiation towards Personalized Medicine..... 1875
Harishchander Anandaram, Sathyabama University, India

Chapter 95
Overview of Cellular Computing-Basic Principles and Applications 1895
Amit Das, University of Kalyani, India
Rakhi Dasgupta, University of Kalyani, India
Angshuman Bagchi, University of Kalyani, India

Chapter 96
From Telecytology to Mobile Cytopathology: Past, Present, and Future..... 1921
Abraham Pouliakis, National and Kapodistrian University of Athens, Greece
Stavros Archondakis, 401 Military Hospital, Greece
Niki Margari, National and Kapodistrian University of Athens, Greece
Petros Karakitsos, National and Kapodistrian University of Athens, Greece

Chapter 97
Examining the Influence of Information Technology on Modern Health Care..... 1943
Edward T. Chen, University of Massachusetts, Lowell, USA

Chapter 98
Early Detection of Dementia: Advances, Challenges, and Future Prospects..... 1963
Stefanos Xefteris, Aristotle University of Thessaloniki, Greece
Evdokimos Konstantinidis, Aristotle University of Thessaloniki, Greece
Antonis S. Billis, Aristotle University of Thessaloniki, Greece
Panagiotis Antoniou, Aristotle University of Thessaloniki, Greece
Charis Styliadis, Aristotle University of Thessaloniki, Greece
Evangelos Paraskevopoulos, Aristotle University of Thessaloniki, Greece
Panagiotis Emmanouil Kartsidis, Aristotle University of Thessaloniki, Greece
Christos A. Frantzidıs, Aristotle University of Thessaloniki, Greece
Panagiotis Bamidis, Aristotle University of Thessaloniki, Greece

Chapter 99
Opportunities and Challenges of Big Data in Healthcare..... 1989
Wafaa Faisal Mukhtar, Sudan University of Science and Technology, Sudan
Eltayeb Salih Abuelyaman, University of Dammam, Saudi Arabia

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Chapter 100
Wireless Body Area Network for Healthcare Applications 2002
Danda B. Rawat, Georgia Southern University, USA
Sylvia Bhattacharya, Georgia Southern University, USA

Chapter 101
Information and Communication Technologies in the Healthcare: Future Trends for Project Success 2018
Jorge Gomes, Universidade de Lisboa, Portugal
Mário Romão, Universidade de Lisboa, Portugal

Chapter 102
Robotics in Surgical Techniques Robotics in Surgical Techniques: Present and Future Trends 2033
Vassilia Costarides, National Technical University of Athens, Greece
Apollon Zygomalas, University of Patras, Greece
Kostas Giokas, National Technical University of Athens, Greece
Dimitris Koutsouris, National Technical University of Athens, Greece

Chapter 103
A Next Generation of IT: A Health Record Example with Terminology Binding 2048
Anthony J. Mallia, Edmond Scientific Company, USA

Index xxx

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Preface

Advancements in data science have created opportunities to sort, manage, and analyze large amounts of data more effectively and efficiently. In contemporary society, medical records and patient information have increasingly become more digitized, with patients required to use patient portals to access their medical information. Additionally, doctors, nurses, hospital staff, and specialists rely on electronic documents that are easy to access and share and that can follow patients that require multiple medical experts. Applying new data science technologies to the healthcare industry, which has vast quantities of patient and medical data and is increasingly becoming more data-reliant, is crucial for refining medical practices and patient care as well as maintaining efficient communication between departments and offices.

Staying informed of the most up-to-date research trends and findings is of the utmost importance. That is why IGI Global is pleased to offer this four-volume reference collection that will shed light on practical applications of healthcare analytics for improved patient care, resource allocation, and medical performance, as well as for diagnosing, predicting, and identifying at-risk populations by providing both broad and detailed perspectives on cutting-edge theories and developments. This reference is designed to act as a single reference source on conceptual, methodological, technical, and managerial issues and to provide insight into emerging trends and future opportunities on the connections between data analytics in the field of medicine.

Data Analytics in Medicine: Concepts, Methodologies, Tools, and Applications is organized into seven distinct sections that provide comprehensive coverage of important topics. The sections are:

1. Fundamental Concepts and Theories;
2. Development and Design Methodologies;
3. Tools and Technologies;
4. Utilization and Applications;
5. Organizational and Social Implications;
6. Critical Issues and Challenges; and
7. Emerging Trends.

The following paragraphs provide a summary of what to expect from this invaluable reference tool.

Section 1, "Fundamental Concepts and Theories," serves as a foundation for this extensive reference tool by addressing crucial theories essential to the understanding of data analytics in medicine. Introducing the book is "A Guideline to Use Activity Theory for Collaborative Healthcare Information Systems Design," by Prof. Carolin Durst (University of Bremen, Germany), Prof. Nilmini Wickramasinghe (Epworth HealthCare, Australia & Deakin University, Australia), and Prof. Jana Riechert (University

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

of Erlangen-Nuremberg, Germany): a great foundation laying the groundwork for the basic concepts and theories that will be discussed throughout the rest of the book. Section 1 concludes and leads into the following portion of the book with a nice segue chapter, "Population Health Management and the Science of Individuality," by Prof. Anastasius Moumtzoglou (Hellenic Society for Quality and Safety in Healthcare, Greece, & P. & A. Kyriakou Children's Hospital, Ilion, Greece) and Prof. Abraham Pouliakis (2nd Department of Pathology, National and Kapodistrian University of Athens, Athens, Greece).

Section 2, "Development and Design Methodologies," presents in-depth coverage of the conceptual design and architecture of data analytics in medicine. Opening the section is "A Yes/No Answer Generator Based on Sentiment-Word Scores in Biomedical Question Answering," by Prof. Mourad Sarrouti (Laboratory of Computer Science and Modeling, FSDM, Sidi Mohammed Ben Abdellah University, Fez, Morocco) and Prof. Said Ouatik El Alaoui (Laboratory of Computer Science and Modeling, FSDM, Sidi Mohammed Ben Abdellah University, Fez, Morocco). Through case studies, this section lays excellent groundwork for later sections that explore present and future applications for data analytics in medicine. The section concludes with an excellent work by Prof. Basant Tiwari (Hawassa University, Awassa, Ethiopia) and Prof. Vivek Tiwari (IIIT-NR, Naya Raipur, India), "An Intelligent Multi-Objective Framework of Pervasive Information Computing."

Section 3, "Tools and Technologies," presents extensive coverage of the various tools and technologies used in the implementation of data analytics in medicine. The first chapter, "Detecting Human Diseases Relatedness: A Spreading Activation Approach Over Ontologies," by Prof. Said Fathalla (Bonn University, Bonn, Germany & Alexandria University, Alexandria, Egypt), lays a framework for the types of works that can be found in this section. The section concludes with "A Study on Lifetime Enhancement and Reliability in Wearable Wireless Body Area Networks," by Prof. Saranya Vasanthamani (Sri Krishna College of Engineering and Technology, Coimbatore, India). Where Section 3 described specific tools and technologies at the disposal of practitioners, Section 4 describes the use and applications of the tools and frameworks discussed in previous sections.

Section 4, "Utilization and Applications," describes how the broad range of data analytics in medicine efforts has been utilized and offers insight on and important lessons for their applications and impact. The first chapter in this section is "Pluralistic Tendencies in Healing Abantu Illness in the Contemporary South Africa," written by Prof. Kholekile Hazel Ngqila (Walter Sisulu University, South Africa). This section includes the widest range of topics because it describes case studies, research, methodologies, frameworks, architectures, theory, analysis, and guides for implementation. The breadth of topics covered in the section is also reflected in the diversity of its authors, from countries all over the globe. The section concludes with "Big Data and IoT-Allied Challenges Associated With Healthcare Applications in Smart and Automated Systems," by Prof. Mamata Rath (Department of IT, C.V. Raman College of Engineering, Bhubaneswar, India), a great transition chapter into the next section.

Section 5, "Organizational and Social Implications," includes chapters discussing the organizational and social impact of data analytics in medicine. The section opens with "Shared Electronic Health Records as Innovation: An Australian Case," by Prof. Troy Pullen (Queensland State Archives, Australia) and Latif Al-Hakim (University of South Australia, Australia). This section focuses exclusively on how these technologies affect human lives, either through the way they interact with each other or through how they affect behavioral/workplace situations. The section concludes with "Forensic Investigation of Digital Crimes in Healthcare Applications," by Prof. Nourhene Ellouze (University of Carthage, Tunisia), Prof. Slim Rekhis (University of Carthage, Tunisia), and Prof. Noureddine Boudriga (University of Carthage, Tunisia).

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Section 6, "Critical Issues and Challenges," presents coverage of academic and research perspectives on analytical tools and applications for maintaining, monitoring, and storing data, among other functions. The section begins with "Bidirectional Spreading Activation Method for Finding Human Diseases Relatedness Using Well-Formed Disease Ontology," by Prof. Said Fathalla (Enterprise Information Systems [EIS], University of Bonn, Bonn, Germany & Faculty of Science, Alexandria University, Alexandria, Egypt) and Prof. Yaman M. Khalid Kannot (Department of Computer Engineering, Arab Academy for Science, Alexandria, Egypt). Chapters in this section examine theoretical approaches and offer alternatives to crucial questions on the use of data analytics in medicine. The section concludes with "The Impact of Healthcare Information Technology on Patient Outcomes," by Prof. Edward T. Chen (University of Massachusetts Lowell, Lowell, USA).

Section 7, "Emerging Trends," highlights areas for future research within the field of data analytics and their specific application within the medical field and opens with "Role of Bioinformatics in Nanotechnology: An Initiation towards Personalized Medicine," by Prof. Harishchander Anandaram (Sathyabama University, India). This section contains chapters that delve into what might happen in the coming years that can extend the already staggering amount of applications for data analytics in medicine. The final chapter of the book looks at an emerging application within the field in the excellent contribution, "A Next Generation of IT: A Health Record Example with Terminology Binding," by Prof. Anthony J. Mallia (Edmond Scientific Company, North Andover, USA).

Although the primary organization of the contents in this multi-volume work is based on its seven sections, offering a progression of coverage of the important concepts, methodologies, technologies, applications, social issues, and emerging trends, the reader can also identify specific contents by utilizing the extensive indexing system listed at the end of each volume. As a comprehensive collection of research on the latest findings related to using technology to providing various services, *Data Analytics in Medicine: Concepts, Methodologies, Tools, and Applications* provides researchers, doctors, hospital staff, medical administrators, nurses, IT consultants, software developers, medical directors, academicians, students, and all medical practitioners with a complete understanding of the development of applications and concepts in data analytics when applied to the medical field. Given the vast number of issues concerning usage, failure, success, policies, strategies, and applications of data analytics in medicine in countries around the world, *Data Analytics in Medicine: Concepts, Methodologies, Tools, and Applications* addresses the demand for a resource that encompasses the most pertinent research in technologies being employed to globally bolster the knowledge and applications of this trending topic.

Nilmini Wickramasinghe
Epworth HealthCare, Australia & Deakin University, Australia

Jana Riechert
University of Erlangen-Nuremberg, Germany

ABSTRACT

In healthcare, collaborative systems serve very different stakeholders: researchers, clinicians, nurses, patients, and administrators for instance. In order to design a collaborative healthcare information system that satisfies the stakeholders' needs, all individual requirements have to be mapped into the software. Traditional system design focuses at technical features and oftentimes ignores social requirements like human factors or organizational structures. Instead of integrating existing processes and working habits into a system, a technical-focused design approach tries to force new behaviors. As a result, stakeholders could refuse to use collaborative healthcare information systems. In line with Kuutti (1991), we recommend activity theory as a rich framework to study and design collaborative information systems. We believe that activity theory analysis is particularly useful for healthcare settings where diverse stakeholders pursue very different goals. This book chapter offers a structured approach to analyze collaborative activities and to design the IT-support accordingly.

INTRODUCTION

The development of collaborative healthcare information systems is a very complex but promising undertaking. Numerous collaborative activities can be optimized by information and communication technologies. The increasing digitalization of those activities and processes results in time saving, error reduction and most important it enables the analysis, evaluation and knowledge creation of the collected data. Healthcare information systems can improve and support patient safety and avoid medical errors (Baxter & Rooksby, 2011). To date, all OECD countries recognize the opportunities of those systems especially in the light of access, quality and value facing healthcare delivery (Wickramasinghe & Schaffer, 2010).

However, system failures can lead to damages with serious consequences. A significant example is the failure of the dispatch system of the London Ambulance in 1992. Up to 30 people died because of technical problems. The system was not able to address and support the established practices of dispatch. This example shows that development approaches for collaborative systems in healthcare need to focus on both: technical aspects and work practices (Baxter & Rooksby, 2011).

In order to raise the aforementioned potentials, the major challenge is the design of such collaborative systems in healthcare due to the diverse stakeholders and complex work practices. Traditional system design approaches often target at technologically driven features. This means, instead of existing processes and work habits forming the system, the design approach tries to push new behaviors (Sawyer, 2013). It is widely acknowledged that adopting a socio-technical approach to system development leads to systems that are more acceptable to end users, delivers better value to stakeholders and overall value to the company. Despite this knowledge, there is a lack of theories and methods which consider human, social and organizational factors (Sawyer, 2013; Whitworth & Ahmad, 2014). In order to design effective systems, it is not sufficient to only understand the process in general, but it must also be clear how the various stakeholders interact and what motivates them to strive for the joint objective (Sadeghi, Andreev, Benyoucef, Momtahan, & Kuziemsky, 2014a).

One attempt to narrow the so called socio-technical gap is provided by Kuuttii (1991). He suggested to employ the concept of “activities” - originating from activity theory - as basic unit of analysis for collaborative information systems design. He argues, that the properties of the activity concept correlate well with the characteristics and social requirements of collaborative activities (Kuutti, 1991). Applying activity theory analysis helps to understand the work practices of all stakeholders involved in the activity and how these individuals interact with technological and non-technological artefacts. With creating and analysing an activity system it is possible to obtain a complete overview of an activity. This overview can not only be used to uncover contradictions between components of the activity systems (e.g. a nurse has problems to work with certain tool) but also to have deeper insights into the activity system e.g. the number of stakeholders, the objectives that are motivating the individuals to fulfil an activity, or the number and quality tools used. The results can be used for both analysing an activity and capturing requirements for collaborative healthcare information systems.

The remainder of the book chapter is structured as follows: After presenting the theoretical background of activity theory, we discuss related work on the application of activity theory in healthcare. Based on this foundation, we propose a guideline to use activity theory for the analysis and the design of collaborative healthcare information systems. The book chapter closes with concluding remarks, pointing to areas of our future research.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

BACKGROUND

Activity Theory

Activity theory has been used in the field of information systems and general HCI research before with promising results (e. g., (Barki, Titah, & Boffo, 2007; Bharosa, Lee, Janssen, & Rao, 2012; Durst & Grottke, 2015; Kamaruddin, Yusop, & Ali, 2011; Riechert, Durst, & Wickramasinghe, 2016; Sadeghi et al., 2014a). The concept, evolved from Russian philosophy, is considered to be a meta-theory or a framework, rather than a predictive theory and aims at providing holistic descriptions for social systems. In this context, an activity is a goal-directed interaction of a *subject* with an *object* mediated by the use of *tools* in order to achieve a certain *outcome* (Leont'ev, 1978; Vygotsky, 1978). These tools can be external such as a scissor or internal such as concepts or heuristics (B. Nardi, 1996).

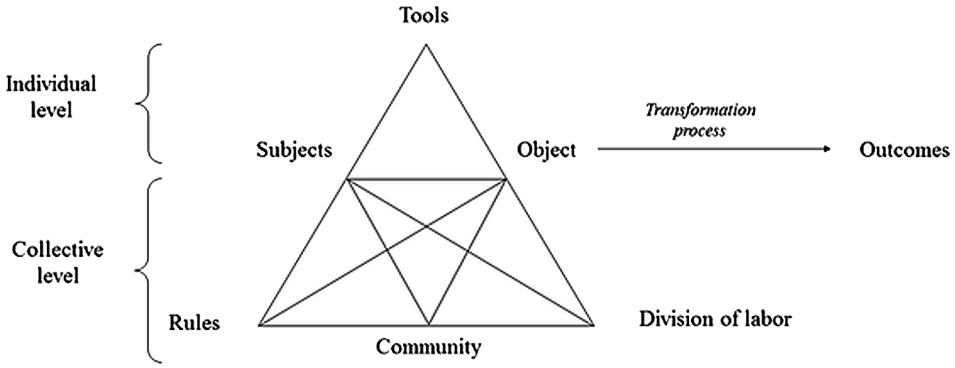
Engeström (1987) extended the original concept of activity to the case of collective activities. He added the element of *community* to the foregoing notion of subject-object interaction in order to enable a three-way interaction between subject, object, and community. Additionally, two types of mediators for each possible interaction between these three elements were defined:

1. *Rules* were introduced to mediate the subject-community interaction.
2. The community-object interaction is mediated by *division of labor* (Engeström, 2000).

The expanded activity system by Engeström can be seen in Figure 1.

According to the principles of activity theory, human activities are always directed towards their objects (Kaptelinin & Nardi, 2012a). As stated by Leont'ev (Leont'ev, 1978), an objectless activity is impossible. "Objects motivate and direct activities, around them activities are coordinated, and in them activities are crystallized when the activities are complete." (Kaptelinin & Nardi, 2012a). Taking on the perspective of a subject, this means that the subject's interactions are organized around objects to achieve an outcome. Analyzing the object of an activity helps to understand activities on an individual and collective level. When defining object, objective, and outcome of an activity it is important to consider the differences between these elements. "Objects have their "objective" meanings, determined by their relationship with other entities existing in the world (including the subject himself or herself)" (Kaptelinin & Nardi, 2012a). The subjects' objectives can be very different, especially in activity systems which

Figure 1. Activity system model of Engeström (2000)



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

involve heterogeneous stakeholders. Objectives can not only be physical but also socially or culturally motivated (Kaptelinin & Nardi, 2012a). In a nutshell: Activity theory explains both the 'how' and the 'why' of human action and thus collaboration.

Activity systems are constantly evolving and by nature internally contradictory. Contradictions in activity systems exist because activities are constantly developing and even most well-planned actions involve failures, disruptions, and unexpected innovations (Kaptelinin & Nardi, 2012a). By analyzing the activity system, the underlying contradictions that lead to these failures, disruptions, or innovations may be recognized and offer possibilities for expansive design adjustments (Engeström, Miettinen, & Punamäki, 1999). In activity theory four types or levels of contradictions can be identified (Kaptelinin & Nardi, 2012a).

- **First-Level Contradictions:** Deal with inner-contradictions of each activity system component: subject, object, community, tools, rules, and division of labor. For example, a physician chooses a more affordable medication over the best available medication that is more expensive (Kaptelinin & Nardi, 2012a).
- **Second-Level Contradictions:** Occur between the components of an activity system. For example, if a certain type of medical treatment is unsuitable for certain patients (Kaptelinin & Nardi, 2012a).
- **Third-Level Contradictions:** Are potential problems emerging between the existing and a more advanced form of the activity system (Kaptelinin, Nardi, & Macaulay, 1999). For example, stakeholders involved in a certain activity could refuse to adapt to new IT-supported work practices.
- **Fourth-Level Contradictions:** Occur between different activity systems that are involved in the achievement of a joint outcome. For example, a positive effect of surgery can be undermined by an improper follow-up rehabilitation (Kaptelinin & Nardi, 2012a).

Activity theory is regarded as a powerful lens for studying complex social systems. It analyzes existing relationships among different elements mediated by tools, rules and division of labor. In addition, activity theory considers different user perspectives of the subjects, too (Greenhow & Belbas, 2007). Even though it is characterized as an analytical framework, activity theory does not offer ready-made techniques and procedures for research (Rogers, 2008). It is considered as an evolving framework that only contains general guidelines and therefore must be further developed (Greenhow & Belbas, 2007).

Activity-Oriented Design Method

In literature, we identified two different methods of executing activity theory analysis: The activity-oriented design method (AODM) by Mwanza (2011) and the activity checklist by Kaptelinin and Nardi (Kaptelinin et al., 1999). The activity checklist offers important aspects for system evaluation and system design. Amongst others, it includes aspects such as "People who use the target technology" or "Criteria for success or failure of achieving target goals". However, there are no specific recommendations of how to gather the needed information (Kaptelinin et al., 1999). The AODM by Mwanza (2011) offers a series of well-structured procedures and stages in order to execute the activity theory analysis (Greenhow & Belbas, 2007). In consequence, we adopt the AODM by Mwanza (2011) for the analysis and the design of collaborative healthcare information systems.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

The AODM was developed to identify contradictions in activity systems (Greenhow & Belbas, 2007). According to Engeström, contradictions are seen as means of expanding and transforming the system and developing human practices. In other words, uncovering contradictions is necessary in order to improve system design (Greenhow & Belbas, 2007). In addition, design insights for further studies and refinement can be derived (Greenhow & Belbas, 2007). The AODM offers four methodological tools to support data gathering, analysis and communication of design insights. These tools are divided into four stages (Sadeghi et al., 2014a):

Stage 1: Defining Activity System (Eight Step Model)

The eight step model of stage 1 puts theory into practice by defining and interpreting the activity system. It is a requirements capture methodology grounded in activity theory (D. Mwanza & Engeström, 2003). Table 1 shows the eight step model with the corresponding questions to ask.

Stage 2: Activity Notation

Stage 2 reduces complexity of the examined activity system by decomposing or breaking down the complex activity system into manageable sub-activities. Three rules-of-thumb, proposed by Mwanza (2011), should be considered:

1. The actor is represented by the subject or community component of the activity system;
2. Tools, rules, or division of labor function as mediators; and
3. The activity focuses on an object. As a result of this stage, a triangle for each sub-activity is created (Sadeghi et al., 2014a).

Table 1. The eight step model

Step	Identification of	Question to Ask
1	Activity of interest	What sort of activity am I interested in?
2	Objective	Why is the activity taking place?
3	Subjects	Who is involved in carrying out this activity?
4	Tools	By what means are the subjects performing this activity?
5	Rules and Regulations	Are there any cultural norms, rules or regulations governing the performance of activity?
6	Division of Labor	Who is responsible for what, when carrying out activity and how are the roles organized?
7	Community	What is the environment in which this activity is carried out?
8	Outcome	What is the desired outcome from carrying out this activity?

Mwanza-Simwami, 2011.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Stage 3: Research Questions

At stage 3, a research question for each sub-activity is generated. Here, either generic questions such as "What tools are used by the subjects to achieve their objects and how do they do that?" or questions specific to the context such as "How do whiteboards help the clinical manager to facilitate the safe and effective transition of patients towards discharge?" (Sadeghi et al., 2014a) are asked.

Stage 4: Data Collection and Technique of Mapping Operational Processes

Based on these questions data is collected and analyzed in stage 4. Stage 4 communicates research insight by modelling inter-relations of operational processes and by modelling study findings (e.g., contradictions identified in the analysis of human practices).

The intended result of AODM is to uncover contradictions. In a next step, these contradictions serve as a starting-point to improve the system design. In order to solve the contradiction, elements of the activity system need to be adapted or changed. For instance, the division of labor is revised, new rules are introduced or tools need to be adapted. Another way of adapting the elements of an activity system is to support them with IT. Examples of IT support are the automation of routines supported by tools and providing data about the object or make the object manipulable. Linking work tasks of several people in order to create a community is another example of IT support (B. Nardi, 1996).

Applications of Activity Theory in Healthcare

Since Kaptelinin and Nardi's work "Synthesis Lectures on Human-Centered Informatics: Activity Theory in HCI: Fundamentals and Reflections" (Kaptelinin & Nardi, 2012b), activity theory analysis is widely accepted in information systems research. A plentiful amount of studies was published in the last years. Examples of these studies are "An activity-theory analysis of corporate wikis" (Hasan & Pfaff, 2012), "Using Activity Theory to Model Context Awareness" (Cassens & Kofod-Petersen, 2006), and "Demonstrations of the Activity Theory Framework for Research in IS" (Crawford & Hasan, 2006). So far, the largest field of application is education. Publications in this field are characterized by their attempt to improve education services, for example "Using activity theory and its principle of contradictions to guide research in educational technology" (Murphy & Rodriguez-manzanares, 2008).

In the context of healthcare, however, activity theory is not widely used and we identified only a couple of authors who applied the concept of activity theory. Engeström's research group (Engeström, 2000; Hasu & Engeström, 2000) belong to the first researchers that applied activity theory analysis to traditional work systems in healthcare. After the digitalization had transformed the traditional healthcare processes, Er and Kay (Er & Kay, 2005), Zao et al. (Zao et al., 2008), Bardram and Doryab (Bardram & Doryab, 2011) and (Sadeghi et al., 2014a) revisited this domain. Er and Kay (Er & Kay, 2005) studied technology issues of a mobile hospital ward system through the lens of activity theory. The authors conducted several semi-structured interviews and observed doctors while conducting their ward rounds and mapped their observations into an activity system. Activity theory was found to be a useful approach to identify additional issues. Zao et al. (Zao et al., 2008) also applied activity theory to a mobile healthcare solution. But in contrast to Er and Kay (Er & Kay, 2005) the authors used the theory to design a new application. In their article, they compared activities to features of the desired mobile solution. This approach was found to be very helpful to structure the design process of their mobile solution to support the

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

elderly, but according to the basic idea of Engeström, activities are more than just "features". Bardram and Doryab (Bardram & Doryab, 2011) and (Sadeghi et al., 2014a) applied activity theory successfully to the newly emerging socio-technical systems and were able to provide insights for the design of work environments. While Bardram and Doryab (Bardram & Doryab, 2011) used activity theory to describe processes of a hospital in a very detailed manner, Sadeghi et al. (Sadeghi et al., 2014a) applied the AODM to analyze the patient discharge process and identified several contradictions. Both approaches were descriptive and did not aim at deriving design recommendations based on the uncovered contradictions (Sadeghi et al., 2014a).

Riechert et al. (Riechert et al., 2016) also applied AODM to analyze the chemotherapy administration process and derived several contradictions as well as design recommendations. Building prior research and the lessons learned from the chemotherapy case, the authors modified and enhanced the initial AODM. The following section presents the derived learnings by means of a guideline to use activity theory for the analysis and design of collaborative healthcare information systems.

GUIDELINE TO USE ACTIVITY THEORY FOR COLLABORATIVE HEALTHCARE INFORMATION SYSTEM DESIGN

Based on the experiences collected during the chemotherapy case study a guideline for using activity theory analysis was developed by extending the AODM. The guideline is represented in Table 2. Literature-based recommendations are also included.

Finally, it is important to mention that both executing the chemotherapy case study and analyzing literature made obvious that the stages of the AODM cannot be applied iteratively. Insights gathered in one stage often lead to changes in another stages, mostly in the eight-step model. Therefore, the application of the proposed guideline is rather cyclic.

DISCUSSION AND CONCLUSION

The successful development of collaborative information systems in healthcare faces several challenges: The work environment in healthcare is complex and dynamic. Health professionals work with multiple technologies, paper, devices, other people, and patients. Many technologies and tools might be used at the same time. Furthermore, it still is a challenge to produce an integrated electronic record. Even though electronic records are already widely used, there are still problems such as ensuring the correct people have access to records or the information is correct and meaningful. In addition, health professionals still like to work with paper because historical information and other notes can be captured and recognized easily.

Table 2. Guideline for using activity theory analysis based on the AODM

Stage	Recommendations
Stage 0: Preparatory Stage	Collect the data that is needed for the following stages (Greenhow & Belbas, 2007) if scope requires or much data are available

continues on following page

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 2. Continued

Stage		Recommendations
Stage 1: Defining activity system – eight- step model	1.1 General	• Use information from people involved or experienced with the activity of interest rather than literature analysis because then the collected information is more significant • Consider that other people might have no knowledge about activity theory analysis • Start with capturing the subjects as this is the easiest start for someone who has little or no knowledge about activity theory analysis • Start with defining subject or outcome because these are the most obvious o Because the outcome might be defined in the strategic management or o Easier to capture in comparison to other elements of the activity system o Capturing the subjects first might be the easiest for someone who has little or no knowledge about activity theory analysis • In general, capture the more obvious elements first • Develop an activity system for each subject in order to be able to consider the different perspectives of these subjects (Greenhow & Belbas, 2007) if scope requires
	1.2 Activity of interest	• First, define the scope of the activity by selecting a specific activity or sub-activity that is further analyzed o Consider that this decision has a high influence on the complexity of the activity theory analysis o Keep in mind time, costs, and quality requirements of the project o Prefer to develop several activity systems instead of one complex one • Double check if the analyzed point of view is correct
	1.3 Object(ive)	• Differentiate between object, objective, and outcome at once • Object: material or mental and can be modified by a subject according to the activities objective (Bedny, 2014) • Objective: aim of the activity e.g. providing better healthcare. Ask "Why is the activity taking place?", is the direct target or aim of activity • Outcome: the activity's result e.g. improved health
	1.4 Subjects	• List all participants of the activity • Consider how subjects are defined in activity theory: Subjects can be individual humans, animals, teams, and organizations (Kaptelinin & Nardi, 2012b) • Capture subjects and their division of labor simultaneously in order to save time (only feasible in dialogue) • Consider that the roles of subject and object can be switched during the execution of an activity and decide for the appropriate point of view
	1.5 Tools	• For initial analysis, take all tools (electronic, paper-based, communications tools etc.) into consideration to get a rich overview • Especially for projects in information technology: all aspects of activity need to be considered e.g. not only software tools but also cognitive tools. Do not only focus on the software in order to ensure completeness. • If the scope of the activity system is adapted, it may would make sense to keep only specific tools or summarize likewise tools into groups • divide artefacts or tools into groups such as social, assignments, cognitive, and technological (Greenhow & Belbas, 2007) if scope requires
	1.6 Rules and regulations	Consider that this section can get very complex depending on the scope of activity (e.g. if code of conduct or corporate guidelines are included)
	1.7 Division of labor	• Describe responsibilities of all subjects • Capture subjects and their division of labor simultaneously in order to save time (only feasible in dialogue) • Include additional roles such as external roles if the scope requires
	1.8 Community	• Ask "Who has an influence on the object/objective/outcome?" e.g. all employees of a department in an organization because only they have access to comment ideas • If it is not clear from the beginning, take a high scope e.g. all employees and break down later
	1.9 Outcome	• Differentiate between object, objective, and outcome at once • Can be seen as overall (or strategic) goal such as increasing flexibility or reducing healthcare costs

continues on following page

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 2. Continued

Stage	Recommendations
Stage 2: Activity notation	• Consider Mwanza's three rules-of-thumb: (1) the actor is represented by the subject or community component of the activity system; (2) tools, rules, or division of labor function as mediators and (3) the activity needs to focus on an object (Daisy Mwanza, 2002) • Double check if the captured activity system is correct because there might have been confusions during the interview
Stage 3: Research questions	• First, refer all research questions to the objective of the activity in order to remain in scope • Second, add additional research questions if necessary for the specific analysis
Stage 4: Data collection and technique of mapping operational processes	• Use the research of the sub-triangles e.g. subject-tools-object to find contradictions • Use the levels of contradictions in order to capture them completely • Define the activity hierarchy in order to get a more valuable overview of the activity • Use dialogue to capture the information because this proved as most efficiently as discussions uncovered many aspects of the activity system

We found, that activity theory analysis is a useful lens to analyse collaborative activities in healthcare settings and to design the IT support accordingly. So far, activity theory analysis was criticized for its descriptive character without delivering predictions for future development (Nardi 1996 cited in Nathanael et al. 2002). This is true but activity theory analysis offers a high value for system analysis and offers a good starting point for system or design improvements. The chemotherapy case study proved that the uncovered contradictions of an activity system can lead to activity system recommendations by changing or adopting the activity elements.

Capturing the elements of the activity system and the sub-systems is critical for the whole analysis, influences all upcoming steps and decides on success or failure of the analysis (Greenhow & Belbas, 2007). It should be done through the lens of the overall objective of the activity system. To date, there is no clear method offered by the AODM, which helps researcher to define this scope. Existing literature does not differentiate clearly between the activity system elements *object*, *objective* and *outcome*. Some even use object and objective synonymously (Greenhow & Belbas, 2007; Sadeghi, Andreev, Benyoucef, Momtahan, & Kuziemsky, 2014b). In order to find contradictions and to derive design recommendations we found, that this differentiation is very crucial. Our guideline builds on the existing AODM. We added our lessons learned while applying the AODM in terms of hints or additional questions and findings from other literature. We want to encourage researchers to take up the identified suggestions, apply and improve them in order to establish activity theory as a solid foundation for collaborative healthcare information system design.

Chapter 2
A Review of Type 1 Diabetes (T1D): To Assist Patients' and Carers' Understanding of This Condition

Eileen O'Donnell
Technological University Dublin, Ireland

Liam O'Donnell
Technological University Dublin, Ireland

ABSTRACT

The diagnosis of Type 1 Diabetes (T1D) will come as an unwelcome surprise to most people. Within a short period of time, the person will have to come to understand and manage this chronic illness. The terminology associated with the T1D condition will also be totally new to the person: diabetes mellitus, pancreas, hyperglycaemia (hyper), hypoglycaemia (hypo), bolus (fast acting insulin), basal (slow acting insulin), ketones and blood glucose levels. The purpose of this article is to assist newly diagnosed patients' understanding of T1D, people who are already living with T1D, carers of people with T1D, partners and family members of someone with T1D, work colleagues, and friends who participate in the same sporting activities or go on holiday with a person who has T1D. In addition, this article reviews how people living with T1D can still enjoy exercise and maintain the best quality of life possible; whilst controlling the blood glucose levels in their body for the rest of their lives to prevent the onset of complications associated with diabetes.

INTRODUCTION

The diagnosis of T1D at any age can be quite shocking. Particularly to an individual or parent who has had no close previous contact with anyone with the condition. "85% of newly-diagnosed patients have no family history of the disease" (Atkinson & Eisenbarth, 2001, p. 224). The diagnosis of T1D, a debilitating autoimmune disease (Wen et al., 2008), has increased substantially over the last thirty years

(Atkinson & Eisenbarth, 2001), and continues to increase (Ang et al., 2017; O'Hara et al., 2017), to the extent that it is now considered to be a global epidemic (Ahmed et al., 2018; Noor, Khan, & Ahmad, 2017; O'Loughlin, McIntosh, Dinneen, & O'Brien, 2010).

T1D is a life-long medical condition requiring frequent monitoring of blood glucose levels throughout the day, constant vigilance of every morsel the patient consumes and other lifestyle choices are necessary to effectively manage this condition (Dinneen, 2010). In addition, the patient or carer must have an appreciation of the effect that personal exercise choices may have on blood glucose levels and how to manage the precise dose of insulin administered to cover for the possible reduction in blood glucose levels experienced during exercise.

Even if a person with Type 1 Diabetes takes great care and manages to keep their blood glucose levels as close to normal as possible, there is still no guarantee that they will not suffer from complications due to diabetes later on in life. Basically, the person has the power to control/modify all of the risk factors through tight monitoring of blood glucose levels, diet, exercise, life style choices, etc. The only factor that is non-modifiable is the fact that a person diagnosed with T1D has it for life, everything else that effects blood glucose levels are modifiable. The pancreas of a person with Type 1 Diabetes no longer produces insulin or produces insufficient doses of insulin to control the amount of glucose in the blood. Therefore, the challenge is to balance insulin doses and everything else (food and drink intake, exercise, sleep, stress, illness, and so forth) to maintain blood glucose levels as near to normal as possible.

T1D is challenging to manage as so many different variables influence the level of glucose in one's blood at any single point in time. "Crucial to achieving glycaemic control is an understanding of the effect of diet, physical activity, and insulin on blood glucose levels" (Jackson et al., 2015, p. 1959). The administration of the most suitable dose of insulin to cover the amount of carbohydrates consumed and the level of activity in which the person engages is paramount to achieving good glycaemic (blood glucose level) control in order to avoid other medical complications in the future. The administration of the most suitable dose is also crucial to ensure that the person who has T1D does not experience a severe hypoglycaemia episode (hypo).

"Type 1 diabetes is a chronic disease in which individuals are unable to produce insulin, which is essential for regulating blood sugar" (Byrne et al., 2012, p. 3), that is characterised by hyperglycaemia and the harm it may cause to the body (Fowler, 2008). Hyperglycaemia means that there is too much glucose in the person's blood stream, which can, if left untreated, lead to other medical complications in later life. Hyperglycaemia can also lead to Diabetic Ketoacidosis (DKA) in the short term. DKA is a life-threatening condition that may affect people who are diagnosed with Type 1 or Type 2 diabetes. Alternatively, a person may present at a Hospital's Accident and Emergency Department with DKA, this being the first sign that they are in fact suffering from diabetes. DKA happens when the levels of glucose (sugar) in the blood rise to dangerous levels because the pancreas is unable to produce sufficient insulin to regulate the level of glucose in the blood. Therefore, the body cannot access glucose from the blood for energy, tissue production and repair, instead the body starts to breakdown stores of fat that are present in the body. This process leads to the production of ketones. The presence of ketones can turn the blood acidic. Acidic blood can make a person feel very unwell, and subsequently if untreated can lead to DKA, a diabetic coma or even death.

The background section discusses the worldwide incidence of T1D and some of the symptoms experienced during the sudden onset of T1D. The section on the diagnosis of T1D includes brief explanations of the following: Self-Monitoring of Blood Glucose (SMBG); blood glucose levels; HbA1c; the use of insulin to control the blood glucose level; acceptable blood glucose level; unique treatment plan

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

required for each patient; pancreas; and the honeymoon phase. The next section covers some factors which may influence the onset of T1D: genetics; environmental; deficiency in Vitamin D; stress; and the use of statins. The following section introduces the equipment, disposables, medication, and the monetary costs required to manage T1D. The responsible administration of insulin is explained in the next section, followed by sections on hypers and hypos. The subsequent section includes some recommendations for the successful management of T1D. Succeeded by some tips for patients with T1D. Then there is a section that briefly mentions medical complications association with diabetes, foot ulceration and nephropathy. The contraindications of administering insulin are noted in the next section. Followed by a section on the positive impact of a diagnosis of T1D, several options worthy of further research, the conclusion, and references.

BACKGROUND

Initially, a diagnosis of T1D may sound very daunting and the requirement to self-manage this complicated condition may seem insurmountable or at least very challenging. "While there has been a focused shift away from the traditional medical models of practice where the clinician is perceived as the expert who holds a position of authority over the patient, some clinicians still struggle with the shift to shared control" (Hurley et al., 2017, p. 1958). A person with T1D must take personal responsibility for injecting themselves with insulin several times a day and also for deciding how many units of insulin to inject at each meal because they may only have a consultation with the clinician once or twice a year.

Type 1 Diabetes Mellitus (T1DM), also known as Type 1 Diabetes (T1D) accounts for 5-10% of the total number of cases of Diabetes Mellitus worldwide (Voltarelli et al., 2007), or approximately 20 million people globally (Thrower & Bingley, 2014). "The term diabetes mellitus describes a metabolic disorder of multiple aetiology characterized by chronic hyperglycaemia with disturbances of carbohydrate, fat and protein metabolism resulting from defects in insulin secretion, insulin action, or both" (Alberti et al., 1998, p. 2). "Hyperglycemia is associated with increased mortality in critically ill patients" (Griesdale et al., 2008, p. 821). "Type 1 diabetes has historically been considered a disorder predominately of children and young adults (the disease is commonly referred to as juvenile diabetes because it has peak expression between ages 10-14 years)" (Atkinson & Eisenbarth, 2001, p. 223). The onset of T1D usually occurs before the age of thirty years (Hex, Bartlett, Wright, Taylor, & Varley, 2012). Young adults with T1D struggle to manage blood glucose levels leading to poor glycaemic control and suboptimal clinical outcomes (Byrne et al., 2017; O'Hara et al., 2016), therefore, "effective interventions to improve self-management and outcomes for young adults with T1DM are needed" (Byrne et al., 2017, p. 2). "The precise incidence of new-onset type 1 diabetes in those over 20 years of age is unknown" (Chiang, Kirkman, & Laffel, 2014, p. 2034). "Half of people with type 1 diabetes are diagnosed as adults" (Gilbert, Millard, & Flynn, 2012, p. 2). "The clinical diagnosis is often prompted by symptoms such as increased thirst and urine volume, recurrent infections, unexplained weight loss and, in severe cases, drowsiness and coma" (Alberti et al., 1998, p. 4). Symptoms can also include difficulty breathing, vomiting and a general sense of feeling unwell. Please see Figure 1.

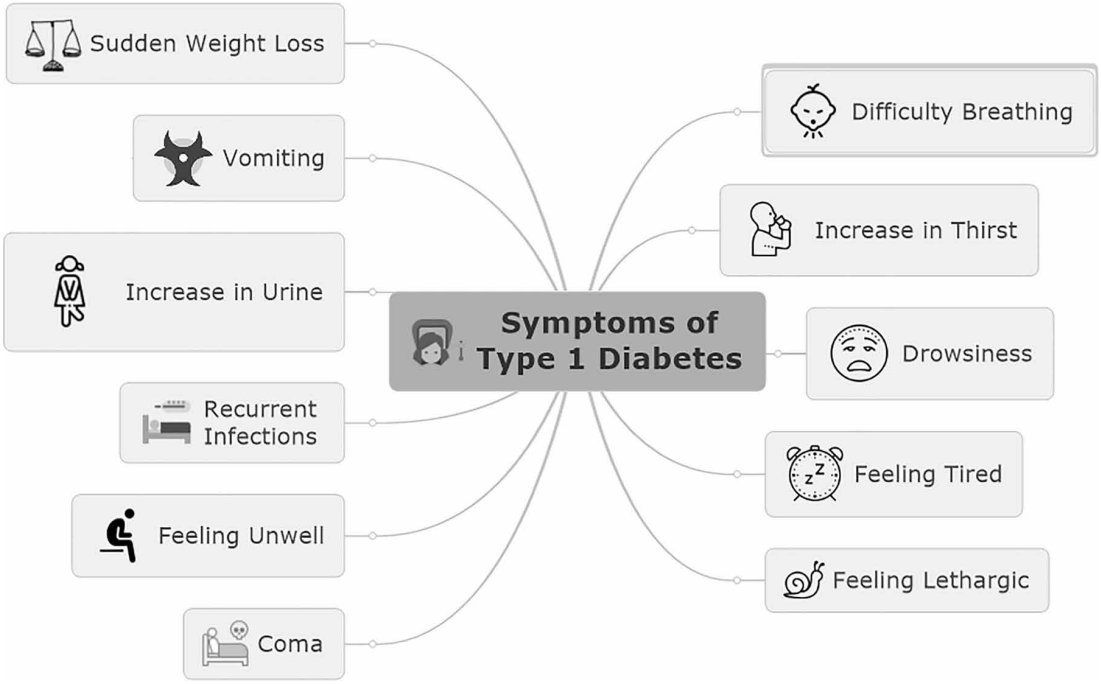
Figure 1. Some of the symptoms of type 1 diabetes



DIAGNOSIS OF T1D

The determination of the presence of T1D in a patient can be assessed through various different medical tests: (i) Fasting blood glucose level, (ii) Oral Glucose Tolerance Test (OGTT), (iii) HbA_{1c} test which provides an average of glycated haemoglobin over approximately the last two to three months, (iv) a random blood glucose level greater than or equal to 11.1mmol/L (200mg/dL).

Self-Monitoring of Blood Glucose (SMBG)

A person who has recently been diagnosed with T1D can broaden and enhance their understanding of this condition by (i) following the advice of the medical professionals on the assigned diabetes care team, (ii) getting the opportunity to discuss the experiences of others who have lived with diabetes and how they have managed their condition, and (iii) reading books, journal articles and online forums. One of the main responsibilities of a person diagnosed with T1D is to avoid experiencing hypos and hypers through regular Self-Monitoring of Blood Glucose (SMBG) (Deiss et al., 2006; Garg, Shah, Akturk, Beatson, & Snell-Bergeon, 2017), and by improving their understanding of the condition by engaging with Structured Education Programmes (SEPs) (Lawton & Rankin, 2010). Unfortunately, Diabetes Self-Management Education (DSME) does not receive the same level of funding as "drugs and devices (which are associated with financial gain)" (Hurley et al., 2017, p. 1958). Achieving near to normal blood glucose levels is challenging (Russell et al., 2014), but very important, as hyperglycaemia is associated with many negative cardiovascular and immunological effects (Egan & Dinneen, 2016). Cardiovascular disease affects the heart, blood vessels and arteries.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Blood Glucose Levels

T1D can be diagnosed from a fasting blood glucose level greater than or equal to 7 mmol/L (126 mg/dL) (Atkinson, Eisenbarth, & Michels, 2014; Chiang et al., 2014; Daneman, 2006; Egan & Dinneen, 2014). "The cut-off point used to define a normal plasma glucose differs between the USA (where the American Diabetes Association (ADA) recommends a concentration of 5.6) mmol/L and the rest of the world (where the World Health Organisation (WHO) recommends 6.1 mmol/L)." (Dinneen, 2010, p. 589). OGTT is the abbreviation for the Oral Glucose Tolerance Test. A Glucose Tolerance Test (GTT) result of 11.01 mmol/L (200mg/dL) or greater (Atkinson et al., 2014; Chiang et al., 2014; Egan & Dinneen, 2014) signifies the presence of diabetes. "The diagnostic cut off points of 7.0 mmol/L (fasting) and 11.1 mmol/L (OGTT 2-hour value) are based on the concentrations at which retinopathy begins to appear in a population" (Egan & Dinneen, 2014, p. 680). Retinopathy is the medical term for damage to blood vessels in the eyes due to high blood sugar levels. The diagnostic cut off point of haemoglobin A1c > 7.0% is associated with patients who are at increased risk of developing Cardiovascular Autonomic Neuropathy (CAN) (Spallone et al., 2011). Neuropathy is the medical term for damage to peripheral nerves resulting in weakness, numbness, and pain. The risk of developing retinopathy and other complications associated with diabetes depends on the duration and severity of the hyperglycaemic episodes experienced (Fowler, 2008). Malone, Pavan, Morrison, & Cuthbertson (2001) suggest that dilated eye examinations that are performed to detect retinopathy should be conducted within the first year after the onset of T1D; as their study found that 20% of the volunteers who lived with diabetes for 1 year tested positive for retinopathy.

HbA_{1c}

People with poor glycaemic control have haemoglobin HbA_{1c} levels in excess of 7% (Davis, 2016). "The American Diabetes Association currently recommends an A1c goal of less than 7.0%, while other groups such as the American Association of Clinical Endocrinologists recommend a goal of less than 6.5%" (Davis, 2016, p. 4). A HbA_{1c} test of 6.5% or higher indicates the presence of diabetes (Egan & Dinneen, 2014). A HbA_{1c} test provides an average of glycated haemoglobin (Byrne et al., 2012) in the blood over the past two to three months (Atkinson et al., 2014). In Dinneen et al.'s (2013) study one of the inclusion criteria to participate in the study was to have "an HbA_{1c} level below 13 percent at recruitment" (Dinneen et al., 2013, p. 30). Dinneen et al. (2013) in their study "Based on pre-study audit data from Irish centres estimated that approximately 20 percent of participants would have a baseline HbA_{1c} below 7.5 percent (59 mmol/mol)" (Dinneen et al., 2013, p. 31).

The Use of Insulin to Control the Blood Glucose Level

"In patients with classic symptoms of hyperglycemia or hyperglycemia crisis, a random plasma glucose ≥ 200mg/dL (11.1 mmol/L)" (Chiang et al., 2014, p. 2036). A person with a random plasma glucose test result of less than 11.1 mmol/L (200mg/dL) is considered not to have diabetes. In a person with normal blood glucose control, their pancreas will deliver the appropriate quantity of insulin to bring their blood glucose level down to normal levels in a short period of time after the consumption of food or drink. Whereby, the pancreas of a person with T1D is incapable of producing sufficient insulin to bring their blood glucose level down in a short period of time or even in a long period of time. Therefore, the

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

person with T1D has to decide whether to administer insulin to reduce their blood glucose level or to engage in some sort of physical activity to reduce their blood glucose level. A 5km walk could reduce blood glucose level by 3/4 mmol/L (54/72 mg/dL), alternatively, hoovering the house could have the same impact. Everybody is different. Therefore, blood glucose levels should be taken before and after exercise until the person knows roughly what blood glucose level to expect. "The endocrine pancreas makes insulin so that the body can use glucose (sugar) for energy. The exocrine pancreas makes enzymes that help the body digest food" (Gilbert et al., 2012, p. 37). Further research is required to investigate if insulin inhibits the release of glucose into the blood from the liver (Manninen, 2004), or if insulin enables the body to use glucose for energy or perhaps both.

Acceptable Blood Glucose Level

A person with diabetes should aim for a glucose goal of 3.9 to 6.7 mmol/L (70 to 120 mg per decilitre) before meals and a blood glucose level of no more than 10 mmol/L (180 mg per decilitre) after meals (Nathan et al., 2005). Nathan et al. suggest that a postprandial (2 hours after the meal was consumed) blood glucose level of no more than 10 mmol/L (180 mg per decilitre) while others would suggest that a postprandial blood glucose level of no more than 11mmol/L (200 mg per decilitre) is acceptable.

Unique Treatment Plan Required for Each Patient

"Type 1 diabetes seems to represent a heterogeneous disease whose pathogenic processes, genetics, and phenotypic characteristics show marked variation" (Atkinson et al., 2014, p. 70). The challenge to diabetes care teams is that each person with diabetes requires an individual treatment plan. Each person requires a specific treatment plan based on their individual lifestyle choices ((food consumption, engagement in various different exercise activities (including housework and paid work), insulin dosing regimen, stress levels, sleep patterns, and many other variables)). Unlike other medical conditions, whereby people can simply follow the dosage plan set out by their medical team, people with T1D need to plan their meals and insulin dosage numerous times a day depending on the activities with which they engage. It is important for people with diabetes to tailor the administration of insulin to suit their exercise plan to avoid episodes of hypoglycaemia (Chiang et al., 2014). Therefore, the successful treatment of people with T1D substantially depends on the person's mindfulness in medicating with insulin to reflect all that they consume, and all that they do every hour of every day. Byrne et al. (2012) suggest that people with higher educational attainment benefit more from attending the Dose Adjustment for Normal Eating (DAFNE) course when compared to people with lower educational attainment. O'Hara et al. (2016) suggest that people without skills will struggle to successfully self-manage T1D even with diabetes education and support. Leelarathna et al. (2011) speculated "that those patients with T1D who do not have access to structured education may be systematically over-insulinised" (Leelarathna et al., 2011, p. e36). Over-insulinised means the administration of too much insulin. The use of excessive insulin can lead to the patient experiencing too many hypos and severe hypos which can lead to hypo unawareness.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Pancreas

The pancreas of a person with T1D has substantially or totally lost the ability to produce insulin. The pancreas of some people after diagnosis of T1D still produce some insulin, known as residual insulin secretion (Alberti et al., 1998), this is known as the honeymoon period, but generally insufficient insulin is produced to maintain good glycaemic control. Therefore, the administration of some exogenous insulin is required, but possibly not as much insulin as would be required by a person whose pancreas no longer produces any insulin at all. Once the pancreas has lost the ability to produce insulin (after the honeymoon period), the level of glucose in the blood may rise to dangerous levels. "Diabetes mellitus is a chronic disorder of glucose metabolism with serious clinical consequences" (Forouhi & Wareham, 2010, p. 602). The most important event in the history of T1D was the discovery of insulin in 1921-22 (Atkinson et al., 2014) by Frederick G. Banting and Charles H. Best (Rotenstein et al., 2012). The discovery of insulin was not a solution to cure or prevent the onset of T1D, but the administration of exogenous insulin was an effective way to control T1D. The perennial hope that islet transplantation would alleviate the need for exogenous insulin has failed to materialise (Shapiro et al., 2000). Further research is required on islet transplantation.

Honeymoon Phase

When a patient is newly diagnosed with T1D, initially a honeymoon phase may be experienced. During the honeymoon period the body may continue to produce some insulin, therefore, less injected insulin is required to self-manage diabetes. Exercise can reduce the need for insulin as the body uses up the sugar in the blood during activity. People with T1D who engage in regular exercise may prolong the honeymoon period, maintain good glycaemic control (control of the level of glucose in the blood), and require less injected insulin for longer than newly diagnosed patients who do not engage in regular exercise. Exercise increases the body's sensitivity to insulin. Therefore, less insulin is required by people with T1D who exercise regularly, however, blood sugar levels must be monitored regularly as blood glucose levels can be very hard to predict. The extent to which the engagement in exercise can extend the honeymoon phase requires further investigation.

FACTORS THAT MAY INFLUENCE THE ONSET OF T1D

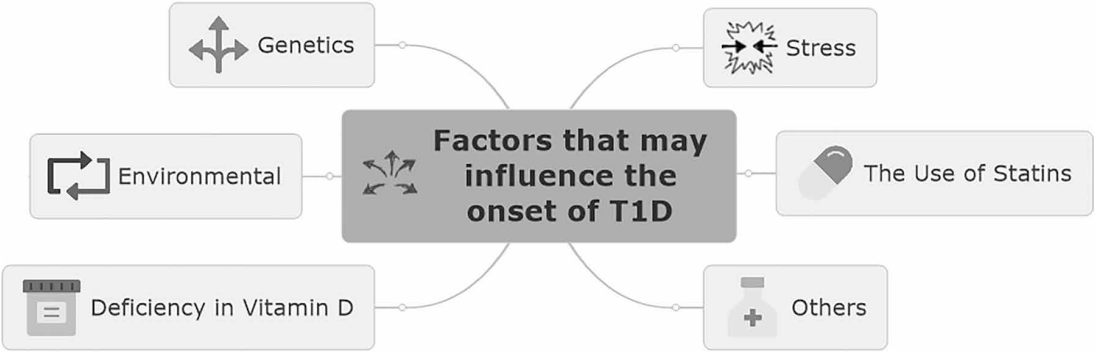
At present, there are no known ways to prevent the onset of T1D and the factors which may influence the onset are not clearly defined. Some of the factors that may influence the onset of T1D are reviewed in this section. Please refer to Figure 2.

Genetics

"Type 1 diabetes (T1D) is a common autoimmune disorder that arises from the action of multiple genetic and environmental risk factors" (Barrett et al., 2009, p. 703). Genetics can have an impact on β-cell dysfunction and death (Eizirik & Darville, 2001). "Results from linkage and association studies in T1D have long supported a model in which the major risk factor for T1D resides in the HLA region on Chromosome 6p21" (Barrett et al., 2009, p. 703). Further research is required to determine factors that trigger the onset of T1D.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. Factors that may influence the onset of T1D



Environmental

"The mechanisms underlying these enigmas in geographical incidence and increased incidence rates of type 1 diabetes are unknown but have largely been attributed to environmental influences" (Atkinson et al., 2014, p. 69). Thrower and Bingley (2014) also suggest that environmental factors could play a role in the rapid increase in the diagnosis of type 1 diabetes mellitus (T1DM). Type 1 Diabetes is also known as Type 1 Diabetes Mellitus. Samuelsson and Lofman (2013) suggest that there is a possible link between the incidence of T1D and some geological factors. Further research is required to identify the specific environmental factors with possible links to the onset of T1D.

Deficiency in Vitamin D

"Vitamin D deficiency increases the risk of many common cancers, multiple sclerosis, rheumatoid arthritis, hypertension, cardiovascular heart disease, and type 1 diabetes" (Holick, 2005, p. 1024). Vitamin D is necessary in the human body to ensure that the immune system is in excellent working order. The immune system protects the body by defending it against viruses and infections. A weakened immune system can leave the body in a very vulnerable state. One such state is the diagnosis of T1D due to an immune-mediated depletion of β-cells. "Type 1 diabetes is characterised by an immune-mediated depletion of β-cells that results in lifelong dependence on exogenous insulin" (Chiang et al., 2014, p. 2034). Exogenous insulin is the insulin injected with a needle or an insulin pump. Endogenous insulin is the insulin made in the pancreas. "Type 1 diabetes (T1D) is an autoimmune disease in which immune cells, notably T Lymphocytes, target and kill the insulin secreting pancreatic beta cells" (Mahaffy & Edelstein-Keshet, 2007, p. 915). Once a large enough percentage of the beta cells have been destroyed, the pancreas stops or greatly reduces the amount of insulin produced, therefore, the glucose levels in the blood rise uncontrollably and the person is left with full blown T1D (Mahaffy & Edelstein-Keshet, 2007). From that point in time onwards, the daily administration of insulin is required for survival "to prevent the development of ketoacidosis, coma and death" (Alberti et al., 1998, p. 17). Ketoacidosis means too much sugar and ketones in the blood which may lead to DKA.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

"Numerous observational studies indicate that deficiencies in vitamins A, D, E and zinc can adversely impact immune function, particularly T-cell responses" (Kau, Ahern, Griffin, Goodman, & Gordon, 2012, p. 6). "Type 1 diabetes is a T-cell-mediated disease that is associated with loss of immunological tolerance to self-antigens" (Lindley et al., 2005, p. 92).

Although some trials have shown that the incidence of T1D in people taking Vitamin D supplements is lower than people who do not take Vitamin D supplements "Randomised controlled trials of vitamin D supplementation as a means of primary disease prevention have shown mixed results" (Thrower & Bingley, 2014, p. 682). In a study conducted by Hyppönen, Laara, Reunanen, Jarvelin, and Virtanen (2001) they concluded that their results suggested "that development of type 1 diabetes is associated with low intake of vitamin D and signs of rickets during the first year of life" (Hyppönen et al., 2001, p. 1502). The best way for the body to obtain Vitamin D is through direct contact with sunlight. During exposure to sunlight previtamin D_3 penetrates the skin, wearing sunscreen reduces the skins ability to absorb Vitamin D (Holick, 2005). The lack of vitamin D and its connection with the onset of T1D is clearly unresolved from previous studies conducted, but this interesting hypothesis is worthy of further investigation.

Stress

"As early as the beginning of the 17th century, the onset of diabetes was linked to "prolonged Sorrow" by an English Physician" (Lloyd, Smith, & Weinger, 2005, p. 121). The use of the term "Prolonged Sorrow" could possibly imply that the person may have suffered from depression. "Stress augments many hormonal and neuronal pathways, possibly over-loading pancreatic beta cells" (Butalia, Kaplan, Khokhar, & Rabi, 2016, p. 590). "Some studies have suggested that stressful experiences might affect the onset and/or the metabolic control of diabetes, but findings have often been inconclusive" (Lloyd et al., 2005, p. 121). Stressful experiences such as a difficult marriage, experiencing the grieving process alone, family breakdowns, and other circumstances may lead to the onset of T1D.

The Use of Statins

Sattar et al. (2010) found that "statin therapy was associated with a 9% increased risk for incident diabetes" (Sattar et al., p. 735). Crandall et al. (2017) also suggest that the use of statins was associated with an increased risk of developing diabetes. Casula et al. (2017) recommend rigorous monitoring of pre-diabetes patients taking statins. Further research is required to establish what causes this increased risk and how to address the risk.

EQUIPMENT, DISPOSABLES, MEDICATION, AND MONETARY COSTS

Test Strips and Lancet Devices

Blood glucose test strips are used to monitor the current level of glucose in the patients' blood. Blood glucose test strips are inserted into a meter, a lancet device is used to prick the finger to obtain a blood sample. The sample of blood is then held up to the blood glucose test strip connected to the meter which displays a number on the screen. This number indicates the level of glucose in the blood at that point

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

in time only. The metre provides no indication to the patient whether or not the blood glucose level is increasing or decreasing. If tested ten minutes later, the result of a blood glucose test could be very different depending on what the person with T1D has consumed, how much insulin was administered, or the level and intensity of exercise the body has undertaken in that time. At times, a person may get an unexpected result, the blood level may be far higher or lower than expected, if this happens, the person should take a fresh sample of blood to place on a blood glucose test strip to confirm the initial level, before taking action to treat a hypo or correct for a hyper.

Ketone test strips are used to monitor the current level of ketones in the patient's blood. Ketone test strips are used with the meter in the same way as blood glucose test strips. After a blood sample has come in contact with the test strip the meter displays the level of ketones in the blood at that point in time only. After checking the blood/ketone level, the lancet (sharp) should be placed in a sharps bucket. Once a sharps bucket is full it can be dropped into a pharmacy or health clinic for safe disposal (incineration), at the same time the patient can collect an empty sharps bucket for future use. A large sharps bucket will take months to fill.

People diagnosed with T1D need to carry a diabetes medical supplies bag with them at all times. The contents of a diabetes medical supplies bag may include: insulin pens (basal and bolus), needles, meter, blood glucose test strips, lancets, diabetes diary, pen, glucose tablets, small red apple, small plastic bottle for used sharps, and whatever else is appropriate. Please refer to Figure 3.

Figure 3. Diabetes medical supplies bag

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

It is always useful to carry a small plastic bottle (for the safe collection of used sharps) and for the safe storage of sharps until the sharps can be deposited in the sharps bucket. It is the responsibility of the person to safely dispose of sharps, the doctor or diabetes care team will be able to guide the patient in this matter. Some pharmacies and health centres provide empty sharps bucket and take them back for safe disposal when full.

Monetary Costs

"Unlike their counterparts in the UK, Irish GPs are currently not reimbursed for delivering diabetes care" (O'Donnell et al., 2013, p. 3). The onset of T1D can be an expensive condition please see Figure 4. In some countries, the cost of disposable testing and treatment equipment, and medication is paid for by the health services. In other countries, the person or the family of the person has to pay for the disposable testing equipment, treatment equipment, and medication (which can be quite expensive). Regular visits to the General Practitioner (GP) are required to obtain prescriptions (every six months) to treat this life-long condition, Yearly visits to podiatrists have to be paid for in person. Expensive specialist footwear may be required to avoid complications of the feet associated with diabetes. Glasses/spectacles/contact lenses may need changing as they may no longer be suitable as the eye prescription may have changed substantially on diagnosis or may change over the years due to diabetes. Salary/wages may not be paid for the time spent in hospital or visits to medical practitioners or the diabetes care team. There may possibly be more ongoing expenses.

Figure 4. Monetary cost of diabetes

THE RESPONSIBLE ADMINISTRATION OF INSULIN

At present, there are no known ways to prevent the onset of T1D or to cure the condition of T1D, but it is possible to manage the condition through insulin dose adjustment and the responsible administration of insulin.

The responsible administration of insulin includes:

- Adjusting the insulin dose if necessary.
- Checking that the correct insulin pen is used: basal or bolus.
- Ensuring that the injection site is clean.
- Monitoring the injection site for changes in the skin texture or colour.
- Shoot some insulin up into the air to remove air bubbles prior to injecting insulin.
- Record the quantity of units administered.
- Confirming hypo treatments are on one's person at all times.

Basal and Bolus Insulin Injections

From the point in time of diagnoses and onwards for the rest of one's life "An immediate need for exogenous insulin replacement is also a hallmark of type 1 diabetes, for which lifetime treatment is needed" (Atkinson et al., 2014, p. 69). Insulin is generally delivered in basal (insulin is active in the body for up to 24 hours or more), and bolus (insulin is active in the body for up to four hours depending on the medication administered and the persons response to the medication) doses. A basal dose of insulin is administered to act in the background for a specific number of hours. The bolus dose of insulin is administered to cover the consumption of meals and the resulting spike in blood glucose levels over several hours. Each form of medication will have its own timeframe for dosing, and each person may respond differently to the medication, therefore, each person will have to take responsibility to monitor their blood glucose levels and discuss changes to their insulin regimen with their diabetes care team.

Basal Insulin

A basal dose of insulin is administered to act in the background all the time, while the bolus dose of insulin is administered to cover the consumption of meals and the resulting spike in blood glucose levels. The more carbohydrates in a meal; the more the blood glucose levels will rise for a number of hours after the meal has been consumed. Snorgaard, Poulsen, Andersen, and Astrup (2016) found that the more that carbohydrates were restricted in the diet the greater the reduction in blood glucose levels in a study of people with type 2 diabetes. The restriction of carbohydrates in the diets of patients with type 1 diabetes also has the effect of reducing blood glucose levels.

Bolus Insulin

A bolus dose of insulin is a rapid acting insulin which is administered at meal time (Neupane & Evans, 2014). The quantity of insulin required will depend on the carbohydrate content of the meal and the activity planned for the hours after the meal. People with T1D require training in accurately counting carbohydrates to enable them to effectively administer the correct dose of bolus (quick acting insulin).

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Bolus insulin should continue to lower blood glucose levels for approximately four hours after injection, depending on the brand of insulin administered. Bolus insulin is injected prior to eating, to prevent a spike in blood sugars after the consumption of food and drink. The diabetes care team should ensure that each patient understands the medication (insulin) that they are given. As with any medication: each one has individual properties and dosing schedules which should be clearly explained.

HYPERGLYCAEMIA (HYPER)

Hyperglycaemia means that the person is experiencing a high blood glucose level, which if left untreated could lead to hospitalisation, complications associated with diabetes, or death. "Current carbohydrate recommendations are based on 1) preventing ketosis, and 2) providing glucose beyond minimal needs" (Manninen, 2004, p. 9). "Ketones in the blood can lead to a condition called Ketoacidosis, also known as DKA, which just stands for diabetic ketoacidosis" (Gilbert et al., 2012, p. 21). Diabetic ketoacidosis (DKA) is life threatening, some undiagnosed, and diagnosed diabetics experience DKA to various degrees of severity. Accident and Emergency medical staff are primed to recognise the signs of DKA, and treat the patient accordingly to safely reduce the levels of glucose and ketones in the blood, and rehydrate the body.

Hyperglycaemia Episodes (Hypers)

Almost everything one consumes is converted into glucose which is released into the blood stream by the liver. Should too much glucose or sugar be consumed, this could lead to the patient going into a hyperglycaemic episode (hypers occurs when a patient's blood glucose level gets to abnormally high levels). "New hyperglycemia was defined as an admission or in-hospital fasting glucose level of 126 mg/dl (7 mmol/liter) or more or a random blood glucose level of 200mg/dl (11.1 mmol/liter) or more on 2 or more determinations" (Umpierrez et al., 2002, p. 978). Newly diagnosed hyperglycaemic patients were associated with a higher admission rate to Intensive Care Units (ICU), longer length of hospital stay, a higher in-hospital mortality rate and a lower functional outcome than previously diagnosed patients and patients with normoglycaemia (Umpierrez et al., 2002). Patients with normoglycaemia have blood sugar levels within the accepted range for the normal population (Pickup, Mattock, & Kerry, 2002). Hyperglycaemia (above normal blood sugar levels) is a dangerous medical condition which can go undetected for quite some time. "It has been thought that chronic high blood glucose levels in the body (hyperglycemia) due to diabetes could be the main cause that leads to nerve damage and thereby diabetic neuropathy" (Abdel-Motal, Abdelalim, Abou-Saleh, & Zayed, 2017, p. 172). Neuropathy can cause the feet to feel unrelenting pain (Archer, Watkins, Thomas, Sharma, & Payan, 1983). Hyperglycaemia has a key role to play in the development of diabetic neuropathies (Pop-Busui, 2010).

Treatment of Hypers

A waking blood glucose level greater than 7 mmol/L (126 mg/dL) or a two-hour postprandial blood glucose level greater than 11.1 mmol/L (200 mg/dL) could signify that the person is at risk of a hyper. A person who is experienced in managing diabetes may have the confidence to reduce their blood glucose levels by taking a correction dose of insulin, drinking plenty of water, or engaging in exercise/

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 5. Balancing insulin administration with food consumption

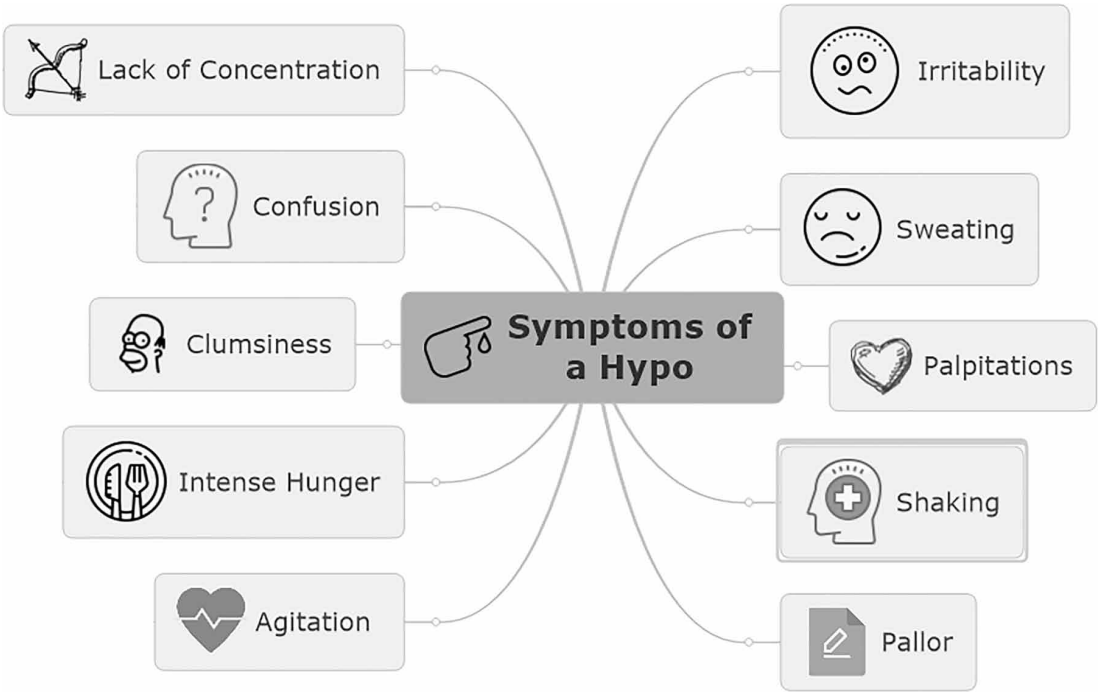
manual labour. Constant monitoring of the level of glucose in the blood is required over the next few hours, regardless of which option or combination of options are chosen to treat the high blood glucose levels. People with diabetes should consult with their diabetes care team on the treatment of hypers. A person with diabetes who is not confident to deal with a hyper themselves, should contact their Doctor/ General Practitioner, diabetes care team, or attend an Accident and Emergency (A&E) Department for treatment and guidance.

HYPOGLYCAEMIA

Calculating the correct dose of insulin to administer with a meal is a very difficult process. Please see Figure 5. Should too much bolus insulin be administered this could lead to the patient having a hypoglycaemic or severe hypoglycaemic episode over the coming hours. "The diagnosis is made by measuring the blood glucose level. If the glucose level is below 2.5mmol/l, you have hypoglycaemia" (Eldemir & Eldemir, 2011, p. 3). Hypoglycaemia is a low blood glucose level that mainly affects patients with diabetes who take insulin. Immediate consumption of glucose tablets, a piece of fruit, fruit drink, honey, or anything high in sugar is required to bring the blood glucose to a normal level and to avoid severe hypoglycaemia. Abnormally low blood glucose levels can result in hypoglycaemia which can pose a serious health threat (Byrne et al., 2012), if not effectively dealt with immediately. Should a patient with T1D on insulin not adequately treat hypoglycaemic in a relatively short time scale, this may lead to a severe hypo. "Severe hypoglycaemia was self-reported and defined as an episode of hypoglycaemia requiring the assistance of another person for treatment" (Dinneen et al., 2013, p. 31). Severe hypos should be avoided if at all possible, as a patient's ability to drive, operative machinery, or perform many other daily activities may be impaired with serious consequences should he/she suffer from a severe hypo. "Overly tight control, however, puts patients at risk of hypoglycaemic episodes (hypos) which may lead to seizures or periods of unconsciousness which may require emergency treatment" (Lawton & Rankin, 2010, p. 486). In a study conducted by Garg, Shah, Akturk, Beatson, and Snell-Bergeon (2017) one significant finding was that men had less fear of suffering from hypos than women.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 6. Symptoms of a hypo



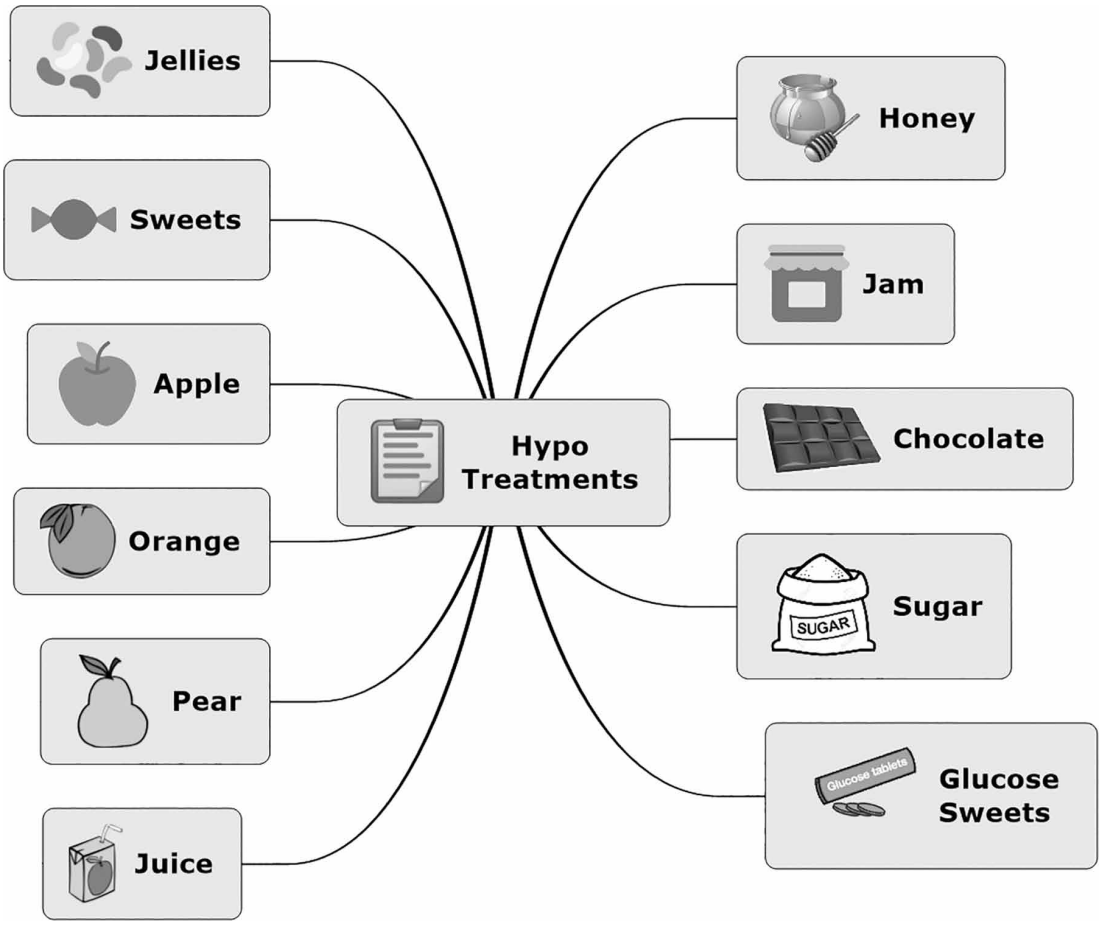
Hypoglycaemic Episodes (Hypos)

Symptoms of a hypoglycaemic episode may include some or all of the following: lack of concentration, confusion, clumsiness, intense hunger, agitation, irritability, sweating, palpitations, shaking, and pallor. Please note Figure 6. The body is basically fighting for survival as the brain feels threatened by the lack of glucose in the blood. The administration of too much insulin can inhibit the body's access to its regular glucose supply. Once the patient realises what is happening they can easily treat the hypo by taking some fast-acting glucose, for example, orange juice, a piece of fruit, or 2/3 glucose sweets. The natural instinct of a person who has just experienced a hypo is to overcompensate by the excessive consumption of sugary foods, which will invariably result in high blood glucose levels. Then the person has to decide how to deal with the high blood glucose levels. This can lead to glycaemic excursions (Deiss et al., 2006), a yo-yo effect as the blood glucose levels go up and down from one extreme to the other, as the person tries to control blood glucose levels that are uncontrollably fluctuating. People need to control the quantity of carbohydrates (carbs) consumed in the treatment of hypos which can prove to be a very challenging task.

The first experience of a hypo can take a person with diabetes on insulin by surprise, they should be alerted to this fact in advance and instructed to always carry some fast acting glucose tablets, sweets, chocolate, a piece of fruit, or fruit juice on their person. Please refer to Figure 7 for some more options for treating hypos. In addition, it is advisable to leave some glucose tablets or some other form of hypo treatment in every room of the house, including the garden shed. Gardening can be a strenuous activity that consumes the glucose in the blood which could lead to a hypo, therefore hypo treatments should always be available in the garden.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 7. Hypo treatments



It is very easy to get locked out of the house, consequently, it is necessary to carry glucose tablets on your person everywhere. Glucose tablets should be stored in an accessible place in the car and also at the work station in the place of employment. See Figure 8 for more important locations to store hypo treatments.

RECOMMENDATIONS FOR THE SUCCESSFUL MANAGEMENT OF T1D

Some individuals with type 1 diabetes mellitus (T1DM), or T1D may be initially treated with diet alone but generally require the administration of daily doses of insulin within months of the initial diagnosis (Thrower & Bingley, 2014). The types of food and beverages consumed by the person, and the volume of activity in which the person regularly engages will influence the daily doses of insulin required to maintain good glycaemic control. The challenge with managing T1D is that every person is unique and therefore requires a unique treatment plan.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 8. Storage locations for hypo treatments

Self-Management of Diabetes

"Despite broad organisational, intellectual, and fiscal investments, no means for preventing or curing type 1 diabetes exists, and, globally, the quality of diabetes management remains uneven" (Atkinson et al., 2014, p. 69). The self-management of T1D requires careful planning and goal planning strategies (Fredrix, McSharry, Flannery, Dinneen, & Byrne, 2018). The quality of the self-management of diabetes may depend on the educational attainment of the patient, the guidance provided by the diabetes care team, the patient's willingness to take control of the condition, diet and exercise. Not only does the quality of diabetes management remain uneven globally, but global disparities in access to insulin also must be addressed (Atkinson et al., 2014). T1D, although it predominantly affects younger members of the population, it can affect anyone at any age of their life. At present, the factors that may influence the onset of T1D are not clearly defined.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Glycaemic Control and Excursions

Some people with T1D can manage their own treatment plans, while others require substantial input from diabetes care teams to maintain good glycaemic control. People with T1D should be educated on the impact that the consumptions of fats and proteins have on glycaemic excursions. "Calculation of insulin to carbohydrate ratios (i.e. the amount of insulin needed to limit glycaemic excursions after meals) allows for increased flexibility in meal planning without sacrificing glycaemic control" (Daneman, 2006, p. 852). The Mean Amplitude of Glycaemic Excursion (MAGE) (Bando, Ebe, Muneta, Bando, & Yonei, 2017; Fritzsche, Kohnert, Heinke, Vogt, & Salzsieder, 2011; Hill et al., 2011; Syafa, Tjokroprawiro, Indra, Sargowo, & Muladi, 2014) is a method used to analyse fluctuations in the blood glucose levels of a person with diabetes. Complications associated with diabetes may be caused by glycaemic variability (Hill et al., 2011).

Glycaemic Control

Glycaemic control refers to the management of glucose levels in the blood. "Glucose control is facilitated by tracking glucose levels, care with food intake, and judging the correct does of insulin to take" (Ryan et al., 2017, p. 33). The administration of too little bolus insulin with a meal could lead to the patient's blood glucose levels reaching too high a level to be considered as good glycaemic control. The administration of too much bolus insulin with a meal could lead to the patient experiencing a hypoglycaemic episode.

HbA_{1c} Value

A HbA_{1c} value of greater than 8.5% (69 mmol/mol) would suggest that the current management of treatment by bolus and basal injections have failed the patient and other treatment methods should be considered (Neupane & Evans, 2014). The HbA_{1c} value indicates the average blood glucose level over the past two to three months, but it provides no information on the amount of time a patient may have spent in hypoglycaemic, severe hypoglycaemic, or hyperglycaemic episodes. Two patients with the same HbA_{1c} value may have experienced a wide variation in the standard deviation of blood glucose levels over the past two to three months. Fear of hypos may impede patients' ability to achieve near-normal glycaemic control. Hypos can cause death or serious injury in the immediate future. The HbA_{1c} test provides information on the probability of long-term complications. Good glycaemic control alongside avoidance of hypoglycaemic episodes would be the safest way for people with diabetes to manage their condition. "When basal-bolus routines are fastidiously applied in conjunction with the other aspects of management, many individuals with type 1 diabetes are able to maintain near-normal glycaemic control" (Daneman, 2006, p. 850).

Educational Programmes for T1D

Byrne et al. (2012) in their study of patients with T1D who participated in the DAFNE structured education programme, used several questionnaires including (i) Diabetes-Specific Quality of Life Scale (DSQOLS), (ii) Problem Areas in Diabetes Scale (PAID), and (iii) the Hospital Anxiety and Depression Scale (HADS). The conclusions to this study were that "Patients with higher baseline levels of anxiety, higher levels of diabetes related distress and higher baseline levels of HbA_{1c} are most likely to experi-

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

ence quality of life gain from participation in self-management programmes such as DAFNE" (Byrne et al., 2012, p. 243). Lower HbA_{1c} levels were significantly associated with adolescents who rated better Quality of Life (QOL) and lower perceived levels of family burden (Hoey et al., 2001).

Health Informatics

Fang, Pouyanfar, Yang, and Chen (2016) discuss the potential use of Big Data, Machine Learning, and Health Informatics to improve the quality of patient care. Privacy issues, ethics, validity of the data used, accessibility, security, are all relevant considerations and challenges to overcome in the use of Health Informatics. Wireless body sensor networks can be used to monitor patients' biometrics (calculation and analysis of body measurements) including blood glucose levels in healthcare (Chen, Lee, Chen, Huang, & Luo, 2009). Data mining applications can be used to analyse large volumes of data that are stored electronically in hospitals to identify trends or patterns and extract useful knowledge from the files of patients. Zaveri and Joshi (2017) suggest that data mining could be used to predict disease in advance. Patterson et al. (2009) suggest that the ability to predict potential new cases of patients with T1D over the coming years would enable European centres for diabetes treatment to plan in advance for funding requirements and health care resources to cater for the future burden of childhood diabetes. Further research is required to ascertain if the use of Big Data, Machine Learning, and Health Informatics can improve the quality of patient care.

Intensive Diabetes Therapy

"Controlled clinical trials of patients with type 1 or type 2 diabetes have not demonstrated a reduction in the occurrence of cardiovascular disease with long term intensive diabetes therapy" (Nathan et al., 2005, p. 2644). Long term intensive diabetes therapy may possibly lead to an increase in the occurrence of hypos, therefore, without substantial evidence to support the use of long-term intensive diabetes therapy, patients may be advised to keep tight control but not too intensive. "Adolescents having at least one severe hypoglycemic episode in the previous 3 months were more worried than those without" (Hoey et al., 2001, p. 1926). People should avoid having hypoglycaemic or severe hypoglycaemic episodes if at all possible; to avoid experiencing undue worry and stress, as worry can interfere with quality of life and stress can elevate blood glucose levels. Hypoglycaemic or severe hypoglycaemic episodes can be avoided by reducing the amount of insulin administered. All people with diabetes controlled by insulin should keep a diary of everything they consume in order to monitor the effects that particular foods and drinks have on their blood glucose levels. Overtime, the person will begin to know and understand their own body's response to the consumption of different foods and drinks. This knowledge should inspire confidence in the management and control of blood glucose levels and doses of insulin.

Psychosocial Outcomes

Nicolucci et al. (2013) conducted a study of diabetes-related psychosocial outcomes, 8596 adults with diabetes from 17 different countries participated in this study, a significant finding of this study was that "Approximately 40% of participants (18.6 – 64.9%) reported that their medication interfered with their ability to live a normal life" (Nicolucci et al., 2013, p. 767). Further research is required to ascertain why 40% felt that their medication interfered with their quality of life. Possibly, improved education on

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

the condition would assist people in controlling their medication so that it does not interfere with their ability to live a normal life. Living in fear of hypoglycaemia, hyperglycaemia, and the possibility of diabetes related complication in the future, can be daunting.

Exercise/Physical Activity

Perhaps, if people could try to improve their understanding of diabetes, how insulin works, and how to manage exercise and general living, their quality of life may improve. Kevin Nolan (2018) a successful Gaelic Footballer with T1D hoped to inspire other people with T1D to enjoy sports. "Exercise confers remarkable benefits to those with diabetes; however, the challenge to compelling patients with diabetes to exercise are formidable" (Jenkins & Jenks, 2017, p. 968). Frequent exercise is key to controlling blood glucose levels. "Contrary to popular belief, insulin is not needed for glucose uptake and utilization in man" (Manninen, 2004, p. 7). Physical activity is one of the things that can greatly impact on glucose uptake and utilization. Therefore, patients on insulin should carefully monitor their use of insulin and blood glucose levels before, during, and for some time after physical exercise, as physical activity can increase the risk of hypoglycaemia (Seaquist et al., 2013). Patients must always reduce their insulin dose prior to engaging in exercise (Lawton & Rankin, 2010), even if it is only going for a walk or hoovering the house, as these activities can quickly consume the glucose in the blood and leave the patient at risk of experiencing a hypoglycaemic episode due to low blood glucose levels. Family members, care givers and staff should be educated on the proper surveillance and treatment of hypoglycaemia (hypos) (Seaquist et al., 2013).

Involvement in physical activities (walking, gardening, hoovering, jogging, cycling, and so forth) lowers the blood glucose levels and also has the added advantage of keeping the person away from food. Gardening may increase absorption of Vitamin D, provide valuable exercise, and reward with a beautiful display of colour as per Figure 9. Controlled consumption of food and drink alongside regular movement of the body are key to the management of blood glucose levels. Further research is required to target the formidable challenge to compel people with diabetes to participate in more exercise.

Figure 9. Picture of flowers growing in the garden

Restricting the Consumption of Carbohydrates

Feinman et al. (2015) suggest that restricting the consumption of carbohydrates has the greatest effect on reducing blood glucose levels and can lead to the reduction or elimination of medications used in the treatment of diabetes. By cutting out or substantially reducing the consumption of foods that are high in carbohydrates (rice, pasta, white flour, potatoes, sugary drinks, cakes, biscuits and confectionery). Instead, by consuming foods that are high in nutritional content but low in carbohydrates (chicken, fish, eggs, beef, pork, full fat cheese, nuts, berries, fruit and vegetables). A person with T1D can substantially reduce the units of basal and bolus insulin administered. It would be in the interest of people living with T1D to keep a record of everything that they eat and drink for as long as it takes for them to realise the effects that different food and drink combinations have on their specific blood glucose levels. During this time, the blood glucose levels should be taken at least six times a day and recorded. Hence, the patient will be able to see exactly what effect each meal is having on their blood glucose levels. Everybody is different, therefore, it is imperative that the patient themselves or parents/carers (Silverstein et al., 2005) take responsibility for managing diabetes tailored to the patient's individual needs. "No need for an insulin head start. Low-carb, high-fat breakfasts usually allow for dosing insulin right as I start eating (or not at all)" (Brown, 2017a, p. 31). Before reducing carbohydrate consumption, the patient must reduce the units of insulin administered. "It should be recognized that the use of low-carbohydrate diets is not a recent experiment and may well approximate the diet used by much of humanity for tens of thousands of years before the rise of agriculture" (Feinman et al., 2015, p. 11). People with T1D have to be prepared to experiment with their foods, to see the effects that every morsel consumed has on blood glucose levels. The best approach is to have a low carbohydrate satisfying meal, tidy up, and walk away from the kitchen, no snacking or grazing, as this will impact on blood glucose levels. If a snack is required consume a small piece of fruit, a bag of nuts, coffee and cream, or some strawberries and cream. The consumption of full fat cream will slow down the release of natural sugars in the strawberries.

Low Carbohydrate Diet

Patients should also reduce the amount of insulin administered before commencing a low carbohydrate diet (Feinman et al., 2015). Some patients who reduced the amount of insulin administered discovered that as a result of taking control by reducing the units of insulin administered that they had also achieved much better glycaemic (blood glucose) control (Lawton & Rankin, 2010).

The Consumption of Fat and Protein Before Carbohydrates

"The temporal sequence of carbohydrate ingestion during a meal has significant impact on postprandial glucose regulation" (Shukla et al., 2017, p. 4). Shukla et al. (2017) suggest that the order in which one consumes food: fat and protein first followed by carbohydrate (carbohydrate last instead of carbohydrate first) has an impact on the absorption of the food and the resulting blood glucose level, patients that consumed carbohydrates last in a meal were found to have improved postprandial glycaemia. Postprandial glycaemia is the level of glucose in the blood two hours after consuming food.

The consumption of fat and protein with every meal provide satiety (Feinman et al., 2015), therefore, there should be no need for snacking between meals. Were a person with T1D to eat a scone with jam as a snack, the result would be a spike in blood glucose levels because there was insufficient protein and

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

fat to slow down the release of glucose to the blood stream. As the spike in blood glucose levels begins to fall, the person with T1D would feel hungry again. People with diabetes should possibly avoid the consumption of scones and jam, a much healthier option would be to enjoy some fresh strawberries/blueberries/raspberries with full fat cream. Full fat cream should be consumed in moderation, as excessive consumption of full fat cream could increase total cholesterol and the amount of lipids circulating in the blood stream, which could lead to other complications.

Need to "Feed" Their Insulin

"Patients who are on insulin or insulin secretagogues are able to reduce their doses on carbohydrate-restricted diets and find they are less likely to need to "feed" their insulin" (Feinman et al., 2015, p. 6). When a person with T1D administers bolus insulin before a meal, the insulin works in the body (reducing blood glucose levels) for approximately up to four hours (everybody is different), and every medication will have a different impact on blood glucose levels. Should the quantity of insulin administered be insufficient to cover the carbohydrate content in the food consumed blood glucose levels will be higher than what is required for good glycaemic control. Should the quantity of insulin administered be in excess of what is needed to cover the carbohydrate content in the food consumed blood glucose levels will drop to a level where the patient may experience a hypoglycaemia or a severe hypoglycaemia episode. On experiencing a hypoglycaemia episode the body immediately craves food and it is difficult for the patient to restrain themselves to eating just a sufficient amount of carbohydrates to return to a safe blood glucose level. Generally, people with T1Ds will over compensate by eating too many carbohydrates after experiencing a hypoglycaemic episode. This behaviour results in the blood glucose levels escalating, feelings of guilt, and the probability that the person may then have to inject more bolus insulin to bring the blood glucose levels back down again. Frequent use of bolus insulin throughout the day can leave a person in a position whereby they are unsure as to whether their blood glucose levels are going up or down. "When blood sugars are out of range, people with diabetes are made to feel like failures" (Brown, 2017b, p. 342). Out of range blood glucose levels do not signify that the person is a failure. Possibly more information and education may be required for the person to better manage this challenging condition.

Triglycerides (TG)

"The lower carbohydrate diets were associated with significant decreases in body weight, body mass index, TG levels, and blood pressure; additionally, they showed improvement in several other metabolic and lipid indicators" (Feinman et al., 2015, p. 7). In fact, Accurso et al. (2008) suggest that "carbohydrate restriction improves all of the features of metabolic syndrome" (Accurso et al., 2008, p. 1). Triglycerides (TG) are a type of fat/lipids found in the blood. A normal level of triglycerides found in the blood is less than 1.7mmol/L (150 milligrams per decilitre). There are many benefits to lower carbohydrate diets. There is no reason why people with T1D should not try a low carbohydrate diet for a few months while closely monitoring blood glucose levels and reducing the amount of insulin administered if they are experiencing too many hypoglycaemic episodes. People can always revert back to their normal eating patterns and insulin doses if the low carbohydrate diet does not suit them or their lifestyle. "More than a dozen additional studies, have failed to show an association between dietary lipids and risk for cardiovascular disease (CVD)" (Feinman et al., 2015, p. 7). Medina-Bravo et al. (2012) suggest that children with type 1 diabetes have higher levels of Total Cholesterol (TC) when compared to healthy subjects. "The

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

TG-to-HDL cholesterol ratio may be related to the processes involved in LDL size pathophysiology and relevant with regard to the risk of clinical vascular disease" (Boizel et al., 2000, p. 1679). High-Density Lipoproteins (HDL) are classed as the good cholesterol in the blood, as HDL transports cholesterol from all over the body back to the liver for disposal. Low-Density Lipoproteins (LDL) are classed as the bad cholesterol in the blood; as LDL can build up in the walls of blood vessels and arteries causing blockages which have the potential to cause heart attacks or strokes. The association between the consumption of dietary lipids and the risk for cardiovascular disease is very relevant to the health of people living with diabetes and the normal population, therefore, this association requires further research.

TIPS FOR PATIENTS WITH T1D

Figure 10. Tips for patients with T1D

MEDICAL COMPLICATIONS ASSOCIATION WITH DIABETES

In the treatment of this chronic condition the person diagnosed with the condition or the parent of a child diagnosed with the condition must take immediate responsibility for administering the medication (insulin); while having limited knowledge or understanding of how diabetes and the medication works. Tight glycaemic control is required on a daily basis to avoid complications associated with diabetes in later life (Byrne et al., 2012).

Complications association with diabetes may include some or all of the following: retinopathy (Fredrix et al., 2018; Hammes, 2018; Raymakers, Gillespie, O'Hara, Griffin, & Dinneen, 2018), neuropathy (Young, Boulton, Macleod, Williams, & Sonksen, 1993), nephropathy (Andersen, Christiansen, Andersen, Kreiner, & Deckert, 1983; Chiang et al., 2014; Fowler, 2008), renal damage (O'Loughlin et al., 2010), foot ulcers (Ahmad, 2016; Fredrix et al., 2018; Noor et al., 2017), blindness, amputation (Cousart & Handley, 2016), stroke (Lawton & Rankin, 2010), cardiovascular disease (Fredrix et al., 2018; Gerstein et al., 2001; Nathan et al., 2005), myocardial infarction (heart attack), angina (chest pain or obstruction) (Nathan et al., 2005), ingrown nails (Vural et al., 2018), decrease in Bone Mineral Density (BMD) (Vestergaard, 2007), impaired ability to heal wounds (Loomans et al., 2004), immunological effects (Egan & Dinneen, 2016), proteinuria (Kiire, Horak, Lee, Klein, & Klein, 2017; Raymakers et al., 2018), anxiety and depression (Raymakers et al., 2018), and an increased risk of infection (O'Loughlin et al., 2010).

"The prevalence of each complication is generally lower with a more recent diagnosis when adjusting for duration of diabetes" (Kiire et al., 2017, p. 11). The sooner the condition is diagnosed and appropriately treated the better the prognosis (future outcomes) for the person.

Foot Ulcerations

Kelly et al. (2010) found that 30% of patients with diabetes who had been screened for foot complications tested positive for pedal neural dysfunction and 17% tested positive for vascular impairment. "Diabetic foot problems are responsible for nearly 50% of all diabetes-related hospital bed days" (Ahmad, 2016, p. 48). Therefore, it is in the patient's best interest to learn to understand how diabetes works and how best to manage the administration of insulin to control blood glucose levels; in order to avoid diabetes complications later on in life and to avoid hypoglycaemic, severe hypoglycaemic episodes, and DKA in the short term. The leading cause of hospitalisation due to diabetes is foot ulceration, foot ulcerations can adversely impact on a persons' quality of life which may lead to depression (O'Loughlin et al., 2010). "Conservative management of foot problems has dramatically reduced the risk of amputation by simple procedures, such as appropriate foot wear, cleanliness, aggressive surgical debridement, … and ulcer management" (Ahmad, 2016, p. 48). Preventative measures can be undertaken to avoid the risk of foot infection associated with diabetes and the potential for amputation (Noor et al., 2017). Comfortable appropriate footwear is necessary to avoid damage to the foot which may lead to ulceration. Frequent changing of socks during the day may be necessary to ensure that the feet are free from sweat or dampness, which could lead to fungal infections or other avoidable conditions of the feet.

People living with diabetes should monitor their feet on a daily basis by checking for dry skin, cuts, ingrown toenails, redness, swelling and/or any other abnormalities. If anything unusual is noted they should visit a podiatrist/chiropodist or their diabetes care team for a consultation and to receive advice on treating the condition. "It is concluded that acute painful diabetic neuropathy is a distinct syndrome,

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

occurring in insulin or noninsulin dependent patients of any duration, and unrelated to other diabetic complications" (Archer et al., 1983, p. 491).

People with diabetes are advised to undergo a comprehensive examination of the feet every year to identify any risk factors that may lead to neuropathy or ulceration (O'Loughlin et al., 2010). Peripheral neuropathy (PN) is more common in people with type 1 diabetes who have had the condition for a longer duration (Abdel-Motal et al., 2017) and mainly affects lower limbs (Zhang et al., 2017). Diabetic peripheral neuropathy (DPN) is more likely to injure small rather than large nerve fibres (Zhang et al., 2017). "In some patients diabetic foot infection is the first presentation of diabetes and they will require diabetology input into the initial blood glucose control and ongoing diabetes management" (Sohrabi & Russell, 2017, p. 500).

Nephropathy

"There are strong associations between glucose control (as measured by haemoglobin A1c [A1C]) and the risk of developing diabetic nephropathy" (Fowler, 2008, p. 78). Nephropathy means damage or disease of the kidney which may lead to renal failure (Alberti et al., 1998). "Our study shows convincingly that diabetes nephropathy is a very severe complication of Type 1 diabetes and that survival after the onset of proteinuria is poor" (Andersen et al., 1983, p. 500). Hb is an abbreviation for haemoglobin. HbA_{1c} is an abbreviation for a blood glucose test that tells the average glycated blood glucose level over the past two to three months, there is no need for a patient to fast for a HbA1c blood test (Saudek et al., 2008). "Normal ranges for haemoglobin A1c in people without diabetes is about 4% to 5.9%" (Davis, 2016, p. 1). A HbA_{1c} of 6.5% has been recommended by an international expert committee as a cut-off point for defining overt diabetes (Dinneen, 2010). A HbA_{1c} level of 6.5% or greater has been recognised as an unmistakeable sign that the patient has diabetes.

THE CONTRAINDICATIONS OF ADMINISTERING INSULIN

"Dead in Bed" Syndrome

"Type 1 diabetes mellitus increases the risk for sudden unexplained death (SUD), generating concern that diabetes processes and/or treatments underlie these deaths. Young (<50 yrs) and otherwise healthy patients who are found dead in bed have been classified as experiencing "dead in bed" (DIB) syndrome" (Secrest, Becker, Kelsey, LaPorte, & Orchard, 2012, p. 293). Not all people with diabetes wake up on experiencing a hypoglycaemic episode during sleep, this can be dangerous as an untreated episode of hypoglycaemia can very quickly progress to an episode of severe hypoglycaemia, if a severe episode of hypoglycaemia is left untreated this could turn into a diabetic coma. Sudden Unexplained Deaths occur up to ten times more frequently in people who have been diagnosed and treated for diabetes mellitus type 1 (Secrest et al., 2012). "SUD in Type 1 DM seems to be increased 10-fold and associated with male sex, while DIB individuals have a high HbA_{1c} and insulin dose, and low BMI. Though sample size is too small for definitive conclusions, these results suggest specific sex and metabolic factors predispose to SUD and DIB" (Secrest et al., 2012, p. 293). Further research is required to establish why people with type 1 diabetes are more likely to experience SUD or DIB syndrome than people who have normal glycaemia.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Severe and Nocturnal Hypoglycaemia

There is a possibility of hypoglycaemia occurring when the level of glucose in the blood drops to ≤ 3.9 mmol/L (≤ 70 mg/dL) (Seaquist et al., 2013). Hypoglycaemia can be fatal, therefore, people who are treated with insulin should closely monitor the level of glucose in their blood on a regular basis throughout the day and always carry on their person treatments for hypoglycaemia (glucose tablets, orange juice, or a piece of fruit). Severe hypoglycaemia can be fatal (Seaquist et al., 2013). In a study conducted by Dinneen et al. (2013) 24% of respondents had experienced episodes of severe hypoglycaemia in the previous year.

People with diabetes should aim to avoid hypoglycaemia and more importantly severe hypoglycaemia episodes if at all possible during waking hours and more critically during sleep (nocturnal hypoglycaemia). "Type 1 diabetes mellitus increases the risk for sudden unexplained death (SUD), generating concern that diabetes processes and/or treatments underlie these deaths. Young (<50 yrs) and otherwise healthy patients who are found dead in bed have been classified as experiencing "dead in bed" (DIB) syndrome." (Secrest et al., 2012, p. 293).

Blood glucose concentration reduces when insulin is administered to fasting patients because it is assumed that glucose uptake into tissues is increased when insulin is administered, both Sonksen (2001) and Manninen (2004) suggest that this is just another metabolic legend and that in fact insulin lowers blood glucose levels through inhibiting hepatic glucose. The suggestion that insulin lowers blood glucose by inhibiting the livers production of glucose rather than lowering blood glucose levels by increasing glucose access into tissues, is an interesting suggestion that warrants further research.

POSITIVE IMPACT OF A DIAGNOSIS OF DIABETES

The diagnosis of T1D can initially be very confusing. Once familiar with this life-long condition, the patient then has the opportunity to take control of their condition and manage their blood glucose levels to suit their lifestyle and also to maintain good health for as long as possible.

Opportunity to Lead a Very Healthy Life

The consumption of too many sugary foods can have detrimental effects on everybody whether they suffer with diabetes or not. Through regular finger pricking, people with diabetes can see the impact that all foods and drinks have on their blood glucose levels. Therefore, they have the choice to consume foods and beverages which will not spike their blood sugars, and hence live a much healthier life by cutting out the consumption of foods and beverages that have high sugar content and little nutritional value.

Weight Loss

The sudden onset of T1D can lead to weigh loss. Some people struggle with their weight for years and never lose weight for long. Many attend various different classes to lose weight, lose a stone or two over a period of time, and then put it all back on (and frequently more weight). So, when a person who is newly diagnosed with T1D has lost weight as a result of their condition, they then have the opportunity to keep the weight off, by managing the condition, exercising, and eating good nutritious food.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Frequent Access to Excellent Medical Professionals

Once diagnosed as a person with T1D, depending on the country of domicile, the patient will be assigned to a diabetes care team. As with everything in life, some diabetes care teams will be better funded and resourced than others. But still the opportunity is there for the patient to tap into the knowledge base of the medical professionals to ensure that they effectively manage their condition while maintaining an excellent quality of life. The diabetes care team perhaps see each patient twice a year. Therefore, blood testing would be conducted twice a year. The results of the blood tests, (analysed by the diabetes care team), give a very clear picture of the overall general health of the patient. Hence, patients with diabetes have access to excellent medical professionals on a regular basis to guide them to a healthier lifestyle. People who are not diagnosed with diabetes, do not get regular blood tests and access to medical teams to guide them on how to improve their overall health, unless, they pay for these regular health check-ups.

Constant Reminder to Eat Well and Be Active

Even though the excessive consumption of carbohydrates and sugars may not spike the blood glucose levels of people without diabetes this may still lead to other unhealthy medical conditions, for example, obesity. "As a guide for the patient with diabetes, the prescription of many agencies to "eat to the meter" seems like a good one" (Feinman et al., 2015, p. 11). The blood glucose reading on the meter can be a wake-up call to the patient; if the reading is higher than the patient would like perhaps they have not engaged in sufficient exercise or work to expend the glucose created from their last meal, so perhaps they should go for a walk, do some housework or gardening prior to the consumption of more food or drink (with the exception of water). Many members of the world's population currently eat more calories per day than their bodies require.

Some people continually graze (eat and drink unconsciously), the effective management of diabetes depends on one's ability to control every morsel of food or drink consumed. Or, at least to record everything consumed, measure the impact on the blood glucose levels and manage the blood glucose levels to bring them to an acceptable level by engaging in exercise or through the administration of an appropriate dose of insulin.

Self-Management of Condition Unlike Other Conditions

In a study conducted by Nicolucci et al. (2013) a notable finding was that "27.7% of respondents reported a positive impact of diabetes on at least one aspect of their life" (Nicolucci et al., 2013, p. 772). Of all the diseases or conditions to get, T1D is possibly one of the easiest to self-manage, providing the patient is sufficiently informed to manage the condition, willing to monitor every morsel consumed, check blood glucose levels regularly, and take responsibility for altering the doses of (basal and bolus) insulin to suit their lifestyle. The management of T1D in babies, children, adolescents, disabled people, and the elderly is totally different to self-management of the condition; as the person responsible for the administration of insulin has no feedback from their own body to warn in advance of hypos. The management of T1D in babies, children, adolescents, disabled people, and the elderly, is deserving of further research.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

FUTURE RESEARCH DIRECTIONS

A number of interesting questions have arisen during this review of T1D which deserve further investigation:

- To investigate if insulin inhibits the release of glucose into the blood from the liver (Manninen, 2004), or if insulin enables the body to use glucose for energy or perhaps both.
- Islet transplantation.
- The extent to which engagement in exercise can extend the honeymoon phase.
- The determination of factors that trigger the onset of T1D.
- The identification of environmental factors with possible links to the onset of T1D.
- The lack of vitamin D and its connection to the onset of T1D.
- The use of statins linked to an increased risk of developing diabetes.
- To ascertain if the use of Big Data, Machine Learning, and Health Informatics can improve the quality of patient care.
- To investigate why people diagnosed with T1D felt that their medication interfered with their quality of life.
- To target the formidable challenge to compel people with diabetes to participate in more exercise.
- The association between the consumption of dietary lipids and the risk for cardiovascular disease.
- To establish why people with T1D are more likely to experience SUD or DIB syndrome than people who have normal glycaemia.
- The management of T1D in babies, children, adolescents, disabled people, and the elderly.

CONCLUSION

The diagnosis of T1D, a debilitating autoimmune disease, is now considered to be a global epidemic. The self-management of T1D is a challenging ongoing process requiring daily focus to maintain good glycaemic control. For the successful treatment of this life-long medical condition the patient or carer requires an understanding of this condition. Self-management of diet, engagement in physical activity, and the daily dosage of insulin administered, are necessary to avoid complications associated with diabetes in the future. One of the main challenges to people with T1D is to avoid hypers and hypos. Hypers occur when the blood glucose levels get too high and hypos occur when the blood glucose levels get too low. Both conditions are potentially dangerous to the patient. Therefore, the successful management of diabetes is for the patient to keep their blood glucose levels under tight control at all times.

A HbA_{1c} result between 4% and 5.6%, a fasting blood glucose level less than 7 mmol/L (126 mg/dl), and an Oral Glucose Tolerance Test (OGTT) below 11.1 mmol/L (200mg/dL) are the levels expected for normoglycaemia (members of the population not affected by diabetes). A person diagnosed with T1D should aim for blood glucose levels near normoglycaemia while avoiding hypos. The quality of the self-management of the condition may depend on the educational attainment of the patient, the expertise of the diabetes care team, and by the patient attending and engaging with diabetes educational programmes. An awareness of simple facts, such as, the consumption of fats and proteins before carbohydrates can delay the release of glucose into the blood and result in a lower postprandial (2 hours after food consumption)

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

blood glucose level. People with T1D are 10 times more likely to suffer from Sudden Unexplained Deaths (SUD) and Dead-in-Bed (DIB) syndrome. It is possible for a person with T1D to control their condition to suit their lifestyle, and therefore possibly avoid complications associated with diabetes in later life.

Chapter 3
For Better Healthcare Mining Health Data

Güney Gürsel
Command post of Gendarme Logistics, School ol of Technical and Auxiliary Forces, Turkey

ABSTRACT

Data mining has great contributions to the healthcare such as support for effective treatment, healthcare management, customer relation management, fraud and abuse detection and decision making. The common data mining methods used in healthcare are Artificial Neural Network, Decision trees, Genetic Algorithms, Nearest neighbor method, Logistic regression, Fuzzy logic, Fuzzy based Neural Networks, Bayesian Networks and Support Vector Machines. The most used task is classification. Because of the complexity and toughness of medical domain, data mining is not an easy task to accomplish. In addition, privacy and security of patient data is a big issue to deal with because of the sensitivity of healthcare data. There exist additional serious challenges. This chapter is a descriptive study aimed to provide an acquaintance to data mining and its usage and applications in healthcare domain. The use of Data mining in healthcare informatics and challenges will be examined.

INTRODUCTION

From primary care institutions to big healthcare centers, every healthcare organization uses an information system. These healthcare information systems (HCIS) store, process and retrieve healthcare data. Healthcare data is very valuable in today's world. By the help of rapidly developing healthcare informatics, there are efforts to use the valuable data stored electronically in HCIS databases to improve healthcare. Healthcare staff expects more than e-recording the data from HCISs. Besides using healthcare data for care giving, healthcare centers and academic centers use these data for education and research. Research in medical area is not limited to healthcare development such as developing new healing techniques and drugs. There are healthcare informatics fields such as structured data entry, constructing longitudinal patient data, image processing, etc. Any research area dealing with huge and valuable data such as medical domain requires creative techniques supported with computers and computer systems to utilize it. Data mining techniques are good examples for these required creative techniques.

Life expectancy has risen. We live longer when we compared to past. This improvement is tremendous for human being. But it has a cost. We spend more to healthcare when compared to past. The healthcare expenses are becoming unmanageable. Payers put pressure on healthcare organizations to decrease the cost. Then is it possible to decrease the cost while increasing the quality of healthcare? The answer is "it depends". It depends on the extent that we utilize the data and information we have.

It is stated that every healthcare institution uses an information system. During the daily healthcare service, every piece of patient data is recorded by means of HCISs. In short, we have huge amounts of patient data and it is growing every day. These huge amounts of data are called as "Big

Data". These "Big Data" should be used to get information and knowledge. The most fundamental challenge about Big Data is to explore the large volumes of data and extract useful information or knowledge for future use (Wu, Zhu, Wu, & Ding, 2014).

Data mining is one of the techniques to utilize this valuable healthcare data. There are many different definitions available in the literature. Drawing from the literature, we can define data mining as the process of analyzing data and discovering knowledge, patterns, associations, rules, anomalies, sequences that are non-trivial, implicit, previously unknown and potentially useful from databases.

Healthcare institutions are geographically distributed to ease healthcare access. Data about a patient can be scattered into many HCIS databases. There should be a technique to handle these scattered data to analyze and mine. Distributed data mining deals with this scattered data problem and will be covered through the chapter.

Patient health data is very sensitive. Researches about patient health data should comply with some ethical and legal issues to protect patient privacy as well as data mining studies. Privacy is term used for notion of the confidentiality and access restrictions of patients' protected health information (PHI) which contains sensitive and personal information (Sun, Zhu, Zhang, & Fang, 2012). Patient privacy refers to any medical data (medical condition, test result, payment information, etc.) in any form (paper, electronic, etc.) that belongs to a patient, the meaning is about what is protected and who will be permitted to use this information (Upstate Medical University, 2011). Protecting patient privacy in data mining will be a part and it is examined in the chapter.

The complexity and toughness of the medical environment is common information in the literature. The complexity and toughness of the medical domain is a challenge to every technology and application as well as data mining. In this chapter, the challenges specific to data mining will also be examined.

This chapter is a descriptive study that examines the concepts, issues related and techniques used in data mining in healthcare big data. The purpose of the study is to give an idea about the data mining tasks and techniques used in healthcare.

The chapter is organized as follows: In the background section, the universal basics, not related to healthcare only, of data mining will be covered. The main part is in the heading of "MEDICAL DATA MINING" comprising the contribution of the data mining to the healthcare, data mining techniques used in healthcare, temporal data mining in healthcare, distributed data mining in healthcare, challenges, privacy and security issues, data mining for healthcare management. In the end, are the future research directions and conclusion parts interpreting the chapter.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

BACKGROUND

Data Mining Basics

In this section, the universal basics, not related to healthcare only, of data mining will be examined. There will be a brief summary of data mining to give idea and get acquaintance. Not to digress from the main subject, details are left to reader; the references in the "Additional Reading" could help.

Data mining is the miracle of technology era. In the electronically stored big data, no matter what area is, companies are in a race to get useful knowledge to gain advantage in the ruthless competition of our age. To give an idea about what can data mining extract from the big data, we can give some examples as (Bramer, 2013):

- Analyzing satellite imagery,
- Analysis of organic compounds,
- Fraud detection,
- Electric load prediction,
- Financial forecasting,
- Medical diagnosis,
- Real estate valuation,
- Targeted marketing,
- Toxic hazard analysis,
- Weather forecasting.

In data mining, the critical part is the quality of data. Before data mining, we have to be sure that data has below features (Kantardzic, 2011):

- **Accuracy:** The data to be mined should be consistent, complete and true.
- **Having Right Data Type:** We have to ensure that the data is stored in the correct form. Numerical value should not be available in character form or vice versa.
- **Integrity:** There shouldn't be any conflicts in the data.
- **Consistency:** The form and the content should not change after integration of large data sets.
- **Being Not Redundant:** Redundancy is an issue that should be avoided or kept to minimum not only in data mining but also in database design. It is the replication of the same data in different tables of database. Redundant data may lead to problems in storing, accessing and analyzing the data.
- **Timeliness:** The time component of the data should be well organized and bias related to data time should be avoided.
- **Being Understandable:** The data should not have misleading form. The user and analyzer should clearly understand what the data stand for.
- **Complete:** Missing values are serious problems for data mining. It should also be kept to minimum.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

The features given above are very critical. In real world, the data in the databases are so messy to deal with which is called as "dirty". They are mostly incomplete, erroneous (noisy) and inconsistent. In order to make the data have desired features given above, data preprocessing is done for data mining. Major tasks in data preprocessing can be listed as (Jiawei & Kamber, 2001):

- **Data Cleaning:** Filling missing values, smoothing noisy data, identifying or removing outliers and resolving inconsistencies.
- **Data Integration:** Integration of multiple databases, data cubes or files.
- **Data Transformation:** Normalization and aggregation.
- **Data Reduction:** Obtains reduced representation in volume but produces the same or similar analytical results.
- **Data Discretization:** Part of data reduction but with particular importance especially for numerical data.

Data mining tasks and techniques are confused and can be misused interchangeably. To eliminate the confusion, it is better to mention about what are data mining tasks and what data mining techniques are.

Data mining tasks are divided into two categories: Descriptive tasks and Predictive tasks. Some sources in literature name these categories as Supervised and Unsupervised. Descriptive tasks present the main characteristics of the data set, a summary of the data points making it possible to study important aspects (Jain & Srivastava, 2013). Descriptive tasks are undirected, find patterns in the data set and leave the interpretation of the patterns to the researcher in which the data speaks for itself (Jain & Srivastava, 2013).

Predictive tasks provide the researcher with the facility to predict an unknown (often future) value of a specific variable (Jain & Srivastava, 2013).

Namely, data mining tasks are:

- Classification,
- Clustering,
- Rule association,
- Description,
- Visualization,
- Outlier detection,
- Time series analysis.

In Classification, we try to find group memberships for the known and predefined labels (classes). Classification is a predictive data mining task.

In Clustering, there is no predefined and known class. Clustering tasks group the data into clusters according to their similarities.

Rule association is another predictive task that is used for searching relationships within data. Antecedent and consequent relationships, meaning which occurs before and after, which situations co-exist, etc. are the possible search criteria.

Description tasks are descriptive and they help us characterize the data. By the help of description tasks, data can be generalized, summarized and characterizations are determined.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Visualization tasks help us understand the results of data mining. Because some data mining techniques are hard to understand for the target managers, by means of visualization, result of data mining becomes accessible and comparable.

Outlier detection is easy to understand from its name. These tasks help us detect the data that are significantly different, we call them as outlier. Especially for fraud and abuse detection, outlier detection tasks are used.

Time series analysis tries to find patterns and rules depending on time.

As to data mining techniques, we can define them as the methods used to perform data mining tasks given above. The common techniques for data mining can be listed as:

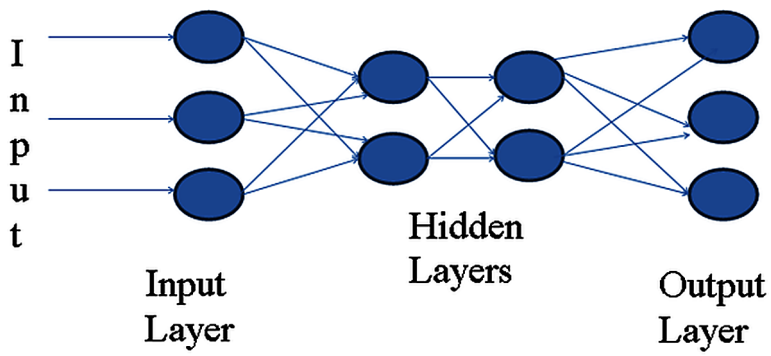
- Artificial Neural Network (ANN),
- Decision Tree (DT),
- Genetic Algorithms (GAs),
- Regression and Correlation methods (such as Logistic Regression),
- Bayesian Networks,
- Support Vector Machines (SVMs),
- Similarity Measures (such as Nearest Neighbor Method),
- Fuzzy Logic,
- Hybrid techniques (such as Neuro-Fuzzy).

Artificial Neural Network (ANN) is the model that tries to emulate human nerve system into computer applications. ANN is an adaptive system that changes its parameters during the training phase, like human nerve system, model learns from the training set. In Figure 1, an ANN design example is given. Number of hidden layers depends on the case and the problem.

Decision Tree (DT) is a structure where each node denotes a test on an attribute value, each branch represents an outcome of the test and tree leaves represent classes or class distribution, it is a predictive model used for classification commonly (Jain & Srivastava, 2013). In Figure 2 an example of DT is given.

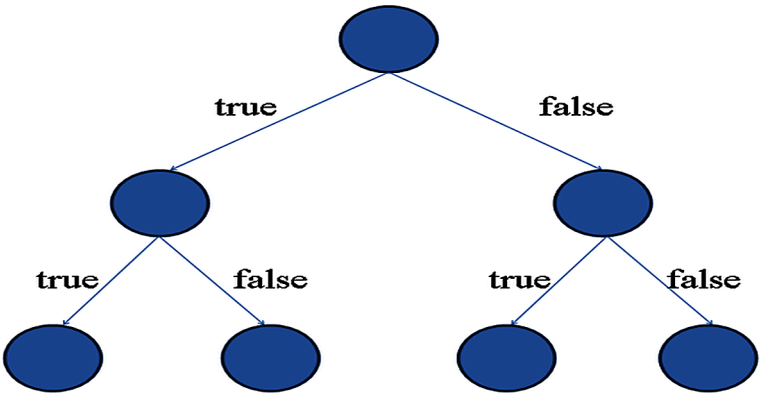
Genetic Algorithms approach is the effort to emulate natural evaluation into computer applications. The idea behind GAs is building a better solution by combining the good parts of other solutions just like nature does by combining the DNA of living beings (Jain & Srivastava, 2013).

Figure 1. ANN example



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. DT example



Regression and Correlation methods (such as Logistic Regression) evaluates the strength of a relationship where regression is a predictive method of future values by fitting the current available values into a curve, and correlation is a descriptive method used to examine the degree of similarity (Jiawei & Kamber, 2001).

Bayesian Network is a statistical multivariate model for a set of variables which is defined in terms of two components, a qualitative component, a directed acyclic graph (DAG), and a quantitative component, a conditional distribution of each variable in the graph(Jensen & Nielsen, 2007).

Support Vector Machines are manly used for classification. It is a type of supervised machine learning method. The method is presented with a set of labeled data instances and the SVM training algorithm aims to find a hyper plane separating the given dataset into a discrete predefined number of classes consistent with the training set (Mountrakis, Im, & Ogole, 2011).

Similarity Measures are used for measuring the similarities in big data. Nearest Neighbor Method, Manhattan distance, and Euclidean distance are the most known forms of similarity measures.

Fuzzy logic is the multivalued logic attempting to emulate human reasoning in the computer applications. In fuzzy logic, instead of using hard borders such as 0-1, white-black, soft computing techniques are employed.

Hybrid techniques combine fuzzy logic methods with other methodologies such as neural network, genetic algorithms, Bayesian reasoning, machine learning, etc.

MEDICAL DATA MINING

Contribution of the Data Mining to the Healthcare

Healthcare service can have huge costs. Food consumed, bed occupied and related services for lodging, surgery preparation laboratory tests, radiology tests, surgery, post-surgery care and post-surgery control laboratory tests... expenditures for the inpatients increase the healthcare cost in a considerable manner. Payers of the healthcare put strong pressure on the healthcare institutions to decrease the costs. By the way, the toughest thing is the quality of the service must increase in spite of the decreased cost not to decrease the attractiveness of the healthcare institution.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

USA spent 2 trillion dollars in 2008 for healthcare (which stands for 16.2% of gross domestic product) (AMA, 2010). Table 1 gives the top-ranked countries in healthcare expenditure (Speights, 2013).

As seen in Table 1, the expenditures are huge. These expenditures are not compatible with the life expectancy, USA is the first to spend but near last to have life expectancy whereas Switzerland is almost last to spend but first to have life expectancy.

American Medical Association's (AMA, 2010) proposal to reduce costs can be summarized as follows:

- Reduce the burden of preventable disease.
  - Reduction of the risk factors for disease;
  - Prevention of the onset of chronic illness;
  - Improvement of patient compliance with medications.
- Reduce nonclinical health system costs that do not contribute to patient care
- Make health care delivery more efficient.
  - Reduction of unnecessary use of services;
  - Increase in use of services with positive return on investment;
  - Increase in availability of information on the effectiveness of different treatments;
  - Improvement in management of chronic illness;
  - Reduction of medical errors.
- Promote value-based decision-making at all levels.

Achievement of all proposed solutions of AMA is directly dependent on the use of information and conversion of the information to knowledge.

Above, we mention that there is a pressure to decrease the costs, but at the same time the healthcare institutions have to increase the quality. Is this possible? The answer is "it depends". It depends on the extent that the managements of the healthcare institutions utilize the big data they have. There are some utilization techniques; one of them is data mining.

Although the discussion about what is data, what is information and what is knowledge took place long ago and these terms are clear in today's world, it will be useful to mention briefly in this chapter to avoid confusion. Data is the raw form and it has no meaning by itself. Wikipedia (2015) explains

Table 1. Countries with the highest healthcare expenditure in OECD

Rank	Country	Percentage in Gross National Product (%)	$ per Person Spent	Life Expectancy (Years)
1	USA	17.9	8,680	78.7
2	Netherlands	12	5,056	80.8
3	Germany	11.6	4,338	80,5
4	France	11.6	3,974	81,3
5	Switzerland	11.4	5,270	82.6
6	Canada	11.4	4,445	80.8
7	Denmark	11.1	4,464	79.3

Source: Speights, 2013.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

the relation between these three concepts in simple and understandable way. Difference between these three terms lies in the level of abstraction. Data is the first level, the raw and meaningless form. With interpreting, the data becomes information. Utilization of information brings the knowledge.

Returning back to our subject, it is said that almost all healthcare institutions use an information system. These systems collect and generate data. These data are not only about patient but also about medical devices, medical resources, their operating times, in short, every item related to healthcare. The healthcare data at hand are growing bigger and bigger as the time passes. The anonymous saying (it is everywhere but no sign about who is the owner) "Drowning in data, starving for information/knowledge" summarizes the situation. We need data mining to extract information and knowledge from these big data in healthcare, use this information and knowledge for decreasing the costs and increasing the quality.

Data mining help healthcare get (Hays, 2012):

- Question based answers,
- Anomaly based discovery,
- New Knowledge discovery,
- Informed decisions,
- Probability measures,
- Predictive modeling,
- Decision support,
- Improved health,
- Personalized medicine.

In the above items, it is clear that the profits of medical data mining are compatible with the proposed solutions of AMA given before. They are very tough to accomplish. All needs long time effort, discrete planning and powerful techniques.

In addition to Hay's list, Canlas (2009) added Evidence based medicine, Reduction of medical errors, Policy making in public health, Early diagnosis, Preventive medicine, Non-invasive diagnosis, Detection of adverse drug events (Canlas, 2009).

Other additional items to this list made by Desikan, Hsu, and Srivastava (2011) are:

- Fraud and abuse detection,
- Customer relationship management decisions of Healthcare organizations,
- Identification of effective treatments and best practices by physicians,
- More affordable healthcare services received by patients.

Association rules are the important aid of the data mining to the healthcare. It gives characteristics of certain information as a consequence or as an antecedent (Milovic & Milovic, 2012). This is very helpful for health professionals who are searching for the relations between diseases and lifestyles or demographics or between survival rates and treatment (Milovic & Milovic, 2012). The associations are used to help strengthen the claims regarding whether to engage or eliminate the rules in the knowledge model (Milovic & Milovic, 2012).

One of the most value adding contributions of data mining to the healthcare is in reimbursement field. Medicare, the national social insurance program administered by US government, declared that it

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

wouldn't reimburse the healthcare organization for medical errors in 2009. This would lead serious cuts in the healthcare organizations. Reduction of medical errors, by means of data mining, not only gives way to more qualified service, but also helps elimination of the deserved fund cuts.

In addition to elimination of fund cuts, data mining also enables organizations to have accurate claims to the reimbursement companies. By the use of the information and knowledge discovered, underestimation or over billing risks will definitely be lower.

Data Mining Techniques Used in Healthcare Informatics

The data mining techniques/methods and data mining tasks may be a point of confusion in the literature as it is mentioned before. To avoid misunderstanding, before starting the section, it is better to clarify that in this chapter, classification, clustering, rule association, description and visualization are called as data mining tasks. The techniques/methods used accomplishing these tasks such as Artificial Neural Networks, Decision Tree, Logistic Regression etc. will be called as data mining techniques/methods.

In healthcare, HCISs record huge amount of data every day. But quality of the data decreases because of the complex nature of healthcare. It is previously mentioned that data should be clean to apply successful data mining applications. There are rigorous data mining tools to handle noisy data. But anyway the healthcare institutions should take measures to capture and store complete, consistent and accurate data for better data mining results.

Healthcare is an endless area for the data mining. So it is hard to tell any technique, not used in it. In this section of the chapter, the most common techniques will be examined and explained briefly.

The most common task used in medical data mining is the classification (Chen, Fuller, Friedman, & Hersh, 2005).

One of the application areas is the detection of tumors in radiology. Radiologists have difficulties in detection of tumors. The neural networks with back-propagation and association rule mining is commonly used for tumor classification in mammograms (Mishra, Padhy, & Panigrahi, 2013). The data mining is effectively used in the diagnosis of lung abnormality that may be cancerous or benign (Mishra, Padhy, & Panigrahi, 2013).

For the detection of high risk breast cancer groups, it is proved possible to find statistically significant associations with breast cancer by deriving a decision tree and selecting the best leaf (Sundar, Latha, & Chandra, 2012).

Statistical neural networks are effectively used for breast cancer diagnosis by applying several neural network structures (Sarvestani, Safavi, Parandeh, & Salehi, 2010).

In the Sundar, Latha, and Chandra's study (2012), results showed that SVM has better results for diabetes and heart disease whereas decision tree is better technique for liver disorders and breast cancer.

In the literature review of Kolçe and Frasheri (2012) for the data mining techniques used in the diagnosis and prognosis of diseases, DTs, ANNs and Bayesian algorithms appeared to be the most well-performing algorithms for diagnosis. For prognosis ANNs, Bayesian algorithms, DTs and Fuzzy algorithms came out to be the most well-performing algorithms respectively. In the same study, literature showed that, in diagnosis of cancer diseases ANNs, in heart diseases Bayesian algorithms and in other diseases DTs, in prognosis of cancer diseases again ANNs, in heart diseases ANNs and Bayesian algorithms are the most well performing techniques.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Temporal Data Mining in Healthcare Informatics

Time is a critical dimension in healthcare knowledge extraction because hidden patterns do not exist throughout the whole time period of healthcare monitorization but only in some time intervals with recurrent and periodic nature (Henriques, Pina, & Antunes, 2013).

Temporal data mining (TDM) can be defined as the attempt to search for interesting correlations and patterns in temporal databases (Bruno & Garza, 2012). TDM tries to discover qualitative and quantitative patterns in temporal databases or in datasets of discrete-valued time series (Lin, Orgun, & Williams, 2002). It has two popular threads (Lin, Orgun, & Williams, 2002):

- In the purpose of finding fully or partially similar patterns in temporal databases(similarity)
- In the purpose of finding fully or partially periodic patterns in temporal databases(periodicity)

Temporal Abstraction is the approach of dealing with time-related data in medical research in which methods give the opportunity to make abstract definition of temporal data by extracting the relevant features (Takabayashi, Ho, Yokoi, Nguyen, Kawasaki, Le, Suziki, & Yokosuka, 2007). It is the transformation of time-stamped data into interval based representation. Temporal Abstraction has two phases:

1. First one is extracting time-stamped data,
2. Second is extracting temporal specific relationships between these extracted data (Takabayashi, Ho, Yokoi, Nguyen, Kawasaki, Le, Suziki, & Yokosuka, 2007).

Batal, Valizadegan, Cooper & Hauskrecht (2012), has divided the clinical variable as medical variables (that uses the abstraction as **on** medication and **of** medication) and lab variables having two types of abstractions, trend abstraction (decreasing, steady, increasing) and value abstraction (e.g. very low, low, high, etc.).

To describe the relations between pairs of state intervals, Allen's temporal logic (1984) is used in TDM not in medicine but in general. Table 2 shows Allen's 7 relations between the time intervals A and B.

One of the most attractive applications of TDM is the extraction of temporal rules from data (Laboratory for Biomedical Informatics, 2015). In temporal rules, the consequent is related to the antecedent of the rule with a kind of temporal relationship, unlike association rules; in addition, a temporal rule suggests a cause-effect association between the antecedent and the consequent of the rule (Laboratory for Biomedical Informatics, 2015).

For example, by the help of TDM, a temporal rule extracted may be, "in many diabetic patients, the presence of hyperglycemia overlaps with the absence of glycosuria" (Patel, Hsu, & Lee, 2008). Another example can be "Low systolic blood pressure AND Low diastolic blood pressure frequently occur before high heart rate frequency" (Concaro, Sacchi,Cerra, Fratino, & Bellazzi, 2011).

Distributed Data Mining in Healthcare Informatics

Healthcare organizations are (and should be) distributed to facilitate easy access of public. In most countries, there is a chain of healthcare that is; the patient visits the primary care health institutions first, if it can't solve the problem, then secondary and third step health institutions are visited respectively. This type of healthcare organization brings some problems for healthcare informatics such as standard-

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 2. Allen's temporal logic

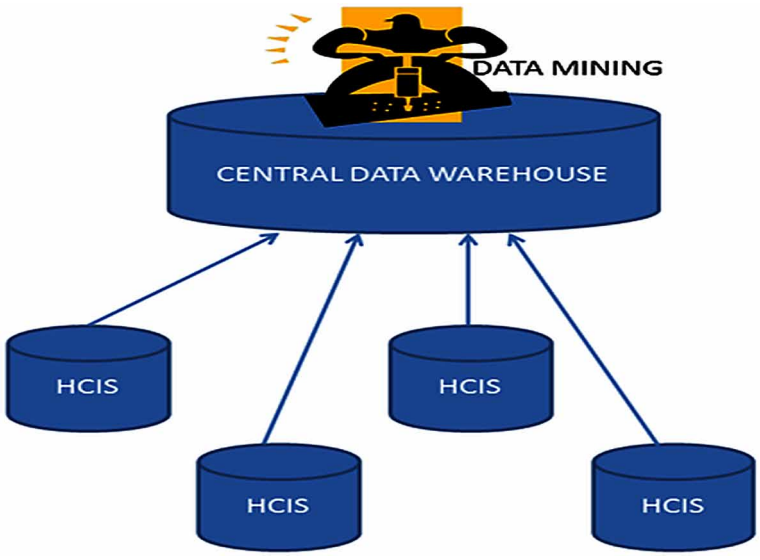
Relation	Notation	Pattern	Name	Inverse Name
Before	A<B	| A | | B |	A before B	B after A
Meets	A m B	| A | | B |	A meets B	B is met by A
Overlaps	A o B	| A | | B |	A overlaps B	B is overlapped by A
Finishes	A f B	| A | | B |	A finishes B	B is finished by A
During	A d B	| A | | B |	A is during B	B contains A
Starts	A s B	| A | | B |	A starts B	B is started by A
Equals	A = B	| A | | B |	A equals B	B equals A

ization of healthcare data, healthcare language problem (called as medical coding systems), electronic communication of the healthcare institutions, collection of patient data scattered to different healthcare institutions, etc. This issue is a challenge to healthcare data mining and will be mentioned in the following sections. There should be a distributed possibility to enable mining scattered healthcare databases and scattered health data of the same patient.

In Figure 3, we see an example of central data mining. All the data in the distributed HCIS databases are transferred to the center data warehouse first, and then they are processed.

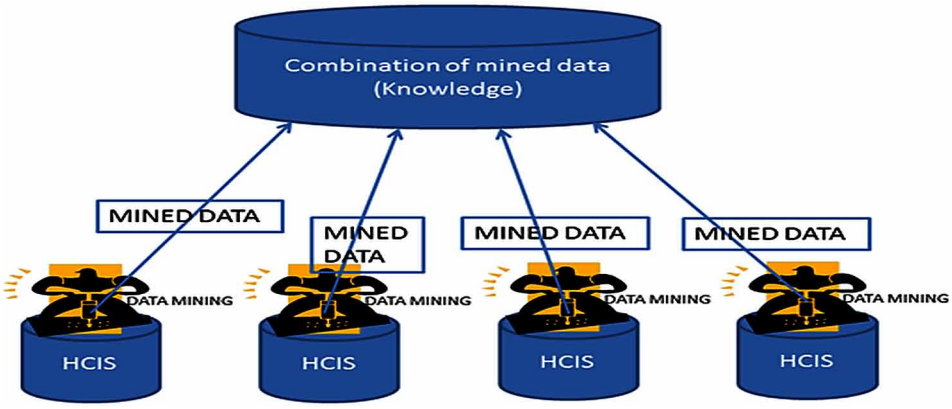
In Figure 4, we see an example of distributed data mining. In this scenario, all the data are processed in the HCIS database cite locally, and the processed results are transferred to the center.

Figure 3. Central data mining



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 4. Distributed data mining



DDM has two possibilities: To process and analyze the data in the distributed centers separately or transfer all data to a center and analyze all centrally. The latter option somehow requires huge resources for the healthcare. There are efforts to have a central database for the patient data but all these efforts have the architecture to have summary data in the center and link them to the original source to avoid the requirement of huge resources and budget. Mining in this central architecture will be nonsense. Then the first option seems more suitable for healthcare

There are efforts to solve DDM in healthcare using agents. The terms agent-based DDM, DDM using intelligent mobile agents, etc. are available in the literature. In such approaches, the idea is deploying a data mining agent to the site and getting analysis from the agent to the center. There is no standard way to accomplish such approaches and it is not easy to perform. There are some studies in the literature having the same idea but proposing different designs.

Challenges for the Use of Data Mining in Healthcare Informatics

In every Introduction to Medical Informatics lecture, the complexity and toughness of the medical environment is emphasized. This "complexity and toughness" is a challenge to every information technology tool and application as well as data mining. In this section of the chapter, the challenges specific to healthcare data mining will be examined.

Heterogeneous Sources and Forms of the Data

In the previous section, scattered nature of the healthcare institutions is mentioned. This scattered structure is a challenge to the healthcare data mining applications and distributed applications are needed to handle this challenge.

The wide range of medical domain also fuels the heterogeneity. There are many different departments of medical domain such as clinics, laboratories, radiology, nuclear medicine, etc. All these departments may have different databases or have a common database if they are the part of the same institution. In either way, they have different type and format of data to mine. For example radiology data have images; laboratory data have number type results whereas clinical data have texts. This "form heterogeneity" is also another challenge for healthcare data mining.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Data Heterogeneity may cause sampling, selection and spectrum bias (Kwiatkowska, Atkins, Ayas, & Ryan, 2007).

Disharmony between Medical and Computer Communities

This challenge is related to the "complexity and toughness" of the medical domain. It is not a specific healthcare data mining challenge but a challenge for all information technology applications. Medical users have tight schedule in dealing with care giving and are not volunteer to use any information technology that costs them additional time. Computer staff urges medical users to enter structured data to have them in computer processable form while medical users want to write down their needs as notes in papers because of the time consumed by dealing with computers.

In addition to this disharmony, the problems of accessibility in hospital exist such as: placing any hardware to sterile areas, entrance of technical staff to these areas for maintenance and fixing can be given as an example.

Legal and Ethical Issues

Privacy and security issues, their protection with the law are another item of challenge that healthcare data mining has to deal with. These issues will be examined in the next section thoroughly. Cios & Moore (2002) describe these challenges as follows:

- **Data Ownership:** Ownership of patient data is not clear. Whether the patients, the physicians, the healthcare institution or the insurance companies own the data collected from patients. The main regulation about the ownership of the data is the Health Insurance Accountability and Portability Act (HIPAA) Privacy Rule.
- **Fear of Lawsuits:** In medical communities, particularly in the Unites States, malpractice and other costly lawsuits is a matter of fear that constitutes a challenge to the application of healthcare data mining.
- **Privacy Issues:** Protecting patient privacy and doctor-patient confidentially constitutes another set of challenges to healthcare data mining. Administrators and researchers should pay utmost attention to privacy and security issues.

Non-Standard Data

This subject deserves being mentioned separately because of its being big challenge for healthcare data mining although it is mentioned in the heterogeneity of data part.

Physician's interpretations in clinical data are written in unstructured form which makes data mining difficult to perform (Milovic & Milovic, 2012). Even the high experienced specialists of the same area cannot agree on common terms that indicate the status of the patient. Different names are used to describe the same disease, different grammatical structures are used to explain the relations between medical entities (Milovic & Milovic, 2012). Although there are considerable efforts to constitute nomenclatures and classifications for structured medical data entry such as International Classification of Diseases (ICD), Systematized Nomenclature of Medicine (SNOMED), International Classification of

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Nursing Practices (ICNP), still there is enormous size of non-standard data in medical domain. For this reason, data mining researchers have to spend great efforts for text mining applications in healthcare.

Noisy Data

In the previous parts, the tight schedule of healthcare staff is mentioned. This tightness brings many handicaps. Missing, corrupted, inconsistent data are some outcomes. In the time of care giving, the user does not think or care about the usefulness of the data he is entering and he miswrites (if it is obligatory field) or leave it blank. This missing, corrupted, inconsistent data is called as "noisy" in short. Noisy data is a big challenge for data mining. Surely there are data cleaning techniques in data mining to handle noisy data but it causes a bias anyway no matter how well it is handled.

Low Quality of Healthcare Data

In the past, HCISs are used to be designed for financial/billing purposes. This leads to low quality of patient data. Additionally, users' unwillingness to use HCIS contributes to low quality patient data. Unavailability of mobile HCIS usage is another source of low quality data. Especially bed site visits for inpatients, surgery side entries and emergency service operations need mobile data entry to HCIS. If there is no such opportunity, offline entry after a time period elapsed can cause incomplete, inconsistent or missing data in short noisy data.

Domain Participation

Healthcare data mining has different perspectives when compared to data mining in other fields. In the previous section "complexity and toughness" of the medical field is emphasized. This "complexity and toughness" needs domain expertise to perform successful data mining applications. To have both medical and data mining expertise is almost impossible so cooperation and team work is needed for healthcare data mining. This can be possible by either having a domain expert in the research team or convincing medical staff for cooperation.

Complexity of Data Mining Methods

Because each data mining algorithm has its own theoretical design, they require user parameters and end users usually do not have sufficient information about the parameters and their selection (Yoo, Alafaireet, Marinov, Pena-Hernandez, Gopidi, Chang, & Hua, 2012). When it is taken into consideration that data mining results are very sensitive to the parameter, it is a big problem for the success of the data mining task.

Dynamism of the Medical Domain

With the help of the technology, online scientific databases and increasing research funds, medicine is developing rapidly. New devices capturing and storing new forms of healthcare data are invented every day or the current devices are improving by additional facilities. New healthcare diagnosis and prognosis techniques are coming out. In this situation, healthcare data mining becomes a shooter to hit a moving target (Anne, 2011).

Privacy and Security of Patients in Healthcare Data Mining

Privacy and security of patient data became critical with the rapid development of electronic storage of data and HCISs. With the help of electronic facilities, the users get the possibility of accessing and storing vast amounts of data which they never had the ability when they were in paper form. As the data electronically stored in HCIS databases and the size increases, it whets many organizations' appetite. They want to mine and use them for different purposes, legal or illegal. To avoid misusage and confusion, it will be better for readers to give brief descriptions about what is intended with patient privacy and security.

Patient privacy refers to any medical data (medical condition, test result, payment information, etc.) in any form (paper, electronic, etc.) that belongs to a patient. The meaning is about what is protected and who will be permitted to use this information (Upstate Medical University, 2011). The Office for Civil Rights, a department of the United States Department of Health and Human Services, created the Health Insurance Portability and Accountability Act (HIPAA) in 1996 and it is updated regularly. HIPAA has privacy rule for patient privacy. This rule creates a national standard for US to protect medical records of patients. HIPAA privacy rule applies to all forms of patients' protected health information (PHI), whether electronic, written or oral (Center of Medicare & Medicaid Services, 2007).

Data miners should be well aware of what is patient privacy and show utmost effort to comply with the regulations arranging the issue. Otherwise they can harm patients. Data miners can also be subjected to penalties of violating patient privacy.

Security risks are available for all information systems and databases, medical research can add additional risks (Berman, 2002). To provide patient privacy, a privacy review board or institution review board is required to supervise every data mining project in the healthcare institutions (Cooper & Collman, 2005). In the universities, there exists an ethical review board to oversight the ethical issues of any candidate research project. Such a board should be constituted for privacy oversight of the researches related to the patient data.

To provide privacy, three approaches appeared to be common for using personal data in research and secondary analysis of organizations (Lowrance, 2002):

- Use of personal data only with the owner's consent,
- Use of personal data without explicit consent of the owner only in a public interest,
- Making the data anonymous before using.

In many countries, there are laws and regulations against the violation of privacy that apply serious sanctions up to loss of license. Bergman (2002) states that, "Researchers have no automatic right to review patient data. Besides developing strategies for minimizing patient risk, as described herein, investigators should take simple steps to characterize their compliance with human subject's requirements".

Security refers to safeguarding the patient privacy. The meaning is how the information will be protected (Upstate Medical University, 2011). Again HIPAA has a rule for security of the patient data which is called as HIPAA Security Rule.

Healthcare data miners should employ several important security practices such as (Cooper & Collman, 2005):

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

- An inclusion of a description of steps to minimize patient risks in the methods sections of research proposals and publication submissions
- For each session and query, good access control and authorization should be used.
- The removal of common identifiers (such as names, addresses) of the data subjects if possible.
- Institution of robust audit practices.
- Training for all principle investigators to reinforce their responsibilities.
- Applications of sanctions for violations of policy and/or procedures.
- Tracking the breaches and sanctions trends over time and usage of these trends in the process of security awareness and training.

Healthcare Informatics Fields of Data Mining

Medical domain is so huge and complex so application of fields of data mining is not an easy task to list. To give an idea about the contribution of data mining to the healthcare, the fundamental fields of data mining applications will be examined in this section.

Hospital Infection Control

Literature says nosocomial infections effect two millions of patients in the USA in each year in 2001 (Gaynes, Richards, Edwards, Emori, Horan, Alonso-Echanove, Fridkin, Peavy, & Tolson, 2001). Association rules can be drawn from culture and patient data obtained from the laboratory database and infection committee can review these rules periodically (Obenshain, 2004).

Standardized Reporting

Hospitals report many incidents and epidemic diseases to the government. Cluster and association analyses can show how risk factors are reported with the use of International Classification of Diseases and by reconstructing patient profiles (Obenshain, 2004).

Identifying High Risk Patients

Data mining applications can report patients that have high risks. This can aid caregivers to take some precautions and save lives (Obenshain, 2004).

Outlier Detection

Outlier Detection, can be also named as Anomaly detection, provides opportunity for identifying rare events in large datasets (Jacob & Ramani, 2012). Detection of extreme observations may prevent incorrect data and human error while at the same time presence of Outliers could lead to novel insights in clinical knowledge discovery (Jacob & Ramani, 2012).

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Fraud and Abuse Detection

Healthcare is prone to fraud and abuse because of the huge amount of money it creates. Both healthcare providers and clients can commit fraud. In healthcare, the most common forms of provider fraud include (Patel, Hsu, & Lee, 2008):

- Billing for services not furnished,
- Misrepresenting the diagnosis to justify payment,
- Soliciting, offering or receiving a kickback,
- Unbundling or "exploding" charges,
- Falsifying certificates of medical necessity, plans of treatment and medical records to justify payment,
- Billing for a service not furnished as billed.

Client abuses can be card-sharing, acting in collusion with a provider for kickbacks, etc. (Patel, Hsu, & Lee, 2008).

Especially medical insurance companies employ data mining applications to detect whether healthcare claims are potentially fraudulent or erroneous, to reduce their losses related to fraud and abuse.

Treatment Effectiveness

Data mining can help about which courses of action prove effective by comparing and contrasting causes, symptoms and courses of treatments (Koh & Tan, 2011). Data mining also helps evolve standardized treatments for specific diseases (Koh & Tan, 2011). Also applications to facilitate early diagnosis, non-invasive diagnosis, determination of adverse drug effects can be made.

Healthcare Management

This section is examined thoroughly in upcoming sections.

Customer Relationship Management (CRM)

In the previous parts it is mentioned that healthcare institutions have to increase the quality. This increase comprises increasing the customer satisfaction as well as the services given. The customers could be patients, pharmacists, physicians or clinics. Detection of usage and purchase patterns and the eventual satisfaction they result in can be used to improve overall customer satisfaction, in many cases, purchasing and usage behavior prediction aid in designing proactive initiatives to reduce the costs and increase the customer satisfaction (Desikan, Hsu, & Srivastava, 2011).

Data mining applications can help healthcare to determine the preferences, usage patterns, current and future needs of individuals, whether a patient is likely to comply with prescribed treatment or whether preventive care is likely to produce a significant reduction in future utilization (Koh & Tan, 2011).

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Reduction of Medical Errors

Medical errors are an important issue in healthcare. According to the report of Institute of Medicine (IOM) at least 44,000, may be as many as 98,000 patents die in the hospitals each year because of medical errors (Duan, Street, & Xu, 2011). Another study states that 195,000 people in the U.S. died due to potentially preventable, in-hospital medical errors out of 37 million patient records (Amin, Agarwal, & Beg, 2013). In addition to the loss of human lives, medical errors have a huge cost of both compensation and loss of reputation. It is seen that medical errors are harmful and costly. This is a giant problem to tackle with. One of the most important application fields of data mining is medical errors. By means of decision support facility, it can help reduce medical errors.

Data Mining for Healthcare Management

Healthcare management is a separate area of science in itself because of its importance and complexity. There are departments in universities about this issue, Master of Science and Ph.D. programs are available on this topic. Naturally there are job positions in the healthcare institutions as "Healthcare Manager". All the educations, researches, positions in healthcare management have one big goal: Managing the healthcare efficiently. Tasks of the healthcare managers can be described as optimization of clinical processes in medical and administrative quality terms as well as the cost/benefit relation (Milovic & Milovic, 2012).

Healthcare managers make very critical decisions about amount of supplies, number of employees, drug needs, hardware and software management, vacant beds required, maintenance needs,etc. These decisions must be on time, true and well supported. To do this, like all management branches, healthcare management needs the effective use of informatics maybe more than any other management field. They need approximate and healthy predictions.

Data mining applications are useful for better identification of and tracking chronic disease states and high-risk patients, for designing appropriate interventions and reducing the number of hospital admissions; claims would help healthcare management (Koh & Tan, 2011). By means of data mining, comparisons across healthcare groups of things such as practice patterns, resource utilization, length of stay, and costs of different hospitals be possible (Johnson, 2001), which are valuable information for the healthcare management.

Data mining can help healthcare managers to (Milovic & Milovic, 2012):

- Discover new hypothesis for indexes of quality for data, standards, plans and treatments;
- Check if the given quality for data, standards, plans and treatments indexes are still valid;
- Improve, strengthen and adjust the quality indexes for data, standards, plans and treatments;

Resource allocation is another field that data mining can help healthcare management. By detecting high risk areas, it should also predict the requirement and usage of various resources accordingly (Sharma & Speights, 2014).

One of the major problems in healthcare is stated as measuring the flow of patients through hospitals along with other healthcare facilities that are being used (Sharma & Mansotra, 2014). If healthcare managers can predict the length of stay of inpatients correctly, planning and management of hospital resources can be easier (Sharma & Mansotra, 2014).

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Healthcare management is not limited to the management of a healthcare institution. It also encompass the public health services given, directed, supervised by governmental organizations. They need multiple sourced data mining applications to manage the public health. In this point, DDM applications are needed for this kind of healthcare management. These applications help managers manage some critical risks such as disease outbreak, epidemic diseases, some trends such as cost of healthcare, mortality rates, birth rates, appearance frequencies of the diseases, their sub information about the cities, ages, etc.

These examples about how data mining may help healthcare management can easily be augmented. The ability of data mining to associate rules and uncover hidden relations provides invaluable support to healthcare management both in organization level and governmental level. Key questions of the process of healthcare quality management are quality of data, standards, plans and treatments all of which can be acquired by the utilization of available data at hand.

FUTURE RESEARCH DIRECTIONS

Healthcare domain is dynamic and we named this issue as a challenge to the data mining. It is also a forcing motivation to the data mining applications in healthcare. This dynamism gives way to new horizons and more data mining applications will be employed to discover new patterns and associations.

In the view of the subjects examined in this chapter, future data mining studies seem to take place, not limited to but in considerable weight, in distributed data mining applications. Nowadays, hospital chains are emerging. All over a country or city, there exist a number of hospitals belonging to an organization. They have distributed solutions as well as central ones. Governmental prediction and management issues are another source of need for DDM applications. In short, needs for DDM applications are growing which is making the DDM a future progress area candidate.

Text mining algorithms are another candidate area of progress. Although the idea of HCIS force users to structured data entry, healthcare is not ready for a fully structured data entry and there are doubts if it can be provided fully. Radiology reports, surgery reports, Nuclear Medicine reports, anamnesis forms and more examples about healthcare are in fully text data form. For mining these data, text mining methodologies will get great efforts most probably.

The low quality of the medical data is mentioned throughout the chapter. In academic literature, these kinds of data are called as dirty and noisy. Although there are rigorous data mining algorithms available that deal with these problems, and there is a preprocessing phase of data mining, healthcare data deserves more research and development in this issue because of its bad reputation and nature.

While developing and improving data mining, patient privacy and security should be the first priority of concern. Health data is the most private data of a person. There may be so sensitive information that can make a person ashamed and upset. There may be some details even the person himself wants to forget. Because of the sensitivity of the data, there should be considerable future work for protecting the security and privacy of EPHI both by private sector and governmental bodies.

CONCLUSION

In the era of information and technology, data is too valuable. Every possibility that lit a light about what future can look like is very welcomed by the organizations. When it comes to healthcare, this importance

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

increases exponentially, because human life is the main subject of the sector. By the help of the improvements in science, the deadly diseases are so trivial now that we do not fear anymore.

Data and its processing is a catalyzer to the improvement in all areas of science. In this era, information and knowledge is the power. Data is all over, the magic is to convert it to information and knowledge, to get the power.

Complexity and toughness of the medical domain makes use of information technologies mandatory. Its scattered nature, text loaded data forms, having the subject of human life and the pressure to decrease costs push healthcare managers to use data effectively and convert it to the information and knowledge. Accomplishment of these tasks is possible with the effective use of data mining.

ACKNOWLEDGMENT

Part of this study was presented at the 2nd International Conference on e-Health and Telemedicine ICEHTM 2014, on 22-24 May 2014, Istanbul/Turkey.

Chapter 4
Population Health Management and the Science of Individuality

Anastasius Moumtzoglou

Abraham Pouliakis
National and Kapodistrian University of Athens, Greece

ABSTRACT

This article espouses that population health management (PHM) has been a discipline which studies and facilitates care delivery across a group of individuals or the general population. In the context of population health management, the life science industry has had no motivation to design drugs or devices that are only effective for a distinct segment of the population. The major outgrowth of the science of individuality, as well as the rising 'wiki medicine', fully recognizes the uniqueness of the individual. Cloud computing, Big Data and M-Health technologies offer the resources to deal with the shortcomings of the population health management approach, as they facilitate the propagation of the science of individuality.

INTRODUCTION

Public health' connotes a relatively narrow field with activities carried out by agencies granted with official functions. 'Population health' a term with broader content, is related to a field relevant to the study of several important factors for health. As a result, it involves many terms, such as outcomes, disparities, determinants, and risk factors (Kindig, 2007).

Notwithstanding the term 'population health' combines the concepts of both health and population, every term has an essential meaning of its own. The population is related to a group of persons being organized into numerous different units of analysis. Similarly, the term health was defined negatively, i.e., the absence of disease. Nowadays, the modern understanding stresses the positive aspects as well, and health is considered to be related to all life issues. Summarizing, today it is debated whether population health and public health are different or identical. Nevertheless, population health is defined as health outcomes and their distribution in a population (Kindig, 2007).

Population health management (PHM) has been defined as 'the technical field of endeavor which utilizes a variety of individual, organizational and cultural interventions to help improve the morbidity patterns (i.e., the illness and injury burden) and the health care use behavior of defined populations (Hillman, 2002). It is differentiated from disease management because it includes (Howe & Spence, 2004):

- More chronic conditions and diseases.
- Uses a single point of contact and coordination and predictive modeling across multiple clinical conditions.

Moreover, PHM is considered a broader term than disease management, as it includes (Coughlin, Pope, & Leedle(Jr), 2006):

- Intensive care management for individuals at the highest level of risk.
- Personal health management for those at lower levels of predicted health risk.

At the provider level, there are three highlighted components (Care Continuum Alliance, 2012):

- The leadership and the central care delivery role of the primary care physician.
- The critical importance of patient activation.
- The capacity expansion of care coordination.

In this context, to successfully achieve all of these requirements, an organization should provide proactive, preventive and chronic care services to all managed patients. Additionally, this should take place both during encounters of patients with the healthcare system and in between. Therefore, providers should maintain regular contact with their patients and support them in the management of their health. Additionally, providers must manage patients at high risk, to prevent the deterioration of their health and avoid the development of complications. Finally, evidence-based protocols for the diagnosis and treatment of patients, consistently and cost-effectively, are also required if for a provider-based PHM approach is followed.

The Federal Agency for Healthcare Research and Quality (AHRQ) developed the concept of 'practice-based population health' (PBPH) and defined it as "an approach to care that uses information on a group of patients within a primary care practice or group of practices to improve the care and clinical outcomes of patients within that practice.' (Cusack, Knudson, Kronstadt, Singer, & Brown, 2010).

Obviously, the implementation of health IT is among the essential components and requirements for planning and implementing PHM. The adoption of Electronic Health Records is just the first step toward the creation of the requisite infrastructure. However, a wide range of other IT applications to automate PHM, track results and engage the patients in their health care is required. Additionally, IT systems should repeatedly be evaluated because of rapid technological changes, new government regulations and new approaches to patient management (Moumtzoglou & Pouliakis, 2015).

AHRQ recommends health IT tools for the stratification and monitoring of populations, as follows:

- Target patients being in greatest need of health services by stratifying the patients and narrowing subpopulations.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

- Make patient-related data actionable by generating alerts to the patients.
- Make data actionable by generating alerts towards health providers, about patient care needs.

Conclusively, population health management is designed around the collective. However, nowadays, to truly drive high-quality care at lower cost, these endeavors must work for the individual, align with their personal goals and intermix with their reality. In this context, the objective of the article is twofold. First, it will deal with the greatest misconception about population health, that is, population health is not about the population. Ultimately, it is about the individual. Secondly, it will show how to connect the dots from the science of individuality to improving health on a massive scale - a bottom-up approach that uses the technologies of cloud computing, Big Data and M-Health.

THE SCIENCE OF INDIVIDUALITY

Unquestionably, the population health management concept requires extensive data, which currently flows from the beneficiaries towards data centers. Such data include a multitude of health and well-being information collected manually or automatically. Moreover, algorithms are required to process such information and alert when health-related actions should be taken. On the other hand, nowadays, there are technologies which provide both the data storage and processing capacity while the mobile device (especially the mobile phone), as well as inter-connectable devices (health gadgets), may serve as data acquisitions points on the individual level.

However, there is a major deficiency of contemporary medicine which is reflected by the use of experts to make recommendations or guidelines for a large proportion of decisions for which no or minimal data exists. These guidelines are published in major specialty journals which have a pronounced impact, as they are believed to represent the standard of care. Overall, there is too much literature which is evidenced by the statistic that only 0.5 percent of the 38 million published papers are cited more than two hundred times, and half were never cited. Moreover, when pooled analyses of prior studies are published, many relevant papers are excluded (Topol, 2012).

In fact, this should be considered ‘eminence-based medicine.’ (Topol, 2012).

Better studies might be part of the solution. However, as we can accrue more meaningful data and information for individuals, the hope is that we can override our dependence on such recommendations. We need evidence which is built not on populations but individuals.

Fortunately, our capacity to get just that information is rapidly arising. An era which is characterized by the right drug and dose, at the right cost and timing has begun (Topol, 2012). Medicine for the common good is not sufficient. A rebooted life science, instead of a mass-population-directed strategy, would leverage the science of individuality, getting the relevant digital readout from an individual to shape a therapy. We now, for the first time, have the devices to, promote a level of prescription precision we have never seen before (Topol, 2012).

The era of individualized medicine ultimately promises to do away with terms like ‘cryptogenic’ and ‘essential,’ fully recognizing the uniqueness of the individual who needs to be seen and treated with utter respect for his or her individuality. It will not be long until digitizing a person unlocks the cause for what is wrong, creating valuable knowledge that can save a life or markedly improve the quality of life. That is a major outgrowth of the science of individuality.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

In this context, the entire classification system of medical conditions and diagnoses is about to be rewritten. Instead of our current reductionist model for which individuals are unwisely assigned to such categories as one of two types of diabetes or cancer of a particular organ, the science of individuality will promote a new molecular taxonomy that invokes the main biologic basis, regarding genes or pathways.

THE TECHNOLOGIES OF INDIVIDUALITY

The data for how many patients search health websites are staggering (Topol, 2012). Although this trend represents an outlier in many respects and an extreme of patient activism, these cases also demonstrate that the current level of being informed is not adequate. Furthermore, they capture a sense of inspiration and independence, the hunt for innovation, and the primacy of the individual. In essence, they are the precursors for the next phase of medicine, in which powerful digital tools will provide data that was heretofore unavailable.

Whether it is sequencing the genome of cancer tissue to determine a specific mutation or being able to anticipate the likelihood of a fatal disease before it has ever manifested, our capabilities greatly expand based on the following technologies.

Cloud Technologies

Cloud computing has emerged rapidly as an exciting new paradigm that offers a challenging model of computing and services. Leveraging cloud computing technology, bioinformatics tools, can be made available as services to anyone, anywhere, and through any device. The use of large bio-datasets, the highly demanding algorithms, and the hardware for sudden computational resources makes large-scale bio-data analysis an attractive test case for cloud computing" (Hsu, Lin, Ouyang, & Guo, 2013). Cloud computing is a concept related to numerous computers that use Internet infrastructure to communicate producing shared resources such as software, hardware, and storage. Nowadays, cloud computing is not widely used for the various tasks related to medicine; however, there are numerous fields that it could be employed; thus, cloud computing is an emerging field having the potential to change the everyday practice of medicine.

Cloud systems are categorized into three different groups according to the offered service type:

- Infrastructure as a Service (IaaS), which means offering hardware, storage and physical devices over the Internet.
- Software as a Service (SaaS), which means offering software and hosted applications over the Internet.
- Platform as a Service (PaaS), which means offering the capability to deploy applications created using programming languages, libraries, services, and tools owned and supported by the provider.

For cloud computing, the user/consumer does not manage or control the underlying cloud infrastructure but has control over the deployed applications as well as the offered services (i.e. storage, networking and processing power). Clouds, according to their hosting, may be public, private, hybrid, and community, especially adapted to the medical field:

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

- Public Clouds are for general use. The cloud owners are responsible for information hosting; public clouds are rarely utilized in the area of medicine and case of use, data are encrypted.
- Private Clouds are only for in-hospital use and are dealing with confidential patient data. The owners or the hospital premises are responsible for information hosting.
- Hybrid Clouds are hosting non-confidential information on public Clouds and confidential information in a private domain.
- Community Clouds are hosting information among members of the same community. Laboratories and hospitals can create a community Cloud while sharing the same infrastructure and software.

There are three fundamental aspects of Cloud-based services (Soman, 2011):

Browser-Based Applications

Browser-based applications are different from native applications, which run on personal computers. Native Applications are those that run entirely on the computer on which they are invoked. A native application uses only the computing resources and storage of the computer which was used to launch the application. Conversely, browser-based applications are applications that run from within Internet Browsers; however, the consumed resources are located on one or more servers. They are conceptually similar to Client Server applications, which require a powerful central computer, but there are two distinct characteristics:

- Browser-based applications can only be invoked from inside a standard browser.
- The Client and the Server are not (necessarily) a part of a Local Area Network or a remote (however accessible) network.

Optimal Utilization of Server Resources

Cloud Service Providers see variable levels of utilization of their services. This variability has two components. Firstly, the number of concurrent users accessing the service is different at different times. Secondly, the processing and storage of resources required by any particular user are never constant.

Technologies for scaling and resource partitioning are at the heart of Cloud Services because without these technologies, the Cloud business model would not be feasible. Load Balancing denotes a mechanism for balanced or even distribution of load across multiple physical resources, such as servers, storage devices or communication links.

A server load balancer is responsible for balancing the load of incoming requests among an array of physical servers. Virtualization allows a single physical resource to be used like many resources or multiple physical resources to be used as a single resource. There are several types of virtualization, depending on the nature of the physical resource that is 'virtualized.' In this context, server virtualization implies that a single physical server is converted into several logical servers, storage virtualization a single storage device that is converted into multiple logical storage devices, or vice-versa, and network virtualization allows the user to split a single communication link into separate channels assigned to different processes.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Finally, multi-tenancy is the principal of architecting applications such that a single instance of the application running on the server is visible as separate cases of the same application for each of the clients connected to it.

Data Centers

The data center is where the user's data is processed and stored. Some of the design considerations for data centers are as below (Moumtzoglou, 2014; Soman, 2011):

- Data centers are typically located in places where the risk of natural disasters and human-made disasters.
- Buildings used to house data centers typically do not accommodate other offices and businesses. The area around the data center is well-lit and easy to monitor. It is easy to control access to the premises where the data center is housed.
- Data centers have areas with raised flooring.
- Data centers have to air-condition.
- Data centers have different levels of physical security.
- Data centers have assured stable electric supply.
- Data centers have state of the art fire prevention and fire protection systems.

From a networking perspective (Moumtzoglou, 2014; Soman, 2011):

- Data centers have high-bandwidth data pipes with various levels of redundancy.
- Data centers have all the elements installed that are required to run Intranet services continually.
- Data centers achieve the most advanced network security tools including intrusion detection, firewalls, antivirus systems, and systems that guard against spamming, Denial of Service Attacks, and all known malware.

Lastly (Moumtzoglou, 2014; Soman, 2011):

- Data centers employ qualified system administrators.
- Data centers support systems and processes in place to keep smooth functioning 24x7 and throughout the year.
- Data centers have a disaster recovery plan.

CLOUD-BASED SYSTEMS FOR HEALTHCARE IT

The healthcare industry is different from most other industries. It is very delicate, and there are several entities that have to deal with healthcare data. That includes regulatory bodies, care providers, hospital administration staff, payers, labs, and patients themselves. The key differences between the healthcare industry and other industries, in which Cloud-based systems have been used, include (Soman, 2011):

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

- **High-Risk Industry:** The healthcare industry impacts individuals to a greater extent than any other industry.
- **Highly Regulated:** Numerous regulations govern the provision of healthcare.
- **Multiple Stakeholders:** There is a large number of interested parties in the healthcare industry. That includes the patients, the physicians, the nurse practitioners, the hospitals/clinics, their administrative staff members, the payers/ insurance companies, employers, pharmaceutical companies, technology vendors, device manufacturers, government bodies, and so on.
- **Slow Pace of Adoption:** The healthcare industry has traditionally been slow to adopt IT, especially the smaller clinics and individual physician practices.
- **Small and Large Providers:** The small providers typically do not have the resources to evaluate or experiment with advanced IT systems. On the other hand, there are several large multi-specialty hospitals whose IT requirements are distinctly different from those of office practitioners.
- **Long-Term Relationships:** Changing IT systems often is not easy, and there is, therefore, an assumption that any product adopted would be advantageous to use for several years. This hypothesis does not follow the need for both the IT systems and individuals to adapt.

Given all of these differences, it is not clear that Cloud-based systems would work as well in the healthcare industry as they have in other industry verticals unless Cloud-based healthcare solutions address these specific attributes of the industry.

From a clinical perspective, an EMR (electronic medical record) leads to improvement in the quality of care provided to patients. Cloud-based EMRs are, therefore, a key component of any Cloud-based healthcare offering. An EMR is a computer-based documentation of a patient's medical history including illnesses, examinations, reports, diagnosis and the care administered. Electronic Medical Records are created and maintained by care providers when a patient avails service from the vendor.

The following key pieces of medical information are a part of virtually all EMR systems (Soman, 2011):

- Patient Identification information
- Information about Patient Allergies and Habits
- Immunization Record
- Medical History
- Benefits of EMR

There are significant advantages to using EMR when compared to the traditional paper-based files and charts (Soman, 2011):

- Storage
- Usage in Emergency
- Duplication and Transportation costs
- Uniformity
- Risks
- Audit/Reporting
- Integration
- Efficiency

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Cloud-based EMR systems have all the features and capabilities of in-house EMR systems. Many Cloud-based systems have rich and especially easy-to-use interfaces along with the ability to customize the fields in the records. Cloud-based EMR systems make it even easier to access or transfer medical information to any point, for example, to the point of care in an emergency (Witzke & Specht, 2017). Cloud-based EMR systems also make it simpler to provide access to the records of the patient via patient portals.

A Cloud-based medical practice management application enables a healthcare provider to manage and streamline business management tasks and workflows. A 'workflow' is a series of steps followed to achieve a specific purpose. Provision of healthcare involves the implementation of various workflows within the practice, mirroring the movement of the patient within the system. Medical Practice Management relates to the operation of various workflows within the practice while Medical Practice Management Systems are the key to ensuring that all transactions within the practice run smoothly and efficiently.

Cloud-based Practice Management software supports features such as (Soman, 2011):

- Appointment scheduling of patients
- Eligibility and authorization
- Physician scheduling, scheduling surgery or other procedures for patients
- Tracking patient referrals
- Patient account management
- Managing patients as they move from admission to discharge including information on hospital rounds
- Managing patient recall
- Claims submission and processing, automated follow-ups, collections and remittance advice
- Managing the schedules of employees of the clinic
- Managing the inventory of medical supplies and office materials
- Inter and Intra clinic/location communication
- HIPAA compliance
- Patient portal

In a Cloud-based Practice Management solution, the software is accessed through a browser over the Internet, which is why continuous Internet availability is crucial. Cloud-based Practice Management solutions can be customized, although admittedly to a limited extent when compared to on-site solutions. However, Cloud-based solutions can effectively compete with the on-site solutions regarding functionality and features.

A patient portal is essentially a website on which patients can log in and access most portions of their medical records. In a patient portal, the information is presented in a manner which makes it easy for the patient to understand the nature of his conditions and his treatment. Most Patient Portals also provide some level of interactivity with the healthcare provider.

Patient Portals represent one of the key advantages of Cloud-based systems over in-house systems. A Patient Portal interfaces with sensitive, private information of individuals, which should be securely available and web-accessible at all times. It is, therefore, best if the responsibility of managing the patient portal is assigned to an entity that has the expertize, the infrastructure, the resources, and experience to develop and achieve high availability, high-security information systems. Most clinics or physician

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

practices do not have this capability, nor is it practically feasible to invest in infrastructure and human resources to undertake such capability. It is, therefore, best to opt for a Patient Portal that is Cloud-based.

Many Practice Management systems and EMR systems include ePrescription capability as a part of their overall functionality. An ePrescription system is a computerized system in which the prescription is either entered by the physician/nurse practitioner or generated by information available to the system. The prescription can be automatically communicated to pharmacies associated with the healthcare provider. Further, ePrescription systems also have inbuilt rules/databases about drug-drug allergies and appropriateness of each drug in the context of various health conditions.

An ePrescription system brings several benefits (Soman, 2011):

- It eliminates the possibility of a prescription being incorrectly interpreted due to poor handwriting, thereby reducing medical errors.
- It reduces the occurrence of drug-drug allergies and the possibility of the inappropriate drug being administered in the view of the patients' comprehensive medical history.
- It makes ordering refills easier since prior prescriptions can be easily accessed electronically.
- ePrescriptions are also found to increase compliance by patients merely because they are more convenient

A Cloud-based ePrescription system is likely to be much more highly available and secure and thus be able to communicate prescriptions to pharmacies with a higher reliability than an in-house system. Secondly, a Cloud-based system is more likely to cooperate with more and more pharmacy chains over time, enhancing the number of pharmacies the ePrescriptions can be sent to.

Even if a clinic does not use Cloud-based systems for practice management, it is a brilliant idea to consider Cloud-based systems for data backup and secondary storage.

The way most Cloud-based backup systems work is as follows (Soman, 2011).

There is software installed on one or more of the computers within the facility (called the backup client) connected to the primary storage. The backup client tracks the changes to the data stored on the primary storage at regular intervals and communicates the changes to the Cloud-based storage space of the service provider.

The backup client encrypts all information before it is transmitted to Cloud storage. Secondly, bandwidth requirements are significantly reduced because the client only communicates the changes that have occurred in the data since the last backup run, rather than transmitting all the details again.

A notable special case of a data backup system, due to the large sizes of medical images, is the Picture Archival and Communication System ('PACS'). In the process of administering health care, various images, graphs, pictures, and scans are generated. That includes images from X-Rays, ultrasound machines, MRI and CT scans, endoscopy, mammograms, computed radiography, etc. Even scanned images of paper documents are often required to be stored when legacy paper-based data is digitized via scanning. To ensure uniformity, a standard format used to store and communicate pictorial information has been defined—the Digital Imaging and Communications in Medicine ('DICOM').

Cloud-based laboratory solutions are available for various functions such as microbiology, histology and cytology processes, Synoptic/Antibiogram reporting, Image/Document capture, Inventory Management, Voice recording, Blood bank. They have all the functionality of on-site solutions.

Cloud-based Radiology systems are similar to PACS systems. These systems support basic Radiology workflows where physicians can register examination requests for existing or new patients, and select ap-

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

propriate billing rules. It is also possible to interface laboratory devices directly to Cloud-based systems. That means that the readings from instruments or captured images are directly uploaded to the cloud.

Overall, cloud-based healthcare IT systems are easier to get started; distinctly cost-effective when compared to on-site solutions; more convenient, especially for smaller clinics and private physician practices, while allowing doctors to collaborate on any medical data easily, and work on the system from anywhere, including from home.

Cloud computing is a novelty that rapidly showed tremendous opportunities for application in medicine and health care improvement (Archondakis, Pouliakis, Margari, & Karakitsos, 2014; Eugster, Schmid, Binder, & Schmidberger, 2013; Glaser, 2011; Kuo, 2011; Lupse, Vida, & Stoicu-Tivadar, 2012; Mirza & El-Masri, 2013; Moumtzoglou & Kastania, 2014; Patel, 2012; A. Pouliakis, Archondakis, Karakitsou, & Karakitsos, 2014; A. Pouliakis, Spathis, et al., 2014; Rosenthal et al., 2010; Waxer, Ninan, Ma, & Dominguez, 2013; Webb, 2012). It is forecasted that there will be an increase in the US cloud computing market for medical images approximately 27% by 2018 at a Compounded Annual Growth Rate (CAGR). That is mainly due to the growing volume of medical images and the increasing costs of the ownership for owning Picture Archiving and Communication Systems (PACS) (GlobalData, 2012).

Big Data

Big Data is a terminology which is used to describe a collection of datasets being so broad and complicated that it becomes challenging to process them using the standard and on-hand database management tools or the available traditional data processing software applications. Although there is no single formal definition of Big Data, most definitions seem to associate to four Vs which include volume, velocity, variety, and veracity. Volume relates to the unusually large data which are produced, collected and exchanged; velocity refers to the need for real-time analysis; variety identifies the different forms of data that are difficult to integrate while veracity emphasizes the issues which are related to trust and uncertainty. However, not all data that occupy a large volume are considered big. Thus, when defining Big Data, the size is not the primary characteristic; the most appropriate characteristic is the number of independent data sources (separate databases), each one having the potential to interact and be interconnected with one or more data sources.

According to the newest market studies (Market Research Future, 2017; Markets and Markets, 2017), the revenue of Big Data by 2020 and 2021 is estimated in the range of 25-35 billion USD. Thus, the Big Data market is continuously increasing. It is a very competitive market, and many stakeholders have presented innovative products and services dealing with Big Data. The Big Data ecosystem has several discrete areas: a) storage and management including data servers, software, networking, monitoring, administration and data management b) tools and technologies specialized for Big Data analytics that generates insight from collected data c) healthcare intelligence for the organization and d) embedding the Big Data framework into the organization's business intelligence infrastructure (Koumpouros, 2015).

There are several Big Data solutions either open source or commercial ones. Open platforms have advantages as they come at no cost for software acquisition and permit the use of various tools for data analytics. However, they require significant effort to install and setup by specialists. The Apache Hadoop framework is the pioneering and mostly used open platform. Other open source systems include NoSQL databases: MongoDB and Cassandra, among others. The Hadoop framework with proper scaling can support the analysis of petabytes of data. In this arena, another platform, Red Hat Enterprise Linux, in companion with the OpenStack hybrid cloud, supports Big Data applications. In the commercial prod-

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

uct arena, Info Sphere is one of the products offered by IBM, another platform based on the Hadoop system. It includes data warehouse and stream computing software to perform real-time analysis on huge volumes of streamed data. Cisco offers the Cisco Common Big Data Platform, which is based on the Cisco's Unified Computing Architecture and concept. Due to the company's networking history, it integrates computing, networking and storage capabilities. Other Big Data platform and services vendors include Cloudera, Hortonworks, Platfora, DataStax, 10Gen, and Amazon, being supporters of Hadoop and NoSQL. As well as Hadapt, Platfora, Splunk, Datameer, and Karmasphere.

One of the major Big Data and cloud service providers are Amazon.The main service is the Elastic MapReduce (EMR), a Hadoop based platform that scales to thousands of nodes per cluster. There is support for easy to use mission –critical, real - time applications, a petabyte scale warehouse service. Finally, it includes business intelligence tools and can operate on datasets of a few hundred gigabytes to petabytes.

Healthcare is probably one of the leading areas in the Big Data arena, because significant amounts of personal and sensitive, health-related data can be continuously collected from patients. In the medical field, those data are collected by different actors, in different locations, for various purposes and is used/viewed differently by each information consumer (Koumpouros, 2015). For the medical specialists, to reach the best possible diagnosis and subsequently, the appropriate therapeutic scenario, accurate and complete information is required; without Big Data, this is not feasible.

Evidence-based medicine (EBM), is another factor that stresses the need for Big Data in healthcare, as it relies on large scale data sets, usually distributed (Beckmann & Lew, 2016; Sniderman, LaChapelle, Rachon, & Furberg, 2013). EBM is used by the physicians as well as by health care management and insurance organizations, paving the way for the acceptance of Big Data.

As far as population health management is concerned, there is already an application of Big Data (Wells et al., 2016). Specifically, the application is mainly based on the U.S. Medicare and Medigap insurance programs. Within this application, data from diverging lines of evidence are used:

- Demographic and contact details along with insurance coverage.
- Insurance claims, submitted by doctors, hospitals, and other providers to Medicare; those data include standardized codes for medical diagnoses and procedures, place of treatment, amounts billed, as well as whether service was provided:
    - In the emergency room
    - Inpatient service
    - Ambulatory service iv)
    - Laboratory
    - Long-term care unit
    - Ancillary service
- Prescribed pharmaceuticals that include the drug name and class, a drug code identifier (applied at the national level), drug dosage, dates, and the number of days for drug usage. It is worth noting that this is a separate database linkable to the medical claims and administrative data from Medicare.
- A questionnaire is measuring experiences with health plans of Medicare which includes the health status, satisfaction, and experiences from healthcare services.
- U.S. Census data which are related to the zip code and are used to identify differences by in the geographic regions.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

- Data from Dartmouth Atlas which describes the supply of healthcare services in a geographically geographical context.
- The AmeriLINK Data Sourcing system which indicates the social and economic status of members.

The processed Medicare data were around 4 million records, and the results of health analytics proved to be very interesting. The aim was to 'get the right person to the right care at the right time.' Individuals that filled the questionnaire had two times more probability to use a Medicare service while increased time in care coordination was linked with fewer hospital readmissions. Thus, those individuals were more likely to visit a physician's office than return to the hospital and increase healthcare costs. Improved depression management enabled reduction of depression symptoms in about 60% of engaged individuals in the program. Finally, Big Data analytics enabled suggestions for participation in a wellness program.

However, there are still numerous issues in the Big Data arena, especially in healthcare. By 2020, experts predict that data will be produced at a rate of about 40 trillion gigabytes per day. Current information technology is not capable of storing and processing such large volumes. Also, there is a shortage of skilled personnel to collect, manage and process these data. Furthermore, there is resistance from health providers and administrators, as they do not understand the benefits of Big Data and especially for population health management. For data collected from the medical facilities, systems' time and technical diversity seem to be a barrier for data collection. Moreover, medical systems are constantly changing, as they adapt to new technological and scientific advances, as well as to emerging organizational and regulatory requirements and newly developed standards. As a sequel, even in a single hospital there are several information systems and often a bridge is required to ensure interoperability. Despite the evolution in medical standards, it seems that several efforts are still needed. Within the healthcare facilities, the replacement of existing systems depends on the willingness and financial capacity of healthcare providers. Additional barriers will emerge due to the application of M-Health; whereas data collection will be more intense, individuals are already able to collect them from their own devices.

M-Health

M-Health describes the use of a broad range of telecommunication and multimedia technologies within the wireless care delivery design and can be broadly defined as the provision of healthcare services via mobile communication devices (Dimitriou et al., 2017; Metelmann & Metelmann, 2017; Rana, 2017). M-Health establishes healthcare communities in which every stakeholder can participate (O'Connor, Heavin, & O'Donoghue, 2015). However, it disrupts the traditional service model where healthcare information, security, and access is centrally managed, maintained and limited, transforming the health sector and destroying components that are slow to adapt.

M-Health interventions range from simple to complex applications and systems that remotely coordinate and actively manage patient care (Abraham Pouliakis, Archondakis, Margari, & Karakitsos, 2016). In this context, it offers an elegant solution to the problem of accessing the right information where and when it is needed within highly fluid, distributed organizations. Moreover, it removes geography and time as barriers to care by establishing connectivity with remote locations and remote workers, creates new points of contact with patients, and changes the frequency and intensity of health care delivery. It also establishes effective new treatment modalities like telehealth, remote patient monitoring, self-care, and home health while it blurs the boundaries between professional medical advice and self-care. Overall, M-Health blends three bodies of knowledge: high technology, life sciences, and human factors.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

M-Health could also be thought as the practice of medicine and public health supported by mobile devices. The use of mobile computing and communication devices, such as mobile phones, tablet computers and personal digital assistants (PDAs), by health professionals, is nowadays rapidly growing. Wireless networks are the answer for the interconnection of ubiquitous devices. However, wireless communications increase security challenges, privacy concerns, and trust issues for the wireless network, the mobile devices, the connected medical devices and e-health applications (Grami & Schell, 2004). Wireless, mobile nodes is a new challenge in the distributed systems which carry out functions like packet forwarding, routing, and network management (Chlamtac, Conti, & Liu, 2003). Various protocols and algorithms are available for mobile ad-hoc networks (Chlamtac et al., 2003) while the quality of service models for mobile ad-hoc networks and network security are significant challenges to be surveyed (Chlamtac et al., 2003). As a result, different quality of service constraints for various services illustrates the need for an automatic wireless technology option (Janevski, 2009; Kitanov, Monteiro, & Janevski, 2016).

Currently, the generations of mobile phone networks (3G/UMTS, 4G and the predecessor of 5G, i.e., 4.5G) are packet-based architectures (Kastania & Moumtzoglou, 2012). Mobile telephony since the 3G technology enabled the seamless delivery of web content to mobile consumers (Wilson, 2006). Users' management involves subscriptions and profiles for different terminals (cell phone, PDA, laptops, desktops) (Hong & Leon-Garcia, 2005) while the choice of a cell/mobile device is heavily influenced by the provided mobile services and device capabilities.

Existing cellular and Wi-Fi networks that have, nowadays, merged with the Internet, represent the 4th Generation (4G) and the predecessor of 5G (i.e., 4.5G) wireless, mobile Internet networks (Gani, Li, Yang, & Zakaria, 2008). 4G generation of wireless enhanced and replaced the 3G systems. 4G is a mobile network, IP-based, providing a connection via always the best available network using seamless roaming and free radio access technologies. In 4G mobile systems, different access technologies are combined, in the best possible way, for various radio environments and service requirements. 4G technologies have already implemented much larger data rates supporting full mobility while enabling wireless connection and access to multimedia services with high-quality voice and high-definition video. 4G wireless telecommunication supports smart multi-media providing higher bit rate and wider bandwidth, 3D image technology, streamed HD TV with remote control, video multimedia and advanced multimedia messaging service. Mobile multimedia provision requires a modern mobile communication system to make ubiquitous communication using mobile characteristics. High-quality voice, video, and data services can be delivered on a metropolitan using Wi-Fi (IEEE 802.11a/b/g/n) as a transition towards 5G. Mobile WiMAX, while expected to fulfill the goals of 4G technology offering full broadband for all services, is not, nowadays, the technology of choice. In this context, global roaming and open interconnection interfaces are essential functions of 4G communications systems.

According to many researchers, mobile applications ensure seamless mobile services for end-users, anywhere, and on any device. However, the shifts towards more advanced networking systems depend on the development of wireless radio access technologies and networking technologies.

Services adding to 4G include 5G, which is expected to be a more intelligent technology for the whole interconnection world without limits. 5G technology is currently implemented and is the standard of mobile telecom providers; it is synonym with the LTE Advanced (Long Term Evolution) and MIMO (multiple input / multiple outputs) technologies that enable the multiplication of capacity and frequency use along with optimization in the urban and indoor environments to handle multi path effects.

5G is planned to provide additional services and have more advantages, related to energy consumption, network coverage, spectrum handling, bandwidth use, and allows users to participate in a fully distributed

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

or cellular-controlled fashion. All IP-based services for heterogeneous wireless access technologies, assisted by mobile IP, are to be provided by 5G mobile communication networks. 5G aims at a higher capacity and simultaneously a higher density of mobile users. Moreover, it supports device-to-device, and machine to machine reliable communications (i.e., mobile ad-hoc networks / MANETs). Thus, 5G aims at lower latency than the 4G equipment and lower battery consumption and is an enabling technology for the Internet of things. Nowadays, there is no standard for the deployment of 5G. However, the expected characteristics include:

- Tens of megabits per second, simultaneously for dozens of thousands of users.
- More than 100 megabits per second for metropolitan networks.
- 1 Gb per second, simultaneously available to all users on the same building floor.
- Capacity for hundreds of thousands of simultaneous connections for the implementation of Internet of Things.
- Spectral efficiency / i.e., more Mbps for the same frequency slot
- Improved coverage
- Significantly reduced latency

MEDICAL APPLICATIONS FOR THE NEXT GENERATION OF MOBILE DEVICES AND NETWORKS

Mobile web services represent the integration of web services between mobile devices without any centralized entities (Srirama, Jarke, Zhu, & Prinz, 2008). Factors influencing mobile hosts are network characteristics, searching capability of the services and computational resources (Srirama, 2006) while collaborative sharing of peer resources is possible for Mobile Hosts in P2P (Srirama, 2006). Mobile Host in JXME JXME allows collaboration, image sharing, and location-based services (Srirama, 2006). Each Mobile Host can provide some services in the wireless network acting, through the cell phone, as both web service client and provider (Srirama, Jarke, & Prinz, 2007). The quality of service (QoS) for the Mobile Host is critical regarding security and scalability.

A mobile phone is a communications device offering wide-area networking capabilities (Roussos, Marsh, & Maglavera, 2005). Cell phones can serve as control devices for ubiquitous systems and information service endpoints with a focus on protecting the user's information (Roussos et al., 2005). Many mobile phones interact with other nearby devices due to the availability of wireless networking capabilities (Itani, Kayssi, & Chehab, 2016; Roussos et al., 2005). Visual tag clicking on camera phone allows user interaction with a mobile service (Toye et al., 2007) while mobile content can be downloaded, in commercially available products scanning visual tags (Toye et al., 2007). Moreover, data rates increase web browsing and offer reduced access times. However, there are constraints associated with small mobile displays and keypads (Toye et al., 2007) while larger data rates increase energy consumption and complexity of the device.

Overall, the smart Internet phone lets the mobile phone select the best connections (Janevski, 2009). Furthermore, all smartphones (cell phones that include PDA functionality) are equipped with the functionality to access high-speed data through a variety of networks including those supported by mobile phone networks (3G and 4G+), local networks (WiFi) and personal area networks (Bluetooth and NFC). Applications for the next-generation of cell phones will provide localized, real-time services and local-

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

ized information services. However, confirmation is needed of the services provided by the smartphones in a wireless network (Srirama et al., 2007).

Handheld computing has already numerous applications such as:

- Ambulatory medicine (K. Banitsas, Perakis, Koutsouris, Konis, & Tachakra, 2005; K. A. Banitsas, Perakis, Tachakra, & Koutsouris, 2006; Kiselev, Gridnev, Shvartz, Posnenkova, & Dovgalevsky, 2012; Pavlopoulos, Kyriacou, Berler, Dembeyiotis, & Koutsouris, 1998; Rosales Saurer, Mueller-Gorchs, & Kunze, 2009; Zerth, Besser, & Reichert, 2012).
- Diabetes management (Quinn et al., 2011; Ribu et al., 2013; Skrovseth, Arsand, Godtliebsen, & Hartvigsen, 2012; Spat et al., 2013).
- Asthma management (Finkelstein, Hripcsak, & Cabrera, 1998; Gupta, Chang, Anyigbo, & Sabharwal, 2011).
- Control of obesity (Patrick et al., 2009).
- Smoking control (Ghorai, Akter, Khatun, & Ray, 2014; Ybarra, Holtrop, Prescott, & Strong, 2014).
- Seizure management (Pandher & Bhullar, 2014).
- Stress management (Clarke et al., 2014) and
- Treatment of depression (Burns et al., 2011) among others.

In the field of M-Health most applications are fitness related (43%) followed by health resource (15.0%) and diet/caloric intake (14.3%,), while the user engagement has the form of self-monitoring and training (74.8%) (Sama, Eapen, Weinfurt, Shah, & Schulman, 2014). On the other hand, despite the applications which target patients, currently, there are rather limited applications targeting physicians and doctor-patient interactions (Martin, 2012). The pioneering field seems to be radiology consultation for X-rays and mostly Computer Tomography (Choudhri et al., 2012; Choudhri et al., 2013; Johnson et al., 2012; Toomey et al., 2010) and ECG transmission (Vaisanen, Makijarvi, & Silfvast, 2003).

However, the mobile device has emerged recently as a technology gadget collecting biomedical data, either in the form of the mobile phone or as a specialized appliance, usually in the shape of a wrist attached device. This plethora of devices has created a new movement, called quantified self (QS) (Fawcett, 2015). QC involves ordinary and usually healthy people that record and process aspects of their lives with the help of (usually) self-collected data. This QS movement has attracted the interest of commercial companies offering products and services (hardware and software). The M-Health applications being of interest to physicians, patients, and the science of individuality include the following.

Mobile MIM (MIM Software, 2017) is a software application for viewing MRI, PET and CT data using mobile devices compatible with the Apples' iPhone series operating system (iPad®, iPhone®, and iPod touch®). MRI, PET, and CT images are transmitted using software, and it is possible to measure the image intensity and distances.

MobiUS™ is an image based series of products (Mobisante Inc., 2017) supporting ultrasound (US) imaging. That is smartphone and tablet-based and is cheaper than traditional US systems; being equipped with specialized monitors. Moreover, this system supports sharing of images among patients and clinicians.

Gyromaniac (Subversus Interactive, 2011) uses the iPhone gyroscope electronic components to help physicians practice spatial orientation: for example, to assist gastroenterologists during training how to perform a colonoscopy (Iltifat, 2010).

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

There are, as well, software platforms for continuous wearable, non-obtrusive ECG data (cardiac) monitoring. Such solutions can be of help for cardiologists to monitor and manage patients with angina, infarction of the myocardium, cardiac interventions such as stents, pacemakers, and bypass, as well as cardiac failures and ambulatory medicine. Such devices have been in service for gynecologists for fetus monitoring (Medical design, 2013; Su & Chu, 2014). That avoids frequent visits to the outpatient department for follow up, the unnecessary waiting time and anxiety for patients. That system also aids proactive management of complications, identifying them with intelligent analysis as and when they occur and addressing them based on evidence.

A recently announced device (Wavelet Health, 2017) incorporates a photoplethysmograph (PPG) sensor; a pulse oximeter illuminating the skin and measuring changes in light absorption; such a device is capable to continuously monitor perfusion of blood to the dermis as well as subcutaneous tissue; therefore, it can detect heart rate as well as blood oxygen levels.

Recent announcements (University of Illinois College of Engineering, 2017) are related to a lab on a chip device that when coupled with a smartphone can perform lab-grade medical diagnostics. Such tests usually require large, specialized and expensive instruments. However, the developed inexpensive microchip incorporates technology common in the three top categories of medical diagnostics. The microchip promises to perform thousands of already available tests. It is based on the mobile phone camera that is used as a spectrometer. Specifically, the biological sample should be in a fluid form; this is illuminated by the cell phone's white LED flash. Subsequently, the light from the fluidic sample is collected by an optical fiber and after being captured by the phone's internal camera can be evaluated by the use of the software. Such technology enables the application of advanced biological tests in remote areas, often in the developing world, and personalized tests at the individual patient level.

In the field of otolaryngology some applications can determine reference sound levels with a minimum l variation; therefore, it is feasible to conduct a hearing screening on devices calibrated with a predefined reference noise level (Masalski, Kipiński, Grysiński, & Kręcicki, 2016).

Also, the advanced communication capabilities allow voice and video conferencing features for patient/doctor and doctor/doctor interactions as well as seamless transmission of captured images and video.

Mobile electroencephalograph (EEG) is another area that mobile devices may become a commodity. Emotiv Insight Brainware (see Figure 1) is a five channel EEG device that can capture brain signals and transmit them via Bluetooth interface to the mobile phone (EMOTIV, 2017). Such commercial and portable EEG devices have already been used to measure auditory potential on children and adults (Barham et al., 2017). They are used to convert brain signal to computer commands, and some identify the mental status and record it for archiving purposes.

Furthermore, modern high-end mobile phones are coupled with sensors that can measure life signals and communicate with commercial devices that measure health signals such as blood glucose. For instance, some cell phones have integrated heart rate sensors with high accuracy and step counters. They also have applications (Figures 2-4) that measure and store data to the cloud, such as exercise and sports activity, heart rate, stress, sleeping duration, consumption of food and liquids, weights and glucose when coupled with appropriate medical devices or when the user wishes to supply such information.

Conclusively, the recent advances of the mobile telephony have contributed to the conversion of the mobile telephones into smartphones; due to the sophisticated operating systems. Especially, during the previous five years, hardware components enriching cell phones became available, including more processing power (8 or more processors), high-definition cameras (more than 15Mpixel) and large display resolutions. Moreover, the 4.5G and WiFi connectivity have created an always open, rather inexpensive,

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. A commercial portable EEG device capable to communicate via Bluetooth with the mobile phone

communication channel with the Internet. Today, there is no more the trend to shrink the telephone; in contrast, mobile phones are becoming larger and complete tablets regarding size and weight; they are easy to use and have capabilities similar to computers available five years ago. It seems that the mobile devices have now the maturity of computers that were used in the health sector five years ago.

Issues, Controversies, Problems

First, we must recognize that to center population health efforts on the patients we are overlooking those who are not patients. Even for those who are exceptionally engaged patients, their interaction with the healthcare system is a mere fraction of health and well-being influences. Consequently, if we design population health efforts solely around patients, we fail to address the enormously significant social determinants of health which include environmental, economic, and cultural factors.

Instead, we need a proactive, holistic, longitudinal, without walls, deeply personal approach to population health management. That means the approach should include not only the care of sick but also well care, as the goal should be lifelong health and quality of life support. That also includes proactively reaching out to hard-to-reach populations. Moreover, the approach should:

- Address the range of psychological, biological and social factors that influence health and wellness.
- Leverage the patient as a source of continuity by engaging him or her as an integral member of the care team.
- Recognize that supporting an individual's lifelong health and well-being cannot be relegated to anyone particular setting.
- Take into account the personal goals, strengths and challenges as for primary drivers of care management, planning and decision-making.

While 'Big Data' has its place for identifying patterns and gaps in care and predictive analysis, the most relevant data regarding the science of individuality are self-reported data. In this context, the population health management strategies will fail to engage patients, reduce costs, and improve outcomes, if they are implemented without the underpinning of person-centered care. Ultimately, the health of a population has nothing to do with data and technology but with the individuals that make up the population.

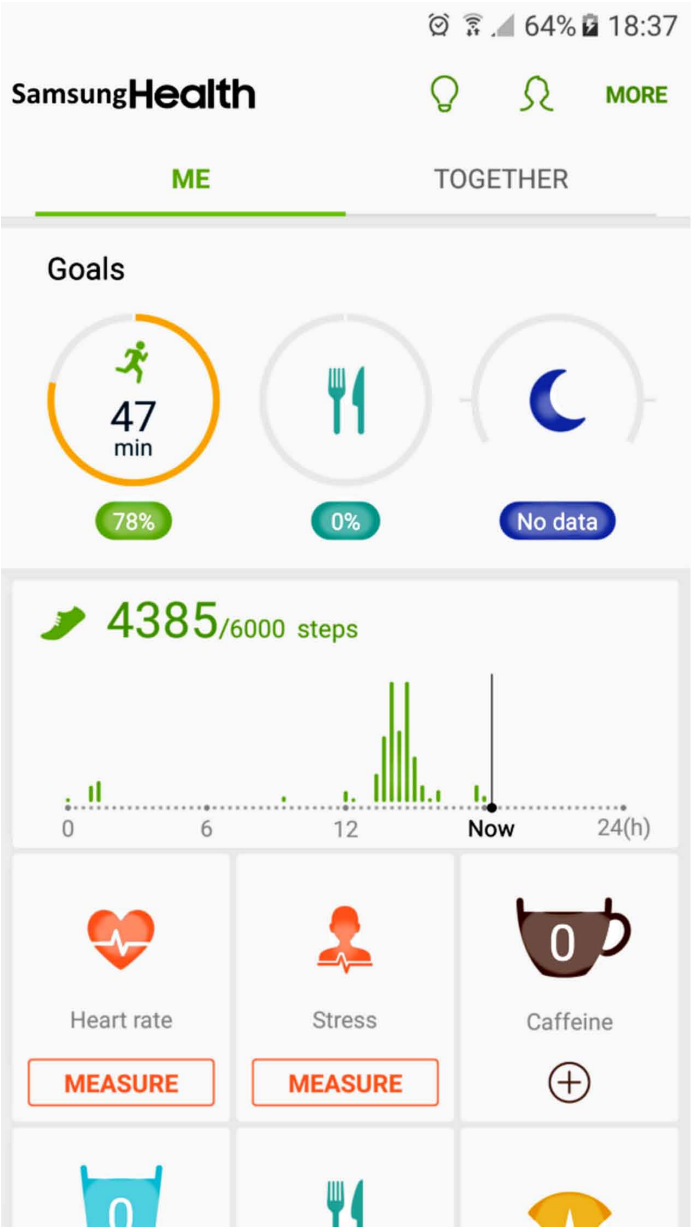
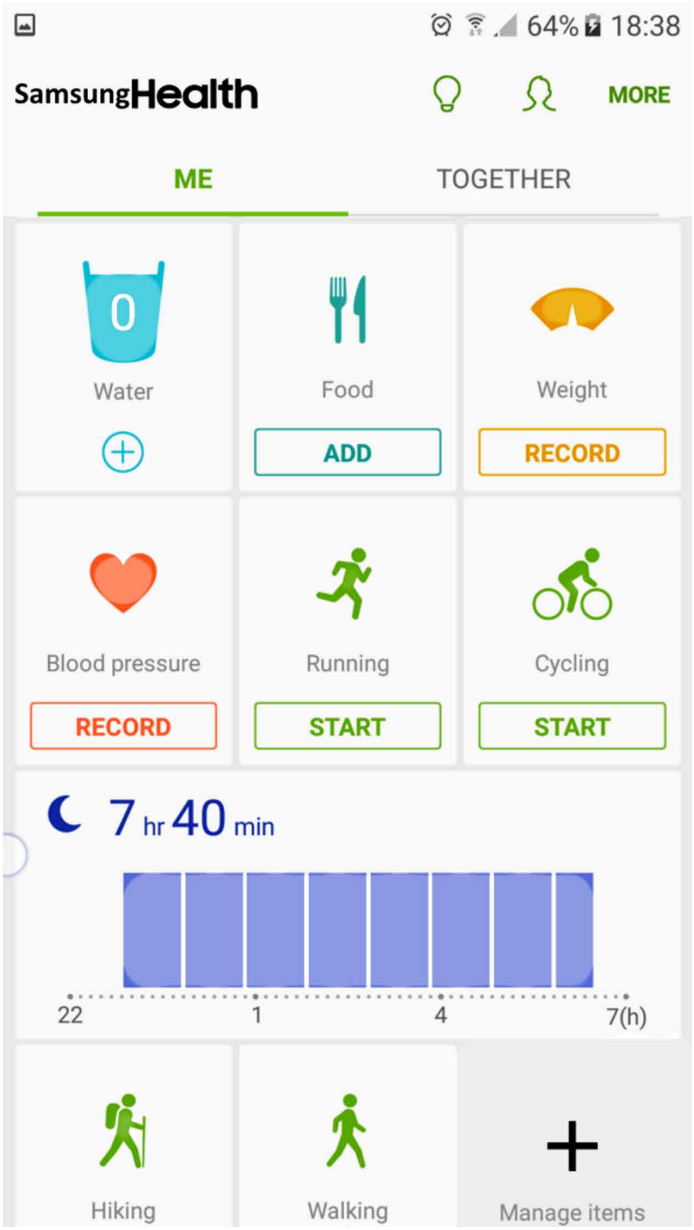
Figure 2. A display of mobile phone applications for the measurement of health and well-being data (part 1)



To this direction, and due to the sensitivity of the stored and transferred information, data security for all of the associated technologies is of essential importance (Spyra, Buchanan, Cruickshank, & Ekonomou, 2014). In this context, the European Union approved (in April 2016) the General Data Protection Regulation (GDPR); the most significant change in the European legal framework the last twenty (20) years. The GDPR will have a direct application in all member states on May 25, 2018, and enforcement is assured by heavy fines on non-compliant organizations. However, the implementation of the GDPR,

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 3. A display of mobile phone applications for the measurement of health and well-being data (part 2)



to a large scale, might be a big issue, as information flowing across the EU borders and data storage in non-EU countries could be essential, taking into account that non-EU countries are not obliged to apply the GDPR. As a result, services offered by organizations residing outside the EU could be vital for e-health applications targeting individuals.

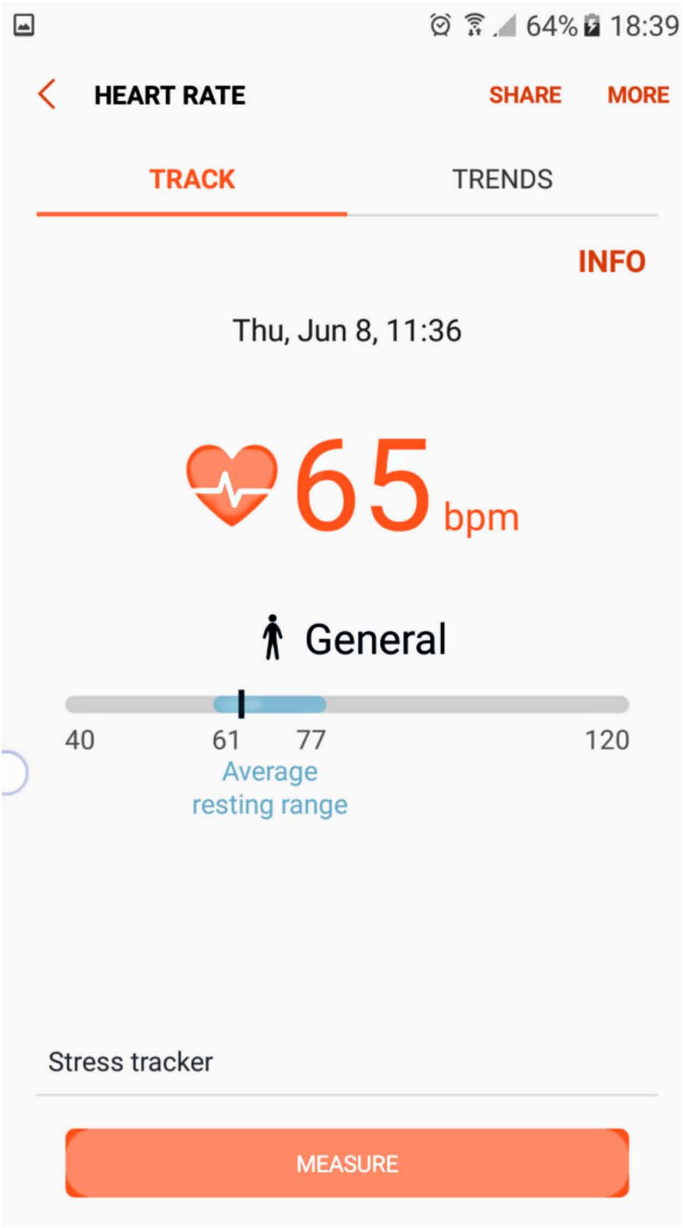
Figure 4. A display of mobile phone applications for the measurement of health and well-being data (part 3)



FUTURE RESEARCH DIRECTIONS

The future of population health management is tied to the rise of cognitive computing. Cognitive computing is the simulation of human thought processes in a computerized model and uses parallel processing and artificial intelligence to convert unstructured into structured data, search the medical literature, and find connections among multiple types of evidence, in short, it creates knowledge.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

The goal of cognitive computing is to build automated IT systems that are capable of solving problems without requiring human assistance. The cognitive computing systems:

- Use natural language processing and machine learning algorithms.
- Mine the data for information.
- Refine the way they search for patterns to become capable of anticipating new problems and modeling solutions.

Heretofore, cognitive computing is used in the following artificial intelligence (AI) applications:

- Expert systems
- Natural language programming
- Neural networks
- Robotics
- Virtual and augmented reality

CONCLUSION

Population health management (PHM) has been, so far, a discipline which studies and facilitates care delivery across a group of individuals or the general population. In the context of population health management, the life science industry has no motivation to design drugs or devices that are only effective for a distinct segment of the population. At the same time, the regulatory agencies are entirely risk-averse and are suppressing remarkable innovative and even frugal opportunities to change medicine.

However, the major outgrowth of the science of individuality, as well as the rising 'wiki medicine', that is, the individualized medicine which respects individuality, fully recognize the uniqueness of the individual. In this regard, it will not be long until digitizing a person unlocks the root cause for what is wrong, creating valuable knowledge that can save or markedly improve the quality of life.

Cloud computing, Big Data and M-Health technologies offer the resources to succeed in dealing with the shortcomings of the population health management approach. Specifically, while population health management focuses on what happens on the bed or a doctor's office., the technologies above facilitate the propagation of the science of individuality by taking the challenges of wellness, prevention and lower cost. Finally, cognitive computing is considered the future of population health management.

Chapter 5
A Yes/No Answer Generator Based on Sentiment-Word Scores in Biomedical Question Answering

Mourad Sarrouti
Sidi Mohammed Ben Abdellah University, Morocco

Said Ouatik El Alaoui
Sidi Mohammed Ben Abdellah University, Morocco

ABSTRACT

Background and Objective: Yes/no question answering (QA) in open-domain is a longstanding challenge widely studied over the last decades. However, it still requires further efforts in the biomedical domain. Yes/no QA aims at answering yes/no questions, which are seeking for a clear "yes" or "no" answer. In this paper, we present a novel yes/no answer generator based on sentiment-word scores in biomedical QA. Methods: In the proposed method, we first use the Stanford CoreNLP for tokenization and part-of-speech tagging all relevant passages to a given yes/no question. We then assign a sentiment score based on SentiWordNet to each word of the passages. Finally, the decision on either the answers "yes" or "no" is based on the obtained sentiment-passages score: "yes" for a positive final sentiment-passages score and "no" for a negative one. Results: Experimental evaluations performed on BioASQ collections show that the proposed method is more effective as compared with the current state-of-the-art method, and significantly outperforms it by an average of 15.68% in terms of accuracy.

INTRODUCTION

The large size of literature in the biomedical domain makes it difficult for information seekers even in their field of interest to find the information they need (McDermid, Kristjanson, & Spry, 2010). The most used for accessing to biomedical information are information retrieval (IR) systems, such as

PubMed[1] which gives access to the MEDLINE[2] biomedical bibliographic database (Hristovski, Dinevski, Kastrin, & Rindflesch, 2015). Indeed, finding sufficient and short precise answers is a challenging task for classical IR systems (Wren, 2011). In addition, in classical IR systems, the users have often to deal with the burden of studying and filtering the returned citations of their queries so as to find the precise information they were looking for. Therefore, to minimize searching and browsing time while maximizing the usefulness of that knowledge is a growing interest for biomedical question answering systems (Bauer & Berleant, 2012). Question answering (QA) regards a sophisticated form of IR characterized by information needs that are expressed as natural language statements or questions (Wren, 2011). It aims at providing inquiries with specific pieces of information as an answer, by automatically analyzing thousands of articles, ideally, in less than a few seconds. Typically, an automated QA system consists of three main processing phases, which can be studied and developed independently (Athenikos & Han, 2010; Cao et al., 2010; Neves & Leser, 2015): (1) question processing, (2) document processing, and (3) answer processing. Figure 1 illustrates the generic architecture of a biomedical QA system.

Given an input biomedical question, the question is first handed over to the question processing phase. The latter consists of the following components: (a) question analysis for extracting some useful information such as biomedical entity names, and semantic relationships; (b) question classification for identifying the answer format and the topic (Cao et al., 2010; Patrick & Li, 2012; Roberts et al., 2014; Lopes et al., 2014; Sarrouti et al., 2015); (c) query formulation for constructing IR-style query by transforming the question into a canonical form. The output of this phase is an appropriate query which is used as input to document processing, the second phase. An IR system is normally used to retrieve the relevant documents (Sarrouti & Alaoui, 2016). Then, passages are extracted which serve as answer candidates as well as an input to the last phase, answer processing; in this phase, the system uses an appropriate answer extraction algorithm to estimate the qualities of the candidate answers. Finally, the top-ranked candidate answers and the raw texts from which the answers were extracted are shown to the user (Sarrouti & Ouatik, 2017).

In spite of the importance of the process, yes/no-style QA has not been intensively studied in the biomedical domain, compared to other types of QA, such as the factoid-style QA (Weissenborn et al., 2013; Yang et al., 2015; Hristovski et al., 2015) and the definition-style QA (Lee et al., 2006; Yu et al., 2007; Cao et al., 2011). Yes/no QA aims at answering yes/no questions, which are seeking for a clear "yes" or "no" answer (Green & Carberry, 1994). For instance, a biomedical yes/no QA system would provide "yes" as an answer for the yes/no question "Does the histidine-rich Ca-binding protein (HRC) interact with triadin?". Even though there are only two possible answers, "yes" or "no," such questions can be quite hard to answer due to the complicated sentiment analysis process of the candidate answers. This challenging task has motivated the recent launch of the BioASQ[3] challenge: an EU-funded support action to set up challenges on biomedical semantic indexing and QA (Tsatsaronis et al., 2015). The BioASQ challenge consists of two main tasks, i.e., task a: large-scale online biomedical semantic indexing and task b: biomedical semantic QA. The major goal of task b is to assess the performance of participating systems in different stages of the QA process. Moreover, task b is sub-divided into two phases: phase A and phase B. Indeed, in phase B, BioASQ provided researchers with biomedical questions and their respective question types (i.e., yes/no, factoid, list, summary) as well as gold-standard information for phase A, such as manually curated relevant concepts, documents, passages and RDF triples (Balikas et al., 2013). The participants were requested to provide an exact answer: "yes" or "no" for yes/no questions, a short paragraph for summary questions, and a single or a list of short answers for factoid and list questions, respectively.

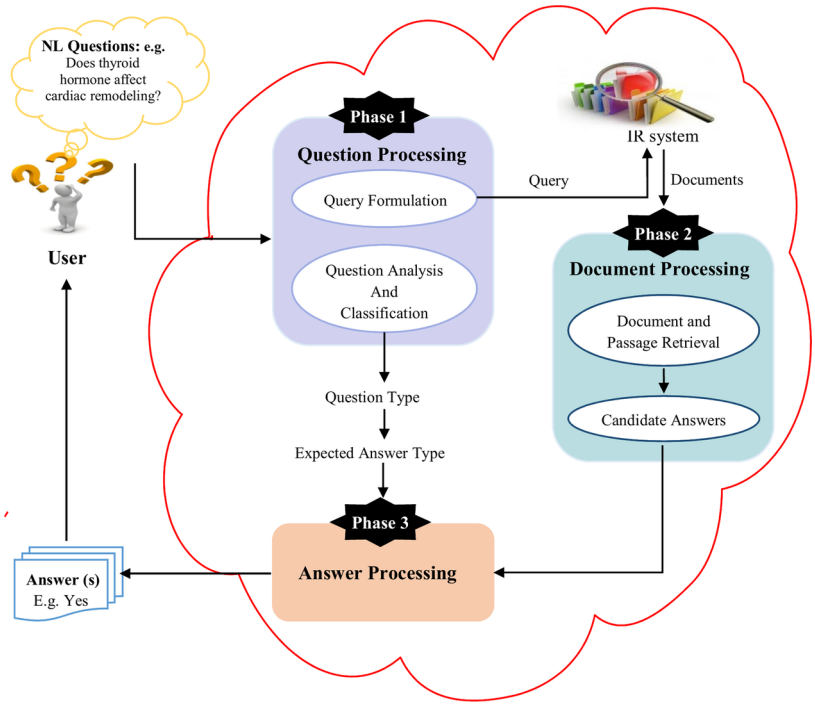
Figure 1. A typical biomedical question answering system architecture



In spite of the launch of the biomedical QA track at the BioASQ challenge and the great effort of biomedical experts to create benchmark datasets, only few answer extraction methods for yes/no questions have been presented in the biomedical domain, compared to other question types such as factoid, list, and summary. The most recent yes/no biomedical answer extraction method is the one which was presented by Neves (2015). The author has made a decision on either the answer is "yes" or "no," based on the sentiment analysis predictions provided by the in-memory based database (IMDB) technology (Plattner, 2013). The IMDB returns 10 types of sentiments, namely "strong positive sentiment," "strong positive emoticon," "weak positive sentiment," "weak positive emoticon," "strong negative sentiment," "strong negative emoticon," "major problem," "weak negative sentiment," "weak negative emoticon" and "minor problem". Indeed, the author has grouped these sentiments into four coarse categories, i.e., "positive strong," "positive weak," "negative strong," "negative weak," and then into the two main sentiments "positive" or "negative" and decision for the answers "yes" or "no" was based on these two coarse sentiments.

Although the previous method has proven to be quite successful at answering yes/no questions in biomedical QA, yes/no answer extraction system still requires further efforts in order to improve its performance. For this purpose, we propose in this paper a yes/no answer extraction method based on sentiment-word scores. We first use the Stanford CoreNLP (Manning, Surdeanu, Bauer, Finkel, Bethard, & Closky, 2014) tool for tokenization and part-of-speech tagging all passages for a given yes/no question. We then assign to each word in passages a sentiment score based on SentiWordNet (Baccianella, Esuli, & Sebastiani, 2010): a publicly available lexical resource for sentiment analysis and opinion mining. Finally, the decision for the answers "yes" or "no" is based on the final sentiment score which is the sum of all word scores: "yes" for a positive final sentiment passages score and "no" for a negative

one. Extensive experiments on BioASQ collections demonstrate the effectiveness of our proposed yes/no answer extraction method. The results show that our method is more efficient as compared with the current state-of-the-art method presented in (Neves, 2015) and outperforms it by an average of 15.68% in terms of accuracy.

The remainder of the paper is organized as follows. In Section 2, we introduce related work and discussion about the main yes/no answer extraction approaches. Section 3 describes the overall architecture of the proposed yes/no answer extraction method. Several comprehensive experiments are performed to evaluate the effectiveness of our approach in Section 4 where experimental settings, evaluation metrics, benchmark datasets, and results are presented. Finally, Section 5 concludes this paper and presents directions for future research.

RELATED WORK

The task of automatically answering natural language questions has been intensively studied, especially since the introduction of QA Track in the Text REtrieval Conference (TREC[4]) in 1999, and the presentation of biomedical QA in the BioASQ challenge (Tsatsaronis et al., 2015). The TREC QA challenge deals only with factoid, list and definitional questions, which were not restricted to any domain. The BioASQ challenge differs from the aforementioned challenge in two main points. First, the questions of the challenge are restricted to the biomedical domain. Second, it includes two new types of questions, namely yes/no questions and summary questions.

In spite of the importance of yes/no biomedical QA system, only few studies have been presented compared to other types of QA, such as the factoid-style QA (Weissenborn et al., 2013; Yang et al., 2015; Hristovski et al., 2015) and the definition-style QA (Lee et al., 2006; Yu et al., 2007; Cao et al., 2011). Moreover, the majority of the proposed yes/no QA systems deal with open-domain yes/no questions, which are not restricted to any domain. Yes/no QA (Green & Carberry, 1994) aims at answering yes/no questions, which are seeking for a clear "yes" or "no" answer. In this direction, Kanayama et al. (2012) have investigated a solution to yes/no QA in the open domain by leveraging the power of information sources accessed through a factoid-style QA system. By aggregating the answers and confidence values from a factoid-style QA system, the authors have determined the correctness of the entire proposition or the substitutions that make the proposition false. He and Dai (2011) have designed a model to score the relevance of the answers and the questions, and a feature function combining the relevance and opinion scores to classify each answer to be "yes" or "no". The authors first have proposed a model to compute the relevance of asymmetric documents and used it as one of the features to give a weight for each sentence in the answers. Then, they have introduced three features, including the relevance feature, the sentiment-word score feature and the position weight feature for classifying the answers to general questions. Finally, they have integrated these three features to find a new feature function that classifies the answers into three types: "yes," "no," and "neutral". Bdour and Gharaibeh (2013) have proposed a formal model for a lightweight semantic-based open-domain yes/no Arabic QA system based on passage retrieval. The authors have shown that using a semantic logical representation based on query expansion techniques frequently improve the precision of the system. Their experimental results demonstrated that employing passage retrieval achieves a better precision by retrieving more passages that contain relevant answers to the questions. Kim et al. (2014) have developed a QA approach to answering yes/no questions relevant to civil laws in legal bar exams. In their proposed system, the authors first have identified legal

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

documents relevant to the exam questions, and then extracted the final answers of the questions by analyzing the relevant documents. They have constructed a knowledge base by analyzing negation patterns and antonyms in the civil law articles. In addition, the authors have extracted deep linguistic features with lexical, syntactic information based on morphological analysis and dependency trees, and lexical semantic information using the Kadokawa thesaurus. Furthermore, they have classified the questions into easy and difficult ones and proposed the two-phase method for answering yes/no questions. They have answered easy questions by negation/antonym detection. For more difficult questions, they have adapted a machine-learning method based on morphological, syntactic, and lexical semantic analysis as features. Abacha and Zweigenbaum (2015) have developed a medical QA system, namely MEANS, based on natural language processing techniques and semantic Web technologies. MEANS consists of three main phases: (1) corpora annotation, (2) question analysis, and (3) answer search. They have proposed a method for answer search based on semantic search and query relaxation. Neves (2015) has proposed a biomedical yes/no answer extraction method based on the sentiment analysis predictions provided by the IMDB technology (Plattner, 2013). As it has already been stated before, the author has grouped the 10 types of sentiments returned by the IMBD into the two main sentiments, "positive" or "negative," in order to decide whether the answer should be "yes" or "no."

The previous biomedical yes/no answer extraction method presented by Neves (2015), which was evaluated on benchmark datasets provided by the BioASQ challenge, has proven to be quite successful at answering yes/no questions in biomedical QA. However, yes/no answer extraction component in biomedical QA still requires further efforts in order to improve its performance. Hence, this paper tackles yes/no QA in the biomedical domain by exploiting sentiment-word scores provided by the SentiWordNet lexical resource. The latter, which is based on lexical approaches, has been widely used in sentiment analysis and opinion mining methods presented in social networks' text mining research area (Abbasi et al., 2011; Paltoglou & Thelwall, 2012; Mostafa, 2013; Thelwall & Buckley, 2013). The key idea behind using the SentiWordNet word score in the proposed yes/no QA is that all passages are somehow related to the yes/no question and that computing sentiment scores of these passages could be used to distinguish between the two possible answers, i.e., "yes" and "no". The contributions that we make in this paper can be summarized in the following points:

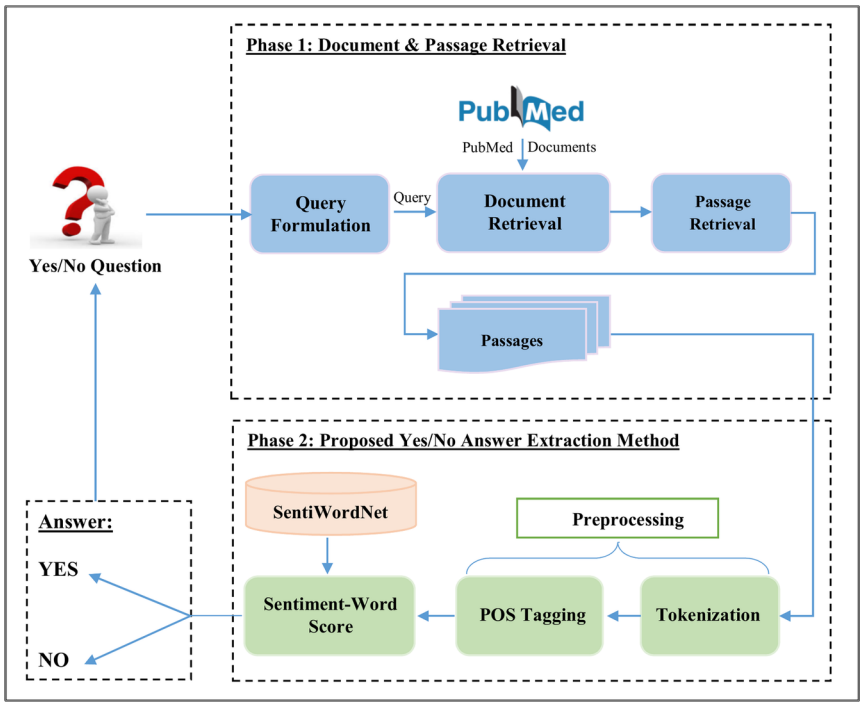
1. As far as we know, there are no studies in the literature that use the SentiWordNet lexical resource for answering yes/no questions;
2. We propose a new yes/no answer extraction method in biomedical QA based on the sentiment word scores provided by the SentiWordNet lexical resource;
3. We conduct experiments on benchmark datasets, demonstrating that the proposed method significantly outperforms the current state-of-the-art method presented in (Neves, 2015).

METHODS

In this section, we present the proposed yes/no answer extraction method, which is comprised of two stages: document & passage retrieval and yes/no answer generator. The flowchart of the proposed method is shown in Figure 2. The two phases are described sequentially in the following subsections.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. System overview of the proposed yes/no answer extraction method



Document and Passage Retrieval

In general, an IR (Sarrouti & Alaoui, 2016) system is used for document and passage retrieval to a given question in QA. However, in this work, we used the golden (correct) documents and passages from benchmark datasets provided by the BioASQ challenge (Tsatsaronis et al., 2015). BioASQ realized a set of biomedical questions with their golden documents and passages in order to evaluate the answer extraction methods in their best way.

Proposed Yes/No Answer Extraction Method

After retrieving the n golden passages $\{p_1, p_2, p_3, ..., p_n\}$ to a given yes/no question from benchmark datasets, we forward them one by one to the Stanford CoreNLP (Manning et al., 2014) for tokenization and part-of-speech tagging in order to extract a set of words accompanied by their POS tags. The Stanford CoreNLP was used since recent research shows a good performance of the latter in the biomedical domain (Lin & Wilbur, 2007). We then compute the sentiment score for each passage to see whether the answer should be "yes" or "no". Assuming that there are k words (w) in a passage p, the final sentiment score (SC) of the passage is defined by the following equation:

$$SC(p) = \sum_{i=1}^{k} \text{SentiWordNet}\ (\text{w}_\text{i}) \tag{1}$$

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

The sentiment score for each word is obtained using SentiWordNet[5] 3.0: a lexical resource for sentiment analysis and opinion mining (Baccianella et al., 2010). The latter assigns to each synset of WordNet three sentiment scores: "positivity," "negativity," and "objectivity". Indeed, the key idea behind using the SentiWordNet 3.0 lexical resource is that it is the result of the automatic annotation of all the synsets of WordNet 3.0 according to the notions of "positivity," "negativity," and "neutrality" (Baccianella et al., 2010). The WordNet, which is a large lexical database of English, is comprised of 155,287 words and 117,659 synsets, also called synonyms (George, 1995). On the other hand, March et al. (2013) have shown that SentiWordNet 3.0 outperforms other sentiment lexicons in the determination of the polarity, such as Bing Liu's Opinion Lexicon (Hu & Liu, 2004) and MPQA Subjectivity Lexicon (Wilson, Wiebe, & Hoffmann, 2005).

Algorithm 1. *Yes/No answer generator*

```

In Algorithm 1, we summarize all steps of the proposed yes/no answer extraction method in biomedical QA. As stated earlier, our approach first takes all golden passages for a given yes/no question. After that, terms and their POS tags of passages are extracted in the preprocessing step. Then, it computes the sentiment score for each passage based on the SentiWordNet-word scores. Finally, the decision on either the answers "yes" or "no" is based on the number of positive and negative passages: "yes" for a positive final sentiment-passages score and "no" for a negative one. Figure 3 shows an example of the whole process, i.e., tokenization, part-of-speech tagging, and sentiment score assignment for one passage of the yes/no question "Does the CTCF protein colocalize with cohesin?"

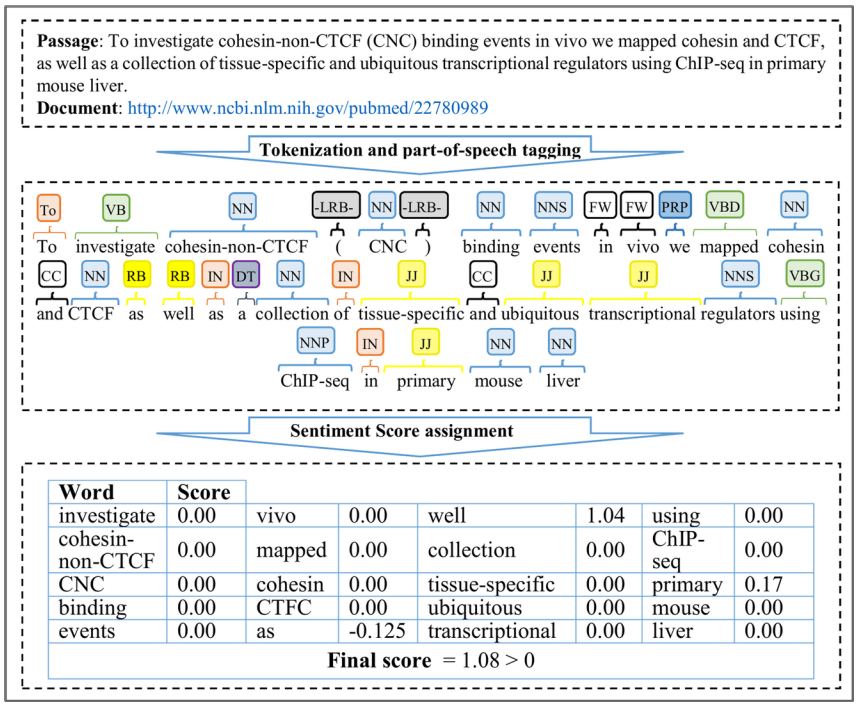
EXPERIMENTAL RESULTS AND DISCUSSION

In this section, we first report our pilot evaluation of the proposed biomedical yes/no answer extraction method on benchmark datasets, provided by the BioASQ challenge. We then compare our method with the current state-of-the-art method. We finally show an error case study to understand the source of errors in yes/no answer extraction.

Datasets

To validate the efficiency of the proposed yes/no answer extraction method in biomedical QA, we used the publicly available benchmark datasets provided by the BioASQ challenge (Tsatsaronis et al., 2015).

Figure 3. An example of tokenization, part-of-speech tagging and sentiment score assignment



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

The challenge, within the 2015 edition, realized a training dataset of 810 biomedical questions-answers pairs and five batches of testing data which are used as test sets to evaluate the participating systems in task b. There were four types of questions: "yes/no," "factoid," "list," and "summary" questions (Balikas et al., 2013). Table 1 shows these five batches of testing datasets and the number of questions assigned to each type.

Furthermore, in phase B of task b, the released biomedical questions were accompanied by the golden (correct) articles as well as passages from benchmark datasets (Balikas et al., 2013). The participating systems had to respond with exact answers (e.g., "yes" or "no" in the case of yes/no questions, named entities in the case of factoid questions, etc.) and ideal answers (paragraph-sized summaries). The following are some examples of yes/no biomedical questions from the BioASQ training dataset:

- Does magnesium sulfate improve outcomes of subarachnoid hemorrhage patients?
- Can NXY-059 be used for treatment of acute ischemic stroke patients?
- Is there an increased risk for cancer in Dyskeratosis Congenita?

Evaluation Metrics

Accuracy is the main evaluation metric used to evaluate the performance of yes/no answer extraction methods in the BioASQ challenge since yes/no QA problem is considered as a binary classification problem (Tsatsaronis et al., 2015). For each yes/no question, the exact answer of yes/no QA system had to be either "yes" or "no." Therefore, the response was compared against the golden exact answer (again "yes" or "no") realized by the BioASQ team of biomedical experts (Balikas et al., 2013). Assuming that there are n yes/no biomedical questions, accuracy is defined in the following equation, where k is the number of correctly answered yes/no questions:

$$\text{Accuracy} = \frac{k}{n} \tag{2}$$

Table 1. The five batches of testing datasets of biomedical questions provided by BioASQ 2015 and the number of questions assigned to each type

Testing Datasets	Question Types				#Questions
	Yes/No	Factoid	List	Summary	
Batch 1	33	26	22	19	100
Batch 2	16	32	28	24	100
Batch 3	29	26	17	28	100
Batch 4	25	29	23	20	97
Batch 5	28	22	24	26	100

RESULTS AND DISCUSSION

Although yes/no answer generator has been widely investigated in open-domain QA, few approaches in the biomedical domain are currently able to answer yes/no questions. In this study, our goal was to develop an efficient yes/no answer generator in biomedical QA. Indeed, the decision on either the answers "yes" or "no" is based on the final sentiment-passages score provided by the SentiWordNet 3.0 lexical resource: "yes" for a positive final sentiment-passages score and "no" for a negative one. The assumption was that all passages are somehow related to the yes/no question and that computing sentiment scores of these passages could be used to distinguish between the two possible answers. Table 2 presents the experimental results of the proposed yes/no answer extraction method, as well as the comparison in terms of accuracy with the current state-of-the-art method presented in Neves (2015) on five batches of testing datasets, provided by the BioASQ challenge (Tsatsaronis et al., 2015). The proposed method achieves good performances compared with Neves's (2015) method.

Moreover, it can be seen clearly from Table 2 that in all batches of testing datasets, the proposed yes/no answer extraction method achieves performance improvements over the state-of-the-art method presented in (Neves, 2015). Compared with the latter, which employs the sentiment analysis predictions provided by the in-memory based database (IMDB) technology (Plattner, 2013), our method gives better results (an average improvement of 15.68% in terms of accuracy). Moreover, the increase performance is statistically significant (the p-value is < 0.00001, the result is significant at $p < 0.01$).

In summary, from the results and the analysis we can draw a conclusion that our proposed yes/no answer extraction method allows answering yes/no questions in biomedical QA with high accuracy. The high accuracy proves that our method is convincing, and successfully hunts out a large amount of the incorrect answers. As stated in Section 1, biomedical QA systems consist of three main steps, i.e., question analysis, document/passage retrieval and answer extraction. Indeed, each of these three steps has a significant impact on the overall performance of a biomedical QA system. Therefore, in addition to other components, the answer extraction module plays a vital role in QA systems since it is the final step which aims at retrieving the answers from the retrieved passages of a given biomedical question. Consequently, by improving the performance of answer extraction methods, the overall performance of biomedical QA systems will inevitably improve too.

Table 2. The overall results of the proposed yes/no answer extraction method and the comparison in terms of accuracy with the current state-of-the-art method on five batches of testing data provided by the BioASQ challenge

Models	Accuracy				
	Batch 1	Batch 2	Batch 3	Batch 4	Batch 5
Proposed method	**69.70%**	**62.50%**	**86.21%**	**76.00%**	**60.71%**
Neves (2015)	66.67%	56.25%	62.07%	56.00%	35.71%
Increase performance	+3.03%	+6.25%	+24.14%	+20.00	+25.00%

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Error Analysis

We performed error analysis to understand the source of errors in yes/no answer extraction. Indeed, we found that there are still some mistakes that the proposed yes/no answer extraction method cannot fix. An example is that, when the question is "Does HER2 under-expression lead to favorable response to trastuzumab?," a positive answer might be "Trastuzumab is a monoclonal antibody targeted to the Her2 receptor and approved for treatment of Her2 positive breast cancer," the sentiment score considers this answer to be a positive as there are both "positive" and "approved" in the passage. However, this example should be counted as a "no" answer because trastuzumab is effective only in cancers where Her2 is over-expressed. Dealing with such problems requires more complex semantic analysis, and we may need to parse the passage to get a grammar tree. Nevertheless, parsing and semantic analysis will bring in new errors and make this challenge even more complicated.

CONCLUSION

In this paper, we have proposed a novel yes/no answer generator which employs sentiment-word scores provided by SentiWordNet in biomedical QA systems. Our contributions can be summarized as follows: 1) for a given yes/no biomedical question, we have used the Stanford CoreNLP for tokenization and part-of-speech tagging all golden passages so as to extract a set of words and their POS tags; 2) we have assigned to each word a sentiment score based on the SentiWordNet lexical resource; 3) the decision for the answers, i.e., "yes" or "no" was based on the obtained sentiment-passages scores. Experiments conducted on BioASQ 2015 datasets have demonstrated the effectiveness of the proposed method. The evaluation results show that the proposed method can achieve 15.68% improvement over the current state-of-the-art method in terms of accuracy.

In future research, we intend to improve the proposed system in order to make it able to answer other question types, such as factoid, list, and summary questions, by exploring unified medical language system (UMLS) concepts and more sophisticated algorithms.

ACKNOWLEDGMENT

The authors would like to thank the BioASQ challenge (Tsatsaronis et al., 2015) organizers who provided the datasets used in this study for evaluating the proposed yes/no biomedical answer extraction method.

Chapter 6
Towards an Integrated Electronic Medical Records System for Quality Healthcare in Ghana:
An Exploratory Factor Analysis

ABSTRACT

This article explores the factors militating against the diffusion integration electronic medical records in Ghana. Structured questionnaires were used to collect data from respondents in the healthcare ecosystem and analyzed quantitatively using descriptive and inferential statistics. The findings revealed non-integration of electronic medical records systems among the stakeholders of the healthcare ecosystem mostly due to and interoperability issues. There is also substantial usage of technology in capturing and storing medical records. The key factors militating against the integration of electronic medical records systems are inadequate funds to purchase database management systems, acquisition and maintenance costs of electronic medical records systems, and an unclear return on investment on the integrated electronic medical records systems. The article recommends sustained government financial support, standardization policy and implementation guidelines to facilitate the integration of electronic medical records systems in the various health institutions.

INTRODUCTION

Electronic medical record (EMR) systems is a collection of tools, technologies and process used to create, gather and manage health-related information on an individual that can be consulted by authorized clinicians and staff within the healthcare organization (Tang, Ash, Bates, Overhage, & Sands, 2006). EMR systems are credited with substantial benefits to physicians, clinic practices, and healthcare organizations by facilitating workflow and improving the quality of patients' care and safety (healthit.ahrq.gov, 2015). When integrated among healthcare providers, EMR systems store patient clinical information electronically, enabling instant access to by all providers in the healthcare chain, thereby facilitating provision of coherent and consistent care (Albert & Manda, 2010).

An integrated electronic medical record (IEMR) is becoming the core of computerized healthcare systems. The electronic storage of clinical information creates the potential for computer-based tools to help clinicians significantly enhance the quality of medical care and increase the efficiency of medical practice (Acquah-Swanzy, 2015). These tools may include reminder systems that identify patients who are due for preventative care interventions, alerting systems that detect contraindications among prescribed medications and coding systems that facilitate the selection of correct billing codes for patient encounters (Kurtin, Harrison, Iraca, & Hassan, 2017).

Integrated electronic medical records (IEMR) systems has transformed healthcare worldwide. Some developed countries have built effective IEMR systems throughout the healthcare value chain based on established national standards (Hochheise & Shneiderman, 2011). However, this is not the case in Ghana where individual health institutions have adopted their own EMR systems resulting in interoperability problems and hindering information sharing among healthcare facilities (Acquah-Swanzy, 2015). The improvements in healthcare facilitated by integrated EMR systems has compelled many developing countries to explore its diffusion into their health care delivery systems. Ghana over the years has shown some level of commitments to implement EMR systems in the health care system as evidenced in the various policies and initiatives (MOH, 2005), (Boateng, 2009).

The Ghana Health Service is making effort to implement integrated EMR system through various health sector policies (Adjorlolo & Ellingsen, 2013). In spite of these policies, the extent of EMRS integration in the healthcare delivery system in Ghana leaves much to be desired. Various hospitals continue to use their own EMR systems run on different operating systems with different data and database management systems (Acquah-Swanzy, 2015). This study therefore aims at ascertaining the extent to which hospitals employ electronic medical records systems, examine the extent of EMRs systems integration and key factors influencing the effective deployment and integration of electronic medical records to improve healthcare delivery in Ghana.

INTEGRATED ELECTRONIC MEDICAL RECORDS IN HEALTHCARE

Integrated Electronic Medical Record (EMR) systems are becoming an essential fabric of modern healthcare. EMR systems have evolved from stand-alone single computer record-keeping to an integrated, enterprise-wide system that ensures real time access to accurate patient healthcare data (Wiliam & Michael, 2009). The ease of data retrieval with a click of mouse from integrated EMR systems and real-time access to patients' information by clinicians and other stakeholders result in efficiency gains and quality care delivery.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Integrated EMR systems also encourage collaboration within the healthcare system through dissemination of health information and sharing data in real-time among stakeholders in the healthcare delivery system. Integrated EMR system has the potential to reduce cost of healthcare delivery in terms of manpower required and savings from stationery thus improving efficiency (Hoque, Rakibul, & Golam, 2016).

Implementation of integrated electronic medical records systems has the potential to improve overall quality of care from both clinical, organizational perspectives. From clinical perspective, improvements in the quality of care, reduction in medical errors, and other improvements in patient-level measures have been evidenced in the deployment of integrated EMR systems. From organizational perspectives, improvements in financial and operational performance, satisfaction among patients and improved performance of clinicians are also well documented (Ashish, et al., 2009).

Enabling Environment for Electronic Medical Records Integration

A successful implementation of integrated electronic medical records systems requires certain enablers if the attributable benefits could be realized.

Availability of effective and efficient network connectivity is a critical enabler for successful implementation of integrated EMR systems. This would ensure that EMR system can link all stakeholders in the health care chain such as laboratories, imaging systems, pharmacies, hospitals and clinics. This would facilitate seamless exchange of patients' laboratory results, prescription and other clinical and personal information in an integrated healthcare environment (HealthIT.gov, 2014).

Appreciable levels of ICT competencies among personnel is also essential for the smooth implementation of integrated EMR system in a healthcare system (Khalifa, 2013). Healthcare personnel with exposure to ICT tools in their working environment are likely to be receptive and could easily adapt to an integrated EMR system environment. User resistance due to lack of ICT skills is known to limit the adoption of ICT innovations in organization (Price, 2013). The absence of existing competent users of computers would require further investments in ICT training to ensure successful implementation.

Positive attitude of staff toward the usage of integrated EMR systems is another important factor that could facilitate effective implementation and utilization. According to Moody et al, 2004, healthcare practitioners believe that EMR systems could result in a decreased workload. However, in spite of the positive effects of integrated EMR system usage in medical practices, the adoption rate is still low and often meets resistance from many stakeholders in healthcare especially clinical staff. The attitude of healthcare towards integrated EMR systems would depend on their prior exposure to such systems and the systems' characteristics such as ease with which the use of the system can learned, its user friendliness and availability of user support (Albert & Manda, 2010).

Cost and availability of funds for the acquisition of the required technological infrastructure could be another influential factor for the diffusion of integrated EMR systems (Khalifa, 2013). Various health institutions have made substantial efforts toward adoption and meaningful use of EMR system but are faced with financial challenges such as hardware, software, implementation, broadband internet connectivity and other equipment costs (Rihab & Helen, 2014). The dwindling government funding for such projects present significant challenges for effective diffusion on integrated electronic medical records systems.

Establishment and enforcement of policy, legal and regulatory framework are also critical to the success of integrated EMR systems. These policies, standards and regulatory frameworks would guide and ensure maintenance the privacy, security and confidentiality of patient data among all users, which are of utmost importance to both patience and clinicians (Albert & Manda, 2010). Various security measure,

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

standards and their compliance at every level of usage is paramount. This require security and systems training for all stakeholders with access to such integrated electronic medical records (HealthIT.gov, 2014).

Challenges of Integrating Electronic Medical Records Systems

Although there are significant evidence of individual healthcare facilities in Ghana adopting one form of electronic medical records or the other, they remain siloed in these institutions with low level of integration among departments in the same health institutions, among hospitals, clinics and among other institutions playing vital roles in the health delivery system such as laboratories and pharmacies (Acquah-Swanzy, 2015).

According to Kristiina et al., 2008, one of main factors militating against the integrating EMR systems is the issue of interoperability: Many different EMR projects do not take into account the need to ensure interoperability with other similar systems. This is often due to the absence of standardization of technologies and implementation platforms such as database management systems and operating systems to be used. A further challenge is the use different in terminologies making interoperability difficult (Ashish et al., 2009)

There also the problem of health institutions using different systems and software, whilst some are using desktop application, others may be using web-based applications or mobile applications. This makes information and health record sharing nearly impossible.

The low levels of adoption of electronic health records in health institutions suggest that policymakers face substantial obstacles to the achievement of healthcare performance goals that depend on health information technology (Faustine & Suzanne, 2008). A policy strategy focused on financial support, interoperability, and training of technical support staff may be necessary to spur the integration of EMR systems (Khalifa, 2013).

Policy Frameworks for Integrated Electronic Medical Records System in Ghana

In Ghanaian, the ministry of health has developed a number of policy frameworks to facility the integration of ICT into the health delivery systems (see Figure 1). Prominent among these policies is the five year programme (2002 to 2006) which had the objectives to improve overall health status and reduce inequalities in the health outcome of people living in Ghana through the use of ICT (Afagbedzi, Obuobi, Aryeetey, & Bosomprah, 2013). The government of Ghana's information and communication technology policy document for accelerated development (ICT4AD) states among others, that, ICT would be utilized to promote national health. The national health ICT policy thus provides the strategic roadmap to deploy an integrated EMR systems to improve the quality of healthcare outcomes. The policies aimed at improving the information and communication technology infrastructure in the health sector by networking all health institutions and providing adequate ICT tools for service delivery and management (MOH, 2005).

The Conceptual Framework for the Study

A conceptual model (Figure 2) based on Technology- Organizational- Environmental framework (Tornatzky & Fleischer, 1990) for innovative technology diffusion is proposed for the study. Using the available literature on the electronic medical records diffusion and integration in healthcare institutions,

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. Healthcare ecosystem in Ghana

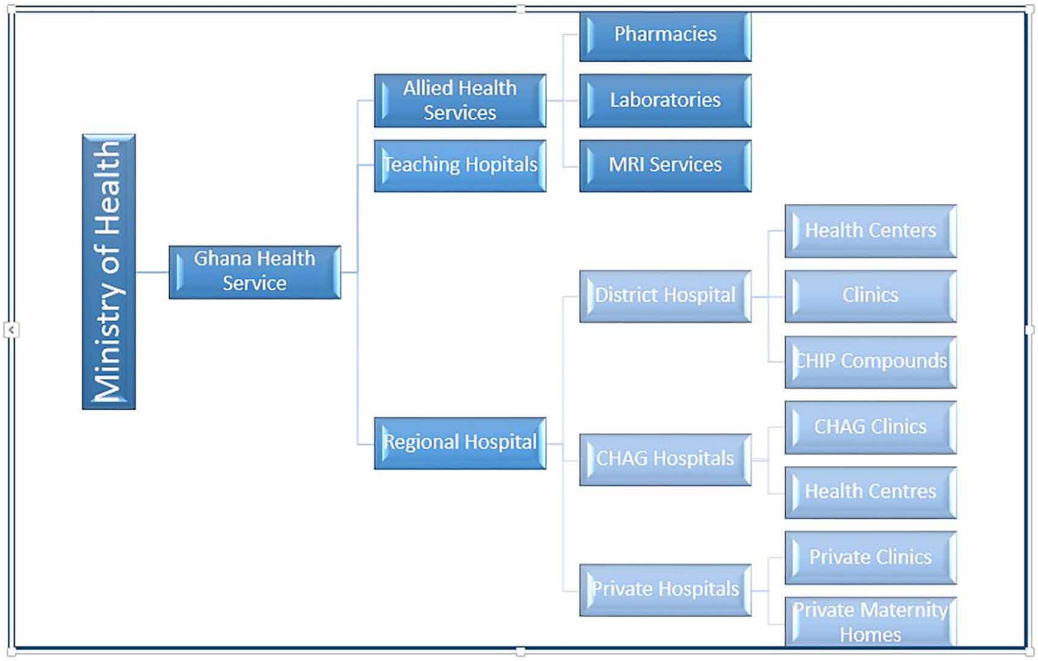

Figure 2. Conceptual model adapted from (Tornatzky & Fleischer, 1990) (Agarwal & Prasad, 1997)

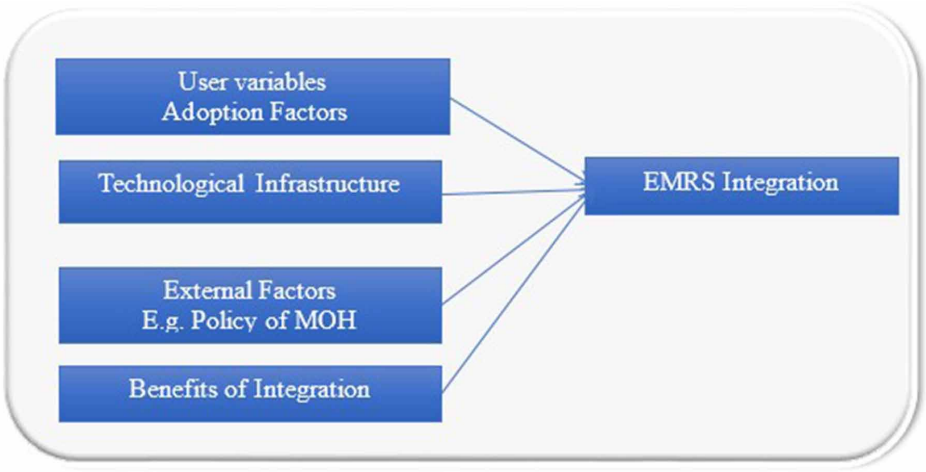

the conceptual framework identified and categorized various factors that could potentially influence the integration of electronic medical records in Ghana.

The study thus, categorizes these main factors into four criterion variables namely, User variables, Existence of Technological Infrastructure, External Factors and Integration Benefits. There are evidences from various studies indication a correlation between these variables and effective integration of electronic medical records for effective healthcare delivery.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

User Variables

These are the various factors relating to healthcare professionals and their demographic characteristics. The variables include the level of the end users' practical knowledge in computer usage which is measure by their level of skill in computing. This categorized them into basic, intermediate, advance and proficiency levels in computing skills (Abell, Bragg-Underwood, Alexander, Abell, & Burd, 2015):

1. The Basic level denotes users are able to use the computer for typing and use of office applications;
2. Intermediate level denotes users who can make use of the internet for sending e-mails and research activities as well as share files;
3. Advanced level denotes user who are able to use or quickly adapt to the use of both web-based and desktop database applications;
4. Proficiency level: Users at this level are able to combine all the skills above their daily activities (Beiter, Sorscher, Henderson, & Talen, 2008).

Technological Infrastructure

Technological infrastructure combines the both hardware and software required for the effective deployment and utilization of integrated ERM systems. These include includes client computer systems, printers, backup drives, servers, uninterrupted power supply (UPS). Availability of network resources which includes the Internet access, switches. Availability of software systems which includes the server operating system, client operating system, application software and database management systems (Hoque, Rakibul, & Golam, 2016).

External Factors

These comprise laws, policies and regulations of the Ministry of Health to support and facilitate the integration of EMR systems (Gilad, 2011). The government of Ghana's information and communication technology policy document for Accelerated Development has stated that, ICT should be utilized to promote national health in order to formulate strategic roadmap to achieve the vision and goal of national health ICT policy. These policies improve the information and communication technology infrastructure in the health sector by networking all health institutions and by providing adequate ICT tools for service delivery and management ((MOH, 2005).

Perceived Benefits of Integrated ERM System

Integrated Electronic Medical Record (EMR) systems are becoming an essential part of the fabric of modern healthcare. EMR systems have evolved from pure record-keeping to an integrated, enterprise-wide system that holds the promise of accurate, real time access to patient healthcare data (Wiliam & Michael, 2009). It is believed stakeholders appreciation of the potential benefits of integration would also facilitate acceptance of the integration (Wang, et al., 2003).

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

This assesses the stakeholders' perceptions on the important role of integrated EMR systems in the provision of quality healthcare such as data quality, information sharing among healthcare institutions, easy retrieval of patient information in order to ensure continuity of care, avoidance of prescription errors and cost savings in healthcare provisioning (Nguyen, Bellucci, & Nguyen, 2014).

METHODOLOGY

The study adopted exploratory cross-sectional study designed. Cross sectional study make inference by basing on the overall findings to generalize for the entire population (Creswell, 2009). Purposive sampling was used to collect data from the targeted 200 health information officers and managers of healthcare institutions and managers across the country through both paper-based questionnaire and email. Quantitative method was used with the variables assigned numeric values on a Likert scale (Neuman, 2007). Permission was sought from the various hospital administrators before the questionnaires were administered. Respondents were assured that all information provided were for academic purpose and would be handled confidentially.

DATA ANALYSIS AND PRESENTATION

The data analyses was carried out with Statistical Package for Social Sciences (SPSS version 21) using both descriptive and inferential statistics. Factor analysis was done to find out the influential factors influencing the integration of EMR Systems in Ghana. Out of the 200 questionnaire administered, 150 responses were received and analysed quantitatively using descriptive and inferential statistics.

Demographics of the Respondents

Table 1 presents the demographic characteristics of the respondents of the research. Out of 150 respondents, 51.3% were between the ages of 18-29 years, 40.7% between 30-39 years, and 8% were 40 years and above.

The gender distribution of respondents shows 52.7% males and 47.3% females.

With respect to educational background of the respondents, 53.3% had the Certificate, Diploma and HND qualification, 38.0% Degree, 4.7% SHS and A&O Level, 2.0% basic education, 2.0% also indicated others.

In terms of positions, 32.7% were Records and Health information officers, 21.3% Physicians and Physician Assistants, 25.0% were managers and administrators whilst Laboratory technicians made up 10.7% and 10.3% were pharmacist and pharmacy assistants.

Computer Usage Proficiency

To assess the user variables, the level of computer literacy among the respondents and their exposure electronic medical records in their institutions were assessed. The responses and the analyses are presented in Table 2.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 1. Demographics of the respondents

Variable	Frequency	Percent
18-29	77	51.3
30-39	61	40.7
40 and above	12	8.0
Total	150	100.0
Variable	**Frequency**	**Percent**
Male	79	52.7
Female	71	47.3
Variable	**Frequency**	**Percent**
Basic Level Education	3	2.0
Secondary/ High School Education	7	4.7
Diploma and HND	80	53.3
Degree	57	38.0
Post Graduate	3	2.0
Variable	**Frequency**	**Percent**
Records and Health information officers	49	32.7
Physicians/Assistants	32	21.3
Managers/Administrators	38	25.3
Lab technicians	16	10.7
Pharmacist/Assistants	15	10.0
Total	150	100.0

Table 2. Level of computer literacy

Variable	Frequency	Percent
Basic	20	13.3
Intermediate	27	18.0
Advanced	22	14.7
Proficiency	81	54.0
Total	150	100.0

Out of the 150 respondents, 20, making 13.3% have basic computer knowledge such working with office applications, 27, 18% have intermediate knowledge such as using emails, 22, 14.7% have advanced knowledge including manipulating data in excel and a greater majority, 81 making up 54.0% are proficient computer users indicating their work schedule requires the use of computers.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Existence of EMR Systems in the Facilities

The Tables 3 and 4 presents the means and the type of data collected and how data is shared in the respondents' facilities. The extent of the use of computers in data collection and sharing data electronically would indicate that the respondents are exposed to the operations of EMR Systems. This would facilitate easy diffusion and acceptance of intergraded ERM system if it is made available.

The responses analysed in Table 3 shows that majority representing 48% capture data both manually and electronically, electronic only was 38.0%, and manual only was 14%. This is an indication that majority of the health care facilities are conversant with electronic medical recording systems. However, 14% still using manual systems in on the high side.

Table 4 presents the analysis of the extent of data sharing practices of the health institutions surveyed. Manual data sharing had a mean score of 3.09 with a standard deviation of 1.400. Data shared electronically has mean scores of 3.24 with a standard deviation of 1.432. Data stored centrally on servers had a mean score of 3.51 with 1.24 standard deviation. Whereas easy access to patients' data had a mean score of 3.99 with standard deviation of 1.033. The generally high standard deviations mean that the values in the responses from the respondents are farther away from the mean score (Rumsey, 2016).

Perception of the Potential Benefits of Electronic Records System

Tables 5 presents respondents' perceptions of the potential benefits of integrated electronic medical records, the study sort to find out the extent to which electronic medical records system could benefit their healthcare facilities and improve the quality of healthcare delivery.

First, perception of the respondent on the effect of integrated EMR systems on quality of healthcare data was ascertained using the characteristics data quality (Raghupathi & Raghupathi, 2014).

Table 3. Means of data capture in health institutions

Variable	Frequency	Percent
Only manual	21	14
Only electronic	57	38.0
Both	72	48.0
Total	150	100.0

Table 4. Data sharing within the facilities

Variable	N	Mean	Std. Deviation
Data Manually Shared	150	3.09	1.400
Data Electronically Shared	150	3.24	1.432
Data Stored Centrally on Servers	150	3.51	1.241
Data Stored on Individual Department	150	3.99	1.033
Valid N (listwise)	150		

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 5. Perceived benefits of electronic medical record systems

Variable	N	Mean	Std. Deviation
Timely data for decision making	150	3.83	.995
Provision of Accurate data	150	3.53	1.001
Generates Consistent Data	150	3.71	1.007
Generates Complete data	150	3.92	.855
Improvement in communication	150	3.70	.857
Facilitates workflow	150	3.79	.966
Ensures patient safety	150	3.79	1.019
Patient access to data	150	3.09	1.300
Patient waiting time has reduced	150	3.26	1.178
Improve diagnosis and outcome	150	3.69	.941

Table 5 presents the analysis of the responses on perception of the respondents of the effect of integrated EMR systems on data quality for the healthcare delivery. Provision of timely data for decision making had mean score of 3.83 with a standard deviation of 0.995. Generate complete and comprehensive data had a mean score of 3.92 with a standard deviation of 0.855. The provision of consistent data to support health delivery had a mean score of 3.71 with a standard deviation of 1.007. Whilst provision of accurate data to improve diagnoses has a mean score of 3.53 with a standard deviation of 1.007.

Integrated EMR systems improve communication among staff in healthcare facilities had a mean 3.70 with a standard deviation of 0.857. Integrated EMR systems facilitate workflow had a mean score of 3.79 with a standard deviation of 0.966. Patients' access to their health records is encouraged by the EMRs had a mean score 3.09 with a standard deviation of 1.300. Improve diagnose and outcome of condition with a mean score of 3.69 with standard deviation of 0.941, reduction in patients' waiting times had a mean score 3.29 with 1.178 standard deviation, whilst ensuring patients' safety had a mean score of 3.79 with 1.019 standard deviation. Again, the generally high standard deviations mean that the values in the responses from the respondents are farther away from the mean score.

The Extent Integration of EMR Systems

The study south to establish the extent of inter-connectivity among the healthcare facilities to facilitate effective exchange of patients' information. The analysis of the result is presented in Table 6.

From Table 6, the Facilities connecting other facilities had a mean score of 2.53 with a standard deviation of 1.35. Sharing health records facilitate exchange information with other health care facilities had a mean score of 2.52 with a standard deviation of 1.422. Sharing the same EMRS with other facilities had a mean score of 2.57 with standard deviation of 1.051. Able to access the health record of patients' facilities using different system had mean 2.52 with a standard deviation of 1.273. Connecting to other facilities through the internet had a mean score of 2.21 with a standard deviation of 1.244, Connecting through Virtual Private Network had a mean score of 2.44 with a standard deviation of 1.234 whilst Facility used web-based electronic records management had a mean score of 2.91 with a standard deviation of 1.274.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 6. The extent of integration of EMR systems

Variables	N	Mean	Std. Deviation
EMRS connects to other facilities	150	2.53	1.354
Sharing Health Records with other facilities	150	2.52	1.422
Share EMRS with other Facilities	150	2.57	1.051
Access patients' records on different system	150	2.52	1.273
Connected to other facility via Internet	150	2.21	1.244
Connected to other facility via VPN	150	2.44	1.234
Uses web-based EMRS	150	2.91	1.274
Valid N (listwise)	150		

Factors Affecting Integration of Electronic Medical Record Systems

To determine the factors affecting the integration and utilization of integrated electronic medical record (EMR) system in the health facilities, the respondents were made to rate the various problems identified from previous studies as to the extent to which the factors affect the diffusion of integrated EMR systems. The responses are analysed in Table 7.

Inadequate capital for the purchase of database is agreed since the mean 3.58 with a standard deviation of 1.271. The cost of acquisition and maintenance of EMR is one of the factors influencing the integration of electronic medical records (EMR) systems since the mean 3.57 with a standard deviation of 1.077. Unavailability of staff with adequate expertise in information technology is agreed since the mean 3.25 with a standard deviation of 1.357. Unclear return on investment on EMRs is agreed since the mean 3.31with a standard deviation of 1.216.

Table 7. Factor affecting EMR systems' integration

	N	Mean	Std. Deviation
Funds for Hardware Acquisition	150	3.58	1.271
Applications and Maintenance costs	150	3.57	1.077
Unclear Return on Investment	150	3.31	1.216
Availability of ICT expertise	150	3.25	1.357
Usage of different systems and different platform	150	3.59	1.124
Absence of Standards	150	3.65	1.135
Lack of interoperability with systems in other facilities	150	3.45	1.308
Resistance of physicians and health workers	150	3.35	1.337
Lack of government policies for integrated EMRS	150	3.77	1.172
Security and privacy concerns of patient's information	150	3.97	1.074
Patients' rights on the release of their information	150	3.89	1.267
Lack of Enforcement Data Protection laws	150	4.21	.992
Valid N (listwise)	150

A Principal Component Analysis of the Influential Factors

Principal components analysis is a method of data reduction. Interpretation of the principal components analysis helps in determining which of the identified variables are most strongly correlated with the determinant variable. The variables with total coefficient farthest from zero in either positive or negative direction in the initial Eigenvalues is considered the most influential factors. Which numbers are considered to be large or small is a subjective decision. There is the need to determine at what level the correlation value will be of importance. In this study, any factor with an initial Eigenvalues above 0.5 is deemed important (Liwicki, Tzimiropoulos, Zafeiriou, & Pantic, 2013).

From Table 8, out of the 12 components, only seven factors were found to have significant influence on the diffusion of Integrated EMR systems in Ghana. These are inadequate capital (4.493), Maintenance of database (2.149); Unclear return on investment (1.338), Unavailability of staff with adequate expertise (1.014), Usage of different systems (.633), absence of standards (.621) and lack of interoperability with initial Eigen value more than 0.5. In factor analysis, if the initial Eigen value is more than 1, it means that, that variable is very significant. This means that, these four components constitute about 75% which gives a clue of the significances of the four factors whiles the rest of the components constitute 25%.

DISCUSSION OF RESULTS, FINDINGS AND CONCLUSION

This study was carried out to analyses the factors influencing the integration of EMRs in the healthcare delivery systems in Ghana. The study identified four key categories of variables that could influence successful diffusion on integrated Electronic Medical Records Systems in Ghana namely User Variables,

Table 8. Principal component analysis of factors

Component	Initial Eigenvalues			Extraction Sums of Squared Loadings			Rotation Sums of Squared Loadings		
	Total	% of Variance	Cumulative %	Total	% of Variance	Cumulative %	Total	% of Variance	Cumulative %
1	4.493	37.442	37.442	4.493	37.442	37.442	3.185	26.545	26.545
2	2.149	17.909	55.351	2.149	17.909	55.351	2.252	18.768	45.314
3	1.338	11.150	66.501	1.338	11.150	66.501	1.816	15.131	60.445
4	1.014	8.450	74.951	1.014	8.450	74.951	1.741	14.506	74.951
5	.633	5.273	80.223						
6	.621	5.176	85.400						
7	.525	4.379	89.779						
8	.416	3.466	93.244						
9	.310	2.582	95.827						
10	.225	1.872	97.699						
11	.160	1.332	99.031						
12	.116	.969	100.000						

Extraction Method: Principal Component Analysis.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Technological Infrastructure, External factors and Benefits of Integration. These factors were studied from the institutional perspectives.

User Variables

Socio-demographic characteristics obtained from the health institutions surveyed indicate that the health facilities employee ad relatively younger majority of whom possess tertiary academic qualification. This indicate youthful group who are easily adaptable to modern ICT platforms in their work environment. This highly educated workforce would make diffusion of any technological innovation in the healthcare delivery systems potentially successful (Marcelo, da Silva & do Amaral Moretti., 2014).

The level of computer literacy among the staff of the institution surveyed was very high with majority indicating they are proficient users. This would have positive influence on the deployment of Integrated Electronic Medical records systems for Healthcare in Ghana. This confirms (Fustian & Suzanne, 2008) which found the successful adoption of EMRS is influenced by well-educated human resource and youthful computer literate workforce.

Technological Variables: Existence EMR Infrastructure

In spite of the computer proficiency of the staff, data collection and data sharing are predominantly manual operations in the institutions with very minimal electronic data sharing in the institutions among various institutions in the healthcare ecosystem. There is average technological infrastructure that could facilitate integrations of EMR systems in the predominantly urban based healthcare facilities, whereas the rural facilities lack such infrastructure. There is low level interoperability of electronic medical record among departments of the same health institutions and among individual institutions. The electronic health records systems used in various health institutions differ. All these would negatively influence the integration of EMRS. However, the availability of networks and internet connectivity found in various institutions can positively influence the diffusion of integrated EMS.

Perceived Benefits of EMR Systems

The knowledge of the respondents of the various benefits of Integrated Medical records was significantly high. Among the benefits identified are provision of timely data for decision making, provision of accurate and timely data among the benefits. The knowledge of these potential benefits would have positive influence on the acceptance and use of integrated medical records once implemented.

The Institutional and External Variables

Out of the twelve institutional and external factors identified as influencing the integration of EMR, seven of them were statistically influential on the diffusion of integration of Electronic medical records (EMR) systems in Ghana. These are, inadequate capital for acquisition hardware required for diffusion of integrated EMR system, the cost applications and maintenance of EMR systems, unclear return on investment of the integrated EMR systems and unavailability of staff with adequate and requisite expertise to implement and manage EMR systems in the healthcare facilities, lack of standards, lack of interoperability of different systems currently in use in the healthcare institutions.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Government policy and support will therefore be crucial in the acquisition and successful diffusion of EMR systems in the healthcare delivery systems in Ghana.

CONCLUSION

The findings of the study points to favorable condition for the diffusion of integrated electronic medical records (EMR) system in the healthcare delivery system in Ghana. However, the absence of enforceable policy by government, the cost of acquisition and maintenance of the systems as well as non-availability of technically skilled manpower in the healthcare institutions are seen as the predominant challenges.

It is therefore recommended that there should be a policy direction for the implementation of integrated electronic medical records in the country to ensure standardization of application, hardware and platforms to be used by all health care delivery. This would ensure interoperability among healthcare institutions in the country. Given the potential benefits identified, government should provide funding for nationwide mandatory diffusion of Integrated EMS throughout the healthcare delivery system in Ghana. This would reduce the burden of cost on the facilities and also ensure availability of technical staff to ensure smooth operation of the systems in Ghana.

Chapter 7
SOA Governance in Healthcare: Beyond Early Ideas to a Structured Framework

Konstantinos Koumaditis
University of Piraeus, Greece, & Aarhus University, Denmark

Marinos Themistocleous
University of Piraeus, Greece & University of Coimbra, Portugal

ABSTRACT

This chapter depicts the gradual development of a conceptual SOA Governance Framework tailored for healthcare organisations. The proposed framework presented herein is based on the authors' previous research and includes nine SOA Governance elements that need to be considered during the SOA process. The identification and conceptualisation of the elements were grounded in the normative literature and further developed to include healthcare specific aspects. This comes as a method to overcome the limitations identified in normative literature and enhance the elements' conceptualisation. Besides, the authors propose a unique design combining nine elements of SOA Governance with SOA Critical Success Factors (CSFs) and Healthcare Information Systems (HIS) challenges. This proposal aims to pinpoint attributes and guidelines for each element, required to successfully govern SOA and tackle longstanding HIS challenges. The framework is intended to be used as a decision supporting tool for SOA Governance in a healthcare setting.

INTRODUCTION

Economic conditions demand that Healthcare Information Technologies (HIS) deliver ever more business value. Today, HIS play a more and more important role in the provision of healthcare. The scope and complexity of HIS projects has increased, requiring excellent project management to fully realize the benefits of such an investment. Unfortunately, healthcare projects are associated with considerable failure rates or having significant cost or budget overruns (Kaplan & Harris-Salamone, 2009). Both re-

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

search and anecdotal evidence suggests that many HIS projects struggle to meet functionality and quality targets. Research has identified multiple reasons for these challenges in HIS projects, such as: project escalation, poor risk management, failure to manage user expectations, poor software development or project management processes, or inability to learn from past mistakes and successes (Dwivedi et al., 2013; Lunt et al., 2011). Yet, integrated technologies that have been employed by healthcare organisations, to tackle these challenges, have not shown great levels of adoption due to their barriers, like: (a) high costs, (b) resistance to change, (c) organisational issues, (d) high complexity, (e) large scale of change, (f) time consuming implementation and (g) politics.

Consequently, the necessity for integrated HIS in a safer, interoperable and more manageable environment motivated organizations to consider the adoption of paradigms, such as SOA. SOA can be beneficial for a healthcare organisation as it provides interoperability and integration of the legacy HIS, attributes need in modern healthcare organisations.

Nevertheless, despite SOA benefits Heffner (2009) indicates that, 41% of SOA users in the Global 2000 firms believe that: (a) SOA has delivered less benefit than expected, (b) 17% claim they face problems and (c) will not expand SOA use. This reveals that even though SOA is considered a valuable architectural paradigm its application, efficiency and performance are affected by various factors. These statistics indicate that almost half the companies that implement SOA have not figured out how to benefit from their projects. This is attributed to unclear or weak governance planning (Stephens, 2008). In a recent research on the global status of IT governance standards and models (like COBIT, ITIL/ISO20000 etc.) the findings reveal a tendency to adopt such frameworks, but also a lack of a clear "winner" amongst them. For example, amongst 834 business executives, from 21 countries and 10 industries reveal that ISO20000 or ITIL is referred in 28% of them, while COBIT in 12% (ITGI., 2011). Yet, out of the 839 respondents only 10% have been healthcare executives, thus the percentages drop lower regarding their focus on IT governance in healthcare.

In an attempt to study this issue, we focused on SOA CSFs in healthcare, like: (a) alignment of SOA, organization, human and legal aspects, (b) clear goals set from the beginning of the endeavour, (c) complexity introduced to the system, (d) cost, funding and sponsoring the SOA project, (e) SOA culture that can create support and communication between the stakeholders, (f) experience, skills and training of the employees, (g) governance plan to provide compliance and check services concerning capability, security and strategic business alignment, (h) long-term planning to include reusable services that fit future business, (i) adequate measurement of the compliance and performance, (j) maturity identification and progress of the organization in aspects as IT, organization etc., (k) identification of the right candidate projects/pilots, (l) security risks (data confidentiality, access control), (m) detailed roadmap, (n) adequate standards (e.g. XML, WSDl, REST, HL7 etc.), (o) a team with understanding and experience in change management and clear vision of SOA, and (p) testing of the services and impact (Koumaditis, Themistocleous, Mantzana, & Souliotis, 2012).

The outcome of the review, demonstrates that the most frequently reported CSF in the cases reviewed is SOA Governance. In a nutshell, they report that SOA implementations require governance mechanisms to excel, otherwise the architecture will end up complex, uncontrolled, brittle and eventually discarded (Marks, 2008). A failure in a healthcare organisation's IT infrastructure is not an option as the literature is full of cases where healthcare IT failures cost patients' lives (Fitzgerald & Russo, 2005; Johnson, 2011; Kaplan & Harris-Salamone, 2009). This motivates us to study SOA Governance in healthcare.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

SOA Governance is a research area with many issues (e.g. scope, model, associations) uncharted. In an attempt to fill this literature void, in a previous publication we introduced a set of SOA Governance issues that we were asked to revisit and provide a more structured and detailed approach in this publication (Koumaditis, Themistocleous, & Morabito, 2013). In doing so, resulting in the development of a framework that can be used to support decision-making on SOA Governance issues.

The remaining of the chapter is structured as follows Section 2 presents the HIS need for integration, Section 3 the SOA Governance literature review, Section 4 the SOA Governance Framework in healthcare, Section 5 the research methodology, Section 6 the discussion and Section 7 conclusions and future research agenda.

HEALTHCARE INFORMATION SYSTEMS: NEED FOR INTEGRATION

Healthcare delivery is a complex practice which uses different devices and machines for performing tests, monitoring patients and completing tasks, spread across many organisations, surgery rooms, patients' wards, and medical labs. All these devices need specific vendor based interfaces to communicate with computers. These interfaces are implemented based on specific protocols and much often there is a lack of integration amongst them or an increased cost to integrate them (Rhoads, Cooper, Fuchs, Schluter, & Zambuto, 2010).

Independent initiatives like: (a) Integrating the Healthcare Enterprise (IHE) and (b) Meaningful Use provide standards (e.g. HL7, DICOM, etc.) and guidelines (e.g. EHR) to enhance the interoperability and information sharing among healthcare organisations (HealthIT, 2014; IHE, 2012). An enabler of these standards is the SOA paradigm. An example of this is the recognized Healthcare Services Specification Program (HSSP) program, which is a collaborative effort between standards groups HL7 and OMG to address interoperability challenges within the healthcare sector, operating on SOA (HSSP, 2013). Additionally, HSSP's working groups emphasise on the need of an effective SOA Governance model, which they portray as a critical dimension to SOA implementations, as it becomes the guidance, the oversight, the enforcement, and ultimately the compliance mechanism needed for SOA (HL7/OMG, 2010).

Additionally, HIS integration has been associated with various aspects, amongst others: strategic, social, and/or organisational (Finnegan & Hamid, 2009). In this regard, there is a common tendency to address HIS integration by an overall approach, seen as integrated patient centered care (Leventhal, Taliaferro, Wong, Hughes, & Mun, 2012). Integrated patient centered care reflects on integrated HIS (with elements as e-health services) requiring coordination across professionals, facilities, support systems that is continuous over time and between patient visits (Singer et al., 2011). This approach is observed on national healthcare strategies that encourage patient involvement in their healthcare treatment. Moreover, in the USA and Europe, online personal health records that allow patients to manage their health data have emerged (Black et al., 2011).

For example in Finland, this integration trend can be observed in a legislation that allows citizens to access and interact with their own Electronic Healthcare Records (EHRs), ePrescriptions and auditlogs via the Internet (Ruotsalainen, Iivari, & Doupi, 2008). Following similar legislative opportunities worldwide, patients increase their involvement with HIS. This is a growing involvement, seen in parallel with mechanisms for the collection of information (obtained by mobile and other sources) in order to develop an enhanced, complete and integrated view of citizens health status. The latter is reflected in Electronic Health Records (EHRs) and Personal Health Records (PHRs), which are being enriched

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

*and exploited by different actors and stakeholders (i.e. health and care professionals, citizens, nutrition experts, hospitals, etc) in the health ecosystem. Three general PHR models have been proposed (Detmer, Bloomrosen, Raymond, & Tang, 2008): a) the stand-alone model, b) Electronic Health Record (EHR) system, and c) the integrated one, which is an interoperable system providing linkage with a variety of patient information sources such as EHRs, home diagnostics, insurance claims etc. The main types of health information supported by PHRs are problem lists, procedures, major illnesses, provider lists, allergy data, home-monitored data, family history, social history and lifestyle, immunizations, medications and laboratory tests (Halamka, Mandl, & Tang, 2008; Tang, Ash, Bates, Overhage, & Sands, 2006). Widely known PHR platforms in terms of centralized web-based portals include Dossia (*www.dossia.org*) and Microsoft Health Vault (*www.healthvault.com/*) platforms. Many systems presented in literature offer integration with already established PHRs platforms (Reti, Feldman, & Safran, 2009; Zhou, Yang, Álamo, Wong, & Chang, 2010). Early experiences from the adoption of PHR-based systems have been found to be positive, showing that such systems can be feasible, secure, and well accepted by patients (Jennett & Watanabe, 2006). Nonetheless, today's EHRs and PHRs are far from being what the citizens consider as of value to their health, since for the public view, health means more than being disease-free.*

Following this trend for patients' empowerment, academics, practitioners and patients advocate in favor of the patient centered healthcare systems. Still the aforementioned advocates have not yet reached a concise definition of Patient-Centered e-Health (PCEH) that is shared across the research disciplines that focus on health and Information Technology (IT) (Wilson & Strong, 2014). The lack of consensus can be attributed, amongst other, (a) on the number of challenges that are involved in transitioning healthcare delivery to a more patient-centered system and (b) the lack of proof-of-concept through well-documented and effective PCEH projects.

Many of these applications are based on SOA as HIS can be easily delivered to both desktop and mobile computer devices using for instance Java and Visual Studio development environments. Mobile technologies and especially smart phones support patients and professionals to interact with integrated EHR and other e-health applications. This is an emerging area of e-health, given the term m-health (Chatterjee, Chakraborty, Sarker, Sarker, & Lau, 2009). Sarasohn-Kan (2010) report that a major mobile application vendor provides 5,805 health, medical and fitness applications with 73% of them used by patients and 27% by healthcare professionals (Sarasohn-Kahn, 2010). The aforementioned approaches empower the patients and allows them to take their own measurements, and provide verbal and written inputs (Clemensen, Rasmussen, Denning, & Craggs, 2011).

Clearly, except the introduction of standards (e.g. HL7) all these endevours require adequate healthcare specific SOA Governance to be developed and run in a manageable way. SOA can facilitate the plan to redesign HIS towards patient-centred systems in parallel to end-to-end integration (Bhandari & Snowdon, 2011; Leventhal et al., 2012; Papakonstantinou, Malamateniou, & Vassilacopoulos, 2010). Moreover, Business Process Management (BPM) techniques and tools bridges SOA and aligns business processes (based on patient needs) to end-to-end integration (Koufi, Malamateniou, Papakonstantinou, & Vassilacopoulos, 2010; Strnadl, 2007). Thus, SOA can transform heterogeneous and incompatible systems in a patient-centred environment of cooperating services based on healthcare business processes and services (Bhandari & Snowdon, 2011). SOA can be directly associated with patient centred design, as sub-categories of SOA like User-Centred SOA (UCSOA) can facilitate the redesign of HIS towards a patient centred design including support for the end user (e.g. patient) (Chang, He, Tsai, Xiao, & Chen, 2006; Lizcano, Soriano, Reyes, & Hierro, 2009). Furthermore, SOA can assist in the m-health endeavors by providing interoperable services, support diverse processing efficiently, enable cross-platform

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

communication and adapt dynamically to meet changing needs (Firat, Moser, & Melliar-Smith, 2008; Themistocleous, Azab, Kamal, Ali, & Morabito, 2012). In addition to this, SOA interoperability can be seen as a way to minimise medical errors, by providing data exchange accurately, effectively, securely and consistently (Mantzana, Koumaditis, & Themistocleous, 2011).

The value of SOA can be realised from a management point of view, when SOA incorporates a well-developed SOA Governance framework (Biske, 2008). This way, SOA Governance ensures an organisation is (a) pursuing an appropriate SOA strategy aligned with business goals, and (b) is executing that strategy in accordance with guidelines and constraints defined by a body of SOA principles and policies (Marks, 2008). By focusing on SOA Governance healthcare organisations can better address issues like complexity, security, standards, education/training and even provide the backbone for more capabilities like cloud computing. In the following section the authors address SOA Governance.

SOA GOVERNANCE LITERATURE REVIEW

Literature indicates that literature reviews especially when addressing a new area of research (e.g. SOA Governance) is required to be rigorous and comprehensibly described (Levy & Ellis, 2006). Only then can readers assess the exhaustiveness of the review and other scholars in the field can more confidently (re)use the results in their own research (vom Brocke et al., 2009). Following this view we proceeded to a rigorous review of the normative literature (Koumaditis & Themistocleous, 2013) which resulted in the creation of a SOA Governance concept map, as seen in Figure 1. Due to limited space, the authors will not proceed to analyse the concept map for this publication, but in the following paragraph briefly discuss its use.

The SOA Governance concept map provides not only a graphical representation of the main concepts, but aids in the discussion of the similarities (common elements), differences (scale, detail and analysis) and limitations (confusion, overlapping, and lack of testing and healthcare aspects).

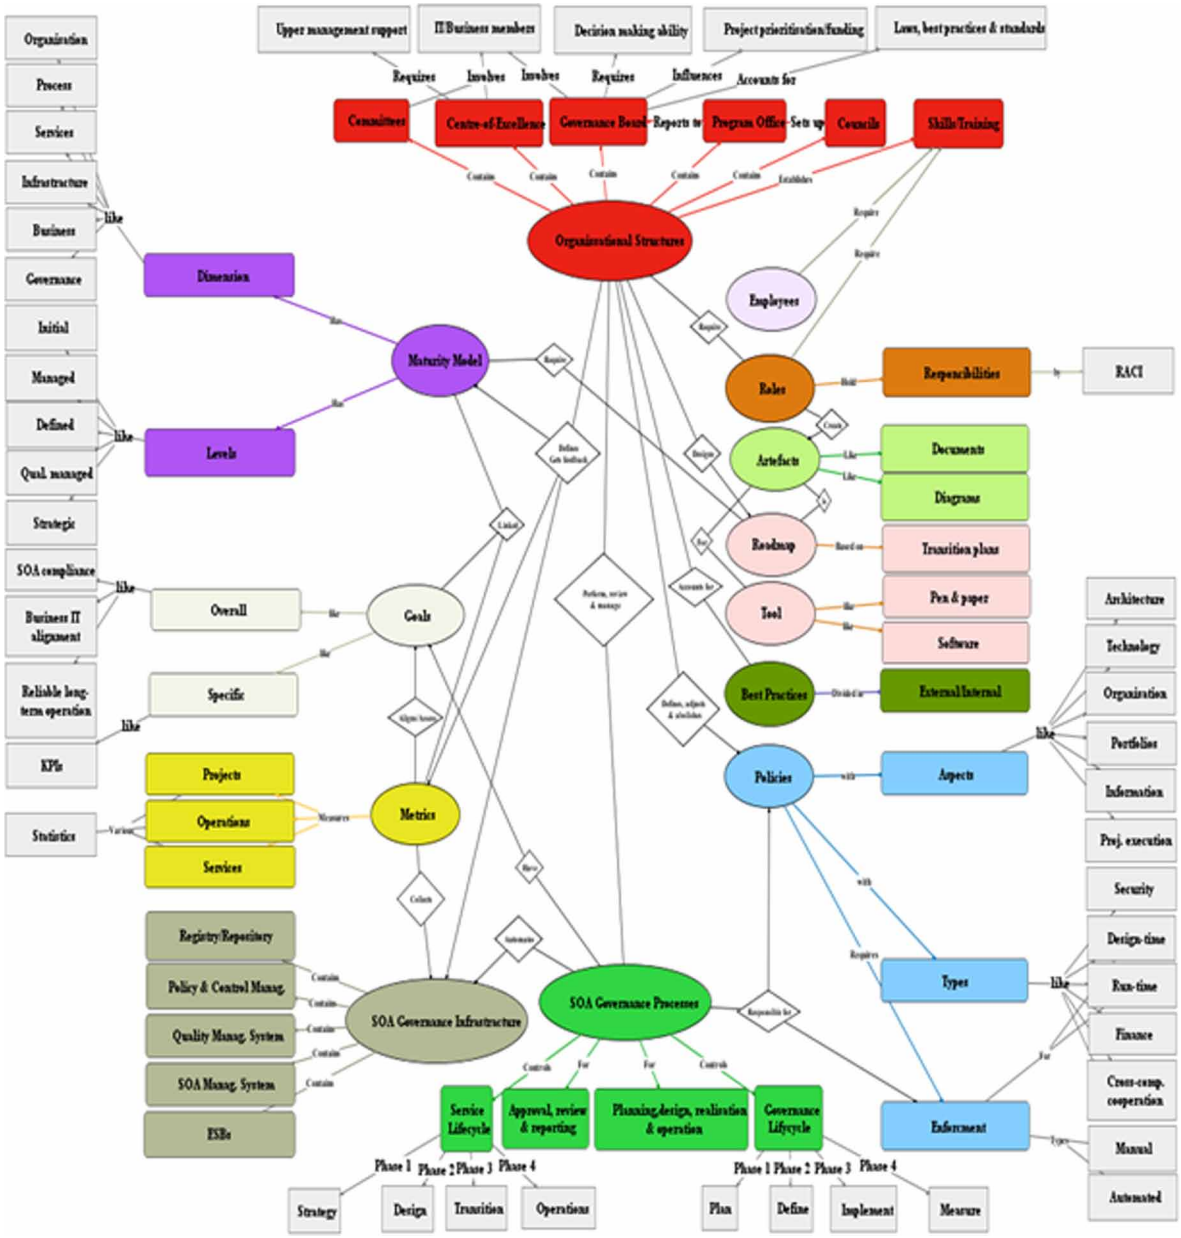
Moreover, the similarities contribute in the construction of the SOA Governance Framework as they provide the common elements and understanding to create the proposition. On the other hand, the differences and limitations as overlapping and confusion, allowed the authors to discard elements as ‘employees’, ‘artefacts’, ‘tool’ and ‘goals’. The decision for exclusion was based on an individual basis. For example, the employees concept overlaps with the organisational structure concept as they both refer to the same notion, while the latter was more frequently observed in the literature and portrayed in more comprehensive conceptualization, thus the first was discarded. The remaining nine common SOA Governance concepts, structure the main elements of the SOA Governance Framework. These elements are:

- **Organisational Structure:** Includes a range of high level structures (e.g. Centre-of-Excellence, boards, offices) and committees/councils dedicated to SOA Governance,
- **Roles:** Concept is identified as newly created or already applied roles with SOA related responsibilities,
- **Maturity Model:** Is an assessment mechanism who provides a comparison between current and future states of SOA aspects (like IT, process, organization),
- **Roadmap:** Concept is portrayed as a transition plan that provides guidance through the SOA endeavor,

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

- **SOA Governance Infrastructure:** Manages governance information, automates processes, enforces policies and collects metrics,
- **Policies:** Comprise rules for deploying and managing SOA with the aid of enforcement mechanisms (manual or automated)
- **Metrics:** Provides visibility of essential parameters of the SOA initiative,
- **Best Practices***:* To collect experiences and supports the successful implementation of SOA,
- **SOA Governance Processes:** Deal with the management and execution of SOA based on the service lifecycle.

Figure 1. SOA Governance Concept Map



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Yet, the authors identified limitations in the normative literature as limited scope and analysis of the concepts (e.g. above mentioned nine elements). To this, the authors propose the following additions:

- The *Organisational Structure* needs to be designed as to compensate for the weaknesses of the current organisational IT structures and incorporate a defined engagement approach with the rest of the organization,
- A list of *Roles* needs to be incorporated in this element exemplifying the corresponding responsibilities,
- Design guidelines to aid in the conceptualization of a *Roadmap* are added to this element,
- The Goal/Questions/Metric method (see (Basili et al., 2010) is utilized as a guideline for *Metrics* element,
- As part of the *Best Practices* element a categorization is included,
- *SOA Governance Processes* are portrayed in four phases: plan, design, implement, measure, and additional attributes are provided for each.

Another limitation identified by the authors is that the nine concepts are tailored for a non-specific sector, whereas the authors emphasise on the need to include healthcare specific aspects as a failure in an IT project directly impacts and endangers patients' quality of care and well-being (Fitzgerald & Russo, 2005; Johnson, 2011; Kaplan & Harris-Salamone, 2009). Thus, the authors propose the use of the SOA CSFs as additions to the nine common issues. This unique grouping is presented in the following section of this chapter.

SOA GOVERNANCE FRAMEWORK FOR HEALTHCARE

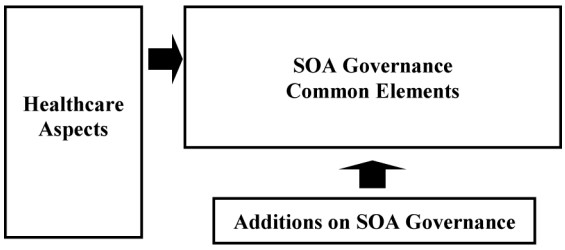
Following the literature review findings of the previous section, the authors proposed the main nine elements that a SOA Governance Framework may consist, namely: (a) Organisational Structures, (b) Roles, (c) Roadmap, (d) Best Practices, (e) Policies, (f) SOA Governance Processes, (g) SOA Governance Infrastructure, (h) Metrics, and (i) Maturity Model. This is identified as the first component of our proposition. The second component are specific additions that were introduced as guidelines to enhance them, like: (a) SOA Governance structure guidelines, (b) example list of SOA roles and responsibilities, (c) SOA roadmap design guidelines, (d) method to construct metrics, (e) best practices categorisation guidelines, and (f) SOA Governance phases and their attributes (examples of the latter). In this section and as a third component, the authors propose specific additions (based on SOA CSFs in healthcare) to the nine elements so as to tackle their lack of healthcare specific conceptualisation. The aforementioned synthesis can be graphically observed in Figure 2.

In more detail, the process of addressing the SOA CSFs is presented in the following paragraphs.

- **Alignment:** Beimborn et al., (2009) suggest that well established SOA Governance structures positively influence the structural dimension of IT/business alignment. The authors agree with the aforementioned view and believe that organisational structures can address this CSF with attributes as dedicated committees and/or individuals who hold alignment related roles and responsibilities (e.g. strategy manager). These individuals can then set specific goals like SOA compliance

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. SOA Governance Framework Synthesis



(e.g. alignment with legal, internal regulations) and business/IT alignment (these goals are also supported by Niemann (2010)), implement SOA Governance processes, design policies that influence the alignment and using appropriate metrics measure and control the level of complexity.

- **Clear Goals:** This is a broadly defined CSF that can be implied for all the elements of the proposed SOA Governance Framework. For example, SOA Governance processes and metrics have specific goals that are set by organisational structures and individuals holding roles in these structures. It is our understanding that the clear definition of these goals is placed on the clarity of the concept they address and the skills of the individuals defining them. Thus, we propose to include in the organisational structure element the guidelines: (a) responsible to set clear goals for all elements and (b) involve individuals with skills that can set clear goals so as to address this CSF.
- **Complexity:** We argue that identifying sources that increase the overall complexity in a system can be placed as a responsibility in individual roles. For example, the SOA architect holds the responsibility for designing and implementing the logical/physical architecture and thus can foresee and manage in some extent the complexity introduced by the implementation. Additionally, individuals with these kinds of responsibilities (e.g. complexity related) can collectively under an organisational structure (e.g. committee, interest groups) or more informally (e.g. intranets, wikis) address potential complexity issues. Yet, as complexity was also identified as a HIS challenge we emphasise the need for this CSF to be adequately addressed. Literature suggestions recommend the utilisation of SOA metric systems that can measure design-time and run-time services and predict unwanted levels of complexity (Hirzalla, Cleland-Huang, & Arsanjani, 2009). We agree with this suggestion and propose that the metrics element (metrics that measure system complexity) need to be utilised so as to provide better governance of the complexity factor.
- **Cost:** Cost and more precisely funding was included in the organisational structure element that can control in certain extent the funding of SOA projects. However, it is our belief that for this CSF to be better dealt the creation of committees in charge of cost planning and control that can also identify service/project sponsors within or outside the organisation, is required. Additionally, funding can be added as an area in the SOA maturity model, so as the healthcare organisation can compare the progress of business processes, technology and other areas with financial data and better govern this factor.
- **Culture:** We argue that the organisational structure can cultivate a SOA friendly culture and gain the trust and cooperation with the rest of the healthcare organisation. This may involve specific governance processes that promote SOA and its beneficial parameters (e.g. educational and communication planning). Thus, we propose the aforementioned additions in the corresponding elements.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

- **Experience and Training:** This CSF including the requirements of experienced personnel and additional training is in great extent covered by the SOA organisational structures' and SOA Governance processes' elements.
- **Governance:** It is our understanding that the proposed SOA Governance elements (Part A and B) and healthcare aspect added in this section (Part C) can address all the requirements for governance (as an CSF) in a healthcare organisation.
- **Long-Term Planning:** We argue that the CSF identified as long-term planning can be represented by the SOA maturity model as a more elaborate approach. For example, one of the application areas that a SOA maturity model examines is the services, these are described starting from an initial and reaching to a final maturity level, expressed in a similar progressive way as in a long-term plan. Thus, we identify this approach to be a useful tool for SOA Governance and propose its utilisation to address this CSF.
- **Measurement:** It can be stated that this CSF can be addressed by the metrics element, as they hold similar conceptualisation, with emphasis on the role of the SOA Governance infrastructure in the collection of metrics and diffusion of feedback about them.
- **Maturity Identification:** The authors accept that this CSF can be represented by the SOA maturity model element.
- **Project Identification:** It can be argued that this factor is addressed as part of the SOA organisational structure and also it is the authors' belief that specific roles, like strategy manager, SOA architect and SOA designer, are responsible for the project identification.
- **Resources:** This CSF is described as a multifaceted one with parameters as financial (budget), technical (software/hardware), and staff (experts, implementation team, consultants) aspects. The financial parameter can be addressed similarly the cost CSF (e.g. from organisational structures and SOA maturity model elements). As far as the technical aspect we believe that is covered by the SOA Governance infrastructure element conceptualisation, since both refer to adequate resources as software and hardware systems. Additionally, the introduction of the roles element can resemble the staffing aspect of this CSF.
- **Risk:** It can be stated that this CSF is addressed by the proposed roles of security manager and tester regarding the security and error risk, and from the organisational structure element regarding the funding and sponsoring risk (in the form of dedicated committees or groups). Yet, it is our understanding that data security and patients' confidentiality are clearly a significant challenge to healthcare and beyond the organisational structures and roles, specific testing, standards, policies and best practices are needed. These will be discussed in the following paragraphs.
- **Roadmap:** It can be stated that this CSF can be addressed by the roadmap element,
- **Roles:** We argue that this CSF can be addressed by the roles element.
- **Standards:** SOA is based on established global standards (e.g. XML, UDDI, SOAP, WSDL, BPEL and REST). In healthcare the standards related to information coding and sharing (e.g. SNOMED, HL7) or protocols (e.g. DICOM) that enhance the interoperability and improve the way HIS share information are usually developed from national central standardisation bodies or independent organisations like IHE (IHE, 2012). This combination between SOA and healthcare standards is an important factor for SOA implementations, regarding aspects of security, interoperability and QoS. Thus, it is our belief that such standards need to be incorporated as best practices and utilised accordingly. In charge of such best practices can be organisational structures (e.g. committees, interest groups) that can identify the standards, evaluate them and recommend

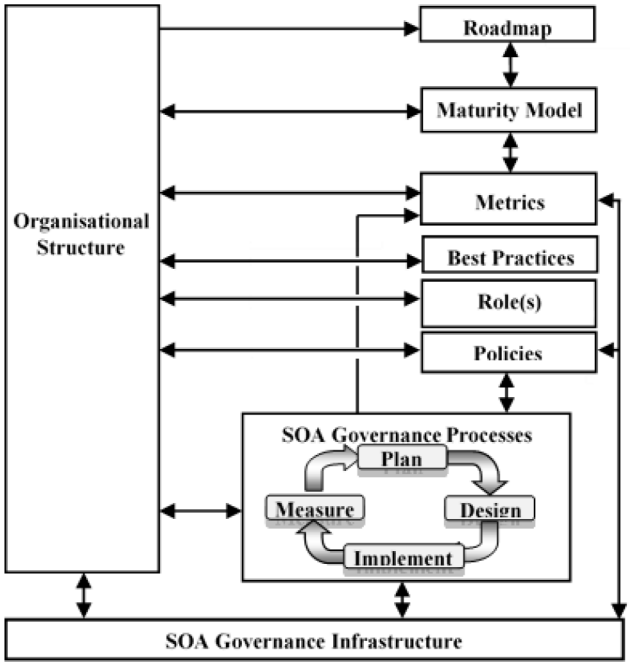
EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

them as best practices and thus minimise the risk in issues like: security, access control and medical errors. Additionally, this activity can be included as a SOA Governance process (e.g. standardisation process).

- **Team:** We argue that this CSF can be addressed by the SOA Governance organisational structures element.
- **Testing:** This CSF was identified requiring tools and methods to test the integration approaches and services before the actual service implementation. The authors extents this CSF's importance to testing in both design- and run-time SOA and believes that specific roles like tester, infrastructure and SOA architect, service developer, process and security manager with the aid of SOA Governance infrastructure can control the criticality of this factor. These roles include a wide spectrum of responsibilities related to testing like error localization for service developer, and/or maintenance for process manager and of course testing for the tester role. Yet, it is our understanding that since testing was identified as a HIS challenge, additional emphasis is required to address this factor. Thus, proposes governance processes that address this factor to be included in the SOA Governance processes element, which with the aid of SOA Governance infrastructure can provide testing capabilities. Furthermore, these processes can be placed in the best practices element and form guidelines that minimize errors.

Up till now, most of the SOA Governance elements were introduced in parts, as common elements in Part A, additions to these elements in Part B and healthcare aspects of the elements in Part C. Following is the synthesis of the nine SOA Governance elements, as the proposed SOA Governance Framework, as depicted in Figure 3.

Figure 3. Proposed SOA Governance Framework



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

The proposed framework in Figure 3 makes a novel contribution at two levels. Firstly, at a conceptual level, it identifies and proposes nine elements that should be considered during the SOA Governance process. The identification of the nine elements is based on the theoretical works conducted by others in this area (see (Koumaditis & Themistocleous, 2013)). As a result, the conceptualisation of the elements is grounded in the normative literature. In addition to this, the framework incorporates additions that are gathered from additional literature resources beyond the ones that composed the elements. This comes as a method to overcome the limitations identified in normative literature and enhance the elements' conceptualisation. Moreover, the authors propose a unique formulation combining the identified common elements of SOA Governance (seen in Part A and B), the SOA CSFs and HIS challenges. This proposal aims to pinpoint attributes and guidelines for each element, required to successfully govern a SOA and tackle longstanding HIS challenges. Secondly, at a practical level, the proposed framework contributes towards a better understanding of the research area (SOA Governance in healthcare).

RESEARCH METHODOLOGY

To test the SOA governance framework an interpretive qualitative research approach is proposed, with the aid of a case study. The decision to utilize such a research strategy was based on the need to study the SOA governance issues surrounding SOA implementations and on the unique nature of healthcare itself.

In more detail, healthcare can be characterized by unique issues, such as: (a) the interactive nature of practitioner/patient relationships, (b) patients' subjective experiences of illness, (c) their own personal understanding of human suffering and (d) stakeholders behavior and interpersonal interactions (A. Miles, 2009). The aforementioned characteristics of healthcare drive effective clinical process to rely not to a single but rather several different kinds of knowledge (e.g. medical, anthropological and instrumental). Consequently, giving the required depth of understanding that can be applied to a given problem situation. The same principle, as in clinical practice, is useful to be applied to the research methodology so as to research a healthcare setting (Fossey, Harvey, McDermott, & Davidson, 2002). Additionally, as to understand the interplay between stakeholders (clinical and non-clinical) and IS, emphasis is required on the meanings, concepts, definitions, characteristics, descriptions and associations rather than numbers and statistics. Thus, as a more suitable candidate the interpretive qualitative research approach is followed in this research, as it can relate closely to the healthcare aspect of the research. Additionally, qualitative research methods are being used increasingly in evaluations of computer systems and IT both within and outside healthcare (Kaplan & Maxwell, 2005). Furthermore, the use to consider a case study strategy is supported, as it is a widely used research mechanism for examining IS frameworks and supports the investigation of: (a) little-known phenomena (SOA governance in healthcare) and (b) complex processes (SOA implementation) in their natural setting (Bairi & Manohar, 2011).

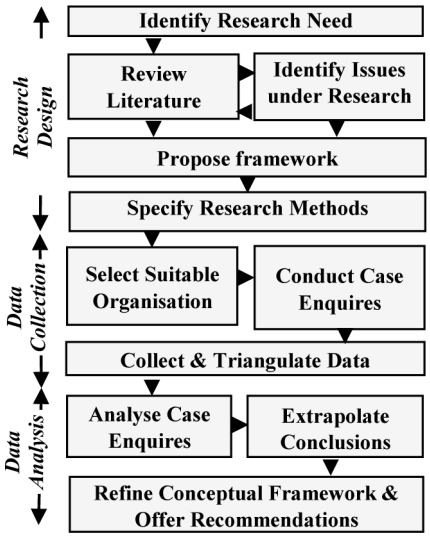
Therefore, the authors propose a qualitative research with three stages: (a) research design, (b) data collection and (c) data analysis, as seen in Figure 4.

DISCUSSION

Healthcare is a unique sector not only due to its relevance to human life, but also due to the big amount of: (a) complexity, (b) legacy systems, (c) data and (d) resources utilized each year. Yet, the develop-

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 4: Research Methodology Design



ment of SOA Governance in healthcare and its impact to healthcare organizations remains unexposed to research. Such research will undoubtedly provide a more compelling basis for the utilization of SOA and a more controlled environment for HIS integration.

This chapter deals with this important research area and addressed HIS integration challenges. These challenges certainly will be very real over the next few years as governance and management of IT projects, as we continue to embrace SOA projects across widely distributed HIS. To this end and with the help of a rigorous literature review the authors developed and proposed a SOA Governance Framework that can address these challenges. An overview of the proposed SOA Governance Framework was presented in Figure 3. Without a doubt, further research is required to enhance our understanding and impact of such proposition in a healthcare organization. To do this, we already brought forward a qualitative research methodology plan (e.g. Figure 4). Yet, further research actions are needed. These are discussed in the following section.

FUTURE RESEARCH DIRECTIONS

The authors have planned to test the SOA Governance Framework with key SOA players in healthcare such as: (a) public and private hospitals and (b) healthcare organizations (e.g. insurance funds). It is our view that the data gathered from the empirical arena will strengthen, refine and highlight our proposition.

Following the aforementioned actions, we also propose to transform the proposed SOA Governance elements' structure and the framework itself (e.g. refined form) into a large-scale survey questionnaire, instant of using interpretive epistemology. Clearly, this approach would not have been possible previously, since the framework did not exist. Miles and Huberman (1994) discuss such a research design starting with a qualitative approach that provides an initial exploratory phase, whose outcomes may be used to create quantitative instruments (e.g. surveys) to collect new data. It is our understanding that such large-scale survey may offer the opportunity to establish generic significance to the issues related

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

to the proposed SOA Governance Framework. In surveying a representative sample of organisations the elements' characteristics related to the proposed framework can be better verified and understood.

KEY TERMS AND DEFINITIONS

HIS Integration: The alignment of HIS in an interoperable environment.
HIS Interoperability: The ability of HIS to work together and exchange information.
HIS: Information systems designed to facilitate healthcare services.
PCEH: Patient Centered e-health.
SOA Governance: Important mechanisms that ensure the reliable long-term operation of an SOA.
SOA: An architectural paradigm to build ecosystems of services.

This research was previously published in Reshaping Medical Practice and Care with Health Information Systems edited by Ashish Dwivedi; pages 266-286; copyright year 2016 by Medical Information Science Reference (an imprint of IGI Global).

ABSTRACT

Being complex systematically, Knowledge Management (KM) has always been challenging in the healthcare industry (HCI) of developing countries like Pakistan due to gap in acquiring and implementing KM processes. Despite the fact that extensive data and related information is available, the Pakistani HCI has been facing a major challenge due to the absence of a sound and solid KM process framework. Hence, the existing healthcare information systems in Pakistan lack the ability to control and cater the diversified nature of new knowledge creation and innovation. Consequentially, it results in inefficient and ineffective organization of knowledge along with inability to properly utilize important resources that are used for decision making activities. In this study, the researchers present and suggest an integrated and inter-operable KM process framework that helps to streamline and integrate a KM process in a phased comportment that identifies, defines, analyzes, collects and manages knowledge along with its innovation, dissemination, sharing and storage in an appropriate way.

INTRODUCTION

"A health system consists of all organizations, people and actions whose primary intent is to promote, restore or maintain health" according to the World Health Organization (WHO). Healthcare organizations are composed of health care professionals from multiple disciplines forming several interconnected care teams that strive to provide safe and consistent care. (Ratnapalan & Uleryk, 2014).

The need for an integrated and reliable Knowledge Management process framework in the healthcare industry of Pakistan has become evident due to evolution and innovation of Knowledge Management practices over the past couple of decades. A Knowledge Management Process Framework ensures that all necessary KM elements (Accountabilities, Processes, Technologies and Governance) are in place, and interconnected (Alavi & Leidner, 2001). With a Management Process Framework, KM can take on the aspects of other management systems, and be made part of normal business, rather than relying on an incongruent set of tools (Akhavan, Jafari, & Fathian, 2005). This ensures that there are no gaps in the system, and that knowledge flows freely through the organization.

Health care organizations have to be able to modify their activities based on sudden changes in the condition of their patients or sudden demands due to public health disasters, without compromising patient safety or quality of care. New knowledge creation, technology advances and other market changes can add new and unexpected demands in health care delivery. Health care organizations have to maintain stability following institutional protocols but have to assess their performance and evaluate protocols to create and incorporate new knowledge (Ratnapalan & Uleryk, 2015).

Knowledge management involves the strategies and processes for identifying, capturing, structuring, sharing and applying an individual's or an organization's knowledge to extract competitive advantage and create sources of sustainable growth (Mahmood, Burney, Abbas, & Rizwan, 2012). All the participants of this community create, share and use knowledge to improve the health care service quality and reduce cost. The success of a medical care depends on how effectively and intelligently knowledge is being used to improve the health care process (Mahmood, Burney, Abbas, & Rizwan, 2012).

The importance of Knowledge Management in Healthcare and Medical industry is evident and pertinent (Mahmood, Burney, Abbas, & Rizwan, 2012). Correct and accurate knowledge for the correct and effective treatment of patience is a matter of life and death. The purpose of this research is to propose an outline and present the stages of KM strategy implementation. In addition, it presents the actions necessary at each stage of development of an integrated and interoperable process framework that combines and interrelates KM process steps. This is done while dealing with knowledge effectively and efficiently in any form it exists in the healthcare organization.

BACKGROUND - DEFINING DATA, INFORMATION AND KNOWLEDGE

Knowledge Management (KM) is a term difficult to understand without knowing and understanding the meaning of the word "knowledge". Further, it is also important to clearly differentiate between knowledge, information and data (Botha, Kourie&Snyman, 2008).

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Perspective on Knowledge, Information and Data – An Overview

In disciplines like information systems the term "knowledge" is frequently used analogously as information. It is understood as something that can be categorized, classified, organized and communicated as shared knowledge by the help of Information Technology (Jones, 2006). For instance, the encyclopedia at "www.fact-archive.com" defines it as: "information that has a purpose or use."

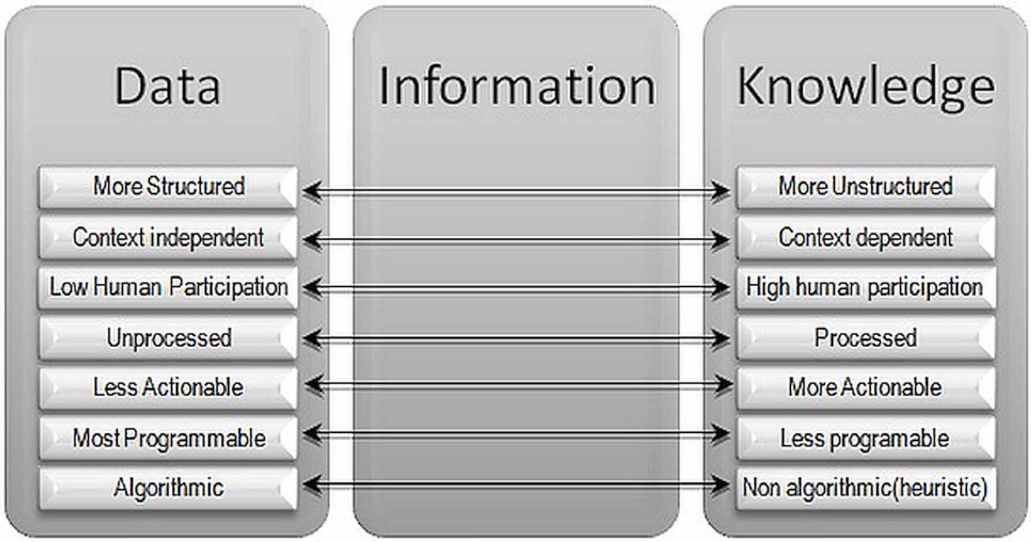
For understanding, a clear distinction between data and information could be done by using narrative that "Data are raw facts and figures that contain bits of information rather than information itself". These bits of information are not useful until they are processed, organized, interpreted, structured and converted into meaningful and useful form. The processed form of data which is converted into meaningful and useful form is known as "Information". The application of data and information is known as Knowledge that extends to appropriate collection of useful information. (Definition of Terms, 2002).

The term "knowledge" is part of our everyday language. It is used interchangeably in between knowhow and wisdom (Altaher, 2011; Davenport, Long & Beer, 1998). At one time, it is used as simple as knowhow about anything and at other time is used at its highest level as wisdom. Many times, it is identically used as "information" also, but actually there is a great amount of difference between them (Gamble & Blackwell, 2001). The perspective on data, information and knowledge is elaborated in Figure 1.

During the 1990s, the usage and application of information technology became increasingly common and the basic simple-minded view of the term "knowledge" was widely spread among the masses (Davenport, Long & Beer, 1998; Heier, Borgman, Hans & Manuth, 2005).

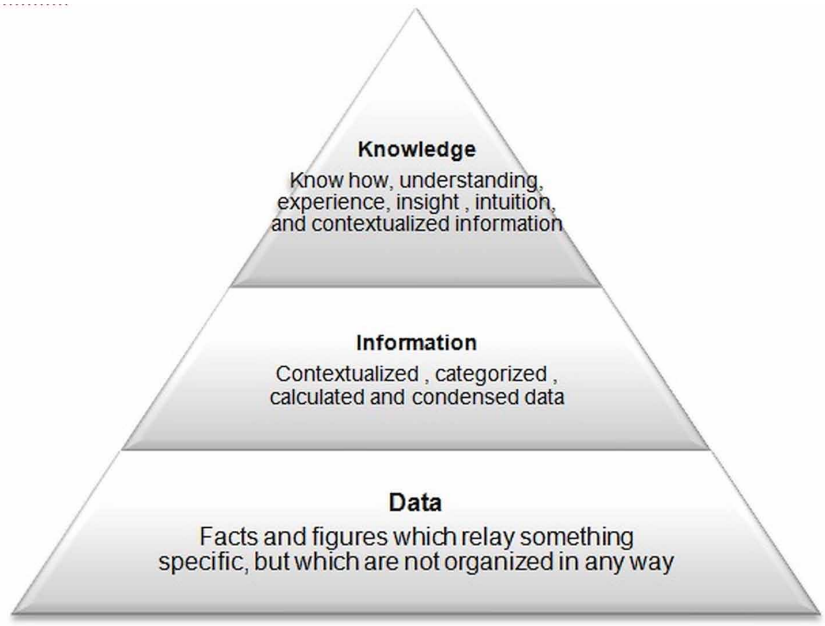
Figure 2 explains the difference between the three elements clearly.

Figure 1. Adapted from data, information and knowledge attributes (Davenport et al., 1998; Probst et al., 2000; Awad & Ghaziri, 2004)



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. Adapted from data, information and knowledge differentiation (Thierauff, 1999), (Davenport & Prusak 2000)



Different Types of Knowledge

Knowledge is considered as a mixture of grounded perception, contextual information, expert intuition, standards, and framed understanding that postulates a specific environment and structure for assessing and integrating new innovations in experiences and information (Nonaka, 1994; Frost, 2010). Today, knowledge is an integral part of organizations that is embedded in routines, practices, norms and repositories of organizations. In order for KM to succeed, one needs a deep understanding of what constitutes knowledge (Gamble & Blackwell, 2001; Frost, 2010). An important and crucial step in KM is to understand different forms of knowledge that exist and ability to differentiate between different types of knowledge (Razzaque & Jalal-Karim, 2010; Pasha, 2012).

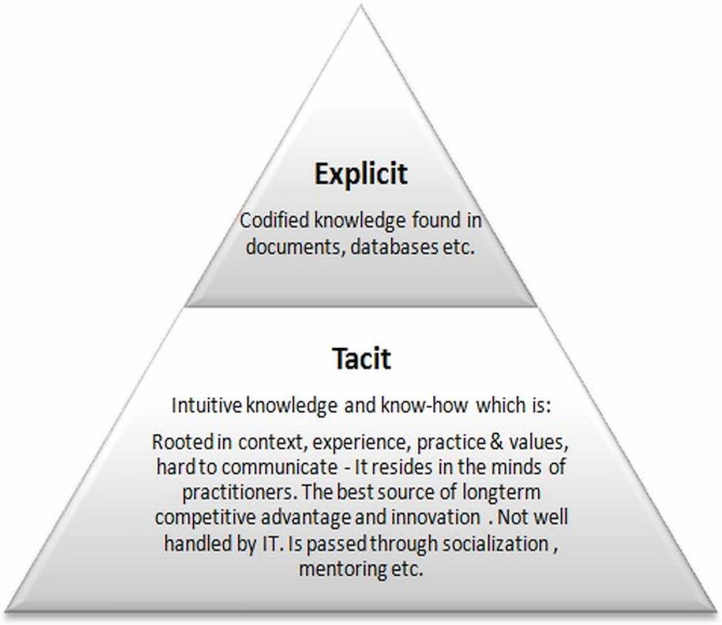
In KM with reference to business terms, knowledge is usually referred to as "Explicit knowledge" that exists in documents in form of codified knowledge and "Tacit knowledge", often mentioned as experience of individuals and is in non-codified form (Bukowitz & Williams, 1999). This division is explained in Figure 3.

The theory of organizational learning in relation to KM is originated and lies in correlation between Explicit and Tacit knowledge. Nonaka developed and explained this concept in the 1990s as a key foundation of this field. Explicit and Tacit knowledge types should not be considered as absolute points. However, for understanding knowledge, it is imperative to define both these terms distinctly (Botha, Kourie & Snyman, 2008).

The source of tacit knowledge is internal discrete processes of organizations that are stored in human beings as a result of their individual experiences and perceiving ability. Such type of knowledge obtained may be occasionally referred to as observation, experience, individual ability or internalization (Botha, Kourie & Snyman, 2008).

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 3. Adapted from (Brown &Duguid 1991, Cook & Brown 1999, Bukowitz & Williams 1999)



Explicit knowledge is normally stored on mechanical or highly technological devices such as electronic documents or databases. This form of knowledge is comparatively less useful until or unless shared among community that uses collaborative technology working together at any given time or place (Thierauf, 1999).

Some researchers make a further distinction and talk of embedded knowledge. In this way, one differentiates between knowledge embodied in people and that embedded in processes, organizational culture, routines, etc. (Woods, Cordata & Horvarth, 2000-01). Gamble & Blackwell (2001) used a scale consisting of represented-embodied-embedded knowledge, where the first two closely match the explicit-tacit. It has also been generally accepted that both the explicit and tacit components of organizational knowledge play an important role in innovation (Hall &Andriani, 2003).

The relationship between data, information, explicit knowledge, tacit knowledge and wisdom is shown in Figure 4.

What is Knowledge Management?

Knowledge management is essentially about getting the right knowledge to the right person at the right time (Grace & Buttler, 2005). Knowledge management may also include new knowledge creation, or it may solely focus on knowledge sharing, storage, and refinement (Davenport, Long & Beer, 1998; Frost, 2010).

It is important to remember that knowledge management is not about managing knowledge for knowledge's sake. The overall objective is to create value and to leverage, improve, and refine the firm's competences and knowledge assets to meet organizational goals and targets (Botha, Kourie & Snyman, 2008; Jones, 2006).

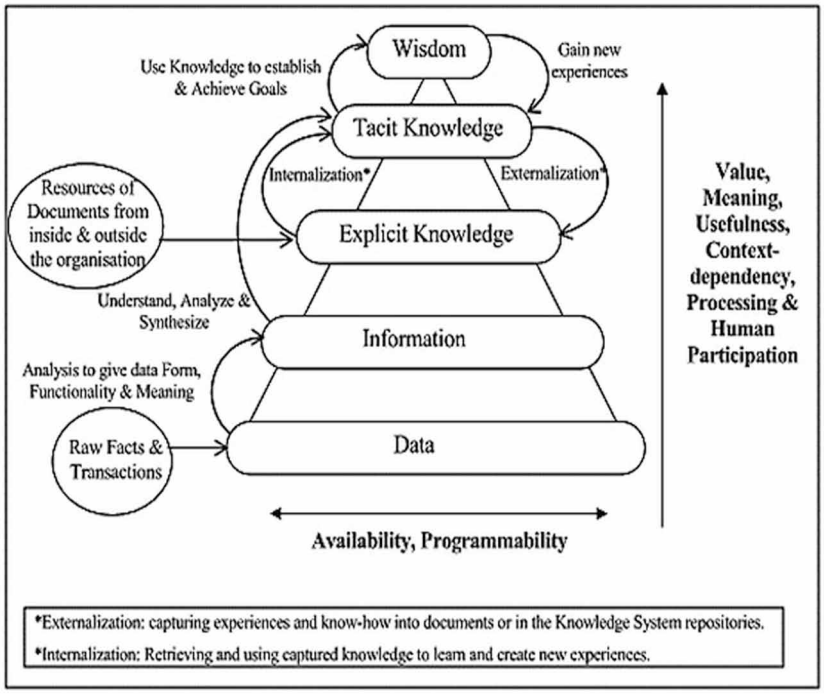
Figure 4. Adapted from data, information, knowledge and wisdom (Davenport et al., 1998; Probst et al., 2000; Awad & Ghaziri, 2004; Bierly et al., 2000; NDR, 2003)



KNOWLEDGE MANAGEMENT IN HEALTHCARE

Overview

In the healthcare industry, the term "Health Informatics" or "Medical Informatics" is referred to the interdisciplinary study of resources and methods for the management of health information in healthcare services planning, management and delivery (NICHSR). (. This information is generated as a result of the production of large amounts of data (also known as "Big Data") in healthcare related studies that included electronic health records, medical health records, medical research, medical terminologies, methodologies, health information exchange, etc. (Rodger, 2015). Big Data in healthcare is not simply about the volume, velocity and variety of the data in storage, it is also about the potential value of the data, how it is processed and converted into information and how knowledge is perceived out of it (Rodger, 2015).

The healthcare industry sits on the hinge of a future in which doctors can instantly share imaging and test results with colleagues in the same building or across the city, country or continent (Persson et al., 2008). Patients should have access to their own medical history and be able to transfer it from one healthcare Centre to another. Innovation is a core competency of all healthcare institutions (Ruaranen, Lansisalmi, Kivimaki & Aalto, 2003). Further, implementation of new and enhanced IT systems and advanced genetic reengineering are drastically changing health care organizations, creating new opportunities for innovation and for the enhancement of the productivity of the actual processes (Leal-Rodríguez et al., 2013).

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Innovation in healthcare continues to be a driving force in the quest to balance cost cuts and health care quality. Consequently, innovation has become a key piece for the achievement of a sustainable competitive advantage (O'Hara et al., 2013). In many instances, knowledge in the healthcare industry is mostly a blend of tacit and explicit knowledge which not only depends upon structured or direct resources of information but also is highly based on individuals' experiences and perceptions, which increase the difficulty of capturing and reusing it for innovation (Hussain & Raza, 2004). On the other hand, one of the other big issues could be "The culture of knowledge sharing and using it instinctively" (Abdul Rahman, 2011).

KM in Healthcare Industry of Pakistan

Pakistan is basically a developing country and is densely populated with more than 60% of the population living in rural areas. The rate of illiteracy is also very high and as time passes by, the population growth rate is also increasing day by day resulting in the increase of problems for healthcare industry. This requires a strong and effective healthcare industry to take care of healthcare problems of the people. Even though there are many well trained and qualified professionals and some state of the art healthcare centers present and scattered throughout the county, they still lack effective and quality knowledge management procedures (Mahmood, Burney, Abbas & Rizwan, 2012).

Importance of KM in Healthcare Industry of Pakistan

Pakistan is among those developing countries where the importance of knowledge management in healthcare services has been realized but its practices have failed to get sufficient attention. Lack of awareness about KM technologies and associated processes are among some common problems reported in recent studies. Also, the complexity involved in KM implementation has led to discouraging results reported in the research. One report shows about 84% of knowledge management projects fail. Thus, many Pakistani managers are reluctant to implement technology based KM in their organizations (Pasha, 2012).

Adoption of KM in Healthcare Industry of Pakistan

While knowledge management is becoming an established discipline with many applications and techniques, its adoption in healthcare has been challenging. Although the growth trend of this industry along with implementation of Knowledge Management Systems (KMS) have shown some notable achievements it still fails to meet the expectations of many with respect to efficiency and effectiveness (Pasha, 2012).

The lack of basic knowledge management procedures and processes also prevents the implementation of E-health, Tele-health or Tele-medicine in the country. These types of systems are generally required in those areas where the population lives far away from healthcare centers and unable to approach a proper healthcare service.

KM, ICT and Healthcare Industry

The use of Information and Communication Technologies (ICT) in health care is generally referred as e-Health, Tele-health or Tele-medicine:

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

- **Tele-Medicine:** Simply put, Tele-medicine is the provisioning of healthcare services at a distance using ICT. E-Health not only refers to the role of ICT in healthcare, but also to a way of thinking, a state of mind, and a commitment to improve the standard of health care being provided worldwide by using the ICT industry;
- **E-Health:** E-Health is the intersection of Information Sciences, Computer Science, Information Technology and Healthcare. It deals with various approaches used in storage, retrieval, and transfer of information in healthcare and biomedicine. It includes computers as well as clinical guidelines, formal medical terminologies, and information and communication systems (Aqil, Zain, Nadeem & Qamar, 2013). The successful implementation of all these systems requires an effective and quality Healthcare Knowledge Management System.

KNOWLEDGE MANAGEMENT PROCESS AND ITS IMPORTANCE

Overview

A solid, comprehensive and integrated KM process framework is the most important resource and asset for an organization to implement Knowledge Management Systems effectively and efficiently and for getting maximum benefit of their KM Strategies. An assimilated KM Process Framework is a step-by-step guideline that provides effective standard operating procedures to manage knowledge assets of an organization for gaining maximum cost and time effective benefit (Arshad, Noordin & Othman, 2016).

Although much research has been accomplished regarding KM frameworks in various fields of studies, the healthcare industry of Pakistan is still lacking a considerable amount of research and literature with respect to effective knowledge management. Still some of the researchers have been striving to conduct true research in this domain. In our opinion, one of the basic reasons for such circumstances is an intersection of the 3 domains of Healthcare, Knowledge Management and Information Technology (Arshad, Noordin & Othman, 2016).

Existing Work

In Table 1, the authors have summarized some of the work done in this domain by researchers related to KM in the healthcare industry of Pakistan. Each has its own Pros and Cons but none of them has presented a KM framework that effectively deals with procedural implications of knowledge management in the healthcare industry of Pakistan (Arshad, Noordin & Othman, 2016).

CASE STUDY – DESCRIPTION

Knowledge Management Practices at Public Sector Healthcare Organizations (Hospitals) in Pakistan

This section provides an excerpt of information from a case study conducted on 2 government hospitals (A & B–pseudonym used to ensure confidentiality) in one of the major provincial capital city in Pakistan. These are among the largest and oldest public healthcare organizations governed and controlled

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 1. Adopted - A review of Knowledge Management Frameworks proposed by some researchers for Healthcare Industry of Pakistan (Arshad, Noordin, Othman, ICT4M2016)

Framework	Description
Fehmida & Ali et al., 2004	**Knowledge Management Framework To Operationalize Experiential Knowledge** • Mapping of explicit form of knowledge with tacit form of knowledge • Objective of this model is that explicit knowledge in the form of Clinical practice guidelines (CPG) is enriched by tacit, experiential knowledge found in the form of documented experience.
Pasha et al., 2012	**A Theoretical Technology Driven Knowledge Management Framework** • Aims to advance the understanding of the key concepts of KM and the relationship between available technologies and Knowledge Processes • Identifies key factors for making a KM initiative successful
Mahmood, Nadeem, et al, 2012	**Healthcare Workflow Management and ICT Model** • Process of management of knowledge involves the ability to identify and capture existing knowledge, create new knowledge and transfer existing knowledge throughout the organization. • Mainly emphasizes on the flow of knowledge from one entity to another.
Jalal, Karim et al, 2010	**The HC KM Model** • Knowledge representation is referred to as storing and processing of information and knowledge so that it can be used by other applications.
Hameed, Shafqat et al, 2012	**The Enhanced HC KM Model** • Enhanced this model by introducing the personal identity (national identity) of a patient to be recorded by the system.

by the local government and comprising of more than 2000 beds collectively. Hospital "A" employs 1,025 healthcare professionals with a total count of 1800 employees and staff in its 36 departments and is one of the oldest public-sector healthcare organizations in Southeast Asia. Hospital B employs 1,225 healthcare professionals with a total count of 2,100 employees and staff in its 32 departments with its roots being older than 70 years. The hospitals seem to be overcrowded with a significant number of in-patients (A > 30000, B > 25000 per year) and out-patients (A > 1000000, B > 900000 per year).

The case study was conducted to obtain an account of information on practical grounds related to existence and implementation of KM processes in the top and famous public sector Pakistani healthcare organizations.

The researchers selected and used a purposive sampling technique to answer the research questions (see Table 2). The researchers collected data and information for their study by help of generalized interviews, structured walkthroughs, existing document reviews and self-observations. While performing their exploratory study, the authors also collected information regarding the KM dimensions (organizational culture, leadership, technology and politics) that have a critical impact on the success of KM implementation in healthcare industry. A substantial number of people including healthcare professionals, IT staff, support staff and some educated patients were met to dig out the information (see Table 3).

The interviews and data collection objectives of the authors were generally based upon the major domains and constructs shown in Table 4.

Findings

The overall findings and results helped the authors to propose an integrated and interoperable KM process framework for healthcare. Table 5 provides the level of agreement of respondents based upon the questionnaire constructs that were conducted by help of interviews.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 2. Case demographics

	Organization Case A	Organization Case B
Status	Public Sector	Public Sector
Type	Healthcare Organization	Healthcare Organization
Beds	1055	945
Employees	1800	2100
Departments	36	32
Inpatients (Per Year)	>30000	>25000
Outpatients (Per Year)	>1000000	>900000

Table 3. Population sampling

Population Sampling	Organization Case A				Organization Case B			
	Participants				Participants			
	Total	Male	Female	Age Group	Total	Male	Female	Age Group
Management	9	6	3	40 – 65	11	7	4	40 – 65
Healthcare Professionals	23	14	9	29 – 45	21	15	6	29 – 45
IT Staff	10	7	3	23 – 43	9	7	2	23 – 43
Support Staff	13	5	8	22 – 37	10	3	7	22 – 37
Educated Patients	15	12	3	33 - 54	11	10	1	33 - 54
Total	70	44	26		62	42	20	
% age	100%	62.85%	37.15%		100%	67.74%	32.25%	

Table 4. Questionnaire constructs

1	Know how about the terminology “Knowledge Management”
2	Know how about the importance of Knowledge Management
3	Role of KM in healthcare
4	Benefits of Knowledge Management in healthcare
5	Organizational Culture
6	Financial and top management support for KM implementation
7	Implementation of KM processes in the organization
8	Knowledge innovation, sharing, usage and storage
9	Existence of Knowledge Management Strategy and framework

Table 5. Level of agreement and responses by the respondents to questionnaire constructs (summarized)

Case Organizations A & B							
Summary of Question Constructs and Responses n = (Out of 132 Respondents)	**Level of Agreement**	**1**	**2**	**3**	**4**	**5**	**6**
		Don't Know n(%)	**Strongly Disagree n(%)**	**Somewhat Disagree n(%)**	**Neutral n(%)**	**Somewhat Agree n(%)**	**Strongly Agree n(%)**
Have knowhow about the term "knowledge management" (KM)		15.71%	7.14%	5.71	10%	54.28%	7.14%
Have knowhow about the importance of KM		15.71%	7.14%	5.71%	10%	54.28%	7.14%
Have awareness about role of KM in healthcare		28.57%	5.71%	5.71%	7.14%	37.71%	17.14%
Aware of benefits of KM in healthcare		28.57%	0%	0%	14.28%	38.57%	18.57%
KM process framework supported by organizational culture		52.85%	12.85%	11.42%	21.42%	1.42%	0%
KM processes implemented in the organization		28.57%	18.57%	24.28%	27.14%	1.42%	0%
KM process framework implementation supported by top management		47.14%	4.28%	5.71%	8.57%	21.42%	12.85%
Financial support available for KM process implementation		28.57%	2.85%	4.28%	7.14%	24.28%	32.85%
Knowledge innovation, usage, sharing and storage supported by organizational culture		28.57%	5.71%	0%	15.71%	28.57%	21.42%
Existence of KM strategy and framework		57.14%	7.14%	4.28%	21.42%	5.71%	4.28%
Role of KM in decision making		52.85%	0%	0%	4.28%	11.42%	31.42%
Implementation of best practices about KM for patient care		48.57%	5.71%	8.57%	31.42%	4.28%	1.42%
KM supported by organizational infrastructure		45.71%	0%	4.28%	2.85%	8.57%	38.57%
Existence of sufficient Technology Infrastructure		37.71%	2.85%	7.14%	2.85%	15.71%	37.71%

The following points were highlighted as findings after the collected data was analyzed and processed. As per the findings of study:

1. Both the organizations were lacking the basic KM process framework implementation;
2. The results of the discussions and observations showed, that most of the professionals and related stake holders from both the healthcare organizations do understand the term Knowledge Management, its importance and benefits for healthcare but none of them succeed to satisfy the researchers about their knowledge of existence of any KM process framework that has been professionally and competently implemented;
3. Despite the fact that both the organizations do possess a sufficient and competent IT infrastructure along with sufficient funds and top management support, none of the knowledge workers were aware of implementation of any professional KM process framework to support decision making processes and operations;
4. As both the cases under study were public sector organizations, it was found that both were working under the strong influence of political framework that was not possible to be further investigated;

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

5. The researchers also found that both the organizations lacked the basic culture of information sharing and usage among knowledge workers and the organizational culture was critically impacted by a strong influence of social culture and other internal and external factors;
6. The researchers also discovered that most of the new knowledge creation and innovation takes place in discussions held between the healthcare professionals over the table talks and tea breaks during the working hours;
7. The healthcare professionals were not aware of any sort of existence of a system or framework which can help them or the other stakeholders to use and disseminate knowledge;
8. There was no concept of Tele-medicine or E-health being used in support of patients;
9. Furthermore, by the help of structured walkthroughs, document reviews and existing system review, it was established that both the healthcare organizations do lack a proper and competent Knowledge Management process framework to support daily based knowledge management activities.

Based upon above case study and findings, the researchers strive to define and propose a competent and completely integrated KM Process Framework to implement in Pakistani Healthcare industry and to support daily based KM operations and activities.

THE PROPOSED KM PROCESS FRAMEWORK

Based upon facts and findings explored during the study that was supported by interviews, structured walkthroughs, documentary reviews and self-observatory process, the researchers strive to propose an integrated and comprehensive process framework of KM for healthcare organizations in Pakistan and represent the main components of the KM process model to facilitate its understanding and to show the relationships among the different phases. The proposed KM process framework consists of ten comprehensive phases as shown in Figure 5, of which each is having its own importance and implications:

Phase 1 starts the KM process by identifying and defining the specific needs and requirements of different types of knowledge for the healthcare organizations e.g. content requirements related to type and format of data and information to be stored.

Phase 2 refers to the identification and segregation of specific type of knowledge to fulfill the needs of healthcare organizations e.g. classification of knowledge into different types.

Phase 3 refers to the identification and definition of all the resources required for knowledge management e.g. technical resources, human resources, financial resources etc.

Phase 4 refers to the identification and definition of influential factors that may affect activities and components of the KM process, and deciding the required procedures and methods to successfully deal with these factors e.g. organizational culture, political culture, social culture, etc.

Phase 5 refers to all the areas that are related to Acquisition, creation or identification of knowledge related processes, procedures, policies & resources e.g. rules and regulations, legal obligations, etc.

Phase 6 refers to deciding, sorting and sequencing of processing procedures and activities to handle and manage all types of knowledge and knowledge management resources.

Phase 7 helps choosing and applying the required ICT system specifications and IT tools that enhance and support the KM activities e.g. hardware requirements, software requirements, etc.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Phase 8 describes the procedures related to retrieval, application, generation, innovation & sharing of new knowledge e.g. the methods and approaches to be used for knowledge production and communications, etc.

Phase 9 is related to the usage of knowledge in an effective and efficient way to gain maximum advantage, e.g., methods for implementation and application of knowledge perceived.

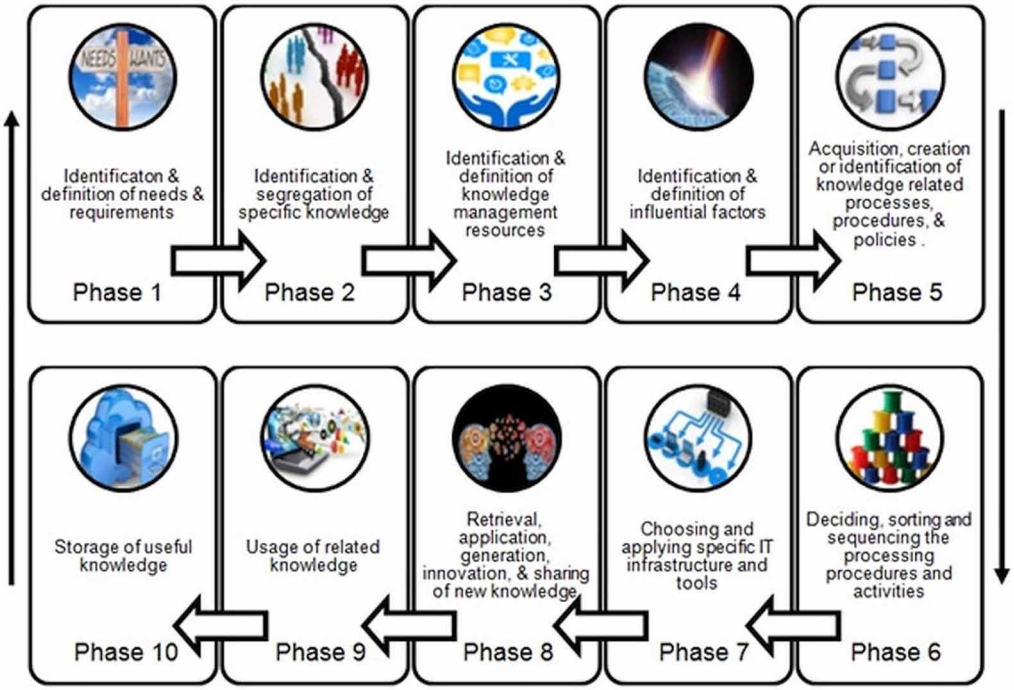
Phase 10 seeks to identify suitable methods and procedures for storage of new knowledge, e.g., effective processes to store useful knowledge in databases in specific format.

Each of the phases defined above has its own importance and implications for knowledge management in the healthcare industry of Pakistan. Collectively, all the phases can be summarized into a compact form which could be divided into 4 broad categories. Figure 6 explains the proposed KM process framework in a summarized way.

The 4 broad categories in which the 10 phases of Knowledge Management Process Framework could be summarized are:

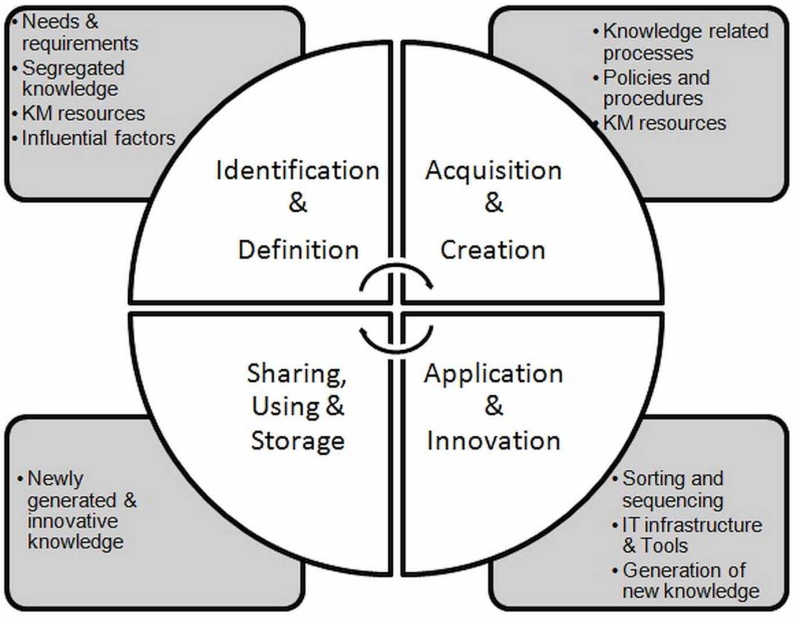
1. **Identification & Definition:** Comprises of needs, requirements, segregated knowledge, resources and influential factors;
2. **Acquisition & Creation:** Comprises of knowledge related processes, policies and procedures and KM resources;
3. **Application & Innovation:** Comprises of sorting & sequencing, IT infrastructure & tools, and generation of new knowledge from existing knowledge;
4. **Sharing, Using & Storage:** Comprises of newly generated and innovative knowledge.

Figure 5. The proposed KM process framework adapted from – (Arshad, Noordin & Othman, 2016)



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 6. Adapted - summarized representation of proposed knowledge management process framework (Arshad, Noordin, Othman, 2016)



The four broad categories are hereby summarized and represented in Figure 6.

KIIPF – KM INTEGRATED INTEROPERABLE PROCESS FRAMEWORK

The authors here emphasize the importance that healthcare is directly related with lives of people. A healthcare professional must have proper and accurate knowledge before dealing with his patients and providing advice or treatment. The importance of Knowledge Management in healthcare can be understood in terms of "right knowledge for the right treatment is a matter of life or death." One must be very specific and selective in this respect.

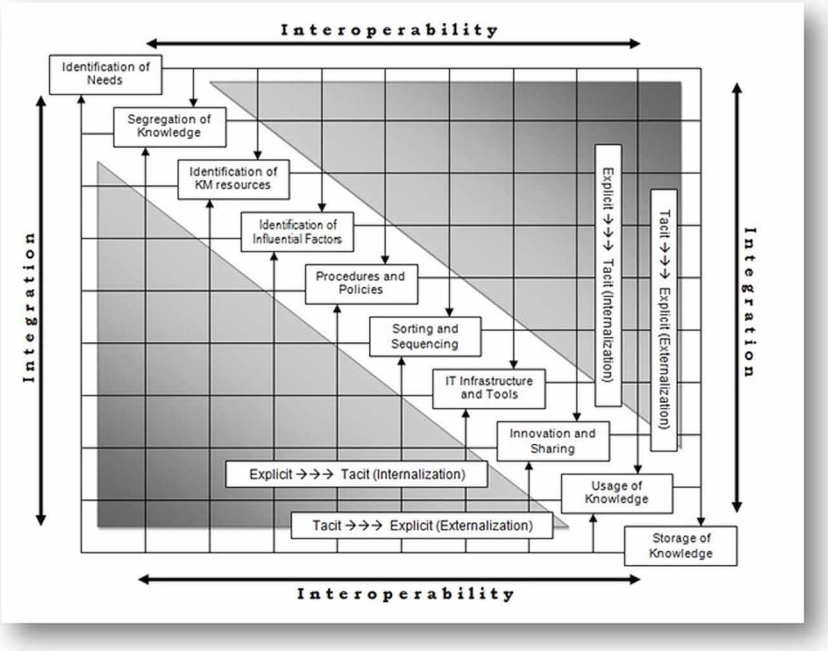
Acquiring the right knowledge depends on how the existing knowledge is managed and how the new knowledge is created with the help of innovative ideas and processes. A proper and scientific knowledge management process framework can make sure the availability of right knowledge to the right person at the right time. This may save many lives.

The KM Process Framework defined in Figure 5 can further be extended and elaborated in terms of Knowledge Management Integrated & Interoperability Process Framework (KIIPF) Grid as shown in Figure 7.

The KIIPF Grid explains clearly how the knowledge management process phases can work together to enhance integration and interoperability among them. This will increase the effectiveness and efficiency of the process framework. Each phase is inter-connected with all other phases in the grid to create interdependency, hence dealing with the sensitivities and margins of errors among each phase. Deficiency in one phase is ultimately going to affect the working of all other phases.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 7. The KIIPF – knowledge management integrated interoperability process framework grid



The last 3 phases in the suggested process framework define the conversion of existing knowledge into new and innovative knowledge, its sharing and usage and in the end storage of the newly created useful knowledge. Hence, their integration and interoperability works mainly for internalization (Explicit to Tacit conversion of knowledge) and externalization (Tacit to Explicit conversion of knowledge) for storage (Nonaka, 1994).

CONCLUSION

A comprehensive analysis emphasizes that there is always an opportunity to improve and enhance the way the knowledge is handled in healthcare organizations. Due to technological innovations and procedural improvements, healthcare organizations in Pakistan are striving to expand and increase dependency on integrated Knowledge Management Process Models and Frameworks that not only improve the effectiveness and efficiency of Healthcare Information Systems in Healthcare Organizations of Pakistan, but also save time and effort to manage knowledge.

The healthcare sector can address the complexity and challenges of KM by adopting practical and effective KM strategies which help to improve the quality of care for patients by providing them continuity and consistency of care. The current state of KM in healthcare is progressing and improving which is a positive sign for healthcare professionals and administrators to deal with pertinent challenges of KM implementation by collaborating and sharing useful knowledge and relying on the best knowledge available. This also helps open new horizons for innovations related to KM and its implementation in Healthcare sector.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

In this study, the authors suggested an integrated interoperable comprehensive phased Knowledge Management Process Framework which helps and guides to pave ways for all the stakeholders in the Healthcare industry of Pakistan to share and use the combined knowledge in most beneficial way increasing competitive advantage and saving valuable resources. The Knowledge in a Healthcare Organization is an asset which must not be compromised upon, so must be managed carefully. The authors believe that the current state of healthcare can be improved by implementing such KM systems that help to increase quality of healthcare by increasing efficiency and effectiveness of KM implementation in healthcare. The outcome results into practicing better evidence based medicine by innovation, collaboration and sharing of knowledge in a proficient and effective way.

It has been mentioned earlier that the case studies were performed on public sector healthcare organizations which work under the control and influence of local government bodies. A direct interference and involvement to implement, evaluate, verify and validate the usefulness of the proposed KM process framework requires government support and authorization without which the study is limited to proposition.

For future and further research, the researchers plan to develop an "Integrated KM Model for Healthcare Industry in Pakistan" based on this KM process framework and evaluate the applicability of the proposed model. After that, a survey will be conducted to evaluate the effectiveness of the KM Model in the healthcare industry of Pakistan.

Chapter 9
Semantic Health Mediation and Access Control Manager for Interoperability Among Healthcare Systems

Abdullah Alamri
University of Jeddah, Saudi Arabia

ABSTRACT

Healthcare systems have evolved to become more patient-centric. Many efforts have been made to transform paper-based patient data to automated medical information by developing electronic healthcare records (EHRs). Several international EHRs standards have been enabling healthcare interoperability and communication among a wide variety of medical centres. It is a dual-model methodology which comprises a reference information model and an archetype model. The archetype is responsible for the definition of clinical concepts which has limitations in terms of supporting complex reasoning and knowledge discovery requirements. The objective of this article is to propose a semantic-mediation architecture to support semantic interoperability among healthcare organizations. It provides an intermediate semantic layer to exploit clinical information based on richer ontological representations to create a "model of meaning" for enabling semantic mediation. The proposed model also provides secure mechanisms to allow interoperable sharing of patient data between healthcare organizations.

1. INTRODUCTION

Over the last decades, healthcare systems have evolved to become more patient-centric. Healthcare is moving towards supporting a continuous medical process by including multiple healthcare professionals and institutions, utilizing ubiquitous computing healthcare environments and embracing technological advances (Martínez-Villasenõr et al., 2016). Nowadays, it is hard to believe that there is still a prevalence of paper-based patient data throughout most of the health sector, despite all efforts to automate and share

electronic health information among practitioners, patients and other stakeholders. Many efforts have been made to transform paper-based patient data to automated medical information by developing Electronic Healthcare Records (EHRs) and standards in order to enable the reuse and sharing of information amongst healthcare systems (Martínez-Villasenõr et al., 2016; Begoyan, 2007).

EHR systems provide a collection of patient health information which includes medications, laboratory test results, demographic data, progress notes, past medical history, radiology data and immunizations, among other health-related data. Some of the advantages of an EHR are digitalized information commonly implies, such as improving the accuracy of medical terminology and availability of relevant and necessary information at the point of care (Ambinder, 2005). Moreover, EHR provides a complete view of a patient's health record which, logically, supports other analytical health-based activities, which in turn will improve the decision-making process and electronic communication. It is important that healthcare systems cooperate and share information in order to improve the quality of healthcare by reducing errors in medical decisions, decreasing health costs, and enhancing patient care.

Interoperability between EHRs plays a significant role in healthcare development as it can deliver more efficient and effective patient care, and helps with the retrieval and processing of patients' clinical information from and to different health databases. A number of approaches to improve the interoperability of health systems have been applied in recent years. Several international EHRs standards have been enabling healthcare interoperability and communication among a wide variety of medical centres. It is a dual-model methodology which comprises of a reference information model and an archetype model. The archetype is responsible for the definition of clinical concepts which has limitations in terms of supporting complex reasoning and knowledge discovery requirements (Lezcano et al., 2011).

Healthcare information is very complex and therefore it is difficult to establish interoperability between EHRs. Hospital health records are extremely heterogeneous. Patient's health data tends to be recorded in different forms and formats. Patient's health information may include different types of recorded data: laboratory test results, treatment notes and medications, progress notes, referrals, imaging, medical charts, nursing notes etc. Healthcare information is stored in different proprietary formats, and in structured formats including databases, and unstructured documents. This lack of consistency leads to severe interoperability problems.

Several scientific researchers have suggested using semantic web technologies and ontology to overcome the aforementioned problems (Kolias et al., 2014; Cannoy and Iyer, 2008). The semantic web technologies provide enhanced capabilities that allow data to be processed in a more effective and accurate way, create the framework for interoperability between healthcare systems and integrate data from various sources by means of their semantic meaning. The interoperability of healthcare systems is defined in the Semantic-health report as "the ability, facilitated by applications and systems, to exchange, understand and act on citizens/patients and other health-related information and knowledge among linguistically and culturally disparate health professionals, patients and other actors and organizations within and across health system jurisdictions in a collaborative manner" (Lezcano et al., 2011; Stroetman et al., 2009).

The motivation to increase the use of EHRs is grounded in evidence that they may improve the quality, efficiency, safety, and patient satisfaction with care. However, the adoption of EHR alone is insufficient to realize the full promise of health improvement. To enable patients to keep track of their health data wherever they receive care, attention is now on health information exchange (HIE), defined as the reliable and interoperable electronic sharing of patient data between healthcare organizations, clinical information among physicians, nurses, pharmacists, other health care providers, and, health data repositories (Hersh et al., 2015).

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

The objective of this paper is to propose a semantic-mediation architecture to support semantic interoperability among healthcare organizations. This paper does not intend to propose a new EHR standard. Instead, it provides an intermediate semantic layer to exploit clinical information based on richer ontological representations in order to create a "model of meaning" for enabling semantic mediation; and to deal with heterogeneity across data sources in EHRs which has yet to be adequately addressed. The proposed model also provides secure mechanisms to allow interoperable sharing of patient data between the healthcare organizations. This paper addresses the following questions:

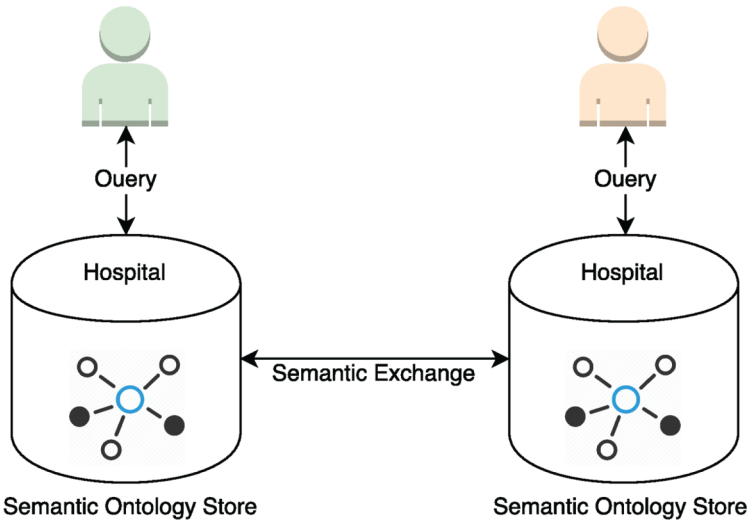
- How can healthcare information be represented using a semantic knowledge base?
- How to create a model that can deal with the issue of heterogeneity?
- How can requests for sensitive patient data disclosure be characterized and modelled?

The rest of the paper is organized as follows: Section 2 presents some background information about the essential aspects of health informatics related to electronic healthcare records (EHRs) and database design. It also presents some background information about the components of a semantic ontology knowledge base. In Section 3, we describe semantic health mediation and the access control manager. The following sections describe the main components of the model architecture. Section 4 presents a motivation example. The paper concludes with a number of suggestions for future research and development.

2. BACKGROUND

This section presents information about the essential aspects of health informatics related to electronic healthcare records (EHRs) and database design. Also, we offer some background information about the components of a semantic ontology knowledge base.

Figure 1. Interoperation Semantic Healthcare Systems



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

2.1. Electronic Health Records

EHR systems facilitate the management and sharing of patients' health information among health care providers. EHRs collect patient health records related to medications, diagnoses, hospital admissions, operations, imaging, laboratory tests, and pathology data. The main benefit of an EHR is that it improves the quality of health care delivery. Since the EHR concept seems to be complex, companies commercializing EHR have been implementing standards. A number of international organizations for standardization that have provided standard solutions for EHR are:

- International Organization for Standardization;
- European Committee for Standardization;
- Health Level Seven accredited by American National Standards Institute in the US.

International Organization for Standardization (ISO): The International Organization for Standardization (ISO) established ISO's Technical Committee ISO/TC 215. This committee introduced several standards related to health informatics. One of these standards, (ISO/TR 20514), defines the structure and context of a basic/generic HER (ISO, 2005). They also published ISO 13606-reference model which used to enhance EHR communication (Martinez-Costa et al., 2014; ISO, 2003).

European Committee for Standardization (CEN) in Europe: the European Committee for Standardization of Health Informatics (CEN/TC 251) presented a reference model, an archetype interchange specification, reference archetypes, security features, and exchange models. Also, CEN/ISO 13606 standard is a European standard approved by ISO designed to achieve semantic interoperability in electronic health record communication. The ISO/CEN 13606 standard is based on a dual-model architecture: archetypes to provide semantic meaning and the reference model structure (CEN, 2008; Lozano-Rubí et al., 2016).

Health Level Seven (HL7) in the US: the term 'HL7' refers to both the organization and to a set of messaging standards. HL7 are the health-messaging standards that support two messaging protocols: HL7 Version 2 and HL7 Version. HL7 Version 3 has developed the Clinical Document Architecture (CDA) for exchanging health data such as progress notes, discharge summaries, and results of physical examinations across healthcare systems (Benson and Grieve, 2016; Mandel et al., 2016; Sinha et al., 2012).

EHR systems have three architectures: basic, universal and distributed. In the basic HER architecture, a centralized EHRs database is developed in one organization (i.e. a hospital) and collects data from all healthcare systems operating in the hospital such as the laboratory system, radiology information system and others. In the universal HER architecture, a centralized EHR database is developed from a number of national/regional EHRs databases. In the distributed architecture, each healthcare organization (i.e. a hospital) has its own EHR with its own data model and with its own terminology standards (El-Sappagh et al., 2012).

2.2. Semantic Ontology Knowledge Base

The Semantic Web is a vision for the future of the World Wide Web where information is given well-defined meaning, providing logical connections of terms. In terms of the Semantic Web, the W3C recommends an RDF (Resource Description Framework) for semantic interoperability (Berners-Lee et al., 2001; Beckett and McBride, 2004; Turhan, 2011; Allemang and Hendler, 2011). RDF provides a powerful triple-based representation language for Universal Resource Identifiers (URIs). RDF Schema

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

(RDFS) provides a data-modelling and structured vocabularies for RDF data. Web Ontology Language (OWL) provides greater expressivity in the objects and relations for describing domain knowledge than RDFS (McGuinness et al., 2004; McBride, 2004). The Semantic Web adopted description logic (DL) as a formal knowledge representation for the ontology language. The DL offers a good trade-off between expressivity, complexity and efficiency in knowledge representation, and reasoning about structured knowledge.

A DL ontology has two conceptual components:

- **TBox:** Terminological part;
- **ABox:** Assertional part.

The TBox is used to describe a conceptualization, assertions about classes, assertions about properties and property hierarchies. The ABox describes property assertions between individuals and membership assertions Figure 2 shows an example of these conceptual components. SPARQL is a semantic query language for semantic data, and has become a W3C standard that is able to retrieve and manipulate data stored in semantic databases (Sirin and Parsia, 2007; Harris et al., 2013; Protocol, 2016).

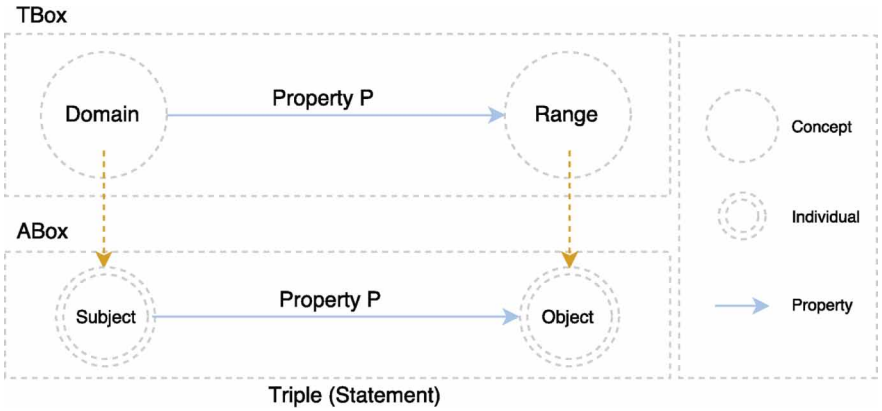
Definition 1: A DL ontology knowledge base is generally composed of (T, A) where:

- T is an intentional knowledge (TBox), which defines the concepts and properties, as well as the axioms of the logical theory;
- A is an extensional knowledge (ABox), which defines the membership of individuals (instances) and couples to concepts of individual relationships.

3. SEMANTIC HEALTH MEDIATION AND ACCESS CONTROL MANAGER

Interoperability between healthcare providers is critical for several reasons as patients may visit many physicians at different healthcare centres and their healthcare records are stored at multiple locations in disparate EHRs. The core goal of the proposed model is to enable physicians to exchange EHR data

Figure 2. An example of TBox and ABox and the relations between them



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

to optimize diagnosis and treatments, while enabling patients to keep track of their health records[1]. To achieve the research goal, a semantic mediation and access control manager is proposed to facilitate care coordination and improve patient safety, and reduce duplicate testing. The proposed model architecture is shown in Figure 3. The architecture has three main components: semantic-aware ontology store, semantic access manager and schema mediation. In the following, the main components of the proposed model are described. The complete algorithm for the semantic mediation and access control manager is presented in Algorithm 1.

3.1. Semantic-Aware Ontology Store

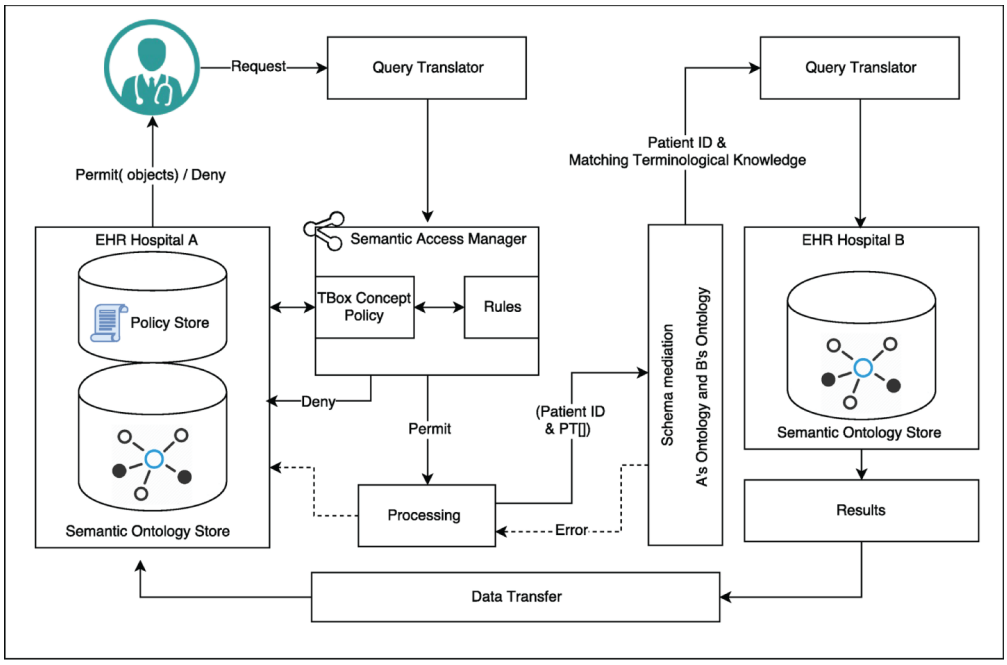
The semantic ontology stores are created for each EHR to interoperate. For this process, the knowledge base domain is represented using the Web Ontology Language (OWL), thereby obtaining the formal knowledge representation for each store.

Definition 2: The formal knowledge representation of EHR store is comprised of two typical parts:

- Terminological knowledge;
- Assertional knowledge.

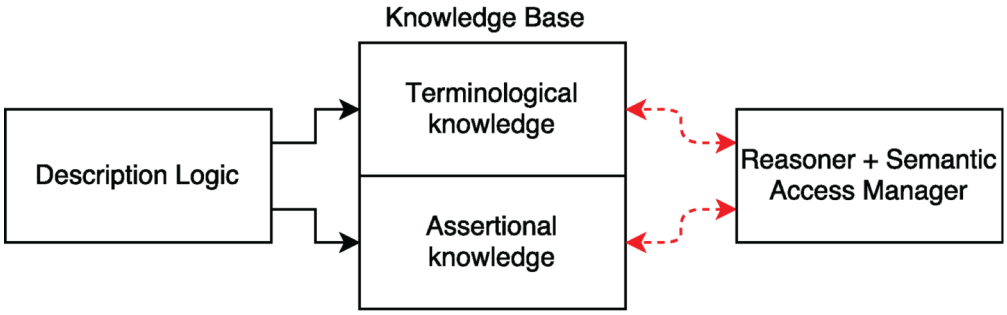
Figure 4 depicts the knowledge representation of an EHR store.

Figure 3. Semantic health mediation and access control manager



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 4. Knowledge representation of EHR store



Definition 3: A DL ontology knowledge is defined by interpretations which is a pair $I = (D, .^I)$, where $D = \varnothing$ of individual objects, called the domain; and $.^I$ is an interpretation function which maps:

- Every concept (class) $C \sqsubseteq D$;
- Every property P is semantic relation on $D \times D$;
- Every individual x is an element $x \in D$.

In OWL, concept is an abstract group, set or collection of objects that represent the individuals (instances) in the domain of discourse. A property, which expresses relationships between two concepts in a given domain, can be further distinguished as an object property or data property. An object property describes the relation between individuals (instances) of two concepts, whereas data property describes the relation between an individual concept and the literal value.

3.2. Semantic Access Manager

Semantic access manager is specifically tailored to regulate access to the knowledge contained in semantic EHR ontology store and to protect the semantic model's concepts and their relationships based on the authorization policy. The authorizations can be expressed by the set of policy rules asserting the access privileges that a user's role has to every terminological knowledge. Therefore, the set of policy rules are used to reason over the knowledge and infer information from the knowledge based on appropriate access policies. In this section, we formalize semantic access manager with an access authorization policy. We define the role; and permission rules as the basic building blocks in the design.

Definition 4 (Syntactic Policy): The following forms the principal semantic domains underlying the semantic access manager syntactic policy:

- S is a set of subjects (users) in this policy;
- R is the role of the user in this policy;
- Pr is a set of the matching capability and permission rules;
- Let $SR \sqsubseteq S \times R$ be a subject–role assignment relation;
- Let $RPr \sqsubseteq R \times Pr$ be a role-permission assignment relation;
- Pr[i] = (Act, Tn), where Act is an operation mode and Tn is a terminological knowledge which the user is permitted to access.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

More precisely, consider two semantic ontology stores, HO(A) and HO(B), in two hospitals A & B. In Step 1, since the user does not know the semantic ontology store schema of hospital B, the user writes a query against hospital A's ontology schema about a patient. In Step 2, the query translator receives an input query. The query is parsed to identify all the target terminological knowledge that it contains. In Step 3, the semantic access manager checks its policy base for the set of access permission rules associated with the user's current role to determine whether the user/role has permission to access the target terminological knowledge in the rewritten queries. If such matching rules exist, the semantic access manager forwards a (Patient identifier, PT[]) pair to the schema mediation module. PT[] defines a set of permission terminological knowledge.

Definition 5: PT[i]= Tn indicates the authorized terminological knowledge (Tn) of the source ontology that is allowed to be accessed by the user's role.

3.3. Schema Mediation

A DL ontology knowledge has been implicitly adopted as a suitable formal knowledge representation of an EHR store. In this phase, a natural generalization is designed to formalize multiple ontology stores interconnected by semantic mappings. Ontologies correspond to description logic theories (terminological knowledge), while semantic mappings correspond to collections of a semantic mapping rule which express how subsumption migrates from semantic ontology store HO (A) to semantic ontology store HO (B) by means of the mappings. Semantic mappings between different semantic ontology stores are expressed via a semantic mapping rule. A semantic mapping rule lists two concepts from two different ontologies and the relations among them. We introduce the following definition to formalize this term.

Definition 6: A semantic mapping rule is defined as: $O^A{:}C \xrightarrow{Map} O^B{:}C$.

A semantic mapping rule describes relations between HO(A) and HO(B) that are allowed to be viewed by the subject role of the A-th ontology. Therefore, the semantic mapping rule describes direct access from the source ontology to the target ontology. To make every description distinct, we will formalize each semantic ontology store with a prefix index. For example, the concept C that occurs in the A-th ontology store is denoted by $O^A{:}C$. Similarly, we use $O^B{:}C$ prefix index to refer to the concept in the B-th ontology store. The semantic mapping rule consists of three elements as stated in definition 6. Figure 5 shows an example of semantic ontology mapping:

- $O^A{:}C$: source concept, which is a concept of the source ontology that;
- $O^B{:}C$: target concept, which is a concept of the target ontology;
- $\xrightarrow{Map}$ mapping which represent the relations from the A-th ontology store O^A to B-th ontology store O^B.

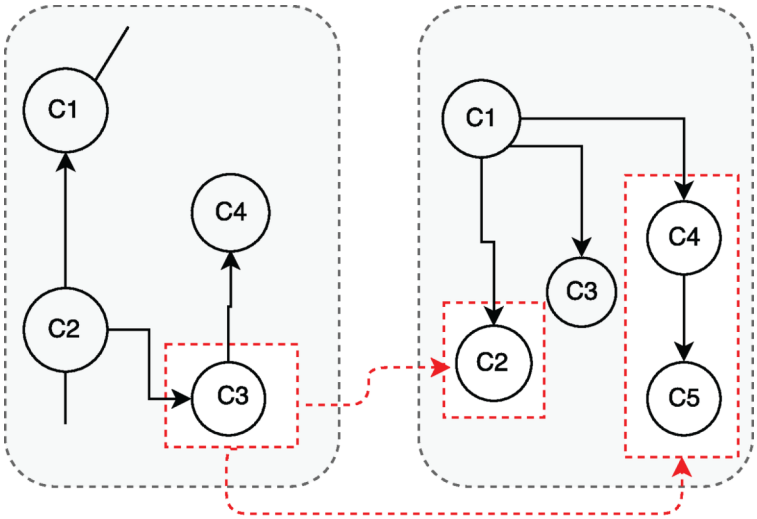
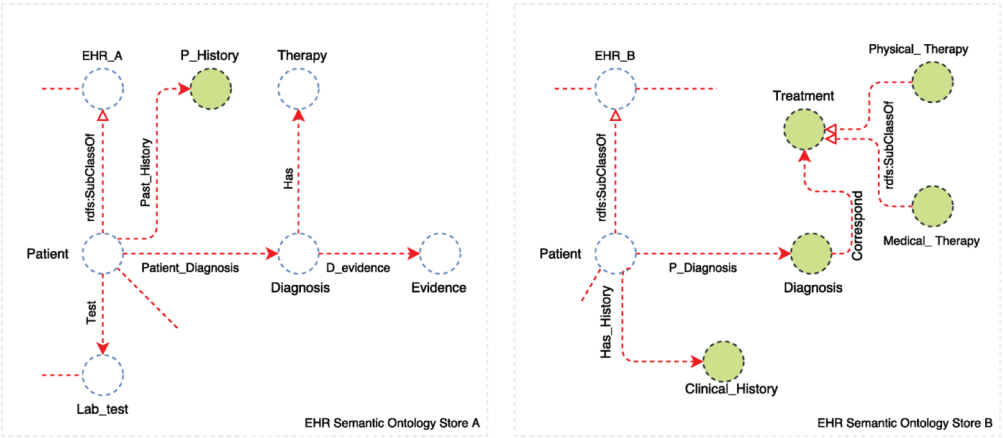
Figure 5. Example of semantic ontology mapping



4. MOTIVATIONAL EXAMPLE

The Semantic Health Mediation and Access Control Manager enables EHR data to be exchanged between healthcare organizations to optimize diagnosis and treatments, while enabling patients to keep track of their health records. The proposed model enforces access rights on a semantic terminological knowledge to secure health data within a semantic ontology store. To illustrate the procedures of the model, we create a hypothetical health knowledge model that is used to define and normalize the structures and relationships of the complex and unstructured health data from EHRs. Figure 6 illustrates a semantic ontology store for two healthcare organizations. Note that in this ontology example, we essentially focus on patients' medical records.

Figure 6. Semantic ontology store HO (A) and HO(B)



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

When a user acting in a role at hospital HO(A) submits a request to retrieve the health information of a patient from semantic ontology store HO(B), the request will be processed in the following 6 steps. Step 1: As the user does not know semantic ontology store schema HO(B), the user writes the query against the HO(A) ontology schema. The query is analysed in order to identify all the target terminological knowledge that the user wants to access in the query. Let us suppose the user acting in a role in HO(A) sends a request to retrieve information about the past history of patient (ID: Patient XZ1SD). Step 2: The semantic access manager retrieves the rule policies of the user's role from HO(A) and determines whether the terminological knowledge that the user's role submitted can be accessed and then generates PT[]. Let us consider that the user's role has a rule to access the request after checking the policy base. Step 3: The semantic access manager forwards an (Patient identifier, PT[i]=C:History) pair to the schema mediation module. Step 4: Mappings between different semantic ontology stores are expressed via a semantic mapping rule. The semantic mapping rule describes relations between HO(A) and HO(B) that are allowed to be viewed by the subject role of the A-th ontology.

Algorithm 1. Semantic health mediation algorithm

Input: Semantic Query Q, Subject/Role (SR $\sqsubseteq$ S $\times$ R in HO(A))
Output: Result Objects (HO(B))
1: The Query Translator
2: Parses Q to identify all the target terminological knowledge Tn
3: Semantic Access Manager
4: Retrieves the rule policies of the user's role from HO (A)
5: Access control verify the following
6: for each Tn do
7: If SR $\xrightarrow{Permit_access}$ Tn then
8: Generate the PT[i]= Tn
9: end if
10: end for
11: Forwards an (Patient identifier, PT[]) to the Schema Mediation
12: Schema Mediation
13: Lookup the Ontology Semantic mapping rule as OA:C $\xrightarrow{Map}$ O^{B}:C
14: if not exist any mapping rule then
15: Return "Failure"
16: else
17: Retrieve the appropriate matching terminological knowledge
18: end if
19: Submit the Patient identifier with matching
20: terminological knowledge to HO(B))
21: Generate the result
22: Transfer results objects to the user's role through the mediator
23: and object transfer

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

O^A:History $\xrightarrow{Map}$ O^B:Clinical History & O^B:Diagnosis & O^B:Treatment. Step 5: The filtered authorized semantic knowledge (Patient identifier, O^B:Clinical History & O^B:Diagnosis & O^B:Treatment) are translated and executed against semantic ontology store HO(B). Finally, Step 6: The resulting objects about the patient in HO(B) are sent to the user by means of semantic mediation and object transfer.

5. CONCLUSION

In this paper, the semantic health mediation and access control manager was proposed a means of providing secure interoperation among healthcare organizations. The proposed model resolves interoperability between healthcare providers and enables access control checks which provide a secure environment. Enabling secure sharing health information among healthcare providers will enhance the quality of healthcare by reducing errors in medical decisions, decreasing health costs, and enhancing patient care. Future work will focus on implementing and improving the model algorithm (Algorithm 1).

Chapter 10
A Conceptual Framework for an Extension Access Control Models in Saudi Arabia Healthcare Systems

Amin Shaqrah
Taibah University, Saudi Arabia

Talal Noor
Taibah University, Saudi Arabia

ABSTRACT

This article aims to develop an extension access control models framework in Saudi Arabian healthcare systems. The conceptual framework acts as an ascendency structure to organize and support the efforts of several health care standards which reflect on the coherent of confidentiality; integrity; and availability triads in order to achieve the strategic business objectives of Saudi Arabian healthcare institutions. It is considered to be three common access control models developed by ACM institute and extended to other criteria identified by the National Institute of Standards and Technology. While literature explains that an easy-to-use access control model can lead to success healthcare system, understanding the extension of access control systems is vital for Saudi Arabian healthcare institutions to protect resources against unauthorized use. This article has taken a step in this direction.

INTRODUCTION

The purpose of information security in Healthcare Information Systems (HIS), in general, is to guarantee the Confidentiality, Integrity, and Availability (CIA) of the data (Srisakthi and Shanthi, 2015). Confidentiality of the data is the protection that only those with appropriate rights and verified permissions might access certain data (Whitman et al., 2013). Data should not be disclosed to unauthorized entities, integrity in general means sustaining and ensuring the accurateness of data over its entire life cycle.

In HIS, integrity of the data means that data should not be modified by unauthorized entities/persons. Protection of data in HIS prevents unofficial or accidental with holding of data or resources. To insure HIS security, countries initiate laws and regulations that healthcare organizations must follow. In the US there are three acts, the Health Insurance Portability and Accountability Act (HIPAA), the Gramm Leah Bliley Act (GLBA), and the Sarbanes Oxley Act (SOX), that involve statements to protect personal information from being revealed or retrieved by unofficial persons, entities, or processes (Gopalan et al., 2012). HIPAA upholds principles for the practice and release of Protected Health Information (PHI), which is any data about health status, provision of health care, or health care expenses that can be connected to an individual (Lerouge, et al., 2007).

To protect PHI, healthcare organizations need to enforce the patients' rights by using a set of policies and technologies. Access control models were introduced to overcome the privacy matter and grant permission to access PHI to only authorized persons. Access control models are used to prevent unofficial use of resources, including using resources in an authorized manner (Zeltsan, 2010). There are many access control models, each of these models have been extended in different ways to cover missing security measures. Healthcare organizations are free to choose the specific access control model that fits the organization's needs and is compatible with PHI privacy regulations. In addition to laws, regulations, policies and technology, standards are also used to confirm the security of the PHI in healthcare information systems (Fichman and Kemerer, 1997). Standards can be used to deliver the basic required measures to help enforcing and maintaining information security procedure in any institution. There are few well-known standardization tier-1 organizations such as the International Organization for Standardization (ISO), the National Institute of Standards and Technology (NIST), and the Association of Computing Machinery (ACM). There are other standardization organizations specific to certain industries. For example, Health Level Seven (HL7) addresses concerns about healthcare informatics. The industry standardization organizations generally adopt the technology that has been used by tier-1 standardization entities (Meyer and Goes, 1998). The literature study did not provide a methodology to extend for achieving the NISTER, the presented paper provides a starting point to meet the need for developing an extension access control model framework that addresses the synergy between secure healthcare systems and access control models considering NISTER 7874. The rest of this paper is structured as follows: Saudi Arabia health care systems, an overview of access control model, assessment access control model, proposed framework, implication, finally the conclusion and future work.

SAUDI ARABIA HEALTH CARE SYSTEMS

The unsettled environment of the healthcare sector growing the importance to adopt new technologies to achieve the vision of healthcare institutions (Samarati et al., 2001, Rossetti et al., 2012 and Hoeur and Kritchanchai, 2015). This section will provide the current requirement for healthcare systems. As mentioned in the definition of the access control, its purpose is to prevent unauthorized access to PHI. Conell and Young (2007) assertion the general privacy needs from the ACM are: 1) Healthcare institutions requirements have the ability of having the choice of designing the security policy, and the resilience to randomly define the security of PHI. 2) Patient requirements to have the ability for having full control over their PHI, right to disclose certain information, and transfer the rights from one healthcare provider to another. 3) Ease of handling ACM. Recently, the office of the National Coordinator for Health Information Technology published guidelines to preserve privacy and security related to PHI (Canada

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Health Infoway, 2015), the guidelines suggested that healthcare institutions have to address the following points: 1) auditing functions, 2) unique user IDs and strong passwords, 3) Role or User- based Access Control, 4) auto time-out, 5) amendments and accounting of disclosures (Cresswell and Sheikh, 2013). Currently, most of the healthcare systems are integrated using traditional technologies and standards (Almadani et al., 2016); security is the most important issue when integrating healthcare systems. The KSA healthcare system currently faces numerous challenges and the MOH is under remarkable pressure from its government to develop a high-quality healthcare system and improve healthcare services to all residents, mainly in rural/remote areas (Khudair, 2008). In 2010, the MOH conducted a study into the adoption of telemedicine stating that telemedicine abilities can improve many challenges of the KSA healthcare system (El-Mahalli et al., 2012). In 2011, the MOH launched the first national project for telemedicine, referred to as the Saudi Telemedicine Network (STN), covering all Healthcare Facilities (HCF) (MOH, 2016).

Alaboudi (2016) noted Saudi Arabia healthcare system exposed to various obstacles and even MOH pressures to offer high quality healthcare services to all residents, mostly in rural areas, ministry of health on (2010) initiate telemedicine adoption. Alkhamis and Hassan (2014) concluded the variances among literature with respect to adopt telemedicine. Alkhamis (2017) and Aljazaeri (2017) resolute the amount which MOH support healthcare systems. Saudi Arabian MOH deploy a complete package of health care management through the main solution to manage the "OASIS" health information system, which offers multi clinical services such as: financial, administrative and focused on facilities. The OASIS system is divided into module, each of these modules address explicit functional requirements. OASIS run on individual self-contained units, and merged with other units, and when the operating system is the integration of all units into a cohesive and powerful system. OASIS information systems in Saudi Arabia hospitals deploy different services that give the systems unique and distinctive center in the health care market, some of these features (MOH, 2016):

1. **Adjustability:** The ability to run applications in a standardized mode to suit different sizes of hospitals requirements, and these topographies and functions necessary hospital services, number of employees and specialization of the hospital play significant role. Applications are complete and very flexible and modular so that the implementation of selected modules only. This also allows the implementation of the system in stages within the hospital. OASIS system comprehensive and deals with an extensive kind of clinical systems. Simultaneously, the system is in the form of units in design, with each unit being address detailed serviceable needs. It is likely to deploy single self-contained units, and merged with other units, and when the system is implemented. All units are integrated into a cohesive and powerful system.
2. **Applicability:** The ability to run applications on a diversity of platforms diverse hardware, it is likely that the deployment of the program on different PC, unrelatedly of ability, iOS which they used starting from advanced systems in servers to small computer networks. This has significant benefits as described below. The system of the laboratory, for case, needs a lot of early group consists of selecting diverse stands such as test codes, ranging bookmark, and excellence control standards, and arrangements current work, and so on. This procedure takes a long time wants a lot of believed and effort of supervising staff. If it was likely to handover this group of raw data to another location with the application, it will save a portion of work through the provision of the laboratory application in every hospital. This would kind the work a great amount of uniformity and consistency in the hospital operations.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

3. **Scalability Interdependence:** The capability to transfer hospitals on the application flat to access from everyplace inside the system, and access to the patient's health history in the past online, this to improve the excellence of treatment and decreases the total cost of patient. Scalability interdependence can be accomplished if there is an active connection on the application level through OASIS application. OASIS application delivers connectivity levels. Such a level of communication removes the stays period and imprecisions customarily related with system. And the stays period related with improved functionality many referral appointments, lab reports and at the end deliver better health care.
4. **Data Management:** The facility to retain and store data in the manner greatest favorable from the viewpoint of data management in the hospital.
5. **User Interface:** Ease of GUI browsing and navigation allows users deal quicker and nearer to PC by providing GUI directly to regulatory databases. And end users can understand the database and prepared by the system to fit their requirements. OASIS system provide a comprehensive range of applications obtainable that provides a elastic mechanism for the facades of data entry, query facilities, reports attached to the writer and GUI interface to present and analyze data visually.
6. **Arabic GUI:** Hospital system has an effect on the whole hospital, and managerial staff, paramedics and medical staff. Humiliation, the dual-language program has the capabilities to store various data about the patient and other managerial particulars in Arabic and English. OASIS after it was deployed in the Middle East proficient of supplying a perfect system. It is fantasy that health data will be in English, while the managerial data perfect. The system also allows the query and prints some of the information in any of the languages were chosen by the employer.

Furthermore, other features that may be of interest to the user like modify the forms flexibly; ease of maintenance; confidentiality and security of data; rapid response; and the availability of local expertise and support (MOH, 2016).

AN OVERVIEW OF ACCESS CONTROL MODELS

Medical information is a standout amongst the most delicate classes of data whose confidentiality and integrity is crucial. Medical information ought to then be available just to the approved social insurance experts and patients. In specific, among social insurance experts, the doctor in charge of the patient's care and medicines is generally dependable for the utilization of the patient's information (care stewardship). Patients ought to have the accessibility to get to their data and to keep up the control over who can get to it by methods for a legitimate notice system, earlier endorsement, and express assent. Since patient's wellbeing is more imperative than information classification and respectability, the standard of delivery of care starts things out must be implemented. The primary outcome of this guideline is that, if there should arise an occurrence of crises, the restorative data of a patient ought to be available to whom can convey care to the patient, regardless of the possibility that she is not unequivocally approved. In these circumstances, get to control strategies might be abrogated. To counteract or find conceivable misuse by means of a post investigation, each access conceded must be recorded in affiliation with the personality of the subject getting to the framework. This paper focused on access control model standards which they are used to provide the minimum requirements for any organization to apply its information systems security policies. In a healthcare system, these standards would be used as a minimum requirement to guarantee

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

that only authorized individuals gain access to PHI and only when needed (Barrows et al., 1996). This paper proposed a framework based on three well-known Access Control Models: Discretionary Access Control (DAC), Mandatory Access Control (MAC), and Role-Based Access Control (RBAC). DAC is one of the earliest access control models. It controls data access by authorized individuals on the basis of the user's identity and approvals that identify the access methods (i.e. read, write, or execute) that the user is permitted to view (Sandhu et l., 1994). DAC can be implemented by using a simple AC matrix or Access Control List (ACL) (Gopalan et al., 2012). DAC is a flexible policy, which makes it appropriate for different systems and applications. On the other hand, it is hard to manage when users need to be removed or added. The second well-known ACM is the MAC; it differs from DAC in the decision process. When using MAC individual data owner cannot give or modify access rights on his own data but the data is governed by a central authority not by an individual owner of the data (Sandhu and Jaehong, 2003). Additional significant field of involvement intensive on extending eXtensible Access Control Markup Language with a new security and privacy authorization policy, which adopts interoperability in the healthcare context and presents policies to impose authorization policies controlling access to information, then possibly stored across enterprise boundaries.

Since in the healthcare situation the benefits of subjects frequently rely on upon their part (e.g., nurse, doctor, patient), and get to control models to bolster both the meaning of Approvals for subjects that can be progressively composed in gatherings and the meaning of a chain of importance of parts. Moreover, get to control models and approaches for medicinal services frameworks ought to bolster the various leveled association of the data to encourage the meaning of approvals. Get to control choices may frequently rely on upon the data put away for the included patient, which incorporates distinctive sorts of information with various security necessities. As a result, a fine-grained access control that confirms regardless of whether to allow access to wellbeing data on trait/property premise is vital. The support for setting data that triggers the initiation of (dynamic) approaches is additionally of principal significance. Truth be told, an access control choice may rely on upon an arrangement of condition components that impact how and when an arrangement is upheld. For example, under ordinary conditions the wellbeing data of patients put away in the database of a healing facility can be gotten to just locally, in the occasion of a pestilence or of uncertain events, physicians working remotely can get to patient information to treat casualties. In spite of the fact that in crisis circumstances arrangements that apply in typical conditions can be abrogated, there are a few accesses that ought to dependably be avoided, since they can't help in overseeing such crisis circumstances and speak to mishandle. Such gets to ought to never be allowed, implying that strategy supersede must be denied. The access determination is made based on the confidentiality level (top secret, secret, confidential, and unclassified) of data and access class of the user. MAC is the same as DAC in the level of difficulty. Additionally, both can be difficult to manage when users need to be added or removed (Gopalan et al., 2012). The third well-known ACM is RBAC; RBAC determines access based on the user's role and the authorizations allowed by each role (Gopalan et al., 2012), RBAC supports features, like least privileges, and policy neutrality. RBAC combines flexible and mandatory access control models. It uses roles which are a normal concept for most organizations (Baracaldo and James, 2013). In RBAC, authorization is allocated to the role that individual users have within an entity (Sandhu and Jaehong, 2003). Users such as doctors, nurses, or clerks take on given roles. The rights of access for PHI are clustered by role name, and the use of resources is limited to individuals who are authorized to accept the associated role. However, the RBAC model supports permission before access and does not offer monitoring of an authorized session. So, if the doctor is accessing an authorized session, the network administrator cannot monitor the doctor activities. Also,

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

in RBAC updating information is based on action or canceling the session (Gopalan et al., 2012). Usage CONtrol (UCON) model was introduced by Park and Ravi that incorporates the old-fashioned ACM, digital rights supervision, and trust supervision (Park and Ravi, 2004). The previous three ACM deal only with the permission decisions on a user's access to gain access to data, But UCON was introduced as a broad view of the access control to cover obligation, continuity, mutability, and conditions (Park and Ravi, 2004). The UCON model incorporates the previous three access control models, plus, Digital Rights Management (DRM) and trust management.

NIST INTERAGENCY REPORT "7874"

In 2006 the National Institute of Standards and Technology (NIST) in the U.S. developed a guideline NISTIR-7316 for any organization that included the minimum requirements to secure its information (Hu et al., 2006). In 2012 NIST extended those guidelines with an evaluation metrics of access control NISTIR-7874 (Hu et al., 2012). In the healthcare system, Health Level Seven (HL7) is an entity that is internationally recognized for developing standards about healthcare informatics. HL7 is concerned with sharing the data between healthcare entities. HL7 adopted RBAC because of it is well-known model that had been explored by many organizations such as NIST, Association of Computing Machinery (ACM), and ISO (HIT, 2015). HL7 issued a third version of the adopted RBAC model. The catalog seeks to target Health Information Technology (HIT) merchants, HIT systems integrators, and healthcare provider organizations (Samarati et al., 2001). National Institute of Standards and Technology Interagency Report (NISTIR) used NISTIR-7316 to provide useful and theoretical guidance, to help organizations with securing their applications and delivering contextual information about access control policies, models, and mechanisms. It explains only the commonly used ACMs. It also discusses the capabilities, limitations, and qualities of these access control protocols that are set for each access control policy. It is proposed to provide useful and theoretical guidance for security administrators, managers, and procurement officers whose proficiency is associated with access control. According to Hu et al., (2006) NISTIR-7316 is divided as follows: 1) introduction, 2) overview of Access Control, 3) capabilities and limitations of access control mechanisms,4) capabilities and limitations of access control for distributed systems, 5) safety limitations, 6) and quality metric for access control systems.

For the purpose of this paper the enforcement mechanisms from NISTIR-7874 will be explained. The NISTIR-7874 explains only the commonly used ACMs which are DAC, MAC, and RBAC. It did give a brief overview, the pros, and cons on each of them. It highlighted the attention to the temporal restrictions which are formal statement of access policies that involve time-based limitations on access to resources. The temporal restrictions depend on the application scenarios. It may be required to limit resource use. Or, it may be to control time-sensitive activities (Samarati et al., 2001). The NISTIR-7874 gives an example of time restrictions statement which is the history-based access control policy. Within the temporal restriction subsection, it gives an overview on two of the popular history-based access control policies. NISTIR-7874 identifies the enforcement as the measures or methods that access control needs to impose rules of the used ACM. These properties affect the efficacy of extracting access control decisions. The enforcement properties included in the evaluation metrics guidelines are: 1) policy combination, configuration, and limitation, 2) bypass, 3) separation of duty, 4) safety, 5) conflict resolution or prevention, 6) operational/situational awareness, 7) granularity of control, 8) expression (policy/model) properties, 9) and adaptable to the implementation and evaluation of access control policies.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

A CONCEPTUAL FRAMEWORK OF AN EXTENSION ACCESS CONTROL MODELS

There is neither best-fit framework nor best-practice solution for telemedicine for all healthcare institution (Healy, 2008). The obstacles adopting telemedicine in a given healthcare institution may not similar telemedicine in another healthcare institution (Yusof, et al., 2008). Most healthcare institution faces expressions obstacles in adopting a specific telemedicine with an important point of dissimilarity. Nevertheless, each healthcare institution will have its own unique sets of obstacles related to its context and macro or micro environment (Yusof et al., 2008). Some of the obstacles and encounters that may limit telemedicine adoption in a given healthcare institution may no longer exist, could partially lessen, or may develop a chance for another telemedicine model healthcare institution (Baker, 2012). Perednia and Allen (1995) noted the eventual realization of adopting and implementing telemedicine in a given healthcare institution is confirmed if these obstacles and encounters are sufficiently addressed. As mentioned, each of the well-known access control model had been extended in different ways to cover missing security measures. This section will discuss some of those extensions based on our hypothetical scenario and how the researcher develops a conceptual framework overcame the missing security measures (Figure 1). The first requirement was temporary permission that should be granted by the access control system to guarantee privacy of PHI.

The temporary permission was introduced to access a control model such as Temporal-RBAC (TRBAC). TRBAC was an extension of RBAC meant to sustain time-based controls to enable/disable roles (Bertino et al., 2001). The main feature of the TRBAC model was to include periodic role permissions and time-based requirements among roles that can be identified over and done with initiators. TRBAC was extended to Generalized-TRBAC (GTRBAC) by creating a clear difference between role permission and role initiation (Joshi et al., 2002). So, the role is permitted if a user can get the authorizations given to it. A role would become active when a user gets authorization. GTRBAC was extended by hybrid role hierarchy (Joshi et al., 2005). The third requirement in the hypothetical scenario is to provide a purpose for access PHI. In an access control system, the purpose can be identified as the reasons for accessing or collecting private information. Lili et al., (2012) proposed to integrate the purpose-based usage in $UCON_{ABC}$ (Lili, et al., 2012). $UCON_{ABC}$ is an extension to UCON and the access decision is granted based on user's Authorization, Obligation, and environmental Conditions required (ABC) (Park and Ravi, 2004). $UCON_{ABC}$ allows updating features of users and data during the approved session. In addition, $UCON_{ABC}$ offers monitoring of an authorized session not like the RBAC, updating information based on action, and canceling the session (Park and Ravi, 2004).

Baracaldo and Joshi (2013) introduced another approach that was integration between risk management and the RBAC model to mitigate insider threats. It can also be applied to a third requirement of such a scenario (Baracaldo and James, 2013). Baracaldo and Joshi's approach is a good combination between preventive (ex-ante) and corrective (ex-post) mechanisms; however it needs a network manager to prevent the risk associated with each level of authorization in the system. There are recent studies that propose an integrated approach between two or more ACMs, Khan and Ken (2012) combined two ACMs (DAC and RBAC) with a context-aware AC to get the rewards of all of them. The context-aware access control would provide the compliance with the HIPAA regulation. DAC would provide the simplicity of implementations. RBAC would provide organizational role, and limited privileges.

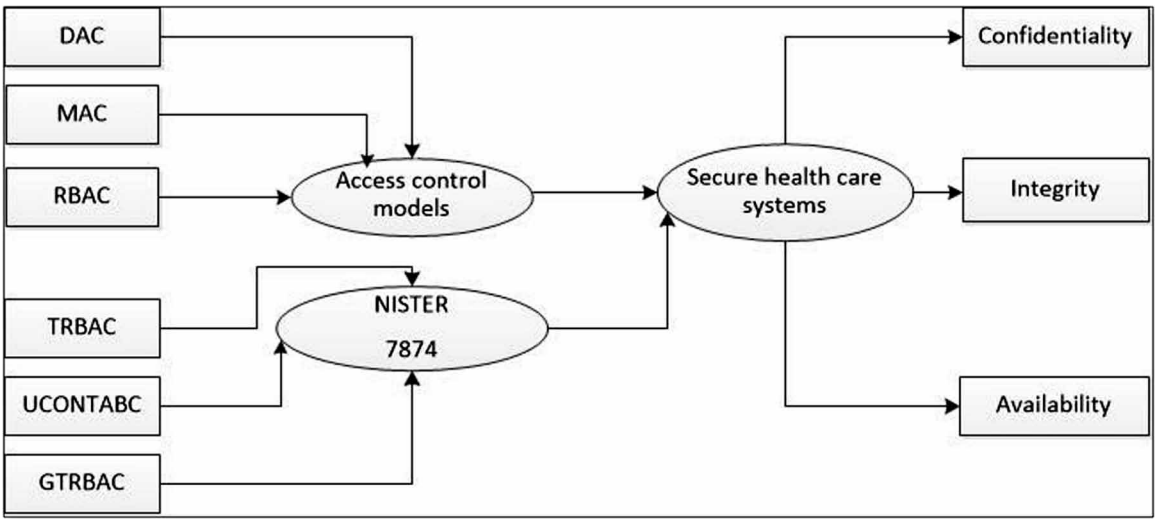
Figure 1. A Conceptual framework of an extension access control models



IMPLICATIONS

Protecting and securing PHI is very important when using ACS. Any breach of such information would reveal the patient's entire healthcare history, which is undesirable (Garcia and Effken, 2013). Unfortunately, none of the three ACMs recommended by NISTIR-7874 would fulfill the general privacy requirements. Moreover, the recommendation is for additional user-based access controls, and amendments to account for disclosure of PHI. Currently, none of the recommended ACMs meet these requirements. NISTIR-7874 and its extension evaluation metrics were used to evaluate the ex-ante measures and none of the evaluation criteria considered the ex-post enforcement measures. It was expected because all the evaluation metrics were built to evaluate older ACMs that dealt only with the authorization decisions on a user's access to gain the right of use/enter data (Rath et al., 2013). By law, it is mandatory from the healthcare organizations to provide defensive measures to protect PHI. With the current standard, NISTIR-7874 is a way behind the current law requirements. The recent approaches in the ACM are the Usage-based access control model. This model incorporates the previous three access control models as well as Digital Rights Management (DRM) and trust management. $UCON_{ABC}$ was introduced eleven years ago and it matured similarly to its predecessor, ACM. $UCON_{ABC}$ allows updating features of users and data during the approved session. It does offer ex-post enforcement mechanisms as monitoring of an authorized session; updating information based on action; or canceling the session, in addition, to the ex-ante enforcement.

From the analysis of the NISTIR-7874, it was found that the standard did include the temporal restriction which is equivalent to auto time-out in the current requirements. However, it did not include the purpose for data access, which is a basic requirement. The purpose of using the PHI is important to guarantee the PHI is used as intended and prevent unnecessary access. According to Masoumzadeh and James (2008) "the purpose of using PHI was integrated the RBAC model as an extension for it". The most recent studies focused on integrated mechanisms between ex-ante and ex-post enforcements. The recent approaches are combining ex-ante measures access control models with ex-post measures

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

such as risk management (Bertino, 2005), risk assessment (Baracaldo and Joshi, 2013), intrusion detection in RBAC (Bertino, 2005). This paper recommends Saudi Arabia MOH that should be added the NISTIR-7874 to his security policy. The first section introduces $UCON_{ABC}$ as a forth recommended for ACMs, second section is TRBAC, and third section is GTRBAC. Such a model if added to the framework would mean: industrial standardization entities like HL7 would have the opportunity to recommend it as a recommended model that can be used in the healthcare organizations; the standard would be compatible with the recent law requirements, and general recent requirements. In our framework, we extended to apply TRBAC; GTRBAC; and UCONTABC considering NISTER-7874 to improve CIA triads at Saudi Arabian ministry of health. This framework represents the first step of applying all access control models into the healthcare institutions to achieve healthcare institutions vision.

CONCLUSION

This paper aims to develop a conceptual framework for the access control solution in healthcare systems at Saudi Arabia ministry of health, to realize the developed five years plan which has positioned telemedicine as a prime transformation agent and enabler. To enable this vision this paper outcomes are expected to contribute critically in achieving the strategic health objectives of the institutions, such as: care for patients; connect providers at all levels of care; improving its public image; measure the performance of healthcare delivery; and transform healthcare delivery to a consistent, world-class standard. The main access control models were introduced and illustrated through a conceptual framework, to ensuring confidentiality, integrity, and availability (CIA). Chiasson and Davidson (2004); Healy (2008) found that "IS healthcare research is the most promising opportunities to push the contextual envelope of IS research''. Explicitly, Author deploying an MAC; DAC; and RBAC for the healthcare context, which extended add TRBAC; GTRBAC; and $UCON_{ABC}$ to proposed framework introduced as recommended access control models.

Furthermore, the Industrial standardization entities as HL7 would have the opportunity to recommend it, the purpose of using the PHI is important to guarantee the PHI is used as it intends for and prevent unnecessary access. The future work would be examining one of the integrated approaches that used the ex-post measures by using the NISTIR-7874 evaluation metrics. NISTIR-7874 founded that the standard did include the temporal restriction which is equivalent to auto time-out in the current requirements. On the other hand, NISTIR-7316 did not include the purpose from data usage which could be considered a basic requirement. There are some limitations which can address for future research, the research framework needs to be tested empirically, although the access control models have been measured in previous research.

ABSTRACT

Virtual screening represents an effective computational strategy to rise-up the chances of finding new bio-active compounds by accelerating the time needed to move from an initial intuition to market. Classically, the most pursued approaches rely on ligand- and structure-based studies, the former employed when structural data information about the target is missing while the latter employed when X-ray/NMR solved or homology models are instead available for the target. The authors will focus on the most advanced techniques applied in this area. In particular, they will survey the key concepts of virtual screening by discussing how to properly select chemical libraries, how to make database curation, how to applying and- and structure-based techniques, how to wisely use post-processing methods. Emphasis will be also given to the most meaningful databases used in VS protocols. For the ease of discussion several examples will be presented.

1. INTRODUCTION

Virtual screening (VS) is a computational technique developed since early 1990s to meet the needs of pharmaceutical companies to maximize their profit when minimizing time and cost (Lavecchia & Di Giovanni, 2013). It is well known that developing a new drug is a complex process, which can take approximately 12-15 years and huge investments of about $1 billion (Hughes et al., 2011).

In the last decades, pharmaceutical companies have radically changed the approach to the discovery and development of new drugs (Everts et al., 2017; Mangiatordi et al., 2016; Myers & Baker 2001) in the attempt to increase competitiveness and innovativeness. The need to speed-up the entire pipeline of drug discovery and development has given new credit to VS approaches as a viable alternative to the High-Throughput Screening (HTS) (Shoichet, 2004; Klebe, 2006). In this scenario, VS has gained a key role for anticipating the discovery of novel hits by reducing the likelihood of failure and, thus, time and costs (Kar& Roy, 2013).

In addition, VS is effective to investigate ligands promiscuity for unveiling polyphamacological actions for the design of multi-target compounds and/or to detect off- target affinity (Chaudhari et al., 2017). The old paradigm of drug design "one-drug one-target" has been overtaken by the need of having polypharmacological drugs enabling to replace combination therapy with multitarget therapy (Anighoro et al., 2014). VS could be also valuable to draw a preliminary toxicological spectrum and especially about drug efficacy and safety (Chaudhari et al., 2017; Nicolotti et al., 2014). In this respect, main causes of market withdrawal are associated with the occurrence of idiosyncratic adverse liver effects, which are often fatal for people (M. Chen et al., 2011; Fontana et al., 2009). Well known is the case of nimesulide, a non-steroidal anti-inflammatory drug (NSAID) marketed as one of the first selective COX-2 inhibitors and currently banned from several countries in Europe and USA.

Traditionally, VS relies on two main strategies that are ligand-based (LBVS) and structure-based (SBVS) virtual screening approaches (Lionta et al., 2014; Nicolotti et al., 2008). The LBVS strategies are based on the assumption that similar chemical structures should exhibit similar binding properties with respect to a given target (Klabunde, 2007; Koeppen et al., 2011). To carry out LBVS studies, at least one active compound (e.g., agonist for a given target) and a pool of structurally similar compounds are necessary (Koeppen et al., 2011; Rognan, 2017).

On the other side, SBVS approaches are employed when the 3D solved structure, or as alternative a reliable homology model, of a target protein is available. For the sake of clarity, homology models having at least 50% sequence identity compared to the template are suitable for SBVS, being docking studies usually able to globally reproduce the reference interactions with high level of accuracy (Bordogna et al., 2011; Cavasotto & Phatak, 2009; Hillisch et al., 2004; Oshiro et al., 2004).

Generally, a SBVS approach is based on two basic steps: (1) one or more libraries of compounds are screened by biasing the active site of the targets protein (or its model) with a number of different molecular poses; (2) the compound-target affinity is evaluated by means of a scoring function whose value is used for ranking compound. A post-processing phase can be also implemented to refine the selection of the top-ranked compounds for prioritizing experimental tests (i.e., *in vitro* and/or *in vivo* assays) (Rognan, 2017). An example of efficient application of SBVS is the identification of molecular scaffolds for developing selective ligands towards human histamine H4 receptor (hH4R). This study was conducted using a library of about 8.7 million 3D-structures screened on a homology model of the hH4R, with 255 compounds selected and successfully tested (Kiss et al., 2008).

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Nowadays, various workflow management tools have been developed to facilitate the automated application of VS strategies (Glaab, 2016). Widely applied are the open-source software KNIME (Beisken et al., 2013; Mazanetz et al., 2012) and the commercial Pipeline pilot (Accelrys http://accelrys.com/). Several other tools have also available including Taverna (Oinn et al., 2004), KDE Bioscience (Lu et al., 2006), Galaxy (Goecks et al., 2010), Kepler (Ludäscher et al., 2006) and SOMA2 (Lehtovuori &Nyrönen, 2006).

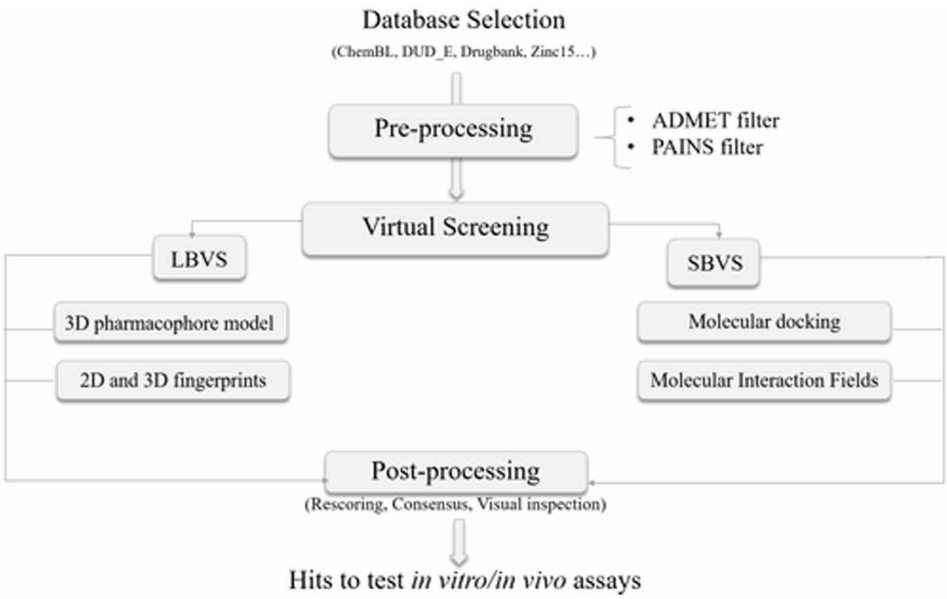
Recently, an innovative SBVS approach exploiting the similarity of X-ray solved binding sites has been developed (Siragusa et al., 2015). It is thus demonstrated that VS is also effective to explore the protein cavities whose 3D structures are known on the basis of the shape similarity and irrespective of the primary structures. Several software (e.g., BioGPS (Siragusa et al., 2015), IsoMIF Finder (Chartier et al., 2016), SuMO (Jambon et al., 2003)) able to compare the binding sites of protein structures have been so far developed.

In the first part of this review, we will survey relevant methodological steps of VS protocol (see Figure 1) including the detailed description of the two principal approaches of VS, LBVS and SBVS. In the second part, some case studies are reported in order to illustrate the pros and cons of this simulating technique.

2. LIBRARY SELECTION AND DATABASE PREPARATION

From a methodological point of view, the first step of VS approach involves the selection of a molecular library exploring a wide range of structural diversity. The selection of asuitable database is essential for increasing the rate of success in VS and computer-aided drug discovery.

Figure 1. Methodological steps of VS protocol



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Basically, molecular libraries can be distinguished as follows: 1) Focused library, library of compounds with certain biological activity (e.g., anticancer, antiviral, analgesic, antibacterial classes); 2) Targeted library, a library built against specific receptors collected into protein class (e.g., "GPCR-targeted libraries"); 3) General library, a library comprising molecules spanning different biological activities.

A number of online databases suitable for VS are known (see Table 1 for additional details). For instance, the ZINC (Irwin & Shoichet, 2005) database is a free collection of commercially-available compounds widely used for VS (Mishra & Siva Prasad, 2011; Chang et al., 2015). The latest release ZINC15 (Sterling & Irwin, 2015) contains over 100 million purchasable chemicals in 3D formats.

The National Cancer Institute (NCI) built a free database of about 250,000 structures available for searching (Ihlenfeldt et al., 2002). For each compound, an accession number (NSC) is available. For each tested chemical, the assay screen result can be indicated as active, moderately active or inactive. Specifically, the test outcomes of the Developmental Therapeutic Program (DTP) AIDS Antiviral Screen have also included.

Pubchem is an open access database structured in three linked databases, i.e., Substance, Compound (Kim et al., 2016) and BioAssay (Wang et al., 2017). These three databases are hosted by the National Center for Biotechnology Information (NCBI), National Library of Medicine (NLM) and National Institutes of Health (NIH). To date, it contains over than 63 million unique structures and more than 1 million BioAssays collected by over 80 international organizations and scientific institutions.

Drugbank 5.0 is a freely accessible database providing a wealth of information about drugs, their targets and pharmacological actions (Law et al., 2014) resulting as a helpful drugs encyclopedia. It comprises 8261 drug entries including 2021 small molecules and 233 biotech (protein/peptide) drugs approved by the Food and Drug administration (FDA). Additionally, data information of 94 nutraceuticals and over 6,000 experimental drugs has also been collected.

ChemBL (Gaulton et al., 2012) is an open manually curated database. Currently, it counts over 2 million of2D structures and a total of 11,538 biological targets. Information concerning physico-chemical or ADMET properties for a large amount of drug-like bioactive compounds are also collected. Data are primary retrieved from literature.

DUD-E (Directory of Useful Decoys Enhanced) (Mysinger et al.,2012) database contains 22,886 clustered ligands obtained from ChemBL and their affinities against 102 biological targets. A total of 50 decoys is available for each active compound having similar physico-chemical properties but dissimilar 2D topologies taken from ZINC database. A previous reduced version, known as DUD (Directory of Useful Decoys), is also available containing 2950 ligands and 40 targets. For each ligand, 36 decoys were generated and a total of 98,266 compounds was collected (Huang et al., 2006). ChemSpider (Williams, 2011) is a free chemical structure database owned by the Royal Society of Chemistry. It provides fast text and structure search access to over 58 million structures from hundreds of data sources.

ChemDB (Chen et al., 2005) is a public database of small molecules built merging digital catalogues of over a hundred version and other public sources.

Commercial Compound Collection (Co.Co.Co.) (Del Rio et al., 2010) is a public wide repository that collects molecular structural information of almost 3.7 million of commercial compounds from various chemical vendors. Co.Co.Co. library represents drug-like and lead-like compounds in ready-to-use format to carry out VS campaigns.

In drug discovery, the keyword is innovation (Rognan, 2017). For this reason, database collecting new synthesizable molecules to explore new original scaffolds and a new possible patent space are very much attractive. The chance of identifying new hit compounds, potentially provided with a biological

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

effect, increases at the enlarging of chemical space of the library. In this respect, one should consider that the chemical space includes about 10^{60} theoretically synthesizable molecules whereas standard molecular libraries are in the range of10^6 compounds (Lavecchia & Di Giovanni, 2013). To the best of our knowledge, GDB-17 database is the largest available database with 166 billion organic small molecules (Ruddigkeit et al., 2012). It enumerates small molecules containing up to 17 atoms. A previous version GBD-13 (Blum & Reymond, 2009) counting about970 million drug-like small molecules composed of up to 13 atoms of C, N, O, S and Cl following simple chemical stability and synthetic feasibility rules are also available.

The Protein Data Bank (PDB, http://www.rcsb.org/) is a public worldwide archive containing all the information of experimentally-determined structures of proteins, nucleic acids, and complexestaken from X-ray crystallography, NMR spectroscopy or, alternatively, by homology models (Berman et al., 2000).

ModBase (https://modbase.compbio.ucsf.edu/modbase-cgi/index.cgi) (Pieper et al., 2014) represents a collection of comparative protein structure models obtained from advanced computer-based modeling. In addition, ModBase gathers information about putative ligand binding sites, single nucleotide polymorphism (SNP) annotations and protein-protein interactions. In Table 1, all the information concerning the online chemical databases is reported. Obviously, the selection of a given database should ensure a large coverage of the chemical space according to project requirements in order to ensure efficient VS campaigns (Blum & Reymond, 2009).

3. DATA HANDLING

Data handling is the process for ensuring that data is stored and archived in a safe way in order to simplify data management as well as preserve the integrity of whole VS strategy. Two main types of data handling can be considered: 1) data curation and 2) data filtration.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Relevant steps in data curation are summarized as follows (Mangiatordi et al., 2016; Cherkasov et al. 2014):

- Treatment of mixtures. It is a hard computational issue as several conditions are encountered: 1) the mixture containing an organic compound and several smaller moieties, either organometallic or inorganic compounds 2) several organic compounds with similar molecular weights, i.e., mixtures of geometric or stereo isomers 3) mixtures where the "inert" or impurity ingredients are unknown.
- Cleaning/ removal of counterions and salts.
- Treatment of tautomeric forms;
- Normalization of specific chemotypes. Same functional groups may be characterized by different structural patterns in the same dataset. For instance, anionic heterocycles and quaternary ammonium ions require a pre-processing and several normalization steps.
- Analysis/removal of structural duplicates. The statistical analysis of dataset requires that each compound is unique. However, structural duplicates are frequently present. If duplicates are identified, the investigation of their associated properties required a manual analysis. Duplicates must be pre-processed and removed prior to VS.
- Manual inspection. The last step of data curation involves the manual inspection of complex molecular structures.

Data filtration is frequently applied to reduce the size of database in order to remove compounds with undesirable properties. The computational filters are low-cost options to quick screen a large number of compounds (Seifert & Lang, 2008). As well known, events connected with absorption, distribution, metabolism and excretion (ADME) and chemical reactivity-related toxicity can influence drug bioavailability (Seifert & Lang, 2008). In this regard, additional filters can be applied in order to remove compounds with uncertain metabolic fate. Metal complex groups, the occurrence of large number of halogens or of unbranched alkyl chain with more than eight methylene groups can be also avoided. Other physical filters can be useful to minimize including too flexible molecules with a high number of rotatable bonds being the exploration of their conformational space too demanding (Lyne, 2002).

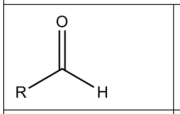
Likewise, structures with undesired functional reactive groups (i.e., Michael acceptors, ketones, aldehydes and all manner of suicide inhibitors) towards protein targets responsible of chemical instability or toxicity can be eliminated (Sirois et al., 2005; Oprea, 2002). In Table 2, all the reactive groups are listed.

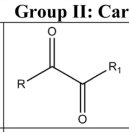
There are several chemicals, known as PAINS (Pan Assay Interference Compounds), that can behave as false positive (FP) in HTS. Dahlin et al. (Dahlin et al., 2015) identified five thiol-reactive chemotypes through a series of orthogonal assay and counter-screens, with the aim to remove noise from reference database and speed up drug discovery process. In fact, as previously highlighted by Baell in 2010 (Baell & Holloway, 2010), there are features not recognizable through traditional filters that can be identified only by assay detection technology.

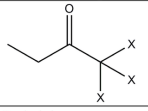
Moreover, compounds likely to interact with target but triggering a known adverse side effect must be also excluded. For instance, many non-antiarrhythmic drugs, characterized by different structures interact with hERG channel are responsible for a prolongation of QT interval in the electrocardiogram (long QT syndrome). This off-target interaction is associated with polymorphic ventricular tachycardia that can degenerate and cause death (Zhou et al., 1998). Thus, the filters potentially able to identify putative hERG blockers represent a valuable option to reduce cardiotoxicity optimizing VS procedure.

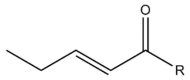
EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

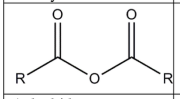
Table 2. Reactive groups list (X = F, Cl, Br, I; R, R_1, R_2, R_3, R_4 = alkyl, aryl, heteroalkyl, heteroaryl)

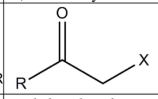
Group I: Halides, n=5				
				Acyl halides	Sulfonyl halides	Sulfenyl halides	Sulfinyl halides	Alkyl halides
Group II: Carbonyl derived compounds, n=9				
				


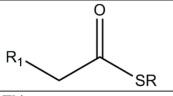


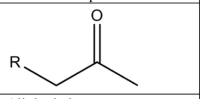


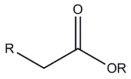


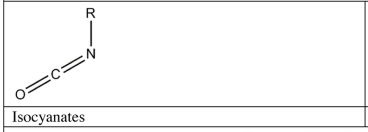
Aldehydes	1,2-dicarbonyl	Perhaloketones	Micheal acceptor	
				


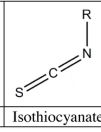


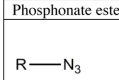


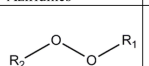


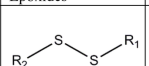
Anhydrides	α - halocarbonyl	Thioesters	Aliphatic ketones	
				


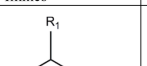
Aliphatic esters				
Group III: Cyanates, n=2				
				


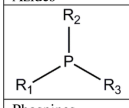


Isocyanates	Isothiocyanates			
Group IV: Miscellaneous, n=11				
				Phosphonate ester	Aziridines	Epoxides	Imines	Halopyrimides
				








Azides	Peroxides	Disulfide	Diazo derivatives	Isonitriles
				


Phospines				

Aronov suggests that identification of hERG blockers can be achieved *in silico* through homology models, QSAR models and classification methods (Aronov, 2005).

A central issue in VS is the identification of hits compounds with a certain pharmacological or biological activity. Lipinski and colleagues (Lipinski et al., 2001) proposed simple experimental rules to establish when a molecule has drug-like properties (i.e., poor absorption or an oral bioavailability profile). These rules are summarized as follows:

- The molecular weight (MW) is less than 500Da;
- The calculated octanol/water partition coefficient (logP) is less than 5;
- No more than 5 H-bond donors – expressed as the sum of O-H and N-H groups;
- No more than 10 H-bond acceptors (expressed as the sum of N and O atoms).

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Compounds matching any three of the rule of five conditions are likely to be oral drugs and can be considered as desirable chemicals with physiochemical properties that overlap with the majority of existing drugs (Lipinski et al., 2001; Cumming et al., 2013). Notably, the Lipinski's rules of five are applied as a filter for VS through a case-by-case evaluation according to the user needs.

The growing need to discover new drug-like compounds has led to develop several methods showing significant improvement of Lipinski's rules of five (Oprea et al., 2000). Based on neural network technique, Frimurer and colleagues trained a model distinguishing potentially drug-like from non-drug-like candidates (Frimurer et al., 2000). The chemicals have been taken from MACC-II Drug Data Report (MDDR) and Available Chemicals Directory (ACD). This method returns a better performance than rules of five, which accepted 74% of ACD compounds but only 66% of MDDR drugs.

Subsequently, Gozalbes and Pineda-Lucena elaborated a Quantitative Structure-Activity Relationships (QSAR) model to predict water solubility of drug-like compounds. They compared two chemical structures databases, the Food and Drug Administration Maximum Recommended Daily Dose database (FDAMMD) and Physical Properties Database (PHYSPROP) and selected the main properties (i.e., physical properties, atom count, adjacency and matrix descriptors) able to distinguish drug-like compounds. These criteria allowed to select 1174 compounds from PHYSPROP database. These chemicals have been adopted to develop several QSAR models, and the best one was selected and further validated with a set of 102 drugs whose solubility data are known in literature (Gozalbes & Pineda-Lucena, 2010).

Alternatively, bioactivity profile based on knowledge approaches can be also used for estimating the likelihood of a molecule exhibiting bioactivity. In this regard, it was reported a method to evaluate activity by analyzing what is currently known about bioactive molecules (Gillet & Nicolotti, 2000). An external chemical is likely to be active if it has physicochemical properties (e.g., such as MW, number of rotatable bonds, H-bond acceptors, H-bond donors, number of aromatic rings, shape descriptor, and ClogP) that are similar to known bioactive molecules. This approach can be also used to determine which chemicals should be screened in VS and to guide compound acquisition programms.

After Lipinski's rule, other studies were conducted. For instance, Veber (Veber et al., 2002) observed that compounds with 10 or less rotatable bonds and with polar surface area equal or less than 140 $Å^2$ showed a good oral bioavailability. Egan and coworkers (Egan et al., 2000) developed a model for human intestinal absorption using as descriptors logP and polar surface area (PSA).

Clearly, it is the combination of multiple filters that allows to prepare a database for an efficient VS. In this respect, Lagorce et al. (Lagorce et al., 2008) developed FAF-Drugs2, a free ADME/tox filtering tool useful in the drug discovery. This tool considers all the filters listed above (i.e., MW, number of rotatable or rigid bonds, heavy atoms, number of atom with a net charge, Veber's rules, Egan's rules, reactive or undesirable functional groups).

4. LIGAND-BASED VIRTUAL SCREENING (LBVS)

As above anticipated, the LB strategy exploits the principle that similar chemicals may exhibit similar properties with respect to the given target. Similarity is computed on descriptors (i.e., MW, logP, number of aromatic ring, rotatable bonds), which can be experimentally and theoretically determined (Koeppen et al., 2011).

Basically, LBVS approaches comprise QSAR strategies (Nicolotti et al., 2009; Nicolotti & Carotti, 2006; Castillo- González et al., 2015) and 3D pharmacophore models (Villoutreix et al., 2007).

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

4.1. QSAR Methods

QSAR is a computational technique aimed to find a correlation between a panel of chemical structures and their biological activity.

The general steps of QSAR methods are summarized as follows (Acharya et al., 2011): 1) availability of a set of congeneric molecules having a wide spectrum of biological activity as well as of chemical diversity; 2) generation of molecular descriptors accounting for structural and physico-chemical properties; 3) derivation of a causative relationships between the molecular descriptors and the biological activity; 4)internal and external validation in order to estimate the predictive power of the QSAR model.

Several methodologies can be employed to develop QSAR models such as those based on statistical approaches (Roy et al, 2015), neural networks (Aoyama et al, 1990), machine learning (King et al, 1993), random forest (Svetnik et al, 2003) and genetic algorithms (Rogers et al, 1993).

In this section, we report a brief overview of the most relevant statistical methods used to calculate the molecular descriptors as well as the main strategies employed in QSAR.

4.1.1. Statistical Methods for QSAR Model Derivation

The wider applied techniques in QSAR are the Multivariable Linear Regression analysis (MLR), Principal Component Analysis (PCA) and Partial Least Square analysis (PLS).

MLR correlates two or more explanatory molecular descriptors having a good correlation with variation in activity. However, the MLR method can be time consuming for large number of descriptors and further analyses should be carried out to avoid redundant variables. MATLAB (http://www.mathworks.com/matlabcentral) or R (Ikhara et al., 1996) are a well-known package largely employed to customize QSAR methods.

PCA analysis is often used as a diagnostic approach to extract from a large number of variables orthogonal physico-chemical information. PLS technique is instead largely adopted to build QSAR models based on latent variables largely used when using grid-like descriptors (Geladi & Kowalski, 1986). Neuronal network is the most applied non-linear regression approach to develop QSAR models (Douali et al., 2003) if no linear correlation occurs between molecular descriptor and bioactivity (Devillers, J, 2004).

Of extreme importance in QSAR is the so-called validation both internal and external. On one side, internal strategies include leave-one-out cross validation (Kohavi, 1995) and/or k-fold cross validation (Weiss & Kulikowski, 1991). On the other side, external validation is based on the predictions made on a dataset of compounds not used for QSAR model derivation (Bleeker, 2003).

4.1.2. 2D- and 3D- QSAR

Developed by Hansh-Fujita (Fujita et al., 1964), 2D-QSAR techniques are based on models where the activity contribution is determined by the substituent according to its position. This approach is effective for congeneric chemicals and is described by a simple mathematical equation including hydrophobic, electronic and steric constant. Likewise, Free and Wilson (Free & Wilson, 1964) elaborated a mathematical model in which activity depends on the presence and absence of structural elements. In particular, 2D-QSAR approaches make use of representative fragments to determine the bioactivity of a pool of compounds. However, the fragment-based descriptors are often inadequate to describe 3D conformation (González et al., 2009). 3D-QSAR includes molecular descriptors that are suitable to distinguish

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

3D conformations having different importance in a spatial QSAR model (Yang, 2010, Dror et al., 2004; Reddy et al., 2007). The mainly used 3D-QSAR techniques are CoMFA, CoMSIA and Catalyst. CoMFA stands for the Comparative Molecular Field Analysis (Cramer et al., 1988) and is based on the alignment of 3D molecules. At each 3D grid point enveloping a given molecule, the value of steric and electrostatic potential energies is calculated. A limitation of the CoMFA is that typically only the lowest energy conformer is considered as bioactive molecule. Unlike CoMFA, the Comparative Molecular Similarity Indices (CoMSIA) (Klebe et al., 1994) includes hydrophobicity and hydrogen bond interactions. Several successful examples are reported in the literature. For instance, Bringman and Rummey used a dataset of 53 antimalarial biaryl compounds to develop a 3D-QSAR model based on CoMSIA descriptors (Bringmann & Rummey, 2003). In 2004, Kuo and coworkers, in a study related to HIV-1 integrase, applied a combined approach of CoMSIA and CoMFA to train a set of 66 compounds (Kuo et al., 2004). Catalyst (Kirchmair et al., 2005) is a 3D-QSAR software that consider ligand flexibility making use of poling algorithm.

4.2. Pharmacophore Models

Pharmacophore is classically defined as the 3D arrangement of molecular features of fragments required for binding then translated into descriptors (Qing et al., 2014). Recently, Ghaffar at al. (Ghaffar et al., 2017) generated a pharmacophore model to identify novel AMPK activators. Indeed, starting from a set of known active chemicals (drugs, natural compounds and xenobiotics) a pharmacophore model was generated to screen a library of ZINC database. The VS resulted hits compounds having binding energies better than the ligand itself. For instance, LigandScout (Wolber& Langer, 2005) is a software performing both LBVS and SBVS based on a 3D pharmacophore model.

Noureen et al. derived a pharmacophore model using Ligand Scout v2.02 to identify inhibitors of histone deacetylases, a key target in cancer therapy (Noureen et al., 2010). This model has been generated analysing a set of 70 compounds of three different classes. Moreover, the software has been successfully used to predict the bioactivity of novel HIV inhibitors. In this context, Barreca and coworkers identify six potential inhibitor exhibiting activity comparable to nevirapine (Barreca et al., 2007).

Alternatively, 2D and 3D fingerprints are also employed in VS to calculate properties based on the molecular structure (Baroni et al., 2007; Floris et al., 2014). Chaac (www.mindthebyte.com/saas-platform/chaac/) is a commercial software to compare a given molecular query with a database of compounds using 2D fingerprints. LiSiCA (Ligand Similarity using Clique Algorithm) (Lešnik et al., 2015) is a recent tool searching for 2D and 3D similarities between a chemical and a benchmark database. LiSiCa Plugin is free only for academic use. ACPC (Auto Correlation of Partial Charges) is an open source tool based on autocorrelation of partial charges that uses a rotation-translation invariant molecular descriptor (Berenger et al., 2014).

5. STRUCTURE-BASED VIRTUAL SCREENING (SBVS)

The number of the scientific publications reporting of SBVS approaches is approximately three times compared to those related to LBVS (Ripphausen et al., 2011). SBVS is based on the prediction of both binding energy and posing of a ligand-protein complex (Lionta et al., 2014). In this part of the review, we will focus mostly on molecular docking, a well-known *in silico* technique simulating how a small

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

molecule can interact with a target protein. Sequentially, the post-docking processes and the criteria for the selection of docked compounds for additional experimental testing will be also described.

5.1. Posing Prediction: The Ligand Flexibility Problem

Ligand bound conformation may differ from the unbounded ligand. For this reason, it is crucial to consider conformational flexibility during docking processes. Theoretically, several mathematical algorithms can simulate the molecular complementarity between the binding poses of ligandand its biological counterpart.

To correctly predict the pose, different strategies can be pursued. For instance, a database containing several conformers for each ligand can be generated and then each conformer rigidly docked on the binding site. This strategy has been implemented in several software, such as Omega (Hawkins et al., 2010) and Catalyst (Kirchmair et al., 2005).

Among others, four methods allowing ligand flexibility has been developed as follows (Sliwoski et al., 2014)

1. Incremental growth approach. In this method, a ligand is fragmented into small parts and then is re-built step by step into the binding site. This method is used, for instance, by FlexX-Scan (Schellhammer & Rarey, 2004) and Dock (Onodera et al., 2007) software.
2. Genetic algorithm. This approach searches minimum energy through analogy with genetics and evolution. In genetic analogy, the state of the ligand corresponds to the chromosome and the variables to a gene while the fitness is the interaction energy between ligand and target (Goldberg, 1989). The automated ligand docking program GOLD (Genetic Optimisation for Ligand Docking) (Jones et al., 1997) makes use of a genetic algorithm to explore a wide range of ligand conformational flexibility.
3. Exhaustive search approach (Learning, 2014). A comprehensive list of rotamer states for each rotatable bound is coupled to a heuristic screen that rapidly eliminates those conformers unsuitable for binding to the receptor. This method has been implemented in several docking programs, i.e., GLIDE (Grid-based LIgand Docking with Energetics) software (Friesner et al., 2004) available in the Schrodinger Suite.
4. Monte-Carlo methods (Metropolis et al., 1953) start from an arbitrary ligand configuration while new configurations are randomly generated within prefixed threshold (i.e., maximal changes in translational, rotational, number of torsional degrees of freedom). AutoDock (Morris et al., 1998; Huey et al., 2007) is a well-known software based on Monte Carlo approach.

5.2. Protein Target Flexibility: Is There a Way Out?

An important issue of docking-based VS is the flexibility of the target (Hou et al., 2015). Nevertheless, several efforts are also made to identify new methods that consider both the ligand and the target protein as flexible. One of these attempts is the so-called “soft docking”: the protein is still treated as a rigid structure but the criteria for steric fit between ligand and receptor are softened. For instance, Ferrari et al. (Ferrari et al., 2004) generated a “soft” scoring function weakening the Lennard-Jones potential term to screen an Available Chemical Directory (ACD) against T4 lysozyme binding site. The study resulted that soft docking shows a better performance than the classical scoring function if a single receptor conformation is used.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Other methods involved the development of algorithms that gaze at protein flexibility limited to low degrees of freedom of side-chain for selected amino acids in the active site (Flick et al., 2012). According to a real biological system, the ideal strategy would be to screen all the possible conformations of a ligand against all freedom degrees of protein structure. To bypass this computational time-demanding system, a recent approach, namely "ensemble docking", is implemented in the several docking programs considering multiple conformations of target protein (Hou et al., 2015; Xiong et al., 2015). A successful application of ensemble docking VS is reported by Hou et al. (Hou et al., 2015) that led to the identification of eight novel lymphoid-specific tyrosine phosphatase inhibitors among 23 hits compounds.

5.3. How can the Ligand-Protein Complex be Evaluated?

Typically, protein-ligand docking simulation consists of three main phases (Kitchen et al., 2004): posing, that is the process that determines the alignment and orientation of the ligand in the active site; scoring, that is the process to calculate the binding energy according to the ligand fit in the active site; ranking, that is the process to reconsider the results from previous step on the basis of a more informed and consensus view.

Scoring functions are used to calculate the strength of the non-covalent interaction between the docked compound and the target (Kitchen et al., 2004). Basically, there are three types of scoring functions developed to estimate the binding energy of a protein-ligand complex: force-field (FF), empirical and knowledge based scoring function.

FF-based scoring functions are generally based on the sum of two contributions: the ligand energy interactions and the internal energy. The former is mostly described by two terms: Van der Waals and electrostatic energy term; the latter is approximated by harmonic springs describing vibration and rotations of the different bonds forming the ligands. For instance, GOLD (Verdonk et al., 2003; Jones et al., 1997) and AutoDOCK (Huey et al., 2007) make use of FF-based scoring functions.

Empirical scoring functions are based on the idea that the experimental data can be reproduced and binding energies can be approximated to the sum of single and unrelated terms (R. Wang et al., 2002). Empirical scoring functions are preferred to shortly screen millions of compounds and a large amount of empirical data is available to train scoring function (Seifert, 2009). LUDI (Böhm, 1994), SCORE (Tao & Lai, 2001) and X-SCORE (R. Wang et al., 2002) are based on empirical methods for binding energy estimation.

Knowledge-based scoring functions are instead aimed to reproduce experimental structure on the basis of the binding geometry of known ligands. DrugScore (Gohlke et al., 2000) and Smog (DeWitte & Shakhnovich, 1996) estimate a free energy using knowledge-based scoring functions.

5.4. A New Challenge in SB Approach: Cavities/ Cavities Comparison

Recently, an increasing interest has been focused on protein binding site comparisons (Najmanovich, 2017; Chaudhari et al., 2017). In this respect, two methods for detecting binding sites have been developed: the first maps and classifies binding site pockets irrespective of any specific ligand; the second is instead ligand oriented (Lavecchia & Cerchia, 2016). In this respect, a popular algorithm for comparing binding sites is FLAP. This algorithm has been implemented in BioGPS (Siragusa et al., 2015). BioGPS is structured in 5 phases: (1) protein refinement (the Fixpdb tool); (2) cavity detection (the Flapsite tool); (3) cavity characterization; (4) cavities comparison; (5) data analysis and interpretation.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

The BioGPS approach has been successfully validated confirming the side effects caused by estrogen receptor modulators (Siragusa et al., 2015). Indeed, the authors demonstrated that the estrogenic compounds cause cardiac abnormalities due to an off-target effect on sarcoplasmic reticulum Ca^{2+} ion channel ATPase (SERCA).

In the last years, the importance of comparing cavities have gained breeding ground and several bioinformatics algorithms able to align the binding site sequences have been developed. For instance, the SMAP web service (Ren et al., 2010) made use of SOIPPA (Sequence Order-Independent Profile–Profile Alignment) (Xie& Bourne, 2008), an algorithm able to detect similarity pockets across all fold protein.

The sequence order of amino acid residues in the functional site is not necessarily conserved and this allows the detection of new evolutionary relationships across apparently different proteins. This software has been applied to identify off-targets for selective estrogen receptor modulators (Xie & Bourne, 2008). SiteHopper is a tool developed by Batista and colleagues (Batista et al., 2014) based on alignments of protein sequences. A 3D shape representation of the active site is evaluated and physico-chemical properties of residues are highlighted by different colors. The active site representations can be rapidly super imposed and investigated to identify shape and chemistry similarity. 3D-surfer is a free web tool widely used to compare proteins based on the surface shape (La et al., 2009). Nevertheless, it is possible to screen a protein cavity represented as a vector of 3D Zernike descriptors against the entire PDB pockets and visualize the superimposition using VisGrid and LIGSITE (Xiong et al., 2014). However, it should be mentioned that despite the increasing amount of available computational approaches developed for comparison of protein binding sites, the number of successful outcomes is still relatively low (Jalencas & Mestres, 2013) this being likely due to the difficulty of explicitly accounting in comparison for protein flexibility and structural waters. In Table 3, all the SBVS and LBVS software and related URL website are summarized.

5.5. Are the Classic Scoring Functions Now Overtaken?

The scoring functions implemented in docking programs work by simplifying the complexity of molecular events behind protein-ligand recognition. For instance, entropy and solvation energy are not taken into account. Despite the success so far obtained (Bauer et al., 2013; Odolczyk et al., 2013), new strategies have been recently developed adopting machine learning based scoring functions (Ain et al., 2015). In classical machine learning, the algorithm is trained on a set of compounds with known experimental data (Wójcikowski et al., 2017). These scoring functions are used for the binary classification (i.e., active/inactive) of external dataset of chemicals and the best performing is the linear kernel algorithm (Melville et al., 2009).

In addition to machine learning, other strategies have been proposed. A recent work (Crunkhorn, 2017) presented a new SBVS approach based on evaluation of structural stability of protein-ligand complex. Likewise, Ruiz-Carmona et al. (Ruiz-Carmona et al., 2014) described a new computational method, known as Duck, to overcome the problem of free binding energy calculation. This method was applied to the VS against molecular chaperone and target Hsp90, with promising results (Crunkhorn, 2017).

6. POST PROCESSING METHODS: HOW DO YOU REMOVE FALSE POSITIVES?

A limit of VS protocol is the selection of suitable docked compounds to address additional experimental tests. Keeping as low as possible the occurrence of FPs is of utmost importance in drug discovery. In this respect, different strategies of post-processing have been developed.

6.1. Efficient Post-Processing

Rescoring hits on the basis of the binding free energies (ΔG) calculation is widely adopted (Zhong et al., 2010; Kitamura et al., 2014). ΔG can be computed by Molecular Dynamics (MD) simulations or can be expressed in three energetic terms as described by Zhong et al. (Zhong et al., 2010). The authors explain that the variation in binding free energy can be calculated in vacuum through quantum mechanical (QM) Hamiltonian or molecular mechanics (MM) force fields. Alternately, it can be measured by means of solvation free energy, computed by continuum solvation models. All these systems contain an apolar component evaluated by solvent-accessible surface area (SA) models. SA models are mostly associated with the Poisson- Boltzmann (PB) and Generalized Born (GB) models referring to MM-PBSA and MM-GBSA methods, respectively. The difference in energy between the complex target-candidate ligand is also evaluated by entropic contribution. Considering ΔG as the sum of two different terms (ΔG

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

$= \Delta H - T\Delta S$), high affinity is reached when both enthalpy (ΔH) and entropy (ΔS) contribute favourably (Freire, 2008). Notably, the enthalpic contribution is more difficult to optimize that the entropic one. Each attempt to improve binding enthalpy had as result a loss of entropy. For such reason, entropic contribution is preferred to evaluate the chance between target bound and unbound. As reported by Malmstrom and Watowich, another rescoring method is the mean-field pathway decoupling free energy of binding calculations (MF-FEB) (Malmstrom & Watowich, 2011). MF-FEB is a widely applied *in silico* screening even if these calculations are computational demanding (Rognan, 2017). Ding et al. (Ding et al., 2013) proposed an integrated approach called model system Molecular Interaction Energy Components - Support Vector Machine (MIEC-SVM) combining the molecular modelling and statistical learning. In this model, the molecular interaction energy (MIECs) is used as descriptor to characterize the ligand–protein interaction. The ligands are thus classified into binding and nonbinding categories training a SVM on these MIECs. The effectiveness of this model was successfully demonstrated through the screening on the HIV-1 protease using a small library of compounds (Ding et al., 2013).

6.2. Consensus Scoring

A computational strategy able to reduce FP hits is the consensus scoring (Anighoro et al., 2014). In order to decrease the scoring function-related error, a well-known strategy is to combine the scores obtained by different algorithm functions (Wang et al., 2003; Wang &Wang, 2001). It was observed that the majority of docking programs show an accuracy of about50% whereas the combination of several docking algorithms using a consensus strategy (three or four are sufficient) increases the performance of about 80% (Rognan, 2017). This method is applied using the same chemical library with different docking programs. The docking scores obtained are compared with the experimental data taken from crystallography pose and the root mean square deviation (RMSD) values are thus calculated (Houston &Walkinshaw, 2013). Similarly, the score associated to each docking pose generated by different algorithms are compared. Wang et al. (Wang & Wang, 2001), proposed three different consensus scoring strategies: these are rank by number; rank by rank, and rank by vote. In the rank by number, the candidate compound is ranked according to the average predicted value given by all the scoring functions considered. In the rank by rank, all the candidates are ranked by the average ranks predicted by all the involved scoring functions. In the rank by vote, if a candidate is predicted to be at the top list from an algorithm (e.g., in the first 10%), a "vote" from that scoring function is given so that each candidate compound will have a final vote given by the sum of votes obtained from all the scoring functions, ranging from 0 to the total number of scoring functions considered.

6.3. SBVS or LBVS?

In the decades, several studies demonstrated the success of the two mentioned strategies of VS. For instance, Xing et al., in 2011 discovered a soluble epoxide hydrolase applying the SBVS approach. The authors, starting from a library of benzoxazole, found out a new potent inhibitor for cardiovascular disease treatment (Xing et al., 2011). Spadaro and co-workers (Spadaro et al., 2012) applied a pharmacophore model to a small library of compounds active on 17β-hydroxysteroid dehydrogenase type 2 receptor. The screen identified interesting active compounds that was further chemically modified. As result, a novel class of 17β-HSD1 inhibitors was discovered.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Although the application of VS approaches is an interesting support for drug discovery studies, some necessary considerations should be done. First of all, an intrinsic limitation of LB technique is the use of starting dataset of congeneric molecules normally provided with low structural variability. SBVS overcomes this issue, benefiting from X-ray/NMR solved crystal structures. On the other side, if ligands are handled with full flexibility, the flexibility of protein target is still an open issue difficult to approach. The inclusion of structural functional water molecules in docking process could increase the accuracy of simulation (McInnes, 2007). To the best of our knowledge, SBVS is also three times more popular than LBVS strategies (Ripphausen et al., 2011).

Building on these considerations, the integrated use of structure and ligand-based approaches is, whenever possible (i.e., availability of both X-ray solved target protein and known active ligands), by great far desirable. In this respect, the interested reader can have a look at the recent study (Mangiatordi et al., 2017) relied on the hierarchical application of multilayer VS employing filters implying: molecular shape similarity, a structure-based pharmacophore model and molecular docking campaigns.

7. EXAMPLES FROM CASE STUDIES

In this section, we reported some recent case studies of VS applications showing how the VS is an effective and versatile technique for toxicological and drug discovery purposes.

7.1. LBVS

Ambure et al (Ambure et al., 2014) recently applied 3D-QSAR pharmacophore modelling in order to identify potential acetylcholinesterase (AChE) inhibitors. In particular, the InterBioScreen's Natural Compound (NC) database (InterBioScreen's NC, 2012) containing 47,868 natural compounds was screened. More specifically, a multi-filter strategy was applied involving: 1) the application of drug-like ADMET properties computed using QikProp (QikProp, 2012); 2) employment of a pharmacophore model as a 3D structural query and 3) molecular docking simulations in order to investigate the ligand-protein interactions. The 3D-Pharmacophore model was generated starting from a small dataset of 404 AChE inhibitors whose IC_{50} bioactivity is well-known in the literature. 85 chemicals, randomly selected (IC_{50} ranging from 0.950 nM to 11,587.77 nM) were adopted as training set and the remaining 319 as test set. The harmonized use of an ADMET based filter, a 3D-QSAR model and molecular docking resulted in the discovery of novel AChE inhibitors showing unreported molecular scaffolds. Hence, this study demonstrates how the wise application of LBVS allows efficiently exploring chemical space in drug discovery.

7.2. SBVS

7.2.1. Docking-based Classification Models to Predict the Estrogenic Potential of Chemicals

Trisciuzziand co-authors (Trisciuzzi et al., 2015) have established an easy-to-run platform to develop classification models based on molecular docking approach in order to predict estrogenic activity of wide collection of chemicals. The estrogen receptor (ER) is one of the most extensively studied targets (Barton et al.,2017; Almeida et al., 2017) for its role in various pathologies, such as osteoporosis (Martinaityte

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

et al., 2017), breast cancer (Gruvberger et al., 2001) and obesity (Cohen 2008; Guillaume et al., 2017). In this regard, numerous *in vitro* and *in vivo* protocols have been applied to identify potential endocrine pathway-mediated effects of well-known Endocrine Disruptor chemicals (EDCs). Nevertheless, the emergence of concerns about EDCs has resulted in the development of *in silico* strategies quickly and low cost. The presented study is framed within the large-scale modeling project CERAPP (Collaborative Estrogen Receptor Activity Prediction Project) (Mansouri et al., 2016) supervised by the US Environmental Protection Agency (US EPA) in partnership with 17 research groups in the Europe and USA.

In this work, starting from a training set (TS) of 1677 chemicals provided from US EPA, 24docking-based classification models were derived and optimized. The model performances were evaluated considering the early Enrichment Factor at 1% (EF1%) and the Area Under the Curve (AUC) of the Receiver Operating Characteristic (ROC) curve. In order to classify the estrogenic potential of chemicals, three probability binding classes were defined. Notably, two thresholds were set on the basis of the tunable sensitivity (SE) values, where SE estimates the proportion of TPs that are correctly predicted at a specific position of the ranked database. The following classes were obtained: 1) $SE \leq 0.25$, the class with high probability of binding (i.e., binder toxic molecules); 2) $SE > 0.75$, the class with low probability of binding (i.e., non-binder safe molecules); 3) $0.25 < SE \leq 0.75$, the class with medium probability of binding (i.e., suspicious molecules).

For toxicological purposes, keeping as low as possible the occurrence of false negative (FNs) is of utmost relevance. In this regard, the Negative Predictive Values (NPVs) at two different SE thresholds ($SE=0.25$ and $SE=0.75$) were also computed. In addition, to overlap the intrinsic limitation of unbalanced starting TS (only 14.13%chemicals were designated as estrogenic chemicals), the positive (at $SE = 0.25$) and the negative (at $SE = 0.75$) likelihood ratio for each of the SE based thresholds have also calculated. A small dataset of 10 well-known compounds (i.e., 5 drugs and 5 widely employed chemicals) and an external blind set shared by the US EPA of about 32,000 compounds have been thus screened against the best performing classification model. To overcome the limitation of single models provided by each CERAPP participants, a consensus strategy has been implemented. The success of this innovative application is confirmed placing as fourth better model of 21 models obtained by the CERAPP initiative. The use of molecular docking, a SB strategy widely applied in drug discovery program, is now adapted to toxicological purpose.

7.2.2. Challenging AQP4 Druggability for NMO-IgG Antibody Binding Using Molecular Interaction Fields and Molecular Docking Approach

The aquaporins are water channels with a physiological role in several organs and tissues. The alteration determining a variation in the rate of water flux through the channel is associated with several disorders. Among the13 isoforms of the aquaporin, the human aquaporin 4 (hAQP4) is also well-documented for its implication in various pathologies including Neuromyelities Optica (NMO). In this regard, a deposition of a typical immunoglobulin, namely NMO-IgG, against isoform hAQP4 was observed in many NMO patients (Wingerchuk et al. 2007).

A recent study (Pisani et al., 2014) has demonstrated that residue D69 at the basis of the loop A plays a key role for AQP4-IgG binding. Hence, developing drugs able to block the interaction between hAQP4 and NMO-IgG at this level might be an interesting therapeutic approach.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Keeping this in mind, Mangiatordi et al. (Mangiatordi et al., 2015; Mangiatordi et al., 2016) investigated the loop A of hAQP4 by means of generating molecular interaction fields (MIF) on the X-crystal structure of hAQP4 (PDB code: 3GD8) using BioGPS software. The sole cavity identified by the FLAPsite algorithm was located at the tophAQP4 surface confirming the previous hypothesis about the relevance of loop A. In order to demonstrate the druggability of this region, a successful analysis was performed against a benchmark dataset of druggable cavities of 43 X-ray solved pharmaceutically targets. In particular, the computed hydrophobic, hydrophilic, and charge-charge/polar interaction descriptors of the cavity fell in the range of those calculated for the druggable dataset confirming the potential druggability of hAQP4.

Moreover, according to the recent experimental observations, an induced-fit docking simulation of three known drugs (i.e., arbidol, tamarixetin and berbamine) having an appreciable inhibition of hAQP4NMO-IgG binding was thus performed. Satisfactorily, all the three compounds were found and almost completely inside the candidate hAQP4 cavity at the top of loop A.

8. CONCLUSION

Although turning its 30th birthday, VS is still a very effective method largely applied in medicinal chemistry. To the best of our knowledge, we illustrate the main methods currently employed for VS presenting some suggestive case studies to guide beginners in this new fascinating field. Moreover, a large room was given to survey molecular databases as they represent the wealth of information that is critical for VS success. Far from being an exhaustive analysis about VS, this review represents a comprehensive and informed view of the most applied strategy mainly in medicinal chemistry program. Indeed, much has been already done in this area but still a lot is in front of us. An interesting future perspective is to integrate as much as possible LB and SB strategies. In this respect, VS can be critical for repurposing old drugs towards new targets, for better designing multi-target agents and for addressing in a next future the large-scale screening of antibodies, whose clinical role is central for personalized medicine protocol. In this respect, finding new and cheaper solutions to approach with protein flexibility is of utmost importance to gather more reliable and trustable results even provided of a solid mechanistic rationale. Finally, we believe that VS could represent a valid starting point to find a hit for the 'hit to lead' approach contributing significantly to the whole drug discovery process. Nevertheless, the visual inspection represents the final filter whose success is very much dependent by chemical feeling and user intuition.

Chapter 12
Relationships between Models of Genetic Regulatory Networks with Emphasis on Discrete State Stochastic Models

Randip Pal
Texas Tech University, USA

ABSTRACT

Genetic Regulatory Networks (GRNs) represent the interconnections between genomic entities that govern the regulation of gene expression. GRNs have been represented by various types of mathematical models that capture different aspects of the biological system. This chapter discusses the relationships among the most commonly used GRN models that can enable effective integration of diverse types of sub-models. A detailed model in the form of stochastic master equation is described, followed by it coarse-scale and deterministic approximations in the form of Probabilistic Boolean Networks and Ordinary Differential Equation models respectively.

INTRODUCTION

Genetic Regulatory Networks (GRNs) represent the interconnections between genomic entities that govern the regulation of gene expression. Since biological regulatory networks are extremely detailed with numerous interactions, a single mathematical model to represent the whole biological regulatory system is generally not feasible. Depending on the purpose of modeling, the mathematical model representing the GRN brings in a level of abstraction. The focus of the modeling can be capturing interactions between RNA expressions, protein-protein interactions or interactions between metabolites. Usually, only parts of the regulome (i.e. genes, proteins and metabolites involved in gene regulation) such as transcription factors, enhancers, microRNA etc. are made explicit in a mathematical model of a GRN.

To provide further background on genetic regulatory network modeling, we present broad classifications of the models that are commonly used to capture the relationships between genomic entities. GRN models usually belong to either static or dynamical models. Static models are concerned with providing the topology of the network (such as the connectivity of various genomic entities) without attempting to model the dynamics of the interactions. Dynamic models on the other hand not only capture the connectivity of the network entities but also provide the time dependent functional relationships that govern the interactions. Commonly used pathway models as presented in databases such as KEGG and StringDB belong to the category of static models as they primarily capture the connectivity structure without the network dynamics. Examples of dynamic models include ordinary differential equation models to model the average concentration of mRNA expressions (Kampen, 1991) or Dynamic Bayesian Network (Murphy, 2002) models. Based on the model complexity involving inference of connectivity and time dependent relationships, the experimental data requirements for elucidating dynamic models are significantly higher as compared to static models.

To further explore various levels of time dependent behavior of genes or proteins, dynamic network models can be essentially categorized as discrete where the amount of genomic entity is modeled as discrete values or continuous where the genomic entities are models as continuous variables. Since the dynamics of biological entities consist of discrete changes based on the number of molecules created or destroyed, a fine-scale discrete model can potentially faithfully capture the dynamics of the genomic entities. Note that we have categorized the dynamic models as discrete or continuous based on the representation of the genomic entity but a similar categorization can be applied based on discrete or continuous representation of time. Some models such as stochastic master equations (also commonly known as Chemical Master Equations) incorporate time as a continuous quantity whereas models like Boolean Networks update states at discrete time intervals. The next level of characterizations is based on whether the models considered are stochastic or deterministic. A number of studies have shown that the generation of mRNA or protein expression is stochastic in nature (Arkin, Ross, & McAdams, 1998) and thus a stochastic model is suitable to capture the true change in state probability distribution with time. However, available experimental data may limit the inference of the parameters of a stochastic model. For instance, common genomic characterizations using microarrays provide an average observation of the mRNA expressions and are not suitable for inferring the parameters of a detailed stochastic model.

Thus, deterministic models such as differential equation models are often used to represent the average behavior of the biological system (De Jong, 2001) or in other words modeling moments of the distribution rather than the detailed distribution. Dynamic models can be further classified as detailed fine-scale models or coarse-scale models where the detail refers to the level of discretization involved in modeling the gene or protein expression. For instance, our interest may be in modeling the up or down regulation of genes and thus a coarse-scale Boolean Network (Kauffman S. A., 1993; Kauffman S., 1969) with ON and OFF states for each gene will be adequate. However, if our interest is in capturing the individual mRNA molecule generation or degradation, a detailed fine-scale model such as stochastic master equations (Gillespie D. T., 1977; Pal & Bhattacharya, 2010) with an enormous state space will be required. The above categorizations are presented in a graphical form in Figure 1.

Based on the above discussion, we observe that fine-scale stochastic discrete dynamical models such as stochastic master equations can provide a detailed representation of the dynamic interactions but maybe limited by the enormous computational complexity involved in its simulation and huge data requirements for estimation of its parameters. This chapter will present a review of stochastic master equation modeling followed by some of its low complexity approximations with focus on reduced state

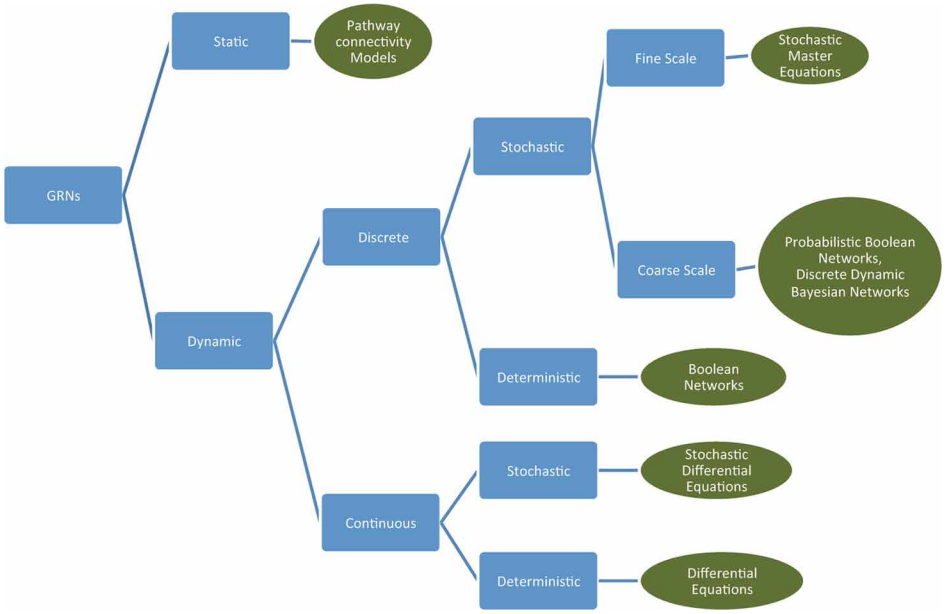
Figure 1. Categorization of commonly used models of genetic regulatory networks (GRNs)



discrete time Probabilistic Boolean Networks. The emphasis will be on the properties maintained by the reduced order models as compared to the original model.

Chemical Master Equation Models

Chemical master equations (CMEs) are considered to be one of the detailed fundamental models for representing dynamic genomic interactions (Pal & Bhattacharya 2010). CMEs model the creation and decay of discrete molecules of involved genomic entities in a stochastic fashion. CME based models have been shown to accurately model processes in bacteriophage lambda that control the switchover from lysogenic to lytic modes of growth (Shea & Ackers, 1985) or model the dynamics of phosphorylation-dephosphorylation cycles with autophosphorylation (Bishop & Qian, 2010) .

To explain the CME models for genetic regulatory networks, let us consider a system with n molecular species and m different reaction channels where the state of the system is defined by $x = [\varphi_1, \varphi_2, ..., \varphi_n]$, $x \in N^n$ is a vector of integers representing a specific population of each of the n molecular species. For such a system, given the probability density vector $p(x, t)$ at time t, the probability that the system will be in the state x at time $t + dt$ is given by

$$p(x;t+dt) = p(x;t)(1 - \sum_{\mu=1}^{m} a_{\mu}(x)dt) + \sum_{\mu=1}^{m} p(x - v_{\mu};t)a_{\mu}(x - v_{\mu})dt \quad (1)$$

where $a_{\mu}(x)dt$ denotes the probability that the μ^{th} reaction will happen in a time step of length dt and v_{μ} is the stoichiometric transition vector. From Equation 1, the differential equation known as *Chemical Master Equation* (CME) (Gillespie D. T., 1977) can be derived:

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

$$\dot{p}(x;t) = -p(x;t)\sum_{\mu=1}^{m} a_{\mu}(x) + \sum_{\mu=1}^{m} p(x-\nu_{\mu};t)a_{\mu}(x-\nu_{\mu}) \tag{2}$$

By considering all the reactions beginning or ending at state x, the time derivative of the probability density of state x can be written in vector form as (Munsky & Khammash, 2006):

$$p(x;t) = [p(x;t).....p(x-\nu_m;t)]\begin{bmatrix} -\sum_{\mu=1}^{m} a_{\mu}(x) \\ ..... \\ a_m(x-\nu_m) \end{bmatrix} \tag{3}$$

As n is finite, the number of different possible vectors for x is countable. Thus, we can map all the possible x's $\in N^n$ to a sequence $x_1, x_2, \cdots$ of elements in N. Let us represent that enumeration as X:= [x_1, $x_2, \cdots$] and rewrite Equation 3 as

$$\dot{P}(X;t) = P(X;t)A \tag{4}$$

where $P(X; t)=[p(x_1, t),p(x_2, t)...]$ is the complete probability density state vector at time t and A is the state reaction matrix. The matrix A has the following properties: it is independent of t, all of its diagonal elements are non-positive, and all of its off-diagonal elements are non-negative and all the rows sum to exactly zero. For the case of finite number of reachable states, the solution can be computed as:

$$P(X;t) = P(X;0)e^{At} \tag{5}$$

An approach to reduce the complexity of simulation of the above solution using Kronecker product analysis and Zassenhaus formula have been considered in (Caglar & Pal, 2013).

CME Model Simulation

The complexity of CME models can be tremendous to allow for direct computation of the analytical solution of the probability density state vector. For instance, n = 5 molecular species with number of molecules ranging from 0 to 99 will have a total of $100^5=10^{10}$ states whose probabilities need to be computed at each time duration. Thus, Monte Carlos based techniques are often utilized to generate the time varying probability density state vectors. The most commonly used technique is known as Gillespie's Stochastic Simulation Algorithm (SSA) (Gillespie D. T., 1977).

The SSA approach is statistically exact in the sense that infinite number of simulations will produce the same distribution as the analytical solution of Equation 2 (Székely Jr. & Burragea, 2014).

The SSA approach simulates multiple trajectories based on the governing CME by selecting the time when the next reaction will happen and what the reaction will be.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

SSA for generating a trajectory can be described using the following algorithm (Higham 2008)

1. Evaluate $a_\mu(x)$ at time t for μ=1 to m.
2. Draw random numbers r_1 and r_2 based on uniform (0 1).
3. Reaction j is selected that satisfies

$$\frac{\sum_{\mu=1}^{j-1} a_\mu(x)}{\sum_{\mu=1}^{m} a_\mu(x)} \leq r_1 < \frac{\sum_{\mu=1}^{j} a_\mu(x)}{\sum_{\mu=1}^{m} a_\mu(x)}$$

4. Time step for next reaction

$$\tau = \frac{-\ln(r_2)}{\sum_{\mu=1}^{m} a_\mu(x)}$$

5. Update time $t=t+\tau$ and state $x=x+v_j$
6. Repeat steps 1-5 until stopping criteria is met.

The stopping criteria is often an upper limit on time or the number of iterations. Readers are referred to (Gillespie D. T., 1977; Higham, 2008) for further details on SSA algorithm. Software for simulation of SSA are also available such as COPASI (Hoops & et.al, 2006), STOCKS (Kierzek, 2002), BioNets (Adalsteinsson, McMillen, & Elston, 2004) and StochKit2 (Sanft, Wu, Roh, Fu, & Petzold, 2011).

The SSA algorithm is simple to understand and implement but has high computational complexity. Tau Leaping (Gillespie D. T., 2000) is an approximation approach to SSA that considers all reactions occurring in a time interval τ before updating the propensity functions $a_\mu(x)$.

The simulation of CME models can also be facilitated by avoiding inclusion of molecular states that will never be reached or will likely have infinitesimal probabilities. (Cao & Liang, 2008) presents an optimal algorithm for simulating the probability landscape for networks with small copy numbers that avoids attempting infeasible state transitions and provides a concise state transition matrix devoid of redundant information. (Munsky & Khammash, 2006) approximates the solution of CME model by truncating the state space to remove states with minimal probabilities and provides a bound on the difference between the truncated space solution and the true solution. (Cao, Lu, & Liang, 2010) considers a method termed discrete chemical master equation (dCME) that is able to directly compute the full steady state probability distribution of lysogeney maintenance network in phage lambda.

MODEL APPROXIMATIONS

CME to Stochastic Differential Equation

An approximation to the discrete stochastic model in the form of a stochastic DE known as *chemical Langevin Equation (CLE)* (Gillespie D. T., 2000) is often used to make the solution analytically and numerically tractable. The approximation can be represented by the following stochastic DE (Cai & Wang, 2007):

$$x(t+dt) = x(t) + \sum_{\mu=1}^{m} \nu_{\mu} a_{\mu}(x(t))dt + \sum_{\mu=1}^{m} \nu_{\mu} \sqrt{a_{\mu}(x(t))} N_{\mu}(t) \tag{5}$$

where $N_{\mu}(t)$ for $\mu=1,\ldots m$ are independent Gaussian random variables with zero mean and unit variance. The conditions for validity of the approximation require that an infinitesimal time interval *dt* is available under which 1) there is no significant change in the propensity functions and 2) the expected number of occurrences of each reaction in *dt* is significantly greater than one. As shown in (Gillespie D. T., 2000), the first two moments of CME and CLE can be related using the truncation of chemical Kramers-Moyal equations (CKME). CKME can be considered an approximation of CME based on Taylor Series expansion and truncation of CKME will result in chemical Fokker-Plank equation representing the CLE. For details, readers are referred to (Gillespie D. T., 2000).

CME to Differential Equation

The relationship between CME and deterministic Differential Equation (DE) models have been well studied analytically by multiple researchers primarily from the perspective of similarity of the average predictive behavior of the two models (Kurtz, 1972; Kampen, 1991). Since the topic of CME to DE approximations have been well studied, this section will illustrate the relationship from a very basic perspective with simulation examples. For detailed analysis, readers are referred to (Kurtz, 1972; Kampen, 1991).

Example

In this example, we will apply CME to DE approximation technique to a generic switch (similar to a genetic toggle switch model without the detailed gene regulation) where there are two competing proteins U_1 and U_2, each of which inhibits the transcription of the other. The decay reactions $U_1 \rightarrow \varnothing$ and $U_2 \rightarrow \varnothing$ have propensities $c\Psi_1$ and $c\Psi_2$ respectively. The transcription of new copies of the proteins are guided by the reactions $\varnothing \rightarrow U_1$ and $\varnothing \rightarrow U_2$ with propensities b/(b $+\Psi_2$) and b/(b $+\Psi_1$) respectively. Our starting Stochastic Master equation model has parameter values $b = 4$ and $c = 0.2$. The corresponding stochastic master equation is

$$p(x;t+dt) = p(x;t)(1 - \sum_{\mu=1}^{m} a_{\mu}(x)dt) + \sum_{\mu=1}^{m} p(x-\nu_{\mu};t)a_{\mu}(x-\nu_{\mu})dt$$

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

with $m = 4$ and $v_1 = [-1, 0]$, $v_2 = [1, 0]$, $v_3 = [0, -1]$, $v_4 = [0, 1]$, $a_1([x_1, x_2]) = cx_1$, $a_2([x_1, x_2]) = b/(b+x_2)$, $a_3([x_1, x_2]) = cx_2$, $a_4([x_1, x_2]) = b/(b+x_1)$.

Our corresponding differential equation approximation is:

$$\frac{dy_1(t)}{dt} = \frac{b}{b + y_2(t)} - cy_1(t)$$

$$\frac{dy_2(t)}{dt} = \frac{b}{b + y_1(t)} - cy_2(t)$$

where $y_1(t)$ and $y_2(t)$ approximates $E_{x1}(x_1(t))$ and $E_{x2}(x_2(t))$ respectively. Figure 2 shows

$E_{x1}(x_1(t))$ (red stars) and $y_1(t)$ (blue line) for a starting distribution of $p(X) = [1, 0, 0 \cdots, 0]$ i.e. the number of protein molecules for both protein is zero for the initial state. It can be seen from Figure 4 that the approximation is very close to the expectation of the actual solution. We can solve for the steady state value of y_1 and y_2 analytically based on the equations $dy_1/dt=0$ and $dy_2/dt=0$.

If the steady state values of y_1 and y_2 are represented by y_{1s} and y_{2s}, then

$$\frac{b}{b + y_{2s}} - cy_{1s} = \frac{b}{b + y_{1s}} - cy_{2s} = 0 \tag{10}$$

Solving the equation gives $y_{1s} = \dfrac{-b + \sqrt{b^2 + 4b / c}}{2}$ which produces $y_{1s} = 2.9$ for the specific parameters of $b = 4$ and $c = 0.2$. The steady state value of 2.9 is also noticeable in Figure 4 for the simulated differential equation. Figure 3 shows the steady state marginal probability distribution of protein 1 simulated using the stochastic master equation. The expectation of this distribution 3.05 is very close to the analytically calculated differential equation steady state 2.9.

To study the effect of the control policy designed on the simpler approximate differential equation model being applied to the original stochastic master equation, we consider a control problem of maintaining the average expression of protein 1 to be around the value *10*. The control input is assumed to decrease the decay of the proteins by decreasing the value of the parameter c to *0.01*. Thus we have two systems, the original with $b = 4$ and $c = 0.2$ and the other corresponding to when control is switched on with parameters $b = 4$ and $c = 0.01$. The response of protein 1 of the network corresponding to parameters $b = 4$ and $c = 0.01$ is shown in Figure 4. The red stars denote the expectation of the distribution of protein 1 at every 2 second interval corresponding to the simulation of the stochastic master equation while the blue dots represent the output of the approximate differential equation model. The similarity of both the curves shows the closeness of the approximation. The value of the steady state corresponding to the DE model can be calculated by solving Equation 10 with $b = 4$ and $c = 0.01$ producing a value of $y_{1s} = 18.1$. The expectation of the steady state distribution calculated from the simulated CME model produces a similar value of *19.1*. The steady state probability distribution of protein 1 corresponding to the CME model is plotted in Figure 5.

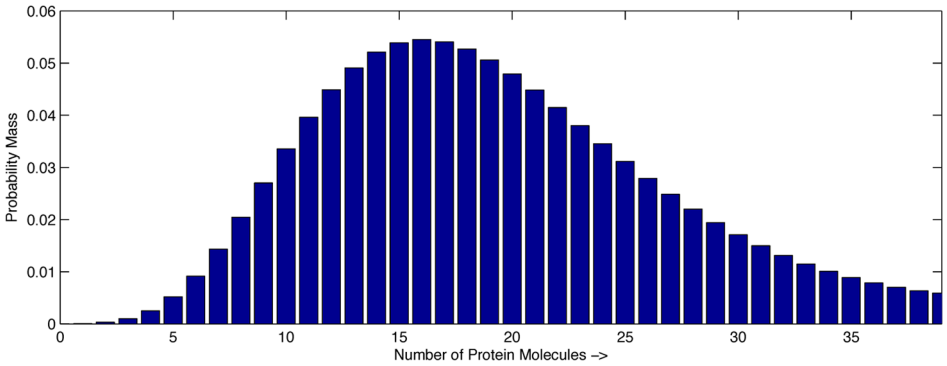
Figure 5. The steady state probability distribution of Protein 1 for the drug treated genetic toggle switch



As stated earlier, our control objective is to maintain the average expression of protein 1 to be around the value 10. We design a simple on off controller with deadzone based on the differential equation model which produces the following control policy: use system 1 (original system, b=4, c=0.2) if the average protein expression is above 10.5 and use system 2 (system when control is on, b=4, c=0.01) if the average protein expression is below 9.5. If the protein expression is between 9.5 and 10.5, maintain the earlier control policy. This is done to avoid indeterminate switching around the reference value of 10. The result of this control policy applied to the CME models is shown in Figure 6.

We notice that the control objective has been almost achieved with the average expression staying between 7.5 to 10.5. The variation could have been reduced if we apply control in much finer time interval than the current time interval of 2 seconds. In actual translational medicine, this time will be dependent on a number of factors like technical limitations on the sampling rate and application of control. Another way to approach the control can be by solving for the value of c producing the desired reference output and change the drug amount to achieve that specific value of c. In this case the drug is decreasing the degradation of the protein but not affecting the generation. We may be aware of the relationship between drug amount and parameter c but do not have the analytical solution relating the steady state output to the parameter c. We have to simulate the CME model for various values of c to arrive at the relationship between c and steady state expression. Our differential equation approximation

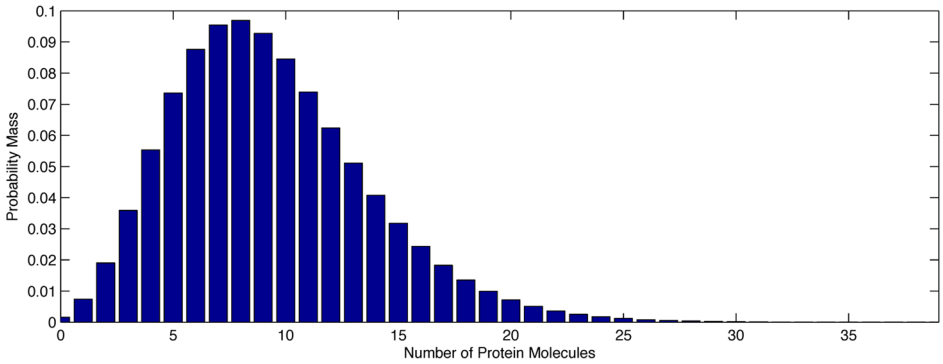
Figure 7. The steady state probability distribution of Protein 1 for the controlled genetic toggle switch

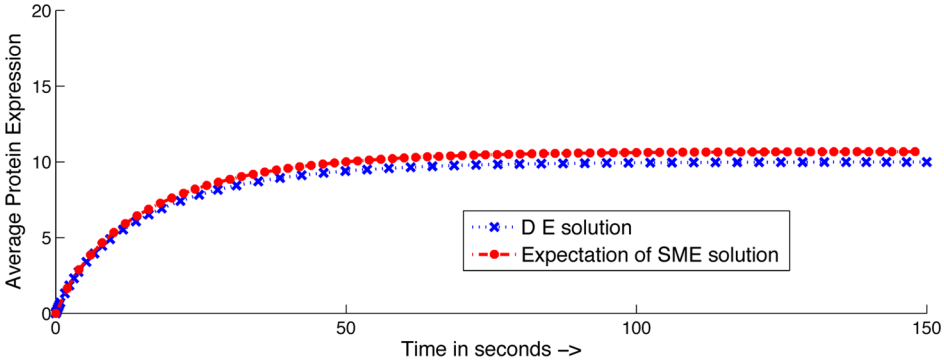


can analytically provide the value of *c* that produces the desired steady state output. Based on our desired response of 10, we get the required value of $c = \sqrt{\frac{b^2}{(20+b)^2 - b^2}}$ to be *0.0286*. Figure 8 shows the average protein expression simulated using stochastic master equation and differential equation model for protein 1 when the parameter *c* is maintained at *0.286*. The steady state output is very close to the desired output of *10*. In terms of numerical values, the expectation of the CME output for protein 1 at steady state is *10.69*.

CME to Probabilistic Boolean Networks

In an CME model, If we consider the number of possible x_i's to be finite, then the exact solution to the CME can be obtained through the exponential equation $P(X; t) = P(X, 0)e^{At}$. This kind of situation can arise in biological systems where the number of mRNA/Protein molecules that can be generated are bounded. If for systems, the dimension of X is infinite, we can apply the Finite State Projection approach (Munsky & Khammash, 2006) to arrive at a finite truncation of the state space. Henceforth,

*Figure 8. The average protein expression simulated using stochastic master equation (red *) and Differential Equation approximation (blue x) for the controlled genetic toggle switch with parameters b = 4 and c = 0.0286*



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

we will consider a CME with finite number of states M and our purpose is to transform that model to a smaller scale Probabilistic Boolean Network (PBN) model while maintaining some characteristics of the CME model.

The PBN model (Pal R., 2010) can be considered as a stochastic version of the Boolean Network (BN) (Kauffman S. A., 1993). A BN $B = (V, \boldsymbol{f})$ on n genes is defined by a set of nodes/genes $V = [x_1,..., x_n]$ and a vector of Boolean functions $\boldsymbol{f} = [f_1,..., f_n]$. The variable $x_i \in [0,1]$ represents the expression level of gene i, with 1 representing high and 0 representing low expression. The vector $\boldsymbol{f}$ represents the regulatory rules between genes. At every time step $t+1$, the value of x_i is predicted by the values of a set W_i of genes at the previous time step t, based on the regulatory function f_i, i.e. $x_i(t+1) = f_i(x_{i_1}(t),.....,x_{i_{k_i}}(t))$. The set of genes $W_i = \{x_{i_1},.....,x_{i_{k_i}}\}$ is called the predictor set of x_i, and the function f_i is called the predictor function of x_i. The pairs (x_i, W_i), $i = 1, ..., n$ induce a digraph G with edges $x_{i_j} \rightarrow x_i$ representing the structural dependencies among the genes. A state of B is a vector $\boldsymbol{s} = [x_1,..., x_n] \in [0, 1]^n$. All of the possible states of the Boolean network comprise its state space S which combined with the functions in $\boldsymbol{f}$ produces a digraph Γ called the state transition diagram of B. Γ represents the dynamics of the Boolean network and can be identified with a $2^n \times 2^n$ matrix P_n with rows and columns indexed by the states in B and entries $p_{ij} = 1$ or 0 if there is a transition from the state $s_i \rightarrow s_j$ in S.

Since constraints on the experimental data may limit the inference of a unique Boolean Network, the uncertainty in estimation along with the stochastic nature of genomic regulation is captured in the form of a PBN model where each gene can have multiple predictor functions. A *context-sensitive* PBN $A = A^{q,p}(V, \boldsymbol{F}, C)$ is defined by a set of nodes/genes $V = \{x_1,..., x_n\}$, a set of vector-valued Boolean functions $\boldsymbol{F} = \{\boldsymbol{f}_1,\ldots,\boldsymbol{f}_r\}$, $f_j: \{0,1\}^n \rightarrow \{0,1\}^n$, $j = 1,\ldots, r$ called *realizations* or *network functions*, a list of selection probabilities $C = \{c_1,\ldots, c_r\}$ for the corresponding realizations, the gene mutation/flipping probability p, and the realization switching probability q (Pal R., 2010). Updating the values of all genes in the network at time t is done synchronously according to the components of the currently used network function, and then the process is repeated. The choice of which network function $\boldsymbol{f}_j$ to apply is governed by a selection procedure. Specifically, at each time point t a random decision is made as to whether to switch the network function for the next transition, with a probability q of a switch being a system parameter. If a decision is made to switch the network function, then a new realization is chosen from among all of the possible realizations $\boldsymbol{f}_j \in \boldsymbol{F}$ of A, according to their individual selection probabilities $c_j \in C$. In other words, each network function $\boldsymbol{f}_j$ represents a deterministic BN B_j and the PBN behaves as a fixed BN until a random decision (with probability of q) is made to change the network function according to the probabilities $\{c_1,\ldots, c_r\}$ from among $\{\boldsymbol{f}_1,\ldots,\boldsymbol{f}_r\}$. In addition to the network switching and selection in the PBN model, there is mechanism which models random gene mutations, i.e. at each time point t there is a probability p of any gene changing its value uniformly randomly. Thus, the PBN model can account for the uncertainties in both data and model selection. The PBN A shares the same state space S with its realizations, and the state transition diagrams Γ_j of the individual B_j's combine naturally into a stochastic state transition diagram Γ representing the dynamics of A. As in the case of deterministic BNs Γ can be identified with a stochastic $2^n \times 2^n$ matrix P_n, also known as *transition* matrix, with non-negative entries p_{ij} and having the property $\sum_{j=1}^{n} p_{ij} = 1$, $i = 1,\ldots, n$. Using this matrix, the dynamics of A can be described using the well-developed theory of Markov chains. One should notice that

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

if the probability of gene flipping p is positive then the Markov chain representing the dynamics of the network is ergodic which implies that it possesses a *steady-state probability distribution* π.

Both the CME and PBN models belong to the class of discrete state stochastic dynamic models but differ in the level of discretization (coarse scale for PBN vs. fine-scale for CME) and the discrete (PBNs) or continuous time (CMEs) updating of the states. In this section, our overall goal is to study mappings from CMEs to PBNs that can maintain some desirable properties. As the steady state distribution of the genetic regulatory network is considered representative of the phenotype, our objective will be to maintain the steady state distribution. The finite state continuous time CME model can be approximated by a discrete-time sampled Markov chain by using a suitable time period Δt. The M × M state transition probabilities of the discrete-time Markov Chain denoted by P_Δ is given by the equation $P_\Delta = e^{A\Delta t}$. We will map these transition probabilities to an N × N transition probability matrix of a PBN denoted by P_r where N will be 2^n for binary levels and 3^n for the case of ternary levels. We will consider binary PBNs from now onwards but the derivation for more than 2 levels will be similar. Let T_i for $i \in [1, 2, \cdots n]$ denote the thresholds for binarization. For instance, if $x(t)=[\Psi_1,\Psi_2,\ldots,\Psi_n]$, then the corresponding state for the PBN is $y=[\psi_1,\psi_2,\ldots,\psi_n]$ where $\psi_1=1$ if $\Psi_i \geq T_i$ or $\psi_i=0$ if $\Psi_i < T_i$ for all $i \in [1, 2, \cdots n]$. As the states of the PBN will be n-dimensional vectors ranging from 00..0 to 11...1, we can represent them by the decimal equivalent state z_t where z_t ranges from 1 to 2^n. Let us consider a sequence $0=a_0,a_1,\ldots,a_N=M$ such that $a_i - a_{i-1}$ for $i \in \{1, 2, ..., 2^n\}$ denote the number of states in the CME model that map to state i in the PBN model. The states of the CME model will be denoted by w_t ranging from 1 to M. The states will be re-ordered such that the states $a_{i-1} + 1$ to state a_i of the CME will be mapped to state i of the PBN for $i = 1, ..., N$. Note that the subscript Δ refers to the higher dimensional discrete time CME model whereas the subscript r refers to the lower dimensional PBN model.

Let the state of the PBN at time be $z_t=i$ and the state at time $t+1$ be $z_{t+1}=j$. The transition probability of going from state i to state j is given by

$$
\begin{aligned}
P_r(i,j) &= P(z_{t+1}=j \mid z_t=i) = \sum_{j_1=a_{j-1}+1}^{a_j} P(\omega_{t+1}=j_1, z_t=i) \\
&= \frac{\sum_{j_1=a_{j-1}+1}^{a_j} P(\omega_{t+1}=j_1, z_t=i)}{P(z_t=i)} = \frac{\sum_{j_1=a_{j-1}+1}^{a_j}\sum_{i_1=a_{i-1}+1}^{a_i} P(\omega_{t+1}=j_1, \omega_t=i_1)}{\sum_{i_2=a_{i-1}+1}^{a_i} P(\omega_t=i_2)} \\
&= \frac{\sum_{j_1=a_{j-1}+1}^{a_j}\sum_{i_1=a_{i-1}+1}^{a_i} P(\omega_{t+1}=j_1 \mid \omega_t=i_1)P(\omega_t=i_1)}{\sum_{i_2=a_{i-1}+1}^{a_i} P(\omega_t=i_2)} = \frac{\sum_{j_1=a_{j-1}+1}^{a_j}\sum_{i_1=a_{i-1}+1}^{a_i} P_\Delta(i_1,j_1)P(\omega_t=i_1)}{\sum_{i_2=a_{i-1}+1}^{a_i} P(\omega_t=i_2)}
\end{aligned}
\tag{11}
$$

We next show that if we use the steady state probabilities of the CME model for $P(\omega_t=i_1)$ in Equation 11, then the steady state probabilities of the resultant PBN, P_r will be the same as the collapsed steady state probabilities of the CME model. Here collapsing refers to the summation of the state probabilities

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

of the detailed model that map to a certain state of the PBN model. For instance, if η represents the M dimensional steady state probability vector for the CME model, then the collapsed steady state vector will be an N dimensional vector represented by

$$\zeta(i) = \sum_{c=a_{i-1}+1}^{a_i} \eta(c) \text{ for } i=1,\ldots N.$$

We next prove the equivalence of ζ and the steady state probabilities of the PBN represented by the following state transition probabilities:

$$P_r(i,j) = \frac{\sum_{j_1=a_{j-1}+1}^{a_j} \sum_{i_1=a_{i-1}+1}^{a_i} P_\Delta(i_1,j_1)\eta(i_1)}{\sum_{i_2=a_{i-1}+1}^{a_i} \eta(i_2)} \tag{12}$$

Theorem I: (Pal & Bhattacharya, 2010) *With Equation 12 denoting the transition probabilities of the PBN, the steady state probability distribution vector, π,* o*f the PBN is given by*

$$\pi(i) = \sum_{i_2=a_{i-1}+1}^{a_i} \eta(i_2) = \zeta(i)$$

Proof: Assuming an ergodic Markov Chain, ζ is the steady state distribution of the PBN if it satisfies the equation $\sum_{i=1}^{N} \zeta(i) P_r(i,j) = \zeta(j)$ for each $j \in 1,2,\ldots,N$

Since η is the steady state distribution for the $M \times M$ CME model P_Δ, it satisfies $\eta(j_1) = \sum_{i_0=1}^{M} \eta(i_0) P_\Delta(i_0,j_1)$.

Thus

$$\zeta(j) = \sum_{j_1=a_{i-1}+1}^{a_j} \eta(j_1) = \sum_{j_1=a_{i-1}+1}^{a_j} \sum_{i_0=1}^{M} \eta(i_0) P_\Delta(i_0,j_1) =$$

$$\sum_{j_1=a_{i-1}+1}^{a_j} \sum_{i=1}^{N} \sum_{i_1=a_{i-1}+1}^{a_i} \eta(i_1) P_\Delta(i_1,j_1) = \sum_{i=1}^{N} \sum_{i_2=a_{i-1}+1}^{a_i} \eta(i_2) P_r(i,j) = \sum_{i=1}^{N} P_r(i,j)\zeta(i)$$

This shows that ζ satisfies the steady state probability equations of the PBN and is equal to π assuming an ergodic Markov Chain. We have established that if the transition probabilities of the PBN are decided based on Equation 12, then the steady state probabilities of the generated PBN is same as the collapsed steady state probabilities of the original detailed network. Thus, we are able to maintain the collapsed

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

steady-state probabilities, which might be indicative of a phenotype. If we revisit Equation 12, we notice that $P_r(i,j)$ can be calculated from the transitions of the network once it has reached the steady state. If we observe the steady-state transitions of the genetic regulatory network modeled by the CME for a long time and generate the state-transition probabilities of the PBN $P_r(i,j)$ based on the number of transitions occurring from state i to state j divided by the total number of transitions from state i, we will arrive at Equation 12. Thus, the mapping described by Equation 12 exists between a network represented by a CME model and a coarse-scale PBN model when the transition probabilities of the PBN are inferred based on state transition data at steady-state.

The following two examples from (Pal & Bhattacharya, 2010) consider well-studied stochastic master equation models of biological networks for illustrating the maintenance of collapsed steady state behavior when the mapping is based on Equation 12.

Example 1

We apply the CME to PBN approximation to the same genetic toggle switch model presented in the earlier case of CME to DE approximation. We have two competing proteins U_1 and U_2, each of which inhibits the transcription of the other. The decay reactions $U_1 \rightarrow \varnothing$ and $U_2 \rightarrow \varnothing$ have propensities $c\psi_1$ and $c\psi_2$ respectively. The transcription of new copies of the proteins are guided by the reactions $\varnothing \rightarrow U_1$ and $\varnothing \rightarrow U_2$ with propensities b/(b $+\psi_2$) and b/(b $+\psi_1$) respectively. Our starting Stochastic Master equation model has parameter values b = 4 and c = 0.05. We truncate the maximum number of protein molecules for U_1 and U_2 to 39 resulting in a total number of 40x40 = 1600 possible states for the CME. Based on the propensity functions and parameter values b=0.4 and c=0.05, the state reaction matrix A_1, is generated and the continuous Markov chain is approximated by a discrete chain using the following equation $P_{\Delta_1} = e^{A_1 \Delta t}$ with a time step of Δt=0.1 seconds. The thresholds for binarization of the proteins U_1 and U_2 are selected to be T_1=T_2=6 molecules. After binarization, the two protein reduced network has 2x2=4 states. We calculated the transition probabilities of the reduced model (PBN) using Equation 12. In our case, the Markov chain is ergodic as all the states are communicating, recurrent and aperiodic. Due to the ergodicity, P_{Δ_1} has a unique steady state probability distribution. The equivalence of the steady state probability distribution π_1 of P_{r_1} and the collapsed steady state probability distribution ζ_1 of P_{Δ_1} is shown in Figure 9 (Pal & Bhattacharya, 2010).

Example 2

In this example, we apply the CME to PBN mapping procedure to a model representing the life cycle of bacteriophage-λ (Hegland, Burden, Santoso, MacNamara, & Booth, 2007) which involves five proteins. The decay reactions $U_i \rightarrow \varnothing$ for i=1,2,…,5 are with propensities $c_i \Psi_i$ for i=1,2,…,5. The generation reactions with their respective propensities are as follows:

1. $\varnothing \rightarrow U_1$ with propensity $\dfrac{a_1 b_1}{b_1 + \Psi_2}$
2. $\varnothing \rightarrow U_2$ with propensity $\dfrac{(a_2 + \Psi_5) b_1}{b_1 + \Psi_1}$
3. $\varnothing \rightarrow U_3$ with propensity $\dfrac{a_3 b_3 \Psi_2}{b_3 \Psi_2 + 1}$
4. $\varnothing \rightarrow U_4$ with propensity $\dfrac{a_4 b_4 \Psi_3}{b_4 \Psi_3 + 1}$
5. $\varnothing \rightarrow U_5$ with propensity $\dfrac{a_5 b_5 \Psi_3}{b_5 \Psi_3 + 1}$

The generation reactions for the proteins originate from the mechanism of transitions between two phases, lysogenic and lytic, present typically in the life of a bacteriophage-λ. Alterations from one phase to another are regulated by a toggle switch of two competing proteins U_1 and U_2, which inhibit each other's transcription. In the lysogenic phase U_2 is abundant while suppressing the production of U_1 via the reaction 1. The generation of U_2 via reaction 2, on the other hand, depends on the amount of U_5. Under a stressed situation U_5 decreases as the phage transitions into the lytic stage. The parameters a_i, b_i, c_i are taken from (Hegland, Burden, Santoso, MacNamara, & Booth, 2007) and shown in Table 1.

The maximum number of protein molecules for U_1, U_2, U_3, U_4, U_5 are truncated to be at 3, 24, 3, 3, and 2, respectively. Thus, the total number of possible states for the CME is 4x25x4x4x3=4800. Using the above propensity functions and values for parameters shown in Table I, the state reaction matrix A_1 is computed and the continuous time Markov chain is approximated by a discrete time chain using equation $P_{\Delta_1} = e^{A_1 \Delta t}$ with a time step of Δt=0.1 seconds. The binarization of the proteins is achieved using thresholds 2, 8, 2, 1, and 1, respectively. After binarization, the five protein reduced network has 2^5=32 states. The transition probabilities of the reduced model (PBN) are calculated using Equation 12. Since all the states are communicating, recurrent and aperiodic, the Markov chain P_{Δ_1} is ergodic and hence

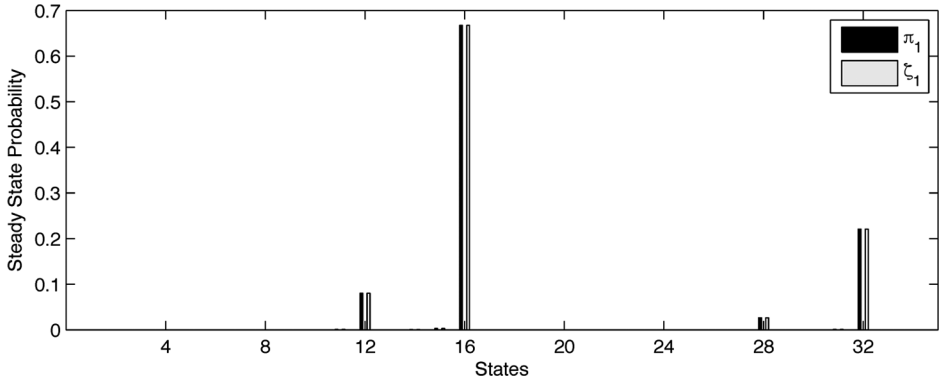
Figure 10. Steady State Probability Distributions π_1 and ζ_1 for example II
Pal and Bhattacharya (2010) © 2010 IEEE



P_{Δ_1} has a unique steady state probability distribution. The equivalence of the steady state probability distribution π_1 of P_{r1} and the collapsed steady state probability distribution ζ_1 of P_{Δ_1} is shown in Figure 10.

Transient Behavior of Coarse-Scale CME Approximation

The mapping presented in Equation 12 maintains the collapsed steady state behavior without enforcing any constraints on the collapsed transient dynamics. Thus, in this section we will evaluate the deviation of the transient dynamics of the PBN as compared to the collapsed CME state probability distribution. Let us consider the difference equation $d_j(t+\Delta t) = |\gamma j_(t+\Delta t) - \tau j(_t+\Delta t)|$ where $\gamma j(_t)$ denote the collapsed probability of states aj–$_{l+1}$ to aj $_o$f the CME model at any time t *a*nd $\tau j(_t)$ denote the probability of state j *a*t any time t *f*or the PBN model. We can bound the difference equation dj$(_t+\Delta t)$ for $\gamma j(_t)=\tau j(_t)$ in the following way (Pal & Bhattacharya, 2012; Pal, Bhattacharya, & Caglar, 2012):

$$d_j(t+\Delta t) \leq \max_{i_1 \in [1,\ldots,N]} \left(\max_{i_2 \in S_{i_1}} q(i_2, j) - \min_{i_2 \in S_{i_1}} q(i_2, j) \right)$$

where $q(i_2, j) = \sum_{j_1 = a_{j-1}+1}^{a_j} P_{\Delta}(i_2, j_1)$.

Similarly, we can extend the difference equation for multiple time steps as follows (Pal & Bhattacharya, 2012):

$$d_j(T\Delta t) \leq \beta \left(\frac{1-\mu_m}{1-\mu_m} \right)^T$$

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

where $\beta = \max_{j\in[1,..N]} \beta_j$ and $\beta_j = \max_{i_1\in[1,...,N]} (\max_{i_2\in S_{i_1}} q(i_2,j) - \min_{i_2\in S_{i_1}} q(i_2,j))$ and $\mu_m = \max_{i_1\in[1,...,N]} (\sum_{i_1=1}^{N} | R(i_1,j) - \rho |)$ where ρ is any constant and $R(i_1,j) = \min_{i_2\in[a_{i_1-1}+1,.....,a_{i_1}]} q(i_2,j)$.

The above-mentioned bounds for single and multiple time steps provide the worst-case bounds that can be difficult to compute as they require the detailed knowledge of the fine-scale transition probability matrix. Thus, a possible approach is to construct stochastic bounds or bounds on the expected deviation based on possible distributions of the entries of the transition probability matrix. Multiple such bounds based on the uniform distribution or distribution centered around different means for the entries of the state transition probability matrix have been considered in (Pal & Bhattacharya, 2012). The next two theorems from (Pal & Bhattacharya, 2012) provide the stochastic bounds for single and multiple steps. The proofs are available in (Pal & Bhattacharya, 2012).

Theorem II (Pal & Bhattacharya, 2012) The expected bound on the deviation β_j for single time step is given by the following equation:

$$E(\beta_j) < 2\sigma(2\log L - \log\log L)^{\frac{1}{2}}$$

where σ denotes the standard deviation for the distribution of $q(i,j)$ and $L = \max_{i=1,...,N} | a_i - a_{i-1} |$.

Theorem III (Pal & Bhattacharya, 2012)

$$E(\mu_m) < (N-1)\sqrt{\frac{2}{\pi}}\sigma_1 + (\xi_2 - \xi_1) erf(\frac{\xi_2 - \xi_1}{\sqrt{2}\sigma_2}) + \sqrt{\frac{2}{\pi}}\sigma_2 e^{-(\xi_2-\xi_1)}$$

where $erf(x) = \frac{2}{\sqrt{\pi}} \int_{t=0}^{x} e^{-t^2} dt$ denotes the error function and the distribution of $R(i,j) = \min_{i_2\in[a_{i-1}+1,...,a_i]} q(i_2,j)$ is approximated by $\aleph(\xi_1,{\sigma_1}^2)$ and $\aleph(\xi_2,{\sigma_2}^2)$ for $i \neq j$ and $i = j$ respectively.

Example 3

In this example, we consider the earlier considered Genetic Toggle Switch in example I with parameters b = 0.8 and c = 0.035 as the initial system. We truncate the maximum number of protein molecules for U_1 and U_2 to 39 resulting in a total number of 40x40 = 1600 possible states for the CME. Based on the propensity functions and parameter values b=0.8 and c=0.035, the state reaction matrix A_1, is generated and the continuous Markov chain is approximated by a discrete chain using the following equation $P_{\Delta_1} = e^{A_1 \Delta t}$ with a time step of Δt=0.5 seconds. The thresholds for binarization of the proteins U_1 and U_2 are selected to be T_1=T_2=20 molecules. After binarization, the two protein reduced network has 2x2=4 states. We calculated the transition probabilities of the reduced model (PBN) using Equation 12. The time evolution of the probability of the four states starting from a uniform distribution is shown in Figure 11.

(a) Probability vs time for state 00

(b) Probability vs time for state 01

(c) Probability vs time for state 10

(d) Probability vs time for state 11

The actual deviation characteristics of the PBN probability and the collapsed CME model are shown in Table II. State denotes the four states (00; 01; 10 and 11) of the reduced model. D_s and D_m denotes the actual maximum deviation in a single time step and multiple time steps, respectively. UB_s and UB_m denotes the stochastic bounds for single time step and multiple time steps, respectively. The ε used to calculate the stochastic bound is $2\frac{(1-d)}{(M-1)}$ with d=0.4 where d is an approximation of a diagonal entry. We are assuming that each diagonal entry is greater than 0.4 which is reasonable as we have a small δ$t$of 0.25 seconds. The μ_m used to calculate the multiple step bound is estimated as follows: the transition probability matrix is given by $e^{A\delta t}$ where A is the reaction matrix. We approximate the transition probability matrix by I+$A\delta t$ $u$sing the first two terms of the series expansion. Based on this approximation, we generated the approximate transition probability matrix and calculated μ s from the approximate matrix. For our case, δt=0.25, c=0.0035, b=0.8, and t1=$_t$2=$_2$0. To calculate the multistep bound, we

Table 2. Transient Response Bounds for the Genetic Switch Model with Parameters b= 0.8 and c = 0.035 (Pal & Bhattacharya, 2012) © 2012 IEEE

State	Ds	Dm	UBs	UBm
00	0.0054	0.2257	0.0479	0.2596
01	0.0027	0.0895	0.0479	0.2596
10	0.0027	0.0917	0.0479	0.2596
11	0.0016	0.0784	0.0479	0.2596

used the maximum of μ s 0.8154 as the μ=m. From Table 2, we note that the stochastic bound for multi-steps (0.2596) is very close to the maximum actual deviations for each state (0.2257, 0.0895, 0.0917, 0.0784).

DISCUSSIONS

In this chapter, we discussed the broad classes of genetic regulatory network models and presented equivalence relationships concerning some of them. We primarily discussed the relationships between CME and PBN type of models that are both discrete state stochastic models with Markovian property but with a hugely different size of the state space. Equivalence relationships among other model types have also been explored in the literature, for instance (Davidich & Bornholdt, 2008) shows that the Boolean Network model is a coarse-grain limit of the differential equation model and demonstrates it on the budding yeast cell cycle network. (Lähdesmäki, Hautaniemi, Shmulevich, & Yli-Harjaa, 2006) illustrates that probabilistic Boolean networks and dynamic Bayesian network models can represent the same multivariate state probability distribution over their common variables. Based on our modeling objectives and available data, different model types can be suitable for different scenarios. For instance, modeling of the basic average inhibition and up regulation of cancer pathways using targeted drugs can often be modeled using Boolean Network based models (Grasso, et al., 2015; Layek, Datta, & Dougherty, 2011; Pal & Berlow, 2012) . However, modeling of detailed stochasticity of gene expression (Kærn, et al. 2005) will require fine scale CME or stochastic differential equation based models. Furthermore, modeling of tumor heterogeneity will either require separate deterministic models for individual sub types or a stochastic model that incorporates the behavior of the diverse subtypes. The most commonly used model of ordinary differential equations is valid when the number of molecules of the modelled entities is sufficiently large. In terms of CME propensity functions, the CME to DE approximation is valid when the propensity functions are linear relationships of state variables (Szallasi, Stelling, & Periwal, 2006).

Furthermore, the mathematical model selected for representing a biological phenomenon will also be dependent on the data type used for inference of the model parameters. For instance, microarray data will provide the average expression of a collection of cells and cannot be used to infer fine-scale stochastic model parameters but are rather suited for DE or coarse scale Boolean Network kind of models. For estimating the parameters of a fine scale stochastic model, we would require individual cell measurements using techniques such as green fluorescent proteins or single cell sequencing. The sampling time period used in data measurements will also constraint the inference of model parameters. For instance, modeling a cyclic biological activity such as circadian rhythm will require measurement time step to be

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

smaller than the period of the biological activity. Some studies measure the gene or protein expression of a cell line at a fixed time and aggregate the responses across multiple samples to reflect the system behavior. This approach can work when the sample behaviors are similar and we have limited variations among the cell lines. However, for inference of dynamic model parameters, time series data is highly desirable as compared to steady state data. The model inference process is often independent of the experimental data generation process and majority of inference analysis is conducted without access to experimental data that is most suitable for high accuracy estimation of model parameters. Model based experiment design can improve the accuracy and decrease uncertainty in inference of model parameters.

One of the benefits of exploring the relationships between various models of GRNs lies in its potential to be used in building whole cell mathematical models where different model types represent the sub-networks. There have been recent attempts at creating whole cell models of smaller organisms such as (Karr, et al., 2012) that creates a whole cell computational model of the life cycle of the human pathogen *Mycoplasma genitalium* by combining 28 dissimilar submodels representing various levels and processes in the cells. (Covert, Xiao, Chen, & Karr, 2008) considers the specific case of integrating flux-balance based central carbon metabolic and transcriptional regulatory model with an ordinary differential equation based detailed model of carbohydrate uptake control for Escherichia coli. (Chandrasekaran & Price, 2010) considers the integration of transcriptional regulatory network with corresponding metabolic network for Escherichia coli and Mycobacterium tuberculosis. Thus, the detailed understanding of relationships between various models of GRNs will enable us to effectively integrate existing sub-models for an organism that have been designed using different model types.

ABSTRACT

The paper reviews certain integral equation approaches and related numerical methods used in studies of biomedical applications of electromagnetic fields pertaining to transcranial magnetic stimulation (TMS) and nerve fiber stimulation. TMS is analyzed by solving the set of coupled surface integral equations (SIEs), while the numerical solution of governing equations is carried out via Method of Moments (MoM) scheme. A myelinated nerve fiber, stimulated by a current source, is represented by a straight thin wire antenna. The model is based on the corresponding homogeneous Pocklington integro-differential equation solved by means of the Galerkin Bubnov Indirect Boundary Element Method (GB-IBEM). Some illustrative numerical results for the TMS induced fields and intracellular current distribution along the myelinated nerve fiber (active and passive), respectively, are presented in the paper.

1. INTRODUCTION

While human exposure to radiation from different electromagnetic interference (EMI) sources has initiated a number of questions regarding potential adverse effects, particularly for the brain and eye exposure to high frequency (HF) radiation, some biomedical applications of electromagnetic fields are of particular importance, as well. Thus, the electromagnetic fields are applied in medical diagnostic and for therapy purposes featuring the use of techniques such as: transcranial magnetic stimulation (TMS) (Cvetković & et al., 2015; Garvey & Mall, 2008; Rajapakse & Kirton, 2013, Yamamoto & et al., 2016), percutaneous electrical nerve stimulation (PENS), transcutaneous nerve stimulation (TENS) (Frijnas & ten Kate, 1994; Rattay, 1999; Zulim & et al., 2015), or intraoperational methods such as transcranial electrical stimulation (TES) and direct cortical stimulation (DCS). Transcranial magnetic stimulation (TMS) is a noninvasive and painless technique for excitation or inhibition of brain regions, and in last few decades is an important tool in preoperative neurosurgical diagnostic/evaluation of patients (Picht & et al., 2013; Deletis & et al., 2014; Rogić & et al., 2014). TMS is also used in therapeutic purposes (i.e. depression), and is subject of interest in neurophysiologic research. Various efficiency aspects of TMS stimulation have been primarily stressed out primarily due to differences in relevant stimulation parameters such as pulse waveform, frequency, intensity of treatment, etc. The choice of optimal stimulation intensity is still investigated in many TMS studies.

The coil orientation and positioning appreciably influence the misalignment from the targeted brain region, thus reducing the TMS efficiency, although by using navigated TMS, this problem could be somewhat alleviated. In addition to the stimulation parameters, being adjustable to the requirements of the TMS operator, to a certain extent, the difference in individual brain morphology, due to age, gender or health status and the biological tissue parameters appreciably influence the distribution of the induced fields in the brain. Most of the parameters are obtained under different measurement on ex vivo animal and human tissues, and usually exhibit large variations from their average values. The level of uncertainty in the values of the brain conductivity and permittivity, is even more pronounced at low frequencies.

Modeling and computer simulation of TMS phenomena could be rather useful in determining the exact location of stimulation, in the interpretation of experimental results as well as in designing some more efficient stimulation setups. Realistic TMS models can also provide a more reliable prediction of the distribution of internal fields and currents by taking into account the variability of the various input parameters.

Furthermore, techniques such as PENS, electro-acupuncture, or TENS are widely used in a treatment of neurological disorders. Basically, there are two types of electric potential occurring in the stimulated nerve cells; the electrotonic potential and the action potential. The electrotonic potential existing due to the local changes in the ion conductivity decays along the fiber, and the passive membrane then shows linear nature which satisfies Ohm's law. The action potential is initiated when the threshold potential to which the membrane potential must be depolarized, is achieved. Studies on electrical excitation of nerves, among other aspects involve: nerve excitation using stimulating electrodes, nerve conduction velocity tests or non-invasive stimulation of nerves. The exceptional nervous system complexity, particularly nerve cells as its basis, and widespread neurological disorders and a need for better insight into complex functioning of the nervous system have been continuously motivating researchers (Golomolzina & et al., 2014) to carry out an efficient and accurate nerve fiber modeling. Thus, such computational models of nerve fibers could provide a study of the nerve fiber response to different stimulus waveforms, often used

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

within various electrotherapy techniques, particularly electro-acupuncture and PENS. Such a model can be beneficial and versatile tool for interpreting experimental results and analyzing variables for which there could be difficulties in the laboratory implementation.

The present work extends the review (Poljak & et al., 2016.a) of integral equation method approach to study TMS induced fields and nerve fiber excitation used in therapeutic procedures such as electro-acupuncture and/or PENS reported in (Poljak & et al. 2016.b) by providing more mathematical details and presenting some additional computational examples. The present work, together with (Poljak & et al. 2016.a) and (Poljak & et al. 2016.b) has been undertaken through tasks and activities within the framework of IEEE/ICES TC95 SC6 EMF Dosimetry Modeling and COST Action BM1309.

2. MODELING OF TMS INDUCED FIELDS

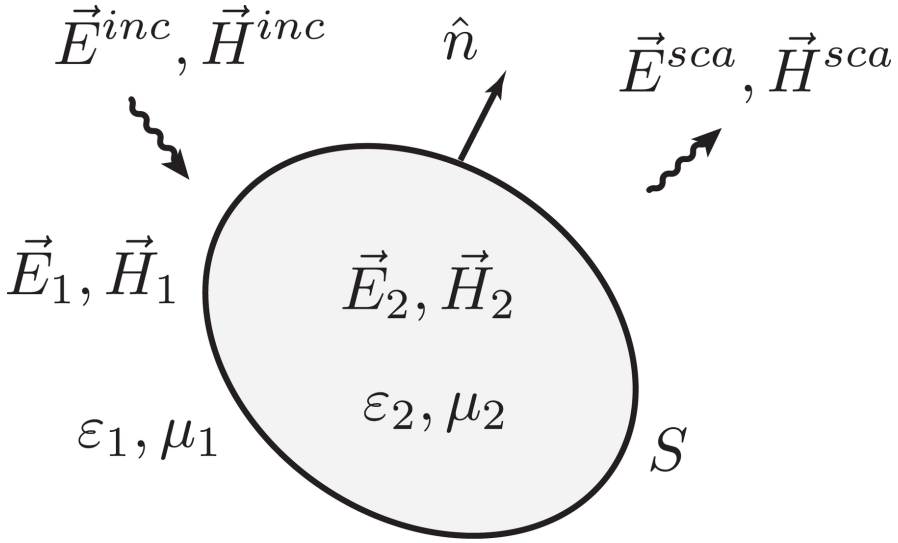
The lossy dielectric model of the brain exposed to TMS electromagnetic field is based on the set of coupled surface integral equations (SIEs) which could be derived from the equivalence theorem and by forcing the corresponding interface conditions for the electric and/or magnetic field, (Cvetković & et al., 2015) as indicated in Figure 1.

The lossy homogeneous object representing the brain is illuminated by the electromagnetic wave characterized by incident electric field $\vec{E}^{inc}$ and incident magnetic field $\vec{H}^{inc}$.

Performing some mathematical manipulations, the following set of coupled surface integral equations is obtained (Cvetković & et al., 2015):

$$\begin{aligned} &j\omega\mu_n \iint_S \vec{J}\left(\vec{r}'\right) G_n\left(\vec{r},\vec{r}'\right) dS' - \frac{j}{\omega e_n} \iint_S \nabla' s \cdot \vec{J}\left(\vec{r}'\right) \nabla G_n\left(\vec{r},\vec{r}'\right) dS' \\ &+ \iint_S \overrightarrow{M}\left(\vec{r}'\right) \times \nabla' G_n\left(\vec{r},\vec{r}'\right) dS' = \begin{cases} \vec{E}^{inc} & n = 1 \\ 0, & n = 2 \end{cases} \end{aligned} \tag{1}$$

Figure 1. The lossy homogeneous dielectric brain model



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

where $\vec{J}$ and $\vec{M}$ represent equivalent electric and magnetic current density, respectively, and G_n is the interior/exterior Green function given by (Cvetković & et al., 2015):

$$G_n\left(\vec{r},\vec{r}'\right)=\frac{e^{-jk_nR}}{4\pi R};\ R=\left|\vec{r}-\vec{r}'\right| \tag{2}$$

and R is the distance from the source to observation point, respectively, while k_n denotes the wave number of a considered medium n.

The brain model is generated from a freely available Google Sketchup rendering of the human brain, as shown on Figure 2.

The set of integral Equation (1) is solved by means of an efficient MoM scheme reported elsewhere, e.g. in (Cvetković & et al., 2015). For the sake of completeness, the MoM procedure is outlined in this section, as well.

As a first step, the equivalent electric and magnetic currents $\vec{J}$ and $\vec{M}$ in (1) are expressed by means of a linear combination of basis functions $\vec{f}_n$ and $\vec{g}_n$, respectively:

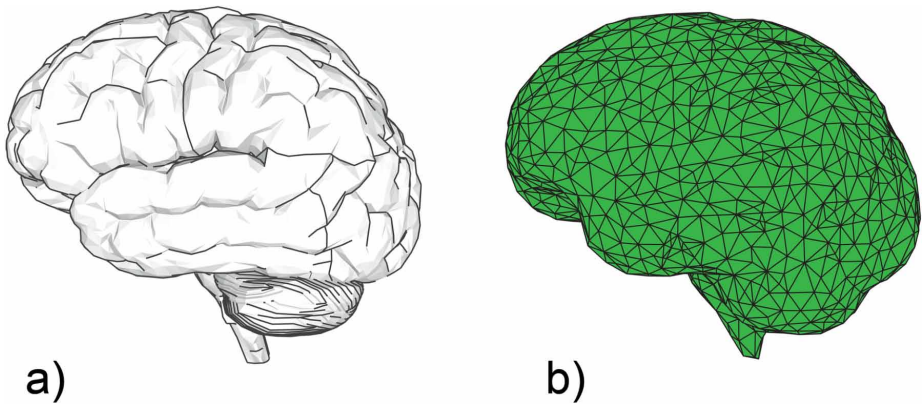
$$\vec{J}\left(\vec{r}\right)=\sum_{n=1}^{N}J_n\vec{f}_n\left(\vec{r}\right) \tag{3}$$

$$\vec{M}\left(\vec{r}\right)=\sum_{n=1}^{N}M_n\vec{g}_n\left(\vec{r}\right) \tag{4}$$

where J_n and M_n are unknown coefficients, while N is the total number of triangular elements.

Applying the weighted residual approach, i.e. multiplying (1) by the set of a test functions $\vec{f}_m$ and integrating over the surface S, after some mathematical manipulations, it follows:

Figure 2. The human brain model for SIE formulation: (a) Detailed 3-D model from Google Sketchup; (b) Final model discretized using the triangular elements



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

$$j\omega\mu_i\sum_{n=1}^{N}J_n\iint_S\vec{f}_m\left(\vec{r}\right)\cdot\iint_{S'}\vec{f}_n\left(\vec{r}'\right)G_i dS'dS+\frac{j}{\omega e_i}\sum_{n=1}^{N}J_n\iint_S\nabla s\cdot\vec{f}_m\left(\vec{r}\right)\iint_{S'}\nabla' s\cdot$$
$$\vec{f}_n\left(\vec{r}'\right)G_i dS'dS\pm\sum_{n=1}^{N}M_n\iint_S\vec{f}_m\left(\vec{r}\right)\cdot\left[\hat{n}\times\vec{g}_n\left(\vec{r}'\right)\right]dS+\sum_{n=1}^{N}M_n\iint_S\vec{f}_m\left(\vec{r}\right)\cdot\iint_{S'}\vec{g}_n\left(\vec{r}\right) \quad (5)$$
$$\times\nabla' G_i dS'dS=\begin{cases}\iint_S\vec{f}_m\left(\vec{r}\right)\cdot\vec{E}^{inc}, & i=1\\ 0, & i=2\end{cases}$$

where subscript *i* denotes the index of the medium. The details of the numerical solution procedure could be found elsewhere, e.g. in (Poljak & et al., 2016.a).

2.1. Numerical Results

Figures 3 and 4 show numerical results for the equivalent electric and magnetic current densities for the case of a) circular coil and b) figure-8 coil. The actual coil insulation and casing are not considered. Each coil is discretized into 80 linear segments. The coils are driven by a sinusoidal current of amplitude I = 2843 A, f=2.44 kHz. The radius of circular coil and figure-8 coil is 4.5 cm and 3.5 cm, respectively, while the number of windings for circular is 14 and for figure-8 is 15 turns.

Figures 5 and 6 show the numerical results for the sagittal and transversal cross-sections of the internal and external field, respectively, due to circular coil and figure-8 coil. In both cases, the coils are positioned tangentially to the brain surface, 1 cm over the primary motor cortex area, i.e. the distance between the coil geometric center and brain surface is 1 cm.

The results shown in Figures 5 and 6 confirm that the maximum electric field of figure-8 coil is induced directly under the coil geometric center, while for the case of circular coil, maximum field is induced under the coil windings. In addition to the induced electric field value, it is important to consider the orientation of the field vector. The results show the obvious importance of the correct TMS coil placement with respect to the brain surface.

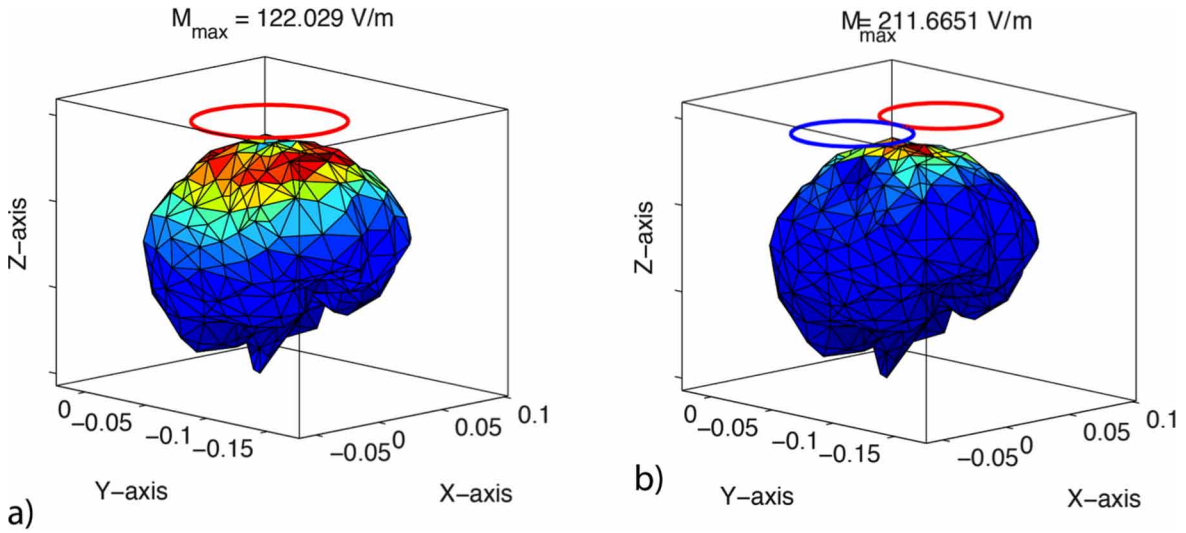

Figure 5. Sagittal cross-section of the electric field induced in the brain model by: a) Circular coil; b) Figure-8 coil. Coils not shown.

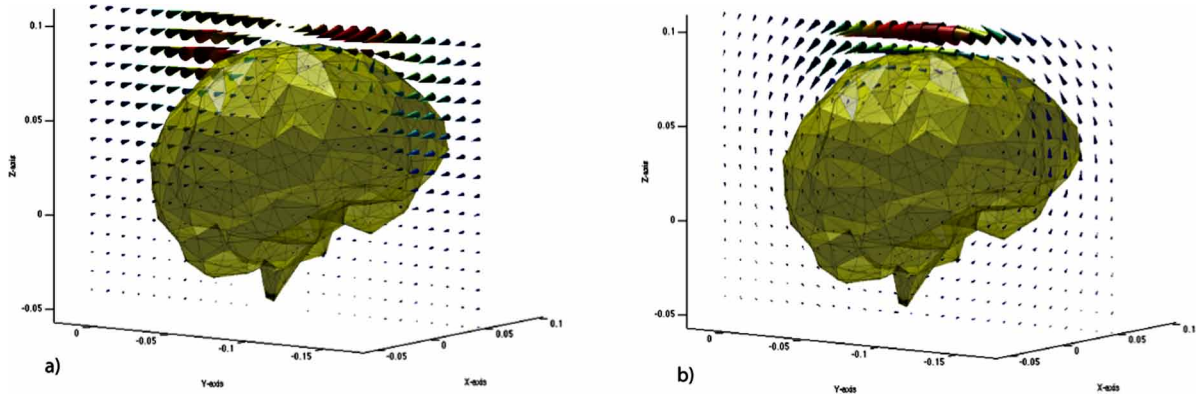

3. MODELING OF NERVE FIBER EXCITATION

Figure 7 shows the myelinated nerve fiber with an arbitrary number of Ranvier's nodes represented by a straight thin wire antenna (Zulim & et al., 2015; Zulim & et al. 2016).

Note that L denotes the fiber length, a is the inner axon radius and b is the radius including the myelin sheath. Electrode nerve fiber stimulation is taken into account by means of the equivalent current source I_g located at the fiber beginning. The current generator I_g represents the nerve fiber stimulation used in electro-acupuncture or percutaneous electrical nerve stimulation *(PENS)*, which both make use of thin needles injected through the skin. The fiber, oriented along the x axis, is assumed to be immersed in an unbounded homogenous lossy medium.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 6. Transversal cross-section of the electric field induced in the brain model by: a) Circular coil; b) Figure-8 coil. Coils not shown.

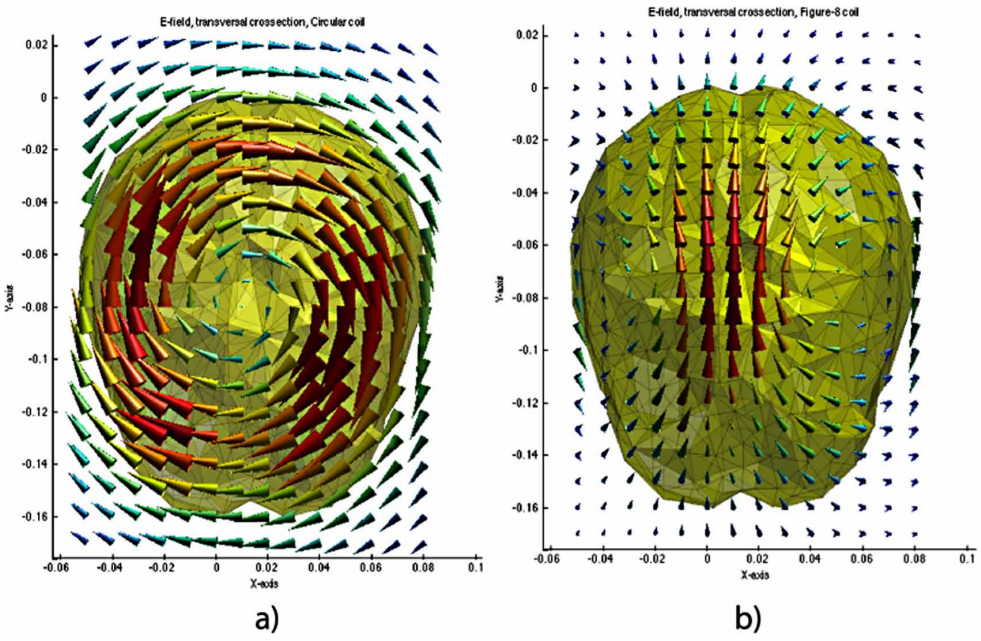

Figure 7. Thin wire antenna model of the myelinated nerve fiber

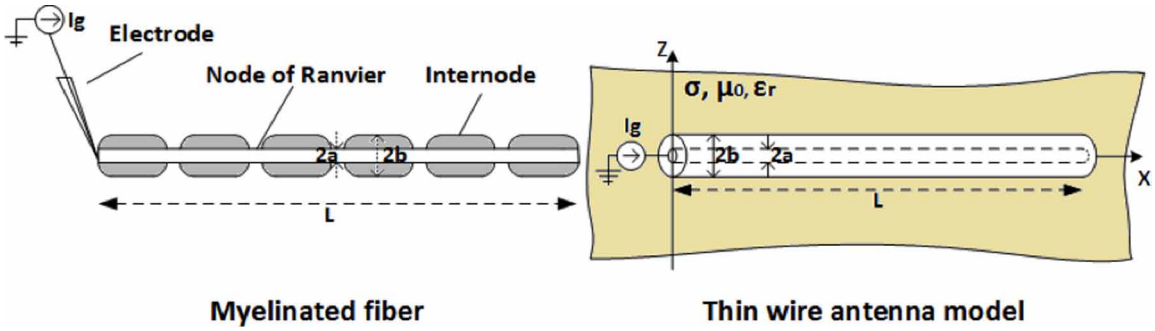


The formulation is based on the homogeneous Pocklington integro-differential equation for the unknown intracellular current I_a along the nerve fiber (Zulim & et al., 2015; Zulim & et al. 2016):

$$-\frac{1}{j4\pi\omega\varepsilon_{eff}}\int_0^L\left(\frac{\partial^2}{\partial x^2}-\gamma^2\right)g\left(x,x'\right)I_a(x')dx'=0 \tag{6}$$

while *g(x,x')* is the lossy medium Green's function defined as:

$$g\left(x,x'\right)=\frac{e^{-\gamma R}}{R} \tag{7}$$

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

where R denotes a distance from the source to the observation point, respectively, γ is the complex propagation constant given by:

$$\gamma = \sqrt{j\omega\mu\sigma - \omega^2\mu\varepsilon_0\varepsilon_r} \tag{8}$$

and ε_{eff} is the complex permittivity of a lossy medium given by:

$$\varepsilon_{eff} = \varepsilon_0\varepsilon_r - j\frac{\sigma}{\omega} \tag{9}$$

with σ, ε_r and ω being the conductivity and relative permittivity of the medium, respectively, and ω is the angular frequency.

The current generator I_g is taken into account via the conditions at the nerve fiber ends:

$$I_a(0) = I_g,\ I_a(L) = 0 \tag{10}$$

It is worth mentioning that the properties of the lossy medium, nerve fiber membrane and myelin sheath are considered via the conductivity and relative permittivity which are obtained from the cable equation and the transmission line equation, respectively, as described in (Zulim & et al., 2015; Zulim & et al. 2016).

The Helmholtz equation for the corresponding transmembrane voltage is given by (Zulim & et al., 2015; Zulim & et al., 2016):

$$\frac{\partial^2 V}{\partial x^2} - \gamma_m^2 V = 0 \tag{11}$$

where:

$$\gamma_m = \sqrt{\frac{1 + j\omega\tau}{\lambda^2}} \tag{12}$$

and V is a transmembrane voltage, while λ is the length constant defined by (Zulim & et al. 2016):

$$\lambda = \sqrt{\frac{r_m a}{2\rho_a}} \tag{13}$$

and τ is the time constant given by (Picht & et al., 2013):

$$\tau = r_m c_m \tag{14}$$

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

ρ_a is the resistivity of axoplasm, r_m the myelin layer resistance for unit area and c_m capacitance of the Ranvier's node membrane per unit area.

The corresponding relations for the conductivity and relative permittivity are obtained by means of the procedure reported in (Zulim & et al., 2015). Homogeneous Pocklington integro-differential Equation (6) is solved via the Galerkin Bubnov Indirect Boundary Element Method (GB-IBEM). The details could be found elsewhere, e.g. in (Zulim & et al. 2016). A more general treatment of a thin-wire embedded in a lossy medium can be found in (Poljak & Doric, 2006.a, Poljak & Doric, 2006.b). For the sake of completeness, the procedure is outlined in this section, as well.

Thus, using the boundary element formalism, (6) is transformed into the set of linear equations, which can be written using the following matrix notation (Zulim & et al. 2016; Poljak, 2007):

$$\sum_{i=1}^{n}\left[Z\right]_{ji}^{e}\left\{\alpha\right\}_{i}^{e}=0,\ j=1,2,...n \tag{15}$$

where n is the number of wire segments, $\left[Z\right]_{ji}^{e}$ is the mutual impedance matrix representing the interaction of the observation segment j with the source segment i and $\left\{\alpha\right\}_{i}^{e}$ is the solution vector, expressed in global nodes. The mutual impedance matrix is:

$$\left[Z\right]_{ji}^{e}=-\frac{1}{j4\pi\omega\varepsilon_{eff}}\left[\int_{\Delta l_j}\int_{\Delta l_i}\left\{D\right\}_{j}\left\{D'\right\}_{i}^{T}g(x,x')-\gamma^{2}\int_{\Delta l_j}\int_{\Delta l_i}\left\{f\right\}_{j}\left\{f'\right\}_{i}^{T}g(x,x')dxdx'\right] \tag{16}$$

where matrices *{f}* and *{f'}* contain linear shape functions and matrices *{D}* and *{D'}* contain their derivatives. Δl_j and Δl_i are the observation and source segment lengths, respectively. The nerve fiber stimulation, in the form of an equivalent current generator, is incorporated into matrix system via boundary conditions (10).

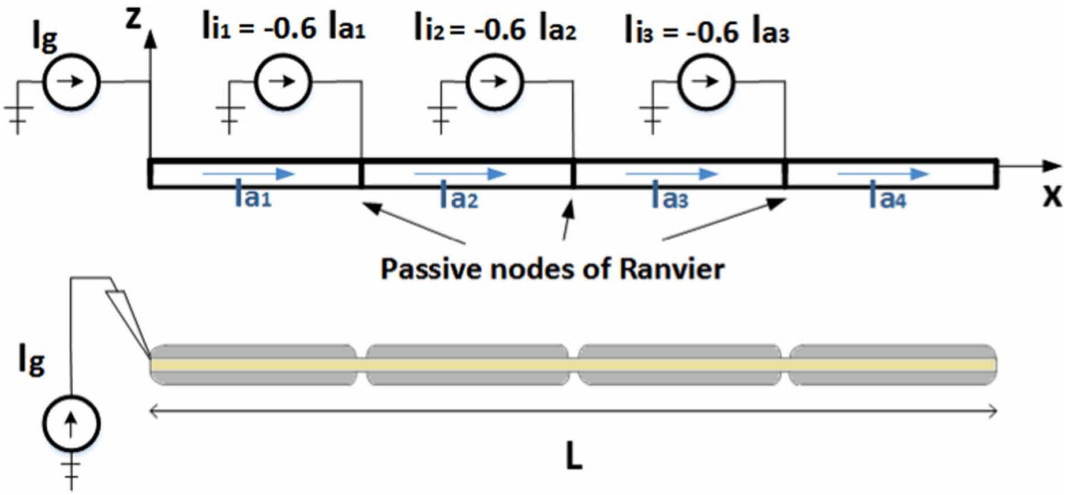
3.1. Passive Nerve Fiber

When modeling the passive nerve fiber, the ionic current in each Ranvier's node is to be considered. Thus, the additional current sources in the non-activated Ranvier's nodes are impressed. Figure 8 shows the passive nerve fiber model having 3 Ranvier's nodes and 4 internodes.

Analyzing the CRRSS (Chiu, Ritchie, Rogert, Stagg and Sweeney) model (Rattay, 1999; Chiu & et al., 1979; Sweeney & et al., 1987) it follows that the ionic current in each non-activated Ranvier's node is approximately equal to -0.6 I_a, where I_a is the intracellular current flowing into the observed Ranvier's node. Intracellular current I_{a2} which leaves the 1st Ranvier's node is equal to 0.4 I_{a1}. By analogy, the intracellular current I_{a3} flowing out of the second Ranvier's node is equal to 0.4 I_{a2} and the intracellular current I_{a4} that leaves the third Ranvier's node is *0.4* I_{a3}.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 8. Passive nerve fiber model



3.2. Numerical Results for Passive Nerve Fiber

The intracellular current is calculated for the nerve fiber of 2 cm, with 9 Ranvier's nodes and 10 internodes. The fiber is stimulated at its beginning, using a subthreshold rectangular current pulse, plotted in Figure 9. The time domain results are obtained from the frequency domain results by means of Inverse Fast Fourier Transform (IFFT).

Ranvier's nodes are located at $x = 2, 4, 6, 8, 10, 12, 14, 16, 18$ mm along the fiber, respectively. The intracellular current distribution along the passive nerve fiber is plotted in Figure 10. The result is compared to the CRRSS model (Rattay, 1999; Chiu & et al., 1979; Sweeney & et al., 1987), and calculated for the time instant $t = 1$ ms.

Figures 11 and 12 show the subthreshold intracellular current versus time in the Ranvier's nodes 2, and 6, respectively.

The results for the intracellular current obtained by the antenna model, seem to be in a rather satisfactory agreement with the results obtained by using the CRRSS model. Note that the intracellular current waveform in Ranvier's nodes follows the excitation pulse form, as due to the subthreshold current stimulation, the voltage gated channels are not activated.

3.3. Active Nerve Fiber

Model of an active nerve fiber is presented on a myelinated nerve fiber with 3 active Ranvier's nodes and 4 internodes, as shown in Figure 13.

Each node is represented by a wire junction of two thin wires representing an active Ranvier's node. Thus, 3 additional current sources at the active Ranvier nodes represent an ionic current I_i of the activated node. The ionic current is determined by analyzing the *CRRSS* model and the analytical expression for the ionic current is obtained by curve fitting procedure (Poljak & et al., 2016.b):

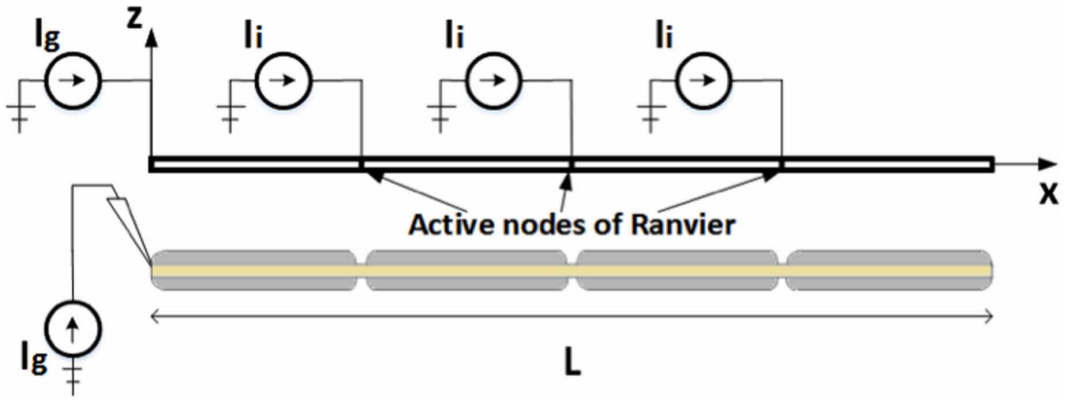
Figure 13. Active nerve fiber model



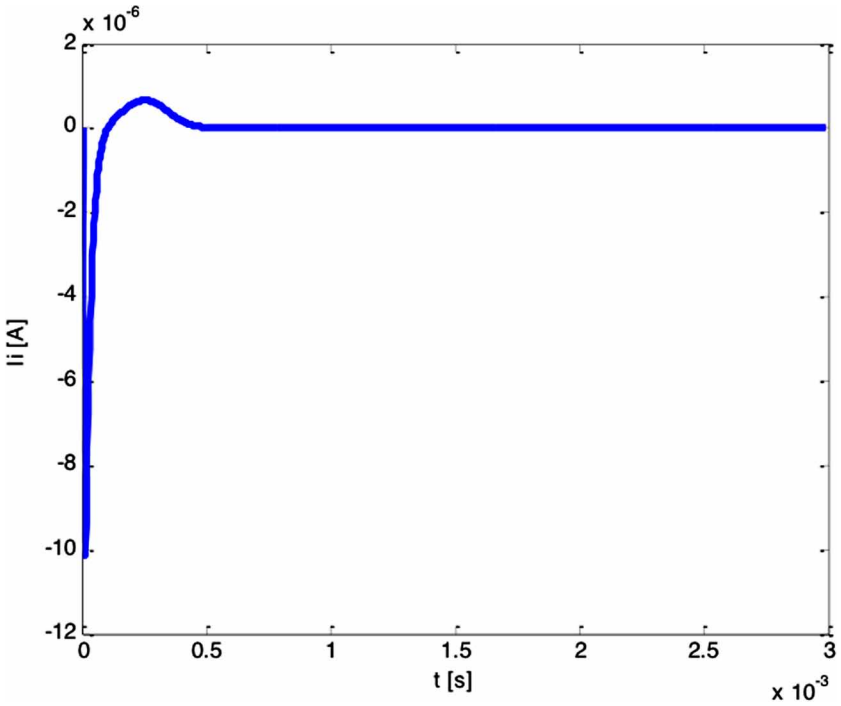
$$I_i(t) = -Au(t-t_1)\left[e^{-B(t-t_1)} - e^{-D(t-t_1)}\right] + Eu(t-t_1)e^{-G(t-t_2)^2} + He^{-K(t-t_3)^2} \tag{17}$$

where t_1 = 0.031 ms, t_2 = 0.252 msA, A = 0.02075 mA/ms, B = 199.9 (ms)$^{-1}$, D = 46.91 (ms)$^{-1}$, E = 0.000664 mA/ms, G = 60 (ms)$^{-2}$. The ionic current is depicted in Figure 14.

A thin wire junction model of the active node, can be represented by two separate thin wires, as shown in Figure 15.

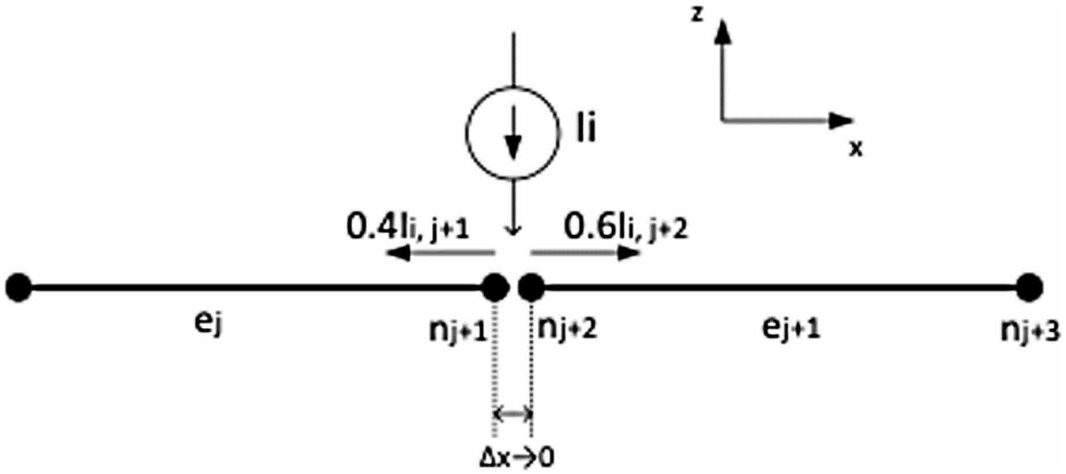
The Kirchhoff's law has to be satisfied at the junction (Poljak & et al., 2016.b):

Figure 14. Ionic current of activated node of Ranvier



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 15. Two wire junction representation of the active node



$$I_i = 0.4I_{i,j+1} + 0.61_{i,j+2} \tag{18}$$

where $I_{i,j+1}$ represents the ionic current value flowing out of the junction in one direction and $I_{i,j+2}$ is current flowing out of the junction in the opposite direction.

First, the nerve fiber is stimulated by a current generator I_g at a fiber beginning, as in the case of the passive nerve fiber. Furthermore, If the stimulating current exceeds the threshold in the corresponding Ranvier's node, the second current source, representing the ionic current, activates. The intracellular current for the activated fiber is a summation of the node activation current and the ionic current of the activated node. The resulting current, flowing out of the activated node, then activates the next node. The same procedure is repeated for each node.

The threshold for the nerve fiber activation depends on the strength and duration of the stimulus (Geddes & Bourland, 1985; Boinagrov & et al., 2010; Ashley & et al., 2005).

3.4. Numerical Results for Active Nerve Fiber

The intracellular current for the active nerve fiber is calculated with 9 Ranvier's nodes and 10 internodes. Rectangular current pulse used to depolarize the nerve fiber membrane is plotted in Figure 16.

The current pulse shown in Figure 16 stimulates the nerve fiber at the fiber beginning. Once a threshold current of 1.5μA reaches the first Ranvier's node, the other current source activates. Summation of the intracellular current activating the node and the ionic current of the second current source yields the resulting intracellular current in the 1st activated Ranvier's node. The resulting current then activates the 2nd Ranvier's node. The related intracellular current plot is shown in Figure 17.

The results for the intracellular current obtained via the antenna and CRRSS model show a rather satisfactory agreement to a certain extent. Some minor discrepancies appear due to the ionic current approximation. Intracellular current part pertaining to the rectangular current pulse is in a very good agreement.

Finally, Figure 18 shows the intracellular current for the 4th Ranvier's node.

Figure 18. Intracellular current in the active Ranvier's node 6, L = 2 cm

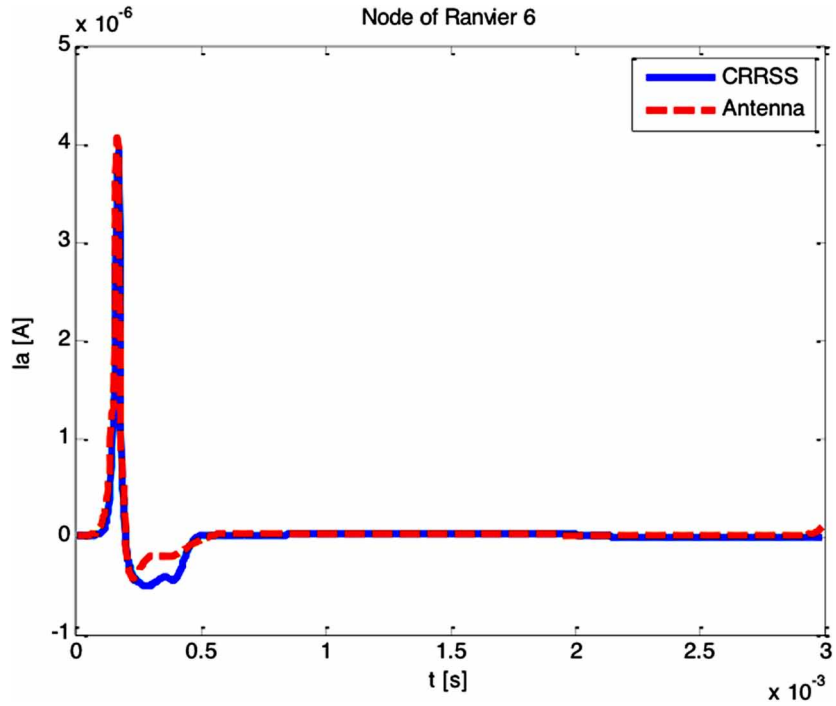

Figure 19. Intracellular current along the active nerve fiber, t = 0.2 ms, L = 2cm

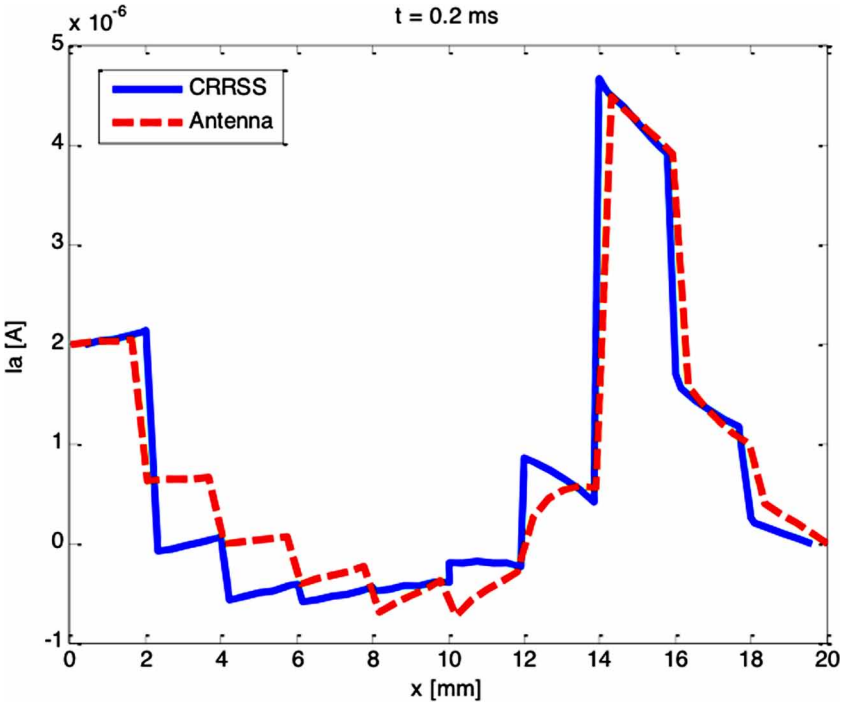

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Obviously, the rectangular current pulse decays along the fiber, while intracellular current part keeps almost the same amplitude at the activated node. The signal of the activated nerve propagates along the fiber almost without attenuation.

Finally, Figure 19 shows the intracellular current distribution along the nerve fiber, plotted for the time instant of 0.2 ms obtained by the antenna and CRRSS model, respectively.

There is a satisfactory agreement between the results, with some visible discrepancies in amplitude of the intracellular current travelling along the fiber, mainly due to the instability of numerical procedure in the antenna model.

4. CONCLUSION

The paper reviews the use of integral equation methods in studies of biomedical applications of electromagnetic fields pertaining to TMS and nerve fiber stimulation. TMS modeling is based on the set of coupled surface integral equations while related numerical solution procedure based on the Method of Moments (MoM) approach.

The integral equation based formulation presents a more rigorous, and hence more accurate description of the TMS, by not having to take into account the inductive and capacitive effects, often being neglected when quasi-static approximation is used.

The myelinated nerve fiber is modeled by the thin wire antenna in passive and active state, respectively, stimulated by a rectangular current pulse at the fiber beginning. The model is based on the corresponding Pocklington integro-differential equation, handled via the GB-IBEM.

The myelinated nerve fiber based on antenna theory presents the completely new concept in the nerve fiber modeling. Interested reader can find the detailed survey of other concepts related to numerical electrostimulation models in (Reilly 2016).

Some illustrative computational examples for the induced field in the brain, due to the TMS treatment and intracellular current along the nerve fiber due to the current source excitation are presented in the paper.

The future work will be related to the development of anatomically realistic model of the human brain based on the integral equation approach. Also, the coupling of the human brain model with the nerve fiber model, i.e. the induced electric field results as the input parameters of the nerve fiber model is the subject of the ongoing activities.

Chapter 14
Efficient Algorithm for Answering Fuzzy Medical Requests in Pervasive Healthcare Information Systems

Wissem Labbadi
University of Tunis, Tunisia

Jalel Akaichi
King Khalid University, Saudi Arabia

ABSTRACT

The progress in mobile devices and wireless networks technologies has considerably contributed to integrate pervasive computing expertise in many domains with the aim of improving the quality of services and users' mobility. However, in many situations, users may face difficult situations, needing faster decisions, where classical systems impose the submission of classic queries in which crisp conditions must be carefully fixed. This inconvenience limits the potential of pervasive applications accessed by users having few times to make the right decisions. To introduce the contributions of this paper, we choose the medical domain as example. We considered a pervasive healthcare application under which physicians haven't enough time to fix carefully their queries in some emergency cases. Therefore, they are allowed to flexibly express their preferences using conjunctive fuzzy queries and to quickly receive best answers anywhere and anytime while treating patients in the shortest time and consequently free resources for eventually other urgent requests. In this work, we consider, in general, the problem of efficiently finding the top-K answers for a conjunctive fuzzy query from the top-N conjunctive query rewritings of the query. In particular, we propose an efficient algorithm called the Top-N rewritings algorithm for finding the top-N query rewritings of a medical conjunctive fuzzy query using a set of conjunctive crisp views. At the best of our knowledge, this algorithm is the first to generate, without computing all possible rewritings, the N best ones ordered according to their satisfaction degrees and that are likely to return the best K-answers for the user fuzzy query. The relevance of a query rewriting is estimated using a second algorithm called the Query-satisfaction computing algorithm proposed to estimate, through the histograms maintained to approximate the distribution of set of values returned by the rewriting and to which fuzzy predicates are related, the pertinence of a conjunctive fuzzy query rewriting rather than accessing the database relations.

INTRODUCTION

The integration of pervasive computing in healthcare has enabled patients to take profit from high quality health care services anytime and anywhere. For this reason, providing continuous remote monitoring especially for elderly patients into the comfort of their home will be certainly less expensive than the cost of in-clinic recovery and more efficient. Furthermore, the advancement in mobile devices and in context-aware technologies has contributed to enhance the quality of healthcare services and the users' mobility from one place to another.

Pervasive healthcare has the potential to reduce medical costs and improve quality of services; however it faces many technical difficulties related to the integration of the different medical information systems interoperating under the same healthcare application and maintaining periodically changeable schemas. In front of this challenging problem, middleware is gaining interest by insulating different systems from proprietary interfaces and providing layers of abstraction giving hence the illusion of using a homogeneous system. In many cases, physicians face problematic situations threatening patients' lives and needing fast and firm decisions; nonetheless classical medical middleware systems used to force physicians to submit traditional queries in which they must inflexibly precise their crisp conditions. This inconvenience limits the potential of the healthcare application used by physicians having few times to save patients' lives. In fact, they might have enough time to fix carefully their queries and can't wait any longer for needed answers. For this reason, we put forward a pervasive healthcare application based on an efficient virtual integration system in order to allow physicians to express freely their preferences using natural language and vague terms and consequently quickly to obtain their desirable answers anywhere and anytime while treating patients in the shortest time and therefore free medical resources for eventually other urgent requests.

In this paper, we propose the Top-N rewritings algorithm, a novel and efficient algorithm for generating ordered top-N query rewritings which are likely to return the top k-tuples fitting with user preferences. This algorithm is the first one to generate the N best rewritings without computing all possible ones while it discards useless rewritings from the query rewritings searching step and hence, generates only the best likely satisfactory ones ordered according to their satisfaction degrees of the user query. We discuss also two different solutions on how exploiting the output of the Top-N rewritings algorithm in order to recover the Top-K tuples considered as best answers. Finally, we envision an implicit query cache memory in the middleware to avoid useless query processing when it is already available in the cache.

In the next section, a brief summary about pervasive healthcare is presented. Section 3 shows the contribution of middleware to help integrating different medical information systems interoperating under the same healthcare application. In section 4, we define a fuzzy medical conjunctive query. Section 5 is devoted to describe the two proposed algorithms. This section describes also how to exploit the Top-N rewritings to determine the Top-K tuples. Section 6 explains when and how using the query memory cache. In section 7 we discuss the feasibility of the study andthe final section concludes the paper.

Pervasive Healthcare Applications

The progress in mobile devices over wireless networks and in context-aware technologies has considerably contributed to integrate pervasive computing in healthcare domain (Bardram, 2004; Bardram & Christensen & Olsen, 2004; Christensen & Bardram, 2002; Favela & Rodriguez & Preciado & Gonzalez, 2004; Varshney, 2003). In fact, by using wireless mobile devices, physicians become able to better com-

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

municate with patients, access updated patient medical records anywhere and anytime, and furthermore to share and exchange medical information with other colleagues in order to provide patients with high quality health care services into medical institutions and/or at the comfort of their own homes.

Pervasive healthcare focuses on the use of pervasive computing technology for developing services to improve quality of medical care. Carrying out a remote consultation or providing continuous remote monitoring especially for elderly patients in their post-operative period into the comfort of their home will be less expensive than the cost of in-clinic recovery and patients are becoming independent from stationary treatment. In addition, pervasive computing aims to higher the quality of healthcare services although user's mobility, so to cope with changing context due to mobility of the user in the environment, applications need to be context-aware in order to identify their locations and assuring real time access to the mobile devices to bring them information about the nearest hospitals, the nearest pharmacies, the nearest emergencies while moving from one region to another. Furthermore, it helps optimize physician meetings. For example, if a doctor needs an in-home help of his colleagues, it is better to choose them between the nearest ones. A wide range of pervasive healthcare systems and smart devices have been proposed over the few past years. In (Shahriyar, Bari, Kundu, Ahamed, & Akbar, 2000), authors present a bio-sensor based mobile health monitoring system named ″Intelligent mobile health monitoring system (IMHMS)″ which improve health monitoring by providing medical feedback to the patients anytime anywhere through mobile devices based on the medical information collected intelligent and miniature bio-sensor nodes, that can be easily integrated into wireless personal or body area networks for mobile health monitoring, which are capable of sensing, processing, and communicating. Many health care projects are developed, before the appearance of the IMHMS, with the objective of providing more and more assistance to the elderly. For example, the project named AHRI (Aware Home Research Initiative) (Ahamed, Haque, Stamm, & Khan, 2007) with the goal is to provide a unified solution for the seniors in the home, enabling them to closely participate in disease detection and health management by themselves. (Halteren et al., 2004) Developed a system named Wellness Assistant (WA) which can be used, through inexpensive handheld devices, by people with obesity, diabetes, or high blood pressure, conditions which need constant monitoring. In (Varshney, 2007), Varshney describes various pervasive healthcare applications and some issues and challenges to the use of wireless technology in the task of monitoring. Varshney is considered among the initiates to work on the integration of wireless networks technologies in healthcare that he addresses and discusses how wireless technologies can be applied in the healthcare environment and how to effectively manage the complexity of wireless and mobile networks in healthcare applications. In (Varshney, 2006a), he discusses and illustrates how mobile and wireless technologies can be applied for location management, intelligent emergency system, patient monitoring and mobile telemedicine applications. He also designed some wireless infrastructure for some future healthcare applications. In (Varshney, 2006b), Varshney determines several of the requirements of using wireless networks and mobile technologies in patient monitoring and show how infrastructure oriented wireless LANs can be used to support patient monitoring in diverse environments.

Some other related work propose to integrate pervasive healthcare into homes in order to be smart homes that allow patients to have a better quality of life due to fact that is a familiar environment. In (Bartolomeu, Fonseca, & Vasques, 2008), authors explain the requirements needed to build a smart home to support the monitoring and care for chronically ill or recovery patients. They describe two systems of Pervasive healthcare in smart homes. Altcare (Sohaib, Elbrandt, Dragon, & Ostermann, 2010) is able to detect the daily events of an elderly using a network of cameras. This system detects emergency situations and automatically contacts the responsible for the patient and also allows doctors at any time to

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

check the patient's condition and thus provides a more comfortable and safe living to the elderly. Smart Condo (Boers, et al., 2009) is a monitoring system for elderly at home with the characteristic that it respects the privacy of individuals by not recording any videos or sound.

An other important work which uses context-aware devices in healthcare is the AWARE project (Bardram, Hansen, Mogensen, & Sogaard, 2006), which implements a context-aware environment in a hospital. The system is essentially composed of a tracking module for clinics and patients, an infrastructure for acquisition, management and distribution of contextual information, and tools like situated displays and mobile phones.

An important recent work which illustrates the interoperability of heterogeneous IoT (Internet of Things) platforms is (Gaglio, Re, Martorella, Peri, & Vassallo, 2014) in which authors developed a mobile health system that enables to monitor distant patients. Such a system based on high-level programming processing can address some important issues arising when heterogeneous devices are requested to cooperate, which is a crucial feature of IoT applications (Lui, Antonio, & Giacomo, 2010).

Finally, (Nitin & Sujata, 2015) proposes a pervasive monitoring of mobile health care using Android for mobile healthcare emergency. With pervasive monitoring, smart phone resources including computing power and energy can be opportunistically gathered to process the computing intensive personal health information during mobile healthcare emergency with minimal privacy disclosure.

Pervasive healthcare has the prospective to reduce medical costs and to increase the quality of services, but then again it likewise faces many technical hitches related to the integration of the diverse medical information systems interoperating under the same healthcare applications. In fact, most of existing implementations of pervasive healthcare applications do not interoperate well due to segmented heterogeneous and autonomous solutions (Black & Segmuller & Cohen, 1995). The different information systems treat various types of information that evolves dynamically which leads to the changing of the underlying schemas of the database and the interfaces dedicated to the other integrated organization systems. The problem persists in how the back-end system managing the different integrated information systems might evolve dynamically?

Middleware Pervasive Healthcare Applications

To face the problem of integrating autonomous medical information systems handling different types of medical information that evolves dynamically incurring consequently the change in the interface offered to the other integrated medical information systems, middleware was gaining interest by insulating different systems from proprietary interfaces and providing layers of abstraction giving hence the illusion of using a homogeneous system. Many prototypes have been developed to ease the design and the integration of the different information systems behind the fine running of the pervasive healthcare applications. In this context, building a pervasive healthcare application based on a virtual information integration system (Lenzerini, 2002) was very promising to integrate medical databases. The system follows the local as view approach where the distributed medical information sources are defined as views over a global schema and a middleware receiving and answering users' queries. Such approach favors the addition of new medical data sources such as new hospitals, pharmacies, emergencies, etc. A virtual medical information integration system provides the healthcare application with a unified schema giving the illusion to the application users of using a unified system without caring about the heterogeneity between the different information sources. For example, a physician may need the recent analysis results and medicines taken by a patient. In this case, the required information must be extracted from

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

different hospitals and pharmacies databases and joined together. That is the role of mediation system which deals with the problem of gathering information from the different medical information sources by finding correspondences between the global and the data sources schemas.

In many cases, physicians face difficult situations related to patients' states needing fast decisions; however classical medical integration systems usually force them to submit classic queries in which they must express precisely their crisp conditions. This inconvenience, obviously, limits the help expected from the healthcare application used by physicians having few time to react according to the patients' states. In fact, they, usually, haven't enough time to fix carefully their queries and couldn't wait any longer for answers.

Fuzzy Medical Conjunctive Query

A fuzzy medical conjunctive query is a conjunctive query (Ullman, 2000) in which fuzzy predicates are related to medical variables such as blood pressure, heartbeat, blood glucose level, etc. A conjunctive query is defined as a rule applied to the extensional database or stored relation by considering all possible substitutions of values for the variables in the body of the query. If a substitution makes all the sub goals true, then the same substitution, applied to the head of the query, is an inferred fact about the head's predicate. A fuzzy medical conjunctive query Q is supposed to respect the following form:

$$Q(X):- \exists\, Y \text{ body } (X, Y), p_1(x_1), \ldots, p_n\,(x_n) \quad (1)$$

Where X are the distinguished variables, Y are so-called the non-distinguished variables and are distinct from the variables in X, body(X, Y) is a conjunction of non-fuzzy predicates, p_i is a fuzzy predicate, related to a single distinguished medical variable (x_i), which assigns to each tuple t_i a score $\mu p_i\,(t_i) \in [0, 1]$ describing the satisfaction degree of the fuzzy predicate p_i by the tuple t_i according to a given membership function.

Let's consider the following relations:

- Patient (PatID, name, age)
- Blood_characteristics (PatID, blood_pressure, blood_glucose_level, time)

An example of a conjunctive fuzzy query is ''Show names of young patients where blood pressure is high''. This query can be formulated, using logical rule notation, as follows:

Answer (y): Patient (x, y, z), Blood_characteristics (x, v, w, a), young (z), high (v)

Flexible and Fast Pervasive Healthcare Applications

To remedy these inconveniences, more flexibility in the definition of user queries is required. In fact, to get the best matched answers, medical applications must allow physicians to express freely their preferences using natural language enhanced by vague or imprecise conditions in their queries, especially when the limits of their conditions are not clear. Therefore, to help users submitting their requests, many fuzzy conditions over many attributes are envisioned, and sers have only to choose the appropriate desired conditions. Moreover, if a user requirement is not defined yet, it can be added, anytime, to the requirement list for an eventual future use. In addition, it is possible to use fuzzy quantifiers inside

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

queries like "many" and "at least" in fuzzy quantified statements. Basing on flexibility advantages of the fuzzy queries, users will no longer care about the exact limits of their conditions in urgent cases when such details can be forgotten.

A simple way to answer a conjunctive fuzzy query submitted to the medical information integration system is to apply Bucket (Levy & Rajaraman & Ordille, 1996), MiniCon (Pottinger & Halevy, 2000) or Inverse rules (Dushka & Genesereh & Levy, 2000) algorithms for answering classical queries using views, in order to determine all possible rewritings which can be sorted according to their computed satisfaction degrees (Labbadi & Akaichi, 2010) and materialize only those with accepted scores. However, this method incurs an unnecessary cost since it determines also the useless query rewritings and causes a waste of resources for useless scores computation. To overcome these drawbacks, we propose a method based on two steps. In the first step, we propose the *Top-N rewritings algorithm* which generates the N best likely satisfactory rewritings ordered according to their satisfaction degrees of the user query. The relevance of a query rewriting is estimated using the *Query-satisfaction computing algorithm* proposed to estimate the pertinence of a fuzzy conjunctive query rewriting rather than accessing the database relations. This algorithm, proposed in (Labbadi & Akaichi, 2010), estimate the satisfaction degree of a fuzzy predicate by a tuple from a materialized view defined as a simple fuzzy selection query of the form "X is P" where P is a fuzzy condition related to attribute X. The estimations are obtained from the histogram constructed dynamically to approximate the frequency distribution of X in the resulting relation.

In the second step, the output of the Top-N rewritings algorithm is used to find the Top-K tuples for the submitted fuzzy query. We consider our solution as an efficient one able to answer medical fuzzy queries because it intends to accelerate the medical integration system processing. In fact, in the first step, only the N best rewritings are determined without computing or searching for all them to evaluate their interest and in the second step, only the best rewritings are used to find the Top-K tuples for users' queries.

In the following, we propose the query satisfaction computing algorithm illustrated with an example to highlight the efficiency of the algorithm and then the top-N rewritings algorithm is provided.

Query Satisfaction Computing Algorithm

The contribution of the algorithm is its ability to estimate the degree of satisfaction of a conjunctive query rewriting of a fuzzy conjunctive query according to the fuzzy predicates occurring in the query. It provides an approximation of the average satisfaction degree of the fuzzy predicates occurring in the query by a tuple of the conjunctive rewriting result and this based on the constructed histograms. The first module of the algorithm estimates the result size of each conjunctive query rewriting; the second module constructs for each rewriting, the histograms approximating the distribution in the rewriting result of values of each attribute with which a fuzzy predicate is associated. The construction process is based on the histograms maintained on these attributes in the sources participating in the query. The inputs of the algorithm are the conjunctive fuzzy query Q, the membership functions defining the fuzzy conditions used in Q and finally the histograms describing the distributions of values in the attributes of interest in the query referred sources.

Let's, first, define the notion of a rewriting of a query using views and then useful present notations used in the algorithm. Given a query Q and a set of view definitions V_1, …, V_n, a rewriting of the query using views is a query Q' that refers only to the views V_1, …, V_n [2].

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

The notations used in the different modules of the algorithm are: T(S) which represents the cardinality of Subgoal S, H[i] is The number of values in the interval I_i, attsum is the summarized attribute, occ(S, X) is the number of copies of one value subgoal S has in attribute X, Att("a") is the attribute containing the constant "a", V (S, X) is the number of distinct values (known or estimated) a Subgoal S has in attribute X, and μ (x) which is the membership degree of a value x to a fuzzy set.

The estimation of the rewriting result size is based on the histograms maintained for the join attributes in the relations participating to the query. The estimation process is described by the following module. See Figure 1.

The second module of the algorithm is devoted to construct the histograms, H_{res}, describing the distributions of values in the attributes to which fuzzy conditions are related. The construction process is described by the following part of the algorithm. See Figure 2.

The last module permits to compute the global satisfaction degree of a conjunctive query rewriting. Having available the histograms constructed by the module 2, the idea to compute the global degree is to determine the average satisfaction value of each fuzzy predicate in the query by a tuple returned by the rewriting, and then the weighted mean of these values in order to have a global vision of the rewriting. In this work, we propose to sum the average satisfaction degrees of the different fuzzy conditions and then to divide the sum by the number of fuzzy conditions or histograms. What we obtain, then, is an approximation of the average satisfaction degree of the conjunctive fuzzy query by a tuple returned by the rewriting. The computation of the global degree is given by the following module. See Figure 3.

Running Example

Let's consider a set of hospitals providing healthcare services where each hospital maintains a database accessible to the public through the Web. Each database lists all the physicians distributed among the different specialties in the corresponding hospital and provides information about their consultations with patients. Let's consider also a medical conjunctive fuzzy query submitted to a mediated system in-

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

tegrating the heterogeneous hospital databases. Each physician has a name and a fee which is the amount of a consultation. The consultation relation lists all the consultations being insured by physicians. An evaluation value is a score, belonging to the range [0, 20], associated to a consultation assured by a given physician in a given date. The hospital database schema is the following. See Figure 4.

The mediated schema exposed to the user is the hospital schema except that the relations Consultation and Physician have an additional attribute "hosp" identifying the hospital at which a consultation is being insured. The mediated schema is described below in Figure 5.

To illustrate the solution, suppose that we have the following two data sources. The first source s_1 lists all the physicians working in a hospital and their fees. This source is described in the mediator by the following view definition in Figure 6.

The second source s_2 lists among the physicians provided by source s_1 those assuring consultations with their evaluations; s_2 is described by the following view definition in Figure 7.

If a user needs to know the physicians having not expensive fees and having good evaluations, he submits to the data integration system the following query in Figure 8.

The data integration system is able to answer the previous query by joining the two sources s_1 and s_2. These sources are determined after reformulating the query, submitted over the mediated schema, into one that uses the crisp views v_1 and v_2 because v_1 (respectively v_2) mentions the relation Physician (respectively Consultation) which is revealed by the query and also selects the attribute name (respectively evaluation) which is also selected by the query. For more information about usability of a view to answer a query see (Halevy, 2001)). This query is then described in the following Figure 9.

Nonetheless, the system doesn't have any information about the quality of the result returned by the previous query. Consequently, the data integration system needs a more efficient way to answer a fuzzy query submitted in terms of its mediated schema; hence the idea of querying the integrated data sources through their summaries.

Let H1, respectively H2 be histograms describing the distribution of values in the attribute price in s_1 respectively in the attribute evaluation in s_2. The evaluation values described by a histogram are

Where     v1.physician_id = v2.physician_id AND
          speciality ='cardiology' AND price is NOT
          EXPENSIVE and evaluation is GOOD.
```

grouped by physician_id and aggregated on average, so that each physician must have a single evaluation value. H1is made of the intervals I_1= [0, 100], I_2 = [101, 200], I_3 = [201, 300]. We have: H1 [1] = 10, H1 [2] = 25 and H1 [3] = 15. H2 is made of the intervals I1= [0, 10], I2 = [11, 20]. We have: H2 [1] = 15 and H2 [2] = 35.

We estimate, according to module 1, the size of the resulting relation based on the histograms maintained on s_1 and s_2. First, we estimate the size of the selection condition based on the histogram H maintained on the attribute Specialty as:

$$T(\sigma_{\text{Speciality="cardiology"}}) = H[I_k] / V(I_k, \text{Speciality}) \quad (5)$$

$$= 50 / 10 = 5$$

To estimate the final query result size, we need to estimate the size of the result of joining the selected tuples with those in the relation s_2. Here we assume that the same partition of the domain of physician_id is organized into fixed sized intervals $I_1, \ldots I_m$ in the two sources s_1 and s_2. The idea is to compute the result size of joining the values of each interval $I_{k\,(k=1 \ldots m)}$ of Hs_1 with those belonging to the interval I_k of Hs_2, and then the different sizes are summed in order to obtain the size of the query result.

$$T(Q) = \sum_{k=1}^{m}(Hs1 \,.\, \sum_{k=1}^{m}(Hs1\, H_{s1} \sum_{k=1}^{m}(Hs1\,.\,[] * T(s1) / T(\sigma_{\text{speciality="cardiology"}})) * H_{s2}[I_k] / \max(V(I_k, s1(\text{physician_id})), V(I_k, s2(\text{physician_id}))) \quad (6)$$

Let $H1_{res}$ and $H2_{res}$ be the histograms describing respectively the distribution of the fees and the evaluation values in the query result. Based on module 2, $H1_{res}$ and $H2_{res}$ are computed as follows.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

$$H1_{res}\left[1\right]=\frac{\left(V\left(I_1,\text{price}\right)*\text{query result size}\right)}{\sum_{k=1}^{3}V\left(I_k,\text{price}\right)}=\left(2*5\right)\Big/\left(2+3+5\right)=10/10=1 \tag{7}$$

$$H1_{res}\left[2\right]=\frac{\left(V\left(I_2,\text{price}\right)*\text{query result size}\right)}{\sum_{k=1}^{3}V\left(I_k,\text{price}\right)}=\left(3*5\right)\Big/\left(2+3+5\right)=15/10=1.5\approx 2 \tag{8}$$

$$H1_{res}\left[3\right]=\frac{\left(V\left(I_3,\text{price}\right)*\text{query result size}\right)}{\sum_{k=1}^{3}V\left(I_k,\text{price}\right)}=\left(5*5\right)\Big/\left(2+3+5\right)=25/10=2.5\approx 3 \tag{9}$$

$$H2_{res}\left[1\right]=\frac{\left(V\left(I_1,\text{evaluation}\right)*\text{query result size}\right)}{\sum_{k=1}^{2}V\left(I_k,\text{evaluation}\right)} \tag{10}$$

$$H2_{res}\left[2\right]=\frac{\left(V\left(I_2,\text{evaluation}\right)*\text{query result size}\right)}{\sum_{k=1}^{2}V\left(I_k,\text{evaluation}\right)} \tag{11}$$

Now having available the desired histograms for the different query rewritings enables to determine how closely each rewriting matches the fuzzy conditions specified in the user query. Let us consider the two fuzzy sets "NOT EXPENSIVE" and "GOOD" defined by the following fuzzy membership functions in Figures 10 and 11.

The module 3 of the algorithm provides the average satisfaction degrees respectively of the two fuzzy predicates "NOT EXPENSIVE" and "GOOD"**:**

((1 * 1) + (0.495 * 2) + (0 * 3))/6 = 1.99/6 ≈ 0.33

((0.35 * 2) + (0.89 * 3))/5 = 3.37/5 ≈ 0.67.

The actual average satisfaction degrees respectively of the fuzzy predicates "NOT EXPENSIVE" and "GOOD" equals 1.5/5 = 0.3 and 4.14/5 ≈ 0.82. In this particular case, the degrees computed (0.33) and (0.67) are relatively good approximations.

Top-N Rewritings Solution

Different techniques have been proposed in the literature to determine the best query rewritings that are likely to return the best answers in the context of answering fuzzy query using views. In (Jaudoin & Colomb & Pivert, 2009), authors deal with the problem of answering query through probable answers instead of certain answers. The authors propose an algorithm for computing the top-K rewritings where a score between 0 and 1 is attached to each rewriting Q' of a query Q, which corresponds to the probability for a tuple returned by Q' to be an answer to Q. The authors of (HadjAli & Pivert, 2008) deal with fuzzy query answering using views where the view descriptions may include fuzzy predicates. The proposed approach associates a satisfaction threshold to each query and the best views, those which provide answers whose satisfaction degree is over the threshold specified by the user, are determined through a matching of the fuzzy query against the fuzzy views. In the same context where the views are fuzzy, the paper (Jaudoin & Pivert, 2011) constitutes a contribution to the definition of flexible Local-As-View mediation systems. It proposes an approach to rewriting fuzzy queries using imprecise views where the query and the views may include fuzzy value constraints. These constraints describe attribute values as a set of elements attached with a degree in [0, 1] that expresses the plausibility attached to a given element while in the queries, they denote preferences.

The essence of Top-N rewritings algorithm is to generate the N best rewritings for a fuzzy query Q without computing its possible rewritings. It tries to achieve significant reduction in query execution time as it considers minimal number of rewritings that are likely necessary to return the Top-K tuples for a submitted medical fuzzy query. It generates the best rewriting fitting user preference first, then the next best rewriting second until having the N required rewritings. We mention that the numbers (N) of the rewritings to find and (K) of the desired tuples are different and N is an internal variable fixed by the middleware depending on the K value. Our algorithm is the first study to generate the Top-N ordered rewritings without computing them or searching all possible ones for a medical fuzzy query. Its originality is for searching the N best rewritings, it considers only N rewritings and it is certain that are the best ones. Top-N rewritings algorithm is inspired from the MiniCon (Pottinger & Halevy, 2000) one generating the maximally contained rewriting of a conjunctive query Q. MiniCon provides a maximally contained rewriting for Q and not an equivalent one because in virtual information integration systems, it is assumed that the sources are incomplete including only a subset of answers and the views defined over the global schema may not refer to all databases stored information (Open World Assumption). MiniCon can be used as part in our algorithm after modifying it. The first modification concerns the input and the

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

output of the algorithm. The input of Top-K rewritings algorithm is a fuzzy conjunctive query, a set of crisp views ordered by their satisfaction degrees for a fuzzy query and the number N, and the output is the N best rewritings according to the fuzzy medical submitted query. The second modification is in the MCD formation step. In fact, this step is not done for all views at the algorithm beginning.

Nevertheless, it is performed for the most important view in the views' list then for the second most important view, etc. The higher view satisfaction degree is, the most important the view is for a rewriting. The second step of the MiniCon algorithm consisting in combining the MCDs is also modified. In fact, Top-N rewritings algorithm searches the best rewritings using the MCDs of the most important view, then the second most important rewritings by combining the MCDs of the most important view and the MCDs of the second most important view, etc. A rewriting importance is evaluated by a monotonic satisfaction function aggregating the satisfaction of the different views composing the rewriting.

Our algorithm stops once it reaches the N needed rewritings.

MiniCon Algorithm

Preleminaries

- **Queries Containment**: A query Q_1 is contained in a query Q_2 if for each database instance D, the result of Q_1 applied to D is included in the result of Q_2 applied to the same instance D (Halevy, 2001).
  - Formally: $Q1 \subset Q2$ *if* $Q1\ (D) \subset Q2\ (D)$.
- **Mapping**: A mapping between two queries Q_1 and Q_2 is a mapping between the variables of Q_1 and the variables of Q_2. To form a mapping between two queries, the following necessary conditions must be satisfied:
  - A variable must not be mapped at the same time to different variables or constants.
  - A constant must not be mapped to a variable or a constant other than itself.
- **Containment Mapping**: Containment mapping is a necessary and sufficient condition to check the containment between queries (Halevy, 2001). This means that to conclude the inclusion between a query Q_2 and a query Q_1, it is sufficient to prove that there is a containment mapping between them without executing them. A mapping (t) is a containment mapping if it maps every sub-goal of Q_2 to a sub-goal of Q_1 and the head of Q_2 to the head of Q_1.
- **Queries Equivalence**: A query Q_1 is equivalent to a query Q_2 if Q_2 is included in Q_1 and Q_1 is included in Q_2.
  - Formally: $Q_1 \equiv Q_2$ *if* $Q_1\ (D) \subseteq Q_2\ (D)$ *and* $Q_2\ (D) \subseteq Q_1\ (D)$.
- **Equivalent Rewritings**: Let A be a schema, $V = \{V_1, V_2, \ldots, V_n\}$ a set of views over A and Q a query over A.
  - Q' is an equivalent conjunctive rewriting (Halevy, 2001) for a conjunctive query
  - Q if:
  - Q' refers only to the views of V.
  - Q' is equivalent to Q.
- **Maximally Contained Rewriting**: A maximally contained rewriting aims at finding as many as possible answers from the provided views. Q' is a maximally contained rewriting for a conjunctive query Q if:
  - Q' refers only to the views of V.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

- Q' is included in Q.
- There is no other rewriting Q_1 such as $Q' \subset Q1 \subset Q$ and $Q' \neq Q_1$.

MiniCon Algorithm

MiniCon algorithm (Pottinger & Halevy, 2001) is proposed in the Tukwila project. It is used to search a maximally contained rewriting for a classic conjunctive query Q using a set of conjunctive views V. It cares about the interaction between the query variables of joined predicates. In fact, if a view contains a target sub-goal participating in a join in the query, the join variables should appear in the considered view head in order to join it with other views. Minicon (see Figure 12) begins by considering each query sub-goal in isolation. Once it finds a partial mapping between a view sub-goal g and a query sub-goal g', it looks at the query variables of the join predicates to find the minimal additional set of the query subgoals that must be mapped to the view sub-goals in order V be usable. This set of query sub-goals that have to be mapped to sub-goals of a view and the related mapping information is called MiniCon Descriptions (MCDs). It says how the query sub-goals can be covered by a view. It is considered as a fragment of the containment mapping from the query to its rewritings.

1. Form the MiniCon Descriptors (MCDs).
2. Combine the MCDs.
3. Return the maximally contained rewriting.

The following conditions have to be respected when forming the MCDs:

- **Condition 1**: Every query distinguished variable or query constant must be mapped to a view distinguished variable.
- **Condition 2**: If a variable X is a part of a join predicate which is not included in a view V then it must appear as a head variable in V to join other views in a query rewriting.

After determining the MCDs of the different views, they are combined to form query rewritings while respecting the next safe condition: rewritings must contain disjoint MCDs covering all the query sub-goals. There is no need to check the containment test as all the formed rewritings are valid ones thanks to the MCDs construction conditions. The maximally contained rewriting is the union of the different valid rewritings from which views' redundancies are removed.

Figure 12. MiniCon algorithm steps

Top-N Rewritings Algorithm

The input of the Top-N rewritings algorithm (see Figure 13) is a sorted list of crips views, the number of rewritings N and the fuzzy conjunctive query Q. The sorted crisp views (V_i,…, V_n) are examined according to their orders in the list (see the following running example): the best crisp view is used first then the second until obtaining the N needed rewritings. When a crisp view V_i is chosen from the ordered list of crisp views, the algorithm looks for the MCDs that can be formed with to cover the query sub-goals. Next, the algorithm searches the rewritings that can be formed using only the MCDs of Vi, then the rewritings that can be formed using the MCDs of V_i and the MCDs of the previous examined crisp views from V_1 to V_{i-1} (if these MCDs exist). The rewriting research is facilitated by the monotonic propriety of the satisfaction function. In fact, the research begins with the rewritings formed by one MCD then by two MCDs then by three MCDs, etc. The limit number of MCDs in a rewriting depends on the number of the previous observed views. Our algorithm abandons the researches ones it reaches the number N of rewritings. The found rewritings are the best that can be searched. See Figure 13.

Running Example

Assume we have four crisp views (from V_1 to V_4) to rewrite a medical fuzzy query Q. Each view has a satisfaction degree (F (V_i)) such that F (V_i) is higher than F (V_{i+1}). Assuming also that each combination of crisp views is a rewriting for Q. Using Top-N rewritings algorithm (Table 1), the rewritings are generated from the most to the least important (from R_1 to R_{14}): R_1 is the best rewriting as it is formed by the view V_1 having the higher view satisfaction degree for Q. Then R_2 is generated having the degree of V_2 then R_3, etc. The generation of R_2 is done before R_3 because a rewriting having the least number of views is the most important in the case of equal satisfaction degrees. Top-N rewritings algorithm stops once it reaches the number N of rewritings. If N is 1, it stops once R_1 is found without exploring all the research space as R_1 is the best rewritings' research. When it finds R_2, it returns R_1 and R_2, etc.

Top-k Tuples Generation

In recent years, many research works have acknowledged the need for flexible ways to access database information. A typical example is the top-K query where the system aims at providing the user with the best K answers. The most relevant research works studied the problem of efficient answering of top-K queries using views (Das & Gunopulos & Koudas & Tsirogiannis, 2006, Xie & Lakshmanan & Wood, 2013).

In (Das & Gunopulos & Koudas, 2006), authors deal with the problem of answering top-K queries using data for example in conjunction from a collection of views where a view in this context is defined as a materialized form of a top-*K* query asked previously according to some monotone combining function defined on a subset of the attributes of a relation. The main contribution is to propose an efficient algorithm called LPTA to identify, among a collection of views, the most promising views to use for query answering.

However, the performance of LPTA suffers because of iterative calls to a linear programming subprocedure, which can be especially problematic when the number of views is large or if the dimensionality of the dataset is high. To improve the efficiency of the LPTA algorithm, authors in (Xie & Lakshmanan

Table 1. Ranked rewritings generation

Query Rewritings	View Satisfaction Degree

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

& Wood, 2013) propose to take advantages of the cached results of previous queries. They propose the LPTA$^+$ algorithm to efficiently answering top-k queries using cached views. The experiment results, studying the performance of the LPTA$^+$ algorithm, show the interesting reduction of waiting time to provide the user with the top K answers.

In this section, we consider the problem of how to efficiently exploit the output of the Top-N rewritings algorithm to retrieve the top-K tuples. Each rewriting of the Top-N ones satisfies in general the fuzzy query but it doesn't affirm that all its tuples are better than those of the succeeding rewriting. Hence, two possible solutions can be envisaged to find Top-K tuples of Q using its top-N rewritings which are:

- Running the Top-N rewritings, sorting the resulting tuples and giving users only the K best ones. If a user wants the second best K tuples, he can require them. This solution gives the best tuples for user query but the disadvantage consists in the running time of the all Top-N rewritings.
- Running the first rewriting from the Top-N ones. If it is resulting tuples cardinality is equal or over than K, the tuples are sorted and only the first K of them are returned for users. Else, the succeeding rewritings are computed one by one until having K tuples to return. This solution helps users quickly obtaining globally satisfying answers for their fuzzy queries. But, they aren't sure that the received answers are the best ones.

Query Cache

To enhance the fuzzy query processing, we suggest a cache memory in the middleware storing the last implicit queries' results triggered by the physicians' PDAs. Same predefined implicit queries can be submitted by different PDAs located in a same region. Consequently, there is no need to re-process them as their Top-K results are readily available in the cache. Cache verification is performed for each submission of an implicit query. If it doesn't exist in the cache, the entire query answering process described in the previous sections will be executed and its result will be stored in the cache else, the answer will be retuned instantly. The cache is initialized for each period of time to have actualized information.

FEASABILITY OF THE STUDY

The system architecture is simple with no complex communication architecture. On one hand, users, that can be either patients or physicians or other healthcare workers, are familiar with the use of mobile devices such as mobile phones. On the other hand, the setup of the bio-sensors is somewhat complex, but the advantages taken from the use of these bio-sensors in the context of improving healthcare services have much more importance comparing to the setup complexity of these bio-sensors. The implementation of the system is not expensive. The bio-sensors are generally low cost and the communication is also cheap due to the use of low cost wireless adapters and low cost mobile devices. The security is a challenging issue which concerns the safety of the communicated information transmitted between the different components. This information should be protected from malicious attacks and security vulnerability. In their turn, the communication protocols are flexible and can be adjusted to the communicated components which can be either personal computers or Cell phones or PDAs, etc.

CONCLUSION

The acknowledged integration of fuzzy logic, in different domains, arises the difficulty of estimating the pertinence of information sources for conjunctive fuzzy queries which is a very challenging problem. However, the introduction of fuzzy logic in the medical domain is very promising in the sense that users can use natural language and vague terms when querying medical applications and efficiently obtain best answers in the shortest waiting time.

In the literature, there are no algorithms proposed in middleware environments to determine the pertinent query rewritings likely to return the best answers for a conjunctive fuzzy query. Therefore, implementing such an algorithm will be very helpful for medical applications users, as we illustrated with a simple case study of a healthcare application.

In this paper, we presented a two steps method destined to find as quickly as possible and efficiently the best satisfying answers for a medical fuzzy query. In the first step, we presented the Top-N rewritings algorithm, a novel algorithm for generating ordered top-N rewritings for a fuzzy medical query. At the best of our knowledge, this algorithm is the first one to generate the N best rewritings without computing or searching all possible ones. N is a variable depending on the K desired tuples considered as best answers. In the second step, we proposed two different solutions on how exploiting the output of the Top-N rewritings algorithm in order to recover the Top-K tuples.

Finally, we briefly discussed the use of a query memory cache in order to avoid useless query processing when it is already available in the cache.

The proposed Top-N rewritings algorithm is based on the hypothesis of the uniform distribution to estimate the pertinence of information sources. As a future work, we plan to improve techniques of estimating the pertinence of information sources in order to obtain reliable results based on more accurate estimates.

ABSTRACT

Infant cry is considered as the first biological signal communicated by the newborns to the mother and the outside world. In NICU, there is a huge need to monitor the physiological conditions of the premature and full term infants. In such environment, the cry signal conveys significant information in terms of the distress of the infant and thereby needs of the infants can be well attended. Establishment of the portable device is thus essential for such scenario. This work enumerates a primitive experimental study on developing portable electronic medical device for infant cry recognition. The setup comprises of a voice recorder, NI My RIO processor with a Lab view followed by the LCD Tablet for display. The cry signals were recorded by placing the voice recorder in the incubator and were qualitatively assessed by the clinician and confirm its suitability for the experimental study. A threshold based classification was employed which sends the voice based alarm to the tablet. The continuous monitoring of such facility in NICU provides the behavioral status of the infant

INTRODUCTION

Infant cry, a biological signal that connects the mother and newborn is considered as valuable information for clinical diagnosis by the neonatologists (Kusaka et al, 2008; Bard et al., 2008; Chang et al.2016). The infant cry helps in recognizing the physical state of the baby such as pain, hunger, discomfort, wet diaper, fear, illness etc. In a typical neonatal intensive care unit (NICU), where pre-mature newborns & full term babies are undergoing treatment, their physical behavioral status needs to be known for any clinical decision. The cry signal reflecting the physical and psychological state of the newborns provides the opportunity for the clinical as well as mother to understand their needs. Though NICU'S combines advanced technology and trained healthcare professionals to provide specialized care, continuous monitoring of babies to cater the needs is a challenging task. It has been reported that the crying behavioral pattern of infants were closely associated with the maternal emotional distress during the post pattern period (Kusaka et al, 2008).

The analysis of the biological infant cry reveals the physical state of the babies including hunger, pain, fear, wet diaper etc. It is the audio frequency (250Hz to 600Hz) that distinguishes the normal cry from pathological cries. In the last two decades, attempts have been made to analyze the cry signals but no technology has been developed to monitor the pre-mature/full term babies in a NICU environment. Studies revealed that due to lack of facilities and continuous monitoring of the babies in the incubator and warmer, the mortality rate is exponentially growing high.

Further current clinical practice mainly relies on the subjective behavioral observation of infants in NICU. There is still lack of sophisticated monitoring system to screen and detect the patho-physiological changes of the infants.

This research work highlights a primitive experimental study on developing portable medical electronics device for infant cry recognition. The portable device comprises of three units, namely: voice recorder, real-time NI myRio processor and LCD tablets. The study simulates the typical NICU unit environment with recording of premature infants & full term babies in an incubator and warmer.

Literature on Infant Cries Detection

Literature works have been emphasized that analysis of infant cry an important field. This part briefly describes the recent methods for analysis of infant cry and pain assessment.

Dhanashri U.S. Talauliker and Nayana Shenvi (2015) have studied the characteristic of cry for preterm and full term infants. The cry characteristic reflects the development and possibly the integrity of central nervous system (CNS). They noticed that there is a difference between the cry patterns of preterm and infants with neuro-physiological conditions with fundamental frequency. Their aim was to preprocessing for eliminating silenced region of cry signal and estimates the fundamental frequency (pitch) using time & frequency domain analysis. The study was of main importance to exploring brain function at early stages of child development for timely diagnosis of neonatal disease malfunction.

D. Bard, P. Runefors, E. Arnbjornsson et al. (2008), discussed about the hypothesis that cry can be used as a tool to detect signs of nocioceptive pain. The pitch frequency is extracted from cry with time domain methods. The fluctuations of these were analyzed in filter. The comparison was done between the original and new results.

Sandhya and Premanand (2016) studied the mechanism of different types of cry. The dataset for the work consisted of 27 babies which represents of 7 hunger cries, 4 sleepy, 10 pain and 6 uncomfortable

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

cries. The studied also considered the Dunstan Baby Language (DBL) for the manual classification. The LFCC features were extracted and VQ codebooks was used to compress the feature vector. High quality results were obtained with LFCC compared to MFCC features.

Warlaumont et al.; (2010) have suggested features with self-organizing map and single-layer perception neural network as pattern classifier. Cries of six infants between 3 and 2 month were considered for the study. The data driver approach classifies the utterance into paralinguistic phonatory conditions.

Rautava et al.; (2006) studied the acoustic quality of cry in very low birth weight infants. The recordings were done after (MMR vaccination) at pediatric clinic and first cry utterance was studied using Praat software. Eleven dichotomist variables were evaluated from the cry pattern of each infant. The differences in the acoustic cry characteristics between the groups were also studied.

An automated infant cry recognition system was proposed to classify normal, deaf and asphyxiating infants (Galaviz & Reyers- Garcia.; 2004). Two features mel frequency cepstral coefficients and linear prediction co-efficient based acoustic features extracted were extracted and input delay neural network with gradient descent back propagation training algorithm was applied. A classification accuracy of 81% was shown.

Chang et al.: (2016) have proposed a sequential forward floating procedure to recognize the best features among time & frequency domain based features proposed for the study. A directed acyclic graph support vector machine was employed for the classification. Three variants hunger, pain, feeling sleepy were considered and an overall classification accuracy of 93.75% was achieved.

N. Sriraam & Tejaswini (2014) have done a pilot study on infant cry detection and pain scale assessment. The study highlights the critical need for the portable system for cries detection. A preliminary that makes use of mel frequency pattern with recurrent neural network classification was applied and the ROC analysis confirmed the efficiency of the classifier.

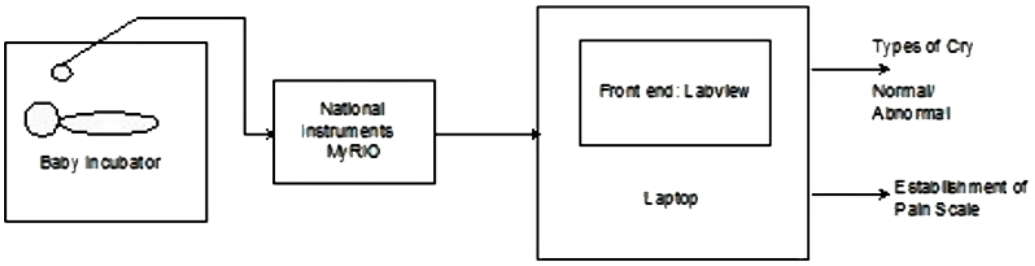
Varsharani & Sardar (2015) have applied linear frequency cepstrum coefficients and vector quantization code book for infants cry detection samples were collected from babies of less than six months old. A recognition rate of 91.58% was attained.

Conceptual Model

Figures 1 and 2 show the conceptual model for the proposed medical device for infant cry recognition considering the NICU environment. The model can be visualized a single baby incubator or multi incubator.

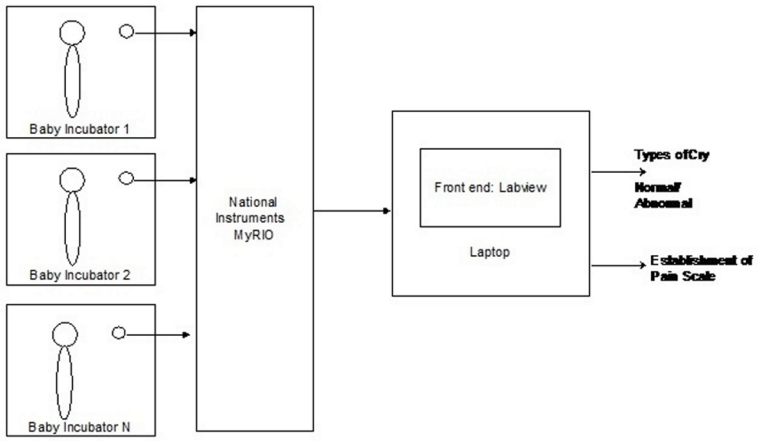
The voice recorder placed inside the incubator can be virtually connected to the real time processor, national Instrument NI My RIO processor. It has the figure potential to connect single and multi-voice

Figure 1. Proposed model for a signal baby incubator in NICU



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. Proposed module for a multi incubator in NICU



recorders through its port facility. For initial study, wired mode is used. The my RIO processor is configured in such a manner that with a help of lab view software the raw recordings are converted into digitized data. The typical block diagram of infant cry system comprises of mainly data acquisition, preprocessing, feature extraction, feature reduction, classification and display.

Data Acquisition

The cry samples that have to be used for this study are collected from few healthy babies aged less than 6 months, few ill, premature infants. The gender is also being considered when recording the cry signals as the fundamental frequency of male infant is greater than female infant. The cry is recorded by using a digital voice recorder in context with babies cry during pain, hunger and fear. The voice recorder with sampling frequency 44.1 KHz with sampling resolution of 16 bits is used.

Preprocessing

The raw cry signal is preprocessed in order to eliminate noise in the recorded cry signal. Normalization, cleaning and filtering is done in order to eliminate noise in recorded signal and it should be suitable to extract the required parameters such as MFCC's, pitch and LPC etc.

Feature Extraction

Mel frequency cepstral coefficients are one of the common and well known acoustic features. MFCC's are used to encode the speech signals that contain irrelevant information with large amounts of storage space into compressed and useful features (A. Zabidi, et al., 2010). The characteristics of the cry can be attributed to the characteristics of vocal tract system and excitation source and supra segmental characteristics. The spectral peaks, bandwidths and slopes are unique for each condition of cry. Hence if we extract this information one can discriminate the infant cry condition (Ali Messaoud, ChakibTadj, 2011). Pitch is one of the important and distinguished acoustic features to analyze the infant cry. Linear

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

prediction analysis is a time domain analysis which has been used frequently in infant cry analysis. Linear prediction analysis attempts to predict a speech sample through linear combination of several previous samples.

Feature Reduction

The extracted features are further processed for acquiring the required signal cry signal. It is possible to apply filter banks of the Mel or Bark scale in order to perform pitch wrapping or subjective loudness warping to the cry segments prior to cry analysis. This in turn selects the extracted feature for classification

Classification

The infant cry signals have distinct patterns which can be recognized with pattern classifiers such as artificial neural network and support vector machine. For example, time delay neural network classifies cries between normal, deaf and asphyxiated infants. Feed forward neural network, recurrent neural network to differentiate between cries from three different stimulus situations such as pain, fear and hunger. Support vector machine using kernels like linear, quadratic, polynomial and radial basis function kernel will be applied to differentiate different types of cry.

Display

The display is the important part of the infant cry system. The processed, classified cry signal is distinguished and named accordingly is displayed on the laptop LCD screen. The display gives the information about the cry which is normal or abnormal. The condition of both the cry is displayed.

The cry of an infant is recorded using speaker which is interfaced to the National Instrument Data Acquisition System. The audio signal is amplified and processed using Labview software for detecting the type of infant cries. Once the optimal solution is arrived, then the proposed scheme will be extended for simultaneous recordings of cries from various babies. The proposed system thus will help to monitor the well-being of the infants in a typical neonatal ward.

Figure 3. Components of the proposed study

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Experimental Study

After due ethical clearance, the cry of the infant was recorded at M.S. Ramaiah Medical Hospital, Bangalore, India. 62 infants, 38 full-term and 24 pre- term babies were involved and the aim was to discriminate the cry and wet diaper. The proposed study aims to record, process and convey the status of the infant to the staff nurse, neonatologist in NICU. To execute this operation, Lab based experimental setup was arranged at the Centre for medical electronic and computing (CMEC):

The prerecorded voice recorder was placed in the incubator. Then the recorder was connected to myRio processor.

The final outcome is shown in the LCD tablet where the alarm will be heard if any pathology is detected. Further voice based signal will be played to indicated the nature of the infant cry.

Figure 4. Experimental setup arrangement

Figure 5. Workstation arrangement kept in different room

METHODOLOGY

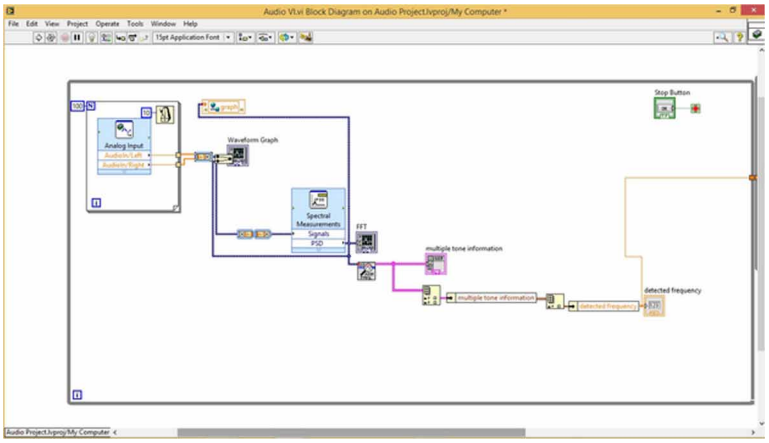
The focus of the primitive study is to understand the various aspects of infant cry analysis and classification. The work proposed implements automatic infant cry analysis which records infant cry which is a vocal signal and the signal is processed and analyzed to differentiate the healthy cries. The differentiated cries will further distinguish the physical state of a healthy infant such as hunger, fear, pain and wet diaper.

The infant cry detection deals mainly with the pitch which is the fundamental frequency from the analysis of infant cry. Infant cry analysis is a pattern recognition problem. It is similar to speech recognition process which comprises two main stages that are signal processing and pattern classification. The sound recorder, webcam &MyRio setup is placed near incubator of infant in NICU.

The system receives the raw cry signal as the input through the microphone. In the signal processing step the raw cry signal is pre-processed (using Labview program), normalized and filtered. The smoothed signal is analyzed by suitable feature extraction called multi tone information technique. One of the important issues in cry analysis is length of the segmented cry samples. Therefore, cry segments of fixed length are extracted from the cry records although the cry utterances are not equal in length. This cry is further processed using FFT module for more information on frequency, pitch, samples other details. The same details of voice signal, FFT signal graph, & multi tone information with vision display of webcam will be done on programming window as a result too. This process is made to run continuously with while loop & a control unit for stopping process. This processed signal is further given to logical comparison program for the classification of the pain level assessment. The resultant infant will be displayed in terms of string message with the cry signal graph, tone information, webcam data display.

These results can be viewed in 2 modes such as work station/ pc display, and another as Smartphone/ tablet display. In work station display, execution of the program will show the entire result on the same pc screen. For the Smartphone display the entire MY Rio setup is connected to the same WiFi network, using this with help of Labview data dashboard we can view the results on Smartphone (graph, message notification, & webcam data display), so it will be helpful for nurses or caring unit to monitor the infants easily.

Figure 6. Labview configuration module



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Advantage of this program is that the care taker/ nurse need not be 24/7 near the babies this can be monitored by remotely via mobile/tabs which should be connected on the same wifi network. The baby monitoring system can be viewed in the workstation laptop which intern controls MYRIO and on doctors' smart phone as shown below.

Figure 7. Workstation displaying the reason for cry, the graph charts of feature extraction and baby image at that instant

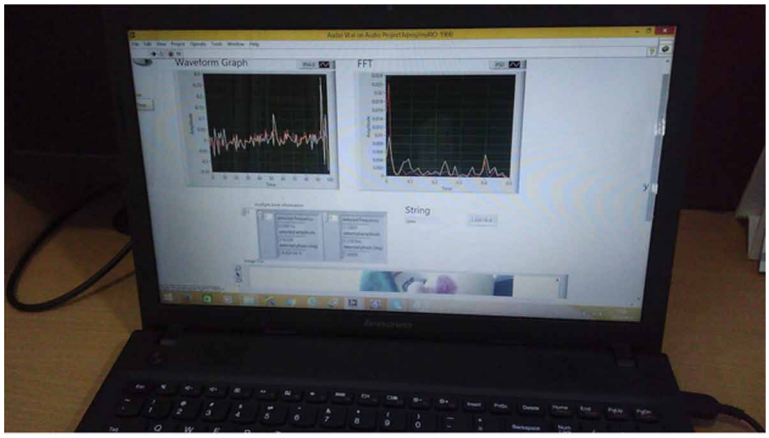


Figure 8. Continuous baby monitoring visualization in smart phone/ doctors phone

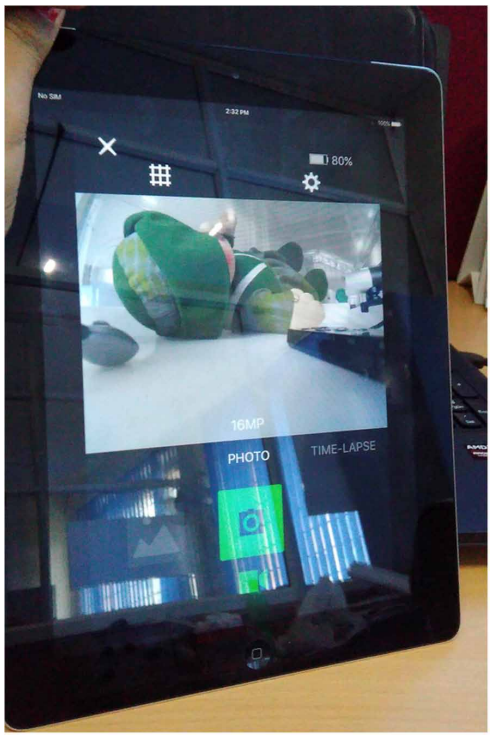

Figure 9. Reason of cry and feature extraction graph displayed on doctor smart phone

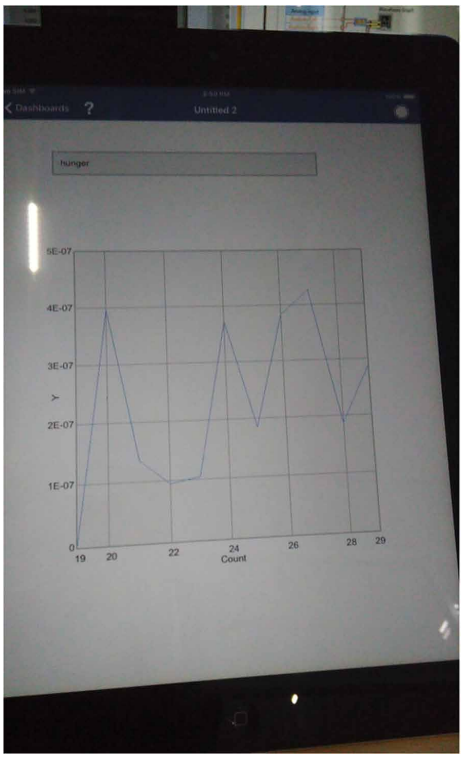

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

The display of message and classification data can be done in 2 parts one on the same screen where program is running & other one on the mobile/tabs which will be connected to the program variables of Labview via the same wifi network. This web services can be made available for concern person to access the data. The Labview data dashboard is used for displaying the data remotely. The webcam data is displayed using YICAM app/ ip cam.

DISCUSSION

The proposed study simulates the scenario of the typical NICU environment. The experimental work was conducted to emphasize the type of cry signal and conducted to video snap shot of the infant kept inside the incubator in the NICU. The voice recorder with a baby phantom kept inside the incubator and the corresponding type of cry was recognized. The real-time myRio processor with a Labview environment provides the graphical interface. Finally, the LCD tablet/mobile which was interfaced with the Laptop shows the display of the phantom (infant) as well as the voice record stating the type of cry. Such arrangements help the staff nurse/duty clinician to attend the baby immediately to cater their needs. Attempts are under process for executing the same process in the real-time scenario at NICU. The performance of the real-time processor is currently ongoing in terms of testing its overall efficiency, processor speed, memory capabilities etc.

CONCLUSION

In a neonatal intensive care unit (NICU), there is a huge need to monitor the physiological conditions of the premature and full term infants. In such environment, the cry signal conveys significant information in terms of the distress of the infant and thereby needs of the infants can be well attended. Establishment of the portable device is thus essential for such scenario. This work suggested a primitive experimental study on developing portable electronic medical device for infant cry recognition. The cry signals were recorded by placing the voice recorder in the incubator/warmer and three variants, hunger wet diaper, and pain were considered for the proposed study. All the recordings were qualitatively assessed by the clinician and confirm its suitability for the experimental study. The real time My Rio processor along with the labview software performed the operation of pre- processing and feature extraction and a threshold based classification was employed which sends the voice based alarm to the tablet. The continuous monitoring of such facility in the centralized nursing station in NICU provides the behavioral status of the infant and thus immediate attention for the clinical needs can be executed without any further delay.

ACKNOWLEDGMENT

The authors would like to thank Vision Group of Science and Technology, Government of Karnataka, Bangalore, Karnataka, India for their financial support to carry out this research project (SMYR/2014-2015/GRD No. 294). The authors would like to acknowledge Department of Pediatrics, M S Ramaiah Medical College & Hospital, Bangalore, India for the assistance and help during recording the cry rhythm.

Hassan Mathkour
King Saud University, Saudi Arabia

Mohammed Amer Arafah
King Saud University, Saudi Arabia

ABSTRACT

The exact string matching is essential in application areas such as Bioinformatics and Intrusion Detection Systems. Speeding-up the string matching algorithm will therefore result in accelerating the searching process in DNA and binary data. Previously, there are two types of fast algorithms exist, bit-parallel based algorithms and hashing algorithms. The bit-parallel based are efficient when dealing with patterns of short lengths, less than 64, but slow on long patterns. On the other hand, hashing algorithms have optimal sublinear average case on large alphabets and long patterns, but the efficiency not so good on small alphabet such as DNA and binary texts. In this paper, the authors present hybrid algorithm to overcome the shortcomings of those previous algorithms. The proposed algorithm is based on q-gram hashing with guaranteeing the maximal shift in advance. Experimental results on random and complete human genome confirm that the proposed algorithm is efficient on various pattern lengths and small alphabet.

1. INTRODUCTION

The problem of finding the occurrences of a predefined pattern in big data or very long sequences is classical problem in computer science and it has been studied intensively by researchers due to the growing of data which are produced day-by-day. There are many applications that depend on the pat-

tern matching, e.g., biological sequences which are produced every day by high throughput sequencing technologies (Morozova & Marra, 2008), natural language processing, or retrieving a specific data from very large databases. Bioinformatics is one of the fields where the pattern matching problem is used widely to search for specific pattern exactly or approximately (Barton, Iliopoulos, & Pissis, 2014; Simone Faro & Lecroq, 2009a; S. Faro & Lecroq, 2012; Kalsi, Peltola, & Tarhio, 2008) where the DNA is considered as a string and the four symbols *A*, *C*, *G*, and *T*, represent the four nucleotides Adenine, Cytosine, Guanine, and Thymine, respectively. Computer networks is the other area where this problem is applied. The binary string matching used in the intrusion detection systems to detect malwares within the heavy load traffic and searching IP addresses in routers swiftly (Chu, Huang, Tsai, & Hsieh, 2008; Liu, Huang, Chen, & Kao, 2004; Tuck, Sherwood, Calder, & Varghese, 2004).

The importance of speeding-up the searching process stems from that there is a need to find the occurrences of a particular pattern and whether the pattern exist or not in terabytes of data. Searching such amount of data offline by uploading the data to memory is not possible due to the memory limitations. In computer networks, Antiviruses are installed on routers or personal computers for detecting malwares so speeding-up the inspecting process increases the performance of the systems.

The problem is formulated as follows. Given a string T of length n and a pattern P of length m, the problem is to find the number of repetitions of P in T. In practice $m \ll n$. Let Σ denotes the set of symbols, then Σ^* denotes the language from which the pattern and the text are drawn and we write $P,T \in \Sigma^*$.

Two types of alphabets are considered in this paper, the DNA alphabet, $\Sigma=\{A,C,G,T\}$, and binary alphabet, $\Sigma=\{0,1\}$. The text and the pattern are represented by arrays of one dimension and the two arrays are indexed starting from 0. We say that the pattern P occurs in the text T, if $P[i]=T[j-m+i+1]$ where $0 \leq i < m$ and $\exists j$ such that $m-1 \leq j < n$.

2. LITERATURE REVIEW

There are so many exact string matching algorithms which are varying between character-based comparison(Al-Ssulami, 2015; Boyer & Moore, 1977; Deusdado & Carvalho, 2009; Franek, Jennings, & Smyth, 2007; Horspool, 1980; James H. Morris & Pratt, 1970; Knuth, James H. Morris, & Pratt, 1977; Lecroq, 2007; Sunday, 1990; Tarhio & Peltola, 1997), automata-based (Allauzen, Crochemore, & Raffinot, 1999; Allauzen & Raffinot, 2000; Blumer et al., 1985; Fan, Yao, & Ma, 2009; He, Fang, & Sui, 2005; Simon, 1994), and bit-parallel based (Baeza-Yates & Gonnet, 1992; Branislav, Durian, Holub, Peltola, & Tarhio, 2010; Cantone, Faro, & Giaquinta, 2010; Chen, Huang, & Lee, 2014; Simone Faro & Lecroq, 2009b; Mohanty & Tragoudas, 2014; Navarro & Raffinot, 2000; Peltola & Tarhio, 2003, 2014; Wu & Manber, 1992). Majority of character-based algorithms depend on the previously published ideas in (Boyer & Moore, 1977; James H. Morris & Pratt, 1970; Knuth et al., 1977) (See Simone Faro & Lecroq, 2013). The automata-based string matching depends on the idea of the finite automata. The algorithms of this type build the minimal deterministic finite automat then the text is parsed with the automata in time complexity of $O(n)$ in case of using an array of size $m|\Sigma|$; otherwise, the search phase costs $O(n\log|\Sigma|)$. The deterministic finite automata DFA is built for the pattern P of length m in time and space complexity of $O(m|\Sigma|)$ if an array is used (See (Simone Faro & Lecroq, 2013)). The bit-parallel based algorithms take the advantage of parallelism the bits inside the computer word. This technique

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

reduces the number of operations by a factor of ω, where ω is the size of computer word, that is, ω comparisons can be performed in a single bitwise comparison. This technique is suitable for simulation of the Non-deterministic finite automata (Simone Faro & Lecroq, 2013).

Recently, A bit-parallel algorithms for binary and DNA random texts is presented by (Peltola & Tarhio, 2014). The authors generalized the FSBNDM (Forward Simplified Backward Non-deterministic DWAG Matching) algorithm to inspect more than one character beyond the current text window. The FSBNDM algorithm by (Simone Faro & Lecroq, 2009b) reads two characters $T[j]$ and $T[j+1]$, where j is the last position in the current text window. Therefore, there are three situations:

1. $T[j]=P[m-1]$, then the reading continues leftwards;
2. $T[j]T[j+1]$ is a factor of P, reading continues leftwards;
3. $T[j]T[j+1]$ is not a factor of P, shifting the text window right by $m \leq 64$ positions (larger shift than SBNDM2 by 1).

(Peltola & Tarhio, 2014) developed *FSB*(q,f) algorithm to do the tests in cases 1 and 2 in one step. Based on the observation that when the q-gram is increased, the efficiency of SBNDMq (Branislav et al., 2010) is also increased. *FSB*(q,f) has been designed to use larger q-gram than 2 and handling f lookahead characters instead of 1, where $0 \leq f < q$.

Another algorithm called Greedy-SBNDM2 (GSB2) is also presented by Peltola and Tarhio (Peltola & Tarhio, 2014) to use a greedy skip loop or bad character heuristics. As a result, the authors proved experimentally that the algorithms *FSB*(q,f) and GSB2 are faster on binary and DNA data. Recently, the SSM algorithm is presented by Al-Ssulami (Al-Ssulami, 2015) to be faster in practice for texts of large alphabets.

The main drawback of *FSB*(q,f) and GSB2 algorithms is that their efficiency is restricted to the size of computer word 64, while SSM and HASHq (Lecroq, 2007) are efficient for large alphabet and long patterns but suffer from small shift in case of binary and DNA data. So in this paper, we present an efficient algorithm to deal with short, long and very long patterns on both binary and DNA texts. The new algorithm, namely HSSMq, consists of determining the q-gram pivot position, initializing the hash table and computing the possible shifts, maximizing the safe shift, and searching by matching the hash values. If the hash value of the q-gram pivot equals the hash value of the corresponding text q-gram, the verification step of matching starts from the rightmost end of the pattern towards the leftmost end.

The experimental results on binary and DNA random texts exhibit that the new algorithm is faster than the recent algorithms on short, long and very long pattern lengths.

The rest of this paper is organized as follows. Section 3 introduces in details HASHq with some figures to show its behavior on different alphabet sizes then the SSM algorithm is introduced with a figure shows how much it was improved over Horspool that we consider as HASH1. After that the pseudo-code of the new algorithm is sketched with experimental results showing how much is improved over HASHq by computing the average shift length, Section 4 shows the experimental results, and Section 5 provides our conclusion and future work.

3. THE ALGORITHMS

In more details, we introduce the well-known and fast algorithm HASHq (Lecroq, 2007) and the recent one (Al-Ssulami, 2015) because they are directly related to the new algorithm. At the end of this section, we present the new algorithm with pseudo-codes and an experiment showing the improvement on the shift length.

3.1. HASHq Algorithm

Let $\hbar_k \in \{0..255\}$. Then ∀ *q*-gram in the pattern *P*, the algorithm computes

$$\hbar_k = \left(\sum_{i=0}^{q-1} 2^i P[k-i]\right) mod 256,$$

where $q\text{-}1 \le k \le m\text{-}2$ and *m* is the length of *P*. The amount of shift is computed and stored in *Shift*[] array as:

$$Shift[\hbar_k] = \begin{cases} m-k-1, & k = \max\{q-1 \le l < m-1 : \hbar_l = \hbar_k\} \\ m-q+1, & if\ \ no\ such\ that\ \hbar_l = \hbar_k \end{cases} \quad (1)$$

The algorithm stores the amount of shift for rightmost *q*-gram in variable $sh_1 = Shift[\hbar_{m-1}]$ and updates $Shift[\hbar_{m-1}] = 0$.

Let us define the current text window as a portion of the text *T* of length *m* where a pointer *j* refers to the rightmost symbol in the window and $m\text{-}1 \le j < n$.

This algorithm uses fast skip loop. It compares the hash value of the rightmost *q*-gram of the current text window with 0. If they are not equal, the current text window slides to right by $Shift[\hbar_j]$; otherwise, it slides by sh_1.

A problem with this algorithm arises when the alphabet is small which means that the value $m\text{-}k\text{-}1$ in Equation (1) is small.

Following is a computation for the expected shift value with different alphabet sizes. In (Baeza-Yates, 1989), the average expected shift length of Horspool algorithm is computed as follows:

$$Shift_{(Horspool)} = |\Sigma|\left(1 - \left(1 - 1/|\Sigma|\right)^m\right) \quad (2)$$

Similarly, we compute the expected shift length of HASHq algorithm by the following equation considering that the hashing function is free of collisions:

$$Shift_{(HASHq)} = |\Sigma|^q \left(1 - \left(1 - 1/|\Sigma|^q\right)^{m-q+1}\right) \quad (3)$$

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

The average expected shift lengths for different alphabet sizes, pattern lengths, and q-grams are shown in Figures 1-3. It turns out that the average shift length is very small when $|\Sigma| \leq 5$.

The figures confirm that HASHq is indeed fast for large alphabet but it suffers from small shift in case of binary and DNA alphabets (small alphabets).

3.2. SSM Algorithm

We found the recent algorithm SSM is suitable to be adapted for small alphabets. It seeks for a pivot position ν in the pattern P such that $P[\nu]$ has maximal shift γ. Equation (4)-(6) describe the pivot ν with the maximal shift γ:

$$\gamma_1 = \begin{cases} \max\left\{\left(\nu - i\right) : 0 \leq i < \nu < m \, and \, P\left[i\right] = P\left[\nu\right]\right\} \\ 1, \quad otherwise \end{cases} \tag{4}$$

$$\gamma_2 = \begin{cases} \max\left\{\left(\nu + 1\right) : where \, P\left[\nu\right] is \, unique \, in \, P\right\} \\ 1, \quad otherwise \end{cases} \tag{5}$$

$$\gamma = \max\{\gamma_1, \gamma_2\} \tag{6}$$

Figure 2. The average expected shift length of HASHq when q=3

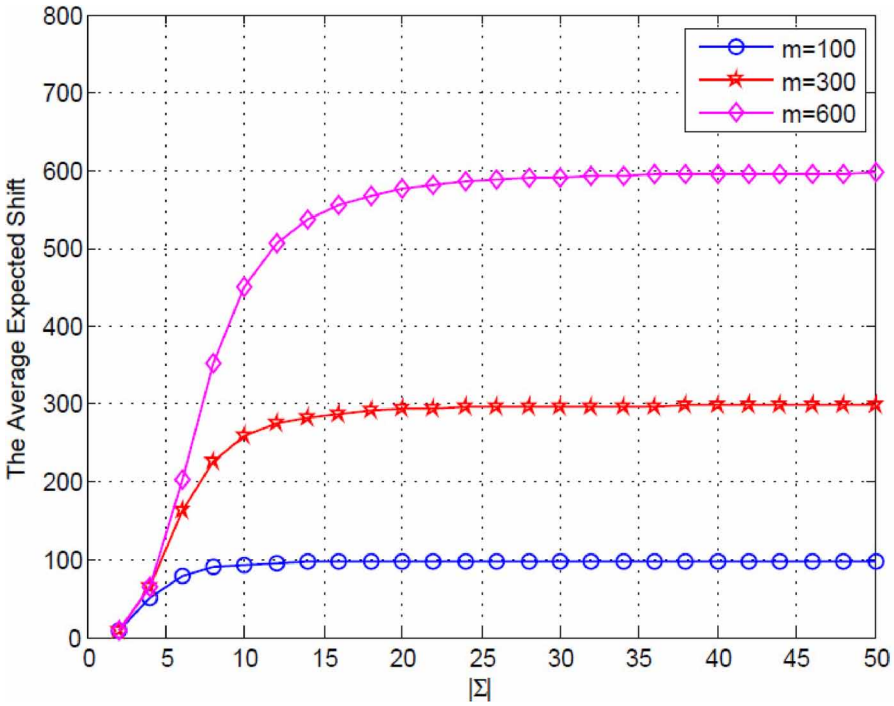

Figure 3. The expected shift length of HASHq when q=4

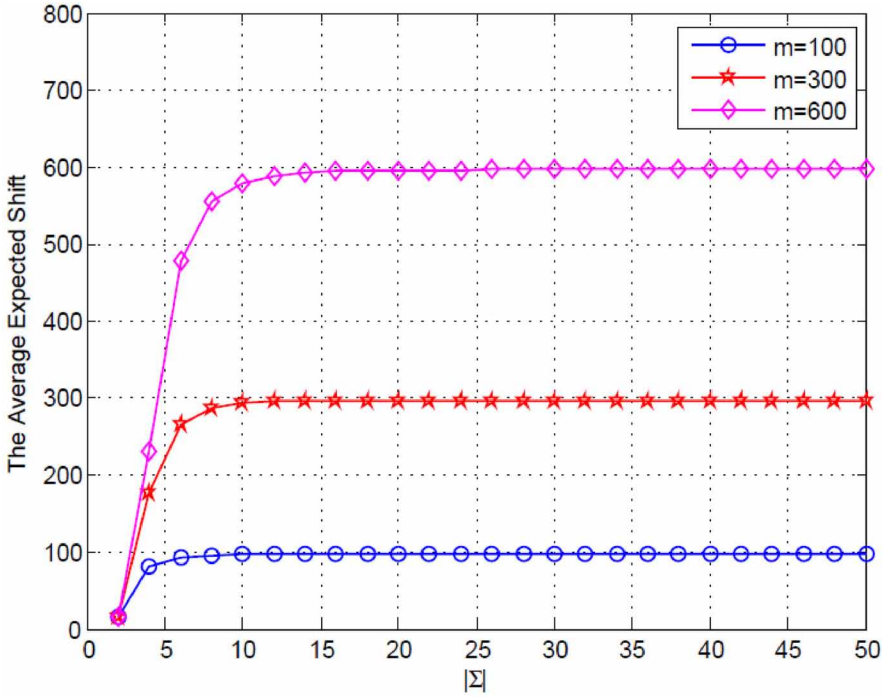


EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

SSM algorithm increases the amount of shift by scanning the pattern from left to right and vice versa which is suitable for long runs. This shift is stored in array *Shift*[]. Finally, a maximization step is made to compare the γ with each value in *Shift*[]and within each step the maximum shift is stored.

This algorithm uses a hash array *Horspool*[]where its entry is a single character, like Horspool. The skip loop condition is a comparison between $P[\nu]$ and $T[j+\nu-m+1]$, where j is the rightmost position of the current text window. If a match occurs, then the matching process is performed from the rightmost end of the pattern towards the leftmost end. This process ends either with a match or a mismatch at any position k and then the window is slided right by *Shift*[]. In case a mismatch occurs at ν, the shift is by *Horspool*[$T[j]$].

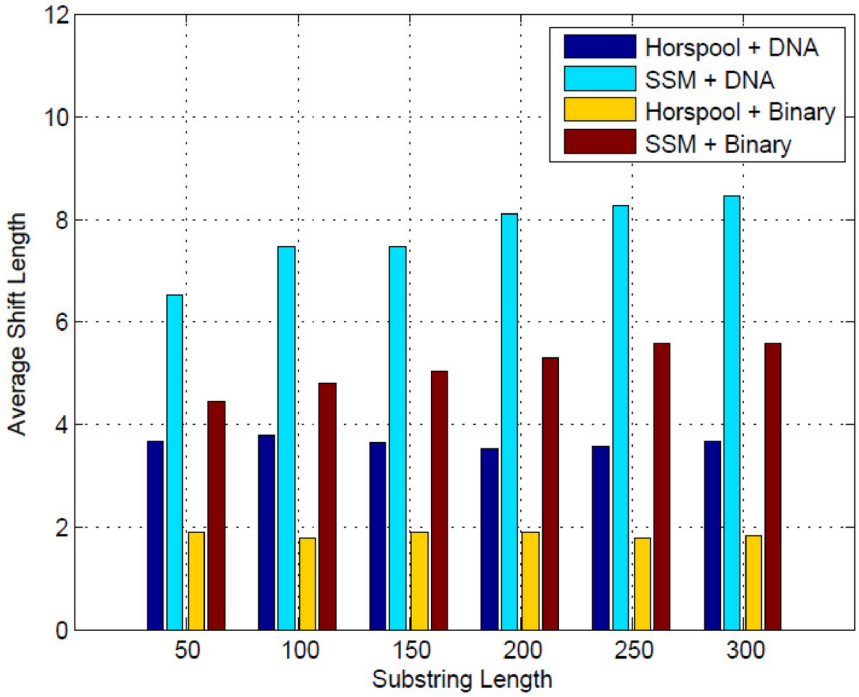
Experimentally, we measured the average shift length of Horspool and SSM algorithms on lengths 50-300 step 50. The results are shown in Figure 4 and confirm that the SSM added improvement over Horspool which can be transferred to HASHq.

The results show that SSM algorithm indeed has longer average shift length than Horspool. From this point, we found that it is possible to extend the idea of SSM to hashing more than a single character and getting better results on both dataset types. So, the new proposed algorithm (HSSMq) is a combination of hashing like HASHq and guaranteeing the maximal shift in advance like SSM algorithm.

3.3. The Proposed Algorithm

As in Figures 1-3, HASHq has longer shift on large alphabets and long patterns but it is not so for small alphabets. In the meanwhile, SSM more efficient than Horspool on small alphabets (See Figure 4) which

Figure 4. The average shift length over 100 runs



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

we consider as a special case of HASHq when q=1. Based on this conclusion, we design the HSSMq to integrates the idea of SSM with the q-gram hashing with some modifications.

The new algorithm consists of two steps, the preprocessing (Algorithms 1- 2) and searching phase (Algorithm 3). The preprocessing phase is represented by two subphases, the initialization and the preprocessing to compute the possible shifts.

Formally, let $Hash_Array_q[]$ denotes the hash array of $\sigma=2^{16}$ entries. Notice that HASHq has smaller size, 2^8. Increasing the size of hash array reduces the hash collisions and hence increasing the shift length. The hash array $Hash_Array_q[]$ is initialized with the maximum shift length $\chi=m-q+1$, (Lines 6-7, Algorithm 1).

Let us define the q-gram pivot ν as the q-gram of the pattern where its rightmost symbol is positioned at ν and gives a maximal shift length γ. So we can rewrite Equation (4)-(6) as:

$$\gamma_1 = \begin{cases} \max\left\{\left(\nu - i\right) : q-1 \le i < \nu < m \, and \, \hbar_i = \hbar_\nu\right\} \\ 1, \quad otherwise \end{cases} \tag{7}$$

$\hbar_i$ is the hash value for the q-gram at position i of the pattern which is computed by Lines 10-14 of Algorithm 1. The value of (ν-i) is represented by Line 18 of Algorithm 1:

$$\gamma_2 = \begin{cases} \max\left\{\left(\nu - q + 2\right) : \quad where \hbar_\nu \, is \, unique \, in \, P\right\} \\ 1, \quad otherwise \end{cases} \tag{8}$$

Equation (8) is represented by Line 16 of Algorithm 1:

$$\gamma = \max\{\gamma_1, \gamma_2\} \tag{9}$$

Line 20-21 of Algorithm 1 represents Equation (9). The pivot position ν is then chosen accordingly.

Equations (7)-(9) determine the pivot ν. The next step is reinitializing $Hash_Array_q[]$ according to Equation (1) of HASHq, but with the new pivot ν as follows:

$$Hash_Array_q\left[\hbar_k\right] = \begin{cases} \nu - k, & where \;\; k = \max\left\{q-1 \le l \left\langle \nu \right| \hbar_l = \hbar_k\right\} \\ \nu - q + 2, & if \;\; no \, such \;\; that \;\; \hbar_l = \hbar_k \end{cases} \tag{10}$$

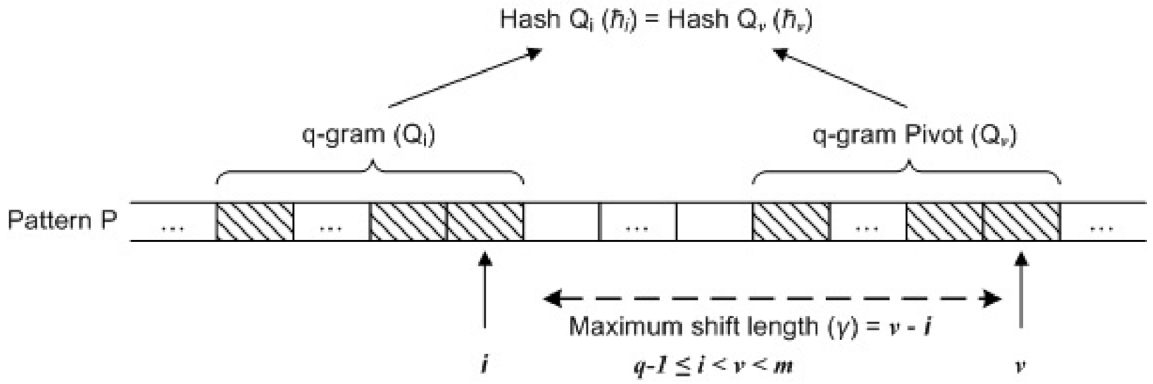
Equation (10) corresponds to Lines 22-30 of Algorithm 1.

Algorithm 2 is the preprocessing of the SSM algorithm. It consists of three steps, computing the shift length from left towards right side (Lines 2-7), updating the shift length from right to left (Lines 8-15), and the maximization step which updates the array $Dist[]$ so that $Dist[i]=\max\{\gamma, Dist[i]\}$ and $0 \le i < m$ as stated in lines 16-19.

Graphically, Figure 5 depicts the pivot q-gram (Q_ν) at position ν which has a maximum distance (γ) of safe shift so that its left q-gram (Q_i) that has the same hash value $\left(\hbar_\nu\right)$ is positioned at i in the pattern where there is no q-gram between i and ν has the same hash value $\hbar_\nu$.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 5. The q-gram pivot with maximum safe shift



The searching phase is sketched in Algorithm 3. Let *j* is the position of the rightmost symbol in the current text window and ranges over text *T* such that $m\text{-}1 \le j < n$. Thus, $\hat{j} = j + \nu - m + 1$ is the text window position that corresponds to ν. $\hbar_{\nu}$ and $\hbar_{\hat{j}}$ are the hash values which are computed according to Line 9 and Line 12, respectively.

Within each jump for *j*, $\hbar_{\nu}$ is compared with $\hbar_{\hat{j}}$. If they are equal, a verification step is triggered (Lines 16-19, Algorithm 3, then *j* is increased by $Dist[i] \le \gamma$ (Line 24)). If they are differ, *j* jumps $Hash_Array_q\left[\hbar_{\hat{j}}\right]$ positions (Line 14).

In recap, if the current text window position is $m\text{-}1 \le j < n$, then the next position $\bar{j}$ is computed by Equation (11):

$$\bar{j} = \begin{cases} Dist[i] + j & if\ \hbar_{\hat{j}} = \hbar_{\nu} \\ Hash_Array_q\left[\hbar_{\hat{j}}\right] + j & otherwise \end{cases} \tag{11}$$

Figure 6 illustrates briefly the layout of the searching process and shows how the different variables are positioned in both pattern and text. As shown from the figure, at position $\hat{j}$, the hash values are not equal $\left(\hbar_{\nu} \neq \hbar_{\hat{j}}\right)$, so a mismatch occurs at that position resulting in sliding the text window to right skipping a set of text symbols without comparisons. In the next attempt, a match, $\left(\hbar_{\nu} = \hbar_{\bar{j}}\right)$, of the hash values occurs at position $\bar{j}$. Thus, a verification step must be performed to make sure whether an exact match occurs or not. This step is performed by matching the characters one by one.

By analyzing the time complexity of the algorithm, it is obvious that the preprocessing time complexity is $O(mq)$, where *m* is the length of pattern and *q* is the size of q-gram and the searching phase takes time complexity of $O(n/m)$ for the average and optimal cases while the worst case is $O(nm)$ and that is the same in general for HASHq, SSM, bit-parallel algorithms.

We measured the average shift length of the two algorithms HASHq and HSSMq on DNA and binary random texts of size 200 MB and 100 runs. The results in Figures 7-8 show that HSSMq has longer shift on both texts.

4. EXPERIMENTAL RESULTS

We conducted the experiments on a PC Intel® Core™ i7 x64-based CPU running at 3.40 GHz and 8 GB RAM and 64-bit Windows 8.1 Pro. All the algorithms are implemented in C# programming language. The implementations of the other algorithms which are used in this study are obtained from the web site by Faro and Lecroq[1]. For all bit-parallel algorithms in this study, we used a bit vector of 64 bits.

We generated a random dataset of size 200 MB where the symbols of each alphabet are statically independent of each other and equiprobable. The symbols of the binary dataset are 0 and 1 and the DNA dataset contains the symbols A, C, G, and T. For each dataset, the program selects 200 patterns randomly from the given data and computes the average running time in thousands of a second. We divided the length of patterns into three groups short (10-80), long (100-800), and very long patterns (1,000-5,000).

The best running times are underlined and boldfaced in all tables. In the experiments, we chose to compare with the related and recent algorithms SSM, SBNDMq, FSBNDM, FSB(q,f), GSB2, and HASHq.

Table 1 shows the running times on the binary dataset for short patterns. The results show that HSSM4 reported the best running time on length 10 and HSSM6 has the best times on lengths 20-80 followed by HASH4 on length 10 and HASH6 on lengths 20-80. Among all the bit-parallel algorithms, FSB(6,2) is the best on length 10, SBNDM4 is better on length 20, FSB(8,3) on length 30, FSB(8,2) reported better running times on lengths 40-60 followed by FSB(8,1) on lengths 70-80. We scaled the running times in Figure 9 to show the difference between these algorithms.

We can say that HSSMq algorithm is a hybrid of SSM and HASHq algorithms. HSSM2 is a hybrid of SSM and HASH2 and so on. Regarding Table 1, it turns out that the running time of SSM is declined as follows. The running time is reduced by 14-42% compared to HSSM2, HSSM3 decreased the running time by 39-65%, with HSSM4 the running time is reduced by 48-78%, and 41-89% with HSSM6.

In Table 1, we also see that HSSM2 reduced the running time of HASH2 by 6-55%, the running time of HSSM3 versus HASH3 is decreased by 2-45%, running time of HSSM4 versus HASH4 is decreased 5-29%, and the running time of HSSM6 versus HASH6 is decreased by 18-21%. Likewise, the running time of HSSM6 versus FSB (8,2) is decreased by 18-33%.

On long patterns and binary dataset, it turns out from Table 2 that HSSM6 is the best overall followed by HASH6 and FSB (8,1). The difference between them is shown in Figure 10.

Likewise, Table 3 presents the running times on very long patterns and binary dataset and the difference in the efficiency between HSSM6, HASH6, and FSB(8,1) is shown in Figure 11.

Considering the DNA text and short patterns, HSSM3 is the best on lengths 10-20, HSSM4 won on lengths 30-60, and HASH6 on lengths 70-80 (see Table 4). Among the remaining algorithms excluding HSSMq class, FSB(3,1) won the second place on length 10, SBNDM4 on lengths 20-70, and HASH4 on length 80. The best running times of these algorithms have been scaled using $\log_2()$function to see the difference in Figure 12.

On DNA and long patterns, it is obvious from Table 5 that HSSM6 is the winner algorithm followed by HASH6. Among those bit-parallel algorithms, SBNDM4 is the best. The difference is clearly shown in Figure 13. The efficiency of these three algorithms is also continued with very long patterns as it is shown in Table 6 and it is illustrated by Figure 14.

It seems that on DNA text as the length of pattern is increased, the difference in time between HSSM6 and SBNDM4 is also increased and the difference between HASH6 and HSSM6 tends to be closer. Also we can see that on lengths longer than 64, the efficiency of bit-parallel algorithms tends to be stable or somewhat fixed because that the efficiency is restricted to the computer word length, 64.

We test the algorithms, SBNDM4, HASH6, and HSSM6 on complete Homo sapiens genome (Assembly GRCh38.p3, Accession GCA_000001405.18)[2]. The elapsed time is computed for the preprocessing, searching, and reading phases and averaged over 500 randomly generated patterns. The results in Figure 15 show that HSSM6 is the most efficient algorithm. HASH6 exhibited unstable running time because the long runs of A's and T's in the genome where the algorithm shifts slower. HSSM6 overcomes this situation.

Overall, we can say that the experimental results prove that our new algorithm HSSMq performs the searching process faster than the previous algorithms.

The significance of this research comes from the importance of the two applications Intrusion Detection Systems and bioinformatics. In Intrusion Detection Systems, this algorithm can be adapted for inspecting the network streams for detecting predefined malwares while in bioinformatics it will be used for searching bioinformatics databases for a particular DNA segment. Since string matching is used frequently on these applications, the impact will be great on the performance of the two applications.

5. CONCLUSION AND FUTURE WORK

An efficient algorithm for binary and DNA texts is presented. The new algorithm combines the merits of HASHq and SSM algorithms. The new algorithm uses the q-gram hashing and guarantees the maximal shift in advance by determining the best q-gram pivot. The searching phase of the algorithm matches the hash value of the q-gram pivot with the hash value of the corresponding q-gram text window. If they are equal, a verification step is performed and the new shift is applied; otherwise, the HASHq shift is applied.

We conducted the experiments on two types of random data, binary and DNA. Then we measured the average shift length of HSSMq against HASHq and we found that there is a clear improvement on the length of shift on both random data, DNA and binary. In addition, we run the algorithms on different lengths and the results demonstrate that the new algorithm is faster than SSM, HASHq, SBNDMq and $FSB(q,f)$ for short, long and very long patterns. Regarding the binary data, HASH6 achieved better performance than the previous algorithms and the new algorithm HSSM6 outperformed HASH6 so that the amount of saved running time was about 18-21% for pattern lengths 10-80, 21-25% for lengths 100-800, and reduced by about 18-23% on lengths 1,000-5,000. On the DNA text, HSSM6 achieved a better performance than all the others. For long patterns (100-800), HSSM6 reduced the running time of HASH6 by about 7-21% and for very long patterns (1,000-5,000), the amount of saved time was 6-9%.

At the end, we run the two algorithms on the complete human genome. The results show that our algorithm is faster. HSSMq searches the whole genome for pattern of length 500 in 432 milliseconds, HASH6 spends 1170 milliseconds, and SBNDM4 takes 1258 milliseconds. So, we recommend to adapting the new algorithm for the Intrusion Detection Systems and bioinformatics.

ABSTRACT

Extracting valuable knowledge from Electronic Health Records (EHR) represents a challenging task due to the presence of both structured and unstructured data, including codified fields, images and test results. Narrative text in particular contains a variety of notes which are diverse in language and detail, as well as being full of ad hoc terminology, including acronyms and jargon, which is especially challenging in non-English EHR, where there is a dearth of annotated corpora or trained case sets. This paper proposes an approach for NER and concept attribute labeling for EHR that takes into consideration the contextual words around the entity of interest to determine its sense. The approach proposes a composition method of three different NER methods, together with the analysis of the context (neighboring words) using an ensemble classification model. This contributes to disambiguate NER, as well as labeling the concept as confirmed, negated, speculative, pending or antecedent. Results show an improvement of the recall and a limited impact on precision for the NER process.

INTRODUCTION

Electronic health records (EHR) constitute an important resource not just for tracing single patient histories but for population studies with clinical or administrative purposes. The nature of EHR, however, presents multiple challenges for doing so. In fact, physicians often complain that EHR systems are oriented towards information storage, but lack the ability to provide information extraction as well, mainly a consequence of the unstructured nature of the information (Menasalvas, Rodriguez-Gonzalez, Costumero, Ambit, & Gonzalo, 2016). Actually, the extraction task involves a combination of structured and unstructured data, including codified clinical classifications, images, test results and narrative text, among others. This paper will focus on the recognition of pre-established entities of interest in EHR extracted from clinical systems. This falls within the task of named entity recognition (NER), responsible for extracting entities and relationships between them, within a specific domain, typically relying on dictionaries, ontologies and thesaurus to do so (Menasalvas et al., 2016). As such, this paper proposes an approach to NER, which is aimed at improving precision and recall by combining different NER methods.

There is a large body of work on methods and tools to process biomedical text in general (Menasalvas et al., 2016). However, as pointed out in Leaman et.al (Leaman, Khare, & Lu 2015), biomedical texts are a highly codified result edited for clarity and intended at a large audience, while clinical narrative texts contained in EHR are written by healthcare professionals about a single patient and are aimed at colleagues or themselves. This implies a variety of notes, which are diverse in language and detail, as well as ad hoc terminology, including acronyms and jargon, far from being highly codified and standard. In practice, these results in EHR systems are country, hospital and even service dependent (Menasalvas et al., 2016). In addition, EHR are often filled under time pressure and with low motivation due to the fact that it takes time away from actual patient care or education. As a result, EHR narrative text usually suffers from low quality reflected in: variable semantics, structure without formal sentences, missing punctuation, missing expected words, misspelling or heterogeneous styles and jargon (Menasalvas et al., 2016). Moreover, independently of the motivation or resulting quality, the clinical language per se implies an additional series of challenges, including term variability, ambiguity and complexity, lack of fine-grained classifications, results followed by units or dosages, incomplete syntactic components in sentences, as well as data availability (Dong, Qian, Guan, Huang, Yu, & Yang, 2016). In NER terms, ambiguity is one of the biggest challenges, because concepts of interest are frequently hypothetical, negated or include temporal relationships (Menasalvas et al., 2016). As such, many existing natural language processing (NLP) approaches become ineffective or insufficient for clinical narrative text.

Moreover, despite numerous NER proposals for EHR, the vast majority are limited to medical text written in English (Menasalvas et al., 2016). Given that NER relies on dictionaries, several are already available, including Unified Medical Language System (UMLS), Systematized Nomenclature of Medicine - Clinical Terms (SNOMED-CT) or International Classification of Diseases (ICD); these are also in English with either no translations or limited versions in other languages. In the context of this paper, EHRs belong to a Spanish speaking hospital and it has already been recognized that for event extraction from EHRs in Spanish, the lack of annotated corpora is perhaps the main difficulty (Casillas, Pérez, Oronoz, Gojenola, & Santiso, 2016). Despite there being ways to avoid a language-specific annotated corpus through supervised machine learning, training the models is costly and using it in complex language sets runs into major performance issues (Dong et al., 2016). In addition, the choice of inference algorithms and managing heterogeneous medical fields further complicates medical NER (Casillas et al., 2016; Dong et al., 2016).

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

This paper proposes an approach for dictionary-based, combined NER aimed at improving entity recall dealing with the aforementioned challenges associated to clinical narratives extracted from EHR systems. To do so, it presents a proposal that combines three different NER techniques and takes into consideration the contextual words around the entity of interest to determine whether the concept is confirmed, negated, speculative, pending or an antecedent. To our best knowledge, our approach is the first including this level of detail in the expression of sense for the healthcare domain in Spanish. The rest of this paper continues with related works. We then go on to present the proposed strategy and present the evaluation results of applying the strategy to a standard data set. Finally, we present some conclusions and suggests avenues for future work.

BACKGROUND

Natural language processing of medical text has a wide variety of tools and methods. For our research work, we made an analysis of some relevant work in NER in the medical and biomedical fields in Table 1, where we proceed to highlight the following characteristics:

- **NER Technique:** This characteristic summarizes the strategy used for identifying the entity;
- **Entities:** Indicates the type of concepts the strategy is able to recognize;
- **Features:** Illustrates whether the approach includes only the entity recognition or other attributes around the entity (e.g. negation);
- **Limitations:** This characteristic highlights the main limitations of the approach.

Based on the previous comparison, we can find no general method for finding named medical entities, which can deal with the ambiguity and complexity of EHR discussed in the introduction. Some of the extant contributions are focused on specific entities (Jiang et al., 2011; Jimeno et al., 2008; Aramaki et al., 2009; Skeppstedt et al., 2014), some contributions (Chang et al., 2002; Zhang et al., 2013; Xu et al., 2012) lack the ability to find entities taking into account the text quality challenges described previously, others (Henriksson et al., 2015; Casillas et al., 2016) analyze the context only for a few entities in the clinical domain. Although there are recent approaches for recognizing the attributes around an entity, they are only available for languages different than Spanish and do not consider the quality problems of the texts that hinder the recognition of the entities. Our proposed approach aims to perform NER in medical texts contained in electronic health records, considering their context and their intrinsic quality or ambiguity. The following section explains in detail this approach.

CONTEXT AWARE NER FOR ELECTRONIC HEALTH RECORDS

In order to extract meaningful information from an analysis over EHR, we require not only the recognition of named entities, but also the identification of the sense they have within the text, since the entity could be negated in a specific context, for example. Moreover, disambiguating and determining the precise use of the entity in context is especially challenging for non-English medical text, where dictionaries and annotated training corpora are scarce or incomplete. In consequence, we propose a context-aware combined NER approach for EHR in Spanish (Quimbaya, Múnera, Rivera et al., 2016). This approach

first identifies the occurrence of important clinical entities such as procedures, medications, diagnosis, adverse events, among others, using a combined dictionary approach, and then analyses the context of the identified entity for detecting its sense using a machine learning approach. Our proposal allows the identification of six different senses associated to entities within EHR text, accordingly: confirmed, negated, speculative, pending, patient antecedent and family antecedent. To the best of our knowledge, our approach is the first to include this level of detail in the expression of sense for the healthcare domain in Spanish.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1 illustrates the phases included in our approach. The first phase recognizes the entities from the text using a dictionary strategy that combines three types of NER techniques and generates a preliminary tag over the relevant entities. The second phase, extracts the context of each one of the entities and generates a set of n-grams that are used as the input for the final phase that applies an ensemble classification model that enriches the preliminary tag including the sense of the entity within the EHR. The following sections explain each phase in detail.

Phase 1: Context Aware NER for Electronic Health Records

Figure 2a and 2b present the strategy proposed to improve the recall of NER in EHR implemented in the first phase of our approach. To deal with possible quality issues in the texts it follows two steps: the first one executes preprocessing tasks (Figure 2a), and the second one performs the NER including three different types of recognition (Figure 2b): exact NER, fuzzy NER and stemmed NER.

The preprocessing phase extracts the lemmas from the domain knowledge base. This task generates a new knowledge base with the lemmas of the concepts that have to be recognized. In addition, it performs preprocessing tasks including tokenization and lemmatization over the EHR.

The objective of the NER phase is to recognize the relevant entities (e.g. diagnosis, treatment, procedures, medical labs), even if they have misspellings or are written with differences with respect to the concepts included in the domain knowledge base. As mentioned, it then uses three different NER techniques. Finally, it includes a merging process that combines the overlapped recognized entities.

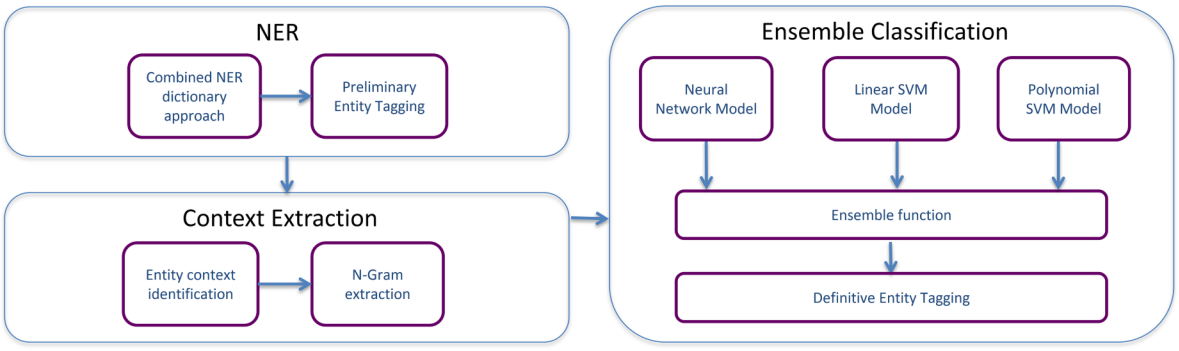
One to One Recognition

The most basic approach to NER when using a dictionary or gazetteer is simply finding exact matches between dictionary and EHR entities. That means having a one to one match between a dictionary term and a portion of the text.

For instance let G be a diagnosis dictionary, and $DocX$ a document in the corpus:

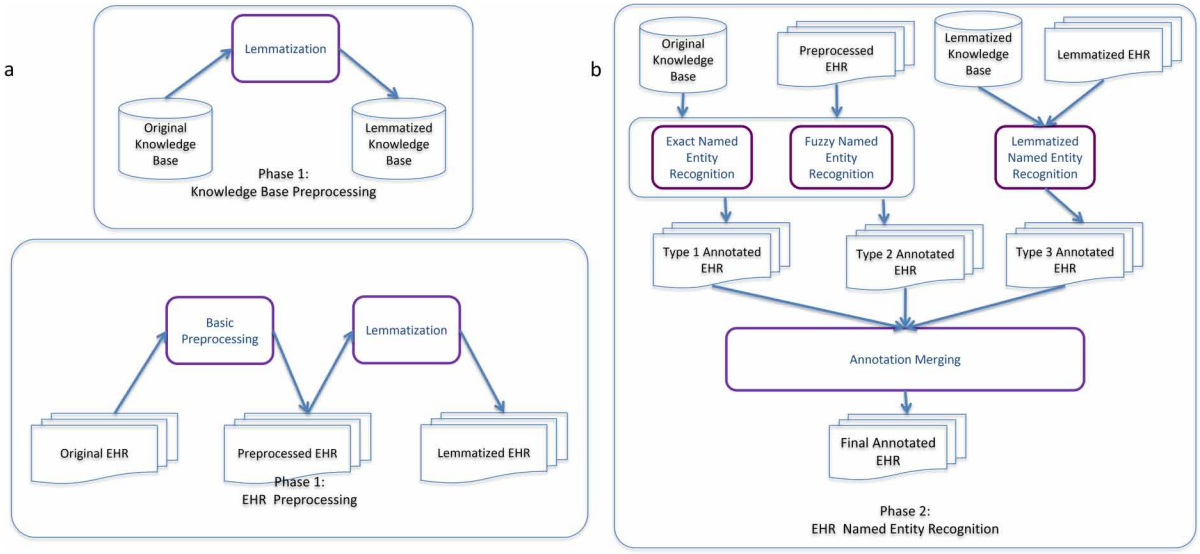
$$G = \{'diabetes','hypertension','COPD','influenza'\} \tag{1}$$

Figure 1. Context aware NER for electronic health records



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. Phase 1 combined dictionary-based NER: (a) Preprocessing phase; (b) NER recognition phase



DocX = 'John Doe is a 67 year-old diabetic white male with a history of COPD, and hypertension. Mr. Doe was hospitalized 20 days ago at High Plains Hospital for pneumonia resulting from influezna ...'

Running NER with the dictionary would result in an annotated document DocXAnnot:

DocXAnnot = 'John Doe is a 67 year-old diabetic white male with a history of [**COPD**], and [**hypertension**]. Mr. Doe was hospitalized 20 days ago at High Plains Hospital for pneumonia resulting from influenza …'

This annotated document contains references for the terms 'COPD' and 'hypertension' and such annotations can be used to flag this document as relevant for such medical terms.

Fuzzy Recognition

EHRs are prone to containing typing and spelling errors. That degrades the recall of exact dictionary-based NER, due to the likelihood of a mismatch between the dictionary and the actual words in the documents. For instance, a dictionary term 'pneumonia' will not match a mistyped 'npeumonia'.

We propose using a Fuzzy Gazetteer approach (Paleo, B. W. 2007) in order to find more instances of the desired named entities, when there may be slight differences between the dictionary term and the EHR term.

In order to compare EHR terms and dictionary terms we make use of the concept of edit distance (Levenshtein, 1966) which is a metric representing the number of character changes among words. We define the threshold for accepting annotations as a proportion to the length of the dictionary term. For instance, we admit more changes in a long term like 'hypertension' than in a short one like 'COPD'. The

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

threshold parameter T ∈ [0, 1] reflects such proportion and corresponds to the maximum proportional edit distance with respect to the term´s length, as expressed in the following equation:

$$T = \frac{maximum\ edit\ distance\ accepted\ for\ a\ term}{length\ of\ \ the\ term}$$

Using the document DocX and the dictionary G with the Fuzzy Gazetteer approach, configured with a value of T = 0.25 would result in the following annotated document:

DocXAnnFuzz = 'John Doe is a 67 year-old diabetic white male with a history of [**COPD:COPD(0)**], and [**hypertension:hypertension(0)**]. Mr. Doe was hospitalized 20 days ago at High Plains Hospital for pneumonia resulting from [**influezna:influenza(2)**] ...'

Each annotation in the document has the form [text: dictionaryTerm(editDistance)] where 'text' represents the matched string in the document, 'dictionaryTerm' the term in the gazetteer and 'editDistance' the distance among them. In this example, T = 0.25, therefore the edit distance between influenza and influenza (2) divided by the term's length (9) satisfies the defined threshold:

$$\frac{2}{9} = 0.2\hat{2} < T$$

Stemmed Recognition

Recognizing entities based on the stem of a dictionary term involves having the dictionary lemmas or stems, then finding the stem of each word in the documents and then comparing the stemmed versions to exclude differences due to, for instance, plurals or conjugation. In the example, we first compute *G':* the stemmed version of the dictionary *G* and then, document *DocX* is processed with the same stemmer and as a result we have a parallel document *DocX'*:

$$G' = \{'diabet','hypertens','copd','influenza'\} \quad (2)$$

DocX'= 'john doe is a 67 year-old diabet white male with a histori of copd and hypertens mr doe was hospit 20 day ago at high plain hospit for pneumonia result from influezna ...'

Note that in *DocX'* words like 'diabetic' and 'hypertension' are respectively replaced with 'diabet' and 'hypertens'.

Once the documents and the dictionary are stemmed, they are matched and annotated. Here the annotation of 'diabet' corresponding to the stem 'diabet' shared by the words 'diabetes' and 'diabetic':

DocXAnnStem = 'john doe is a yearold [**diabet**] white male with a histori of [**copd**] and [**hypertens**] mr doe was hospit day ago at high plain hospit for pneumonia result from influezna...'

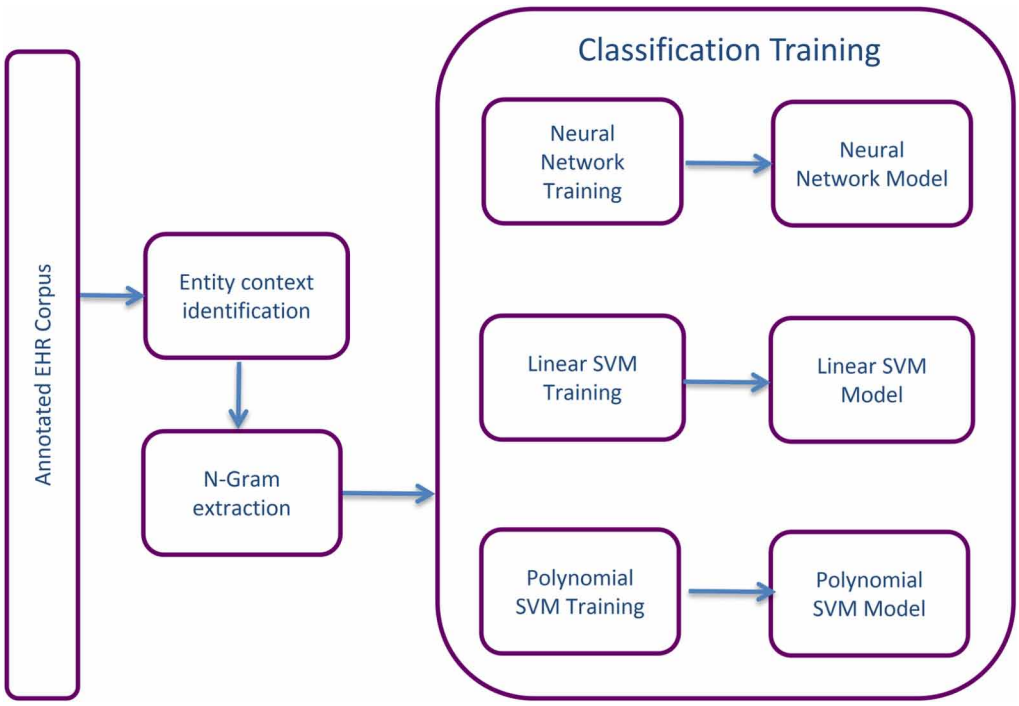
Phase 2 and 3: Context Analysis and Entity Classification

As Figure 1 illustrates, the second phase of our proposal reads the tags included in the first phase and extracts their context, which is composed of the neighboring words that may affect the sense of the entity. Tests over a large corpus of EHR allowed us to detect that a nine-word context, seven before the entity and three after it, produced the best results in terms of precision. Nevertheless, for comparison purposes we also applied our approach using a context of four words (evaluation illustrates the results). Using the context, this phase generates a set of nine 3-gram. Subsequently, the third phase of our approach takes each one of the 3-gram to feed the ensemble model that includes three classifiers: a neural network, a linear support vector machine and a polynomial support vector machine. The combination function of the model uses a weighted voting method based on the level of confidence of the result generated by each model. Given the set of results for each model this function aggregates the confidence for each resulting class and chooses the class with the biggest aggregated confidence. For instance, the neural network classifier determines a "Negated" class with 1.0 confidence, but both the linear and polynomial SVMs agree on a "Confirmed" class with 0.9 and 0.95 confidence levels, then the final class would be "Confirmed" because the aggregated confidence for this class would be 1.85 compared to a 1.0 aggregated confidence for "Negated". That would not only work for three models as presented in our approach but could admit any number of them, so long as they include a confidence value.

The classification models used in this phase were previously trained using manually expert annotated portions of texts extracted from EHR of a general hospital. As can be seen in Figure 3, the training process identifies the contexts and generates the n-grams from the annotated texts in the same way as it is made in the general process. The annotations include six classes:

Figure 3. Sense classification training



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

1. **Confirmed:** This includes notes in an EHR implying a positive, affirmed presence of a specific medical condition, as well as diagnostic or treatment procedures. As an example, in the EHR it could appear a paragraph like: "Female patient hospitalized for *acute decompensated heart failure* that today refers… ". The sentence implies the confirmed presence of the disease in bold;
2. **Negated:** An entity whose presence is negated in a given context, such as "Patient with neither *erythema* nor other local infection signs suggestive of phlebitis" denies that diagnosis;
3. **Speculative:** Sometimes in EHRs the health professionals will record differential diagnosis or different therapeutic options that cannot yet be confirmed or negated and as such are registered in a speculative fashion. For example, "Patient 40 years old with first episode of dyspnea and wheezing that could be associated with *chronic obstructive pulmonary disease (COPD) exacerbation or asthmatic crisis*" is speculative for both diagnoses;
4. **Pending:** On occasion, an EHR will contain an entity related to a procedure that is planned or pending for a patient, without if being confirmed or negated, as results are still not available. For instance, "Patient with confirmed diagnosis of acute appendicitis who will be scheduled for *appendectomy* according with surgery room availability" refers to the procedure as a future event;
5. **Patient Antecedent:** Occasionally personal antecedents are not registered in structured fields on an EHR. It is risky or misleading to assume the presence of such an entity for a given query, without taking into consideration that it refers to a past condition or event which may no longer be valid. It can be seen in notes like "Patient with two previous hospitalizations in 2009 for *urinary tract infections* who …" which recalls the past and not the present condition of the patient;
6. **Familiar Antecedent:** This case is similar to the last one, with the added risk or ambiguity stemming from the fact that it does not relate to the patient directly, but to his or her family, such as, "Mother with *early myocardial infarction*".

The complete algorithm for the 3 phases is expressed as follows:

```
FUNCTION ner(document,gazetteer)
        mentions={ }
        mentions=mentions UNION findAllExactMatches(document,gazetteer)
        mentions=mentions UNION findAllFuzzyMatches(document,gazetteer)
        mentions=mentions UNION findAllStemmMatches(document,gazetteer)
        FOR EACH mention IN mentions
                senseLinearSVM=classifyLinearSVM(context(mention))
                sensePolynomialSVM=classifyPolynomialSVM(context(mention))
                sensePaum=classifyPaum(context(mention))
                sense=weightedVoting(senseLinearSVM,sensePolynomialSVM,sensePa
um)
                addAnnotation(document,mention,sense)
END
```

EVALUATION

The evaluation of our approach comprises the analysis of precision and recall measures over the NER phase as well as the precision and recall of the concept attribute labeling process. For the first part, we used a previously annotated NLP data set as the gold standard; for the second process, we developed an online software tool that facilitates the annotation process over a set of EHR. This tool allows medical doctors to classify an entity, according to the sense it has in context from the above six types or unclassified if the context is not enough to determine the sense. The results of these annotations were used as the gold standard. In both cases, the texts come from real Spanish EHR systems and they may contain typing errors, such as the ones described in the introduction. In the following sections, we present the results of our evaluation: *NER evaluation* explains the methodology and results of the combined dictionary based approach, *Data set and configuration for classification evaluation* and *Results in the classification task* illustrate details on the data set used for evaluation purposes and results of the concept attribute labeling, respectively.

NER Evaluation

The recognition of named entities was tested using the e i2b2 NLP Data Set #7b: Heart Disease Risk Factors Challenge Data Set (Stubbs, Kotfila, Xu, & Uzuner, 2015a; Stubbs, & Uzuner, 2015b). The annotations found by our approach were compared to direct mentions in the data set. The dictionary of terms was extracted from the UMLS metathesaurus (Lindberg, Humphreys, & McCray, 1993), specifically including names of diseases and medications as well as their synonyms, extracted from the MEDLINE data source. Different configurations were tested to compare the impact a direct match, fuzzy, and stemmed methods, showing an increase in recall when the fuzzy and stemmed NER annotations were introduced, while as expected the precision decreased. The test resulted in a gain of 9% in the amount of annotations, producing new information that the direct match did not include, as can be seen in Table 2. The impact of the fuzziness threshold T was also measured with a similar result in Table 3: the bigger the threshold, the bigger the amount of annotations, but after 0.15 precision becomes strongly degraded.

Data Set and Configuration for Classification Evaluation

The dataset used for training and testing the context analysis and concept attribute labeling consisted of 1477 sentences manually taken from real EHRs and manually annotated into seven classes. The six classes mentioned in 3.2: confirmed, negated, speculative, pending, patient antecedent, familiar antecedent, and an additional class N/A used for unclear fragments, which either did not have enough context or did not fit into the aforementioned classes.

0,25	**9356**	6379	15735	7210	0,595	**0,565**	0,579	0,570
0,30	**9356**	8088	**17444**	**7210**	0,536	**0,565**	0,550	0,559

The dataset was then split into two groups, one for training the models consisting of 739 annotations and one for testing them with the remaining 738.

We also wanted to compare the nine words context with a smaller one consisting of two words before and two words after the entity. Since we are using 3-grams, the smaller context always contains the entity as part of the 3-grams group and we wanted to measure the impact of including it as input for the classification models.

The model was implemented as a GATE application both for training and testing. GATE is a well-known computer architecture for natural language processing tasks that allows to include machine learning algorithms. The testing application also had the responsibility of assembling the results of the different models into one final entity classification.

Results in the Classification Task

The results for both the long context and the short context approaches are summarized in Tables 4 and 5 as confusion matrices. Each matrix represents the amount of manual annotation for each class as the gold standard (rows) vs. the amount of annotations classified into such classes (columns). For instance, in Table 2, 190 "Negated" sentences were correctly classified as "Negated" but 1 originally "Negated" sentence was incorrectly classified as "Patient. Ant." (Second row, fifth column). The diagonal of the

Table 4. Confusion Matrix for long context classification (7 words before, 2 words after)

Table 5. Confusion Matrix for short context classification (2 words before, 2 words after)

Gold \ Results	Confirmed	Negated	Speculative	Pending	Patient Ant.	Familiar Ant.	na	Recall
Confirmed	387	14	0	1	4	0	2	0,949
Negated	30	171	0	0	0	0	0	0,851
Speculative	14	0	0	0	1	0	0	0,000
Pending	12	0	0	1	0	0	0	0,077
Patient Ant.	42	3	0	0	3	0	1	0,061
Familiar Ant.	11	0	0	0	0	1	0	0,083
na	36	1	0	0	1	0	0	0,000
Precision	0,727	0,905	0,000	0,500	0,333	1,000	0,000	

Total Accuracy: 0.765

matrix corresponds to the true positives for each class, the last row to the precision and the last column to its recall measure.

Regarding the results illustrated in the confusion matrix, our model has a better performance using a nine-word context. This fact rejects the hypothesis that having the entity within the n-gram would improve the performance of the classification. Additionally, as it can be seen, improved results are related to the most frequent classes: Confirmed and Negated. In contrast, we do not have conclusive results with the other classes.

It is possible that the marginal improvement seen in our results is a consequence of having, on the one hand, an unbalanced training set, which includes far more cases of the most common types of senses in which the entities are included in the EHR (confirmed or negated). On the other hand, our assumption regarding the impact of quality (misspelling in particular) did not prove as problematic in the i2b2 test set; however, we do expect other EHR contexts (where entry and coding practices differ) to have more significant quality issues. We did manage to oversample the test to deal with the unbalanced corpus, but the improvement was insignificant. Additional techniques to deal with our unbalanced set can be tested (e.g. Bingel & Haider, 2014). Furthermore, despite the minimal added value of including fuzzy and stemmed NER, our general approach allows for additional NER techniques to be included in a similar fashion.

CONCLUSION

This paper presents an approach that combines named entity recognition and concept attribute labeling over EHR narrative texts. The objective is to recognize important entities in health records such as procedures, medical labs, diagnosis, as well as the context where these entities are written, in order to determine whether they are confirmed, negated, speculative, pending or an antecedent.

Named entity recognition in the healthcare domain is difficult because of the particular and unique characteristics of texts in health records (codified, condensed, jerky language). Due to this, we combine a direct match technique with fuzzy and stemmed matching during the recognition phase. This phase was tested using the i2b2 NLP Data Set which includes a gold standard with annotations. Experimental results on this data set shows an improvement of the recall while having a limited impact on precision.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Nevertheless, when analyzing the text, the proposed methods do not take into account the surrounding words (the context) appearing near a named entity candidate.

The second phase involves the analysis of the context of the recognized entity using a concept attribute labeling method that includes six different classes: Confirmed, negated, speculative, pending, patient antecedent, familiar antecedent. This phase comprises an ensemble classification method including SVM and neural networks models. Experimental results over this phase are promising, especially when the entity is confirmed or negated. The results over the other classes are not conclusive yet, mainly because the training and test set do not include a sufficient set of cases.

A limitation of this study is the use of an unbalanced training set, resulting in equally unbalanced assignation by the NER algorithms. That suggests future work using techniques oriented to deal with unbalanced training sets in machine learning. In addition, we are going to improve the concept attribute labeling using the punctuation and part of speech tags as input for the classification model. Our research also suggests that it is important to include in a future version of our solution an engine for regular expression annotations in order to increase the precision and recall of the non-prevalent classes. We made preliminary tests using regular expressions patterns for the speculative class and obtained promissory results; now we have to extend it for the other infrequent classes. Finally, the ensemble classification is going to be enriched with other methods, including k-nearest neighbors, decision trees and deep learning.

Chapter 18
Knowledge Management Process-Oriented Strategy for Healthcare Organizations

Nurhidayah Bahar
UCSI University, Malaysia

Shamshul Bahri
University of Malaya, Malaysia

ABSTRACT

This article explores Knowledge Management (KM) practices among doctors and nurses in Malaysia. A total of 59 interviews were conducted with doctors and nurses from two hospitals. The data analysis employed in vivo coding and process coding techniques. The findings suggest a process-oriented strategy for managing knowledge among doctors and nurses in a clinical work environment. The development of this strategy can help the healthcare workers and management to evaluate and further improve their current KM practices. Additionally, this article adds another KM strategy to the literature that is tailored to supporting healthcare organization. Future studies may want to replicate the proposed strategy in different settings such as other clinical or non-clinical departments within the hospital, other public or teaching hospitals or private hospitals.

INTRODUCTION

Knowledge plays an important role in today's organizations. It facilitates decision-making capabilities and builds a learning organization (Garvin, 2003). The collection, creation, and application of knowledge have become critical factors in achieving organizational competitiveness and increasing organizational performance (Asrar-ul-Haq & Anwar, 2016; Supyuenyong, & Swierczek, 2013). Consequently, Knowledge Management (KM) is crucial for organizations that wish to promote best practices, increase their chances of success, and create new business knowledge (Adams & Lamont, 2003; Chapman & Magnus-

son, 2006). KM refers to the practice of selectively applying knowledge from previous experiences of decision making to current and future decision-making activities with the express purpose of improving organizational effectiveness (Jennex, 2005).

Healthcare has embraced KM. Healthcare aims to enhance the overall quality of lives, meeting the health needs of target populations. This aim is achieved through clinical activities such as assessment, diagnosis, treatment, monitoring, and prognosis. These activities involve knowledge seeking and exchange among clinicians which assist in clinical decision-making. Nevertheless, KM does not yet exist as a full-fledged solution in many healthcare organizations. Few studies have explored knowledge management in the context of healthcare, especially in terms of the contributions of healthcare practitioners in developing systematic KM process in this sector (Abidi, 2001; Agarwal et al., 2011; Beveren, 2003).

This study was motivated by certain weaknesses in previous studies on KM in the healthcare setting. They often focus on a single step of the process such as knowledge acquisition, retention, or dissemination. Few studies have considered the entire KM process from start to finish (Wills et al., 2010). Therefore, these studies were unable to identify how each step affects the next step of the KM process and how it is affected by the previous one. Additionally, many previous studies separated analysis of the processes, people, and technologies employed in the management of knowledge in a healthcare setting (Bhatt, 2000). As a result, these studies missed many nuances that can affect the successful implementation of KM strategy in healthcare. Thus, there is a need to study processes, people, and technologies in tandem.

This study investigates how and when KM occurs in healthcare organizations and the activities required for handling knowledge among doctors and nurses. The study aims to determine the activities needed for managing knowledge and the steps of the KM process, as well as develop a KM process model for healthcare organizations as part of a strategy for implementing systematic KM in this sector.

This study will benefit both healthcare researchers and practitioners. For healthcare researchers, this study contributes to understanding of how knowledge is managed in the healthcare setting. For healthcare practitioners, the findings from this study will lead them to the most appropriate strategies for managing knowledge in the healthcare setting. Hopefully, this knowledge will enhance the success rate of KM implementation in healthcare.

The rest of this paper is structured as follows. The following section presents a review of the relevant literatures followed by methodology, findings, and discussion. The final section discusses study contributions and future research agenda.

LITERATURE REVIEW

KM Strategy as Part of KM Success Model

A KM strategy is an important construct in many KM Success models. KM Success model is useful in predicting success of the design and implementation of a KM initiative (Jennex, 2017). A KM strategy specifically focuses on identifying knowledge users, knowledge for capture and reuse, and process planning, formatting, and context of the knowledge to be stored (Jennex, 2012).

In 1998, Jennex et al. (1998) proposed a KM success model after an ethnographic case study of KM in an engineering organization. They did this by adopting the DeLone and McLean IS Success model (1992). They customized the dimensions to reflect the System Quality and Use constructs relevant in an Organizational Memory System (OMS). The model was then modified by Jennex and Olfman (2002)

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

after conducted a longitudinal study in an engineering organization. Their model was also based on the DeLone and McLean (2003) revised IS Success model, and expands on the OMS Success model by including the Information Quality construct.

Another KM Success model was developed by Holsapple and Joshi (2001). This model reflects KM success is based on understanding a process-oriented KM strategy. Subsequent to this study, Massey, Montoya-Weiss and O'Driscoll (2002) develop a process-based KM Success model from their Nortel case study. Their finding suggests that KM cannot be applied generically and that a process approach to KM will assist organization on KM application to improve its performance.

Subsequent to this model, Jennex and Olfman (2006) proposed a model incorporating their experience to design a Knowledge Management System (KMS). Additionally, they incorporated other KM/KMS success factor research from the literature. The model consists of three dimensions: System Quality, Knowledge Quality, and Service Quality. Each dimension consists of three constructs. The KM strategy/process is one of the constructs of Knowledge Quality.

In 2017, Jennex reexamined the Jennex Olfman KM Success Model by incorporating the revised knowledge pyramid. Quantitative research into the artefacts of KM success and targeted papers have used the model. This model consists of System Quality, which reflects how well the KMS assists user in capturing, finding, retrieving, manipulating, and using the knowledge; Knowledge Quality, which reflects the usefulness and accuracy of the content as well as its ability to aid users' duties; and Service Quality, which reflects an organization's ability in ensuring that the KMS provides the expected benefits from knowledge use. KM strategy is one of the constructs in Service Quality that addresses identifying KM goals, alignment, metrics, and knowledge sharing/use incentives.

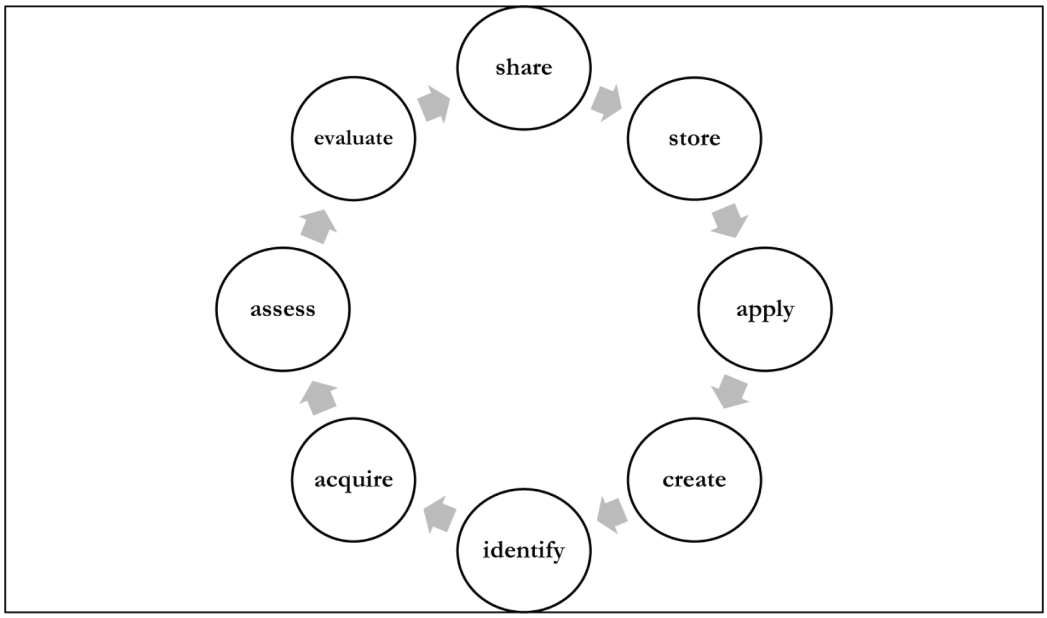
It is evident that KM strategy is vital to successful KM. Many scholars have incorporated KM strategy into their KM/KMS Success models (Massey et al. 2002; Maier, 2002; Jennex & Olfman, 2006). Realizing the importance of KM strategy, Jennex (2012) identified important KM strategy components by examining at successful KM projects/initiatives. He considers the components of a KM strategy as follows: (1) creation/modification of knowledge associated to key performance indicators; (2) increase the awareness/mapping of knowledge sources and users; (3) creation of new/additional knowledge capture processes; (4) changes to the way an organization assesses knowledge use; (5) increase resources for KM systems and its repositories; (6) changes to an organization' s KM goals; and (7) changes in the organization's incentives for knowledge use and sharing. The study found that successful KM project and initiatives are more inclined to the items in the list. Additionally, the findings show that the KM strategy items proposed in the literature are supported by real-world KM project and initiatives.

KM Process Model

In order to identify the activities required for handling knowledge in healthcare organizations, the researchers examined the existing process models. Forty KM process models from the literature were identified and examined (see Table 3 in Appendix 1). Within these models, 179 distinctive terms represent KM activities/process/stages were identified. Some terms more frequently used in various literatures include 'Share/Sharing' within 15 models, 'Create/Creation' in 13 models, 'Apply/Application' in 10 models and 'Storing/Store' in 7 models. These various terms have been classified and grouped into eight broad categories of KM activities (see Table 4 in Appendix 2). The categories are as follows: (1) share; (2) store; (3) apply; (4) create; (5) identify; (6) acquire; (7) assess, and (8) evaluate. Accordingly, the generic activities in most KM models is shown in Figure 1.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. Generic knowledge management model



The notion of cyclical sequence of knowledge processing steps demonstrates that knowledge management is not a simple sequential process (McAdam & McCreedy, 1999; Bukowitz & Williams, 2000).

Knowledge Management in Healthcare Setting

Many KM studies conducted in healthcare organizations focus on decision-support services, examining the role of ICT in facilitating KM practice, assessing healthcare workers' role and their practice in managing knowledge, and developing conceptual models (Abidi, 2001; Bhargava, 2013; Sullivan et al., 2015). For example, Abidi (2001) introduced Strategic Healthcare Decision-Support Services (SHDS) to improve the delivery of quality healthcare services. SHDS acts as a suite of knowledge or data-driven, strategic and decision-support services derived from both healthcare data and health enterprise knowledge bases. In addition to KMS, scholars have also investigated the roles of other Information Communication Technologies (ICT) such as technical infrastructure, decision support architecture, tools for knowledge sharing (Whiddett et al., 2012) and enhancing knowledge transfer (Sheng et al., 2013).

Scholars are also concerned in assessing healthcare workers' roles and behaviors. For instance, Dehaghi et al. (2015) conducted a study to investigate the relationship between the quality of work life of nurse managers and their participation in KM implementation. They found that the participation in implementing KM among nurse managers may increase if there is an improvement of nurse managers' work life quality, such as in decision-making. Finally, studies relating to KM in healthcare have considered model development. Beveren (2003) explored KM within an Australian regional healthcare organization and found a number of obstacles inherent in its organizational structure. He concluded that new models, tools, and techniques for KM specific to the health sector are necessary. Subsequent to this finding, Lau (2004) described the conceptual organizing scheme for managing knowledge within the healthcare. This

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

focuses on the concepts of production, use, and refinement of three types of knowledge sources, namely policy, evidence, and experience. According to Lau (2004), these concepts can be operationalized through a set of KM methods and tools tailored to the healthcare setting.

RESEARCH METHOD

The study was divided into two stages. First was the development of the generic process model based on examination of existing KM process models from the literature. Jennex (2005) proposed a model that is based on other widely supported models and is more generalizable. The generic process model was used in developing the interview questions. To generate the model, the researchers searched knowledge management related journals using three key phrases: knowledge management model, knowledge management process and knowledge framework. Forty KM process models from the literature were examined and a generic process model was developed. The generic model consists of eight activities: (1) share; (2) store; (3) apply; (4) create; (5) identify; (6) acquire; (7) assess; and (8) evaluate.

Second, the study included interpretive case studies in order to gain in-depth understanding and insight into the KM practice in clinical care environment. This study was conducted in two hospitals: a public hospital (Case I) and a teaching hospital (Case II). The healthcare organizations used for this case study are among the largest. They are located in central Malaysia that serve a large population ranging from around 680,000 to 780,000 people. These organizations are responsible for improving the health of the public. Primary healthcare is provided in the community and includes general practitioners, psychiatrists, dentists, pharmacists and wide range of health professionals. Input for the case studies was received from doctors and nurses from the generic medical department in both hospitals.

The researchers were required to seek approval from the Ministry of Health's and hospital's Medical Ethics Committee before conducting the field study. Prior to ethical clearance, a co-supervisor from among the doctors of both hospitals was appointed and approval was sought from each hospital's Medical Ethics Committee through an online application. Upon completion of the field study, the researchers were required to report the findings to the co-supervisors and produce the final report.

The researchers followed a purposeful sampling approach, gathering informants to collect responses to the formulated research questions. Interviews were conducted with twenty-nine doctors and thirty nurses from the generic medical department in both hospitals. All informants first received information about the study and the interview via e-mail, after which interviews were scheduled either via e-mail or phone. Topics covered during the interviews included the backgrounds and roles of interviewees, their beliefs structures about the nature of valuable knowledge, knowledge search and/or acquisition patterns and modes of using knowledge.

The different types of roles selected in this study were treated as multiple sources for assessing similarities and differences in KM practices. Doctors and nurses are most actively engaged in direct patient care and provide leadership in the clinical work environment. They work closely together to make collective decisions for patient care. They collaborate by sharing personal and professional knowledge and joint responsibility to ensure the utilization of best knowledge to produce positive patient outcomes.

In addition to providing patient care, doctors and nurses play a leading role in generating medical evidence and engaging in clinical research. They collect, track, and analyze clinical and patient data to help build the scientific groundwork for clinical practice, avoidance, and enhanced patient health outcome, as well as evaluating and enhancing their own practice. Table 1 provides a breakdown of the informants.

Table 1. Informants

Case	Doctor	Nurse
Case I	17	18
Case II	12	12
Total	**29**	**30**
Grand Total	**59**	

The informants had from three to thirty years' work experience. The interviews were conducted at informants' premises and lasted about forty-five minutes to one and a half hours. To ensure the privacy of the research informants and to comply with regulations, the researchers followed the approval and notification procedures as prescribed by the hospital's Medical Ethics Committee. The informants were informed about the research and its purposes. An information sheet was provided regarding their rights to confidentiality and anonymity. Their consent was also obtained prior to participation. The interviews were conducted at informants' premises fir forty-five minutes to one and a half hours. They were electronically recorded with the consent of the parties involved for data reorganization and analysis purposes.

Data Analysis

Data analysis was carried out as the data collection progressed. Interweaving data collection and analysis from the very start helps to cycle back and forth between thinking about the existing data and generating strategies for collecting new data (Miles, Huberman & Saldana, 2013). The interviews were recorded, while notes were taken to identify the major points. The recordings were then transcribed verbatim.

First, cycle coding was used to initially summarize segments of data. The researchers employed in vivo coding and process coding techniques. In vivo coding uses words or short phrases from the participant's own language in the data record as codes, while process coding method uses gerunds ("-ing" words) to connote observable and conceptual action in the data (Miles, Huberman & Saldana, 2013). Table 2 shows samples from first cycle coding methods.

FINDINGS

Analysis indicates that doctors and nurses from the two hospitals have similar patterns in terms of clinical practices. These practices are examples of decision-making and knowledge utilization situations in healthcare organizations. Based on their practices, a KM process-oriented strategy for clinical work environment was developed. Figure 2 depicts the process model and the linkages among the activities. Building on the generic KM model, KM practice among the doctors and nurses consists of ten activities: (1) identifying; (2) discovering; (3) acquiring; (4) gathering; (5) analyzing; (6) capturing; (7) organizing; (8) disseminating/communicating; (9) applying/experimenting; and (10) evaluating:

• The changing nature of knowledge requires us to bring our know-how to date. It is therefore very important to search for the latest information especially the diagnosis and prognosis made by the doctors. This is very important that places a patient between life and death.	We know how to find what we don't know.	Discovering
• Normally, we refer to CPG in conducting clinical care. However, CPG and internal resources alone are insufficient. We do consult with expert from other hospitals to assist decision-making and diagnosis. • I access online resources such as UpToDate website to get the latest information.	We know where to find what we don't know.	Acquiring
• Nurse will perform the first-level assessment and provide us (doctors) the outcome. • I will verify the outcomes from the assessment before making decision. • Patient's story is important because they know their body better. • Lab tests and medical record can be accessed from our electronic medical record system. It aids the process of deciding what to do.	We make judgments based on numerous evidences.	Gathering
• Based on patient's data, I have to deliberate on what could happen and thus look for evidence to support my assumption. • I will have to carefully review patient's records and examine lab test results. • We analyze problems to figure out solutions.	We look for patterns and compare with precious cases.	Analyzing

- **Identifying Knowledge/Information:** In the first activity, doctors, and nurses indicate what knowledge/information is involved in order to perform their clinical care process such as assessment, diagnosis, treatment, monitoring, prognosis, and patient disposition. This study found four types of knowledge/information in the clinical work environment; (1) personal knowledge and competency; (2) patients' experience of illness and health condition; (3) clinical evidence and practice guideline; and (4) technological know-how. As both doctors and nurses require strong knowledge and competence to care for their patients, they must keep their knowledge and skills up-to-date by engaging in lifelong learning. According to one of the doctors:

It is important to keep our knowledge and skills up-to-date from time to time. By attending seminar, training, and medical course, we (doctors) will get the latest updates on guidelines and procedures to reflect the latest disease symptoms.

- **Discovering Knowledge/Information:** Once the required knowledge is identified, the next step is discovery. In this context, discovery means finding and locating the required knowledge/information. This study found common techniques practiced by the doctors and nurses in searching for personal knowledge, patient experience, clinical evidence and guideline as well as the know how to use IT/IS in their profession. Doctors and nurses discover or update knowledge through medical school, seminars, continuing medical/nurse education, research and development, clinical practice and online medical reference sites. One of the doctors quoted:

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

The changing nature of knowledge requires us to bring our know-how to date. It is very important to search for the latest information especially the diagnosis made by doctors will place a patient between life and death.

- **Acquiring Knowledge:** Discovery activities will lead to knowledge acquisition, in which doctors and nurses extract information from the identified sources to enhance their knowledge. They validate whether the extracted information is what they need. If there is missing information, the process will go back to identifying then discovering knowledge. Acquiring knowledge from the identified sources by doctors and nurses will lead to enhancing personal knowledge, skill, and competency; better understanding on patient's health condition; ability to manage different clinical problems and situations; and additional evidence to support judgments and decisions. As they gain more experience over time, they will be able to build a set of cases with identifiable patterns that will serve as valuable background knowledge when dealing with their day-to-day situations. These activities are exemplified by the following observations:

In straightforward or common situations, I often make such decisions informally; For example, during a flu epidemic, a healthy adult who has had fever, aches and harsh cough for 2 days is likely to be recognized as another case of influenza. (Doctor)

For a complex situation, we have to make good judgment.... beyond the scope of protocols and guidelines. So, we must be able to recognize when to apply protocols.... recognize changing circumstances and adapt them to the situation at hand. (Doctor)

- **Gathering Knowledge/Information:** The information use in clinical care process is gathered through direct observations, examinations, patient-related history their concerns, EMR or hard-copy reports, and clinical lab test results. Nurses take charge to collect patient information and medical history, perform initial assessments, and order clinical lab tests such as blood, urine and swab tests. This information will then be presented to doctors for further assessment and judgments. At this stage, doctors and nurses will also gather opinions from peers and seniors. Additionally, doctors will look for evidence from best practice guidelines such as Clinical Practice Guidelines (CPGs), Quick Reference (QR), and Training Manual (TM). These guidelines consist of detail instructions of the following situations: (1) determining the appropriate screening tests or diagnostics; (2) specifying medical or surgical services; (3) the duration of stay in hospital; or (4) other details of clinical practice. One of the nurses quoted:

I normally start with talking to the patient before assessment. Patient's story is important because they know their body better. On top of that, I accessed lab test results and medical record from our electronic medical record system. It aids the process of deciding what to do.

- **Analyzing the Gathered Knowledge:** Once knowledge and information are acquired, doctors and nurses systematically determine relevant points before analysis. This involves reviewing and examining data. Based on the analyzed data, doctors make judgments on what they think could be happening, looking for patterns and assessing if there is any additional information needed. At

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

this stage, doctors play an important role in the diagnosis of patient. They must have the ability to combine exact and interpreted information with their existing knowledge base in order to make accurate decisions.

- **Capturing Knowledge/Information:** After analysis, useful knowledge and information will be recorded. The outcomes from solving the clinical problems are beneficial for future use and reference. Therefore, doctors and nurses feel that it is important to remember and record how to resolve certain problems. They keep information in a useful form. Such knowledge/information is mainly recorded in individual memory. Details such as patient's information, medical report, physical examination result and final diagnosis are recorded in a hard copy form or electronic medical record. This activity is exemplified in the following quotes:

I know how to conduct some clinical protocols from practical session. For example, to examine patient's abdomen requires a few steps starting from observation and then sequentially performing auscultation, palpation, and percussion. I can do it better because I have seen how my seniors are doing it. (Nurse)

Well, most of the times I have no chance to systematically keep notes from my clinical experience… But, if there's anything new, I am sure it is recorded in my personal memory. It's natural process to me. (Doctor)

- **Organizing the Knowledge:** Once the important knowledge/information is captured, it must be organized accordingly. At this stage, the information that comes from various sources should be restructured. The study found that knowledge in healthcare organization exists in individual experts, databases, documented organizational procedures such as Clinical Practice Guidelines (CPGs) and standard operating procedures (SOPs). Analysis suggests that in the clinical work environment, knowledge is mainly possessed by individuals (i.e. clinicians) as they are the main actors to capture knowledge. This includes collecting and organizing the documents in a meaningful manner for easy access to and retrieval of knowledge content. Each doctor and nurse captures and organizes knowledge in their own way in an individually embedded manner. Knowledge is normally stored in personal notebooks and documents.
- **Disseminating/Communicating Knowledge:** Doctors and nurses spread their intellectual knowledge amongst themselves. There are various tools which doctors and nurses normally use to disseminate information. Informal methods include social media and instant messaging applications, while more formal methods include medical/nurse educational training and courses, meetings, and emails. These methods allow for the dissemination of detailed information and data to others as well as electronic news services from organization websites. Doctors and nurses also utilize social media to create awareness and educate the public by posting health related information or articles. In that way, they reach a much broader audience of people. Most doctors claimed that the organizations encourage them to publish educational articles in medical journals so that they can share their experiences and educate others. After clinical practice, they normally write a report for future reference, especially when they come across a novel issue or finding that they would like to write about. From there, doctors might start writing an educational article.
- **Applying/Experimenting Knowledge:** At the clinical level, knowledge use is seen as a process through which clinicians formulate a solution in order to solve their day-to-day problems in providing patient care. They apply their knowledge to make judgments and prioritize these judgments based on the current patients, situation and environment. This means eventually deciding what

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

to do and how to do it, as well as determining who should be informed or consulted. When they apply, and at the same time they experiment where they can evaluate whether the outcome of the decision determined is the desired outcome that has been achieved, as represented in the following descriptions:

Every patient has a different reaction to medicine or treatment. We need to find out the most suitable treatment for them. When the patient comes back to us with better health condition after our treatment, we know that the treatment given is suitable for such cases. (Doctor)

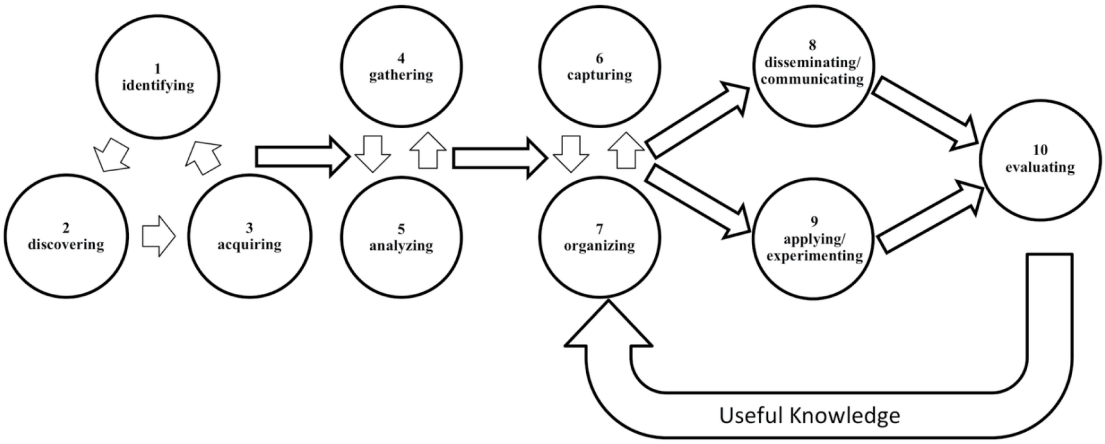
Evaluating an Outcome/Result

Doctors and nurses are active decision makers who determine who needs what and when. Once a decision is made, evaluation must take place to ensure decision effectiveness. Based on the interviews, doctors and nurses practice post-treatment evaluation to assess the significance or quality of outcomes derived from the previous activities i.e. clinical decisions. This activity is essential to clarify whether a decision has been effective and to help to refine their existing knowledge. As part of the evaluation process, doctors are responsible to administer a particular medical treatment to be given to the patients. The idea is to ensure that they're making the best choice and avoid negative consequences. It also helps to enhance practice delivery in future.

DISCUSSION

To recap, the generic KM model that was adopted in this study consists of eight elements: (1) share; (2) store; (3) apply; (4) create; (5) identify; (6) acquire; (7) assess; and (8) evaluate. As the researchers conducted this study in healthcare organizations, five additionally elements were identified: (1) discovering; (2) gathering; (3) analyzing; (4) capturing; and (5) organizing.

Figure 2. Knowledge management process-oriented strategy



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

The KM process-oriented strategy proposed knowledge management activities in healthcare begins with identifying, discovering, and acquiring knowledge. Many studies, however, collapse these activities into the category of identifying (Lai & Chu, 2002; Andersen & APQC, 1996; Tikhomirova et al., 2008). In the healthcare setting, these activities are distinct and requires particular action rather than a combination, as each involves particular action from the knowledge seeker.

Few studies were found to have included assessment as part of their KM process model. Assessment activities in previous models tend to occur towards the end of the process, indicating that the models did not suggest knowledge filtering before use and storage (Meyer & Zack, 1996; Karadsheh et al., 2009, Amirkhani et al., 2012; Chauhan et al., 2016; Sullivan et al., 2015). This process is unacceptable in a healthcare setting. Knowledge must be assessed for fitness before use. The doctors and nurses see the importance of assessing the knowledge before passing it to the next stage. The process of acquiring knowledge involves diverse sources, and such knowledge may be inaccurate or worthless (Sun & Hao, 2006).

Minimal studies have included evaluation at the end of the process. In healthcare setting, this activity is crucial to determine the relevance and effectiveness of the decision-making process. For example, if the treatment plan is found to be effective, knowledge will be captured and organized for future reference. However, if the action taken is deemed to be irrelevant or insufficient, they will then review, reflect, and adapt the lessons learned. Doctors and nurses learn from events so that they are not repeated.

KM is not a linear process, and the process-oriented strategy in this study reflects that point. There are three iterative stages in this process; (1) identifying, discovering, and acquiring; (2) gathering and analyzing; and (3) capturing and organizing information. These iterative processes represent a cycle of operations before achieving the desired result or outcome. For example, in order to acquire information in solving clinical problem, doctors will identify the required information and choose the possible sources to search for (discover) the information. Once information has been found to be irrelevant or additional information is required, doctors will repeat previous activities until the desired information meets their needs. Finally, the overall components of a KM strategy proposed in this study is consistent with that of Jennex (2008, 2012), as a KM strategy must include identification of users, sources of knowledge, knowledge to be captured, and how captured knowledge is to be stored and represented, among other factors.

CONCLUSION

This study explores knowledge management in healthcare organizations. The healthcare industry faces diverse factors characterizing patients (e.g. physical traits, experience of illness and medical history), professional disciplines (e.g. doctors, nurses, pharmacists, radiologists and administrators), treatment options, delivery processes, and the interests of various stakeholder groups (patients, regulators, health agencies and civil society organizations) (Fichman et al., 2011; Kothari et al., 2011). Healthcare organizations are typically inter-organizational collaborations with a multitude of actors and stakeholders.

The study found that both healthcare organizations do not have a full-fledged KM in practice. Therefore, this study proposes a process-oriented KM strategy in implementing systematic KM in healthcare. This model has been tailored exclusively to healthcare organizations, with their unique characteristics and limitations. Studies on knowledge management in healthcare setting is lacking in integrated knowledge management process model. Healthcare processes are knowledge-intensive in nature (Myllärniemi et al., 2012). This study has helped to uncover a knowledge management process-oriented strategy that

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

suits clinical processes and decision-making. The proposed strategy aims to achieve greater and more relevant application of KM in the healthcare setting. This will encourage comprehensive knowledge management views, activities, and technologies in healthcare organizations.

The development of this process-oriented strategy will help healthcare workers and management to evaluate current knowledge management practices and potential improvements. Solving problems and making optimal decisions in healthcare is heavily dependent on access to knowledge. Thus, healthcare organizations should provide opportunities to incorporate knowledge management practices provide the best possible healthcare through operational excellence. These goals are achievable if a well-organized and effective strategy for knowledge management in healthcare is implemented.

Based on the current findings, this study indicates the following avenues for further research. Future studies may replicate the proposed KM strategy in different settings within the broader healthcare context. Such settings may include other clinical or non-clinical departments, other public or teaching hospitals, or private hospitals. Future research would also benefit from collecting data from different informant profiles (e.g. pharmacists, radiologists and other hospital staff members).

The proposed process-oriented strategy is focused on clinical activities from only two hospitals. Thus, the results may lack generalisability. However, its use in other contexts should not be dismissed as long as necessary adjustments are made.

Chapter 19
Use-Case Driven Approach for a Pragmatic Implementation of Interoperability in eHealth

Karima Bourquard
IHE – Europe, France

Alexander Berler
IHE – Europe, Belgium

ABSTRACT

Innovation in IT solutions introduces new usages in ehealth that allows the patient to be more active in his (her) health care and well-being. Strong expectations on electronic exchanges or shared medical documents from healthcare professionals and patients are pushing decision makers and stakeholders to develop quickly efficient and structured data enabled health IT infrastructures. One of the challenges of this paradigm shift is to provide at the point of care interoperable solutions in full compliance with regulations, ethics, organizational and technical states of the art. This paper describes this approach developed as a four steps process and defines the basic concepts for designing an interoperability infrastructure. For each of the steps, examples will be provided and discussed accordingly with the different interoperability layers (legal, policy, process, information and technical) developed in the Refined eHealth European Interoperability Framework (ReEIF) (eHealth Network, 2015).

INTRODUCTION

A pragmatic approach for a more efficient deployment of solutions in eHealth is now more and more expected by the user stakeholders as well as by public authorities due to the acceleration of the technological and digital divide and by the paradigm shift in healthcare in term of users:

- Patients develop more interest in their health and well-being and therefore demand a more comprehensive and direct access to their data and care plan;

- Innovative solutions provide more information that needs to be filtered depending on their usages and provide adequate access to entrusted users;
- New medical processes have not yet sufficiently evaluated (i.e., behavioral health, precision medicine, etc.).

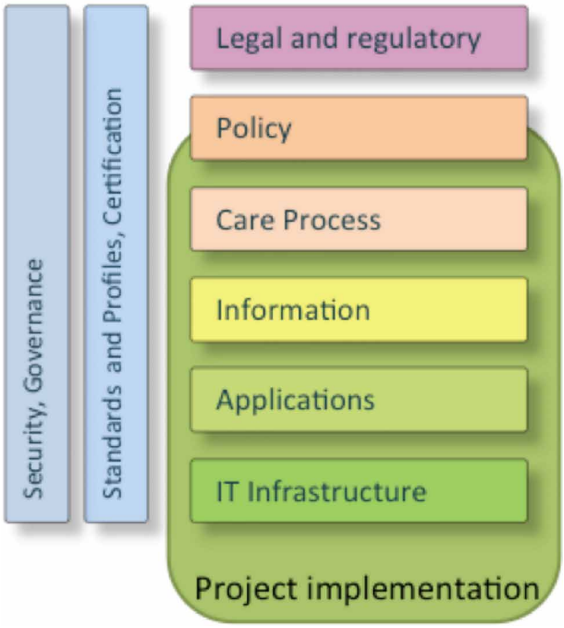
All these new processes require more direct and secure communication channels between healthcare professionals and patients taking into account the need for improved quality of data, extended care pathways where professionals are exchanging information within a collaborative process.

To facilitate the integration of those innovative solutions with the healthcare processes (current and future), and to involve end-users in the structured definition of their needs, a use case driven approach achieves faster a consensus among end users, stakeholders and healthcare software producers in order to develop interoperable solutions and services. That is the main objective of this paper: to demonstrate how this approach will help decision makers, project implementers as well as stakeholders to define and implement solutions that fit with interoperability requirements in a transparent and formal process. After a presentation of the concepts used, the methodology is presented, and experiences and best practices will complete the demonstration.

BACKGROUND

It is now consensually accepted that the interoperability concept [IEE[1], 1990] covers multiple dimensions (interoperability layers as a part of an interoperability framework) that were well described in the Antilope project (2015) and synthesized in Figure 1.

Figure 1. Refined Interoperability model (Antilope, 2015)



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Interoperability is defined in the layers mentioned below:

- The legal and regulatory layer that defines the legal constraints and rules for establishing lawful health information exchange;
- The policy layer that defines the needed organizational rules, as well as, how the stakeholders will work together when the patient provides his (her) consent;
- The care process layer is aligning with the medical and social processes;
- The information layer contains both semantic and syntactic interoperability rules (terminologies, coding, etc.);
- The applications layer describes the import export, messaging and display mechanisms of healthcare information;
- The infrastructure layer describes communication and protocols layer (networks, etc.).

A foreseen interoperable implementation has to consider all these layers in order to manage to have a successful deployment.

The transversal layers, security, standards and profiles are applicable for all the interoperability layers by addressing the complexity of such projects. Indeed, to bridge all these layers harmoniously, it requires a careful selection of security rules, standards and integration profiles to be used in order to avoid disruption or gaps in the chain of trusts or information exchanges. To minimize such drawbacks, the use case driven approach accompanies the designer and architect of the system during all the phases of the project.

The ISO DTR-28380 Part 3 (ISO, 2014) document proposes concepts and definitions, as well as, a process for deploying IHE profiles. This paper espouses and accepts the result of this approach and provides guidelines that will facilitate and support Information Technology (IT), eHealth industry, healthcare professionals and systems architects and engineers to implement and deploy their own project properly.

A use case describes in natural language the needs and requirements from an end-user point of view, clinicians, or patients, and provides quick access to underlying information related to deeper details or technical specifications. However, the description needs to follow a formalized template that provides proper guidance (eStandards, 2016). From the use case, we derive the realization scenarios which describe in more detail and translate into technical processes the steps to be supported by the systems or solutions (eStandards, 2016). Here again, a specific template (eHealth, 2015) guides the architects and facilitates the description of the implementation they want to do.

From one use case, one or more realization scenarios can be derived:

- The use case is described at high level, and sometimes it is better to cut it into one or more realization scenarios for better control of the implementation step as well as for priority related reasons (important steps, timing of procedural steps, mandatory actions, alternative inputs or outputs, etc.);
- Two or more interoperability implementations are technically feasible to support the transition phase, especially in the cases of technological gaps between existing systems and future implementations.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

USE CASE DRIVEN APPROACH

The objective for designers and architects is to design rapidly a robust and implementable infrastructure based on pre-existing best practices. The existing landscape of standards and profiles is vast, and it is not easy to find the proper path in this "forest" when not sufficiently familiar enough or when new standards appear and request recognition.

A use case driven approach facilitates the access to established standards because:

- This approach has been now deployed for more than 15 years with success;
- References, documentation, guidelines are now largely available and accessible (IHE, 2016a; IHE, 2016b; Jacobson, Christophe, Johnsson & Overgaard, 1992; Antilope, 2015);
- A repository of use cases (developed in eStandards project (2016)) is easily accessible providing examples of interoperable realization scenarios and set of profiles and standards;
- A Conformity assessment scheme (IHE, 2015) with a process description and testing tools are available for supporting projects that want to assess their solutions before final deployment.

The approach is supported by the four following methodological steps:

Step 1: Describe the use cases in natural language.
Step 2: Prioritize and select the most higher needs to start.
Step 3: Specify the realisation scenarios and define the eHealth architecture support of the use cases and select standards and profiles based consultation of the use case repository.
Step 4: Select testing tools and analyse when a conformity assessment process can be introduced in the project.

Step 1: Describe the Use Cases

The Refined European Interoperability Framework (ReHIF) developed in Antilope project (Antilope, 2015) as well as the support tools to describe methodologically the use cases were validated by the eHealth Network[2] in November 2015. The ReEIF proposes:

- A set of use cases distributed among ten domains (medication, radiology, laboratory, Patient summary, referral and discharge reporting, participatory healthcare, telemonitoring, multidisciplinary consultation, antenatal care and public health);
- A template that allows harmonization of the use case description that provides a common language and facilitates their reusability among stakeholders (see Figure 2).

Additionally, in order to facilitate adoption and taking-up, a use case data repository (eStandards, 2016) was developed from the eStandards project. A multi-criteria research feature allows the end-users access similar use cases to the ones they intend to implement.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. Set of the ReEIF use cases

#	Medical domain	Description	Scale
1	Medication	e-Prescription and e-Dispensing	1a) Cross-border 1b) National/Regional 1c) Intra-organisational 1d) Citizens at home
2	Radiology	Request and results sharing workflow for radiology	2a) National/Regional 2b) Intra-organisational
3	Laboratory	Request and results sharing workflow for laboratory	3a) National/Regional 3b) Intra-organisational
4	Patient Summary	Patient Summary sharing	4a) Cross-border/International 4b) National/regional 4c) Citizens at home
5	Referral- and Discharge reporting	Cross-enterprise Referral and Discharge Reporting	National /Regional 5a) Referral of patient from primary to secondary care 5b) Discharge report from secondary care
6	Participatory healthcare	Involvement by chronic patients in electronic documentation of healthcare information	Citizens at home
7	Telemonitoring	Remote monitoring and care of people at home or on the move using sensor devices	Citizens at home
8	Multidisciplinary consultation	Medical Board Review	National/Regional
9	Public Health	Immunization	National/regional Intra Organizational
10	Antenatal care	Antenatal care	National/Regional

Each use case provides information on the:

- **Relevance:** Describes in natural language the needs;
- **Domain:** One of the ten domains;
- **Scalability:** Use case implemented at the local, regional/national, European or international levels;
- **Context:** Challenges, ehealth strategy or objectives to be reached, benefits, etc.;
- **Information:** Medical information that will be shared among stakeholders;
- **Participants:** Healthcare professionals and patient involved in the use case;
- **Process flow:** Describes the information flow among participants;
- **Associated realization scenario(s):** One or more realization scenarios answer the needs and are described in more detail in the allocated template.

  Example: Relevance of the Patient Summary at the national/regional scale.

"For the exchange of medical information about a patient, a Patient Summary provides the participants in a healthcare pathway with the 38 basic medical background information. In collaborative healthcare, in the transfer of a patient to another hospital, and in a multidisciplinary board review, the Patient Summary functions as the standardized information set of medical information. The structuring of basic information such as current medication, allergies, advance directives, diagnoses, and therapies allows the different healthcare information systems to absorb the information from any other healthcare information system. The treatment of patients without proper medical background information is hazardous and should be avoided. This Use Case proposes a way towards solving this problem."

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Step 2: Prioritize the Use Cases

Best practices showed that the best way to deploy healthcare information exchange is to define an iterative approach based on use case selection. Therefore, the set of use cases will be implemented incrementally and step by step regarding a list of criteria established by each project based on its priorities and goals. For each functional or technical criterion, a weighting is defined related to their relevance and impact on the country or project objectives. For example, the list of criteria could contain:

- Health challenges:
  - **Benefit for the population:** Increase of the quality of life and the patient safety, health effectiveness, decrease of cost of care, etc.;
  - **Benefit for the healthcare professionals:** Better access to the patient medical information, to the peer expertise, to the decision support, etc.
- Maturity of the use case:
  - Number of deployed equivalent projects over the world;
  - Level of complexity;
  - Use case is requested by several channels (end-users, projects, national programs, etc.);
- Technical criteria:
  - Maturity and availability of technologies and standards that will support the use case;
  - Derivation of the use case on realization scenario is available;
  - Estimated timescale and cost for the use case deployment;
  - Infrastructure relationships between use cases that will be implemented;
- Cost Criteria:
  - Cost of implementation versus available funds (Capital expenses – CAPEX);
  - Cost of operation versus generated income or savings (operational expenses - OPEX);
  - Budgeting – funding restrictions.

Of course, this list is not exhaustive. Other criteria can be found according to the project's context of a specific country or region.

Step 3: Specify Realization Scenarios

One or more realization scenarios are closely coupled to a specific use case. They describe high-level interoperability implementation and more specifically the systems' actors and their interaction using standards and profiles. They are formalized in a template which includes:

- The related use case that the realization scenario implements;
- The context that describes the interoperable architecture and specific technical requirements;
- The actors that are systems or solutions involved in the workflow;
- The transactions that correspond to: the messages, documents exchanging or shared data between systems;

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

- The technical process flow(s) that can be represented by an interaction diagram or in a description depicting actors and transactions in the flow;
- The associated profiles and standards underneath;
- Other possible issues raised during the specification process which may cover security issues, options not yet chosen, architecture issues, custom interfacing with legacy systems and much more.

In the eStandards use case repository, the use cases are associated with the realization scenarios offering the possibility to easily access a specific selection of profiles and standards that serve a scenario. Interaction diagrams or interaction descriptions indicate the way to implement the scenario and can be adapted for specific usages.

The benefits for the implementers are quite obvious:

- Provide guidance to implementers who are not familiar with the ehealth standard complexity;
- Provide examples of architecture implementation proposals;
- Provide quick access to the specifications of profiles and standards;
- Provide the list of European Profiles eligible for referencing in public procurement (European Commission, 2015).

After having chosen the set of profiles and standards that are already available, a gap analysis should be performed in order to check if all the needs of end users are well covered. If it is not the case, the implementers shall select additional messages from standards already selected or add new profiles or standards.

The use case data repository demonstrates that several use cases can benefit from the same set of IHE profiles and therefore supported by the same set of services and infrastructure which optimizes their deployment.

Step 4: Select Testing Tools

Tooling for interoperability is becoming more and more available to the ehealth ecosystems increasing the level of quality of the ehealth project. Two types of tests can be performed:

- The conformance testing checks if the messages or documents provided by the systems conform to given specifications; conformance testing can be done with simulators to simulate processes and actors and validators to validate input and outputs (documents, messages, tokens, etc.);
- The Interoperability testing checks that at least two systems are exchanging correctly information using specific protocols/profiles or profiles/standards in a given workflow. Interoperability testing can be achieved in testing events either face to face or in virtual environments.

Table 1 presents different categories of tools as examples (not exhaustive).

A list of tools is available from the Antilope project deliverable 3.1 (Antilope Testing Tools - WP3.1, 2015). The IHE Gazelle environment proposes a large number of open source tools that allow any implementer to test the conformity of their development using the Gazelle external validation[8] (see Figure 3).

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 1. Different categories of tools as examples

Type of Tools	Tools	Examples
Specification	Localise the standards for a project, create analytical business rules specifications in documents	Art Décor for HL7 CDA[3] documents (Boufajha, Poiseau, Tomazon & Bergé, 2015)
Validator or conformance tester	Validation of the conformity to the standard	Gazelle™[4] HL7 validator DICOM[5] validator Assertion validator IHE XD*[6] metadata
Simulator	Play the role of the systems performing the behavior of one or several actors	Gazelle™ simulators for IHE profiles
Management	A tool that manages the testing session including the validation report, the test plan and registers the systems under test and their performed tests for traceability, the testers identification and the monitors identification	Gazelle™ TestBed
Proxy	A tool that captures messages exchanged between systems or actors. The validation of the messages can be performed afterward by using the other tools	Gazelle™ proxy
Test data generator	Demographic data server (DDS) Private Key Infrastructure (PKI)for testing	Gazelle™ DDS
Other Support tools	Libraries, examples of implementation, issue tracker, terminology servers, and much more	

Note:

HL7 Clinical Document Architecture standards specify the structure of a clinical document such as Patient Summary, ePrescription or any other document clinical specialties.

DICOM is the standard for exchanging or sharing medical imaging developed by NEMA[7] (the Association of Electrical Equipment and Medical Imaging Manufacturers)

IHE XD* are IHE integration profiles are used for exchanging or sharing medical documents between healthcare enterprise. The specifications describe actors (supported by systems), transactions (messages that are exchanging among actors) and metadata.

Gazelle is a test bed developed by IHE

Figure 3. Gazelle external validation (IHE International)

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

This interface offers testing tools for the most deployed standards and provides opportunities for testing implemented specifications of documents or messages for projects such as:

- **epSOS[9] (Europe):** Assertions, audit messages, HL7, XD* metadata[10], CDA documents;
- **CI-SIS[11] (France):** Documents in CDA;
- **eSens[12] (Europe):** eID[13], REM[14], and SMP[15];
- **EFA[16] (Germany):** EFA CDA documents and HL7v2 messages.

IHE has established an international conformity assessment scheme (IHE, 2015) where several of the most popular profiles used in an exchanged or shared infrastructure are selected for thorough testing based on ISO 17025 standard (IS0, 2005): vendors can sell products after having successfully passed a conformance assessment, and then stakeholders can choose to trust high-quality interoperable solutions that abide by those conformity assessment schemes such as the one globally proposed by IHE International.

BEST PRACTICES AND EXPERIENCES

In Europe, several countries have selected use cases related to:

- Patient Summaries and discharge letter for the coordination of the Patient care (pathways) between the hospital and the General Practitioners (GP); This is the case in Luxembourg, France, The Netherlands, Austria, Veneto region; Belgium and other countries and regions;
- eDispensation to have a view on what are the current dispensations for a patient and to analyze the economic impact at the national/regional level (France, Greece, Croatia, etc.);
- ePrescription in Nordic countries (Denmark, Sweden) and Greece, Croatia.

Other use cases are also be considered such as laboratory reports (Luxembourg in concept design progress, Austria, etc) or radiology reports (regional tele Imaging projects in different countries). With the development of the Telemedicine, new challenges are raised with a high demand for Interoperability solutions for:

- Patient at home such as chronic patients (diabetes, COPD, allergies);
- Teleconsultation, tele-expertise or telemonitoring.

The healthcare infrastructures that are emerging shall obviously serve all kinds of use cases or needs. This model can be replicated in any circumstance across the healthcare delivery.

During the past years, European Member States experimented cross-border healthcare exchanges based on XDS architecture, exchanging Patient Summaries, ePrescription and eDispensation in the epSOS project (2015). With the EXPAND project (2015), the demonstration of exchanging medical data was a success, and several lessons were learned (EXPAND project, 2015).

In Table 2, the main issues to be analyzed when setting up a new Health Information Exchange facility are presented.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 2. Main issues when setting up a new health information exchange facility

Layers	National	Cross Border
Legal and regulatory	Verify that the legal framework is relevant for sharing or exchanging medical data (confidentiality and privacy, patient consent, patient and healthcare professionals directories)	Compliant to the Patient' rights Directive (European Parliament, 2011) and European data protection directive. Overview on General Data Protection Regulation (GDPR) (European Commission,2012) A country shall verify that the legal context is compliant with the legal framework developed in epSOS project and updated by the eHN Country shall sign the multilateral agreement (MLA)
Policy and Care process	Agreement between healthcare organizations is in place describing the responsibilities related to the care process and the creation/consumer of the shared documents, etc.	Guideline on Organisational Framework (eHealth Network, 2015)
Information	National/Regional Interoperability framework that includes terminologies, medical documents specifications, identification of objects.	Patient Summary and ePrescription guidelines; Master Value set Catalogue, NCP specifications
Technical services	National/regional infrastructure and services connected to the cross-border infrastructure (interfaces)	National Contact Point (NCP) reference eHealth DSI (eHealth Digital Service Infrastructure
Testing services	National/Regional Conformity Assessment Scheme	European Conformity Assessment Scheme (in progress)

CONCLUSION

The interoperability use case driven approach demonstrates its robustness, and it is now used as a basis when stakeholders want to deploy an interoperable project in eHealth.

It will facilitate the access to the technical specifications that exist in standards and integration profiles. The objective for the next years is to get more harmonization over Europe even if the complete standardization in interoperability is not fully realistic due to specificities in each country or region. It will provide more transparency and openness that will encourage stakeholders and patients to collaborate and to share their experiences. It will also allow implementers and vendors to become more extrovert and create products and services that could apply to more than specific and closed markets.

Use cases and realization scenarios that are supported by the Use Case repository, are defined at high level (or large grain) in order to avoid the multiplicity of use cases that will be not easy to manipulate or not easy to map with operational projects by the stakeholders. It will be efficient to link this approach with the approach described in ISO DTR 28380 (2014) that presents more granular technical use cases directly linked to only one IHE profile.

This approach also provides support to contracting authorities and stakeholders to provide better specifications in their tenders. Next steps will be a better deployment of all these available guidelines and tools at the European level for fostering the harmonization between countries in order to facilitate cross-border exchanges. New use cases will benefit from this approach and the first implementation of existing use cases shall be developed much faster than in the past and will complement and meet the user needs.

Chapter 20
Agent-Based Modelling in Multicellular Systems Biology

Sara Montagna
Università di Bologna, Italy

Andrea Omicini
Università di Bologna, Italy

ABSTRACT

This chapter aims at discussing the content of multi-agent based simulation (MABS) applied to computational biology i.e., to modelling and simulating biological systems by means of computational models, methodologies, and frameworks. In particular, the adoption of agent-based modelling (ABM) in the field of multicellular systems biology is explored, focussing on the challenging scenarios of developmental biology. After motivating why agent-based abstractions are critical in representing multicellular systems behaviour, MABS is discussed as the source of the most natural and appropriate mechanism for analysing the self-organising behaviour of systems of cells. As a case study, an application of MABS to the development of Drosophila Melanogaster is finally presented, which exploits the ALCHEMIST platform for agent-based simulation.

INTRODUCTION

The chapter reviews the role of *agent-based modelling* (ABM) in the simulation of biological systems, focussing on the simulation of multicellular systems. Modelling multicellular systems requires tools that can support multi-scale models, where different cells form large-scale, dynamic networked systems – as, e.g., in tissues of cells, organs, and even full embryos – and where both the biochemical reactions that occur inside each cell and the molecules diffusion along the tissue (mediating the interaction among nuclei/cells) can be reproduced (Dada & Mendes, 2011; Deisboeck, Wang, Macklin, & Cristini, 2011).

Despite its recognised value for modelling complex systems (Bonabeau, 2002), and also for modelling biological systems (Holcombe et al., 2012), ABM is still not completely accepted as a suitable modelling

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

approach in the literature on multicellular systems—whereas, dually, multicellular systems are not usually considered as a valid application domain in the ABM literature. This provides the first motivation behind this chapter: that is, pointing out the potential of ABM in the context of multicellular systems.

ABM grounds on top of the three fundamental abstractions for multi-agent systems (MAS) (Zambonelli & Omicini, 2004):

- **Agent:** The autonomous source of activity in the system,
- **Society:** A group of interacting agents, and
- **Environment:** The context where agents and societies live and interact. As such, agent-based models are perfectly suited for studying the systemic and emergent properties that characterise a multicellular system, meant to be reproduced *in virtuo*.

ABM looks a promising approach in this context given the direct mapping between agent-based abstractions and multicellular systems: agent-cell (with internal and interacting behaviour), agent society-multicellular system, environment-extracellular matrix.

As an example, *developmental biology* is used as a reference scenario to demonstrate the power of *multi-agent based simulation* (MABS). Developmental biology is a challenging branch of life science that studies the process by which organisms develop, focussing on the genetic control of cell growth, differentiation and movement: as such, it analyses multicellular systems during their formation and development. In particular, the chapter illustrates the application of MABS to the development of *Drosophila Melanogaster* based on the ALCHEMIST agent-based simulation framework (Pianini, Montagna & Viroli, 2013; Montagna, Omicini & Pianini, 2016). In the overall, the contribution of the chapter can be articulated as follows:

1. Reviewing the actual state-of-the-art in MABS applied to multicellular systems biology, as well as making an argument for the value of agent-based approaches in the field;
2. Reporting on a case-study of agent modelling and simulation;
3. Discussing the specific issue of developmental biology – that is, one of the hottest and most challenging field in biology –, and verifying which specific achievements were obtained in the last years by adopting the agent metaphor within biological studies;
4. Providing an example of MABS platform for biological systems; and
5. Supplying biologists with a tool possibly helping them finding insights into the biological phenomena, experimenting working hypotheses, performing the so called *what-if* analysis, and making prediction on system behaviour.

BACKGROUND

The field of research devoted to understanding biological cell functionalities by means of modelling and simulation techniques is called *Systems Biology*. The field originally emerged around year 2000, in particular the pioneering work of Kitano (2002). Systems biology is grounded on the idea that the high complexity of phenomena and mechanisms regulating biological system dynamics cannot be understood by *in-vivo* experiments alone—mostly, due to the limitation of experimental techniques in investigating the coordinated activities among system components. In order to understand biological systems, other

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

concepts and tools are required that could enable the execution of *in-silico* experiments, *i.e.*, modelling and simulation techniques to understand how the integration and interaction of components can yield emergent behaviours.

Systems biology mainly focuses on the analysis of mechanisms at the intracellular scale—such as pathways, genetic, and metabolic regulation. Recently, a massive trend of research moved towards the analysis of the entire multicellular system (Hoehme & Drasdo, 2010), and a new field of research emerged: multicellular systems biology. Accordingly, the remainder of this section provides a description of the main biological facts involving multicellular systems, and points out the critical issues that make such systems particularly interesting from the research viewpoint.

Multicellular Systems Biology

Multicellular systems biology studies multicellular systems. *Multicellular systems are living organisms that are composed of numerous interacting cells*.[1] Humans and most of the animals are multicellular organisms. Research focuses in analysing specific tissues of the entire organism, such as neural system, immune system, adult stem cells etc., that are leading specific biological functions. Moreover, many research initiatives are devoted to analysing systems during embryogenesis and population of cancer cells.

All of the aforementioned systems share some features and properties, which make their understanding particularly challenging. The main property is that they are inherently *multi-scale*—see Figure 1. As such, the global behaviour emerges by mechanisms working across multiple space and time scales. Each scale integrates information from strata above and below, according to the principle of *upward and downward causation* (Uhrmacher, Degenring, & Zeigler, 2005). The building block for the vast majority of mechanisms at each level is the *interactions* among components.

It is possible to identify three main hierarchical levels for multicellular systems (Setty, 2012): molecular, cellular, and tissue.

Intracellular regulatory network controls molecular mechanisms, such as gene expression, receptor activity and protein degradation. The dynamic at intracellular level brings each cell into a state that affects the architecture and function on the cell level. However, the intracellular regulatory processes is not enough for understanding the emergent processes: an individual cell decides on its next developmental step, proliferation, fate determination, and motility, according to intracellular state as well as to constrains deriving from the level above. Cell population acts in concert to develop its anatomy and function.

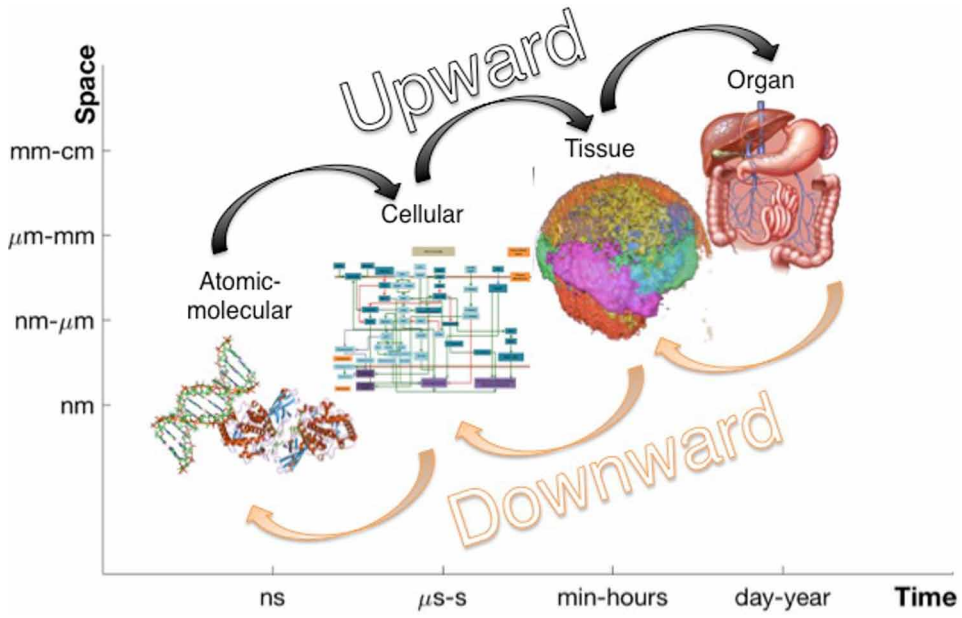
Computational Model Requirements

In the literature, a *middle-out modelling approach* is suggested as a possible technique to reproduce the behaviour of these systems. It starts with an intermediate scale (the cell, the basic unit of life), and it gradually expands to include both smaller and larger scales for reproducing the intra- and inter-scale interactions and integration. It should then be multi-scale in nature, so as to capture several spatial and temporal scales.

Also, it should feature abstractions for modelling diffusion of molecules across cells and in extracellular matrix, for studying the effects of short and long range signals, and for modelling the compartment membrane. Moreover, it should be stochastic, in order to capture the aleatory behaviour characteristic of those systems involving few entities; also, the cell topology should be dynamic, for modelling cell

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. A biological system is articulated over at least four levels with different spatial and temporal scales. Each level influences the dynamic at the level above (upward causation) and below (downward causation)



division and movement. Finally, it should be able to capture cell heterogeneity, so as to model individual structures and behaviours of different entities of the biological system.

From the validation perspective, the field is particularly critical since it requires multiple data: molecular data such as gene expression profiles and image data such as spatial-temporal growth pattern.

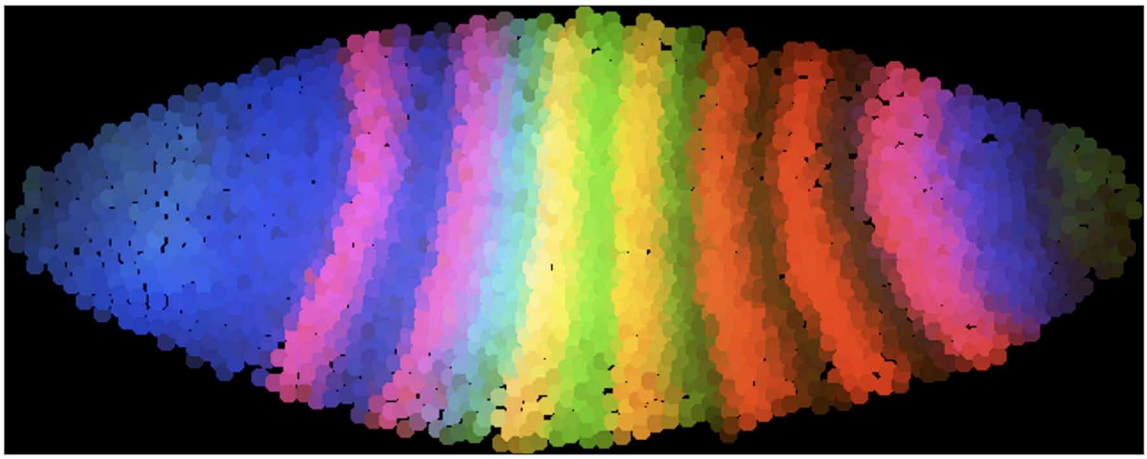
Developmental Biology

Among the different and challenging branches of multicellular systems biology, the chapter focuses on developmental biology, which studies the processes by which multicellular organisms develop. Multicellular organisms pass through similar stages during development. The life of animals begins with the fertilisation of the egg; *fertilisation* stimulates the egg to begin development. A series of extremely rapid and synchronous *mitotic divisions* of cells or cellular nuclei characterises the cleavage stage of development. After that, cells start the process of gene transcription and protein synthesis: cells *differentiate* in that each type expresses a diverse set of genes. Cell diversity is organised into a precise spatial distribution (*embryo regionalisation*), as shown in Figure 2 for the *Drosophila Melanogaster* embryo.

Developmental biology focuses on the genetic control of cell growth, differentiation, and movement, for understanding the mechanisms that make the process of embryo regionalisation so robust, making it possible for an organism to evolve from one cell to the same morphology every time (Hohm & Zitzler, 2009). Answering the big questions of development – such as "How do local interactions among cells and inside cells give rise to the emergent self-organised patterns that are observable at the system level?" – has a double meaning. On the one hand, it should make the fascinating process of multicellular organisms morphogenesis clear. On the other hand, since the molecular and biochemical processes regulating

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. The pair-rule gene even-skipped (red) together with hb (blue) and Kr (green) in Drosophila embryo at the cleavage cycle 14A temporal class 8. Reconstructed image from (Pisarev et al., 2009). Embryo name: ba3



cell proliferation, differentiation, survival, and death also play a central role in tissue homeostasis and cancer cells, it could reveal the key mechanisms that drive cancer progression, paving the way towards the identification of new therapies that can control tumour growth.

ABM IN MULTICELLULAR SYSTEMS BIOLOGY

The interdependent nature of multicellular processes often makes it difficult to apply standard mathematical techniques to separate out the scales, uncouple the physical processes or average over contributions from discrete components. (Cooper & Osborne, 2013)

Individual-based models (IBM) are often presented in literature as one of the main alternative to mathematical models based on differential equations. Both cellular automata (CA) and agent-based modelling (ABM) are representative of the class of IBM. Altogether, their computational models are similar, since they are organised around an abstraction of *individual* entities – *cells* in CA, agents in ABM – and the concept of *space*, defining the notion of neighbourhood for each entity. On the other hand, cells in CA are simpler then agents in ABM, since their behaviour is defined with update rules that change their states, switching between boolean values in the basic case, based on the state of the cell itself and of its neighbours. Also, the grid of cells is usually static, so that movement or cell replication is allowed. However, CA cannot model with sufficient accuracy cell proliferation and movement, which are crucial mechanisms especially in tumourogenesis.

This is where the theory of agents and multi-agent systems (MAS) steps in, promoting IBM where individual entities can express a more articulated autonomous behaviour, living, moving, and replicating in a possibly dynamic and complex environment. In the literature, agent-based systems, and MAS in particular, are considered as an effective paradigm for modelling, understanding, and engineering *complex systems* (Omicini & Zambonelli, 2004), and biological systems in particular (Cannata, Corradini, Merelli,

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Omicini, & Ricci, 2005), since they provide a basic set of high-level abstractions that make it possible to directly capture and represent the main aspects of complex systems, such as interaction, multiplicity and decentralisation of control, openness, and dynamism (Uhrmacher & Weyns, 2009; Merelli et al., 2007; Macal & North, 2010; An, Mi, Dutta-Moscato & Vodovotz, 2009; Gelfand, 2013).

As from the pioneer work of Bonabeau (2002), an ABM describes the system *from the perspective of its constituent units*. Moreover he states that (Bonabeau, 2002:

The benefits of ABM over other modeling techniques can be captured in three statements:
1. *ABM captures emergent phenomena*;
2. *ABM provides a natural description of a system*; and
3. *ABM is flexible*.

Emergent phenomena result from the interactions of individual entities. By definition, they cannot be reduced to the systems parts: the whole is more than the sum of its parts because of the interactions between the parts. An emergent phenomenon can have properties that are decoupled from the properties of the part. [...] ABM is, by its very nature, the canonical approach to modeling emergent phenomena: in ABM, one models and simulates the behavior of the systems constituent units (the agents) and their interactions, capturing emergence from the bottom up when the simulation is run.

Given that the above definition shares its crucial concepts with the one of systems biology, ABM looks particularly adequate for modelling multicellular systems.

By adopting ABM, biological systems can be modelled as a set of interacting autonomous components, i.e., a set of agents, and their chemical environment can be modelled by suitable environment abstractions, enabling and mediating agent interactions (Weyns, Omicini, & Odell, 2007). In particular, ABM provides a straightforward way to model:

1. The diverse individual structures and behaviours of different entities of the biological system as different agents (heterogeneity);
2. The heterogeneous – in space and time – environment structure and its dynamics; and
3. The local interactions between biological entities/agents (locality) and their environment.

Executing an agent-based model makes it possible to study its evolution through time, in particular:

1. Observing individual and environment evolution;
2. Observing global system properties as emergent properties from agent-environment and inter-agent local interaction; and
3. Performing in-silico experiments.

In ABM each cell is typically modelled as an agent, accounting for independent cell behaviour as well as for cell interactions. In the context of biological system, agent-based models can therefore account for individual cell biochemical mechanisms – gene regulatory network, protein synthesis, secretion and absorption, mitosis and so on – as well as the extracellular matrix dynamic – diffusion of morphogens, degradation and so on – and their dynamic influences on cell behaviour. On top of the cells/agents system, then, there is the whole population, whose behaviour can be observed through simulation, thus show-

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

ing the relationship between microscopic behaviours of the single agents and macroscopic behaviours of cell population. A further benefit of ABM in multicellular systems biology is that each agent can be associated to a different autonomous behaviour, thus capturing cell heterogeneity that plays a crucial role in a lot of multicellular phenomena.

Different ABM techniques can be found in the literature, such as lattice-based, lattice-free, cellular Potts, lattice-gas, and subcellular element modelling methods (Anderson, Chaplain, & Rejniak, 2007). Typically, they mostly differ for how they model the agent distribution over the environment: for instance, lattice-based models, such as cellular Potts models, organise agents into a lattice structure.

In the Literature

The idea presented in this chapter is supported by related literature that reports about platforms specifically developed for building agent-based models of multicellular systems and running simulation. Generally, a significant number of applications of ABM to biological systems can be found in the literature—even though some of them mainly specifically refer to intracellular networks only (Montagna, Riccim & Omicini, 2008; González et al., 2003; González Pérez, Omicini, & Sbaraglia, 2013; Pogson, Smallwood, Qwarnstrom, & Holcombe, 2006). However, for their very nature, ABM fits multicellular systems, becoming a common method in multicellular system biology (Gorochowski et al., 2012). This is why the remainder of this section will only mention the works related to multicellular systems. In particular, most of the works couple ABM with reaction-diffusion systems that model intracellular or microenvironmental dynamics of substrates.

Platforms

In the following the main ABM platforms are mentioned and shortly described. Since providing details on how to implement a model within each platform is out of the scope of this chapter, interested readers can refer to the original platform documentation.

- **COMPUCELL3D:** (Cickovski et al., 2005) is probably the best example of a hybrid platform that combines a lattice-based ABM (to model cell interactions) and continuous models based on reaction-diffusion equation (to model chemical diffusion). Each compartment – which can be a cell, or even a subcellular compartment – is associated to a set of attributes (like cell type, volume, area), is characterised by a state, and has a behaviour defined by a set of formula changing the value of a variable called *effective energy*, which implements most cell properties, and also governs internal and interacting dynamics. For instance, it accounts for cell adhesion, or elastic constraints that consider volume and surface constraints. In the overall, COMPUCELL3D looks like a very promising framework, whose main limitation is the lack of a realistic model for cell internal behaviour.
- **Morpheus:** (Starruß, de Back, Brusch & Deutsch, 2014) is also is a hybrid framework embodying both ABM and mathematical models such as ordinary differential equation and reaction diffusion systems. Moreover, an integration of the two modelling approaches is possible: each compartment is an agent that, according to the cellular Potts model, defines compartment shape and motility, and whose internal behaviour is usually linked to models of intracellular biological networks specified in the form of ordinary or stochastic differential equations. Morpheus is enhanced with

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

a full-featured graphical user interface that supports the user during model definition and editing as well as during simulation, providing tools for interacting with the simulation and visualising simulation output and results in various ways.

- **ALCHEMIST:** (Pianini, Montagna & Viroli, 2013; Montagna, Omicini & Pianini 2016) is a novel platform based on the concept of nodes/agents, whose behaviour is specified by chemical-like rules. It is particularly suited for modelling biological systems, being its main abstractions very close to the main components of such systems. Details on that will be given in the next section.
- **Other Platforms:**. Beyond the aforementioned platforms, which are the best examples of ABM platforms specifically developed for multicellular systems, other examples are worth to be mentioned shortly in the following. CellSys (Hoehme & Drasdo, 2010) implements a class of lattice-free agent-based models permitting realistic simulations of tissue growth. Currently, the platform seems to be not maintained anymore.

Other platforms are built for developing ABM-MABS in diverse domains, thus without specific abstractions devoted to modelling biochemical mechanisms. For instance, FLAME (Holcombe et al., 2012) implements a pure agent-based model. The behaviour is here modelled in terms of state machines, i.e., a set of states with transition rules or functions that determine how to make the agent evolve. In biology, it has been applied to the modelling of stem cells. Repast (North et al., 2013), MASON (Luke, Cioffi-Revilla, Panait, Sullivan & Balan, 2005), NetLogo (Wilensky, 1999) are the most popular MABS platforms. As such, they provide tools for implementing the typical ABM abstractions. Agent behaviours are defined in different ways: the most general-purpose one is by programming languages (Java for MASON and Repast; a Logo-inspired language for NetLogo) by which any possible behaviour can be given to the agent and to the environment that contains the agents.

Successful Applications

Mostly because it makes it possible to model cell diversity, ABM has been frequently adopted in order to simulate cancer growth, also accounting for the stochasticity of genetic mutations. Wang et al. (2015) provide a review of the most recent ABM approaches developed for studying different aspects of cancer growth. Accordingly, in the following the most representative works showing how ABM can capture the main mechanisms of cancer development are shortly introduced and discussed.

Macklin et al. (2012) describe an agent-based cell model of ductal carcinoma in situ (DCIS), which is a type of breast cancer. Each cell is modelled as a mobile agent that moves according to adhesive, repulsive, and motile forces. Heterogeneity is accounted for by associating each agent to a phenotypic state, and by means of rules that govern phenotypic transitions depending on the internal state of the cell and the local microenvironment. Cellular volume is also reproduced accounting for variations during proliferation and necrosis processes. Such a model is coupled with a reaction-diffusion model for modelling substrate dynamics, namely for describing how cells affect the concentration of molecules in their microenvironment and the dynamic of intracellular molecular signalling. The model predicts that DCIS tumours grow, in agreement with mammographic data.

Olsen and Siegelmann (2013) design an ABM of various cancer types, focussing in particular on cancer growth. It has three levels of representations: the cellular, tissue, and molecular ones.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Cells are agents, and a notion of environment is explicitly represented: it mainly models blood vessels that bring nutrients to cells, thus modelling the molecular level. Agents are organised into a three-dimensional grid: the tissue level emerges from the agents and the environment dynamics and interactions. Their behaviour is represented via flow-charts.

Finally, it is worth mentioning a number of other multicellular systems whose mechanics has been investigated in terms of ABM. Gorochowski et al. (2012) analyse the relationship between single-bacterial-cell dynamic and the population level characteristics for studying the collective behaviours observable in many bacterial populations. In Rouillard and Holmes (2014) a case of ABM application to myocardial cells has been reported. It studies the long-term consequences of therapies that alter infart mechanics. These therapies aim at reducing complications of heart attack by altering heart structure, mechanics, and function over time. Walker, Wood, Southgate, Holcombe, and Smallwood (2006) present an extension of the *Epitheliome*, an agent-based model of epithelial cells. There, agents represent individual cells that, in the original *Epitheliome* model, iteratively change their state according to a set of rules based purely on observations and responsible for injecting behaviours into the agents, such as proliferation, intercellular adhesion, migration, and apoptosis. In the last version presented by Walker et al. (2006), a mathematical model is integrated within each agent, to directly model intracellular pathways that cause cell proliferation, thus making a connection between molecular-level events and growth on a tissue level.

Given this big picture of related works supporting the crucial role that ABM has in multicellular systems biology, hereafter we provide details on the computational model of a specific platform and we then show how it applies to modelling a case of embryo development. The goal is to provide readers with an example of what we described until now, an example that can possibly guide interested readers in this fascinating field. Among the tools described before, we choose ALCHEMIST because it is particularly suited to model the case study, and also because, being developed by our research group[2], we are particularly competent on the platform. The example is extracted from a literature paper (Montagna, Pianini, & Viroli, 2012).

AN ILLUSTRATIVE EXAMPLE: THE ALCHEMIST PLATFORM FOR SIMULATING *DROSOPHILA MELANOGASTER* DEVELOPMENT

The ALCHEMIST platform[3] was specifically developed for running models composed by interacting compartments whose internal behaviour is defined by a set of chemical-like rules (Pianini, Montagna, & Viroli, 2013). The basic idea was to overcome the limits we found in other platforms, where the computational model is hard to understand. There, the representation of biological phenomena is far from the real mechanisms actually occurring in biological systems, where everything is a reaction.

The engine is based on two optimised versions (Gibson & Bruck, 2000; Slepoy, Thompso, & Plimpton, 2008) of the popular and successful Gillespie's stochastic simulation algorithm (SSA), originally defined for the simulation of chemical systems (Gillespie, 1977). The computational model was then extended to shift the paradigm from the pure chemistry towards the word of ABM, by specifying the agent (internal and interacting) and environment behaviours through the concept of reactions, properly extended from the original concept of pure chemistry found in Gillespie.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Thus, while ALCHEMIST makes it possible to simulate multiple, separate, interacting, and possibly mobile entities, its approach to ABM is still structured around the concepts of *reaction* and *compartment*. As a result, ALCHEMIST computational model, based on these two key concepts, is ideal for modelling multicellular systems, where the basic mechanisms are reactions, and the basic entities are compartments.

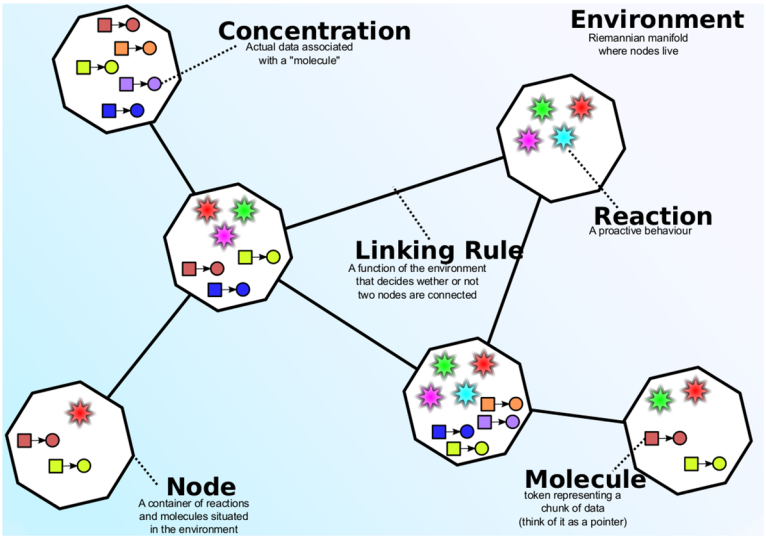
In the following the notions on top of which the ALCHEMIST computational model is grounded are described. Then we show how it is possible to develop a model of a multicellular system using the abstraction provided by ALCHEMIST by using a literature example, the *Drosophila Melanogaster* development shown in a previous work of ours (Montagna, Pianini, & Viroli 2012).

The ALCHEMIST Computational Model

In ALCHEMIST a compartment can represent an agent, and all the possible events in the model should, in the end, break down to a set of reactions (see Figure 3). As such the notion of agent we can deal with, modelling a system with ALCHEMIST is a soft one, *i.e.*, meaning that we can hardly give to agents cognitive capabilities −as it can be required in other simulation domains such as social sciences. However it is perfectly suited for cellular systems. Accordingly, in the following discussion the terms compartment and agent will be used interchangeably as synonyms.

To equip ALCHEMIST with all the abstractions proper of ABM, as first step, the notion of environment, missing in chemistry-derived SSAs, is introduced as a first-class abstraction (Weyns, Omicini & Odell, 2007). The environment has the responsibility to provide, for each compartment, a set of compartments that are its neighbours. The function of the current environment state that determines whether or not two compartments are neighbours can be arbitrarily complicated. Also, it is responsible of exposing possible physical boundaries, namely, to limit movements of compartments situated within the environment.

Figure 3. In the ALCHEMIST computational model, a system is composed of interacting agents whose state is defined by the molecules it contains. The agent state changes over time for the execution of a set of reactions that model the agent behaviour



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

The fact that reactions are the only abstraction the modeller can rely upon in order to specify the agent behaviour and to let the simulated system progress does not actually hinder expressivity. In fact, the ALCHEMIST model does not use a strictly-chemical agent behavioural model (White & Pagurek, 1998), rather it generalises the concept of reaction as: *"a set of conditions that, when matched, trigger a set of actions on the environment"*. Accordingly, a condition is a function that associates a numeric value ranging from zero to positive infinity to each possible state of the environment and of agent internal state. Conditions can be everything: for instance, in computational biology, with conditions the modeller can verify the number of neighbouring compartments, the presence of specific molecules inside the agent or in the surrounding environment. If the value associated to condition is zero, the event cannot be scheduled; otherwise, it is up to the reaction to interpret the number. In this framework, actions are arbitrary changes to the environment and/or to agent state. Examples can be the movement of agents, the creation or destruction of molecules, the creation of new agents.

Reactions compute their own expected execution time. Such a putative time is generated by a function ("rate equation" in the following) taking as input all the values generated by conditions and a time distribution. The engine may require putative time to be updated in case that:

1. The reaction has been executed, or
2. Another reaction that the reaction depends on has been executed.

The injection of a time distribution as a parameter for the rate equation makes it possible to model a whole set of events that are not exponentially distributed: imagine, for instance, a burette dropping some quantity of reactant in a compartment every fixed time interval. Such an event is clearly not memoryless, and can be modelled in the proposed framework with a reaction having no condition and a single action increasing the reactant concentration in the compartment. Such a reaction can be fed with a Dirac comb, and the resulting system would seamlessly mix exponential and non-exponential events.

A Case Study in Developmental Biology

To show how to build a model of a multicellular system on top of ALCHEMIST, hereafter we present a case of embryo development. We inspire our discussion to a model of *Drosophila Melanogaster* development presented in Montagna et al. (2012). Drosophila is one of the best-known multicellular organisms. The model reproduces the process of *Drosophila* development from the fertilised egg until the pattern formation of the products of a set of crucial genes called gap genes—*hb*, *kni*, *gt*, and *Kr*.

A schematic representation of what happens in the embryo in the first hours after fertilisation is shown in Figure 4. The schema sketches (from top to bottom) how the concentration of diverse gene products (mRNA and proteins) varies: starting with a unique cell with a polarised distribution of maternal proteins, the downstream transcription of different genes divides the embryo in regions that are stripe-like patterns of expression that strongly characterise the *Drosophila* embryo—as shown in Figure 2. The formation of this pattern is crucial since these segments are closely related to the final anatomical structure. At the same time, fast compartment divisions happen so that the embryo – at that stage – consists of about 6000 separate cells. Understanding how it is possible to create such a precise spatial distribution of gene products, thus generating an exact arrangement of different cell types, is the fascinating challenge of developmental biology, for which the help of modelling techniques is crucial.

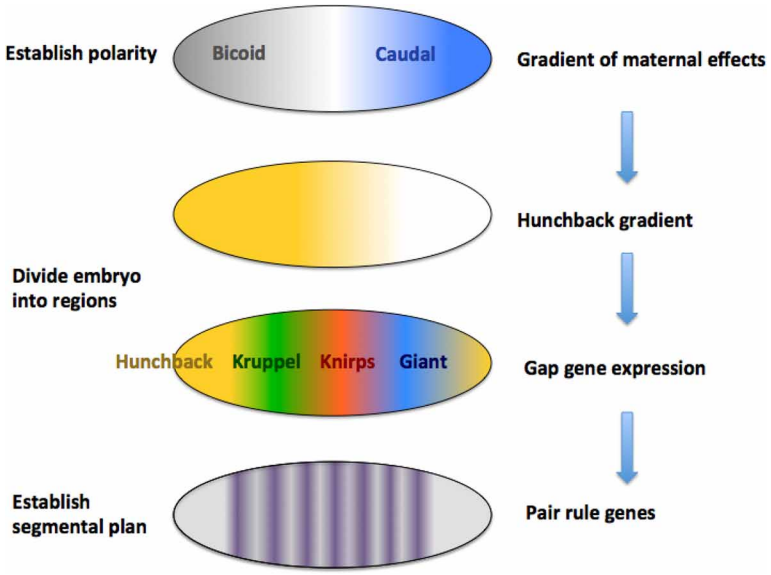
Figure 4. Hierarchy of genes establishing the anterior-posterior body plan of the Drosophila Melanogaster embryo



The Model

The whole embryo is modelled as a unique elliptic environment. Each cell is a compartment/agent situated inside the environment. It carries different types of molecules, can move and divide. The 2D continuous environment regulates the position of agents, specifically during movement and growth that must occur within its boundaries. Moreover it is filled with diffusing proteins. The mechanisms explicitly modelled are:

1. Molecule interactions,
2. Molecule diffusion,
3. Agent divisions, and
4. Agent migration.

Molecule Interactions

According to the literature, the gene regulatory network involving gap genes and maternal protein is modelled as a set of reactions where each gene is activated or inhibited by the others. In particular the four gap genes are the molecular actors of this model. They are modelled in two different states, active and inactive (for instance, for the *hb* gene, we have respectively gHb0 and gHb1). Their products are also explicitly modelled. For instance, for the *hb* gene, we have pHb. To exemplify this rule we provide here an example through the reaction that models the inhibition of the *hb* gene by the *Kni* protein: the conditions is that the agent comes with at least one *Kni* protein and the *hb* gene active; the action changes the state *hb* gene from active to inactive. The reaction looks like:

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

[pKni + gHb1] --> [pKni + gHb0]

The whole network, including all the interactions among gap genes, and their activation by maternal proteins is fully described by Montagna et al. (2012).

Molecule Diffusion

Diffusion occurs from / to agents and inside the environment along the x and y axis. Molecules move from one agent into the environment, or, the other way round, from one location of the environment into a neighbouring agent. Depending on the type of diffusion (passive or active transport), conditions – for this reaction to be scheduled – are diverse, such as the presence of membrane proteins or of energy in the form of ATP. A simple example follows:

[pHb in cell] --> [pHb in environment]

Agent Division

It is modelled as a chemical-like reaction, whose condition is given by the maximum number of other agents in the neighbourhood and whose action is the creation of a new agent. The new agent is situated close to the dividing one in a casual direction, provided that an other agent does not occupy the new position, and owns half of its molecular content. The rate of compartment division is determined according to the rate observed in the real system. In particular we refer to data reported in Montagna et al. (2010). Since experimental data show a given synchronisation between dividing cells, the phenomena was modelled through a non-Markovian reaction. The reaction looks like:

NumberOfNeighbors < 6 --> Division

Agent Migration

Movement of agents is based on biomechanical forces of repulsion among neighbouring agents: if two agents are closer than a distance – given as a parameter – that models agent surface (spatial extension), a repulsive force is generated and a new position for them is computed. The nearer two agents are, the stronger is the repulsion. Moreover they are forced to remain within the membrane-delimited area so as to filling pretty homogeneously the available space.

Simulation Results

The initial set up for simulations resembles the initial state of the embryo, where only one compartment is present, and where maternal proteins form a gradient in the environment as from experimental data (Pisarev et al., 2009). Simulations results are shown in Figure 5-6-7. They are evaluated observing the time evolution of the compartment number and of the gene expression pattern—see Figure 8. Figure 5 shows the initial condition with only one agent and the egg polarised by maternal effects localised in the extreme pole: *bcd* on the left and *cad* on the right. During the first minutes of simulation only agent divisions occur so as to fill the whole maternal cell at the end of cleavage cycle 9, *i.e.*, after 9 compart-

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

ment divisions, with around 250 agents (half of the total 500), as shown in Figure 6. Finally, Figure 7 reproduces the expression pattern of the four gap genes, whose spatial organisation is compared with experimental data of Figure 8. Cells are coloured of yellow, red, blue, and green—if, in order, they express *hb*, *kni*, *gt* and *Kr*, and their size is proportional to the protein concentration.

FUTURE RESEARCH DIRECTIONS

Directions for future research can be summarised into two main issues. The first theoretical issue is to refine the way multicellular systems are mapped into an agent-based model and the way simulations are executed, analysing the algorithms adopted to make time proceeds and events execute accordingly.

Secondly – to demonstrate the feasibility and effectiveness of ABM and MABS – our next focus is to apply the ALCHEMIST framework to the analysis of the main morphogenetic signalling pathways and of their interactions. This is a crucial problem in developmental biology, given that they are also involved in tumour growth. Since the integrated phenomenon is highly complex, involving a large set of mechanisms mediating cell-to-cell and intracellular interactions, literature evidences (Dada & Mendes, 2011; Deisboeck et al., 2011) show that novel algorithms and tools from computer science can significantly contribute in supporting experimental biologists to ravelling out such complexity.

To make the model description more clear, and to support the reproducibility and evaluation of the model, we plan to adopt protocols and standards, such as the ODD (Overview, Design concepts, and Details) one (Grimm et al., 2010), which should make agent-based models easier to write and read—and, more generally, the ABM approach easier to embrace for the multicellular systems biology community.

Figure 5. The initial configuration of the simulation is characterised the fertilised egg, characterised by only one compartment and by the gradient of maternal product, bcd (grey) and cad (light blue), in the environment

CONCLUSION

The goal of this chapter is to present a promising and challenging application domain for ABM: multicellular systems biology. The constituting characteristics of multicellular systems in fact highlight a clear mapping between the real system entities and the ABM abstractions. This makes building models and interpreting simulation results intuitive. For this reason we think that ABM is particularly suited for multicellular systems biology. To support our vision, we recollect the literature reporting on successful applications of ABM in this field, as well as a list of ABM platforms specifically developed for building models of interacting cells. To help the reader to better understand better the big picture, we finally choose one platform, ALCHEMIST, and motivate its adoption for ABM of multicellular systems. Finally we describe an example from the literature, which specifically shows how to model a system of interacting cells.

KEY TERMS AND DEFINITIONS

Cellular Potts Model: A lattice model evolved as a time-discrete Markov chain, where the transition probabilities are specified with the help of a *Hamiltonian* or *energy* function.

Cleavage Cycle: A cell cycle occurring during the cleavage stage of embryo development and resulting in the synchronous division of the cells in the early embryo.

Gene: DNA is composed of thousands of genes (the number varies with the organism). A gene contains the set of instructions needed to code a specific protein.

Gene Expression: The process that, beginning with the information contained in a gene and passing through different steps, end up in the synthesis of a functional gene product, that in most of the cases is a protein.

Lattice Model: A physical model where space is defined on a lattice, *i.e.*, on a structure with a regular periodic unit.

mRNA: During the process of gene expression, the first step synthetizes a mRNA molecule that contains all the genetic information stored in the gene and necessary for the next step. From the mRNA cell is then able to code for a specific protein.

Ordinary Differential Equation: One of the most common modelling approaches in Systems Biology is mathematical and adopts the ordinary differential equations. They involve derivative of one or more dependent variables with respect to a single independent variable.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Protein: The basic functional unit of a cell is the protein. Depending on their tridimensional structures, they perform most of the activities inside a living cell.

Reaction Diffusion Systems: They are differential equations with two independent variables that normally account for the change in space and time of molecules.

Chapter 21
The Role of Artificial Intelligence in Clinical Decision Support Systems and a Classification Framework

Steven Walczak
University of South Florida, USA

ABSTRACT

Clinical decision support systems are meant to improve the quality of decision-making in healthcare. Artificial intelligence is the science of creating intelligent systems that solve complex problems at the level of or better than human experts. Combining artificial intelligence methods into clinical decision support will enable the utilization of large quantities of data to produce relevant decision-making information to practitioners. This article examines various artificial intelligence methodologies and shows how they may be incorporated into clinical decision-making systems. A framework for describing artificial intelligence applications in clinical decision support systems is presented.

INTRODUCTION

As far back as the early 1960's computer technology has been applied to help solve healthcare issues (Saba, Johnson, & Simpson, 1994). Starting in the 1970's, intelligent computer applications to improve healthcare problem solving had arrived (Schwartz, 1970). While Schwartz (1970) incorrectly implied that computers would eventually replace physicians, many of the other forecasts on the impact of computer technology in healthcare, such as improving data availability and improving decision making, have been realized. Nearly four decades later, health information technology professionals continue to advocate for further development of information systems technologies in healthcare to create a nationwide infrastructure for sharing health information to improve patient outcomes and reduce medical costs (Chopra, 2009).

The advent of electronic health records (EHRs) and health information exchanges (HIEs) have certainly provided a means for more rapid and reliable access to patient information to improve the quality of care (Topaz et al., 2013). EHRs are utilized worldwide to improve health delivery systems (Wager, Lee, & Glaser, 2013).

However, EHRs still experience resistance to use from physicians and staff (McAlearney et al., 2015; Wang et al., 2015). Despite improved information flow afforded by EHRs and HIEs, this resistance has resulted in information overload and the need to find better ways to extract reliable information (Huang et al., 2015). For instance, Pickering et al. (2013) demonstrated that physicians use a relatively small amount of information available in EHRs when determining which patients to admit to an ICU, indicating that often too much information is available for decision making and leading to information overload.

Although there is still a long way to go before the ubiquitous acceptance of healthcare information technologies (HIT), healthcare is becoming an ever more information based and information dependent science (Ikram, Ghani, & Abdullah, 2015). Advances in information and communication technologies have led to the availability and generation of vast amounts of data (Esfandiari et al., 2014), especially in clinical medicine (Bellazzi & Zupan, 2008).

Clinical decision support systems, which are defined as "computer systems designed to impact clinician decision making at the point in time that these decisions are made (Berner & Lande, 2007, pg. 3)," are providing mechanisms for delivering clinical information in a usable format to decision makers (Bellazzi & Zupan, 2008). Improving rates of acceptance of clinical decision support systems may be due in part to the concern of physicians and other medical providers about the quantity of information needed to provide high quality health care and to avoid costly and life-threatening errors (Musen, Shahar, & Shortliffe, 2006).

Research has shown that utilizing artificial intelligence alone (Miller & Brown, 2018) or with EHR technology can improve clinical decision support (El-Sappagh & El-Masri, 2014). There is a tremendous need for incorporating artificial intelligence into clinical decision making to improve clinical outcomes (Park & Han, 2018). Artificial intelligence, which is based on the principal of making machines intelligent so that they can perform at expert human levels or better, enables the rapid assimilation of large amounts of highly complex data into multi-criteria decision-making models that can heuristically determine outcomes to clinical and other healthcare related problems (Callahan & Shah, 2018). Applied research in medicine and healthcare is already showing how to use artificial intelligence to improve decision making for detecting and diagnosing diseases or other healthcare issues, planning treatment, allocating critical healthcare resources, and scheduling and monitoring of patients. Pandey and Mishra (2009) document for the field of medicine: 56 knowledge-based expert systems, 33 artificial neural network applications, and 41 genetic algorithm or fuzzy logic-based systems. Other literature review research of artificial neural network, genetic algorithm, and fuzzy set methods applied in medicine found over 1000 reported applications from 1995 through 2007 (Yardimci, 2009) and for intelligent agents solving various treatment and monitoring problems 20 different applications are reported (Isern, Sánchez, & Moreno, 2010). From 1994 through 2014 across 14 specializations of medicine and health care management, Ghaheri et al. (2015) reported on 72 different healthcare information systems applications of genetic algorithms or genetic algorithms used in combination with artificial neural networks. As an indicator of the growth of artificial intelligence research and practice in medicine, a search conducted on EBSCO using the search terms artificial intelligence, artificial neural network, expert system, knowledge based system, machine learning, genetic algorithm, and fuzzy set combined with the search terms medical, medicine,

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

doctor, physician, hospital, and healthcare and limited to academic journal publication in English from January 2010 to December 2017 yielded 138,688 results and an identical search on titles and abstracts in PubMed produced 7,670 articles.

Clearly artificial intelligence-based applications research in medical domains is prevalent and continuing to grow. However, knowledge models in many clinical and medical domains are lacking and new knowledge models are still needed (Bohada, 2012). Diagnostic, treatment, and prognosis problems in the field of healthcare are quite complex (Nealon & Moreno, 2003) and consequently lend themselves to artificial intelligence solutions.

HISTORICAL PERSPECTIVE

Interest in applying artificial intelligence to medical domain problems has existed for at least 30 years. The early days of artificial intelligence in medicine primarily saw knowledge-based or expert systems applied to simulate physician expertise in diagnosis and treatment of various medical conditions and automate the reasoning process required in making complex medical decisions. These systems used Socratic-like reasoning methods to provide oracle like results (Miller & Masarie, 1990). One of the early medical expert systems and perhaps the most well-known is MYCIN, introduced in the early 1970's, which diagnosed and planned treatment for bacteriological infections (Shortliffe et al., 1975). Internist-I, developed in the mid-1970's through the early 1980's expanded upon MYCIN by emulating the knowledge of a domain expert across much of internal medicine (Miller, Pople & Myers, 1982). The last example expert system, though there exist many others, is PUFF which was used to diagnose pulmonary disease (Aikins et al., 1983). Many other standalone expert systems were developed following MYCIN through the early 1990's. One of the key features of these expert system approaches is their explanation facilities where they could demonstrate the reasoning involved in reaching and thereby justifying their conclusions.

In the early 1990's focus shifted away from expert system approaches to soft computing approaches including artificial neural networks and genetic algorithms (Yardimci, 2009). The artificial neural network diagnostic approach, similar to the narrow focus of earlier expert systems, focused on solving specific problems. Artificial neural networks enabled the creation of nonparametric, complex, and nonlinear diagnostic models. Unsupervised learning based artificial neural networks were primarily used in medical image processing to facilitate diagnosis, while supervised learning networks were primarily used in clinical diagnostics and other areas such as resource allocation. A full discussion of how expert systems and artificial neural networks work is beyond the scope of this article; however, numerous guides and introductory books exist and the reader is encouraged to peruse these (e.g., see Medsker & Leibowitz, 1993).

The ability of artificial neural networks to capture significant anomalies in medical images with high precision (Egmont-Petersen, de Ridder, & Handels, 2002; Hall et al., 1992; Scott, 1993; Wu et al., 1993) was one gain to the medical profession. Additionally, artificial neural network models of disease diagnosis started to become more accepted, with Reggia (1993) showing 11 examples between 1988 and 1992. The work by Baxt (1990, 1991) helped propel the recognition of artificial neural networks as a legitimate medical diagnostic modeling methodology and his artificial neural network solution for diagnosing acute myocardial infarction was demonstrated to be more accurate than emergency department physicians (Baxt & Skora, 1996).

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

The twenty-first century brought a focus on combining artificial intelligence methodologies into integrated systems (Pandey & Mishra, 2009). Knowledge-based systems and soft computing systems each have their strengths and also perceived weaknesses, such as the black box nature of artificial neural networks. Combining artificial intelligence techniques into a single hybrid system helps maintain the strengths of a particular artificial intelligence methodology while reducing the effect of any perceived weaknesses, consequently producing even more accurate and dependable decision support systems (Ramesh et al., 2004; Walczak, 2012). Integration of mixed artificial intelligence methods (El-Sappagh & El-Masri, 2014) also helped lead the way for cross platform integration of artificial intelligence into traditional healthcare systems, including EHRs.

ARTIFICIAL INTELLIGENCE IN CLINICAL DECISION SUPPORT SYSTEMS

Traditionally, one of the most significant barriers to utilization of artificial intelligence in healthcare has been lack of physician acceptance (Bhattacherjee & Hikmet, 2007; Walter & Lopez, 2008), a circumstance that also extends to nurses and other healthcare professionals (Khong, Holroyd, & Wang, 2015). Lack of acceptance of artificial intelligence-based HIT has been shown to be an international phenomenon (Gagnon et al., 2014; Hsiao & Chen, 2016). The advent of the 2009 HITECH Act in the United States along with rapid worldwide adoption of EHRs (Wager, Lee, & Glaser, 2013, Appendix C) and additionally the third stage of meaningful use, which requires advanced use of EHR technology to improve patient outcomes (HealthIT.gov, 2015), is opening the door for advanced decision-making applications becoming embedded in traditional healthcare IT.

The implementation of EHRs and the availability of HIEs drastically increases the quantity and quality of information available for decision making (Esfandiari et al., 2014; Goldstein & Shahar, 2016; Patel et al., 2009). Artificial intelligence methods, in particular artificial neural networks, decision trees, and rule-based expert systems are frequently used as datamining approaches for medical information, enabling decreased time spent finding and analyzing relevant evidence and also reducing errors (Obenshain, 2004). Datamining of both structured and unstructured information (e.g., clinical notes) via artificial intelligence methods is having an increasingly important impact on clinical decision making (Robson & Boray, 2016).

The heuristic nature of artificial intelligence enables clinical decision support systems to equal or often surpass the performance of medical personnel (Chappell, Lee, & Taylor, 1992; Kentala et al., 1998; Wolf et al., 2015). The improved decision-making capabilities of artificial intelligence based clinical decision support has several sources. First, expert and other knowledge-based systems using knowledge engineering typically gather the collective experience of multiple experts and encapsulate this expertise into a single system (Hernández-Chan et al., 2016; Wolf et al. 2015). In addition, artificial neural networks and other artificial intelligence soft computing methods such as genetic algorithms employ high powered mathematics to determine complex and sometimes nonlinear associations between independent and dependent clinical variables that are problematic for human experts to discover (Nealon & Moreno, 2003). Artificial intelligence techniques are thus able to apply expert decision-making knowledge incorporating all relevant data regardless of how large and combine these in complex and nonlinear ways to improve the quality of clinical decision making.

A Framework for Classifying AI Applications in CDSS

Artificial intelligence applications in clinical and other medical domains may be classified along a number of different properties. These properties include 1) type of artificial intelligence used in the system, 2) medical specialty or domain in which the application is used, 3) users of the system, 4) beneficiaries of the system, and 5) type of problem being solved (e.g., diagnosis or prognosis). As an example, an artificial neural network application that predicts the transfusion requirements of emergency room (ER) patients (Walczak, 2005) uses the artificial intelligence machine learning method of artificial neural networks, for the medical domain of trauma medicine, used by ER surgeons, benefiting ER patients (as well as hospital administrators), and is a resource allocation type of problem within healthcare. Many artificial intelligence applications in clinical decision support may utilize multiple features within each of these classification types, such a system that uses multiple types of artificial intelligence within a single application like the combination of artificial neural networks and fuzzy logic to perform diagnosis of calcifications in digital mammograms (Verma & Zakos, 2001).

The increased importance of fitting artificial intelligence applications in medicine into the clinical work flow (Patel et al., 2009) emphasizes the need for incorporating the decision maker user into the classification of artificial intelligence based clinical decision support systems.

The first is the artificial intelligence methods being employed within the decision support system: expert system, artificial neural network, genetic algorithm, fuzzy system, intelligent agent, computer vision, natural language processing, support vector machines, other machine learning, or other heuristic methodology. Another useful classification is the target user: physicians, nurses, pharmacists, other healthcare practitioner, healthcare facility, healthcare organization, management, or patient. Within each of these end user types are diverse tasks or goals of the decision support system. Healthcare providers will triage, diagnose, and plan treatment, while facilities and organization may be tasked with making sure sufficient and proper resources are available and patients are tasked with information transfer, scheduling, and health maintenance among other tasks.

The purpose of this article is not to serve as a literature review, but rather to highlight advances in artificial intelligence in clinical decision support and illustrate the capabilities of these systems. Table 1 shows an example of different artificial intelligence methods applied for various clinical end users. As indicated in the literature reviews cited in the Introduction, numerous other examples are available, but beyond the scope of this article.

Another example of using the classification framework is performed using the search terms specified in the Introduction section on Google Scholar. The Google Scholar search was limited to scholarly articles and book chapters appearing from January through April 2018 and was sorted by relevance to the search terms. Analysis of the first 50 articles returned that specify an artificial intelligence system in a medical domain. Abstracts of conference presentations and literature reviews or summaries were then excluded. The analysis is presented in Table 2, which uses the users of the system and the medical specialty or domain for the 2x2 grid and specifies the type of artificial intelligence system used and the type of problem solution within the Table 2 cells.

In addition to the numerous ways in which artificial intelligence supports and improves clinical decision making directly to various providers, artificial intelligence also may contribute

to scientific discovery of new diagnosis and treatment paradigms. Additionally, resource scheduling to complement needs based on clinical decisions may also be accomplished. Walczak (2008) provides

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 1. Sample artificial intelligence applications for various medical user types

	Expert systems	Artificial neural networks	Other artificial intelligence methods
Physicians/ dentists	Expert system to interpret lab results for diagnosis (Osuagwu & Okafor, 2010)	Neural network that predicts occurrence of pulmonary embolism in surgical patients (Walczak, Brimhall, & Lefkowitz, 2006)	Natural language processing system that summarizes longitudinal health data (Goldstein & Shahar, 2016)
Other healthcare professionals*	A fuzzy expert system that evaluates pain level (Padma & Balasubramanie, 2011)	Neural network to model and predict nurse-to-patient communication problems (Bagnasco et al., 2015)	Genetic algorithm to perform constraint satisfaction nurse scheduling (Lin et al., 2015)
Hospitals, clinics & resources	Expert system that helps select locations for new hospitals (Lin, Lee, & Chen, 2010)	Neural network that predicts length of stay (LaFaro et al., 2015)	Natural language processing system to prevent HIPAA violations by detecting PHI (Yang & Garibaldi, 2015)
Patients	Expert system that facilitates interpretation of laboratory test results (Semenov & Kopanitsa, 2016)	Neural network to predict quality of life for oncology patients (Takehira et al., 2011)	Agent based system to provide healthcare over mobile devices (Santos et al., 2016)

* Other healthcare professionals include nurses, nurse practitioners, physician assistants, pharmacists, anesthesiologists, physical and occupational therapists, dental assistants and hygienists, among others.

a framework for utilizing artificial neural networks to evaluate new medical decision-making heuristics and create new heuristics.

Other artificial intelligence methods may also be utilized for evaluation and creation of new heuristics, including: genetic algorithms and other machine learning (ML) methods like case-based reasoning (CBR), hidden Markov models (HMM), and decision trees. Genetic algorithm-based systems have been shown to function well as diagnostic classification systems (Marín et al., 2011). Other machine learning methods include support vector machines (SVM) which have been used to identify all medication information from patient medical records (Patrick & Li, 2010) and recognize EKG heart rhythms (Goh et al., 2006), and Bayesian classifiers which have been used to classify bone fractures and diagnose ischemic heart disease (Kononenko, 2001). These approaches may also be used to validate new clinical guidelines using historic data.

Other Artificial Intelligence Methods in Medicine

Knowledge-based systems and soft computing methods such as artificial neural networks have been highlighted above, but other artificial intelligence research regularly impacts the field of medicine and the world around us. Two such artificial intelligence methods are natural language processing (NLP) and intelligent agent systems.

NLP has been around for a long time and has resulted in some products which many individuals no longer associate with artificial intelligence (Patel et al., 2009). One such tool is the Dragon natural language system that enables clinicians to dictate their notes using a mobile tablet directly to a patient's EHR without need of further transcription and thus time and costs to their medical organization (Peek et al., 2015). As recently as 2006, voice recognition systems were not widely available in hospitals (Ward et al., 2006). Due to the nature of unstructured physician and other clinical personnel communications and notes, NLP is a critical resource for finding, documenting, and reasoning with medical knowledge.

Table 2. Artificial intelligence in medicine articles published in 2018

	Physician	Other clinicians	Hospital/clinic	Patient
Abdominal (endocrine, excretory, gastrointestinal, hepatic)	diagnostic ML (Feng et al., 2018); diagnostic random forest[1] (López et al., 2018); prognostic fuzzy random forest[1] (Saleh et al., 2018)	prognostic (kidney) ensemble (Kazemi & Mirroshandel, 2018)	N/A	diagnostic (kidney) agent & ANN (Abdelaziz et al., 2018); prognostic (diabetes) ML/CBR (Brown et al., 2018); (diabetes) ANN (Kang, 2018)
Anesthesia/ Surgery	prognostic fuzzy rule-based (Mendez et al., 2018)	N/A	N/A	N/A
Brain	diagnostic ANN (Lacy et al., 2018); prognostic fuzzy system (Garza-Rodríguez et al., 2018); diagnostic SVM & Bayesian (Mumtaz et al., 2018a; Mumtaz et al., 2018b)	N/A	prognostic SVM/ML (Lin et al., 2018)	prognostic SVM and ensemble (Hosseini et al., 2018)
Cellular	diagnostic SVM (Rahman et al., 2018)	N/A	N/A	N/A
Circulatory/ Heart/Blood	diagnostic HMM (Akrivos et al., 2018); diagnostic ML (Gunčar et al., 2018); prognostic ML (Kalscheur et al., 2018)	N/A	diagnostic SVM & ANN (Hu et al., 2018)	prognostic (malaria) Bayesian (Haddawy et al., 2018)
Disease (non-specific)	N/A	N/A	N/A	prognostic (infections) KBS[2]/ML (Shen et al., 2018)
Elderly/Aging	N/A	N/A	prognostic (falls) ANN (Beauchet et al., 2018)	N/A
Oncology	prognostic ANN (Walczak & Velanovich, 2018); diagnostic ML (Xiao et al., 2018)	prognostic ANN (Lee et al., 2018)	N/A	N/A
Opthamology/ Eye	diagnostic ANN ensemble (Orlando et al., 2018); diagnostic ML (Samant & Agarwal, 2018)	N/A	N/A	N/A
Resource planning	N/A	NLP/text analytics for note extraction (Moradi & Ghadiri, 2018)	Markov model for patient scheduling (Li et al., 2018); genetic algorithm for ER planning (Yousefi et al., 2018)	N/A
Respiratory/ Lung	diagnostic ANN (Tajbakhsh & Suzuki, 2018)	N/A	N/A	N/A
Trauma	diagnostic Bayesian (Schetinin et al., 2018)	N/A	GA/ANN ensemble for patient scheduling (Jiang et al., 2018)	diagnostic ML (Nijeweme-d'Hollosy et al., 2018)

NLP may be used to examine and determine applicable clinical guidelines to enable physicians to adhere to existing guidelines. One example is a natural language based clinical decision support system which outperformed domain experts in identifying optimal surveillance periods, according to the guidelines, for colon cancer Imler, Morea, & Imperiale, 2014). Another example is an NLP system embedded

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

in an EHR that automatically identified heart disease risk factors from the clinical notes of office visits (Khalifa & Meystre, 2015). Other examples of NLP based clinical decision support systems may be found in Demner-Fushman, Chapman, and McDonald (2009).

Intelligent agents have a long history in the field of medicine as well as more general use. Many people already take advantage of intelligent agents whenever they perform a web search. Early agent-based systems in medicine performed patient appointment reminders and scheduling (Silverman, Andonyadis, & Morales, 1998). Agents enable rapid and efficient search of medical data (Isern, Sánchez, & Moreno, 2010), which is frequently spread across numerous databases, the EHR, and other sources. Recently agents have been employed to deliver treatment planning and monitoring over mobile devices (Chan, Ray, & Parameswaran, 2008; Horan & Schooley, 2007; Santos et al., 2016). The numerous sources and distributed nature of clinical information makes intelligent agents an ideal methodology for working with this type of data.

CHALLENGES AND ROADBLOCKS TO ADOPTION OF ARTIFICIAL INTELLIGENCE IN MEDICINE

As indicated previously the largest challenge for artificial intelligence in clinical decision support systems is acceptance and adoption by physicians. The underlying reasons are often not technological in nature, but stem from organizational, monetary, or cultural reasons (Patel et al., 2009). Additional reasons for the non-acceptance of artificial intelligence-based decision support systems include interruption of workflow, dislike of template-like treatment plans (especially from clinical decision support systems), and wariness of administrative oversight and intervention enabled by HIT systems (Romanow, Cho, & Straub, 2012). One path for improving acceptance and consequent utilization of artificial intelligence-based decision support in clinical systems is the widespread integration of these techniques into existing HIT systems, such as EHRs, which will help alleviate workflow concerns. Other methods to improve acceptance fall into traditional user interface design through creation of simple and easy to understand interfaces to increase perceived ease of use by healthcare professionals. Even when accepted, physicians and other clinicians may feel that artificial intelligence enhanced EHRs have other negative impacts such as reduction in desired social rituals and perceived increase in burnout from alert overloads (Verghese, Shah, & Harrington, 2018).

Heuristic problem solving does save time when datamining medical data sources. However, the heuristic nature of most of artificial intelligence in trying to mimic and surpass human expertise does not always produce the optimal answer. Therefore, it is incumbent on artificial intelligence researchers to build in safeguards and remind medical personnel that the clinical recommendations may require further analysis. The users of artificial intelligence based clinical decision support systems must be educated to understand that these systems can and do make errors, even if errors are less frequent than their human counterparts. For example, an oncology physician may make a correct diagnosis 90 percent of the time and decides to use an artificial intelligence clinical decision support tool which has been shown to deliver accurate diagnosis 95 percent of the time (a 5 percent overall improvement), but this still implies a 5 percent error of misdiagnoses.

While one of the advantages for using expert systems is their explanation facility, informing users of the reasoning employed to make a decision, soft computing artificial intelligence methods such as artificial neural networks and genetic algorithms operate more as a black box. While it is possible to

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

generate rules from these black boxes (Hayashi, 2013) and consequent explanations, the process is not commonly used. As indicated above, this doesn't mean that these artificial intelligence methods should be ignored, but rather that discretion is required in applying them to obtain optimal clinical outcomes. The black box nature may also be better accepted by medical personnel as explanation facilities could cause an interruption to the workflow which in turn would lead to non-acceptance of the artificial intelligence clinical decision support tools.

When MYCIN (Shortliffe et al., 1975) was first introduced, artificial intelligence research demonstrated that similar results could be obtained utilizing other artificial intelligence-based methods, such as Bayesian reasoning (Adams, 1976). Yet et al. (2014) point out that simply building models that fit data well is not as important as providing high quality information to healthcare decision makers, both care givers and recipients, to enable optimal healthcare outcomes for the patients. Thus, new research in clinical decision support must keep in mind the desired end goals of improving decision making and the quality of health outcomes. Therefore, clinical artificial intelligence decision support systems must satisfy several criteria (related to technology acceptance): high quality recommendations that fit within existing workflow (perceived usefulness) and results that are easy to interpret and understand (perceived ease of use).

It is critical for artificial intelligence in medicine researchers and application designers to focus on clinical workflow. Additionally, making decision support systems easy to understand and navigate will also increase utilization. Working with the targeted healthcare users of the artificial intelligence clinical decision support is a necessity that cannot be overlooked if these systems are to be used and ultimately improve healthcare processes and outcomes.

CONCLUSION

Clinical information systems and particularly clinical decision support systems are leading the way in improving access to clinical data, improving clinical decision making, and improving the quality of care delivered to patients (Ward et al., 2006). This article has shown how artificial intelligence research and applications serve to further improve decision making in the clinical process from triage to diagnosis to treatment planning.

Artificial intelligence soft computing methods are widely used to perform medical data mining. In addition to acquiring, mining, and organizing medical data, artificial intelligence applications may also serve as a knowledge repository by capturing and preserving clinical expertise and other clinical decision-making protocols or guidelines. This expertise may then be shared and utilized by other clinical personnel as well as directly consumed by patients.

Patients are benefiting from artificial intelligence research applications to become better informed health consumers. Intelligent agents serve to locate reliable health information to assist with patient decision making (Santos et al., 2016) and also to assist with monitoring and following treatment plans (Silverman, Andonyadis, & Morales, 1998). Expert systems and natural language processing assist patients in understanding medical jargon including laboratory tests (Semenov & Kopanitsa, 2016). Future artificial intelligence research should continue to provide applications for patients.

Artificial intelligence research in medicine and applied in clinical decision support systems will continue to improve the efficiency and effectiveness of care while simultaneously helping to reduce healthcare costs. Applications of artificial intelligence decision making must respect the clinical work-

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

flow. One way to accomplish this is to continue research on embedding artificial intelligence applications into existing clinical decision support systems already used by physicians and other medical staff (El-Sappagh & El-Masri, 2014), such as EHRs.

Ideally, artificial intelligence research in clinical decision making is focused on making sure that the correct diagnosis is always made and the optimal treatment plan for each patient is discovered. Artificial intelligence in medicine research however needs support and funding to accomplish these goals. Governments and other investors need to continue funding and promoting artificial intelligence research so that the quality of clinical decision making may continue to be improved for the timely, cost effective, and high-quality delivery of care in clinical settings.

ABSTRACT

As part of a data mining competition, a training and test set of laboratory test data about patients with and without surgical site infection (SSI) were provided. The task was to develop predictive models with training set and identify patients with SSI in the no label test set. Lab test results are vital resources that guide healthcare providers make decisions about all aspects of surgical patient management. Many machine learning models were developed after pre-processing and imputing the lab tests data and only the top performing methods are discussed. Overall, RANDOM FOREST algorithms performed better than Support Vector Machine and Logistic Regression. Using a set of 74 lab tests, with RF, there were only 4 false positives in the training set and predicted 35 out of 50 SSI patients in the test set (Accuracy 0.86, Sensitivity 0.68, and Specificity 0.91). Optimal ways to address healthcare data quality concerns and imputation methods as well as newer generalizable algorithms need to be explored further to decipher new associations and knowledge among laboratory biomarkers and SSI.

INTRODUCTION

Surgical Site Infections are one of the most common Hospital Acquired Infections (HSI). The United States based Centers for Disease Control and Prevention (CDC) has developed criteria, as part of its SSI surveillance program, that define surgical site infection (SSI) as any infection that occurs at or near the surgical incision after an operative procedure within 30 days of the procedure, expanded up to 90 days if prosthetic material is implanted at surgery (Horan, Gaynes, Martone, Jarvis, & Emori, 1992). SSIs are commonly confined to the incision site even though, they can extend deep into the underlying tissues. SSI is a significant burden to the post-operative patients, overall responsible for up to 30% of all hospital acquired infections and complicates 23% of abdominal surgeries (Magill et al., 2012; Aga et al., 2015; de Lissovoyet al., 2009). SSI contributes to increased morbidity, poor quality of life, mortality (up to 3%), prolonged hospital stay (up to 10 days), increased readmission rate and healthcare expenditure (Owens, Barrett, Raetzman, Maggard-Gibbons, & Steiner, 2014). There are many known and yet-to-be-known factors that play a role in SSI and a clear understanding of those factors are needed to reduce SSI and improve surgical outcomes (Lawson, Hall, & Ko, 2013; Ke et al., 2017).

LABORATORY TESTS IN THE ERA OF BIG DATA

One of the time-tested resource that has played a significant role in helping providers make decisions about choosing patients, readiness for surgery as well as intra and post-operative management are laboratory test results, such as blood counts, blood sugars including metabolic panels and inflammatory markers. These lab test results are indispensable for all aspects of patient management. The information content in lab test results could be a valuable resource to decipher unknown associations between various post-operative complications such as SSI.

Widespread adoption of Health Information Systems (HIS) including Electronic Health Records (EHR) and laboratory Information Systems has generated massive amounts of both quantitative data (e.g., laboratory values) and qualitative data (e.g., text based clinical notes), partly fueled by funding, by the Health Information Technology for Economic and Clinical Health Act of 2009. It is but inevitable that the big data management and analytics that are successfully applied in retail sales and other domains will be researched in healthcare (Murdoch & Detsky, 2013). Recent advances in computational machine learning methods and predictive modeling could be applied to analyze the information content of those lab tests and draw valuable knowledge from any associations with SSI (Sohn et al., 2017). But, clinical laboratory data (and most healthcare data) is inherent with various constraints that need to be addressed and pre-processed before applying machine learning algorithms. The sampling of lab tests is purely based on the clinical condition of the patient, as assessed by the providers, and thus the temporality of sampling is extremely variable in time/ space as well as the type of tests done. Some tests are usually done just once (e.g., ABO blood grouping) and some others are repeated multiple times (e.g., glucose, electrolytes, hemoglobin). Other than in research settings, only a core set of lab tests are done routinely on most patients during day to day clinical care and a subset of patients may be tested for disease specific lab biomarkers. This variability of sampling, both the type/ number of tests as well as temporality (time and space) contrasts with the statistical and predictive analytic tools which very much rely on systematic and regularly sampled data.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Choosing the relevant and representative features (lab tests) for a given data modeling task can be challenging, requiring significant domain expertise. Modeling with all or most of the represented laboratory tests in the patient population will have to address many missing values in the data matrix. Removing patients with missing data may lead to significant loss of sample size as well as inaccurate assessments and predictions. Thus, the clinical lab data could be sparse with many missing values in the dataset to be consumed by the predictive/statistical tools that have led to experiments with various imputation methods. Imputation methods have been successfully applied to simulate regular sampling to address the missing values. There are many imputation methods and ideal methods are still being sought and researched (Hu et al., 2017).

In this project, as part of a challenge by the American Medical Informatics Association Knowledge Discovery and Data Mining Working Group (AMIA KDDM WG), to develop better predictive models, the dataset had similar concerns. Researchers discuss the data preprocessing, imputation methods used and the various machine learning techniques – Random Forest (RF), Logistic Regression (LR) and Support Vector Machine (SVM) applied to develop predictive models.

METHODS

The data provided had all the features and analytic complexities of a big data - volume, variety, veracity, except that it was a static set of retrospective data lacking the 'velocity' of a big data. Cleaning and formatting the data for consumption by ML tools and choosing the clinically important and relevant lab tests as features for predictive modeling of the already dimension reduced data was the challenge during the pre-processing phase. Dimensions that are commonly associated with healthcare data such as presenting complaints, symptoms and signs, diagnoses and other investigations such as imaging, procedures, medications and clinical outcomes were not part of the data provided. Researchers propose a semi-automated computational method of the model development. Figure 1 illustrates the overall process flow of the proposed model. The training data set provided included a vast number of investigation results spanned over many days both before and after the day of surgery. Further, for some of the relevant investigations, data was sparse across the patient population and there were many missing values. Thus, the first part of the proposed method was to preprocess the data based on investigations, time frame and imputing the missing values. In the next step relevant features were extracted and a training model was built using appropriate and common machine learning algorithms. The performances of selected machine learning algorithm based models were evaluated to classify patients with SSI and patients without. The steps were repeated with the unlabeled test data, and after preprocessing the developed training models were applied to test data to discriminate and develop a list of potential SSI patients.

DATA DESCRIPTION

The training dataset had lab tests done on 909 patients with 183 patients having SSI and 726 not having SSI, and the test set had 228 patients with 50 having SSI, although data was blinded without SSI labels (Table 1).

As shown in Table 1, in the training set, males (54% of the population) were more prone to SSI compared to females (23.34% vs 16.22%). The age distribution was from 5 years to 110 years and most of

Figure 1. Preprocessing steps for feature selection

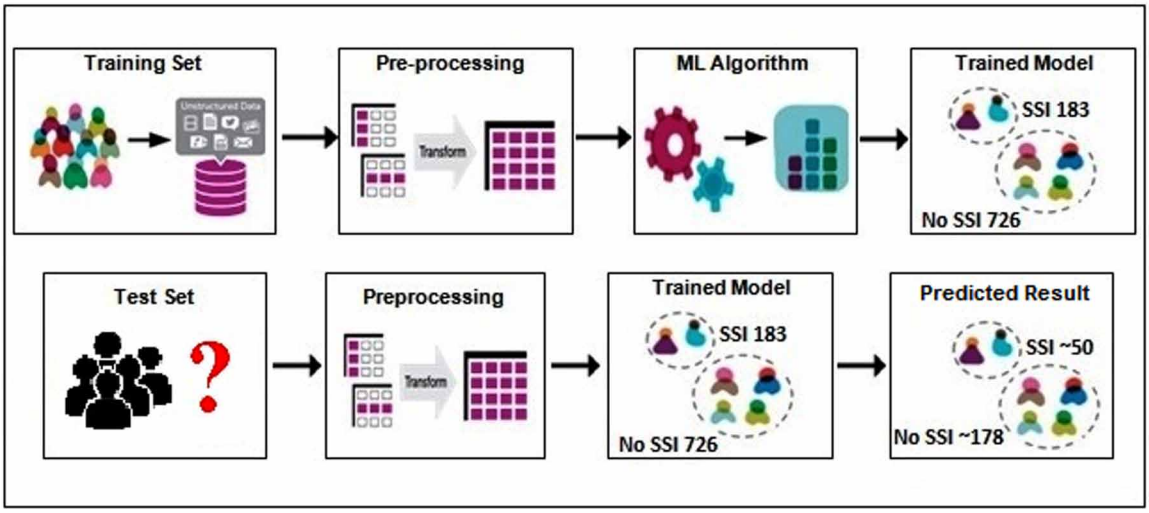

Table 1. Demographic distribution of patients in the training and test datasets

File Types	The Number of Cases Infected	The Number of Controls	Males	Females	Males Infected	Females Infected	Total Number
Training	183 (25.5%)	726	490 (53.91%)	419 (46.09%)	115 (23.34%)	68 (16.22%)	909
Testing	50 (28.08%)	178	123 (53.94%)	105 (46.05%)	?	?	228
	Who are those?						

the patients who underwent surgery were in the age group 50 to 80 years with the corresponding increase in infection rate. A small number of patients below age 19 and above 94 didn't have SSI (Figure 2).

With regards to the timing of blood tests to surgery, most patients had tests done before, on the day of surgery and in the post-operative period. About 32 in the training set (2 with SSI) and 6 patients in the test set had tests done only in the post-operative period, whereas 18 in the training set and 1 in the test set had tests done only during the pre-operative phase.

The data was from the department of Gastrointestinal Surgery at University Hospital of North Norway. The lab test types were in Norwegian and there was no associated metadata. There was a total of 504,675 blood test result records in the dataset having 811 unique lab test types. Not all the 811 tests were done on all the patients, probably based on clinical indications, for example, a tumor marker such as Carcinoembryonic Antigen (CEA) was done on patients with neoplasms. Only a small core subset (~10%) of them conducted routinely on significant patient population, at variable intervals, often repeated many times, and associated with many results.

Patients with lab test result values that were outside the normal range (abnormal) in the dataset were flagged with a star ("*"). However, the marking of test result values was variable with some high and low results not marked as abnormal (e.g., CPR of 295 not marked as abnormal with a star, normal <5)

compared to what is available in the literature, even though normal ranges were not provided by the organizers. The data spans over 15 years from 1994 till 2013 and over time, and it represents many methods to measure (e.g., biochemical assay, mass spectrometry) and different specimen sources (e.g., venous, arterial and capillary blood) for some of the molecules, with corresponding differing normal ranges. There were 5 different types of CRP (CRP, CRP (H, N), CRP sensitive, CRP TMS, CRP semikvantitativt). Most of them were in small numbers and were excluded during preprocessing, but, CRP (H, N) was in significant number, was treated as a separate test from CRP and in fact was ranked within the top ten relevant tests by all the three classifiers (LR, RF and SVM). Some of the data elements were of varied data types (e.g., date), adding to the complexity of handling such data. After cleaning the data, the major task was feature selection, to eliminate features that were identified clinically and statistically irrelevant and imputation to address the missing values to resemble regularly sampled data to be consumable by statistical/ predictive modeling tools to boost their performance.

DATA PRE-PROCESSING

Feature Selection

A series of procedures were identified and followed for feature selection. First, all the abnormal result values were extracted by pattern matching the star flagging (“*”) along with their test types. This gave a list of test types for which abnormal values were observed. If a test was not out of range during the study period (15 years) for many patients, it is possible that its potential to discriminate normal from abnormal is limited and may not add value with classifying patients as having an infection or no infection. This list of test types was reviewed and compared to the original test types by a clinician (PS) and observed that all the clinically important and relevant test types were in the list. Only these test types

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

were used for further data processing and rest of the test types were eliminated as they were deemed clinically irrelevant. Using the list of processed lab test types, all Patient IDs (PIDs) whose lab test types matched were identified to create a subset of PIDs. All the patients with SSI were further identified by the patient labels having 1 or 2 in the 'infection' column in the original dataset.

In the next step, after formatting the date data type, the dataset had records of a patient whose tests spanned 15 years before and after the surgery. Results of tests done more than 1 year before the day of surgery are unlikely to help with classifying infected and not infected, and lab test type value records of one year before and after the date of surgery (-1 to +1 year from surgery) were retained. The number of test types reduced to 174. Further if only one or very few patients had a test type, then that test type is probably not relevant for all. If a test has been performed on at least 10 patients with SSI, then such test types were preserved, and the remaining test types were eliminated which reduced the number of test types (features) to 107. This was further validated by a clinician. Researchers experimented with using mode or standard deviation for further feature selection (instead of 10 patients with SSI), but, no two test result values were same and selecting features based on two standard deviations resulted in the loss of clinically significant test types such as hemoglobin. The 107 test types were used as the training dataset to model using RF, SVM and LR and other records were eliminated. In a second model, the time duration was further reduced to 30 days before and after surgery, excluding the day of surgery, and the number of features further reduced to 74 test types, yet retaining all clinically relevant test types.

An analysis of population mean results of some of the frequently done tests distinctly demonstrated discriminatory potential, between patients with SSI and no-SSI, especially during the post-operative period (Figure 3). These mean values contributed in training the model taking a cumulative value for each test done on a patient for the considered span of time.

A data matrix was developed (Table 2), with test types in the x-axis and patient (PID) represented in the y-axis. For each PID, mean of values of Test (Test 1…Test m) for the patient for each test type is plotted. Not Available (NA) was substituted for records where test type was not conducted for a patient. For example, if HbA1c test is not done on PID 1234 then the table has a value NA.

Imputation Methods

To address the missing test type results, the within range (normal) values from training dataset was determined by extracting all test result values not being flagged with a star ("*"). The test types for each of these values were extracted and the mean of normal values for each test type was computed. This

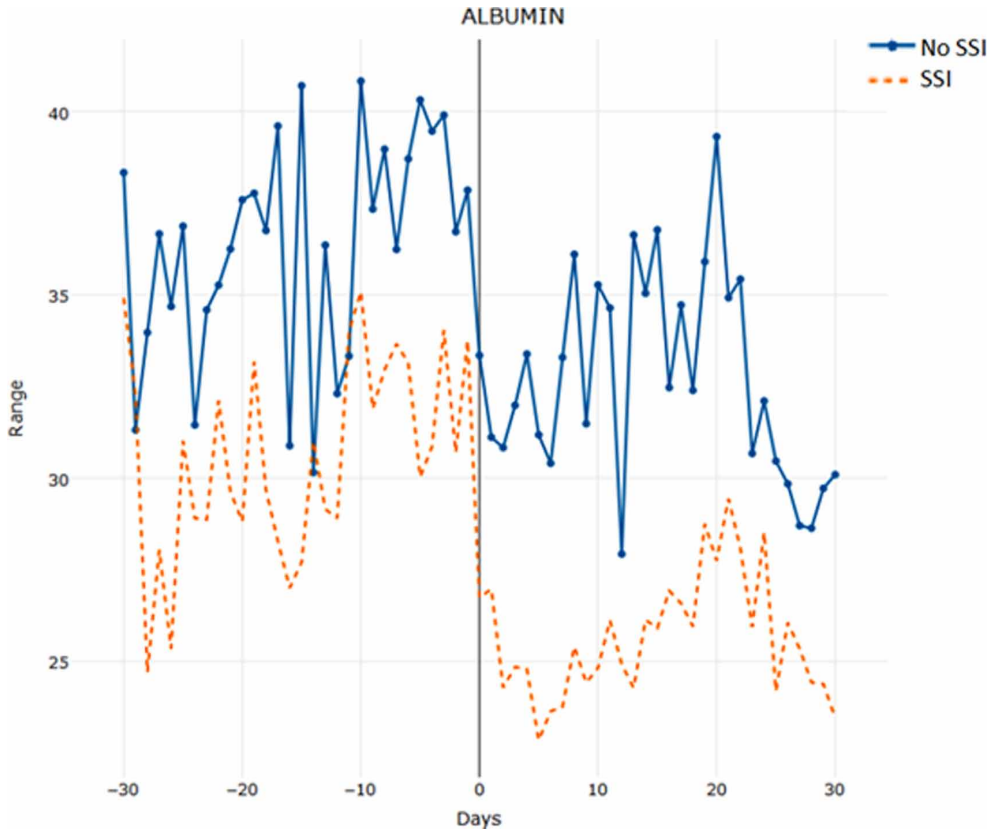
Figure 3. Sample Mean for Albumin 30 Days Pre-Post Surgery



mean was imputed for all missing lab test type result values (NA), both with SSI and without, in the final training dataset. The mean of 'normal' test result values were used to impute all the patients as the 'abnormal' test result values had a wider range, including a few outliers with extreme values. Soguero-Ruiz et al. (2015) proposed a way to impute values for the missing data but they did not consider the abnormal cases while imputing.

Machine Learning Methods

Machine learning is a branch of artificial intelligence and ML algorithms iteratively tries to understand and learn the pattern space and its associated labels. Once the pattern space is understood, they predict the incoming test patterns and assign appropriate labels. Supervised machine learning is tasked with inferring a function from the labeled training dataset. A detailed description of SVM, Random Forest and Logistic Regression is beyond the scope of this manuscript and a brief review is provided below.

SVM is a supervised machine learning technique. Training examples are mapped to points in high dimensional space using the values of the features. SVM computes a hyperplane and separates the positive points from negative points with the maximum margin. Test examples are classified as positive or negative based on which side of the hyperplane they belong. Random Forest is an ML method that creates an ensemble of decision trees, using dataset bagging, feature set bagging and other techniques.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Bagging is a procedure to reduce the statistical variance in the training data during tree splitting. RF uses averaging (voting) of the constituent decision tree classifiers to improve the accuracy of predictions and control over-fitting (Breiman, 2001). Logistic Regression is a widely used generalized linear classification model.

From the literature (Sanger et al., 2016; Van Esbroeck, Rubinfeld, Hall, & Syed, 2014; Gbegnon, Monestina, & Cromwell, 2014) it's evident that machine learning approaches are better suited for predicting surgical site infections. Random Forest (Liaw & Wiener, 2002; Statnikov, Wang, & Aliferis, 2008; Kuhn, 2012), SVM (Bennett & Campbell, 2000; Chang& Lin, 2011; Cortes & Vapnik, 1995; Schölkopf, Smola, Williamson, & Bartlett, 2000) and Logistic Regression were used to train, test and compare the accuracy of prediction by clinically relevant features.

Many models were developed, and researchers discuss some of the best performing models. Random Forest was the preferred method for various reasons:

- RF is an ensemble learning method for classification, regression and other tasks and randomization at many (data and model) levels.
- The data provided was already split 4:1 into training and test sets by the organizers and further splitting data into training/ test sets is usually not required for RF.
- Early modeling with the training data, RF performance was better than SVM and LR and researchers preferred RF for most of the modeling work.

RESULTS

After preprocessing and imputing the data as mentioned above, 1 year pre and post-surgery data with 107 test types were used to train models using three different ML methods SVM, LR and RF. Predictive models were evaluated with respect to two criteria namely classifier accuracy and clinical relevance of the lab test types (features) indexed by the algorithms.

The Receiver Operating Characteristic (ROC) curves are one of the most commonly used and key statistical tool to evaluate the accuracy of diagnostic tests in healthcare. They are often used to establish relationships between a continuous variable for a binary outcome. It represents 1-specificity and sensitivity pair, plotted as a graph for all possible threshold values, demonstrating the trade-off between false positive rate (1-specificity) and true positive rate (sensitivity) for the different possible cutpoints of a test (Yin & Vogel, 2017). The closer the curve follows the left-hand and top borders of the ROC space, the more accurate the test and the area under the curve (AUC) is a measure of test accuracy. Figure 4 shows the ROC of training data from all the three classifiers. It is evident from the ROC plot that false positive rate for logistic regression is high compared to SVM and RF.

Even though accuracy was variable between classifiers (SVM = 91.32%, LR = 89.24%, RF = 99.89%), some of the important lab test types selected are clinically relevant and already been implicated in the literature as predictors of SSI. The CRP, including CRP (H, N), Albumin and Platelets are identified by all the three methods as of high relevance (Ge et al., 2017). RF produced the best results with the training set with an accuracy of 99.89%, Sensitivity (SN) of 0.9945, Specificity (SP) of 1.0 and 0 False Positives. RF also predicted the most clinically relevant lab tests as evaluated by a clinician when compared to SVM and LR classifiers. Table 3 shows the comparison of different ML models with top relevance indexed features and their clinical importance among the infected and non-infected cohorts of patients.

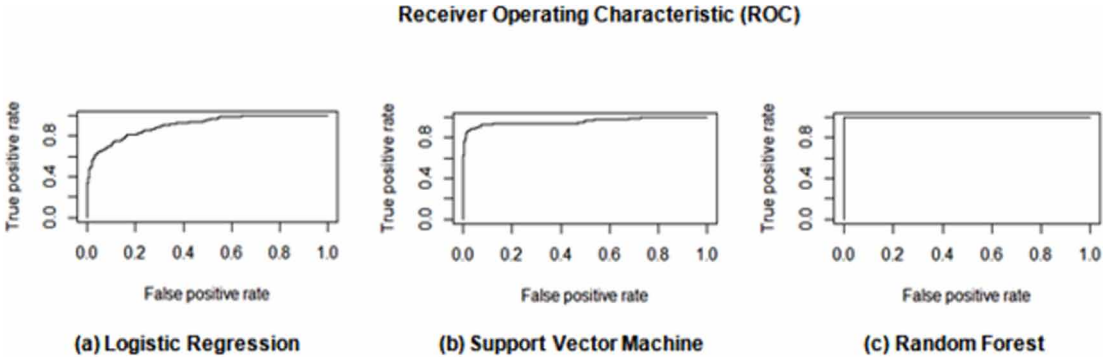
Figure 4. Receiver operating characteristics (ROC) for the training dataset using different classifiers



In the model using RF and top 10 features on test dataset, results of which were submitted to the organizers for validation, about 55 patients were predicted as having SSI, 5 more than anticipated. Once the test set SSI labels were made available, only 33 out of 55 patients were found to have SSI, with prediction Accuracy of 82.89%, SN 0.66, SP 0.87, Positive Predictive Value (PPV) 0.6 and Negative Predictive Value (NPV) 0.901. Among the many models the researchers developed, the 30 days pre-post, excluding the day of surgery (homeostatic perturbance are high on the day of surgery), produced the best results with 74 lab tests, correctly predicting 35 patients as having SSI in the test set (Accuracy 86.4%, SN 0.7, SP 0.91, PPV 0.686, NPV 0.915). The confusion matrix comparing the output of the above models, using RF classifier on test dataset, with true SSl labels are shown in Table 4 and test dataset ROC curves are shown in Figure 5. Even though questions about overfitting were raised, especially with RF, it was deemed unlikely with a training sample size of 897 (+/- 1 year) and 823 (+/- 30 days) and consistent performance by modeling with RF using various combinations of features (test types).

To check the least number of lab tests that may be able to predict SSI, researchers also developed models based on various combinations of the top 5 lab tests (CRP, Albumin, Leukocytter, Haemoglobin and Trombocytter), but, none of the combinations improved the predictive performance. In literature, Prealbumin and Procalcitonin have been found to be useful for predicting SSI. In the provided dataset, there were only 86 patients who had Prealbumin tests, 18 of them had SSI and the sample mean did not show any significant variation between patients with and without SSI. There were no Procalcitonin test results in the dataset (De Magistris et al., 2016).

CONCLUSION

The methods researchers followed for feature selection and imputation of missing data are implemented for the first time considering all the longitudinal lab test results of the patients. The pre-and-post-operative phases were not considered separately as the goal was to predict patients with SSI in the test dataset, fully utilizing the variations in test type results between patients, irrespective of the phase of surgery. This is particularly of importance as most patients were already ill preoperatively, requiring surgery, with abnormal blood test results (e.g., Hemoglobin, CRP, Albumin and Phosphate). Other contributing factors for abnormal test results such as comorbidities, blood and blood product transfusions, medications and other patient dimensions were not available. The performance of RF classifier was the best on the

processed data compared to SVM and LR, and identified the most clinically relevant test types (features) such as CRP, albumin, hemoglobin, platelets and leukocytes. As anticipated, the performance of models built on combined pre and post-operative data was better than preoperative data alone (1 year). This suggests that the information content and predictive value of certain lab tests and their longitudinal values are more robust at classifying patients with and without SSI, with continued monitoring during both pre and post-operative phases. Previous studies with machine learning tools have shown that, in general, thrombocytes, ALP, CRP, albumin, creatinine and leukocytes, were most useful features in predicting SSI (Soguero-Ruiz et al., 2015). The implicated lab tests also validate the many years of established clinical practice of dependence on those biomarkers to monitor SSI.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Feature selection is critical in any predictive modeling, and utilizing the top 10 features selected from the training set in the first model (1-year pre-post), RF classified the test set identifying SSI patients (55) more towards the target infected population of 50. However, the first model identified only 33 true positives in the test set (Accuracy 82.89%, SN 0.66, SP 0.87, PPV 0.6, and NPV 0.9). In the best performing model (30 days pre-post), 74 features were used, predicted about 51 patients as having SSI in the test set, among which 35 were true positives (Accuracy 86.4%, SN 0.7, SP 0.91, PPV 0.68, NPV 0.91). This suggests that given the test results, 91% of the time you can predict who may not get SSI whereas 68% of the time those who may get SSI. As anticipated, there was a reduction in accuracy, sensitivity, specificity, PPV and NPV between the training set and test set. However, the reduction in sensitivity and PPV are more evident compared to specificity and NPV. The decay in performance between training and test sets is probably related to many factors. The same feature selection methods used for training set (considering out of range lab tests only, 1 year and 30 days post-surgery, and tests done on 10 infected patients and above) could not be applied to test set as it would have resulted in eliminating patients in the test set. Excluding patients in the test set was not an option as researchers did not want to reduce the test set sample size and there also existed a potential of eliminating true positive SSI patients from the test set. Small test sample size, and imputation of feature values with the mean of the normal range of test types, could be other reasons. Researchers plan to test further models in RF as well as SVM with larger sample size to address many questions including an optimal set of features and imputation methods that improve predictive accuracy. Advances in neural networks may afford more generalizable algorithms to model and improve predictive performance.

It is clear from various experiments that the lab tests are important predictors of SSI that could help surgeons predict who may not or may get SSI, so that they can make informed decisions about appropriate preventative measures. With big data infrastructure and analytic tools, the above methods could be used to develop local live dynamic models, to predict at the bedside, who may not and who may get SSI, using lab test types and other patient parameters (Hu et al., 2015). This could be a valuable resource at a time where hospital acquired infections, including SSI, are a global menace further fueling the development of antibiotic resistance.

ACKNOWLEDGMENT

We would like to thank the AMIA Knowledge Discovery and Data Mining (AMIA - KDDM) Work Group Data Competition Program Committee, 2016, for organizing and conducting the competition and the University Hospital of North Norway for providing the data creating an opportunity for us to participate in the project.

Chapter 23
Towards Semantic Interoperability in Health Data Management Facilitating Process Mining

ABSTRACT

As an evidence-based business process analysis method, process mining can be used to investigate variations in delivery of care. Existing approaches are only based on one data source. A variety of data sources means different domain languages and understanding, special processes workflows in various organizations, varying documentation with different goals and different designations and varying use of coding systems. This article describes a modular, rule-based information extraction algorithm based on CDA and compares it to a proprietary healthcare reference model approach and a resource-based extraction of healthcare data using the new standard FHIR. All three approaches can be used to derive models to extract clinical and patient pathways. Similarities and differences according to interoperability and process mining tasks are described. It is concluded that standards-based approaches allow for more interoperability and can be used for a wide range of systems to provide process insight, thus facilitating better healthcare management across institutional boundaries.

INTRODUCTION

Efficient and patient-centered delivery of care across different hospital settings and healthcare providers requires intensive coordination between concerned organizations. Clinical pathways are used as management tools to define the best process in a healthcare organization, using the best procedures and timing, to treat patients with specific diagnoses or conditions according to evidence-based medicine (Panella, Marchisio and Di Stanislao, 2003). (Partington et al., 2015) propose the application of process mining as an evidence-based business process analysis method to gain insight into and enable comparative analysis of clinical practice and delivery of care across different organizations.

The objective of this publication is to give an overview of available models that facilitate process mining in Healthcare. Since information on (proprietary) models is often lacking, or not publicly available, the scope of this research is limited to models based on international standards, which are free of charge.

Existing approaches which use process mining for healthcare management are only based on data sources within one organization. More precisely the formal representation and the semantics (including code systems and value sets) of the different data sources are basically the same (Partington et al., 2015; Mans et al., 2008). To investigate variations in clinical practice and delivery of care across different healthcare domains, various data sources have to be taken into account (as shown in Table 1): Integrating the Healthcare Enterprise (IHE) and Health Level Seven (HL7) Clinical Document Architecture (CDA) are used in wide parts of the US and Europe as a technically interoperable solution to exchange healthcare data between healthcare providers (Franz et al. 2011). The use of standardized mechanisms increase the interoperability of information systems and minimize integration efforts (Norgall, 2003, Sunyaev et al., 2008). Nevertheless, there is still a lot of healthcare data exchange done using proprietary systems. New standards like HL7 Fast Healthcare Interoperability Resources (FHIR) try to cover this gap and allow a resource efficient data transfer (publication). OpenEHR and the use of ontology-based archetypes is another approach to allow interoperable healthcare data management. Since it uses SNOMED-CT (IHTSDO) to support automated clinical processes, which is subject to a fee, it is not taken into account in this article. (Mans, van der Aalst and Vanwersch, 2015) describe a (proprietary) healthcare reference model (HRM) that aims to help locating the needed data in healthcare information systems and thus facilitate the data extraction for process mining.

A variety of data sources means different domain languages and understanding, special processes and workflows in various organizations, varying documentation with different goals, varying structures in documentation, different designations and varying use of standards and coding systems. Thus, to extract data out of the (distributed) data sources and to transform them into the structure needed for process mining algorithms, preprocessing steps are necessary. This work describes and evaluates different approaches as a preceding step to enable the development of clinical pathways and medical guidelines.

Preceding Steps for Process Mining

Process mining algorithms work on event logs with a certain structure. Event logs must contain only data related to a single process and it must be ensured that all events in the log can be related to this process. Moreover, each event in the log must represent an activity and refer to a single process instance (case). The Extract, Transform and Load (ETL) steps preceding the actual process mining tasks describe: (a) extraction data from outside sources, (b) transforming it to fit operational needs (dealing with syntactical

Table 1. Overview of existing approaches that facilitate process mining, and reasons for in/exclusion in this publication

Model	Included / Excluded	Reason
FHIR	yes	Defining Processes and Documenting their Execution are part of the standard
HRM	yes	Used in scientific literature to enable process mining. Proprietary HIS models are often transposed into HRM for analysis.
openEHR	no	Use of SNOMED-CT to support modeling of automated clinical processes
Proprietary approaches	no	Publicly available information not sufficient
RIM (CDA/IHE)	yes	HL7 RIM is widely used in healthcare, including IHE profiles that define process(steps) for medical use-cases.

and semantical issues while ensuring predefined quality levels), and (c) loading it into the target system, e.g. a data warehouse or relational database (Van der Aalst, 2011). Thus, interoperability between various healthcare data sources is a prerequisite to allow for significant process mining.

BACKGROUND

Interoperability Between Healthcare Providers

Integrated care and the achievement of high quality healthcare over institutional borders require three levels of interoperability between different healthcare providers (Heitmann and Gobrecht, 2009, Serrano et al., 2015):

- **Technical Interoperability:** Exchange of meaningful, actionable information between two or more systems across organizational boundaries
- **Semantic Interoperability:** A shared understanding of the exchanged information
- **Process Interoperability:** An agreed expectation for the response to the information exchange and requisite quality (reliability, fidelity, security) of services and processes.

Since technical interoperability has been the focus of standards organizations, alliances and consortia for many years, standards and implementations supporting this level of interoperability are generally available (e.g. IHE, HL7). Strategies for informational interoperability, however, which includes the whole area of semantic and process interoperability, are less mature (Serrano et al., 2015). Since all three levels of interoperability are necessary to achieve high quality healthcare over institutional borders, the focus of this article lies on these types of interoperability for the comparison of the various modeling approaches. Using pre-defined use cases and based on the interoperability levels described above, the HRM-, the FHIR- and the CDA-approach are analyzed how they add semantic information to the models and whether they support the ETL process.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Healthcare Reference Model

(Mans, van der Aalst and Vanwersch, 2015) use the healthcare reference model (HRM) to compare processes of two different hospitals. The model was specifically designed for the healthcare domain to locate the data in the proprietary healthcare information systems, thus facilitate the data extraction for process mining. The HRM was developed in reverse engineering the data model of a running i.s.h.med[1] hospital information system (HIS) based on the actual database table structure, expert interviews and hands-on inspection validated via interviews with HIS professionals of other hospitals (Mans, van der Aalst and Vanwersch 2015).

The HRM data model comprises 122 UML classes, which are grouped in several sub-models such as General Patient and Case Data, Radiology and Document Data and include the key elements needed for process mining (Mans, van der Aalst and Vanwersch, 2015). The developers of the HRM do not claim completeness of the model since HISs of different vendors may contain data not present in the model.

Reference Information Model

HL7 Clinical Document Architecture (CDA) is a well-established document-based exchange standard, specifically developed for the health sector to allow a uniform understanding of objects and processes in the healthcare environment. It defines the exchange of messages, document-based communications as well as cooperating services, their implementation and necessary infrastructural services (Benson and Grieves, 2016). The core is described in Refined Message Information Models (R-MIM), which are derived from the HL7 Reference Information Model (RIM), which is a generic healthcare specific information model (Kühne, 2006). The base of this model are four core classes (Act, Entity, Role and Participation) and two additional classes (ActRelationship and RoleLink). The use of RIM provides specifications to structure, type, content as well as semantics, used vocabulary and underlying processes necessary for data transfer and interoperability, following a top-down approach.

For the representation of clinical and patient pathways HL7 proposes the care plan model, for which a three-layered modelling approach was applied to allow separation of business, information and interoperability requirements (HL7, 2016):

- **Layer 1:** The Care Plan Conceptual Model identifies necessary concepts and the relationships between them. It consists of an abstract concept Plan that is associated with further concepts, e.g. Care Giver, Patient, Provider, Activity. These are directly derived from high level business requirements and thus build the foundation for the consecutive layers.
- **Layer 2:** The Care Plan Organizing Framework builds the meta-model for coordination of care interaction and collaboration and defines relationships between a subset of the concepts defined in layer 1.
- **Layer 3:** The Care Plan Logical Information Model adds data properties to the concepts defined in the preceding layers, which captures information relevant for dynamic coordination of care interactions and point in time data exchange.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

The resulting care plan structure is thus applicable in a wide range of scenarios and use cases (HL7, 2016), consisting of discipline- or treatment-specific plans as well as comprehensive multidisciplinary plans, e.g. in case of tumor board review meeting. An implementation of the Care Plan Model defined by HL7 is currently developed as part of HL7s standard Fast Healthcare Interoperability Resources and the CarePlan resource respectively.

Fast Healthcare Interoperability Resources

Fast Healthcare Interoperability Resources (FHIR) is a resource-based data exchange standard for healthcare information. FHIR resources can be viewed in different formats, such as a Structural View, UML, XML, JSON and Turtle for understanding and rapid prototyping. Further, FHIR Resources contain mapping information to the HL7 RIM, defining which fields of a resource correspond to which RIM concept. All resources, which are currently defined in HL7 FHIR, are listed in the current STU 3 version (HL7 2018). FHIR follows the Pareto Principle, better known as the 80/20 rule, and thus defines only the data exchange information 80% of identified use cases require. Specializations for the other 20% that may be required, can be modeled by implementers using Extensions and Profiles (Benson and Grieves 2016). FHIR is being updated regularly, with the next release planned in spring 2018.

FHIR is organized in different levels building upon each other:

- **Level 1:** The basis of the standard, such as the API description, Data Types and Data Formats.
- **Level 2:** Security and Implementer information as well as Terminology Bindings and Conformance Resources such as Structure Definitions describing FHIR Resources.
- **Level 3:** Contains the basis for real world use-cases such as the Patient and Practitioners.
- **Level 4:** Deals with data exchange in healthcare including clinical, diagnostic, medical, financial and workflow data.
- **Level 5:** Describes clinical reasoning and contains resources enabling automation in that sector.

MODELING CONTEXT-SPECIFIC PATHWAYS

This section describes how the HRM, CDA and FHIR can be used to model clinical and patient pathways, while taking context into consideration.

Using HRM to Model Pathways

For the HRM the definition and execution of pathways is described using 10 UML classes (see Figure 1). A pathway (pathway) consists of multiple items (pathway item) which may be connected to each other (connection). A pathway is executed for a patient (patient pathway) and information about each performed step is recorded (step of patient pathway). Finally, each performed step may be linked to a service that is executed for the patient (services performed) (Mans, van der Aalst and Vanwersch, 2015).

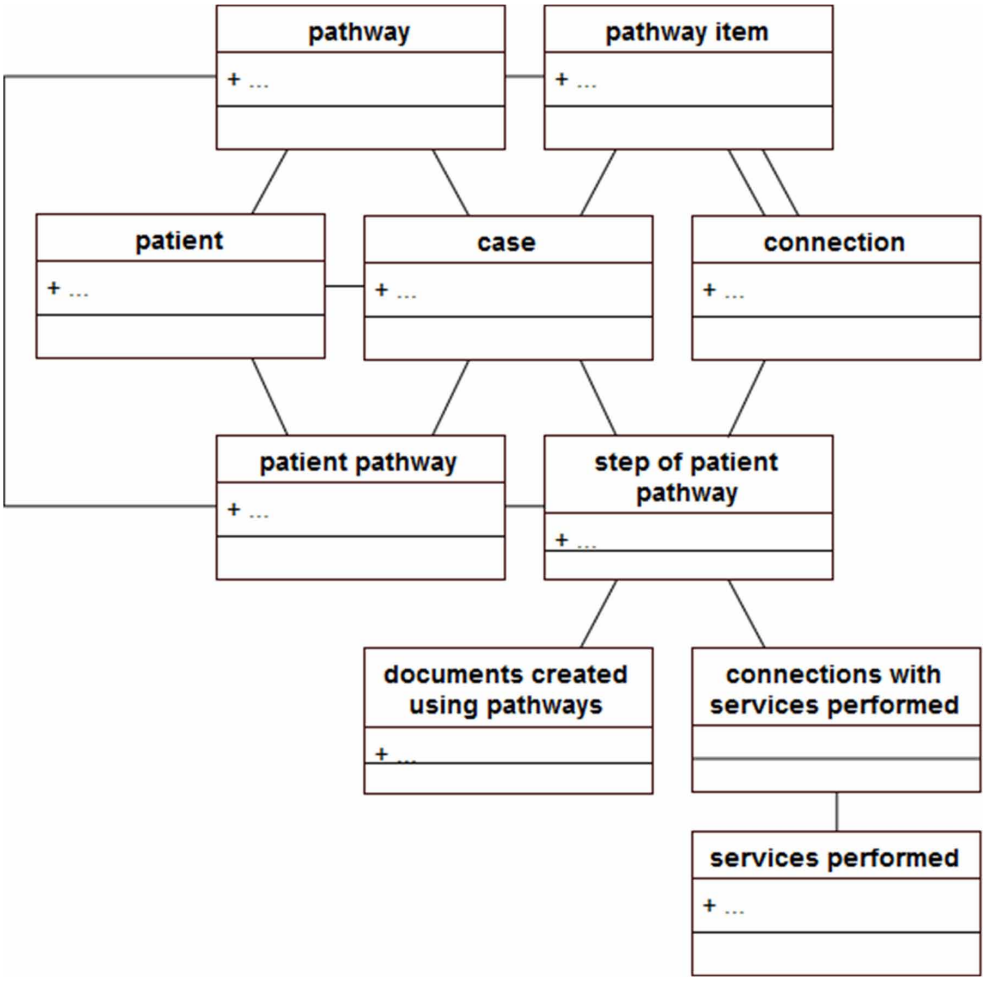
Figure 1. The UML classes used to describe clinical pathways in the HRM. The original figure in (Mans, van der Aalst and Vanwersch, 2015, p. 49) also contained the ~150 attributes of those classes and provides cardinalities for the relations

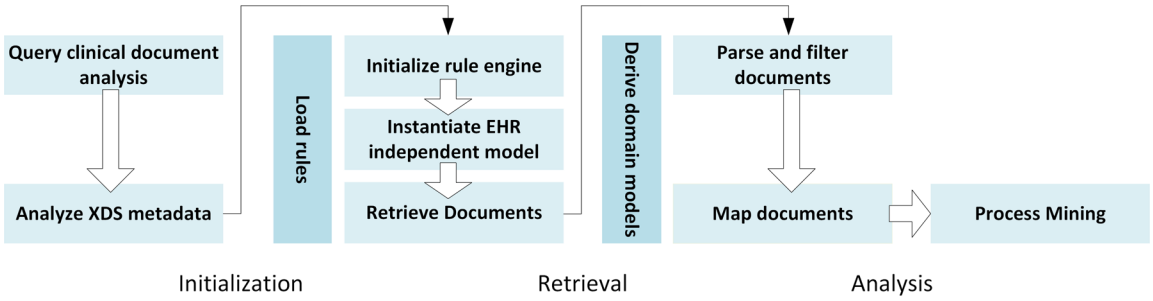


Using Clinical Document Architecture to Model Pathways

Integrating the Healthcare Enterprise uses existing standards such as CDA to enable healthcare interoperability. The IHE IT Infrastructure framework describes the profile Cross-Enterprise Document Sharing (XDS), which can be used to store and transmit medical documents. The XDS metadata allows to derive rules for creating an electronic health record (EHR) independent model (see Figure 2). The RIM model, which CDA is based on, can be used to develop a model for the healthcare data and documents. This model guarantees that data is structured in such a way that it is easily interpretable. This is necessary to develop a semantic model based on different data models. For example, for nursing care, it could describe the content of the care summary, its semantics and interpretation to guarantee semantic interoperability. This requires standardized structures for documents and a common language between the mentioned healthcare service levels, which is defined in documentation guidelines and schematron

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. Modular, Rule-based Information Extraction Algorithm



rules. Provided terminologies can be accessed through a terminology server. In order to define key issues e.g. for the above-mentioned care summary example, the semantic model has to be developed in cooperation experts, in this case with healthcare personnel, favoring the use of internationally accepted and validated standards, for example. Thus, a basis for cross-enterprise exchange of care information is developed which provides the basics for the integration of healthcare service providers and process models.

Using Fast Healthcare Interoperability Resources to Model Pathways

The definition of clinical pathways in FHIR is modelled with the *PlanDefinition* resource, which defines a goal that shall be achieved and a set of actions to achieve that goal. Actions have a timing when they can/should occur, as well as trigger definitions and conditions if and when they are applicable. Each action has participants, explaining who is involved in the action and relations to other actions (HL7 2018), which allows the definition of highly complex clinical pathways. The FHIR *PlanDefinition* resource represents only an abstract concept of what should happen in a medical pathway and does not relate to a specific context such as actual patients or groups of persons.

To specify context-specific clinical pathways, such as one real patient to be treated, *CarePlan* resources can be used, which is based on a PlanDefinition, but can modify defined steps as needed for patient-specific treatment. Additionally, it documents activities, e.g. the steps performed during execution of the CarePlan and accompanying treatments. Each activity includes a template of what is going to happen (resource draft), or alternatively contains the resource that documents what happened. An example is a *MedicationRequest* documenting the administration of a medication, or an *Appointment* for the next treatment. Unlike the *PlanDefinition*, the steps in a *CarePlan* have no relation to each other (HL7, 2018).

Using FHIR, security auditing can be specified, which can be used for a fine-grained view of a medical pathway. The *AuditEvent* resource documents every single access to a FHIR resource according to the Five Ws (Who, What, When, Where, Why). Additionally, the *Provenance* resource tracks similar information when a resource is being modified (HL7, 2018).

Comparison

All three models support modelling clinical pathways. The HRM provides clearly defined classes to enable the modelling. CDA is based on the RIM and provides a document structure that enables mapping of documents to mine patient pathways from them. HRM and FHIR have clearly defined structures that make

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

modelling of pathways possible in one structured overview. In comparison, the view of CDA is distributed over several documents which need to be collected into one. CDA and FHIR enable semantic interoperability by using codings and value sets that define these codings. Such a mechanism is lacking in HRM. Both HRM and FHIR contain methods of logging an executed process, and allow the modelling of such logs. CDA itself is missing this functionality, but is provided similar mechanisms through IHE Auditing.

Interoperable ETL Approaches

To achieve high quality healthcare over institutional borders, all three levels of interoperability defined in the background, are needed between different healthcare providers. Based on existing use cases and using the methods for modelling clinical pathways, the HRM approach, the CDA approach and the FHIR approach are analyzed concerning semantic interoperability, especially how they add semantic information to the models, and process interoperability with focus on whether they support the ETL process. A detailed overview can be found in Table 2.

Analysis of the HRM

The analysis of the HRM is based on six use cases listed by (Mans, van der Aalst and Vanwersch 2015), where data described via the HRM was gathered from hospitals and used for process mining tasks like model discovery, conformance checking, bottleneck analysis and comparative analysis.

ETL Using the HRM

According to (Mans, van der Aalst and Vanwersch 2015), the HRM is instrumental in locating the data needed and facilitating the actual extraction. It supports the ETL process by giving the analysts an idea about what kind of process-related data can be found in a HIS.

The abstract HRM does not directly refer to the database structure and thus does not support the operation of *Extracting* of data. The *Transform* and *Load* steps of the ETL process are not described (Mans, van der Aalst and Vanwersch 2015).

Semantics in the HRM

The HRM model does not explicitly refer to code lists, structured value sets or nomenclatures. Attributes listed in the UML classes are identified by name, the semantics for those attributes are not provided in the textual description of the models (Mans, van der Aalst and Vanwersch 2015).

Analysis of HL7 FHIR

The FHIR approach was analyzed using a system for Multidisciplinary Team Meetings (MDTM) as described in (Krauss et al., 2017). MDTM are modeled in HL7 FHIR using the *PlanDefinition* resource. The models are then automatically transformed into the Business Process Model Notation (BPMN) and executed with a Workflow Engine. The process is documented using the *CarePlan* resources as well as FHIR *Auditing*. An ETL process, as described in the preceding section, could generate XES Event Logs, subsequently enabling Process Mining.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

ETL Using FHIR

FHIR implicitly enables the entire ETL process. The *Extraction* from a data source is a given for any healthcare system implementing the FHIR standard, as the FHIR API allows reads and searches on resources.

The *Transformation* process can be executed directly in FHIR. In addition to the *ConceptMap* which allows semantic transformations, the *StructureMap* allows the mapping of any FHIR Resource to (or from) any other *Concept* defined by a *StructureDefinition*. This allows the implementer the definition of *StructureDefinitions* tailored to the exact requirements of the process-mining target. From there the *StructureMap* can describe how a regular FHIR resource can be transformed into the required structure – e.g. the eXtensible Event Stream (XES) used in recent process mining tools (Verbeek et al. 2010). Since the *StructureMap* contains machine-executable rules for transformation this mapping can be done fully-automated in a standardized way.

The *Loading* of the transformed resources can be achieved in several different ways. For one the FHIR API once again allows the access to the transformed resources similar to the *Extraction* process. Alternatively, the data-mining application can use the FHIR *Subscription* service to receive push messages while the process is executed. In another push-based approach one can create a FHIR *Operation* that publishes the transformed resources directly to the data mining application.

Semantics in the FHIR Model

Machine readable semantics of FHIR resources are handled through *Codings* that represent fields of resources, similar to *Codings* in the HL7 RIM. Each *Coding* consists of a *System* that defines the Code, the actual *Code* for machine-readability, and a *DisplayName* for human-readability. HL7 FHIR uses LOINC, SNOMED CT, HL7v3, ICD-10, and DICOM among others. (HL7 2018)

FHIR enables the restriction of allowed values in a *Coding*, and often provides default sets, or enforces usage of a specific set. This is documented in the *ValueSet* resource which groups *Codings* into a set. To enable semantic interoperability between different *Codings* the *ConceptMap* Resource exists to define unidirectional mappings between *ValueSets*. In addition, FHIR defines a *Terminology Service* specification that uses these resources to enable usage and transformation between *ValueSets* (HL7 2018).

Comparison of the Interoperability Status

The described models allow the interaction of technical components and systems. Further, they enable a larger interconnected system capability that transcends the local perspective of each participating subsystem, which complies with the technical interoperability defined by (Serrano et al., 2015). Besides technical standards, agreements are essential, how medical and domain specific terminologies are used, which have to be maintained and further developed over time. This way it is possible to relate pathways across various healthcare institutions, while preserving the intended meaning, which conforms to the definition of semantic interoperability in (Heitmann and Gobrecht, 2009). Thus, the analysis of non- and semi-structured health information should be based on a semi-automated approach, which allows semantic enrichment of the extracted and transformed models and provides semantic services to access terminology descriptions.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 2. Evaluation of model approaches based on interoperability levels

	HRM	FHIR	CDA
Use Case	Evaluation is based on use cases listed by (Mans, van der Aalst and Vanwersch 2015).	Multidisciplinary Team Meetings (MDTM) as described in (Krauss et al. 2017).	Based on the various definitions by IHE Technical Infrastructure
ETL	Supports parts of the ETL process. It does not support the operation of Extracting of data. The Transform and Load steps of the ETL process are not described (Mans, van der Aalst and Vanwersch 2015).	FHIR implicitly enables the entire ETL process.	Not supported in CDA as it only defines the data structure. Entire ETL enabled by IHE Profiles.
Semantics	No specification of semantics	Semantics specified through codings. ValueSet defines valid codings. ConceptMap enables unidirectional mapping between Valuesets Terminology Service enables usage and transformation between ValueSets.	Semantics specified through codings. ValueSet defines valid codings.
Interoperability	Complies to the technical interoperability defined by (Serrano et al. 2015).	Conforms to the definition of semantic interoperability in (Heitmann and Gobrecht 2009).	Enables technical and semantic interoperability due to implementation guides.
Automatic semantic interoperability	No since no form of coding exists.	Yes, through Terminology services. Process-Interoperability also possible with PlanDefinition	Yes.

Since the HRM model does not explicitly refer to code lists and semantic details are neither provided in the model definition nor description, semantic interoperability can hardly be achieved in an automated way using the HRM.

For IHE and CDA-based health data communication, XDS metadata as well as implementation guides and derived schematron rules are used to extract the clinical document types and which terminologies, coding sets and concepts are provided in the exchanged clinical information. Without a user-centred approach and the consideration of processes, semantic interoperability is not possible. Vice versa, knowledge about processes can only be extracted using semantic information provided by models. Thus, the information models are semantically enriched through aggregation and conversion of select information, profiles and codes based on the structure and requirements of the target domain. This not only allows the mapping of models from one domain to another (semantic) domain, which is partially based on (XSLT) templates, but further enriches derived process models and descriptions.

Thus, it also enables a sound interpretation of the content and enables to compare different data, find contradictory or incomplete data, and complete or correct the data. The models can also be used to check the plausibility of various values if the model supports similarity values. Through IHE compliance, the models provide interoperability across healthcare enterprises. Healthcare data can be exchanged electronically through the independent model, and the data can efficiently be combined/integrated and interpreted in context. Furthermore, these models allow the easy integration of further systems, services and processes.

For FHIR-based health data exchange, the operations framework is used to get definitions for a concept / find a concept within a ValueSet. Semantic interoperability is achieved using common information models and the terminology service, thus enabling process definitions in a certain domain as well

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

as across various domains or communities. The FHIR resources described above allow the definition (*PlanDefinition*, *CarePlan*) as well as the documentation (coarse granularity: *CarePlan*; fine granularity: *AuditEvent*, *Provenance*) of a medical pathway. This also allows a comparison between what should happen versus what actually did happen, which can be used to further process interoperability as well as check, compare and evaluate clinical pathways in and across institutions.

CONCLUSION

This article compares healthcare data models, which facilitate process mining, on a conceptual basis and analyzes their ability to describe clinical and patient pathways. Models resulting of standardized approaches are, although partially complex, easier to analyze than proprietary models, as information on standardized approaches is publicly available and overcome the limitations provided by approaches based on singular (hospital) information systems (Tang et al. 2006). Furthermore, it describes how the model and their design approaches support the ETL process to prepare data from different sources for subsequent process mining. By analyzing the different approaches and their implications regarding the support of the ETL process, the use cases for the models become apparent. In the Epilogue of (Mans, van der Aalst and Vanwersch 2015) the authors highlight the importance of the HRM to reason about questions that may or may not be answered using process mining. Moreover the HRM produces awareness of the data present in a hospital.

It is concluded that a standards-based top-down approach, and the derived FHIR approach respectively, is able to provide similar insights and, on top of that, operational support for the ETL process on all interoperability levels. As described above, the main reason for that is the ability to (automatically) integrate data from different sources by taking their syntactic and semantic properties into account. The proposed standardized approaches enable the analysis of even complex processes, allowing mining results like the causes of the increased length of stay, the lack of some essential care interventions in the treatment, the problems in following clinical guidelines, the discovery new care pathways, the discovery of best practices, the anomalies and the exceptions which may exist in processes, providing a better understood where to take action to improve the healthcare processes.

In conclusion all three analyzed models - HRM, CDA and FHIR – allow the modelling of clinical pathways. HRM and FHIR have specific features for this, and CDA contains metadata that allows the reconstruction of such pathways. HRM partially supports the ETL process, with the exception of data exctraction. FHIR, and CDA through the use of IHE Profiles, support the full ETL process. FHIR and CDA contain enough information to enable automatic semantic interoperability. This is not provided by HRM.

All three models have their merit for process mining, and clear strengths and weaknesses depending on the specific Use-Case process mining is applied in:

- HRM is weak when requiring semantic interoperability. But its connection to various proprietary solutions, and clear modelling of pathways make it useful when dealing with non-standardized systems.
- CDA has a clear advantage over HRM concerning semantic interoperability. Its major disadvantage is that it does not contain a definition for clinical pathways itself, and so while the pathways can be extracted from CDA a different representation, or alternatively a HL7 RIM template, is required.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

- FHIR combines both advantages of HRM and CDA by being semantically interoperable and defining clear structures both for defining clinical pathways, as well as tracking them through execution. Its disadvantage over CDA is that, at the time of writing, IHE has little FHIR integration, making FHIR less widely used. The disadvantage over HRM is dealing with different standards or proprietary models. FHIR contains a Mapping Definition and Language to other models (not necessarily standardized!) but at the time of writing no publicly available implementation that enables automated transformations based on this definition exists.

Further research on the implementation of archetype-based systems should be conducted to complete the variety of data sources.

Chapter 24
A Secure Robust and Privacy Enhanced Mobile Healthcare Framework

Hisham M. Alsaghier
Majmaah University, Kingdom of Saudi Arabia

Shaik Shakeel Ahamad
Majmaah University, Kingdom of Saudi Arabia

ABSTRACT

This article describes how the exponential growth of mobile applications has changed the way healthcare services function, and mobile healthcare using the Cloud is the most promising technology for healthcare industry. The mobile healthcare industry is in a continuous transition phase that requires continual innovation. There has been identified some of the challenges in the area of security protocols for mobile health systems which still need to be addressed in the future to enable cost-effective, secure and robust mobile health systems. This article addresses these challenges by proposing a secure robust and privacy-enhanced mobile healthcare framework (SRPF) by adopting a Community Cloud (CC), WPKI cryptosystems, Universal Integrated Circuit Cards (UICCs) and a Trusted Platform Module (TPM). All the security properties are provided within this framework. SRPF overcomes replay attacks, Man in the Middle (MITM) Attacks, Impersonation attacks and Multi-Protocol attacks as SRPF was successfully verified using a scyther tool and by BAN logic.

1. INTRODUCTION

Mobile cloud computing (MCC) is a new technology based on mobile web services. MCC is likely to play a vital role in mobile healthcare. Mobile cloud computing (MCC) is an integration of cloud computing (CC) into the mobile healthcare applications of mobile devices. In the cloud healthcare data can be stored and transmitted to hospitals and doctors, but security and privacy of this information is the major drawback and bottleneck of healthcare systems so in order to overcome these flaws US govern-

ment introduced Health Insurance Portability and Accountability Act (HIPAA) to regulate US healthcare industry. Following are the motivations for adopting MCC in healthcare. MCC can improve healthcare services by providing Centralization, Performance, Modernization, Scalability, Portability, Collaboration and Virtualization. The main advantage of Mobile healthcare is it provides users easy and quick access to the healthcare infrastructures which includes PHR (patient health records) and doctors.

1.1. Motivations for the Research

1. According to ABI Research **a**ll the healthcare infrastructures are susceptible to attacks, in spite of this healthcare industry is spending very less amount for cybersecurity **(**Steven C. Morgan, 2015);
2. By 2020, 80 percent of healthcare data will be at cloud at some point of time (Julie Bird, 2016).

1.2. Related Work

(Mohammad Wazid, Sherali Zeadally, Ashok Kumar Das & Vanga Odelu, 2016)

Paper identifies some challenges in the realm of security protocols for mobile health systems which needs to be addressed in the future in order to ensure cost-effective, secure and robust mobile health systems. Following are the challenges outlined in this research work.

Challenge 1: Confidentiality, data integrity, accountability, availability, and access control are the most important security requirements for mobile health systems. For ensuring these security requirements, developing efficient key distribution protocols becomes challenging task in the mobile health system.

Challenge 2: Recent studies in the literature have shown that the public key operations (for example, elliptic curve cryptography) are practical in mobile devices. However, the Digital signature generation is very costly because of their computational complexity. Thus, efficiency of these credentials needs to be addressed. Since mobile healthcare applications deal with sensitive patient data, authenticity of the public keys should be efficient and cost effective to protect the data from unauthorized access.

Challenge 3: In contrast to public-key cryptography, symmetric key cryptography is superior and is easier to implement in term of its computational efficiency. However, symmetric key cryptography is not suitable because it relies on distributing the key in the mobile health system to provide different security services which include privacy of credentials, mutual authentication, and secrecy of session keys. Hence, designing efficient and flexible key distribution protocols for mobile healthcare applications needs to be addressed in the future.

Challenge 4: Obtaining passwords from unconscious patients is not possible so biometric mechanisms should be used for authentication. However, the biometric methods that work with unique biometric features from unconscious patients for identification purposes still needs further research attention in order to correctly authenticate an unconscious patient.

Challenge 5: The privacy of the information stored in the mobile healthcare application must be guaranteed. In this case, designing lightweight, efficient, and robust privacy enhancing techniques for the wearable sensors remains an area of future research.

1.3. Contributions Made

Secure Robust and Privacy enhanced Mobile Healthcare Framework based on Secure Element and Community Cloud: Formally Verified by BAN Logic and Scyther Tool.

Following are the contributions made by us:

1. We propose a Secure Robust and Privacy enhanced Mobile Healthcare Framework based on MHCC (Mobile Healthcare Community Cloud), CACC (Certifying Authority Community Cloud), UICC (Secure Element for both patient & Doctor) WPKI cryptosystems and Trusted Platform Module (TPM) at the Community Clouds;
2. We propose a procedure for personalizing mobile healthcare application at the patient and doctor side and a protocol in the proposed SRPF framework;
3. Our proposed framework consumes fewer resources as all the stakeholders are in the same Community Cloud (CC);
4. SRPF ensures Mutual authentication, data integrity, message confidentiality, Non-repudiation and Privacy (Patient) properties are ensured in this framework;
5. SRPF overcomes all the known attacks such as replay attacks, Man in the Middle (MITM) Attacks, Impersonation attacks and Multi-Protocol attacks as SRPF was successfully verified using scyther tool and BAN logic.

The rest of the paper is organized as follows: Section 2 proposes SRPF framework, Section 3 provides security analysis of the framework, Section 4 provides formal verification of SRPF protocol, Section 5 brings comparative analysis of the proposed framework with related work, Section 5 provides discussion, Section 6 concludes the work and the Appendix provides the SPDL code for SRPF and Results of SRPF in Simulation Environment provided by Scyther tool.

2. PROPOSED FRAMEWORK

2.1. Entities and Architecture of SRPF Framework

Our proposed secure mobile healthcare framework based on SRPF consists of the following participants:

1. **Patient (P):** Patient (P) is an important entity in the proposed framework possessing mobile phone with UICC;
2. **Trusted Service Manager (TSM):** Certifying Authority (CA) is responsible for issuing and authenticating of public keys. It issues certificates, binds public keys, manages serial numbers, and revokes certificates. Our Proposed framework allocates an additional responsibility of Trusted Service Manager (TSM) for CA. TSM is trusted by all the stakeholders in the ecosystem;
3. **Mobile Network Operator (MNO):** MNO is involved indirectly involved in this framework. It provides 4G connectivity and helps in enabling OTA (Over The Air) transaction. UICC of both the patient and doctor are issued by MNSP;
4. **Doctor:** Doctor is an important entity in our proposed SRPF framework;

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

5. **Mobile Healthcare Community Cloud (MHCC):** MHCC caters the needs of Healthcare services to the citizens. It provides services to the patients by bringing all hospitals in the same cloud. It uses mobile web services to connect the mobile web using internet technology. MHCC will be managed by the central government of the country. Mobile Healthcare Community Cloud (MHCC) consists of Hardware Security Module HSM's of hospitals personalized by the respective hospitals. The connectivity between MHCC and Patients are through 4G/5G networks protected by TLS protocol, ECDSA and AES algorithms. Our proposed MHCC caters the needs of Healthcare services to the citizens. It provides services to the patients by bringing all hospitals in the same cloud.

2.1.1. Components at the MHCC

1. **UDDI Registry:** UDDI registry contains information about MHCC services and communication standards and interfaces used;
2. **Secure Token Service (STS) Server:** This entity authenticates patients and doctors credentials which are issued by TSM and issues a token which is used to carry out transactions. Communication Manager (ComM) acts as a catalyst between patients, doctors and MHCC by establishing a secure and reliable communication channel thereby ensuring reliable communication security;
3. **Time Stamping Authority (TSA):** It offers time stamping services for the messages generated in the MHCC;
4. **Synchronization Manager (SyM):** The main responsibilities of Synchronization Manager include personalization of mobile healthcare application of both patient and doctor. It also exchanges encrypted messages with both patient and doctor and finally it ensures scalability in the framework;
5. **Security and Auditing Manager (SAM):** The Security Manager is responsible for managing the credentials of all the stakeholders such as user name, passwords, biometric data, public keys and symmetric keys. The Security Manager verifies the certificates of all patients and doctors before exchanging messages with them. The Security Manager archives all the evidences in its database, evidences include digital signatures, cryptographic hash of password and encrypted messages using symmetric keys and finally Logs are backed up once in a month. In case of disputes among the stakeholders SAM can provide proof in the court of law with Long term validity preservation of Digital Signature and encrypted messages (using symmetric keys) even after completely destroying/losing all the keys and ECDSA algorithm once signed can prove that data is valid – by matching confirmation data with log data, time stamps, nonce and old certificates;
6. **Certifying Authority Community Cloud (CACC):** CACC caters the needs of both PKI and Wireless PKI services to its citizens. CACC will be managed by the central government of the country. It provides security services to the citizens by bringing all the stakeholders (RA, TSA & Directory of CA) in the same community cloud. CACC will be managed by CA under the directions of central government of the country. CACC consists of Hardware Security Module HSM's for all the stakeholders and these are personalized by CA only. The connectivity between CACC and Patients are through 4G/5G networks protected by TLS protocol, ECDSA and AES algorithms. CACC contains a Registration Authority (RA) for checking the credentials of the patients, Time Stamping Authority (TSA) provides time stamping services, OCSP which helps in checking the validity of the certificates and Directory of CA maintaining all the X.509 and short lived certificates.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

2.2. Procedure for the Personalization of MHA and TPM in Community Cloud

Step 1: If Patient (P) and Doctor (D) does not possess public key then Hospital (H) acts as a Registration Authority (RA) for both Patient (P) and Doctor (D) for issuing certificates. Certification Authority (CA) issues both X.509 and Short Lived Certificates (SLC) to all the stakeholders. RA checks the certificate of the SEs of both Patient (P) and Doctor (D) and maps the serial number and SE certificate to the Patient (P) and Doctor (D) national identity. All the stakeholders in the proposed framework generate their credentials in the tamper resistant hardware such as Secure Element (Patient (P) and Doctor (D)) and the Trusted Platform Module (TPM)/HSM of the Hospital in the community cloud.

Step 2: Trusted Platform Module (TPM) of the Hospital in the community cloud builds the database of the registered Patient (P) and Doctor (D).

Step 3: All the Patient (P) and Doctor (D) will be issued certificates and Patient (P) will be issued with a Traceable Anonymous Certificate (TAC) as per the RFC 5636 (S.Park, H.Park,Y.Won,J.Lee,Kisa & Kent, 2009) [14].

Step 4: Patient (P) and Doctor (D) will be asked to download mobile healthcare application which will be uploaded by the hospital in the community cloud, before downloading the mobile healthcare application Patient (P) and Doctor (D) will check the authenticity of the mobile healthcare application by downloading the certificate. If the checking is successful they accept the mobile healthcare application or report about its failure to the hospital.

Step 5: Patient (P) and Doctor (D) will check the TPM certificate belonging to the hospital which is in the community cloud. If the checks are successful they can start using Mobile healthcare application:

1. Patient (P) and Doctor (D) validates the platform certificate of TPM of the hospital which is in the community cloud by using the validation procedure given in D.R. Stinson 2006 for certificates;
2. Patient (P) and Doctor (D) delegates OCSP to validate Mobile Healthcare Application Certificate;
3. If the responses from OCSP is positive, Patient (P) and Doctor (D) requests Hospital TPM to download and install Mobile Healthcare Application on the SE. /* provisioning step */;
4. University TPM personalizes Mobile Healthcare Application which is in the SE's of Patient (P) and Doctor (D).

Step 6: SRPF personalizes mobile healthcare application of both the Patient and Doctor separately which is in their UICC of their respective applications using the protocol given in (Ahamad, Sastry & Udgata, 2014).

Step 7: SRPF allocates shared symmetric key for both the Patient and Doctor separately in their respective applications of UICC.

Step 8: MHCC sends the information of allocation of Doctor to the Patient (P) and sends Doctor's public key and Doctor's identity using the shared symmetric key between Patient and Hospital.

Step 9: Mobile healthcare application of the patient is personalized in such a manner that when the application senses abnormality in patient it sends message to both hospital and Doctor with the location of the patient.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

2.3. Proposed Protocol

We propose a secure mobile healthcare protocol (SRPF):

$$Step\ 1: MHCC \rightarrow D: \{MS1\}_{SYYKEY_{DMhcc}}$$
$$MS1: \{UN, PW, PID, SYYKEY_{PMhcc}, T_{Mhcc}, N_{Mhcc}\}$$

Step 1: MHCC allocates Doctor to the Patient (P) and sends a message containing symmetric key shared between Patient and MHCC in order to decrypt the patient's encrypted files from the MHCC database in emergency. The message also contains Timestamp, Nonce, Username (UN), PW (Password) and PID (Patient Identity). UN and PW are needed to authenticate doctor into the MHCC database containing all the patients' records.

$$Step\ 2: D \rightarrow MHCC: \{MS2\}_{SYYKEY_{DMhcc}}$$
$$MS2: \{ACK, PID, SYYKEY_{PMhcc}, T_{Mhcc}, N_{Mhcc}, T_D, N_D\}$$

Step 2: Doctor acknowledges (ACK) for receiving shared symmetric key between Patient and MHCC. Doctor encrypts the sent message with the shared symmetric key between Doctor and MHCC.

$$Step\ 3: MHCC \rightarrow P: \{MS3\}_{SYYKEY_{PMhcc}}$$
$$MS3: \{PID, DID, SYYKEY_{PMhcc}, T_{Mhcc}, N_{Mhcc}\}$$

Step 3: After receiving acknowledgement (ACK) from Doctor, MHCC sends PID (Patient Identity), DID (Doctor's Identity) in step 3.

$$Step\ 4: P \rightarrow MHCC: \{MS4\}_{SYYKEY_{PMhcc}}$$
$$MS4: \{ACK, PID, SYYKEY_{PMhcc}, T_{Mhcc}, N_{Mhcc}, T_P, N_P\}$$

Step 4: Patient acknowledges (ACK) for doctors information allocated to him in step 4.

3. SECURITY ANALYSIS

Our proposed protocol ensures all the security properties such as authentication, data integrity and non-repudiation as the messages are exchanged using Digital Signatures based on ECDSA and encrypted using AES algorithm. Our proposed protocol ensures as intruder fails in forging patient's signature because he will be not in possession of patient's private key. Confidentiality is ensured using shared symmetric keys. In our proposed SRPF framework privacy of the patient is ensured using Traceable Anonymous Certificate (TAC) as per the RFC 5636 (Park et al., 2009). This section provides theoretical analysis of our proposed protocol in order to prove that the proposed protocol withstands attacks on authenticity, confidentiality, integrity and non-repudiation.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

3.1. Assumptions

We have made a number of practical and realistic assumptions in our proposed protocol. In the following, we first describe those assumptions.

Assumption 1: In our proposed framework Certifying Authority (CA) is a Trusted Service Manager (TSM) for all the stakeholders in the ecosystem and is fully trusted by all the stakeholders. Important duties of CA includes issuing certificates to all the stakeholders and Application testing and certification.

Assumption 2: Patient credentials were generated (by the patient) and they reside in the trusted part of tamper resistant Secure Element i.e. UICC of the patient and no one is authorized to access and manipulate these credentials as they are protected by password and biometric.

Assumption 3: In our proposed framework, symmetrically encrypted messages cannot be decrypted by any other stakeholders, unless they have the session/shared key used to encrypt/decrypt the message by the sender.

Assumption 4: In our proposed framework, messages are digitally signed by the sender using private key resided in the trusted part of the tamper resistant Secure Element (i.e. UICC) using ECDSA algorithm.

Assumption 5: SRPF framework adopts (TAC) given in RFC 5636 (Park et al., 2009) which offers privacy or anonymity to the Patient's identity, TAC is a X.509 certificate containing a pseudonym of Patient (P). CA has the ability to map TAC to the real identity of the Patient (P).

Assumption 6: Mobile Healthcare Application (MHA) of the patient and doctor is personalized by the Mobile Healthcare Community Cloud (MHCC) i.e. a symmetric key is agreed between MHCC and patient and MHCC and doctor.

3.2. Threat Model

We define our threat model as follows:

Definition 1 (Attack on authentication): A malicious intruder (In) is an intruder with the ability to monitor, intercept and introduce new stakeholders on behalf of genuine stakeholders.

Definition 2 (Attack on confidentiality or Information Privacy): An intruder (In) is an unauthorized entity who is capable of viewing the data before it reaches the receiver.

Definition 3 (Attack on integrity): An intruder (In) is an unauthorized entity who is capable of modifying the data before it reaches the receiver.

Definition 4 (Attack on Non-repudiation): See below:

1. Digital signatures generated in SRPF framework are called as Qualified Electronic Signatures because they are generated in Secure Signature Creation Device (SSCD);
2. A malicious intruder (In) attack on Non repudiation, in which an adversary is capable of generating Qualified Electronic Signature on behalf of any one or all the stakeholders (using private key) of SRPF framework.

Definition 5 (Attack on Anonymity of the patient): Doctor with malicious intension tries to know the real identity of Patient (P).

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Definition 6 (Attack on Communication Privacy): A malicious intruder (In) tries to capture the data communicated during the transit.

3.3. Security Proof

In this sub-section, we prove our proposed framework (SRPF) is secure against the threat model given in B sub section of this section considering the assumptions explained in Section 1. This is achieved through seven theorems with corresponding proofs as follows:

Theorem 1: Mobile Healthcare Application (MHA) of the Patient (P) is personalized by the MHCC (i.e. Shared symmetric key is agreed and installed in the MHA).

Proof: Mobile Healthcare Application (MHA) of the Patient (P) is personalized by the MHCCC Server by following the procedure proposed in (Shaik Shakeel Ahamad, V.N. Sastry, Siba K. Udgata, 2014).

Theorem 2: An Intruder (In) cannot read and modify the secret information transmitted by the stakeholders during the transit.

Proof: In SRPF framework messages are transmitted by encrypting (AES algorithm) and digitally signing (ECDSA algorithm) by all the stakeholders.

Theorem 3: Doctor fails in getting the real identity of the patient.

Proof: Patient (P) gets anonymous identity from CA; Hospital and CA knows the real identity of P. CA issues TAC to the Patient (P), so Doctor will not be revealed with the original identity of Patient (P).

Theorem 4: SRPF consumes fewer resources from the patient's perspective.

Proof: SRPF framework uses digital signature mechanism based on ECDSA which consumes very less resources. Patient (P)'s interaction with the other stakeholders in the framework is very less thereby consuming fewer resources for the patient.

Theorem 5: SRPF framework ensures both communication security.

Proof: SRPF framework ensures communication security using SSL/TLS protocol.

Theorem 6: SRPF framework generates Qualified Electronic Signatures.

Proof: Secure Signature-Creation Device (SSCD) configures software or hardware or both in order to implement Signature-Creation Data (SCD). Signature-creation data (SCD) contains private keys used to generate digital signature or electronic signature. Stakeholders in SRPF framework generate digital signatures in UICC (which is a secure element) and in the Grid of Secure Elements (at the TSM and at MHCC) so they are considered as Qualified Electronic Signatures.

Note: UICC (which is a secure element) and Grid of Secure Elements are Secure Signature Creation Device (SSCD).

Theorem 7: SRPF framework withstands all the known attacks.

Proof: Our proposed framework can withstand all the attacks; SRPF uses timestamps and nonce in order to ensure the freshness of the messages which avoids replay attacks, SRPF overcomes impersonating attacks as the intruder does not possess P's private key and SRPF framework withstands Man In The Middle (MITM) Attack as the attacker do not possess MHCC/Patient/Doctor's private key.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

4. FORMAL VERIFICATION OF SRPF PROTOCOL

4.1. Formal Verification Using BAN Logic

A security protocol is a communication protocol which exchanges encrypted messages by using cryptographic mechanisms (Muhammad et al., 2006). Popular and carefully designed protocols were found out to have security breaches (Muhammad et al., 2006). We have analyzed the protocol using BAN logic ((Abadi et al., 1993) and (Burrows et al., 1990)).

4.2. Assumptions for the Analysis and Verification of the Proposed Protocol

4.2.1. Assumptions About Keys and Secrets

'S' is a set of stakeholders containing {P, MHCC, D and CA}. These assumptions gives a brief overview of public and private keys possessed by all the stakeholders. CA certifies all the certificates and knows all the public keys of the stakeholders (AS1, AS2).

AS1. CA **believes** $\left(\forall S \in \{\text{P, MHCC, D and CA}\} \overset{K_s}{\mapsto} S \right)$. Certification Authority CA believes that all the stakeholders have their own public keys to communicate.

AS2. $S \in$ {P, MHCC, D and CA} believes $\overset{K_{ca}}{\mapsto} CA$. All the stakeholders in the framework knows the public key and certificate of the certification authority CA.

4.2.2. Assumptions About Freshness

Assumption **AS3** specifies freshness of quantities. For instance, if the Patient P sees quantity (N_p) n a message then the Patient P can conclude that it is a replay message.

AS3. P believes freshness (N_p), MHCC believes freshness (N_{Mhcc}), D believes freshness (N_d).

Every stakeholder believes nonce generated by him/her is fresh.
Assumption **AS4** is about validity time of certificates and timestamps which ensures timeliness.

AS4. TS_x TS_y are the timestamps generated by the stakeholders X and Y ({U, IB, AB, PG, CP, RI, and CA}) which ensures **timeliness** of the messages exchanged.

4.2.3. Assumptions About Trust

These assumptions give a brief overview of trust level on each stakeholder.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

AS5. ($\forall S, Q \in$ {P, MHCC, D and CA}. S **believes** CA **controls** $\overset{K_{ca}}{\mapsto} Q$. Every stakeholder trusts the Certification Authority CA.

AS6. $\forall$ belief X, CA **believes** (W **controls** (P **believes** X)). The Certification Authority CA trusts the Patient P that UICC or Secure Element (SE) (W) to relay Patient P's beliefs.

4.3. Verification of Our Proposed Protocol Using BAN Logic

$$Step\ 1: MHCC \rightarrow D: \{MS1\}_{SYYKEY_{DMhcc}}$$

$$MS1: \{UN, PW, PID, SYYKEY_{PMhcc}, T_{Mhcc}, N_{Mhcc}\}$$

D decrypts the received $\{\boldsymbol{MS}1\}_{\boldsymbol{SYYKEY_{DMhcc}}}$ from the assumptions **AS1, AS2, AS5, AS6 & AS7**

D **believes** $\{\boldsymbol{MS}1\}_{\boldsymbol{SYYKEY_{DMhcc}}}$ statement (1)

D verifies the public key of MHCC (**AS7**) received from MHCC which mainly includes [9] (D.R. Stinson 2006).

If the verification of certificate is successful then:

D **believes MHCC said** $\{\boldsymbol{MS}1\}_{\boldsymbol{SYYKEY_{DMhcc}}}$ statement (2)

D **believes fresh** $\boldsymbol{T_{Mhcc}}$ from **AS3** statement (3)

D **believes fresh** $\boldsymbol{N_{Mhcc}}$ from **AS4** statement (4)

So from the statements 1 to 4:

D **believes** $\{\boldsymbol{MS}1\}_{\boldsymbol{SYYKEY_{DMhcc}}}$

$$Step\ 2: D \rightarrow MHCC: \{MS2\}_{SYYKEY_{DMhcc}}$$

$$MS2: \{ACK, PID, SYYKEY_{PMhcc}, T_{Mhcc}, N_{Mhcc}, T_D, N_D\}$$

MHCC decrypts the received $\{\boldsymbol{MS}2\}_{\boldsymbol{SYYKEY_{DMhcc}}}$ **from D** from the assumptions of **AS1, AS2, AS5, AS6 & AS7**

MHCC **believes** $\{\boldsymbol{MS}2\}_{\boldsymbol{SYYKEY_{DMhcc}}}$ statement (5)

MHCC validates the public key of D (**AS7**) received from D which mainly includes [9] (D.R. Stinson 2006):

If the verification of certificate is successful then:

MHCC **believes D said** $\{\boldsymbol{MS}2\}_{\boldsymbol{SYYKEY_{DMhcc}}}$ statement (6)

MHCC believes **fresh** $\boldsymbol{T_D}$ from **AS3** statement (7)

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

MHCC **believes fresh** N_D from **AS4** statement (8)

So from the statements 5 to 8:

D **believes** $\{MS2\}_{SYYKEY_{DMhcc}}$

$$Step\ 3: MHCC \rightarrow P: \{MS3\}_{SYYKEY_{PMhcc}}$$
$$MS3: \{PID, DID, SYYKEY_{PMhcc}, T_{Mhcc}, N_{Mhcc}\}$$

P decrypts the received $\{MS3\}_{SYYKEY_{PMhcc}}$ **from MHCC** from the assumptions of **AS1, AS2, AS5, AS6 & AS7**

D **believes** $\{MS3\}_{SYYKEY_{PMhcc}}$ statement (9)

P validates the public key of MHCC (**AS7**) received from MHCC which mainly includes (D.R. Stinson 2006).

If the verification of certificate is successful then:

P **believes MHCC said** $\{MS3\}_{SYYKEY_{PMhcc}}$ statement (10)

P **believes fresh** T_{Mhcc} from **AS3** statement (11)

P **believes fresh** N_{Mhcc} from **AS4** statement (12)

So from the statements 9 to 12:

P **believes** $\{MS3\}_{SYYKEY_{PMhcc}}$

$$Step\ 4: P \rightarrow MHCC: \{MS4\}_{SYYKEY_{PMhcc}}$$
$$MS4: \{ACK, PID, SYYKEY_{PMhcc}, T_{Mhcc}, N_{Mhcc}, T_P, N_P\}.$$

MHCC decrypts the received $\{MS4\}_{SYYKEY_{PMhcc}}$ from P from the assumptions of **AS1, AS2, AS5, AS6 & AS7**

MHCC **believes** $\{MS4\}_{SYYKEY_{PMhcc}}$ statement (13)

MHCC validates the public key of P (**AS7**) received from P which mainly includes (D.R. Stinson 2006).

If the verification of certificate is successful then:

MHCC **believes P said** $\{MS4\}_{SYYKEY_{PMhcc}}$ statement (14)

MHCC believes **fresh** T_P from **AS3** statement (15)

MHCC **believes fresh** N_P from **AS4** statement (16)

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

So from the statements 13 to 16:

MHCC believes $\{MS4\}_{SYYKEY_{PMhcc}}$

4.4. Formal Verification Using Scyther Tool

Our proposed protocol is written in Security Protocol Description Language (.spdl) of the Scyther simulation environment. Scyther tool is used to verify the security protocols (security services provided in Table 1). We define the role of HC, D and P, where HC is the Healthcare Center, D is Doctor and P is the Patient for scythe tool. In our scenario, MC, D and P exchange information. We introduce five types of attacks. The first type of attack is defined for the transmission among MC, D and P (integrity), the second attack is defined where an adversary acquires the properties of any one of the three entities and sends the attack data packets to other entities involved in the framework (authentication) and the third attack is defined adversary try to read the data within interval *t* (Confidentiality). We have experimented with 100 numbers of runs for each claim to found out that there are no attacks in our proposed protocol, in addition to these, we follow the default properties (Table 2) of Scyther tool. Outcomes provided in Table 3.

Table 1. Mapping between security objectives and security properties

Claims of Security	Scyther Security Services that Verify Claims
Authenticity	Alive, WeakAgree, NiAgree
Detection of replay, reflection and MITM attack	NiSynch
Confidentiality of the message	claim_HC1 (HC, Secret, Khcd); claim_HC2 (HC, Secret, nhc); claim_HC3 (HC, Secret, np);
Non repudiation	Agreement (NiAgree, NiSynch) between the roles, Aliveness and Authenticity using WeakAgree

Table 2. Setting parameters for the Scyther verification tool

Verification Parameters		Advanced Parameters	
Title	**Value**	**Title**	**Value**
Maximum number of runs	100	Search Pruning	Find all attacks
Matching Type	Typed matching	Maximum number of patterns per claim	100

Table 3. Summarized outcome of automated security claims using Scyther verification tool

ROLES	Weakagree	Secrecy	Alive	Nisynch	Niagree	Comment
Patient (P)	Pass	Pass	Pass	Pass	Pass	Pass
Doctor (D)						
HC

- **Attack model:** In our framework we focus on integrity attacks, confidentiality attacks and authentication attacks as discussed above. In integrity attacks, an attacker observes the encrypted data travelling on the network that contain information. In confidentiality attack, attacker continuously observe the data flow and try to read the data. In authentication attacks, an attacker can observe a source node, and try to get the behavior of the source node. We assume that he/she is able to determine the source node's behavior. In such cases, the attacker can introduce an authenticated node and act as the original source node. In our concept, we are using trusted modules in sensors to store the secret information and procedure for key generation and encryption (such as TPM);
- **Results:** Our proposed protocol SRPF is written in SPDL (Security Protocol Description Language) for simulating in Scyther environment. Scyther (Cremers. 2006) & (Cremers & Lafourcade, 2007) is a tool which is used to verify, falsify and analyze security protocols. Scyther (Cremers. 2006) & (Cremers & Lafourcade, 2007) has many unique features which make it popular for analyzing infinite sets of traces in terms of patterns, unbounded verification with guaranteed termination and finally analyzing multi-protocols. Box 1 in the Appendix presents the code of SRPF in SPDL with results. The result window in Figure 1 of the Appendix shows simulation environment of scyther tool with its parameters. The result window in Figure 2 of the Appendix shows the "Verification Claim" Procedure of Scyther Tool and the result window in Figure 3 of the Appendix shows the "Automatic Claim" Procedure of Scyther Tool.

5. COMPARATIVE ANALYSIS OF SRPF WITH RELATED WORK

Results in Table 4 are as follows. Yes: the protocol protects against that attack or provides that feature; No: the protocol does not protect against that attack or does not provide that feature. N.A.: not applicable

6. DISCUSSION

Following are the remedies provided by SRPF to challenges outlined in (Wazid et al, 2016) for enabling cost-effective, secure and robust mobile health systems.

6.1. Remedy to Challenge 1

Mobile Healthcare Application (MHA) of the patient and doctor is personalized by the Mobile Healthcare Community Cloud (MHCC) i.e. a symmetric key is agreed between MHCC and patient and MHCC and doctor. In SRPF symmetrically encrypted messages cannot be decrypted by any other stakeholders, unless they have the session/shared key used to encrypt the message by the sender, messages are digitally signed by the sender using private key resided in the trusted part of the tamper resistant Secure Element (i.e. UICC) using ECDSA algorithm. So all the security properties such as confidentiality, mutual authentication, data integrity, non-repudiation and access control are ensured using efficient key distribution protocol in the proposed framework.

Table 4. Comparative analysis of SRPF with related work

Protocols Functionality Features	(Arshad et al., 2015)	(Mishra et al., 2014)	(Mir, et al., 2015)	(Das et al., 2015)	(Siddiqui et al., 2013)	(Das, 2015)	(David, 2016)	(Moon et al., 2016)	(Mir et al., 2015)	SRPF
Ensures Confidentiality	No	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes
Ensures Data Integrity	Yes	Yes	No	Yes	Yes	No	Yes	Yes	No	Yes
Ensures Non-Repudiation	No	Yes	Yes	Yes	No	No	No	No	No	Yes
Ensures two factor authentication	Yes	No	No	No	No	No	No	No	Yes	Yes
Ensures three-factor authentication	No	Yes	Yes	Yes	Yes	Yes	No	Yes	No	Yes
Ensures Patient's anonymity	Yes	No	Yes	Yes	No	Yes	No	Yes	Yes	Yes
Ensures mutual authentication	Yes	Yes	Yes	Yes	No	Yes	Yes	Yes	Yes	Yes
Ensures session key agreement	Yes	No	Yes	Yes	No	Yes	Yes	Yes	Yes	Yes
Withstands Replay attacks	Yes	Yes	Yes	Yes	Yes	Yes	Yes	No	No	Yes
Withstands Impersonation attacks	Yes	Yes	Yes	Yes	Yes	Yes	No	Yes	Yes	Yes
Withstands Man In The Middle Attacks	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes
Withstands Multi-Protocol Attacks	No	No	No	No	No	No	No	No	No	Yes
Withstands stolen smart card/mobile device attack	Yes	Yes	Yes	Yes	Yes	Yes	No	Yes	Yes	Yes
Formal Verification of Protocol	No	No	No	No	No	No	No	No	No	Yes

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

6.2. Remedy to Challenge 2

In our proposed framework SRPF messages are digitally signed by the sender using private key resided in the trusted part of the tamper resistant Secure Element (i.e. UICC) using ECDSA algorithm. Patient credentials were generated (by the patient) and they reside in the trusted part of tamper resistant Secure Element i.e. UICC of the patient and no one is authorized to access and manipulate these credentials as they are protected by password and biometric. Mobile Healthcare Application (MHA) of the patient and doctor is personalized by the Mobile Healthcare Community Cloud (MHCC) i.e. a symmetric key is agreed between MHCC and patient and MHCC and doctor. So the authenticity of the public keys are efficient and cost effective as they protect data from unauthorized access because of the personalization (for private key) of UICC (of the patient and doctor) and TPM (for private key at the MHCC) by the patient, doctor and by the Hospital.

6.3. Remedy to Challenge 3

Mobile Healthcare Application (MHA) of the patient and doctor is personalized by the Mobile Healthcare Community Cloud (MHCC) i.e. a symmetric key is agreed between MHCC and patient and MHCC and doctor thereby achieving credentials privacy, mutual authentication, and session key security using symmetric key cryptography.

6.4. Remedy to Challenge 4

Patient credentials were generated (by the patient) and they reside in the trusted part of tamper resistant Secure Element i.e. UICC of the patient and no one is authorized to access and manipulate these credentials as they are protected by fingerprint biometric. So our proposed SRPF framework uses fingerprint biometric that has unique biometric features as it works in unconscious patients for identification purposes.

6.5. Remedy to Challenge 5

In our proposed framework, Mobile Healthcare Application (MHA) of the patient and doctor is personalized by the Mobile Healthcare Community Cloud (MHCC) i.e. a symmetric key is agreed between MHCC and patient and MHCC and doctor. So symmetrically encrypted messages cannot be decrypted by any other stakeholders, unless they have the session/shared key which is used to encrypt the message by the sender.

7. CONCLUSION

In this article, we propose a Secure Robust and Privacy enhanced Mobile Healthcare Framework (SRPF) which addresses the challenges outlined in the literature by adopting Community Cloud (CC), WPKI cryptosystems, Universal Integrated Circuit Card (UICC) and Trusted Platform Module (TPM). All the security properties such as Mutual Authentication, Integrity of the message, Privacy of the messages exchanged, Non-repudiation and Privacy of the Patient are ensured in this framework. SRPF overcomes

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

all the known attacks such as replay attacks, Man in the Middle (MITM) Attacks, Impersonation attacks and Multi-Protocol attacks as SRPF was successfully verified using scyther tool and by BAN logic.

Chapter 25
An Intelligent Multi-Objective Framework of Pervasive Information Computing

Basant Tiwari
Hawassa University, Ethiopia

Vivek Tiwari
IIIT-NR, India

ABSTRACT

This article describes how electronic healthcare has been the key application of pervasive computing innovations to enhance healthcare quality and protect human lives. Specific patients of constant sicknesses and elderly individuals, by and large, may oblige continuous observing of their wellbeing status wherever they are. In this regard, remote patient monitoring technology plays the various important role through wearable devices to monitor patient's physiological figures. But, this must ensure some broad issues like, wearability, adaptability, interoperability, integration, security, and network efficiency. This article proposes a data-driven multi-layer architecture for pervasively remote patient monitoring that incorporates aforesaid issues. It enables the patient's care at the real time and supports anywhere and anytime requirement with using network infrastructure efficiently.

1. INTRODUCTION

Nowadays, the population of aging people who have incessant illnesses such as diabetes, heart disease and much more is increasing. In addition, youngsters are also experiencing diseases like asthma and obesity due to a lavish lifestyle (Jensen, Jensen, and Brunak, 2012). With all such issues, there is an increase in healthcare costs that demand cost-effective, reliable and pervasive patient healthcare systems. If a patient's health could regularly be observed over an extended amount of time, the doctor could diagnose serious health problems at an early stage and may also provide more accurate treatment.

The Republic of India; a young nation, with the world's most populous community, has battled for making emergency medical care safe and economical (Srinivisan, 2012). Nowadays, Government is thinking about its socioeconomic expansion through Digital India and Skilled India, but it also plagues many challenges (Srinivisan, 2012; Fernald, Capriotti, Daneshjou, Karczewski, and Altman, 2011). The private medical sector of India is holding more or less 81% medical services and 88% medical professionals (Srinivisan, 2012). Health Workforce in India remains inadequate and underutilized, and India started its health reforms journey in the most recent decade. This mission now needs to pick up momentum. Home-based self-monitoring devices are required to become self-reliant for non-invasive and periodic self-monitoring of chronic diseases (Gudwani, Puri, and Vaidya, 2012; Anshari, Alas, and Guan, 2016).

Pervasive healthcare frameworks utilize ubiquitous computing technologies, for example, wearable biomedical sensors with the remote system, to build the modalities and spatiotemporal measurements in which medicinal services administrations can be accommodated enhancing the patient well-being. The most accurate information about the patient at the right time is essential to obtain the best possible service for the patient (Shumer, Tang, Shrivastava, Lombrozo, and Druker, 2008). The goal of Pervasive Healthcare (PH) is to utilize ubiquitous computing technologies to provide continuous health care services from anywhere and outside the scope of traditional medical places, such as hospitals and medical clinics (Kuhn and Prettner, 2016). Pervasive healthcare is aiming to change this conventional way (Visiting a physician /specialist) into pervasive patient monitoring from anywhere and at any time. It exploits the sensing and communication technologies to monitor patient round the clock.

Pervasive healthcare encourages patient-doctor collaboration and can give exact, precise, and upright care to all (Mukherjee, Kolui, and Datta, 2014; Wu et al., 2017; Hart, 2013). This is especially helpful nowadays, since the population is expanding quickly, medical institutions are confronting deficiencies of medical staff, and the cost of healthcare is soaring (Fernald et al., 2011; Hajheydari, Khakbaz, and Farhadi, 2013). The electronic healthcare framework has been the primary application of pervasive computing to enhance healthcare quality and preserve human lives. A number of frameworks consisting of many devices have been invented for remote observation to gain the patient well-being (He, Zeadally, Kumar, and Lee, 2016; Yu and Tseng, 2007; Yuan and Herbert, 2011; Andreu-Perez, Poon,Merrifeld, Wong, and Yang, 2015).

Due to technological advancements in different fields like a wireless network, microchip, integration, and tininess of devices, sensors, and the internet, it is easy to modernize the way of healthcare services and focus on early diagnosis of chronic diseases (Chondrogiannis, Andronikou, Tagaris, Karanastasis, and Varvarigou, 2017).

These systems are structured in such a way that it can react to crisis and manage illness rather than wellness (Banaee, Ahmed, and Loutfi, 2013). In this view, Body Sensor Network (BSN) is a feasible solution, because it is an appropriate blend of modest wearable gadgets connected to the patient's body for observing the patient's physiological information. Sensors continuously screen and gather the patient's information and send it to a remote server through a network that is referred as Database Server (DBS) (Tiwari and Kumar, 2012).

2. ISSUES AND CHALLENGES

A noteworthy challenge is to give continuous and persevering medical services via wearable human services gadgets. Furthermore, numerous patients are more concern about privacy especially, when

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

they realize that their data is open over remote channels. Thus, one most crucial issue is that medicinal services suppliers must secure the patient's data. Significant challenges with Patient Monitoring and Remote Medical Care System are:

1. Since the patient's physiological data are highly sensitive, and BSN is very receptive to attacks; therefore, it must be ensured that the patient's identity should not be exposed and altered as well as the patient's data should not fall into the hands of unauthorized users.
2. We frequently come across data values which are successively similar in content and context, and it does not contribute towards any diagnosis. So, the overall performance of the information computing can be improved by identifying and removing such repeating data (Tiwari and Thakuar, 2016).
3. Electronic health records (EHR) is a fast way to transfer patient data among experts to enhance the quality of clinical issues (Mirani and Harpalani, 2013). For the protection of EHR, Many countries are implementing privacy laws that ensure the confidentiality of such HER data. Furthermore, they even facilitate patient to control and manages the access right of their own records. A data-driven Role Based Access Control (RBAC) might be one of the solutions for data authorization (Sohr, Mustafa, Bao, and Ahn, 2008).
4. Real-time physiological value acquisition.
5. Real-time data analysis and decision making.
6. Strong Decision-Making Policy for patient- authentication system.

This paper incorporates these issues in an architecture which provides solutions for pervasively secured remote patient monitoring. In this regard, we take up an investigation for the development of secure and pervasive architecture which focuses on issues such as minimizing redundant data, compression, and reliable transmission of BSN data with efficient access control policy for accessing the patient's data from the database server. A multi-layered architecture is proposed for pervasively remote patient monitoring to accommodate aforesaid challenges.

3. LITERATURE REVIEW

Majorly, remote patient monitoring systems include a traditional communication system like a telephone network to transmit physiological signals using high-frequency carrier signal (Weiskopf, Hripcsak, Swaminathan, and Weng, 2013; Charles, Gabriel, and Furukawa, 2013; Lau et al., 2011). In spite of the fact that these frameworks permit constant checking, they have an inadequate bandwidth, high telephone charges and degradation due to noise. In recent years, a lot of work has been done in this field.

Yu & Tseng (2007) propose wireless patient monitoring system architecture for a mobile patient monitoring, which provides remote access capability. It consists hardware and software module for the collection and transmission of patient data. They used IEEE standard 802.11 and WMTS for communication purpose and implemented architecture which highly emphasized only on the communication system.

Trinugroho et al. (2012) presented a framework for a real-time web-based health monitoring architecture by using Enterprise Service Bus (ESB). This architecture consists a web-based Service Oriented Architecture (SOA) with ESB that uses subscribe message exchange pattern functionality. PDA like smartphone device is used to implement applications for remote patient monitoring. A wireless body

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

area network has been organized for the accumulation, preparing and transmission of information to various users of patient data including relatives, nurses, and doctors.

Ogunduyile et al. (2013) presented a "Service Oriented Wireless Body Area Networks" (SOWBAN) to monitor physiological data such as SPO2, HR of patients along with the location and activity. Moreover, it contained 3-axis accelerometer and a wireless pulse oximeter (SpO2) as a significant component. Authors discussed the overall functioning of the architecture in three significant layers: (i) Biomedical Sensor (BS) Arduino Layer, (ii) Central Intelligent Node (CIN) layer and (iii) Medical Health Server (MHS) layer. BS Arduino layer implements various body sensors installed on patient's body to collect data. CIN layer receives and process the data and sends it to MHS layer. Where, the data are maintained as a central repository for future reference.

Kang et al. (2013) developed a Wireless Patient Monitoring System (WIPAMS) that monitors the patient's data in real time and transfers to a remote server for further processing. The authors have developed an embedded display board where Android OS was installed. The primary three modules are developed, where, the first module consists sensors, and the second module implements an Android based control logic. The last module poses a dashboard that visualizes collected data. Android OS maintains various threads to monitor vital sign and communication process. Basically, threads are developed for pre-processing of patient's data. Authors conclude their work by providing a specification of developed WIPAMS board (Odroid-X).

Tagad & Matte (Labarère, Bertrand, and Fine, 2014) discussed a Point-of-Care (POC) patient monitoring system that monitors out-patients who require care. They enhanced the traditional system with automatic remote monitoring. A fundamental wireless communication system is developed to transfer data into a centralized data repository. These data are generated by wearable sensors, Bluetooth and Zigbee. It also provides an alarm generation system, which informs to concern doctor if things go wrong via SMS.

Mukherjee et al. (2014) presented an architecture for electronic health care which uses wireless infrastructure with the smartphone-like device for collection, monitoring, and analysis of patient's data at a real-time emergency situation. The architecture consists of three layers; (i) perception layer, (ii) Middleware & APIs layer and (iii) E-Health application & service layer. Perception layer consists a set of medical sensors to collect the patient's physiological data. It measures the information like id, value measuring unit, timestamp, etc. and convert this data into metadata and finally send it to the next layer. Middleware & APIs layer implements cloud infrastructure with a set of APIs for (i) patient registration, (ii) profile creation, (iii) storage, (iv) patient history queries, etc. E-Health Application & Service Layer provide outsourcing services for patient's data and healthcare advice services to the patient. Authors also describe various security requirements for patient's medical data.

Yuan & Herbert (2011) introduced a web-based Context-Aware Real-time Assistant (CARA) architecture to monitor patient's physiological data with contextual information. Authors demonstrated 3-tier architecture for real-time patient monitoring in which body area network, the Internet and CARA server are implemented on each layer respectively. Protocol of CARA system is developed through XML. Security and privacy issues for protecting patient's privacy are also included in the work.

Various architectures for remote patient monitoring are introduced, but many significant issues are not considered effective as a whole package such as access control, redundancy reduction and security of patient's data as well as network issues like better utilization of network bandwidth.

4. MULTI-OBJECTIVE FRAMEWORK

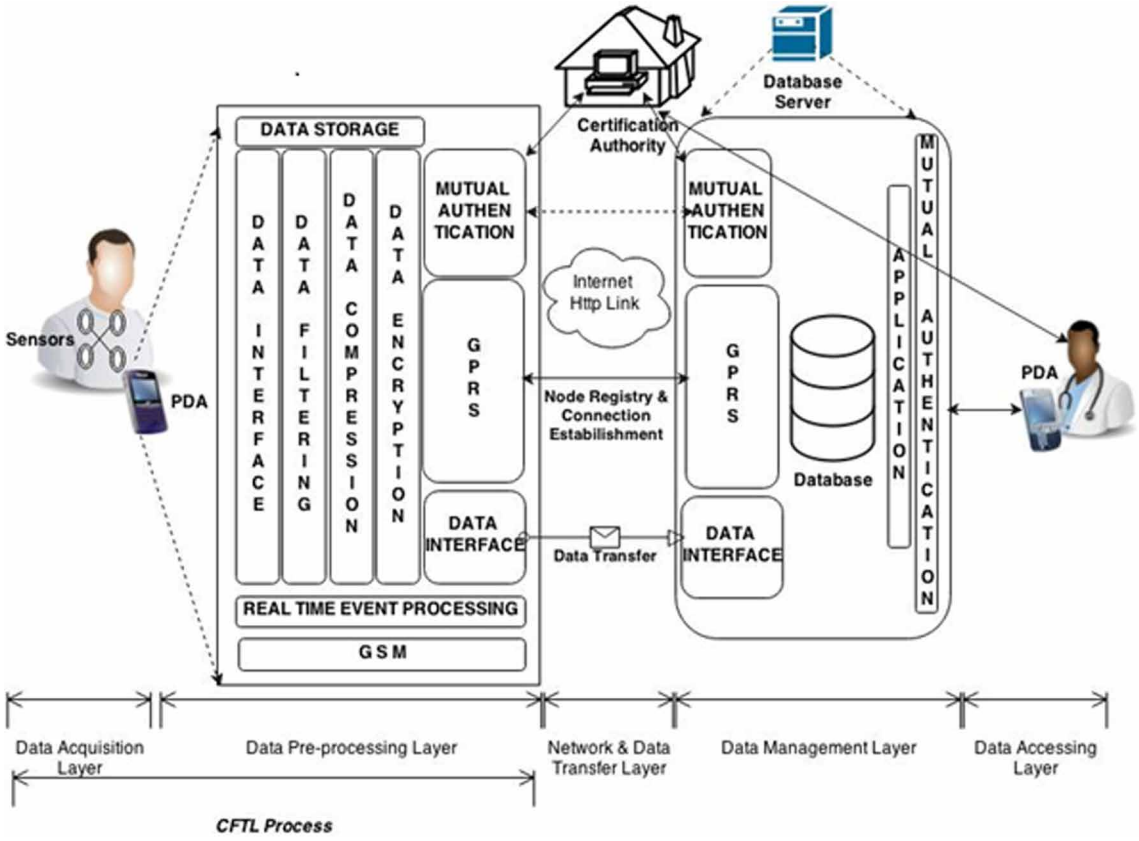
This section is devoted to the layered architecture for pervasive healthcare for remote patient monitoring and is presented in Figure 1.

Majorly, it comprises of five layers as:

1. Data Acquisition Layer, (Layer 0)
2. Data Pre-processing Layer, (Layer 1)
3. Network and Data Transfer Layer, (Layer 2)
4. Data Management Layer, (Layer 3) and
5. Data Accessing Layer (Layer 4).

Data Acquisition and Data Pre-processing (Layer 0 and 1) work at the patient site and collectively launch a process called CFTL process (Collect, Fuse, Transform and Load process). Data Management Layer (Layer 3) works at the remote Database Server (DBS) where all patient data are stored. Data Access Layer (Layer 4) work at the healthcare provider site and Network and Data Transfer Layer (Layer 2) use network infrastructure to transfer the data from patient site to DBS.

Figure 1. Patient remote monitoring system architecture



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

CFTL process includes sensor devices installed in the patient's body and the personal server called PDA (Personal Device Assistant). In CFTL process, sensors collect the patient data with fixed interval according to their functionality and specifications. Received data is pre-processed at PDA, where different types of patient's data are filtered, compressed, encrypted, fused and transformed into a single packet and is loaded as a single entity. The primary purpose of CFTL Process are:

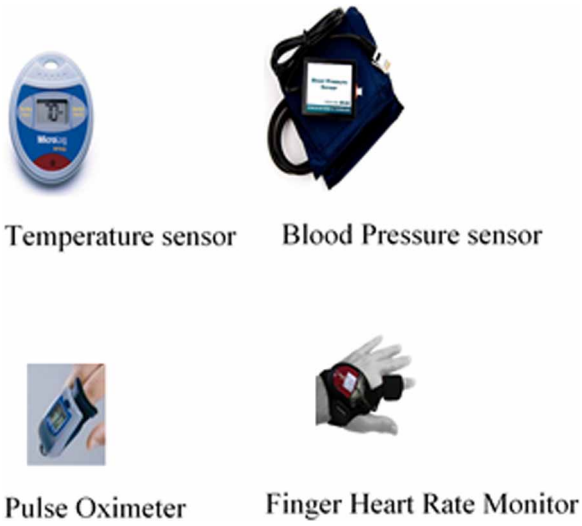
1. Increase the utilization of the bandwidth of the wireless channel
2. To reduce redundant values transmission
3. Easy to maintain authenticity, confidentiality, and integrity of patient's data
4. Energy and cost saving

4.1. Data Acquisition Layer (Layer-0)

It is primarily used for sensing and collecting the data and is equipped with the wearable body Sensors as depicted in Figure 2. These sensors measure various physiological and environmental signals. Sensor devices communicate wirelessly with network gateways (Smart Phones or PDAs) which store, analyse and communicate vital information to Layer-1 in real time.

Such sensor cannot work by themselves; they need a microprocessor, local storage and a wireless radio for functioning. With these things, the sensor becomes a sensor node which is an embedded device. There are various mote platforms available, each having a different configuration like processor and radio specification, but device configuration and specifications are more or less similar. TinyOS is an embedded operating system specially developed for sensors and do not have full functionality of a regular operating system (Linderman, Mechitov, and Spencer, 2013). The nodes which can be used are the Moteiv-Tmote-Sky based on the TelosB platform. The Tmote Sky has a 8MHz TI MSP430 microprocessor which has 10kB of RAM and 48kB of flash memory available. This microcontroller is

Figure 2. Various Sensors



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

used in wireless sensor network devices. Wireless communication takes place among nodes using the Chipcon CC2420 radio. The CC2420 is a 250kbps, IEEE 802.15.4 (Zigbee) compliant radio operating at 2.4GHz. These motes run the TinyOS operating system (Linderman et al., 2013).

Data acquisition from the sensor is possible by taking the set of sensors S_k, where k is the number of the sensor implanted over patient's body such as $S_k = \{s_1, s_2, ..., s_k\}$. Each sensor senses the physiological value as per their functionality and specifications, i.e. Skpv. At last, data is sent to the next layer for further processing.

4.2. Data Pre-Processing Layer, (Layer-1)

This layer is a part of CFTL process and installed on PDA for data pre-processing. PDA is a processing and connectivity device that can interact with the sensor nodes through various IEEE standards like Bluetooth and Zigbee at one end and another end. It may also contain a user interface or an interface to a connecting network. PDA provides more processing power than the sensor node and uses its internal memory to store the data and program to execute. PDA memory can be expanded with a flash memory card for real-time storage and pre-processing of sensor data.

In the proposed architecture, this layer consists of various sub-layers for patient data pre-processing such as:

1. Data Interface Sub-layer
2. Data Filtering Sub-layer
3. Data Compression Sub-layer
4. Data Encryption Sub-layer

Collected patient data are passed through these sub-layers and processed according to the functionality of each sub-layer. The functionalities of each sublayer are:

4.2.1. Data Interface Sub-Layer

This is an interface between sensor devices at layer-0 and other sub-layers of layer-1. It collects the various sensed data and sends to data filtering sublayer. PDA provides multiple wireless interfaces that can be used for healthcare application. Cellular and Wi-Fi, Bluetooth, NFC are wireless communication protocols included in PDA, where Cellular and Wi-Fi are used for Internet connectivity (Jantunen, 2012). Bluetooth and NFC can be used connecting PDA to the sensor devices. Wi-Fi is expensive due to the high data rate and high-power consumption. It also requires continuous energy sources at both ends (at PDA and Sensor devices) for the communication (Chang, 2014). In this way, Bluetooth can be a reasonable choice made up especially for sensor devices. Another feasible option for data communication between the sensor device and PDA may be Zigbee protocol and specially intended for low information rates and low power consumption (Wang, Chen, Lin, Fang, and Lee; 2015). Zigbee technology is simple and less expensive than Wi-Fi and Bluetooth. Nowadays, Zigbee based PDA are available in the market but does not have vast expansion as with Bluetooth, i.e., it is freely available on all smartphones.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

4.2.2. Data Filtering Sub-layer

It has been observed that at some point in time non-rehashed, yet repetitive values transmitted unnecessarily. These repetitive values do not give to any conclusions on the ground, i.e., it demonstrates the same state of the patient for a broadened timeframe. These values ultimately increase overhead on preprocessing, communication time and database server memory.

In this view, data filtering technique reduces the communication cost, especially in the case of energy constrained devices. Initially, screening process classifies the data according to sensors values, i.e., for example, Heart-Rate sensor's physiological values are grouped; similarly, Blood-Pressor sensor's physiological values are arranged, etc. Furthermore, Standard Deviation (SD) method is applied to filter the physiological data (Tiwari and Kumar, 2015). Here, we have considered 'Window Size' concept for the range of physiological values, such as heart rate will be 60-80 bpm for a normal adult male is defined as normal, blood pressure 80-120 mm/gm, etc. Such values are standard and having a proper interpretation in the medical field. This concludes that the span of physiological values is fixed, and hence the window size will also be fixed (i.e. the elasticity of window is zero). The proposed method enlarges the elasticity of window at both ends (MIN/MAX) without upsetting the performance. This improves data reduction automatically. An elasticity of the window is calculated by representing the patient's HR data as vector (h_1, h_2, h_3, …, h_n) at the PDA over a particular span of time and then calculate the mean over that data $h' = \sum_{I=1}^{n} h_i / n$. The deviation is measured for each sensed value by subtracting the mean value i.e. $D_I = h_i - h'$ for each h_i and variance is calculated as, i.e., $\left(\sum_{I=1}^{n} D_i^2\right) \Big/ n$. SD is calculated by taking the square root of variance, i.e. $SD = \sqrt{(\sum_{I=1}^{n} D_i^2) / n}$. This SD is considered as an elasticity at both upper and lower end, and so, it enlarges the elasticity of HR value. It has been shown that the amount of data transmitted is reduced up to 40%.

4.2.3. Data Compression Sub-Layer

Data compression techniques can save energy as well as provide efficient utilization of network bandwidth by enormously diminishing the size of information, sent on the remote channel. Hence, there requires a lossless compression technique which can reduce the data in significant size without losing their meaning or any byte especially, when dealing with patient's physiological data. Aggregated Deflate RLE (ADR) is found the best suitable algorithm to this end (Tiwari et al., 2012). ADR offers to improve compression ratio and lowest compression time concerning different standard method such as Huffman, LZW, and Deflate. ADR implements look-ahead buffer of LZ77, that is an ingredient of Deflate. It works well with small file sizes (1KB, 2KB, 5KB, 10 KB and 20 KB) and hence, suitable for BSN data. ADR is tested on many parameters such as Compression and Decompression Time (CT/DT), Compression Ratio (CR), Factor (CF) and Saving Percentage (SP). Intel core i3 IInd Generation processor at 2.30 GHz with 32-bit OS and 2 GB RAM is taken for implementation of this approach. Various observation is taken which conclude that ADR algorithm is found to be the best out of other algorithms taken into consideration. It has been found that ADR provides high CF and SP with lowest CR. These are main aspects when

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

dealing with data compression. It is also noticed that CT and DT are found comparatively more, but it is in the millisecond that is acceptable. The beauty of the proposed system is that data compression is applied to less sensitive information to keep the trust on analytical outcomes. It is best suitable and efficient because of the contextual data partition. An administrator can decide the contexts (less sensitive data) based on domain knowledge where data compression is required or not.

4.2.4. Data Encryption Sub-Layer

As the name suggests, this sub-layer encrypts the compressed data which is pushed by the just preceding data compression sublayer. Data compression layer ensures information security of physiological data which flow through a network. There are various symmetric, and asymmetric encryption algorithms exist as a choice, but the algorithm with the minimum functional requirement is suggested to choose. In this view, a Physiological Value based Encryption and Mutual Authentication (PVEMA) mechanism is best suitable that facilitates mutual authentication as well as data encryption (Tiwari and Kumar, 2013). PVEMA is based on the Elliptic Curve Cryptography (ECC) with Message Authentication Code (MAC) and Symmetric Encryption technique for ensuring integrity, confidentiality and authenticity (i.e., previously stored Physiological value is used as input for key generation.)

PDA executes ECIES algorithm which is a variation of ECC that uses generated keys for encryption. In the process of PVEMA, we have found domain parameters a, b, G and n using chosen elliptic curve then key generation process executes which leads to Encryption/Decryption process. The mutual authentication process initially calls a Certification Authority when the system is setup that is described in section-5 of this paper. The encryption process takes data M and shared physiological values S1 and S2 and a triplet (R, C, D) is generated as output or encrypted message. The process initiated by taking a random number k i.e. $k \in [1, n- 1]$ and then it calculates the $R = kG$. Here a Key Derivation Function (KDF) is used to derive key for symmetric encryption of message which generated C and then MAC is used for tagging operation which produces the D. These three values are grouped into triplet as an output of encryption procedure. Now, this triplet is sent to Database Server (DBS) where physiological values are stored for future use. DBS executes decryption process using same ECIES algorithm. This uses the same generated keys and parameters that are shared during system setup and key deployment procedure. Here the triplet (R, C, D) is taken as input with shared physiological values S1 and S2 and output message M is generated. Here the same KDF is used for key generation and same MAC for tag verification. Once tag verified as matched, the symmetric decryption process generates the message M. This work ensures data confidentiality, integrity, and unforgeability. It also avoids various attacks like reply attack, Man in the Middle attack, chosen cipher attack. Now the patient data at DBS is stored in the form of EHR.

4.3. Network and Data Transfer Layer (Layer-2)

Layer-1 combines all the data after pre-processing as a single unit in the form of packets. This packet contains all patient's EHR with the address of DBS. Now PDA transmits it to DBS. The pervasive nature of the Internet enables patient's data to be transmitted in real time. In the proposed architecture, layer-2 is responsible for transmission. This layer implements a client-server architecture, where PDA works as a client while DBS works as a server. The transmission uses TCP/IP protocol suite for transmission of patient's data. This layer uses General Packet Radio Service (GPRS services) to make connections

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

between PDA and DBS and then to transfer of data also. PDA uses 3G or 4G cellular services with the data rate of minimum 2 Mbit/s. GPRS enabled PDA user SIM card slot and allowed transfer of files to another device like DBS.

4.4. Data Management Layer (Layer-3)

Vital Sign sensed and collected by a sensor at layer-0, after pre-processing at layer-1, is forwarded to a remote and centralized back-end repository that is implemented at layer-3 called data management layer which aggregated all patient information called Healthcare Records (EHR) in the form of centralized database. A Healthcare record comprises of Personal information, Insurance Information, and Medical data. The personal information contains patient-id, patient-name, gender, age, address, etc. Insurance information includes insurance date, insurance type, amount, claimed amount, etc., while Medical data comprise of patient's collected sensor data, his/her lab conducted data and also Sensitive data like HIV, mental and sexual data. This heterogeneity in data is at context and format level and so, proposed to handle by dividing the data as per underlying contexts. This repository works as a Database Server (DBS) or server repository. This remote and centralized database server manages all information in a real-time manner. It stores and shares the health-related data of a patient. This server repository works only online and provides access to all patient data to only authorized users like health care providers in an emergency situation for their clinical trials, insurers, relatives and some time to research students.

Database server interface implements various software system calls that are used by the users or administrator to manage the database. System calls may be inserted (), querying (), update () etc. All the patient information is accessed only after establishing secure connection and authentication of the user.

4.5. Data Accessing Layer (Layer-4)

This layer deals with accessing and transferring medical data from a remote database server on the request of EHR users. This layer provides the convenient methods access patient information among various users while keeping the access verifiability (Sohr et al., 2008. Because such medical history data pose sensitive information and it forced to implement methods to ensure confidentiality. So this layer performs various approaches to access control. These access control approaches may be Discretionary Access Control (DAC), Mandatory Access Control (MAC) or Role Based Access Control (RBAC). This layer combines works with the CA to prevent unauthorized access and to provide security and privacy to EHRs.

In continuation, "Role-Based Access Control through On-Demand Classification of Electronic Health Record" (Tiwari and Kumar, 2015) is based on Access Control through Classification (AC^2) algorithm that uses the logistic regression to classify the patient's data as per underlying user's role. Furthermore, various roles are used as the class, and each class has their feature vector for classification of HER, and this describes the user authority. EHR is categorized majorly three access level (Personal data, Insurance, and EHR). Multi-level data categorization is also possible as far as EHR is concerned, for example, personal information may be considered at first level that may further be categorized into the name, date of birth, gender, age, address and live status, etc. Furthermore, binomial feature 'live status' (dead, alive) containing sensitive information such as if death is true to have further one more level granularity like death reason, location and considered to access to the personal doctor. Similarly, Nurse may have access to personal patient data and sensed physiological values, the Normal user has right to access merely abstract personal information and so on. The objective of proposed work was to describe user's au-

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

thorities only. AC2 algorithm takes User role (Ur'), Patient-Id (Pid), Global Feature Vector (Gfv), Access Policies (AP) and class label (C) as input and it generates Class (Dt'). Where, Dt' $\in$ Dt as output where Dt is a given patient's record and Dt' is subset of Dt with respect of given user's role. Initially, the feature-vector is set to Null and the according to user role the selection is performed on global feature vector (Gfv) (i.e. Fv = σ user role= Ur (Gfv)) and selected features are stored at the Fv. Now from global EHRDB, the patient's EHRDB is created using patient-id and selection operator over EHRDB i.e. PEHRDB = σ Patient-id= Pid (EHRDB). Now 1:1 mapping of user role to assigned policy is defined (g: Ur $\rightarrow$ Pu) and then m-dimensional feature vector space is created. Now as per the user policy attribute values are fetched from the Patient's EHRDB by Scanning [Dt] with respect to Vur where Vur is the set of values of respective features. The bottom-up paradigm has been adopted to better fitment for access control where data values itself comes together to make classes. It also provides automatic access control model whereas and when user login the system, according to user's role the fraction of global data is grouped. The work also provides on-demand data classification whereas and when user role change the data classification is modified since the user's access rights will either increase or decrease.

5. CERTIFICATION AUTHORITY

Nowadays, the rapid growth of internet transactions is emphasizing the importance of secure authentication of network entities. For reliable and authorized data transmission between PDA & database server and healthcare providers & database, the involvement of trusted third party, such as a Certification Authority (CA) is necessary. CA is responsible for providing essential primitives for mutual authentication as well as secure transmission of patient's data among the EHR users. CA works online in real-time that issues and manages security credentials like security keys for maintaining the integrity and authorized access. The certification authority is governed and controlled by government bodies which provide trustworthy relations between network entities. CA contains the identity of network entities like domain owner and online servers for authenticated transactions.

In this regard, similar approach PVEMA (Tiwari et al., 2013) has been taken, where, the moment patient is equipped with a new BSN, it establishes a connection with DBS and when a link is set up, both PDA and DBS get in touch with CA to receive a certificate. For certificate creation, PDA and DBS both shares their public keys (Q_{pda} and Q_{dbs}) with CA. Now, CA generates the signature using their private key. CA used Elliptic Curve Digital Signature Algorithm to generate certificates and sends certificates (r_{pda},s_{pda}) for PDA and ($_{rdbs}$,s_{dbs}) for DBS with own public key Q_{ca}. When both the parties start mutual authentication process between them, these certificates and CA's public key is used.

6. CONCLUSION

We have investigated and developed a safe and pervasive model for patient monitoring and care. Here all requirements regarding patient privacy, security of data, removing redundancy without loss of data semantics, energy and bandwidth saving by data compression, reliable access control mechanism, etc. are fulfilled. In conclusion, presented work attempts to maintain privacy, secrecy, authenticity, and integrity of patient's data with energy and bandwidth saving which gives a significant cost reduction for pervasive patient monitoring. The presented multi-objective framework seems as an analytical system

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

for Healthcare for budgetary, operational, quality and process enhancement and works as the source framework for populating different contextual data. It is a healthcare analytics tool that dispenses with the need to compose SQL, empowers publishing of reports and fit for creating an extensive range of visualization (charts, crosstabs, tables, and graph).

ABSTRACT

Due to the ubiquitous availability of the information on the web, there is a great need for a standardized representation of this information. Therefore, developing an efficient algorithm for retrieving information from knowledge graphs is a key challenge for many semantic web applications. This article presents spreading activation over ontology (SAOO) approach in order to detect the relatedness between two human diseases by applying spreading activation algorithm based on bidirectional search technique. The proposed approach detects two diseases relatedness by considering semantic domain knowledge. The methodology of the proposed work is divided into two phases: Semantic Matching and Diseases Relatedness Detection. In semantic matching, diseases within the user-submitted query are semantically identified in the ontology graph. In diseases relatedness detection, the relatedness between the two diseases is detected by using bidirectional-based spreading activation on the ontology graph. The classification of these diseases is provided as well.

1. INTRODUCTION

Usually, computers were used to perform tasks with none sort of intelligence or semantics, thus there is a necessity to make computers as intelligent as human (Antoniou & Harmelen, 2004). The defect of non-semantic applications is painted by the statement "lack of semantics" particularly when the talk is concerning information retrieval. Numerous semantic-based applications require an efficient algorithm for querying large ontologies. The semantic web gives the meaning of knowledge, making software systems can perform intelligent tasks instead of users using a semantic content called ontology (Berners-

Lee, Hendler & Lassila, 2001). Ontology is a repository in which information is organized and used in semantic-based applications (Shadbolt, Berners-Lee & Hall, 2006). Therefore, ontologies are widely used as a semantic knowledge base in different areas of computer science such as information retrieval (Oberle, 2014), text classification (Fathalla, Hassan & El-Sayed, 2012), scholarly communication (Fathalla, Vahdati & Auer, 2017) and bioinformatics (Fathalla & Kannot, 2017).

The use of ontologies in the field of health informatics has become a mainstream activity within bioinformatics due to the vast growth of healthcare system. In bioinformatics, ontology is used for the representing and organizing medical vocabularies.

In neurophysiology, communications between neurons are demonstrated by a way of activation, which propagates from one neuron to another via connections called synapses to transmit information using signals (Ali, 2009). This phenomenon observed in the nervous systems of living organisms and called spreading activation. This phenomenon was later exploited in Artificial Intelligence as a method for searching associative networks, neural networks, or semantic networks (Schumacher, et al., 2008). Spreading activation in a generic form is a set of methods suitable for mining multidimensional networks with oriented weighted links. Collins and Loftus (1975) discussed in their research that the Spreading Activation (SA) runs on semantic networks (Anderson et al., 1983) and is used for information retrieval process (Burns et al., 1981). The spreading activation algorithm is suitable to work with incomplete data and with large datasets. It runs on a graph structure that comprises a set of nodes connected by edges. The concepts are nodes which have an activation value and the relations between them are represented by edges between these nodes. An activation value is assigned to each node in the graph and then the algorithm spreads to the nodes with the highest activation value. The algorithm runs in a set of iterations and terminates when a stopping condition is reached. The output of the algorithm is the list of nodes that have been fired according to their activation values. For each iteration or cycle, there are three substantial actions:

- The list of nodes is expanded by adding adjacent nodes of the latest activated nodes.
- The activation value of each node in the list is recomputed based on the activation value of the node itself and the weight of links which exist between other nodes.
- The list is filtered by excluding the nodes with activation values less than a given threshold.

This paper intended to demonstrate how to identify whether two human diseases are related to each other or not. If so, what are the set of diseases connecting them. For instance, is there a relatedness between “Vasculogenic impotence” and “Transvestism”? And if so, what is the path (set of diseases) of the relatedness?

Finding a relatedness between diseases is important because physicians can treat patients not only based on the symptoms they suffer from but treat the real cause of this disease which may be related to another disease that causes these symptoms, i.e., physicians can treat the cause disease, not the symptoms.

To the best of our knowledge, it has not yet been established whether biomedical ontologies could be used to detect relations between human diseases. After reviewing the literature, we believe that this approach is a first such attempt of detecting the relations between diseases using ontologies combined with Descriptive Logic (DL) rules. We have added several Descriptive Logic (DL) rules to the ontology to be able to infer the semantic relations between diseases which are not explicitly provided. In addition, we have also developed the semantic matching and relatedness detector algorithm for identifying user-submitted diseases in the ontology graph and detecting the relatedness.

The remainder of this article is organized as follows. Section 2 gives a brief overview of the related work. Section 3 presents the disease ontology utilized by the proposed approach which is used as a semantic knowledge base. In Section 4, the methodology of the proposed work is discussed. In Section 5, the workflow of the proposed approach is described. In Section 6, a running example is presented. Finally, the conclusion and the directions for future work are presented in Section 7.

2. RELATED WORK

There are a numerous amount of literature on biomedical knowledge management and medical decision making due to the explosion of biomedical knowledge over the last two decades. Therefore, biomedical knowledge available on the web is growing considerably as most of the biomedical research papers are published online. Semantic matching is used to match information which is semantically related based on the meaning of the data rather than keyword-based matching (Giunchiglia et al., 2007). This could be achieved by analyzing the meaning of concepts, not just the labels. There are essentially two approaches to make use of the hierarchical ontology structure for determining the semantic similarity between concepts: edge-based or node-based approach (Bernstein, 2005). In recent years there has been considerable interest in semantic matching (Fathalla & Kannot, 2017; Giunchiglia et al., 2004; Hasan and Curry, 2014; Gonzalo et al., 2014; Guo et al., 2014; Wu et al., 2017). Some examples of individual approaches addressing the matching problem can be found in (Dhamankar et al., 2004; Do & Rahm, 2002). Identifying named text features in user-submitted query is a crucial procedure for efficient semantic matching and text analysis. The analysis may include term normalization; phrase analysis, word sense analysis, and the matching may be performed on phrase aspect and word sense aspect (Kacholia, et al., 2005). In their cutting-edge paper of 2004, Kanavos, Theodoridis, and Tsakalidis (2014) proposed a metasearch engine over PubMed[1]. It provided an accurate clustering of results according to their specific topic using a biomedical ontology, named MeSH[2] in addition to RxNorm[3] that is a US-specific terminology in medicine that semantically links clinical drug vocabularies and supports the interoperation between them. Ngo, Cao and Le (2010) proposed an ontology-based vector space model for semantic annotation and semantic search which combines different ontologies. It took the advantage of ontological features of both named entities and WordNet vocabularies and develops a spreading activation algorithm for query expansion. As anticipated, their experiments demonstrated that the proposed model is better than the solely keyword-based model and also better than the ones using only WordNet or named entities. In addition, they merged various ontologies to improve the semantic search process. De Maio et al. (2011) proposed a project named ODINO which uses a fuzzy knowledge approach for disease diagnosis which supports medical decision making. ODINO has three main features which are a faceted search of diseases through taxonomy constraints, disease catalog browsing, and preliminary medical diagnosis.

Many efforts have been made to represent medical information as a semantic knowledgebase for further processing by semantic applications. Despite the existence of many medical ontologies, it is important to reuse and integrate the ontologies and to establish mappings between their concepts. Recently, there is a growing interest in ontology matching and integration (Shvaiko and Euzenat, 2013; Euzenat, 2011). Shvaiko and Euzenat (2013) surveyed the state of the art of ontology matching and addressed some worthy challenges for ontology matching techniques and also, they conjecture that significant improvements can be obtained. In addition, they analyzed the results of recent ontology matching evaluations. Below some of the famous medical-related ontologies will be listed.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

- *Human Disease Ontology* (DO)[4] is a standardized biomedical ontology which contains a considerable number of disease terminologies. Compound disease names, conjunction of two disease terms, are not included.
- *Vaccine Ontology* (VO)[5] contains more than 2000 vaccines and relationships between them (He et al., 2009). VO is written in the Web Ontology Language (OWL).
- *Infectious Disease Ontology* (IDO)[6] is a biomedical ontology which represents infectious diseases and relations between them.
- *Ontology for Biomedical Investigations* (OBI)[7] is an ontology represents life-science and clinical practice concepts.
- *Ontology for General Medical Science* (OGMS)[8] (formerly, Clinical Phenotype Ontology) is an ontology represents diseases and symptoms for human diseases.

3. THE DISEASE ONTOLOGY

Resource Description Framework (RDF) data model is used to describe data semantically, including concepts and relationships between them. The main purpose of developing ontology is to use it as a semantic knowledge base representation for identifying concepts in a specific domain and find out its semantics and the relationships between them (Fathalla, Hassan & Kholief, 2013). The authors of Köhler (2014) and Croft (2014) discuss in their research that the human disease data is considered a cornerstone of biomedical research, therefore, there is an enormous need for a consistent representation of human disease for robust data analysis (Colomb, 2007; LePendu et al., 2011). Creating a biomedical knowledgebase in the form of ontologies creates a rigid knowledgebase for semantic annotation of biomedical data through defined concepts and relations connecting them (Hoehndorf, Dumontier & Gkoutos, 2012). Below a group of definitions that is used as a basis for the formulation of the term ontology and its components (Fonseca, Davis & Câmara, 2003):

Definition 1. A concept in the ontology (Ψ) is a triple (τ) of the form: $\tau = [\alpha, \beta, \Omega]$, $\tau \in \Psi$, where α is the URI of the concept or a blank node, β is the predicate/property and Ω is an URI, a literal or a blank node.

Definition 2. (Semantic Relation)

A semantic relation between any two concepts in the ontology is one of the relations among the set of semantic relations $\Sigma = \{\text{Hypernym, Hyponymy, Synonymy}\}$. Semantic Relations are either taxonomic (hierarchal) or non-taxonomic relations (Ali, Fathalla, Kholief, & Hassan, 2017).

Definition 3. (Hyponym, Hypernym)

A hyponym is a word whose semantics is enclosed in another word which called its Hyperonym or Hypernym. For instance, *vaccine*, *rabies*, and *smallpox* are all Hyponyms of *viral infectious disease* (their Hypernym); that, in turn, could be a hyponym of disease by the infectious agent (Fromkin & Robert, 1998).

Definition 4. (Co-hyponyms)

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

If concept C has two hyponyms A and B, then A and B are identified as co-hyponyms.

The disease ontology (DO) used in this work is a standardized biomedical ontology for describing human diseases. The objective of DO is to provide the biomedical community with a convenient, reusable and robust knowledgebase of human disease concepts, phenotype characteristics, and related medical vocabulary disease concepts. It is developed by the collaboration of different research organizations such as Northwestern University, Center for Genetic Medicine and the University of Maryland. The human disease ontology is concentrated on representing predominant and rare disease concepts captured across biomedical resources in order to provide a disease interface for human disease terminologies. Major enhancements to the DO database since 2012 has been made including: the content has had several revisions, addition of 760 terms, addition of definitions, improvement of the structure and switch to web ontology language (OWL) (Kibbe et al. 2014). The Disease Ontology database has been updated to the latest ontology as of 02-03-2017. The DO project has had a considerable influence on the development of biomedical resources, as evidenced by 291 citations of the first paper (Schriml et al., 2012) of DO. Do has imported five ontologies and contains about 33,000 classes (see Table 1).

With SPARQL, the World Wide Web Consortium standard query language for RDF, it is possible to make RDF data available through a standard interface and query it using a standard query language. The example below shows SPARQL query for finding superclasses for "Hyperuricemia" disease. SPARQL query consists basically of three parts except for the prefix declarations (lines 1–3): (a) the result specification part including solution modifiers (line 3), (b) the dataset definition part (line 4), and (c) the restriction definition part (lines 5–9) (Hartig & Heese, 2007). SPARQL query is executed against RDF triples in the RDF graph by matching these triples with criteria in the WHERE clause.

```
PREFIX rdf: <http://www.w3.org/1999/02/22-rdf-syntax-ns#>
PREFIX rdfs:<http://www.w3.org/2000/01/rdf-schema#>
PREFIX oboInOwl:<http://www.geneontology.org/formats/oboInOwl#>
SELECT ?sc ?label ?superlabel
WHERE {
{?person rdfs:label ?label FILTER regex(str(?label),"Hyperuricemia", "i")}.
?person rdfs:subClassOf ?sc .?sc rdfs:label ?superlabel
}
```

Table 1. DO statistics

Type	Local	Imported	Inferred	Total
Number of Triples	187957	89224	2390	279453
AnnotationProperty	25	0	0	25
Class	8720	25030	0	33750
DatatypeProperty	1	0	0	1
ObjectProperty	0	1	0	1
Ontology	1	5	0	6

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

The regex function is used to match two given strings. In the example above it matches the value of the variable (*?label)* with the string "*Hyperuricemia*". The purpose of the third parameter *(i)* in the regex function is that there will be case insensitive matching.

One way to access the data in the RDF model is via the Jena-embedded query engine ARQ (Seaborne, 2010) that is distributed with Jena. ARQ supports both standard SPARQL and SPARQL 1.1 for querying ontologies.

4. METHODOLOGY

The methodology of the proposed work is divided into two phases: Semantic matching and Diseases relatedness detection. In semantic matching, diseases in the user-submitted query are semantically identified in the ontology. The output of this phase is whether these diseases are found in the ontology or not. If there is a relation between them, the Uniform Resource Identifier (URI) of both diseases is retrieved. In Disease relatedness detection, the URI of each disease is forwarded to the relatedness detector to find whether they are related or not. If they are related, the algorithm returns the set of diseases that connect them in the path and the classification of both is provided as well.

4.1. Semantic Matching

The aim of this phase is to identify user-submitted diseases in the ontology graph. It is assumed that, when searching for a concept, it is also important to get synonyms of that concept. Semantic matching conducts more analysis in the matching process. The analysis is carried out to identify candidate diseases in the disease ontology (Liu, et al., 2005). A *concept matching* is obtained after disambiguation by querying WordNet lexical dictionary (Fellbaum, 1998), DO and medical datasets such as MedlinePlus (Miller, Lacroix, & Backus, 2000) and WebMD (WebMD, 2017). Each disease name in the query is first disambiguated into concepts using vector space models (Bernstein, 2005), representing concepts as vectors of features in a k-dimensional space where (k) is the number of unique relevant keywords for a given disease in the query. In other words, each disease in the query is represented by a vector of relevant keywords found through WordNet and medical datasets. Relevant keywords are *Hyponyms, Direct-Hypernyms,* and *Synonyms* of the disease. After sense disambiguation, the proposed matching algorithm returns the URIs of matched concepts.

For example, the synonyms of the disease "*Hyperuricemia*" are "*Hyperuricaemia*" and "*Uricacidemia*" therefore, diseases describing these concepts are retrieved as well. The main objective of this phase is to identify whether diseases in the query text exist in the ontology or not. The proposed algorithm iterates through ontology resources and performs semantic matching between each disease and ontology resources. When matched, sets a flag α to true and then repeat this process for the second disease. Otherwise, the disease is not found in the ontology.

4.2. Diseases Relatedness Detection

In disease relatedness detection phase, the two diseases relatedness is detected by using bidirectional spreading activation on the ontology graph which consists of several cycles including checks for termination conditions. The worthiness of bidirectional search is the speed and it requires less memory, especially

15. ***If*** (α≠false **OR** β≠false) ***then***
16. Print ("One of the two diseases is not found");
17. **Return** null;
18. ***End if***
End for

when dealing with large graphs such as our ontology (see Table 1) (Li & Xu, 2014). The algorithm starts with two initial nodes, i.e. the diseases concepts in the ontology graph, and follows the following steps.

1. Assume all nodes in the graph have activation values of zero. Starting nodes take an activation value of 1.0.
2. For each link $L_{i,j}$ connecting the source node η_i with target node η_j, compute $a_j = \sum_{i=1}^{n} a_i \omega_{i,j}$. where n is the number of nodes connected to η_i and ω_{ij} represents a relatedness weight, which has a value between 0.0 and 1.0.
3. If a target node receives an activation value exceeds 1.0, then set its new activation value to 1.0. Terms of the disease ontology receive the highest value of $\omega_{ij} = 1.0$ if they are one of the relevant keywords of the current activated node (i.e. hyponyms, direct-hypernyms or synonyms), because they build the taxonomy using (*is_a*) relation. A low value of $\omega_{ij} = 0.0$ is assigned to any other relations which are not always effective.
4. A firing threshold (F) determines whether to include the activated node.
5. Nodes with activation value exceeds *F* are activated.
6. Once a node has activated it will not activate again.
7. The procedure terminates when a node is reached from more than one path (i.e. *sexual disorder* in the running example shown in Figure 2).

The algorithm can identify relevant keywords by using Descriptive Logic (DL) rules in a rule base (RB). For instance, if two diseases have a relatedness type Hypernyms, then they considered the same disease. In mathematical notation, these rules defined in Table 2. These rules are formally introduced as a syntactic fragment of first-order logic. An ambiguity may arise if two homonyms are used in the search query but there is no relatedness between them. For example, "*Stewart''* in "*Stewart-Treves syndrome*",

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

(a malignancy that arises within chronic lymphedema), is different from the one in "*Stewart-Bluefarb syndrome*". The latter is a type of *acro angiodermatitis* which was described independently by Stewart as well as by Bluefarb and Adams on the legs of patients with Arterio-venous malformations (Al Aboud, 2012).

By incorporating these rules, semantically matched diseases could be found using Jena reasoners. One feature of Jena is the support of different reasoners, which infer additional knowledge (Jena, Joseki & Pellet, 2004). These rules have been divided into three types: Transitive Rules, Symmetric Rules, and Co-Reflexive Rules. Jena inference system contains several inference engines (reasoners). These engines are used to check the consistency of the ontology and to infer additional RDF assertions. The primary use of this mechanism is to support the use of languages such as RDFS and OWL which allow additional facts to be inferred from instance data and class descriptions. The built-in reasoners included in Jena are (Jena, 2013):

- **Transitive Reasoner**: Supports transitive and reflexive properties traversal.
- **RDFS rule Reasoner**: Supports RDFS entailments.
- **Generic Rule Reasoner**: Supports forward chaining, backward chaining and hybrid execution strategies for user-defined rules.

The idea of a bidirectional search is to cut back the search time by looking out forward from the beginning and backward from the goal at the same time. When the two search paths meet, the algorithm constructs one path starting from the beginning node through the intersection to the goal.

5. WORKFLOW OF THE PROPOSED APPROACH

In this section, the layered architecture of the proposed method has been introduced. There are mainly three layers within the proposed conceptual architecture, namely the *Presentation Layer*, the *Middleware Layer* and the *Data Layer*. Figure 1 depicts the layered-architecture of the proposed approach.

- **Presentation Layer:** The presentation layer is responsible for providing end users the Graphical User Interface (GUI) through which users can submit queries and get the results.
- **Middleware Layer:** The primary role of the middleware layer is to provide an abstraction for ontology access. This role is implemented using Java programming language and Jena API and reasoners, which isolates clients from different API implementations and provides a unified inter-

Table 2. Rule base for the proposed method

Rule#	Mathematical Notation	Description
R_1	∀disease a, band $c \in D$: if $(aHb \wedge bHc) \rightarrow aHc$	D is the disease set in the ontology H is the "hyponym" relation.
R_2		S is the "synonym" relation.
R_3		
R_4	∀disease a, band $c \in D$: if $(aQb \wedge cQb) \rightarrow aHc$	Q is the "Hypernyms" relation.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

face for querying different data models in the data layer. The second role of this layer is: 1) apply pre-processing techniques to the query, 2) formulate the semantic query, 3) query the underlying ontology and then 4) send the results back to the presentation layer.

- **Data Layer:** This layer offers access to physical data stores which is the disease ontology and medical datasets. The data stores are queried two times. One is for identifying the two diseases in the ontology, and the second is for detecting the relatedness between them.

Furthermore, SAOO prototype exemplifies how the proposed method is used. SAOO automatically processes user-submitted query in the following steps.

1. The user submits the two diseases as a string using the system interface.
2. Perform Pre-processing on input.
    a. **Intelligent Tokenization and Stop List Elimination:** This step includes tokenizing the query stream, by breaking it down into understandable segments. Then, stop words have been removed. The intelligence here is that the method does not blindly remove all stop words like traditional techniques, but using a concept tokenization technique in which the keyword is taken with the preposition after it as a concept. If that concept has a match in the ontology, then this proposition will not be removed otherwise it will be removed (Fathalla, Hassan & Kholief, 2013). Tokenization is carried out using *StringTokenizer* Java class.
    b. **Stemming:** Stemming removes word suffixes: both inflectional suffixes (*-s, -es, -ed*) and derivational suffixes (*-able, -ability*) are stemmed (Fan, Huang & An, 2006). Stemming is carried out using *Porter stemmer* (Willett, 2006) Java class.
3. Formulate semantic query using SPARQL (Jena, Joseki & Pellet, 2004) query language and executes it using the Jena-embedded query engine (ARQ) against the ontology which performs the semantic matching process described in the methodology section.
4. The diseases relatedness is detected by using bidirectional-based spreading activation on the ontology graph if the diseases found in the matching process. The output of this process is a set of diseases that builds the path between the two diseases. In addition, the classification of these diseases could be detected by performing one more cycle of the spreading process which is the disease name in one level up (if available) in the hierarchy.

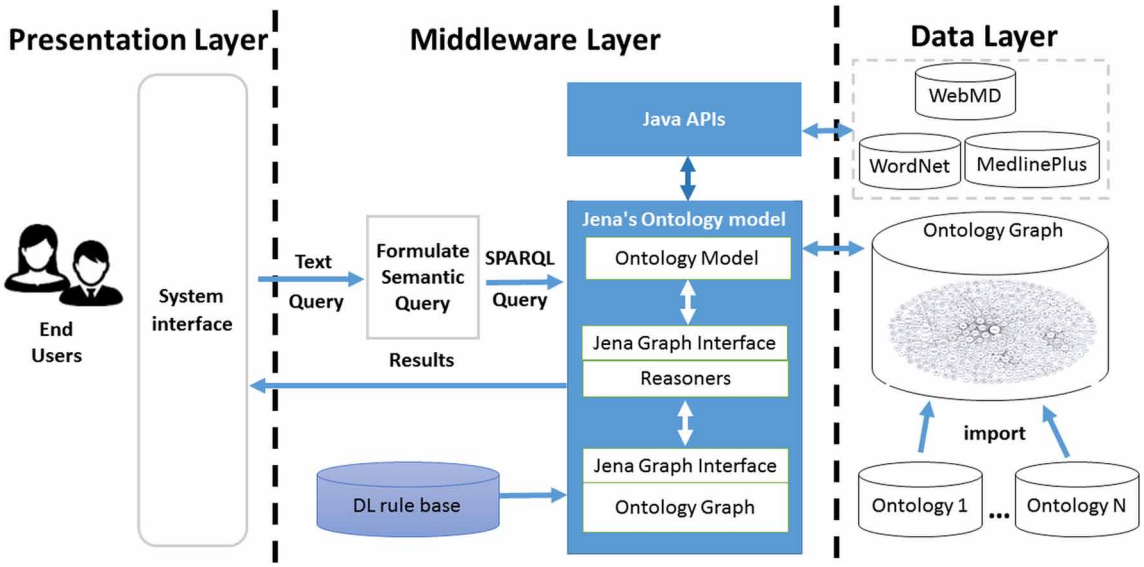
6. RUNNING EXAMPLE

As a running example in this paper, a query includes the two diseases ("*Joubert syndrome with orofaciodigital defect*" and "*Meckel syndrome*") will be used as a user-submitted query. The results of relatedness detection may consist of a set of different diseases. The relatedness between *Joubert syndrome with orofaciodigital defect* and *Meckel syndrome* diseases are detected by the intersection node *Ciliopathy*. The algorithm runs in the following steps and the whole spreading process is summarized in Table 3.

1. Initiate with two initial nodes *Joubert syndrome with orofaciodigital defect* and *Meckel syndrome* (marked in light gray).
2. In the first cycle of the activation process, one more node will be activated from each of the starting nodes, which is Joubert syndrome (from node 1) and *Ciliopathy* (from node 2).

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. Layered architecture of the proposed method



3. In the second cycle of the activation process, one more node will be activated from each of the latest activated nodes in each path which is *Ciliopathy* and *Genetic Disease* diseases from the first and second path respectively.
4. The algorithm detects an intersection node which is *Ciliopathy* and stops.

As shown in Figure 2, the algorithm originated at nodes *Vasculogenic impotence* and *Transvestism* (filled with light-grey) which has an initial activation value of 1.0. Two cycles of spreading activation have occurred. Then, they meet at the intersection node "*Sexual disorder*". Activation is spread over the graph with paths marked with bold lines and nodes filled with dark-grey. Therefore, it could be inferred that *Vasculogenic impotence* is a *sexual dysfunction,* which is *sexual disorder* and *Transvestism* is a *fetishism* which is a *paraphilia* which is also a *sexual disorder*. One more cycle can be performed to get one more up-level disease connecting both which could be considered as a classification of both diseases.

Table 3. The spreading process tracing of the running example

1st Initial Node	Joubert syndrome with orofaciodigital defect
2nd Initial Node	Meckel syndrome
Path from node 1	Joubert syndrome- Ciliopathy
Path from node 2	Ciliopathy
Intersection	Ciliopathy

7. CONCLUSION AND FUTURE WORK

In this paper, a layered architecture of the proposed method named Spreading Activation over Ontology (SAOO) has been proposed in order to detect the relatedness between two human diseases. This relatedness can be detected by running spreading activation algorithm using the bidirectional search technique on a well-formed disease ontology. One key feature of SAOO is to identify whether two human diseases are related to each other or not. Moreover, identify related diseases that may connect them in a common path. The importance of the relatedness is that the physicians can treat patients not only based on the symptoms they suffer from but treat the real cause of this disease which may be related to another disease that causes these symptoms. Therefore, the physician can treat the main cause, not just the symptoms. Consequently, SAOO helps in medical decision support. The proposed method improves the non-semantic medical systems by considering semantic domain knowledge to infer diseases relatedness. For future work, authors are planning to find the relatedness between more than two diseases using multiple-goal search algorithms and provide the relatedness graph between them not only a simple path. In addition, a relatedness set is returned to the user which is a subset of the power set of the set of input diseases. In other words, which of these diseases is related to the others? Finally, it is planned to integrate different ontologies in the medical domain using and ontology matching and integration services.

Chapter 27
An Artificial Neural Network Classification of Prescription Nonadherence

Steven Walczak
University of South Florida, USA

Senanu R. Okuboyejo
Covenant University, Nigeria

ABSTRACT

This study investigates the use of artificial neural networks (ANNs) to classify reasons for medication nonadherence. A survey method is used to collect individual reasons for nonadherence to treatment plans. Seven reasons for nonadherence are identified from the survey. ANNs using backpropagation learning are trained and validated to produce a nonadherence classification model. Most patients identified multiple reasons for nonadherence. The ANN models were able to accurately predict almost 63 percent of the reasons identified for each patient. After removal of two highly common nonadherence reasons, new ANN models are able to identify 73 percent of the remaining nonadherence reasons. ANN models of nonadherence are validated as a reliable medical informatics tool for assisting healthcare providers in identifying the most likely reasons for treatment nonadherence. Physicians may use the identified nonadherence reasons to help overcome the causes of nonadherence for each patient.

INTRODUCTION

Prescription (pharmaceutical) treatment plans require a specific pharmaceutical drug to be taken in specific amounts at specific intervals for a specific period of time. Nonadherence is the violation of any of these specified treatment requirements: not taking the correct dosage (too little or too much), missing or delaying scheduled administrations of the pharmaceutical, or not completing the treatment (Hugtenburg et al., 2013). Nonadherence to pharmaceutical treatment plans is a worldwide dilemma and prior research results examining the rate of nonadherence in 20 countries are shown in Table 1. As

may be seen, documented nonadherence rates vary in different cultures, but range from 10% to 88%. Prescription nonadherence is a persistent problem in healthcare today (Lehane & McCarthy, 2007) and nonadherence through underuse of a medication is rising significantly in prevalence (Kirking et al., 2006).

Nonadherence, especially to antibiotics and antimalarials, causes increased risks to the population by enabling evolution of resistant strains of malaria and other diseases (Andrajati et al., 2016; Awad & Eltayeb, 2007; Okuboyejo, 2014; Pechère, 2001) and harms population health by promoting further spread of diseases due to resulting ineffective treatment (Andrajati et al., 2016; Awad & Eltayeb, 2007; Center for Disease Control, 2013; Gibson et al., 2011; Okuboyejo & Eyesan, 2014). The Center for Disease Control states that pharmaceutical treatment nonadherence leads to significant economic and well-being impacts with direct costs estimated at $289 billion annually and 125,000 deaths annually (Center for Disease Control, 2013).

Reasons for patient nonadherence with the pharmaceutical portion of their treatment plans vary. Self-medication is a rising worldwide problem (Agarwal, Yewale, & Dharmapalan, 2015) especially in regions of the world where antibiotics and other medications are available without prescription, and has been identified as a contributing factor to improper treatment including nonadherence to recommended treatment plans (Awad & Eltayeb, 2007; Grigoryan et al., 2006; Zhu et al., 2016). Other reasons for pharmaceutical nonadherence are: cost of medication (Center for Disease Control, 2013; Gibson et al., 2011; Hirth et al., 2012; Kirking et al., 2006), negative attitude toward drug or don't like taking drugs (Kirking et al., 2006; Okuboyejo, 2014; Urquhart, 2005), lack of time/employment/travel (Au et L., 2014; Okuboyejo, 2014), don't trust or other issues with physician (Okuboyejo, 2014, Zhu et al., 2016), lack of (Kirking et al., 2006; Urquhart, 2005), forgetfulness (Au et al., 2014), religious or cultural reasons (Urquhart, 2005), fear of side effects (Gottlieb, 2000; Kirking et al., 2006), and other personal reasons (Urquhart, 2005). It is important to note that each patient may have multiple reasons for being nonadherent (Okuboyejo, 2014; Urquhart, 2005).

Various methods have been proposed to lessen nonadherence, including: better physician-patient communication (Agarwal, Yewale, & Dharmapalan, 2015; Buckalew & Sallis, 1986; Okuboyejo, 2014), other patient education (Oyelami, Okuboyejo, & Ebiye, 2013), and sending automatic reminders (Eyesan & Okuboyejo, 2013; Okuboyejo, Omoregbe, & Mbarika, 2012). Each of these proposed solutions is generic for a whole population of patients and typically addresses only a single reason for nonadherence. Identifying an individual patient's specific reasons for nonadherence would enable tailored individualized responses to address the reasons for nonadherence relevant to each patient. An artificial neural network (ANN) informatics tool to predict the nonadherence reasons for individual patients is developed based on Social Learning Theory. The ANN is tested for predicting individual nonadherence reasons on a population of patients in Nigeria.

BACKGROUND

Brief Background on Artificial Neural Networks

ANNs are nonparametric machine learning systems inspired by the human brain and composed of processing elements arranged in layers and highly interconnected (see Figure 1) (Caudill, 1987). Each connection is initially assigned a randomized value or weight. Input layer nodes receive raw numeric values representing the independent variables. Additional processing nodes are arranged into some number of

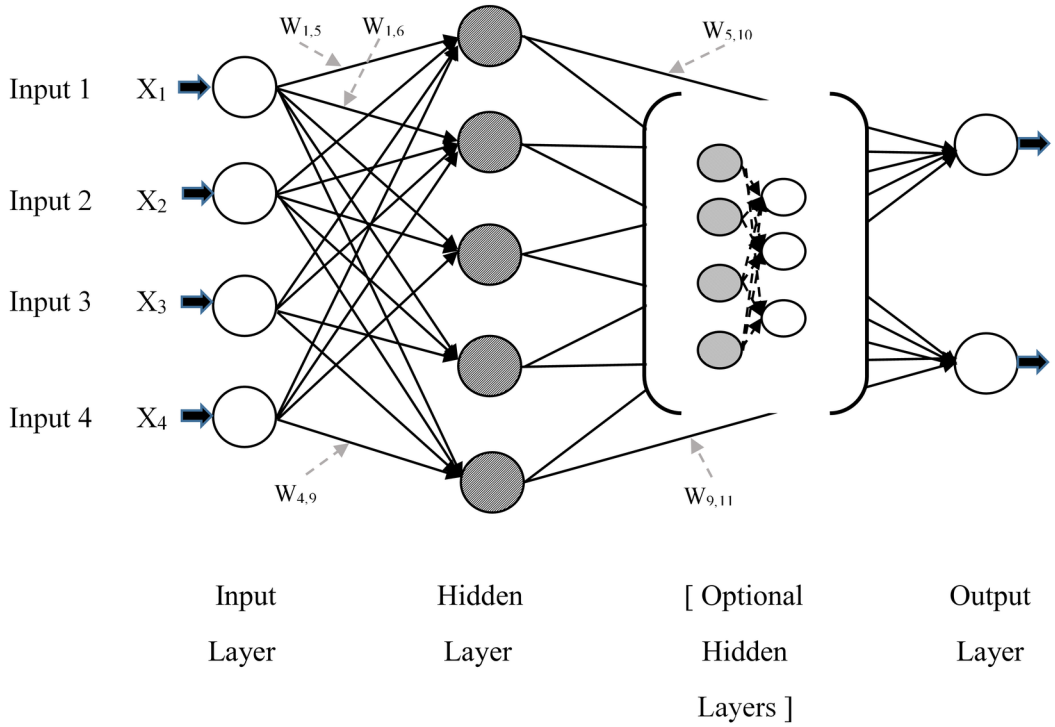
hidden processing layers and finally an output layer, which represents the dependent variable(s). All hidden and output nodes receive the aggregation of the product of the incoming nodes and the associated connection weights, thus if summation is used as the aggregation function then a node's input value is equal to $\Sigma\, w_{ij}x_i$, where w_{ij} is the weight on the connection from node *i* to node *j*, coming from node x_i. Each processing element performs its own computation on this input value, known as a transfer function, before transmitting it along its outbound connections. Transfer and aggregation functions may be any function defined by the user, such as sum or average or maximum for the aggregation function and sigmoid or a hyperbolic tangent function for the transfer function.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. Artificial neural network architecture (only a few connection weights shown for clarity)



The backpropagation learning algorithm, learns by propagating the error term of the output produced by a given set of input against the known values backwards through the network to adjust the connection weights. Backpropagation is known as a supervised learning system since it requires training records with known outcomes in order to calculate the correct output error.

One advantage of ANNs over other modeling paradigms is that since they are nonparametric they may work with any type of numeric input values and those values have no constraints as in other statistical models, such as requiring normal distribution or heteroskedastic error. Translating data into numeric representations for use in an ANN is easy to perform, such as representing a categorical variable with a corresponding number of input variables (one for each category) that are set to true or false. Second, since ANNs are learning systems, they are able to find optimal solution surfaces to model the given training data. This includes complex nonlinear solution surfaces. Additionally, once trained, ANNs are highly tolerant of noise in future input data. Disadvantages are that ANNs are sensitive to the independent variables selected, which must not be highly correlated, and the number of nodes in each hidden layer, which can cause poor out of sample performance due to memorization (Smith, 1993; Walczak & Cerpa, 1999). These disadvantages may be overcome by first testing desired independent variables with a correlation test, such as Pearson's Correlation Matrix, and by developing and testing multiple hidden node and layer architectures to find the optimal quantity of layers and processing nodes.

A more detailed explanation of ANNs is beyond the scope of this paper. Many tutorials exist and readers are encouraged to pursue these for additional explanation (see (Jain, Mao, & Mohiuddin, 1996; Rodvold, McLeod, & Brandt, 2001; Walczak & Cerpa, 1999; Zhang, 2007) for examples, guidelines, and further information on ANN development).

Prescription Nonadherence Research

As shown in Table 1, research on prescription nonadherence has been conducted that examines populations from around the world for at least the last sixty years (DiMatteo, 2004). Most of the reported research consists of empirical studies on specific populations for a single or small set of medical reasons (DiMatteo, 2004). Different theoretical models commonly used in prescription nonadherence research include: the Health Belief Model, Social Learning Theory, Theory of Planned Behavior, and the Transtheoretical Model (Bowen, Helmes, & Lease, 2001; DiMatteo & Martin, 2002).

Prescription nonadherence research uses multiple direct and indirect methods in evaluating nonadherence (Farmer, 1999). Indirect methods include patient self-reporting and pill counting. The research reported in this article uses self-reporting. Direct methods involve urine or blood tests to detect the presence of the desired amount of the prescribed pharmaceutical.

Despite the plethora of research on prescription nonadherence, results have not been either cost effective or clinically effective in reducing nonadherence (Lehane & McCarthy, 2007). Several systematic studies have been performed over this large body of existing literature (DiMatteo, 2004; Hayes et al., 2002; McDonald, Garg, & Haynes, 2002) and commonly classify reasons for nonadherence as either intentional factors including physician-patient communication or unintentional factors such as forgetfulness (Lehane & McCarthy, 2007).

METHOD

Population and Data Collection

A survey based on Akers (1977) Social Learning Theory is designed using prior surveys examining pharmaceutical treatment nonadherence in Africa (Ekwunife, Udeogaranya, & Adibe, 2010; Erah & Arute, 2008; Ikechuwku, Obinna, & Ogochukwu, 2010; Uzochukwu et al., 2009). The survey contained five demographic questions (age, sex, marital status, education level, and payer) and 25 questions covering intentional and unintentional reasons for being nonadherent.

After obtaining informed consent and guaranteeing anonymity, the survey is given to 600 outpatients from university and government hospitals and clinics in southwest Nigeria who were taking any type of pharmaceutical as part of their prescribed treatment. A total of 474 responses are returned for a response rate of almost 79 percent.

Data Preparation and Independent Variable Definition

The anonymized raw data is then transcribed into a spreadsheet format for analysis and preparation to further format the data for the ANN. Ten of the responses are discarded because the respondents indicated they were not currently on a pharmaceutical treatment plan. Since respondents were instructed that they didn't have to answer any question which made them feel uncomfortable, numerous responses were missing values. Whether the missing values are due to discomfort or other reasons including laziness is unknown. Further preparation of the response data for use by the ANNs eliminates responses with too many missing values (Cherkassky & Lari-Najafi, 1992), leaving a total of 237 usable responses. The usable responses are divided into a training set of 137 responses and a validation set or hold-out sample

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

of 100 responses. Three-fold cross validation is used to enable each response to serve as both a training and validation sample, but for different training instances of each ANN. The validation samples are never seen during the ANN training and can thus simulate real-world usage of the ANN for predicting individual patient reasons for nonadherence. Each response is only counted as a validation item a single time.

The survey specifies 23 specific reasons for nonadherence behavior and respondents are able to select as many as apply to them. These 23 individual reasons are further classified into seven distinct classifications of reasons for nonadherence which are: a lack of understanding or education, issues with the doctor (e.g., distrust or dislike), cost of the medication, religious objections, concern over side effects, lack of time or other time issues, and other personal reasons. Lack of understanding or education, time issues, and other personal reasons fall under unintentional reasons, while the remaining four categories of nonadherence reasons are intentional. These seven categories serve as output variables for the ANN.

ANN Design and Development

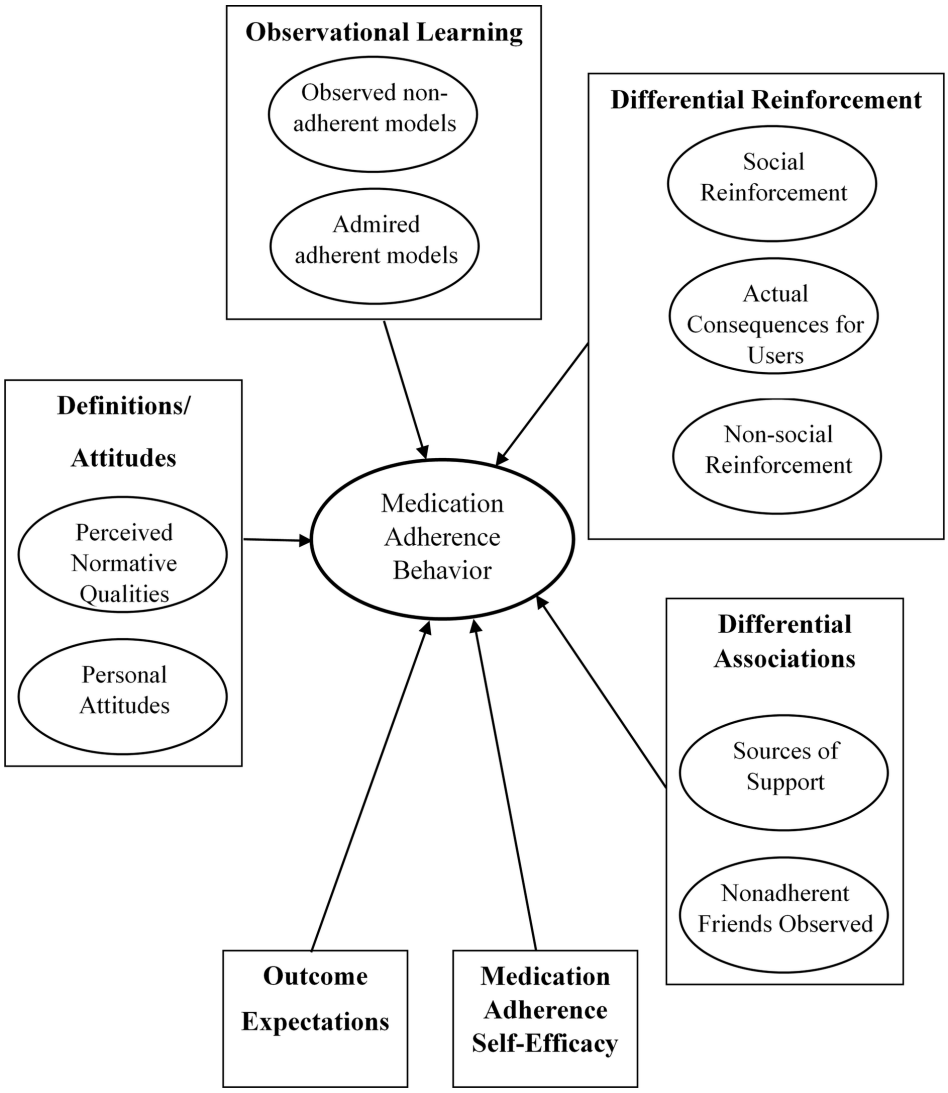
The demographic variables age, marital status, sex, education, and primary source of payment (self, family, work, insurance, charity, other) and 25 additional variables representing observational learning, differential association, differential reinforcement, medication adherence self-efficacy, outcome expectations, and personal attitudes towards adherence that are proposed influences on adherent behavior, as displayed in Figure 2. This creates a 34 variable input vector, since some of the demographic variables are treated as categorical variables.

Various training methods including radial basis function (RBF), traditional backpropagation or multi-layer perceptron, and backpropagation with two-layer forward connections are evaluated for classifying nonadherence reasons. The backpropagation with forward connections outperformed the other two learning methods and is the only one discussed for the remainder of this article. Backpropagation is the most common learning and training method used in ANNs and because of its robustness and ease of implementation and enabling easier comparison with future ANN research in nonadherence (Given, Given, & Simoni, 1978). Both single and two hidden layer architectures are investigated. The single layer architectures performed at least as well as the two hidden layer architectures and for simplicity (reducing the total number of connections in the ANN), the single hidden layer models were selected as the best performing architecture. The best performing ANN architecture had 34 input values, 42 hidden layer nodes in a single hidden layer, and seven output nodes. Using just a single hidden layer is informative as it indicates the solution surface is a hyperplane with a single concavity or convexity with no additional nonlinearities in the surface (Walczak & Cerpa, 1999).

After finding a single hidden layer ANN architecture that produced the best classification performance for likely nonadherence reasons for individual patients, further examination of the data revealed that less than three percent of individuals indicating cost was a reason had someone other than themselves or their family paying for the medication. Almost a third of those that self-paid had concerns about cost. Additionally, 85 percent of the respondents indicated that lack of education was a reason for nonadherence, but this answer may have been biased since a university was conducting the survey and this type of answer would seem desirable for a university research outcome. Therefore, if we assume that cost is usually an issue and that good communication between the physician and patient to educate them about the benefits of their medication is needed, then a new ANN model may be developed examining the remaining five nonadherence reasons for individual patients. Additionally, instead of using the 25 elements for the six factors influencing adherence shown in Figure 2, these are represented by the individual

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. Factors influencing medication adherence



factors (two were used for attitudes and definitions). The best performing architecture for this new ANN is 13 input nodes, 11 hidden nodes in a single layer, and five output nodes as shown in Figure 3. This new ANN reduces the total number of connections in the best performing ANN from 1722 to 198 and thus reduces the chance for overfitting the data and consequent improvement to generalization of the results.

RESULTS

Population Demographic Results

Respondent age is captured in 10 year increments with a minimum of 18 (18-27) and a maximum of 67 (58-67). The median and mode for age are both the 28-37 year old group. Fifty percent of the respondents

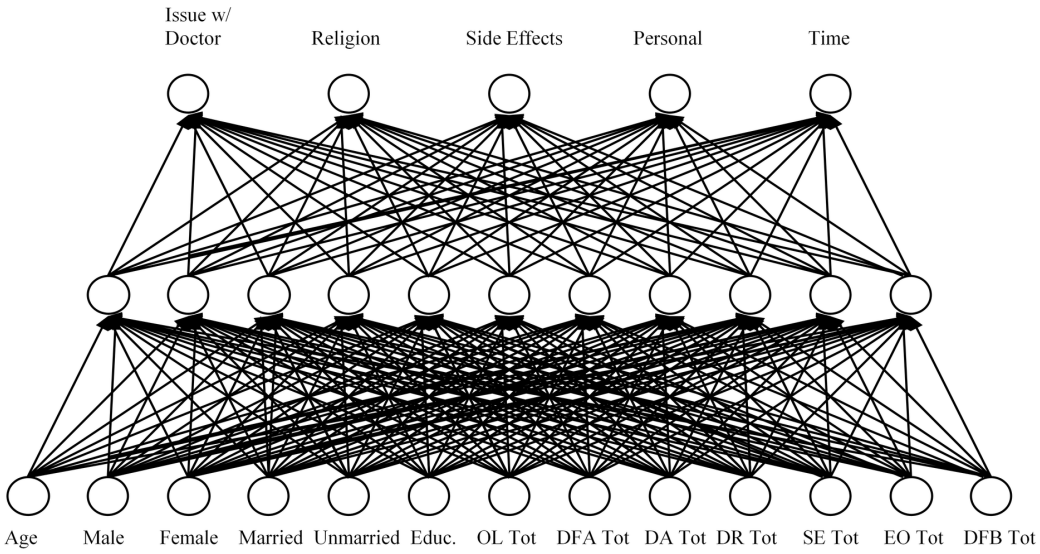
Figure 3. Backpropagation ANN architecture for predicting reasons for prescription nonadherence (not all connections shown)



were married and 44.8 percent were single or divorced or widowed, with the remaining having a missing value. Males represented 46 percent and females 47 percent of the population with the remaining having a missing value. Three quarters were employed or self-employed, with 18.2 percent reporting unemployment and 6.8 percent unknown.

ANN Prediction Results

The resulting ANN system is called INReP (Individual Nonadherence Reason Predictor). Results for the INReP ANN predicting all 7 categories of nonadherence are shown in Table 2. The INReP ANN did best predicting when religious concerns were or were not a nonadherence reason. For every nonadherence reason, INReP was correct over 54 percent of the time. The results may be further analyzed with results to specificity and sensitivity. A total of 550 true positive predictions (where positive indicates the respondent indicated this was a reason for their nonadherence), 493 true negatives, 132 false positives, and 128 false negatives resulted, producing a sensitivity to nonadherence reasons of 64.5 percent and a specificity to lack of nonadherence reasons of 61.2 percent.

The INReP ANN that predicted the 5 class subset of nonadherence reasons is shown in Table 3. A total of 479 true positive predictions, 384 true negatives, 197 false positives, and 125 false negatives resulted, producing a sensitivity to nonadherence reasons of 79.3 percent and a specificity to lack of nonadherence reasons of 66.1 percent.

Table 2. INRePP ANN results for predicting up to seven possible reasons for nonadherence

Nonadherence Category	INRePP ANN correct predictions* ($N = 237$)
Education/Understanding	175 (73.8%)
Issues with Doctor	135 (57.0%)
Cost	138 (58.2%)
Religion	183 (77.2%)
Concern over Side Effects	152 (64.1%)
Time	130 (54.9%)
Other Personal	130 (54.9%)
Total	1043 (62.9%)

*A prediction is considered correct if it was either a true positive or a true negative

Table 3. INRePP ANN results for predicting only 5 reasons for nonadherence (minus education and cost)

Nonadherence Category	INRePP ANN correct predictions* (N = 237)
Issues with Doctor	166 (70.0%)
Religion	197 (83.1%)
Concern over Side Effects	175 (73.8%)
Time	147 (62.0%)
Other Personal	178 (75.1%)
Total	863 (72.8%)

*A prediction is considered correct if it was either a true positive or a true negative

DISCUSSION

As shown above, the two INRePP ANN models both have reasonably high sensitivity for predicting the reasons a specific patient will become nonadherent and specificity for eliminating individual reasons of nonadherence. Naturally, assuming better education is always required and will improve medication adherence (Erah & Arute, 2008) and that cost is commonly an issue for self-payers, produces better prediction results, specifically an almost 23 percent improvement in sensitivity and an 8 percent improvement in specificity.

In addition to promoting increased patient communication with their physicians, other means may provide alternatives for patients to become better informed about their drugs and the need to complete treatment. The Internet is becoming much more widely used in Nigeria and provides a valuable resource for patient education (Oyelami, Okuboyejo, & Ebiye, 2013). Education can help address multiple nonadherence reasons beyond education or understanding, including concern over side effects, overcoming observational learning and social reinforcement effects, and personal reasons associated with dislike of medicine or concerns over drug habits.

Methods for overcoming lack of time or the personal reason of forgetfulness have been recommended in the literature. These include placing automated telephone calls to patients (Eyesan & Okuboyejo, 2013) and sending text messages (Okuboyejo, Omoregbe, & Mbarika, 2012) to remind patients of current drug

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

delivery times. Patients may also use or be provided alarm mechanisms (e.g., watch or cell phone) and carrying cases to assist them with remembering prescription administration time and enabling them to have their prescriptions readily available, though such mechanisms will increase the overall cost of care.

A need for future research to examine embedding ANN decision support into electronic heath records (EHRs) is still needed to make the results of the ANNs more readily available to physicians when getting ready to prescribe a pharmaceutical-based treatment plan. EHRs have been shown to improve patient safety within hospitals while enabling the improvement in the quality of care delivered in hospital setting (Bourgeois & Yaylacicegi, 2010). Patient safety and outcome concerns however, do not end at the hospital door. Patients being treated pharmacologically, are commonly monitored for adverse drug effects (Gupta et al., 2007), but this needs to be extended to assisting patients to follow and complete their prescription treatment courses to the fullest in order to obtain desired health outcomes.

Decision support regarding dangerous drug interactions already exist in EHRs (Helmons et al., 2015) and including the INReP ANN prediction of nonadherence reasons along with other drug related decision support should be a simple extension to existing EHRs (Kuperman et al., 2007). Research has shown that when EHRs are available 65 percent of physicians use them to examine drug interactions and to get recommendations when prescribing pharmaceuticals (DeMello & Deshpande, 2012). With the INReP predictions embedded in the EHR utilized by a healthcare practice or hospital, physicians can optimize patient outcomes by including education, reminders, or other initiatives to overcome individual patients' reasons for nonadherence, thus improving outcomes not only for the individual patient, but for the population health as well.

Another area for further research, but outside of the scope of information systems research is that of response bias. Recall that while the survey had a reasonable response rate of 79 percent, only half of these responses could be used in the ANN research due to missing values. Missing data values increases the uncertainty related to the data and nay cause to decrease the subsequent reliability of various modeling paradigms, including ANNs. Further research should investigate the reasons why respondent elect to not answer all of the questions, especially values critical to the research, in medically oriented domains to determine if further explanation or guarantees of anonymity could alleviate this problem.

A short questionnaire provided to patients during check-in or triage would produce the values needed by the ANN clinical decision support informatics tool for predicting nonadherence reasons for individual patients. These values would then be directed to the ANN, which would also access the patient's EHR to determine desired demographic values for the ANN's input vector. The ANN prediction of nonadherence reasons would then be written directly to the EHR so the physician would have this information available should a pharmaceutical treatment plan be diagnosed and enable the physician to direct the patient to various resources to overcome their potential nonadherence. Figure 4 represents the ANN clinical informatics tool relative to other resources.

CONCLUSION

An ANN method for predicting individual patient reasons for nonadherence to treatment has been presented and shown to be able to identify reasons, including multiple reasons, for nonadherence for 64 to 79 percent of the individual patients. Once incorporated into the EHR workflow, physicians will readily have this information available. Physicians or other clinical staff can then use these medical informatics classifications as recommendations on how to plan for ways to overcome their patients' nonadherence

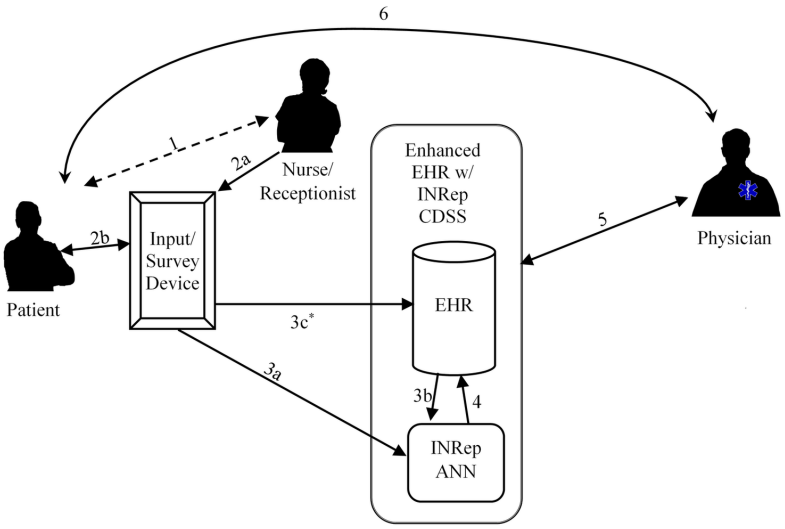
Figure 4. ANN clinical informatics tool in healthcare



*The patient survey device may also be used for check in and will then communicate via the office network with the EHR in addition to the INRep ANN

and consequently improve medical outcomes and a healthy lifestyle for these patients. Improving the health outcomes for pharmaceutically treatable conditions may also further promote a healthier population at large through decreased spread of the respective illnesses.

Future research may address how to facilitate incorporation of new features into EHRs and the clinician's natural workflow to enable identification of nonadherence or other dangerous behaviors of patients related to their treatments. Early identification of causes for non-optimal healthcare outcomes will enable education and other efforts, such as automated notifications or reminders, to improve healthcare outcomes.

ABSTRACT

Conventional computing methods face challenges dealing with real world problems, which are characterised by noisy or incomplete data. To find solutions for such problems, natural systems have evolved over the years and on analysis it has been found these contain many simple elements when working together to solve real life complex problems. Swarm Intelligence (SI) is one of the techniques which is inspired by nature and is a population based algorithm motivated by the collective behaviour of a group of social insects. Particle swarm optimization (PSO) is one of the techniques belonging to this group, used to solve some optimization problems. This chapter will discuss some of the problems existing in computational biology, their contemporary solution methods followed by the use of PSO to address those problems. Along with this several applications of PSO are discussed in few of the relevant fields are discussed having some future research directions on this field.

INTRODUCTION

A massive growth is seen in gathering biological information by scientific communities in these years. This information comes in the form of genomes, protein sequences and gene expression data and so on which causes a need for and efficient computational tools to store, analyze and construe these data. The term bioinformatics and CB always used interchangeably in the field of computer science, which literally means the science of informatics as applied to biological research. Informatics on the other hand is the management and analysis of data using various advanced computing techniques. Hence, in other words, bioinformatics can be described as the application of computational methods to make biological discoveries and explorations (Clote & Backofen, 2000). It can also be defined as the appliance of

computer technology to the management of biological information, encircling a study of the inherent genetic information, underlying molecular structure, resulting biochemical functions, and the exhibited phenotypic properties (Sushmita Mitra, Yoichi Hayashi,(2006)). The final goal and attempt of this area is to create new insights into the science of life as well as developing a global perspective (Das, Abraham & Konar, 2008). Three major objectives of bioinformatics can be put forward as to develop:

- Algorithms and mathematical models for searching the relationships among the members of huge biological dataset.
- Analyze and interpret the variety of heterogeneous data including nucleotide and amino acid sequences, protein domains and protein structures.
- Tools that enable proficient and effective storage, retrieval and management of high-volume biological databases.

In recent times, large number of biologically motivated algorithms have been developed and are being used for handling many complex problems. For instance, neural computing (Haykin, 1999) attempts to imitate the biological nervous systems of the living creatures inspired by the amount of parallel and distributed processing done inside the brain of a human. Genetic algorithm (GA) is inspired by the Darwinian evolutionary process through cross-over and mutation of biological chromosomes. They have successfully been used in many bioinformatics tasks that need intelligent search, optimization and machine learning approaches. Sushmita Mitra and Yoichi Hayashi, (2006) provide a comprehensive survey of the research in this direction. For the past few years there has been a slow but steady increase of research papers reporting the success Computational Intelligence (CI) based searching, classification and clustering techniques applied to the field of **CB** (Das, Panigrahi & Pattnaik, 2009). CI is constituted with the study of a set of nature-inspired computational methodologies, techniques and approaches to address complex real-world problems to which traditional approaches are ineffective or infeasible. While traditional models often fail to handle uncertainty, noise and the presence of an ever-changing context, CI provides solutions for complicated real problems. It primarily includes artificial neural networks (ANN), evolutionary computation (EC) and fuzzy logic (FL). In addition, CI also embraces biologically inspired algorithms such as SI, artificial immune systems, which can be seen as a part of EC.

This chapter presents some fundamental problems present in CB, the existing and traditional solution methods to answer these problems, the issues and challenges associated with these. Some of the contemporary problems solving approaches based on CI are then discussed.

BACKGROUND

To understand bioinformatics in any meaningful way, it is necessary for a computer scientist to understand some basic biology. In this chapter a short and basic introduction to the fundamentals and relevant to computational thing is given which are illustrated below.

Genetic Material: An Overview

Biology at the microscopic level began in 1665 when, Robert Hooke discovered that organisms are composed of individual compartments called cells. A cell's traits were inherent in its genetic information,

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

which was passed to its offspring, and the same was organized into genes that resided on chromosomes. Later on proteins and DNA (Dioxyribo Nucleic Acids) were discovered in 1869 by Johann Friedrich Miescher which consist of four types of bases: Adenine (A), Thymine (T), Guanine (G), and Cytosine (C). Later biologists discovered that not all Ribo Nucleic Acids (RNAs) are destined to serve as templates for building proteins. Some RNAs (like transfer RNA described below) play a different role.

DNA: TAC CGC GGC TAT TAC TGC CAG GAA GGA ACT

RNA: AUG GCG CCG AUA AUG ACG UC CUU CCU UGA

Protein: Met Ala Pro Ile Met Thr Val Leu Pro Stop

The process of turning an mRNA into a protein is called translation, since it translates information from the RNA (written in a four-letter alphabet) into the protein (written in 20-letter alphabet). All proteins, including the ones necessary for this process, are produced by this process. This flow of information is emphatically referred to as the central dogma in molecular biology.

DNA → transcription → RNA → translation → protein,

Figure 1 describes the analysis of DNA.

Figure 1. DNA analysis

MAIN FOCUS OF THE CHAPTER

In this section, we provide a basic understanding of the fundamentals problems of computational biology like protein structure, folding, DNA microarray data interpretation, inferring the gene regulatory networks that are relevant to this article.

Protein Structure Prediction

Proteins are built up by polypeptide chains of amino acids, which consist of DNA as the building block. An amino acid is an organic molecule made up of an amine (NH) and a carboxylic (CO) acid group (backbone), collectively bonded with a side-chain (hydrogen atom and residue R) that creates separation between them. Proteins are polypeptides, created in cells as a linear chain of amino acids. Chemical properties that differentiate the 20 individually different amino acids cause the protein chains to fold up into specific3-D structures that define their particular functions in the cell. Given the primary structure of a protein, in terms of a linear sequence of amino acids, folding tries to predict its stable 3-D structure. All these interactions governed by the laws of physics and chemistry to predict 3-D positions of different atoms in the protein molecule. Protein folding is a reaction involving other interacting amino acids and water molecules. The two-dimensional (2-D) secondary structure can involve an α-helix (with the CO group of the ith residue hydrogen (H) bonded to the NH group of the $(i+4)^{th}$ one) or a β-sheet (corrugated or hairpin structure) formed by the H-bonds between the amino acids. The parts of the protein that are not characterized by any regular H-bonding patterns are called random coils or turns. The tertiary structure refers to the 3-D conformation of the protein.

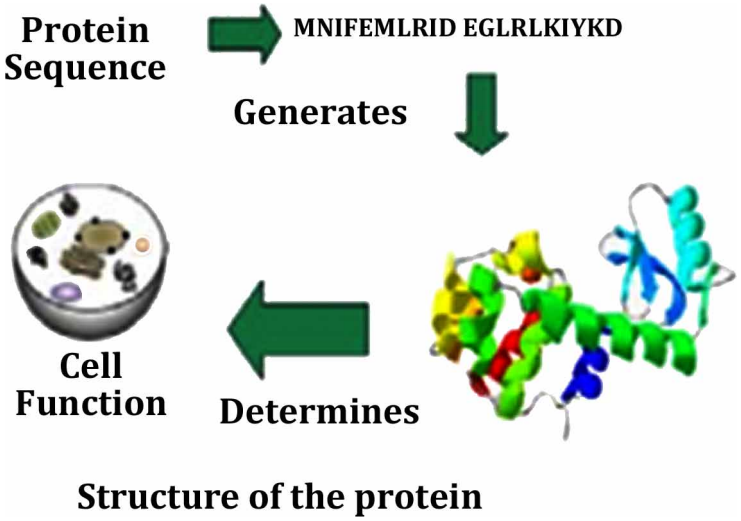
The total number of experimentally determined structure is less compare to actually known protein sequences (Schulze-Kremer, 2000). The difficult determination of these structures, using experimental methods such as X-ray or nuclear magnetic resonance (NMR), contributes to increase this gap between sequence and protein structures. Therefore, it is necessary the use of computational methods which predict 3D protein structures in a cheaper and faster way. According to biological approximation the methods for PSP falls into three groups: (1). Homology based Comparative modeling, (2) *ab* initio methods and (3). Threading (Priyadarshini, Dash, & Rout, 2012). The comparative model uses the predicted structures from the Protein data bank. These methods are based on the hypothesis that similar protein sequences determine similar 3D structures. Figure 2 shows the relation between protein sequence and their structure.

The problem of protein structure prediction has two dimensions:

1. **Secondary Structure:** A step on the way to a prediction of the full 3-D structure of protein is predicting the local conformation of the polypeptide chain, called the secondary structure. The whole framework was pioneered by Chou and Fasmann. They used a statistical method, with the likelihood of each amino acid being one of the three (alpha, beta, coil) secondary structures estimated from known proteins. The data consist of proteins obtained from the PDB. A fixed size window constitutes the input to the machine learning model. The machine classifier predicts the secondary structure corresponding to the centrally located amino-acid of the sequence within the window. The contextual information about the rest of the sequence in the window is also considered according to the model of the machine.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. Protein Sequence-Structure-Function Relationship



2. **Tertiary Structure and Folding:** Protein structure comparison is often used to identify set of residue equivalencies between proteins based on their 3-D coordinates, and has a wide impact on the understanding of protein sequence, structure, function, and evolution. The determination of an optimal 3-D conformation of a protein corresponds to folding, and has manifold implications to drug design. An active site structure determines the functionality of a protein. A ligand (enzyme or drug) docks into an active site of a protein. Many automated docking approaches have been developed, and can be categorized as: 1) rigid docking: both ligand and protein are rigid; 2) flexible-ligand docking: ligand flexible and protein rigid; and 3) flexible-protein docking: both ligand and protein are flexible (only a limited model of protein variation allowed, such as side-chain flexibility or small motions of loops in the binding site).

Primary Genome Sequence Analysis

The nucleus of a cell carries chromosomes that are built upon the double helical DNA molecules. In the human case the DNA genome is arranged into 24 dissimilar chromosomes. Each chromosome contains a number of genes, which are the fundamental physical and functional units of heredity. But, genes encompass only about 2% of the human genome; the remainder consists of non-coding regions, whose functions may embrace providing chromosomal structural integrity and regulating where, when, and in what amount and quantity proteins are built. DNA is transcribed to generate messenger (m)-RNA, which is then translated to make protein. The m-RNA is single stranded and has a ribose sugar molecule. A gene contains "Promoter" and "Termination" sites, which are responsible for the initiation and termination of transcription. Translation consists of mapping from triplets (codons) of four bases to the 20 amino acids building block of proteins. Genes are typically organized as exons (coding regions) and introns (noncoding regions). Hence, the main task of gene identification, from the primary genomic sequence, involves coding region recognition and splice junction4 detection. Sequence data are typically dynamic and order-dependent. A protein sequence motif is a signature or consensus pattern that is embedded

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

within sequences of the same protein family. Identification of the motif leads to classification of an unknown sequence into a protein family for further biological analysis. Available protein motif databases include PROSITE5 and PFAM.

Microarrays Data Analysis

A microarray is a glass slide on to which DNA molecules are statically set in an orderly manner at precise and definite positions called spots (or features). A microarray may contain thousands of spots and each spot may contain a few million copies of identical DNA molecules that uniquely correspond to a gene. This measures the relative m-RNA profusion between two samples, which are labelled with different flourescent dyes, viz., red and green. The m-RNA binds (hybridizes) with the Codon DNA(cDNA) probes on the array. The relative abundance of a spot or gene is measured as the logarithmic ratio between the intensities of the dyes, and constitutes the gene expression data. Gene expression levels can be determined for samples taken:

1. At multiple time instants of a biological process (different phases of cell division) or
2. Under various conditions (e.g., tumor samples with different histopathological diagnosis).

Each gene corresponds to a high-dimensional vector of its expression profile. The data contain a high level of noise due to experimental procedures. Moreover, the expression values of single genes demonstrate large biological variance within tissue samples from the same class. A major cause of coexpression of genes is their sharing of the regulation mechanism (coregulation) at the sequence level. Clustering of coexpressed genes, into biologically meaningful groups, helps in inferring the biological role of an unknown gene that is coexpressed with a known gene(s). Cluster validation is essential, from both the biological and statistical perspectives, in order to biologically validate and objectively compare the results generated by different clustering algorithms.

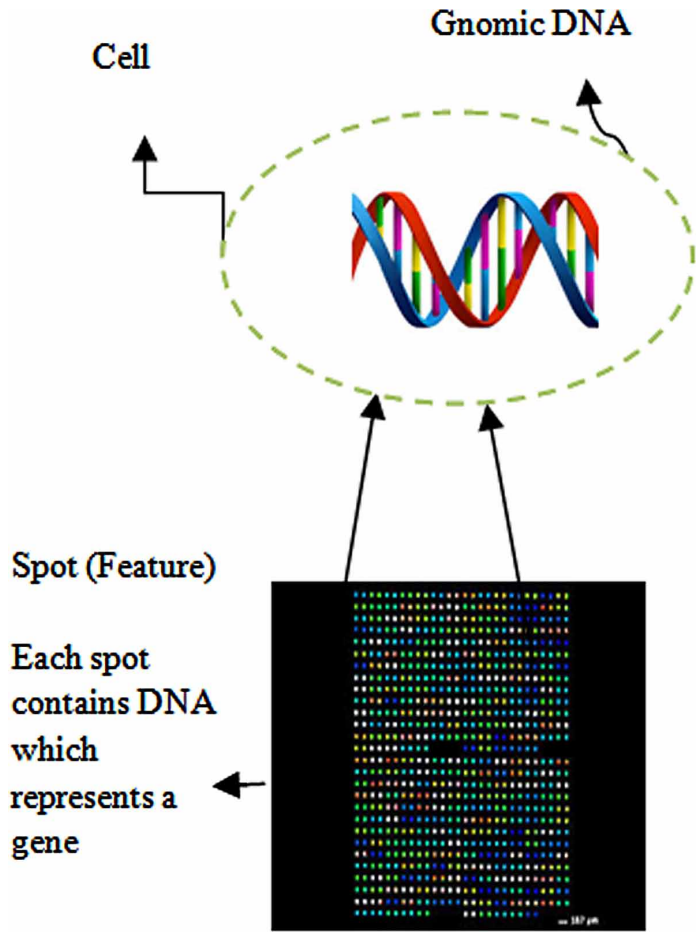
In Figure 3, a microarray may contain thousands of spots. Each spot contains many copies of the same DNA sequence that uniquely represents a gene from an organism. Spots are arranged in an orderly fashion into Pen groups. Figure 4 represents schematic of the experimental protocol to study differential expression of genes. The organism is grown in two different conditions (a reference condition and a test condition). RNA is extracted from the two cells, and is labelled with different dyes (red and green) during the synthesis of cDNA by reverse transcriptase. Following this step, cDNA is hybridized onto the microarray slide, where each cDNA molecule representing a gene will bind to the spot containing its complementary DNA sequence. The microarray slide is then excited with a laser at suitable wavelengths to detect the red and green dyes (Das et al. 2006).

Understanding Gene Regulatory Network

A gene regulatory network or genetic regulatory network (GRN) is a group of related regulators intermingle with each other and with other external substances in the cell which are responsible to manage the gene expression levels of mRNA and proteins. The regulator can be RNA, protein and their complex. The interaction can be direct or indirect (through their transcribed RNA or translated protein). In this processes they may generate mass, energy, information transfer, and cell-fate specification. The whole process of a cell during this is integrated through a complex network of cellular constituents and

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

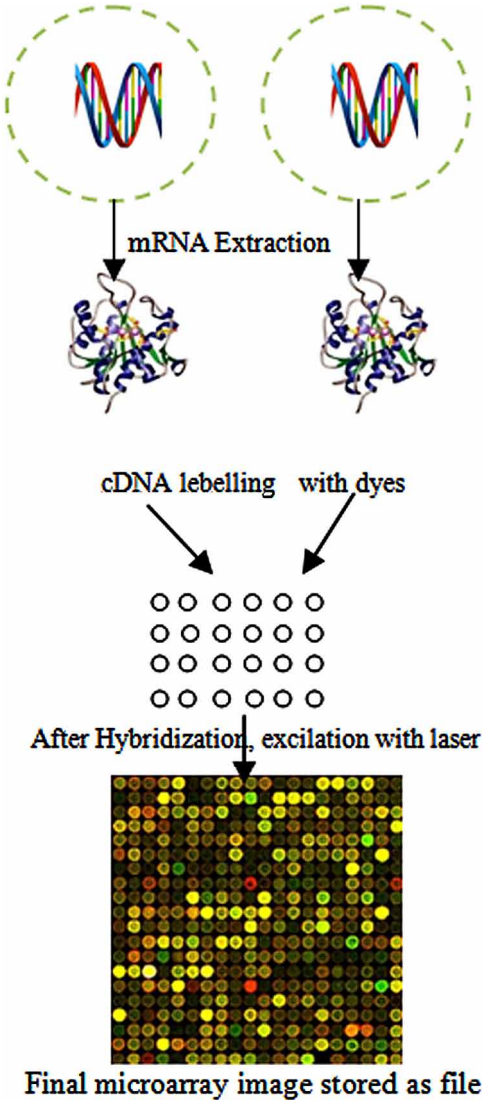
Figure 3. Microarray expressions



reactions. Such a metabolic network consists of nodes, i.e., substrates (genes or proteins), that are interconnected through links. The degree of interconnectivity of the network may be characterized by its diameter, which is the shortest biochemical pathway averaged over all pairs of substrates. The topology of a network reflects a long evolutionary process molded for a robust response toward internal defects and environmental fluctuations. Despite significant variation of individual constituents and pathways, metabolic networks have the same topological scaling properties and exhibit striking similarities to the inherent organization of complex, robust non-biological systems. It is a knowledge base for systematic analysis of gene functions in terms of the networks of genes and molecules. The data objects are represented as graphs, and various computational methods are developed to detect graph features that can be related to biological functions. For example, it can: 1) reconstruct biochemical pathways from the complete genome sequence; 2) predict gene regulatory networks from gene expression profiles, obtained by microarray experiments; and 3) Single-stranded DNA that is complementary to mRNA or DNA that has been synthesized from messenger RNA by the enzyme reverse transcriptase. Predicting the gene expression levels is a main task associated with these networks. Along with the conventional approaches like directed graph, Boolean network, Bayesian network etc. some machine learning approaches is used to model these networks (Chan, Havukkala, Jain, Hu, & Kasabov, 2008). So that they can be interpreted

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 4. Experimental gene expression data



well, this in turn predicts the expression level more accurately. If the level of accuracy percentage is more, then it provides a better way to explore how drugs affect a system of genes as well as for finding which genes are interrelated in a particular process.

Sequence Alignment

It is the way of arranging biological sequences such as DNA, RNA, or protein sequence to identify regions of similarity that may be a consequence of functional, structural, or evolutionary relationships between the sequences. Aligned sequences of nucleotide or amino acid residues are typically represented as rows within a matrix. Gaps are inserted between the residues so that identical or similar characters are aligned in successive columns. These techniques are grouped into two categories a) pair-wise sequence alignment

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

b) Multiple sequence alignment. If alignment is done on two sequences, it is said to be pair wise else it is said to be multiple alignment. Either the whole input sequence is aligned from the beginning to the end of the sequence; otherwise some of the conserved regions are only aligned with the given sequence. In the first case it is said to be the global alignment and the latter case is said to be local alignment.

CI METHODS FOR SOLVING COMPUTATIONAL BIOLOGY PROBLEMS

Several CI methods like ANN, fuzzy logic, GA, SVM are being used for solving different kinds of bio-informatics problems, which are discussed in this section.

Methods for Solving Protein Structure Prediction

The main SC paradigms for the application of PSP are ANN, EC and SVMs (Márquez-Chamorroa, Asencio-Cortes, Santiesteban-Toca & Aguilar-Ruiz, 2015).

Neural Network Methods

The authors in Casadio, Compiani, Fariselli, and Vivarelli (1995) present a feed-forward neural network which is trained with matching sets of amino acid sequences and two different types of structural information. The corresponding secondary structure and the contact map of known proteins. The input of the network consists of a window of 61 residues. The hidden layer has 300 neurons and the output layer 30 neurons used to predict contacts between the amino acid that occupies the central positions in the window and the rest of the residues of the window. Three additional neurons are used to predict the tertiary motifs. The method proposed in Cho and Ryu (2002) is based on two input neurons which use input vectors with information about the residue–residue contact and its environment, the number of amino acids and the separation between amino acids. In addition, several variables are added, such as the hydrophobicity of the environment, as well as evolutionary information.

A supervised feed-forward network which is Radial basis function (RBF) network, is being used (Casadio, Compiani, Fariselli & Vivarelli, 1995) to optimally predict the free energy contributions of proteins due to hydrogen bonds, hydrophobic interactions, and the unfolded state, with simple input measures.

Support Vector Machines

SVM techniques performs classification tasks building a hyper-plane in a multidimensional space, trying to maximize the margin between each different classes. The function that performs the transformation of the space is called kernel function. SVMs are used as a machine learning tool to predict tertiary structure from the primary sequence. The input to the classifier are the result of multiple sequence alignment (MSA) (Cheng & Baldi, 2007) data of similar proteins after transformation to a specific input domain, amino acid physic chemical properties or contact potentials, local window features of the sequences.

As limitations of these types of methods, it can be cited that the kernel models over fits the model selection criterion, the difficulty in the selection of the optimal kernel function parameters and the algorithmic complexity and extensive memory requirements in large-scale tasks.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Evolutionary Computation (EC)

Methods based on EC may use various possible representations of a protein structure: dihedral or torsion angles and lattice models. According to the representation models the evolutionary models may differ. Some methods use dihedral or torsion angles some use 3- torsion angles without using the mutation operator (Cui, Chen & Hung, 1998; Schulze-Kremer, 2000). The fitness function consists of hydrophobic interactions and Vander Waals contact measures. A force field model, that represents chemical reactions and physical forces that occur in a protein is developed for GA. Mainly the fitness function used here are for minimizing the potential energy of the hydrogen bonds of the amino acids which makes a 3D structure of a protein as stable.

Methods for Genome Sequence Analysis

Neural Networks

ANN is used for predicting both types of genes, that is, protein coding and RNA coding (Goel, Singh & Aseri, 2013). One of the earliest attempts to ANN network for gene prediction is made in 1991, GRAIL (gene recognition and analysis internet link). A multilayer feed-forward neural network is applied in GRAIL-I, that accepts input from seven statistical measures taken on a 99-base window. A similar system to GRAIL came in 1993. A program named Gene Parser, which is employed to predict protein genes in genomic DNA sequences. This program uses the content statistics as well as site statistics to predict exons, introns, and their boundaries. Both single and multilayer neural networks are used here to unite information from these statistics and database search information. Here a recursive optimization procedure based on dynamic programming is used to find the most probable combinations of exon and introns. Many gene prediction techniques utilize homology information, which helps in improving the prediction results. In the latest version of Grail, homology information has been incorporated. The new system resulted in improved performance and named as GrailExp (Vimaladevi & Kalaavathi, 2014). A computational gene prediction system GIN (gene identification using neural nets and homology information) was developed in 1998 to avoid false positive predictions. The technique combines homology information from protein and expressed sequence tag databases into back-propagation neural network (Márquez-Chamorroa et al. 2015). The program can recognize multiple genes within genomic DNA. GIN performs better than other methods (e.g., GeneID or GeneParser3) that make use of homology information to predict genes. The performance of the system is better than GENSCAN in gene level accuracy. This technique does not work well in the absence of homology information.

Methods for Microarray Data Analysis

Microarray data analysis domain is the management of complicated experimental data for application of computational methods in biology. Complicated experimental data causes two types of problems. The first one is data need to be pre-processed. Pre-processing is the process by which the data needs to be modified which would be suitably used by computational intelligence methods. The second is the analysis of the specific data which depends on what we intend to search for. Most microarray data analysis packages implement five distinct steps in microarray data analysis (Dembele & Kastner, 2003; Babu, 2004):

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

1. Data pre-processing (intra-chip and inter-chip normalisation).
2. Gene Selection (identifying differentially expressed genes).
3. Clustering (identifying common expression patterns – co-expression analysis).
4. Functional Enrichment/Biological Pathway analysis (identifying the biological significance of the selected genes).
5. Classification (developing a classification system for unclassified samples).
    a. Fuzzy Systems

Fuzzy c-means is a popular fuzzy based algorithm used for clustering microarray overlapping data. Different features of the functions regulations can be explored by fuzzy clustering which enables genes to belong to multiple groups at the same time. Fuzzy c-means algorithm has been applied to cluster microarray data (Sarhan, 2009). The value of the fuzzifier is appropriately chosen and fine-tuned for selection of genes, based on resultant distribution of distances between them. The clusters are formed by tight association and coupling among the genes.

ANNs

The two major mining tasks, modelled here, are clustering and classification. While unsupervised learning is self-organized, supervised learning helps incorporate known biological functions of genes into the knowledge discovery process of gene expression pattern analysis for gene discovery and prediction:

1. **Clustering:** Kohonen's Self Organising Maps (SOM) are used to make clusters of gene expression data (Dembele &. Kastner, 2003). It provides a good visualization as well as generates a robust and accurate clustering of large and noisy data. SOMs require a selected node in the gene expression space (along with its neighbours) to be rotated in the direction of a selected gene expression profile (pattern). However, the pre definition of a 2-D topology of nodes can often be a problem considering its biological relevance.
2. **Classification:** A wide range of supervised learning algorithms have been applied to microarray data for sample classification. Techniques ranging from ANN to SVM, from K Nearest Neighbour (KNN) to Naïve Bayesian Classifiers (NBC) have been applied to microarray data classification and their adequacy assessed.

Classification of acute leukemia has been made by combining a pair of classifiers trained with mutually exclusive features (Cho & Ryu, 2002). A neural network combines the outputs of the multiple classifiers. Feature selection with non-overlapping correlation encourages the classifier ensemble to learn different aspects of the training data in a wide solution space. Ahmad M. Sarhan (2009) has presented a stomach cancer detection system based on ANN, and the Discrete Cosine Transform (DCT). DCT has been used to extract classification features from stomach micro arrays in this system. The extracted features from the DCT coefficients are being applied to an ANN for classification (tumor or non-tumor). The micro array images used in this study have been obtained from the Stanford Medical Database (SMD). Bharathi and Natarajan (2010) have tried to fetch the minimum set of genes that can ensure accurate classification of cancer to a higher rate from micro array data. They used supervised machine learning algorithms. Bo Li, Chun-Hou Zheng, De-Shuang Huang, Lei Zhang and Kyungsook Han (2010) have discussed that the gene expression data collected from DNA micro array are characterized by a large amount of genes

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

but with only a small amount of observations (experiments). They have proposed a manifold learning method which can map the gene expression data to a low dimensional space, and then tried to discover the internal structure of the features which could classify the micro array data with more accuracy. The proposed algorithm could able to bring the gene expression data into a subspace with high intra-class compactness and inter-class separability. Their experimental results on six DNA micro array datasets have shown that the used method is effective for discriminant feature extraction and gene expression data classification (Vaishali & vinayababu, 2011).

SOLUTIONS AND RECOMMENDATIONS

SI is a discipline which deals with natural and artificial systems composed of many individual components which coordinate among themselves using decentralized control and self-organization (Blum & Merkle, 2008). This discipline focuses on the collective behaviour of individual objects with local interactions of the individuals with each other and with their environment which comprises of Particle Swarm Optimization (PSO), Artificial Bee Colony (ABC), and Ant Colony Optimization (ACO).

A swarm is a cluster of same type of, simple agents which interacts among themselves locally, and their environment. They do not have central control over themselves. Swarm-based algorithms have recently emerged as a new class of nature-inspired, population-based algorithms that are capable of providing low cost, fast, and robust solutions to several complex real life problems. SI can be defined as a relatively new branch of Artificial Intelligence that is used to model the collective behaviour of social swarms in nature, such as ant colonies, honey bees, and bird flocks. Although these agents (insects or swarm individuals) are having limited capabilities on their own, they are interacting together with certain behavioural patterns to cooperatively achieve the goal towards the tasks necessary for their survival (Belal, Gaber, El-Sayed & Almojel, 2006; Dorigo, Bonabeau & Theraulaz, 2000). There can be direct or indirect social interactions among swarm objects. The pheromone trail secretion can be taken as the example of indirect contact where on a change by the individual in the present environment, other objects respond to this. The indirect interaction which involves the environment is referred to as stigmergy, means communication with the help of the environment.

Characteristic of a Swarm Intelligence System

The typical swarm intelligence system has the following characteristics:

- It is composed of more than one individual objects, each called as an agent or a particle;
- The particles or agents are relatively homogeneous (i.e., they are either all identical or they belong to a particular and specific category);
- The rules through which the interactions among the individuals happens are based on local information that the individuals exchange either directly or indirectly through the surroundings (stigmergy);
- The interactions of individuals with each other and with their environment is represented as the overall collective behaviour or group behaviour of the system results from their interaction, which is termed as, the group behaviour self-organizes. (Dorigo, 1992; Karaboga, 2005; Karaboga & Basturk, 2007).

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

The collective and social behaviour of living creatures inspired researchers to commence the study of SI (Lim, Jain, & Dehuri, 2009). The phrase Swarm Intelligence was coined by Beny and Wang in late 1980s (Couzin ID, Krause, James, Ruxton & Franks, 2002) in the context of cellular robotics. In spite of having no centralized control to guard how individual agents should behave, they are controlled globally by local interactions between themselves which lead to the emergence of global behavior (Das, Panigrahi & Pattnaik; Panigrahi, Shi & Lim, 2011). These examples are found in our surrounding such as fish-schools and bird flocks. may change shape and direction, they come into sight to move as a single coherent entity. The main properties of collective behavior are shown in Figure 5:

- **Homogeneity**: Every bird in flock has the same behavioural model. Without any specific leader flock moves, even though momentary leaders seem to emerge.
- **Locality**: Its nearest flock-mates are only influenced by the motion of each bird. Vision is considered to be the most important senses for flock organization.
- **Collision Avoidance**: They avoid colliding with nearby flock mates.
- **Velocity Matching**: They try to match with the velocity of nearby flock mates.
- **Flock Centering**: All of them in the cluster attempt to reside in close proximity with the nearby flock mates. Each of them attempts to maintain a minimum distance between them sat all times. (Couzin ID et.al, 2002) identified four collective dynamical behaviors as illustrated in Figure 4.
- **Swarm**: An aggregate with cohesion, but a low level of polarization (parallel alignment) among members.
- **Torus**: Individuals perpetually rotate around an empty core (milling). The direction of rotation is random.
- **Dynamic Parallel Group**: The individuals are polarized and move as a coherent group, but individuals can move throughout the group and density and group form can fluctuate.
- **Highly Parallel Group**: Much more static in terms of exchange of spatial positions within the group than the dynamic parallel group and the variation in density and form is minimal (Panigrahi & Pattnaik, 2009).

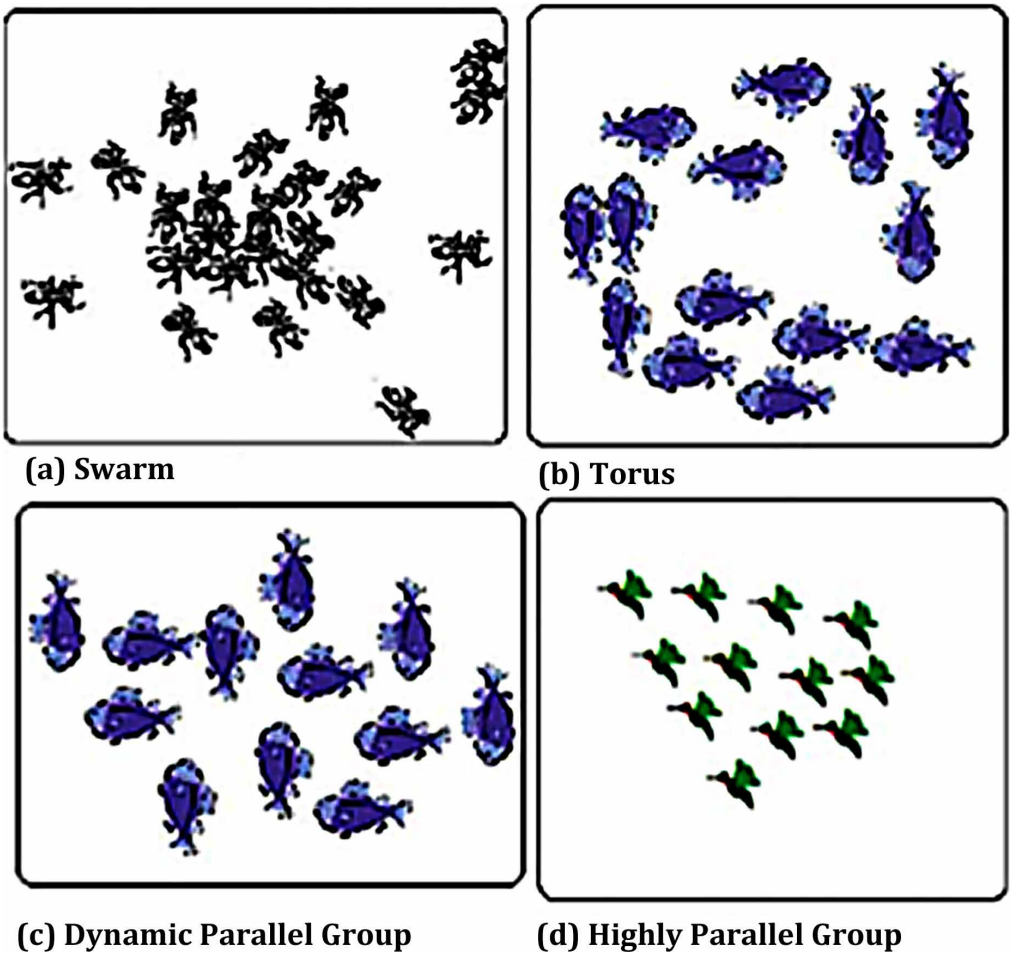
The SI algorithms are mainly stochastic search and optimization techniques, which are followed by the principles of collective behaviour and self-organization of insect swarms. Coincidentally many jobs in bioinformatics entail optimization of different parameters (like energy, alignment score, overlap strength and so on. For finding the solutions of bioinformatics problems always we go for some in-exact but robust, fast and nearly optimal solutions, for which SI based PSO algorithm are suitable (Engelbrecht, 2002).

PSO: An Insight

Particle swarm optimization (PSO) is a population based stochastic search and optimization technique, which was introduced by Kennedy and Eberhart in (1995). It is a multi-objective optimization method to find optimal solution to the problems having multiple objectives. It does not require any gradient information of the function to be optimized uses only primitive mathematical operators and is conceptually very simple. Particles are conceptual entities which fly through the multi-dimensional search space. At any particular instant, each particle has a position and a velocity. The position vector of a particle with respect to the origin of the search space represents a trial solution of the search problem. At the beginning a population of particles is initialized with random positions marked by vectors Xi and random veloci-

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 5. Different models of collective behavior (adapted from 8)



ties V_i. The population of such particles is called a 'swarm' S. A neighbourhood relation N is defined in the swarm. N determines for any two particles Zi and Zj whether they are neighbours or not. Thus for any particle Z, a neighbourhood can be assigned as N(Z), containing all the neighbours of that particle. The goal is to reach to the global optimum of some multidimensional and possibly nonlinear function or system (Hsieh, 2014). Initially particles are randomly distributed over the search space. So each particle gets a virtual position that represents a possible potential solution to optimization problem. It is an iterative process where in each iteration every particle moves to a new position, navigating through the entire search space. Each particle keeps track of its position in the search space and its best solution so far achieved. The personal best value is called as pBest and the ultimate goal is to find the global best called as gBest. The standard PSO algorithm broadly consists of the following computational steps

Initialize particles with random positions and velocities;
For each value of k [where 'k' represents the number of particles]
do
Evaluate fitness of each particle's position (p)

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

If fitness(p) better than fitness(pbest) then pbest= p
Set best of pBests as gBest
Update particles velocity and position
End of for
Stop: giving gBest, optimal solution. (www.swarmintelligence.org(retrived on 20-07-02015))
Here, a particle refers to a potential solution to a problem in d- dimensional design space with k particles.
Each particle is characterized by
Position vector….. xi(t) and Velocity vector…...vi(t)

Each particle has individual knowledge pbest, its own best-so-far position, Social knowledge gbest, pbest of its best neighbour

The equations for velocity and position updates are given below

$$v(t+1)=(w * v(t))+(c1 * r1 *(p(t) – x(t))+(c2*r2*(g(t) – x(t)) \quad (1)$$

$$x(t+1) = x(t) + v(t+1) \quad (2)$$

The first equation updates a particle's velocity. The term v (t+1) is the velocity at time t+1. The new velocity depends on three terms. The first term is w * v (t). The w factor is called the inertia weight and is just a constant between 0 to 1. Here the value of w is taken as 0.73, and v (t) is the current velocity at time t.

The second term is c1 * r1 * (p (t) – x (t)). The c1 factor is a constant called the cognitive (or personal or local) weight. The r1 factor is a random variable in the range [0, 1) which is greater than or equal to 0 and strictly less than 1. The p (t) vector value is the particle's best position found so far. The x(t) vector value is the particle's current position.

The third term in the velocity update equation is (c2 * r2 * (g (t) – x (t)). The c2 factor is a constant called the social, or global, weight. The r2 factor is a random variable in the range [0, 1). The g (t) vector value is the best known position found by any particle in the swarm so far. Once the new velocity, v (t+1) has been determined, it is used to compute the new particle position x (t+1).

The updates in PSO can be either synchronous or asynchronous (Aziz, Mubin, Saberi Mohamad & Aziz2, 2014).

Types of PSO

Binary PSO

PSO was originally developed to optimize continuous valued parameters. Kennedy and Eberhart proposed a binary PSO to optimize binary-valued parameters. Here position vectors are binary vectors, and the velocity vectors are still floating-point vectors.

However, velocities are used to determine the probability that an element of the position vector is bit 0 or bit 1.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Angle Modulated PSO

It is developed by Pampara, Engelbrecht and Franken to optimize binary valued parameters by evolving a bit string generating function,

$$g(x)=sin\,(2\pi\,(x-a)\times b\times cos(2\,\pi\,(x-a)\times c))+d$$

The task is then to find values for a,b,c and d, where these values are floating-points.
Some Advantages of the basic PSO are:

- It can be applied into both scientific research and engineering use.
- PSO have no overlapping and mutation calculation. The search can be carried out by the speed of the particle.
- PSO adopts the real number code, and it is decided directly by the solution. The number of the dimension is equal to the constant of the solution (Qinghai Bai (2010.)

Disadvantages of the basic particle swarm optimization algorithm:

- The method easily suffers from the partial optimism, which causes the less exact at the regulation of its speed and the direction.
- The method cannot work out the problems of scattering and optimization (Yonggang, Fengjie & Jigui, 2006 (In Chinese).
- The method cannot work out the problems of non-coordinate system, such as the solution to the energy field and the moving rules of the particles in the energy field (Bai, 2010).

Use of PSO in Computational Biology Problems

In this section the solutions of the some of the problems in computational biology are discussed using PSO for some of the reason.

PSO for Clustering Gene Expression Data

The standard clustering algorithms such as hierarchical clustering, principle component analysis (PCA), GA and ANNs have been used to cluster gene expression data. But in 2003, Xiao et al. used a new approach based on the hybridization of PSO and the Self Organizing Maps (SOM) for making clusters on them. Authors achieved good and encouraging results by using hybrid SOM-PSO algorithm over the gene expression data of Yeast and Rat Hepatocytes (Xiao, Dow, Eberhart, Miled & Oppelt, 2003).

Jun Sun et al. in 2012 has used the quantum behaved-PSO for gene expression data analysis with clustering methods. The problem of clustering gene expression data consists of N genes and their corresponding N patterns. Each pattern is a D-dimensional vector storing the expression levels of the genes at each of the D time points. The objective of applying MEQPSO clustering algorithm is to divide a gene expression data set into user-defined K groups by taking Euclidean distance as similarity measure, such that this partition minimizes the Total Within-Cluster Variation.

PSO for Protein Structure Prediction

Nashat Mansur et al. in 2012 present a particle swarm optimization (PSO) based algorithm for predicting protein structures in the 3D hydrophobic polar model. Starting from a small set of candidate solutions, their algorithm claimed to efficiently explore the search space and returns 3D protein structures with minimal energy. A particle is a candidate solution given by an array of length n (with index 0, 1, . . ., n-1), where n is the number of amino acids in the respective protein. Each element in the array represents the position X_d of the corresponding amino acid 'd' with respect to the preceding one and its value can be one of six characters {b, f, u, d, l, r} indicating six directions {backward, forward, up, down, left, right}. Initially, the swarm is populated with a set of N candidate solutions which are randomly generated. All the velocities are initially set to 0. A particle is invalid if it experiences collision. Collision occurs if two or more amino acids lie at the same point on the cubic 3D lattice. Invalid particles are not accepted in their algorithm and are repaired using a backtracking repair function, which takes as input the invalid particle and returns as output the repaired one. At last the repaired output is returned. It explores the search space of possible solutions and returns the 3D structure with low energy. It starts with a set of randomly created potential solutions or particles gathered in a swarm. These particles are evaluated against their energy function values. At each iteration this swarm is updated using a function which updates the velocity of the particle. This operator's work is to discover new places of the search space to get the optimal solutions.

PSO for Identifying Gene Regulatory Networks

PSO can be utilized very effectively to solve the GRN identification problem. Each particle may represent the real valued expression levels of all the genes. Each gene has a specific expression level for another gene; thus a total of N genes correspond to N2 expression levels. Fitness of the particles may be computed from the absolute error with generated expression pattern (sum of all expressions) from the target expression pattern.

Role of PSO in Some Other Problems Relevant to Computational Biology

PSO for Feature Selection Using Gene Expression Data

Gene expression data represents the state of a cell at a molecular level, play an important role in medical diagnosis. One of the characteristics of gene expression data there are higher number of genes but comparatively smaller sample size. For which many researchers are presently learning how to select genes effectively before using a classification method to decrease the predictive error rate. In general, gene selection is based on two aspects: one is to find a group of genes having same functions and a close relationship, the other finds the smallest set of genes that can provide meaningful diagnostic information for disease prediction without compromising accuracy. Feature selection uses relatively fewer features since only selective features need to be used which in turn improve predictive error rate. The available training data are less in cancer classification, which is a challenge for some classification methodologies. So a PSO can be used here for doing the work of feature selection from a large number of features. An Improved binary particle swarm optimization (IBPSO) can be used in this case to do feature selection (4. In a binary PSO the individual particles can be represented as binary (0/1) forms which shows the

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

straightforward "yes/no" choice of whether a feature needs to be selected or not. The changes in particle velocity can be interpreted as a change in the probability of finding the particle in one state or another. Since this change is a probability which is limited to a range of {0.0–1.0} (Chuang, Chang, Tu & Yang, 2008).

PSO for Rule Extraction in Medical Diagnosis

While applying conventional neural networks to the medical field it is very difficult to interpret appropriately, in a physically meaningful way, because the learned knowledge is numerically encoded in the trained synaptic weights. So some authors tried to generate if- then rules for transforming the synaptic weights in a neural network into a set of crisp rules. But after training, it is found that some if-then rules are present which are ineffective for classifying the positive instances. In this case a PSO can be used to reduce the rules which are mostly effective for classifying the positive data samples generated by a trained Neural Network, while the recognition performance will not be degraded, rather be improved. The membership function here chosen which measures the degree with which a data pattern, x, belongs to an input space. Initially the crisp rules generated are used as the particles, than the fitness function is evaluated to choose the best out of them (Hsieh, Chun & Wang, 2014).

PSO for Heating System Planning (HSP)

The whole world today faces serious energy and environment problems, with the increase of greenhouse gas emissions in the atmosphere the environments have already reached concerning levels in terms of their potential to cause climate change. Air pollution, acid precipitation, and stratospheric ozone depletion are other serious environmental concerns. An important action to address energy and environmental challenges lies in the intelligent and efficient use of energy, including reducing energy waste and using low- carbon fuels. Sustainable development of heating system requires application of planning procedures, which includes optimization of both demand and supply sides of heating. Here PSO algorithm can be used to design models for owners in making sustainable heating system investment decisions and to improve their decision-bases for administration. The objective function in HSP is the total heat production coast, which has to be minimized, for which PSO can be applied (Ma, Yu, & Hu, 2013).

Cancer Classification by BPNN-PSO

In medical field cancer is one of the major researches. Accurate prediction of various tumour types has huge value in offering better treatment possibilities and toxicity minimization on the patients. DNA microarrays performs biologist to calculate the expression of thousands of genes continuously on a small chip. These microarrays perform the large amount of data and proposed methods are needed to analyze them. The large amount of data needs more time for training when they are passed through a classifier. So to speed up the training time PSO is used. Searching process is started from initializing a group of random inputs. First, all the particles are updated, until a new generation set of particles are generated, and then those new particles are used to search the global best position in the solution space (Vimaladevi & Kalaavathi, 2014; Cho & Ryu, 2002).

FUTURE RESEARCH DIRECTION

One of the foremost important problems associated with all population-based search algorithms is that they provide satisfactory results but there is no heuristic algorithm that could provide a superior performance than others in solving all kind of optimizing problems. In other words, an algorithm may solve some problems better and some problems worse than others (Rashedi, Nezamabadi-pour & Saryazdi, 2009). Hence, proposing new high performance heuristic algorithms are helpful. Recently some emerged techniques like gravitational search algorithms (GSA) can be used in place of PSO. This technique is different from PSO in many ways. In both GSA and PSO the optimization is obtained by agents' movement in the search space, but the strategy of movement is different. Some important differences are:

1. In PSO the direction of an agent is calculated using only two best positions, $pbest_i$ and gbest. But in GSA, the agent direction is calculated based on the overall force obtained by all other agents.
2. PSO uses a kind of memory for updating the velocity (due to $pbest_i$ and gbest). However, GSA is memory-less and only the current position of the agents plays a role in the updating procedure.
3. These advantages of GSA on PSO can be best experimented with the biological problems discussed in this chapter. Recently, an explosive growth is seen in the genomic sequences, proteins in available form, so, managing and manipulating these data and deriving the information accurately in a stipulated time bound has emerged as a challenging and fascinating field of science. So always there is a need to find suitable method and technology to handle big amount of data and the algorithms to process this information in an effective way. This may possibly be handled with suitable parallelization of algorithms. Hybridizing the intelligent soft computing tools with the heuristic swarm intelligence techniques in a parallel environment can be thought of as the future directions to find better solutions to address the above cited problems.

CONCLUSION

SI algorithms have recently gained wide popularity among the researchers, for their remarkable ability in obtaining nearly optimal solutions to a number of NP hard, real world search problems. A survey of the bioinformatics literature discloses the fact that the field has a surplus of problems that needs fast and vigorous search mechanisms. Problems coming under this group include (but are not limited to) the multiple sequence alignment (MSA), protein secondary and tertiary structure prediction, protein ligand docking, promoter identification and the reconstruction of evolutionary trees. Classical deterministic search algorithms and the derivative based optimization techniques are of no use for them as the search space may be massively large and discontinuous at certain parts. SI presents a collection of multi-agent parallel search techniques that can be effectively used for solving bioinformatics related problems of this sort. In this chapter we have tried to address some of the bioinformatics problems and their solutions using the computational intelligence. Then one of the popular and simple swarm intelligence based technique, the PSO has been discussed in various computational biology problems. But this field is not limited to the above. There is always a scope to innovate and renovate a better algorithm to produce a superior performance which will be suitable for answering the problems belonging to this domain.

KEY TERMS AND DEFINITIONS

Agent: An agent is something that acts in an environment.

Bioinformatics: Bio-informatics can be described as the application of computational methods to make biological discoveries and explorations.

Bio-Inspired Computing: It is field which helps to tackle complex real problems using computational methods based on biology.

Collective Behaviour: Behaviour of a group of social insects.

Fuzzy System: It is a component machine learning techniques which takes membership values within 0 to 1 unlike crisp sets.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Gene: It is a portion of DNA molecule which serves as the basic unit of heredity.

Heuristic: Rule or method based on trial and method that helps us to solve problems quicker.

Neural Network: Neural network is a soft computing paradigm inspired by the working of human brain to inculcate intelligence in machines.

Optimization: A mathematical method to find the solution of a problem towards achieving better performance either in form of minimum or maximum under one or more given constraint.

Protein: Organic macro molecules composed of one or more amino acids.

Swarm Intelligence (SI): SI is one of the techniques which is inspired by nature and is a population based algorithm motivated by the collective behaviour of a group of social insects.

This research was previously published in the Handbook of Research on Computational Intelligence Applications in Bioinformatics edited by Sujata Dash and Bidyadhar Subudhi; pages 119-143; copyright year 2016 by Medical Information Science Reference (an imprint of IGI Global).

APPENDIX

PSO for Data Classification: A Case Study

Problem Definition:

Here we are considering a simple classification problem or we can say a prediction problem, where we are given with an input dataset sample having some instances and their predefined class. The main task in this problem is to partition the group of input objects to their corresponding classes.

In this work the bench mark datasets taken from UCI learning repository for verification and validation of the PSO based model is chosen (Marquez-Chamorroa, Asencio-Cortes, Santiesteban Toca & Aguilar-Ruiz, 2015) A brief of the datasets are as follows

Dataset Description:

The dataset consists of 150 samples which consists of a set of Iris flowers, where the goal is to predict three classes based on sepal (green covering) length and width, and petal (the flower part) length and width. This is the most popular and the simplest of the classification data containing three predictable attributes such as setosa, versicolor and virginica.

```
Input: iris dataset
Output: The instance and its corresponding class
Fitness function chosen is the minimum distance among the features.
Matlab Code:

Table 1. Simulation Accuracy of Iris Dataset

Number of classes	Number of Simulation Result Accurate up to				Total no of test samples
	4 decimal places	3 decimal places	2 decimal places	1 decimal places	
Class 1	10	10	10	10	10
Class 2	10	10	10	10	10
Class 3	09	09	09	09	10
Percentage of Accuracy	98%	98%	98%	98%	Total=30

```
end
 cd1
cd2
 cd3
```

Note: At first the data set will be divided into two sets. The first set will contain 2/3rd of the data which will be treated as training data and rest of the 1/3rd of the data will be treated as the test data. The output of this program will give the value of cd1, cd2 and cd3 which belong to class-1, 2 and 3 respectively for the training dataset. For the testing purpose any classifier can be used .Suppose an artificial neural network will be used as a classifier, the network will be trained by the calculated optimized features using PSO and the test data can be simulated by the classifier.

The Table 1 given below shows the simulated output of iris dataset. The results are compared by accuracy percentage and accuracy up to number of decimal places. Here 120 samples are taken as training and rest 30 are taken as test set.

Chapter 29
Semantic Reconciliation of Electronic Health Records Using Semantic Web Technologies

Karim El Guemhioui
University of Quebec in Outaouais, Canada

Steven A. Demurjian
University of Connecticut, USA

ABSTRACT

In this paper, the authors present an approach to reconcile the semantics of distinct medical terms found in personal health records (PHRs - that store data controlled by patients) and electronic medical records (EMRs - that store data controlled by providers) that are utilized to describe the same concept in different systems. The authors present a solution for semantic reconciliation based on RDF and related semantic web technologies. As part of the solution, the authors utilize a centralized repository of ontologies to: uniformly interrogate the medical coding systems in which those terms are defined, extract all of their published synonyms, and save the results as RDF triples. The final step in the process is to employ a reasoner to infer non-explicit synonymy among those terms, hence evidencing the underlying semantics to the PHR and EMR systems for possible further processing.

1. INTRODUCTION

In this age where smartphones are ubiquitous, and computer apps geared towards personal health issues proliferate, people are becoming more and more self-conscious of their health and incline to resort to these apps to keep track of their medical condition.[1] As a result, many of them end up assembling in apps health and fitness data from different sources that include several personal health records (PHRs)[2] that maintain data controlled by patients and electronic medical records (EMRs) that maintain data managed by medical providers. Patients utilize the mobile health (mHealth)[3] apps that seem to deal with distinct and unique health issues while in fact they are referring to the same health condition. While a medical

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

provider is easily able to identify related different terms in PHRs and/or EMRs referring to the same condition (i.e., problem), this exercise is less obvious for most individuals (whose medical knowledge is usually superficial), and outright impossible for the machine hosting these electronic records and the computer applications we rely on to make some sense out of this data.

The multiplication and affordability of electronic mobile devices (smartphones, phablets, tablets, "Fitbits", wearable healthcare devices, etc.), and their embracing of the technologies by an increasing number of diverse stakeholders (e.g., patients, family members, home health care aids, therapists, etc.) are paving the way for a shift in the gathering and integration of personal healthcare data from PHRs and EMRs coupled with its readiness for the various healthcare and medical service providers. Therefore, the integration of PHRs and EMRs will play a pivotal role in this move to a safer, centralized, more efficient, consumer-driven healthcare system. Just to give a simple example: mHealth applications that provide access to health and fitness data, gathered from multiple PHRs and EMRs, will allow us to have our medical history available in case of emergency, when traveling, seeking a second opinion, or switching health insurance companies (HealthIt, 2014).

To accomplish this goal, we are starting to see official efforts focused on encouraging provider organizations to give consumers access to their own data; e.g., the Blue button initiative (HealthIT, 2016). More and more sophisticated PHR apps are also starting to support access to and/or import of electronic medical records (EMRs) or electronic health records (EHRs)[4]. A new term has even been coined: a tethered (or connected) PHR to designate a PHR linked to a specific healthcare organization's electronic health record (EHR) system or to a health plan's information system (Daglish & Archer, 2009). With a tethered PHR, patients can access their own records through a secure portal and see, for example, the trend of their lab results over the last year, their immunization history, or due dates for screenings.

While there is no agreed upon standard for a PHR, a significant amount of standardization efforts has been done regarding the annotation, classification, and tagging of health and fitness data in EMRs and EHRs. Among the most widespread standards, at least in North America, are: HL7 v2.x (1989), CDA (2005), LOINC[5], SNOMED[6], UMLS[7], and FHIR (2014). PHRs accessing/downloading these remote electronic data are therefore exposed to their underlying format. This paper focuses on the data in the PHR obtained/constructed from remote EMRs/EHRs sources, and leverages existing standardization efforts to propose an approach to the semantic reconciliation of some critical information appearing in PHRs (and especially tethered PHRs). As for the medical terms used in these EHRs to describe a health condition, a treatment, a medication, etc., we are assuming that they comply with agreed upon terminologies defined in specialized thesauri, controlled vocabularies, reference books, dedicated ontologies, etc., which we will call generically "medical coding systems" in the remainder of this paper. Also, for the sake of clarity, we are limiting ourselves in this work to clinical terms describing a medical condition (i.e., an observed problem).

This paper presents a solution for semantic reconciliation that utilizes a centralized repository of ontologies to identify the relevant terms, extract all published synonyms, and save the results as RDF triples. To facilitate the discussion, we present a scenario that illustrates a rather common issue in PHRs, namely, that the same medical condition is being designated by different medical terms in different EMRs/EHRs, creating therefore a semantic hiatus and preventing appropriate machine processing. This scenario is utilized to demonstrate our approach to semantically reconcile these related terms, whether they have been chosen from the same or from distinct medical coding systems. The proposed solution is built around the Resource Description Framework (RDF) and its related standards RDFS, OWL, SPARQL, etc. (Allemang and Hendler, 2011). Note that the presented approach straightforwardly extends to terms dealing with others issues than medical condition (e.g., medication, treatment, lab results).

The remainder of this paper is organized into five sections. In Section 2, we provide some background information and definitions relevant to our work including: the different types of health information technology systems (PHRs, EMRs, EHRs) and the role of health information exchange among these systems. In Section 3, we explain the challenge resulting from the multiplication of healthcare concept definitions of medical nomenclature, and provide a use case scenario that will serve to illustrate our approach. Section 4, the main focus of this paper, details and explains our approach to reconcile semantic data in EMRs/EHRs in order to reconcile terms across multiple systems to present a unified version to patients via their mHealth apps. Section 5 discusses the semantic harmonization issue that involves the ability to achieve the desired reconciliation utilizing the new FHIR (2014) standard. Section 6 concludes this paper.

2. BACKGROUND AND RELATED WORK

A personal health record (PHR) is a collection of information about an individual's health that is maintained by the individual. A PHR system is an electronic application used by patients to maintain and manage their health information in a private, secure, and confidential environment. Thus, the PHR concept is patient centric in the sense that its management remains primarily the responsibility of the patient. Genitsaridi, Kondylakis, and Koumakis (2015) have identified a number of five functional criteria that an ideal PHR system should meet:

1. **Problem, Diagnosis and Treatment (PDT) Basic:** This category is of most importance to our work and will be detailed next.
2. **Self-Health Monitoring:** This category includes functions that help the patient monitor her own health status. The data recorded by functions in this category are unofficial and generated by the patient.
3. **Communication Management:** This category includes functions that provide services such as appointment scheduling, appointment reminders, recording of healthcare professionals' information (name, phone, address ...), etc.
4. **Security and Access Control:** This category involves security (authorization and authentication) as well as access control (privileges and permissions).
5. **Intelligence Factors:** This category includes all functions that illustrate intelligent behavior, such as intelligent data presentation, intelligent data export, intelligent system alerts, interaction with other electronic health record (EHR) systems, etc.

   The first category includes functions that provide the following services:
   - Recording of a patient's problem or an incident.
   - Recording of the diagnosis process related data such as diagnostic tests (e.g., blood, laboratory tests, imaging tests, EKGs, etc.), diagnostic procedures (e.g., therapy, surgery, etc.), diagnostic material (e.g., allergies, family history, immunizations, etc.), and diagnostic results.
   - Recording of the treatment process related data such as treatment procedures, medications and hospitalizations.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

The data that are recorded by this category's functions are official facts generated by medical providers in the form of Electronic Medical Records (EMRs) or Electronic Health Records (EHRs). In this paper, we are mainly interested in PHR systems that support this category's functions. A PHR differs from an EMR or an EHR, which are owned and stored by medical providers. An EMR is a digital version of a paper chart that contains the standard medical and clinical data gathered in one provider's office. Electronic health records (EHRs) go beyond the data collected in the provider's office and include a more comprehensive patient history. For example, EHRs are designed to contain and share information from all providers involved in a patient's care. EHR data can be created, managed, and consulted by authorized providers and staff from across more than one health care organization (HealthIT, 2014). Unlike EMRs, EHRs also allow a patient's health record to move with them, to other health care providers, specialists, hospitals, nursing homes, etc.

Anytime a PHR holder moves, switches medical providers, or seeks medical treatment during a vacation, he/she will be asked to provide his/her health history which, usually, is difficult to remember. The availability of a PHR allows an individual to more easily answer any questions such as vaccinations and medications/dosages. A PHR can also be a live saver in an emergency situation. For example, if a person were to experience a health emergency at work or on a trip with friends, his/her companions would hardly be able to answer questions about his/her health history and current medical providers. Furthermore, in such a time of crisis, it can be difficult to remember important and potentially life-saving information, whereas a PHR can provide the health information promptly and reliably.

In order for the electronic health information exchange (HIE) to succeed, it is imperative that the medical providers agree on an exchange standard. Several exchange standards (e.g., HL7 v2.x (1989), CDA (2005), LOINC, SNOMED, UMLS; and FHIR (2014)) have been developed over the years, each new standard purporting to overcome the shortcomings of the previous one. The latest one is FHIR – Fast Healthcare Interoperable Resources (Bender & Sartipi, 2013), which builds on previous data format standards from the Health Level Seven International Organization, and is supposedly easier to implement. One of the goals of FHIR is to facilitate interoperation between legacy healthcare systems, to make it easy to provide healthcare information to medical providers and individuals on a wide variety of devices from computers to tablets to smartphones, and to allow third-party application developers to provide medical applications which can be easily integrated into existing systems. A more detailed review of these electronic exchange standards is beyond the scope of our work, and has been abundantly addressed in the scientific literature (Eichelberg et al., 2005; Smits et al., 2015).

3. MEDICAL CODING SYSTEMS AND UNDERLYNG SEMANTICS

Healthcare data electronically exchanged among medical providers can take up varying formats and use non-compatible terminology. Ultimately, some of this data ends up in PHRs that appear to describe distinct medical problems, while in fact they convey the same semantics. This regrettable situation can be retraced to the existence of a multitude of standardized terminologies from which to choose those medical terms. Section 3.1 briefly reviews the nomenclature in the medical field, while Section 3.2 introduces a use case scenario of healthcare to be utilized for examples throughout the rest of the paper.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

3.1. The Medical Terminology Bazaar

For health information exchange (HIE), as discussed in Section 2, to succeed agreeing on an exchange standard is necessary but not sufficient. There must also be some agreement on the clinical terminology used in those electronic messages. Unfortunately, there exist several competing medical coding systems with distinct or overlapping terms to designate the same concept or a closely related one; and medical providers familiarized with one coding system are very reluctant to switch to another one. In this work, we limit ourselves to three ontologies (SNOMED-CT, CD-10, and OBO DOID) to illustrate our point regarding the profusion of terms of equivalent meaning within and among coding systems, and hence the semantic gap that arises.

The Systematized Nomenclature of Medicine - Clinical Terms (SNOMED-CT, 2016) is a standardized, multilingual vocabulary of clinical terminology used by physicians and other health care providers for the electronic exchange of clinical health information. The standard CD-10-CM (2016) is the 10th revision of the International Statistical Classification of Diseases and Related Health Problems (ICD), a medical classification list by the World Health Organization (WHO). Lastly, the standard Human Disease Ontology (OBO DOID, 2016) is an ontology defined by the Open Biomedical Ontologies Foundry for describing the classification of human diseases organized by etiology. In most of these medical coding systems, there are usually several synonyms that are utilized to represent the same concept. To disambiguate the situation, a unique identifier is assigned to the concept and shared by all the synonyms. Furthermore, at least one of the terms is designated as the preferred one, to spur its use by the medical providers (the others are alternate terms). Finally, note that medical providers must comply with these medical coding systems in order for their EHRs to be intelligible and in the US to satisfy certification[8] for Health IT systems. Further, there is also the Center of Medicare and Medicaid Services Meaningful Use Stage 3 guidelines[9] that require all health information in EMRs and PHRs to meet certain requirements regarding standards and availability of data via cloud services. This means that there are efforts in the US to insure a commonality in standards.

3.2. A Use Case Scenario

The following scenario will be used to illustrate our approach in reconciling the semantics of critical data in EHRs. Let's consider a person, say Mr. John Smith, who likes to keep track of his medical history. For that purpose, he uses an application ("apps") that gathers all of his medical records on his smartphone.

1. June 15th, at around 3:45 pm, Mr. John Smith who is at home feels a severe chest pain. Because his family doctor is at least 40 min drive, and on the insistence of his wife, an ambulance is summoned that takes Mr. John Smith to the emergency room (ER). There, he is diagnosed by an intern with a "Cardiac infarction," and an EHR is produced.
2. The following day, Mr. John Smith consults his family doctor. A second EHR mentioning that Mr. John Smith has suffered from an "Attack - heart" is produced. Mr. John Smith is referred to a cardiologist for further treatment.
3. Eight days later, Mr. John Smith manages to be seen by the heart specialist who diagnoses a "Myocardial infarction" and produces a third EHR. The electronic message in FHIR format is shown in the next section (Figure 1).

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

4. Ten days later, a follow up with the cardiologist results in a fourth EHR indicating that Mr. John Smith suffers from a "Microinfarct of heart."

Ultimately, all of these data from these EHRs end up in Mr. John Smith's PHR and are accessible via his mHealth application. The mechanics of the way that he obtains access to his personal EMR/EHR via his PHR are beyond the scope of this paper.

Though a person in the healthcare domain may, more or less easily, recognize that the first three medical records refer to 3 occurrences of the same incident, i.e., a "Myocardial infarction" (preferred term in the SNOMED-CT coding system), it would be desirable for other systems and mHealth apps to be able to do the same, specifically, to detect that the three medical terms employed are semantically equivalent. This semantic reconciliation is essential for the proper and consistent functioning of mHealth apps, their correct processing of the data they feed upon, and the accuracy and/or reliability of the results they present us with. Furthermore, the mHealth apps user, in our specific case, Mr. John Smith, should also be able to clearly and quite immediately relate the three concepts, regardless of whatever other functionalities the apps provides. Remember that though Mr. John Smith may be quite knowledgeable with respect to his medical situation, his use of mHealth apps being a clear indication of his commitment, it's not obvious under the described scenario that he would adequately relate the three incidents. One reason could be that his deteriorating health may have affected his cognitive functions. The fourth medical condition, in our scenario, will allow us to explore a more complex situation, since the term used is not a synonym of the first three. We believe that this scenario is not contrived and illustrates a very common problem in the medical/healthcare world which is the proliferation of terms to designate the same concept or a very closely related one.

4. AN APPROACH TO ESTABLISH SEMANTIC EQUIVALENCE OF MEDICAL CONCEPTS

This section is the core of the paper to present an approach that allows the semantic equivalence of medical concepts to be achieved. The discussion is organized into three parts. First, Section 4.1 discusses the way that relevant health data can be captured and represented as RDF triples. Next, Section 4.2 presents the usage of the Simple Knowledge Organization System (SKOS)[10] for knowledge representation based on the resource definition framework (RDF)[11] in conjunction with the SPARQL[12] database query language for data stored in RDF format. Finally, Section 4.3 explores an approach to infer more complex semantic relationships, such as the "Microinfarct of heart" in the fourth EHR of the scenario in Section 3.2 that will be reconciled with the synonymous terms in the other three EHRs.

4.1. Capturing Relevant Healthcare Data into Triples

EHRs/EMRs can come in different shapes with varying APIs, in essence, the data they encompass are usually stored in either relational or XML repositories with the ability to export information into HL7 for potential sharing. For semantic reconciliation, we would want to transition data retrieved from an EHR/EMR/PHR via XML into the RDF format. This allows data that is retrieved from the four different EHR sources in the Scenario of Section 3.2 to be uniformly stored in RDF format as triples: subject – property/predicate - object. This very uniform and regular structure will significantly ease the parsing

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

and processing of the medical information we are interested in. Otherwise we would have to resort to complex parsing code/scripts to isolate the medical terms whose semantics we want to explicit.

A great deal of work has been done regarding the automatic conversion of XML files and/or relational tables into RDF triples (Breitling, 2009; Bohring, & Auer, 2005; Sahoo et al., 2009). Though the exact mechanics of these transformations are beyond the scope of this paper, we can reasonably assume that the automatic conversion from the four EHRs of the scenario into RDF and its related standards, such as RDFS and OWL, is fairly achievable. Furthermore, if the data portion we are mostly interested in (i.e., imported EHR data) is acquired using a standardized messaging format for exchanging information electronically, there probably already exists syntactic transformations to convert it into RDF triples. While for some imported standard messages, such as HL7 v2.x, the transformations can be rather complex and/or found wanting (Prasser et al., 2012; Kawazoe, Imai, & Ohe, 2016); for some others, such as FHIR messages, substantial work is being done in defining mappings to RDF (and its related standards: RDFS, OWL). We believe that automated transformation and validation tools should begin to appear.

As an example, the FHIR Working Group of the HL7 organization has a section dedicated to RDF[13]. As an illustration, we provide below an example of a FHIR message in XML format (one of the two fully supported formats, the other being JSON) and its translation into a FHIR/RDF compliant format. The original FHIR/XML message (slightly truncated for brevity) in Figure 1 represents the EHR produced by the cardiologist following his first examination of Mr. John Smith (the third medical condition in our scenario). The FHIR message clearly identifies (highlighted by us in blue): the coding system used, the unique identifier for the medical condition reported, and a textual value.

The translation of this message into FHIR/RDF, using the Turtle syntax, is shown in Appendix A. The Turtle code provided has been validated using the Apache Any23 tool[14]. Note that this same tool (though there are many others) allows one to convert the terse RDF Triple Language notation (Turtle) into the simpler N-Triples notation which is even easier for software to parse.

4.2. SKOS and SPARQL to the Rescue

To support the semantic reconciliation process, we seek to transition from RDF triples to the usage of the Simple Knowledge Organization System (SKOS) for knowledge representation based on the resource definition framework (RDF) and the SPARQL database query language. As already mentioned, our objective is to make possible for the machine/apps to infer that the first 3 EHRs of our scenario in Section 3.2 are in fact referring to the same medical condition. A naive and tedious approach would be to take each medical condition mentioned in our scenario, look it up in the coding system in which it is defined and retrieve all of its synonyms, if any. The next step would be to compare each one of them with all the synonyms for the other medical conditions to see if there is a match. If yes, then the involved EHRs are referring to the same medical condition; if not, we cannot at this stage reject since there might still exist some close relatedness between the different data stored in the three EHRs, as will be illustrated in Section 4.3 with the 4th medical condition of our scenario in the fourth EHR. There is a need for us to leverage both SKOS and SPARQL in order to come up with a unified process to extract and compare data from different EHRs. Without these technologies, we would need to formulate a correct lookup query for each EHR utilizing the specific medical coding system of that EHR. That would be problematic for multiple EHRs with different coding systems that are not compatible. Therefore, our approach is intended to support the issuance of generic queries to arbitrary medical coding systems (thesauri, ontologies,

</Condition>
```

etc.) to fetch the medical concepts that we are interested in, without having to concern ourselves with the specific structure/format of each coding system, nor the knowledge of which coding system actually contains the information we are after. SKOS and SPARQL can facilitate this process.

Fortunately, this is possible (with very reasonable limits) due to the efforts of the National Center for Biomedical Ontology (NCBO) who has developed BioPortal[15]. BioPortal is an open and comprehensive repository of biomedical ontologies (more than 400) with services that provide access to those ontologies (SPARQL endpoint, REST API) and a set of tools for working with them (browser, text annotator, etc.) (Noy et al., 2009; Salvadores et al., 2012). The two aspects that are of most interest to us are: (1) the hosted ontologies (i.e., medical coding systems) that have been transformed into RDF triples from their original formats (OWL, OBO, UMLS/RRF, ...) and asserted into a triple store; and, (2) metadata that have been injected on top of original related terms by using the predicates of SKOS, skos:prefLabel and skos:altLabel[16] (Miles et al., 2005), to single out the preferred name and the synonyms, respectively (usually, as identified by those who submitted the ontology to the portal).

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Let's consider each one of the medical conditions mentioned in our scenario and demonstrate the way that it is possible to establish their semantic equivalency or relatedness, if any. We start with the 3rd medical condition for which a FHIR message correctly filled out (see Figure 1 again) has been provided. Since the coding system and the unique identifier are known, the trivial SPARQL query, shown in Figure 2, provides us with all the valid names the reported medical condition is also known under this coding system. For clarity, we will characterize all semantically equivalent terms as synonyms (i.e., the fact that one of them is labeled as preferred term is inconsequential for our purpose).

It is important to note that to write this query, there is no need to be knowledgeable about SNOMED-CT, its internal organization, what's the name of the property for an equivalent term, etc. We are only relying on two well known properties of the widely published ontology SKOS namely, skos:prefLabel and skos:altLabel. We are also assuming that the mappings of these 2 properties to their counterparts in the BioPortal ontologies have been done correctly; and note that this issue is a different research problem out of the scope of our paper.

The intent of the process is to arrive at a list of synonymous terms, as shown in Figure 3, where the term used by the cardiologist turns out to be the preferred name (after all she is an expert), and it has 10 other alternate names, for a total of 11 synonyms for the same medical condition (and just for US English).

While the information in Figure 3 is very informative for a human, it is not directly "processable" by the machine. What we really need is to have the query results formatted as triples so that they can be stored locally for further processing. This is easily achievable in SPARQL by using the CONSTRUCT keyword as shown in Figure 4.

This query in Figure 4 creates a set of triples, in which the subject is always the unique identifier of the concept we are interested in, the predicate is some property that conveys the idea of synonymy, and the object is any term by which the concept is also known. Instead of creating our own property (e.g., prefixForOurNameSpace:isSemanticallyEquivalentTo) which wouldn't be recognized by the BioPortal, we adopt a property already known to the system, namely, the owl:sameAs[17]. Note that the controversy that has surrounded this predicate (Halpin et al., 2010) is insignificant in our context. The result is shown in Figure 5 and stored locally. Note that for brevity, we have shortened the subject namespace http://purl.bioontology.org/ontology/SNOMEDCT to SNOMEDCT, and the predicate namespace http://www.w3.org/2002/07/owl to owl).

Next, we consider the first medical condition of our scenario, for which, obviously, we don't know the unique identifier. However, we assume that we know the coding system utilized (namely, SNOMED-CT). Again, though the term utilized for the medical condition (i.e., "Cardiac infarction") can easily be spotted by a human in the previous results, the machine doesn't know that yet. The SPARQL query in Figure 6 produces human readable results (akin to Figure 3), while the change shown in Figure 8 to this SPARQL query generates the RDF triples we need to store.

Figure 4. SPARQL query by CONTRUCT

<SNOMEDCT/22298006> <owl#sameAs> "Infarction of heart, NOS"@EN .
<SNOMEDCT/22298006> <owl#sameAs> "Heart attack"@EN .
<SNOMEDCT/22298006> <owl#sameAs> "Cardiac infarction, NOS"@EN .
<SNOMEDCT/22298006> <owl#sameAs> "Myocardial infarction (disorder)"@EN.
<SNOMEDCT/22298006> <owl#sameAs> "Cardiac infarction"@EN .
```

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Since we don't know if the medical term we are looking up is a preferred term or an alternate one, we need to try both cases. The result produced by the query in Figure 6 is as follows (Figure 7).

To produce the result formatted as triples, we just need to replace the line of code "SELECT DISTINCT *" in Figure 6 with the code shown in Figure 8.

This substitution yields the following triples (namespaces shortened as explained earlier) which we also store locally:

```
<SNOMEDCT/22298006> <owl#sameAs> "Myocardial infarction"@EN .
<SNOMEDCT/22298006> <owl#sameAs> "Cardiac infarction"@EN .
```

In our approach, we are taking advantage of the support of regular expressions in SPARQL to search for exact matches. Of course if the search came empty, we could broaden our search criteria in several ways (case insensitive, empty spaces, substrings, etc.). The example in Figure 9 illustrates one possibility.

Figure 6. SPARQL query for human readable results in SNOMED-CT

Figure 9. Using regular expressions to broaden search

```
FILTER (  ( CONTAINS  (UCASE(str(?prefLabel)), "CARDIAC")   &&
            CONTAINS  (UCASE(str(?prefLabel)), "INFARCTION"))
           ||
           ( CONTAINS  (UCASE(str(?synonym)), "CARDIAC")   &&
            CONTAINS  (UCASE(str(?synonym)),"INFARCTION"))  )
```

To continue the discussion, we proceed to the 2nd medical condition of our scenario in Section 3.2 which was diagnosed by the family doctor. This time not only the unique identifier is missing, but also the medical coding system used. A human observer may be tempted to conclude that this condition is the same as the first one (since the expression "Heart attack" appears as one of the synonyms for the first condition of scenario). But again, we would like the machine to infer such a result, which cannot be done based only on the two involved strings: "Heart attack" and "Attack – heart". Furthermore, not knowing which medical coding system this latter term was taken from, we cannot be sure of the specific medical condition it describes, the vagueness of the expression being often used as a catch-all for various heart related pathologies. The SPARQL query in Figure 10 provides an answer to our concerns.

Since we have not specified which ontologies to search (via the FROM keyword), the default behavior will be to explore all of the ontologies in the repository. However, the query in Figure 10 could not run its course since the SPARQL BioPortal endpoint is an experimental one (in beta version), for demo purposes, that cannot handle such huge search space. To overcome this limitation, we included in the search space a number of ontologies as shown in Figure 11.

Figure 10. SPARQL query for second medical condition

```
PREFIX  owl:   <http://www.w3.org/2002/07/owl#>
PREFIX  skos:  <http://www.w3.org/2004/02/skos/core#>
SELECT DISTINCT   *
### No ontology to search is specified
WHERE {
          {
            ?termURI   a        owl:Class  ;
             skos:prefLabel    ?prefLabel  ;
             skos:altLabel     ?synonym  .
             FILTER (regex(?prefLabel, '^Attack - heart$'))
          } UNION {
            ?termURI   a        owl:Class  ;
             skos:prefLabel    ?prefLabel  ;
             skos:altLabel     ?synonym  .
            FILTER (regex(?synonym, '^Attack - heart$'))
          }
}
```

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 11. SPARQL with added Ontologies

```
PREFIX owl:  <http://www.w3.org/2002/07/owl#>
PREFIX skos: <http://www.w3.org/2004/02/skos/core#>
SELECT DISTINCT  *
FROM <http://bioportal.bioontology.org/ontologies/ICD9CM>
FROM <http://bioportal.bioontology.org/ontologies/ICD10CM>
FROM <http://bioportal.bioontology.org/ontologies/HP>
FROM <http://bioportal.bioontology.org/ontologies/DOID>
FROM <http://bioportal.bioontology.org/ontologies/TMO>
#FROM <http://bioportal.bioontology.org/ontologies/SNOMEDCT>
FROM <http://bioportal.bioontology.org/ontologies/globals>
WHERE { # same code as the previous query }
```

In Figure 11, the SNOMED-CT ontology had to be commented out since it was the one triggering the time out before the end of the search. We nevertheless made sure that we weren't missing anything by running the query on the SNOMED-CT alone, and it came empty[18]. Below is the result of our query and also a clear indication of the medical coding system used, namely the OBO DOID, also known as the Human disease ontology (see Figure 12).

As before, by replacing the line starting with SELECT (in Figure 11) with the following code:

```
CONSTRUCT  {  ?termURI    owl:sameAs     ?prefLabel,
?synonym  .
  }
```

```
<http://purl.obolibrary.org/obo/DOID_5844>
  <http://www.w3.org/2002/07/owl#sameAs>
   "myocardial infarction"^^<http://www.w3.org/2001/XMLSchema#string> .
<http://purl.obolibrary.org/obo/DOID_5844>
  <http://www.w3.org/2002/07/owl#sameAs>
    "Attack - heart"^^<http://www.w3.org/2001/XMLSchema#string> .
```

The 15 generated triples stored in our local machine must then be fed to an inference engine to evidence the existing semantic equivalence. After saving the newly inferred triples, we can run the SPARQL code in Figure 13 to produce a cleaned out output. The predicate owl:sameAs being symmetric and transitive, we have to filter out undesirable results (every term is same as itself). To keep just the textual values of the medical terms, we also filter out the unique identifiers.

Figure 12. Result of query

termURI	prefLabel	synonym
<http://purl.obolibrary.org/obo/DOID_5844>	"myocardial infarction"	"Attack - heart"

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 13. SPARQL code to remove redundant results

```
CONSTRUCT { ?a  owl:sameAs  ?b . }
WHERE {
        ?a  owl:sameAs  ?b  .
        FILTER (  (?a != ?b)  && (!isURI(?a)) && (!isURI(?b)) )
}
```

For demonstration purposes, we have resorted to a "quick and dirty" shortcut to clearly visualize the results, by loading our "mini ontology"[19] into the open-source ontology editor and framework Protégé, and running its default reasoner (FACT++). The system has then inferred that the first three medical conditions of our scenario were semantically equivalent, as shown in Figure 14 where the inferred terms found semantically equivalent, have a yellow background. Thought we had 15 triples, only the 13 distinct terms are shown (2 triples were asserting duplicate information).

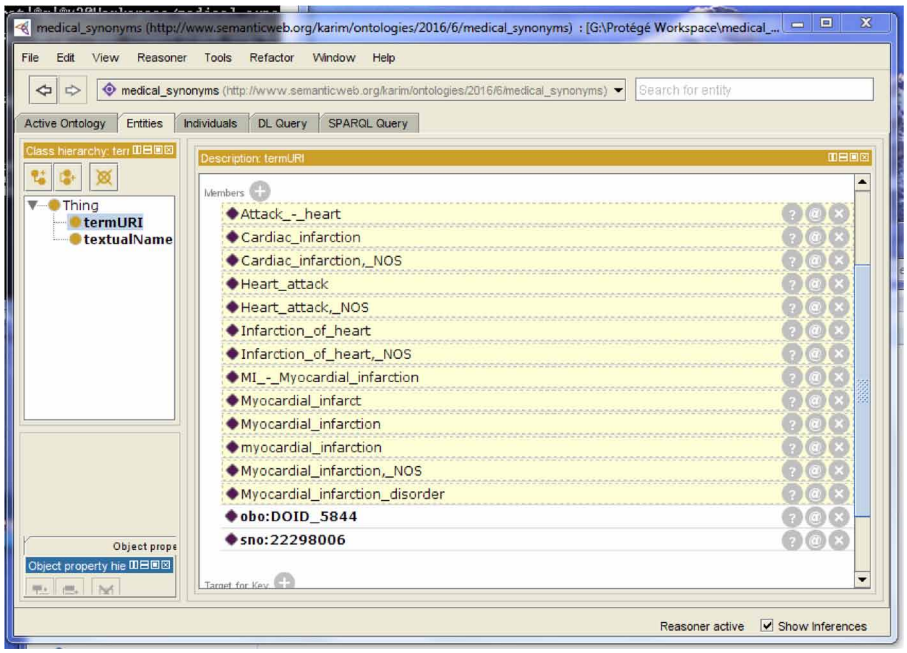
We can also, and more simply, verify semantic equivalence on a case by case basis.

```
ASK WHERE { "Cardiac infarction"   owl:sameAs  ?any . }
```

This query will yield TRUE because several matches will be found in our local triple store.

```
ASK WHERE { "Microinfarct of heart"   skos:sameAs  ?any . }
```

Figure 14. Visualizing the results in Protégé



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

This query will yield FALSE because this medical condition never appears in our triple store as the subject or the object of the predicate owl:sameAs.

4.3. Inferring More Complex Semantic Relationships

This section infers more complex semantic relationships, such as the a "Microinfarct of heart" in the fourth EHR of the scenario in Section 3.2 that need to be reconciled with the synonymous terms in the other three EHRs. Specifically, we are interested in determining if the 4th medical condition of our scenario ("Microinfarct of heart") is closely related to the other three. Several kinds of explorations can be done with SPARQL. For brevity, we will restrict ourselves to an obvious one: is this concept a subclass of the concept depicted in the first three situations of our scenario (whose unique identifier is 22298006) as shown with the SPARQL query and result in Figure 15.

The result at the bottom of Figure 15 demonstrates that this last medical condition is a subclass of the previous one. Again, we have first tried to look for an exact match of the medical textual term used by the cardiologist. If the search had come empty, we would have relaxed the search criteria to ignore for example the letter case, etc. We notice also that this last medical condition has two synonyms. To generate the triple to store locally, we need to replace the FILTER line in Figure 15 with:

```
CONSTRUCT  { ?child  skos:broader   ?parent  . }

<http://purl.bioontology.org/ontology/SNOMEDCT/42531007>
       <http://www.w3.org/2004/02/skos/core#broader>
             <http://purl.bioontology.org/ontology/SNOMEDCT/22298006> .
```

For simplicity, we have related the child and parent concepts by using the **skos:broader** property, since the SKOS ontology has already been imported. We recall that this property means that the first concept (the child class) has a broader concept (the parent class).

5. FHIR AND SEMANTIC RECONCILIATION OF MEDICAL CONCEPTS

The FHIR standard for exchanging healthcare information electronically has been touted as the lingua franca that would help resolve the existing heterogeneity in healthcare data formats which could then be leveraged to reconcile the underlying semantics. FHIR is also intended to support health information exchange and provide a means for mHealth applications to easily gather data from multiple HIT systems (EMRs/EHRs/PHRs) via the common FHIR standard. While attaining the first goal can be trivial if all the stakeholders in the healthcare field adopt the same data exchange format, namely FHIR, there is still the problem of ensuring that the semantics of the exchanged data is preserved from one record to another. To achieve semantic interoperability, FHIR advocates that the data be encoded using standardized coding schemes/systems (e.g., SNOMED-CT for problems, LOINC for observations, RxNorm for medications, etc.), and that the text to display be one of the preferred names. However, nothing in the standard prevents the use of two different coding systems for the same issue (e.g., SNOMED-CT and ICD-10-CM for medical problems). Consider, for example, the two FHIR records in Figures 16 and 17, respectively (abridged for clarity), the first from a physician in a walk-in clinic using SNOMED-CT to report a medical condition (Figure 16), and the second from a family doctor using ICD-10-CM to record the same medical condition, namely a common cold (Figure 17).

Despite the fact that both records in Figures 16 and 17 comply with the same exchange standard (FHIR), it is impossible for the system and/or machine to infer from the provided information that both records actually describe the same medical condition. Whereas, by using the approach we presented in Section 4.2 and 4.3, we can quickly obtain RDF triples from which to infer the semantic equivalence of the two medical concepts. Due to space constraints, we limit the presentation to two quick queries evidencing that both medical conditions share the same semantics. The first query for SNOMED with SPARQL (Figure 18) and its results (Figure 19) clearly shows that the reported condition ("Common cold") is also known as an "Acute nasopharyngitis" which is the medical term used in the second FHIR/XML record in Figure 21.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

The second query for ICD-10 with SPARQL (Figure 20) and results (Figure 21) confirms that the reported medical condition is a common cold. As already explained, by generating the related triples (using the CONSTRUCT keyword) and storing them locally, we can make the appropriate inferences.

Through this simple example, we have shown how our approach applies to FHIR records to evidence synonymy of medical terms.

6. CONCLUSION

This paper has tackled a quite common issue in attempting to integrate data from multiple EMRs/EHRs into a single PHR in which the co-existence of several records in different systems utilize different medical terms to refer to the same medical problem. To set the stage for the work, Section 2 reviewed background information on different types of health information technology systems (PHRs, EMRs, EHRs) and the role of health information exchange. This was followed in Section 3 by a review of the nomenclature in the medical field and the introduction of a use case scenario of healthcare that was utilized for examples throughout the rest of the paper. Section 4 presented the main focus of our paper, a proposed approach to identify and reconcile synonymy of diverse medical terms occurring in multiple EMRs/EHRs. Our approach in Section 4 queried the relevant coding systems to single out and generate a set of RDF triples asserting known and published synonymy, and inferring from those triples potential semantic equivalences in our medical terms. Section 5 extended the work of Section 4 by exploring the semantic harmonization issue that involves the ability to achieve the desired reconciliation utilizing the new FHIR (2014) standard.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

One final important conclusion is that our approach does not require any specific knowledge of the internal structure of the medical coding systems, and relies on a simple and generic formulation to generate the RDF triples from which further inferred synonymy can be evidenced to the system hosting the PHRs. Note also that for clarity, we have not tried to take advantage of advanced features of SPARQL (BIND, VALUES, sub-SELECT[20], etc.) to optimize or beautify our code[21] (e.g., avoid hard-coded medical strings in queries). An obvious extension to our work would be to implement the presented solution into an open-source PHR system to allow data collected from multiple EHRs/EMRs to be semantically reconciled to be presented to a patient via an mHealth application. This work requires additional algorithms and processes to parse the PHR data to identify the coding systems used and to isolate the medical terms whose semantic equivalence we want to verify. Further, the SPARQL queries would need to be transmitted to the endpoint using a RESTFul protocol. Note also that the work in this paper has been influenced in part by this research on security for digital healthcare (Demurjian, et al. 2014/2016) that includes the attainment of role-based access control in XML for the HL7 standard (De La Rosa Algarin, et al. 2013/2016). Semantic reconciliation will play a vital role in the security of healthcare data to insure that the correct terms are delivered to the authorized individuals.

Chapter 30
Principles and Analysis of Biological Networks:
Biological Pathways and Network Motifs

Manika Sehgal
Institute of Microbial Technology, India

TirathaRaj Singh
Jaypee University of Information Technology, India

ABSTRACT

The biological network complexity is growing enormously and in order to reveal confined properties of these intricate networks, detection of crucial network components may assist in gaining effortless perceptive on the underlying biological processes. Analyzing complex biological pathways for their disease association is still a drawn-out process and requires an integrative approach for comprehensive examination of proteins and interactions to identify candidate markers underlying major malignancies and genetic disorders. There is a need for an amalgamated approach to annotate all the sub-components and their associated interactions in a biological system. It is anticipated that analysis of biological pathways would serve as a valuable accompaniment for analyzing biomarkers in disease pathways and will also contribute scientific knowledge towards their better understanding.

INTRODUCTION

In present era, the advent of human genome sequence, high-throughput techniques and massive generated information has revolutionized the biomedical research (Bentley D. R., 2006). This huge amalgamation of genomic data is rising exponentially due to employment of next generation technologies and application of modern biology (Bentley D. R. 2006; Voelkerding. K. V et al., 2009; Mamanova L, et al. 2010). However, less emphasis is remunerated on the obligatory genomic analysis; subsequently there is a need to apply extensive computational approaches that could deal abreast with the remarkable

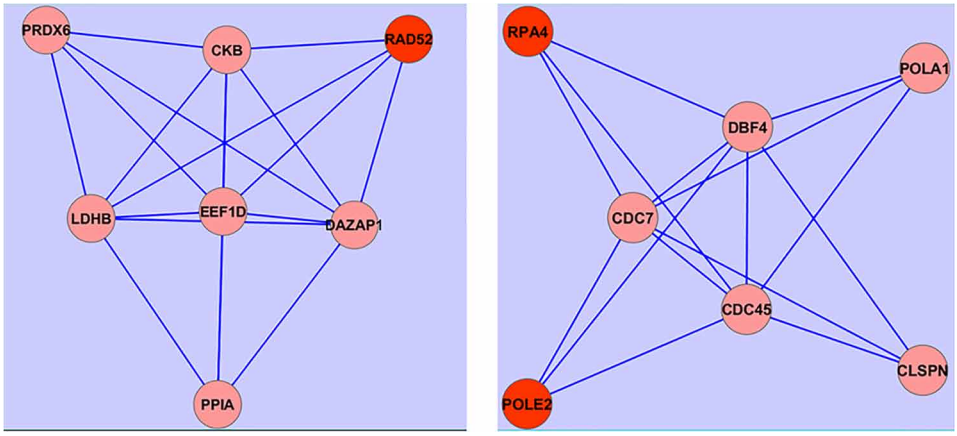
growth in generated biological data (Barabasi A. L. & Oltvai Z.N. 2004; Jeong H., et al. 2000, Jeong H. et al. 2001). Since, the human system is very complex and the ultimate challenge is to decipher numerous multifaceted processes involved in its regulation therefore biological network analysis has major relevance which assists in wide-ranging understanding of an entire system as a whole (Jeong H., et al. 2001). These biological networks present several processes such as cellular mechanisms, signaling cascades, transcriptional regulation, expression profiles and protein-protein interactions (Barabasi A. L. & Oltvai Z. N. 2004; Jeong H. et al., 2000). In Figure 1, these networks comprise of nodes as entities and edges as relationships among them. In general terms a network may be any social interaction, electric circuits, internet and food chain, etc. In biological context, these nodes may vary from a range of macromolecules for instance DNA, RNA, proteins and metabolites. The applications of networks can be observed in ecological networks, expression networks, gene regulatory networks, metabolic networks, protein interaction networks.

Recently, pathway analysis and reconstruction has also gained a lot of attention as it assists in unravelling unknown parameters concerning many precarious diseases. Therefore, the study of networks, their modelling, visualization and simulation are an important aspect for extensively understanding the underlying processes to make sense of the complex available data. Biological networks can be broadly classified into following types:

1. Protein-Protein Interaction (PPI) Networks

The PPI networks form the basis for a vast majority of cellular events, including signal transduction and transcriptional regulation. An extensive understanding of a biological system is feasible only once all the interactions are characterized. These interactions are very well deduced from numerous high-throughput experiments such as protein arrays, co-immunoprecipitation, microarrays and predicted from computational resources developed over time. These *in silico* tools and databases include Search Tool for the Retrieval of Interacting Genes/proteins (STRING), Biomolecular Interaction Network Database (BIND), Molecular INTeraction database (MINT) and Database of Interacting Proteins (DIP). These PPI databases help us effortlessly access the existing information for biological interactions among a

Figure 1. Representation of a sub-network comprising of nodes as entities and edges as relationship/ association with nodes



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

variety of species. The published literature and methods used to exemplify the interaction studies are also described. These resources boost up the understanding of underlying processes which aid the scientific community for designing their future experiments.

2. Signal Transduction and Gene Regulatory Networks

The gene regulatory networks consist of clusters of genes (or gene products) with evidence of co-expression and are generally associated with cascade of processes. In this form of networks, connections usually represent degrees of co-expression where the in-depth knowledge of process is not necessary. Here, the networks are usually non-predictive in nature. The signal transduction networks are induced from some external signals (neurotransmitters, peptides, growth factors) followed by a series of processes involving binding with receptors.

3. Expression Networks

The expression networks deal with the sequence of changes occurring from transcription of DNA into mRNA which is the most regulated step in gene expression. Further, mRNA encodes for proteins i.e. directly proportional to the expression status. Most genes are regulated at the transcriptional level and 5-10% of protein-encoding genes encode regulatory proteins. The interactions between regulated genes and regulatory proteins constitute a complex web called transcriptional network or expression network.

4. Metabolic Networks

The metabolic networks comprises of all the interactions that sums up for the entire chemical reactions taking place within a cell. These processes are implicated mainly in providing energy for the vital cellular and metabolic processes. The metabolic network represents a series of chained reactions where the connections depict quantifiable contacts between the molecules. Since, a metabolic network illustrates a chained reaction, the enzymatic process is evidently elucidated where the changes are predictable downstream.

Currently, the spotlight of major resources is on the metabolic pathways, signaling and regulatory networks to fill in the research gaps and missing links between pathways. Ultimately, all these networks comprising of signal transduction, gene regulatory, metabolic and protein-protein interactions further interact with each other and build a complicated system where these networks are species–specific and may vary among different taxas (Mamanova L, et al. 2010, Jeong H., et al. 2001*)*. There are a variety of macromolecules like enzymes, transcriptional regulators, ribosomes, other biological entities that form complex biological networks to carry out fundamental cellular functions.

BACKGROUND

For a comprehensive perspective on biological complexity and underlying intricate networks, exclusive monitoring of whole system to component level entities is required. Initially, entire pathway is analyzed which is a sequence of interactions between biochemical compounds for controlling the flow of information and energy in the cell. There are myriad of molecular compounds, molecules and cofactors that are

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

component of a network. These include proteins, their complexes, amino acids, peptides, sugars, lipids, cofactors, prosthetic groups, metabolites and other essential compounds like Sulphur, phosphorous, iron and radicals. The analysis of biochemical pathways have become easier with the advancements in experimental technologies like microarrays, proteome analysis, yeast two-hybrid system and phosphorylations of proteins which deal with understanding of interactions among entities. Once, the PPI interactions are clearly elucidated, the reconstruction of a biological pathway becomes simpler which may further be subjected to simulation for estimating the system dynamics. This domain of pathway reconstruction and classification has led to an emerging field of network analysis that assists in wide-ranging analysis of biological pathways. This area basically employs bioinformatics approaches and utilizes computational tools for carrying out functional enrichment, annotation and defining ontologies for a biological system. The results from pathway/network analysis can also be subjected to gene ontology (GO) analysis for governing their involvement in biological processes, cellular compartments and molecular functions. The key feature for network analysis is to postulate vital conserved patterns that may be functionally significant which in turn reveals candidate genes/proteins.

The complexity of the genome becomes multi-folded as the pathways consecutively chain together to form larger pathways and intricate networks. Specific conserved patterns in these networks contribute to the disease etiology in several species. Although, cancers and multi-system defects are a major threat to mankind but still dealing with harmful consequences of these damages is not adequately feasible and also there is no absolute therapy for cancer. The understanding of major cellular processes and its implications through network analyses could help reveal important aspects regarding the same. There is an imperative need to understand these biological mechanisms and triggered signalling cascades so that damages could be sensed well in advance. Upon sensing the damage, factors involved in the regulation of pathways should be clearly elucidated along with their biological roles and positions where they exert their functions (Jeong H., et al. 2001, Jeong H., et al. 2000). Thus, to unravel the complexity hidden in intricate biological phenomenon, a pathway-level analysis for biological networks is essential for the interaction of genes/proteins/networks for understanding myriad of cellular processes.

The knowledge pertaining to interacting partners assists in examining the impact of individual proteins in the overall pathway. In general, a network has a highly complex structure comprising of thousands of nodes with connected edges representing general properties. In order to estimate these properties, absolute acquaintance on kinetics and functional dynamics is obligatory. Once, the node, edges and their properties are calibrated the ultimate challenge is to bridge both the levels. Although, the redundancy and conserved patterns can easily be exemplified further leading to identification of candidate genes/proteins in disease specific pathways. Additionally, analyzing the interaction architecture even helps in setting up a framework for mathematic models where analyzing individual components may not provide meaningful insights; therefore whole pathway analysis is the primary requisite for the study of complex systems.

MAIN FOCUS OF THE CHAPTER

In recent times, various bioinformatics and statistical approaches have been applied to thoroughly understand the structural, functional and evolutionary evidences latent in biological networks of interest. Numerous approaches are available to elucidate important findings from these intricate biological pathways, their comparisons, reconstructions and designing. Figure 2 represents the methodology that could be applied for identifying key players from a biological network. Additionally, vital network components

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

referred as network motifs (Alon U, 2007), found in elevated frequencies that could generally be expected by chance in a pathway could also be identified, as in Figure 3. These network motifs provide statistically overrepresented sub-structures (sub-graphs) in a network and are recognized as simple building blocks of a complicated network. These network motifs play a central role in recognition and analysis of specific patterns in biological networks and yield significant insights into understanding complex biological processes involved in intricate human diseases (Kim W, et al. 2011). Major key candidates and network components or motifs can also be deduced from these complex interactions therefore confining the search to a few important genes.

To thoroughly understand the dynamics of a biological system, a comprehensive perspective on the complex interactions and its topology is required. The chapter highlights details on network properties (Assenov Y, et al. 2008) such as shortest path length, clustering coefficient, neighbourhood connectivity and other crucial parameters as depicted in Figure 4. The shortest path length $L(n,m)$ is the length of shortest path between two nodes n and m. The shortest path length distribution gives the number of node pairs (n,m) with $L(n,m) = k$ for $k = 1,2,....,z$. Whereas, the neighborhood connectivity of a node n is defined as the average connectivity of all its neighbours. The neighborhood connectivity distribution gives the average of the neighborhood connectivity's of all nodes n with k neighbors for $k = 0,1,....,z$. The average clustering coefficient distribution gives the average of clustering coefficients for all nodes n with k neighbors for $k = 2,...,z$. In directed network, the clustering coefficient C_n of a node n is defined as:

$$C_n = e_n/(k_n(k_n\text{-}1))$$

where k_n is the number of neighbors of n and e_n is the number of connected pairs between all neighbors of n. The clustering coefficient is a ratio N / M, where N is the number of edges between the neighbors

Figure 2. Methodology for detecting key candidates from the pathway

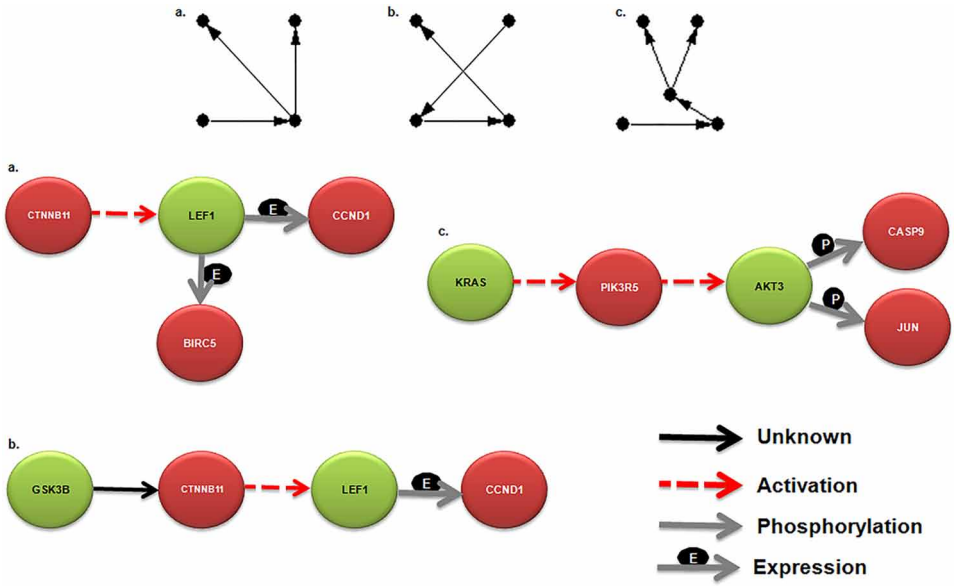
Figure 3. Identified and annotated network motifs in colorectal cancer
Sehgal M., et al., 2015.



of *n*, and *M* is the maximum number of edges that could possibly exist between the neighbors of *n*. The clustering coefficient of a node always ranges from 0-1. The average clustering coefficient has already presented its utilization in metabolic networks where the modular organization has been studied.

COMPUTATIONAL METHODS AND APPROACHES AVAILABLE FOR PATHWAY ANALYSIS

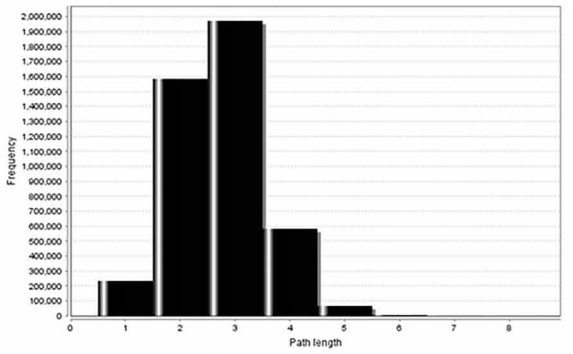
The rapid growth of knowledge on functional analysis of genes, proteins and cellular processes demands wide-ranging databases and novel computational methods and approaches to be devised for efficient representation of proteins as well as their functional interactions whereas the chapter extensively focus on the important available approaches. The methods and resources (Smoot M. E.,et al. 2011, Wernicke S. & Rasche F. 2006, Schreiber F. & Schwobbermeyer H. 2005, Kashtan N.,et al., 2004) for studying biological networks include:

Cytoscape

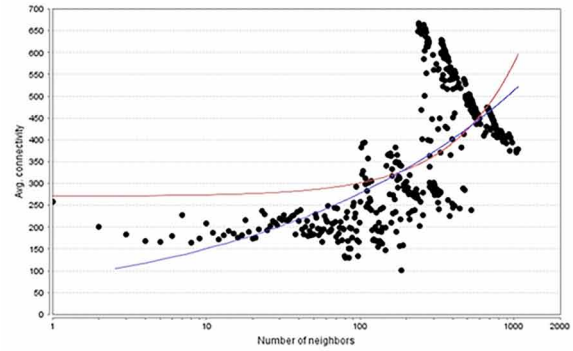
Cytoscape is a very widely used open source software platform for visualization of molecular interaction networks and biological pathways. It allows integration of the networks with single nucleotide polymorphism (SNP) data, phenotypes, gene expression profiles and other molecular states leading to annotations and functional enrichment. Cytoscape has an additional feature for loading nodes, edges and networks where different attributes could be mapped for extensive understanding of biological processes. User can easily access and analyze the expression results and GO annotations in the platform. There are various apps and plugins available for annotation of these networks incorporating data from a variety of datasets

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

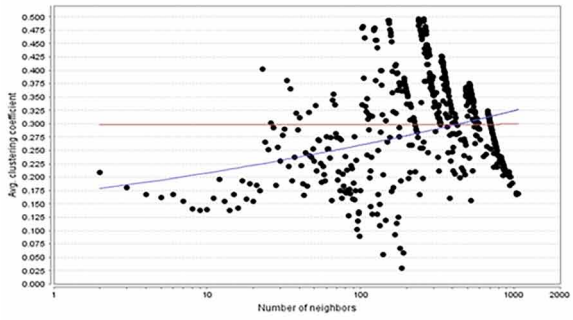
Figure 4. Statistical parameters elucidating significance of the biological pathway



a. Shortest path length



b. Neighborhood connectivity (In and Out)



c. Average clustering coefficient

from microarrays and high-throughput studies. These plugins are generally freely available and stimulate easy visualization of complex biological data. A classical example of statistical inferences made from network analyzer plugin has already been observed in Figure 4. It has numerous features available for data integration, analysis, visualization, molecular profiling analyses, new layouts, additional file formats support and connection with databases. Cytoscape supports many standard network and annotation file formats such as SIF (Simple Interaction Format), BioPAX, PSI-MI, GraphML, KGML (KEGG XML), SBML and Gene Association. Cytoscape is considered most influential when utilized in juxtaposition with larger databases of protein-protein, protein-DNA and genetic interactions.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Fanmod

Fanmod is a tool for fast network motif detection. It is better than its counterparts (explained below) in terms of efficiency and speed when dealing with larger motifs generally more than 8-node sub- graphs. It randomly detects over-represented sub-graphs in a network called as network motifs which are recurring patterns of interactions and are statistically significant. It exploits the most efficient RAND-ESU algorithm for the detection of motifs. It provides with motifs ranging from 3-8 node sub-graphs with colored edges and have filtering done on the basis of z-score and p-values. Fanmod can be easily downloaded on a system and be used as a standalone software which performs calculations at a faster rate.

MAVisto

Like Fanmod, MAVisto is used for the exploration of motifs in a network. It provides a flexible motif search algorithm and different views for the analysis and visualization of network motifs. The MAVisto tool is written in Java and has an editor for graphs visualization and a toolkit for implementing graph algorithms. It is also available freely for academic purposes at http://mavisto.ipk-gatersleben.de/mavisto.jnlp. Usually, three different types of analyses can be performed with MAVisto by considering only edge labels, only vertex labels or both, edge and vertex labels.

Mfinder

The motif finder (mfinder) is another software tool for detecting network motifs. It identifies the network motifs in biological pathways by using two algorithms i.e. firstly it takes into account the full enumeration of sub-graphs and then sampling of sub-graphs is done for estimating the sub-graph concentrations. It employs switching method for the generation of random motifs. The standalone version can be easily downloaded from the following URL

https://www.weizmann.ac.il/mcb/UriAlon/download/network-motif-software.

The basic steps for the identification of network motifs from any of the above mentioned tool comprise of the following basic steps:

1. Identify all sub-graphs of n nodes in the network.
2. Randomize the network, while keeping the number of nodes, edges, and degree distribution unchanged.
3. Identify all sub-graphs of n nodes in the randomized version.
4. Sub-graphs that occur significantly more frequently in the real network, as compared to the randomized one, are designated as motifs.

RESOURCES AND DATABASES FOR BIOLOGICAL NETWORKS

The genome sequencing and the latest research strategies have generated huge and complex genomic and proteomic data which is available in repertoire of online resources and databases. Enormous research

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

tools are also available for the extensive analysis of these complex interactomes. There are a variety of resources on biological networks and their analysis available online which can be classified on different means as follows:

General Pathway Repositories

This module supplies information on available general biological pathway databases. The pathway databases mainly highlight entire cascade of processes instead of individual components. Although it do provide insights into smaller components or interacting proteins but the ultimate aim is to understand the system as a whole.

BioCyc/MetaCyc

It stands for biological encyclopedia/ metabolic encyclopedia. Biocyc is a pathway/genome database for organisms with completely sequenced genomes where species-specific pathways are inferred form MetaCyc whereas MetaCyc is a non-redundant reference database for metabolic pathways, reactions, enzymes and compounds.

Kyoto Encyclopedia of Genes and Genomes (KEGG)

KEGG is mainly considered as a common platform for consolidated set of databases that cover genomics (GENE), chemical compounds (LIGAND) and reaction networks (PATHWAY). It has a broad coverage related to other databases concerning on metabolics, signal transduction, disease, *etc*. It contains pathways from numerous species and allows only static visualization services where the pathways can be downloaded in KGML format for further annotation and analysis (Kanehisa, M.,et al. 2016).

BioCarta

It is a corporate-owned and publicly curated pathway database which provides an interactive user interface with cartoon pathway maps. BioCarta focuses mainly on human and mouse related biological pathways.

BioModels Database

BioModels is a database on published quantitative models for biochemical processes. It contains information on all models/pathways that are curated manually. It allows the models to be created in SBML format for quantitative modeling.

Some other pathway databases include PathDB, Signaling PAthway Database (SPAD) and Cytokine Signaling Pathway Database.

Protein Interaction Databases

The protein interaction databases section provides an exclusive compendium for various species-specific, function-specific, interaction type-specific and general protein-protein interaction databases.

4. **General Protein-Protein Interaction Databases:**
   a. **BIND:** Biomolecular Interaction Network Database,
   b. **BindingDB:** The Binding Database,
   c. **MINT:** A database of Molecular INTeractions,
   d. **PATIKA:** Pathway Analysis Tool for Integration and Knowledge Acquisition,
   e. **PFBP:** Protein Function and Biochemical Pathways Project, and
   f. PIM (Protein Interaction Map) .

PATHWAY EXCHANGE FORMATS

There are numerous pathway exchange formats developed for easy exchange of information from one platform to another. The exchange formats help maintain a standard for representing pathway data or easy understanding among different researchers. Some of the exchange formats have been described below:

Extensible Markup Language (XML)

XML is a standard of representing information in a machine-readable manner. It is a division of SGML and is much better than hyper text markup language (HTML) in terms of its extensibility in defining tags that enclose data. For instance:

```
<XMLInfo>
        <someTag>Some data here</someTag>
        <anotherTag>Additional data </anotherTag>
```

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

```
        <attributeTag data="embedded in tag" />
</XMLInfo>
```

Systems Biology Markup Language (SBML)

SBML is a representation format based on XML for exchange and storage of computational models of biological processes. It is a machine-readable exchange format and its strength lies in the representation phenomena at the scale of biochemical reactions. Several tools use this format for standard input and output operations in order to remove chances for errors in translation and assuring a common starting point for analyses and simulations *(Keating, S. M, et al. 2006).* SBML's framework is suitable for representing models commonly found in research on topics like gene regulation, cell signaling pathways, metabolic pathways, biochemical reactions, and many more. Example of its format is given below:

```
<?xml version="1.0" encoding="UTF-8"?>
<sbml xmlns=http://www.sbml.org/sbml/level1
level="1" version="2">
<model name="gene_network_model">
  <listOfUnitDefinitions>
        . . .
  </listOfUnitDefinitions>
<listOfCompartments>
        . . .
</listOfCompartments>
<listOfSpecies>
        . . .
</listOfSpecies>
<listOfParameters>
        . . .
</listOfParameters>
<listOfRules>
        . . .
</listOfRules>
<listOfReactions>
        . . .
</listOfReactions>
   </model>
</sbml>
```

ISSUES, CONTROVERSIES, PROBLEMS

The pathway analysis as a whole is a cumbersome task and there has been many controversies on its analysis as some researchers suggest studying individual interactions can be more beneficial instead being spellbound by the complicated system whereas others support the idea of systems biology as the

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

biological systems are basically dynamic in nature. In the knowledge of intricate pathways/networks, regulatory DNA motifs are considered as bar codes to retrieve the building blocks which may help in gaining better insights in pathway studies. A combination of high-throughput experiments, prior knowledge and bayesian network inference is also indispensable for thorough understanding of a biological problem. Furthermore, efficient analyses on biological networks require robust computational infrastructure for specialized housing, accessing and analyses of ever-growing and amplifying complex biological data. Usually, the complete network of integrated biological pathways is the blueprint of life whereas the genome is only an archiving system of building blocks. Therefore, it is proposed that a better idea is to follow an integrative approach where both the component-levels and system-levels are taken into consideration. In order to achieve this goal, top-down and bottom-up techniques could be applied in an amalgamation.

SOLUTIONS AND RECOMMENDATIONS

The biological pathway/network analysis is a hot spot in current research domain and bioinformatics. This area has a variety of sub-fields that could be taken up by young minds to solve the mysteries of various biological problems. The fundamental themes that could be extensively deliberated include development of new algorithms, tools and comprehensive databases for understanding and visualizing pathways with noteworthy statistical inferences. The areas of research focus on valid implications of metabolic pathways from genomes, designing and development of schemas for constructing pathway related databases and classification systems for biological pathway data.

FUTURE RESEARCH DIRECTIONS

Since, major tools and resources dealing with pathway data don't have a common format for exchange of information and results, work primarily on developing exchange formats can be another valuable alternative in this area. Although systems biology markup language (SBML) solves the problem to some extent but for a consistent and straightforward perceptive, other easily understood formats are the need of the hour for exchange of pathway data. Reconstruction of biological pathways via layout algorithms from the knowledge obtained from interaction studies, simulation and molecular dynamics analysis could also yield significant insights in major biological problems. The study of protein-protein interactions has provided important insights into the functions of many of the known oncogenes, tumor suppressors, and DNA repair proteins assisting in cancer research. Moreover, pathway analysis has evidently proved its implication in the domain of pharmacogenetics research targeting specific drug transporters, drug receptors and drug targets. For any research area such as vaccine development, treatments, designing disease strategies, preventing symptoms, clinical trials and drug development to be promising, the major challenge lies in the understanding of disease mechanisms which is feasible only through widespread pathway and system-level understanding.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

CONCLUSION

The chapter endows with crucial insights on major biological networks, their reconstruction and visualization, computational methods and approaches available for their analyses, online resources and databases containing information on these networks and pathways. The main challenge till date is to find appropriate targets in a diseased pathway leading to drug discovery process which has been a time consuming and expensive affair. Thus, knowledge of biological pathways will assist the readers and scientific community in gaining insights on intricate networks and available tools and resources for their study. The pathway level analysis of these networks may provide vital clues about putative but predictive biomarkers for numerous diseases. Additionally, top-down and bottom-up approaches could be applied for the annotation of complex biological networks and this functional enrichment would generate biological meaningful information. It is expected that once the biological networks are broadly analyzed, it will also provide innovative paradigms for genetic susceptibility, prevention, diagnosis and rational therapy.

KEY TERMS AND DEFINITIONS

Annotation: Annotation is defined as a measure of estimating the properties of an entity (gene, protein, metabolite, pathways) such as its functions, localizations and implicated processes. Annotation can be done through manual curation or automation depending on the availability of resources.

Network Motifs: Network motifs are defined as over-represented sub-graphs in a network. These are recurrent patterns occurring in a network with higher frequency compared to other randomly generated networks.

Chapter 31
Multiple Sequence Alignment Optimization Using Meta-Heuristic Techniques

Mohamed Issa
Zagazig University, Egypt

Aboul Ella Hassanien
Cairo University, Egypt

ABSTRACT

Sequence alignment is a vital process in many biological applications such as Phylogenetic trees construction, DNA fragment assembly and structure/function prediction. Two kinds of alignment are pairwise alignment which align two sequences and Multiple Sequence alignment (MSA) that align sequences more than two. The accurate method of alignment is based on Dynamic Programming (DP) approach which suffering from increasing time exponentially with increasing the length and the number of the aligned sequences. Stochastic or meta-heuristics techniques speed up alignment algorithm but with near optimal alignment accuracy not as that of DP. Hence, This chapter aims to review the recent development of MSA using meta-heuristics algorithms. In addition, two recent techniques are focused in more deep: the first is Fragmented protein sequence alignment using two-layer particle swarm optimization (FTLPSO). The second is Multiple sequence alignment using multi-objective based bacterial foraging optimization algorithm (MO-BFO).

INTRODUCTION

Bioinformatics is a field that combines computer science and mathematics for analyzing and managing biological data. Developing large databases and complex tools for gene and protein analysis and modeling are the main tasks of bioinformatics besides organization, storing and retrieving biological data (Cohen, 2004). Sequence alignment becomes an essential tool of bioinformatics and it is vital in various tasks such as genomic annotation, protein secondary and tertiary structure prediction, phylogenetic

tree construction, modeling binding sites, homology searches, gene regulation networks and functional geneomics (Das, Abraham, & Konar, 2008 ; Durbin, Eddy, & Krogh, 1998). From biological point of view all organisms have a common ancestors and so the similarity between DNA or protein sequences exist. The function of newly known sequences with a known sequence can be known with measuring the similarity (Alberts et al., 2007; Arthur, 2002 ; Zvelebil & Baum, 2008).

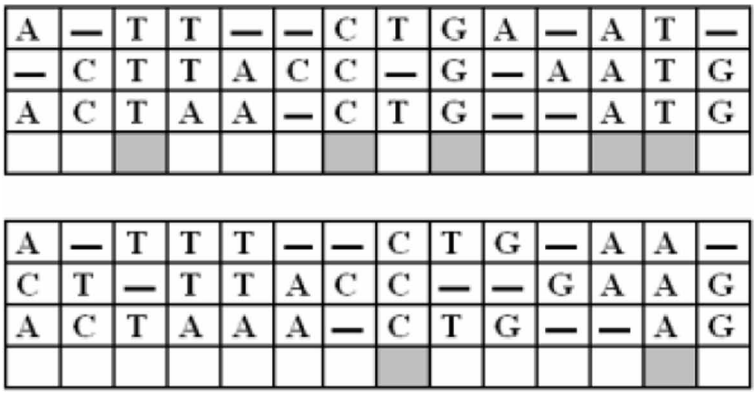
Sequence alignment arranges DNA, RNA and protein sequences to locate conserved blocks or region of similarity. It lining up the nucleotides (A,C,G and T) in DNA or amino acids (20 different amino acids) in protein sequences to achieve the maximum possible level of similarity (Song.J, Liu, Song.Y, & Qu, 2007). The function similarity between sequences is predicted corresponding to the regions of similarity. This arrangement needs insertion of gaps in positions that maximize the alignment score and nucleotides/residues matching.

Finding sequence alignment experimentally is sensitive to less accuracy due to experimental errors with much time consuming and cost. Hence, many efforts in the last years to develop software tools that propose efficient model for accurate alignment. Aligning two sequences is called pairwise sequence alignment. While aligning more than two sequences is called multiple sequence alignment (MSA) as shown in Figure 1 (Sievers & Higgins, 2014). MSAs computation is almost computationally expensive and it classified as NP-complete problem. This chapter focus on the MSA techniques.

The MSA's methods are divided into four approaches: Exact, Progressive, Consistency based and iterative approach (Notredame, 2002). In the exact method (DP) was used for pairwise global alignment by computing the alignment over the entire length of the sequences, (Needleman & Wunsch, 1970). In DP a matrix is created and filled with the partial alignment scores of the two sequences. DP tries to find the shortest path with maximum alignment cost between the start and end of the sequences. The main limitations of DP approach are time and space complexities especially for number of sequences more than 2 sequences (Lipman, Altschul, & Kececioglu, 1989; Carrillo & Lipman, 1988)

Progressive approach solve the problems of the exact method by decreasing the time and space complexties (Taylor, 1988 ; Feng & Doolittle, 1987) The idea of using progressive technique is aligning the most related sequences and then incrementally adding the more distant one by one. The common MSA techniques that based on the progressive approach are CLUSTALW (Thompson, Higgins, &Gibson, 1994), MUSCLE (Edgar, 2004), CLUSTAL OMEGA (Sievers & Higgins, 2014) and Multi-Align

Figure 1. Example of Aligning 3 DNA sequences (MSA)
Öztürk & Aslan, 2016.



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

(Devereux, Haeberli, & Smithies, 1984). The limitations of progressive approach are that final results depend on the initial pairwise sequence alignment and the alignment scoring scheme used. Besides, the time complexity depends mainly on the number of aligned sequences. Iterative and consistency based approaches outperform the progressive alignment in the point of accuracy. Iterative approach based on dividing the alignment into sub-alignment and re-alignment the sub-alignment. The main techniques based on iterative approach are MAFFT (Katoh, Misawa, Kuma, & Miyata, 2002), DALIGN (Morgenstern, Dress, & Werner, 1996), T-COFEE (Notredame, Higgins, & Heringa, 2000) and MUSCLE (Edgar, 2004).

In the consistency based approach the alignment not depend only on the scoring function used but on the behavior of other alignments also. For example, if three sequences A, B and C are to be aligned, if residue A_i is aligned with residue B_i . If residue Ai aligned with residue C_i then this implies residue B_i can be aligned with residue C_i. The limitation of iterative and consistency based approaches is the time complexity. Where the consistency approach has time complexity of $O(k^3n^2)$ where k is number of aligned sequences and n is the maximum length of aligned sequences. The most common techniques based on consistency approach are PCMA (Pei, Sadreyev, & Grishin, 2003), ProbCons (Do, Mahabhashyam, Brudno, & Batzoglou, 2005) and MUMMALS (Pei & Grishin, 2006). The accuracy of the alignment is reflected by computing the scoring function of MSA. This scoring function measure the performance of the technique and two scoring schemes are used:

- Column Score (CS) which is used to increase the number of matched column and is computed using Equation 1.

$$CS = \sum_{i=1}^{L} M_t(1 + \frac{M_t}{n}) \tag{1}$$

where M_t is the number of matched residues, n is the number of aligned sequences and L is the number of columns in the alignment.

- Sum of Pair (SOP) is the second scoring scheme used for increasing the similarity between two aligned sequences and is computed using Equation 2.

$$SOP = \sum_{i=1}^{L} Score(S(i)_1, S(i)_2) \tag{2}$$

where S_1 and S_2 are the aligned sequences.

For proteins, there are matrices give weight for the bases comparisons. The most common ones are BLOcks of amino acid SUbstitution Matrix (BLOSUM) (Henikoff, S., & Henikoff, J. G., 1992) and Point Accepted Mutation (PAM) (Altschul et al., 1990). There are penalty for contagious gaps instead of separated gaps, so the general gap penalty is used. g_0 and g_e are the gap open and gap extension penalties (Gotoh, 1982).

BACKGROUND

Meta-heuristics is a branch of computational intelligence which use heuristics techniques to explore the feasible search space in efficient way. Two main categories of meta-heuristics: single based and population based methods. Single based methods use only one solution and improve it until reach its optimum. The common techniques for single based solutions are Tabu Search (TS) (Glover, 1986), Simulated Annealing (SA) (Kirkpatrick, Gelatt, & Vecchi, 1983), Variable Neighborhood Search (VNS) (Mladenović, 1997 ; Mladenovic, 1995) and Iterated Local Search (ILS) (Stützle, 1999). Population based techniques use many solutions to find the optimum one. The most common ones are Particle Swarm Optimization (PSO) (Kennedy, 2011), Ant Colony Optimization (ACO) (Dorigo, 1992), Genetic Algorithms (GA) (Aryanezhad & Hemati, 2008), Firefly algorithm (Yang, 2010a), Bat-inspired algorithm (Yang, 2010b), Bacterial for aging Optimization (Carillo and Lipman, 1988) and Scatter Search (SS) (Glover, 1998). Two terms related the optimization techniques diversification and intensification. Diversification represents the exploration of the feasible search space. While, intensification represents focusing in certain region of feasible search space. Single based techniques have the property of intensification while population based solution have the property of diversification.

MAIN FOCUS OF THE CHAPTER

MSA problem was solved using simulated annealing like (Kim, Pramanik, & Chung, 1994 ; Simons, Kooperberg, Huang, &Baker, 1997 ; Lukashin, Engelbrecht, &Brunak, 1992). The main problem of simulated annealing is the slow of execution but it well as alignment improver. Genetic algorithm also was used for optimizing MSA in many work like genetic algorithm by optimizing the alignment scoring function (Bucak & Uslan, 2011 ; Botta & Negro, 2009], Progressive Alignment Method using Genetic Algorithm (Naznin, Sarker, & Essam, 2012), Multiple Sequence Alignment using Genetic Algorithm (MSA-GA) (Gupta, Agrwal, & Soni, 2013), Rubber Band Technique using Genetic Algorithm (RBT-GA) (Taheri & Zomaya, 2009) and Vertical Decomposition with Genetic Algorithm (VDGA) (Naznin,, Sarker, & Essam, 2011). Another development using genetic algorithm was using the multi-group and migration technique(Luo, Zhang, & Liang, 2011). Genetic algorithm alignment works well for small number of sequences. With increasing the number of aligned sequences the exponential growth of time is observed. Particle swarm optimization was used for optimizing MSA and proved its superiority in speed of convergence than simulated annealing and genetic algorithm. Also, its ability for aligning sequences more than genetic algorithm. The reason of PSO' success are it has a few parameters to adjust and it needs low memory allocation. A lot of research work proved these properties like (Xu & Chen, 2009; Lalwani, Kumar, & Gupta, 2013; Yadav & Banka, 2016 ; Moustafa, Elhosseini, Taha, & Salem, 2016). Ant Colony Optimization (ACO) and Artificial Bee Colony (ABC) were used for optimizing MSA (Lee & King, 2014 ; Rubio-Largo, Vega-Rodríguez, & González-Álvarez, 2016 ; Öztürk & Aslan, 2016).

BFO is one of the recent nature inspired optimization techniques that mimics bacteria (swarm of E.coli bacteria) for searching for nutrients (Passino, 2012). During bacteria foraging locomotion is achieved by a group of tensile flagella. Flagella lead to tumble or swim operation for the E.coli bacteria. These two operation are performed during the bacteria foraging. Each flagellum pulling on the cell during the bacteria rotating the flagella in the clockwise direction. This action lead to reduce the number of bacteria tumbling. However, in the harm places the tumbling process is increased to find a nutrient gradient.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Rotating the flagella in the counter-clockwise direction lead to swimming of the bacteria at a fast rate. Clockwise and counter-clockwise movements take place to find a nutrient solution. When the bacteria get enough food they are increased. From this phenomenon BFO was inspired. A review for optimizing some applications using BFO exists (Das, Biswas, Dasgupta, & Abraham, 2009). In the following FTLPSO and MO-BFO techniques are presented.

FTLPSO

Fragmented protein sequence alignment using two-layer particle swarm optimization (FTLPSO) (Moustafa, Elhosseini, Taha, & Salem, 2016) is presenting efficient result for optimizing MSA using particle swarm optimization tecniques. FTLPSO based mainly on fragmenting the long sequences to prevent PSO from trapping in local minima. In addition, The two layer (main layer and secondary layer) also increase the local minima immunity. The main layer uses the column score objective function while the secondary uses the sum of pair objective function. Each particle in the main layer has many particles in the secondary layer that is as shown in Figure 2. Each particle in the secondary layer point to the gap positions in a fragment. Two vectors of each particle the first one contains the positions of gaps in each fragment. The second vector has a dimension as the number of aligned sequences. Each element of the vector has the value of the number of consecutive gaps in the first vector to be inserted in the corresponding aligned sequence fragment. For example, for a particle *m* assume the first vector contain the following first vector: *m=[3,8,10,1,6,9,10]* and the second vector is: μ *= [1,2,4].* As shown in Figure 3 in the right three fragments of sequences after insertion the gaps represented by one particle. In the secondary layer, the populations in the same group each iteration determine the global best particle. At the end of each iteration this best particle is mutated to reduce the risk of trapping in the local minima. After finishing the iterations of secondary layer the global best particle of each group become the head of this group in the main layer. So, the main layer contains the global best particles of all groups in the secondary layer. The best particle of the global best particles is determined to be the overall global best and the iteration of secondary layer is repeated guiding this new global best particle.

Comparison between FTLPSO and standard PSO was performed using Balibase dataset of different lengths. For short lengths PSO and FTLPSO success to find the same score but for long sequences FTLPSO outperform standard PSO as shown in Figure 4.

In all, this tool is a reliable for finding alignment of MSA. Comparison between it and the common tools for MSA alignment (CLUSTAL OMEGA, TCOFFEE and KALIGN) shows verification of the result as shown in Table 1. The reasons of success of this tool are: first, the fragmentation and mutation reduce the risk of trapping in local minima. Second, Failing of one particle to don't find the optimum score don't affect on the other particles.

MO-BFO

Most of the available technique for optimizing the MSA are used on of the two common objective functions CS and SOP or hybrid between it. So, the objective of is to maximize the objective function which is called unary objective optimization. Another category of optimization for multi objectives as this technique presented. The objectives that were used to optimize MSA are:

Moustafa, Elhosseini, Taha, & Salem, 2016.

1. **Maximization of Similarity:** The similarity was estimated using the following formula:

$$Similarity = \frac{dv(m)}{l}$$

$$dv(m) = \max_{n} \left\{ f(n,m) \right\}, m=1,2,3,4,\ldots,l$$

where f(n,m) is the score value of amino acid or nucleotide n on the column m. l is the sequence alignment length.

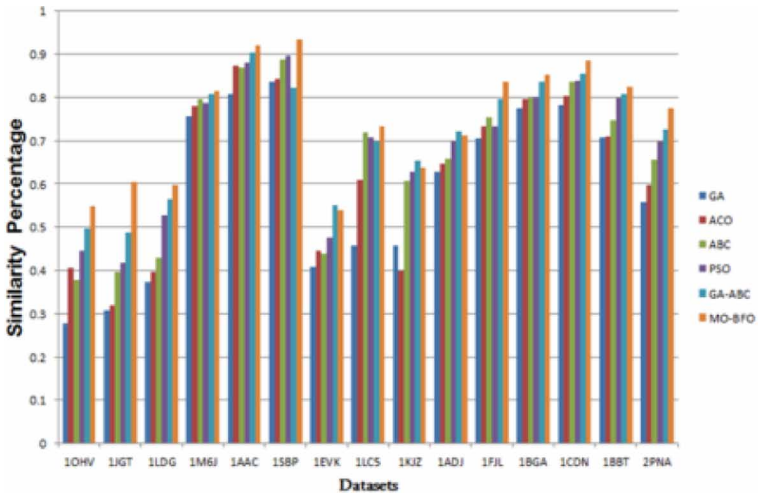
2. **Minimization Gap Penalty:** This objective mean reducing the insertion of gaps as possible that is due to this leads to increasing the alignment score. Column of aligned gap is not allowed. Affine and variable length gap scheme were used in this technique.
3. **Maximize Non-Gap Percentage:** Non gap percentage is defined as the total number of amino acids in the sequence with respect to the number of gaps in the sequences.
4. **Maximize Conserved Blocks:** Regions of the aligned sequences are conserved or identical are called conserved blocks. These region are suitable for phylogenetic analysis or determine common function and structure.

The proposed technique was tested using Balibase datasets version 3.0 and compared with five optimized MSA techniques Genetic Algorithm, ABC, ACO, PSO and hybrid between genetic algorithm and ABC. Figure 5 shows the similarity percentage of various datasets with different lengths. As shown MO-BFO outperform other techniques in almost all datasets. The technique depend on the nature of the sequences if the sequences in the datasets have high difference in length this leads to low similarity and accuracy as shown for datasets *1EKV*, *1KJZ* and *1ADJ*.

Figure 6 shows the result of Non-Gap percentage for the same datasets. MO-BFO has the greatest percentage overall. Gap penalty for all datasets are the minimum for MO-BFO as shown in Figure 7. The performance of MO-BFO was measured by estimating SOP and TCS alignment scores. Table 2 shows the result of comparison of SOP and TCS alignment scores with GA, ACO, ABC, PSO and GA-ABC. The comparisons with online tools such as MAFFT, CLUSTAL OMEGA, K-ALIGN and MUSCLE as shown in Table 3. As shown in Tables 2 & 3 MO-BFO outperform the other methods in term of performance which verify its efficiency. Maximization of conserved blocks is the last objective

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 5. Similarity Percentage of MO-BFO compared with other optimization approaches for MSA was tested on Balibase datasets



of MO-BFO. The technique succeeded to maximize the number of conserved blocks with near optimal scores for other objectives (Similarity, Gap penalty and Non Gap percentage). For example, alignment the dataset 1SBP as shown in Figure 8 shows the conserved patterns in the alignment with non-gap percentage 87% and similarity 93%.

CONCLUSION

This chapter review the recent research for developing MSA using Meta-heuristics or stochastic techniques. Stochastic techniques success in a lot of research to compute the accurate alignment near to that of DP technique. Also, chapter focus deeply on two techniques for MSA are FTLPSO and MO-BFO. FTLPSO use two layer PSO for MSA that decrease the probability of trapping in local minima. MO-BFO use the bacterial foraging technique for optimizing multi objectives of MSA. This chapter conclude the methodology of the two techniques and their performance is compared with other stochastic MSA METHODS and online methods.

Chapter 32
GEView (Gene Expression View) Tool for Intuitive and High Accessible Visualization of Expression Data for Non-Programmer Biologists

ABSTRACT

This article describes how the last decade has been characterized by the production of huge amounts of different types of biological data. Following that, a flood of bioinformatics tools have been published. However, many of these tools are commercial, or require computational skills. In addition, not all tools provide intuitive and highly accessible visualization of the results. The authors have developed GEView (Gene Expression View), which is a free, user-friendly tool harboring several existing algorithms and statistical methods for the analysis of high-throughput gene, microRNA or protein expression data. It can be used to perform basic analysis such as quality control, outlier detection, batch correction and differential expression analysis, through a single intuitive graphical user interface. GEView is unique in its simplicity and highly accessible visualization it provides. Together with its basic and intuitive functionality it allows Bio-Medical scientists with no computational skills to independently analyze and visualize high-throughput data produced in their own labs.

INTRODUCTION

Advanced high-throughput technologies have been developed and extensively used in the last decades (microarrays since the mid-1980s (Schena, Shalon, Davis, & Brown, 1995) and Next Generation Sequencing (NGS) (Goodwin, McPherson, & McCombie, 2016) since the mid-2000s). Mass spectrometry technologies were originally invented almost 100 years ago and further developed during the 1990s (Glish & Vachet, 2003). All these technologies and others are being routinely used by Bio-medical (Bio-Med) scientists for production of high-throughput data. However, currently, it is very difficult for Bio-Med researchers with no computational skills to analyze their own data. Various free, online and user-friendly tools have been developed and are routinely used for gene expression and proteomics data analysis. For example, Expander (Ulitsky et al., 2010), Chipster (Kallio et al., 2011), SAM (Tusher, Tibshirani, & Chu, 2001), Limma (Ritchie et al., 2015), DESeq (Love, Huber, & Anders, 2014), Morpheus (https://software.broadinstitute.org/morpheus/), MeV (Howe, Sinha, Schlauch, & Quackenbush, 2011) for gene expression analysis, and MaxQuant (Cox & Mann, 2008) for proteomics data analysis. However, these tools usually perform a large range of tasks, which are sometimes not straightforward and may necessitate some computational skills. In addition, they usually lack a single-gene trivial visualization (such as box plots), which is a basic request of lab researchers in order to study the expression pattern of a specific gene of interest. While the Morpheus tool (https://software.broadinstitute.org/morpheus/) does provide box plots for single genes, it has the limitation of not providing differential expression statistical analysis of more than two groups of samples. The result is that many Bio-Med researchers are reluctant to use such tools and often outsource for the analysis of their data. Outsourcing creates a gap in time and expenditure of financial resources, in addition to the fact that it is performed by a computational expert, who doesn't necessarily have a biological view of results. Thus, there is a need for a more basic and intuitive tool, with functionalities such as quality control measures, simple statistics, differential expression analysis and intuitive visualization of the results, including single-gene visualizations.

GEView is a free, easily downloadable tool suitable for Windows and Linux platforms, written in MATLAB (https://www.mathworks.com). It provides intuitive quality control analysis of the experiment, outlier exclusion and easy identification of differential expression of gene, microRNA or protein data. The great advantage of GEView is its usage simplicity and the output Excel table which provides immediate visualization of the analyzed data on a single-gene basis. It serves all available expression platforms, given that expression values for each gene/microRNA/protein are provided in a tab-delimited file as input, after normalization. GEView is freely available to non-commercial users and can be downloaded from http://www.weizmann.ac.il/complex/compphys/software/geview/. It includes a convenient "help" menu and an example test data (Teuffel et al., 2004).

We believe GEView may be highly useful for Bio-Med researchers who are not computational experts. Such researches, who were previously reluctant to use computational tools and were dependent on external bioinformatics services, have now an opportunity to analyze their own data. In addition, the readily available single-gene graphical representation enables laboratory scientists to simply return to the results table each time they become interested in a new gene or protein and explore its expression pattern in their data. Thus, by improving the access to basic expression analysis, GEView improves the ability of laboratory scientists to produce significant results from their various experiments.

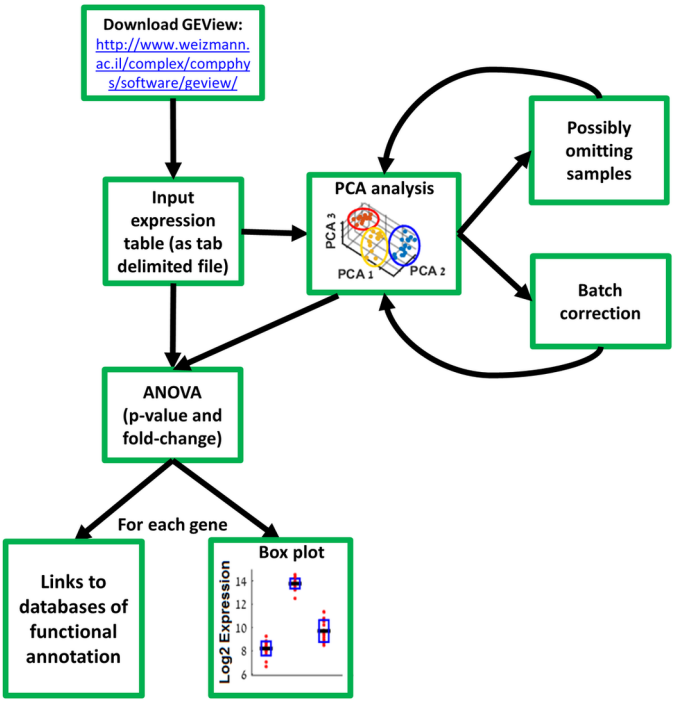
EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

IMPLEMENTATION

In this paper we present GEView, a useful tool for various types of expression analysis (genes, microRNAs and proteins). Our aim is to enable the Bio-Med researchers with no computer-science skills, to simply analyze and visualize high-throughput data produced in their wet experiments (see workflow in Figure 1), using an intuitive user interface (see Figure 2).

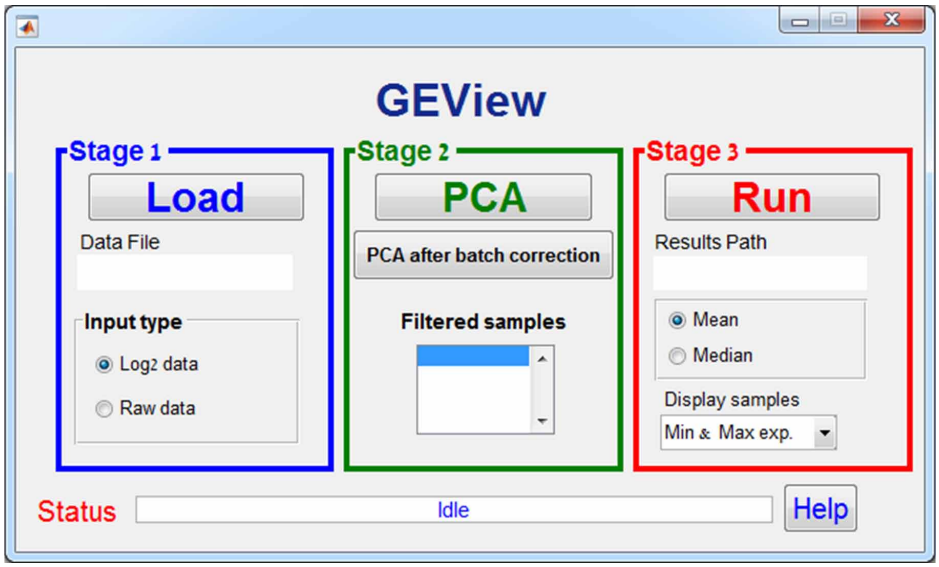
GEView performs a basic quality control step of Principal Component Analysis (PCA) (Jolliffe & Cadima, 2016). The researcher may correlate PCA output with experimental design and sample replicates and examine whether all biological replicates cluster together (otherwise, unknown variables may have affected the data). It may also indicate biological outliers among the samples. In addition, various experimental batches resulting from experimental design and/or other technical constraints can be easily corrected using GEView, implementing the ComBat batch correction algorithm (Johnson, Li, & Rabinovic, 2007; Leek, Johnson, Parker, Jaffe, & Storey, 2012). Moreover, GEView uses Analysis Of Variance (ANOVA) (Bewick, Cheek, & Ball, 2004) (http://www.mathworks.com/help/stats/anova1.html) to identify genes (/microRNAs /proteins) which are differentially expressed between the various experimental conditions. The single output Excel file provides immediate visualization of all genes' differential expression in the various experimental conditions (box plots) together with ANOVA P-values and fold-change values, through a click on each gene-link in the output file. The expression pattern of each single gene can be easily and immediately viewed by clicking on the link in the output file, which opens a pre-computed box plot (for illustration, see an example of a results table in Table 1; the links in the column "Box Plots" open a box plot for each of the genes). In order to complete data examination

Figure 1. GEView flow chart



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. GEView user interface



and analysis, links are also provided for GeneCards (Safran et al., 2010), UCSC (Kent et al., 2002) and NCBI (https://www.ncbi.nlm.nih.gov/gene) databases, for each specific entry (for illustration, see the links in columns 3-5 of Table 1).

RESULTS

Test Data: The "Zurich" Dataset

In order to demonstrate GEView functionality, we use a gene expression dataset of leukemia blood samples that were processed at the department of Oncology, University Children's Hospital, Zurich, Switzerland (Teuffel et al., 2004) and measured by Affymetrix HG-U133A microarrays. We utilize as an example three sample groups that represent three leukemia subtypes, each with different genomic characteristics: E2A-PBX1 (E2A; 5 samples), High hyperdiploid (HD; 4 samples) and TEL-AML1 (TEL; 8 samples). E2A-PBX1 is characterized by a translocation that fuses two genes, E2A and PBX1, High hyperdiploid is characterized by gain of chromosomes (overall 51-67 chromosomes) and TEL-AML1 is characterized by a translocation that fuses two genes, TEL and AML1.

Data Input File and Details for Obtaining It

A tab-delimited text file with normalized expression values for each entry (resulting from microarray, NGS or proteomics) is required as input by GEView. Data can be provided as raw expression data or log 2 transformed, according to the user`s preference. The format is fully described in the "help" document; an example input table is given in Additional File 1 (http://www.weizmann.ac.il/complex/compphys/software/geview/0.4/Additional_File1_Zurich_HD_TEL_E2A_data_labeled.txt).

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Various tools are available for free download in order to obtain the normalized expression values. EXPANDER tool (Ulitsky et al., 2010) (http://acgt.cs.tau.ac.il/expander/) or the Expression console tool (for Affymetrix microarray data; https://www.affymetrix.com/support/technical/byproduct.affx?product=expressionconsole) can be used for microarray data, Chipster (Kallio et al., 2011) (http://chipster.csc.fi/) may be used for NGS data, MaxQuant (Cox & Mann, 2008) may be used for proteomics data and R software (https://www.r-project.org/), which requires programing skills, can be used for all types of data. Commercial tools such as Partek Genomics suite (http://www.partek.com/) and MATLAB (https://www.mathworks.com) may also be used.

Load Data

Use the "Load" button (blue; see Figure 2) in order to browse through the input data file in the computer directory. After choosing the data file, the status bar will indicate when its loading is completed.

Principal Component Analysis (PCA) and Batch Effect Correction

In order to evaluate sample quality and homogeneity, PCA (Jolliffe & Cadima, 2016) may be plotted (using the "PCA" green button, see Figure 2), implemented by MATLAB software (http://www.mathworks.com/help/stats/pca.html). The PCA calculation is based on the 1,000 highest variance genes (if there exists less than 1000 genes, then all genes are used). In Figure 3A the PCA of the "Zurich" test data is plotted. It can be seen that one of the TEL (yellow square) samples is clustered within the HD group (red triangles), and not with its own group. Using GEView, the researcher can exclude this sample from the analysis where, for instance, there is evidence that it was mislabeled, by right clicking on it (see Figure 3B). It should be noted that such a decision should be taken carefully, as it has the potential to bias the results.

If various batches are seen by PCA or are known in advance, normalization according to experimental batches may be applied. "PCA after batch correction" button may be used to re-view the new PCA after the batch correction.

Batch Correction Example

When combining datasets from various origins (for example, in case datasets were processed in different dates or laboratories), the samples are often clustered according to the technical origin instead of the experimental conditions. GEView implements the ComBat batch correction algorithm (Johnson et al., 2007; Leek et al., 2012) to enable correction of such technical artifacts. In the following example, we added to our test data that were processed at the department of Oncology, University Children's Hospital Zurich, Switzerland (Teuffel et al., 2004) (labeled "Zurich") an additional dataset, that was processed at St Jude Children's Research Hospital, Memphis, TN (Ross et al., 2003) (labeled "StJude"). These datasets share two of the sample groups, TEL and HD. However, it can be seen in Figure 4A, where the samples are shaped and colored according to data origin (batches: "Zurich" – red triangles, "StJude" – blue circles), that the samples are grouped according to the batches; Zurich to the right and StJude to the left. After applying the batch correction algorithm (using the "PCA after batch correction" button, see Figure 2), it can be seen in Figure 4B that the batch effect disappeared, and the samples are grouped solely according to the experimental conditions (HD and TEL).

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 3. PCA quality control visualization: A) PCA is plotted for the "Zurich" dataset. Each of the experimental conditions is shaped and colored differently: E2A in blue circles, HD in red triangles and TEL in yellow squares. The colored large circles were added in order to emphasize the clustering into 3 biological groups. B) PCA is plotted for the "Zurich" dataset in the same manner as in A), after removing the outlier TEL sample (marked by the text "Removed").

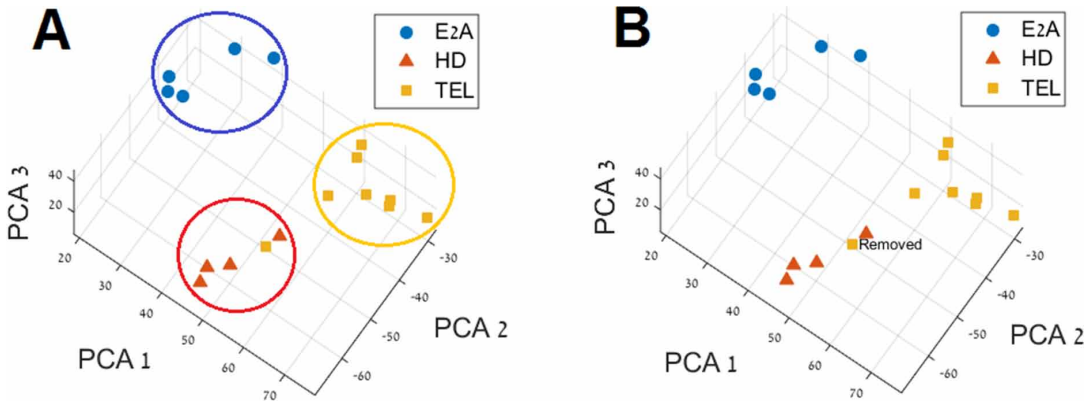


Figure 4. Batch correction example: A) PCA is plotted for the union of HD and TEL samples from both "Zurich" and "StJude" datasets, before the batch correction is applied. The samples are shaped and colored by batch (red triangles for "Zurich" and blue circles for "StJude"). B) PCA is plotted for the union of HD and TEL samples from both "Zurich" and "StJude" datasets after the batch correction was applied. The samples are shaped and colored by experimental conditions (blue circles for HD, red triangles for TEL).

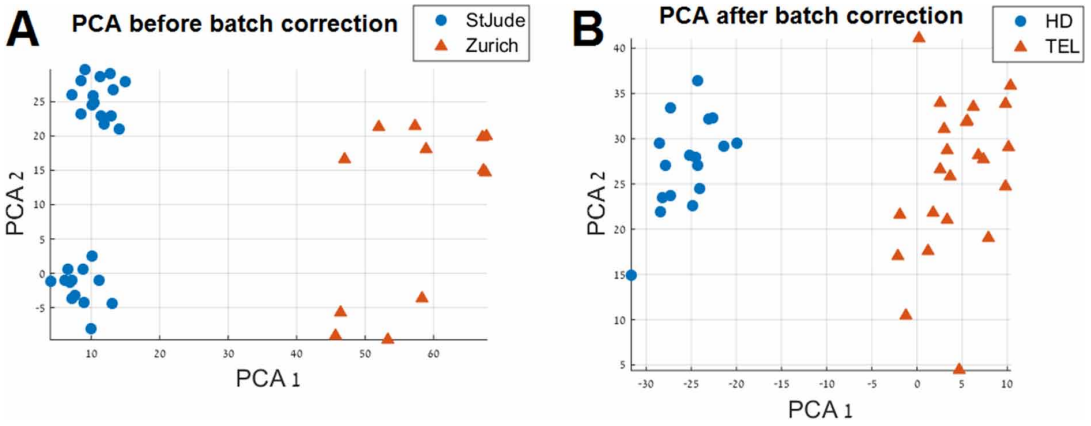

Run Statistical Analysis

By pressing the "RUN" red button (see Figure 2), ANOVA is applied for each probe set (gene/microRNA/protein), testing whether the means of its expression significantly differ between each of the different conditions (see http://www.mathworks.com/help/stats/anova1.html for more details). P-values and Q-values (corrected P-values for multiple comparisons (Benjamini & Hochberg, 1995) are being calculated

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

for each probe set. Running the statistical analysis of a typical dataset containing about 20,000 entries may take up to a few hours, using a computer with basic requirements such as 8GB RAM and Intel Core i7 processor of 3.40 GHz. Running progress can be viewed by the status line at the bottom of the user interface (see Figure 2).

This stage generates a single Excel file which summarizes in each line the results for a specific probe set. Table 1 represents the resulting Excel table for 10 probe sets (see Additional File 2 for the complete ANOVA table for ~ 17,000 probe sets http://www.weizmann.ac.il/complex/compphys/software/geview/0.4/Additional_File2_results_Zurich_HD_TEL_E2A_data_labeled.xlsx).

Exploring the Results

The output single Excel file provides immediate visualization of all genes' differential expression in the various experimental conditions (box plots) together with ANOVA P-values and fold-change values, through a click on each gene-link in the output file (Table 1 contains 10 rows, out of ~17,000, for illustration; the links on the "Box Plots" column can be clicked on). For example, in Figure 5, box plots of two genes are plotted, PBX1 and ELK3.

Each row represents a probe set ID, identified by a gene symbol (second column). Please note that 3 different probe set IDs for PBX1 gene and 2 for ELK3 gene are present. The Box plots column contains a link to a box plot of the mean expression values with standard errors and statistics resulting from ANOVA for each probe set. For each entry, links to GeneCards, UCSC and NCBI genome browser databases are provided. In addition, the same Excel file contains fold change values between each pair of experimental conditions. In case there are more than two experimental conditions, Tukey's test (Tukey JW, n.d.) for multiple comparisons is performed (http://www.mathworks.com/help/stats/multcompare.html), comparing between each pair, and the p-values are given.

As shown in Figure 5, probe sets belonging to the same gene are plotted together. This is done in order to estimate whether the different probe sets that belong to the same gene share a similar expression pattern (if they do, it significantly strengthens the validity of the pattern). It can be seen that PBX1 has 3 probe sets, all of which show a similar and significant expression pattern – high expression in E2A-PBX1 sample group and low in the rest (Figure 5A). E2A-PBX1 leukemia subtype is characterized by a fusion between the transcription factor E2A and PBX1 gene. While normally PBX1 is not expressed in lymphoid cells, the fusion with E2A causes its expression (Aspland, Bendall, & Murre, 2001). Thus, PBX1 is indeed expected to be expressed in E2A-PBX1 sample group and not expressed in the rest. The concordance between all 3 probe sets (Figure 5A) significantly increases the validation of this pattern. Another example of the gene ELK3, can be seen in Figure 5B. It has two probe sets, one showing a significant differential expression ($Q= 0.024$), while the other shows a different, non-significant pattern. Thus, the expression pattern of ELK3 is less validated than that of PBX1. When there is a need to decide on which gene to focus and perform further investigations and wet experiments, this information is crucial. Therefore, the simple grouping of the box plots of different probe sets of the same gene can improve the decision-making process.

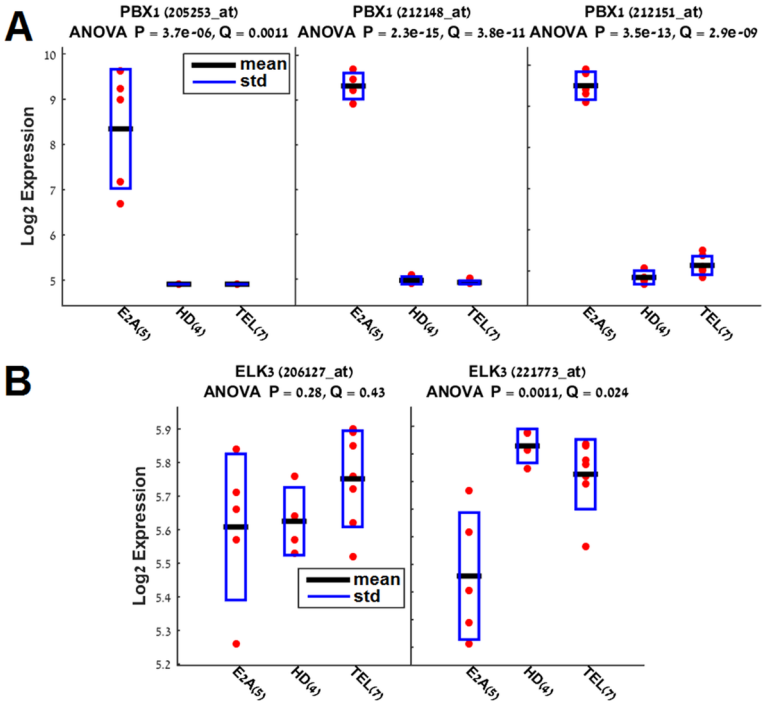
Figure 5. Box plots of PBX1 and ELK3 genes: A) Box plots for the 3 probe set IDs present in the "Zurich" dataset for the gene PBX1 are plotted. In the title of each plot, the gene symbol and probe set ID (in parentheses) are presented. In addition, the ANOVA P and Q values (corrected p-value (Benjamini & Hochberg, 1995)) are provided. The Y-axis represents the Log2 expression value and the X-axis represents the 3 experimental conditions (see E2A, HD and TEL X-labels). The number of samples in each experimental condition is written in parentheses. Each sample expression value is marked by a red dot and the mean and standard deviation in each experimental condition are marked by a black line and a blue box, respectively. B) Box plots for the 2 probe set IDs present in the "Zurich" dataset for the gene ELK3 are plotted in the same manner as in A.



HELP DOCUMENT

A comprehensive Help document can be easily accessed through GEView (press the "Help" button in the right lower corner of the user interface, as plotted in Figure 2; the full Help document is also given as Additional File 3 http://www.weizmann.ac.il/complex/compphys/software/geview/0.4/Additional_File3_help.docx). The Help document contains:

- Installation instructions;
- Input format description for all data types;
- Description of the analysis flow, including a detailed description of the user interface functionality and the running parameters;
- Detailed description of each analysis type provided by GEView, including results of the "Zurich" test dataset.

DISCUSSION

There are many tools that perform gene or protein expression analysis. We offer GEView, a tool that implements basic analyses and intuitive visualization of the results for the non-programmer biologist. The great advantage of GEView is its intuitive, accessible and comprehensive results table, given in an Excel file with links to graphics and databases. Specifically, it provides a single results table, including pre-calculated ANOVA p-values and links to pre-computed figures of the expression pattern of each of the genes/microRNAs/proteins across the experimental conditions. This is a significant improvement to the commonly available results tables, which usually include only p-values and fold-change differences and don't provide visualization of expression patterns of single genes. The intuitive graphical representation, using box plots, enables the laboratory scientist to simply investigate many genes of interest. Gene expression patterns may easily be explored in the same results table, without the need for further external resources, through direct links to GeneCards, UCSC and NCBI databases for each gene (see Table 1).

CONCLUSION

GEView was developed for Bio-Med researchers who are not computational experts. We believe that researchers who were previously dependent on external services for the analysis of their own data, will have a new opportunity to analyze expression results with GEView. Upon input of expression data of various types, GEView provides PCA analysis, batch correction and analysis of differential expression, with immediate graphical view and functional annotation of the results, in a single simple Excel file. While all algorithms used are published, implemented by standard and validated MATLAB functions (in the case of ComBat algorithm, using the original R software code (Leek et al., 2012), wrapping them together in a simple and intuitive tool with immediate access to graphical representation on a single-gene basis will enable the Bio-Med researcher to:

1. Perform basic analyses without the need for external resources;
2. Have immediate access to the visualization and statistics of the data;
3. Compare the expression pattern validity of different gene probes for better wet experiments decision making;
4. Improve their ability to produce significant results out of their various experiments.

COMPETING INTERESTS

The authors declare that they have no competing interests.

FUNDING

This work was funded by a NARSAD Young Investigator Grant from the Brain & Behavior Foundation, the National Institute of Psychobiology in Israel (Grant number 132-14-15) and the Leir Charitable Foundation.

APPENDIX

Availability and Requirements

Project name: GEView
Project site: http://www.weizmann.ac.il/complex/compphys/software/geview/_
Programming Language: MATLAB (https://www.mathworks.com). In order to facilitate the installation step, GEView contains the following R packages: sva (Leek et al., 2012), R.matlab (Bengtsson, n.d.) and their subsidiaries.
Operating Systems: The compiled version can be launched on either Windows or Linux. Using the MATLAB source code, that can be downloaded from GEView website (http://www.weizmann.ac.il/complex/compphys/software/geview/), GEView can run on any operating system with MATLAB installed, including Mac OS.
Restrictions to use by non-academics: None
How to Cite GEView: The present paper should be cited if GEView is used in the preparation of a manuscript

Declarations

Ethics approval and consent to participate

As was stated before (see (Teuffel et al., 2004), (Bornhauser et al., 2007) for the "Zurich" dataset and (Ross et al., 2003) for the "StJude" dataset), patients who were enrolled in these studies or their guardians had given informed consent in accordance with the Declaration of Helsinki. Approval was obtained from each institutions' review board.

Consent for Publication

Not applicable

Availability of Data and Materials

The two datasets that were analyzed during the current study are available through download-links that appear in the following references: St Jude Children's Research Hospital, Memphis, TN (Ross et al., 2003) for the "StJude" dataset, and Departments of Oncology University Children's Hospital Zurich, Switzerland (Teuffel et al., 2004) for the "Zurich" dataset.

Chapter 33
An Affordable Hybrid Cloud Based Cluster for Secure Health Informatics Research

Basit Qureshi
Prince Sultan University, Saudi Arabia

ABSTRACT

This article describes how a major risk factor in the deployment of patient health records systems in the cloud is the security and privacy of data. Hybrid cloud solutions have been proposed that leverage the public and private cloud deployment to manage and alleviate accessibility, access control and privacy concerns. This article presents a privacy preserving and secure architecture for data acquisition, storage, processing and sharing. The proposed architecture is composed of a public cloud-based services that interact with a low-cost cloud computing cluster (LoC4) as a backend. A lightweight data security eco-system based on attribute based encryption is developed to provide security for public cloud-based data storage. Performance of the deployment is evaluated in a real-time deployment environment. The results show that the proposed ABE-based system is 2.3 times faster than AES-based for a variety of sizes of data blocks. It is further noted that the low-cost and affordability of LoC4 platform offers excellent opportunities for academic research in cloud based health informatics.

1. INTRODUCTION

Electronic health record (EHR) and personal health record (PHR) systems are widely available and use different technologies and standards (Bahga, 2015; Sun, 2013). The variety and size of medical health records data makes it difficult for researchers to accurately and easily integrate data from various sources. Due to the high cost of building and maintaining specialized data centers many healthcare providers have been outsourcing PHR systems to third part cloud service providers such as Microsoft Health Vault, Google Health, General Electric's Centricity Patient Online, eClinicalWorks and many more. Cloud computing provides storage for large scale data on external servers allowing researchers and develop-

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

ers to easily access the data (Fang, 2016). Although the technology is being used in recent years with many benefits such as reducing the cost for maintaining servers whereas improving the availability of the systems, there have been wide spread privacy concerns since personal healthcare information can be exposed to unauthorized parties.

Due to the sensitivity of personal information, the cloud based PHRs could potentially become targets of various malicious behaviors. Furthermore, Guo et. al. in (Guo, 2016) and (Abbas, 2017) describe various security issues and threats in cloud computing environment. In (Asija R., 2016), researchers develop a security aware public cloud based SaaS model for healthcare applications embedding XML based meta data for PHRs. Works presented in (ZhouJ, 2015), (ZhouCao, 2015) and (Li, 2013) have proposed several cloud-based secure systems, especially cloud-based PHR systems using encryption where PHR data is encrypted and stored in cloud based storage. In (Man, 2017), (Wang, 2014) and (Zhou, 2015) authors deduce that any public cloud based security model may have inherent threats of trust, security and privacy. They highlight that the complexity of key management in encrypted PHR systems increases for the owners and users resulting in Quality of Service issues. (Liu, 2017) note that hybrid cloud environment integrating the public and private cloud infrastructure is a more applicable solution for PHR sharing.

In this paper, we take inspiration from (Liu, 2017) to investigate requirements for the deployment of a secure hybrid cloud environment for a PHR system. A two-tier hybrid cloud architecture is proposed addressing security and privacy preserving mechanisms for information storage and retrieval in the cloud. A light weight data security eco system is developed to provide Attribute Based Encryption (ABE) for public cloud based data storage that enables multiple users to share data. We further introduce LoC4, an affordable and low-cost cloud computing cluster for health informatics research in universities and academic institutions. The proposed hybrid cloud based PHR system is developed and deployed using an experimental setup coupling public and private cloud based implementations. We conduct several experiments to analyze the performance criteria including computation efficiency, storage and network efficiency, task completion rate, response time etc. Furthermore, we compare the performance the proposed Encryption scheme and compare the response time for task execution for various sizes of data blocks. Results show that LoC4 provides an affordable hybrid cloud based backend solution for low cost, energy efficient and secure deployment.

The contributions of this paper are in the following:

- Requirements of a secure hybrid cloud environment for a PHR system are presented. Based on an extensive investigation, a three-layered architecture is proposed including: i) secure data acquisition, ii) storage of PHRs in public cloud and iii) encryption and privacy layers;
- A two-tier, light weight encryption eco-system is developed encompassing public cloud service and private cloud based cluster deployment;
- Design details and implementation of a LoC4 cluster using SBCs is provided. The Cluster deployment parameters are optimized for performance and energy efficiency;
- A light weight middleware for communication and interaction between public cloud service and the LoC4 Cluster is developed. This middleware enables real time performance measurement of the proposed system.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

The remainder of this paper is organized as follows: Section 2 provides description of requirement specifications for hybrid cloud architecture for PHR systems. Section 3 details the two-tier light weight eco-system. Section 4 provides design details for the LoC4 cluster as well as performance specific variables for deployment of Apache Hadoop on the cluster. Performance evaluation of the proposed system is presented in section 5. Section 6 presents related works with conclusions and future works presented in section 7.

2. REQUIREMENTS SPECIFICATIONS FOR A CLOUD BASED PHR SYSTEM

A hybrid cloud based PHR system is composed of various subsystems interacting in a public and private cloud environment. Figure 1 shows various parts of a hybrid cloud deployment of a PHR systems for a Healthcare provider (HCP). Data deemed secure and private is kept in a data center composed or various clusters whereas unsecure data or data with no privacy concerns is kept for public access in a public cloud. In this section, we provide requirements specifications for a secure hybrid cloud based PHR system.

2.1. Storage in Cloud Based PHR System

A cloud based PHR system needs to address secure data acquisition and storage requirements before further processing of data. Figure 2 shows an architectural map of the three layers of data flow in a PHR system. In what follows, we describe requirements for these data flows.

At the acquisition stage, data is collected using various mechanisms for data entry. It could be as complex as a Wireless Body Area Network (WBAN) (Page, 2014) (Page, 2015) consisting of various wireless wearable sensors for specific medical applications such as blood pressure, thermometer etc. These sensors and devices can connect to a data collection device using Bluetooth, Zigbee protocols or similar wireless communication medium, and transmit the information to an intermediate cloudlet for synchronizing and processing information (Soyata, 2016). This data could be acquired, stored on the cloudlet or transmitted on demand for access by the HCPs.

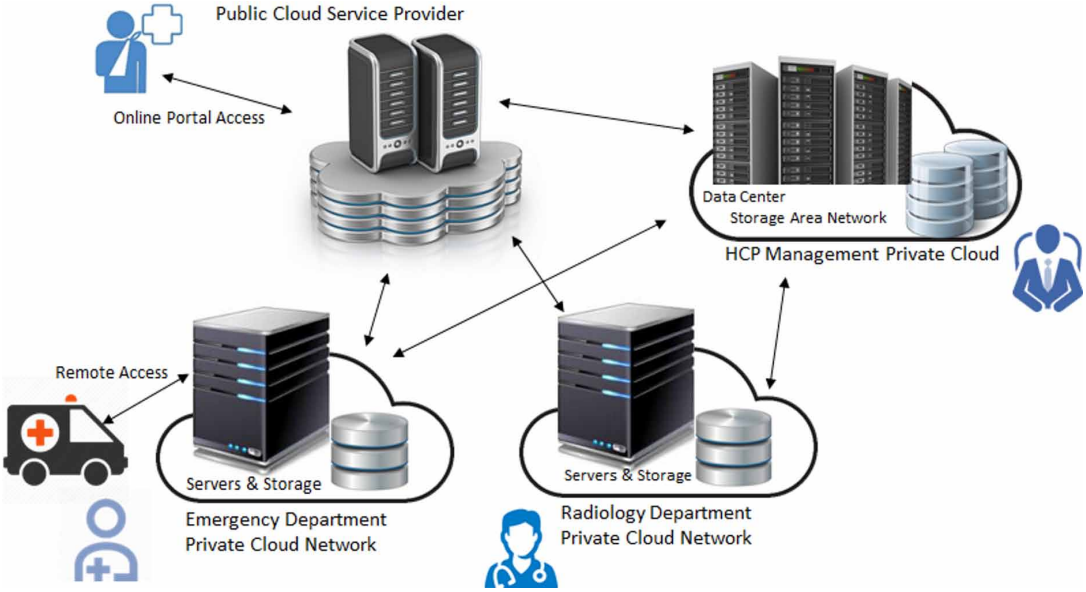
Reliable, scalable and secure storage in the cloud is perhaps the most important functionality of Cloud based PHR systems. Storage services based on public clouds such as Microsoft's Azure storage service and Amazon's S3 provide customers with scalable and dynamic storage. These services allow users to move their data into the cloud and avoid costs of building and maintaining a private storage infrastructure using pay as you go cost model. This offers various benefits such as availability (i.e., being able to access data from anywhere) and reliability (i.e., not having to worry about backups) at a relatively low cost. Consumers can trade privacy for convenience of software services, however enterprises and government agencies are more concerned with the preservation of confidentiality and integrity of data.

2.2. Data Privacy Requirements

The Health Insurance Portability and Accountability Act (HIPAA) (HIPAA US, 2006) states that data privacy must be protected within every layer of a PHR system. Here we describe the requirements for each layer of the system:

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. A hybrid cloud environment for a PHR system at HCP



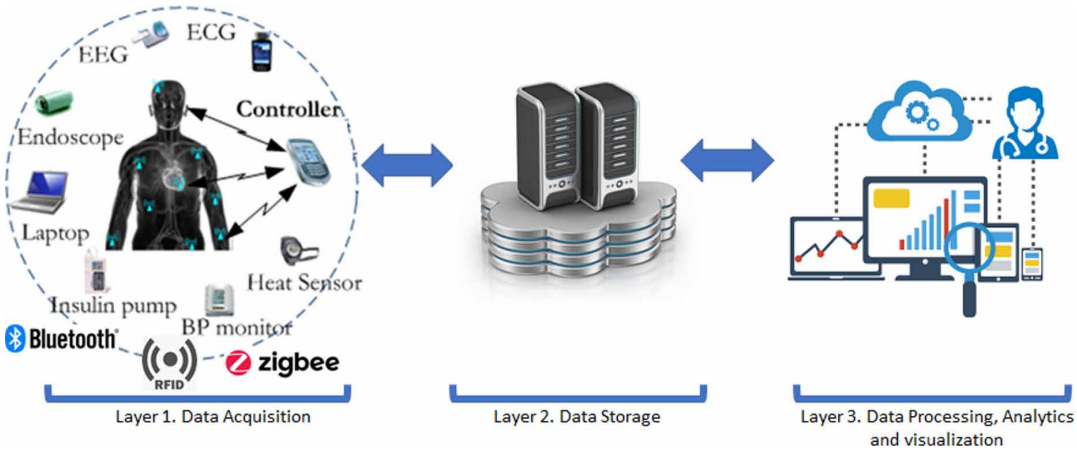
1. **Data acquisition Layer:** The acquisition layer in Figure 2 is composed of Wireless Body Area Network sensor devices. Typically, these devices have limited computational capacities and operate on finite battery power. Encryption schemes used to protect the communication within BAN sensors and BAN-to cloudlet communications should not be computationally intensive. (Page A., 2014) present a privacy preserving mechanism for secure information exchange using Advanced Encryption Standard (AES);
2. **Data Storage Layer:** There can be various stakeholders involved in storage, retrieval and sharing of data from the system including, patient, doctor/nurse, emergency unit staff etc. Allowing Cloud service providers to manage sensitive information such as EHR could potentially raise security issues. An untrustworthy Cloud service provider may leak PHR to medical companies for profit. It is suggested to encrypt all the data placed in the Cloud, however, this could have a severely negative affect on the Quality of Service as the volume of data grows. Furthermore, the cost of encryption also increases linearly in time and space.

Another issue is the QoS in searching and indexing of data. To enable searching over the data, a user must either store an index locally, or download all the (encrypted) data, decrypt it and search locally. Both approaches negate the benefit of cloud computing and are therefore poor choice for processing of large scale data thus increasing the overhead of security and volume of communications.

Conventional encryption techniques such as symmetric key encryption does not work as it requires both parties to use a symmetric key. Asymmetric encryption techniques such as Identity based encryption (IBE) may work, but it requires one party to decrypt, other than this party, no one can decrypt the data. It can be suitable in a scenario when a data record is shared only between two parties, however for multiple actors such as doctors, nurses, insurance companies, patients, etc., management becomes an overhead:

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. Architectural layout of cloud based PHR system requirements



3. **Data Processing, Analytics and Visualization Layer:** To process data, it must first be decrypted. Decryption of this data in the intermediate stage requires trusted storage infrastructure possibly at the site of the HCP necessitating a private cloud infrastructure. After the data has been processed, it needs to be removed from the intermediate storage. Furthermore, this encryption and decryption of data adds to overall overhead of computation, processing and visualization of data. Efficiency, reliability and integrity must be preserved for data processed in the system.

It is imperative that in an enterprise environment, many stakeholders may have access to various kinds of data. Doctors, patients, nurses, emergency unit staff, medical insurance personnel etc. to name a few, require strict access control mechanisms in place. Furthermore, in WBAN environment, various devices could be owned by a consumer or even shared by others. For any efficient solution, it is crucial to address the above-mentioned issues thoroughly and effectively.

3. SECURE HYBRID CLOUD ARCHITECTURE FOR PHR SYSTEMS

In this section, we present the design and architecture for a secure hybrid cloud based PHR system. The proposed architecture considers the requirements of data acquisition, storage and analysis while preserving the data privacy requirements. We present a high-level architecture of the proposed system in Figure 3 which incorporates various components into public and private cloud tiers. All services interact together to provide secure, reliable and scalable solution.

3.1. Public Cloud Service

The public cloud service consists of various components including encrypted data storage, open access data storage, Health analytics engine, Audit Logs, Enterprise Access control list and Key verification module for data integrity. We adopt attribute-based encryption (ABE) as the cryptographic primitive to serve this purpose. By using ABE, access control definitions express the user attributes (meta-data) or data (PHR) which enable a user to selectively share their data without knowledge of the other party's identity.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

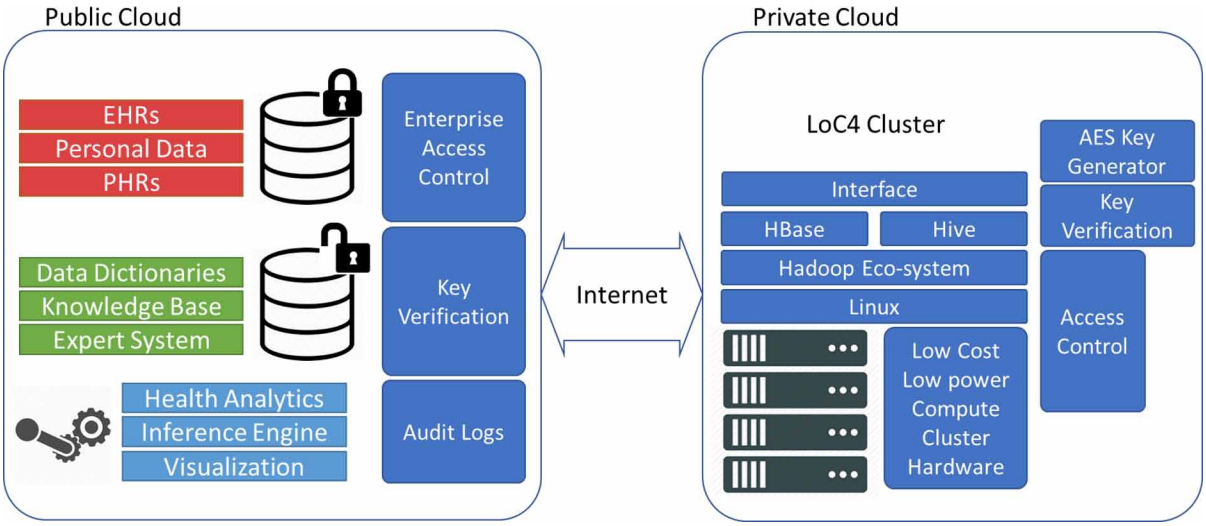
Privacy critical data such as personal health records need to be secured on the public cloud, whereas data with low privacy requirements such as data dictionaries etc. or intermediary data such as data generated from health analytics or visualization, many not require stringent security measures. It is important to classify these kinds of data to improve the efficiency of the system by leveraging the amount of computations and time consumed in communication. Large volumes of data generated at the Data acquisition layer needs to be stored and shared with appropriate consumers with valid credentials. Access Control parameters are defined to identify appropriate levels of users mapped with data in storage. This mechanism allows stakeholders with appropriate credentials to access and share data. Access Control parameters are defined in the private cloud service and are periodically updated in the public service.

We develop a custom encryption approach that is efficient and reliable and is described further in this section. Audit logs are stored for all transactions carried out by various consumers. These logs are beneficial for forensics in determining illegal behavior. The public cloud service is implemented in an open access system and deployed on a public cloud service provider.

3.2. Private Cloud Service

The private cloud service essentially hosts a cluster of machines implementing a small data center at the premises of the enterprise. The infrastructure is secured in the enterprise locale with physical, data and network security measures in place. The data center hosts low cost, efficient and eco-friendly LoC4 cluster. The machines in the LoC4 cluster run open source operating system such as Linux with Hadoop eco-system deployment for distributed task processing and management. Access control information for the enterprise is stored in HBase and Hive data warehouse which are encrypted using commonly available encryption techniques. Additional modules for encryption key generation and verification are implemented in the private cloud. These are necessary for efficient and reliable storage and sharing of data. Communication takes place through the interface which implements a light weight communication protocol for data transmission between the public and private cloud services. Section 4 details the design and implementation of the LoC4 cluster which is deployed using low cost low power Single Board Computers (SBCs).

Figure 3. High-level architecture



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

3.3. Security and Privacy

Here we address the security implications and proposed solutions at the various layers of data in a PHR system.

3.3.1. Data Acquisition Layer

Data acquisition devices usually have limited capabilities for storage or processing large scales of data. This implies that any encryption schemes used for security in data acquisition must not be computationally intensive. An obvious solution is to use the Zigbee protocol which is based on the AES encryption scheme and can easily be implemented. Communicating devices must agree on a secret-key before using AES encryption by using generic key exchange algorithm such as Diffie-Hellman (DH) (Diffie, 2006). Irrespective of the kind of encryption scheme, a consumer must agree on key(s) to encrypt/decrypt messages with a service provider. Advanced Encryption Standard (AES) is one of the most widely used symmetric key encryption algorithms and is accepted as an industry and a government applications standard. AES is optimized for speed, low memory footprint and energy efficiency. Its low resource intensity allows AES to run on a wide range of hardware platforms. Communication of devices can be also secured by using biomedical signals as noticed in (Venkatasubramanian, 2010).

3.3.2. Secure Data Storage, Sharing and Processing

We use a variant of Attribute based encryption (ABE) scheme. Attributes set is defined where each member of this set is given associated private keys which are generated by third parties. The HCP provides encryption with a token, any user with appropriate attribute set can decrypt the data as long as it fulfils the token. The token can be generated such that the retrieval procedure reveals nothing about the files or the keywords (meta-data) except that the files contain a keyword in common. This light weight technique addresses the inefficiency of downloading an entire encrypted block and processing only a limited part of it. Furthermore, the coupling of access control mechanisms (attributes) allows reliable sharing of appropriate data with proper stakeholders.

The data is encrypted using an access control policy based on credentials. Only the user whose credentials satisfy the access policy can have access to the data. The attributes can be the profession (e.g., Doctor, Nurse) or the department (e.g., Cardiology, Emergency) of the user. An access policy can be defined as joints and disjoints with various attributes such as:

(Doctor AND Pediatrics) OR (Nurse OR Intensive-Care-Unit)

Which gives access to a Doctor in Pediatrics Department or a Nurse or an Intensive-Care-Unit staff member.

We present a publisher/subscriber model for the encryption and decryption of Data Blocks. Two algorithms are defined PushDataBlock (Algorithm 1) and PullDataBlock (Algorithm 2), that control read / write of data blocks using a combination of key and access control meta data, in the public cloud service. In the following text, we describe the working of these two algorithms to enable secure data communication and storage of a data block in the public cloud service.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Algorithm 1. PushDataBlock

```
input: DataBlock B_i, SecretKey S_k, AccessControlMetaData AC_MDi
output: Encrypted DataBlock EB_i
  for i = 1 to n - 1 do
     KeyGenerator(B_i, S_k, AC_MDi)
     PushCloud(EB_i)
  end
```

Algorithm 2. PullDataBlock

```
input: SecretKey S_k, Keyword
output: Decrypted DataBlock DB_i
  for i = 1 to n - 1 do
     RequestToken(AC_MD, S_k, Keyword)
     AcquireToken(S_k)
     PushToken(token, S_k)
     PullDataBock(DB_i)
     VerifyDataBlock(DB_i)
 end
```

Each subscriber is allocated a Key S_k to facilitate access to the private cloud service, these keys are managed by the administrators at the enterprise and assigned to stakeholders with appropriate access control credentials.

Assuming a data block B_i was generated (data acquired from WBAN cloudlet, etc.) consisting of one or many records / files and is ready to be uploaded to the public cloud storage, the publisher would call the *PushDataBlock* with an access control meta data AC_{MDi} for this data block B_i.

The *KeyGenerator* is responsible for properly indexing and encrypting the data block. KG is responsible for encrypting various data blocks using access control information provided and appends metadata for identification of datablocks such as timestamp, size, keywords, ownership etc. It encrypts the data block in such a way that given a *token*, a subscriber can retrieve pointers to the encrypted records/files that contain a *keyword*. Without appropriate *token*, the data block would not be decrypted. The tokens cannot be generated without a secret key S_k. It must be noted that the retrieval procedure does not reveal any details within the data block except only the searchable keywords. Once the *KeyGenerator* has encrypted the DataBlock B_i, *PushCloud*(B_i) is called to push the data block to the public cloud storage.

When a subscriber intends to access a data block for processing or sharing, it needs to call the *PullDataBlock* with the secret key S_k, and the access control meta data AC_{MD}. *RequestToken* call is made for a search keyword term to the private cloud service. Based on the access control policy, the *AcquireToken*(S_k, AC_{MD}) generates a token which is then sent to the public cloud service using the *PushToken*(*token*). The public cloud service uses the token to find the appropriate encrypted documents. The *PullDataBlock* call returns the selected documents as data blocks to the subscriber. At any point and time, the subscriber can verify the integrity of the data blocks by calling the *VerifyDataBlock* call.

Figure 4, shows the publisher subscriber model used for encryption of Data Blocks. In the next sections, we present details for deployment of the proposed model on a LoC4 cluster.

4. DESIGN OF LOC4 CLUSTER

This section presents the architecture and configuration of the LoC4 cluster deployed in this experimental study.

4.1. Single Board Computers

A single-board computer (SBC) is a complete computer built on a single circuit board (Baun, 2016). A SBC incorporates microprocessor(s), memory, I/O as well as host of other features required by a functional computer. A wide range of programming languages are supported by these platforms. In this work, we investigate use of Raspberry Pi Model 3B (RPi, 2017) as well as Hard Kernel Odroid Xu-4 (Odroid, 2017). A summary of various features of these computers can be seen in Table 1.

4.2. LoC4 Cluster Deployment

This section presents the architecture and configuration of the LoC4 cluster deployed in this experimental study.

4.2.1. Design of the Cluster

The LoC4 cluster is composed of 11 SBCs of which five are RPi Model 3B computers in addition to six Odroid Xu-4 computers interconnected with power supplies, network cables, storage modules, connec-

tors and cases. All the Raspberry Pi computers are equipped with 16 GB Class-10 SD cards for primary bootable storage. The Odroid Xu-4 devices are equipped with 32GB eMMCv5.0 modules. The Odroid Xu-4s are housed in a compact layout racks using M2/M3 spacers, nuts and screws. The Raspberry Pi 3B's are housed in cases and connected to the rest of the cluster. Currently each Raspberry Pi computer is individually supplied by 2.5Amp power supply; each Odroid Xu-4 computer is supplied by a 4.0Amp power supply that provides ample power for running each node. Each SBC's network interface relates to a Cat6e Ethernet cable through the RJ-45 Ethernet connector. All Ethernet cables connect to a 16-port Cisco switch which in turn is connected to the university network equipment. The size of the cluster can be easily scaled by introducing a core switch that connects to the 16-port switch. Additional nodes can be included in the network configuration scaling the size of the cluster.

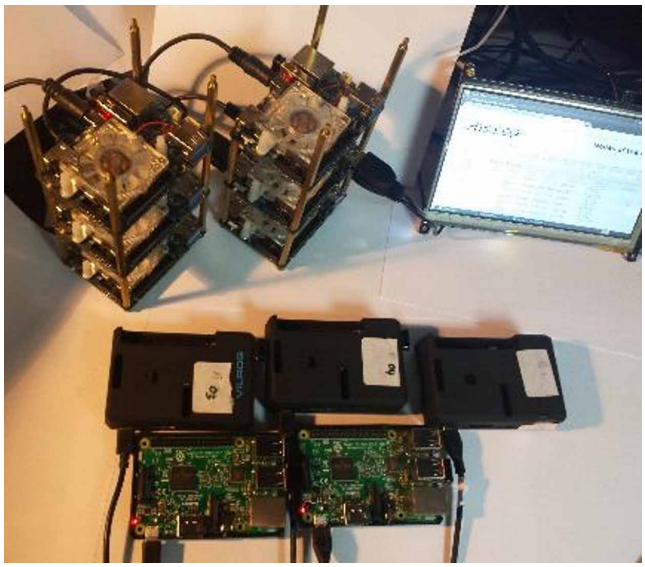
For Hadoop deployment, one of the Xu-4 SBC is used as the master node whereas the rest of the nodes server as slaves' nodes. We compare the performance of Xu-4 sub cluster (composed of five Xu-4 nodes) with RPi sub cluster also composed of five RPi 3B nodes. Figure 5 shows the layout of the LoC4 cluster. The purchase cost for all equipment for the LoC4 Cluster was $1179.

4.2.2. Hadoop Deployment

Apache Hadoop (Hadoop, 2014) is an open source framework that provides distributed processing of large amounts of data in a datacenter. Hadoop version 2.6.2 was installed due to availability of YARN daemon which improves the performance of the map-reduce jobs in the cluster. To optimize the performance of these Clusters, yarn-site.xml and Mapred-site.xml were configured with 512 MB of resource size allocation. The primary reason for this setting is the limited amount of RAM available in the RPi Model 3B. The Raspbian operating system as well as the shared GPU memory bus consume over 200MB or RAM out of a total of 1GB. The default container size on the Hadoop Distributed File System (HDFS) is 128 MB. Each SBC node was assigned a static IPv4 address based on the configuration and all slave nodes were registered in the Master node. Table 2 provides detail of important configuration properties for the Hadoop environment.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 5. The LoC4 cluster with 6 Xu4 (rack mounted) and 5 RPi 3B in cases



For YARN Resource manager, we allocated up to 4 cores which means up to 4 containers can execute per node (one container per core). The replication factor for HDFS is 2 which means only two copies of each block would be kept on the file system. The LoC4 Cluster was tested extensively for performance using TeraSort benchmark.

The LoC4 cluster was connected to the Internet using a static IP address for experimental evaluation presented in the next sections.

5. PERFORMANCE EVALUATION

In this section, we present a performance evaluation study of the proposed Hybrid Cloud based PHR system. We first look at the performance evaluation of the LoC4 cluster in terms of processing speed, storage read/write and networking. The objective of this study is to highlight the intrinsic capabilities of SBCs as well as to showcase the performance of these SBC when deployed as a cluster. We use popular benchmarking techniques widely used in the literature to highlight the capabilities of LoC4. Second, we present performance in terms of Response time for the *PushDataBlock* and *PullDataBlock* algorithms presented in section 3.

5.1. Evaluation of LoC4

5.1.1. CPU Execution Times

The benchmark suite Sysbench[1] was used to measure the CPU performance. We execute the Sysbench benchmark[2], testing each number up to value 10,000, if it is a prime number, for *n* number of threads. Since each computer has a quad core processor we run the sysbench CPU test for 1, 2, 4, 8 and 16

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 2. Hadoop configuration properties for LoC4 cluster

mapred-site.xml Properties	Value
yarn.app.mapreduce.am.resource.mb	512
mapreduce.map.cpu.vcores	1
mapreduce.reduce.cpu.vcores	1
mapreduce.map.memory.mb	512
mapreduce.reduce.memory.mb	512
mapreduce.input.fileinputformat.split.minsize	8 MB
YARN-site.xml Properties	
yarn.nodemanager.resource.memory-mb	1024
yarn.nodemanager.resource.cpu-vcores	1
yarn.scheduler.minimum-allocation-mb	256
yarn.scheduler.maximum-allocation-mb	1024
yarn.scheduler.minimum-allocation-vcores	1
yarn.scheduler.maximum-allocation-vcores	4
yarn.nodemanager.vmem-pmem-ratio	2
hdfs-site.xml Properties	
dfs.replication	2

threads. We measure the performance for this benchmark test for Raspberry Pi Model 2B, Odroid Xu-4 as well as an Intel i7 3.0 GHz 4th Generation personal computer (for comparison purposes). The CPU execution times scale well with increased number of threads. Sysbench test runs with n = 2 and n = 4 threads significantly improves the execution times performance for all processors by 50%. With n = 8 and n = 16 threads the test results yields almost similar execution times with little improvement in performance. Table 3 shows results for the Sysbench. The execution times for Odroid Xu-4 are 6 times better as compared to Raspberry Pi Model 3B. The increased number of threads (larger than 8) does not provide gain in performance of Odroid Xu-4 over Raspberry Pi. It is also noted that the execution time for Raspberry Pi is further extended with larger *n*.

5.1.2. Storage Performance

Poor storage read/write performance can be a bottleneck in clusters. Compared to a server machines, an SBC is handicapped in terms of availability of limited storage options. In our experimentation, the Raspberry Pi's were equipped with 16GB SanDisk Class 10 SD Cards, whereas the XU-4 devices were equipped with 32GB eMMC memory cards. Both memory cards were loaded with bootable Linux distributions.

FIO[3] was used for benchmarking of random read and write with various block sizes. We consider the throughput with 8 threads each working with a file of size 512MB with a total 4GB of data. These parameters were set specifically to avoid buffering and caching in RAM issues which is managed by the underlying operating systems that can distort the results; i.e. the data size (4GB) selected is larger than the onboard RAM available on these devices. Table 4 shows the comparison of buffered and non-

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

buffered random read and write from both devices with block size 8KB. As can be seen from Table 4, the read throughput (buffered) of Odroid with eMMC memory is at least twice as fast as the Class 10 SD Card on the Raspberry Pi whereas the non-buffered read is more than three times better. Similarly, for buffered write operations, Odroid Xu-4 with eMMC module throughput is more than twice better when compared to the Class 10 SD Card in Raspberry Pi.

5.1.3. Network Performance

was measured using the iperf 4v3.13 with the NetPIPE5 benchmark version 3.7.2. Through various sets of runs, iperf states the network throughput to be 82-88Mbits per second for the RPi as well as the Xu-4 SBCs. The NPtcp, NetPIPE benchmark using TCP protocol, involves running transmitter and receiver on two nodes in the cluster. In our experimentation, we executed the receiver on the LoC4 master node (Xu-4 device) with 1000 KB as maximum transmission buffer size for a period of 240 milliseconds. The transmitter was executed on the individual SBCs one by one. As can be seen from Figure 6, the network latency for both devices with small payload is almost similar. As the payload increases we observe slight increase in network latency between both sets of devices. On the other hand, we observe a spike in throughput with message size 1000 bytes. This proves that network layer communication overhead dominates the overall transfer time for small payloads. For larger payloads, the communication rate correlates with data rate at the network link, utilization of the communication medium at the time or the traffic at the network switch. Contrasting the performance of Xu-4 and RPi SBCs we note the visible difference in throughput between the two, which is due to the poor overall Ethernet performance of the Raspberry Pi.

Table 3. The average CPU execution time for nodes with n threads

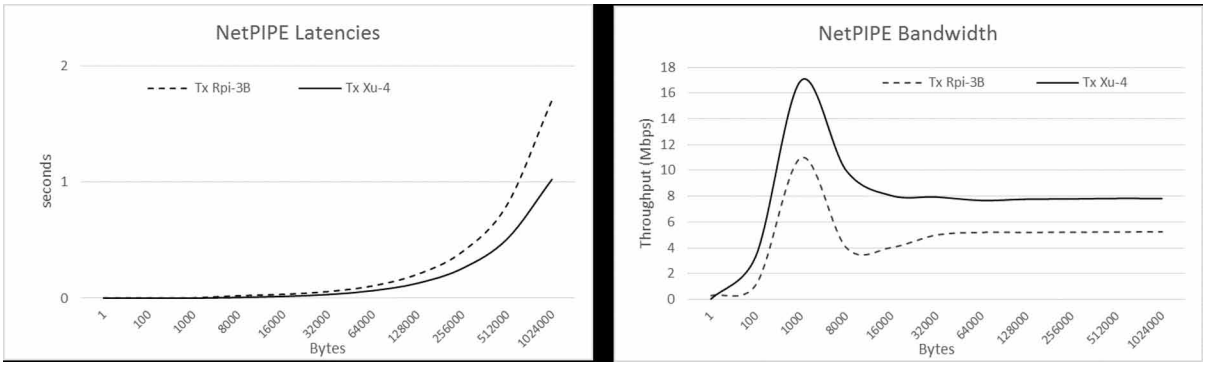
	CPU Cores	Clock Rate GHz	CPU Execution Time with *n* Threads				
			1	2	4	8	16
Raspberry Pi 3B	4	1.2	382.2	192.07	96.31	98.69	99.73
Odroid Xu-4	8	2.0 and 1.4	83.38	41.68	25.336	17.66	18.02
Intel i7 4th Gen	4	3.0	8.508	4.272	2.228	2.27	2.23

Table 4. Read and write throughput (KB/sec) for individual devices in the clusters using FIO

	Read Throughput (KB/second)		Write Throughput (KB/second)	
	Buffered	Non-Buffered	Buffered	Non-Buffered
Raspberry Pi 3B with 16 GB Class 10 SanDisk SD Card	3,688	2,341	1,318	1,267
Odroid Xu-4 with 32GB eMMCv5.0 Module	9,197	6,883	3,220	2,519

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 6. NetPIPE benchmark results for Xu4 and RPi devices considering latencies and bandwidth with data size in terms of bytes on the x-axis



5.1.4. Hadoop TeraSort Benchmark

Hadoop provides various benchmarks for performance of the Hadoop cluster. TeraSort is used in this study to observe the performance of LoC4 cluster in terms of task execution time. TeraSort combines testing the HDFS and MapReduce layers of a Hadoop cluster and consists of three MapReduce programs, TeraGen, TeraSort and TeraValidate. TeraGen is used to generate large amounts of data blocks, consequently, TeraGen is a write intensive I/O benchmark. TeraSort generates set of sample keys by sampling the input data generated by TeraGen before the job is submitted and writes the list of keys into HDFS. The input and output format, which are used by all three MapReduce programs, reads and writes the text files in the correct format. The TeraSort benchmark is CPU bound during the map phase and I/O bound during the reduce phase. TeraValidate verifies that the output of the TeraSort is globally sorted. We run TeraGen, and TeraSort on LoC4 cluster with 400MB, 800MB, 1,600MB and 3,200MB data sizes.

We observe the job execution time for each run for comparison and analyze the performance on the cluster. Since TeraGen is I/O intensive, the write speeds of the memories/storage in corresponding nodes in the clusters plays a major role in degrading the overall job completion time. The average job completion times for RPi and Xu-4 sub-clusters can be seen in Figure 7. The completion time for TeraGen on Xu-4 and RPi is correlating for various data sizes with Xu-4 being 3 times faster compared to RPi. We compute the execution time for TeraSort. For all experiments, we use the same number of map and reduce tasks on each cluster. The TeraSort benchmark is CPU bound during the map phase, i.e. reading input files and sorting tasks are carried out whereas it is I/O bound during the reduce phase, i.e. writing output files in the HDFS. We observed that 33-40% of job completion time occurred in map phase while 49% or more time was spending in reduce tasks overall for the majority of TeraSort jobs run on the cluster. We observe that as the data size increases the execution time also increases for RPi. Figure 7 also shows the comparison of the ratio of execution time degradations for RPi against Xu-4 sub-cluster. For smaller data size of 400MB the Xu-4 is 3 times faster whereas for larger data size of 3.2 GB, the Xu-4 is 3.4 times faster.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

5.2. Evaluation of Hybrid Cloud Based PHR

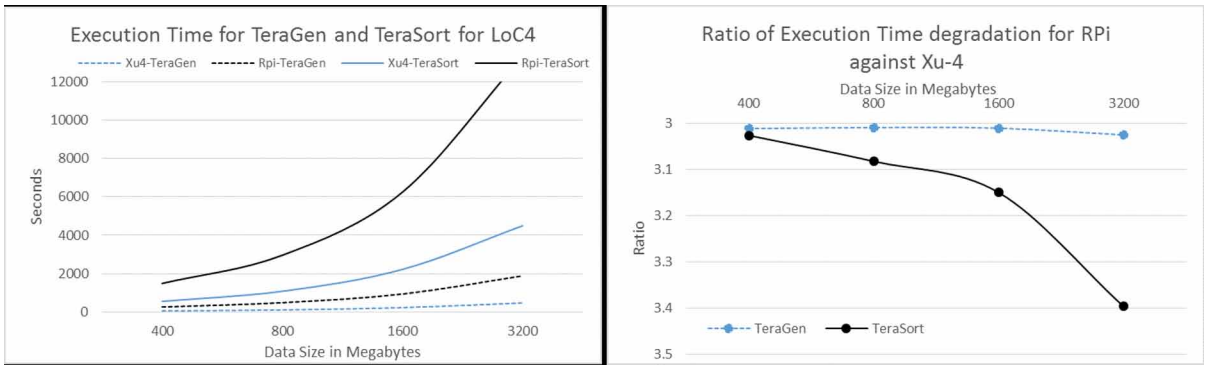
In this section, we evaluate the performance of the Hybrid Cloud based PHR system presented in section 3, in two phases. First, we write a Linux based script to encrypt data blocks of various sizes using AES and push these to a public cloud service and observe response time. Next, we compare the response time with the ABE based *PushDataBlock* encryption algorithm to determine the cost of encryption in terms of response time. Second, we measure response time at the public cloud service by executing the subscribe modules. The data blocks are pulled from the cloud based on user provided attributes. For this experimental study, xml files of various sizes are used to mimic datablocks. Each file is assigned with access control information and useful meta-data such as filename, keywords, etc.

5.2.1. Response Time for Publisher

The purpose of this set of experiments is to validate the functioning of all modules for publisher access in the Hybrid Cloud based PHR System. A Ubuntu based virtual machine instance with 4 CPU cores, 2GB RAM and 50GB storage is launched in DreamHost. A standalone Hadoop 2.6.2 installation is initiated on this virtual machine. Various sets of xml files are generated with different sizes and are pushed into a HDFS directory from the master node in the LoC4 cluster. These files are encrypted using Advanced Encryption Standard (AES) with 128-bit length keys. We measure the response time in terms of task completion time, at the master node in the LoC4 cluster.

Next, we write a light weight middleware using bash script which is responsible for executing the publisher components of the system. The *KeyGenerator* Module is called to encrypt xml files of various sizes (1.8 MB to 394MB) using the access control parameters including up to 40 attributes and meta data for files. Access control parameters were generated for four users (Doctor, Nurse, Manager and Patient). These files were then pushed to the public cloud using the *PushDataBlock*. Again, we measure the response time in terms of task completion time at the LoC4 cluster master node. Table 5 shows the comparison of response time (time to completion) of both sets of experiments. Results show that the proposed scheme using ABE is on average 2.3 times faster than the AES based scheme in terms of response time for task completion. Figure 8 shows the response time for execution of the AES based technique versus the proposed mechanism. It must be noted however, as the Data block size increases the task completion time for both also increase linearly.

Figure 7. TeraGen and TeraSort execution time for LoC4 cluster



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

5.2.2. Response Time for Subscriber

These experiments validate the subscriber modules of the proposed system, namely, *KeyGenerator*, *PullDataBlock*, *RequestToken* and *AcquireToken*. Bash script is written in the DreamHost based virtual machine requesting data blocks based on a query. Given the access control parameters and the search keywords as part of the query, *RequestToken* sends a request to the LoC4 Cluster. The LoC4 *AcquireToken* provides a token which is sent to the public cloud service. Using this token, *PullDataBlock* decrypts the block that can be accessed by the user on the public cloud.

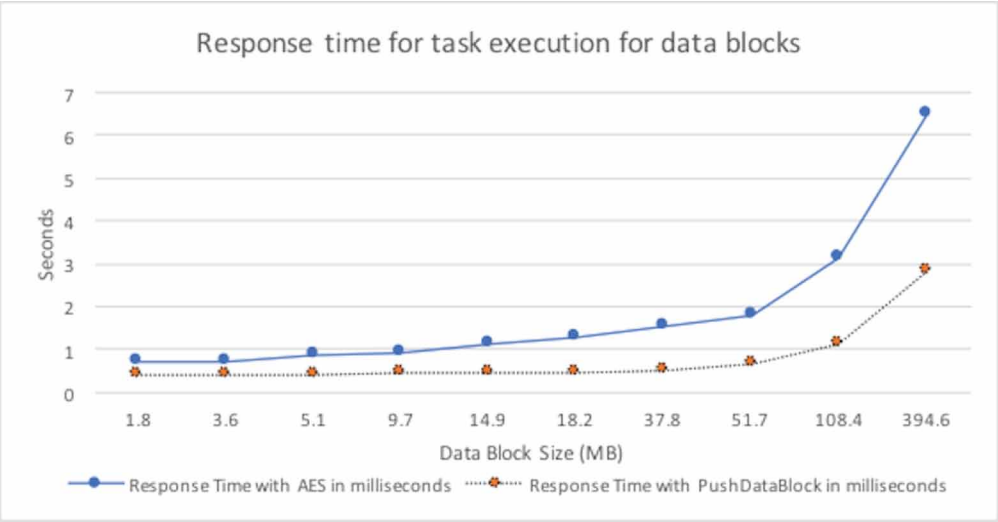
Our results show that the subscriber is successfully implemented with reasonable response times. It must be noted due to the settings in the SBC based LoC4 cluster, the minimum response time for executing Hadoop jobs is approximately 3 seconds. Given these conditions the response time for smaller workloads i.e. less than 50MB for the proposed system is within two seconds. It is observed, as the size of the *DataBlocks* increases, the time to completion also increases linearly.

6. RELATED WORKS

In recent times, many cloud service providers such as Google, Microsoft and Amazon have provided PHR services through the cloud. A PHR inherently saves privacy data of individuals which leads to the need for prevention of this data from unauthorized access. Gou et.al in (Gou, 2016) present a survey on various security issues and challenges in cloud computing environment.

In (Asija, 2016), researchers develop a security aware public cloud based SaaS model for healthcare applications embedding XML based meta data for PHRs. Work detailed in (ZhouCao, 2015) presents a privacy preserving protocol for cloud assisted e-healthcare data sharing. Authors in (Li, 2013) proposed a cloud-based PHR systems framework using encryption where PHR data is encrypted and stored in cloud based storage. (Qureshi, 2014) provide a cloud based framework for big data applications in healthcare.

Figure 8. Response time for task execution of data blocks using AES and proposed schemes



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 5. Response time for various publisher access tasks

DataBlock(s) Size in MB	Response Time With AES in Milliseconds	Number of Attributes	Response Time With *PushDataBlock* in Milliseconds
1.8	7098.2	20	4009.9
3.6	7211.9	20	4101.2
5.1	8633.6	20	4208.1
9.7	9221.1	20	4304.8
14.9	11013.9	20	4408.0
18.2	13009.8	40	4610.0
37.8	15291.3	40	5022.6
51.7	18050.2	40	6814.0
108.4	31167.0	40	11089.1
394.6	64985.2	40	28223.1

The proposed framework leverages the benefits of cloud computing for addressing many issues in traditional PHR systems. A proof of concept is provided although no details of implementation or deployment of the framework are available. Basu et. al in (Basu, 2012) present Fusion, an experimental open, cloud-based platform for large-scale, low-cost delivery of healthcare applications. Fusion addressed use of patient-centric management of electronic health records and facilitates the secure and seamless sharing of EHRs among stakeholders within a healthcare system. (Peyton, 2017) provide a Health informatics system design approach to support community based care delivery.

Authors in (Wan, 2013) present a detailed study on cloud-enabled architecture and its applications in pervasive healthcare systems. They provide a prototype implementation of the proposed mobile healthcare system. Wang et.al. in (Wang, 2014) use a case study of mobile-cloud based electrocardiograph monitoring and analysis and develop a hybrid mobile-cloud prototype. The experimental results show that the proposed approach can enhance the conventional mobile-based medical monitoring. (Alghabban, 2017) develop a cloud based mobile healthcare framework for dyslexic students. The proposed tool was used as a e-learning tool to enhance students learning capabilities. Nepal et.al in (Nepal, 2015) address the requirements for deploying secure hybrid clouds for Healthcare data. They stress on the need for encryption of PHR in public cloud environments and availability of secure development APIs.

In (Man HoAu, 2017) authors deduce that any public cloud based security model may have inherent threats of trust, security and privacy. They highlight that the complexity of key management in encrypted PHR systems increases for the owners and users resulting in Quality of Service issues. (Zhou, 2015) note that hybrid cloud environment integrating the public and private cloud infrastructure is a more applicable solution for PHR sharing. (Liu, 2017) present a PHR access control scheme allowing access policies to be embedded into PHRs. They conduct simulations studies to verify that the proposed scheme is suitable for mobile-cloud health care. (Zhang, 2017) provide a Quality of Service perspective in Cloud services computing and provide a systematic and practical overview of Quality of Service prediction in cloud and service computing.

Most existing work has adopted ABE (Ostrovsky, 2007) as the cryptographic tool to achieve fine-grained access control in cloud- based PHR systems. The original ABE system supports only monotone access policy and depends on a single private key generator. However, much work has been done in enhancing

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

the ABE scheme. (Man HoAu, 2017) provide a general framework for secure sharing of PHR data. They modify the ABE scheme to encrypt access control information which allows stakeholders to encrypt and decrypt data without losing privacy preserving mechanisms. (Liu, 2018) present a modified Comparison based Encryption technique (CBE). The proposed hierarchical comparison-based encryption (HCBE) scheme incorporates an attribute hierarchy into CBE. The proposed scheme encrypts a ciphertext with a small number of generalized attributes at a higher level rather than many specific attributes at a lower level, greatly improving the encryption performance.

The work presented in this paper addresses the requirements for deploying a secure, low cost low power cluster for storage/ retrieval of personal healthcare records. We provide architecture of a hybrid cloud based PHR system that allows secure access and sharing of PHR based on access control parameters. The proposed security mechanism is based on Attribute based Encryption scheme. Our work is unique in terms of deployment of a power efficient system using a low-cost cloud computing cluster.

7. CONCLUSION AND FUTURE WORK

In this work, we have presented a design and architecture of a hybrid cloud environment for personal health records management using a low cost low power cluster built using two kinds of Single Board Computers. Details for requirements specifications for the proposed system were presented by classifying the requirements at three levels of data handling and data privacy: i) Data acquisition, ii) Data storage in Cloud, iii) Data Processing, analytics and visualization. Based on these requirements, a light weight architecture coupling the public and private cloud implementations was presented. Detailed aspects of encryption mechanisms based on ABE scheme were also presented. A low lost low power Hadoop cluster was deployed using two kind of single board computers, Raspberry Pi 3B and Odroid Xu4. Various experiments were conducted to evaluate the performance of the LoC4 cluster for computation time, storage management and network communications. Response time and task execution time were computed for various sizes of datasets to validate the security mechanism using a virtual machine in the proposed system.

Results from these studies show that a SBC based LoC4 cluster can be successfully deployed in a hybrid cloud environment. Although RPi computers are 50% cheaper than the Odroid Xu-4, the Odroid computer outperform RPi computers in all aspects of performance parameters. Xu-4 performs 3.8 times faster for Task execution times, 2.4 times faster for buffered read and write, 1.8 times faster for network throughput and at least 3 times faster for Hadoop based job executions. While SBC based clusters are energy efficient overall, the operation cost to performance ratio can vary based on the workload compared to a Personal Computer. In terms of power efficiency, for smaller workloads the Xu4 clustered devices performs 1.7 times better compared to RPi devices. Based on these observations, we conclude that LoC4 cluster is ideal for a hybrid cloud deployment where light weight applications can run on the back end. For heavier workload application, such as big data applications, due to the inefficient capabilities of these devices compared to high end server, the SBC based clusters may not be a performance effective choice. It is however possible to tweak Hadoop configuration parameters to adjust with given resources to improve the overall performance.

We provide response time evaluation experiments to validate the proposed scheme for encryption of data blocks based of ABE scheme. Results from the implementation of ABE based hybrid cloud scheme show on average a 43% improvement compared to AES based scheme for data block sizes of 1.8 MB to

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

400 MB. The proposed encryption scheme performs 2.3 times faster compared to AES based scheme. The current implementation is limited to xml based data files mimicking a PHR data record. We intend to extend the proposed system to include Apache Hive based Database on the back-end LoC4 cluster with further deployment of MySQL based implementation in the virtual machine running in the public cloud. We also did not consider using secure communication channels. The current system relies on network sockets for listening and responding over TCP/IP protocol. In the future, we intend to incorporate secure and reliable communications mechanisms in the proposed system. We intend to further investigate the effects of various QoS parameters on the communication in the proposed system.

ABSTRACT

The use of paper health records and handwritten prescriptions are prone to preset errors of misunderstanding instructions or interpretations that derive in affecting patients' health. Electronic Health Records (EHR) systems are useful tools that among other functions can assists physicians' tasks such as finding recommended medicines, their contraindications, and dosage for a given diagnosis, filling prescriptions and support data sharing with other systems. This paper presents EEMI, a Children EHR focused on assisting pediatricians in their daily office practice. EEMI functionality keeps the relationships among diagnosis, treatment, and medications. EEMI also calculates dosages and automatically creates prescriptions which can be personalized by the physician. The system also validates patient allergies. This paper also presents the current use of EHRs in Mexico, the Mexican Norm (NOM-024-SSA3-2010), standards for the development of electronic medical records and its relationships with other standards for data exchange and data representation in the health area.

1. INTRODUCTION

Mexico, like other developing countries, holds a social debt for its citizens with respect to the provision of health services. In particular, one of the most vulnerable groups is the infant population. Even though the global child mortality rate (considering children under five years old) has been declining from 90 to 48 deaths per 1000 live births between 1990 to 2012 (WHO 2013), there is still work to be done. In urban parts of Mexico, the infant mortality rate is 16.2 deaths per 1000 live births, but the number in rural areas is even higher, where children present symptoms of malnutrition, untracked growth and untracked immunizations. However, more than a half of child deaths in general (rural and urban areas) are due to diseases that are preventable and treatable through simple and affordable interventions. Some of the deadliest childhood diseases like measles, polio, diphtheria, tetanus, pertussis and pneumonia have immunizations available that can protect children from illness and eventually, death (WHO 2013).

Electronic Health Records (EHRs) systems with key functionality for pediatricians can help reduce these problems (malnutrition, untracked growth and untracked immunizations) by recording a child's information, generating immunization schedules and comparing child growth with recommended world charts (WHO 2007). EHRs assist pediatricians, who, as many other medical professionals, have a heavy work load and a priority for up to date knowledge. Pediatricians manage the physical, behavioral and mental health of children from birth up to age 21. They are trained to diagnose and treat a broad range of childhood illness, ranging from minor health problems to serious diseases. Unfortunately, pediatricians just like any human being, are susceptible to make mistakes, can feel tired and/or be distracted, and then write incorrect dosages, misspell a medication name or simply write an illegible prescription (Bates et al 2001).

The National Coordinating Council for Medication Error Reporting and Prevention (NCCMERP) defined a medication error as "any preventable event that may cause or lead to inappropriate medication use or patient harm while the medication is in the control of the health care professional, patient, or consumer (NCCMERP 2015). According to the American Society of Health-System, Pharmacists prescription errors are any incorrect drug selection, dose, dosage form, quantity, concentration, rate of administration, instructions of use, and any illegible prescriptions that lead to errors (ASHP 1993). The dose selection errors represent more than 50% of all prescribing faults, but other possible errors could be due to inaccuracy in writing, poor legibility of handwriting, use of abbreviations or incomplete writing of a prescription because all of these errors can lead to misinterpretation by pharmacists and patients (Velo, G.P., & Minuz, P. 2009).

In a study conducted at a Mexican university (Zavaleta-Bustos, M., et al., 2008), a sample of 370 prescriptions were randomly selected for analysis. The results indicated that 214 prescriptions (58%) of the sample had at least one error. The most common errors were incorrect indication, patient allergy to a medication, incorrect dosification, unjustified medications and duplicity of medications. Many of these errors were produced during the act of writing out a prescription.

Pediatricians, when confronted with an adult-oriented EHR, complain about not having specific functions for child medical care. The pediatricians' software requirements for EHRs are: immunization management, growth tracking, and medication dosing. Without these functions in an EHR, pediatricians are not capable to provide with quality care (Spooner, S. A., et al 2007).

An EHR system that fully supports pediatric practice must allow the recording of multiple immunizations and be able to analyze immunization data to determine the age when each vaccine should be administered. In addition, the system must provide graphic information of a child's body measurements

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

(weight, height, head circumference, body mass index) over time, as pediatricians make judgments based on these measurements. Another requirement is the method for calculating drug dosages; the system must be able to calculate doses based on weight or age depending of the medication (Spooner, S. A., et al 2007). Based on these needs, EHR should be adopted as a helpful tool for physicians. However, in developed countries existing EHRs are expensive, difficult to use, developed from the hospital administration point of view, or do not meet physician's needs. As a consequence, unless there is a clear benefit (economical or better job status) for using EHR, physicians do not use EHRs and usually see these systems as a waste of time.

This papers presents EEMI (abbreviated by its name in Spanish, Expediente Electrónico Médico Infantil or Child Electronic Health Record) a system for the administration of medical records planned for pediatric medical practice. EEMI was designed and tested with the active participation of experienced pediatricians working at one of the top hospitals in the metropolitan area of Monterrey, Mexico. The objective of EEMI is to help pediatricians to minimize the possibility of errors, optimize consultation time (spend more time with patient, rather than filling forms) and keep track of patients' information.

The rest of this paper is organized as follows. Section 2 presents the use of EHR in context, including the barriers that this type of system faces during its adoption or rejection by medical professionals; a brief discussion of standards and international norms for EHRs; and a comparison of current EHRs including EEMI. Section 3, formally presents EEMI through the description of its functionality. Section 4 describes the technology used in EEMI. Finally, Section 5 discusses current status and future work.

2. BACKGROUND AND RELATED WORK

This section includes a description of the adoption barriers that EHRs face with the physician community; describes the standards and regulations currently available for EHR's; and concludes with a brief description of the main EHRs used in the US and in Mexico.

2.1. Adoption Barriers

According to some studies (Humpage, S. 2010, NCCMERP 2015, Spooner, S. A., et al 2007, Velo, G.P., & Minuz, P. 2009), and our own experience (Quintas Ruiz I, 2011) the use of EHRs, increases productivity by 20%, reduces waiting time up to 60% and saves 80% of paper work cost. Additionally, EHRs have other benefits such as: increasing security on patient sensitive data; providing easy and fast access to patient information; decreasing negative medical events (overmedication, incorrect treatment, etc.); and decreasing cost by unnecessary or repetitive treatments or laboratory tests. Despite their benefits, EHRs have not been fully adopted due to factors such as change resistance, cost, lack of incentives and complex customization (Hsiao C.J., & Hing E.2013, Humpage, S. 2010, Spooner, S. A., et al 2007, Spooner, S. A., 2007, Quintas Ruiz I, 2011).

2.1.1. Diverse Technology and Adoption Speed

There is no clear measure of how successful is the use of EHR, because doctors, patients and hospitals are using diverse technologies, and some of them are not using any at all. Some EHR systems run on standalone machines, others use mobile devices and internet services.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

2.1.2. Resistance to Change

Resistance to change is the main barrier for adoption, particularly by physicians. Arguments given by physicians include system cost, job overload and concerns about information security and privacy. Physicians which use EHR, do because they have been instructed by their superiors or see a benefit, for example an economic bonus or a job promotion.

2.1.3. Cost

Cost is another barrier for adoption of EHRs. Most of electronic health record systems are implemented in large medical centers with complex functionality; from administrative activities management (insurance processing, billing, patient's registration, etc.) to health information management (patient medical history, lab analysis, surgery schedules, etc.). Therefore, the cost of EHR increases and only large medical centers can afford to have electronic health records. It is difficult to quantify the benefits that Physicians find in their practice when using EHR. It is hard to evaluate the increase in productivity, cost reduction, and the return of investment (ROI).

2.1.4. Incentives Wrongly Aligned

Cost savings by using an EHR may not have a direct impact in the physician income, but in the patient cost or in the health insurance company earnings. For example, an EHR can alert when a medicine is prescribed to an allergic person, then the patient or his/her insurance company can save money with the avoidance of the need for further anti-allergy-related treatment.

2.1.5. Personalization and Work Flow

Successful systems are customizable to different types of users (physicians in this case) but such a customization may be complex and time consuming. Additionally, physicians have a personal style to do their job and they see EHR as an unwelcome change in the way they work, affecting their productivity.

During the design and development of EEMI, pediatricians worked directly with the development team in order to correctly map their needs into EEMI functionality, minimize resistance to change and technology adoption. Deployment of EEMI was done in increments; doctors had a functional version of the system, on every release. Also workflow templates were generated for a less complex customization and a successful implementation.

2.2. Health Standards and the Mexican Norm

EHRs are nowadays subject to regulations with respect to how they represent, store and share information with other systems. A brief description of the Mexican norm for electronic health systems and international health information standards follows.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

2.2.1. Norma Oficial Mexicana

The Mexican Norm (Norma Oficial Mexicana NOM-024-SSA3-2010 and NOM-024-SSA3-2012) (Secretaría de Salud. 2010, 2011) are the standards that set the objectives and functional requirements that an electronic health record must have in order to guarantee the interoperability, confidentiality, security, and information catalogs. Among its specification the Mexican Norm states that electronic health records have to demonstrate that a minimal set of data is generated. The Mexican Norm requires the use of international standards for disease classification (ICD), interoperability (HL7) and medical images format (DICOM). Systems that are regulated by the norm include those used in outpatient consultation, inpatient care, emergency care, pharmacy, laboratories, surgery, and imaging.

2.2.2. International Classification \of Diseases (ICD)

The International Classification of Diseases (ICD) (WHO 2015) is the standard diagnostic tool for epidemiology, health management and clinical purposes. This includes the analysis of the general health situation of population groups. It is used to monitor the incidence and prevalence of diseases and other health problems, proving a picture of the general health situation of countries and populations. The ICD is published by the World Health Organization. The Mexican Norm requires that EHR use a disease catalog such as the ICD.

2.2.3. Logical Observation Identifiers Names and Codes (LOINC)

Logical Observation Identifiers Names and Codes (LOINC) (LOINC 2015) is the standard for identifying medical laboratory observations. LOINC includes categories for chemistry, hematology, and microbiology, among others in its laboratory section. The clinical observations section includes vital signs, electrocardiograms and echocardiograms among other categories.

2.2.4. Digital Imaging and Communications in Medicine (DICOM)

Digital Imaging and Communications in Medicine (DICOM) (DICOM 2015) is the standard for medical images. DICOM defines how to handle, store, print and transmit information in medical imaging. It includes a file format definition and a network communications protocol. This standard is implemented in almost all devices used in radiology, cardiology, and ultrasound. The standard is also being applied to ophthalmology and odontology. The Mexican norm, mentions DICOM as the standard to be used for medical images by EHRs.

2.2.5. Health Level Seven (HL7)

Health Level Seven (HL7) (Benson, T 2010, Health Level Seven International 2015) is a set of standards for the transference of clinical and administrative data between different health software applications including EHRs. HL7 refers to the focus of the standards in the application layer (or layer 7) in the Open System Interconnection (OSI) model. There are two versions: HL7 Version 2 and HL7 Version 3 from which Version 2 is the most widely used in health related systems. Communication between applications as defined in HL7 is through well-formed text documents. Mexican Norm requires data exchange between health systems to follow the HL7 standard.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

2.3. EHR Systems Comparison

In the US, the adoption of EHR has increased in the last years, in part due to government incentives, maturity of the EHRs, and better acceptance by medical professionals. EHR enterprises have perceived the market growth and therefore they have developed a great variety of products, as shown in Table 1 (EPIC 2015, Cerner 2015, Allscripts 2015, DrChrono Inc. 2015, Entrada 2015, Smart EMR 2015, eClinicalWorks 2015, PracticeFusion Inc 2015, Athenahealth, Inc 2015, iCare 2015, Bush, J. & Baker, S 2014, Atlassian.2015).

In Mexico, after the release of the Mexican Norm for Electronic Health Records in 2010) (Secretaría de Salud. 2010, 2011), new EHR's have been developed. The majority of these EHR implementations are in public health system hospitals and some in private medical centers. Public institutions such as IMSS (Social Security Institute for Mexico), ISSSTE (Social Security Institute for State Workers), PEMEX Hospitals (Mexican National Oil Company), Secretaría de Marina (Mexican Navy) and the private ABC Hospital have their in-site developed EHR. There are few commercial systems such as eMedix, Med2k, and, Alert. None of the reviewed systems for Mexico has a patient version or portal. Table 2 shows the characteristics of EHR in Mexico (ISSSTE. 2010, Estado de Colima 2015, Secretaría de Marina Armada de México 2015, Yacamán, R. 2010, Camacho Ortega V. 2014, eMedix 2015, Med2k 2015, Alert 2015).

EEMI	Web	Physician	Prescription creation	ICD-10	Automatic creation of immunization schedule.

The information summarized in Table 1 and Table 2 helped us to define and design the functionality on EEMI. One of the key factors we found in the analysis was the need to keep record of immunizations, create prescriptions automatically but in an editable by physicians' format and of course the imperative to follow the Mexican Norms (Secretaría de Salud. 2010, 2011) as well as international standards. In the following sections, a detailed discussion on EEMI is presented.

3. EEMI SYSTEM DESCRIPTION

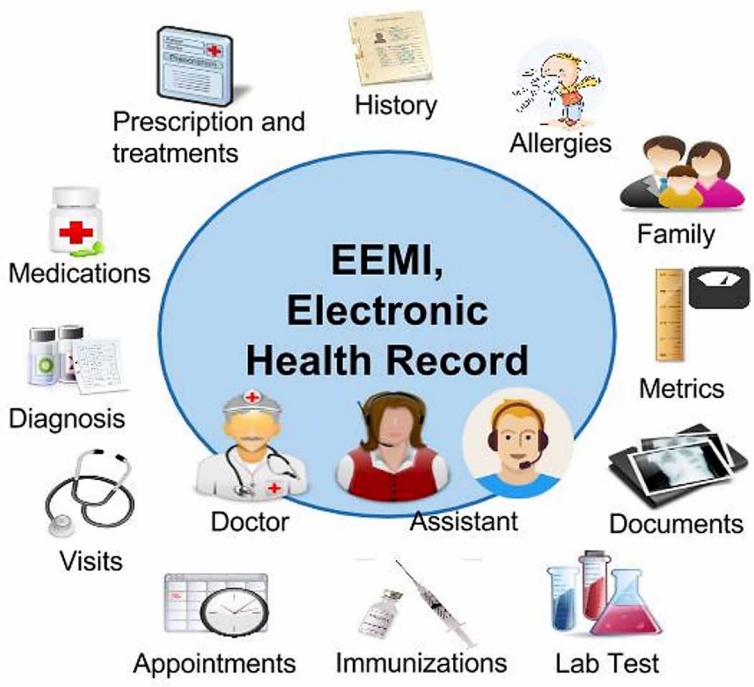
EEMI is an electronic health record system based on the practice experience of pediatricians in Monterrey, Mexico. The system follows the Mexican norm in its functionality and data exchange. Figure 1 represents a contextual overview of the services provided by EEMI. Users of the Child Electronic Health Record, presented in this paper, are physicians and their office assistants. The following paragraphs describe EEMI services.

3.1. Appointment Administration

This module allows to creates and manage appointments. This service resolves date conflicts with national holidays and personal physician calendar. The Physician can manage his/her own calendar to mark his/her vacations or define days out of the office.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. EEMI contextual overview



3.2. Visits Management

This module includes access to previous diagnosis, known treatments and related medications to facilitate and speed up the physician consultation. The system is able to automatically generate a prescription based on the diagnostic and calculate the medication dosage. The automatically generated prescription can be edited by the physician according to his/her consideration.

3.3. Medical Record Management

This module allows the management of information such as physical measurements, medical history, family, documents, laboratory results, immunizations, appointments, and visits history. New information can be added or current information can be updated.

3.4. Diagnosis

This module allows the specification of visit diagnosis based on the International Classification of Diseases (WHO 2015)

The system has a section for the diagnosis, treatments, medications, medications generic and brand names. This information is presented in form of lists that are related with each other and whenever a physician selects a diagnosis the system will display the possible treatments for that diagnosis, when a physician selects a treatment the system will display the possible medications for that treatment and the same goes for the medications generic and brand names.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Every time a physician selects a diagnosis the system will learn the relationships between diagnosis, treatment, medication and brand names and also the information for each one of them. This eliminates the need for the physician to type the same information every time for the same diagnosis. However, the possibility of modifying the selected treatment is kept always open, since there are no fixed combinations of diagnostic-treatment-medication-generic-brand name.

Each physician can create, modify and save his/her own catalogs of diagnosis, treatments, medications generic and brand names and the information could be used by another physician but could also be modified in case of an error, or a different treatment preference, choice of medication or a different brand name. The creation of this medical collaboration will reduce the errors in diagnosis.

Additionally, the system identifies frequent diagnosis in the last "n" days and every time a physician selects one of them, the system will suggest a full diagnosis, set of diagnosis-treatment-medication and brand name based on the most recently used. This suggestion makes faster the process of consulting a patient and is also helpful because many diseases have different prevalence depending on the season of the year and have a tendency to appear as clusters.

Every time a medication is added to the prescription, the system validates that the medication doesn't have an incompatibility with other medications in the same prescription. EEMI also validates medication against patient's known allergies.

3.5. Prescriptions and Dose Calculation

Once the diagnosis is selected, the system creates the prescription based on the information of every treatment and medication; it calculates the dose and generates a text for each medication that contains the presentation, dose, administration route, dispensing time and duration of treatment. The physician can print the prescription and give the patient a legible prescription that will not cause any misinterpretation. The dose calculation for every medication can be calculated by body weight or patient's age.

3.6. Immunization Schedule

The immunization schedule is automatically programmed based on the recommendations by the Mexican Ministry of Health (SSA). The doctor can personalize this schedule adding new immunizations not considered by the SSA. The system records the immunization and the age range of application. The recommended immunization date will be used for calculating the estimated date of application for a child and will create an appointment for that date. When a child is born and visits the pediatrician for the first time, the physician's assistant uses the system to schedule a full calendar of immunizations and appointments. This automation helps to keep track of the child's immunizations and allows the assistant and the physicician to remind the family for future visits. EEMI sends automatic e-mail remainders to parents or tutors of child's immunizations appointments.

3.7. Growth Graphs

The system displays the child's anthropometric measurements (weight, height, head circumference, body mass index) in a percentile chart, so the physician can assess the growth over time but is also able to compare with statistical data, because the system also displays the percentile distribution of all population values.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

With EEMI, the pediatrician can view, print or save in various graphic formats data of weight for age, height for age, weight for height, head circumference for age, and body mass index for age.

In a weight for age graph the pediatrician can easily identify when a child presents overweight or malnutrition by just comparing the child weight and check if the value is outside the normal values. Figure 2 shows an example of a low weight for age graph, where the blue dots are the child's weight and the color lines are the normal values.

3.8. EEMI Benefits

The following are the benefits of EEMI adoption according to observations by the initial testing group. Most of the benefits are not directly quantifiable in monetary terms, but qualitative in terms of a better interaction between physicians and patients.

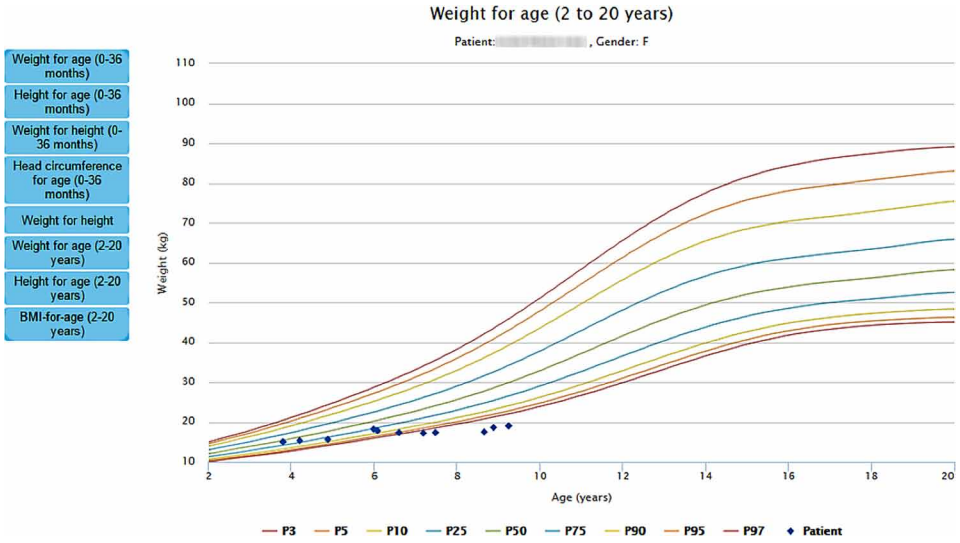
3.8.1. Tax Deductible Cost

In its current implementation as a service, EEMI is tax deductible by the Mexican fiscal legislation. Therefore, there is no a direct economic cost to the physicians that are using EEMI. Other EHR that were developed as standalone desktop applications are not considered services by the fiscal law, and the investment and other monetary cost are covered by the adopters

3.8.2. Optimization of Visit Time

During the visit, physicians spend more time talking with patients and understanding his/hers needs that looking for past visits records or writing down prescriptions and indications.

Figure 2. Growth graph (weight vs age)



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

3.8.3. Elimination of Prescription Errors

One key functionality of EEMI is the automatic (and editable) creation of prescriptions. This feature reduces common errors that physicians may do while handwriting or even typing prescription. It also allows to reduce or even eliminate medication incompatibility errors by looking for contra-indications for medicines in the prescription.

3.8.4. Patient Data Consistency and Privacy

Other key benefit mentioned by adopters of EEMI is the consistency in the information that is included in the prescriptions, such as medicines, dosage and particular indications. By having all this information at hand from visit to visit allows physicians a better understanding of the patients' progress.

3.8.5. Elimination of Paper Storage

The use of EEMI has permitted to reduce or eliminate the physical space required for storage of paper records.

3.9. EEMI Adoption and Barriers

EEMI has been evaluated by a group of physicians during its testing period. Even though, the acceptance of EEMI has been generally good, there are still some adoption barriers among the medical community. The most prevalent are:

Change resistance. As in any professional group, there is a group of physicians that is not willing to accept an EHR of any kind, and keeps attached to the traditional way to do a consult.

Use customization. One aspect for a good acceptance of an EHR according to the evaluation group has been the customization of the systems to the physician practice. EEMI has been successfully adapted to the way pediatricians work, however it is possible that other physicians find EEMI workflow inadequate to their practice.

Information transfer. Another key element for delay in the adoption of EEMI has been the burden of the initial transfer of patient information from one legacy system to EEMI. Without this feature, physicians face the dilemma of capturing (typing) again all their patient records or to keep the legacy systems for old time patients and record the new patients in EEMI,

4. EEMI TECHNOLOGY DESCRIPTION

EEMI is built based on the N-Tier Architecture, specifically 3-Tier Architecture. It's a client-server architecture where the logic, view and data are in different tiers. The data tier can contain one or more databases, the business tier contains all the logic of the project and the presentation tier contains the user interface. Currently EEMI is being implemented on a Service Oriented Architecture (SOA) (Schuldt, H. 2009) that provides a loosely coupled approach that allows interoperability, maintenance and updates. The use of Web Services allows data sharing between applications.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

A study showed that physicians have an urgent requirement to access the electronic health record systems with personal devices such as tablets or smartphones; therefore, a Service Oriented Architecture is suggested in the study (Wu, Y., & Yang, H. 2012). With this architecture we can develop native applications for diverse operating systems (iOS and Android) that cover the mobile devices alternatives in the market. This is possible by only developing the presentation tier and using the Web services.

The Figure 3 shows the architecture of the system, which is composed of three tiers. The presentation tier contains all the interfaces that presents data to the end users and allows the data manipulation. The business logic tier contains all the web services that will obtain and modify the database. The data tier is responsible for the database management. This separation of tiers improves scalability, reusability, flexibility, and maintainability, because we have loosely coupled and highly cohesive methods in each tier that are easy to change or reuse. Is important that the system has these attributes because we want to extend this system to other medical areas like gynecology.

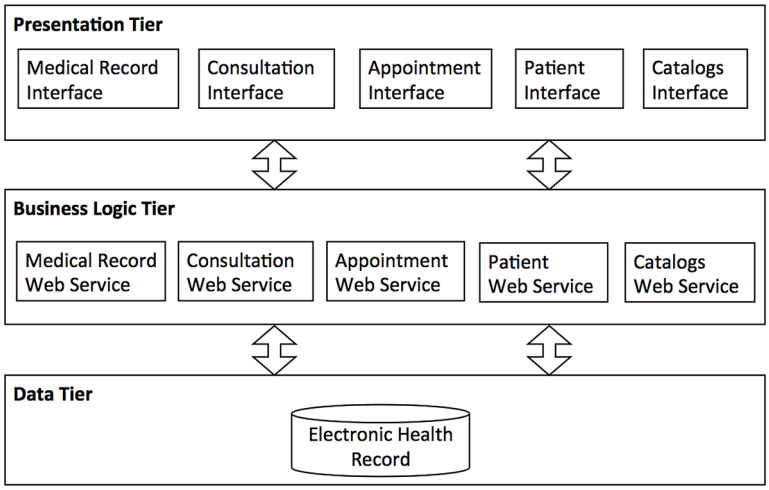
EEMI is implemented using .NET Framework 4.5 for the development of this system. The presentation tier was developed in ASP.NET, the business logic tier in Windows Communication Foundation (WCF) and for the data tier we use SQL Server 2012.

5. CURRENT STATUS AND FUTURE WORK

At the time of writing this paper, EEMI has been in the acceptance testing phase with a pilot in a group of pediatricians in Monterrey, Mexico. We will review the results and observations of this phase for include improvements in the production version. The production version was completed by the end of August 2015.

As future work, EEMI will be integrated with the project for Monitoring and Assisting Maternity-Infant Care in rural areas (MAMICare) (Lavariega, J., Córdova, G., Gomez-Martinez, G, & Ávila, A.2013). The MAMICare project monitors pregnant women to detect anomalies and prevent maternity and infant deaths. The EEMI system will continue with the monitoring of the child by keeping track of the growth and immunizations of the child.

Figure 3. SOA for EEMI



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

New electronic devices are being reviewed. These devices send information via Bluetooth to automatically register the measurements in the system. One key idea is to incorporate these devices in the process of taking measurements to eliminate the possibility of the injection or errors.

This system can be accessed from any tablet or smartphone because it is a Web application, but the interface may look different. One objective for the short terms is to develop native iOS and Android applications of this electronic medical record, a decision has to be made upon including only the most important requirements for these new applications or include everything that is available in the main EEMI system.

6. CONCLUSION

In general, EEMI enhances the process of a pediatric medical consultation due to the automation of several common activities. It also reduces the possibility of error that could be incurred any time the physician types a repetitive diagnosis. Due to the automated functions, the physician can focus on giving a better medical care. As a consequence of fewer typing errors, patient information is more accurate and a sense of security can be established between doctor and patients.

EEMI is a useful tool for keeping track of the child's growth and creating an immunization schedule for each child. The graphs will help the pediatrician to make decisions based on the weight, height, head circumference, and body mass index of a child.

With the use of a Service Oriented Architecture the system is scalable, reusable, flexible, and maintainable. This architecture makes it easier to make changes in the system, and reuse code because of the highly cohesive and loosely coupled methods. We can create native applications for iOS and Android by just developing the presentation tier and use the Web Services that are already developed in the business logic tier.

ABSTRACT

Current high-end graphics processing units (abbreviate to GPUs), such as NVIDIA Tesla, Fermi, Kepler series cards which contain up to thousand cores per-chip, are widely used in the high performance computing fields. These GPU cards (called desktop GPUs) should be installed in personal computers/servers with desktop CPUs; moreover, the cost and power consumption of constructing a high performance computing platform with these desktop CPUs and GPUs are high. NVIDIA releases Tegra K1, called Jetson TK1, which contains 4 ARM Cortex-A15 CPUs and 192 CUDA cores (Kepler GPU) and is an embedded board with low cost, low power consumption and high applicability advantages for embedded applications. NVIDIA Jetson TK1 becomes a new research direction. Hence, in this paper, a bioinformatics platform was constructed based on NVIDIA Jetson TK1. ClustalWtk and MCCtk tools for sequence alignment and compound comparison were designed on this platform, respectively. Moreover, the web and mobile services for these two tools with user friendly interfaces also were provided. The experimental results showed that the cost-performance ratio by NVIDIA Jetson TK1 is higher than that by Intel XEON E5-2650 CPU and NVIDIA Tesla K20m GPU card.

1. INTRODUCTION

Current high-end graphics processing units (abbreviate to GPUs) become very popular in the high performance computing community fields. These GPU cards, such as NVIDIA Tesla, Fermi, Kepler series, contain up to thousand cores per chip. For example, NVIDIA Tesla K20m GPU card has 2496 CUDA cores. They contain massive multi-threaded processors; moreover, the thousands of threads can be declared and executed simultaneously to fully utilize GPU computing power. However, these GPU cards, called desktop GPUs, should be installed in a personal computer or a server with desktop CPUs. Moreover, the cost and power consumption of constructing a high performance computing platform with these desktop GPU cards are high. For example, a NVIDIA Tesla or Fermi GPU card may be needed to spend thousands of US dollars and a personal computer or a server may also spend about hundreds to thousands of US dollars. The overall power consumption by this platform may be up to a kilowatt. Besides, this platform is hard to provide the immediate and mobility requirements, i.e., the developers should demo the program by the remote control.

Jetson TK1 (or called Tegra K1, http://elinux.org/Jetson_TK1) released by NVIDIA is a full-featured platform for embedded applications and it contains 192 CUDA Cores (Kepler GPU), 4 ARM Cortex-A15 CPUs and 2 ISP cores. NVIDIA Jetson TK1 also contains Bluetooth and Wi-Fi modules for mobile applications. The cost of a NVIDIA Jetson TK1 is less than three hundred US dollars and its power consumption is about tens of watts by the tests (Paolucci et al., 2014). Several reports or literatures have been proposed to compare NVIDIA Jetson TK1 with other embedded platforms, desktop CPUs and desktop GPUs, respectively. In the NVIDIA Jetson TK1 Development Kit (http://www.nvidia.com/object/jetson-tk1-embedded-dev-kit.html), it shows that the speedup ratios and the performance per watt by NVIDIA Jetson TK1 are better than those by Apple A7 used in the iphone5. James Wolfer (Wolfer, 2015) compared NVIDIA Jetson TK1 with Raspberry PI Model in terms of time and speedup ratios. The results showed that the single NVIDIA Jetson TK1 outperforms Raspberry PI Model in these two items. P.S. Paolucci *et al*. (Paolucci et al., 2014) also compared the ARM Cortex-A15 CPU in NVIDIA Jetson TK1 with the Intel XEON E5620 CPU in the SuperMicro server in terms of joule per synaptic event, total energy, power consumption, and execution time. For the first two items, NVIDIA Jetson TK1 achieves 4.5 and 4.4 times performance better than the SuperMicro server, respectively. NVIDIA Jetson TK1 achieves 14.4 times performance better than SuperMicro server for the power consumption. However, the execution time by NVIDIA Jetson TK1 is 3.3 times larger than that by the SuperMicro server. S. Fu *et al*. (Fu et al., 2015) do the comparison of performance, power efficiency, and cost efficiency among desktop Intel i7-3770 multi-core CPU, desktop NVIDIA GTX 690 GPU card and NVIDIA Jetson TK1. The results proved that the power efficiency and cost efficiency by NVIDIA Jetson TK1 are both better than those by desktop Intel i7-3770 CPU and desktop NVIDIA GTX 690 GPU card, respectively; the performance by NVIDIA Jetson TK1 is close to that by desktop Intel i7-3770 multi-core CPU, and the desktop NVIDIA GTX 690 GPU has the best performance. From above results, NVIDIA Jetson TK1 is a comparable embedded and mobile board by comparing with other embedded boards and desktop CPUs; moreover, NVIDIA Jetson TK1 has the low cost and low power consumption advantages by comparing with other desktop GPU cards. Hence, it will become a new research direction to study NVIDIA Jetson TK1 in the high performance computing community fields.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Compute Unified Device Architecture (abbreviate to CUDA, (Nickolls et al., 2008)) could access GPUs and has made the supercomputing available to the mass. In the past, many parallel algorithms, CUDA programs and tools have been developed based on these desktop GPU cards in several high-speed computing fields, such as the meteorology, image and video processing, fluid dynamics simulation, seismic analysis, and etc. For example, in the computational biology, there are several tools, such as MUMmerGPU (Schatz et al., 2007), CUDA-MEME (Liu et al., 2010), CUDA-BLASTP (Liu, Schmidt, Mu¨ller-Wittig, 2011), and etc. ClustalW (Thompson, Higgins, Gibson, 1994) is a progressive multiple sequence alignment tool, which is the commonly used approach to align a set of sequences by repeatedly aligning pairs of sequences and previously generated alignments. The idea of progressive multiple sequence alignment is to align pairs of sequences according to the orders in the phylogenetic tree which was built by the similarity scores calculated from each pair of sequences. In the previous work, we have proposed a GPU version of ClustalW v2.0.11, called CUDA ClustalW v1.0 (Hung et al., 2015), by using the intra-task parallelization (Liu, Maskell, Schmidt, 2009) on single- and multi-GPUs. CUDA ClustalW v1.0 based on desktop NVIDIA Tesla C2050 GPU card can achieve more than 33x speedups for overall execution time by comparing to ClustalW v2.0.11 based on desktop Intel XEON X5550 CPU of 2.67GHz.

Computer-Aided Drug Design (abbreviated to CADD) (John, 2007) becomes an emerging research field, and it is helpful to improve the efficiencies of drug design and development. By CADD, the potential inhibitors can be found for the target genes or proteins. After that, in general, these potential inhibitors will be used to compare with compound databases, such as ZINC (Irwin and Shoichet, 2005), in order to find other compounds with the similar structure. Therefore, the compound comparison has been an important and commonly-used task for the computational chemistry. Many algorithms, such as LINGO method (Vidal, Thormann, Pons, 2005) and fingerprint methods (Grant et al., 2006), have been proposed to do the compound comparisons in the past. However, it will be time-consuming when comparing with a large amount of compounds. In the previous work, we have proposed a GPU-based parallel algorithm for multiple compound comparisons, called CUDA-MCC (Lin et al., 2014), on single- and multi-GPUs. CUDA-MCC based on desktop NVIDIA Tesla K20m GPU card can achieve 45 times and 391 times faster than its CPU version based on desktop Intel XEON E5-2650 CPU of 2.0 GHz.

Therefore, in this paper, we construct a mobility and acceleration computing platform for bioinformatics with NVIDIA Jetson TK1. Based on this platform, CUDA ClustalW v1.0 and CUDA-MCC were re-ported, called ClustalWtk and MCCtk, and tested in this paper, respectively. From the experimental results, these tools both can achieve 3 and 4 times speedup ratios on single NVIDIA Jetson TK1 by comparing with their CPU versions on single Intel XEON E5-2650 CPU or single ARM Cortex-A15 CPU, respectively. Moreover, the cost-performance ratio by NVIDIA Jetson TK1 is higher than that by the desktop NVIDIA Tesla K20m GPU card. The user friendly interface can allow users to easily access GPU computational power of the proposed tool; moreover, NVIDIA Jetson TK1 contains Bluetooth and Wi-Fi modules for mobile applications. Hence, the web and mobile services for these two tools with user friendly interfaces also were provided in this work.

The rest of this paper is organized as follows. Preliminary concepts are introduced in Section 2. Section 3 presents the bioinformatics platform constructed on NVIDIA Jetson TK1 and the details of ClustalWtk and MCCtk tools. Experimental results are given in Section 4. Conclusions are drawn in Section 5.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

2. PRELIMINARY CONCEPTS

2.1. CUDA and NVIDIA GPU Architecture

CUDA is an extension of commonly-used programming languages, such as C/C++, in which users can write multithreading programs for practical applications. The CUDA program is implemented in two parts: host executed by CPU and device executed by GPU. The function executed on the device part is called a kernel, which is invoked as a set of concurrently executing threads. These threads are grouped into a hierarchical architecture: thread blocks and grid. A grid is a set of thread blocks, and a thread block contains many threads. The size of grid is the number of thread blocks per-grid, and the size of thread block is the number of threads per-thread block. Threads in a thread block can communicate through a per-thread block shared memory and synchronize with each other. In addition to shared memory, there are five memory types, includes per-grid private local memory, global memory for data shared by all thread blocks, texture memory, constant memory, and per-thread private registers. The basic processing unit in NVIDIA's GPU architecture is called the streaming processor or CUDA core. Many streaming processors perform the computations on GPU. Several streaming processors can be integrated into a streaming multiprocessor according to various architectures, such as 32 and 192 streaming processors per-streaming multiprocessor for Fermi and Kepler architectures, respectively. The caches of texture memory and constant memory are limited to 8KB per-streaming multiprocessor. Fermi and Kepler architectures have real configurable L1 per-streaming multiprocessor and unified L2 caches among streaming multiprocessors. Hence, L2 caches can be accessed by the global memory and each streaming multiprocessor can use the L1 caches and shared memory. While the program runs the kernel, the device schedules thread blocks for the execution on the streaming multiprocessor. The SIMT scheme refers to threads running on the streaming multiprocessor in a small group of 32, called a warp. The warp scheduler simultaneously schedules and dispatches instructions. The performance by a CUDA program is deeply influenced by the number of threads per-thread block and the number of thread block per-grid.

2.2. ClustalW

ClustalW (Thompson, Higgins, Gibson, 1994) is a progressive multiple sequence alignment tool; and its procedure can be divided into three steps: (1) the distance matrix calculation, (2) the guide tree creation, and (3) the progressive alignment. In most of cases, the computation time of distance matrix calculation step occupied most of overall execution time by ClustalW (Li, 2003). In the distance matrix calculation step, the similarity scores were calculated from each pair of biological sequences by using the pairwise alignment algorithm, such as Needleman and Wunsch algorithm (Needleman and Wunsch, 1970). For aligning two sequences both with length of n, the time and space complexity both is $O(n^2)$ by using Needleman and Wunsch algorithm. For aligning k sequences with length of n by ClustalW, it needs to do $k^2/2$ pairwise alignments and the total time complexity is $O(k^2n^2)$. In the guide tree creation step, a rooted phylogenetic tree was built according to the calculated distance matrix (similarity scores in step1) by using the phylogenetic tree construction algorithm. The time complexity of this step is $O(k^3)$ for most of phylogenetic tree construction algorithms, such as UPGMA (Sneath and Sokal 1973). The built guide tree could be used to decide the orders of following progressive alignment step. In the progressive alignment step, the pairwise alignment results were generated according to the orders in the guide tree (created in step2). Although this step still needs to use the pairwise alignment algorithm to

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

obtain the pairwise alignment results, and then combines the previously generated alignments, the times of pairwise alignments in this step generally is far less than that in the distance matrix calculation step.

2.3. Multiple Compound Comparisons (MCC)

In general, molecules (compounds) can be represented as fingerprints (Grant et al., 2006) and SMILES (Vidal, Thormann, Pons, 2005), and then the work of compound comparison can be seen as the string comparison. The Tanimoto coefficient is the most popular measurement between two molecules. For a pairwise compound comparison (denoted as one to one comparison, O2O), the time complexity is $O(n^2)$, where n is the maximal length of compounds. In general, the length of compound is short (tens to hundreds) and the computation time is small. However, it will be time-consuming when comparing with a large amount of compounds. For the MCC problem, it can be done to compare a compound with a set of compounds (denoted as one to all comparisons, abbreviated to O2A) or to compare two sets of compounds (denoted as all to all comparisons, abbreviated to A2A). For A2A, the intrinsic time complexity of MCC problem is $O(k^2n^2)$ with k compounds of length n. The LINGO method (Vidal, Thormann, Pons, 2005) is to model a molecule as a collection of substrings of SMILES representation. Thus, a SMILES string is fragmented into all substrings with length of q by using the sliding window scheme. These substrings are stored as a set of q-Lingos. When doing O2O, two sets of q-Lingos from two molecules are used to find the same Lingos. The number of same Lingos is then used to calculate the Tanimoto coefficients.

3. METHOD

3.1. Constructing Bioinformatics Platform

In this paper, a bioinformatics platform is constructed on NVIDIA Jetson TK1, which can be separated into four parts: *system setting up*, *program porting*, *performance tuning*, and *interface design*. For *system setting up*, some preparation works need to be done, such as refresh system image, set up network and install some software in the proposed computing platform. For *program porting*, for ClustalWtk and MCCtk, the compile commands and program codes of CUDA ClustalW v1.0 and CUDA-MCC should be regulated and modified, respectively. For *performance tuning*, it is necessary due to the different of numbers of thread blocks and threads per-thread block between NVIDIA Jetson TK1 and desktop GPU cards. ClustalWtk and MCCtk will be evaluated on NVIDIA Jetson TK1 by various numbers of thread blocks and the number of threads per thread block, respectively. For *interface design*, various interfaces by Qt, web and mobile services are designed for ClustalWtk and MCCtk, respectively.

3.1.1. System Setting Up

All the works in this paper are implemented on Linux for Tegra (abbreviate to L4T) R21.1. System image and device driver are downloaded from NVIDIA Developer Zone (https://developer.nvidia.com/linux-tegra-rel-21), which provides some useful development tools for NVIDIA. The decompression path of these downloaded files is very important, e.g., for device driver, it must be placed in the child directory of system image, named “rootfs”. It then is further compiled by executing “apply_binaries.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

sh" on the top directory of system image. A micro USB cable is used to be connected between NVIDIA Jetson TK1 and Linux PC-host. To place system in the "Force USB Recovery Mode", the device must be powered off, not suspend or sleep state. Then reset button is pressed while force recovery button is held. To examine whether the device is entered the "Force Recovery Mode", the command "lsusb" is utilized to check if "NVidia Corp" exists or not. If "NVidia Corp" exists, NVIDIA Jetson TK1 has successfully connected with Linux PC-host. In order to flash device, the command "sudo ./flash.sh -S 14580MiB jetson-tk1 mmcblk0p1" is executed. After finished this flashing action, default account and password are used to login the L4T.

NVIDIA Jetson TK1 can be accessed in two possible ways: *direct access* and *remote access*. The first way is using keyboard, mouse and HDMI monitor to directly access to NVIDIA Jetson TK1 in the "GUI mode". The other is using Ethernet port to access to the board (NVIDIA Jetson TK1) in the "remote mode". Since DHCP and SSH both are default "on", NVIDIA Jetson TK1 can be accessed by using SSH in the "remote control mode". IP is assigned by DHCP server when NVIDIA Jetson TK1 is connected to a router. It is important to tell "apt" not to overwrite the file "libglx.so" in L4T R19 if you upgrade the system. It seems to be fixed in L4T R21. "libglx.so" is a specific file in the NVIDIA's graphics driver that might get replaced by an incorrect version from Ubuntu that stops users from being able to boot into the graphical environment. Therefore, it should execute "sudo apt-mark hold xserver-xorg-core" on NVIDIA Jetson TK1 before connecting it to Internet or perform an update.

The version CUDA 6.5 is installed on NVIDIA Jetson TK1. The ".deb" file of the CUDA Toolkit for L4T is also downloaded from NVIDIA Developer Zone. In order to install the CUDA repo metadata, "sudo dpkg -i cuda-repo-l4t-r21.1-6-5-prod_6.5-14_armhf.deb" is executed (downloaded manually for L4T). "sudo apt-get update" is executed to download and install the actual CUDA Toolkit including the OpenGL toolkit from NVIDIA. "sudo apt-get install cuda-toolkit-6-5" is executed to install the package and the account should be added to the "video" group to allow access GPU. It is also necessary to add "export PATH=/usr/local/cuda/bin:$PATH" and "export LD_LIBRARY_PATH=/usr/local/cuda/lib:$LD_LIBRARY_PATH" to "bashrc" file and then to source it.

Other development tools also should be installed. Gcc and G++ are necessary for building OpenMPI and Qt; Apache and PHP are essential for application interfaces design; Gcc, G++, Apache, PHP, mail server, and Qt4 are available on apt package manager which can be directly installed by executing "sudo apt-get install gcc g++ apache2 php5 libapache2-mod-php5 mailutils qt4-dev-tools libqt4-dev libqt4-core libqt4-gui libqt4-opengl" on terminal (Qt: https://devtalk.nvidia.com/default/topic/752892/qt-anyone-/; mailutils: http://askubuntu.com/questions/12917/how-to-send-mail-from-the-command-line; Apache: https://www.digitalocean.com/community/tutorials/how-to-install-linux-apache-mysql-php-lamp-stack-on-ubuntu). OpenMPI is download from the OpenMPI website (http://www.open-mpi.org/) as ".tar.gz" file. The OpenMPI source file is decompressed and configured with the building path: "—prefix=/usr/local/openmpi". After "make all" and "sudo make install" have finished, "export OPENMPI=/usr/local/openmpi", "export LD_LIBRARY_PATH=$OPENMPI/lib" and "export PATH=$OPENMPI/bin:$PATH" should add to the "bashrc" file and then to source it.

A Wi-Fi module (Intel 7260 mini PCIE) is installed on the NVIDIA Jetson TK1; however, the system kernel seems not support this module. Several reports (https://github.com/jetsonhacks/install7260LT4211) have been tried to fix this problem. Device driver for the Intel 7260 miniPCIE card is compiled for the NVIDIA Jetson TK1 under LT4 R21.1, which is available from GitHub website (https://github.com/). To avoid crashes, "/etc/rc.local" and the "cfg80211.ko" and "mac80211.ko" files are backed before proceeding. After "install7260Driver.sh" has been executed, the Wi-Fi module installation is successful.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

3.1.2. Program Porting

In this part, the program codes of ClustalWtk and MCCtk are modified from CUDA ClustalW v1.0 and CUDA-MCC designed for the desktop GPU cards, and then they both were compiled on NVIDIA Jetson TK1, respectively. The details of ClustalWtk and MCCtk are described in the Section 3.2 and Section 3.3, respectively. Some errors have been reported in the compiler, such as: "library could not found. Fixing Configure and Makefile is necessary". In this case, the library path for CUDA should be forced to use x86 path, and device compute capability should be set at 3.2. For program with OpenMP, "-Xcompiler -fopenmp" is added to the compile command. The parameter "-O3" is also attached to achieve the better performance.

However, the running time is incorrect in NVIDIA Jetson TK1 when the input data is large. Many experiments have showed that the device would return tiny or negative running time when it is longer than two thousand seconds. This situation is not appeared on the desktop CPU. The running time is computed by clock() function and stored in the type clock_t. According to the definition in "time.h" file, type "clock_t" is type "long". The maximum of type "long" on NVIDIA Jetson TK1 is 2147483647, and on the desktop CPU, such as Intel XEON E5-2650, is 9223372036854775807. The maximum of type "long" on NVIDIA Jetson TK1 is divided by CLOCKS_PER_SEC (1000000) is about 2147, in line with the aforementioned situation. Since the clock() function will cause the overflow, the "ftime()" function and "timeb" structure are the better choice. The "timeb" structure consists of "time_t" time and unsigned short "millitm". The running time divided into two parts for the storage can be calculated for the longer time.

3.1.3. Performance Tuning

For ClustalWtk and MCCtk, *performance tuning* is further divided into two parts: *number of thread blocks/threads per-thread block* and *hardware control*. For the first part, when the numbers of thread blocks and threads per-thread block is set at 128 and 64, respectively, the best performance by ClustalWtk or MCCtk is obtained. These numbers set for ClustalWtk and MCCtk are different to those of CUDA ClustalW v1.0 and CUDA-MCC. For the second part, "cat /sys/devices/system/cpu/online" is used to check the status of CPUs. Since only one CPU core is default on in NVIDIA Jetson TK1, other CPUs should be turned on by hand. For example, CPU2 is turned on by "echo 1 > /sys/devices/system/cpu/cpu2/online". According to the consumption of battery (power), the modes of CPU are separated into three types: "quiet", "normal" and "performance". To obtain the best power efficiency, default "quiet" mode is turned off to enter the "performance" mode. "echo 0 > /sys/devices/system/cpu/cpuquiet/tegra_cpuquiet/enable" is used to turn off the "quiet" mode. "echo performance > /sys/devices/system/cpu/cpu2/cpufreq/scaling_governor" is used to keep frequency on static instead of a range. CPU frequency can be set by writing this: "echo <*frequency*> > /sys/devices/system/cpu/cpu0/cpufreq/scaling_setspeed". If the type is running on the "quiet" mode, the following frequencies (Hz) are available: 51000, 102000, 204000, 312000, 564000, 696000, 828000, 960000, 1092000. And if the type is running on the "performance" mode, the following frequencies (Hz) are available: 204000, 312000, 564000, 696000, 828000, 960000, 1092000, 1122000, 1224000, 1326000, 1428000, 1530000, 1632000, 1734000, 1836000, 1938000, 2014500, 2116500, 2218500, 2320500. To manually control the clock frequencies (Hz) of the GPU, supported rates should be first determined by "cat /sys/kernel/debug/clock/gbus/possible_rates". Then

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

set a rate (e.g. 852000 kHz) by "echo 852000000 > /sys/kernel/debug/clock/override.gbus/rate" and "echo 1 > /sys/kernel/debug/clock/override.gbus/state". Finally, the rate is verified by "cat /sys/kernel/debug/clock/gbus/rate".

3.1.4. Interface Design

The user friendly interfaces are designed for ClustalWtk and MCCtk by Qt and Web, respectively. Qt is accessed through SSH and X11 forwarding and only available on PC-host. Web is accessed through IP address and has more device compatibility.

The stable version Qt 4.8 has more materials on internet or bookstore. Qt application is accessible to operating CUDA program through SSH and X11 forwarding. X11 forwarding is default on when NVIDIA Jetson TK1 is out of the factory. "ssh -X <*IP*>" can be used to connect device with X11 forwarding on Linux or Mac, and "Xming" and "Putty" application are the solution for Microsoft Windows. "QFile" is used to read and write file on NVIDIA Jetson TK1, and "QProcess" is used to start external programs and to communicate with them. The CUDA program is executed by "start()" function. "Connect()" function is used to report the state while CUDA program has finished. In "start()" function, bash command is invalid since the system environment is not work in it. Absolute path of program is added instead of using "$HOME" variable or relative path. In the end, bash command "mail -s <*subject*> -A <*attached file*>" is added in the "system()" function to send result data to users. No permission problem will be appeared if the account (ubuntu) has been added to "video" group.

Bootstrap is employed as the website framework for popular feature in developing responsive, mobile first projects on the web. It can be applied on the mobile phone, pad and PC. HTML provides users to set up input file and parameters, and send it to PHP script by AJAX techniques. According to user's choice, PHP script executes CUDA program in CPU or GPU version. The running time of CUDA program, such as ClustalWtk or MCCtk, is averaged more than 30 seconds, largely depending on input data and algorithm. As the default running time for PHP script is limited to 30 seconds, it is necessary to set the max execution time value before running. "set_time_limit(0)" is added to PHP script, and zero means unlimited. The "shell_exec()" function is utilized to execute CUDA program on PHP script. "cuda device not found" are reported when PHP runs CUDA program. The main reason is that apache account (www-data in ubuntu/L4T) does not have permission to access GPU. Hence, "www-data" is added to "video" group and it work perfectly.

3.2. ClustalWtk

In ClustalWtk, the distance matrix calculation step is implemented on GPU and several optimization methods were designed to enhance the performance by ClustalWtk. In the distance matrix calculation step, the similarity scores were calculated from each pair of sequences by using pairwise alignment algorithm. For *k* sequences, ClustalWtk used the intra-task parallelization to assign a pairwise alignment to a thread block, which each pairwise alignment is implemented by the *Synchronous Diagonal Multiple Threads* (*SDMT*) type (Lin and Lin, 2014). The pairwise alignment algorithm used in ClustalWtk includes three paths: forward path, reverse path, divide and conquer path. In order to do the computations in the forward array and the reverse array concurrently, the threads in a thread block are divided into two parts, one for forward array and another for reverse array. Only one thread in a thread block is then used to merge the scores in the last row of forward array and reverse array in order to find the break point

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

and then divide the original two-dimensional array into two sub-arrays. The divide and conquer path is done by the loop function. Besides, in ClustalWtk, several optimization methods below were designed for the distance matrix calculation step:

- **Load balancing strategy:** Using the intra-task parallelization, a pairwise alignment is assigned to a thread block. Although there is only one streaming multiprocessor in NVIDIA Jetson TK1, a streaming multiprocessor can deal with one or more thread block(s). For k sequences in ClustalWtk, a kernel function only deals with a fixed number of pairwise alignments with the similar length of sequences. The number of threads per-thread block and the number of thread block per-grid in ClustalWtk are 64 and 128, respectively, according to Section 3.1.3;
- **Memory allocation:** For a pairwise alignment, the inputs are two sequences and a substitution matrix. These two sequences are stored in the shared memory and the substitution matrix is stored in the texture memory. All of sequences and the distance matrix are stored in the 2GB RAM;
- **Unsigned char data type:** Since each pair of sequences stored in the shared memory, the shared memory usage will affect the occupancy of streaming multiprocessors. These two sequences are stored by using the *unsigned char* data type, not *int*, in order to reduce the shared memory usage and increase the occupancy;
- **Precision adjustment:** Since the single-precision floating-point operations in CUDA are not designed according to the IEEE-754 standard. In ClustalWtk, *__fdiv_rn*() function was used to replace the built-in division operator.

3.3. MCCtk

In MCCtk, the goal is to compare two sets of compounds (A2A) listed as Query and Database at first, and then find the compounds in Database with more than 0.85 Tanimoto coefficient for each compound in Query. There are three phases in MCCtk: *preprocessing*, *comparison* and *output*. In the *preprocessing* phase, the compounds in Query and Database are stored as a two dimensional string arrays (represented as the SMILES code), *Q* and *Db*, respectively. After that, each SMILES code (a compound) is then fragmented into a set of 4-Lingos (as sub-strings) by using the sliding window scheme with an offset 1. For each 4-Lingo, it will be transformed into a 32-bit integer (called LINGO score) according to the ASCII code table. The LINGO length, LINGO number and LINGO magnitude are calculated, respectively, according to the number of 4-Lingos, the times of each 4-Lingo appeared in the SMILES code and the number of 4-Lingos without repeats. For the *comparison* phase, a compound in Query will be used to compare with all compounds in Database by all threads (the inter-task parallization) when executing the kernel function once. In a thread block, each thread is used to compare a compound in Query with one of compounds in Database. Hence, the computing workload of each thread in a thread block should be equal in order to achieve high performance. A load-balancing strategy can be used to accelerate the computation speed on NVIDIA Jetson TK1 by considering the LINGO score, LINGO length, LINGO number, and LINGO magnitude. After the *comparison phase*, in the *output* phase, for each compound in Query, the compounds in Database with more than 0.85 Tanimoto coefficients are reported.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

4. EXPERIMENTAL RESULTS

In this work, ClustalWtk and MCCtk were implemented by C+CUDA on single NVIDIA Jetson TK1. In order to evaluate these two tools, a machine and a NVIDIA Jetson TK1 are used in the experimental tests. This machine has eight Intel XEON CPU cores, four GPU cards and 128GB RAM. Each Intel XEON CPU core is 4 Intel XEON E5-2650 processors of 2.0 GHz and each GPU card is NVIDIA Tesla K20m with 4.8GB RAM and 13 streaming multiprocessors, each multiprocessor has 192 CUDA cores of 0.706 GHz. The NVIDIA Jetson TK1 has 1 ARM Cortex CPU core, 1 Tegra K1 Soc and 2GB RAM. The ARM Cortex CPU core is 4 Cortex-A15 processors of 2.32GHz and the Tegra K1 is NVIDIA Kepler GK20a with 1 streaming multiprocessor, which has 192 CUDA cores of 0.852 GHz. ClustalW v2.0.11 and MCC are run based on Intel XEON E5-2650 CPU in the machine and ARM Cortex-A15 CPU in NVIDIA Jetson TK1, respectively; CUDA ClustalW v1.0 and CUDA-MCC are run based on NVIDIA Tesla K20m GPU card in the machine; ClustalWtk and MCCtk are run based on NVIDIA Kepler GK20a in NVIDIA Jetson TK1.

For the evaluation of ClustalW v2.0.11, CUDA ClustalW v1.0 and ClustalWtk, the test protein sequences (C.-L. Hung et al., 2015) were downloaded from the NCBI website (www.ncbi.nlm.nih.gov/), and these sequences can be classified into eight test sets: (c1) 100 sequences with length of 97, (c2) 100 sequences with length of 498, (c3) 100 sequences with length of 1002, (c4) 100 sequences with length of 1523, (c5) 1000 sequences with length of 97, (c6) 1000 sequences with length of 498, (c7) 1000 sequences with length of 1002, (c8) 1000 sequences with length of 1523. For the evaluation of MCC, CUDA-MCC and MCCtk, the test compounds are randomly selected from the ZINC database [14] and then these compounds are divided into Query and Database sets. There are three test sets used in the following experiment tests: (m1) 4096 compounds in Query and Database, respectively, (m2) 8192 compounds in Query and Database, respectively, (m3) 16384 compounds in Query and Database, respectively.

The first test is to evaluate ClustalW v2.0.11, CUDA ClustalW v1.0 and ClustalWtk for these eight test sets on the machine and single NVIDIA Jetson TK1, respectively. Figure 1(a) shows the execution time (unit: second), which is represented by $\log_{10}$, by ClustalW v2.0.11, CUDA ClustalW v1.0 and ClustalWtk on various test sets, respectively. From Figure 1(a), we can see that the execution time by CUDA ClustalW v1.0 on single NVIDIA Tesla K20m GPU card and that by ClustalWtk on single NVIDIA Jetson TK1 all is less than that by ClustalW v2.0.11 on single Intel XEON E5-2650 CPU and ARM Cortex-A15 CPU, respectively. ClustalWtk can achieve 3 times speedup ratio by comparing the execution time on single NVIDIA Jetson TK1 with that by ClustalW v2.0.11 on single Intel XEON E5-2650 CPU. ClustalWtk can achieve 4 times speedup ratio by comparing the execution time on single NVIDIA Jetson TK1 with that by ClustalW v2.0.11 on single ARM Cortex-A15 CPU. The execution time by CUDA ClustalW v1.0 on single NVIDIA Tesla K20m GPU card is less than that by ClustalWtk on single NVIDIA Jetson TK1. The reason is that the number of CUDA cores on single NVIDIA Tesla K20m GPU card is 13 times than that on single NVIDIA Jetson TK1. However, the execution time by ClustalWtk on single NVIDIA Jetson TK1 is only 5 times than that by CUDA ClustalW v1.0 on single NVIDIA Tesla K20m GPU card. Hence, in ClustalWtk, the cost-performance ratio by NVIDIA Jetson TK1 is better than that by NVIDIA Tesla K20m GPU card.

The second test is to evaluate MCC, CUDA-MCC and MCCtk for these three test sets on the machine and single NVIDIA Jetson TK1, respectively. Figure 1(b) shows the execution time (unit: second), which is represented by $\log_{10}$, by MCC, CUDA-MCC and MCCtk on various test sets. From Figure 1(b), we can see that the execution time by CUDA-MCC on single NVIDIA Tesla K20m GPU card and that by

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

MCCtk on single NVIDIA Jetson TK1 all is less than that by MCC on single Intel XEON E5-2650 CPU and ARM Cortex-A15 CPU, respectively. MCCtk can achieve 3 times speedup ratio by comparing the execution time on single NVIDIA Jetson TK1 with that by MCC on single Intel XEON E5-2650 CPU. MCCtk can achieve 4 times speedup ratio by comparing the execution time on single NVIDIA Jetson TK1 with that by MCC on single ARM Cortex-A15 CPU. In Figure 1(b), for the comparisons of NVIDIA Tesla K20m GPU card and NVIDIA Jetson TK1, we have the same observations from the Figure 1(a). In MCCtk, the cost-performance ratio by NVIDIA Jetson TK1 is also better than that by NVIDIA Tesla K20m GPU card.

User friendly interfaces designed by Qt for ClustalWtk and MCCtk are shown in Figures 2(a) and 2(b), respectively. For ClustalWtk, Figure 2(a-i) is the initial interface for ClustalWtk and the input "biological sequences" can be pasted on the interface; the input also can be selected from the directory as shown in Figure 2(a-ii); one of two tools, ClustalW runs on desktop CPUs and ClustalWtk runs on NVIDIA Jetson TK1, can be selected by users to obtain the alignment results as shown in Figure 2(a-i); the execution time by ClustalW or ClustalWtk can be listed in the interface as shown in Figure 2(a-i); the output "multiple sequence alignment results" can be shown in the interface as shown in Figure 2(a-iii). For MCCtk in the left side of Figure 2(b), the Query and Database files can be selected from the directory; the compound in Query also can be assigned in the interface; the other compounds with similar structure are calculated by MCCtk and the information of these compounds is shown. The 3D structure visualization of selected compound can be shown in the right side of Figure 2(b).

The web and mobile services also can be designed in the NVIDIA Jetson TK1 by Ethernet and Wi-Fi modules. The interfaces of the web and mobile services by ClustalWtk and MCCtk are shown in Figures 3 and 4, respectively. For ClustalWtk, Figure 3(a-i) is the initial interface on the web service; the input sequences can be selected or pasted on the web as shown in Figure 3(a-ii); the one of two tools, ClustalW and ClustalWtk, can be selected to obtain the results of multiple sequence alignment as shown in Figure 3(a-ii); the execution time by ClustalW or ClustalWtk can be displayed in the Figure 3(a-iii); the results are shown in Figure 3(a-iv). Figure 3(b-i) is the initial interface on the mobile service; the input sequences can be selected and then be uploaded to NVIDIA Jetson TK1 as shown in Figure 3(b-ii); the output is displayed in the Figure 3(b-iii). For MCCtk, Figure 4(a-i) is the initial interface on the web service; the inputs, Query and Database files, can be selected on the web as shown in Figure 4(a-ii); the information of compounds with similar structure are listed in Figure 4(a-iii). Figure 4(b-i) is the initial interface on the mobile service; the execution time by MCCtk is shown in Figure 4(b-ii); the information of resulted compounds are listed in Figure 4(b-iii).

5. CONCLUSION

In this paper, a mobility and acceleration computing platform for bioinformatics by NVIDIA Jetson TK1 was constructed. Moreover, ClustalWtk and MCCtk were designed based on the platform. From the experimental results, two observations for ClustalWtk and MCCtk were summarized in this work: (1) they both achieved 3 and 4 times speedup ratios on single NVIDIA Jetson TK1 by comparing with ClustalW v2.0.11 and MCC on single Intel XEON E5-2650 CPU and ARM Cortex-A15 CPU, respectively. (2) The cost-performance ratio by NVIDIA Jetson TK1 is better than that by NVIDIA Tesla K20m GPU card. The user friendly interfaces of Qt, web and mobile services were designed for ClustalWtk and

Chapter 36
Genetic Diagnosis of Cancer by Evolutionary Fuzzy-Rough based Neural-Network Ensemble

Sujata Dash
North Orissa University, India

Bichitrananda Patra
KMBB College of Engineering and Technology, India

ABSTRACT

High dimension and small sample size is an inherent problem of gene expression datasets which makes the analysis process more complex. The present study has developed a novel learning scheme that encapsulates a hybrid evolutionary fuzzy-rough feature selection model with an adaptive neural net ensemble. Fuzzy-rough method deals with uncertainty and impreciseness of real valued gene expression dataset and evolutionary search concept optimizes the subset selection process. The efficiency of the hybrid-FRGSNN model is evaluated by the proposed neural net ensemble learning algorithm. Again to prove the learning capability of ensemble algorithm, performance of the component classifiers pairing with FR, GSNN and FRGSNN are compared with proposed hybrid-FRGSNN based ensemble model. In addition to this, efficiency of neural net ensemble is compared with two classical and one advanced ensemble learning algorithms.

1. INTRODUCTION

Microarray technology produces high dimensional datasets by measuring the expression levels of tens of thousands of genes in a single experiment under varying conditions. It has become an indispensable tool for biological, medical and pharmaceutical researchers to get a better understanding of the diseases at genomic level. On the other hand, the inherent problem i.e., large number of features and small sample

size of microarray dataset makes the analysis process difficult for the problem. Typically, a relatively small number of features are found to be strongly correlated with the phenotypes in question. Therefore, to identify these discriminative features from gene expression dataset, a data mining tool (Witten, Frank & Hall, 2011) known as feature selection technique plays an important role.

The methods specifically used for feature selection can be categorized into two major groups namely, filter and wrapper methods (Saeys, Inza & Larranaga, 2007; Guyon, Nikravesh, Zadeh, 2006). Filter methods select features considering individual characteristic of each feature without taking into account the mutual dependencies among features. Then the features are sorted by their assigned ranks. The top ranked features are kept for further analysis by removing low ranked features. Actually, these selected features are used to develop the diagnostic model to efficiently predict the diseases. On the contrary, in wrapper methods a search algorithm is wrapped around a learning algorithm: so that an estimated learning accuracy for all subsets can be calculated to derive an optimal one. This method is computationally intensive in comparison to filter methods because to obtain an optimal subset of features all possible subsets need to be examined which is practically a difficult task. Thus, to alleviate this difficulty in wrapper methods an intelligent search strategy (Ghosh & Jain (Eds), 2005; Akadi, Amine, Ouardighi & Aboutajdine, 2009; Dash, 2016) may be adopted from a set of heuristic or stochastic algorithms which can be able to generate an optimal subset effectively.

Rough set theory (RST) was introduced by Pawlak (1982) and has been used widely by researchers as a classifier and selection technique. Primarily, it removes redundant data (Dash & Patra, 2012) while keeping intact the characteristics of the problem for classification. The main drawback of rough set (Dash & Patra, 2013) is it cannot handle real valued data whereas microarray dataset contains all real valued gene expression data. In this case, the expression values of genes are discredited before being used and the dataset loses some information during this process which makes the dataset inadequate for analysis purpose. The best alternative to get rid of this problem is either using real valued rough set or fuzzy-rough set theory (Zahi, 2011; Jensen & Shen, 2004; Dash, 2015). Both of them handle the concept of vagueness and indiscernibility which is prevalent in most real life problems (Xu, Miao & Wei, 2009) by complementing each other.

The ensemble learning approach constructs several classifier models for the original dataset and then combines the predictive outputs to identify an unknown sample. The motivation of combining several classifiers is to improve the classification efficiency which in turn depends on the accuracy and diversity (Yang P., Yang H., Bing, Zomaya, 2010) of the base classifiers. The ensemble technique is very popular in the field of classification and pattern recognition as it increases the generalization and percentage of classification by aggregating (Chen, Hong, Deng, Yang, Wei & Cui, 2015) the outcome of finite number of neural network classifiers (Lee, Hong & Kim, 2009a). However, neural network ensemble learning has been used in many problems, such as, face recognition (Lee, Hong & Kim, 2009 b), digital image processing (Liu, Cui, Jiang & Ma, 2004) and medical diagnosis (Huang, Zhou, Zhang & Chen, 2000) and has given outstanding performance in terms of classification accuracy.

In this study, a hybrid gene selection model (Dash & Patra, 2012) is introduced by hybridizing fuzzy-rough filter model (FR) with an evolutionary genetic search based wrapper model (GSNN) (Ghosh & Jain (Eds), 2005). The efficiency of the hybrid model (FRGSNN) (Yang, Chuang & Yang, 2009) is evaluated by the proposed adaptive neural net ensemble learning algorithm. Again to prove the learning capability of ensemble algorithm, performance of the component classifiers pairing with FR, GSNN and FRGSNN are compared with proposed hybrid FRGSNN based ensemble model. In addition to this, efficiency of neural net ensemble is compared with two ensemble learning algorithms.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

The paper is structured in the following way: section 2 gives an outline of the proposed learning scheme followed by section 3 furnishing the background of rough set theory, fuzzy-rough set and genetic algorithm. Section 4 and 5 illustrate the proposed learning model and all eight microarray datasets respectively. Experimental setup, results, analysis of comparison of the model, discussion and future scope are presented in section 6. Section 7 presents concluding remarks followed by exhaustive references.

2. AN OUTLINE OF THE LEARNING SCHEME

In this section, an outline of the learning scheme is presented. For a given gene expression dataset, DATA, the proposed learning scheme will work as follows:

Step 1: Replace all missing values with the means of the dataset.
Step 2: *[Filter Method, FR]* Fragment dataset into lower and upper approximations using rough set theory; *DATA → (DATA+) U (DATA -).*
Step 3: Apply fuzzy-rough feature selection method to remove redundant features.
Step 4: Measure the quality of the features using weak gamma evaluator in fuzzy rough lower approximation.
Step 5: [*Wrapper Search, GSNN*] Use reduct sets as the candidate solution of the initial population of genetic search method.
Step 6: Construct a fitness function using KNN learning algorithm and evaluate the fitness values of current population.
Step 7: Chose two fittest chromosomes from the population and apply crossover and mutation to produce new population.
Step 8: Estimate the fitness function for new population and continue the process as long as the value of fitness function increases or the termination condition is satisfied.
Step 9: *[Hybrid search FRGSNN]* Select the optimal subset of features combining filter (FR) and wrapper (GSNN) search.
Step 10: Estimate effectiveness of the selected discriminatory subset using adaptive neural network ensemble consisting of three base classifiers such as Linear Vector Quantization (LVQ), Self-Organizing Map (SOM), Back Propagation algorithm (BP). Apply majority voting to combine probability distribution of base classifiers and evaluate predictive accuracy using test set / 10-fold cross validation method as performance evaluation measure.

3. BACKGROUND

3.1. Fuzzy Set Theory

Fuzzy set is an extension of conventional crisp set and was introduced by Zadeh (1965). A fuzzy set A is defined on a universe of discourse U, and is represented as a set of ordered pairs:

$$A = \left\{ \left(x; \mu_A \left(x \right) \right) \mid x \epsilon U \right\} \tag{1}$$

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

where $\mu_A(x)$ is the membership value of $x \in U$ in fuzzy set A. The mapping $\mu_A: U \longrightarrow [0, 1]$ is established through membership function $\mu_A(.)$ to evaluate membership values in set A.

3.2. Rough Set Theory

This mathematical concept was introduced by Z. Pawlak (1982) to handle vagueness which is complementary to the concept of fuzzy set. Rough set approximates the conventional set by a pair of sets known as lower and upper approximation of the original set. The approximation / information space is denoted by a pair $<U, A>$, where U is the universe of discourse and A is the knowledge of U and the information function f is defined as: $f: U \times A \longrightarrow V$, where V is the domain of A. Therefore, an equivalence/ indiscernibility relation IND (P) can be defined on a subset P of the knowledge set A on U as:

$$IND\left(P\right) = \left\{\left(x_i, x_j\right) \epsilon U \times U \mid \forall a \epsilon P, f_a\left(x_i\right) = f_a\left(x_j\right)\right\} \tag{2}$$

$IND\ (P)$ creates a partition on U which is denoted as:

$$U \mid IND\left(P\right) = \left\{\left[x_i\right] P : x_i \epsilon U\right\} \tag{3}$$

where $[x_i]_P$ represents equivalence class or information granules. The elements of $[x_i]_P$ are equivalent or indiscernible with respect to the subset of attributes $P \in A$.

Any given arbitrary set $X \dot{\subseteq} U$, can be characterized in the approximation space $<U, A>$ by a pair of lower and upper approximations is shown in Figure 1 and defined as:

$$Lower - P\left(X\right) = U\left\{\left[x_i\right]_P \mid \left[x_i\right]_P \subseteq X\right\} \tag{4}$$

$$Upper - P\left(X\right) = U\left\{\left[x_i\right]_P \mid \left[x_i\right]_P \cap X \neq \Phi\right\} \tag{5}$$

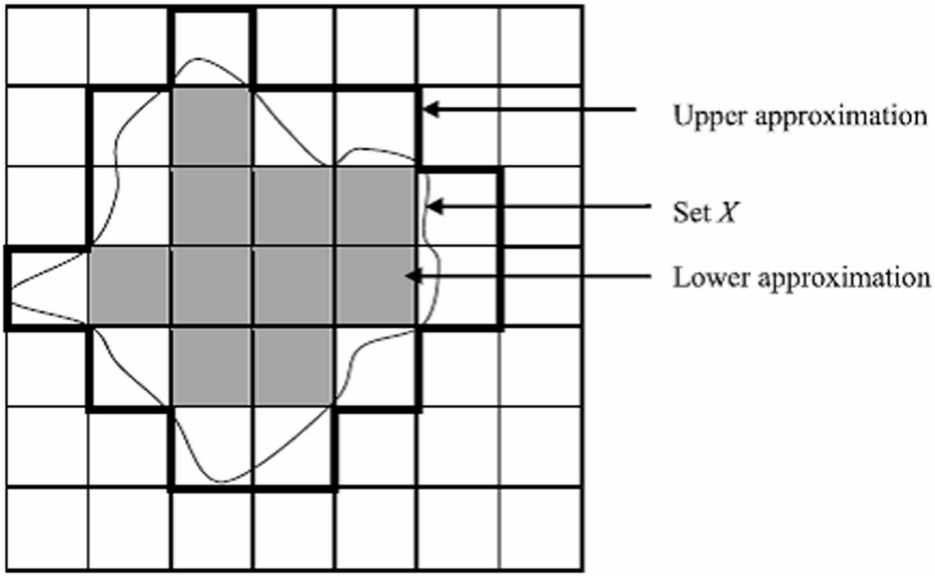
Now, set X can be represented as a pair of elements or tuple $<Lower\text{-}P(X), Upper\text{-}P(X)>$ in the approximation space $<U, A>$ and can referred to as rough set of X. Hence, $Lower\text{-}P(X)$ / $Upper\text{-}P(X)$ is the collection of those elements of U that belongs to X positively / possibly. The $Lower\text{-}P(X)$ is also called positive region and denoted as $POS_P(X)$.Set X is termed as exact set in $<U, A>$ if $Lower\text{-}P(X) = Upper\text{-}P(X)$ otherwise called a rough set. Boundary set is denoted by $BN_P(X) = Upper\text{-}P(X) \setminus Lower\text{-}P(X)$.

3.3. Fuzzy-Rough Sets

Rough sets generate a family of crisp equivalence classes by making crisp partitioning of the universe. Similarly, a family of fuzzy equivalence classes are generated by fuzzy equivalence relation or fuzzy knowledge granule (Jensen & Shen, 2004) by inducing a fuzzy partition on the universal set.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. Lower and upper approximations of a rough set, X



Let represent the fuzzy equivalence space (Zhai, 2011) by <*U, A*> and a fuzzy subset of *U* by *X*. This indicates all decision and condition attributes are fuzzified. Then *fuzzy Lower-P and Upper-P* approximations can be defined as (Jensen & Shen, 2004):

$$Lower - \mu_{PX}\left(F_i\right) = \inf_x \left\{\max\left\{\left(1 - \mu_{FI}\left(x\right)\right).\mu_X\left(X\right)\right\}\right\}, \forall i \tag{6}$$

$$Upper - \mu_{PX}\left(F_i\right) = \sup_x \left\{\min\{\mu_{FI}\left(x\right)), \mu_x\left(X\right)\}\right\}, \forall i \tag{7}$$

where F_i is fuzzy equivalence class belongs to *U/P* and $\boldsymbol{\mu}_X(x)$ is the membership of x in X. However, the above definitions of fuzzy approximation deviate from the crisp upper and lower approximation, as the memberships are not available explicitly for all objects in the approximation space. Hence, fuzzy lower and upper approximations can be defined as (Xu, Miao & Wei, 2009):

$$Lower - \mu_{PX}\left(x\right) = \sup_{FI \in \frac{U}{P}} \min\left\{\mu_{FI}\left(x\right), Lower - \mu_{PX}\left(F_i\right)\right\} \tag{8}$$

$$Upper - \mu_{PX}\left(x\right) = \sup_{FI \in \frac{U}{P}} \min\left\{\mu_{FI}\left(x\right), Upper - \mu_{PX}\left(F_i\right)\right\} \tag{9}$$

Now the tuple <*Lower-P(X), Upper-P(X)*> is called a fuzzy-rough set which can be used for selecting real valued attributes from fuzzy lower approximation space.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

3.4. Genetic Algorithms

Genetic algorithms are evolutionary optimization methods motivated by biological phenomenon of natural selection and evolution and have wide applications in many different problems (Lee, Hong & Kim, 2009; Dash & Patra, 2013). It generates new population of chromosomes that is considered as the candidate solution in the iteration. Each chromosome is encoded as a string of binary, real, etc., version of a candidate solution. The fitness of each string of chromosome is then evaluated by a fitness function *f(x)*. Two fittest chromosomes having more fitness value are likely to be selected from the population and the genetic operator crossover and mutation are applied to generate new offspring from new population. The variation is introduced to the selected individuals for obtaining global optimum solution using crossover and mutation (Park & Cho, 2003; Luque-Baena, Urda, Subirats, Franco & Jerez, 2014).

4. THE PROPOSED LEARNING SCHEME

4.1. Evolutionary Hybrid Fuzzy-Rough-Genetic Search Method for Feature Selection

The first key element of the hybrid-FRGSNN model is its fuzzy-rough feature selection method which computes the reduct sets. Then an evolutionary search based wrapper model GSNN is employed on the outcome of filter FR method to select an optimal subset of features which is the outcome of the hybrid search FRGSNN model. Genetic algorithm is adopted here as a search tool to perform this operation. The reduct sets produced from fuzzy rough reduction process is used as the population of the genetic search which generates a reduced set of individuals in each new generation. In this scheme, *KNN* is used as a fitness function to evaluate the fitness of each individual elected from the population and then the operators like crossover and mutation are applied to reproduce new offspring. The primary motive of the proposed method is to optimize the search process to identify subset of features which improves the classification accuracy. It also focuses on reducing the size of the selected subset without compromising the accuracy rate of the problem. The detail configuration of genetic search is given below:

- **Encoding of Chromosome:** Each individual in the solution space is encoded in to a string of binary bits called chromosomes. Each bit of the string represents the state of each feature/gene in the reduct set derived from fuzzy-rough filter model (1 if feature is selected else 0).
- **Crossover:** A two-point crossover mechanism is employed to swap the substrings between the two points selected to generate new offspring.
- **Mutation:** Crossover cannot provide a satisfactory result if the encoded information of the population is not sufficient to solve the given problem. In such cases, a flip bit mutation operator is applied to the new offspring to generate a new chromosome spontaneously.
- **Selection:** Selection operator selects eligible parents for mating for the next generation. The parents are selected with a selection probability which is proportional to their fitness values. This operation is analogous to survival of the fittest in theory of evolution. In the proposed hybrid-FRGSNN model a binary tournament procedure will be used for selection of parents in each generation.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

4.2. Proposed Neural Network Ensemble for Classification

Adaptive neural network (Liu, Cui, Jiang & Ma, 2004; Luque-Baena, Urda, Subirats, Franco & Jerez, 2014) consists of a large number of massively interconnected neurons which function simultaneously to find solution of problems. Adaptive neural network (Lee, Hong & Kim, 2009) has the ability to learn how to perform tasks based on the data given for training or initial experience. Neural networks are efficient in recognizing patterns and classifying data in a large dataset with little information. They are best suited for predicting high dimensional datasets like microarray datasets. The architecture of the multilayer neural network consists of three types of layers of neurons such as input, hidden and output layer. The behaviour of the neural net increasingly depends on the connections between the components. These inputs and weighted connections between input and hidden layers determine the performance of the hidden layers. Similarly the performance of output layer is determined by the weight vector connecting hidden and output layer neurons. The objective of the network is to establish a mapping function which can minimize the error between desired and estimated output.

A single neural network cannot build a stable and generalized learning model for finding optimal solution for some specific problems. In this paper, we have ensemble (Yang P., Yang H., Zhou & Zomaya, 2010; Hansen & Salomon, 1990) three variants of neural networks such as LVQ, SOM and BP, in an attempt to find an efficient solution to this problem. Usually, the learners show some biasness to different attribute selection models (Zhou, Jiang, Yang & Chen, 2002). The performance of the ensemble depends on the meta-algorithm which aggregates the output of individual classifiers. A simple combination rule like majority voting has been applied in combining the resultant of the classifiers. The majority voting consensus for *k* classifiers in a given *n* classifiers where:

$$k = \begin{cases} \frac{n}{2} + 1 if\, n\, is evven \\ \frac{n+1}{2} if\, n\, is odd \end{cases}$$

The component classifiers used in the ensemble classifier namely LVQ, SOM and BP are combined and aggregated as a consensus committee. The subset of features produced by evolutionary fuzzy-rough feature selection phase will be fed into the ensemble classifier. The three base classifiers contained in this ensemble will use the input features to learn and classify the dataset separately. Finally, majority voting is used for calculating the consensus from the classification accuracy obtained from each classifier by using certain feature combination. Many significant advantages of ensemble learning algorithm over individual have been shown by many authors (Tan & Gilbert, 2003; Rosenwald, 2002).

The multi-net systems i.e., combination of a finite number of neural networks (Zhou, Jiang, Yang & Chen, 2002) has been used in different areas of research shown in Figure 2. The combined output of more than one classifier often provides improved accuracy over the output of individual network. However, the recent study of computational biology has witnessed an increasing use of ensemble learning because of the unique advantages in handling complex data structure, small sample size and high-dimensionality. The aim of this kind of ensemble learning is to achieve better generalization by combining the outputs of individual networks. The advantages of the ensemble learning i.e., how the problem of stability of the classifier can be improved compared to an individual classifier has been demonstrated in (Hansen & Salomon, 1990; Tan & Gilbert, 2003; Jiang, Yang & Chen, 2002).

5. DATASETS ILLUSTRATION

A large amount of gene expression data is available in several datasets. In this paper, eight publicly available gene expression datasets are being used to evaluate the performance of the proposed feature selection and classification scheme. First five datasets, namely, DLBCL-NIH, DLBCL-Stanford, DLBCL-Harvard, CNS embryonal tumour outcome and Lung Harvard are collected from http://datam.i2r.a-star.edu.sg/datasets/krbd/ and last three, namely, ALL-AML, Brain Tumour and SRBCT are collected from http://www.gems-system.org/ which are illustrated in Table 1.

6. EXPERIMENTAL RESULTS AND DISCUSSION

In this paper, eight microarray datasets are used to ascertain the validity of the projected scheme. Out of these eight datasets, five datasets i.e., DLBCL–NIH, DLBCL-Stanford, DLBCL-Harvard, Central system (CNS) and ALL-AML are of binary category and the remaining three i.e., Lung-Harvard, Brain-Tumor-GEMS, SRBCT-GEMS belong to multi-class datasets. DLBCL data samples are taken from three different sources and studied their behaviour applying the proposed scheme. The databases utilized in this experiment are summarized in Table 1. All the learning algorithms used in this work are taken from WEKA machine learning package.

The experimental method is composed of feature selection and classification method. In feature selection process, the proposed hybrid FRGSNN model is applied to all datasets to identify subset of potential genes/ biomarkers by reducing the computational complexity of the problem. Traditional feature selection methods such as FR-filter and GSNN-wrapper model are applied to all datasets for comparison purpose. The parameters of genetic search algorithm used in wrapper and hybrid model are set as follows: crossover probability = 0.6, mutation probability = 0.033, maximum generation = 50 and population size = 100. The potential genes identified by hybrid FRGSNN, FR-filter and GSNN-wrapper are recorded in Table 3 for all the datasets. Then the representative subset of genes obtained from the above processes is classified by the proposed ensemble model and other learning algorithms. In addition to this, the reduced set of features are classified by classical ensemble methods namely, bagging, boosting and an advanced SVM ensemble. The performance of the learning algorithms is validated by using test dataset for DLBCL-NIH, ALL-AML and Lung cancer and ten-fold cross validation was applied to measure the statistically reliable predictive accuracy for the remaining datasets.

The proposed neural network ensemble is trained with three component neural networks and then combines the outputs of all the networks into an integrated output using majority voting (Liu, Cui, Jiang & Ma, 2004; Kuncheva, 2004). The subset of features is fed to each component classifiers, Bagging, Boosting ensembles and to the proposed ensemble for each dataset. Then the classification accuracy of each component classifiers and classical ensembles are compared with the accuracy obtained from proposed ensemble classifier. For all base neural network classifiers, the parameters are set as follows: BP learning is configured with 10 hidden nodes in a single hidden layer, output nodes equivalent to number of class of the datasets, learning rate varies from 0.01~0.10, momentum equals to 0.9 and maximum number of iterations fixed to 500. In LVQ learning, codebook vectors are fixed to 25, learning rate varies in the range 0.01~0.10, learning function is set to static, momentum sets to 0.1 and maximum iterations is 1000. In SOM learning, a 5 x 5 rectangle shape initial map is set with neighbourhood size 16, learning function sets to static, learning rate varies within the range 0.1~0.9 and maximum iterations is set to 2000. When they are used as independent classifiers, a small variation is made to the above parameters for learning purpose.

In this study, predictive accuracy *(A_{CC})* and kappa statistic *(k)* are used to measure the performance of learning algorithms. Predictive accuracy is computed using four base line statistical components (Liu, Cui, Jiang & Ma, 2004; Dash & Behera, 2016) namely, TP and FN denote the number of positive samples which are accurately and falsely predicted, respectively and TN and FP represent number of negative samples that are predicted accurately and wrongly, respectively:

$$A_{CC} = TP + TN / (TP + TN + FP + FN) \tag{10}$$

where TP denotes the correct classifications of positive samples, TN represents correct classifications of negative samples, FP represents the incorrect classifications of negative samples into positive class and FN is the incorrect classifications of positive samples into negative class. The description in Table 2 gives four baseline statistical components, where TP and FN denote the number of positive examples which are accurately and falsely predicted, respectively, and TN and FP represent the number of negative samples that are predicted accurately and wrongly, respectively.

Kappa statistic (*k),* as a statistical metric, measures the percentage of agreement (Kuncheva, 2004) between accuracy and diversity of base learners, which is shown along with the ensemble performance. The reliability of classification is measured using the formula:

$$k = \text{observed agreement} - \text{chance agreement} / (1 - \text{chance agreement}) \tag{11}$$

The value of *k* ranges from 0 to 1, when k= 1 shows a better agreement than value 0.

Table 2. Confusion matrix

	Predicted positive class	**Predicted negative class**
Real positive class	True positive (TP)	False negative (FN)
Real negative class	False positive (FP)	True negative (TN)

Table 3. Selection of genes using FR-filter, GSNN-wrapper and hybrid FRGSNN method

6.1. Results

We have aimed at finding a generalized prediction model for both binary and multi-class problems by exploiting the capability of ensemble by combining the output of base classifiers for predicting the solution of the problem. In this paper, we have compared the predictive accuracy of individual base learners as well as some established ensembles with the proposed ensemble neural network for all the available datasets using feature selection techniques.

Table 4 summarizes the classification accuracy of each component classifiers and proposed neural network ensemble on the subset of genes obtained from FR-filter, GSNN-wrapper and hybrid FRGSNN model. When results of the pair <FR-filter, classifier> and <GSNN-wrapper, classifier> compared with <hybrid-FRGSNN, classifier> methodology, it is observed that the pairing of proposed ensemble with hybrid-FRGSNN model yields better performance and also statistically significant difference is observed in all the datasets. It can also be observed from last column of Table 4 that hybrid FRGSNN model selects only 0.96% of genes from the largest Lung cancer dataset, 0.63% from CNS which is least and highest percentage 3.08% of genes from DLBCL-Stanford dataset.

The predictive accuracy of proposed ensemble algorithm for reduct set of genes obtained from FR-filter is better than the performance of component neural network learning algorithms. Similarly, for GSNN-wrapper model, comparison of results show a significant performance obtained by proposed ensemble method for six datasets achieving more than 90% accuracy. But, a highly remarkable performance is observed by ensemble method for the genes obtained from hybrid FRGSNN model for all the datasets in comparison to component classifiers. The analysis clearly indicates that the proposed learning scheme outperforms the predictive results of all three component classifiers. The same conclusion is drawn when compared with the findings of (Lee, Hong & Kim, 2009; Liu, Cui, Jiang & Ma, 2004; Tan & Gilbert, 2003).

Table 4 also provides a comparison between the classification accuracy of proposed ensemble classifier and the value of kappa statistic *(k)* for all the subsets. The classification accuracy and the value of kappa statistic *(k)* obtained from the proposed learning scheme has established a proper balance between accuracy and diversity. It is worth to note that, a small value of k denotes high diversity among the learners. Kappa statistic k measures the diversity between the pair of base learners, which is shown along with the ensemble performance. Hence, proposed method has achieved proper balance between diversity and accuracy and at the same time fulfilled the objective of finding a generalized prediction model.

Table 5 summarizes the predictive accuracy of the proposed ensemble and other ensembles such as B**agging and Boosting** for the subset of genes obtained from hybrid FRGSNN model for all the datasets. The analysis of the table proved that the other three ensembles work effectively for a particular microarray dataset, i.e., bagging performs well for ALL-AML, boosting does for Lung-Harvard using hybrid FRGSNN model. The predictive results obtained by Bagging and Boosting ensemble are not consistent across the datasets whereas the results obtained by neural network ensemble are remarkably significant across all the datasets.

Figure 3 shows the estimated accuracy obtained by all datasets using elementary classifiers such as LVQ, SOM, BP and the proposed neural network ensemble where Vote combines probability distribution of all three neural networks such as LVQ, SOM and BP using majority voting combination rule. We can see the accuracy obtained by ensemble is better for DLBCL-Harvard, ALL-AML, Lung-Harvard and Brain Tumor than other datasets. Here the performance of ensemble is enhanced by the hybrid FRGSNN

feature selection method which selects optimal subset using genetic search. The accuracy of ensemble is ranges from 69.375% ~ 98.3333% with average of 83.854% whereas for element classifiers it ranges from 64.126% ~ 93.9759% with average of 79.44683%. This analysis clearly demonstrates, the proposed neural network ensemble outperforms the efficiency of element classifiers for all three types of feature selection methods (Lee, Hong & Kim, 2009; Liu, Cui, Jiang & Ma, 2004; Tan & Gilbert, 2003).

Table 6, shows the comparison of predictive results based on test set with the results published by Liu et al. (2004), Heesung Lee et al. (2009) and Tan and Gilbert (2003) for two major datasets. Again proposed learning scheme achieves 100% result which is significantly better than Tan and Gilbert (2003)

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 6. Comparison of predictive accuracy using test set

Author	Ensemble Classification	Datasets	
		ALL / AML	Lung
Tan and Gilbert (2003)	Bagged DT	91.18	93.29
Liu et al. (2004)	Neural Network Ensemble	100	100
Hessung Lee et al. (2009)	Neural Network Ensemble	98.82	-
Proposed Learning scheme	Neural Network Ensemble	99.444	100.00

Table 7. Comparison of predictive accuracy using 10-fold CV

Author	Ensemble Classification	Datasets	
		CNS	DLBCL
Tan and Gilbert, 2003	Bagged DT	88.33	-
Liu et al., 2004	Neural Network Ensemble	-	95.74
Proposed Learning Scheme	Neural Network Ensemble	99.67	100.00

for ALL-AML and Lung cancer in comparison to the results obtained by Liu et al (2004). In Table 7, using 10-fold cross validation, Tan and Gilbert (2003) reported 88.33% predictive accuracy for CNS and 95.74% for DLBCL reported by Liu et al. (2004) which is less than the proposed one.

6.2. Discussion

Feature selection plays an important role in enhancing the classification accuracy of the problem. Potential features influence the predictive ability of the classification model. In this study, a hybrid feature selection method and an ensemble neural network classifier are introduced for selection and classification of gene expression datasets. The proposed method outperforms the results published by other authors. We found the discrimination ability of the ensemble classifier is highly significant when search strategy like filter, wrapper and hybrid methods are concerned. Further, we used the same features for predicting component classifiers such as BP, SOM and LVQ and for two other ensembles such as bagging and Boosting and found that the results are not better than the proposed one. Hence, these significant improvements of the proposed scheme can be attributed to the fact that the evolutionary hybrid feature selection mechanism optimizes different combinations of genes that enhances the classification accuracy thereby improves the stability and generalization capability of the ensemble network.

The most important issue in ensemble learning is to establish a proper balance between the accuracy and diversity of the constituent base learners. In fact, the base learners used in an ensemble classifier need to have high classification accuracy and should avoid making misclassification errors. The diversity would be more among base learners if the misclassification error increases in the process of classification. It is also evident from Table 4 that the proposed methodology could provide a generalized prediction model which is the main objective of this research (Yang, Huei, Chuang & Yang C. Hong, 2009; kuncheva, 2004). In order to measure the level of agreement between a pair of base learners, a k-metric or kappa statistic (kuncheva, 2004) is used while correcting the chance.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

We believe that, ensemble classifiers are more appropriate for bioinformatics problems because it helps to design classifiers from noisy and incomplete data. Another inherent problem of microarray data is the relatively small number of samples compared to the dimension of the dataset. This problem is really a difficult task for a single learning classifier to induce an optimal hypothesis for this type of dataset. This can be appropriately addressed by ensemble learner which combines component classifiers. As a result, the network becomes stable and attains global minima instead of being trapped in local minima. But how many component classifiers need to be combined to capture the true hypothesis is still an open problem.

In this problem, we emphasized both feature selection and classification aspects of the problem. But we have not studied the importance of individual gene and relation among them which specifically help to get more information about the disease. This aspect of the problem is left for our future research.

7. CONCLUSION

Experimental results show that the evolutionary feature selection techniques effectively selected subset of marker genes for each component learner and increased the discriminatory power of the neural network ensemble. Also it is evident from the study that ensemble classifier performs better than classical ensembles and component classifiers for all datasets. The proposed method has achieved the highest averaged generalization ability compared to its counterparts and established an acceptable level of diversity among the base learners for majority of the analyzed benchmark datasets.

KEY TERMS AND DEFINITIONS

Ensemble Method: Ensemble methods are learning algorithms that construct a set of classifiers and then classify new data points by taking a weighted vote of their predictions. It's of two types: homogeneous and heterogeneous ensemble.

Fuzzy-Rough Feature Selection (FRFS): Provides a means by which discrete or real-valued noisy data or a mixture of both can be effectively reduced without the need for user-supplied information.

Genetic Algorithm: Genetic algorithms are evolutionary optimization methods motivated by biological phenomenon of natural selection and evolution.

Hybrid Ensemble Learning: The potential of ensemble learning is augmented by combining the characteristics of another learning algorithm

Neural-net Ensemble: Neural network ensemble can significantly improve generalization accuracy of networks by training several networks and combining their results.

Chapter 37
Wired and Wireless Distributed e-Home Healthcare System

ABSTRACT

The proactive development in electronic health (e-health) has introduced seemingly endless number of applications such as telemedicine, electronic records, healthcare score cards, healthcare monitoring etc. Yet, these applications confront the key challenges of network dependence and medical personnel necessity, which hinders the development of universality of e-health services. To mitigate such key challenges, this chapter presents a versatile wired and wireless distributed e-home healthcare system. By exploiting the benefit of body sensor network and information communication technology, the dedicated system model methodically integrates some of the comprehensive functions such as pervasive health monitoring, remote healthcare data access, point-of-care signal interpretation and diagnosis, disease-driven uplink update and synchronization (UUS) scheme and emergency management to design a complete and independent e-home healthcare system.

INTRODUCTION

Along with socioeconomic progress and development, three global crises come into being that threatens human medical service industry, including population aging, prevalence of chronic diseases, and soaring health cost. Driven by falling fertility rate and increasing life expectancy, older population (above age 65) is escalating with surprising speed and will outnumber young children (under age 4) in the very near future. As reported by World Health Organization (WHO, 2011), between 2010 and 2050, the propor-

tion of older adults will double from 7.7% to 15.6%. While global population aging represents a triumph of medical, social, and economic advances over diseases, it also presents tremendous challenges to the society and healthcare services. What's more, such demographic changes result in inevitable increase in the prevalence of chronic diseases or non-communicable diseases (NCDs). As the leading cause of fatality throughout the world, according to Mathers and Loncar (2006), NCDs take up 63% among the total deaths and the aged-related NCDs mortality is projected to rise to 69% in 2030. Among the four main types of NCDs, cardiovascular disease (CVD) is prevalent and closely linked with aging population. According to the survey conducted by WHO in 2008, 17 million, which represents 30% of global deaths, were due to CVD and it is estimated that by 2030, this could further increase to 23 million. To effectively prevent the mortality rate due to CVD, early detection and timely treatment would be the ideal choice. However, this imposes huge burden on the medical personnel during long-term monitoring and diagnosis. To make things worse, the cost of healthcare service is increasing continuously and outpaces economic growth in gross domestic product (GDP). As revealed by the third national health survey by Liu et al. (2007), during 1998–2003 the annual increase of healthcare expense was 11.8% whilst the average income of people in rural areas increased by only 2.4% annually during the same period. The skyrocketing health cost not only prevents lot of people from seeking for early medical care, but also brings about large disparities in service quality and accessibility among different income groups and between rural and urban populations (Powell, 2005).

Therefore, in view of demographic and epidemiologic needs and escalating expenditure of the current healthcare system, improving healthcare service is a top priority issue throughout the entire world. Targeting at developing long-term, low-cost, sustainable, and accessible healthcare service, practical enactment of taking preventive measures in the traditional healthcare environment has always been a challenge. Thus, exploiting the advancement of multiple key technologies including information & communication technology (ICT), mobile technology, wireless body sensor networks (WBSN), intelligent technology etc., research over the past decade has focused on improving the quality, safety and efficiency of healthcare services by creating an electronic healthcare (*e*-healthcare) environment. With the aim to provide healthcare to anyone, anytime and anywhere, the development of *e*-healthcare has not only improved the convenience and quality of healthcare services towards patients and healthcare consumers, but also has drastically facilitated medical personnel to pursue early detection and diagnosis of various pathologies. In realizing the vision of *e*-healthcare systems, there exist numerous technical and non-technical challenges. Here, some of the crucial requirements and challenges are listed as follows.

1. **Privacy and Security:** Since wireless/wired transfer of biomedical signals and pathological information are concerned in *e*-healthcare systems, user privacy should be guaranteed to avoid malicious and illegal abuse. Security of the entire system, WBSN, and wireless/wired network is of great significance (Kara, 2001; Zhang et al., 2002);
2. **Reliability:** To ensure the successful message transfer between healthcare consumers and providers, reliability of the networks should be strictly controlled with low error tolerance. Particularly for wireless network, robust infrastructure and protocols are demanded to support the reliability and quality of wireless communication (Varshney, 2007);

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

3. **Patient Engagement:** Taking into consideration of various users with varying education level/ knowledge, an accessible *e*-healthcare system with user-friendly operations and comprehensible functions are desired. Especially for elder population who have very little interests in accessing state-of-the-art technologies, the key challenge allies on effectively engaging them to properly use such systems (White et al., 2006);
4. **Interoperability:** With the advent of more and more *e*-healthcare systems, interoperability may become a serious issue, such as semantic intelligibility (Adibi, 2012), interoperability between different platforms, interference with medical devices (Varshney, 2007), etc.
5. **Agreement and Other Management Issues:** Such as ownership of medical and health data, multilayer infrastructure management (Adibi, 2012), payment (Varshney, 2007), etc.

During the past decades, many *e*-healthcare systems have been proposed (Adibi, 2012; Caldeira et al., 2012; Kyriacou et al., 2003; Niyato et al., 2009; Patra et al., 2009; Ren et al., 2010; Varshney, 2007; Wang et al., 2010; White et al., 2006;). Such developments include remote health monitoring (Varshney, 2007; Ren et al., 2010; Niyato et al., 2009; Wang et al., 2010), telemedicine (Kyriacou et al., 2003), electronic health records (EHR) (Patra et al., 2009), intelligent emergency management system, medical information management system etc. Some of the successful models from literature include a remote patient monitoring system by integrating multiple wireless technologies (Niyato et al., 2009). In this model, before delivering the acquired signals to healthcare service provider, heart rate is first recorded and its severity is analyzed. If the heart rate is examined to be in the critical range, the medical record of that particular patient is transmitted to the hospital with higher priority by temporarily bypassing all the other patients' data in queue. Based on telecommunication technology, a telemedicine system is proposed in (Kyriacou et al., 2003). Such a system consists basically of two units: telemedicine unit at hospital site for performing effective emergency management and a base unit at patient's location for receiving and displaying the incoming data to the patient. Also to support the functional operation of telemedicine, literature show that researchers have explored various key technologies to enable remote health record access, a distributed EHR system (Patra et al., 2009) could be cited as a particular example. Finally, with the trend of developing mobile health (m-health) system on mobile devices, Adibi (2012) presents an m-health solution on BlackBerry mobile phones. It uses mobile networks (3G/4G), mobile phones work as a transmission and communication platform for end-to-end data transmission.

Yet, it is evidenced that though such developments offer various benefits for improving healthcare services, they suffer from some critical challenges. First of all, such systems are incapable of self-diagnosis and leave the burden of interpretation to hospital doctors. This in fact increases the burden on medical personnel as they are now required to attend to both on-site and remotely connected patients. Secondly, these systems are network dependent and rely on cable or wireless network to transmit signals and receive results from hospital server or centralized computation station, thus such models are not suitable for rural areas or network unavailable users.

In light of above, this chapter focuses on transforming the hospital-rescue-centered healthcare scheme to patient-prevention-centered approach and introduces a framework of wired and wireless distributed *e*-home healthcare system for CVD health monitoring. The dedicated system principally integrates the comprehensive functions, such as pervasive health status monitoring, remote healthcare data access, point-of-care signal interpretation and diagnosis, disease-driven uplink update and synchronization (UUS) scheme and as well as emergency management to support various users diversified medical demands.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

The functional architecture of the proposed model consists of three functional modules, namely upstream (hospital server), midstream (patient's local computer) and downstream (embedded-link mobile devices). In the downstream, the biomedical signals, specifically electrocardiogram (ECG), sphygmogram (SPG) and heart sound (HS) are acquired from the subject with the proposed multi-vital sign acquisition system. To efficiently work with the resource limitation of portable mobile devices in downstream, a preliminary health monitoring model is designed to monitor the cardiac condition through analysis of hemodynamic parameters derived from SPG signal. Through exploiting the advancement in AI technology, an efficient and more reliable intelligent monitoring and diagnosis model is built on the local computer in midstream. The proposed model in midstream executes a hierarchical analysis and interpretation of various biological signals to provide comparatively more reliable point-of-care to the user. Finally, as both down- and mid-stream form as independent health monitoring modules implemented in the portable mobile devices and local computers for home users respectively, it becomes critical to introduce some element of intervention during emergency and necessity situations. Thus, upstream module which is installed in the hospital server is developed. The upstream module is mainly designed with a top-level intelligent CVD monitoring and diagnosis system (TICMD). As the users of *e*-home healthcare system ultimately rely on the diagnosis made by upstream module during emergency and necessity situations, the proposed TICMD system employs both non-invasive biological signals such as SPG, ECG, HS etc., and invasive blood test parameters (BTP) to diagnose various CVD. With the support of a stronger knowledge base from doctors and data base from acquired patients' records, the diagnosis results are highly accurate. Through implementing system-level hierarchical diagnosis, both on-line and locally off-line diagnosis with ranked accuracy is delivered to users, thus satisfying various user demands in varying situations.

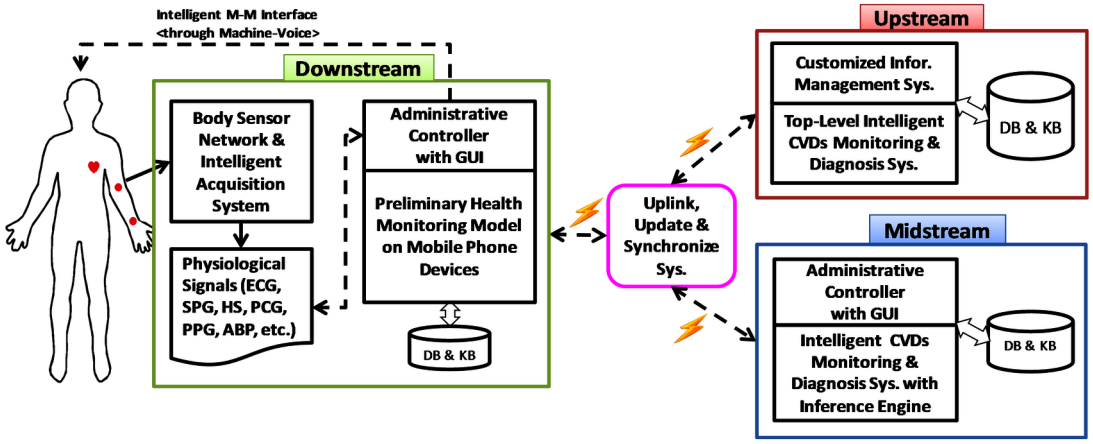
Finally, to systematically interconnect the three modules of *e*-home healthcare system, an UUS scheme is proposed. The UUS acts as a specialized backyard on-line assistance to support the communication between thousands of home users, healthcare center and hospital server. Thus, allowing the distributed *e*-home healthcare system to work as a whole. The main benefit of the proposed *e*-home healthcare system is that at normal conditions it would function independently and only at emergency situations it would automatically connect with hospital server for further support.

FUNCTIONAL ARCHITECTURE OF DISTRIBUTED *e*-HOME HEALTHCARE SYSTEM

The functional architecture of distributed *e*-home healthcare system for CVD health monitoring is illustrated in Figure 1. The proposed architecture can be majorly divided into three functional modules, which include the downstream (embedded-link devices e.g. smart phone, iPad, PDA etc.), midstream (local computer) and upstream (hospital server). Furthermore, these modules are interconnected by a mutual network communication through our proposed UUS system. The hierarchical ordering of the modules also represents the hierarchical diagnosis process, in the sense that the downstream with its limited computational ability, storage space and knowledge base (KB) serves with a quick preliminary diagnosis results. Subsequently the midstream, which consists of an intelligent diagnosis model, designed using various signal processing techniques and hybrid artificial intelligence (AI) technologies provides a better diagnosis results in a home healthcare environment. Finally, the upstream which incorporates KB from hospital with the information acquired from mid-stream and down-stream, provides a high-precision diagnosis results to the patient.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. Overall functional diagram of the wired and wireless distributed e-home healthcare system for CVD diagnosis



Now, to decide on which of the above module would be sufficient or necessary to make an efficient and reliable diagnosis decision, the UUS is introduced. UUS basically acts as the backend support and remote assistance system which interconnects the down- and mid- stream with the up-stream of the system model. Whenever the diagnosis system in lower streams encounters doubt in the results or failed diagnosis caused by insufficient KB, the UUS is triggered to send help request to the remotely-linked upstream. UUS principally manages the requests, feedback the absent KB rule to lower streams and perform re-diagnosis with the help of customized information management system built using abundant KB rules and comprehensive data base (DB) of all user clients' information. Overall, the key significance of UUS is that it covers the deficiency and limitation in lower streams and supports various user demands, thereby effectively supports the functionality of the overall distributed *e*-home healthcare system.

In the following sections, to understand the operation of the proposed wired and wireless distributed *e*-home healthcare system, in this chapter the key features and operation of each functional module will be further elaborated in details.

Downstream Functional Module

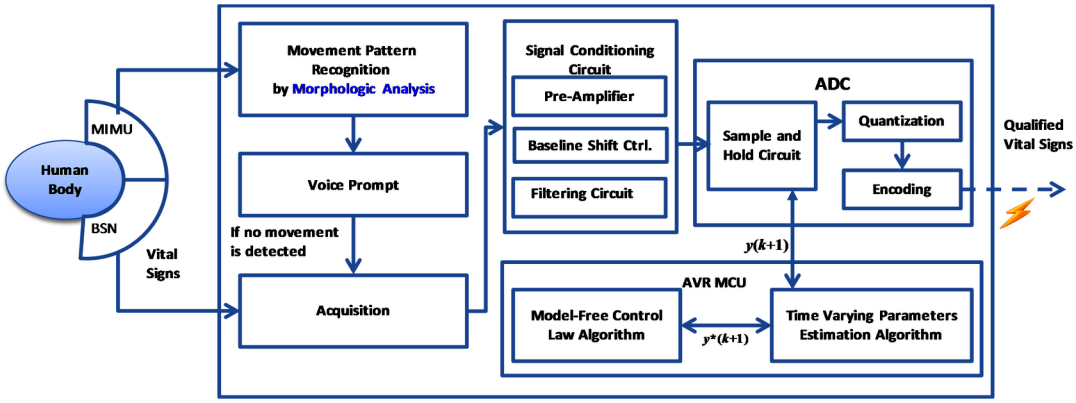
The downstream mainly comprises of an intelligent portable/wearable biological signal acquisition system and a preliminary health monitoring model designed based on WBSN and embedded link system. The main functionality of the downstream is to efficiently acquire and store multi-vital signs including ECG, SPG and HS from the subject and provide preliminary health monitoring status of the patient.

Intelligent Wearable Biological Signal Acquisition System

The rapid advancement in wireless communication and network technologies, linked with the progress of multi-sensor data fusion and miniaturized pervasive health monitoring devices, led to the evolution of WBSN and embedded link system technologies. To facilitate the research and development (R&D) of pervasive health monitoring system, such key technologies are exploited to design the architecture of an intelligent portable/wearable multi-vital sign acquisition system.

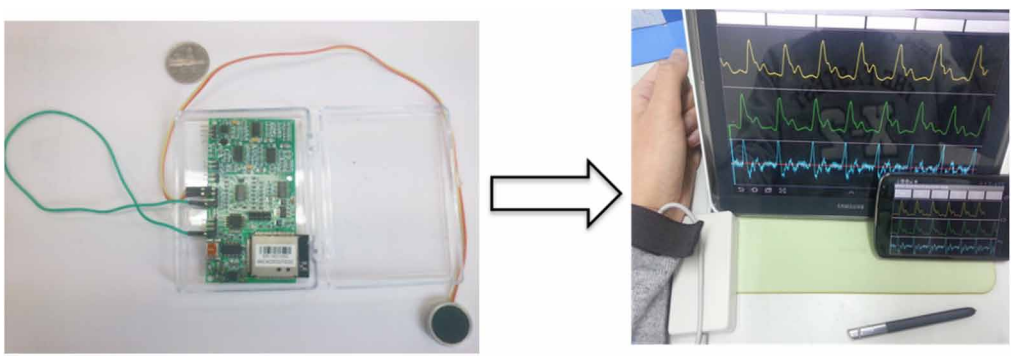
EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. Architecture of an intelligent portable/wearable multi-vital sign acquisition system



The designed multi-vital sign acquisition system presented in Figure 2 comprises of biosensors, micro inertial measurement unit (MIMU), signal pre-processing and conditioning module and a closed-loop control unit. The biosensors attached to the user through embedded link system detect multi-vital sign, whereas the MIMU detects any physical movement hindering the stable biological signal acquisition process. Through the proposed spatial movement tracking and pattern recognition approach (Gan et al., 2014), MIMU recognizes the movement pattern of the user and immediately initiates a voice prompt to guide the user in proper operation of the biological signal acquisition system. Once the MIMU detects stabilized movement pattern, the bio-sensors attached to the user through embedded link system would automatically sample and record the biological signals. The sampled signals would then be subsequently processed in the signal pre-processing and conditioning module. Here, the sampled signals are de-noised through filtering and normalized with pre-amplification and baseline shift. In addition, a closed-loop control unit with an analog to digital (ADC) converter is constructed with automatic voltage regulator (AVR) and micro control unit (MCU) to adaptively self-adjust and record stable multi-vital sign. A prototyping system designed with the proposed architecture is presented in Figure 3. Here, the designed embedded-link device transmits the acquired multi-vital sign to the portable device in the downstream and to the patient's local computer in the midstream through wireless/wired transmission for further analysis, interpretation and diagnosis.

Figure 3. Architecture of an intelligent portable/wearable multi-vital sign acquisition system



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

One aspect worth noting here is that as the proposed model is designed to be linked with portable devices such as smart phone, iPad, PDA etc., minimum storage space becomes the main limitation. However, massive multi-media medical data generated during long-term monitoring and diagnosis not only imposes a huge threat to such source-limited devices in terms of efficient storage but also introduces unaffordable burden during band-restricted mutual communication. To address such key challenges, an effective and reliable data compression technique to efficiently store and retrieve biomedical signal is proposed by hybridizing adaptive Fourier decomposition (AFD) and symbol substitution (SS) technique (Ma et al., 2015). The functional design of proposed method for compressing and decompressing biomedical signals is depicted in Figure 4.

In the proposed model, for biomedical signal compression, two stages are considered. First, after projecting the input signals into hardy space, AFD performs lossy compression by decomposing projection signals into weighted polynomial basis components in modified Takenaka-Malmquist (TM) system (Qian et al., 2011). Different from other transform compression methods, AFD adaptively generates tailor-made basis according to various input signals, implying comprehensive applicability for compressing multi-vital signs. With the aid of maximal projection principle (MPP), only a few items are enough to reconstruct the input signals with high efficiency and fidelity. In the second stage, AFD decomposition results are further compressed losslessly using SS technique. SS substitutes the compressed results of long bits with sequence number of short bits referring to a customized encoding table. In the meanwhile, SS fulfills built-in data encryption simultaneously benefiting from shuffling encoding tables. Therefore it alleviates the challenge of information disclosure in most existing methods. As for decompression, it is the inverse process of compression and possesses quite low computation complexity. After decoding the SS substitution results, the projection signal is obtained by summing up the weighted components. Finally, the original input signal is recovered with little distortion through back projection. By validating using ECG, SPG, and HS signals, the proposed method exhibits a good tradeoff between compression efficiency and reconstruction quality, pushing forward the compression performance to an unexploited region.

Figure 4. Compression and decompression method using AFD and SS technique

Preliminary Health Monitoring Model for Portable Device

Once the multi-vital signs are acquired by the embedded-link device, the immediate expectation of the user is to obtain the diagnosis result in his/her portable device. Thus, in the proposed design, taking into consideration of the resource limitation of portable device to store and process adequate knowledgebase (KB) and inference rules, a preliminary health monitoring model to efficiently provide warning messages to patient is developed.

The design of proposed model consists of three important parts, which include the KB framework design, KB customization and finally the inference engine to analyze the cardiac condition and generate warning messages to the user. Now, as knowledge management in resource-limited downstream unit is quite challenging, only the KB and inference rules generated with 32 hemodynamic parameters (HDP) derived from SPG signal (Li et al., 2005) are stored and analyzed in portable mobile device connected with the embedded-link system. The other biological signals including ECG and HS are analyzed by the patient's local computer in midstream.

For developing the proposed preliminary health monitoring model for portable device, Java development kit with its common adaptability on embedded-link devices is chosen. However it must be emphasized that the proposed model can also be developed on other software platform.

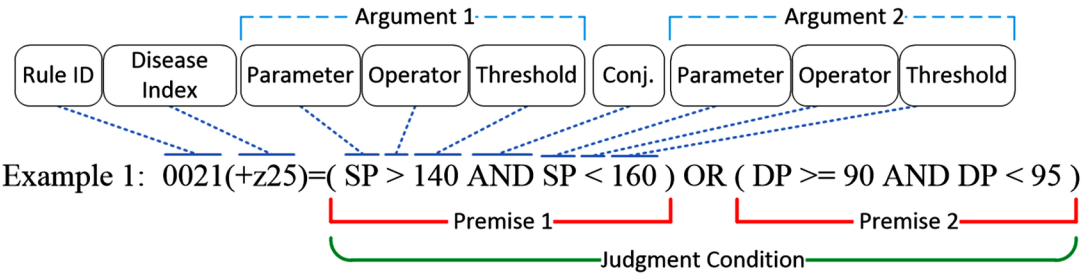
Knowledgebase Framework Design and Customization

In the design of KB framework for a potable mobile device, some of the important technical specifications considered necessary include

1. Storage of the essential medical data and inference rules in limited resource;
2. Define the inference rules in a systematic and consistent structure;
3. Extensibility to perform efficient knowledge update from the server;
4. Efficiently retrieve specific knowledge for the diagnosed pathology.

Thus, in the proposed KB framework, with the acquired KB from doctors, the inference rules are predefined in machine language and stored in text format for easy access and process (Choi et al., 2014). As illustrated in Figure 5 the structure of inference rule is defined in a systematic format, which composes

Figure 5. Inference rules for cardiovascular disease knowledgebase



Example 2: 0010(+z11)=(VPE >= {1.2*[2*Weight+45]*0.0112})

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

of three parts: rule identification (ID) number, disease index and judgment condition. Here, each rule is identified by its rule ID number, which could range from 0001 to 9999. Due to resource limitation and also as only preliminary diagnosis is performed in portable device; proposed model consists of inference rules generated through the analysis of HDP derived from SPG. In a specific inference rule, the disease index is represented by "z" followed by a unique number, which corresponds to a specific pathological condition. Here, the symbol "+/-" indicates that the succeeding judgment condition is for/against the listed disease. As for the judgment condition, multiple premises can be represented in the same rule by defining them within brackets and distinguishing them with a conjunction/disjunction node. Finally, argument is the basic component of a premises, which compares the real value of certain biomedical parameter, computed from the site-sampled user's vital sign with a pre-defined fixed threshold value or a condition presented within "{ }". Two inference rules defined using the proposed KB framework is shown in Figure 5. The main advantage of the proposed KB framework is that it is resource saving as each rule with varying complexity would occupy approximately 60 ~ 300 bytes, which implies that on an average 1000 bytes of storage space can accommodate more than 1000 rules, an absolute necessary feature to be considered in the design of KB framework for portable device. Furthermore, the inference rules are stored in text format, the proposed KB framework can be applied in various mobile devices and as well as in the local computer in midstream. Also, as the inference rules are defined in systematic format, it becomes relatively easier for performing KB update and synchronization between local computer in midstream and the portable device in downstream.

Knowledgebase Customization

As in any diagnostic model, the reliability and accuracy of the model will directly rely on the diversity of rules in local KB framework. However, it is difficult to store all the useful rules in resource-limited portable mobile devices. Therefore, in the proposed approach a customized KB is generated to utilize the storage space in local computer in midstream and offset the resource limitation in portable device.

In the customized KB model, the pre-defined inference rules are divided into two groups: fundamental disease group and specific disease group. The fundamental disease group will basically contain all the inference rules relevant to the diagnosis of common types of CVD, while the specific disease group would contain sub-groups of inference rules for diagnosing different disease categories. In the proposed model, the KB framework in the portable mobile device only contain the fundamental disease group and the specific disease group being larger in size would be stored in the local computer memory. However, to increase the reliability of diagnosis in portable device, at the startup of *e*-home healthcare system, the user will be allowed to further customize the portable device by downloading one or a set of specific disease group. For example, if the user is suffering from hypertension and needs to specifically monitor the relevant parameters regularly, he/she could download the sub-group of inference rules relevant to hypertension into the portable mobile device. This would allow the user to not only monitor his cardiac system as a whole but also specifically monitor his/her hypertension levels, reliably at the convenience of the portable mobile device.

Inference Engine

With the constructed KB framework, the proposed inference engine will adapt the basic inference tree structure to perform preliminary diagnosis on the embedded-link portable platform. As the inference rules in individual branches of the tree are pre-defined, the inference engine will hierarchically judge

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

the conditions of the relevant branch based on the acquired biomedical parameters and subsequently diagnose the potential heart pathology. In the diagnosis process, the inference engine will record the corresponding disease indexes whose inference rules have been satisfied. Then based on the inference results, the user will be indicated on his/her health status, possible/potential heart pathologies and the relevant warning messages. The warning message is an important feature of the preliminary CVD diagnosis model in a portable device as it could guide the user to take timely action. Basically, the warning message could include one or more of the following similar messages:

1. Improve the cardiac function with some exercise;
2. Pay attention to a particular biomedical parameter;
3. Update the KB by downloading some specific disease group package;
4. Test your biomedical signals in local computer;
5. Seek medical treatment, etc.

In conclusion, the preliminary health monitoring model on portable device provides the user with comprehensive health status information to help the user to regularly monitor his/her health status and take appropriate action accordingly.

Testing Results of Downstream Module

To validate the intelligent wearable biological signal acquisition system and the preliminary health monitoring model proposed and designed for the downstream module, the following tests are conducted.

First of all, as the downstream module is operated by the user in a home environment, it is highly critical to guide the user in recording stable multi-vital sings for further analysis. Thus, as proposed a MIMU is mounted on the biosensor (e.g. SPG acquisition unit placed on the wrist) to detect any movement during recording. Based on spatial movement tracking, the MIMU basically detects any movement of the wrist or forearm during SPG signal recording. To test the MIMU, a volunteer is requested to make some specific movements during recording to observe the corresponding trajectory results. The trajectory results in Figure 6(a) and 6(b) show that the MIMU could very well track the rectangular and triangular movement prompted by the volunteer. This indicates that the MIMU could effectively recognize any type of unexpected movement from the user during recording biological signal and accordingly guide in proper signal acquisition through a voice prompt.

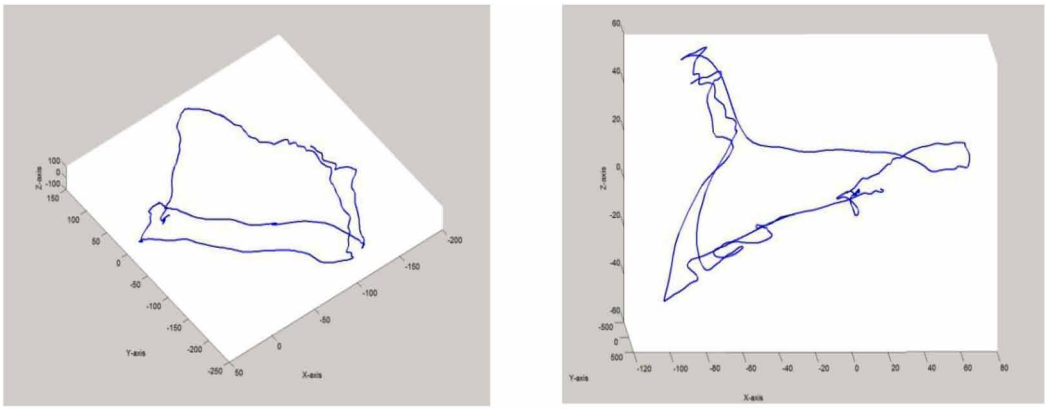
For validating the data compression technique to efficiently store and retrieve multi-vital sign, three ECG records acquired from lead I from MIT-BIH arrhythmia benchmark database (Mark & Moody, 1998), two SPG records acquired from patients from hospital in China and two HS records acquired from eGeneralMedical.com (n.d.), USA, database are utilized.

Three indices namely compression ratio (CR), percentage root mean square difference (PRD) and the normalized PRD (PRDN) as defined in Equations 1, 2, and 3 are assessed to measure the quality of compression output of the biological signals.

$$CR = \frac{b_o}{b_r} \tag{1}$$

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 6. (a) Rectangular spatial tracking result; (b) triangular spatial tracking result



(a) (b)

where, b_o and b_r denote the number of bits in original and reconstructed signals respectively.

$$PRD\left(\%\right) = \sqrt{\frac{\sum\left(f-g\right)^2}{\sum f^2}} \tag{2}$$

$$PRDN\left(\%\right) = \sqrt{\frac{\left(f-g\right)^2}{\left(f-f_m\right)^2}} \tag{3}$$

where, f, g represents the original and recovered signals respectively and f_m is the mean value of original signal.

In assessing the compression results, higher CR and lower PRD and PRDN are expected to attain an efficient and reliable data compression. Table 1 compares the testing results of the proposed method with the ones proposed in literature.

It is observed from Table 1 that the proposed method exhibits competitive performance with existing state-of-the-art works presented in literature.

Finally, to examine on whether the downstream module could operate as an independent unit, a patient suffering from hypertension tests the unit by recording his biological signals and examining the parameters in the mobile portable device connected to the *e*-home healthcare system. The result displayed in the mobile device is illustrated in Figure 7.

The warning message in the mobile device indicates the patient to monitor the blood pressure regularly. Also, the hypertension extension package is listed in the interface for customized update. In conclusion, the preliminary health monitoring model in the downstream module provides the user with comprehensive health status information to help users to monitor health status and take appropriate actions accordingly.

MIDSTREAM FUNCTIONAL MODULE

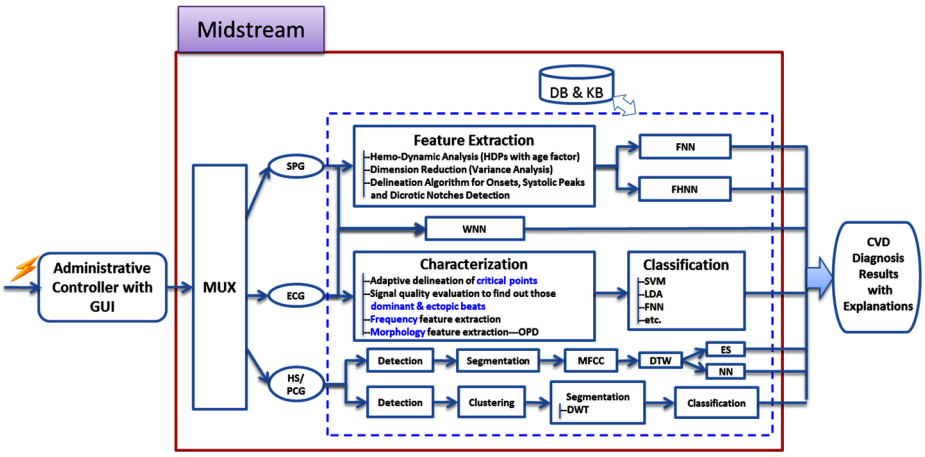
As the main goal of the proposed wired and wireless distributed *e*-home healthcare system is to transform hospital-rescue-centered healthcare to patient-prevention-centered approach, it is crucial that an efficient and reliable intelligent monitoring and diagnosis system (IMDS) is built on the local computer in midstream. Thus, by exploiting the advancement in AI technology, the proposed IMDS executes a hierarchical analysis and interpretation of various biological signals and provides a more efficient and reliable point-of-care CVD diagnosis to the user. The proposed architecture of the IMDS is illustrated in Figure 8. Here, the pre-processed multi-vital signs are transmitted to the local computer through wired or wirelessly connected embedded-link biological signal acquisition system. In the midstream, as all the three biological signals including SPG, ECG and HS/PCG are analyzed, the reliability and accuracy of the IMDS is comparatively more powerful than the preliminary health monitoring model built on the portable device in downstream.

In the proposed architecture of IMDS, a user-friendly administrative graphic user interface (GUI) is provided to help the user to conveniently interact with IMDS in biological signal analysis and diagnosis. Based on the diagnosis output, the user will be prompted to take some precaution or connect to the remotely-linked diagnosis system in the upstream for an even more accurate diagnosis using both non-invasive and invasive parameters. Yet, as the main goal of the proposed *e*-home healthcare system is to limit the need of connecting to the hospital server in the upstream, our research team have researched and developed various algorithms and techniques to diagnose CVD using the non-invasive biological signals including SPG, ECG and HS/PCG signals (Choi et al., 2014; Lei et al., 2007a, 2007b; Sekar et al., 2011, 2012; Shi et al., 2009; Zheng et al., 2013). In the following sections, some of the more efficient and reliable methods developed will be described in details.

Intelligent Diagnosis System using SPG

SPG is one of the most fundamental biomedical signals and carries profuse medical information needed for health monitoring of cardiovascular system. SPG signal can provide clinically useful information beyond the brachial measure of blood pressure and could ideally reflect four different aspect of a car-

Figure 8. Architecture of intelligent monitoring and diagnosis system in midstream



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

diovascular system, including the heart functionality (e.g. coronary artery status, oxygen consumption), arterial status (e.g. elasticity, peripheral resistance and compliance), blood status (e.g. blood viscosity and volume) and microcirculation function (e.g. circulation time period).

From literature study, one could note that majority of research have been devoted towards the development of various medical devices/instruments for recording arterial blood pressure (ABP) and SPG signal (Hwang et al., 2004; Im & Lessard, 1995; Miao, 1992). Whereas, another stream of research have been devoted to defining cardiovascular system model to evaluate the cardiac function and vascular properties of the cardiovascular system. One such study is the derivation of hemodynamic parameters (HDP) from SPG signal for analyzing the pathological condition of heart (Ursino et al., 1996). This requires extraction of morphological feature from SPG signal and derivation of HDP thereof. These HDP would include series of critical risk factors, such as cardiac output (CO), stroke volume (SV), total peripheral resistance (TPR) systematic arterial compliance (SAC) etc., derived from the morphological features of the SPG signal. The proposed diagnosis model in midstream mainly focuses on analyzing these HDP for CVD classification.

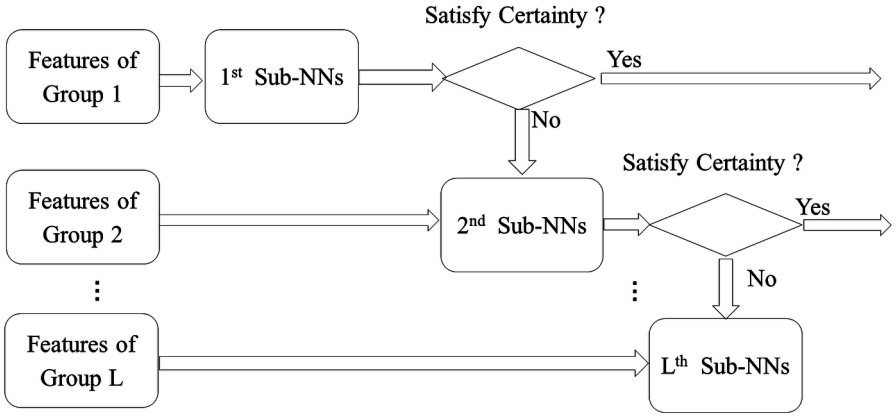
In the following sections, an intelligent diagnosis model designed based on fused hierarchical neural networks (FHNN) will be elaborated in details.

Fused Hierarchical Neural Networks

With advancement in AI technology, recent studies show that integration of AI technologies such as fuzzy logic (FL), artificial neural networks (ANN), expert system (ES) etc., have their unique advantage in scientific research. In this study, integration of ANN and hierarchical networks is proposed to design a layered neuronal structure to more effectively solve a diagnosis/classification problem. Based on the exploration of some of the hierarchical formation (Bagher-Ebadian et al., 2004; Calado & Sa da Costa, 1998; Kovalerchuk et al., 1997) from literature, a fused hierarchical neural networks as shown in Figure 9 is proposed.

According to the proposed scheme, FHNNs are hierarchically constructed by using diverse sub-NNs. The input features are categorized into a number of groups based on their influence on discriminating the hypotheses, group 1 with highest importance/priority and so on. Then as shown in Figure 9, the 1st

Figure 9. Proposed scheme of fused hierarchical neural networks



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

sub-NNs would intake features of group 1, and will attempt to deduce conclusion rapidly. If outputs of 1st sub-NNs satisfy the pre-set acceptance criteria, that is if the deduction certainty is satisfied, the outputs of 1stsub-NNs would yield as the overall output result of FHNNs; else the 2nd sub-NNs would be introduced, which would intake features of group 2 along with the midway outputs of former sub-NNs as inputs. Sequentially, the features, group by group from high to low priority, are in taken by subsequent sub-NNs; until either the deduction certainty is satisfied or all features are completely used.

With such scheme introduced, the question now arises to see how such a scheme can be adapted for a particular application. Specifically, the key challenges now would be to categorize the input parameters according to their importance/priority and then propose appropriate sub-NNs in each layer of the hierarchical structure to efficiently solve the classification problem. Thus, in this chapter with a systematic approach, methods to address both these key challenges are proposed and an intelligent CVD diagnosis model using HDP is designed and validated.

Categorization of Input Parameters

To design the proposed model, site-sampled medical data are acquired from two hospitals in China, namely Beijing Changping Chinese Medicine hospital and the first affiliated hospital of Guangxi Medical University. These include each patient's physiological attributes, original SPG waveforms, HDP and doctor's clinical diagnostic results. Here, the medical symptom space is denoted as $MSS \in R^N$, where $N = 38$, includes 6 physiological attributes and 32 HDP. Totally, 2267 medical records of 165 patients were randomly collected.

These samples were first pre-processed to remove any outliers and then with the implementation of variance analysis (Gelman, 2005), *F*-statistic is computed to categorize the 32 HDP and 6 physiological parameters according to their importance/priority in classifying three types of CVD, including coronary heart disease (CHD), hypertension (HT), and hyperlipidemia (HL). Table 2 shows the categorization results obtained using variance analysis. Based on the confidence coefficients range of [99%, 100%], [95%, 99%] and [0, 95%] respectively, 4 parameters were classified into the sensitive (more important) group, 12 parameters as the auxiliary and the remaining 22 parameters as the replenish (less important) group.

Selection of Sub-NNs for FHNN

According to the proposed scheme of FHNN presented in Figure 9, one of the main key challenges was to identify the most suitable type of NNs structure in each layer of FHNN that would be efficient in solving the classification problem. Thus, in the proposed approach to support such selection, the categorized input parameters in Table 2 were tested on three different NNs structure, including pure fuzzy NNs (FNNs), fuzzy probabilistic NNs (FPNNs) and fuzzy learning vector quantization networks (FLVQ) in diagnosing three types of CVD (CHD, HT and HL) and their combination. The structural architecture of these NNs will be discussed later. Now, such testing results presented in Table 3, clearly shows which category of input parameters are best analyzed with what type of NNs structure.

According to Table 3, FPNNs and FLVQ obviously surpass the basic FNNs in classifying the three types of CVD and their combination. Now in comparing FPNNs and FLVQ, FPNNs have better performance in utilizing sensitive and auxiliary HDP groups to detect CVD, whereas FLVQ performs better in utilizing replenish HDP group. This inspires one to construct FHNNs by using FPNNs as 1st as well as 2nd sub-NNs and FLVQ networks as the 3rd sub-NNs.

Network Structure of Sub-NNs

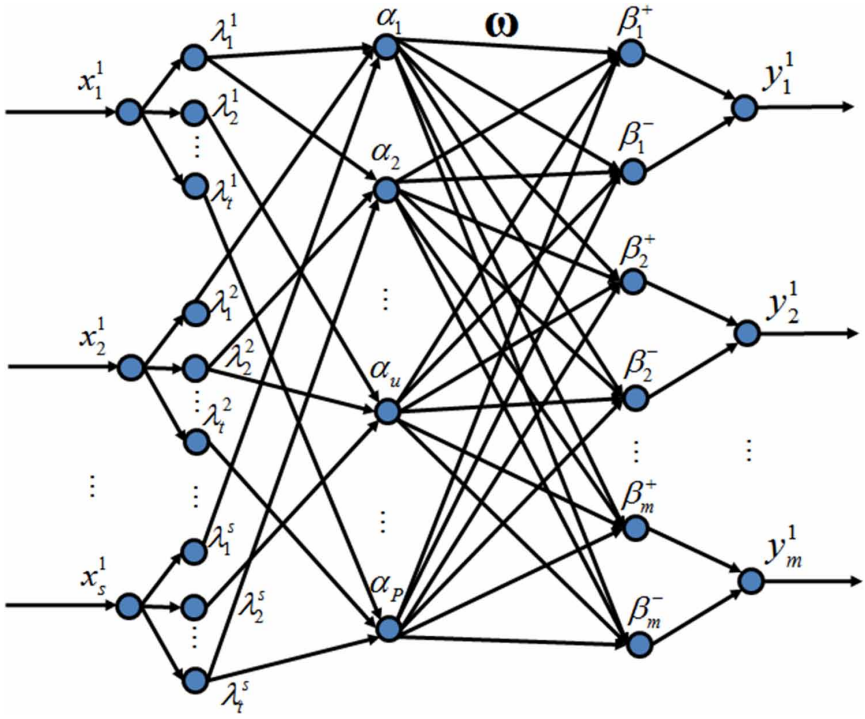
1. Fuzzy Probabilistic Neural Networks

The probabilistic neural networks (PNNs) would basically execute a Bayesian decision making process. PNNs generally memorize the training cases, so during testing if it is presented with a similar case; the PNNs would normally classify it accurately. Literature show, PNNs and FPNNs have been applied for solving various classification problems (Asgary & Mohammadi, 2005; Georgiou & Vrahatis, 2008; Mishra et al., 2008; Song et al., 2007).

The proposed FPNNs shown in Figure 10 are a five layer network structure, comprising of input, fuzzification, pattern matching, synthesis and output layers. As FPNNs is used as the sub-NNs in the first and second layers of FHNNs in Figure 9, the number of inputs in the first and second sub-NNs

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 10. Network structure of FPNNs



equals to the number of parameters in the sensitive and auxiliary group respectively. Moreover, thesecond sub-NNs will also analyze the output of third layer of first sub-NNs for further classification. Here, a detailed exposition of the FPNNs as executed in first layer of FHNNs will be made.

In Figure 10, the input vector of the 1st layer of FPNNs is denoted as $x = \left[x_1^1, x_2^1, \ldots, x_s^1\right]^T$. In the 2nd layer, the input vectors are fuzzified to obtain the corresponding fuzzy membership grade (FMG) with $\lambda \in [0,1]$. The membership functions are pre-defined based on the age factor adjustment as described in our paper (Shi et al., 2010). Denoting the level of fuzzification as *t*, the number of output vectors from 2nd layer would be $t \times s$.

The 3rd layer computes the matching degrees α to fuzzified training patterns using Equation 4.

$$\alpha_u = \frac{1}{s\sigma} \sum_{i-1}^{s} e^{-\frac{(\lambda_i - \lambda_i^u)^2}{\sigma^2}} \tag{4}$$

where *u* is the u^{th} number of nodes in the 3rd layer, its maximum value equals to the number of training patterns *P*; λ_i is the FMG of i^{th} sensitive feature; and $\sigma$is smoothing parameter.

The 4th layer consists of 2*m* nodes to reflect two types of output: *m* positive and *m* negative CVD nodes. The nodes summate the corresponding training pattern matching degrees together according to Equation 5, and then forward it to the 5th layer.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

$$\beta_j^+ = \sum_{j=1}^{P}\left(\omega_j^+ \cdot \alpha_j\right), \beta_j^- = \sum_{j=1}^{P}\left(\omega_j^- \cdot \alpha_j\right) \tag{5}$$

where ω_j^+ is j^{th} link weight connecting j^{th} positive CVD nodes, ω_j^- caters for negative CVD in similar way. ω in Figure 10 denotes link-weight matrix comprising of β_j^+ and β_j^-, j=1, 2, …, P.

The 5th layer with m category nodes is the output layer, which selects the sign of winner between positive and negative CVD assumed nodes as output according to Equation 6:

$$y_k^1 = \left(\beta_k^+ - \beta_k^-\right), \left(k = 1,2,...,m\right) \tag{6}$$

where y_k^1 represents the k^{th} CVD output of the 1st sub-NNs, positive y_k^1 means k^{th} CVD patient and negative y_k^1 means that it is free of k^{th} CVD. Absolute value of $\left(\beta_k^+ - \beta_k^-\right)$ is defined as the certainty for diagnosing k^{th} CVD.

2. Fuzzy Learning Vector Quantization Networks

Learning vector quantization (LVQ) networks is a special type of ANNs, in the sense that LVQ classification algorithms do not approximate density functions of class samples and directly define class boundaries based on the prototype, a nearest-neighbor rule and a winner-takes all paradigm. Therefore, it maintains rapid convergence and minimizes classification errors. FLVQ has been specifically applied for solving pattern recognition problem (Baghshah et al., 2006; Jatmiko et al., 2009).

In the proposed model, FLVQ is used as the sub-NNs in the 3rd layer of FHNNs to analyze the input parameters from the replenish group. The input vector is thus denoted as $\boldsymbol{x}^{\boldsymbol{L}} = \left[x_1^L, x_2^L, ..., x_r^L\right]^T$, here L=3.

The input vectors are then fuzzified as FMG and represented as vector $\boldsymbol{\kappa}$ in the $2n^d$ layer of FLVQ. When the fuzzification level remains t, then the number of output in $2n^d$ layer is computed as t×r.

$$\boldsymbol{\kappa} = \left[\kappa_1^1, \kappa_2^1, ..., \kappa_t^1, \kappa_1^2, \kappa_2^2, ..., \kappa_t^2, ..., \kappa_1^r, \kappa_2^r, ..., \kappa_t^r\right]^T \tag{7}$$

The 3rd layer of FLVQ produces a vector that represents the negative of distances between FMG and vectors formed by link-weights. The v^{th} row of link-weight matrix $\boldsymbol{\eta}$ can be denoted as

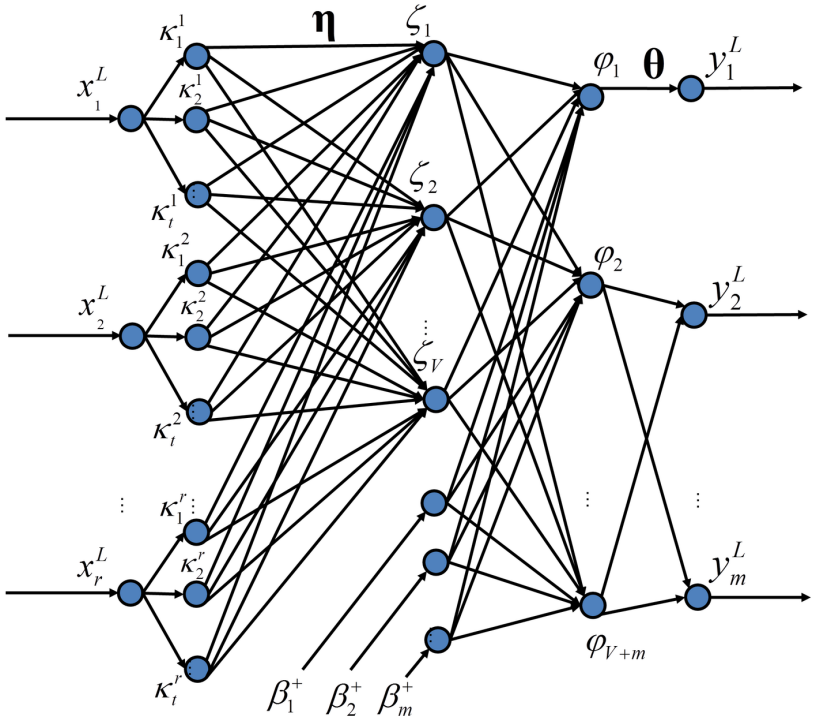
$$\boldsymbol{\eta}^{\boldsymbol{v}} = \left[\eta_1^v, \eta_2^v, \ldots, \eta_{t\times r}^v\right].$$

Here, the maximum v is denoted as V, which is the number of learning patterns as well as the number of nodes in 3rd layer. The output of 3rd layer is marked as

$$\boldsymbol{\zeta} = \left[\zeta_1, \zeta_2, ..., \zeta_V\right]^T = \boldsymbol{\eta} \times \boldsymbol{\kappa},$$

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 11. Network structure of FLVQ



which quantizes the similarity between FMG and learning vector.

The 4th layer outputs of former 2nd sub-NNs are presented as partial input to the 3rd layer of FLVQ. The outputs β^+ of *m* positive CVD nodes are taken as inputs to next FLVQ layer. So there are *V*+*m* nodes in 3rd layer of FLVQ.

The 4th layer is a competitive layer, composed by same number of nodes as 3rd layer. The competitive layer accepts inputs similarly and returns neuron outputs of zero for all neurons except for the winner. The output vector is denoted as ϕ, it's *i*th element is calculated by following Equations 8, 9, and 10.

$$\varepsilon = \max\left(\zeta_1, \zeta_2, ..., \zeta_V, \beta_1^+, \beta_2^+, ..., \beta_m^+\right) \tag{8}$$

$$\phi_i = \begin{cases} 1, & \forall \zeta_i = \varepsilon \\ 0, & \forall \zeta_i < \varepsilon \end{cases}, when\ i = 1, 2, ..., V \tag{9}$$

$$\phi_i = \begin{cases} 1, & \forall \beta_{i-V} = \varepsilon \\ 0, & \forall \beta_{i-V} < \varepsilon \end{cases}, when\ i = V+1, V+2, ...V+m \tag{10}$$

The 5th layer transforms the output of competitive layer into predefined target classifications. The patterns learned by the competitive layer are referred to as subclasses of categories.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

The outputs of the 3rd sub-NNs, FLVQ, are calculated by $\left[y_1^L, y_2^L, ..., y_m^L\right]^T = \boldsymbol{\theta} \times \boldsymbol{\varphi}$, where L=3, $\boldsymbol{\theta}$ is link-weight matrix of the last layer with m rows by $V+m$ columns.

The purpose of training FLVQ is to adjust link-weight matrix $\boldsymbol{\theta}$. For every input vector, the networks will give a CVD classification result. If the result of classification is correct, the connection weights value can be corrected by Equation 11:

$$\theta_k\left(\tau+1\right) = \theta_k\left(\tau\right) + \xi * \left(y_k^L - \theta_k\left(\tau+1\right)\phi_\tau\right) \tag{11}$$

If it is wrong, the link-weights should be adjusted by Equation 12:

$$\theta_k\left(\tau+1\right) = \theta_k\left(\tau\right) - \xi * \left(y_k^L - \theta_k\left(\tau+1\right)\phi_\tau\right) \tag{12}$$

where $\xi \in (0,1)$, $\theta_k(\tau)$ is τ^{th} training vector of k^{th} category, $k = 1, 2, \ldots, m$.

This process is repeated until the achieved classification rate is satisfied or the maximum epoch number is reached. After learning, the FLVQ is ready and the whole FHNNs can be used to detect the CVD.

Intelligent Diagnosis System Using ECG

ECG is perhaps the most commonly recognized and used biomedical signal so far. In general practice, cardiologists manually examine the tracing of ECG recording to identify any abnormalities. As such procedure is oppressive and time-consuming, literature show that abundance research has focused on developing automated methods of ECG interpretation and classification. Some of the related researches include ECG signal de-noising (Oster et al., 2010), detection-delineation algorithms to detect critical points (Ghaffari et al., 2009), signal stability and quality evaluation (Zhang et al., 2011), feature point characterization (Husser et al., 2009), recognition and classification to assist medical diagnosis (Chiang et al., 2010).

It can be noted from literature study that the development of an automated ECG interpretation and classification system would first require R&D of an effective technique to accurately and completely capture the cardiac information from the ECG signal. Such information would include the duration, amplitude and level of the component waves as well as their inter-component interval etc. Then, an intelligent decision-making system would have to be developed to analyze the recorded feature vectors and diagnose the relevant heart pathologies. The development of a reliable decision-making system would be influenced by three fundamental factors, including accurate data, pertinent KB and appropriate problem-solving scheme.

In the proposed model, Hermite based orthogonal polynomial decomposition (OPD) is explored for ECG interpretation and support vector machines (SVM) is deployed for developing ECG classification algorithm. Hermite model is adapted here for its unique benefits. Its orthogonal property allows no redundancy between feature vectors, the width parameter provides an efficient estimation of beats with large differences in QRS duration and finally the series expansion of Hermite polynomials can offer a concise representation of ECG signal. In addition, SVM is an advanced tool which has been mainly used

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

for solving classification and pattern recognition problems with high dimensional data. In contrast to ANN, the reasoning of SVM is much easier to be comprehended, a feature which is specifically useful in the design of *e*-home healthcare system. In the following section the proposed ECG interpretation and classification model using Hermite model and SVM will be described in details.

Feature Extraction using Hermite Function Decomposition

In Hermite's decomposition, the QRS complex of ECG signal $x(t)$ is expanded into a linear combination of Hermite polynomials.

$$x\left(t\right) = \sum_{n=0}^{N-1} a_n \varphi_n \left(t, \sigma\right) \tag{13}$$

$$\varphi_n \left(t, \sigma\right) = \frac{1}{\sqrt{\sigma 2^n n \sqrt{\pi}}} e^{-t^2/2\sigma^2} . H_n \left(t / \sigma\right) \tag{14}$$

Here, $H_n(t,\sigma)$ are the Hermite polynomials and the width parameter σ is proportional to the duration of QRS complex. The coefficients a_n indicates the morphological similarity between the ECG segment and various Hermite polynomials. The optimum value of coefficients a_n and width b are obtained by minimizing the error e_r between the input and synthesized signal.

$$a_{i+1}^n = a_i^n - 2 \cdot \mu_a \cdot \frac{\partial E_i}{\partial a_i^n} \tag{15}$$

$$b_{i+1} = b_i - 2 \cdot \mu_b \cdot \frac{\partial E_i}{\partial b} \tag{16}$$

$$e_r = \sum \left(x\left(t_i\right) - \sum_{n=0}^{N-1} a_n \varphi_n \left(t_i, b\right) \right)^2 \tag{17}$$

The QRS complex is centered at the R peak with a 200ms window. This size is obtained by long-term exploration by considering that both normal (60 ~ 100ms) and abnormal beats (<200ms) are covered. Validation of the selected window size was examined on arrhythmia dataset, as the length of such ECG signal would normally vary. The results show that with 10 sets of Hermite coefficients a_n and width parameter σ, a good reconstruction of the curve with most important features could be attained.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

ECG Classification with Support Vector Machines

SVM belongs to a family of generalized linear classifier, which was originally designed for binary classification. However, recent studies show the theory being extended for solving multi-class classification problems (Aiolli & Sperduti, 2005; Hsu & Lin, 2002). The more commonly adapted approach views it as a collection of binary classification problem and decomposes it to a series of two-class problems. In the proposed model, one-against-all (OAA) method is adapted to execute SVM multi-class classification. In this approach, a set of binary classifiers are trained to be able to separate each individual class from other.

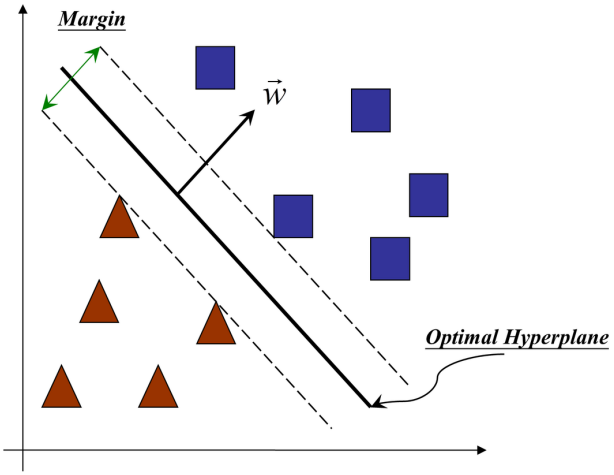
SVM classifier basically relies on the optimal hyperplane on the decision surface so that the geometric margin between two classes is maximized as shown in Figure 10. Here, the *N* set of samples be denoted as $\left(\bar{x}_i, y_i\right)$, $\bar{x}_i \in R^n$ and $y_i \in \{-1,+1\}$ are the training sample and class label respectively. The hyperplane is denoted as $f\left(\bar{x}\right) = \left\langle \bar{w}, \bar{x} \right\rangle + b = 0$, where $f\left(\bar{x}\right) > 0$ for one class and $f\left(\bar{x}\right) < 0$ for another. $\bar{w} \in R^n$ is normal vector to the hyperplane, $\left|b\right| / \left\|\bar{w}\right\|$ is the perpendicular distance from the hyperplane to the origin and $\left\|\bar{w}\right\|$ is the Euclidian norm of *w*. To obtain the hyperplane to distinguish the two classes with largest margin, the following conditions are met.

$$\left\langle \bar{w}, \bar{x} \right\rangle > +b \geq +1 \text{, } y_i = +1 \tag{18}$$

$$\left\langle \bar{w}, \bar{x} \right\rangle + b \leq -1 \text{, } y_i = -1 \tag{19}$$

As shown in Figure 12, let $d^+(d^-)$ be the shortest distance from the hyperplane to its closest positive (negative) instance. The perpendicular distance between the origin and two hyperplanes represented by Equations 18 and 19 are given by $\left\|1-b\right| - \left|-b\right\| / \left\|\bar{w}\right\|$ and $\left\|-1-b\right| - \left|-b\right\| / \left\|\bar{w}\right\|$ respectively. The margin $(d^+ + d^-)$ is equal to $2 / \left\|\bar{w}\right\|$. Smaller the value of $\left\|\bar{w}\right\|$, larger is the margin. With Equations 18 and 19, the following set of inequalities are obtained to increase the separation of the margin.

Figure 12. Support vector machines classifier



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

$$y_i \cdot \left(\left\langle \overline{w}, \overline{x} \right\rangle > +b \right) \geq 1, \forall i \tag{20}$$

In addition, kernel-based nonlinear SVM function could project the samples to a feature space of higher dimension via a nonlinear mapping function φ. Gaussian, polynomial and sigmoidal functions are some of the more frequently used kernel functions, which can be defined as

$$K\left(x_i, x_j\right) = \varphi\left(x_i\right) \cdot \varphi\left(x_j\right).$$

In order to maximize the distance between the margin, minimized values of $\left\|\overline{w}\right\|$ should be computed with respect to $\overline{w}$ and *b,* with the constraint of inequalities in Equation 20. Thus, with such complexity of optimization process involved, with Equation 21 the problem is converted to minimized Lagrangian function in primal space of parameters $\overline{w}$ and *b.*

$$L_P(w, b, \alpha) = \frac{1}{2}\left\|\overline{w}\right\| - \sum_{i=1}^{N} \alpha_i \left[y_i \left(< \overline{w}, \varphi\left(\overline{x}_i\right) > +b \right) - 1 \right] \tag{21}$$

where α_i is the Lagrangian multiplier and the derivative of primal Lagrangian function with respect to $\overline{w}$ and *b* as follows.

$$\frac{\partial L_P}{\partial b} = 0 \quad \Rightarrow \quad \sum_{i=1}^{N} \alpha_i \cdot y_i = 0 \tag{22}$$

With above equations, the dual Lagrangian formula $L_D(\alpha)$ can be computed as in Equation 23.

$$L_D(\alpha) = \sum_{i=1}^{N} \alpha_i - \frac{1}{2} \sum_{i=1}^{N} \sum_{j=1}^{N} y_i y_j \alpha_i \alpha_j K\left(\overline{x}_i, \overline{x}_j\right) \tag{23}$$

To find the optimal hyperplane, the dual Lagrangian $L_D(\alpha)$ must be maximized with respect to the non-negative multiplier ($\alpha_i \geq 0$). The dual Lagrangian can thus be expressed in terms of training data on the scalar products of input patterns ($x_i \bullet x_j$), a property that would be useful for analyzing nonlinear decision boundaries.

Through solving the dual optimization problem, the parameters $\overline{w}^{opt}$ and b^{opt} of the optimal hyperplane can be obtained as follows.

$$\overline{w}^{opt} = \sum_{i=1}^{N} \alpha_i^{opt} y_i \varphi\left(\overline{x}_i\right) \tag{24}$$

$$b^{opt} = \frac{1}{N_{SV}} \left[\sum_{s=1}^{N_{SV}} \left(\frac{1}{y_S} - < \overline{x}, \overline{w}^{opt} > \right) \right] \tag{25}$$

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Now, with OAA approach to execute multi-class classification by separating each class from other, the radial basis kernel

$$K\left(x,y\right)=\exp\left(-\frac{\gamma\cdot\left(x-y\right)^{2}}{2\Delta^{2}}\right)$$

is chosen as the kernel function with $\gamma=2$ and $\Delta=1$. The i^{th} SVM is trained with all the training examples of the i^{th} class with positive labels and all the others with negative labels. Subsequently in an iterative process, the multi-class classification is achieved. All the values for SVM multi-class classification are determined by a series of numerical experiments on the learning and testing data to achieve the best generalization ability.

Intelligent Diagnosis System Using HS

HS by auscultation is one of the most traditional biomedical signal, as indicated by fact that the stethoscope was invented in year 1816 and has been carried and used by physicians ever since. In fact, CVD diagnosis by HS could be traced back even before the invention of stethoscope, when physicians placed their ears against patient's chest to listen to cardiac abnormality.

Even today in modern society, with more sophisticated medical techniques such as ECHO, ECG, ballistocardiogram (BCM) etc., available, HS examination through stethoscope still serves as the cheapest primary heart health screening method. Many CVD, especially the valve related diseases such as mitral valve prolapse which sometimes show no physiological symptoms are often detected during a routine examination by a general practitioner (GP) through HS examination using stethoscope. However, such diagnosis may initially go unnoticed if the GP is not experienced or confident in cardiac auscultation. An automatic analysis/diagnostic tool would thus be desirable to either implement in *e*-home healthcare system or assist GPs in diagnosing HS signals.

Exploiting the benefit of multiple technological advancements, research over the past decade has focused optimistically on the development of such tools. HS being a non-stationary time-dependent signal, researchers explored into various time-variant methods, which include the time-dependent models, time-frequency and time-scale analyses methods (Staszewski & Robertson, 2007). The time-variant approaches offered powerful solution to both de-noising (Zhao & Cao, 2009) and HS characterization (Tomas & Roncevic, 2009). In fact, these time-variant methods also extended to the development of diagnostic models. The predominant models in literature are based on HS segmentation, feature extraction and classification (Fu et al., 2010). In such approach the HS signals are first segmented into individual HS components, S1, S2, S3, S4 and murmurs. The feature vectors such as duration of individual frequency components, peak intensity, time interval etc., are extracted and then classified by relating the features to various pathological conditions. HS segmentation is done based on referencing ECG signal, time domain characteristics, frequency domain characteristics, Shannon energy etc. Time-variant methods such as S-transforms, short-time Fourier transform (STFT), wavelet transform (WT) etc., are used for feature extraction. And finally, for classification, researchers mainly adapted artificial intelligence (AI) technologies, which include hidden Morkov models, expert systems (ES), neural networks (NN) etc.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

In the proposed approach, discrete wavelet transform (DWT) algorithm is applied in multi-resolution analysis (MRA) for de-noising the HS signal, envelogram for segmentation, mel-scale frequency cepstral coefficients (MFCC) algorithm is applied for HS feature extraction and dynamic time warping (DTW) is adapted for HS signal classification and CVD diagnosis. The proposed method will be further elucidated in the following sections.

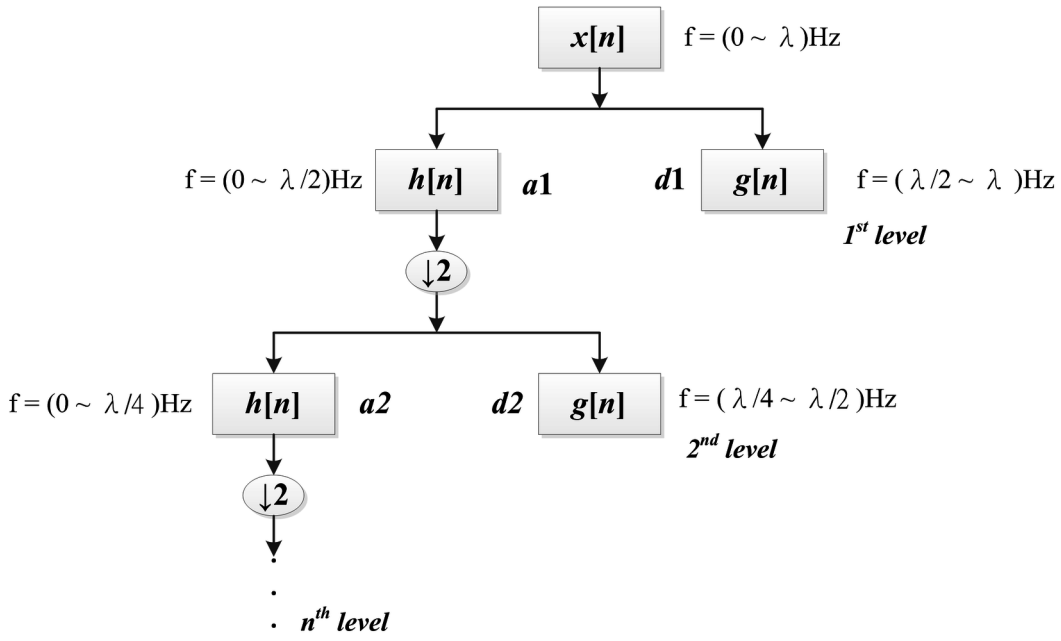
HS De-Noising with DWT in MRA

HS signal de-noising is considered to be an essential signal pre-processing step in developing computer assisted heart auscultation model. Many sources of noise including the ambient noise, lung and breath sound, fetus heart sound (if the subject is pregnant), stomach rumble, muscle tremors, noise from the recording device etc., can pollute the HS signal. As the frequencies of these signals overlap with the HS signal frequency, de-noising the HS signal without the loss of useful information has been a great challenge.

Literature shows that WT has served as a powerful tool for noise reduction (Zhao & Cao, 2009). In the proposed model, MRA algorithm based on DWT is proposed to decompose the HS signal at discrete intervals of time and scale to subsequently eliminate the noisy signal from real useful information.

A DWT is executed by using Mallat's algorithm (Mallat, 1989), which states that 'any conjugate mirror filter would characterize a wavelet that generates an orthonormal basis of $L^2(R)$'. A fast DWT is executed by cascading these conjugate mirror filters. The DWT signal decomposition can be obtained using digital FIR filters with MRA theory. The signal decomposition using DWT can be obtained as shown in Figure 13.

Figure 13. Signal decomposition using Discrete Wavelet Transform



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

The signal obtained after MRA with DWT decomposition can be expressed as in Equation 26.

$$f\left(x\right)=\sum_{k}W_{\varphi}\left(j_{0},k\right)\varphi_{j_{o},k}\left(x\right)+\sum_{j=0}^{J-1}\sum_{k}W_{\psi}\left(j,k\right)\psi_{j,k}\left(x\right) \tag{26}$$

where, $\varphi(x)$ and $\psi(x)$ are scaling and wavelet function respectively; x=0,1,2,…,N is data size of original signal; *j, k* are indexes of lattice which corresponds to discrete scale step and discrete translation step respectively; constant J is the level number of the scaling coefficients. Low frequency coefficients W_{φ} and high frequency coefficients W_{ψ} can be expressed as in Equations 27 and 28.

$$W_{\varphi}\left(j_{0},k\right)=\sum_{x}f\left(x\right)\varphi_{j_{0},k}\left(x\right) \tag{27}$$

$$W_{\psi}\left(j,k\right)=\sum_{x}f\left(x\right)\psi_{j,k}\left(x\right) \tag{28}$$

With the DWT decomposition, the signal can be distributed in different frequencies band, thus the noise in specific band can be identified and eliminated using signal reconstruction with inverse DWT (IDWT). However, as some of useful information could be mixed with the noise signal in the specific frequency band, wavelet coefficient thresholding can be applied to eliminate only the noise without the loss of useful information. A brief review of the wavelet thresholding methods are presented in (Mallat, 1989). In the proposed model, the orthogonal wavelet Daubechies (db6) is chosen for wavelet decomposition and Rigorous Sure threshold estimator is used for defining the thresholding vectors.

HS Segmentation with Envelogram

HS component segmentation refers to partitioning of the HS signal into cardiac cycles and then further segmenting the individual HS components namely S1, S2, S3, S4, murmur and the systolic and diastolic intervals. HS component segmentation are basically done using two approaches:

1. With external reference to ECG and Carotid pulse (CP)),
2. Direct HS localization using signal processing techniques.

In the first approach, the relationship between the ECG, CP and HS signal is analyzed in time domain to detect the HS components and segment them subsequently. The ECG gating approach can be termed as the most robust segmentation method. However the main difficulty in this approach is that both HS and ECG sample have to be acquired from the patient simultaneously. Such complicated procedure of acquiring both ECG and HS signal, given the fact that ECG recording requires many electrodes attached to the subject would not be considered optimal in the design of *e*-home health care system.

This led researcher to explore the second approach, direct HS localization using signal processing techniques. The important step in this approach is to transform the signal to specific domain and then localize the HS components. Various transformation methods have been presented in literature which

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

could be majorly classified as time-domain, frequency-domain, envelogram, matching pursuit and adaptive filtering method. Among these, envelogram approach is identified to be the most popular in direct localization of HS signal components. In this approach, envelope of HS signal is estimated by detecting and smoothly connecting the peak points of the signal. Then through analysis of the obtained envelope, the cardiac components of HS signal are identified and subsequently segmented for further analysis. Few examples which use envelogram for HS segmentation are the Shannon energy (Chauhan et al., 2008), homomorpic filtering (Gupta et al., 2007), etc.

The main point to be noted while estimating the envelope of the signal is that the algorithm has to attain a balance between loosely connecting only the prominent peak points to obtain a rough envelope of the signal or closely connecting all the detected peaks to result into an over fitted envelope that almost resembles the original signal itself. Thus, the envelogram estimation algorithm should identify the essential peaks of the signal and smoothly connect them to obtain the envelope of the signal for further segmentation.

Thus, in the proposed approach the piecewise cubic spline interpolation theory (Marsden, 1974) is investigated to attain a smooth curve of the amplitude envelope that approximately matches the main peaks of HS waveform. With this theory, a series of unique cubic polynomials are fitted between each extrema position of the HS waveform with the stipulation that the estimated envelope is continuous and smooth. This method provides a reliable estimation of the envelope that closely follows the sudden variations in amplitude of waveform and avoids ripples in more stable regions. The envelope detection of pathological HS signal with late systolic murmur using piecewise interpolation function is shown in Figure 14. The HS components are detected by measuring the interval difference between the boundary of the slope where the upper and lower envelope intersect. Based on the fact that the systole (I1) is much shorter than diastole (I2), S1 and S2 components of HS signal are easily identified and subsequently segmented.

Figure 14. Envelope detection of HS signal using piecewise interpolation function

HS Feature Extraction using MFCC

Generally for feature extraction, signal processing is carried out to convert the raw signal to some type of parametric representation. The parametric representation is then processed to represent the features of the signal which are then used for further recognition or classification purpose. MFCC is a parametric representation which to a certain degree simulates the properties of the human auditory system. Thus, the derived MFCC coefficients could attain more sound characteristics from low frequencies and fewer from high frequencies. MFCC was mainly developed for analyzing auditory signals and has been well applied for automatic speech recognition (Davis & Mermelstein, 1980). Also, recent studies show that MFCC has been frequently applied for HS analysis and has attained high classification accuracy (Gupta et al., 2007).

Figure 15 shows the functional block diagram for computing MFCC. As described above, HS signal is first de-noised, segmented and normalized before treated for computing MFCC. Now, once the HS signal is pre-processed, the segmented HS component is processed using framing. In this step the HS signal is divided into frames of 8~15ms length, with each overlapping with a shift of 1/2 of the frame. Then hamming window is applied to frames to minimize the spectral leakage and obtain a smooth transition between frames (Fu & Wang, 2010).

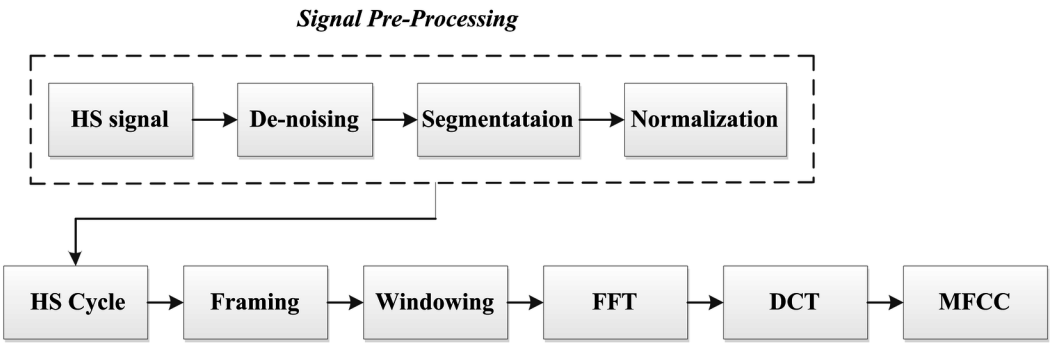
FFT is then computed on each window samples to extract the frequency components of the signal from the time domain. Subsequently, MFCC coefficients are obtained from a Discrete Cousine Transform (DCT) of the logarithm of the short-term energy spectrum expressed on a mel-frequency scale. The desired mel-frequency scale is obtained using triangular band pass filters. Equation 29 expresses the relationship between mel-frequency and actual frequency:

$$Mel(f) = 1125 \ln\left(1 + \frac{f}{700}\right) \tag{29}$$

Here, *f* is the physical frequency in Hz and *Mel(f)* is the perceived frequency in mels.

A DCT is applied to the logarithm of the filter bank outputs to calculate the MFCC as described in Equation 30.

Figure 15. Functional block diagram for computing MFCC



EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

$$C_n = \sum_{k=1}^{N} E_k \cos\left[n\left(k-\frac{1}{2}\right)\frac{\pi}{K}\right] \tag{30}$$

Here, C_n denotes the n-th MFCC coefficient, E_k is the logarithm output of the k-th filter bank channel, K is the number of filter bank channels, n=1,2, …K and N is the number of filter banks.

HS Classification using Dynamic Time Warping

DTW algorithm aims at comparing the similarity between two sequences of data points which could vary in time or speed. DTW was first introduced in 1960s (Bellman & Kalaba, 1959) and then extensively explored for speech recognition in 1970s (Sakoe & Chiba, 1978). Subsequently, it has been employed in countless applications including online biometric recognition (Faundez-Zanuy, 2007), computer animation (Müller, 2007), protein sequence analysis (Vial et al., 2009) etc.

DTW works in time domain by iteratively 'warping' between the two sequences axis until an optimal match is found. Hence, the main advantage of DTW over other methods such as Euclidean distance is that the sequence of data under analysis need not be of equal length. It allows elastic shifting of time axis to accommodate sequences which are similar but out of phase.

As an example, for two sequences A=(a_1,a_2,…,a_m,…,a_M) and B=(b_1,b_2,…,b_n,…,b_N) of varying lengths M and N respectively, a_m is the m^{th} element of sequence A and b_n is the n^{th} element of sequence B. The distance between the two points can be represented as in Equation 31, which tries to find the shortest path between the two points.

$$d_{m,n} = d(a_m, b_n) = (a_m - b_n)^2 \tag{31}$$

As shown in Figure 16, the warping path W would measure the continuous set of matrix to map the distance between the two sequences A and B.

Now, as brute force approach of finding the shortest warping path would not be efficient, DTW algorithm uses two specific features that include some constraints and dynamic programming.

First to limit the number of paths to explore in mapping the distance between two sequences, DTW follows some reasonable constrains, which include monotonicity, continuity, boundary, warping window and shape. These constraints are elaborately described in (Kurbalija et al., 2011).

With the k^{th} element of warping path W is defined as w_k=$(m,n)_k$.

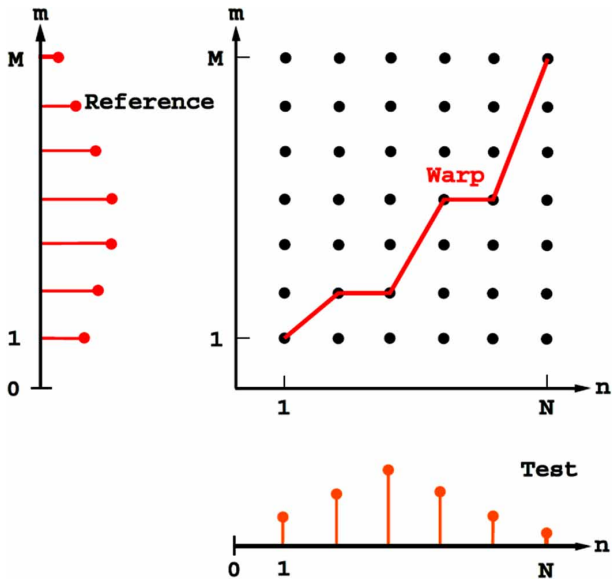
$$\begin{aligned} &W = w_1, w_2, \cdots, w_k, \cdots, w_K \\ &\max(M,N) \le K \le M+N-1 \end{aligned} \tag{32}$$

The total cost of the warping path between A and B can now be defined as in Equation 33.

$$C_W\left(A,B\right) := \sum_{k=1}^{K} w_k \tag{33}$$

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 16. Measure of warping path from A to B using DWT



Secondly, DTW uses dynamic programing using Equation 34 to find the best alignment in a recursive manner.

$$c(m,n) = d(a_m, b_n) + \min\left\{c(m-1,n-1), c(m-1,n), c(m,n-1)\right\} \tag{34}$$

The optimal warping path between *A* and *B*, which holds minimal total cost of all possible warping paths can be defined as in Equation 35.

$$DTW\left(A,B\right) := \min\left\{C_W\left(A,B\right)\right\} = min\sum_{k=1}^{K} w_k \tag{35}$$

Testing Results of Midstream Module

As the IMDS in the midstream utilizes three non-invasive biological signals including SPG, ECG and HS, each of the proposed and designed intelligent diagnosis models will be tested individually.

Three indices, namely the sensitivity (SE), specificity (SP) and accuracy (A) defined in Equations 36, 37, and 38 are used to evaluate the performance level of the proposed IMDS.

$$SE = \frac{True_Positive}{True_Positive + False_Negative} \times 100\% \tag{36}$$

$$SP = \frac{True_Negative}{True_Negative + False_Positive} \times 100\% \tag{37}$$

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

$$A = \frac{True_Positive + True_Negative}{True + False} \times 100\% \tag{38}$$

First to test the intelligent diagnosis model using FHNNs designed for SPG analysis, records from the site-sampled data sets obtained from two hospitals in China are tested. To carry out the validation process, 52 CHD, 48 HT, 63 HL and 50 normal records are selected to test the performance level of the trained FHNNs.

The validation results of proposed model shown in Figure 17 indicate that 'P-P-L' FHNNs performs better than all other schemes of fusing FNNs (denoted as F), FPNNs (denoted as P) and FLVQ (denoted as L).This can be evidenced for classifying all the three types of CVD and the mixed CVD taken for testing.

Secondly, to validate the proposed ECG classification using Hermite based orthogonal polynomial decomposition and SVMs, ECG records of normal sinus rhythm and seven types of arrhythmia are obtained from the MIT-BIH Arrhythmia database (Mark & Moody, 1998). The validation is made based on both intrapersonal and interpersonal scheme. Here intrapersonal (interpersonal) testing represents the interactive influences contained within (between) the person. For testing the intrapersonal and interpersonal scheme, a total of 6138 and 3174 beats are segmented from the acquired ECG records.

Tables 4 and 5 show the testing results of intrapersonal and interpersonal classification.

The testing results from Table 4 and 5 show that the proposed method is competitive in classifying ECG samples based on intrapersonal scheme, however, further improvement in the algorithms can be made in classifying based on the more complicated interpersonal scheme.

Finally, to validate the proposed HS classification method using MFCC and DTW, HS samples with varying pathologies are acquired from eGeneralMedical.com, (n.d), USA; University of Michigan heart sound and murmur library, (n.d); University of Washington School of Medicine, (n.d); University of Dundee, (n.d) etc., databases.

Table 5. The validation result of interpersonal classification

ECG Beat Type	Sensitivity (%)	Specificity (%)
Normal sinus rhythm	80.61	99.42
Ventricular premature beat	79.95	99.68
Left bundle branch block	62.40	92.93
Right bundle branch block	85.60	97.23
Ventricular flutter wave	N/A*	99.81
Fusion of paced and normal beat	N/A	97.35
Fusion of ventricular and normal beat	N/A	94.90
Atrial premature beat	N/A	96.06
Total	**77.14**	**97.17**

*N/A denotes the case of zero denominators.

Table 6 shows the performance evaluation of the proposed method of HS analysis and classification.

The testing results in Table 6 show that the proposed method of HS analysis and classification is competitive and can be reliably adapted in the design of *e*-home healthcare system.

UPSTREAM FUNCTIONAL MODULE

With the proposed architecture of distributed *e*-home healthcare system, so far it can be recognized that already the down- and mid-steam could independently offer reliable monitoring of the cardiac status of the patient at the comfort of their home environment. Yet, to design a more reliable *e*-home healthcare system as a whole, it is important to have element of intervention by the hospital during emergency situations. Thus, as depicted in Figure 1, the upstream module is introduced. The upstream basically consists of two sub-systems, namely customized information management system (CIM) and top-level intelligent CVD monitoring and diagnosis system (TICMD) (Tang, 2014). While CIM works with UUS

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Total	**82.9**	**98.6**	**97.4**

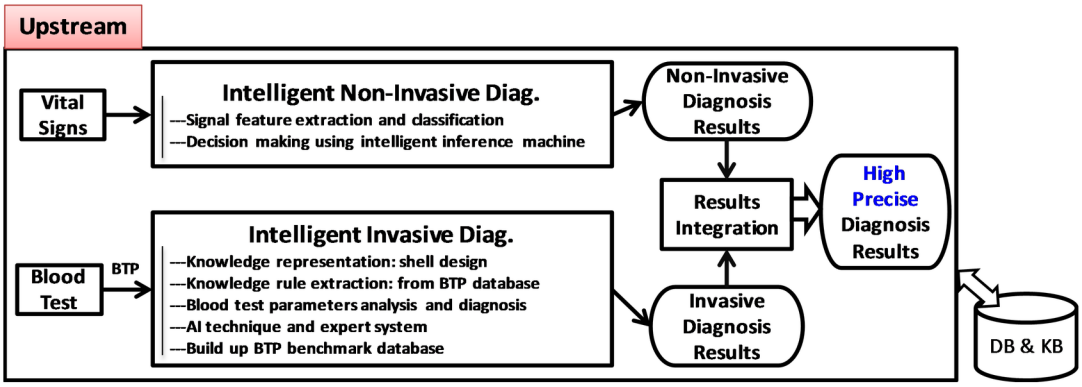
to manage the help requests from lower streams, TICMD performs high precision diagnoses with detailed explanations and suggestions. As any failure of diagnosis in lower streams due to resource limitation would seek for support from a stronger KB and diagnosis model in upstream, a special attention has to be paid in the design of TICMD. The designed TICMD should provide absolutely authoritative and eminently trustworthy reference for the overall *e*-home healthcare system.

Thus, the proposed functional architecture of TICMD for upstream as illustrated in Figure 18, employs both non-invasive multi-vital signs including SPG, ECG, HS and invasive blood test parameters (BTPs) extracted from routine blood test to diagnose various CVD.

Note that different from biomedical signals interpretation, the intelligent diagnosis and computer-aided analysis of BTPs are seldom exploited in literature. Thus, to construct such a model, 241 site-sampled BTPs records from 241 patients with different CVD are acquired from Shaoshan People's Hospital, China. Based on these records, a dedicated DB is constructed. In order to provide standard for BTPs related studies and guarantee clarity, consistency, extensibility, and interoperability of DB, the frame structure and shell design is employed to develop the DB. Also, a KB system is devised to explain the mapping relationship between certain CVD and related BTPs. Through cooperation with medical specialists and clinical validations, 26 KB rules with specialized architecture are pre-defined. Grounded on the KB rules and input BTPs in DB, an intelligent inference engine is developed to conclude the accurate diagnostic results with detailed explanations with corresponding warning messages. After obtaining both invasive and non-invasive diagnostic results, final decisions can be integrated by considering the influence factor of different parameters for different diseases.

EBSCOhost - printed on 2/10/2023 8:17 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 18. Functional architecture of upstream



Testing Results of Upstream Module

To validate the designed TICMD, 200 site-samples, BTPs records containing 26 different types of CVD obtained from Shaoshan People's hospital were tested. The disease distribution of all the acquired records are listed in (Tang, 2014).

The quantitative judgment and evaluation on diagnosis performance of proposed TICMD is evaluated by computing the diagnostic accuracy (*DA*) using Equation 39.

$$DA\left(\%\right) = \frac{N_{sim}}{N_{tot}} \times 100\% \tag{39}$$

where, N_{sim} is the number of similar diagnostic results obtained against the actual clinical results from medical professionals and N_{tot} denotes the total number of CVD types present in the acquired database.

With the proposed TICMD, the testing samples are diagnosed automatically. The recorded diagnostic results are compared with doctor's clinical results to obtain the performance index *DA*. The distribution of *DA* for all tested records is plotted in Figure 19.

It is observed form Figure 19 that for most of the records, the *DA* is greater than 80% and the averaged *DA* obtained is 84.38%. Such results show that the proposed TICMD is reliable and the achieved performance is adequate for the implementation of *e*-home healthcare system.

UPLINK, UPDATE, AND SYNCHRONIZATION SYSTEM
